To create definitions for data objects that you store in the base workspace or in a Simulink data dictionary, use the Custom Storage Class designer to create a definition in a package. For these data objects, you apply code generation settings to the data object instead of applying them in the mapping of a model. When an item in a model uses the data object and its code generation settings, the code mapping for the item reflects the specification of the data object. For more information, see “Create Storage Classes by Using the Custom Storage Class Designer” on page 37-14 and “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

## Use Package Code Definitions in Embedded Coder Dictionaries

If you want to use the same code generation definition in the Code Mappings editor and in data objects, you do not need to store one copy of the definition in an Embedded Coder Dictionary and another copy in a package. Instead, store the definition in a package (by using the Custom Storage Class Designer). Then, configure one or more Embedded Coder Dictionaries to refer to the definition in the package. With this technique, when you want to make changes to the definition, you make the changes in only one place, the package.

To create a code generation definition in a package by using the Custom Storage Class Designer, see “Create Storage Classes by Using the Custom Storage Class Designer” on page 37-14. Then, to configure an Embedded Coder Dictionary to refer to the package, see “Refer to Code Generation Definitions in a Package”.

For more information about maintaining definitions in packages and dictionaries, see “Migrate Package Definitions to Embedded Coder Dictionary to Use in Code Mappings” on page 31-21.

## Constrain Use of Storage Class Code Mappings

When defining a storage class in the Embedded Coder Dictionary, you can specify whether users can map the storage class to parameters, signals, or parameters and signals. To constrain the use of a storage class, the **Data Initialization** property must be set to **Auto** or **None**. Then, in the Property Inspector, under **Allowed Usage**, select **Parameters**, **Signals**, or **Parameters and Signals**. For more information, see **Embedded Coder Dictionary**.

## Deploy Code Generation Definitions to Users

In a large organization with multiple models and users, you can share code generation definitions by storing them in a mutually accessible location. The process of sharing code definitions is called deployment. For more information, see “Deploy Code Generation Definitions” on page 31-10.

## Interact with Code Generation Definitions Programmatically

You can create and interact with code definitions by using the Embedded Coder Dictionary API.

- 1 Represent the Embedded Coder Dictionary by using a `coder.Dictionary` object. Use the object to access the sections of the dictionary: Storage Classes, Memory Sections, and Function Customization Templates. If you have a package of code definitions, use the `coder.Dictionary` object to load and refresh the package in the dictionary.
- 2 Represent a section of the dictionary by using a `coder.dictionary.Section` object. Use the section to access code definitions.
- 3 Represent a code definition by using a `coder.dictionary.Entry` object. Use the entry to interact with the code definition and its properties.

You can also use functions such as `coder.dictionary.copy` and `coder.dictionary.move` to perform operations on Embedded Coder Dictionaries. For more information, see “Create Code Definitions Programmatically” on page 31-5.

## Create Code Definitions Programmatically

This example shows how to programmatically create code definitions in an Embedded Coder Dictionary. To automate the creation of an Embedded Coder Dictionary in a script or to create definitions programmatically, use this programming interface.

In this example, you create an Embedded Coder Dictionary in a Simulink data dictionary so that multiple models can share the code definitions. You create code definitions that control the naming and placement of global data and functions. You also use a memory section definition that includes a pragma to place the data and functions in fast memory. To verify the architecture that you set up through the code definitions, apply the definitions to a model, and then generate code.

### Set Up Embedded Coder Dictionary

Create a Simulink data dictionary to store the code definitions. Storing the definitions in a data dictionary enables you to use the definitions in multiple models by linking each model to the data dictionary as shown in Apply Code Generation Definitions on page 31-0 .

```
dataDictionary = Simulink.data.dictionary.create('dataDictionary.sldd');
```

Create an Embedded Coder Dictionary in the data dictionary. When you create the dictionary, represent it with a `coder.Dictionary` object. Use the object to perform operations on the entire Embedded Coder Dictionary and to access sections of it.

```
codeDictionary = coder.dictionary.create('dataDictionary.sldd');
```

The `coder.Dictionary` object contains three `coder.dictionary.Section` objects that represent the sections of an Embedded Coder Dictionary: Storage Classes, Memory Sections, and Function Customization Templates. A `coder.dictionary.Section` object contains `coder.dictionary.Entry` objects that represent the definitions in that section. To interact with a definition and access its properties, use the `coder.dictionary.Entry` object that represents it.

The screenshot displays the Embedded Coder Dictionary interface. On the left, a sidebar lists sections: Functions, Function Defaults, Function Customization Template, Memory, Data Default, Storage Class, and Memory Section. A bracket labeled "Sections: coder.dictionary.section objects" points to this list. The main area shows a table of Storage Classes with columns for Storage Class and Data Source. A bracket labeled "Code Definitions: coder.dictionary.Entry objects" points to the table. On the right, a Properties of Code Definition panel shows details for the selected "ExportToFile" entry, including Name, Description, Storage Type, File Placement, Data Scope, Header File, Storage, Data Initialization, and Memory Section. A bracket labeled "Properties of Code Definition" points to this panel. At the bottom, a Pseudocode Preview window shows the generated code for the selected entry.

Storage Class	Data Source
ExportedGlobal	Built-in

Definition:
/* CSC definition comment generated by default */
For parameters:
 DATATYPE DATANAME(DIMENSION) - {...};
For constants:

```

When you create an Embedded Coder Dictionary, the dictionary loads definitions from the Simulink package so that the Embedded Coder Dictionary then contains built-in definitions. If you have custom code definitions stored in a package, load that package to the dictionary. When you use the Embedded Coder Dictionary to configure the code interface for a model, you can apply definitions from packages that you loaded.

## Memory Sections

To create memory section definitions, add entries to the Memory Sections section. Storage classes and function customization templates residing in the same dictionary can use these memory sections. For this example, add a memory section named `FastMem`, which allocates memory by using a pragma. When you apply the memory section to a storage class or function template, their generated definitions and declarations are in the memory section.

```
memorySections = getSection(codeDictionary, 'MemorySections');
msFast = addEntry(memorySections, 'FastMem');
set(msFast, 'PreStatement', '#pragma begin FAST');
set(msFast, 'Comment', '/*Fast onchip RAM*/');
set(msFast, 'PostStatement', '#pragma end FAST');
```

## Storage Classes

For this example, create a storage class named `ExportToPrivateHeader`, which generates a global variable declaration in the header file `$R_private.h` and definition in `$R_private.c`. The token `$R` signifies the name of the root model for which you generate code. To use a variable in external code, apply this storage class to the data element and include the header file in the external code.

```
storageClasses = getSection(codeDictionary, 'StorageClasses');
exportToPrivateH = addEntry(storageClasses, 'ExportToPrivateHeader');
set(exportToPrivateH, 'HeaderFile', '$R_private.h', 'DataScope', 'Exported');
```

To apply the memory section `FastMem` to the storage class, use the `coder.dictionary.Entry` object that represents the memory section.

```
set(exportToPrivateH, 'MemorySection', msFast);
```

Create another storage class definition named `ImportFromHeader` for data that external code defines. Because the storage class has `'DataScope'` set to `'Imported'`, the generated code reads and writes to the variable defined by your external code.

```
importFromH = addEntry(storageClasses, 'ImportFromHeader');
set(importFromH, 'DataScope', 'Imported', 'HeaderFile', '$R_input.h', 'DataInit', 'Dynamic');
```

## Function Customization Templates

To create a function customization template, create another `coder.dictionary.Section` object that represents the Function Customization Templates section. Add an entry to this section, which represents a definition that controls the appearance of generated entry-point functions. Apply the memory section `FastMem` to the function template.

```
functionTemplates = getSection(codeDictionary, 'FunctionCustomizationTemplates');
fcGlobal = addEntry(functionTemplates, 'GlobalFunctions');
set(fcGlobal, 'FunctionName', 'RN');
set(fcGlobal, 'MemorySection', msFast);
saveChanges(dataDictionary);
```

## Apply Code Generation Definitions

Confirm the settings of your code definitions by applying them to a model and generating code. You can configure the model code interface to use the code definitions programmatically or by using the Code Mappings editor.

Open the model `rtwdemo_configinterface` and link the model to the data dictionary that you created.

```
rtwdemo_configinterface
set_param('rtwdemo_configinterface','DataDictionary','dataDictionary.sldd');
```

The model contains four inports. In1 is configured to use the storage class `ImportFromFile`. For this example, you configure the other inports to read data from external code by default. The model also contains state data for the Delay block that you configure to be accessible by external code. When you apply the storage classes `ImportFromHeader` and `ExportToPrivateHeader` to the model elements, the generated code conforms to this architecture.

To configure the model with the code generation definitions, get the code mapping for the model.

```
cm = coder.mapping.api.get('rtwdemo_configinterface');
```

Use the code mapping to configure data to use your storage class definitions. For the state data in the Delay block, specify the storage class `ExportToPrivateHeader`.

```
setState(cm,'rtwdemo_configinterface/Delay','StorageClass','ExportToPrivateHeader');
```

Specify the default storage class `ImportFromHeader` for root inport data. For inports of the model, by default, the generated code uses data that external code defines in the file `rtwdemo_configinterface_input.c`. To compile and link this external file when you build the

generated code, set the configuration parameter CustomSource to rtwdemo\_configinterface\_input.c.

```
setDataDefault(cm, 'Inports', 'StorageClass', 'ImportFromHeader');
set_param('rtwdemo_configinterface', 'CustomSource', 'rtwdemo_configinterface_input.c');
```

Specify the function customization template GlobalFunctions for the default code generation of execution functions.

```
setFunctionDefault(cm, 'Execution', 'FunctionCustomizationTemplate', 'GlobalFunctions');
```

Verify that the code definitions reflect your specifications.

- 1 Open the Code Mappings editor. In the Simulink Editor, open the Embedded Coder app. On the **C Code** tab, select **Code Interface > Default Code Mappings**.
- 2 In the Code Mappings editor, on the **Data Defaults** tab, expand the **Inports and Outports** section. The **Inports** category shows the storage class ImportFromHeader. On the **Inports** tab, the inports In2, In3, and In4 use the model default storage class ImportFromHeader. The inport In1 has a different storage class specified, ImportFromFile. This setting overrides the default storage class so that In1 reads data from a different external file.
- 3 On the **Signals/States** tab, the state X shows the storage class ExportToPrivateHeader.
- 4 On the **Function Defaults** tab, the **Execution** category shows the template GlobalFunctions.
- 5 Open the Embedded Coder Dictionary. On the **C Code** tab, select **Code Interface > Embedded Coder Dictionary**. The code definitions that you added to the dictionary appear in the tabs.

### Generate and Verify the Code

Generate code for the model.

```
slbuild('rtwdemo_configinterface', 'generateCodeOnly', true);
```

```
Starting build procedure for: rtwdemo_configinterface
```

```
tf = logical
 0
```

```
Successful completion of code generation for: rtwdemo_configinterface
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_configinterface	Code generated	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)

Build duration: 0h 1m 30.077s

The header file rtwdemo\_configinterface\_private.h defines the Delay block state data according to the storage class ExportToPrivateHeader. External code can access this state data.

```
file = fullfile('rtwdemo_configinterface_ert_rtw', 'rtwdemo_configinterface_private.h');
rtwdemodbtype(file, /* Storage class', ...
 '#endif');
```

```

/* Storage class 'ExportToPrivateHeader' */

/*Fast onchip RAM*/

#pragma begin FAST

extern MYTYPE X; /* '<Root>/Delay' */

#pragma end FAST

```

Because the inports use the storage class specifications, the generated header files do not define inport data. Instead, the generated file `rtwdemo_configinterface.h` includes the external header file that you specified in the storage class definition. The generated code reads inport data from the variables defined in the external file `rtwdemo_configinterface_inputs.c`.

In the generated source file `rtwdemo_configinterface.c`, the execution (step) function reflects the settings of the function customization template `GlobalFunctions`. Because the template `GlobalFunctions` uses the memory section `FastMem`, the execution function is stored in the memory section and reflects the prestatement, poststatement, and comments that you set in the `FastMem` definition.

```

file2 = fullfile('rtwdemo_configinterface_ert_rtw','rtwdemo_configinterface.c');
rtwdemodbtype(file2,'/* Model step function */', ...
 '/* Logic:');

/* Model step function */

/*Fast onchip RAM*/
#pragma begin FAST

void rtwdemo_configinterface_step(void)
{

```

After you configure the Embedded Coder Dictionary, you can share the dictionary with your team or organization. You and other users can apply your definitions to multiple models so that the models use the same software architecture.

- “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2
- “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15

## Deploy Code Generation Definitions

As described in “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2, you can create code generation definitions that you and other users can apply to model elements such as data and functions. The code definitions control the appearance of those elements in the generated code.

In a large organization with multiple models and users, you can share code generation definitions by storing them in a mutually accessible location. The process of sharing code definitions is called deployment.

### Share Code Generation Definitions Between Multiple Models and Users

When you create custom code generation definitions, to share the definitions between models and other users:

- When you create definitions in a package by using the Custom Storage Class Designer, for each user, place the folder containing the package folder on the MATLAB path. For more information, see “What Is the MATLAB Search Path?”.
- When you create definitions in an Embedded Coder Dictionary, store the definitions in a Simulink data dictionary. Then, link each model to a separate data dictionary. Configure each separate dictionary to refer to the dictionary that contains the code generation definitions. For an example, see “Share Embedded Coder Dictionary Definition Between Models” on page 31-12.

### Dictionary Usage for Models Created with Different Versions of Simulink

Simulink provides version handling for Embedded Coder Dictionaries. When these events occur, Simulink synchronizes data in a data dictionary, including the Embedded Coder Dictionaries, for use with a model regardless of the Simulink version used to create the model.

- You link a model to a data dictionary that was saved in a previous version of Simulink (for example, you link a model that you develop in R2018b with a dictionary saved in R2018a).
- You open a model, which has a local Embedded Coder Dictionary, in a version of Simulink that is older than the current version (for example, you developed a model that uses a local dictionary in R2018a and you open that model in R2018b to continue development).

You also have the option to export (save) an Embedded Coder Dictionary for use with models created with a different version (previous or older) of the code generator.

For more information, see “Dictionary Usage for Models Created with Different Versions of Simulink”.

### Configure Default Code Mapping in a Shared Dictionary

While setting up an Embedded Coder Dictionary intended to be shared by multiple models, you can map default code definitions for categories of model data and functions. In this example, you map default code definitions for the Embedded Coder Dictionary in `exSharedCodeDefs.sldd`.

- 1 If not already defined, define code definitions (storage classes, function customization templates, and memory sections) in a data dictionary. For this example, you define code definitions in data dictionary `exSharedCodeDefs.sldd`. Place a copy of this file in a writeable location.
- 2 In **Current Folder** pane of the MATLAB Command Window, double-click the file name of your copy of `exSharedCodeDefs.sldd`.
- 3 In the **Model Hierarchy** pane of the Model Explorer, right-click the dictionary node and select **Show Empty Sections**.
- 4 Open the Embedded Coder Dictionary. In the **Model Hierarchy** pane, click **Embedded Coder Dictionary**. Then, in the right pane, click **Open Embedded Coder Dictionary**.
- 5 In the Embedded Coder Dictionary dialog box, on the left pane, click **Data Defaults**.
- 6 In the **Data Defaults** table, configure default code definitions for categories of data and functions.

Model Element Category	Description
Inports	Root-level input ports of a model, such as Inport and In Bus Element blocks.
Outports	Root-level output ports of a model, such as Outport and Out Bus Element blocks.
Signals, states, and internal data	Data elements that are internal to the model, such as block output signals, discrete block states, data stores, and zero-crossing signals.
Shared local data stores	Data Store Memory blocks that have the block parameter <b>Share across model instances</b> set. These data stores are accessible only in the model where they are defined. The data store value is shared across instances of the model.
Global data stores	Data stores that are defined by a signal object in the base workspace or in a data dictionary. Multiple models in an application can use these data stores. To view and configure these data stores in the Code Mappings editor, click the <b>Refresh</b> link to the right of the category name. Clicking this link updates the model diagram.
Model parameter arguments	Parameters in the model workspace that you configure as model arguments. These parameters are exposed at the model block to enable each model instance to provide its own value. To specify a parameter as a model argument, select the <b>Model Data Editor &gt; Parameters &gt; Argument</b> check box.
Model parameters	Parameters that are defined within a model, such as parameters in the model workspace. Excludes model arguments.
External parameters	Parameters that you define as objects in the base workspace or in a data dictionary. Multiple models in an application can use these parameters. To view and configure these parameters in the Code Mappings editor, click the <b>Refresh</b> link to the right of the category name. Clicking this link updates the model diagram.

Model Element Category	Description
Constants	<p>Constant-value block output and parameters that could not be inlined. These values are stored in variables for one of the following reasons.</p> <ul style="list-style-type: none"> <li>• The value is an array larger than the loop unrolling threshold.</li> <li>• The value address is needed in the code.</li> </ul>

The default mapping for a category applies to elements in a category throughout a model.

For this example, set the storage class for data categories **Inports**, **Outports**, and **Global data stores** to `ExportedGlobal`.

- 7 In the Embedded Coder Dictionary dialog box, on the left pane, click **Function Defaults**. Configure the function customization template and, if applicable, a memory section, for these categories of functions:

Model Function Category	Description
InitializeTerminate	Entry-point functions for initialization and termination
Execution	Entry-point functions for initiating execution and resets
Shared utility	Shared utility functions

- 8 Apply your changes by clicking **Save** and close the Embedded Coder Dictionary and Model Explorer.

## Share Embedded Coder Dictionary Definition Between Models

This example shows how to create a storage class that yields separate global variables in the generated code and share the storage class between two models, `rtwdemo_roll` and `rtwdemo_configinterface`. Then, you configure each model to use the storage class as the default code generation setting for internal data, which includes block states.

It is a best practice to store shared code generation definitions in a standalone data dictionary, which means that no models are linked directly to the dictionary. Then, you can link the target models to one or more additional, intermediate dictionaries, which you configure to refer to the standalone dictionary. With this modular dictionary hierarchy, each model can store other data, such as design data, separately from the code generation definitions.

In a hierarchy of referenced data dictionaries (see “Dictionary Referencing”), only one dictionary can store code generation definitions in an Embedded Coder Dictionary. If a model has access to multiple Embedded Coder Dictionaries through referenced data dictionaries, use the functions `coder.dictionary.move` and `coder.dictionary.remove` to transfer and delete Embedded Coder Dictionaries until only one exists in the dictionary hierarchy.

The figure shows an example dictionary hierarchy. In the figure:

- `modelOne.slx` and `modelTwo.slx` are different model files.
- `dataForModelOne.sldd` and `dataForModelTwo.sldd` are data dictionaries. Each dictionary stores design data, such as numeric MATLAB variables, for one of the models.
- `coderDefs.sldd` is a shared data dictionary that stores code generation definitions for both models. The other dictionaries reference `coderDefs.sldd`.

### Create Code Generation Definition in Standalone Data Dictionary

Create a data dictionary. Then, create the storage class in the dictionary.

- 1 At the command prompt, open the Model Explorer.  

```
daexplr
```
- 2 In the Model Explorer, select **File > New > Data Dictionary**.
- 3 Name the dictionary `coderDefs.sldd`.
- 4 In the Model Explorer **Model Hierarchy** pane, right-click `coderDefs` and select **Show Empty Sections**.
- 5 Select the **Embedded Coder Dictionary** node.
- 6 In the Dialog pane (the right pane), click **Open Embedded Coder Dictionary**.
- 7 In the Embedded Coder Dictionary dialog box, on the left pane, click **Storage Class**.
- 8 In the **Storage Classes** section, click **Create**.
- 9 For the new storage class, in the property inspector pane, set **Name** to `internalsInFile`.
- 10 In the Embedded Coder Dictionary, click **Save**.

### Link Models to Data Dictionaries

Link each model to a separate data dictionary. Configure each dictionary to refer to the standalone dictionary (`coderDefs.sldd`).

- 1 Open the models.  

```
rtwdemo_configinterface
rtwdemo_roll
```
- 2 In `rtwdemo_roll`, on the **Modeling** tab, in the **Design** gallery, click **Link to Data Dictionary**.
- 3 In the Model Properties dialog box, click **New**.
- 4 Create a dictionary named `rtwdemo_roll_data.sldd` by using the Create a new Data Dictionary dialog box.
- 5 In the Model Properties dialog box, click **OK**.

Simulink links the model to the new dictionary. The dictionary does not contain any data because the model does not use data in the base workspace.

- 6 Open the dictionary in the Model Explorer. In the lower-left corner of the model, click the model data badge, then click the **External Data** link. Under the **External Data** node, select `rtwdemo_roll_data.sldd`.
- 7 In the Dialog pane, under **Referenced Dictionaries**, click **Add**.
- 8 In the Open Data Dictionary dialog box, double-click `coderDefs.sldd`.
- 9 Use the **Model Hierarchy** pane to save the changes you made to `rtwdemo_roll_data.sldd`.
- 10 Link `rtwdemo_configinterface` to a dictionary named `rtwdemo_configinterface_data.sldd`.

`rtwdemo_configinterface` uses a variable in the base workspace. To migrate the variable into the dictionary, in the Model Properties dialog box, click **Migrate data**. Then follow the instructions to link the model to the dictionary and copy the referenced variables.

- 11 Configure `rtwdemo_configinterface_data.sldd` to refer to `coderDefs.sldd`.

### Apply Code Generation Definition in Models

Confirm that the shared definition is available for use in the models by applying it as a default setting for internal data and inspecting the generated code.

- 1 In `rtwdemo_roll`, click the **C Code** tab. If the toolstrip does not show the **C Code** tab, open the Embedded Coder app.
- 2 Under **Code Mappings > Data Defaults**, for the **Signals, states, and internal data** row, set **Storage Class** to `internalsInFile`.
- 3 In `rtwdemo_configinterface`, use the Code Mappings editor to set **Storage Class** to `internalsInFile` for the **Signals, states, and internal data** row.
- 4 Generate code from `rtwdemo_roll`.
- 5 In the **Code** view, inspect the generated file `rtwdemo_roll.c`. The file defines global variables that correspond to state data in the model, such as the state of the Integrator block in the `BasicRollMode` subsystem.

```
/* Storage class 'internalsInFile' */
real32_T rtwdemo__FixPtUnitDelay1_DSTATE;
real32_T rtwdemo_roll_Integrator_DSTATE;
int8_T rtwde_Integrator_PrevResetState;
```

- 6 Optionally, generate code from `rtwdemo_configinterface` and confirm that the code appears as expected.

### Migrate Definitions from Model File to Shared Data Dictionary

If you create code generation definitions in the Embedded Coder Dictionary of a model, the definitions are stored in the model file. If you want to share the definitions between models:

- 1 Create a shared data dictionary as shown in “Share Embedded Coder Dictionary Definition Between Models” on page 31-12. Before you proceed to the next step, make sure all of the target models have access to the shared dictionary.
- 2 Use the `coder.dictionary.move` function to migrate the definitions from the source model file to the shared data dictionary.
- 3 Optionally, copy Code Mappings editor settings from the source model to other models by using the programmatic interface of the Code Mappings editor (see “Configure Default Data and Function Code Generation Programmatically” on page 32-24).

In this example, you convert a subsystem to a referenced model. Then, you create a storage class in the Embedded Coder Dictionary of the top model and use the storage class in the Code Mappings editor. To use the same Code Mappings editor settings for the top model and for the referenced model, you must extract the storage class into a shared data dictionary (.sldd).

### Create Referenced Model

- 1 Open the example model `rtwdemo_roll`.
 

```
rtwdemo_roll
```
- 2 In the model, right-click the `BasicRollMode` subsystem and select **Subsystem & Model Reference > Convert to > Referenced Model**.
- 3 Click **Convert**.

The new referenced model, `BasicRollMode`, opens. The model file is in your current folder.

### Create and Apply Storage Class

- 1 In the top model `rtwdemo_roll`, click the **C Code** tab. If the toolstrip does not show the **C Code** tab, open the Embedded Coder app.
- 2 Click **Code Interface > Embedded Coder Dictionary**.
- 3 In the Embedded Coder Dictionary dialog box, on the **Storage Class** tab, click **Create**.
- 4 For the new storage class, set these property values:
  - **Name** to `internalsInFile`.
  - **Header File** to `$R_internal.h`.
  - **Definition File** to `$R_internal.c`.
- 5 In the model, in the Code Mappings editor, for the **Data Defaults > Signals, states, and internal data** row, set **Storage Class** to `internalsInFile`.

The referenced model cannot access the code generation definitions in the Embedded Coder Dictionary of the parent model. Now, move the storage class out of the parent model and into a shared data dictionary.

### Move Storage Class to Shared Data Dictionary

As a best practice, link each model to a separate data dictionary (.sldd), create a shared, standalone data dictionary to store the code generation definition (the storage class), and configure dictionary referencing so that all of the models can use the code generation definition.

To link the models to separate dictionaries:

- 1 In `rtwdemo_roll`, on the **Modeling** tab, in the **Design** gallery, click **Link to Data Dictionary**.
- 2 In the Model Properties dialog box, click **New**.
- 3 Use the Create a new Data Dictionary dialog box to create a dictionary named `rtwdemo_roll_data.sldd`.
- 4 In the Model Properties dialog box, click **OK**.
- 5 In the Link Model to Data Dictionary dialog box, click **Change this model only**.
- 6 In the `BasicRollMode` model, use the Model Properties dialog box to link the model to a new data dictionary named `basicRollMode_data.sldd`.
- 7 Click, **OK**.

To create the shared, standalone dictionary and store the code generation definition in it:

- 1 In both models, open the dictionary in the Model Explorer. At the lower-left corner of the block diagram, click the model data badge, then click the **External Data** link. Under the **External Data** node, select the dictionary.
- 2 In the Model Explorer, select **File > New > Data Dictionary**.
- 3 Create a data dictionary named `coderDefs.sldd`.
- 4 In the Model Explorer **Model Hierarchy** pane, select the `rtwdemo_roll_data` node.
- 5 In the Dialog pane (the right pane), under **Referenced Dictionaries**, click **Add**.
- 6 Add a reference to `coderDefs.sldd`.
- 7 Configure `basicRollMode_data.sldd` to refer to `coderDefs.sldd`.
- 8 In the **Model Hierarchy** pane, right-click the `rtwdemo_roll_data` node and select **Save Changes**.
- 9 At the command prompt, move the code generation definitions from the `rtwdemo_roll` model file to the `coderDefs.sldd` data dictionary.

```
coder.dictionary.move('rtwdemo_roll','coderDefs.sldd');
```

Now, both models have access to the storage class `internalsInFile`.

### Copy Code Mappings Editor Settings from Parent Model to Referenced Model

The new referenced model does not use the Code Mappings editor settings that the parent model uses. To copy the settings from the parent model to the referenced model, use the programmatic interface of the Code Mappings editor.

At the command prompt, copy the storage class setting for **Signals, states, and internal data** from `rtwdemo_roll` to `BasicRollMode`.

```
roll_mapping = coder.mapping.api.get('rtwdemo_roll');
roll_sc = getDataDefault(roll_mapping,'InternalData','StorageClass');

mode_mapping = coder.mapping.api.get('BasicRollMode');
setDataDefault(mode_mapping,'InternalData','StorageClass',roll_sc);
```

Now, both models use the same Code Mappings editor settings. For more information about the programmatic interface of the Code Mappings editor, see “Configure Default Data and Function Code Generation Programmatically” on page 32-24.

### Use Data Dictionary to Store Code Definitions but Not Design Data

A Simulink data dictionary can store design data such as MATLAB variables and `Simulink.AliasType` objects (see “Global and Shared Data: Data Dictionary”). However, migrating the design data of a large model or of multiple models from the base workspace to a data dictionary can take time and careful planning.

If you want to store shared code generation definitions in a data dictionary but do not want to migrate the design data of a model, in the Model Properties dialog box, on the **External Data** tab, select the **Enable model access to base workspace** property. The model can use design data from the base workspace and code generation definitions from the dictionary or from a referenced dictionary. For more information, see “Continue to Use Shared Data in the Base Workspace”.

## Generate Code to Conform to Software Architecture by Sharing and Copying Default Settings Between Models

In a project where you generate code from many models, you can configure the models with the same default code settings so that they generate code that conforms to your software architecture standards. These settings include:

- Configuration parameter settings
- Code interface definitions such as storage classes
- Code mappings that specify code definitions for categories of model data and functions

As projects expand and you and your colleagues create more models, manually configuring the default settings for each new model takes time. To reduce this manual data entry, you can use tools to configure many models by default. You can copy settings between models, enabling each model to later change the settings independently of each other. Alternatively, you can share settings, enabling you to change the settings for multiple models simultaneously with minimal effort.

### Share Common Code Generation Settings among Multiple Models

One way to make models conform to code generation standards is by storing the settings in one location and sharing them among the models. Share settings that you might want to change so that when you do change the settings, the models are updated. To share code generation settings among multiple models, store the settings in a standalone Simulink data dictionary. Then, link each model to one or more additional, intermediate dictionaries. Configure the intermediate dictionaries to refer to the standalone dictionary. With this modular dictionary hierarchy, each model can store other data, such as design data, separately from the shared settings. For an example that shows how to store shared data in a dictionary, see “Partition Data for Model Reference Hierarchy Using Data Dictionaries”. Once you set up the data dictionary hierarchy for your models, choose which code generation settings that you want to share by using the dictionary.

#### Model Configuration Parameter Settings

Configuration parameters control model-wide settings including code generation options such as the system target file, target language, and custom code files. A model's configuration parameters are stored in the configuration set. For code generation parameters on the **Code Generation** pane and links to the pages for the code generation sub-panes, see “Model Configuration Parameters: Code Generation”. Some systems that include multiple models require that many of the configuration parameter settings be consistent across the models. For example, when you generate code for a model reference hierarchy, the models in the hierarchy must have the same settings for many of the code generation parameters. In this type of system, share one configuration set with the models.

To share configuration settings among multiple models, store the settings in a standalone configuration set object. Save the configuration object in a Simulink data dictionary that the models share. For each model, activate a configuration reference that points to the shared configuration set. For an example of how to share a configuration set among multiple models, see “Share a Configuration with Multiple Models”. When you want to change parameter settings, edit the shared configuration set. The models that reference it use the new settings. To quickly share a configuration set among referenced models in a hierarchy, see “Share a Configuration Across Referenced Models”.

#### Code Interface Definitions

For the code interface of many models to conform to the same specifications, define the interface in a set of shared code interface definitions in an Embedded Coder Dictionary. Use a code definition to

specify many detailed code properties. Then you can control the code interface of your data items and functions by applying the code definitions using the code mapping. Code interface definitions include:

- Storage classes
- Memory sections
- Function customization templates

Once you create your code interface definitions, apply them to a model by mapping model data and functions to the definitions. Sharing one set of code definitions among multiple models enables you to quickly apply the same set of interface specifications by mapping the data and functions in each model to the definitions.

To share a set of code definitions among multiple models, create the definitions in the Embedded Coder Dictionary section of the Simulink data dictionary that the models share. Then, map the data and functions in the model to the shared definitions. For an example of how to share definitions among multiple models, see “Share Embedded Coder Dictionary Definition Between Models” on page 31-12.

### **Code Mappings**

Models can also share the default mapping configuration that applies the definitions to data and function categories. In the shared Embedded Coder Dictionary, you configure the dictionary default mapping. When you link a model to the dictionary, the model uses the dictionary mapping by default. You can still change the default mapping and individual mapping for an individual model if the model requires a different configuration. For more information about sharing the dictionary default mapping among multiple models, see “Configure Default Code Mapping in a Shared Dictionary” on page 31-10.

### **Copy Code Generation Settings to New Models**

If you do not want to share code generation settings from one source, you can use other tools to configure models by copying the code generation settings. When you use these techniques, you can easily change the settings for an individual model after the initial configuration. If you want to change a setting for many models that are already configured, you must change each model individually. In the model development process, consider when you want to apply the settings to your models and use one of these techniques.

### **Template Models**

If you want new models to be configured at the time they are created, use a template model. You can create a template model that has preconfigured settings such as configuration parameter settings and Code Mappings editor settings. To create a model, you and others can instantiate the template. Each new model can later change their settings independently of other models. See “Create Template from Model”.

When you create a model by instantiating a template, the new model is not linked to a data dictionary. If the preconfigured settings in the template model depend on shared data that you store in a data dictionary, you must configure dictionary linking and referencing for each new model.

### **Template Projects**

If you want new models to use data that you store outside of the models, such as in a data dictionary, use template projects. You can create a template project that contains models, data dictionaries, and other artifacts. You can also write project shortcuts that execute custom code to create models, copy

settings, and make shared settings stored in a dictionary available to new models. For more information about using template projects, see “Create Templates for Standard Project Settings”.

### **Programmatic Configurations**

If you want to copy settings to a model after you create it, you can write scripts, callbacks, and shortcuts that use the programmatic interfaces to configure code generation settings. Configure these code generation settings by using the corresponding programmatic interfaces:

- For configuration parameter settings, use the `set_param` and `get_param` functions. You can write a script that sets many parameters, as described in “Automate Model Configuration by Using a Script”.
- For code interface definitions in an Embedded Coder Dictionary, see the example “Create Code Definitions Programmatically” on page 31-5.
- For Code Mappings editor settings, see “Configure Default Data and Function Code Generation Programmatically” on page 32-24.

Choose how to execute the code by considering when you want to configure the models. You can execute this code in:

- A script. You can configure the models at any time by running the script manually.
- A model callback. A callback uses your code to configure the model each time the callback is called. For example, you can use the `PreLoadFcn` callback, which executes whenever you open a model. See “Model Callbacks”.
- A project shortcut. The shortcut can create a model and copy settings into the model. See “What Can You Do With Project Shortcuts?”.

After you use the code to configure the models, you can change the settings on each individual model as needed.

## Manage an Embedded Coder Dictionary

After you create code definitions for standardization and software architecture conformance and deploy them to your users, keep the definitions and their usage up to date. When you and other users create models for code generation, make your code definitions available to the models. If the standards for your generated code change, you might need to update your code definitions. Consider how these standards changes impact models that use your code definitions and update the models accordingly.

### Share Available Code Definitions with New Models

If you share code definitions in a Simulink data dictionary, make the definitions available to new models that you or your users create for code generation. A model that you create from the Simulink Start Page or by using the `new_system` function is not linked to a Simulink data dictionary. The new model cannot access code generation definitions that you store in a data dictionary.

To make code definitions available to a new model automatically, write callbacks and other code that immediately links the model to a data dictionary that contains the definitions.

- For a simple example that shows how to link a model to a data dictionary programmatically and for information about configuring dictionary referencing programmatically, see “Store Data in Dictionary Programmatically”.
- If you use a project, consider creating a project shortcut that creates a model and immediately links the new model to a data dictionary. For information about projects and project shortcuts, see “What Are Projects?”.

To manually share the definitions with a new model, see “Share Embedded Coder Dictionary Definition Between Models” on page 31-12.

### Migrate Package Definitions to Embedded Coder Dictionary to Use in Code Mappings

If you create a storage class in a package and you want to use it in the Code Mappings editor, refer to the package from one or more Embedded Coder Dictionaries. To refer to a package from an Embedded Coder Dictionary, see “Refer to Code Generation Definitions in a Package”. Then, for models that have access to the Embedded Coder Dictionary, you can apply storage classes from the package by using the Code Mappings editor.

When you want to make changes to the definition, make changes only in the package. To apply the changes to the Embedded Coder Dictionaries, refresh the package. To refresh the package, open each Embedded Coder Dictionary.

To apply a storage class to a model data element that is not resolved to an external data object, use the Code Mappings editor. To make the package definitions appear in the Code Mappings editor, refer to the package from the Embedded Coder Dictionary that the model uses.

These unresolved model elements include:

- Inport blocks
- Outport blocks

- Signal lines
- Block states
- Data stores
- Parameter objects in the model workspace

To map these model elements to a package-based definition, refer to the package from the Embedded Coder Dictionary that the model uses.

Beginning in R2020b, if an existing model includes these model elements and they are configured with package-based definitions, Simulink references the package from the Embedded Coder Dictionary. If the model is linked to a Simulink data dictionary, Simulink uses the Embedded Coder Dictionary in the data dictionary to reference the package.

## Change Code Generation Definitions

If the requirements for your generated code change, you might need to update your code definitions to reflect the latest interface standards. Changing or deleting a code definition can affect models that use the code definition. When you make changes to code definitions, assess the impact of the changes. Then, deploy the changes and fix the affected usage points.

To make changes to definitions in a package, use the Custom Storage Class designer. For more information, see “Create Storage Classes by Using the Custom Storage Class Designer” on page 37-14.

To make changes to definitions in an Embedded Coder Dictionary:

- Use the Embedded Coder Dictionary tool, as described in **Embedded Coder Dictionary**.
- Use a script, as described in “Create Code Definitions Programmatically” on page 31-5. You can write a script to automatically make a change to many code definitions in an Embedded Coder Dictionary.

If you store the Embedded Coder Dictionary in a Simulink data dictionary, save the data dictionary after you update the code definitions.

## Assess the Impact of Code Definition Changes

Depending on the storage location of the code definition, changing or deleting the definition can break usage points. This table shows the impact of different changes based on the location of the definition. Check if usage points are affected by the change and fix them by making the corresponding updates.

Definition Changes	Storage Location	Updates
Change the name of a definition	Package	For a memory section, update other definitions in the package that use the memory section. In the Custom Storage Class designer, specify the new memory section name.

Definition Changes	Storage Location	Updates
		For a storage class, update data objects that use the storage class. Specify the new storage class name for the data object.
		In Embedded Coder Dictionaries that reference the package, refresh the package.
		In models that use the definition in the Code Mappings, specify the new definition name. Use either the Code Mappings editor or a script that uses the <code>coder.mapping.api.CodeMapping</code> object.
	Embedded Coder Dictionary	None
Change properties of a definition	Package	In Embedded Coder Dictionaries that reference the package, refresh the package.
	Embedded Coder Dictionary	None
Delete a definition	Package	For a memory section, update other definitions in the package that use the memory section. In the Custom Storage Class designer, specify a different memory section or no memory section.
		For a storage class, update data objects that use the storage class. Specify a different storage class or no storage class for the data object.
		In Embedded Coder Dictionaries that reference the package, refresh the package.
		In models that use the definition in the Code Mappings, specify a different storage class or no storage class. Use either the Code Mappings editor or a script.
	Embedded Coder Dictionary	For a memory section, update other definitions in the dictionary that use the memory section. Specify a different memory section or no memory section. Use either the Embedded Coder Dictionary or a script.

<b>Definition Changes</b>	<b>Storage Location</b>	<b>Updates</b>
		In models that use the definition in the Code Mappings, specify a different storage class or no storage class. Use either the Code Mappings editor or a script.
Add a definition	Package	In Embedded Coder Dictionaries that reference the package, refresh the package.
	Embedded Coder Dictionary	None

## Migration of Memory Section and Shared Utility Settings from Configuration Parameters to Code Mappings

For a model created in a release before R2018a, when you open the Embedded Coder app or use the `coder.mapping.create` function, Simulink migrates memory section and shared utility settings from the configuration parameters to the code mappings of the model. As part of the migration, Simulink configures the Embedded Coder Dictionary that the model uses:

- To refer to the package that defines the memory sections, as described in “Refer to Code Generation Definitions in a Package”.
- To contain a function customization template that specifies the naming rule and, if applicable, memory section settings that you specified for shared utilities.

### Effects of Migration

- The migration process makes changes to the model file, which you must save. The changes include:
  - Translating the configuration parameter settings into code mappings.
  - If the model is not linked to a data dictionary, configuring the Embedded Coder Dictionary in the model file to refer to the memory section package and to contain a function customization template.
- If the model is linked to a data dictionary, the migration process makes changes to the dictionary, which you must save. The changes include:
  - If the configuration parameters are stored in the model file (the model does not refer to a `Simulink.ConfigSet` object), configuring the Embedded Coder Dictionary of the data dictionary to refer to the memory section package and to contain a function customization template.

If the data dictionary references other dictionaries, the migration process configures the dictionary at the bottom of the reference hierarchy so other models and dictionaries in the hierarchy can use the memory section and function template definitions.

- If the model refers to a `Simulink.ConfigSet` object, configuring the Embedded Coder Dictionary of the data dictionary that stores the object.

### Considerations Before Migrating

- When you open the Embedded Coder app, Simulink executes the migration process. Do not open the Embedded Coder app unless you are ready to migrate memory section and shared utility naming settings.

If a model has multiple configuration sets (one active and one or more inactive) or refers to a `Simulink.ConfigSet` object, the Embedded Coder app displays an informational message indicating that information from the referenced configuration set has been imported into the Embedded Coder Dictionary and code mappings.

- If you use Simulink data dictionaries, before you or other users open the Embedded Coder app for a model, consider creating and configuring the dictionaries first.

In a hierarchy of referenced data dictionaries (for example, a dictionary hierarchy that parallels a model hierarchy), only one dictionary can contain an Embedded Coder Dictionary. Setting up data

dictionaries before migrating associated models enables you to control where the Embedded Coder Dictionary resides in the dictionary hierarchy. Create or identify a data dictionary at the bottom of the hierarchy so that models in the hierarchy can access the memory section and function template definitions. Then, when you initiate migration by opening Embedded Coder app for a model, Simulink configures that data dictionary.

For information about sharing an Embedded Coder Dictionary between models by using referenced dictionaries, see “Share Embedded Coder Dictionary Definition Between Models” on page 31-12.

- The migration process makes changes based on the active configuration set of the model (see “Manage Configuration Sets for a Model”) when you open the model in the Embedded Coder app. Before you open the model in the Embedded Coder app, activate the configuration set whose settings you want the migration process to use.

The process ignores settings in inactive configuration sets. If different configuration sets of the model specify different settings, you must choose one set to migrate.

## Considerations After Migrating

- In a branching hierarchy of referenced models and referenced data dictionaries, after you or other users migrate referenced models in different branches, opening the Embedded Coder app in a parent model can generate an error due to the presence of multiple Embedded Coder Dictionaries in the data dictionary hierarchy. To resolve these errors, use `coder.dictionary.move` and `coder.dictionary.remove` to transfer and delete Embedded Coder Dictionaries until only one dictionary remains. Place the remaining Embedded Coder Dictionary in a data dictionary at the bottom of the hierarchy so that the models in the hierarchy can access the memory section and function template definitions.

For information about sharing an Embedded Coder Dictionary between models by using referenced dictionaries, see “Share Embedded Coder Dictionary Definition Between Models” on page 31-12.

- After you migrate a model, memory section and shared utility model configuration parameters are not accessible. If you use `set_param` or `get_param` to access these configuration parameter settings programmatically, the functions generate errors. To change these settings, use the Code Mappings editor or the programmatic interface as described in “C Data and Function Interfaces”.

If a model contains atomic subsystems that have nondefault memory section settings, you can select the memory sections from built-in packages that are loaded into the Embedded Coder Dictionary. See “Override Default Memory Placement for Individual Data Elements” on page 42-6 and “Override Default Memory Placement for Subsystem Functions and Data” on page 42-7.

- If a model refers to a `Simulink.ConfigSet` object, after migration, the model does not use the memory section and shared utility settings in the object. If you used the object to set the configuration parameters of multiple models:
  - Changing memory section and shared utility settings in the object affects only models that you have not migrated.
  - Migrated models do not acquire memory section and shared utility settings from a single location (the `Simulink.ConfigSet` object). To change the settings for these models, use the Code Mappings editor of each model.

## Flexible Storage Class for Different Model Hierarchy Contexts

This example shows how to use one storage class throughout a model hierarchy to generate code that is unstructured for single-instance data and structured for multi-instance data. When a model hierarchy contains single-instance and multi-instance data, use a flexible storage class to specify the settings for the two contexts instead of creating two separate storage classes.

This example uses the single-instance top model `ex_mdltreftop_dd`, which references the multi-instance model `ex_mdltreftbot_dd` three times. Both models share the data dictionary `ex_mdltreft_dd.sldd`. When you define the storage class in the shared data dictionary, you can apply the class to data items in both models.

- 1 Open the example model `ex_mdltreftop_dd`.

```
addpath(fullfile(docroot, 'toolbox', 'ecoder', 'examples'))
ex_mdltreftop_dd
```

- 2 Open the shared data dictionary. On the **Modeling** tab, click **Design > Data Dictionary**.
- 3 Open the shared Embedded Coder Dictionary. In the Model Explorer **Model Hierarchy** pane, expand the `ex_mdltreft_dd` node and click **Embedded Coder Dictionary**. In the right pane, click **Open Embedded Coder Dictionary**.
- 4 On the left pane, click **Storage Class**.
- 5 The built-in storage class `MultiInstance` is configured to generate a structure for multi-instance data. Duplicate this storage class so that you can edit other properties. Select the `MultiInstance` storage class and click **Duplicate**. For more information about the built-in storage class, see “MultiInstance” on page 33-83.
- 6 In the **Storage Classes** section, click **Create**.
- 7 For the new storage class, in the property inspector pane, set these property values:
  - **Name** — `MyStorageClass`
  - **Use different property settings for single-instance and multi-instance data** — selected.
  - **Single-instance storage > Storage Type** — Unstructured.
  - **Multi-instance storage > Storage Type** — Structured.

The screenshot shows the Embedded Coder Dictionary interface. The main window is titled "CODER DICTIONARY". On the left, there is a "FILE" menu with a "Save" icon. Below the menu is a navigation pane with categories: "Functions", "Memory", and "Data Defaults". Under "Data Defaults", "Storage Class" is selected. The main area displays a list of storage classes with their associated dictionary files. "MyStorageClass" is highlighted, with the dictionary file "ex\_mdref\_dd.sldd". Below the list are "Manage Packages" and "Create" buttons. On the right, the "Definition File" is set to "\$N.c". The "Storage" section is expanded, showing "Use different property settings for single-instance" checked. Under "Single-instance storage", the "Storage Type" is "Unstructured". Under "Multi-instance storage", the "Storage Type" is "Structured", the "Type Name" is "\$R\$N\$GSM", and the "Instance Name" is "\$G\$N\$M". The "Data Initialization" is set to "Auto".

Below the dictionary view is the "Pseudocode Preview" section. It has two tabs: "For single-instance data" and "For multi-instance data". The "For multi-instance data" tab is active, showing the following code:

```
Code in multi-instance child model: MODELNAME
typedef struct tag_RTM_MODELNAME_T RT_MODEL_MODELNAME_T;
typedef struct {
 FIELDTYPE FIELDNAME;
} MODELNAME_MyStorageClass;
struct tag_RTM_MODELNAME_T {
```

When you apply `MyStorageClass` to a data item, the Embedded Coder Dictionary implements the single-instance settings or the multi-instance settings depending on the type of data and the context of the model within the model reference hierarchy. Review the implementations for the different settings in the pseudocode preview.

- 8 Apply the storage class to internal data items by specifying it as a dictionary default. In the Embedded Coder Dictionary, click **Data Defaults**. For the **Signals, states, and internal data** row, set **Storage Class** to `MyStorageClass`. Click **OK**.

Because `ex_mdleftop_dd` and `ex_mdleftbot_dd` share the dictionary `ex_mdref_dd.sldd`, both models use `MyStorageClass` as the default storage class for internal data.

- 9 Open the Embedded Coder app for the model `ex_mdleftop_dd`.
- 10 Generate code for the model.
- 11 Review the generated code for the referenced model. To open the referenced model in the editor, double-click the Model block, `CounterA`. The reference model code appears in the Code view. In `ex_mdleftbot_dd.h`, the reference model code defines the storage class structure in which it stores the internal data of the referenced model.

```
/* Storage class 'MyStorageClass', for model 'ex_mdleftbot_dd' */
typedef struct {
```

```
 real_T PreviousOutput_DSTATE; /* '<Root>/Previous Output' */
} ex_mdrefbot_dd_MyStorageClass;

/* Real-time Model Data Structure */
struct ex_mdrefbot_dd_tag_RTM {
 const char_T **errorStatus;
 ex_mdrefbot_dd_MyStorageClass *MyStorageClass_ex_mdrefbot_dd;
};
```

Because the referenced model is multi-instance, the definition implements the multi-instance data settings of `MyStorageClass`. The reference model code stores the internal data in the structure `ex_mdrefbot_dd_MyStorageClass`.

- 12** Navigate back to the top model and review the generated code. In `ex_mdrefbot_top_dd.c`, the top model code defines its internal data for each Model block by instantiating the storage class of the referenced model, `ex_mdrefbot_dd_MyStorageClass`.

```
/* Storage class 'MyStorageClass' */
ex_mdrefbot_dd_MdlrefDW ex_mdrefbot_top_dd_CounterA_InstanceData;
ex_mdrefbot_dd_MdlrefDW ex_mdrefbot_top_dd_CounterB_InstanceData;
ex_mdrefbot_dd_MdlrefDW ex_mdrefbot_top_dd_CounterC_InstanceData;

/* Storage class 'MyStorageClass' */
ex_mdrefbot_dd_MyStorageClass MyStorageClass_CounterA;

/* Storage class 'MyStorageClass' */
ex_mdrefbot_dd_MyStorageClass MyStorageClass_CounterB;

/* Storage class 'MyStorageClass' */
ex_mdrefbot_dd_MyStorageClass MyStorageClass_CounterC;
```

Because the top model is single-instance, these definitions implement the single-instance data settings of `MyStorageClass`. The top model also packages its own internal data as standalone variables by using the single-instance data settings. The top model code does not contain a structure definition for internal data.

## Separation of Code Definitions from Model-Specific Data and Function Configurations

By using the Embedded Coder Dictionary, you can define specifications that control data and functions in the generated code. You create custom specifications as *code interface definitions*, such as storage classes, memory sections, and function customization templates. To configure your model to use the definitions, map data items and functions in the model to the definitions.

Using an **Embedded Coder Dictionary** to specify your code, you can:

- Create, store, and maintain the specifications for your generated code in one place.
- Apply code definitions in the default mapping for your model.
- Configure the code for many different elements throughout your model.
- Choose how to apply your definitions with flexibility.
- Configure the generated code for multiple models.
- Use one model to generate code that is configured differently for different computing platforms.

### Manage Code Specifications in One Location

When you create code definitions in an Embedded Coder Dictionary, you can manage the specifications for your generated code in one place. You do not need to specify your code customizations on each individual data item or function that you want to configure. By specifying your code in the Embedded Coder Dictionary, you can:

- View and compare code definitions and their properties.
- Find and fix code specifications that do not conform to requirements.
- Change many code definitions quickly when software interface standards change.

### Apply Definitions to Model Elements with Flexibility

Storing your code definitions in a dictionary gives you flexibility in applying the definitions to your model because the code definitions in a dictionary are separate from the elements in your model. Configure data elements and functions in your model by mapping them to code definitions. When you map an item to a code definition, the code generated for that item reflects the specifications in your code definition. To map model elements to code definitions, use the **Code Mappings Editor - C**. You can apply a code definition to one model element or to many model elements.

To configure many elements of the same type to use the same code definition, specify the definition in the default mapping. When you map a category of data elements or functions to a code definition, items in that category use the code definition by default for generating code. For example, if you want the input ports in your model to generate code that reads data from a specific file, define the data specifications in a storage class definition. Then, map the input ports data category to your storage class. By default, the input ports of the model generate code that reads data according to the specifications in your definition.

To configure an individual item to generate code according to its own specifications, map the item to its own code definition. If the item is in a category for which you have already specified a default mapping, the mapping for the individual item overrides the default mapping. The default and

individual mappings enable you to configure many items in your model at once with the flexibility to configure items individually.

## Generate Standardized Code from Multiple Models

Separating code definitions from your model means that you can standardize the code generated from many models by sharing one set of code definitions. Because the definitions in your Embedded Coder Dictionary are separate from your model elements, you can share the definitions by storing the Embedded Coder Dictionary in a Simulink data dictionary outside of your model. The figure shows an example of two models sharing a dictionary. In the figure:

- `modelA.slx` and `modelB.slx` are separate models that generate code.
- Each model is linked to a Simulink data dictionary, in this case, the dictionaries are `modelA.sldd` and `modelB.sldd`.
- The separate Simulink data dictionary, `CodeDefinitions.sldd`, contains the code interface definitions.
- The dictionaries for the models, `modelA.sldd` and `modelB.sldd`, reference the dictionary `CodeDefinitions.sldd`.
- For `modelA` and `modelB`, categories of model elements are mapped to the code definitions in `CodeDefinitions.sldd`. Both models generate code that reflects the specifications in the definitions.

To store your code definitions in a shared Simulink data dictionary:

- 1 Create a standalone Simulink data dictionary. In this dictionary, create code definitions to share with multiple models.
- 2 From each model with which you want to share the code definitions, create and link a Simulink data dictionary for model-specific design data.
- 3 From each model-specific data dictionary, reference the dictionary that contains the shared code definitions.

For the models that are linked to the dictionary, you can configure the default mapping. In the shared Embedded Coder Dictionary, such as `CodeDefinitions.sldd`, you can set the *dictionary default* code definition for a category of model data or functions. Models that are linked to the dictionary use the definition by default to generate code for the associated category of data or functions. You can apply code interface definitions to your linked models by default without modifying the individual models.

You can still configure a linked model to use definitions that are different from the dictionary defaults. In the linked model, configure the default mapping and the individual mapping by using definitions that the model has access to, including definitions in the shared dictionary.

## Generate Code for Different Platforms

By separating code definitions from your design data, you can generate code for different platforms from the same model or model hierarchy. For each platform:

- Maintain a dictionary of code definitions that specify code interface behavior for the platform.
- The models map model elements to definitions in the dictionary for the platform.
- When you specify the associated system target file, the models use the mapping for the platform.

For example, you can share an Embedded Coder Dictionary with your models for an embedded real-time (ERT) target platform. For each of the models, maintain a separate AUTOSAR dictionary with definitions for an AUTOSAR platform. To configure the models for the ERT platform:

- 1 Specify an ERT-based system target file for the models.
- 2 Create code interface definitions in the shared Embedded Coder Dictionary.
- 3 For each model, in the Code Mappings editor, map categories of model elements and individual model elements to definitions in the Embedded Coder Dictionary.

When you specify the ERT-based system target file, the models use this code mapping.

To configure the models for the AUTOSAR code generation target:

- 1 Specify an AUTOSAR-based system target file.
- 2 Create code definitions in the AUTOSAR dictionaries.
- 3 In the Code Mappings editor, map model elements and categories to the definitions in the AUTOSAR dictionary.

When you specify the AUTOSAR-based system target file, the models use the AUTOSAR code mapping.

To generate code for either platform, specify the system target file. The code mapping for the model is updated to reflect the mapping and definitions that you specified for that platform.

## C Code Generation Configuration for Model Interface Elements

The code generator provides tooling for you to control the representation of the data and, if you have Embedded Coder, entry-point functions in the generated code. For example, you can configure data and functions for code generation to comply with code standards and guidelines, integrate generated code with external code, or address memory requirements.

The code generator produces code for model data elements and functions:

- Data such as inports, signals, states, and parameters, which your application code can read from and write to.
- Entry-point functions such as `model_step`, which your application code calls to execute the model algorithm.

You can configure model data elements and functions for code generation by using the **Code Mappings Editor - C** or code mappings programming interface (`coder.mapping.api.CodeMapping`). Embedded Coder is required to configure functions. For data elements, use the Code Mappings editor or code mappings API instead of, or in addition to, creating and configuring Simulink data objects. The editor and API enable you to configure:

- Default code generation settings that apply throughout a model for a category of data elements or functions
- Configuration settings that apply to individual data elements or functions

This diagram shows the overall workflow:

### Migration

When you open a model created in a release before R2020b, Simulink® migrates code definitions specified in the model to the model code mappings.

If necessary, as part of the migration, Simulink configures the Embedded Coder Dictionary that the model uses. When you save the model, the code mappings are saved as part of the model.

For more information, such as effects of migration and what to consider before migrating, see “Migration of Model Data Configurations to Code Mappings” on page 32-103 .

## Code Definitions

Code definitions include storage classes, function customization templates, and memory sections. A storage class defines properties, such as appearance and location, that the code generator uses when producing code for the associated data. A function customization template defines how the code generator produces code for functions. For a function category, you can define a rule for naming functions and a location in memory for function definitions (memory section).

Memory sections control the placement of data and function definitions in memory. In some cases, you can select a specific memory section that you want when configuring data elements and functions.

The code generator provides predefined code definitions for data elements. If you have Embedded Coder, you can use the Embedded Coder Dictionary to create and share code definitions, for example, to standardize code that you generate from multiple models or to create definitions for different application run-time environments. Creating custom definitions enables you to achieve code generation objectives that predefined definitions cannot satisfy. For data elements, you also have the option of creating code definitions created in packages by using Embedded Coder Custom Storage Class Designer.

Code definitions that you create by using the Embedded Coder dictionary appear in the **Code Mappings Editor - C** and are accessible by using the code mappings API. For some definitions that you create by using the Custom Storage Class Designer, you can make the definitions appear in the Code Mappings editor by configuring an Embedded Coder Dictionary to refer to them.

By default, code definitions that you create by using the Embedded Coder Dictionary for a model are stored in the model file. You can share code definitions between models and projects by storing the definitions in a Simulink data dictionary. With a data dictionary, to modify a shared definition, you change a definition in one place—the Embedded Coder Dictionary.

For more information, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2 and “Create Storage Classes by Using the Custom Storage Class Designer” on page 37-14.

## Data Default Configurations

Reduce the effort of preparing a model for C code generation by specifying default configurations for categories of data elements, for example inports or model workspace parameters, across a model. Applying default configurations can save time and reduce the risk of introducing errors in code, especially for larger models and models from which you generate multi-instance code.

Default configurations apply throughout a model, excluding referenced models. Simulink saves a separate set of code mappings as part of each model in a model reference hierarchy.

If a model includes a significant number of elements of a given category (for example, more than 10), it is more efficient to configure the category by using a default setting, and then override that setting for special cases.

The default settings can help you to reduce manual data entry.

- As you add blocks and signals to a model, new data elements inherit the default settings.
- To change code generation settings for many data elements at once, make the changes in one place—the default settings.

- For efficiency, use naming rules as you make changes elsewhere in the model.

You configure data defaults by using the **Code Mappings Editor - C Data Defaults** tab or the `setDataDefault` function.

### Model Data Categories

You configure data defaults by using the **Code Mappings Editor - C Data Defaults** tab or the `setDataDefault` function. In the **Data Defaults** tab or function call, you can select or specify these categories of data elements.

Model Element Category	Description
Inports	Root-level input ports of a model, such as Inport and In Bus Element blocks.
Outports	Root-level output ports of a model, such as Outport and Out Bus Element blocks.
Signals, states, and internal data	Data elements that are internal to the model, such as block output signals, discrete block states, data stores, and zero-crossing signals.
Shared local data stores	Data Store Memory blocks that have the block parameter <b>Share across model instances</b> set. These data stores are accessible only in the model where they are defined. The data store value is shared across instances of the model.
Global data stores	Data stores that are defined by a signal object in the base workspace or in a data dictionary. Multiple models in an application can use these data stores. To view and configure these data stores in the Code Mappings editor, click the <b>Refresh</b> link to the right of the category name. Clicking this link updates the model diagram.
Model parameter arguments	Parameters in the model workspace that you configure as model arguments. These parameters are exposed at the model block to enable each model instance to provide its own value. To specify a parameter as a model argument, select the <b>Model Data Editor &gt; Parameters &gt; Argument</b> check box.
Model parameters	Parameters that are defined within a model, such as parameters in the model workspace. Excludes model arguments.
External parameters	Parameters that you define as objects in the base workspace or in a data dictionary. Multiple models in an application can use these parameters. To view and configure these parameters in the Code Mappings editor, click the <b>Refresh</b> link to the right of the category name. Clicking this link updates the model diagram.
Constants	Constant-value block output and parameters that could not be inlined. These values are stored in variables for one of the following reasons. <ul style="list-style-type: none"> <li>• The value is an array larger than the loop unrolling threshold.</li> <li>• The value address is needed in the code.</li> </ul>

If you set the default storage for a category of data elements to `Default`, you have the option of specifying a memory section.

## Considerations for Configuring Default Code Generation Settings for Data

Before configuring default code generation settings for data elements, take into account the considerations listed in this table.

Consideration	More Information
What categories are relevant to your model?	The data element categories in the preceding table
Does the model use several instances of data that is in a category? If the answer is yes, applying default mappings is beneficial. Otherwise, consider configuring code generation for each data element individually.	<ul style="list-style-type: none"> <li>• “Configure Root-Level Inport Blocks for C Code Generation” on page 32-30</li> <li>• “Configure Root-Level Outport Blocks for C Code Generation” on page 32-41</li> <li>• “Configure Signal Data for C Code Generation” on page 32-50</li> <li>• “Configure Parameters for C Code Generation” on page 32-61</li> <li>• “Configure Block States for C Code Generation” on page 32-74</li> <li>• “Configure Data Stores for C Code Generation” on page 32-82</li> </ul>
Which storage class aligns with your code generation requirements for each category?	“Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75
Do you want model data to be structured? For example, if you configured the model for multi-instance code generation, structures can improve code efficiency and readability.	“Organize Data into Structures in Generated Code” on page 33-145
Is the code generator required to store data in specific areas of memory? For example, consider whether to store initialization data in slow memory and algorithmic or computational data in fast memory.	<ul style="list-style-type: none"> <li>• “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2</li> <li>• “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2</li> </ul>
Do you want to prevent optimizations from eliminating specific data from the code?	“Elimination of Categories of Data by Optimizations” on page 32-6
Do you need to define new storage classes that you can select in the Code Mapping editor?	<ul style="list-style-type: none"> <li>• “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2</li> <li>• “Create Storage Classes by Using the Custom Storage Class Designer” on page 37-14</li> </ul>

After you configure one or more categories of model elements, setting memory sections and **Shared utilities identifier format** model configuration parameters has no effect on the model configuration. When you open a coder app, Simulink migrates the model configuration parameter settings to the Code Mappings editor. As part of the migration, Simulink configures the Embedded Coder Dictionary that the model uses, as described in “Migration of Memory Section and Shared Utility Settings from Configuration Parameters to Code Mappings” on page 31-25.

## Elimination of Categories of Data by Optimizations

Code generation optimizations can eliminate data from the code, which means your application code cannot interact with the data. For general information about data elimination by optimizations, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49.

The optimizations can eliminate data in these categories only:

- **Model parameters**
- **Model parameter arguments**
- **External parameters**
- **Internal data**

After eliminating data with optimizations, the code generator applies the default code generation settings in the code mappings to the remaining data. For parameters and signal lines, optimizations can eliminate data for an entire category. If this elimination occurs, default settings that you specify for that category do not apply to data.

To prevent optimizations from eliminating individual data elements, explicitly apply a storage class to the individual element. The storage class controls the appearance of the data in the generated code. To force a data element to use the default storage class that you specify, explicitly apply the storage class `Model default`. See “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.

## Shared Dictionary Data Defaults

If you link a model to a Simulink data dictionary, which includes a coder dictionary that configures default code definitions for categories of data, you can use the Code Mappings editor to apply the dictionary defaults. In the Code Mappings editor, on the **Data Defaults** tab, select a category and set the storage class to `Dictionary Default`. If someone makes a change to the default settings in the shared coder dictionary, the code generator applies the updated default settings when producing code for your model. See “Configure Default Code Mapping in a Shared Dictionary” on page 31-10.

## Function Default Configurations

Reduce the effort of preparing a model for C code generation by specifying default configurations for categories of and functions, such as initialize/terminate and execution functions, across a model. Applying default configurations can save time and reduce the risk of introducing errors in code, especially for larger models and models from which you generate multi-instance code.

Default configurations apply throughout a model, excluding referenced models. Simulink saves a separate set of code mappings as part of each model in a model reference hierarchy.

If a model includes a significant number of functions of a given category (for example, more than 10), it is more efficient to configure the category by using a default setting, and then override that setting for special cases.

The default settings can help you to reduce manual data entry.

- As you add blocks and signals to a model, new functions inherit the default settings.
- To change code generation settings for many functions at once, make the changes in one place—the default settings.

- For efficiency, use naming rules as you make changes elsewhere in the model.

### Model Function Categories

You configure function defaults by using the **Code Mappings Editor - C Function Defaults** tab or the `setDataDefault` function. In the **Function Defaults** tab or function call, you can select or specify these categories of functions.

Model Function Category	Description
Initialize/Terminate	Entry-point functions for initialization and termination
Execution	Entry-point functions for initiating execution and resets
Shared utility	Shared utility functions

The code generator uses default naming rules to name entry-point functions. To integrate generated code with existing external code or to comply with naming standards or guidelines, you can adjust the default naming rule. Adjusting the default naming rule can save time, especially for multirate models for which the code generator produces a unique `step` function for each rate.

You might need to define a function customization template in the Embedded Coder Dictionary. Unless someone has defined function customization templates for a model, the Code Mappings editor presents `Default` as the only template option.

### Considerations for Configuring Default Code Generation Settings for Functions

Before configuring default code generation settings for functions, take into account the considerations listed in this table.

Consideration	More Information
What categories are relevant to your model?	The function categories in the preceding table
Does the model use several instances of functions that are in a category? If the answer is yes, applying default mappings is beneficial. Otherwise, consider configuring code generation for each function individually.	“Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113
Which function customization template aligns with your code generation requirements for each category?	“Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2
Do categories require the code generator to store function code in specific areas of memory? For example, consider whether to store initialization data in slow memory and algorithmic or computational data in fast memory.	<ul style="list-style-type: none"> <li>• “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2</li> <li>• “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2</li> </ul>

Consideration	More Information
Do you need to define new function customization templates that you can select in the Code Mapping editor?	<ul style="list-style-type: none"> <li>• “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2</li> <li>• “Create Storage Classes by Using the Custom Storage Class Designer” on page 37-14</li> </ul>
Do you have function naming requirements? If the answer is yes, what are they? To which categories do the requirements apply?	<ul style="list-style-type: none"> <li>• “Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113</li> <li>• “Identifier Format Control” on page 52-17</li> </ul>

After you configure one or more categories of model elements, setting memory sections and **Shared utilities identifier format** model configuration parameters has no effect on the model configuration. When you open a coder app, Simulink migrates the model configuration parameter settings to the Code Mappings editor. As part of the migration, Simulink configures the Embedded Coder Dictionary that the model uses, as described in “Migration of Memory Section and Shared Utility Settings from Configuration Parameters to Code Mappings” on page 31-25.

### Shared Dictionary Function Defaults

If you link a model to a Simulink data dictionary, which includes a coder dictionary that configures default code definitions for categories of functions, you can use the Code Mappings editor to apply the dictionary defaults. In the Code Mappings editor, on the **Function Defaults** tab, select a category and set the function customization template to **Dictionary Default**. If someone makes a change to the default settings in the shared coder dictionary, the code generator applies the updated default settings when producing code for your model. See “Configure Default Code Mapping in a Shared Dictionary” on page 31-10.

## Configurations for Individual Data Elements and Functions

After you configure model-wide default settings, you can override the defaults for individual data elements and functions. An individual data element or function configuration applies to a specific data element or function in a model. Configure data elements and functions individually when:

- The model includes a few elements of a given category that have unique source, naming, or placement requirements.
- You configured default settings and you want to override the default setting for an individual element.

For individual data elements, initially the storage class is set to **Auto**, which means that the code generator might eliminate or change the representation of relevant code for optimization purposes. If optimizations are not possible, the code generator applies the model default configuration.

- To avoid optimizations and force the code generator to use the default configuration, set the storage class to **Model default**.
- To override the default configuration, specify the storage class that meets the code generation requirements for that data element.

If a data element in a model is unnamed (for example, a signal has no label or a state has no name), you must specify a code identifier for the data element when configuring it for C code generation. Set the code identifier by specifying a value for the storage class property **Identifier**.

For individual functions, you can customize the function name. For execution functions, such as the step functions and Simulink functions for a model, you can configure function arguments.

## Configure Data

- 1 Open the Embedded Coder app.
- 2 Configure default mappings for categories of data elements. Select **Code Interface > Default Code Mappings**. In the Code Mappings editor, on the **Data Defaults** tab, select a model element category and set the storage class. In the Property Inspector, set storage class properties to align with model requirements.

If you need to define a storage class, use the Embedded Coder Dictionary. Select **Code Interface > Embedded Coder Dictionary**.

- 3 Decide whether to override default configuration settings for individual data elements. If you choose not to override settings, go to step 8.
- 4 Identify MATLAB variables that you want to configure individually and store the configurations in the model file. In the Model Explorer, convert the variables to `Simulink.Parameter` objects. The resulting data objects appear in the Code Mappings editor as model parameters.
- 5 Identify signals representing algorithm data that you want to monitor while the generated code executes and configure those signals individually. For each signal that you identify, do one of the following:
  - For signal data that is specific to a model (not shared), add the signals to the Code Mappings editor.
  - For shared signal data, create and configure `Simulink.Signal` objects.
- 6 Configure individual data elements. In the Code Mappings editor, click a category tab, select a data element, and set the storage class. In the Property Inspector, set storage class property values. To change the setting of model configuration parameter **Default parameter behavior**, click the link indicating the behavior when the storage class is set to `Auto`. In the Model Configuration Parameters dialog box, change the parameter setting to `Tunable` or `Inline`.

For information on configuring specific types of data elements, see:

- 7 To view and configure external data objects that are stored in the base workspace or a data dictionary, in the Code Mappings editor, on the **Data Defaults** tab, click the `Refresh` link to the right of the category name.
- 8 Generate and review code.

For more details and examples, see:

- “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2
- “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15
- **Code Mappings Editor - C**
- “Configure Root-Level Inport Blocks for C Code Generation” on page 32-30
- “Configure Root-Level Outport Blocks for C Code Generation” on page 32-41
- “Configure Signal Data for C Code Generation” on page 32-50
- “Configure Parameters for C Code Generation” on page 32-61

- “Configure Block States for C Code Generation” on page 32-74
- “Configure Data Stores for C Code Generation” on page 32-82
- “Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113

## Configure Functions

- 1 Open the Embedded Coder app.
- 2 Configure default mappings for categories of functions. Select **Code Interface > Default Code Mappings**. In the Code Mappings editor, on the **Function Defaults** tab, select a function category and set the function customization template.

You might need to define a function customization template. Templates are not available by default. To define a function customization template, use the Embedded Coder Dictionary. Select **Code Interface > Embedded Coder Dictionary**.

- 3 Decide whether to override default configuration settings for individual functions. If you choose not to override settings, go to step 5.
- 4 Configure individual entry-point functions. In the Code Mappings editor, click **Functions** tab, select a function, and set the function customization template. Alternatively, you can specify a function name. For execution functions, such as a model step function, you can customize the function arguments. Clicking a function preview link opens a dialog box that you can use to customize the entire function interface.
- 5 Generate and review code.

For more details and examples, see:

- “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2
- “Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113
- “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15

# Code Definition and Mapping Limitations and Considerations

## Limitations

- If a data element in a model is unnamed (for example, a signal has no label or a state has no name), you must specify a code identifier for the data element when configuring it for C code generation. Set the code identifier by specifying a value for the storage class property **Identifier**.
- You cannot use code mappings to configure MATLAB variables that are used as block parameters. Convert the variables to `Simulink.Parameter` objects in the model workspace. The resulting data objects appear in the Code Mappings editor as model parameters.
- Use code mappings to configure only one discrete state per block in a model.
- To map these data categories to a storage class defined in an Embedded Coder Dictionary, you must set the storage class property **Data Initialization** to `AutoDynamic` or `None`:
  - **Inports**
  - **Outports**
  - **Signals, states, and internal data**
  - **Shared local data stores**
- You cannot map data categories **External parameters** and **Global data stores**. For referenced models you cannot map data categories **Inports** and **Outports** to structured storage classes that are defined in an Embedded Coder Dictionary.
- You cannot map categories of data to:
  - Predefined structure-based storage classes, `Struct` and `BitField`
  - Package storage classes of type `FlatStructure` or `Other` that you create by using the Custom Storage Class Designer
- If you configure a model to use a code replacement library that includes a data alignment specification, you cannot configure default code mappings that involve storage classes defined in the Embedded Coder Dictionary for that model. For more information, see “Data Alignment for Code Replacement” on page 69-105.
- If a model contains a tunable, nonfinite parameter, for example, with a value of `inf`:
  - The code generator does not apply a specified default parameter mapping. The parameter appears as a field in the default parameter data structure `rtP` (see “Real-Time Model Data Structure” on page 33-32).
  - You cannot map an individual element to a storage class defined in an Embedded Coder Dictionary. If you do, the code generator returns an error. Choose one of these workarounds:
    - For the individual nonfinite parameter, set the storage class to a value other than `Auto` or `Model default`, as described in “Configure Parameters for C Code Generation” on page 32-61.
    - If only one block uses the variable or object, instead of using the variable or object, specify the nonfinite value directly in the model, in the block parameter.

## Default Code Mapping Constraints

- Map parameter categories to storage classes that are defined with the **Data Initialization** property set to `Auto`, `Static`, or `None`.

- If a model includes a reusable subsystem (a subsystem that has the block parameter **Function packaging** set to Reusable function) that contains a shared local data store, map the category **Shared local data stores** to a storage class that is defined in the Embedded Coder Dictionary for that model. For more information, see “Generate Reentrant Code from Subsystems” on page 7-33.
- For top and referenced models configured for multi-instance use, map data categories to storage classes that have the **Storage Type** property set to Structured. See “Generate Reentrant Code from Top Models” on page 7-18 and “Generate Reentrant Code from Simulink Function Blocks” on page 7-23.
- Default code mappings for categories **External parameters** and **Global data stores** must be the same for models throughout the model reference hierarchy.
- When a model is configured for compact file packaging, you cannot map a data category to a storage class defined with the **Data Scope** property set to Exported and the **Header File** property set to a naming rule other than \$N.h.
- When evaluating storage class settings for variant control variables, the code generator ignores default code mappings. For more information, see “Represent Subsystem and Variant Models in Generated Code” on page 26-22.

## Unresolved Code Definitions

If someone removes the definition for a storage class, function customization template, or memory section from the Embedded Coder Dictionary associated with a model, the Code Mappings editor identifies the definition as Unresolved. For example, this figure shows that the function customization template for execution entry-point functions was removed from the dictionary associated with the model.

Data Defaults		Function Defaults	
		Filter contents	
	Model Function Category	Function Customization Template	
<i>fx</i>	Initialize/Terminate	exSlowFunction	
<i>fx</i>	Execution	! Unresolved	
<i>fx</i>	Shared utility	Default	

To fix the unresolved code definition, do one of the following:

- Select a different definition in the **Storage Classes**, **Function Customization Templates**, or **Memory Sections** column.
- If you have Embedded Coder, replace or add a definition to the Embedded Coder Dictionary. Then, update the mapping.
- Consult with someone, such as the system architect for your project, about adding a definition to the Embedded Coder Dictionary. Then, update the mapping.

## Model Editing Operations and Individual Data Element Code Mappings

While editing a model in the context of a coder app, you should be aware of the relationship between Simulink model editing tools, such as copy and undo, and code mappings. In the context of a coder

app, when you perform copy-and-paste or cut-and-paste editing operations within a model, the coder app preserves the code mappings for individual data elements. For example, within a model, if you copy and paste the source block of a signal that is configured with a specific storage class, the pasted version of the signal port retains the same storage class.

While you can use undo and redo operations for editing actions on model data elements, they are unavailable while configuring code mappings. For example, if you delete a state block, and then click **Undo**, the block reappears in the model canvas and the code configuration for the state reappears in the code mappings. In the Code Mappings editor, if you change the storage class setting for a state from **Auto** to **Model default**, and then click **Undo**, the storage class does not revert to **Auto**. In this case, the change pertains to the code mapping, not to the model data element.

## Storage Classes and Reentrant, Multi-Instance Models and Components

The code that you generate from a model or component (referenced model or subsystem) is multi-instance code if it allows your application to maintain multiple independent instances of the component during execution. For example, you can generate reentrant, multi-instance code from an entire model by setting the model configuration parameter **Code interface packaging** to **Reusable function**. For general information about multi-instance models and components, see “Code Reuse”.

Under some circumstances, applying storage classes can:

- Prevent you from generating multi-instance code.
- Cause some data elements to appear in the generated code as singletons, which means that each instance of the model or component directly accesses the same shared, global data, creating dependencies between the instances.

To avoid errors and unexpected generation of single-instance code and singleton data, observe the guidelines and limitations below.

### Directly Applied Storage Classes

When you apply a storage class directly to a data element (see “C Code Generation Configuration for Model Interface Elements” on page 32-2):

- To generate multi-instance code, you must apply the storage class only to parameter objects, global data stores, shared local data stores, and root-level I/O.
- The storage class yields only singleton data.

### Storage Classes Applied by Default

When you apply a default storage class (see “C Code Generation Configuration for Model Interface Elements” on page 32-2):

- For these data categories, you can generate only singleton data:
  - **Model parameters**
  - **External parameters**
  - **Global data stores**
  - **Shared local data stores**

- For **Internal data**, you can generate only instance-specific data, which means each instance of the model or component operates on a separate copy of the data. For this category, you must use the example storage class `SignalStruct`, which appears after preparing a model for code generation with the Quick Start tool. Alternatively, you can create and use your own structured storage class by using an Embedded Coder Dictionary.

For more information, see “What Is Reentrant Code?” and “Choose Storage Class for Controlling Data Representation in Generated Code”.

## Copy Code Mappings When Converting Subsystems to Referenced Models

You can copy code mappings when you convert a subsystem to a referenced model.

- In the **Model Reference Conversion Advisor**, select **Copy code mappings**.
- In the MATLAB command window, use the `Simulink.SubSystem.convertToModelReference` function with the comma-separated pair consisting of `'CopyCodeMappings'` and `true`.

### See Also

### More About

- “C Code Generation Configuration for Model Interface Elements” on page 32-2

## Configure Default C Code Generation for Categories of Data Elements and Functions

Reduce the effort of preparing a model for C code generation by specifying default configurations for categories of data elements and functions across a model. Applying default configurations can save time and reduce the risk of introducing errors in code, especially for larger models and models from which you generate multi-instance code.

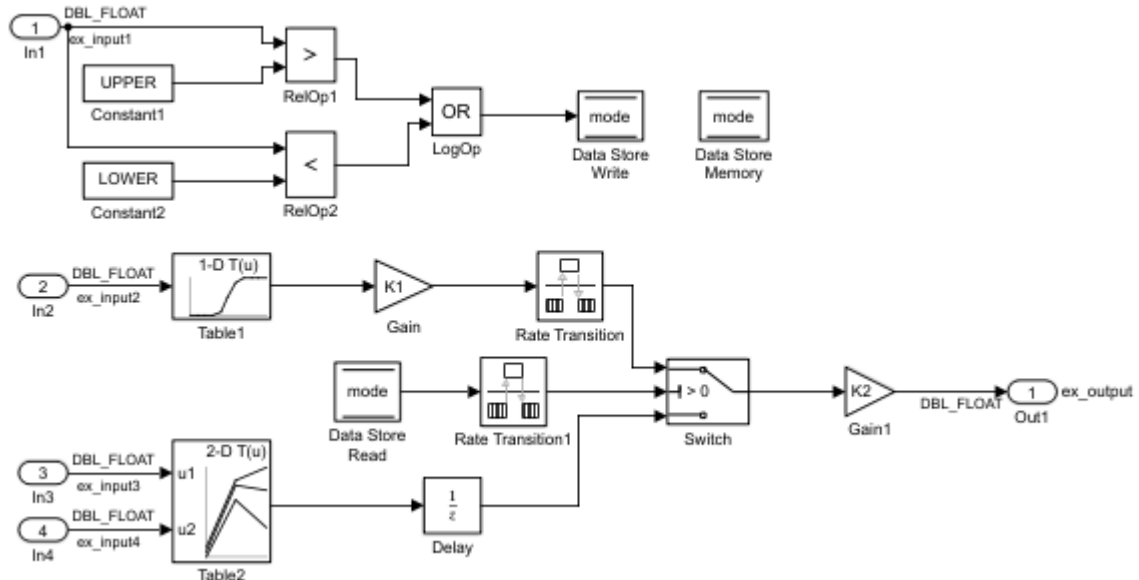

You must have set up the example environment, as described in “Set Up Example Environment” on page 32-15.

### Set Up Example Environment

- 1 Copy these external source and header files from `matlabroot/toolbox/rtw/rtwdemos` to a writable working folder. These files define and declare the external data type and data that the generated code uses.

File	Description
<code>exDbfFloat.h</code>	Defines the project data type alias for double, <code>DBL_FLOAT</code> . Simulink uses the <code>PreLoadFcn</code> callback specified for the model to parse this header file and create a corresponding <code>Simulink.AliasType</code> object.
<code>exInDataMem.c</code>	Includes <code>exInDataMem.h</code> and defines variable <code>ex_input1</code> .
<code>exInDataMem.h</code>	Includes <code>exDbfFloat.h</code> and declares variable <code>ex_input1</code> .
<code>exInDataLut.c</code>	<code>exInDataLut.c</code> includes <code>exInDataLut.h</code> and defines variables <code>ex_input2</code> , <code>ex_input3</code> , and <code>ex_input4</code> .
<code>exInDataLut.h</code>	Includes <code>exDbfFloat.h</code> and declares variables <code>ex_input2</code> , <code>ex_input3</code> , and <code>ex_input4</code> .
<code>exCodeDefs.sldd</code>	Data dictionary
<code>rtwdemo_configdefaults.slx</code>	Example model.

- 2 Open your copy of example model `rtwdemo_configdefaults`.

- 3 In the apps gallery, open the **Embedded Coder** app.

## Configure Default Code Generation for Data

This example shows how to use the Code Mappings editor to specify code generation requirements for model data. The model uses multiple execution rates and is configured for single-instance usage.

This example assumes these code generation requirements for data:

- Use project type definition `DBL_FLOAT` defined in header file `exDb1Float.h`.
- Get data element `ex_input1` from header file `exInDataMem.h`. The data is used for computing a value stored in memory, and then used in an if-else condition of a Switch block.
- Get data elements `ex_input2`, `ex_input3`, and `ex_input4` from header file `exInDataLut.h`. The data is used in lookup tables `Table1` and `Table2`.
- Data imported into the model from header files `exInDataMem.h` and `exInDataLut.h` is of type `DBL_FLOAT`, a project standard.
- Parameter `K1` must be tunable to enable calibration.
- Data store `mode` defines data that is shared within the model. The Logical Operator block writes to the data store and a Rate Transition block reads from the data store.
- Data element `X` represents the delay for the Unit Delay block.
- Store data that is internal to the model, such as delay `X`, in a section of memory labeled `internalDataMem`.
- Export output data declarations to header file `exSysOut.h` and definitions to `exSysOut.c`.
- Name variables representing inports and outports in the generated code as specified in this table so they match variable names in the external header and definition files.

Although the model uses single instances of some data, the example configures default settings to demonstrate different types of mappings. As you add blocks to the model, new data elements acquire the default code generation mappings.

### Configure Default Settings for Root Inports

Specify an external header file that declares input data. Three of the four root inports read input from variables declared in header file `exInDataLut.h`. Set that header file as the default.

- 1 Open model `rtwdemo_configdefaults`. Save a copy to a writable location.
- 2 Open the **Embedded Coder** app.
- 3 In the **C Code** tab, select **Code Interface > Default Code Mappings**. This opens the Code Mappings editor **Data Defaults** tab.
- 4 In the **Data Defaults** tab, expand **Inports and Outports**. Then, select **Inports**.
- 5 Set the storage class to `ImportFromFile`.
- 6 Click the  icon and set **Header File** to `exInDataLut.h`.

### Configure Default Settings for Model Parameters

Configure default settings for model workspace parameters that you want to be tunable.

- 1 In the Code Mappings editor, click the **Data Defaults** tab.
- 2 In the **Data Defaults** tab, expand **Parameters**.
- 3 In the row for **Model parameters**, click the text 'Auto' will be inlined. The Model Configuration Parameters dialog box opens to the **Code Generation > Optimization** pane. Set **Default parameter behavior** to `Tunable`. Apply the change and close the dialog box. In the Code Mappings editor, the text to the right of **Model parameters** now reads 'Auto' will be tunable.
- 4 To include global variable definitions and declarations in the generated code for model parameters, set the storage class for the **Model parameters** category to `ExportedGlobal`.

### Define Memory Section for Internal Data

Define a memory section for storing unit delay  $X$ , data that is internal to the model.

- 1 Open the Embedded Coder Dictionary by selecting **Code Interface > Embedded Coder Dictionary**.
- 2 In the Embedded Coder Dictionary, on the left pane, click **Memory Section**.
- 3 Click **Create**.
- 4 In the new row of the table, name the new memory section `internalDataMem`. Also set:
  - **Pre Statement** to `#pragma start INTERNALDATA`
  - **Post Statement** to `#pragma end INTERNALDATA`
  - **Statements Surround** to `Group of variables`
- 5 Close the dictionary.

For more information, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

### Configure Default Settings for Internal Data

Set up the default code generation configuration for internal data to include memory section `internalDataMem`.

- 1 In the Code Mappings editor, click the **Data Defaults** tab.
- 2 In the **Data Defaults** tab, expand **Signals**.
- 3 Select category **Signals, states, and internal data**.
- 4 Click the  icon and set **Memory Section** to `internalDataMem`.

### Configure Default Settings for Root Output

Specify the default external header and definition files for variables to which the generated code writes output.

- 1 In the Code Mappings editor, click the **Data Defaults** tab.
- 2 In the **Data Defaults** tab, expand **Inports and Outports**.
- 3 Select category **Outports**.
- 4 Set the storage class to `ExportToFile`.
- 5 Click the  icon and set **Header File** to `exSysOut.h` and **Definition File** to `exSysOut.c`.

### Apply Default Configurations to Individual Data Elements

Unless you explicitly map individual data elements to alternative storage class settings, the Code Mappings editor assumes the storage class for elements is `Auto`. When the storage class for a data element is `Auto`, the code generator might eliminate or change the representation of relevant code for optimization purposes. If optimizations are not possible, the code generator applies the model default configuration.

- To avoid optimizations and force the code generator to use the default configuration, set the storage class for the individual element to `Model default`.
- To override the default configuration, specify the storage class that meets the code generation requirements for that data element.

For this example, configure the code generator to apply the default storage class setting to these data elements:

- Inports `In2`, `In3`, and `In4`
- Outputport `Out1`
- Model parameter `K1`
- State `X`

- 1 In the Code Mappings editor, click the **Inports** tab.
- 2 Select the rows for inports `In2`, `In3`, and `In4`. Then, for one of the selected inports, set the storage class to `Model default: ImportFromFile`. The storage class for the three selected inports changes to `Model default: ImportFromFile`.
- 3 Click the **Outports** tab. For outputport `Out1`, set the storage class to `Model default: ExportToFile`.
- 4 Click the **Parameters** tab. Expand **Model Parameters**. Then, for parameter `K1`, set the storage class to `Model default: ExportedGlobal`.
- 5 Click the **Signals/States** tab. Expand **States**. For state `X`, set the storage class to `Model default: Default`.

## 6 Save the model.

### Generate and Verify Code

Generate code and verify the generated code.

- In the file `rtwdemo_configdefaults.h`, search for `#include` statements that include the header files that declare external input data.

```
#include "exInDataMem.h"
#include "exInDataLut.h"
```

- Open file `rtwdemo_configdefaults.c`. The code initializes the gain variable `K1` and uses the variable in the model step function `exFast_step1`.

```
DBL_FLOAT K1 = 2.0;
.
.
.
void exFast_step1(void)
{
 DBL_FLOAT rtb_Gain;

 rtb_Gain = K1 * look1_binlc(ex_input2, (&(rtTable1_bp01Data[0])),
 (&(rtTable1_tableData[0])), 10U);

 rtDWork.RateTransition_Buffer0 = rtb_Gain;
}
.
.
}
```

- In file `rtwdemo_configdefaults.c`, find `#pragma` control lines that define memory sections for `INTERNALDATA` (the local data store, unit delay, and constants).

```
#pragma start INTERNALDATA
D_Work rtDWork;
#pragma end INTERNALDATA
.
.
.
#pragma start INTERNALDATA
static RT_MODEL rtM_;
#pragma end INTERNALDATA
.
.
.
#pragma start INTERNALDATA
extern D_Work rtDWork;
#pragma end INTERNALDATA
```

- Open file `exSysOut.c`. The file includes an exported data definition for `ex_output`.

```
#include "rtwdemo_configdefaults.h"

DBL_FLOAT ex_output;
```

- Open shared file `exSysOut.h`. The file declares `ex_output`. To gain access to `ex_output`, external code can include this header file.

```
extern DBL_FLOAT ex_output;
```

## Configure Default Code Generation for Functions

This example shows how to use the Code Mappings editor to specify code generation requirements for model functions. The model uses multiple execution rates and is configured for single-instance usage. The code generator produces initialize, execution, and terminate entry-point functions. Because the model uses multiple rates, the code generator produces an execution function for each rate.

This example assumes these code generation requirements:

- Store generated initialize and terminate functions in memory section `functionSlowMem` and execution functions in memory section `functionFastMem`.
- Use the naming rule `exSlow_$N` to name `initialize` and `terminate` functions. Use the naming rule `exFast_$N` to name execution functions.

### Define Memory Sections

Define the two memory sections: `functionSlowMem` for initialize and terminate functions and `functionFastMem` for execution functions.

- 1 Open the **Embedded Coder** app.
- 2 Open the Embedded Coder Dictionary by selecting **Code Interface > Embedded Coder Dictionary**.
- 3 In the Embedded Coder Dictionary, on the left pane, click **Memory Section**.
- 4 Click **Create**.
- 5 In the new row of the table, name the new memory section `functionFastMem`. Then, set:
  - **Pre Statement** to `#pragma start FASTMEM`
  - **Post Statement** to `#pragma end FASTMEM`
- 6 Click **Add** again. Name the memory section `functionSlowMem`. Then, set:
  - **Pre Statement** to `#pragma start SLOWMEM`
  - **Post Statement** to `#pragma end SLOWMEM`

### Define Function Customization Templates

To configure categories of functions, define function customization templates. Unless you define templates in the Embedded Coder Dictionary that are associated with a model, the only available template is `Default`. Based on the requirements, in the dictionary, define two function customization templates: one to specify the naming rule and memory section for initialize and terminate functions and one to specify the naming rule and memory section for execution functions.

- 1 In the Embedded Coder Dictionary, click **Function Customization Template**.
- 2 Click **Create**.
- 3 In the new row of the table, name the new template `exFastFunction`. Then, set:
  - **Function Name** to `exFast_$N`. This naming rule applies the prefix `exFast_` to the name that identifies the default code generator name of the function (for example, `initialize` or `step`).
  - **Memory Section** to `functionFastMem`. This mapping associates the memory section that you defined in “Define Memory Sections” on page 32-20 with the new template.

- 4 Click **Create** again. Name the template exSlowFunction. Then, set:
  - **Function Name** to exSlow\_\$.N.
  - **Memory Section** to functionSlowMem.
- 5 Close the dictionary.

### Configure Default Settings for Functions

- 1 In the **C Code** tab, click **Code Interface > Default Code Mappings**.
- 2 In the Code Mappings editor, click the **Function Defaults** tab.
- 3 Configure the initialize and terminate entry-point functions. For category **Initialize/Terminate**, select template exSlowFunction.
- 4 Configure the execution entry-point functions. For category **Execution**, select template exFastFunction.
- 5 Save the model.

### Generate and Verify Code

- 1 Generate code.
- 2 In the **Code** view:
- 3
  - Open file rtwdemo\_configdefaults.c. Click in the **Search** field. A menu lists the generated entry-point functions:
    - exFast\_step0 (called periodically, every 0.5 seconds)
    - exFast\_step1 (called periodically, every 1 second)
    - exFast\_step2 (called periodically, every 1.5 seconds)
    - exSlow\_initialize
  - To gain access to the entry-point function code in rtwdemo\_configdefaults.c, click the function name. Verify the pragma control statements that surround the function code. For example:

```

.
.
.
#pragma start FASTMEM

void exFast_step2(void) /* Sample time: [1.5s, 0.0s] */
{
 boolean_T rtb_DataStoreRead;

 rtb_DataStoreRead = ((ex_input1 > 10.0) || (ex_input1 < -10.0));

 rtDWork.RateTransition1_Buffer0 = rtb_DataStoreRead;
}

#pragma end FASTMEM

#pragma start SLOWMEM

void exSlow_initialize(void)
{
 /* (no initialization code required) */
}

#pragma end SLOWMEM
.
.
.

```

- Open file `rtwdemo_configdefaults.h`. Use **Search** to find `#pragma` control lines that define memory sections for FASTMEM and SLOWMEM. Verify the `pragma` control statements surround the declarations. For example:

```

.
.
.
#pragma start SLOWMEM

extern void exSlow_initialize(void);

#pragma end SLOWMEM
#pragma start FASTMEM

extern void exFast_step0(void);

#pragma end FASTMEM
.
.
.

```

## Configure Model Elements for Code Generation with Definitions Stored in Shared Data Dictionary

You have the option of configuring default data and function code generation with definitions that are set up in a Simulink data dictionary. A data dictionary enables sharing of code definitions between models. This example shows how to change a model from using code definitions in a model-specific Embedded Coder Dictionary to using definitions in an Embedded Coder Dictionary that is in a shared data dictionary. If you have completed the examples in “Configure Default Code Generation for Data” on page 32-16 and “Configure Default Code Generation for Functions” on page 32-20 you have added these code definitions to the Embedded Coder Dictionary associated with model `rtwdemo_configdefaults`.

- Memory section `internalDataMem` with **Pre Statement** set to `#pragma start INTERNALDATA` and **Post Statement** set to `#pragma end INTERNALDATA`.
- Memory section `functionFastMem` with **Pre Statement** set to `#pragma start FASTMEM` and **Post Statement** set to `#pragma end FASTMEM`.
- Memory section `functionSlowMem` with **Pre Statement** set to `#pragma start SLOWMEM` and **Post Statement** set to `#pragma end SLOWMEM`.
- Function customization template `exFastFunction` with function naming rule `exFast_$N` and memory section `functionFastMem`
- Function customization template `exSlowFunction` with function naming rule `exSlow_$N` and memory section `functionSlowMem`

Update model `rtwdemo_configdefaults` to use the same code definitions in data dictionary `exCodeDefs.sldd` instead of definitions in the local model Embedded Coder Dictionary.

You must have set up the example environment, as described in “Set Up Example Environment” on page 32-15.

### Link Model to Shared Data Dictionary

- 1 In the Simulink Editor, select **Modeling > Link to Data Dictionary**.
- 2 In the Model Properties dialog box, in the **External Data** tab, browse to the location of your copy of data dictionary file `exCodeDefs` and select that file.

- 3 Click **Migrate data**.
- 4 In the Link Model to Data Dictionary dialog box, click **Apply**.
- 5 In the Migrate Data dialog box, click **Migrate**. When the data migration is complete, click **OK**.

### Review Contents of Linked Data Dictionary

- 1 In the lower-left corner of the model canvas, click the **Model data** icon.
- 2 From the list of model data sources, click **External Data**.
- 3 In the Model Explorer, in the **Model Hierarchy** pane, expand the **exCodeDefs** node.
- 4 Right-click **Embedded Coder Dictionary**.
- 5 Click the **Open Embedded Coder Dictionary** button that appears.
- 6 In the Embedded Coder Dictionary, review the definitions in the **Function Customization Template** and **Memory Section** tabs.
- 7 Close the Embedded Coder Dictionary.

### Remove Model Sourced Code Definitions from Model Embedded Coder Dictionary

- 1 Open the **Embedded Coder** app.
- 2 In the **C Code** tab, select **Code Interface > Embedded Coder Dictionary**.
- 3 Remove the code definitions created locally in the model.
  - In the **Function Customization Templates** table, select the rows for `exSlowFunction` and `exFastFunction` that have **Source** set to `rtwdemo_configdefaults`. Click the **Delete** icon.
  - In the **Memory Sections** table, select the rows for `functionFastMem`, `functionSlowMem`, and `internalDataMem` that have **Source** set to `rtwdemo_configdefaults`. Click the **Delete** icon.
- 4 Close the dictionary.
- 5 Save the model.

### Configure Default Categories for Code Generation

- 1 In the **C Code** tab, select **Code Interface > Default Code Mappings**.
- 2 In the Code Mappings editor, click the **Data Defaults** tab.
- 3 Expand **Signals**. Select category **Signals, states, and internal data**.
- 4 Click the  icon. Set **Memory Section** to `internalDataMem`.
- 5 Click the **Function Defaults** tab.
  - For the **Initialize/Terminate** category, select function customization template `exSlowFunction`.
  - For the **Execution** category, select template `exFastFunction`.
- 6 Save the model.
- 7 Generate and review code.

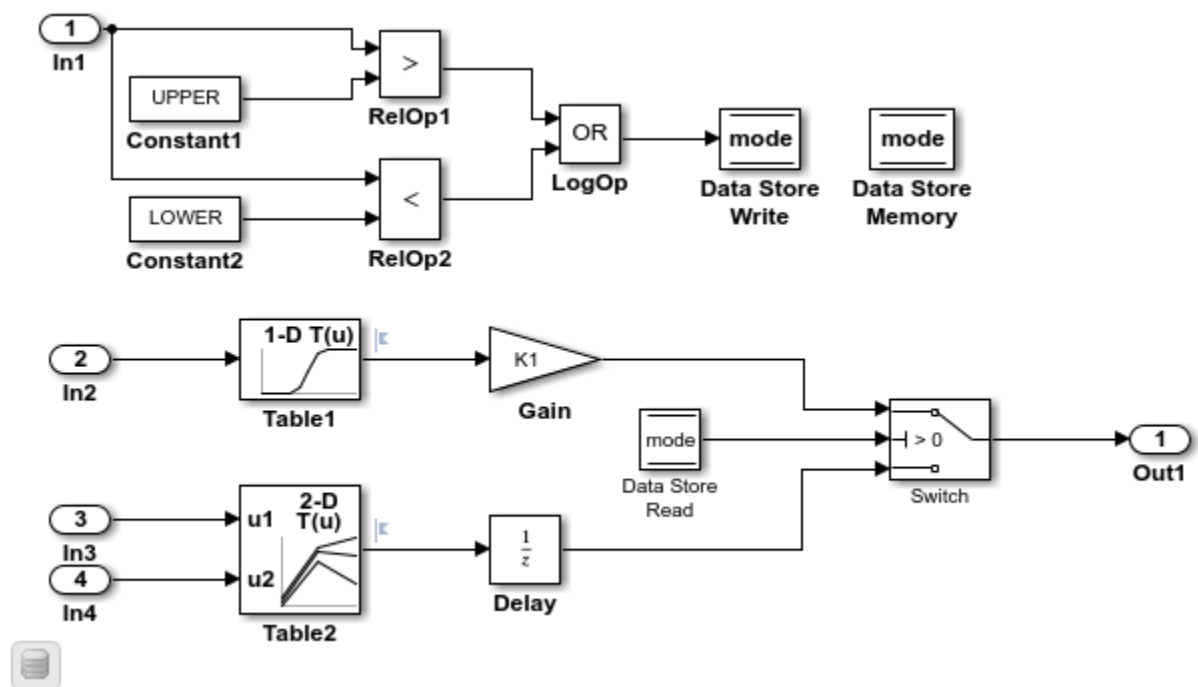

For more information about setting up an Embedded Coder Dictionary, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2.

## Configure Default Data and Function Code Generation Programmatically

This example shows how to configure default data and function code generation for example model `rtwdemo_configdefaults`. The example uses the default mapping programming interface to specify code generation requirements for model data and functions. Use that interface to automate the configuration, or if you prefer to configure models programmatically. For information about configuring the default data and function code generation by using the Code Mappings editor, see “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15.

### Open the Model

The model `rtwdemo_configdefaults` uses multiple execution rates and is configured for single-instance usage.

```
open_system('rtwdemo_configdefaults')
```

### Code Generation Requirements

For this example, these are the code generation requirements:

- Import project type definition for data of type `double`, `DBL_FLOAT`, from header file `exDblFloat.h`.
- Import signal `ex_input1` for computing a value stored in memory and used in an if-else condition in the Switch block. Import the signal data from header file `exInDataMem.h`.
- Import signals `ex_input2`, `ex_input3`, and `ex_input4` for lookup tables `Table1` and `Table2`. Import the signal data from header file `exInDataLut.h`.
- Data imported into the model from header files `exInDataMem.h` and `exInDataLut.h` is of type `DBL_FLOAT`, a project standard.

- Parameters UPPER, LOWER, K1, and K2 are parameter objects stored in the model workspace. Represent the parameters as global variables in the generated code.
- Data element X represents the delay for the Unit Delay block.
- Store data that is internal to the model in memory section `internalDataMem`.
- Store generated initialize and terminate functions in memory section `functionSlowMem` and execution functions in memory section `functionFastMem`.
- Use the identifier naming rule `exSlow_$N` to name `initialize` and `terminate` entry-point functions. Use the naming rule `exFast_$N` to name execution functions for .5 second and 1.5 second periodic functions. Set the name of the 1 second periodic function to `exFast_1sec`.
- Export output data declarations to header file `exSysOut.h` and definitions to `exSysOut.c`.

For this example, someone, such as a system architect, has previously created these code definitions in an Embedded Coder Dictionary that is part of Simulink data dictionary `exCodeDefs.sldd`:

- Memory sections `internalDataMem`, `functionFastMem`, and `functionSlowMem`.
- Function customization templates `exFastFunction` and `exSlowFunction`.

### Get Data and Function Code Mappings for Model

Get the code mappings for example model `rtwdemo_configdefaults` by specifying the name of the model in a call to function `coder.mapping.api.get`. The function returns an object that represents the code mappings for the model. You specify that object as the first argument in subsequent calls to other functions in the API.

If code mappings do not exist for a model, create a code mappings object by calling `coder.mapping.utils.create`.

```
cm = coder.mapping.api.get('rtwdemo_configdefaults');
```

### Set Relevant Category, Property, and Value Combinations

Set relevant category, property, and value combinations with calls to `setDataDefaults` and `setFunctionDefaults`. The first two arguments that you specify for these functions are the code mappings object returned by `coder.mapping.api.get` and the name of a data or function category. In addition, you specify name-value pair arguments that specify the default configuration information that you want to set, such as the storage class and storage class properties.

In this example, you set the default:

- Storage class for Inport blocks, Outport blocks, and model parameters
- Memory section for internal data (for example, `signald` and block states)
- Header and definition files for Inport and Outport blocks
- Function customization template for initialize, terminate, and execution functions

```
% Configure data defaults
setDataDefault(cm, 'Inports', 'StorageClass', 'ImportFromFile', 'HeaderFile', 'exInDataLut.h');
setDataDefault(cm, 'Outports', 'StorageClass', 'ExportToFile', 'HeaderFile', 'exSysOut.h', ...
 'DefinitionFile', 'exSysOut.c');
setDataDefault(cm, 'ModelParameters', 'StorageClass', 'ExportedGlobal');
setDataDefault(cm, 'InternalData', 'MemorySection', 'internalDataMem');
```

```
% Configure function defaults
```

```
setFunctionDefault(cm, 'InitializeTerminate', 'FunctionCustomizationTemplate', 'exSlowFunction');
setFunctionDefault(cm, 'Execution', 'FunctionCustomizationTemplate', 'exFastFunction');
```

### Verify Default Mappings

Verify default mappings with calls to `getDataDefaults` and `getFunctionDefaults`. The first two arguments that you specify for these functions are the code mappings object returned by `coder.mapping.api.get` and the name of a data or function category. In addition, you specify the name of the configuration information that you want the function to return, such as the name of the storage class or a storage class property.

In this example, you verify these default settings:

- Storage class for Inport blocks, Outport blocks, and model parameters
- Memory section for internal data (for example, signal data and block states)
- Header and definition files for Inport and Outport blocks
- Function customization template for initialize, terminate, and execution functions

```
% Verify default data configurations
defscInports = getDataDefault(cm, 'Inports', 'StorageClass')

defscInports =
'ImportFromFile'

defhfileInports = getDataDefault(cm, 'Inports', 'HeaderFile')

defhfileInports =
'exInDataLut.h'

defscOutport = getDataDefault(cm, 'Outports', 'StorageClass')

defscOutport =
'ExportToFile'

defhfileOutport = getDataDefault(cm, 'Outports', 'HeaderFile')

defhfileOutport =
'exSysOut.h'

defdffileOutport = getDataDefault(cm, 'Outports', 'DefinitionFile')

defdffileOutport =
'exSysOut.c'

defscParams = getDataDefault(cm, 'ModelParameters', 'StorageClass')

defscParams =
'ExportedGlobal'

defmemInternal = getDataDefault(cm, 'InternalData', 'MemorySection')

defmemInternal =
'internalDataMem'

% Verify default function configurations
deftempInitTerm = getFunctionDefault(cm, 'InitializeTerminate', 'FunctionCustomizationTemplate')
```

```

deftempInitTerm =
'exSlowFunction'

deftempExecution = getFunctionDefault(cm, 'Execution', 'FunctionCustomizationTemplate')

deftempExecution =
'exFastFunction'

```

### Configure Individual Data Elements to Use Default Configuration Settings

The storage class for each model data element is set to `Auto`, which means that the code generator might eliminate or change the representation of relevant code for optimization purposes. If optimizations are not possible, the code generator applies the model default configuration.

- To avoid optimizations and force the code generator to use the default configuration, set the storage class to `Model default`.
- To override the default configuration, specify the storage class that meets the code generation requirements for that input.

For this example, you configure the code generator to apply the default storage class setting to the `Inport` blocks, the `Output` block, model parameters, and state `X` for the `Unit Delay` block. Use the `find` function to get the names of the data elements in the model of the different categories. Then, use the values returned by `find` in calls to `setInport`, `setOutputport`, `setModelParameter`, and `setState` to set the storage class to `Model default`. Use calls to `getInport`, `getOutputport`, `getModelParameter`, and `getState` to verify the storage class settings.

In each of the function calls, you specify the code mappings object returned by `coder.mapping.api.get`. In addition:

- In the call to the `find` function, you specify a value indicating code mapping information that you want the function to return.
- The calls to `setInport`, `setOutputport`, `setModelParameter`, and `setState` identify data elements that you want to configure and a name-value pair argument that specifies the configuration information that you want to set, such as the storage class or a storage class property.
- The calls to `getInport`, `getOutputport`, `getModelParameter`, and `getState` identify a data element for which you want to return configuration information and the type of information that you want the function to return.

```

input = find(cm, 'Inports');
setInport(cm, input, 'StorageClass', 'Model default');

output = find(cm, 'Outputports');
setOutputport(cm, output, 'StorageClass', 'Model default');

params = find(cm, 'ModelParameters');
setModelParameter(cm, params, 'StorageClass', 'Model default');

states = find(cm, 'States');
setState(cm, states, 'StorageClass', 'Model default');

scIn1 = getInport(cm, 'In1', 'StorageClass')

scIn1 =
'Model default'

```

```
scIn2 = getInport(cm, 'In2', 'StorageClass')
scIn2 =
'Model default'
scIn3 = getInport(cm, 'In3', 'StorageClass')
scIn3 =
'Model default'
scIn4 = getInport(cm, 'In4', 'StorageClass')
scIn4 =
'Model default'

scK1 = getModelParameter(cm, 'K1', 'StorageClass')
scK1 =
'Model default'
scTable2 = getModelParameter(cm, 'Table2', 'StorageClass')
scTable2 =
'Model default'
scK2 = getModelParameter(cm, 'K2', 'StorageClass')
scK2 =
'Model default'

scX = getState(cm, 'rtwdemo_configdefaults/Delay', 'StorageClass')
scX =
'Model default'
```

### Override Default Header File Setting for Inport Block In1

Previously, you set the default header file for inports to `exInDataLut.h`. The requirements specify that you import data for Inport block In1 from header file `exInDataMem.h`.

For Inport block In1, override the default storage class to `ImportFromFile` and set the header file to `exInDataMem.h` with a call to `setInport`. The function call specifies the code mappings object returned by `coder.mapping.api.get`, the name of the Inport block to configure, and name-value pair arguments specifying that the function set `StorageClass` to `ImportFromFile` and `HeaderFile` to `exInDataMem.h`.

```
setInport(cm, 'In1', 'StorageClass', 'ImportFromFile', 'HeaderFile', 'exInDataMem.h');
```

### Verify Header File Setting

Verify the updated header file setting for Inport block In1 with a call to `getInport`. The function call specifies the code mappings object returned by `coder.mapping.api.get`, the name of the Inport block of interest, and the configuration information to return.

```
hfileIn1 = getInport(cm, 'In1', 'StorageClass')
hfileIn1 =
'ImportFromFile'
```

## Override Default Function Name Setting for Step Function

Previously, you set the default function customization template for execution functions to `functionFastMem`, which applies the naming rule `exFast_$N` to the three step functions generated for the model. The requirements specify that the name for function `Periodic:D2`, which has a sample time of 1 second, be named `exFast_1sec`.

Set the function name with a call to `setFunction`. The function call specifies the code mappings object returned by `coder.mapping.api.get`, the source of the function, `Periodic:D2`, and the name-value pair argument specifying that the function set the function name to `exFast_1sec`.

```
setFunction(cm, 'Periodic:D2', 'FunctionName', 'exFast_1sec')
```

## Verify Function Name Setting

Verify the updated function name setting for execution function `Periodic:D2` with a call to `getFunction`. The function call specifies the code mappings object returned by `coder.mapping.api.get`, the function of interest, and property `FunctionName`.

```
functionName = getFunction(cm, 'Periodic:D2', 'FunctionName')

functionName =
'exFast_1sec'
```

## Configure Root-Level Inport Blocks for C Code Generation

To use code that you generate from a model, you call generated entry-point functions. The calling environment and generated functions exchange input and output data, for example, as global variables or function arguments. Root-level Inport blocks (inports) constitute the input data of the interface. To integrate and deploy the generated code into applications, you can customize how the code generator produces the interface code, including how input data is declared and handled. Customizations can:

- Minimize the modifications that you must make to existing code.
- Generate stable interfaces that do not change or minimally change when you make changes to your model.
- Generate code that exchanges data more efficiently (for example, by using pointers and pass-by-reference arguments for nonscalar data).

Enable and Trigger blocks (function-call inports) also load data into a system from outside the system. From a code generation perspective, these modeling elements are exported functions. For an exported function, the code generator produces an entry-point function, which you can configure. See “Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113.

For code generation, examples show how to customize the inport interface for model `rtwdemo_configinterface`. You can configure code mappings by using the **Code Mappings Editor - C** or code mappings API (`coder.mapping.api.CodeMapping`).

### Choose Customization Options for Inport Interface

By default, root-level inports in a model appear in generated code as fields of a global data structure named `model_ExtU`. Based on your code interface requirements, decide whether to customize generation of root-level inport data. If you do not configure customizations, the code generator determines whether to eliminate or change the representation of inports in generated code for optimization purposes. If you configure customizations, decide:

- Whether to set up a default configuration

If a model includes a significant number (for example, more than 10) of root-level inports, it is more efficient to configure the inports with a default setting, and then override that setting for special cases. If the model includes a few root-level inports that have unique source, naming, or placement requirements, consider configuring the inports individually.

- How to declare and handle root-level inport data in the generated interface
  - As separate global variables
  - To read input data from global variables defined in external code
  - For referenced model inports, as global variables (void-void)
  - As calls to access functions. Requires Embedded Coder
  - As entry-point function arguments. Requires Embedded Coder

For more information about these options, see “Control Data and Function Interface in Generated Code” on page 33-44.

Other considerations include whether to:

- Name inports in the generated code by using Inport block labels that appear in the model or by using unique code identifiers.
- Include the `volatile` type qualifier in global variable definitions and declarations. Requires Embedded Coder. See “Protect Global Data with `const` and `volatile` Type Qualifiers” on page 42-13.
- Place data read into a specific area of memory. Requires Embedded Coder. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

For a list of interface requirements that are relevant to inports with corresponding storage classes and storage class properties, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.

For example model `rtwdemo_configinterface`, inport interface requirements are:

- Use project type definition `DBL_FLOAT` defined in header file `exDbFloat.h`.
- Get data for inport `In1` from header file `exInDataMem.h`. The data is used for computing a value that is stored in memory, and then used in an if-else condition of code generated for the Switch block.
- Get data elements for inports `In2`, `In3`, and `In4` from header file `exInDataLut.h`. The data is used in lookup tables `Table1` and `Table2`.
- Variables representing the inports in the generated code must be named `input1`, `input2`, `input3`, and `input4`.

For this example, configure inports in `rtwdemo_configinterface` to meet these code generation requirements.

## Configure Default Code Generation Settings for Root-Level Inports

A default code generation setting for root-level inports can reduce the effort of preparing a model for code generation, especially if a model has a significant number of inports. Choose configuration settings once, and the code generator applies those settings to the inports across the model. Simulink stores the default configuration as part of the model.

Consider configuring default code generation settings for model root-level inports if your model uses multiple root-level inports that do not have unique requirements or uses a shared Embedded Coder Dictionary.

This example shows how to use the **Code Mappings Editor - C** to configure default settings for root-level inports for model `rtwdemo_configinterface`. Specify an external header file that declares input data. Three of the four root inports read input from variables declared in header file `exInDataLut.h`. Set that header file as the default input source for inports.

- 1 Open example model `rtwdemo_configinterface`. Save a copy of the model to a writable location.

- 2 Open the **Embedded Coder** app.
- 3 In the **C Code** tab, select **Code Interface > Default Code Mappings**.
- 4 In the Code Mappings editor, under **Inports and Outports**, select category **Inports**. Set the default storage class to `ImportFromFile`.
- 5 Click the  icon, set **Header File** to `exInDataLut.h`.

Model Element Category	Storage Class
Inports	ImportFromFile
Outports	ExportToFile
Signals, states, and internal data	Default
Shared local data stores	Default

- 6 Save the model.

## Configure Code Generation Settings for Individual Root-Level Inports

You can configure individual root-level inports for code generation. For example, if a model has two root-level inports that have unique code generation requirements, configure the inports individually. Or, if you configure default settings for inports, configure individual inports to use the default settings or unique settings.

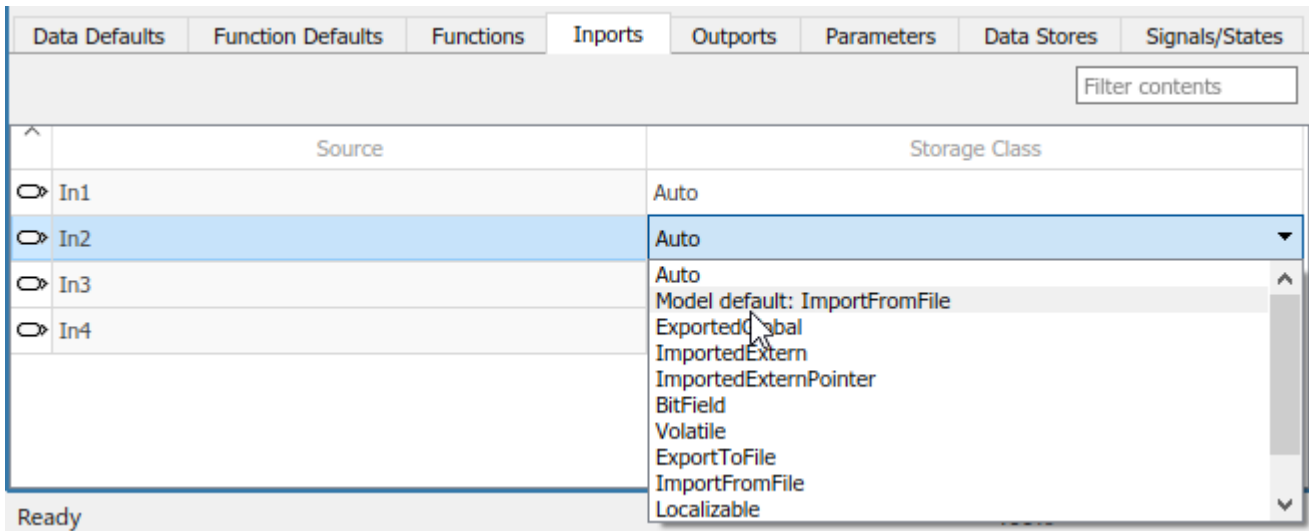

If your model meets at least one of these criteria, consider configuring code generation settings for root-level inports individually:

- Uses multiple inports that have unique requirements.
- Uses few inports.
- Has a default configuration for inports and you need to override the configuration for some specific inports.

This example shows how to use the Code Mappings editor to override the default code generation configuration for one of the inports in model `rtwdemo_configinterface`. In the preceding example, you set the default storage class for inports to `ImportFromFile`. The model requires that inport `In1` read input data from a global variable instead of a global variable pointer.

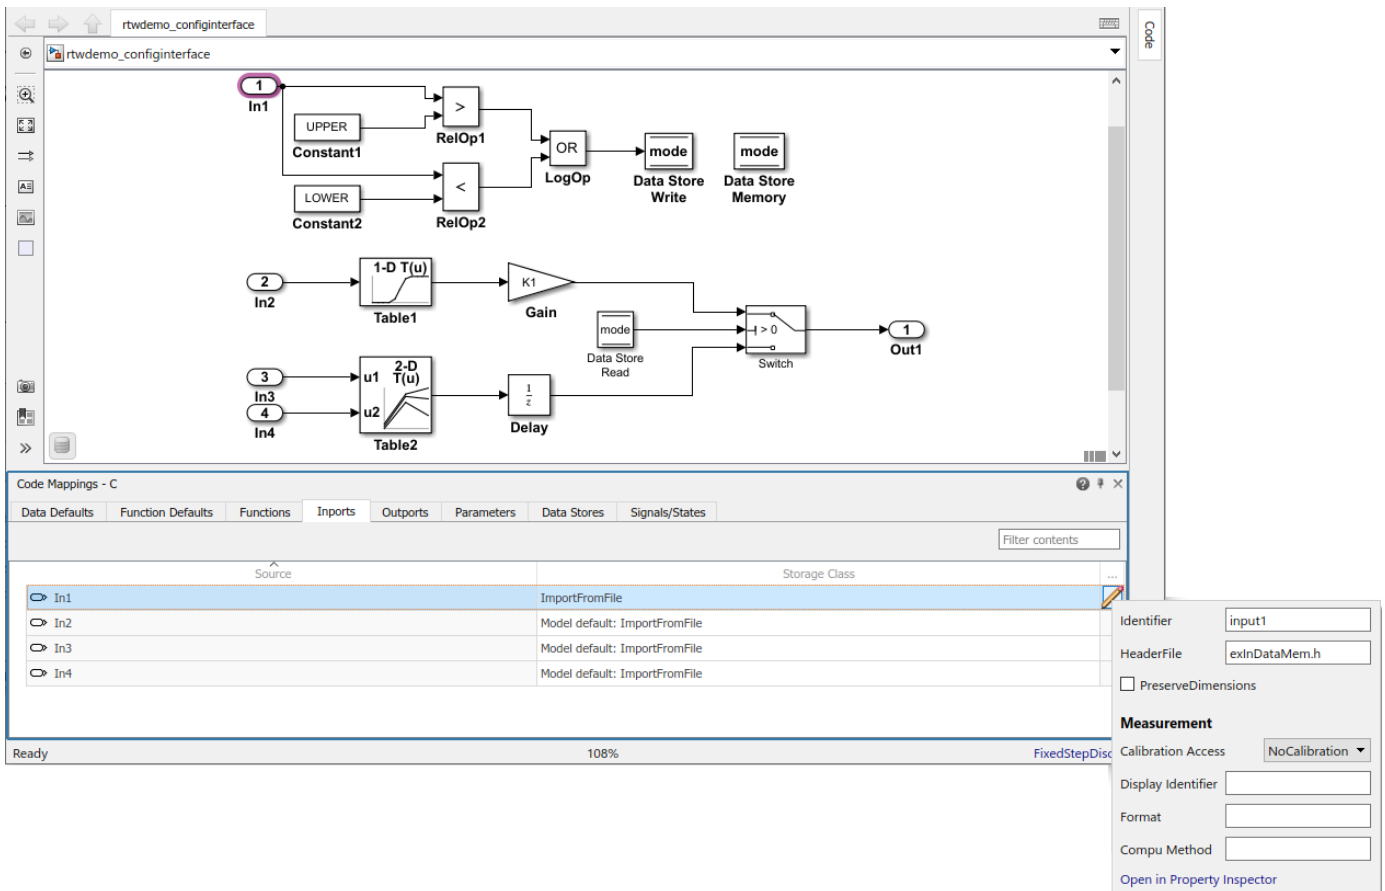

The example also shows how to configure identifiers that the code generator uses for naming the four inports in the generated code. You can specify code generation identifiers, for example for integration, without having to modify the model design.

- 1** If you have not already done so, complete the steps in “Configure Default Code Generation Settings for Root-Level Inports” on page 32-31.
- 2** In the Code Mappings editor, click the **Inports** tab. The editor lists the names of Inport blocks and bus elements that are in the model. If a port resolves to a signal object, a resolve-to-signal-object icon appears to the right of the element name. The storage class for each inport is set to `Auto`, which means that the code generator might eliminate or change the representation of relevant code for optimization purposes. If optimizations are not possible, the code generator applies the model default configuration. For this example, the model default configuration specifies storage class `ImportedFromFile`.
  - To avoid optimizations and force the code generator to use the default configuration, set the storage class to `Model default`.
  - To override the default configuration, specify the storage class that meets the code generation requirements for that inport.
- 3** Configure the code generator to apply the default storage class setting to inports `In2`, `In3`, and `In4`. Select the rows for the three inports. Then, for one of the selected inports, set the storage class to `Model default: ImportFromFile`.

The storage class for the three selected imports changes to **Model default: ImportFromFile**.

- 4 For input In1, override the default storage class setting. Set the storage class to **ImportFromFile**. Click the  icon and set **Header File** to **exInDataMem.h**.

- 5 Configure code identifiers for the inports so that the interface argument names in the generated code match the interface names in the external header and definition files. In the Code Mappings editor, select the row for each inport. Click the  icon and set the **Identifier** property to these values.

Inport	Code Identifier
In1	input1
In2	input2
In3	input3
In4	input4

- 6 Save the model.
- 7 Generate and view the code. For example, in `rtwdemo_configinterface.c` find where variables `input1`, `input2`, `input3`, and `input4` are used in the step entry-point function.

```
void rtwdemo_configinterface_step(void)
{
 mode = ((input1 > rtwdemo_configinterface_UPPER) || (input1 <
 rtwdemo_configinterface_LOWER));

 dout_Table1 = look1_binlc(input2, ((const MYTYPE *)&(Table1.BP[0])), ((
 const MYTYPE *)&(Table1.Table[0])), 10U);
 .
 .
 .
 dout_Table2 = look2_binlc(input3, input4, ((const MYTYPE *)&(mp_Table2.BP1[0])),
 ((const MYTYPE *)&(mp_Table2.BP2[0])), ((const MYTYPE *)&(mp_Table2.Table[0])),
 ((const uint32_T *)&(rtwdemo_configi_Table2_maxIndex[0])), 3U);

 dstate_X = dout_Table2;
}
```

## Configure Code Generation Settings for Root-Level Inports Programmatically

To automate configuration of root-level inports for code generation, use the programming interface for code mappings. For example, when creating custom block libraries or part of an application test environment, use the programming interface to automate data configuration.

This example shows how to use the programming interface to configure default settings for root-level inports for model `rtwdemo_configinterface`. Specify an external header file that declares input data. Three of the four root-level inports read input from variables declared in header file `exInDataLut.h`. You set that file as the default header file. Then, you override the default code generation configuration for `In1`, which requires that input data be read from header file `exInDataMem.h`.

In addition, you configure code identifiers for the inports so that global variable names in the generated code match the variable names defined in an external file.

- 1 Open the example model.

```
open_system('rtwdemo_configinterface')
```

- 2 Create object `cm` by calling function `coder.mapping.api.get`. The object stores the data and function code generation configuration for model `rtwdemo_configinterface`.

```
cm = coder.mapping.api.get('rtwdemo_configinterface');
```

- 3 Configure default settings for inports by calling function `setDataDefault`. For the arguments, specify these values:

- The object returned by `coder.mapping.api.get`
- Inports for the default category
- Property name `StorageClass` with property value `ImportFromFile`
- Property name `HeaderFile` with property value `exInDataLut.h`, the name of the external file that contains the input data

```
setDataDefault(cm, 'Inports', 'StorageClass', 'ImportFromFile', 'HeaderFile', 'exInDataLut.h')
```

- 4 Verify your default configuration for inports. Issue two calls to `getDataDefault` that specify the object returned by `coder.mapping.api.get` and category `Inports`. In the first call, specify the third argument as property `StorageClass`. In the second call, for the third argument, specify `HeaderFile`.

```
getDataDefault(cm, 'Inports', 'StorageClass')
```

```
ans =
```

```
 'ImportFromFile'
```

```
getDataDefault(cm, 'Inports', 'HeaderFile')
```

```
ans =
```

```
 'exInDataLut.h'
```

- 5 Override the default inport configuration for inport `In1`. The requirements for that inport differ from requirements of the other three inports.

By default, Simulink sets the storage class for individual inports to `Auto`. When the storage class is `Auto`, the code generator:

- Determines whether to eliminate the data from the generated code for optimization purposes.
- If retaining the data, determines how to efficiently represent the data in the generated code, taking into account default configuration settings.

To control the storage class and header file configuration for an inport, configure settings for the inport with function `setInport`. Configure code generated for inport `In1` to read input data from global variables defined in external header file `exInDataMem.h`, as specified in the requirements. Issue two calls to function `setInport` that specify the object returned by `coder.mapping.api.get` and Inport block named `In1`. In the first call, also specify property name `StorageClass` and property value `ImportFromFile`. In the second call, specify property name `HeaderFile` and property value `exInDataMem.h`.

```
setInport(cm, 'In1', 'StorageClass', 'ImportFromFile')
```

```
setInport(cm, 'In1', 'HeaderFile', 'exInDataMem.h')
```

- 6 Verify your configuration for inport `In1` by calling function `getInport`.

```
getInport(cm, 'In1', 'StorageClass')
```

```
ans =
```

```
 'ImportFromFile'
```

```
getInport(cm, 'In1', 'HeaderFile')
```

```
ans =
```

```
 'exInDataMem.h'
```

- 7** Configure the code generator to apply your default inport settings to inports In2, In3, and In4. For each inport, call function `setInport`. Specify the object returned by `coder.mapping.api.get`, the Inport block name, property name `StorageClass`, and property value `Model default`.

```
setInport(cm, 'In2', 'StorageClass', 'Model default')
```

```
setInport(cm, 'In3', 'StorageClass', 'Model default')
```

```
setInport(cm, 'In4', 'StorageClass', 'Model default')
```

- 8** Verify your configuration changes for inports In2, In3, and In4 with calls to function `getInport`.

```
getInport(cm, 'In2', 'StorageClass')
```

```
ans =
```

```
 'Model default'
```

```
getInport(cm, 'In3', 'StorageClass')
```

```
ans =
```

```
 'Model default'
```

```
getInport(cm, 'In4', 'StorageClass')
```

```
ans =
```

```
 'Model default'
```

- 9** Configure code identifiers for the inports so that the global variables that represent inports in the generated code match the variable names in the external definition file. For each inport, call function `setInport`. Specify the object returned by `coder.mapping.api.get`, the Inport block name, property name `Identifier`, and one of these property values.

Inport	Code Identifier
In1	input1
In2	input2
In3	input3
In4	input4

```
setInport(cm, 'In1', 'Identifier', 'input1');
```

```
setInport(cm, 'In2', 'Identifier', 'input2');
```

```
setInport(cm, 'In3', 'Identifier', 'input3');
```

```
setInport(cm, 'In4', 'Identifier', 'input4');
```

- 10** Verify your configuration changes for the inports by using calls to function `getInport`.

```
getInport(cm, 'In1', 'Identifier')
```

```

ans =
 'input1'
getInport(cm,'In2','Identifier')
ans =
 'input2'
getInport(cm,'In3','Identifier')
ans =
 'input3'

getInport(cm,'In4','Identifier')
ans =
 'input4'

```

**11** Save the model.

**12** Generate and view the code. For example, in `rtwdemo_configinterface.c` find where variables `input1`, `input2`, `input3`, and `input4` are used in the step entry-point function.

```

void rtwdemo_configinterface_step(void)
{
 mode = ((input1 > rtwdemo_configinterface_UPPER) || (input1 <
 rtwdemo_configinterface_LOWER));

 dout_Table1 = look1_binlc(input2, ((const MYTYPE *)&(Table1.BP[0])), ((
 const MYTYPE *)&(Table1.Table[0])), 10U);
 .
 .
 .
 dout_Table2 = look2_binlc(input3, input4, ((const MYTYPE *)&(mp_Table2.BP1[0])),
 ((const MYTYPE *)&(mp_Table2.BP2[0])), ((const MYTYPE *)&(mp_Table2.Table[0])),
 ((const uint32_T *)&(rtwdemo_configi_Table2_maxIndex[0])), 3U);

 dstate_X = dout_Table2;
}

```

## Choose Storage Class and Storage Class Properties for Root-Level Inports

Depending on your code generation requirements, choose from these storage classes to configure code generation for root-level inports.

Requirements	Storage Class
Enable optimizations, potentially generating more efficient code.	“Auto” on page 33-77 (Individual mappings only)
For data elements that cannot be optimized, represent data as a field of a standard data structure.	“Default” on page 33-77 (Default mapping only)

Requirements	Storage Class
Prevent optimizations from eliminating storage for a data element and use the default mapping for the data element category.	“Model Default” on page 33-77 (Individual mappings only) , Dictionary Default (Individual mappings only)
Generate a structure that stores Boolean data in named bitfields.	“Bitfield” on page 33-79 (Individual mappings only)
Generate a global variable definition and declaration that have the <code>volatile</code> type qualifier.	<code>Volatile</code> (See “Const, Volatile, and ConstVolatile” on page 33-79)
Generate a global variable definition and declaration.	“ExportedGlobal” on page 33-78
Generate a global variable definition and declaration to a specified file.	“ExportToFile” on page 33-80
Generate code that interacts with data by calling your custom accessor functions.	“GetSet” on page 33-81
Generate code that reads from and writes to a global variable or global variable pointer defined by your external code.	“ImportedExtern, ImportedExternPointer” on page 33-78
Read input data for the inport from a specified external header file.	“ImportFromFile” on page 33-82
Generate variables that are local to functions.	“Localizable” on page 33-82
Generate a global structure that has a name, which you can specify.	“Struct” on page 33-83 (Individual mappings only)
Generate a global variable that enables buffer reuse.	“Reusable” on page 33-83 (Individual mappings only)

The list of available storage classes might include other project-specific storage classes defined in an Embedded Coder Dictionary. If you have special requirements that are not met by the listed storage classes and you have Embedded Coder software, you can define a storage class. See “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2.

For an individual inport, use the **Identifier** storage class property to configure a name for the variable representing the inport in the generated code. With Embedded Coder, depending on the storage class that you choose, you can also configure these properties.

Property	Description	Storage Classes
DefinitionFile	Source definition file that contains definitions for global data, which is read by the inport and external code	ExportToFile and Volatile
GetFunction	Inport appears in the generated code as a call to a specified <code>get</code> function	GetSet
HeaderFile	Source header file that contains declarations for global data that is read by the inport and external code	ExportToFile, GetSet, ImportFromFile, and Volatile
Memory Section (default inport configuration only)	Memory section that contains data read by the inport	Default

Property	Description	Storage Classes
Owner	Code generator places the definition for inports in the code generated for one of multiple models in a model hierarchy that share definitions. You must select the model configuration parameter <b>Use owner from data object for data definition placement</b> . See “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2.	ExportToFile and Volatile
PreserveDimensions	Code generator preserves dimensions of inport data that is represented in generated code as a multidimensional array. You must set model configuration parameter <b>Array layout</b> to Row-major. See “Preserve Dimensions of Multidimensional Arrays in Generated Code” on page 44-2.	ExportToFile, ImportFromFile, Localizable, and Volatile
SetFunction	Inport appears in the generated code as a call to a specified <b>set</b> function.	GetSet
StructName	Name for a structure in the generated code for inport.	BitField and Struct

## Configure Root-Level Output Blocks for C Code Generation

To use code that you generate from a model, you call generated entry-point functions. The calling environment and generated functions exchange input and output data, for example, as global variables or function arguments. Root-level Outputport blocks (outputports) constitute the output data of the interface. To integrate and deploy the generated code into larger applications, you can customize how the code generator produces the interface code, including how output data is declared and handled. Customizations can:

- Minimize the modifications that you make to existing code.
- Generate stable interfaces that do not change or minimally change when you make changes to your model.
- Generate code that exchanges data more efficiently (for example, by using pointers and pass-by-reference arguments for nonscalar data).

For code generation, examples show how to customize the outputport interface for the model `rtwdemo_configinterface`. You can configure code mappings by using the **Code Mappings Editor - C** or code mappings API (`coder.mapping.api.CodeMapping`).

### Choose Customization Options for Outputport Interface

By default, root-level outputports in a model appear in generated code as fields of a global data structure named `model_ExtY`. Based on your code interface requirements, decide whether to customize generation of outputport data. If you do not configure customizations, the code generator determines whether to eliminate or change the representation of outputports in generated code for optimization purposes. If you configure customizations, decide:

- Whether to set up a default configuration

If a model includes a significant number (for example, more than 10) of root-level outputports, it is more efficient to configure the outputports with a default setting, and override that setting for special cases. If the model includes a few outputports that have unique source, naming, or placement requirements, consider configuring the outputports individually.

- How to declare and handle outputport data in the generated interface
  - As separate global variables
  - To write output data to global variables defined in external code
  - For referenced model outputports, as global variables (`void-void`)
  - As calls to access functions. Requires Embedded Coder
  - As entry-point function arguments. Requires Embedded Coder

For more information about these options, see “Control Data and Function Interface in Generated Code” on page 33-44.

Other considerations include whether to:

- Name outputports in the generated code by using Outputport block labels that appear in the model or by using unique code identifiers.
- Include the `volatile` type qualifier in global variable definitions and declarations. Requires Embedded Coder. See “Protect Global Data with `const` and `volatile` Type Qualifiers” on page 42-13.

- Write data from a specific area of memory. Requires Embedded Coder. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

For a list of lists interface requirements that are relevant to outports with corresponding storage classes and storage class properties, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.

Outport interface requirements for example model `rtwdemo_configinterface` are:

- Use project type definition `MYTYPE` defined in `rtwdemo_configinterface_data.m`.
- Declare a variable for outport `Out1` in generated external header file `exOutSys.h` and define the variable in source definition file `exOutSys.c`. The data written to `Out1` is the output of code generated for the `Switch` block.
- The variable representing the outport in the generated code must be named `output1`. That name is the variable name that the external code interface uses to access the output data.

For this example, configure the outport in `rtwdemo_configinterface` to meet these code generation requirements.

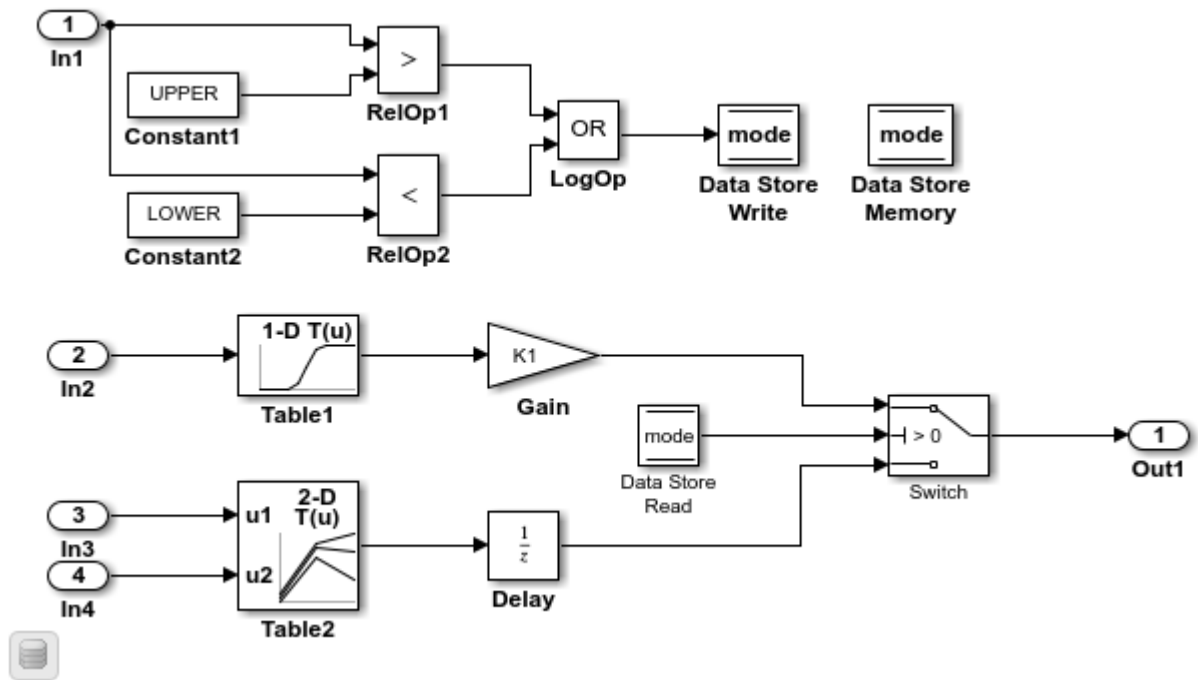

## Configure Default Code Generation Settings for Root-Level Outports

A default code generation setting for root-level outports can reduce the effort of preparing a model for code generation, especially if a model has a significant number of outports. Choose configuration settings once, and the code generator applies those settings to outports across the model. Simulink stores the default configuration as part of the model.

Consider configuring default code generation settings for model outports if your model uses multiple root-level outports that do not have unique requirements or uses a shared Embedded Coder Dictionary.

The example model `rtwdemo_configinterface` includes one root-level outport. This example shows how to use the **Code Mappings Editor - C** to configure default settings for root-level outports. Specify that the code generator declare and define variables to represent root outports in generated external header and definition files. Name the generated default external header file `exOutSys.h` and the generated definition file `exOutSys.c`.

- 1 Open example model `rtwdemo_configinterface`. Save a copy of the model to a writable location.

- 2 Open the **Embedded Coder** app.
- 3 In the **C Code** tab, select **Code Interface > Default Code Mappings**.
- 4 In the Code Mappings editor, under **Imports and Outputs**, select category **Outputs**. Set the default storage class to `ExportToFile`.
- 5 Click the  icon and set **Header File** to `exOutSys.h` and **Definition File** to `exOutSys.c`.

- 6 Save the model.

## Configure Code Generation Settings for Individual Root-Level Outports

You can configure individual root-level outports for code generation. For example, if a model has two root-level outports that have unique code generation requirements, configure the outports individually. Or, if you configure default settings for outports, configure individual outports to use the default settings or unique settings.

If your model meets at least one of these criteria, consider configuring code generation settings for outports individually:

- Uses multiple outports that have unique requirements.
- Uses few outports.
- Has a default configuration for outports and you need to override the configuration for some specific outports.

This example shows how to use the Code Mappings editor to apply the default code generation configuration for outports in model `rtwdemo_configinterface`. In the preceding example, you set the default storage class for outports to `ExportToFile`. A requirement specifies that outport `Out1` write output data to a global variable declared and defined in generated header and definition files accessible to external code.

The example also shows how to configure an identifier that the code generator uses for naming the outport in the generated code. You can specify code generation identifiers, for example for integration, without modifying the model design.

- 1 If you have not already done so, complete the steps in “Configure Default Code Generation Settings for Root-Level Outports” on page 32-42.
- 2 In the Code Mappings editor, click the **Outports** tab. The editor lists the names of Outport blocks and bus elements that are in the model. If a port resolves to a signal object, a resolve-to-signal-object icon appears to the right of the element name. The storage class for the outport in the example model is set to `Auto`, which means that the code generator might eliminate or change the representation of relevant code for optimization purposes. If optimizations are not possible, the code generator applies the model default configuration. For this example, the model default configuration specifies storage class `ExportToFile`.
  - To avoid optimizations and force the code generator to use the default configuration, set the storage class to `Model default`.
  - To override the default configuration, specify the storage class that meets the code generation requirements for that outport.
- 3 Configure the code generator to apply the default storage class setting to outport `Out1`. Select the row for the outport. Set the storage class to `Model default: ExportToFile`.

The storage class for the selected output changes to `Model default: ExportToFile`.

- 4 Configure the code identifier for the output so that the interface argument name in the generated code matches the interface name used by the external code. In the Code Mappings editor, select the row for the output. Click the  icon and set the **Identifier** property to output.
- 5 Save the model.
- 6 Generate and view the code. For example, in the file `rtwdemo_configinterface.c`, find where variable `output` is used in the step entry-point function.

```
if (mode) {
 output = (real_T)mp_K1 * dout_Table1;
} else {
 output = dstate_X;
}
```

## Configure Code Generation Settings for Root-Level Outputs Programmatically

To automate configuration of root-level outputs for code generation, use the programming interface for code mappings. For example, when creating custom block libraries or part of an application test environment, use the programming interface to automate data configuration.

This example shows how to use the programming interface to configure default settings for root-level outputs for model `rtwdemo_configinterface`.

Configure code an identifier for the output so that global variable name in the generated code matches the variable name in the external code interface.

- 1 Open the example model.

```
open_system('rtwdemo_configinterface')
```

- 2 Create object `cm` by calling function `coder.mapping.api.get`. The object stores the code generation configuration for data elements and functions in model `rtwdemo_configinterface`.

```
cm = coder.mapping.api.get('rtwdemo_configinterface');
```

- 3 Configure default settings for outputs by calling function `setDataDefault`. For the arguments, specify these values.

- The object returned by `coder.mapping.api.get`
- `Outports` for the default category
- Property name `StorageClass` that has property value `ExportToFile`
- Property name `HeaderFile` that has property value `exOutSys.h` and property name `DefinitionFile` that has property value `exOutSys.c`, the names for the generated files that declare and define the output data

```
setDataDefault(cm,'Outports','StorageClass','ExportToFile','HeaderFile','exOutSys.h',...
'DefinitionFile','exOutSys.c')
```

- 4 Verify your default configuration for outports. Issue three calls to `getDataDefault` that specify the object returned by `coder.mapping.api.get` and category `Outports`.

- In the first call, specify the third argument as property `StorageClass`.
- In the second call, for the third argument, specify `HeaderFile`.
- In the third call, for the third argument, specify `DefinitionFile`.

```
getDataDefault(cm,'Outports','StorageClass')
```

```
ans =
```

```
 'ExportToFile'
```

```
getDataDefault(cm,'Outports','HeaderFile')
```

```
ans =
```

```
 'exOutSys.h'
```

```
getDataDefault(cm,'Outports','DefinitionFile')
```

```
ans =
```

```
 'exOutSys.c'
```

- 5 Apply the default output configuration for output `Out1`.

By default, Simulink sets the storage class for individual outports to `Auto`. When the storage class is `Auto`, the code generator:

- Determines whether to eliminate the data from the generated code for optimization purposes.
- If retaining the data, determines how to efficiently represent the data in the generated code, taking into account default configuration settings.

To control the configuration for an output, call function `setOutputport`.

Issue a call to `setOutputport` that specifies:

- Object returned by `coder.mapping.api.get`
- Output block name `Out1`
- Default storage class previously set for the outputport by using property `StorageClass` and property value `Model default`
- Property `Identifier` and property value `output`

```
setOutputport(cm,'Out1','StorageClass','Model default','Identifier','output');
```

- 6 Verify your configuration changes by calling function `getOutputport`. Specify the object returned by `coder.mapping.api.get`, name of the output block, and property `StorageClass` or `Identifier`.

```
getOutputport(cm, 'Out1', 'StorageClass')
```

```
ans =
```

```
 'Model default'
```

```
getOutputport(cm, 'Out1', 'Identifier')
```

```
ans =
```

```
 'output'
```

- 7 Save the model.
- 8 Generate and view the code. For example, in the file `rtwdemo_configinterface.c`, find where variable `output` is used in the step entry-point function.

```
if (mode) {
 output = (real_T)mp_K1 * dout_Table1;
} else {
 output = dstate_X;
}
```

## Choose Storage Class and Storage Class Properties for Root-Level Outputs

Depending on your code generation requirements, choose from these storage classes to configure code generation for root-level outputs.

Requirements	Storage Class
Enable optimizations, potentially generating more efficient code.	"Auto" on page 33-77 (Individual mappings only)
For data elements that cannot be optimized, represent data as a field of a standard data structure.	"Default" on page 33-77 (Default mapping only)
Prevent optimizations from eliminating storage for a data element and use the default mapping for the data element category.	"Model Default" on page 33-77 (Individual mappings only) , Dictionary Default (Individual mappings only)
Generate a structure that stores Boolean data in named bitfields.	"Bitfield" on page 33-79 (Individual mappings only)
Generate a global variable definition and declaration that has the <code>volatile</code> type qualifier.	<code>Volatile</code> (See "Const, Volatile, and ConstVolatile" on page 33-79)
Generate a global variable definition and declaration.	"ExportedGlobal" on page 33-78
Generate a global variable definition and declaration to a specified file.	"ExportToFile" on page 33-80
Generate code that interacts with data by calling your custom accessor functions.	"GetSet" on page 33-81

Requirements	Storage Class
Generate code that reads from and writes to a global variable or global variable pointer defined by your external code.	“ImportedExtern, ImportedExternPointer” on page 33-78
Generate code that reads from and writes to a global variable defined by your external header file.	“ImportFromFile” on page 33-82
Generate variables that are local to functions.	“Localizable” on page 33-82
Generate a global structure that has a name, which you can specify.	“Struct” on page 33-83 (Individual mappings only)

The list of available storage classes might include other project-specific storage classes defined in an Embedded Coder Dictionary. If you have special requirements that are not met by the listed storage classes and you have Embedded Coder software, you can define a storage class. See “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2.

For an individual outport, use the **Identifier** storage class property to configure a name for the variable representing the outport in the generated code. With Embedded Coder, depending on the storage class that you choose, you can also configure these properties.

Property	Description	Storage Classes
DefinitionFile	Source definition file that contains definitions for global data, which is read by the outport and external code	ExportToFile and Volatile
GetFunction	Outport appears in the generated code as a call to a specified <code>get</code> function	GetSet
HeaderFile	Name of generated source header file that contains declarations for global data, which is written by the outport and external code	ExportToFile, GetSet, ImportFromFile, and Volatile
Memory Section (default outport configuration only)	Memory section that contains data written by the outport	Default
Owner	Code generator places the definition for outports in the code generated for one of multiple models in a model hierarchy that share definitions. You must select the model configuration parameter <b>Use owner from data object for data definition placement</b> . See “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2.	ExportToFile and Volatile

Property	Description	Storage Classes
PreserveDimensions	Code generator preserves dimensions of outport data that is represented in generated code as a multidimensional array. You must set model configuration parameter <b>Array layout</b> to Row-major. See “Preserve Dimensions of Multidimensional Arrays in Generated Code” on page 44-2.	ExportToFile, ImportFromFile, Localizable, and Volatile
SetFunction	Outport appears in the generated code as a call to a specified set function.	GetSet
StructName	Name for a structure in the generated code for outport.	BitField and Struct

- “C Code Generation Configuration for Model Interface Elements” on page 32-2
- “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75
- “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15
- “Control Data and Function Interface in Generated Code” on page 33-44
- “Configure Model Data Elements for ASAP2 File Generation” on page 63-2

## Configure Signal Data for C Code Generation

Signal data consists of variables that store intermediate results in global memory as generated algorithmic code computes values of block output signals from block input signals, excluding signals that connect to root Inport and Outport blocks. Signal data is not signal lines in a model diagram. For example, in these cases, a signal line has no data representation in generated code:

- Feeds a function-call port
- Exits a message block, such as the Send block
- Crosses subsystem boundaries with no computation blocks in between

When you configure a model for code generation, you choose the block input and output signals to make accessible in the generated code. For example, configure signal data to:

- Make the data accessible for interaction and monitoring while the generated code executes.
- Minimize the amount of data that is stored in memory.
- Control where the code generator places signal data in memory.
- Promote signal data to the model interface so that other components and systems can access that data.
- Improve readability and traceability of the generated code.

The code generator checks for signal line configuration consistency. For example, the code generator verifies that the configuration of a signal line feeding into a subsystem matches the configuration of the signal line that exits the corresponding subsystem inport.

For code generation, examples show how to configure block signals for the model `rtwdemo_configinterface`. You can configure code mappings by using the **Code Mappings Editor - C** or code mappings programming interface (`coder.mapping.api.CodeMapping`).

### Choose Code Configuration Options for Signals

Based on your code generation requirements, decide which block signals to represent in the generated code and how to represent the signal data. By default, signals in a model appear in generated code as fields of a global data structure named `model_B`. If you do not configure customizations, the code generator determines whether to eliminate or change the representation of signals in generated code for optimization purposes. If you configure customizations, decide:

- Which signals to make accessible in the generated code

You must add signals that you want to make accessible in the generated code to the model code mappings.

- Whether to set up a default configuration

If you need to gain access to a significant number (for example, more than 10) of signals, it is more efficient to configure the signals with default settings and then override those settings for special cases. If you need to gain access to a few signals that have unique source, naming, or placement requirements, consider configuring the signals individually.

- How to declare and handle signal data in the generated code
  - As separate global variables

- To read input data from global variables defined in external code
- As calls to access functions. Requires Embedded Coder

For more information about these options, see “Control Data and Function Interface in Generated Code” on page 33-44.

Other considerations include whether to:

- Name signals in the generated code by using signal labels that appear in the model or by using unique code identifiers.
- Include the `volatile` type qualifier in global variable definitions and declarations. Requires Embedded Coder. See “Protect Global Data with `const` and `volatile` Type Qualifiers” on page 42-13.
- Place signal data into a specific area of memory. Requires Embedded Coder. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

For a list of interface requirements that are relevant to signals with corresponding storage classes and storage class properties, see “Choose Storage Class and Storage Class Properties for Data Stores” on page 32-89.

Signal requirements for example model `rtwdemo_configinterface` are:

- Configure signals that feed into and exit from the Switch block for code generation. Retain that signal data for monitoring while the generated code executes.
- Represent signals as separate global variables.
- Apply prefix `dout_` to names of variables that represent signals.

Set the default representation of signals in the generated code as global variables that have the `static` type qualifier. Then, you configure the output signals of the two lookup table blocks to use the default storage class and unique code identifiers that include the required prefix `dout_`.

## Add Signals to Model Code Mappings

Before you can configure a signal for code generation, add the signal to the model code mappings. Add the output signals for the two lookup table blocks to the model code mappings.

- 1 Open example model `rtwdemo_configinterface`. Save a copy of the model to a writable location.

- 2 Open the **Embedded Coder** app.
- 3 In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
- 4 In the Code Mappings editor, click the **Signals/States** tab. No signals are listed.
- 5 Add signals to the code mappings. For the output signal of lookup table blocks Table1 and Table2:
  - a In the model, select the signal.
  - b Pause on the ellipsis that appears above or below the signal line to open the action bar. Click the **Add Signal** button.

In the Code Mappings editor, the **Signals** node expands and lists the two signals that you added.

Data Defaults			Function Defaults			Functions			Inports			Outputs			Parameters			Data Stores			Signals/States		
Source			Storage Class			Path																	
Signals (2) <ul style="list-style-type: none"> <li>Table1:1</li> <li>Table2:1</li> </ul>			Auto			rtwdemo_configinterface																	
States (1)																							

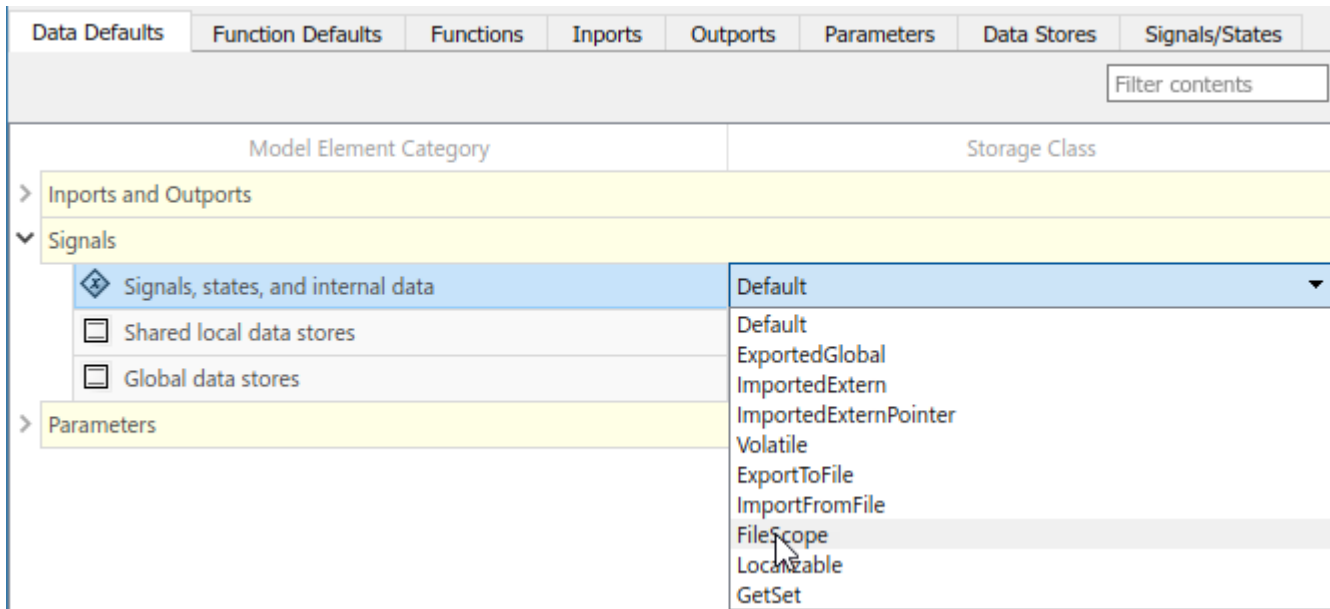

## Configure Default Code Generation Settings for Signals

A default code generation setting for signals can reduce the effort of preparing a model for code generation, especially if a model has a significant number of signals that you want to monitor while the generated code executes. Choose configuration settings once, and the code generator applies those settings to signals across the model. Simulink stores the default configuration as part of the model.

Consider configuring default code generation settings for model signals if your model uses multiple signals that do not have unique requirements or uses a shared Embedded Coder Dictionary.

This example shows how to use the **Code Mappings Editor - C** to set the default storage class for signals in the model `rtwdemo_configinterface` to `FileScope`. With that storage class setting, the code generator represents signal data in the generated code as global variables that have the `static` type qualifier.

- 1 If you have not already done so, add signals to the model code mappings as described in “Add Signals to Model Code Mappings” on page 32-51.
- 2 In the **C Code** tab, select **Code Interface > Default Code Mappings**.
- 3 In the Code Mappings editor, on the **Data Defaults** tab, under **Signals**, select category **Signals, states, and internal data**. Set the default storage class to `FileScope`.

- 4 Save the model.

## Configure Code Generation Settings for Individual Signals

You can configure individual signals for code generation. For example, if a model has two signals that have unique code generation requirements, configure the signals individually. Or, if you configure default settings for signals, you can override those settings for specific signals.

If your model meets at least one of these criteria, consider configuring code generation settings for signals individually:

- Uses multiple signals that have unique source, naming, or placement requirements.
- Uses a few signals.
- Has a default configuration for signals and you need to override the configuration for some specific signals.

This example shows how to use the Code Mappings editor to apply your default storage class setting to the output signals of lookup table blocks `Table1` and `Table2` in model `rtwdemo_configinterface`. The example also shows how to configure code identifiers for those output signals. You can specify code generation identifiers, for example for integration, without modifying the model design.

- 1 If you have not already done so, complete the steps in “Configure Default Code Generation Settings for Signals” on page 32-53.
- 2 In the Code Mappings editor, click the **Signals/States** tab. Expand **Signals**. The editor lists the names or block port identifiers of signals that you added to the code mappings. If a signal resolves to a signal object, a resolve-to-signal-object icon appears to the right of the element name or port identifier. The storage class for each signal is set to `Auto`, which means that the code generator might eliminate or change the representation of relevant code for optimization purposes. If optimizations are not possible, the code generator applies the model default configuration. For this example, the model default configuration specifies storage class `FileScope`.

- To avoid optimizations and force the code generator to use the default configuration, set the storage class to `Model default`.
  - To override the default configuration, specify the storage class that meets the code generation requirements for that signal.
- 3 In the Code Mappings editor, select the output signals for blocks `Table1` and `Table2`. Set the storage class to `Model default: FileScope`.
  - 4 Configure the code identifier for the output signals for the two lookup table blocks with names that include the prefix `dout_`. In the Code Mappings editor, select signal `Table1:1`. Click the  icon and set the **Identifier** property to `dout_Table1`. For signal `Table2:1`, set **Identifier** to `dout_Table2`.

The screenshot displays a Simulink model window titled 'rtwdemo\_configinterface'. The model contains several blocks: 'In1' (input 1), 'UPPER Constant1', 'LOWER Constant2', 'RelOp1', 'RelOp2', 'OR LogOp', 'mode Data Store Write', 'mode Data Store Memory', 'In2' (input 2), '1-D T(u) Table1', 'Gain K1', 'mode Data Store Read', 'Switch', 'In3' (input 3), 'In4' (input 4), '2-D T(u) Table2', 'Delay', and 'Out1' (output 1). Below the model is the 'Code Mappings - Component Interface' window. It has tabs for 'Data Defaults', 'Function Defaults', 'Functions', 'Inports', 'Outports', 'Parameters', 'Data Stores', and 'Signals/States'. The 'Signals/States' tab is active, showing a table with columns for Source, Storage Class, and Path. The table lists two signals: 'Table1:1' and 'Table2:1', both with 'Model default: FileScope' as the storage class and 'rtwdemo\_configinterface' as the path. A pencil icon is visible next to the 'Table1:1' row. To the right of the table is a property inspector for the selected signal, showing the 'Identifier' property set to 'dout\_Table1'. Other properties like 'Calibration Access', 'Display Identifier', 'Format', and 'Compu Method' are also visible.

Source	Storage Class	Path
Table1:1	Model default: FileScope	rtwdemo_configinterface
Table2:1	Model default: FileScope	rtwdemo_configinterface

- 5 Save the model.
- 6 Generate and view the code. For example, in `rtwdemo_configinterface.c`, find the data definitions for the lookup table data.

```
static MYTYPE dout_Table1;
static MYTYPE dout_Table2;
```

Find where lookup table data is used in the step entry-point function.

```
.
.
.
dout_Table1 = look1_binlc(input2, ((const MYTYPE *)&(mp_Table1.BP[0])), ((
```

```

 const MYTYPE *)&(mp_Table1.Table[0])), 10U);

 if (mode) {
 output = (real_T)mp_K1 * dout_Table1;
 } else {
 output = dstate_X;
 }

 dout_Table2 = look2_binlc(input3, input4, ((const MYTYPE *)&(mp_Table2.BP1[0])),
 ((const MYTYPE *)&(mp_Table2.BP2[0])), ((const MYTYPE *)&(mp_Table2.Table[0])),
 ((const uint32_T *)&(rtwdemo_configi_Table2_maxIndex[0])), 3U);

 dstate_X = dout_Table2;
}

```

## Remove Signals from Model Code Mappings

- 1 In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
- 2 In the Code Mappings editor, click the **Signals/States** tab.
- 3 For each signal that you want to remove:
  - a In the model, select the signal.
  - b Pause on the ellipsis that appears above or below the signal line to open the action bar. Click the **Remove Signal** button.

## Configure Code Generation Settings for Signals Programmatically

To automate configuration of signals for code generation, use the programming interface for code mappings. For example, when creating custom block libraries or part of an application test environment, use the programming interface to automate data configuration.

This example shows how to use the programming interface to configure signals for model `rtwdemo_configinterface`. Set the default representation of signals in the generated code as global variables that have the `static` type qualifier. Then, configure the output signals of the two lookup table blocks to use the default storage class and unique code identifiers that include the required prefix `dout_`.

- 1 Open the example model.

```
open_system('rtwdemo_configinterface')
```
- 2 Create object `cm` by calling function `coder.mapping.api.get`. The object stores the code generation configuration for data and functions for model `rtwdemo_configinterface`.

```
cm = coder.mapping.api.get('rtwdemo_configinterface');
```
- 3 Configure default settings for signals by calling function `setDataDefault`. For the arguments, specify these values:
  - The object returned by `coder.mapping.api.get`
  - `InternalData` for the default category
  - Property name `StorageClass` with property value `FileScope`

```
setDataDefault(cm, 'InternalData', 'StorageClass', 'FileScope');
```
- 4 Verify your default configuration for signals. Issue a call to `getDataDefault` that specifies the object returned by `coder.mapping.api.get` and category `InternalData`. Specify the third argument as property `StorageClass`.

```
getDataDefault(cm, 'InternalData', 'StorageClass')
```

```
ans =
```

```
 'FileScope'
```

- 5** Get handles to the output ports for lookup table blocks Table1 and Table2. You use the port handles to add the signal data to the model code mappings.

```
lut1D_ports = get_param('rtwdemo_configinterface/Table1', 'PortHandles');
lut2D_ports = get_param('rtwdemo_configinterface/Table2', 'PortHandles');
```

```
lut1D_outPort = lut1D_ports.Outport;
lut2D_outPort = lut2D_ports.Outport;
```

- 6** Add the output signals of the lookup table blocks to the model code mappings.

```
addSignal(cm, [lut1D_outPort, lut2D_outPort]);
```

- 7** Apply the default configuration for signals to the output signal of the lookup table blocks.

By default, Simulink sets the storage class for individual signals to Auto. The code generator:

- Determines whether to eliminate the data from the generated code for optimization purposes.
- If retaining the data, determines how to efficiently represent the data in the generated code, taking into account default configuration settings.

To control the configuration for a signal, call function `setSignal`.

For each signal, issue a call to `setSignal` that specifies:

- Object returned by `coder.mapping.api.get`
- Port handle for the signal, `lut1D_outport` or `lut2D_outport`.
- Default storage class previously set for signals by using property `StorageClass` and property value `Model default`.
- Property `Identifier` and property value `dout_Table1` or `dout_Table2`

```
setSignal(cm, lut1D_outPort, 'StorageClass', 'Model default', 'Identifier', 'dout_Table1');
setSignal(cm, lut2D_outPort, 'StorageClass', 'Model default', 'Identifier', 'dout_Table2');
```

- 8** Verify your configuration settings by calling function `getSignal`. Specify the object returned by `coder.mapping.api.get`, the port handle for the signal (`lut1D_outport` or `lut2D_outport`), and property `StorageClass` or `Identifier`.

```
getSignal(cm, lut1D_outPort, 'StorageClass')
```

```
ans =
```

```
 'Model default'
```

```
getSignal(cm, lut1D_outPort, 'Identifier')
```

```
ans =
```

```
 'dout_Table1'
```

```
getSignal(cm, lut2D_outPort, 'StorageClass')
```

```
ans =
```

```

 'Model default'

 getSignal(cm, lut2D_outPort, 'Identifier')

 ans =

 'dout_Table2'

```

- 9 Save the model.
- 10 Generate and view the code. For example, in `rtwdemo_configinterface.c`, find the data definitions for the lookup table data.

```

static MYTYPE dout_Table1;
static MYTYPE dout_Table2;

```

Find where lookup table data is used in the step entry-point function.

```

.
.
.
 dout_Table1 = look1_binlc(input2, ((const MYTYPE *)&(mp_Table1.BP[0])), ((
 const MYTYPE *)&(mp_Table1.Table[0])), 10U);

 if (mode) {
 output = (real_T)mp_K1 * dout_Table1;
 } else {
 output = dstate_X;
 }

 dout_Table2 = look2_binlc(input3, input4, ((const MYTYPE *)&(mp_Table2.BP1[0])),
 ((const MYTYPE *)&(mp_Table2.BP2[0])), ((const MYTYPE *)&(mp_Table2.Table[0])),
 ((const uint32_T *)&(rtwdemo_configi_Table2_maxIndex[0])), 3U);

 dstate_X = dout_Table2;
}

```

## Choose Storage Class and Storage Class Properties for Signals

Depending on your code generation requirements, choose from these storage classes to configure code generation for block signals.

Requirements	Storage Class to Choose
Enable optimizations, potentially generating more efficient code.	“Auto” on page 33-77 (Individual mappings only)
For data elements that cannot be optimized, represent data as a field of a standard data structure.	“Default” on page 33-77 (Default mapping only)
Prevent optimizations from eliminating storage for a data element and use the default storage class for the data element category.	“Model Default” on page 33-77 (Individual mappings only) , Dictionary Default (Individual mappings only)
Generate a structure that stores Boolean data in named bitfields.	“Bitfield” on page 33-79 (Individual mapping only)
Generate a global variable definition and declaration that have the <code>volatile</code> type qualifier.	<code>Volatile</code> (See “Const, Volatile, and ConstVolatile” on page 33-79)
Generate a global variable definition and declaration.	“ExportedGlobal” on page 33-78

Requirements	Storage Class to Choose
Generate a global variable definition and declaration to a specified file.	“ExportToFile” on page 33-80
Generate a global variable definition and declaration that have the <code>static</code> type qualifier.	“FileScope” on page 33-81
Generate code that interacts with data by calling your custom accessor functions.	“GetSet” on page 33-81
Generate code that reads from and writes to a global variable or global variable pointer defined by your external code.	“ImportedExtern, ImportedExternPointer” on page 33-78
Generate code that reads from and writes to a global variable defined by your external header file.	“ImportFromFile” on page 33-82
Generate variables that are local to functions.	“Localizable” on page 33-82
Generate a global structure that has a name, which you can specify.	“Struct” on page 33-83 (Individual mappings only)
Generate a global variable that enables buffer reuse.	“Reusable” on page 33-83 (Individual mappings only)

The list of available storage classes might include other project-specific storage classes defined in an Embedded Coder Dictionary. If you have special requirements that are not met by the listed storage classes and you have Embedded Coder software, you can define a storage class. See “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2.

For an individual signal, use the **Identifier** storage class property to configure a name for the variable representing the signal in the generated code. With Embedded Coder, depending on the storage class that you choose, you can also configure these properties.

Property	Description	Relevant Storage Classes
DefinitionFile	Source definition file that contains definitions for global data, which is read by the signal and external code	ExportToFile and Volatile
GetFunction	signal appears in the generated code as a call to a specified <code>get</code> function	GetSet
HeaderFile	Source header file that contains declarations for global data, which is read by the signal and external code	ExportToFile, GetSet, ImportFromFile, and Volatile
Memory Section (default signal configuration only)	Memory section that contains data read by the signal	Default

Property	Description	Relevant Storage Classes
Owner	Code generator places the definition for signals in the code generated for one of multiple models in a model hierarchy that share definitions. You must select the model configuration parameter <b>Use owner from data object for data definition placement</b> . See “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2.	ExportToFile and Volatile
PreserveDimensions	Code generator preserves dimensions of signal data that is represented in generated code as a multidimensional array. You must set model configuration parameter <b>Array layout</b> to Row-major. See “Preserve Dimensions of Multidimensional Arrays in Generated Code” on page 44-2.	ExportToFile, FileScope, ImportFromFile, Localizable and Volatile
SetFunction	Signal appears in the generated code as a call to a specified <b>set</b> function.	GetSet
StructName	Name for structure in the generated code for signal.	BitField and Struct

## More About

- “C Code Generation Configuration for Model Interface Elements” on page 32-2
- “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75
- “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15
- “Configure Model Data Elements for ASAP2 File Generation” on page 63-2

## Configure Parameters for C Code Generation

When configuring a model for code generation, you can identify and configure parameters for tunability, for example for calibration. Types of parameters that you can configure are listed in this table.

Type of Parameter	Description
Model parameter argument	Block parameter in the model workspace that you configure as a model argument. Each instance of a model that includes the model parameter argument can have the argument set to a unique value.
Model parameter	Parameter defined within a model, such as a parameter in the model workspace.
External parameter	Parameter defined as an object in the base workspace or in a data dictionary.
Constant	Constant parameter.

To configure a parameter for code generation, you must associate the parameter with a data object. For example, before configuring a MATLAB variable for code generation, in the Model Explorer, convert the variable to a parameter object.

When you open a model in the **Embedded Coder** app, model parameters, model parameter arguments, and constants that are associated with data objects appear in the Code Mappings editor. In the editor, you can configure the parameters for code generation. If a model uses external parameters, you can add them to the Code Mappings editor by clicking the Refresh link to the right of the parameter name. That link initiates an update diagram and, in the editor view, adds external parameters that are used by the model.

Configure parameter data to:

- Make the data accessible for interaction while the generated code executes.
- Minimize the amount of data that is stored in memory.
- Control where the code generator places parameter data in memory.
- Promote parameter data to the model interface so that other components and systems can access that data.
- Improve readability and traceability of the generated code.

To control whether the parameters throughout a model are tunable, you can gain access to model configuration parameter **Default parameter behavior** by using the 'Auto' will be tunable/inline link on the Code Mappings editor **Data Defaults** tab. For example, you can use that link to make parameters tunable in these cases:

- Refine parameter settings during rapid prototyping
- Calibrate parameters
- Optimize parameters for production code

For code generation, examples show how to configure model parameters and model parameter arguments for the model `rtwdemo_configinterface`. You can configure code mappings by using the **Code Mappings Editor - C** or code mappings programming interface (`coder.mapping.api.CodeMapping`).

## Choose Customization Options for Parameters

By default, parameters in a model appear in generated code as fields of global data structures named:

- `model_P` for model parameters
- `model_InstP` for model parameter arguments
- `model_ConstP` for constant parameters

Based on your code interface requirements, decide whether to customize generation of parameter data. If you do not configure customizations, the code generator determines whether to eliminate or change the representation of parameters in generated code for optimization purposes. If you configure customizations, decide:

- Whether to set up a default configuration

If a model includes a significant number of parameters of a category that must be tunable (for example, more than 10), it is more efficient to configure the parameters of that category by using a default setting, and then override that setting for special cases. If the model includes a few parameters of a given category that have unique source, naming, or placement requirements, consider configuring the parameters individually.

- How to declare and handle model parameter data in the generated code
  - As separate global variables
  - To read model parameter data from global variables defined in external code
  - As calls to access functions. Requires Embedded Coder

For more information about these options, see “Control Data and Function Interface in Generated Code” on page 33-44.

Other considerations for model parameters include whether to:

- Name parameters in the generated code by using parameter names in the model or by using unique code identifiers.
- Support preprocessor conditionals defined by compiler flags or options. Requires Embedded Coder. See “Use Variant Models to Generate Code That Uses C Preprocessor Conditionals” on page 26-73.
- Include the `static` type qualifier in global variable definitions and declarations, for example, to prevent name clashes. Requires Embedded Coder. See “Prevent Name Clashes by Configuring Data Item as static” on page 34-8.
- Include the `const`, `volatile`, or `const` and `volatile` type qualifier in global variable definitions and declarations. Requires Embedded Coder. See “Protect Global Data with `const` and `volatile` Type Qualifiers” on page 42-13.
- Generate a macro (`#define`) or code that uses a macro defined in an external header file. Requires Embedded Coder. See “Macro Definitions (`#define`)” on page 25-54.
- Generate a global data structure with a name that you specify. Requires Embedded Coder. See “Organize Data into Structures in Generated Code” on page 33-145.
- Place parameter data into a specific area of memory. Requires Embedded Coder. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

For a list of interface requirements that are relevant to parameters that have corresponding storage classes and storage class properties, see “Choose Storage Class and Storage Class Properties for Data Stores” on page 32-89.

Parameter requirements for example model `rtwdemo_configinterface` are:

- By default, retain model parameters in the generated code for tuning. Do not optimize the code by inlining the parameters.
- Represent model parameters as separate global variables defined and declared with the `const` and `volatile` type qualifiers.
- Apply prefix `mp_` to names of variables that represent model parameters.
- Enable constant parameters `UPPER` and `LOWER` to have different values for each instance of the model.
- For each instance of a model parameter argument, by default, allocate an area of memory represented as a uniquely named field in an exported structure.
- Model parameter arguments appear as individual model function arguments in the generated code. Enable the code generator to optimize model parameter arguments that are not used by blocks in the model.

For this example, configure model parameters and model parameter arguments in `rtwdemo_configinterface` to meet these code generation requirements.

## Configure Default Code Generation Settings for Parameters

Default code generation settings for parameters can reduce the effort of preparing a model for code generation, especially if a model has a significant number of parameters with which you need to interact while the generated code executes. Choose configuration settings once, and the code generator applies those settings to parameters across the model. Simulink stores the default configuration as part of the model.

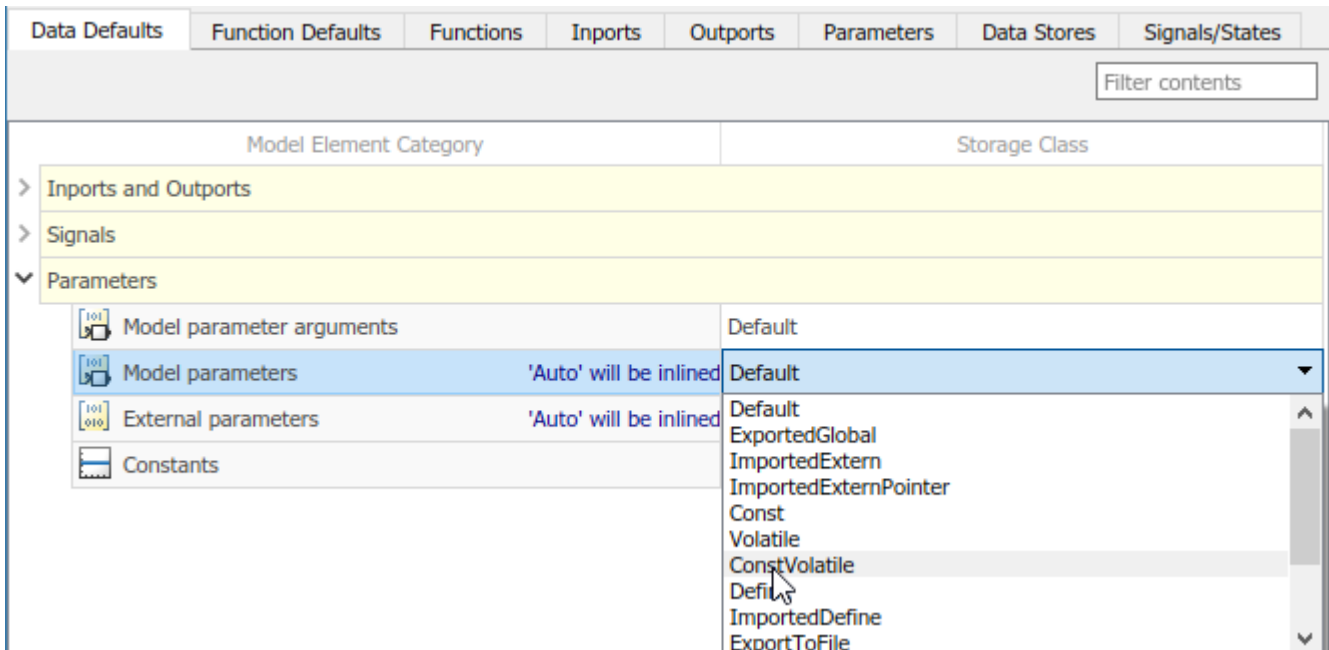

Consider configuring default code generation settings for model parameters if your model uses multiple parameters for the same category that do not have unique requirements or use a shared Embedded Coder Dictionary.

This example shows how to use the **Code Mappings Editor - C** to configure default settings for model parameters and model parameter arguments for the model `rtwdemo_configinterface`. Configure model parameters so that they are tunable and are defined and declared in the generated code as separate global variables that have type qualifiers `const` and `volatile`. Configure model parameter arguments to use default settings, where the code generator allocates an area of memory represented as a uniquely named field in an exported structure for each argument instance.

- 1 Open model `rtwdemo_configinterface`. Save a copy of the model to a writable location.

- 2 Open the **Embedded Coder** app.
- 3 In the **C Code** tab, select **Code Interface > Default Code Mappings**.
- 4 In the Code Mappings editor, select **Model parameter arguments**. Leave the storage class set to **Default**. The code generator allocates a separate area of memory for each argument instance.
- 5 In the Code Mappings editor, under **Parameters**, select category **Model parameters**. Link text 'Auto' will be inlined indicates that the code generator is configured to inline model parameters by default. A requirement for this example is model parameters be tunable. Click 'Auto' will be inlined.
- 6 In the Model Configuration Parameters dialog box, set model configuration parameter **Default parameter behavior** to **Tunable**. Save the change and close the dialog box. In the Code Mappings editor, the link text changes to 'Auto' will be tunable.
- 7 In the Code Mappings, with the **Model parameters** category still selected, set the storage class to **ConstVolatile**.

8 Save the model.

## Configure Code Generation for Individual Parameters

You can configure individual parameters for code generation. For example, if a model has two parameters of the same category that have unique code generation requirements, configure the parameters individually. Or, if you configure default settings for a category of parameters, you can override those settings for specific parameters.

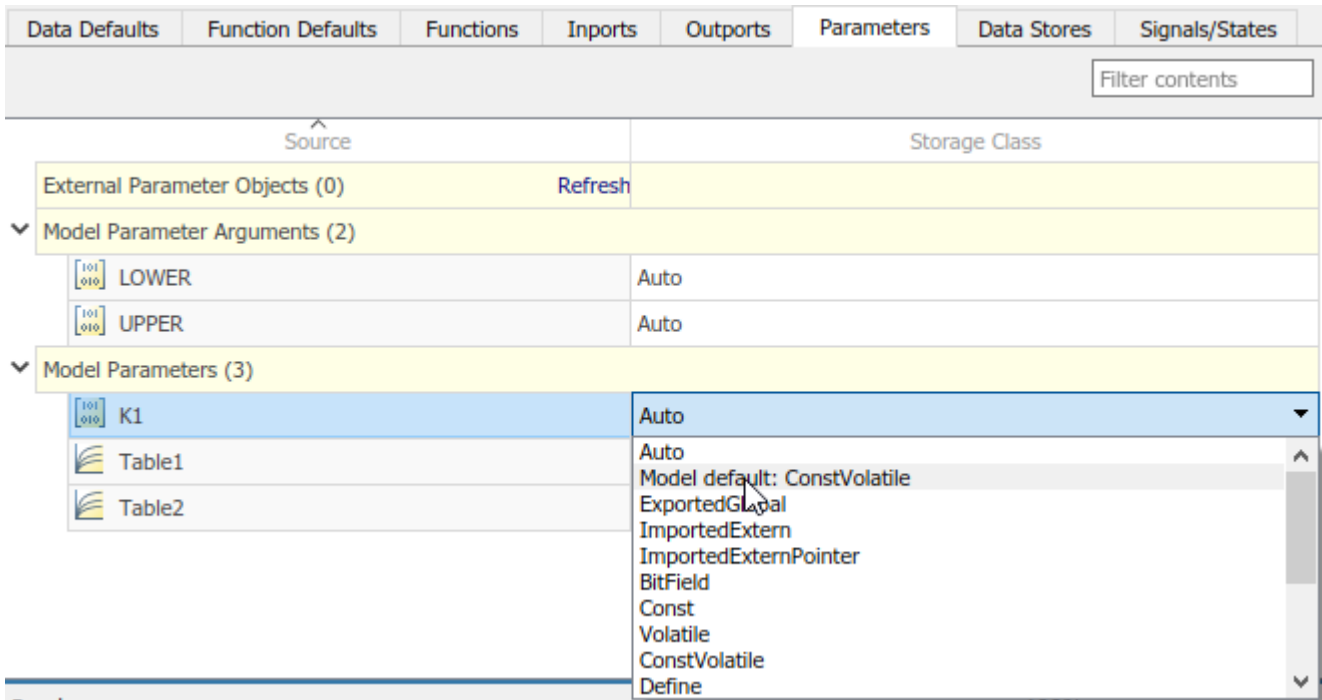

If your model meets at least one of these criteria, consider configuring code generation settings for parameters individually:

- Uses multiple parameters of the same category that have unique source, naming, or placement requirements.
- Uses a few parameters of the same category.
- Has a default configuration for a category of parameters and you need to override the configuration for some specific parameters.

This example shows how to use the Code Mappings editor to apply your default storage class setting for model parameters to parameters `K1`, `Table1`, and `Table2` in model `rtwdemo_configinterface`. You configure code identifiers for those parameters and for model parameter arguments `LOWER` and `UPPER`. You can specify code generation identifiers, for example for integration, without modifying the model design.

- 1 If you have not already done so, complete the steps in “Configure Default Code Generation Settings for Parameters” on page 32-63.
- 2 In the Code Mappings editor, click the **Parameters** tab. Expand **Model Parameter Arguments**. By default, the storage class for each model parameter is set to `Auto`, which means that the code generator might eliminate or change the representation of relevant code for optimization purposes. If optimizations are not possible, the code generator applies the model default configuration. For this example, leave the storage class set to `Auto`.

- 3 Expand **Model Parameters**. By default, the storage class for each parameter is set to Auto. Use the model default configuration, which specifies storage class ConstVolatile.
  - To avoid optimizations and force the code generator to use the default configuration, set the storage class to `Model default`.
  - To override the default configuration, specify the storage class that meets the code generation requirements for that parameter.
- 4 In the Code Mappings editor, under **Model Parameters**, select parameters K1, Table1, and Table2. Set the storage class to `Model default: ConstVolatile`.

- 5 Configure the code identifiers for model parameters with names that include the prefix `mp_`. In the Code Mappings editor, select model parameter K1. Click the  icon and set the storage class property **Identifier** to `mp_K1`. For parameters Table1 and Table2, set **Identifier** to `mp_Table1` and `mp_Table2`.

The screenshot displays the MATLAB/Simulink environment. The main workspace shows a Simulink model with several blocks: 'Constant1' (UPPER), 'Constant2' (LOWER), 'RelOp1' (>), 'RelOp2' (<), 'LogOp', 'OR', 'Data Store Write', 'Data Store Memory', 'Table1' (1-D T(u)), 'Gain' (K1), 'Data Store Read', 'Table2' (2-D T(u)), 'Delay', and 'Switch'. The 'Code Mappings - Component Interface' window is open, showing a table of model parameters. The table has columns for 'Source', 'Refresh', and 'Storage Class'. The 'Model Parameters (3)' section is expanded, showing parameters 'K1', 'Table1', and 'Table2', all with a 'Model default: ConstVolatile' storage class. A property inspector for 'mp\_K1' is open on the right, showing fields for 'Identifier', 'Calibration Access', 'Display Identifier', 'Format', and 'Compu Method'.

Source	Refresh	Storage Class
External Parameter Objects (0)		
Model Parameter Arguments (2)		
LOWER		Auto
UPPER		Auto
Model Parameters (3)		
K1		Model default: ConstVolatile
Table1		Model default: ConstVolatile
Table2		Model default: ConstVolatile

- Save the model.
- Generate and view the code. For example, find the data definitions for model parameter `mp_K1` in `rtwdemo_configinterface.c`.

```
const volatile int8_T mp_K1 = 2;
```

Find where the parameter is used in the step entry-point function.

```
if (mode) {
 output = (real_T)mp_K1 * dout_Table1;
} else {
 output = dstate_X;
}
```

## Organize Parameter Data into a Structure by Using Struct Storage Class

This example shows how to use the `Struct` storage class to organize block parameter values into a structure in the generated code. You apply the storage class directly to individual data items in a model.

To create a custom structure of parameter data in the generated code, consider creating a corresponding structure in Simulink. See “Organize Data into Structures in Generated Code” on page 33-145.

### Create the Example Model

Create this example model with three Constant blocks and three Output blocks. Name the model `ex_struct_param`.

### Set Up Constant Parameters

- 1 Open the Model Data Editor. On the **Modeling** tab, click **Model Data Editor**.
- 2 In the Model Data Editor, select the **Parameters** tab.
- 3 In the model, select the upper Constant block.
- 4 In the Model Data Editor, use the **Value** column to set the constant value to p1. Next to p1, click the action button  and select **Create**.
- 5 In the Create New Data dialog box, set **Value** to `Simulink.Parameter(1.0)` and click **Create**.

Simulink adds a `Simulink.Parameter` object named p1 to the model workspace.

- 6 In the property dialog box for p1, click **OK**.

If you did not have to set up other parameters, you could click the **Code Generation** tab. Then, click the **Configure in Coder App** button, which opens the **Embedded Coder** app and Code Mappings editor.

- 7 Use the Model Data Editor to set the other constant values by using parameter objects named p2 (value 2.0) and p3 (value 3.0).

### Configure Constant Parameters for Code Generation

- 1 Open the **Embedded Coder** app.
- 2 On the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
- 3 In the Code Mappings editor, click the **Parameters** tab.
- 4 Expand **Model Parameters**.
- 5 Set the storage class for parameters p1, p2, and p3 to `Struct`.
- 6 Select parameter p1. Click the  icon and set property **StructName** to `my_struct`. For parameters p2 and p3, set **StructName** to `my_struct`.
- 7 Save the model.

### Generate and Inspect Code

Generate and inspect the code.

The file `ex_struct_param.h` defines structure type, `my_struct_type`.

```
/* Type definition for custom storage class: Struct */
typedef struct my_struct_tag {
 real_T p1;
 real_T p2;
}
```

```

 real_T p3;
} my_struct_type;

```

The file `ex_struct_param.c` defines global variable `my_struct`.

```

/* Definition for custom storage class: Struct */
my_struct_type my_struct = {
 /* p1 */
 1.0,

 /* p2 */
 2.0,

 /* p3 */
 3.0
};

```

## Configure Code Generation Settings for Parameters Programmatically

To automate configuration of parameters for code generation, use the programming interface for code mappings. For example, when creating custom block libraries or part of an application test environment, use the programming interface to automate data configuration.

This example shows how to configure default settings for model parameters and model parameter arguments for model `rtwdemo_configinterface`. Configure model parameters so that they are tunable and are defined and declared in the generated code as separate global variables that have type qualifiers `const` and `volatile`. Configure model parameter arguments to use default settings, where the code generator allocates an area of memory represented as a uniquely named field in an exported structure for each argument instance. Apply your default storage class setting for model parameters to parameters `K1`, `Table1`, and `Table2`. Configure code identifiers for those parameters.

- 1 Open the example model.

```
open_system('rtwdemo_configinterface');
```

- 2 Set model configuration parameter **Default parameter behavior** to Tunable.

```
model='rtwdemo_configinterface';

set_param(model,'DefaultParameterBehavior','Tunable');
```

- 3 Create object `cm` by calling function `coder.mapping.api.get`. The object stores the code generation configuration for data elements and functions in model `rtwdemo_configdefaults`.

```
cm = coder.mapping.api.get('rtwdemo_configinterface');
```

- 4 Configure default settings for model parameters by calling function `setDataDefault`. For the arguments, specify these values:

- The object returned by `coder.mapping.api.get`
- `ModelParameters` for the default category
- Property name `StorageClass` with property value `ConstVolatile`

```
setDataDefault(cm,'ModelParameters','StorageClass','ConstVolatile');
```

- 5 Configure default settings for model parameter arguments. In the call to `setDataDefault`, specify these values for arguments:

- The object returned by `coder.mapping.api.get`.
- `ModelParameterArguments` for the default category.
- Property name `StorageClass` with property value `Default`.

```
setDataDefault(cm, 'ModelParameterArguments', 'StorageClass', 'Default');
```

- 6 Verify your default configuration for model parameters and model parameter arguments. Issue calls to `getDataDefault` that specify the object returned by `coder.mapping.api.get`, category `ModelParameters` or `ModelParameterArguments`, and `StorageClass`.

```
getDataDefault(cm, 'ModelParameters', 'StorageClass')
```

```
ans =
```

```
 'ConstVolatile'
```

```
getDataDefault(cm, 'ModelParameterArguments', 'StorageClass')
```

```
ans =
```

```
 'Default'
```

- 7 Apply the default configuration for model parameters to parameters `K1`, `Table1`, and `Table2`.

By default, Simulink sets the storage class for individual parameters to `Auto`. When the storage class is `Auto`, the code generator:

- Determines whether to eliminate the data from the generated code for optimization purposes.
- If retaining the data, determines how to efficiently represent the data in the generated code, taking into account default configuration settings.

Configure the code generator to apply your default model parameter settings to parameters `K1`, `Table1`, and `Table2`. For each parameter, call function `setModelParameter`. Specify the object returned by `coder.mapping.api.get`, the parameter name, property name `StorageClass`, and property value `Model default`.

```
setModelParameter(cm, 'K1', 'StorageClass', 'Model default');
setModelParameter(cm, 'Table1', 'StorageClass', 'Model default');
setModelParameter(cm, 'Table2', 'StorageClass', 'Model default');
```

- 8 Verify your configuration changes for parameters `K1`, `Table1`, and `Table2` by using calls to function `getModelParameter`.

```
getModelParameter(cm, 'K1', 'StorageClass')
```

```
ans =
```

```
 'Model default'
```

```
getModelParameter(cm, 'Table1', 'StorageClass')
```

```
ans =
```

```
 'Model default'
```

```
getModelParameter(cm, 'Table2', 'StorageClass')
```

```
ans =
```

```
 'Model default'
```

- 9** Configure code identifiers for the model parameters. For each parameter, call function `setModelParameter`. Specify the object returned by `coder.mapping.api.get`, the parameter name, property name `Identifier`, and one of these property values.

Model Parameter	Code Identifier
K1	mp_K1
Table1	mp_Table1
Table2	mp_Table2

```
setModelParameter(cm,'K1','Identifier','mp_K1');
setModelParameter(cm,'Table1','Identifier','mp_Table1');
setModelParameter(cm,'Table2','Identifier','mp_Table2');
```

- 10** Verify your configuration changes for the model parameters by using calls to function `getModelParameter`.

```
getModelParameter(cm,'K1','Identifier')

ans =

 'mp_K1'

getModelParameter(cm,'Table1','Identifier')

ans =

 'mp_Table1'

getModelParameter(cm, 'Table2', 'Identifier')

ans =

 'mp_Table2'
```

- 11** Save the model.
- 12** Generate and view the code. For example, find the data definitions for model parameter `mp_K1` in `rtwdemo_configinterface.c`.

```
const volatile int8_T mp_K1 = 2;
```

Find where the parameter is used in the step entry-point function.

```
if (mode) {
 output = (real_T)mp_K1 * dout_Table1;
} else {
 output = dstate_X;
}
```

## Choose Storage Class and Storage Class Properties for Model Parameters

Depending on your code generation requirements, choose from these storage classes to configure code generation for model parameters. For constants, only `Default` applies. For model parameter arguments, only `Auto`, `Default`, and `Model default` apply.

Requirements	Storage Class
Enable optimizations, potentially generating more efficient code.	“Auto” on page 33-77 (Individual mappings only)
For data elements that cannot be optimized, represent data as a field of a standard data structure.	“Default” on page 33-77 (Default mapping only)
Prevent optimizations from eliminating storage for a data element and use the default mapping for the data element category.	“Model Default” on page 33-77 (Individual mappings only) , Dictionary Default (Individual mappings only)
Generate a structure that stores Boolean data in named bitfields.	“Bitfield” on page 33-79 (Individual mapping only)
Support preprocessor conditionals defined by using a compiler flag or option.	“CompilerFlag” on page 33-79
Generate a global variable definition and declaration that has the <code>const</code> , <code>volatile</code> , or <code>const</code> and <code>volatile</code> type qualifiers.	“Const, Volatile, and ConstVolatile” on page 33-79
Generate a macro ( <code>#define</code> directive) or code that uses a macro defined in a header file in your external code.	“Define, ImportedDefine” on page 33-80
Generate a global variable definition and declaration.	“ExportedGlobal” on page 33-78
Generate a global variable definition and declaration to a specified file.	“ExportToFile” on page 33-80
Generate a global variable definition and declaration that has the <code>static</code> type qualifier.	“FileScope” on page 33-81 (Local and shared local data store mappings only)
Generate code that interacts with data by calling your custom accessor functions.	“GetSet” on page 33-81
Generate code that reads from and writes to a global variable or global variable pointer defined by your external code.	“ImportedExtern, ImportedExternPointer” on page 33-78
Generate code that reads from and writes to a global variable defined by your external header file.	“ImportFromFile” on page 33-82
Generate a global structure that has a name, which you can specify.	“Struct” on page 33-83 (Individual mappings only)

The list of available storage classes might include other project-specific storage classes defined in an Embedded Coder Dictionary. If you have special requirements that are not met by the listed storage classes and you have Embedded Coder software, you can define a storage class. See “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2.

For an individual model parameter, use the **Identifier** storage class property to configure a name for the variable representing the parameter in the generated code. With Embedded Coder, depending on the storage class that you choose, you can also configure these properties.

Property	Description	Storage Classes
DefinitionFile	Source definition file that contains definitions for global data, which is read by the parameter and external code	ExportToFile and Volatile

Property	Description	Storage Classes
GetFunction	Parameter appears in the generated code as a call to a specified get function	GetSet
HeaderFile	Source header file that contains declarations for global data, which is read by the parameter and external code	ExportToFile, GetSet, ImportFromFile, and Volatile
Memory Section (default parameter configuration only)	Memory section that contains data read by the parameter	Default
Owner	Code generator places the definition for parameters in the code generated for one of multiple models in a model hierarchy that share definitions. You must select the model configuration parameter <b>Use owner from data object for data definition placement</b> . See “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2.	ExportToFile and Volatile
PreserveDimensions	Code generator preserves dimensions of parameter data that is represented in generated code as a multidimensional array. You must set model configuration parameter <b>Array layout</b> to Row-major. See “Preserve Dimensions of Multidimensional Arrays in Generated Code” on page 44-2.	ExportToFile, FileScope, ImportFromFile, Localizable and Volatile
SetFunction	Parameter appears in the generated code as a call to a specified set function.	GetSet
StructName	Name for a structure in the generated code for parameter.	BitField and Struct

## Configure Block States for C Code Generation

Block states, such as the state of a Unit Delay block, retain a state value between execution cycles of an algorithm. When configuring a model for code generation, you can configure state data to:

- Minimize the amount of data that is stored in memory.
- Control where the code generator places state data in memory.
- Promote state data to the model interface so that other components and systems can access that data.
- Improve readability and traceability of the generated code.

For code generation, examples show how to configure a block state for model `rtwdemo_configinterface`. You can configure code mappings by using the **Code Mappings Editor - C** or code mappings programming interface (`coder.mapping.api.CodeMapping`).

### Choose Code Configuration Options for States

Based on your code generation requirements, decide how to represent state data. By default, states in a model appear in generated code as fields of a global data structure named `model_DW`. If you do not configure customizations, the code generator determines whether to eliminate or change the representation of states in generated code for optimization purposes. If you configure customizations, decide:

- Whether to set up a default configuration

If you need to gain access to a significant number of states (for example, more than 10), it is more efficient to configure the states with default settings and then override those settings for special cases. If you need to gain access to a few states that have unique source, naming, or placement requirements, consider configuring the states individually.

- How to declare and handle state data in the generated code
  - As separate global variables
  - To read input data from global variables defined in external code
  - As calls to access functions. Requires Embedded Coder

For more information about these options, see “Control Data and Function Interface in Generated Code” on page 33-44.

Other considerations include whether to:

- Name states in the generated code by using state labels that appear in the model or by using unique code identifiers.
- Include the `volatile` type qualifier in global variable definitions and declarations. Requires Embedded Coder. See “Protect Global Data with `const` and `volatile` Type Qualifiers” on page 42-13.
- Place state data into a specific area of memory. Requires Embedded Coder. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

For a list of interface requirements that are relevant to states with corresponding storage classes and storage class properties, see “Choose Storage Class and Storage Class Properties for Data Stores” on page 32-89.

State requirements for example model `rtwdemo_configinterface` are:

- Retain the state data of the Unit Delay block for accessibility while the generated code executes.
- Represent the state as a separate global variable.
- Apply prefix `dtemp_` to the name of the variable that represents the state.

For this example, you set the default representation of the state in the generated code as a global variable with the `static` type qualifier. Then, you configure the state of the Unit Delay block to use the default storage class and a unique code identifier that includes the required prefix `dtemp_`. The code identifier capability enables you to specify code generation identifiers without having to modify the model design.

## Configure Default Code Generation Settings for States

A default code generation setting for states can reduce the effort of preparing a model for code generation, especially if a model has a significant number of states that you want to gain access to while the generated code executes. Choose configuration settings once, and the code generator applies those settings to states across the model. Simulink stores the default configuration as part of the model.

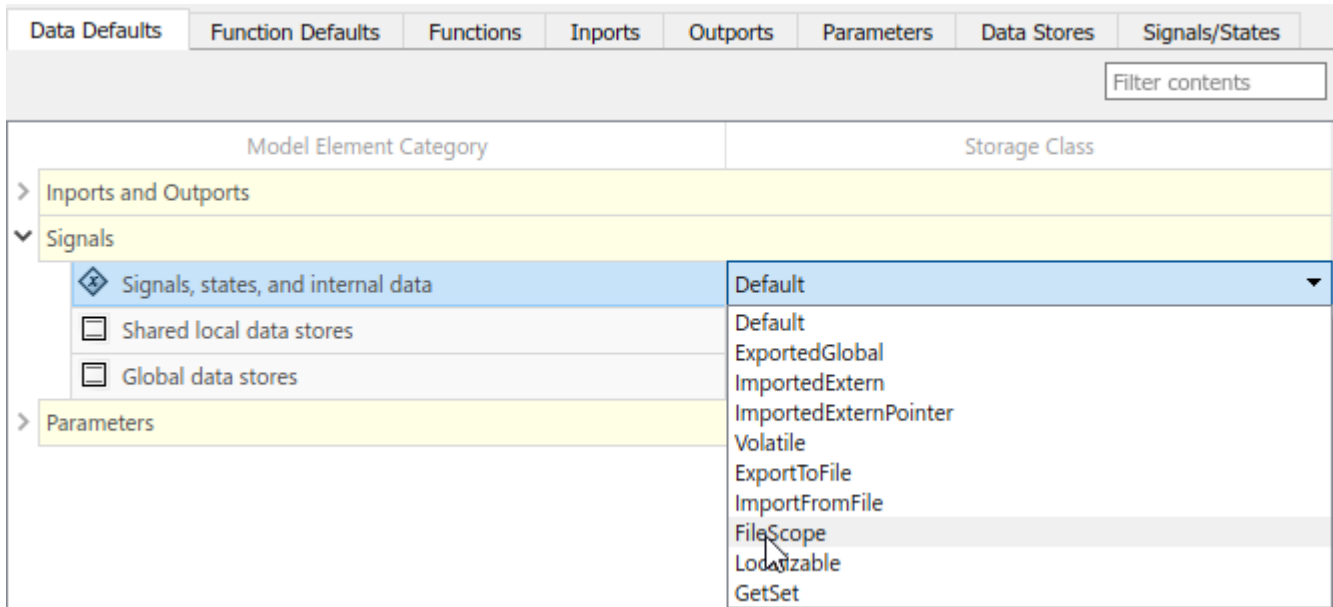

Consider configuring default code generation settings for model states if your model uses multiple states that do not have unique requirements or uses a shared Embedded Coder Dictionary.

This example shows how to use the **Code Mappings Editor - C** to configure default settings for states. Use the Code Mappings editor to set the default storage class for states in model `rtwdemo_configinterface` to `FileScope`. With that storage class setting, the code generator represents state data in the generated code as global variables that have the `static` type qualifier.

- 1 Open model `rtwdemo_configinterface`. Save a copy of the model to a writable location.

- 2 Open the **Embedded Coder** app.
- 3 In the **C Code** tab, select **Code Interface > Default Code Mappings**.
- 4 In the Code Mappings editor, under **Signals**, select category **Signals, states, and internal data**. Set the default storage class to **FileScope**.

- 5 Save the model.

## Configure Code Generation Settings for Individual States

You can configure individual states for code generation. For example, if a model has two states that have unique code generation requirements, configure the states individually. Or, if you configure default settings for states, you can override those settings for specific states.

If your model meets at least one of these criteria, consider configuring code generation settings for states individually:

- Uses multiple states that have unique source, naming, or placement requirements.
- Uses a few states.
- Has a default configuration for states and you need to override the configuration for some specific states.

This example shows how to use the Code Mappings editor to apply your default storage class setting to the Unit Delay block state X in model `rtwdemo_configinterface`.

The example also shows how to configure a code identifier for that state. You can specify code generation identifiers, for example for integration, without modifying the model design.

- 1 If you have not already done so, complete the steps in “Configure Default Code Generation Settings for States” on page 32-75.
- 2 In the Code Mappings editor, click the **Signals/States** tab. Expand **States**. The storage class for the state is set to **Auto**, which means that the code generator might eliminate or change the representation of relevant code for optimization purposes. If optimizations are not possible, the

code generator applies the model default configuration. For this example, the model default configuration specifies storage class `FileScope`.

- To avoid optimizations and force the code generator to use the default configuration, set the storage class to `Model default`.
  - To override the default configuration, specify the storage class that meets the code generation requirements for that state.
- 3 In the Code Mappings editor, select state X. Set the storage class to `Model default`: `FileScope`.
  - 4 Configure the code identifier for the state with a name that includes the prefix `dstate_`. In the Code Mappings editor, select state X. Click the  icon and set the storage class property **Identifier** to `dstate_X`.

The screenshot shows the Simulink Code Mappings editor for state X. The main window displays a Simulink block diagram with inputs In1, In2, In3, In4 and outputs Out1. A 'Code Mappings - Component Interface' table is visible at the bottom, showing state X with 'Model default: FileScope' and 'rtwdemo\_configinterface'. A property inspector on the right shows the 'Identifier' set to 'dstate\_X'.

Source	Storage Class	Path
Signals (0)		
States (1)		
X	Model default: FileScope	rtwdemo_configinterface

- 5 Save the model.
- 6 Generate and view the code. For example, in `rtwdemo_configinterface.c`, find the data definitions for the state data.

```
static MYTYPE dstate_X;
```

Find where the state data is used in the step entry-point function.

```
.
.
.
if (mode) {
 output = (real_T)mp_K1 * dout_Table1;
} else {
 output = dstate_X;
}
.
.
.
dstate_X = dout_Table2;
}
```

## Configure Code Generation Settings for States Programmatically

To automate configuration of states for code generation, use the programming interface for code mappings. For example, when creating custom block libraries or as part of creating an application test environment, use the programming interface to automate data configuration.

This example shows how to use the programming interface to configure states for model `rtwdemo_configinterface`. Set the default representation of states in the generated code as global variables that have the `static` type qualifier. Then, configure state X of the Unit Delay block to use the default storage class and unique code identifier that includes the required prefix `dstate_`.

- 1 Open the example model.

```
open_system('rtwdemo_configinterface')
```

- 2 Create object `cm` by calling function `coder.mapping.api.get`. The object stores the code generation configuration for data and functions for model `rtwdemo_configinterface`.

```
cm = coder.mapping.api.get('rtwdemo_configinterface');
```

- 3 Configure default settings for states by calling function `setDataDefault`. For the arguments, specify these values:

- The object returned by `coder.mapping.api.get`
- `InternalData` for the default category
- Property name `StorageClass` with property value `FileScope`

```
setDataDefault(cm, 'InternalData', 'StorageClass', 'FileScope');
```

- 4 Verify your default configuration for states. Issue a call to `getDataDefault` that specifies the object returned by `coder.mapping.api.get` and category `InternalData`. Specify the third argument as property `StorageClass`.

```
getDataDefault(cm, 'InternalData', 'StorageClass')
```

```
ans =
```

```
 'FileScope'
```

- 5 Apply the default configuration for states to state X.

By default, Simulink sets the storage class for individual states to `Auto`. The code generator:

- Determines whether to eliminate the data from the generated code for optimization purposes.
- If retaining the data, determines how to efficiently represent the data in the generated code, taking into account default configuration settings.

To control the configuration for a state, call function `setState`.

Issue a call to `setState` that specifies:

- Object returned by `coder.mapping.api.get`
- State name X
- Default storage class previously set for states by using property `StorageClass` and property value `Model default`.
- Property `Identifier` and property value `dstate_X`

```
setState(cm,'X','StorageClass','Model default','Identifier','dstate_X');
```

- 6** Verify your configuration changes by calling function `getState`. Specify the object returned by `coder.mapping.api.get`, name of the state, and property `StorageClass` or `Identifier`.

```
getState(cm,'X','StorageClass')
```

```
ans =
```

```
 'Model default'
```

```
getState(cm,'X','Identifier')
```

```
ans =
```

```
 'dstate_X'
```

- 7** Save the model.

- 8** Generate and view the code. For example, in `rtwdemo_configinterface.c`, find the data definitions for state data.

```
static MYTYPE dstate_X;
```

Find where the state data is used in the step entry-point function.

```
.
.
.
if (mode) {
 output = (real_T)mp_K1 * dout_Table1;
} else {
 output = dstate_X;
}
.
.
.
dstate_X = dout_Table2;
}
```

## Choose Storage Class and Storage Class Properties for States

Depending on your code generation requirements, choose from these storage classes to configure code generation for block states.

Requirements	Storage Class
Let the code generator handle how to represent the state in the generated code. For example, for optimization purposes, the code generator might eliminate or change the representation of data.	"Auto" on page 33-77 (Individual mappings only)
For data elements that cannot be optimized, represent data as a field of a standard data structure.	"Default" on page 33-77 (Default mapping only)
Prevent optimizations from eliminating storage for a data element and use the default mapping for the data element category.	"Model Default" on page 33-77 (Individual mappings only) , Dictionary Default (Individual mappings only)
Generate a structure that stores Boolean data in named bitfields.	"Bitfield" on page 33-79 (Individual mapping only)

Requirements	Storage Class
Generate a global variable definition and declaration that has the <code>volatile</code> type qualifier.	<code>Volatile</code> (See “Const, Volatile, and ConstVolatile” on page 33-79)
Generate a global variable definition and declaration.	“ExportedGlobal” on page 33-78
Generate a global variable definition and declaration to a specified file.	“ExportToFile” on page 33-80
Generate a global variable definition and declaration that has the <code>static</code> type qualifier.	“FileScope” on page 33-81 (Local and shared local data store mappings only)
Generate code that interacts with data by calling your custom accessor functions.	“GetSet” on page 33-81
Generate code that reads from and writes to a global variable or global variable pointer defined by your external code.	“ImportedExtern, ImportedExternPointer” on page 33-78
“ExportToFile” on page 33-80	“ImportFromFile” on page 33-82
Generate variables that are local to functions.	“Localizable” on page 33-82
Generate a global structure that has a name, which you can specify.	“Struct” on page 33-83 (Individual mappings only)
Generate a global variable that enables buffer reuse.	“Reusable” on page 33-83 (Individual mappings only)

The list of available storage classes might include other project-specific storage classes defined in an Embedded Coder Dictionary. If you have special requirements that are not met by the listed storage classes and you have Embedded Coder software, you can define a storage class. See “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2.

For an individual state, use the **Identifier** storage class property to configure a name for the variable representing the state in the generated code. With Embedded Coder, depending on the storage class that you choose, you can also configure these properties.

Property	Description	Storage Classes
<code>DefinitionFile</code>	Source definition file that contains definitions for global data, which is read by the state and external code	<code>ExportToFile</code> and <code>Volatile</code>
<code>GetFunction</code>	State appears in the generated code as a call to a specified <code>get</code> function	<code>GetSet</code>
<code>HeaderFile</code>	Source header file that contains declarations for global data, which is read by the state and external code	<code>ExportToFile</code> , <code>GetSet</code> , <code>ImportFromFile</code> , and <code>Volatile</code>
<code>Memory Section</code> (default state configuration only)	Memory section that contains data read by the state	<code>Default</code>

Property	Description	Storage Classes
Owner	Code generator places the definition for states in the code generated for one of multiple models in a model hierarchy that share definitions. You must select the model configuration parameter <b>Use owner from data object for data definition placement</b> . See “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2.	ExportToFile and Volatile
PreserveDimensions	Code generator preserves dimensions of state data that is represented in generated code as a multidimensional array. You must set model configuration parameter <b>Array layout</b> to Row-major. See “Preserve Dimensions of Multidimensional Arrays in Generated Code” on page 44-2.	ExportToFile, FileScope, ImportFromFile, Localizable and Volatile
SetFunction	State appears in the generated code as a call to a specified <b>set</b> function.	GetSet
StructName	Name for a structure in the generated code for state.	BitField and Struct

- “C Code Generation Configuration for Model Interface Elements” on page 32-2
- “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75
- “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15
- “Configure Model Data Elements for ASAP2 File Generation” on page 63-2

## Configure Data Stores for C Code Generation

Data stores enable subsystems and referenced models to share data without using I/O ports to pass the data from level to level (see “Data Store Basics” and “Data Stores in Generated Code” on page 33-93). Types of data stores include the types listed in this table.

Type of Data Store	Description
Local data store	Data store that is accessible from anywhere in a model hierarchy that is at or below the level at which you define the data store. You can define a local data store graphically in a model by including a Data Store Memory block or by creating a signal object (synthesized data store) in the model workspace.
Shared local data store	Data Store Memory block with the block parameter <b>Share across model instances</b> set. These data stores are accessible only in the model where they are defined. The data store value is shared across instances of the model.
Global data store	Data store that is defined by a signal object in the base workspace or in a data dictionary. Multiple models in an application can use these data stores.

When you open a model in the **Embedded Coder** app, local and shared local data stores appear in the Code Mappings editor, where you can configure the data stores for code generation. If a model uses global data stores, you can view them in the Code Mappings editor by clicking the **Refresh** link that appears to the right of the data store name. That link initiates an update diagram and adds global data stores that the model uses in the editor view.

Configure data stores to:

- Make data accessible for interaction while the generated code executes.
- Control where the code generator places data in memory.
- Improve readability and traceability of generated code.

For code generation, examples show how to configure a data store for model `rtwdemo_configinterface`. You can configure code mappings by using the **Code Mappings Editor - C** or code mappings API (`coder.mapping.api.CodeMapping`).

### Choose Customization Options for Data Stores

By default, local data stores in a model appear in generated code as fields of a global data structure named `model_DW`. Shared local data stores appear as a field of global data structure `model_SharedDSM`. Based on your code interface requirements, decide whether to customize code generation of data stores. If you do not configure customizations, the code generator determines whether to eliminate or change the representation of data stores in generated code for optimization purposes. If you configure customizations, decide:

- Whether to set up a default configuration

If a model includes a significant number (for example, more than 10) of data stores for a given category that must be accessible during program execution, it is more efficient to configure the data stores with a default setting, and then override that setting for special cases. If the model

includes a few data stores for a given category that have unique source, naming, or placement requirements, consider configuring the data stores individually.

- How to declare and handle model data stores in the generated code
  - As separate global variables
  - To read from data stores as global variables defined in external code
  - As calls to access functions. Requires Embedded Coder

For more information about these options, see “Control Data and Function Interface in Generated Code” on page 33-44.

Other considerations for model parameters include whether to:

- Name data stores in the generated code by using data store names in the model or by using unique code identifiers.
- Include the `static` type qualifier in global variable definitions and declarations, for example, to prevent name clashes. Requires Embedded Coder. See “Prevent Name Clashes by Configuring Data Item as static” on page 34-8.
- Include the `volatile` type qualifier in global variable definitions and declarations. Requires Embedded Coder. See “Protect Global Data with `const` and `volatile` Type Qualifiers” on page 42-13.
- Generate a global data structure with a name that you specify. Requires Embedded Coder. See “Organize Data into Structures in Generated Code” on page 33-145.
- Place data stores in a specific area of memory. Requires Embedded Coder. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

For a list of interface requirements that are relevant to data stores with corresponding storage classes and storage class properties, see “Choose Storage Class and Storage Class Properties for Data Stores” on page 32-89.

For example model `rtwdemo_configinterface`, data store requirements are:

- Represent local data stores as separate global variables defined and declared with the `static` type qualifier.
- Represent shared local data stores as separate global variables defined and declared with the `volatile` type qualifier.
- Apply prefix `ds_` to names of variables that represent data stores.

For this example, you set the default representation for local data stores in the generated code as global variables that have the `static` type qualifier and shared local data stores as global variables that have the `volatile` type qualifier. Then, you configure the local data store in the model to use the default storage class and a unique code identifier that includes the required prefix `ds_`. The code identifier capability enables you to specify code generation identifiers without having to modify the model design.

## Configure Default Code Generation Settings for Data Stores

Default code generation settings for data stores can reduce the effort of preparing a model for code generation, especially if a model has a significant number of data stores that you want to gain access to while the generated code executes. Choose configuration settings once, and the code generator

applies those settings to data stores across the model. Simulink stores the default configuration as part of the model.

Consider configuring default code generation settings for model data stores if your model uses multiple data stores for a given category that do not have unique requirements or use a shared Embedded Coder Dictionary.

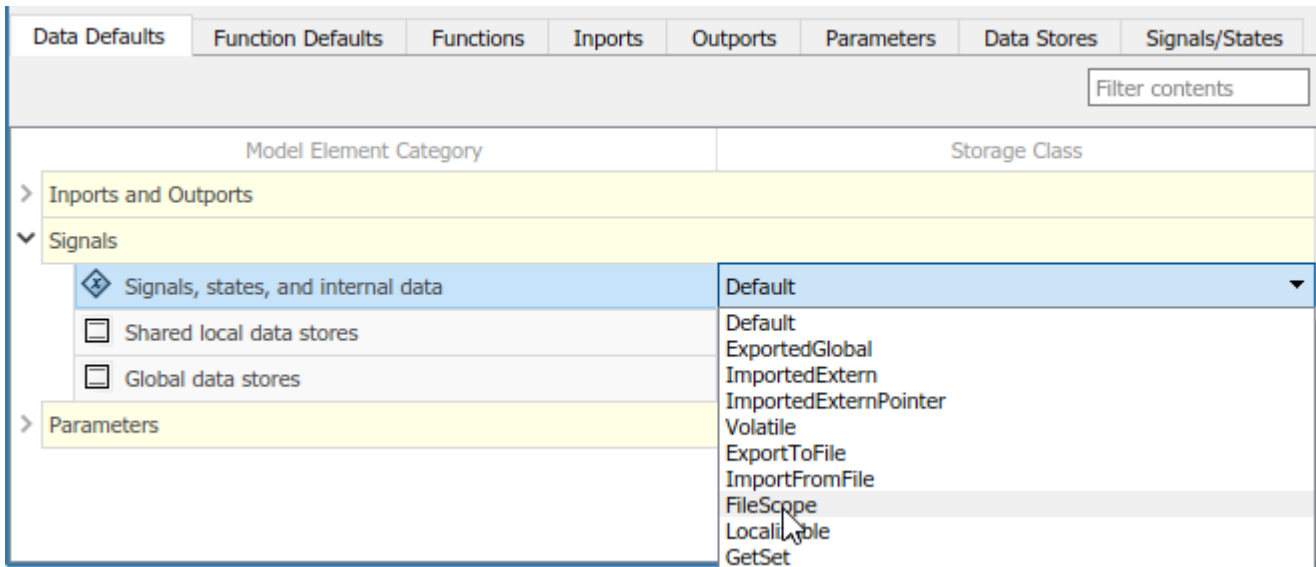

This example shows how to use the **Code Mappings Editor - C** to configure default settings for data stores. Use the Code Mappings editor to set the default storage class for local and shared local data stores in model `rtwdemo_configinterface` to `FileScope` and `Volatile`, respectively. With those storage class settings, the code generator represents the data stores in the generated code as global variables that have the `static` and `volatile` type qualifiers.

- 1 Open model `rtwdemo_configinterface`. Save a copy of the model to a writable location.

- 2 Open the **Embedded Coder** app.
- 3 In the **C Code** tab, select **Code Interface > Default Code Mappings**.
- 4 Configure default code mappings for local data stores. In the Code Mappings editor, on the **Data Defaults** tab, expand the **Signals** node. Select category **Signals, states, and internal data**. Set the storage class to `FileScope`.

- 5 Configure default code mappings for shared local data stores. Select category **Shared local data stores**. Set the storage class to **Volatile**.
- 6 Save the model.

## Configure Code Generation for Individual Data Stores

You can configure individual data stores for code generation. For example, if a model has two data stores of the same category that have unique code generation requirements, configure the data stores individually. Or, if you configure default settings for a category of data stores, you can override those settings for specific data stores.

If your model meets at least one of these criteria, consider configuring code generation settings for data stores individually:

- Uses multiple data stores of the same category that have unique source, naming, or placement requirements.
- Uses a few data stores of the same category.
- Has a default configuration for a category of data stores and you need to override the configuration for some specific states.

This example shows how to use the Code Mappings editor to apply your default storage class setting to the Data Store Memory block mode in model `rtwdemo_configinterface`. The example also shows how to configure a code identifier for that data store.

- 1 If you have not already done so, complete the steps in “Configure Default Code Generation Settings for Data Stores” on page 32-83.
- 2 In the Code Mappings editor, click the **Data Stores** tab. Expand **Local Data Stores**. The storage class for data store `mode` is set to `Auto`, which means that the code generator might eliminate or change the representation of relevant code for optimization purposes. If optimizations are not possible, the code generator applies the model default configuration. For this example, the model default configuration specifies the storage class `Volatile`.
  - To avoid optimizations and force the code generator to use the default configuration, set the storage class to `Model default`.

- To override the default configuration, specify the storage class that meets the code generation requirements for that data store.
- In the Code Mappings editor, select local data store `mode`. Set the storage class to `Model default: Volatile`.
  - Configure the code identifier for the data store with a name that includes the prefix `ds_`. In the Code Mappings editor, select shared local data store `mode`. Click the  icon and set the storage class property **Identifier** to `ds_mode`.

Code Mappings - C

- Save the model.
- Generate and view the code. For example, in `rtwdemo_configinterface.c`, find the data definitions for the data store.

```
static boolean_T ds_mode;
```

Find where the state data is used in the step entry-point function.

```
.
.
.
ds_mode = ((input1 > rtwdemo_configinterface_UPPER) || (input1 <
 rtwdemo_configinterface_LOWER));
.
.
.
if (ds_mode) {
 output = (real_T)mp_K1 * dout_Table1;
```

```

 } else {
 output = dstate_X;
 }
 .
 .
 .

```

## Configure Code Generation Settings for Data Stores Programmatically

To automate configuration of data stores for code generation, use the programming interface for code mappings. For example, when creating custom block libraries or part of an application test environment, use the programming interface to automate data configuration.

This example shows how to use the programming interface to configure data stores for model `rtwdemo_configinterface`. Set the default representation of local and shared local data stores in the generated code as global variables that have the `static` and `volatile` type qualifier, respectively. Configure the Data Store Memory block mode to use the default storage class and a unique code identifier that includes the required prefix `ds_`.

- 1 Open the example model.

```
open_system('rtwdemo_configinterface')
```

- 2 Create object `cm` by calling function `coder.mapping.api.get`. The object stores the data and function code generation configuration for model `rtwdemo_configinterface`.

```
cm = coder.mapping.api.get('rtwdemo_configinterface');
```

- 3 Configure default settings for local data stores by calling function `setDataDefault`. For the arguments, specify these values:

- The object returned by `coder.mapping.api.get`
- `InternalData` for the default category
- Property name `StorageClass` with property value `FileScope`

```
setDataDefault(cm, 'InternalData', 'StorageClass', 'FileScope');
```

- 4 Configure default settings for shared local data stores by calling function `setDataDefault`. Specify these values for arguments:

- The object returned by `coder.mapping.api.get`.
- `SharedLocalDataStore` for the default category.
- Property name `StorageClass` with property value `Volatile`.

```
setDataDefault(cm, 'SharedLocalDataStore', 'StorageClass', 'Volatile');
```

- 5 Verify your default configuration settings for local and shared local data stores. Issue a call to `getDataDefault` that specifies the object returned by `coder.mapping.api.get`, category `InternalData`, and the property `StorageClass`. In a second call to `getDataDefault`, replace the category with `SharedLocalDataStore`.

```
getDataDefault(cm, 'Internal', 'StorageClass')
```

```
ans =
```

```
 'FileScope'
```

```
getDataDefault(cm, 'SharedLocalDataStore', 'StorageClass')
```

```
ans =
 'Volatile'
```

- 6** Apply the default configuration for local data store mode.

By default, Simulink sets the storage class for data stores to `Auto`. When the storage class is `Auto`, the code generator:

- Determines whether to eliminate the data from the generated code for optimization purposes.
- If retaining the data, determines how to efficiently represent the data in the generated code, taking into account default configuration settings.

To control the configuration for an individual data store, call function `setDataStore`. Issue a call to `setDataStore` that specifies:

- Object returned by `coder.mapping.api.get`
- Data store name `mode`
- Default storage class previously set for the data store by using property `StorageClass` and property value `Model default`.
- Property `Identifier` and property value `ds_mode`

```
setDataStore(cm,'mode','StorageClass','Model default','Identifier','ds_mode');
```

- 7** Verify your configuration changes by calling function `getDataStore`. Specify the object returned by `coder.mapping.api.get`, the name of the data store, and property `StorageClass` or `Identifier`.

```
getDataStore(cm,'mode','StorageClass')
```

```
ans =
 'Model default'
```

```
getDataStore(cm,'mode','Identifier')
```

```
ans =
 'ds_mode'
```

- 8** Save the model.
- 9** Generate and view the code. For example, in `rtwdemo_configinterface.c`, find the data definition for the data store.

```
static boolean_T ds_mode;
```

Find where the data store is used in the step entry-point function.

```
.
.
.
ds_mode = ((input1 > rtwdemo_configinterface_UPPER) || (input1 <
 rtwdemo_configinterface_LOWER));
.
.
.
if (ds_mode) {
 output = (real_T)mp_K1 * dout_Table1;
} else {
 output = dstate_X;
```

```

}
.
.
.

```

## Choose Storage Class and Storage Class Properties for Data Stores

Depending on your code generation requirements, choose from these storage classes to configure code generation for data stores.

Requirements	Storage Class
Enable optimizations, potentially generating more efficient code.	"Auto" on page 33-77 (Individual mappings only)
For data elements that cannot be optimized, represent data as a field of a standard data structure.	"Default" on page 33-77 (Default mapping only)
Prevent optimizations from eliminating storage for a data element and use the default storage class for the data element category.	"Model Default" on page 33-77 (Individual mappings only) , Dictionary Default (Individual mappings only)
Generate a structure that stores Boolean data in named bitfields.	"Bitfield" on page 33-79 (Individual mapping only)
Generate a global variable definition and declaration that has the <code>volatile</code> type qualifier.	<code>Volatile</code> (See "Const, Volatile, and ConstVolatile" on page 33-79)
Generate a global variable definition and declaration.	"ExportedGlobal" on page 33-78
Generate a global variable definition and declaration to a specified file.	"ExportToFile" on page 33-80
Generate a global variable definition and declaration that has the <code>static</code> type qualifier.	"FileScope" on page 33-81 (Local and shared local data store mappings only)
Generate code that interacts with data by calling your custom accessor functions.	"GetSet" on page 33-81
Generate code that reads from and writes to a global variable or global variable pointer defined by your external code.	"ImportedExtern, ImportedExternPointer" on page 33-78
Generate code that reads from and writes to a global variable defined by your external header file.	"ImportFromFile" on page 33-82
Generate variables that are local to functions.	"Localizable" on page 33-82
Generate a global structure that has a name, which you can specify.	"Struct" on page 33-83 (Individual mappings only)
Generate a global variable that enables buffer reuse.	"Reusable" on page 33-83 (Individual mappings only)

The list of available storage classes might include other project-specific storage classes defined in an Embedded Coder Dictionary. If you have special requirements that are not met by the listed storage classes and you have Embedded Coder software, you can define a storage class. See "Define Storage Classes, Memory Sections, and Function Templates for Software Architecture" on page 31-2.

For an individual data store, use the **Identifier** storage class property to configure a name for the variable representing the data store in the generated code. With Embedded Coder, depending on the storage class that you choose, you can also configure these properties.

Property	Description	Storage Classes
DefinitionFile	Source definition file that contains definitions for global data, which is read by the data store and external code	ExportToFile and Volatile
GetFunction	Data store appears in the generated code as a call to a specified get function	GetSet
HeaderFile	Source header file that contains declarations for global data, which is read by the data store and external code	ExportToFile, GetSet, ImportFromFile, and Volatile
Memory Section (default data store configuration only)	Memory section that contains data read by the data store	Default
Owner	Code generator places the definition for data stores in the code generated for one of multiple models in a model hierarchy that share definitions. You must select the model configuration parameter <b>Use owner from data object for data definition placement</b> . See “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2.	ExportToFile and Volatile
PreserveDimensions	Code generator preserves dimensions of data stores that are represented in generated code as a multidimensional array. You must set the model configuration parameter <b>Array layout</b> to <b>Row-major</b> . See “Preserve Dimensions of Multidimensional Arrays in Generated Code” on page 44-2.	ExportToFile, FileScope, ImportFromFile, Localizable and Volatile
SetFunction	Data store appears in the generated code as a call to a specified set function.	GetSet
StructName	Name for a structure in the generated code for the data store.	BitField and Struct

## More About

- “C Code Generation Configuration for Model Interface Elements” on page 32-2
- “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75
- “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15

- “Configure Model Data Elements for ASAP2 File Generation” on page 63-2

## Manage Multiple Code Mappings for a Model

Code mappings separate code generation configurations from model designs. This separation enables you to design models that are platform-neutral and ready to deploy to different target platform environments. If you have access to the necessary products, you can associate a model with code mappings for several different platforms.

Platform	System Target File	Programming Language	Required Products
C rapid prototyping	GRT-based	C	Simulink Coder
C production	ERT-based	C	Embedded Coder
C++ production	ERT-based	C++	Embedded Coder
AUTOSAR classic	AUTOSAR	C	AUTOSAR Blockset, Embedded Coder (for generating code)
AUTOSAR adaptive	AUTOSAR Adaptive	C++	AUTOSAR Blockset, Embedded Coder (for generating code)

You can generate code for the different platforms from a model or model hierarchy. Associate the models in a model hierarchy with the same platform.

Simulink activates an existing code mapping when you do one of the following:

- In the Simulink Editor, open a coder app for a model and specify an output type that supports code mappings.
- Use the code mappings API to create a code mapping.

The Code Mappings editor and code mappings programming interface display and operate on the active code mapping.

### Configure Alternative Code Mappings by Using Configuration Sets

You can configure alternative code mappings for a model by creating multiple model configuration sets and changing which configuration set is active. Simulink creates or opens an existing code mapping for a model based on settings of these model configuration parameters:

- **System target file**
- **Language**
- **Code interface packaging**

Create a configuration set for each platform for which you want to generate code for a model. Code mappings are supported for these combinations of parameter settings.

Platform	System target file	Language	Code interface packaging
C/C++ rapid prototyping	grt.tlc or derivative of grt.tlc	C/C++	Nonreusable function or Reusable function
C/C++ production	ert.tlc or derivative of ert.tlc	C/C++	Nonreusable function or Reusable function
C++ production	ert.tlc or derivative of ert.tlc	C++	C++ class
AUTOSAR classic	autosar.tlc	C	Nonreusable function or Reusable function
AUTOSAR adaptive	autosar_adaptive.tlc	C++	C++ class

For C++ platforms, reusable and nonreusable functions use C code mappings.

Activate the configuration set of interest. Then, open the corresponding code mappings in the Simulink Editor, as described in “Activate Code Mappings in the Simulink Editor” on page 32-93 or the code mappings API in “Create and Activate Code Mappings Programmatically” on page 32-94.

## Activate Code Mappings in the Simulink Editor

When you open a model in the Simulink Editor, Simulink activates an existing code mapping for the model based on settings of these model configuration parameters:

- **System target file**
- **Language**
- **Code interface packaging**

When you open one of the following coder apps, Simulink checks whether the system target file setting of the active configuration set aligns with your coder app selection, which can be one of these:

- **Simulink Coder** (GRT-based system target file)
- **Embedded Coder** (ERT-based system target file)
- **AUTOSAR Component Designer** (AUTOSAR system target file)

When Simulink detects a misalignment, the editor displays a message that identifies the current system target file setting and questions whether you want to change it and open the selected coder app. You can cancel the operation and open the app that aligns with the current system target file setting or continue with changing the system target file and open the app that you selected.

If the current system target file aligns with your coder app selection, Simulink opens the coder app and adds a code tab (for example, **C Code** or **AUTOSAR**) to the editor toolstrip.

After a coder app opens, on the toolstrip, for **Output**, select the C or C++ code setting or, for AUTOSAR, select one of the AUTOSAR platforms. Then, use the **Code Interface** menu to open the Code Mappings editor.

## Create and Activate Code Mappings Programmatically

You can use the code mappings functions `coder.mapping.utils.create` and `coder.mapping.api.get` to create and activate code mappings for GRT- and ERT-based model platforms.

- 1 Set up multiple model configuration set objects (`Simulink.ConfigSet`) for the model. For example, you might set up GRT and ERT C code configurations or two ERT code configurations, one for generating reusable functions and one for generating nonreusable function code. Name the configuration sets and attach them to your model.

```
grtConfigObj = Simulink.ConfigSet;
set_param(grtConfigObj, 'Name', 'grtConfig');
attachConfigSet('myModel', grtConfigObj);
```

```
ertConfigObj = Simulink.ConfigSet;
set_param(ertConfigObj, 'Name', 'ertConfig');
attachConfigSet('myModel', ertConfigObj);
```

- 2 Activate and create a code mapping for one of the configuration sets by calling `setActiveConfigSet` and `coder.mapping.utils.create`.

```
setActiveConfigSet('myModel', 'grtConfig');
grt_cm = coder.mapping.utils.create('myModel');
```

- 3 Activate and create a code mapping for the second configuration set.

```
setActiveConfigSet('myModel', 'ertConfig')
ert_cm = coder.mapping.utils.create('myModel');
```

- 4 Activate the model code mappings by using calls to `coder.mapping.api.get` that specify the code mapping type, `SimulinkCoderC` or `EmbeddedCoderC`.

```
grt_cm = coder.mapping.api.get('myModel', 'SimulinkCoderC');
.
.
.
Configure model data elements
.
.
.
ert_cm = coder.mapping.api.get('myModel', 'EmbeddedCoderC');
```

## Code Mappings and Embedded Coder Dictionary

If you have Embedded Coder, you can use the Embedded Coder Dictionary to generate standardized code from multiple models. Because the definitions in the Embedded Coder Dictionary for a model are separate from your model elements, you can share the definitions by storing the Embedded Coder Dictionary in a Simulink data dictionary outside of your model. See “Separation of Code Definitions from Model-Specific Data and Function Configurations” on page 31-31.

## **More About**

- “C Code Generation Configuration for Model Interface Elements” on page 32-2
- “Code interface packaging”
- “Manage Configuration Sets for a Model”

## Configure Model Data Interface for C Code Generation

To integrate the generated code with external code or to generate code that complies with coding standards and guidelines, you can configure how data elements in a model, such as block parameters and signals lines, appear in the generated code. You can configure default code generation settings for categories of data elements and configure individual elements by using the Code Mappings editor or code mappings API. For example, you can configure settings that:

- Control placement of declarations and definitions in generated and external (exported and imported) files.
- Package multiple data items into structures.
- Apply storage type qualifiers `const` and `volatile`.

This example shows how to configure data elements for code generation for example model `rtwdemo_configinterface`.

### Explore Example Model

Open example model `rtwdemo_configinterface`.

```
model = 'rtwdemo_configinterface';
open_system(model)
```

The example shows how to configure these model data elements for code generation:

- Inport blocks In1, In2, In3, and In4
- Outport block Out1
- Model parameter arguments LOWER and UPPER

- Model parameters K1, Table1, and Table2
- Local data store mode
- Signal lines sourced from lookup table blocks Table1 and Table2
- State X (delay)

### Configure Default Settings for Inport Blocks

- 1 Open the **Embedded Coder** app.
- 2 In the **C Code** tab, select **Code Interface > Default Code Mappings**.
- 3 In the Code Mappings editor, under **Inports and Outports**, select category **Inports**. Set the default storage class to `ImportFromFile`.
- 4 In the Property Inspector, set **Header File** to `exInDataLut.h`.

### Configure Default Settings for Output Block

- 1 On the **Data Defaults** tab, under **Inports and Outports**, select category **Outports**. Set the default storage class to `ExportToFile`.
- 2 In the Property Inspector, set **Header File** to `exOutSys.h` and **Definition File** to `exOutSys.c`.

### Configure Default Settings for Parameters

- 1 On the **Data Defaults** tab, under **Parameters**, select category **Model parameter arguments**. Leave the storage class set to `Default`. With that setting, the code generator allocates a separate area of memory for each argument instance.
- 2 Select category **Model parameters**. Link text `'Auto' will be inlined` indicates that the code generator is configured to inline model parameters by default. For this example, configure the model parameters to be tunable. Click `'Auto' will be inlined`. The Model Configuration Parameters dialog box opens.
- 3 Set model configuration parameter **Default parameter behavior** to `Tunable`. Save the change and close the dialog box. In the Code Mappings editor, the link text changes to `'Auto' will be tunable`.
- 4 In the Code Mappings editor, with the **Model parameters** category selected, set the storage class to `ConstVolatile`.

### Configure Default Settings for Signals, States, and Data Stores

- 1 On the **Data Defaults** tab, under **Signals**, select category **Signals,states, and internal data**. Set the default storage class to `FileScope`.
- 2 Configure default code mappings for shared local data stores. Select category **Shared local data stores**. Set the storage class to `Volatile`.
- 3 Save the model.

### Configure Code Generation Settings for Individual Inport Blocks

- 1 In the Code Mappings editor, click the **Inports** tab. The editor lists the names of root-level **Inport** and **In Bus Element** blocks that are in the model. If a port resolves to a signal object, a resolve-to-signal-object icon appears to the right of the element name. The storage class for each inport is set to `Auto`, which means that the code generator might eliminate relevant code for optimization purposes. If optimizations are not possible, the code generator applies the model default configuration. For this example, the model default configuration specifies storage class `ImportedFromFile`. To avoid optimizations and force the code generator to use the

default configuration, set the storage class to `Model default`. To override the default configuration, specify the storage class that meets the code generation requirements for that inport.

- 2 Configure the code generator to apply the default storage class setting to inports In2, In3, and In4. Select the rows for the three inports. Then, for one of the selected inports, set the storage class to `Model default: ImportFromFile`. The storage class for the three selected inports changes to `Model default: ImportFromFile`.
- 3 For inport In1, override the default storage class setting. Set the storage class to `ImportFromFile`. In the Property Inspector, set **Header File** to `exInDataMem.h`.
- 4 Configure code identifiers for the inports so that the variables in the generated code match the interface names in the external header and definition files. In the Code Mappings editor, select the row for each inport. In the Property Inspector, set the **Identifier** property to these values: `input1`, `input2`, `input3`, and `input4`.

### Configure Code Generation Settings for Individual Output Blocks

- 1 In the Code Mappings editor, click the **Outputports** tab. The editor lists the names of root-level `Outputport` and `Out Bus Element` blocks that are in the model. If a port resolves to a signal object, a resolve-to-signal-object icon appears to the right of the element name. The storage class for the outputport in the example model is set to `Auto`, which means that the code generator might eliminate relevant code for optimization purposes.
- 2 To avoid optimizations and force the code generator to use the default configuration, set the storage class to `Model default: ExportToFile`. The storage class for the selected outputport changes to `Model default: ExportToFile`.
- 3 Configure the code identifier for the outputport so that the variable in the generated code matches the interface name used by the external code. In the Code Mappings editor, select the row for the outputport. In the Property Inspector, set the **Identifier** property to `output`.

### Configure Code Generation Settings for Individual Parameters

- 1 In the Code Mappings editor, click the **Parameters** tab. Expand **Model Parameter Arguments**. By default, the storage class for each model parameter argument is set to `Auto`, which means that the code generator might eliminate relevant code for optimization purposes. If optimizations are not possible, the code generator applies the model default configuration. For this example, leave the storage class set to `Auto`.
- 2 Expand **Model Parameters**. By default, the storage class for each model parameter is set to `Auto`. For this example, you want to avoid optimizations and for the code generator to use the default storage class setting, `ConstVolatile`.
- 3 In the Code Mappings editor, under **Model Parameters**, select parameters `K1`, `Table1`, and `Table2`. Set the storage class to `Model default: ConstVolatile`.
- 4 Configure the code identifiers for model parameters with names that include the prefix `mp_`, as the requirements specify. In the Code Mappings editor, select model parameter `K1`. In the Property Inspector, expand the **Code** node. Set the storage class property **Identifier** to `mp_K1`. For parameters `Table1` and `Table2`, set **Identifier** to `mp_Table1` and `mp_Table2`.

### Configure Code Generation Settings for Individual Data Stores

- 1 In the Code Mappings editor, click the **Data Stores** tab. Expand **Local Data Stores**. The storage class for data store mode is set to `Auto`, which means that the code generator might eliminate relevant code for optimization purposes. For this example, you want to avoid optimizations and for the code generator to use the default storage class setting, `Volatile`.

- 2 In the Code Mappings editor, select local data store mode. Set the storage class to `Model default: Volatile`.
- 3 Configure the code identifier for the data store with a name that includes the prefix `ds_`. In the Code Mappings editor, select shared local data store mode. In the Property Inspector, expand the **Code** node. Set the storage class property **Identifier** to `ds_mode`.

### Configure Code Generation Settings for Individual States

- 1 In the Code Mappings editor, click the **Signals/States** tab. Expand **States**. The storage class for the state is set to `Auto`, which means that the code generator might eliminate relevant code for optimization purposes. For this example, you want to avoid optimizations and for the code generator to use the default storage class setting, `FileScope`.
- 2 In the Code Mappings editor, select state X. Set the storage class to `Model default: FileScope`.
- 3 Configure the code identifier for the state with a name that includes the prefix `dstate_`, as the requirements specify. In the Code Mappings editor, select state X. In the Property Inspector, expand the **Code** node. Then, set the storage class property **Identifier** to `dstate_X`.

### Configure Code Generation Settings for Individual Signals

Add signals that you want to configure to the model code mappings. For this example, add to the model code mappings the output signals for the two lookup table blocks. Then, configure those signals.

- 1 In the Code Mappings editor, click the **Signals/States** tab. No signals are listed.
- 2 Add signals to the code mappings. For the output signals of lookup table blocks `Table1` and `Table2`, in the model, select a signal, pause on the ellipsis that appears above or below the signal line to open the action bar, and click the **Add Signal** button. In the Code Mappings editor, the **Signals** node expands and lists the names or block identifiers of the two signals that you added. If a signal resolves to a signal object, a resolve-to-signal-object icon appears to the right of the element name or port identifier. The storage class for each signal is set to `Auto`, which means that the code generator might eliminate relevant code for optimization purposes. For this example, you want to avoid optimizations and for the code generator to use the default storage class setting, `FileScope`.
- 3 In the Code Mappings editor, select the output signals for blocks `Table1` and `Table2`. Set the storage class to `Model default: FileScope`.
- 4 Configure the code identifier for the output signals for the two lookup table blocks with names that include the prefix `dout`. In the Code Mappings editor, select signal `Table1:1`. In the Property Inspector, expand the **Code** node. Set the storage class property **Identifier** to `dout_Table1`. For signal `Table2:1`, set **Identifier** to `dout_Table2`.
- 5 Save the model.

### Configure Data for Code Generation Programmatically

Alternatively, use the code mappings API to configure model data elements programmatically.

1. Get the object that represents the code mappings for the model by calling `coder.mapping.api.get`. You specify the returned object as the first argument in subsequent calls to code mapping functions.

```
cm = coder.mapping.api.get(model);
```

2. Configure default code generation settings for categories of data elements with calls to `setDataDefaults`. In each call, include the object returned by the call to `coder.mapping.api.get`, the name of a data element category, and name-value pair arguments that specify the storage class and storage class properties. Use `setDataDefaults` to configure these default settings:

- Inport blocks with storage class `ImportFromFile` and header file `exInDataLut.h`
- Outport blocks with storage class `ExportToFile` and header file `exOutSys.h` and definition file `exOutSys.c`
- Model parameter arguments with the code generator default configuration
- Model parameters with storage class `ConstVolatile`
- Internal data (signals, states, and local data stores) with storage class `FileScope`
- Shared local data stores with storage class `Volatile`

```
setDataDefault(cm, 'Inports', 'StorageClass', 'ImportFromFile', 'HeaderFile', 'exInDataLut.h');
setDataDefault(cm, 'Outports', 'StorageClass', 'ExportToFile', 'HeaderFile', 'exOutSys.h', ...
'DefinitionFile', 'exOutSys.c');
setDataDefault(cm, 'ModelParameterArguments', 'StorageClass', 'Default');
setDataDefault(cm, 'ModelParameters', 'StorageClass', 'ConstVolatile');
setDataDefault(cm, 'InternalData', 'StorageClass', 'FileScope');
setDataDefault(cm, 'SharedLocalDataStore', 'StorageClass', 'Volatile');
```

Set model configuration parameter `DefaultParameterBehavior` to `Tunable`, so that model parameters are accessible during program execution.

```
set_param(model, 'DefaultParameterBehavior', 'Tunable');
```

3. Configure individual Inport blocks with calls to `setInport`. To avoid optimizations, apply the default configuration for Inport blocks to `In2`, `In3`, and `In4`. For `In1`, override the default configuration, by setting the storage class to `ImportFromFile` and the header file to `exInDataMem.h`. Also, configure code identifiers for the inports so that the global variables that represent inports in the generated code match the variable names in the external definition file. In each call to `setInport`, specify the object returned by `coder.mapping.api.get`, the Inport block name, and name-value pair arguments for storage class and property settings.

```
setInport(cm, 'In1', 'StorageClass', 'ImportFromFile', 'HeaderFile', 'exInDataMem.h', ...
'Identifier', 'Input1');
setInport(cm, 'In2', 'StorageClass', 'Model default', 'Identifier', 'Input2');
setInport(cm, 'In3', 'StorageClass', 'Model default', 'Identifier', 'Input3');
setInport(cm, 'In4', 'StorageClass', 'Model default', 'Identifier', 'Input4');
```

4. Configure individual data element settings for Outport block `Out1` with a call to `setOutport`. To avoid optimizations, apply the default configuration. Also, configure a code identifier for the outport. In the call to `setOutport`, specify the object returned by `coder.mapping.api.get`, the Outport block name, and name-value pair arguments for the storage class and code identifier property settings.

```
setOutport(cm, 'Out1', 'StorageClass', 'Model default', 'Identifier', 'output');
```

5. Configure individual model parameters with calls to `setModelParameter`. To avoid optimizations, apply the default configuration. Also, configure code identifiers for the parameters. In each call to `setModelParameter`, specify the object returned by `coder.mapping.api.get`, the parameter name, and name-value pair arguments for the storage class and code identifier property settings.

```
setModelParameter(cm, 'K1', 'StorageClass', 'Model default', 'Identifier', 'mp_K1');
setModelParameter(cm, 'Table1', 'StorageClass', 'Model default', 'Identifier', 'mp_Table1');
setModelParameter(cm, 'Table2', 'StorageClass', 'Model default', 'Identifier', 'mp_Table2');
```

6. Configure individual data element settings for local data store mode with a call to `setDataStore`. To avoid optimizations, apply the default configuration. Also, configure a code identifier for the data store. In the call to `setDataStore`, specify the object returned by `coder.mapping.api.get`, the data store name, and name-value pair arguments for the storage class and code identifier property settings.

```
setDataStore(cm, 'mode', 'StorageClass', 'Model default', 'Identifier', 'ds_mode');
```

7. Configure individual data element settings for state X with a call to `setState`. To avoid optimizations, apply the default configuration. Also, configure a code identifier for the state. In the call to `setState`, specify the object returned by `coder.mapping.api.get`, the path for the block that uses the state, and name-value pair arguments for the storage class and code identifier property settings.

```
setState(cm, 'rtwdemo_configinterface/Delay', 'StorageClass', 'Model default', ...
 'Identifier', 'dstate_X');
```

8. Add signals to the code mappings and configure them with calls to `setSignal`. To add the port handles to add the signal data to the model code mappings with calls to `get_param`. Then, specify the block handles in a call to `addSignals`. To avoid optimizations, apply your default configuration for signals. Also, configure code identifiers for the signals. In each call to `setSignal`, specify the object returned by `coder.mapping.api.get`, the path or block handle of the signal source, and name-value pair arguments for the storage class and code identifier property settings.

```
lut1D_ports = get_param('rtwdemo_configinterface/Table1', 'PortHandles');
lut2D_ports = get_param('rtwdemo_configinterface/Table2', 'PortHandles');
```

```
lut1D_outPort = lut1D_ports.Outputport;
lut2D_outPort = lut2D_ports.Outputport;
```

```
addSignal(cm, [lut1D_outPort, lut2D_outPort]);
```

```
setSignal(cm, lut1D_outPort, 'StorageClass', 'Model default', 'Identifier', 'dout_Table1');
setSignal(cm, lut2D_outPort, 'StorageClass', 'Model default', 'Identifier', 'dout_Table2');
```

## Generate and View Code

1. Generate code.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_configinterface
```

```
tf = logical
 0
```

```
Successful completion of code generation for: rtwdemo_configinterface
```

```
Build Summary
```

```
Top model targets built:
```

Model	Action	Rebuild Reason
-------	--------	----------------

```
=====
rtwdemo_configinterface Code generated Code generation information file does not exist.

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 40.945s
```

2. View the code. For example, in `rtwdemo_configinterface.c`, find where these variables are used in the step entry-point function: `input1`, `input2`, `input3`, `input4`, `output`, `mp_K1`, `ds_mode`, `dstate_X`, `dout_Table1`, and `dout_Table2`.

## Migration of Model Data Configurations to Code Mappings

Starting in R2020b, the recommended approach to configure model data for code generation is to use the Code Mappings editor or code mappings API. From one interface, you can configure default settings for categories of data, and then override those settings, as needed, for specific data elements. For parameters, you can specify whether they are inlined or tunable by default. When producing code for data, the code generator uses the code definitions that you specify to determine how to represent the data in the generated code.

When you open a model created in a release before R2020b, Simulink migrates code definitions specified in the model to the model code mappings.

If necessary, as part of the migration, Simulink configures the Embedded Coder Dictionary that the model uses. When you save the model, the code mappings are saved as part of the model.

### Effects of Migration

For data configured within a model, the migration process replaces existing storage class specifications with equivalent code mappings. Data configured for code generation within a model includes data represented by:

- Outport blocks
- Signal lines
- Block states
- Data stores
- Parameter objects in the model workspace

This table lists specific model conditions and their corresponding migration results.

Condition	Migration Results
Model is a library model or a model configured with an AUTOSAR system target file.	Simulink discards the code configuration associated with data configured within the model.
Data element is configured for code generation within the model and the data element is associated with a <code>Simulink.CoderInfo</code> object, the <code>StorageClass</code> property for that object is set to <code>Custom</code> , and the <code>CustomStorageClass</code> property is set to <code>Default</code> .	Simulink changes the storage class setting from <code>Custom (Default)</code> to <code>ExportedGlobal</code> and displays a warning.

Condition	Migration Results
<p>Model uses data objects configured for use with the <code>TypeQualifier</code> storage class property for a built-in storage class, such as <code>ExportedGlobal</code> or <code>ImportedExtern</code>. You might have set the property as:</p> <ul style="list-style-type: none"> <li>• <code>CoderInfo.TypeQualifier</code> property for data objects in a workspace or data dictionary</li> <li>• Port parameter <code>RTWStorageTypeQualifier</code></li> <li>• Block parameter <code>RTWStateStorageTypeQualifier</code> for Data Store Memory, Discrete Filter, Discrete State-Space, Discrete-Time Integrator, Discrete Transfer Fcn, Discrete Zero-Pole, and Memory blocks</li> </ul>	<p>Simulink issues a warning indicating that the property is no longer supported. Other interfaces are available for achieving the same results.</p>
<p>Model uses the <code>Simulink.CoderInfo</code> object <code>Alignment</code> property for data configured within the model.</p>	<p>Simulink issues a warning indicating that the property is no longer supported for model-specific data. You can use the property for data stored in the base workspace or a data dictionary.</p>
<p>You initialize the model workspace for the model from an external data source, such as a MAT-file, MATLAB file, or data dictionary.</p>	<p>Simulink moves code configuration for the parameter object to the code mappings for that model.</p>
<p>For an individual subsystem from which you generate code and executable programs by right-clicking the Subsystem block, you configure the storage class and storage class properties for the subsystem input and output signals outside of the subsystem.</p>	<p>Generated code does not include variables for the input and output interface data.</p>

If you perform these operations, you might need to take action:

- Use the Simulink Editor to copy a block line to another model. Simulink does not copy the code configuration information associated with the copied modeling element. For more information, see “Copy Blocks and Signal Lines Between Models” on page 32-107.
- Switch the system target file setting for a model between a GRT-based and ERT-based system target file. Simulink ignores the code configuration information for the system target file of the source version of the copied model. For more information, see “Switch Between GRT- and ERT-Based System Target Files” on page 32-108.

## Considerations Before Migrating

Before migration, consider the preparation suggested in the following sections if these conditions exist:

- Data configured within a library or AUTOSAR model
- Storage class `TypeQualifier` property
- Data alignment for code generation

- Code configuration for parameter objects initialized in the model workspace
- Code configuration for subsystem I/O interface

### Data Configured Within Library or AUTOSAR Model

If your model is a library model or a model configured with an AUTOSAR system target file, reconfigure code generation for data. For library models, reconfigure code generation for data in the context of models that use the library (see “Code Interface Configuration”). For AUTOSAR models, see “Map AUTOSAR Elements for Code Generation” (AUTOSAR Blockset).

To avoid losing the code configuration for data configured within the model, in an earlier release, load the model and create and run a MATLAB script that:

- 1 Loads the model data.
- 2 Finds data configured for code generation within the model.
- 3 Converts the representation of the data to data objects that you store in an external source, such as a MAT-file, MATLAB file, or data dictionary.
- 4 Updates the model to use the external data objects.

### Storage Class TypeQualifier Property

If your model configures data objects with built-in storage classes, such as `ExportedGlobal` and `ImportedExtern`, and uses the storage class `TypeQualifier` property, when you load the model in release R2020b or later, Simulink issues a warning. To eliminate the warning and update a model to use a supported alternative, in an earlier release, load the model and create and run a MATLAB script that:

- 1 Loads the model data objects from the model workspace, base workspace, or data dictionary.
- 2 Finds data objects with the `TypeQualifier` property set to a non-empty string value.
- 3 Changes the storage class setting to a storage class predefined with the required type qualifier (for example, storage class `Const` includes qualifier `const` in data declarations and definitions).

This example script loads model data objects from the base workspace, finds instances of data configured with the storage class `TypeQualifier` property, and changes the storage class setting to `Const`.

```
vars = who;
for idx = 1:length(vars)
 thisVar = evalin('base',vars{idx});
 if (isa(thisVar,'Simulink.Parameter') && (isequal(thisVar.CoderInfo.TypeQualifier, 'const')))
 thisVar.CoderInfo.TypeQualifier = '';
 thisVar.CoderInfo.StorageClass = 'Custom';
 thisVar.CoderInfo.CustomStorageClass = 'Const';
 end
end
```

Starting in R2020b, to include type qualifiers in the generated code, use the Code Mappings editor or code mappings API to associate data with a storage class that specifies use of the `const` or `volatile` keyword (see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75). If none of the available storage classes meets your application requirements and you are using Embedded Coder, define a new storage class by using the Embedded Coder Dictionary (see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2). Then, map the model data to the new storage class.

### Data Alignment for Code Generation

To preserve data alignment information configured for a model, represent data with data objects outside of the model. For example, open the model in a previous release of Simulink and perform the actions listed in this table.

Type of Data Element	Action
Parameter object in the model workspace	Use the Model Explorer to move the object from the model workspace to the base workspace or a data dictionary. Then, set the storage class and alignment properties of the object. Save the model.
Signal line	Open the Signal Properties dialog box, specify a name for the signal and select <b>Must resolve to signal object</b> (storage class must be Auto). Create a <code>Simulink.Signal</code> object in the base workspace or a data dictionary and set the storage class and alignment properties of the object. Save the model.
Block state	Open the Block Parameters dialog box, specify a name for the state and select <b>State must resolve to signal object</b> (storage class must be Auto). Create a <code>Simulink.Signal</code> object in the base workspace or a data dictionary and set the storage class and alignment properties. Save the model.

Alternatively, create and run a MATLAB script that:

- 1 Loads the model data.
- 2 Finds data objects that set `Simulink.CoderInfo.Alignment`.
- 3 Converts the representation of the data to data objects that you store in an external source, such as a MAT-file, MATLAB file, or data dictionary.
- 4 Sets `Simulink.CoderInfo` object property `Alignment` for the new data objects.

For example, this script checks whether `Alignment` is set for parameter, lookup table, and breakpoint data objects and captures the data objects found in MAT-file `savedData.mat`.

```
filename = 'savedData.mat';
varList = who;
tosaveVars = {};
for idx = 1 : length(varList)
 variable = eval(varList{idx});
 if ((isa(variable, 'Simulink.Parameter') || ...
 isa(variable, 'Simulink.LookupTable') || ...
 isa(variable, 'Simulink.Breakpoint')) && ...
 variable.CoderInfo.Alignment ~= -1)
 tosaveVars{end+1} = varList{idx};
 end
end
if ~isempty(tosaveVars)
 save('savedData.mat', tosaveVars{:});
end
```

Evaluate the script in the model workspace with these commands:

```
mws = get_param(bdroot, 'ModelWorkspace');
evalin(mws, 'SaveMWSParamsWithAlignment');
```

For parameter objects in the model workspace, alternatively, you can use the Model Explorer interface to move the objects from the model workspace to the base workspace or a data dictionary. Then, select the **Alignment** property for the storage class.

### Code Configuration for Parameter Objects Initialized in Model Workspace

After loading a model in release R2020b or later and initializing the model workspace for the model from an external data source, such as a MAT-file, MATLAB file, or data dictionary, Simulink:

- Saves the contents of the `Simulink.CoderInfo` object to the model code mappings.
- Removes the `Simulink.CoderInfo` object from the `Simulink.Parameter` object defined in the external data source.

Use the Code Mappings editor or the code mappings API to get and set parameter code configuration settings. See “Code Interface Configuration”.

### Code Configuration for Subsystem I/O Interface

In release R2020b or later, for individual subsystems from which you generate code and executable programs by right-clicking the Subsystem block, to include signal data in the generated subsystem code interface, configure the storage class and storage class properties for the subsystem input and output signals within the subsystem. If you configure the signals outside of the subsystem, the generated code does not include variables for the input and output interface data.

For more information, see “Generate Code and Executables for Individual Subsystems” on page 3-2.

## Copy Blocks and Signal Lines Between Models

Starting in R2020b, when you use the Simulink Editor to copy a block or signal line to another model, Simulink does not copy the code configuration information associated with the copied modeling element.

To work around this change, copy and paste the code configuration information for data elements by using the code mappings API.

- 1 Open the source and destination models for the copy operation.
- 2 Use the code mappings API to get the code mappings object for the source model.
- 3 Use the code mappings API to get code mapping information for the model element that you are copying.
- 4 If a code mappings object does not exist for the destination model, use the code mappings API to create one.
- 5 For the model element that you are copying to the destination model, use the code mappings API to set code mapping information to the same values as for the source model.
- 6 Close the source model.
- 7 Save and close the destination model.

For example:

```

:
:
:
srcMdl = 'my_src_mdl';
destMdl = 'my_dest_mdl';

```

```
open_system(srcMdl);
open_system(destMdl);

% Get data configuration from source model
srcCM = coder.mapping.api.get(srcMdl);
srcSC = getSignal(srcCM, srcPort, 'StorageClass')

% Set data configuration for destination model to setting of source model
destCM = coder.mapping.api.get(destMdl);
setSignal(destCM, destPort, 'StorageClass', srcSC);

close_system(srcMdl);
save_system(destMdl);
close_system(destMdl);
.
.
.
```

## Switch Between GRT- and ERT-Based System Target Files

Starting in R2020b, when you switch the system target file setting for a model between a GRT-based and ERT-based system target file, Simulink applies alternative code configurations for each system target file. This switch can occur if you:

- Alternate between the Simulink Coder and Embedded Coder apps.
- Change the active configuration set for a model.
- Change the setting of model configuration parameter **System target file**.

To preserve the code configuration information for data configured within the model, create and run a MATLAB script that uses the code mappings API to copy relevant code mappings.

- 1 Open the model with the source system target file and code mappings that you want to preserve.
- 2 Use the code mappings API to get the code mappings object for the model and get data mappings objects for the data elements.
- 3 Use the code mappings API to get the code mappings object for the model and set data mappings objects for the data elements.
- 4 Save and close the model.

This script fragment shows how to use the code mappings API to preserve the storage class of a signal object when switching from a GRT system target file to an ERT system target file.

```
.
.
.
mymdl = 'my_shared_mdl';

open_system(mymdl);

% Get data configuration for Simulink Coder (GRT-based) code generation
scCodeMapping = coder.mapping.api.get(model, 'SimulinkCoderC');
scStorageClass = getSignal(scCodeMapping, srcPort, 'StorageClass')

% Set data configuration for Embedded Coder (ERT-based) code generation
ecCodeMapping = coder.mapping.api.get(model, 'EmbeddedCoderC');
setSignal(ecCodeMapping, srcPort, 'StorageClass', scStorageClass)

save_system(mymdl);
```

```
close_system(myhdl);
.
.
.
```

## Workflow Changes

Starting in R2020b, configure model data elements for code generation by using the Code Mappings editor or code mappings API instead of or in addition to creating and configuring Simulink data objects. Use this workflow:

- 1 Open the **Embedded Coder** app.
- 2 In the Code Mappings editor, configure default behavior for storage representation. This capability was introduced in R2018a. See “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15..
- 3 Decide whether to override default configuration settings for individual data elements. If you choose not to override settings, skip to step 8.
- 4 Identify MATLAB variables that you want to configure individually and store the configurations in the model workspace. In the Model Explorer, convert the variables to `Simulink.Parameter` objects. The resulting data objects appear in the Code Mappings editor as model parameters.
- 5 Identify signals representing algorithm data that you want to monitor while the generated code executes and configure individually. For each signal that you identify, do one of the following:
  - For signal data that is specific to a model (not shared), add the signals to the Code Mappings editor. In the model, pause on the ellipsis above a signal line to open the action bar. Click the **Add Signal** button to add the signal to the Code Mappings editor.
  - For shared signal data, create and configure `Simulink.Signal` objects. See “C Code Generation Configuration for Model Interface Elements” on page 32-2 and “Control Signal and State Initialization in the Generated Code” on page 33-174.
- 6 Configure individual data elements. In the Code Mappings editor, click a category tab, select a data element, and set the storage class. In the Property Inspector, set storage class property values. To change the setting of model configuration parameter **Default parameter behavior** click the link indicating the behavior when the storage class is set to `Auto`. In the Model Configuration Parameters dialog box, change the parameter setting to `Tunable` or `Inline`.
- 7 To view external data objects that are stored in the base workspace or a data dictionary, in the Code Mappings editor, click the Code Mappings editor **Refresh** button.
- 8 Generate and review code.

## Dimension Preservation of Multidimensional Arrays

### Dimension Preservation in Generated Code

The code generator produces one-dimensional arrays in the C/C++ code for multidimensional model data. For example, consider matrix `matrixParam`.

```
matrixParam =
 1 2 3
 4 5 6
```

By default, MATLAB stores data in column-major format. The code generator defines matrix `matrixParam` in the generated code as:

```
/* const_params.c */
matrixParam[6] = {1, 4, 2, 5, 3, 6};
```

The code generator initializes matrix `matrixParam` in the generated code as:

```
/* model.c */
extern const real_T matrixParam[6];

for(int i = 0; i < 6; i++) {
 ... = matrixParamValue[i];
}
```

When you set the model configuration parameter **Array layout** to **Row-major**, you can preserve dimensions of multidimensional arrays in the generated code. Preserving array dimensions in generated code enhances integration with external code.

For example, in row-major array layout, the code generator preserves the array dimensions in type definition in the generated code as:

```
/* const_params.c */
const real_T matrixParam[2][3] = {{1, 2, 3}, {4, 5, 6}};
```

The code for initializing the multidimensional data is nested as:

```
/* model.c */
extern const real_T matrixParam[2][3];

for(int i = 0; i < 2; i++) {
 for (int j = 0; j < 3; j++) {
 ... = matrixParam[i][j];
 }
}
```

### Difference in Dimension Preservation Between MATLAB and C

When you define a multidimensional array in the MATLAB Command Window, MATLAB stores the array in column-major format. For example:

```
>> matrixParam.Value = [1 2 3; 4 5 6]; % Data initalized in row-major

>> matrixParam.Value % Data displayed in row-major
ans =
 1 2 3
 4 5 6
```

```
>> matrixParam.Value(:)' % Data stored in column-major
ans =
 1 4 2 5 3 6
```

Even if the data is initialized in row-major format in the MATLAB Command Window, MATLAB serializes data in memory in column-major format.

When the code generator preserves dimensions, the generated code is:

```
real_T matrixParam[2][3] = { { 1.0, 2.0, 3.0 }, { 4.0, 5.0, 6.0 } } ;
```

For 2-D arrays, the index order and data definition are consistent with what you see in the MATLAB Command Window and the generated code.

For n-D arrays, when the code generator produces row-major code and preserves array dimensions, the index order is consistent with MATLAB. The data definition of n-D arrays in the generated code is not consistent with the data displayed in the MATLAB Command Window. For example, consider that `matrixParam` is a `Simulink.Parameter`:

```
>> matrixParam.Value = reshape(1:24,[4 3 2])

>> matrixParam.Value
ans(:,:,1) =
 1 5 9
 2 6 10
 3 7 11
 4 8 12
ans(:,:,2) =
 13 17 21
 14 18 22
 15 19 23
 16 20 24

>> matrixParam.Value(:)'
ans =

Columns 1 through 10
 1 2 3 4 5 6 7 8 9 10

Columns 11 through 20
 11 12 13 14 15 16 17 18 19 20

Columns 21 through 24
 21 22 23 24
```

In row-major array layout, the code generator preserves the array dimensions during type definition in the generated code as:

```
/* const_params.c */
const real_T matrixParam[4][3][2] = { { { 1.0, 13.0 }, { 5.0, 17.0 }, { 9.0, 21.0 } },
 { { 2.0, 14.0 }, { 6.0, 18.0 }, { 10.0, 22.0 } }, { { 3.0, 15.0 }, { 7.0, 19.0
 }, { 11.0, 23.0 } }, { { 4.0, 16.0 }, { 8.0, 20.0 }, { 12.0, 24.0 } } };
```

The code for initializing the multidimensional data is nested as:

```
/* model.c */
extern const real_T matrixParam[4][3][2];

for (i = 0; i < 3; i++) {
 for (i_1 = 0; i_1 < 4; i_1++) {
 for (i_0 = 0; i_0 < 2; i_0++) {
 ... = ... + matrixParam[i_1][i][i_0];
 }
 }
}
```

# Configure Generated C Function Interface for Model Entry-Point Functions

## What Is an Entry-Point Function?

An entry point is a location in code where a transfer of program control (execution) occurs. The main function (`main()`) is the entry point to a C/C++ program and is called when the application starts executing. Calls to other functions, for example from the `main` function, provide entry points to function code. Program control is transferred to the called function. The function code executes, and when finished, returns control to the `main` or other calling function.

When producing code for a model, the code generator defines a set of entry-point functions that you can call to execute the generated code. You can call the generated functions from external code or from a version of the generated main function that you modify.

The Code Interface Report section of the code generation report lists the entry-point functions that the code generator produces for a model. For more information, see “Analyze the Generated Code Interface” on page 51-13.

## Types of Generated Entry-Point Functions

The code generator produces entry-point functions for these types of model functions.

Type of Model Function	Model Source Name	Default Generated Function Name	Description
Exported function (requires Embedded Coder)	ExportedFunction: <i>slIdentifier</i> , where <i>slIdentifier</i> is the name of the function-call Inport block in the model	<i>function-call-inport-block-name</i> or <i>signal-label</i> (if specified)	For an exported-function model, the exported function for a subsystem.
Initialize function	Initialize	<i>model_initialize</i>	Initialization code for a model. At the start of the application code, call the function <i>once</i> . Do not use this function to reset the real-time model data structure (rtM).
Partition function	Partition: <i>slIdentifier</i> , where <i>slIdentifier</i> is a partition that was created explicitly from a block in the model and shown in the Simulink® Schedule Editor (for example, P1)	<i>model_stepn</i> , where <i>n</i> uniquely identifies the function generated for one of the model sample periods	For a model partition, output and update code. Model configuration parameter <b>Single output/update function</b> is selected (the default).

Type of Model Function	Model Source Name	Default Generated Function Name	Description
Partition update function	PartitionUpdate: <i>slIdentifier</i> , where <i>slIdentifier</i> is a partition that was created explicitly from a block in the model and shown in the Simulink® Schedule Editor (for example, P1)	<i>model_outputn</i> and <i>model_updaten</i> , where <i>n</i> uniquely identifies the function generated for one of the model sample periods	For a model partition, output and update code in separate functions. Model configuration parameter <b>Single output/update function</b> is cleared.
Periodic multitasking function	Periodic: <i>slIdentifier</i> , where <i>slIdentifier</i> is an annotation that corresponds to the sample time period for a periodic or continuous rate of a multitasking model (for example, D1)	<i>model_stepn</i> , where <i>n</i> uniquely identifies the function generated for one of the model sample periods	For blocks in a rate-based model configured for multitasking, output and update code. The code generator produces a function for each sample period. Model configuration parameter <b>Single output/update function</b> is selected (the default).
Periodic multitasking update function	PeriodicUpdate: <i>slIdentifier</i> , where <i>slIdentifier</i> is an annotation that corresponds to the sample time period for a periodic or continuous rate of a multitasking model (for example, D1)	<i>model_outputn</i> and <i>model_updaten</i> , where <i>n</i> uniquely identifies the function generated for one of the model sample periods	For blocks in a rate-based model configured for multitasking, output and update code in separate functions. The code generator produces output and update functions for each sample period. Model configuration parameter <b>Single output/update function</b> is cleared.
Periodic single-tasking function	Periodic	<i>model_step</i>	For blocks in a rate-based model configured for single-tasking, output and update code. Model configuration parameter <b>Single output/update function</b> is selected (the default).

Type of Model Function	Model Source Name	Default Generated Function Name	Description
Periodic single-tasking update function	PeriodicUpdate	<i>model_output</i> and <i>model_update</i>	For blocks in a rate-based model configured for single-tasking, output and update code in separate functions. Model configuration parameter <b>Single output/update function</b> is cleared.
Reset function	Reset: <i>slIdentifier</i> , where <i>slIdentifier</i> is the name of the reset function in the model	<i>model_reset-function-name</i>	If the model includes a Reset Function block, reset code generated. To reset conditions or state, call the function from the application code.
Simulink Function	Simulink Function: <i>slIdentifier</i> , where <i>slIdentifier</i> is the name of the Simulink Function block in the model	<i>function-name</i> for a global Simulink Function block or <i>model_function-name</i> for a scoped Simulink Function block	For an exported-function model, the exported function for a Simulink Function block.
Terminate function	Terminate	<i>model_terminate</i>	Code for turning off a system. For ERT-based models, you can suppress generation of this function by clearing the model configuration parameter <b>Terminate function required</b> (set by default).

If you have Embedded Coder software, to facilitate integration of external and generated code and achieve compliance with code standards and guidelines, you can configure how the code generator produces function interfaces from a model or subsystem.

## Configure Whether Entry-Point Functions Are Reusable

By default, for top models, the code generator produces code that is not reusable or reentrant. Entry-point functions have a `void-void` interface. Code communicates with other code by directly accessing global data structures that reside in shared memory.

If your application requires reusable, multi-instance entry-point function code, you can configure the code generator to call each function (instance) with unique data. In this case, the code is reentrant.

You configure whether entry-point functions are reusable with the model configuration parameter **Code interface packaging** and related parameters. The parameter settings that you choose depend

on factors such as configuration selections for the system target file, programming language, and argument interface.

### Default Configurations for Single-Instance C Entry-Point Functions

By default, for GRT- and ERT-based system target files, the code generator produces single-instance C entry-point functions. The generated code:

- Creates an execution function without arguments (`void-void`).
- Allocates memory statically (at compile time) for model data structures.

The default model configuration parameter settings for configuring single-instance entry-point function code are:

- **Language** set to C.
- **Code interface packaging** set to `Nonreusable` function.

### Generate Reusable, Multi-Instance C Entry-Point Functions

You can configure the code generator to produce reusable entry-point functions in C for either a GRT- or ERT-based system target file. However, the function interfaces that the code generator produces by default varies. Assuming that model configuration parameter **Language** is set to C and **Code interface packaging** is set to `Reusable` function, the code generator produces this entry-point function code for each system target file scenario.

System Target File	Interface
GRT-based	<ul style="list-style-type: none"> <li>• Reusable, multi-instance C entry-point functions that are reentrant.</li> <li>• Packs values of model root-level Inport blocks and Outport blocks into the real-time model data structure. Passes that structure to the execution function as an argument by reference.</li> <li>• Allocates memory dynamically at runtime for the data of a model instance. Allocates the memory by calling a function, such as <code>malloc</code>.</li> </ul>
ERT-based	<ul style="list-style-type: none"> <li>• Reusable, multi-instance C entry-point functions that are reentrant.</li> <li>• Passes the value of each model root-level Inport block and Outport block to the execution function as a separate argument.</li> <li>• Allocates memory statically for model data structures.</li> </ul>

If you are using an ERT-based system target file and want to generate reusable, multi-instance C entry-point functions that are reentrant, consider:

- Using dynamic memory allocation to initialize model data structures. Select **Use dynamic memory allocation for model initialization**.
- Packing values of model root-level Inport blocks into a structure, packing values of root-level Outport blocks into a second structure, and passing the structures to the execution function as arguments by reference. Set **Pass root-level I/O as** to `Structure` reference.
- Packing values of model root-level Inport blocks and Outport blocks into the real-time model data structure and passing that structure to the execution function as an argument by reference. Set **Pass root-level I/O as** to `Part of model data structure`.

## Choose an Approach for Configuring Generated C Function Interfaces

To facilitate integration of external and generated code and achieve compliance with code standards and guidelines, you can use the Code Mappings editor or code mappings API to configure how the code generator produces function interfaces from a model or subsystem.

Configuration	More Information
Default naming rules for categories of functions (initialize/terminate, execution, and shared utility) across a model	“Configure Default Code Generation for Functions” on page 32-20
Name for individual entry-point functions (override the default naming rule)	“Configure Names for Individual C Entry-Point Functions” on page 32-118
Step function interface (function name, return value, and argument C type qualifiers, names, and order) for the base rate step entry-point function interactively	“Configure Name and Arguments for Individual Step Functions” on page 32-119
Function interfaces (function name, return value, and argument C type qualifiers, names, and order) for Simulink Function and Function Caller blocks interactively	“Configure Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-2

You can use software-in-the-loop (SIL) testing to verify code generated for customized entry-point functions. Create a SIL block by using your generated code. Then, integrate the SIL block into a model to verify that the generated code provides the same result as the original model or nonvirtual subsystem. For more information, see “Choose a SIL or PIL Approach” on page 82-11.

## Configure Default Code Generation Settings for a Function Category

Reduce the effort of preparing a model for C code generation by specifying default configurations for categories of functions across a model. For example, you can configure function name rules and placement of function code in memory sections. Applying default configurations can save time and reduce the risk of introducing errors in code, especially for models that have a large number functions.

The code generator produces entry-point functions for these categories of model functions:

Function Category	Description
Initialize/Terminate	Functions that initialize and turn off a system
Execution	Functions that initiate execution and resets
Shared utility	Shared utility function code

Configure default code mappings for functions by using the **Code Mappings Editor - C** or code mappings API function `setFunctionDefault`. Using these interfaces, you can associate a function category with a function customization template defined in the model's Embedded Coder Dictionary.

If your application requires that you configure the placement of entry-point functions in memory, for example, to optimize the generated code for specific hardware, you can apply a default memory section to a category of functions across a model. In the Code Mappings editor, map a function category to a function customization template that is defined to use a specific memory section. See .

If a function customization template does not exist, you can create one by using the Embedded Coder Dictionary (see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2).

For an example of how to configure default configurations for function categories, see “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15.

## Configure Names for Individual C Entry-Point Functions

For your generated C code to adhere to code standards and guidelines or to more easily integrate that code with external code, you can configure the name of an individual entry-point function. For example, you can name the initialize function generated for a model `myInitFunc`.

If your model meets at least one of these criteria, consider configuring the names of functions individually:

- Uses multiple functions that have unique naming requirements.
- Uses few functions.
- Has a default configuration for a function category and you need to override the configuration for a specific function.

Configure function names for individual step functions by using the Code Mappings editor or code mappings API function `setFunction`. Using these interfaces, you can associate a function with a function customization template that is defined in the model's Embedded Coder Dictionary and specify a function name.

This example shows how to change the name of the `initialize` function for model `rtwdemo_fcnprotoctrl`.

- 1 Open and save a copy of model `rtwdemo_fcnprotoctrl` in a writable location.
- 2 Open the **Embedded Coder** app.
- 3 On the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
- 4 In the Code Mappings editor, **Functions** tab, change the function name by using one of these methods:
  - In the **Function Name** column, enter a name for the function.
  - In the **Function Preview** column, click the function prototype hyperlink to open a configuration dialog box. In the **C Initialize Function Name** field, enter the function name. Click **Apply** to verify the change in the **C function prototype** field or click **OK** to exit the dialog box and view the function name in the **Function Preview** column of the Code Mappings editor.

For this example, change the name of the `initialize` function to `fcnprotoctrl_init`.

- 5 Save the model.
- 6 Generate code.
- 7 Verify the changes in the generated code. In the **Code** view, find instances of function name `fcnprotoctrl_init`. The function name appears in generated files `rtwdemo_fcnprotoctrl.h` and `rtwdemo_fcnprotoctrl.c`.
  - In `rtwdemo_fcnprotoctrl.h`:

```
extern void fcnprotoctrl_init(void);
```

- In `rtwdemo_fcnprotoctrl.c`:

```
void fcnprotoctrl_init(void)
{
 ...
}
```

## Configure Name and Arguments for Individual Step Functions

For your generated C code to adhere to code standards and guidelines or to more easily integrate the code with external code, you can configure the name and arguments of individual step functions generated for Simulink periodic functions. You can customize these aspects of a step function:

- Function name
- Argument names
- Order of the arguments
- Return value and argument data qualifiers
- Buffering optimizations for arguments

If your model meets at least one of these criteria, consider configuring the name and arguments of a step function individually:

- Is a periodic, single-tasking model for which the code generator produces one step function.
- Has a default configuration for **Execution** function category and you need to override the configuration for a specific step function.

Configure code mappings for individual step functions by using the Code Mappings editor or code mappings API function `setFunction`. Using these interfaces, you can associate a function with a function customization template that is defined in the model's Embedded Coder Dictionary and completely customize the step function prototype.

This example shows how to customize the step function name and arguments for a rate-based, single-tasking model.

### Open the Configuration Dialog Box

1. Open and save a copy of model `rtwdemo_fcnprotoctrl` to a writable location.
2. Open the **Embedded Coder** app.
3. On the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
4. In the Code Mappings editor, click the **Functions** tab.
5. For the step function row, in the **Function Preview** column, click the prototype hyperlink to open the Configure C Step Function Interface dialog box.

In the Configure C Step Function Interface dialog box, the **C function prototype** field displays a preview of changes that you make to the function prototype.

For models configured to generate multi-instance code, see “Generate Reentrant Code from Top Models” on page 7-18.

### Customize the Function Name

1. In the Configure C Step Function Interface dialog box, set **C Step Function Name** to `fcnpctroctrl_run`. The function preview is updated to reflect the new function name.

2. Click **Apply**, close the dialog box, and save the model.

3. Generate code and verify the name change.

- Click the **Code** tab. In the **Code** view file list, select file `rtwdemo_fcnpctroctrl.h`. In the **Search** field, verify that the list of code elements includes function name `fcnpctroctrl_run`. To view the declaration, select the function name.

The declaration is highlighted in the code:

```
/* Model entry point functions */
extern void rtwdemo_fcnprotoctrl_init_custom(void);
extern void fcnprotoctrl_run(void);
```

- Verify the name change in file `rtwdemo_fcnprotoctrl.c`. To view the source code (definition), in the **Search** field, select `fcnprotoctrl_run`.

```
/* Model step function */
void fcnprotoctrl_run(void)
{
```

For more examples, see “Configure Names for Individual C Entry-Point Functions” on page 32-118.

## Customize Function Arguments

### Configure Global Data Structures

By default, a top or referenced model uses a `void-void` step function to pass data. This type of function enables generated code to communicate with external code by accessing global data stored as data structures that reside in shared memory.

To configure a model to have a `void-void` step function, open the Configure C Step Function Interface dialog box and clear the **Configure arguments for Step function prototype** check box. Verify the change in the **C function prototype** preview.

### Configure Arguments

Rate-based model step functions can use arguments to pass data. You can customize these argument settings:

- Return value
- Type qualifiers
- Names

- Order

**Example**

1. Open the Configure C Step Function Interface dialog box. In the Code Mappings editor, click the **Functions** tab. Then, click the function preview for the step function.
2. In the Configure C Step Function Interface dialog box, select **Configure arguments for Step function prototype**.
3. Click **Get default**. The dialog box expands to show a field for configuring the function return value and a table that lists input and output arguments with default settings.

Configure the generated C function interface, including function name and arguments.

C function prototype: void fcnprotoctrl\_run([\* self], arg\_In1, \* arg\_In2, \* arg\_In3, arg\_In4, \* arg\_Out1, \* arg\_Out2)

C Step Function Name:

Configure arguments for Step function prototype

(\* invokes update diagram)

C return argument

Port Name	Port Type	C Type Qualifier	C Identifier Name
In1	Inport	Value	arg_In1
In2	Inport	Pointer	arg_In2
In3	Inport	Pointer	arg_In3
In4	Inport	Value	arg_In4
Out1	Output	Pointer	arg_Out1
Out2	Output	Pointer	arg_Out2

Drag and drop rows to specify argument order

(\* invokes update diagram)

Press Validate button to get validation results.

4. Customize the return value of the step function. Set **C return argument** to either void or one of the output arguments. For this example, select void.

5. For each argument, specify a **C Type Qualifier**.

#### Type Qualifiers:

- **Value:** Value, for example, `arg`
- **Const:** Value with the `const` qualifier, for example, `const arg`
- **Pointer to const:** Value with `const` qualifier and referenced by pointer, for example, `const *arg`
- **Pointer:** Reference by pointer, for example, `*arg`
- **Const pointer to const:** Value with `const` qualifier, reference by pointer, and the pointer itself, for example, `const *const arg`

### Models that include a referenced model

- For a referenced model, the type qualifier for a root input argument in the step function interface is set to `Auto`. The code generator uses the interface specification by generating a type cast that discards the `const` qualifier from the source signal.
- For the parent of the reference model, the type qualifier for the source signal is set to a value other than `Auto`. To override this behavior, add a `const` type qualifier to the referenced model.

For this example, make no changes to the C type qualifier.

6. Customize the argument names by editing values in the **C Identifier Name** column.

For this example, change the names of the arguments by removing the underscores, for example, change `arg_In1` to `argIn1`.

7. Customize the argument order by dragging table rows to new positions.

For this example, move `Out1` to the first position. Move `Out 2` to the third position.

8. Validate, apply your changes, close the dialog box, and save the model.

9. Generate code and verify the changes in the **Code** view.

- Verify your changes in file `rtwdemo_fcncnprotoctrl.h` by checking that the **Search** field includes function `fcncnprotoctrl_run`. To view the function declaration, select the function name.

```
/* Customized model step function */
extern void fcncnprotoctrl_run(boolean_T *argOut1, real_T argIn1, BusObject
 *argOut2, BusObject *argIn2, BusObject *argIn3, uint8_T argIn4);
```

- Verify your changes in file `rtwdemo_fcncnprotoctrl.c`. To view the definition for the function, select function name `fcncnprotoctrl_run`.

```
/* Model step function */
void fcncnprotoctrl_run(boolean_T *argOut1, real_T argIn1, BusObject *argOut2,
 BusObject *argIn2, BusObject *argIn3, uint8_T argIn4)
{
```

### Prototype Different From Preview

In the Configure C Step Function Interface dialog box, the function prototype preview for a referenced model can show fewer arguments than the function prototype in the generated code.

For example, consider a model named `mdlref_counter` with an inport (`arg_input`), an outport (`arg_output`), and a saturation block with limits that have workspace parameter argument names `lower_saturation_limit` and `upper_saturation_limit`. The Configure C Step Function Interface dialog box shows a function prototype preview as:

```
mdlref_counter_custom(arg_input, arg_output)
```

In the generated code, the prototype includes the parameter arguments:

```
mdlref_counter_custom(real_T arg_input, real_T arg_output, real_T
 rtp_lower_saturation_limit, real_T rtp_upper_saturation_limit)
```

### Optimize Buffering for Arguments

You can optimize the buffering required for I/O arguments in the step function for a model. If you adhere to these requirements when configuring an inport and outport pair, the code generator merges the corresponding arguments and reuses the associated buffer.

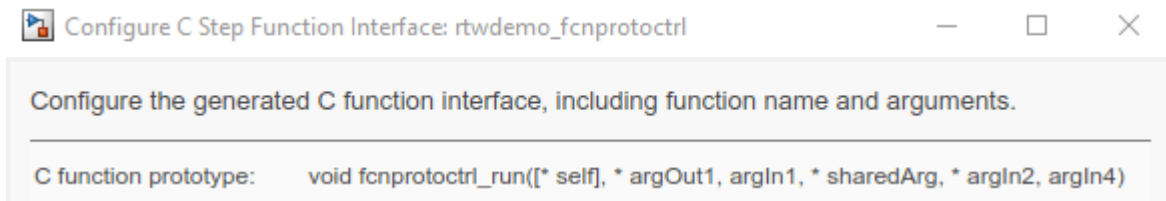

- The Inport and Outport blocks must have the same properties, including data type, dimension, and sample rate.
- The sample rate of the Inport and Outport blocks must be the same as the base rate of the model.
- A conditionally executed subsystem cannot drive the Outport block.
- A single, nonvirtual block output must drive the Outport block. For example, a Mux block, which merges multiple buffers, cannot drive the Outport block.
- In the Configure C Step Function Interface dialog box, you must configure the Inport and Outport with the same C type qualifier and identifier name.

This example shows how to merge arguments for ports `In3` and `Out2` for example model `rtwdemo_fcnpctctrl`.

1. Open the Configure C Step Function Interface dialog box for the model `rtwdemo_fcnpctctrl`.
2. Open the display for the arguments by selecting **Configure arguments for Step function prototype**.
3. For ports `In3` and `Out2`, set **C Type Qualifier** to `Pointer` and **C Identifier Name** to `sharedArg`.

Port Name	Port Type	C Type Qualifier	C Identifier Name
Out1	Outport	Pointer	argOut1
In1	Inport	Value	argIn1
In3	Inport	Pointer	sharedArg
Out2	Outport	Pointer	sharedArg
In2	Inport	Pointer	argIn2
In4	Inport	Value	argIn4

4. Verify that the preview shows the merged argument for `argIn3` and `argOut2`.

5. Validate, apply your changes, close the dialog box, and save the model.
6. Generate and view the code. In the **Code** view, search for the `fcnprotoctrl_run` function and check the function interface. For this example, the shared argument appears in read code for the Inport block and write code for the Outport block.

```

/* Model step function */
void fcnprotctrl_run(boolean_T *argOut1, real_T argIn1, BusObject *sharedArg,
 BusObject *argIn2, uint8_T argIn4)
{
 /* Output: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant1'
 * Constant: '<Root>/Constant2'
 * Inport: '<Root>/In1'
 * Logic: '<Root>/LogOp'
 * RelationalOperator: '<Root>/RelOp1'
 * RelationalOperator: '<Root>/RelOp2'
 * UnitDelay: '<Root>/Unit Delay'
 */
 *argOut1 = ((rtDWork.UnitDelay_DSTATE > 10.0) || (argIn1 < 2.0));

 /* Switch: '<Root>/Switch' incorporates:
 * Inport: '<Root>/In2'
 * Inport: '<Root>/In4'
 */
 if (argIn4 != 0) {
 S1 = *argIn2;
 } else {
 S1 = *sharedArg;
 }

 /* End of Switch: '<Root>/Switch' */

 /* BusCreator: '<Root>/BusConversion_InsertedFor_Out2_at_inport_0' */
 *sharedArg = S1;

 /* Update for UnitDelay: '<Root>/Unit Delay' incorporates:
 * Inport: '<Root>/In1'
 */
 rtDWork.UnitDelay_DSTATE = argIn1;
}

```

## Configure Code Generation Settings for C Entry-Point Functions Programmatically

To automate configuration of model functions for C code generation, use the programming interface for code mappings. For example, when creating custom block libraries or part of an application test environment, use the programming interface to automate function configuration.

Typical uses of these functions include:

- Create a function interface.
- Modify an existing function interface.
- Create a function interface, starting with default configuration information from a model.
- Reset the model function interface to the default ERT function configuration.

For an example of how to configure code generation settings for C entry-point functions programmatically, see “Configure Default Data and Function Code Generation Programmatically” on page 32-24. That example shows how to configure default settings for function categories and individual functions.

## How to Interface with Generated Entry-Point Functions

- 1 After generating code for a model, use the **Code** view to review the generated entry-point functions and, if applicable, variables representing external input and output ports.
- 2 Add `#include` statements to your external code that include the generated header files that declare the model entry-point functions.
- 3 Add an `#include` statement that includes the generated file `rtwtypes.h`. This file provides type definitions, `#define` statements, and enumerations.
- 4 Initialize target-specific data structures and hardware, such as ADCs or DACs.
- 5 If applicable, initialize data for each instance of a reusable model.
- 6 If applicable, write input data to generated variables that represent model Inport blocks.
- 7 Call the generated entry-point functions or set up use of the `rt_OneStep` function.
- 8 If applicable, read data from generated variables that represent model Outport blocks.

For more information, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 68-2.

## C Function Interface Customization Limitations

These limitations apply to customizations for generated C function interfaces:

- You must select the model configuration parameter **Single output/update function**.
- Multirate models are supported, but you must configure the models for single tasking.
- You must configure root-level inports and outports to use the `Default` storage class.
- If you choose to customize a function interface, you must provide your own custom `main` program. You cannot configure the function interface with the static `rt_main.c` that MathWorks provides. Specifying a function interface configuration other than the default creates a mismatch between the generated code and the default static `rt_main.c`.
- The code generator removes the data structure for the root inports of the model unless a subsystem implemented by a nonreusable function uses the value of one or more of the inports.
- The code generator removes the data structure for the root outports of the model except when you enable MAT-file logging or if the sample time of one or more of the outports is not the fundamental base rate (including a constant rate).
- If you copy a subsystem block to create a block in a new model or the same model, the function interface information from the original subsystem block is not copied to the new subsystem block.

- If you have Stateflow, for a Stateflow chart that uses a model root inport value or that calls a subsystem that uses a model root inport value, do one of the following to generate code:
  - Clear the **Execute (enter) Chart At Initialization** check box in the Stateflow chart.
  - Make the Stateflow function a nonreusable function.
  - Insert a Simulink Signal Conversion block immediately after the root inport. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- If a model root inport value connects to a Simscape conversion block, insert a Simulink Signal Conversion block between the root inport and the Simscape conversion block. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- When building a referenced model that is configured with a function interface, do not use virtual buses as inputs or outputs to the referenced model. Use nonvirtual buses instead.
- If the C function interface is not the default, the value is ignored for the model configuration parameter **Pass fixed-size scalar root inputs by value for code generation**. For more information, see “Pass fixed-size scalar root inputs by value for code generation”.

- “C Code Generation Configuration for Model Interface Elements” on page 32-2
- “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15

## Configure Multi-Instance Code Generation

By default, for top models, the code generator produces code that is not reentrant. Entry-point functions have a `void-void` interface. Code communicates with other code by sharing access to global data structures that reside in shared memory.

For applications that can benefit from code reuse and require that each use or instance of the code maintains its own unique data, configure a model such that the code generator produces reentrant, multi-instantiable code. Multiple programs can use reentrant code simultaneously. When you configure a model for reentrancy, the execution (step) entry-point function uses root-level input and output arguments instead of global data structures.

### Configure a Top Model for Multi-Instance Code Generation

Set model configuration parameter **Code interface packaging** to `Reusable` function.

Apply additional diagnostic and code generation control by setting these model configuration parameters:

- To select the severity level for diagnostic messages that the code generator displays when a model does not meet requirements for multi-instance code, set parameter **Multi-instance code error diagnostic** to `None`, `Warning`, or `Error`.
- To control how the generated code passes root-level model input and output to the reusable execution (step) function (requires Embedded Coder), set parameter **Pass root-level I/O as** to `Individual arguments`, `Structure reference`, or `Part of model data structure`.
- To include a function in the generated file `model.c` that uses `malloc` to dynamically allocate memory for model data structures (requires Embedded Coder), set parameter **Use dynamic memory allocation for model initialization** to `On`.

For more information, see “Generate Reentrant Code from Top Models” on page 7-18.

### Configure a Referenced Model for Multi-Instance Code Generation

Set model configuration parameter **Total number of instances allowed per top model** to `Multiple`. With this parameter setting, a model can be referenced more than once in a model hierarchy, if it contains not constructs that preclude multiple references. An error occurs if the model cannot be referenced multiple times, even if only one reference exists.

For more information, see “Generate Reentrant Code from Simulink Function Blocks” on page 7-23.

## Configure Data Interfaces

### Configure Default Code Generation for Data

- 1 Click the **Code Mappings - C** tab.
- 2 In the Code Mappings editor, update the model to include the latest model data by clicking the update model data button.
- 3 Click the **Data Defaults** tab.
- 4 In the **Data Defaults** table, select a row for a model data element category.
- 5 In the **Storage Class** column, select a storage class. If your model is linked to a Simulink data dictionary that includes a shared coder dictionary for which defaults are set up, you can select **Dictionary Default**. For help on choosing a storage class, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75. For information on using dictionary defaults, see “Configure Model Elements for Code Generation with Definitions Stored in Shared Data Dictionary” on page 32-22. If you need to define a new storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2.
- 6 In the Property Inspector, add values for unspecified properties. For example, if you select storage class **ImportFromFile**, specify a value for the property **HeaderFile**.
- 7 Save the model.

### Override Default Data Interface for Individual Data Elements

- 1 Click the **Model Data Editor** tab.
- 2 Update the model to include the latest model data by clicking the update model data button.
- 3 In the Model Data Editor, with the view set to **Code**, click the tab for the type of data element that you want to configure.
- 4 In the filter text box, enter a string that will help you find the row for that data element.
- 5 In the **Storage Class** column, select a storage class. For example, you might want to change the storage class setting for Model Workspace parameters to **Model default**.
- 6 In the table or Property Inspector, set values for available properties.
- 7 Save the model.

## Configure Entry-Point Function Interfaces

### Define Function Customization Templates

Unless someone has defined function customization templates for a model, the Code Mappings editor presents `Default` as the only template option. To define a template, use the Embedded Coder Dictionary.

- 1 Open the Embedded Coder Dictionary. In the **C Code** tab, select **Settings > Embedded Coder Dictionary**.
- 2 In the Embedded Coder Dictionary, click the **Function Customization Templates** tab.
- 3 Click **Add**.
- 4 In the new row of the table, name the template.
- 5 As required by your function interface:
  - In the **Function Name** column, specify a default naming rule for entry-point functions.
  - In the **Memory Section** column, specify the name of an available memory section.

The preview shows the results of your changes and additions.

- 6 Close the dictionary.

### Configure Default Code Generation for Entry-Point Functions

- 1 Define a function customization template in the Embedded Coder Dictionary.
- 2 In the Code Mappings editor, click the **Function Defaults** tab.
- 3 In the **Function Defaults** table, select a row for a model function category.
- 4 In the **Function Customization Template** column, select a customization template. If your model is linked to a Simulink data dictionary that includes a shared coder dictionary for which defaults are set up, you can select `Dictionary Default`. For information on using dictionary defaults, see “Configure Model Elements for Code Generation with Definitions Stored in Shared Data Dictionary” on page 32-22. If you need to define a new customization template, for more information, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2.
- 5 Save the model.

### Override Default Code Generation for Entry-Point Functions

- 1 In the Code Mappings editor, click the **Functions** tab.
- 2 In the **Source** column, select an entry-point function for which you want to override the default interface configuration.
- 3 As required by your function interface:
  - Select a function customization template.
  - Specify a unique function name.
- 4 If your entry-point function is an execution function, you can customize the interface arguments. By default, the code generator produces a `void-void` interface (without arguments) and

assumes variables are global. To configure the interface to pass arguments, in the **Function Preview** column, click the prototype hyperlink to open a configuration dialog box.

- 5** In the function interface configuration dialog box, select **Configure arguments for Step function prototype**.
- 6** Click **Get Default**. A table shows a list of current argument settings.
- 7** In the table, you can change C type qualifiers, identifier names, and argument order as required by the function interface. Change the order of the arguments by dragging them to locations in the list. As you make changes, use the prototype preview near the top of the dialog box to verify the results.
- 8** Validate your changes and save the model.

## Configure Internal Data

### Configure Default Representation of Internal Data

- 1 In the Code Mapping Editor, click the **Data Defaults** tab.
- 2 Select the row representing the category of internal data that you want to configure.
- 3 In the **Storage Class** column, select a storage class. If your model is linked to a Simulink data dictionary that includes a shared coder dictionary for which defaults are set up, you can select **Dictionary Default**. For help on choosing a storage class, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75. For information on using dictionary defaults, see “Configure Model Elements for Code Generation with Definitions Stored in Shared Data Dictionary” on page 32-22. If you need to define a new storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2.
- 4 In the Property Inspector, add values for unspecified properties. For example, if you select storage class **Const**, specify values for properties **HeaderFile** and **DefinitionFile**.
- 5 Save the model.

### Override Default Representation for Individual Internal Data Elements

- 1 Click the **Model Data Editor** tab.
- 2 In the Model Data Editor, with the view set to **Code**, click the tab for the type of data element that you want to configure.
- 3 Update the model to include the latest model data by clicking the update model data button.
- 4 In the filter text box, enter a string that will help you find the row for the data element.
- 5 In the **Storage Class** column, select a storage class. For example, you might want to change the storage class setting for Model Workspace parameters to **Model default**.
- 6 In the table or Property Inspector, set values for available properties.
- 7 Save the model.

## Configure Subsystem Function Packaging and Interface

- 1 In the Simulink Editor, select the subsystem that you want to configure.
- 2 In the Property Inspector, expand **Code Generation**.
- 3 Set **Function packaging** to `Nonresuable function` or `Reusable function`.
- 4 Configure the function name. Set **Function name options** to `Use subsystem name` or `User specified`. If you select `User specified`, specify a value for the **Function name** property.
- 5 Configure the file name for the function code. Set **File name options** to `Use subsystem name`, `Use function name`, or `User specified`. If you select `User specified`, specify a value for the **File name (no extension)** property.
- 6 If you set **Function packaging** to `Nonresuable function`, configure the function interface. Set **Function interface** to `void-void`, `Allow arguments (Optimized)`, or `Allow arguments (Match graphical interface)`.
- 7 If you want the code generator to declare subsystem data independently from parent model data, select property **Function with separate data**.
- 8 Save the model.

For more information, see “Generate Subsystem Code as Separate Function and Files” on page 3-7.

## Preserve Variables in Generated Code

As you iteratively develop a model, you capture the values of signals and states that model execution generates. You also tune parameter values during execution to observe results on the signals and states. You can then base your design decisions upon analysis of these outputs. To access signal, state, and parameter data in a rapid prototyping environment, you can configure the generated code to store the data in addressable memory.

Depending on the system target file that you use (such as `grt.tlc`), by default, optimization settings can make the generated code more efficient by:

- Eliminating unnecessary global and local storage for signals and some states.

However, the optimizations do not eliminate storage for root-level Inport and Outport blocks, which represent the primary inputs and outputs of a system. To access this data, you do not need to take optimizations into consideration.

- Inlining the numeric values of block parameters. The code does not store the parameters in memory, so you cannot interact with the parameters during code execution.

To generate code that instead allocates addressable memory for this data, you can disable the optimizations, or override the optimizations by specifying code generation settings for individual data items.

## Access Signal, State, and Parameter Data During Execution

As you iteratively develop a model, you capture output signal and state data that model execution generates. You also tune parameter values during execution to observe results on the outputs. You can then base your design decisions upon analysis of these outputs. To access this signal, state, and parameter data in a rapid prototyping environment, you can configure the generated code to store the data in addressable memory.

By default, optimization settings make the generated code more efficient by eliminating unnecessary signal storage and inlining the numeric values of block parameters. To generate code that instead allocates addressable memory for this data, you can disable the optimizations or specify code generation settings for individual data items.

### Explore Example Model

Run a script that prepares the model `rtwdemo_configrpinterface` for this example.

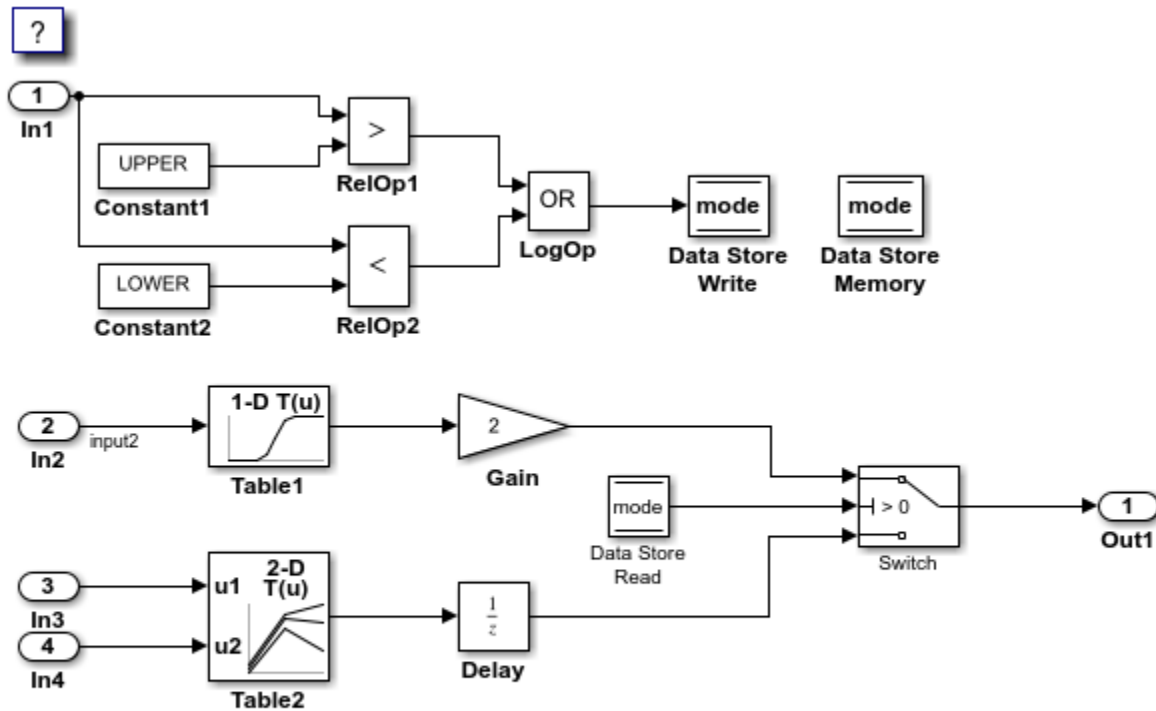

```
prepare_rtwdemo_configrpinterface
```

This data is configured for code generation:

- Parameters `UPPER`, `LOWER`, `K1`, `Table1`, and `Table2`
- Signals `In1`, `In2`, `In3`, `In4`, and `Out1`
- States `X` (delay) and `mode` (data store memory write)

Open the example model, `rtwdemo_configrpinterface`.

```
rtwdemo_configrpinterface
```

Copyright 1994-2020 The MathWorks, Inc.

The model loads numeric MATLAB variables into the model workspace. The workspace variables set some block parameters in the model. However, the Gain block in the model uses the literal value 2.

### Disable Optimizations

1. In the model, clear the model configuration parameter **Signal storage reuse**. When you clear this optimization and other optimizations such as **Eliminate superfluous local variables (expression folding)**, the generated code allocates memory for signal lines. Clearing **Signal storage reuse** disables most of the other optimizations.

```
set_param('rtwdemo_configrpinterface', 'OptimizeBlockIOStorage', 'off')
```

2. Set the model configuration parameter **Default parameter behavior** to Tunable. When set to Tunable, this configuration parameter causes the generated code to allocate memory for block parameters and workspace variables.

```
set_param('rtwdemo_configrpinterface', 'DefaultParameterBehavior', 'Tunable')
```

3. Generate code.

```
slbuild('rtwdemo_configrpinterface')
```

```
Starting build procedure for: rtwdemo_configrpinterface
Successful completion of build procedure for: rtwdemo_configrpinterface
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_configrpinterface	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 1m 21.427s

4. In the code generation report, view the file `rtwdemo_configrpinterface.h`. This header file defines a structure type that contains signal data. The structure contains fields that each represent a signal line in the model. For example, the output signal of the Gain block, whose name is `Gain`, appears as the field `Gain`.

```
file = fullfile('rtwdemo_configrpinterface_grt_rtw','rtwdemo_configrpinterface.h');
rtwdemodbtype(file,'/* Block signals (default storage) */',...
 'B_rtwdemo_configrpinterface_T;',1,1)
```

```
/* Block signals (default storage) */
typedef struct {
 real_T Delay; /* '<Root>/Delay' */
 real_T Table2; /* '<Root>/Table2' */
 real_T Table1; /* '<Root>/Table1' */
 real_T Gain; /* '<Root>/Gain' */
 boolean_T RelOp1; /* '<Root>/RelOp1' */
 boolean_T RelOp2; /* '<Root>/RelOp2' */
 boolean_T LogOp; /* '<Root>/LogOp' */
 boolean_T DataStoreRead; /* '<Root>/Data Store Read' */
} B_rtwdemo_configrpinterface_T;
```

The file defines a structure type that contains block parameter data. For example, the **Gain** parameter of the Gain block appears as the field `Gain_Gain`. The other fields of the structure represent other block parameters and workspace variables from the model, including initial conditions for signals and states.

```
rtwdemodbtype(file,'/* Parameters (default storage) */',...
 '/* Real-time Model Data Structure */',1,0)
```

```
/* Parameters (default storage) */
struct P_rtwdemo_configrpinterface_T_ {
 Table1_Type Table1; /* Variable: Table1
 * Referenced by: '<Root>/Table1'
 */
 Table2_Type Table2; /* Variable: Table2
 * Referenced by: '<Root>/Table2'
 */
 real_T LOWER; /* Variable: LOWER
 * Referenced by: '<Root>/Constant2'
 */
 real_T UPPER; /* Variable: UPPER
 * Referenced by: '<Root>/Constant1'
 */
 real_T Gain_Gain; /* Expression: 2
 * Referenced by: '<Root>/Gain'
 */
};
```

```

real_T Delay_InitialCondition; /* Expression: 0
 * Referenced by: '<Root>/Delay'
 */
uint32_T Table2_maxIndex[2]; /* Computed Parameter: Table2_maxIndex
 * Referenced by: '<Root>/Table2'
 */
boolean_T DataStoreMemory_InitialValue;
 /* Computed Parameter: DataStoreMemory_InitialValue
 * Referenced by: '<Root>/Data Store Memory'
 */
};

```

5. View the file `rtwdemo_configrpinterface_data.c`. This source file allocates global memory for a parameter structure and initializes the field values based on the parameter values in the model.

6. View the source file `rtwdemo_configrpinterface.c`. The code allocates global memory for a structure variable that contains signal data.

```

file = fullfile('rtwdemo_configrpinterface_grt_rtw','rtwdemo_configrpinterface.c');
rtwdemodbtype(file, /* Block signals (default storage) */,...
 'B_rtwdemo_configrpinterface_T rtwdemo_configrpinterface_B;',1,1)

/* Block signals (default storage) */
B_rtwdemo_configrpinterface_T rtwdemo_configrpinterface_B;

```

The code algorithm in the model `step` function calculates the signal values. It then assigns these values to the fields of the signal structure. To perform the calculations, the algorithm uses the parameter values from the fields of the parameter structure.

### Exclude Data Items from Optimizations

When you want to select code generation optimizations such as **Signal storage reuse**, you can preserve individual data items from the optimizations. The generated code then allocates addressable memory for the items.

Select the optimizations that you previously cleared.

```

set_param('rtwdemo_configrpinterface','OptimizeBlockIOStorage','on')
set_param('rtwdemo_configrpinterface','LocalBlockOutputs','on')
set_param('rtwdemo_configrpinterface','DefaultParameterBehavior','Inlined')

```

1. In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
2. In the Code Mappings editor, inspect the **Signals/States** tab.
3. In the model, select the output signal of the Gain block.
4. Pause on the ellipsis that appears above or below the signal line to open the action bar. Click the **Add Signal** button. In the Code Mappings editor, the **Signals** node expands and lists the signal that you added.

```

cm = coder.mapping.api.get('rtwdemo_configrpinterface');
gain_ports = get_param('rtwdemo_configrpinterface/Gain','PortHandles');
gain_outPort = gain_ports.Outputport;
addSignal(cm,gain_outPort);

```

5. Apply the default storage class for Outports to the signal by setting **Storage Class** to Model default.

```
setSignal(cm,gain_outPort,'StorageClass','Model default','Identifier','Gain');
```

6. In the model, select the Gain block.

7. In the Property Inspector, set the gain value to the model workspace parameter object K1.

8. In the Code Mappings editor, on the **Parameters** tab, expand **Model Parameters**.

9. Select parameter K1. Apply a storage class other than Auto by setting **Storage class**. For example, use the storage class Model default. By using Model default, K1 acquires the default storage class specified for model parameters, Default, and appears as a field of the global parameters structure.

```
set_param('rtwdemo_configrpinterface/Gain','Gain','K1');
setModelParameter(cm,'K1','StorageClass','Model default');
```

10. Generate code.

```
slbuild('rtwdemo_configrpinterface')

Starting build procedure for: rtwdemo_configrpinterface
Successful completion of build procedure for: rtwdemo_configrpinterface

Build Summary

Top model targets built:

Model Action Rebuild Reason
=====
rtwdemo_configrpinterface Code generated and compiled Generated code was out of date.

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 38.219s
```

11. In the code generation report, view the file `rtwdemo_configrpinterface.h`. The structure that contains signal data now defines only one field, Gain, which represents the test-pointed output of the Gain block.

```
file = fullfile('rtwdemo_configrpinterface_grt_rtw','rtwdemo_configrpinterface.h');
rtwdemodbtype(file,'/* Block signals (default storage) */',...
 'B_rtwdemo_configrpinterface_T;',1,1)
```

```
/* Block signals (default storage) */
typedef struct {
 real_T Gain; /* '<Root>/Gain' */
} B_rtwdemo_configrpinterface_T;
```

The structure that contains block parameter data defines one field, K1, which represents the parameter object K1.

```
rtwdemodbtype(file,'/* Parameters (default storage) */',...
 '/* Real-time Model Data Structure */',1,0)
```

```
/* Parameters (default storage) */
```

```

struct P_rtwdemo_configrpininterface_T_ {
 int8_T K1; /* Variable: K1
 * Referenced by: '<Root>/Gain'
 */
};

```

### Access Data Through Generated Interfaces

You can configure the generated code to contain extra code and files so that you can access model data through standardized interfaces. For example, use the C API to log signal data and tune parameters during execution.

Copy this custom source code into a file named `ex_myHandCode.c` in your current folder.

```

#include "ex_myHandHdr.h"

#define paramIdx 0 /* Index of the target parameter,
determined by inspecting the array of structures generated by the C API. */
#define sigIdx 0 /* Index of the target signal,
determined by inspecting the array of structures generated by the C API. */

void tuneFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr)
{
 /* Take action with the parameter value only at
 the beginning of simulation and at the 5-second mark. */
 if (*tPtr == 0 || *tPtr == 5) {

 /* Local variables to store information extracted from
 the model mapping information (mmi). */
 void** dataAddrMap;
 const rtwCAPI_DataTypeMap *dataTypeMap;
 const rtwCAPI_ModelParameters *params;
 int_T addrIdx;
 uint16_T dTypeIdx;
 uint8_T slDataType;

 /* Use built-in C API macros to extract information. */
 dataAddrMap = rtwCAPI_GetDataAddressMap(mmi);
 dataTypeMap = rtwCAPI_GetDataTypeMap(mmi);
 params = rtwCAPI_GetModelParameters(mmi);
 addrIdx = rtwCAPI_GetModelParameterAddrIdx(params,paramIdx);
 dTypeIdx = rtwCAPI_GetModelParameterDataTypeIdx(params,paramIdx);
 slDataType = rtwCAPI_GetDataTypeSLId(dataTypeMap, dTypeIdx);

 /* Handle data types 'double' and 'int8'. */
 switch (slDataType) {

 case SS_DOUBLE: {
 real_T* dataAddress;
 dataAddress = dataAddrMap[addrIdx];
 /* At the 5-second mark, increment the parameter value by 1. */
 if (*tPtr == 5) {
 (*dataAddress)++;
 }
 printf("Parameter value is %f\n", *dataAddress);
 break;
 }
 }
 }
}

```

```

 case SS_INT8: {
 int8_T* dataAddress;
 dataAddress = dataAddrMap[addrIdx];
 if (*tPtr == 5) {
 (*dataAddress)++;
 }
 printf("Parameter value is %i\n", *dataAddress);
 break;
 }
 }
}

void logFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr)
{
 /* Take action with the signal value only when
 the simulation time is an integer value. */
 if (*tPtr-(int_T)*tPtr == 0) {

 /* Local variables to store information extracted from
 the model mapping information (mmi). */
 void** dataAddrMap;
 const rtwCAPI_DataTypeMap *dataTypeMap;
 const rtwCAPI_Signals *sigs;
 int_T addrIdx;
 uint16_T dTypeIdx;
 uint8_T slDataType;

 /* Use built-in C API macros to extract information. */
 dataAddrMap = rtwCAPI_GetDataAddressMap(mmi);
 dataTypeMap = rtwCAPI_GetDataTypeMap(mmi);
 sigs = rtwCAPI_GetSignals(mmi);
 addrIdx = rtwCAPI_GetSignalAddrIdx(sigs, sigIdx);
 dTypeIdx = rtwCAPI_GetSignalDataTypeIdx(sigs, sigIdx);
 slDataType = rtwCAPI_GetDataTypeSLId(dataTypeMap, dTypeIdx);

 /* Handle data types 'double' and 'single'. */
 switch (slDataType) {

 case SS_DOUBLE: {
 real_T* dataAddress;
 dataAddress = dataAddrMap[addrIdx];
 printf("Signal value is %f\n", *dataAddress);
 break;
 }

 case SS_SINGLE: {
 real32_T* dataAddress;
 dataAddress = dataAddrMap[addrIdx];
 printf("Signal value is %f\n", *dataAddress);
 break;
 }
 }
 }
}

```

2. Copy this custom header code into a file named `ex_myHandHdr.h` in your current folder.

```

#include <stdio.h>
#include <string.h>
#include <math.h>
/* Include rtw_modelmap.h for definitions of C API macros. */
#include "rtw_modelmap.h"
#include "builtin_typeid_types.h"
#include "rtwtypes.h"
void tuneFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr);
void logFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr);

```

These files use the C API to access signal and parameter data in the code that you generate from the example model.

3. Set model configuration parameters **Include headers** and **Source files** to #include "ex\_myHandHdr.h" and ex\_myHandCode.c, respectively.

```

set_param('rtwdemo_configrpinterface', 'CustomHeaderCode', '#include "ex_myHandHdr.h"')
set_param('rtwdemo_configrpinterface', 'CustomSource', 'ex_myHandCode.c')

```

4. Select model configuration parameter **MAT-file Logging**. The generated executable runs only until the simulation stop time (which you set in the model configuration parameters).

```

set_param('rtwdemo_configrpinterface', 'MatFileLogging', 'on')

```

5. Select C API model configuration parameters **parameters**, **signals**, **states**, and **root-level I/O**.

```

set_param('rtwdemo_configrpinterface', 'RTWCAPIParams', 'on')
set_param('rtwdemo_configrpinterface', 'RTWCAPISignals', 'on')
set_param('rtwdemo_configrpinterface', 'RTWCAPIStates', 'on')
set_param('rtwdemo_configrpinterface', 'RTWCAPIRootIO', 'on')

```

6. Load the Custom Code block library.

```

custcode

```

These blocks allow you to insert custom code into specific files and functions.

7. Add a System Outputs block to the model.

```
add_block('custcode/System Outputs','rtwdemo_configrpinterface/System Outputs')
```

8. In the System Outputs block dialog box, set **System Outputs Function Execution Code** to this code:

```
{
rtwdemo_configrpinterface_U.input2++;
rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_configrpinterface_M).mmi);
tuneFcn(MMI, rtmGetTPtr(rtwdemo_configrpinterface_M));
}
```

9. In the block dialog box, set **System Outputs Function Exit Code** to this code:

```
{
rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_configrpinterface_M).mmi);
logFcn(MMI, rtmGetTPtr(rtwdemo_configrpinterface_M));
}
```

Alternatively, to configure the System Outputs block, at the command prompt, use these commands:

```
temp.TLCFile = 'custcode';
temp.Location = 'System Outputs Function';
temp.Middle = sprintf(['\nrtwdemo_configrpinterface_U.input2++;'...
'\nrtwCAPI_ModelMappingInfo *MMI = '...
'\nrtmGetDataMapInfo(rtwdemo_configrpinterface_M).mmi);'...
'\ntuneFcn(MMI, rtmGetTPtr(rtwdemo_configrpinterface_M));\n']);
temp.Bottom = sprintf(['\nrtwCAPI_ModelMappingInfo *MMI = '...
'\nrtmGetDataMapInfo(rtwdemo_configrpinterface_M).mmi);'...
'\nlogFcn(MMI, rtmGetTPtr(rtwdemo_configrpinterface_M));\n']);
set_param('rtwdemo_configrpinterface/System Outputs','RTWdata',temp)
```

10. Generate code.

```
slbuild('rtwdemo_configrpinterface')

Starting build procedure for: rtwdemo_configrpinterface
Successful completion of build procedure for: rtwdemo_configrpinterface

Build Summary

Top model targets built:

Model Action Rebuild Reason
=====
rtwdemo_configrpinterface Code generated and compiled Generated code was out of date.

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 34.492s
```

11. In the code generation report, view the interface file `rtwdemo_configrpinterface_capi.c`. This file initializes the arrays of structures that you can use to interact with data items through the C API. For example, in the array of structures `rtBlockSignals`, the first structure (index 0) describes the test-pointed output signal of the Gain block in the model.

```
file = fullfile('rtwdemo_configrpinterface_grt_rtw','rtwdemo_configrpinterface_capi.c');
rtwdemodbtype(file,'/* Block output signal information */',...
'\n/* Individual block tuning',1,0)

/* Block output signal information */
```

```

static const rtwCAPI_Signals rtBlockSignals[] = {
 /* addrMapIndex, sysNum, blockPath,
 * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
 */
 { 0, 0, TARGET_STRING("rtwdemo_configrpinterface/Gain"),
 TARGET_STRING(""), 0, 0, 0, 0, 0 },

 {
 0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
 }
};

```

The fields of the structure, such as `addrMapIndex`, indicate indices into other arrays of structures, such as `rtDataAddrMap`, that describe the characteristics of the signal. These characteristics include the address of the signal data (a pointer to the data), the numeric data type, and the dimensions of the signal.

12. In the file `rtwdemo_configrpinterface.c`, view the code algorithm in the model step function. The algorithm first executes the code that you specified in the System Outputs block.

```

file = fullfile('rtwdemo_configrpinterface_grt_rtw','rtwdemo_configrpinterface.c');
rtwdemodbtype(file,'/* user code (Output function Body) */',...
 '/* Logic: '<Root>/LogOp' incorporates:',1,0)

/* user code (Output function Body) */

/* System '<Root>' */

rtwdemo_configrpininterface_DW.X = 0.0;
}

/* Model terminate function */
void rtwdemo_configrpininterface_terminate(void)
{
 /* (no terminate code required) */
}

```

This code first perturbs the input signal `input2` by incrementing the value of the signal each time the `step` function executes. The code then uses the built-in macro `rtmGetDataMapInfo` to extract model mapping information from the model data structure `rtwdemo_configrpininterface_M`. The pointer `MMI` points to the extracted mapping information, which allows the functions `tuneFcn` and `logFcn` to access the information contained in the arrays of structures that the C API file `rtwdemo_configrpininterface_capi.c` defines.

13. View the function `tuneFcn` in the file `ex_myHandCode.c`. This function uses the C API (through the model mapping information `mmi`) and a pointer to the simulation time to print the value of the parameter `K1` at specific times during code execution. When the simulation time reaches 5 seconds, the function changes the parameter value in memory. By using a `switch case` block, the function can access the parameter data whether the data type is `int8` or `double`.

14. View the code algorithm in the model `step` function again. Near the end of the function, the algorithm executes the code that you specified in the System Outputs block. This code calls the function `logFcn`.

```

rtwdemodbtype(file, '/* user code (Output function Trailer) */', ...
 '/* Matfile logging */', 1, 0)

/* user code (Output function Trailer) */

/* System '<Root>' */
{
 rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo
 (rtwdemo_configrpininterface_M).mmi);
 logFcn(MMI, rtmGetTPtr(rtwdemo_configrpininterface_M));
}

```

15. View the function `logFcn` in the file `ex_myHandCode.c`. The function uses the C API to print the value of the test-pointed signal. The function can access the signal data whether the data type is `single` or `double`.

16. At the command prompt, run the generated executable `rtwdemo_configrpinterface.exe`.

```
system('rtwdemo_configrpinterface')
```

The parameter and signal values appear in the Command Window output.

For more information about data interfaces, including the C API, see “Calibration and Measurement”.

## Configure Data Accessibility

Goal	Considerations and More Information
Configure signals as accessible and parameters as tunable by default	<p>Clear the model configuration parameter <b>Signal storage reuse</b> and set the configuration parameter <b>Default parameter behavior</b> to <code>Tunable</code>. These settings prevent the elimination of storage for signals and prevent parameter inlining. Each block parameter and signal line appears in the generated code as a field of a structure. For more information about these data structures, see “How Generated Code Exchanges Data with an Environment” on page 33-35 and “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49.</p> <p>For more information about <b>Default parameter behavior</b>, see “Default parameter behavior”. For more information about optimizations that eliminate storage for signals, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49 and “Minimize Computations and Storage for Intermediate Results at Block Outputs”.</p>
Preserve accessibility and tunability of a data item after you select optimizations	<p>You can generate more efficient code by selecting optimizations such as <b>Signal storage reuse</b>, but the code generator eliminates storage for as many data items as possible. To exclude individual data items from the optimizations:</p> <ul style="list-style-type: none"> <li>• Configure signals in the Code Mappings editor. In the editor you can set the default configuration for signals, add signals of interest to the code mappings, and then set the storage class for individual signals to the default storage class or another storage class. Signals can be named by setting the <code>Identifier</code> storage class property.</li> <li>• Apply a storage class, such as <code>ExportedGlobal</code>, to states and parameters. See “C Code Generation Configuration for Model Interface Elements” on page 32-2.</li> </ul>
Represent a data item as a separate global variable in the generated code	<p>When you disable optimizations, signal lines, block states, and parameters appear in the generated code as fields of structures. You cannot control the names of the structures without Embedded Coder. To instead store a data item in a separate global variable whose name, file placement, and other characteristics you can control, apply a storage class to a signal, state, or <code>Simulink.Parameter</code> object. See “C Code Generation Configuration for Model Interface Elements” on page 32-2.</p>

Goal	Considerations and More Information
Generate a standardized C-code interface for accessing data	You can configure the generated code to contain extra code and files so that you can access model data through standardized interfaces. For more information, see “Exchange Data Between Generated and External Code Using C API” on page 59-2.
Tune parameters and monitor signals during external mode simulation	<p>When you generate code and an external executable from a model, you can simulate the model in external mode to communicate with the running executable. You can tune parameters and monitor signals during the simulation. However, in this simulation mode, parameter tunability limitations that apply to code generation also apply to the simulation. For information about the code generation limitations, see “Limitations for Block Parameter Tunability in Generated Code” on page 33-120.</p> <p>For information about external mode, see “External Mode Simulations for Parameter Tuning and Signal Monitoring” on page 57-2.</p>
Tune parameters and monitor signals with Simulink Real-Time	If you have Simulink Real-Time, you can tune parameters and monitor signals during execution of your real-time application. Make signals accessible and parameters tunable by clearing optimizations and applying test points and storage classes. See “Parameter Tuning with Simulink Real-Time Explorer” (Simulink Real-Time).

## Limitations

For information about limitations that apply to the tunability of parameters in the generated code, see “Limitations for Block Parameter Tunability in Generated Code” on page 33-120.

## Access Signal, State, and Parameter Data During Execution

As you iteratively develop a model, you capture output signal and state data that model execution generates. You also tune parameter values during execution to observe results on the outputs. You can then base your design decisions upon analysis of these outputs. To access this signal, state, and parameter data in a rapid prototyping environment, you can configure the generated code to store the data in addressable memory.

By default, optimization settings make the generated code more efficient by eliminating unnecessary signal storage and inlining the numeric values of block parameters. To generate code that instead allocates addressable memory for this data, you can disable the optimizations or specify code generation settings for individual data items.

### Explore Example Model

Run a script that prepares the model `rtwdemo_configrpinterface` for this example.

```
prepare_rtwdemo_configrpinterface
```

This data is configured for code generation:

- Parameters UPPER, LOWER, K1, Table1, and Table2
- Signals In1, In2, In3, In4, and Out1
- States X (delay) and mode (data store memory write)

Open the example model, `rtwdemo_configrpinterface`.

```
rtwdemo_configrpinterface
```

Copyright 1994-2020 The MathWorks, Inc.

The model loads numeric MATLAB variables into the model workspace. The workspace variables set some block parameters in the model. However, the Gain block in the model uses the literal value 2.

### Disable Optimizations

1. In the model, clear the model configuration parameter **Signal storage reuse**. When you clear this optimization and other optimizations such as **Eliminate superfluous local variables (expression folding)**, the generated code allocates memory for signal lines. Clearing **Signal storage reuse** disables most of the other optimizations.

```
set_param('rtwdemo_configrpininterface', 'OptimizeBlockIOStorage', 'off')
```

2. Set the model configuration parameter **Default parameter behavior** to Tunable. When set to Tunable, this configuration parameter causes the generated code to allocate memory for block parameters and workspace variables.

```
set_param('rtwdemo_configrpininterface', 'DefaultParameterBehavior', 'Tunable')
```

3. Generate code.

```
slbuild('rtwdemo_configrpininterface')
```

```
Starting build procedure for: rtwdemo_configrpininterface
Successful completion of build procedure for: rtwdemo_configrpininterface
```

Build Summary

Top model targets built:

```

Model Action Rebuild Reason
=====
rtwdemo_configrpintr Code generated and compiled Code generation information file does not
face

1 of 1 models built (0 models already up to date)
Build duration: 0h 1m 21.427s

```

4. In the code generation report, view the file `rtwdemo_configrpintrface.h`. This header file defines a structure type that contains signal data. The structure contains fields that each represent a signal line in the model. For example, the output signal of the Gain block, whose name is `Gain`, appears as the field `Gain`.

```

file = fullfile('rtwdemo_configrpintrface_grt_rtw','rtwdemo_configrpintrface.h');
rtwdemodbtype(file, '/* Block signals (default storage) */', ...
 'B_rtwdemo_configrpintrface_T;', 1, 1)

```

```

/* Block signals (default storage) */
typedef struct {
 real_T Delay; /* '<Root>/Delay' */
 real_T Table2; /* '<Root>/Table2' */
 real_T Table1; /* '<Root>/Table1' */
 real_T Gain; /* '<Root>/Gain' */
 boolean_T RelOp1; /* '<Root>/RelOp1' */
 boolean_T RelOp2; /* '<Root>/RelOp2' */
 boolean_T LogOp; /* '<Root>/LogOp' */
 boolean_T DataStoreRead; /* '<Root>/Data Store Read' */
} B_rtwdemo_configrpintrface_T;

```

The file defines a structure type that contains block parameter data. For example, the **Gain** parameter of the Gain block appears as the field `Gain_Gain`. The other fields of the structure represent other block parameters and workspace variables from the model, including initial conditions for signals and states.

```

rtwdemodbtype(file, '/* Parameters (default storage) */', ...
 '/* Real-time Model Data Structure */', 1, 0)

/* Parameters (default storage) */
struct P_rtwdemo_configrpintrface_T_ {
 Table1_Type Table1; /* Variable: Table1
 * Referenced by: '<Root>/Table1'
 */
 Table2_Type Table2; /* Variable: Table2
 * Referenced by: '<Root>/Table2'
 */
 real_T LOWER; /* Variable: LOWER
 * Referenced by: '<Root>/Constant2'
 */
 real_T UPPER; /* Variable: UPPER
 * Referenced by: '<Root>/Constant1'
 */
 real_T Gain_Gain; /* Expression: 2
 * Referenced by: '<Root>/Gain'
 */
}

```

```

real_T Delay_InitialCondition; /* Expression: 0
 * Referenced by: '<Root>/Delay'
 */
uint32_T Table2_maxIndex[2]; /* Computed Parameter: Table2_maxIndex
 * Referenced by: '<Root>/Table2'
 */
boolean_T DataStoreMemory_InitialValue;
 /* Computed Parameter: DataStoreMemory_InitialValue
 * Referenced by: '<Root>/Data Store Memory'
 */
};

```

5. View the file `rtwdemo_configrpininterface_data.c`. This source file allocates global memory for a parameter structure and initializes the field values based on the parameter values in the model.

6. View the source file `rtwdemo_configrpininterface.c`. The code allocates global memory for a structure variable that contains signal data.

```

file = fullfile('rtwdemo_configrpininterface_grt_rtw','rtwdemo_configrpininterface.c');
rtwdemodbtype(file, /* Block signals (default storage) */,...
 'B_rtwdemo_configrpininterface_T rtwdemo_configrpininterface_B;',1,1)

/* Block signals (default storage) */
B_rtwdemo_configrpininterface_T rtwdemo_configrpininterface_B;

```

The code algorithm in the model `step` function calculates the signal values. It then assigns these values to the fields of the signal structure. To perform the calculations, the algorithm uses the parameter values from the fields of the parameter structure.

### Exclude Data Items from Optimizations

When you want to select code generation optimizations such as **Signal storage reuse**, you can preserve individual data items from the optimizations. The generated code then allocates addressable memory for the items.

Select the optimizations that you previously cleared.

```

set_param('rtwdemo_configrpininterface','OptimizeBlockIOStorage','on')
set_param('rtwdemo_configrpininterface','LocalBlockOutputs','on')
set_param('rtwdemo_configrpininterface','DefaultParameterBehavior','Inlined')

```

1. In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
2. In the Code Mappings editor, inspect the **Signals/States** tab.
3. In the model, select the output signal of the Gain block.
4. Pause on the ellipsis that appears above or below the signal line to open the action bar. Click the **Add Signal** button. In the Code Mappings editor, the **Signals** node expands and lists the signal that you added.

```

cm = coder.mapping.api.get('rtwdemo_configrpininterface');
gain_ports = get_param('rtwdemo_configrpininterface/Gain','PortHandles');
gain_outPort = gain_ports.Outport;
addSignal(cm,gain_outPort);

```

5. Apply the default storage class for Outports to the signal by setting **Storage Class** to Model default.

```
setSignal(cm,gain_outPort, 'StorageClass', 'Model default', 'Identifier', 'Gain');
```

6. In the model, select the Gain block.

7. In the Property Inspector, set the gain value to the model workspace parameter object K1.

8. In the Code Mappings editor, on the **Parameters** tab, expand **Model Parameters**.

9. Select parameter K1. Apply a storage class other than Auto by setting **Storage class**. For example, use the storage class Model default. By using Model default, K1 acquires the default storage class specified for model parameters, Default, and appears as a field of the global parameters structure.

```
set_param('rtwdemo_configrpinterface/Gain', 'Gain', 'K1');
setModelParameter(cm, 'K1', 'StorageClass', 'Model default');
```

10. Generate code.

```
slbuild('rtwdemo_configrpinterface')

Starting build procedure for: rtwdemo_configrpinterface
Successful completion of build procedure for: rtwdemo_configrpinterface
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_configrpinterface	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 38.219s

11. In the code generation report, view the file `rtwdemo_configrpinterface.h`. The structure that contains signal data now defines only one field, Gain, which represents the test-pointed output of the Gain block.

```
file = fullfile('rtwdemo_configrpinterface_grt_rtw', 'rtwdemo_configrpinterface.h');
rtwdemodbtype(file, '/* Block signals (default storage) */', ...
 'B_rtwdemo_configrpinterface_T;', 1, 1)
```

```
/* Block signals (default storage) */
typedef struct {
 real_T Gain; /* '<Root>/Gain' */
} B_rtwdemo_configrpinterface_T;
```

The structure that contains block parameter data defines one field, K1, which represents the parameter object K1.

```
rtwdemodbtype(file, '/* Parameters (default storage) */', ...
 '/* Real-time Model Data Structure */', 1, 0)
```

```
/* Parameters (default storage) */
```

```

struct P_rtwdemo_configrpininterface_T_ {
 int8_T K1; /* Variable: K1
 * Referenced by: '<Root>/Gain'
 */
};

```

### Access Data Through Generated Interfaces

You can configure the generated code to contain extra code and files so that you can access model data through standardized interfaces. For example, use the C API to log signal data and tune parameters during execution.

Copy this custom source code into a file named `ex_myHandCode.c` in your current folder.

```

#include "ex_myHandHdr.h"

#define paramIdx 0 /* Index of the target parameter,
determined by inspecting the array of structures generated by the C API. */
#define sigIdx 0 /* Index of the target signal,
determined by inspecting the array of structures generated by the C API. */

void tuneFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr)
{
 /* Take action with the parameter value only at
 the beginning of simulation and at the 5-second mark. */
 if (*tPtr == 0 || *tPtr == 5) {

 /* Local variables to store information extracted from
 the model mapping information (mmi). */
 void** dataAddrMap;
 const rtwCAPI_DataTypeMap *dataTypeMap;
 const rtwCAPI_ModelParameters *params;
 int_T addrIdx;
 uint16_T dTypeIdx;
 uint8_T slDataType;

 /* Use built-in C API macros to extract information. */
 dataAddrMap = rtwCAPI_GetDataAddressMap(mmi);
 dataTypeMap = rtwCAPI_GetDataTypeMap(mmi);
 params = rtwCAPI_GetModelParameters(mmi);
 addrIdx = rtwCAPI_GetModelParameterAddrIdx(params,paramIdx);
 dTypeIdx = rtwCAPI_GetModelParameterDataTypeIdx(params,paramIdx);
 slDataType = rtwCAPI_GetDataTypeSLId(dataTypeMap, dTypeIdx);

 /* Handle data types 'double' and 'int8'. */
 switch (slDataType) {

 case SS_DOUBLE: {
 real_T* dataAddress;
 dataAddress = dataAddrMap[addrIdx];
 /* At the 5-second mark, increment the parameter value by 1. */
 if (*tPtr == 5) {
 (*dataAddress)++;
 }
 printf("Parameter value is %f\n", *dataAddress);
 break;
 }
 }
 }
}

```

```

 case SS_INT8: {
 int8_T* dataAddress;
 dataAddress = dataAddrMap[addrIdx];
 if (*tPtr == 5) {
 (*dataAddress)++;
 }
 printf("Parameter value is %i\n", *dataAddress);
 break;
 }
 }
}

void logFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr)
{
 /* Take action with the signal value only when
 the simulation time is an integer value. */
 if (*tPtr-(int_T)*tPtr == 0) {

 /* Local variables to store information extracted from
 the model mapping information (mmi). */
 void** dataAddrMap;
 const rtwCAPI_DataTypeMap *dataTypeMap;
 const rtwCAPI_Signals *sigs;
 int_T addrIdx;
 uint16_T dTypeIdx;
 uint8_T slDataType;

 /* Use built-in C API macros to extract information. */
 dataAddrMap = rtwCAPI_GetDataAddressMap(mmi);
 dataTypeMap = rtwCAPI_GetDataTypeMap(mmi);
 sigs = rtwCAPI_GetSignals(mmi);
 addrIdx = rtwCAPI_GetSignalAddrIdx(sigs, sigIdx);
 dTypeIdx = rtwCAPI_GetSignalDataTypeIdx(sigs, sigIdx);
 slDataType = rtwCAPI_GetDataTypeSLId(dataTypeMap, dTypeIdx);

 /* Handle data types 'double' and 'single'. */
 switch (slDataType) {

 case SS_DOUBLE: {
 real_T* dataAddress;
 dataAddress = dataAddrMap[addrIdx];
 printf("Signal value is %f\n", *dataAddress);
 break;
 }

 case SS_SINGLE: {
 real32_T* dataAddress;
 dataAddress = dataAddrMap[addrIdx];
 printf("Signal value is %f\n", *dataAddress);
 break;
 }
 }
 }
}

```

2. Copy this custom header code into a file named `ex_myHandHdr.h` in your current folder.

```

#include <stdio.h>
#include <string.h>
#include <math.h>
/* Include rtw_modelmap.h for definitions of C API macros. */
#include "rtw_modelmap.h"
#include "builtin_typeid_types.h"
#include "rtwtypes.h"
void tuneFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr);
void logFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr);

```

These files use the C API to access signal and parameter data in the code that you generate from the example model.

3. Set model configuration parameters **Include headers** and **Source files** to #include "ex\_myHandHdr.h" and ex\_myHandCode.c, respectively.

```

set_param('rtwdemo_configrpinterface', 'CustomHeaderCode', '#include "ex_myHandHdr.h"')
set_param('rtwdemo_configrpinterface', 'CustomSource', 'ex_myHandCode.c')

```

4. Select model configuration parameter **MAT-file Logging**. The generated executable runs only until the simulation stop time (which you set in the model configuration parameters).

```

set_param('rtwdemo_configrpinterface', 'MatFileLogging', 'on')

```

5. Select C API model configuration parameters **parameters**, **signals**, **states**, and **root-level I/O**.

```

set_param('rtwdemo_configrpinterface', 'RTWCAPIParams', 'on')
set_param('rtwdemo_configrpinterface', 'RTWCAPISignals', 'on')
set_param('rtwdemo_configrpinterface', 'RTWCAPIStates', 'on')
set_param('rtwdemo_configrpinterface', 'RTWCAPIRootIO', 'on')

```

6. Load the Custom Code block library.

custcode

These blocks allow you to insert custom code into specific files and functions.

7. Add a System Outputs block to the model.

```
add_block('custcode/System Outputs','rtwdemo_configrpinterface/System Outputs')
```

8. In the System Outputs block dialog box, set **System Outputs Function Execution Code** to this code:

```
{
rtwdemo_configrpinterface_U.input2++;
rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_configrpinterface_M).mmi);
tuneFcn(MMI, rtmGetTPtr(rtwdemo_configrpinterface_M));
}
```

9. In the block dialog box, set **System Outputs Function Exit Code** to this code:

```
{
rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_configrpinterface_M).mmi);
logFcn(MMI, rtmGetTPtr(rtwdemo_configrpinterface_M));
}
```

Alternatively, to configure the System Outputs block, at the command prompt, use these commands:

```
temp.TLCFile = 'custcode';
temp.Location = 'System Outputs Function';
temp.Middle = sprintf(['\nrtwdemo_configrpinterface_U.input2++;'...
'\nrtwCAPI_ModelMappingInfo *MMI = '...
'\nrtmGetDataMapInfo(rtwdemo_configrpinterface_M).mmi);'...
'\ntuneFcn(MMI, rtmGetTPtr(rtwdemo_configrpinterface_M));\n']);
temp.Bottom = sprintf(['\nrtwCAPI_ModelMappingInfo *MMI = '...
'\nrtmGetDataMapInfo(rtwdemo_configrpinterface_M).mmi);'...
'\nlogFcn(MMI, rtmGetTPtr(rtwdemo_configrpinterface_M));\n']);
set_param('rtwdemo_configrpinterface/System Outputs','RTWdata',temp)
```

10. Generate code.

```
slbuild('rtwdemo_configrpinterface')

Starting build procedure for: rtwdemo_configrpinterface
Successful completion of build procedure for: rtwdemo_configrpinterface

Build Summary

Top model targets built:

Model Action Rebuild Reason
=====
rtwdemo_configrpinterface Code generated and compiled Generated code was out of date.

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 34.492s
```

11. In the code generation report, view the interface file `rtwdemo_configrpinterface_capi.c`. This file initializes the arrays of structures that you can use to interact with data items through the C API. For example, in the array of structures `rtBlockSignals`, the first structure (index 0) describes the test-pointed output signal of the Gain block in the model.

```
file = fullfile('rtwdemo_configrpinterface_grt_rtw','rtwdemo_configrpinterface_capi.c');
rtwdemodbtype(file,'/* Block output signal information */',...
'\n/* Individual block tuning',1,0)

/* Block output signal information */
```

```

static const rtwCAPI_Signals rtBlockSignals[] = {
 /* addrMapIndex, sysNum, blockPath,
 * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
 */
 { 0, 0, TARGET_STRING("rtwdemo_configrpinterface/Gain"),
 TARGET_STRING(""), 0, 0, 0, 0, 0 },

 {
 0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
 }
};

```

The fields of the structure, such as `addrMapIndex`, indicate indices into other arrays of structures, such as `rtDataAddrMap`, that describe the characteristics of the signal. These characteristics include the address of the signal data (a pointer to the data), the numeric data type, and the dimensions of the signal.

12. In the file `rtwdemo_configrpinterface.c`, view the code algorithm in the model step function. The algorithm first executes the code that you specified in the System Outputs block.

```

file = fullfile('rtwdemo_configrpinterface_grt_rtw','rtwdemo_configrpinterface.c');
rtwdemodbtype(file,'/* user code (Output function Body) */',...
 '/* Logic: '<Root>/LogOp' incorporates:',1,0)

/* user code (Output function Body) */

/* System '<Root>' */
{
 rtwdemo_configrpinterface_U.input2++;

 (rtwdemo_configrpininterface_M)));

/* Start for DataStoreMemory: '<Root>/Data Store Memory' */
mode = false;

/* InitializeConditions for Lookup_n-D: '<Root>/Table2' incorporates:
 * UnitDelay: '<Root>/Delay'
 */
rtwdemo_configrpininterface_DW.X = 0.0;
}

/* Model terminate function */
void rtwdemo_configrpininterface_terminate(void)
{
 /* (no terminate code required) */
}

```

This code first perturbs the input signal `input2` by incrementing the value of the signal each time the `step` function executes. The code then uses the built-in macro `rtmGetDataMapInfo` to extract model mapping information from the model data structure `rtwdemo_configrpininterface_M`. The pointer `MMI` points to the extracted mapping information, which allows the functions `tuneFcn` and `logFcn` to access the information contained in the arrays of structures that the C API file `rtwdemo_configrpininterface_capi.c` defines.

13. View the function `tuneFcn` in the file `ex_myHandCode.c`. This function uses the C API (through the model mapping information `mmi`) and a pointer to the simulation time to print the value of the parameter `K1` at specific times during code execution. When the simulation time reaches 5 seconds, the function changes the parameter value in memory. By using a `switch case` block, the function can access the parameter data whether the data type is `int8` or `double`.

14. View the code algorithm in the model `step` function again. Near the end of the function, the algorithm executes the code that you specified in the System Outputs block. This code calls the function `logFcn`.

```

rtwdemodbtype(file, '/* user code (Output function Trailer) */', ...
 '/* Matfile logging */', 1, 0)

/* user code (Output function Trailer) */

/* System '<Root>' */
{
 rtwCAPI_ModelMappingInfo *MMI = (&rtmGetDataMapInfo
 (rtwdemo_configrpininterface_M).mmi);
 logFcn(MMI, rtmGetTPtr(rtwdemo_configrpininterface_M));
}

```

15. View the function `logFcn` in the file `ex_myHandCode.c`. The function uses the C API to print the value of the test-pointed signal. The function can access the signal data whether the data type is `single` or `double`.

16. At the command prompt, run the generated executable `rtwdemo_configrpinterface.exe`.

```
system('rtwdemo_configrpinterface')
```

The parameter and signal values appear in the Command Window output.

For more information about data interfaces, including the C API, see “Calibration and Measurement”.

## Data Structures in the Generated Code

The code generator organizes the data used by the model in data structures. For each model, the code generator stores data, such as signals and states, in global structures that are also referred to as standard data structures. Use these data structures to access the data in the generated code.

Real-time model (`rtModel`) data structure is a top level data structure that contains instance-specific data, which is used by the model for reusable functions. The code generator uses this data structure for only multi-instance code generation.

### Standard Data Structures

In a model, root-level Inport and Outport blocks represent the primary inputs and outputs of the block algorithm. By default, the code generator aggregates these blocks into standard structures that store input and output data.

Signal lines, block parameters, states, and other model data appear in the generated code as fields of standard structures. For general information, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49.

The table shows some common data structures in the generated code. The name of the structure type and, if applicable, structure variable in the code that you generate from a model depends on the model settings. Regardless of the settings, the name of the structure type in the code contains the short name from the **Short Name of Structure Type** column in the table.

#### Data Structures Generated for a Model

Short Name of Structure Type	Data Represented in the Structure
ExtU	Data from root Inport blocks
ExtY	Data from root Outport blocks
B	Block output signals
ConstB	Block outputs that have constant values
P	Block parameters
ConstP	Constant parameters
DW	Discrete block states
XDis	Status of enabled subsystems
InstP	Parameter arguments
SharedDSM	Shared local data stores

You can exclude data from appearing in these structures by using:

- Direct application of storage classes. For example, you can use storage classes to represent signals, tunable parameters, and states as individual global variables. For more information, see “C Code Generation Configuration for Model Interface Elements” on page 32-2.
- Configuration parameters, such as those on the **Optimization** pane in the Configuration Parameters dialog box. You can adjust these configuration parameters to control the default representation of data. For more information, see “Model Configuration Parameters: Code Generation Optimization”.

## Real-Time Model Data Structure

To access the fields of an S-function's simulation data structure (`SimStruct`), the Simulink software provides a set of functions. The code generator replaces `SimStruct` with an optimized real-time model (`rtModel`) data structure.

Code generation by using the GRT and ERT system target files uses the real-time model data structure (`rtModel`). This structure encapsulates model-specific information in a much more compact form than the simulation structure `SimStruct`. Depending on the model, the model-specific information includes data such as internal data for reusable functions and error state.

When you set **Code interface packaging** to `Reusable function`, the code generator packages model data (such as block I/O, Dwork, and parameters) into the real-time model data structure. The code generator passes the real-time model structure by reference to generated model entry-point functions. If you set **Pass root-level I/O as** to `Part of model data structure`, the code generator packages root-level model input and output into the real-time model data structure.

Efficient capabilities of the generated code depend on generation of `rtModel` rather than `SimStruct`, including:

- Integer absolute and elapsed timing services
- Independent timers for asynchronous tasks
- Generation of improved C API code for signal, state, and parameter monitoring
- Pruning the data structure to minimize its size (ERT-derived system target files only)

The real-time model data structure is defined in the `main.c` or `main.cpp` file that is generated when you build your model. For ERT models, if you clear the model configuration parameter **Generate an example main program**, `rtmodel.h` file is generated. The `rtmodel.h` file contains `#include` directives required by the `rt_main.c` or `rt_cppclass_main.cpp` static main program module. The `rt_main.c` or `rt_cppclass_main.cpp` includes `rtmodel.h` to access model-specific data structures and entry points because the static main program module is not created at code generation time.

The code generator provides a set of macros for accessing the `rtModel` data structure. These macros are analogous to the `ssSetxxx` and `ssGetxxx` macros that S-functions use to access `SimStruct` data, including noninlined S-functions compiled by the code generator.

Use the set of macros `rtmGetxxx` and `rtmSetxxx` to access the real-time model data structure. These macros are used in the generated code as well as in the `main.c` or `main.cpp` module of your external code. If you are customizing `main.c` or `main.cpp` (either a static or a generated file), use `rtmGetxxx` and `rtmSetxxx` instead of the `ssSetxxx` and `ssGetxxx` macros.

Usage of `rtmGetxxx` and `rtmSetxxx` macros is the same as for the `ssSetxxx` and `ssGetxxx` versions, except that you replace `SimStruct S` by real-time model data structure `rtM`. This table lists `rtmGetxxx` and `rtmSetxxx` macros that are used in `rt_main.c` and `rt_main.cpp`.

**Macros for Accessing the Real-Time Model Data Structure**

<b>rtm Macro Syntax</b>	<b>Description</b>
<code>rtmGetdX(rtm)</code>	Get the derivatives of block continuous states
<code>rtmGetOffsetTimePtr(RT_MDL rtm)</code>	Return the pointer to vector that stores sample time offsets of the model associated with rtm
<code>rtmGetNumSampleTimes(RT_MDL rtm)</code>	Get the number of sample times of a block
<code>rtmGetPerTaskSampleHitsPtr(RT_MDL)</code>	Return a pointer to NumSampleTime × NumSampleTime matrix
<code>rtmGetRTWExtModeInfo(RT_MDL rtm)</code>	Return an external mode information data structure of the model (used by code generator only for external mode)
<code>rtmGetRTWLogInfo(RT_MDL)</code>	Return a data structure used by code generator logging (used by code generator only)
<code>rtmGetRTWRTModelMethodsInfo(RT_MDL)</code>	Return a data structure of real-time model methods information (used by code generator only)
<code>rtmGetRTWSolverInfo(RT_MDL)</code>	Return data structure containing model solver information (used by code generator only)
<code>rtmGetSampleHitPtr(RT_MDL)</code>	Return a pointer to Sample Hit flag vector
<code>rtmGetSampleTime(RT_MDL rtm, int TID)</code>	Get task sample time
<code>rtmGetSampleTimePtr(RT_MDL rtm)</code>	Get pointer to a task sample time
<code>rtmGetSampleTimeTaskIDPtr(RT_MDL rtm)</code>	Get pointer to a task ID
<code>rtmGetSimTimeStep(RT_MDL)</code>	Return simulation step type ID (MINOR_TIME_STEP, MAJOR_TIME_STEP)
<code>rtmGetStepSize(RT_MDL)</code>	Return the fundamental step size of the model
<code>rtmGetT(RT_MDL, t)</code>	Get the current simulation time
<code>rtmSetT(RT_MDL, t)</code>	Set the time of the next sample hit
<code>rtmGetTaskTime(RT_MDL, tid)</code>	Get the current time for the current task
<code>rtmGetTFinal(RT_MDL)</code>	Get the simulation stop time
<code>rtmSetTFinal(RT_MDL, finalT)</code>	Set the simulation stop time
<code>rtmGetTimingData(RT_MDL)</code>	Return a data structure used by timing engine of the model (used by code generator only)
<code>rtmGetTPtr(RT_MDL)</code>	Return a pointer to the current time
<code>rtmGetTStart(RT_MDL)</code>	Get the simulation start time
<code>rtmIsContinuousTask(rtm)</code>	Determine whether a task is continuous
<code>rtmIsMajorTimeStep(rtm)</code>	Determine whether the simulation is in a major step
<code>rtmIsSampleHit(RT_MDL, tid)</code>	Determine whether the sample time is hit
<code>rtmGetErrorStatus(rtm)</code>	Get the current error status
<code>rtmSetErrorStatus(rtm, val)</code>	Set the current error status
<code>rtmGetErrorStatusPointer(rtm)</code>	Return a pointer to the current error status
<code>rtmGetStopRequested(rtm)</code>	Return whether a stop is requested

<b>rtm Macro Syntax</b>	<b>Description</b>
<code>rtmGetBlockIO(rtm)</code>	Get the block I/O data structure
<code>rtmSetBlockIO(rtm, val)</code>	Set the block I/O data structure
<code>rtmGetContStates(rtm)</code>	Get the continuous states data structure
<code>rtmSetContStates(rtm, val)</code>	Set the continuous states data structure
<code>rtmGetDefaultParam(rtm)</code>	Get the default parameters data structure
<code>rtmSetDefaultParam(rtm, val)</code>	Set the default parameters data structure
<code>rtmGetPrevZCSigState(rtm)</code>	Get the previous zero-crossing signal state data structure
<code>rtmSetPrevZCSigState(rtm, val)</code>	Set the previous zero-crossing signal state data structure
<code>rtmGetRootDWork(rtm)</code>	Get the DWork data structure
<code>rtmSetRootDWork(rtm, val)</code>	Set the DWork data structure
<code>rtmGetU(rtm)</code>	Get the root inputs data structure (when root inputs are passed as part of the model data structure)
<code>rtmSetU(rtm, val)</code>	Set the root inputs data structure (when root inputs are passed as part of the model data structure)
<code>rtmGetY(rtm)</code>	Get the root outputs data structure (when root outputs are passed as part of the model data structure)
<code>rtmSetY(rtm, val)</code>	Set the root outputs data structure (when root outputs are passed as part of the model data structure)

## How Generated Code Exchanges Data with an Environment

To use the code that you generate from a model, you call the generated entry-point functions such as `step` and `initialize`. The environment in which you call these functions must provide input signal data and, depending on your application, scheduling information. The generated algorithm then calculates output data that the calling environment can use. The environment and the algorithm can exchange this data through global variables or through formal parameters (arguments).

The set of input and output data and the exchange mechanisms constitute the interfaces of the entry-point functions. When you understand the default interfaces and how to control them, you can:

- Write code that calls the generated code.
- Generate reusable (reentrant) code that you can call multiple times in a single application.
- Integrate the generated code with other, external code in your application.

In a model, root-level Inport and Outport blocks represent the primary inputs and outputs of the block algorithm. By default, the code generator aggregates these blocks into standard structures that store input and output data.

For information about how the generated code stores internal data, which does not participate in the model interface, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49.

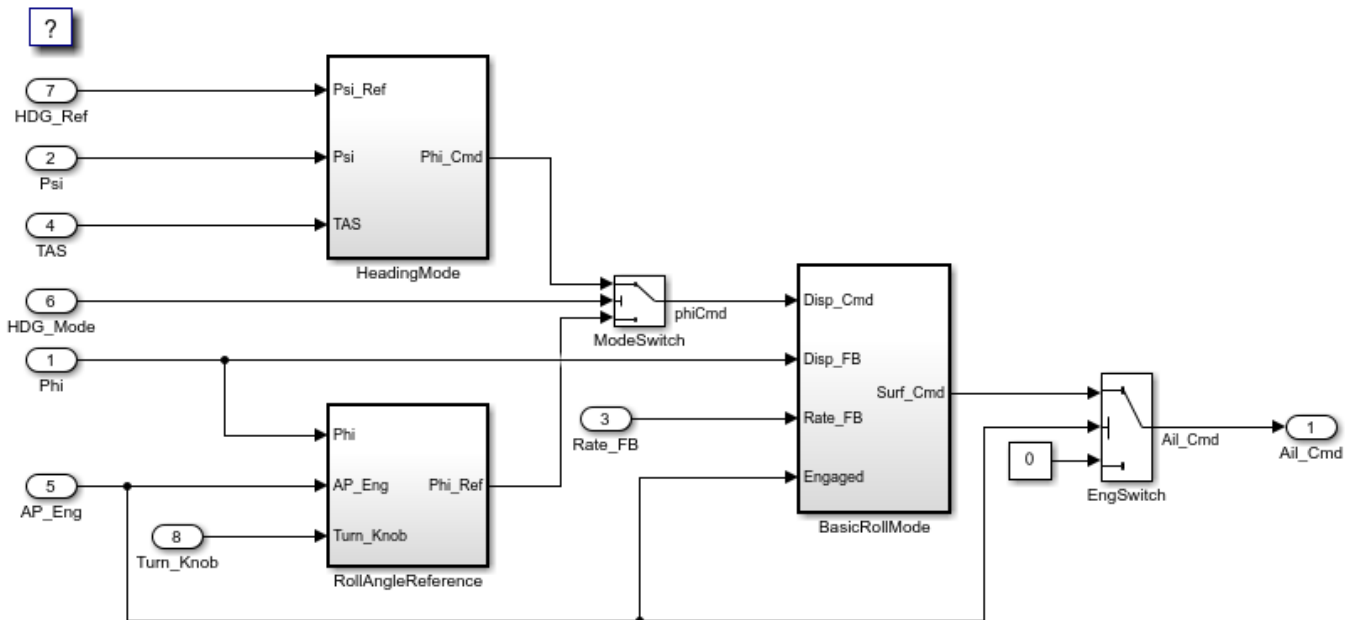

### Data Interfaces in the Generated Code

This example shows how the generated code exchanges data with an environment.

#### Explore Example Model

Open the example model `rtwdemo_roll`.

```
open_system('rtwdemo_roll')
```

Copyright 1990-2020 The MathWorks, Inc.

At the root level, the model has a number of Inport blocks and one Outport block.

In the model, set **Configuration Parameters > Code Generation > System target file** to `grt.tlc`.

```
set_param('rtwdemo_roll', 'SystemTargetFile', 'grt.tlc')
```

Inspect the setting for **Configuration Parameters > Code Generation > Interface > Code interface packaging**. The setting `Nonreusable` function means that the generated code is not reusable (not reentrant).

For this example, to generate simpler code, clear the **Configuration Parameters > Code Generation > Interface > Advanced parameters > Mat-file logging**.

```
set_param('rtwdemo_roll', 'MatFileLogging', 'off')
```

### Generate Nonreusable Code

Generate code from the model.

```
slbuild('rtwdemo_roll')
```

```
Starting build procedure for: rtwdemo_roll
Successful completion of build procedure for: rtwdemo_roll
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
=====		

```

rtwdemo_roll Code generated and compiled Code generation information file does not exist.

 real32_T Phi; /* '<Root>/Phi' */
 real32_T Psi; /* '<Root>/Psi' */
 real32_T Rate_FB; /* '<Root>/Rate_FB' */
 real32_T TAS; /* '<Root>/TAS' */
 boolean_T AP_Eng; /* '<Root>/AP_Eng' */
 boolean_T HDG_Mode; /* '<Root>/HDG_Mode' */
 real32_T HDG_Ref; /* '<Root>/HDG_Ref' */
 real32_T Turn_Knob; /* '<Root>/Turn_Knob' */
} ExtU_rtwdemo_roll_T;

/* External outputs (root outports fed by signals with default storage) */
typedef struct {
 real32_T Ail_Cmd; /* '<Root>/Ail_Cmd' */
} ExtY_rtwdemo_roll_T;

```

Each field corresponds to an Inport or Outport block at the root level of the model. The name of each field derives from the name of the block.

The file also defines a structure type, the *real-time model data structure*, whose single field stores a run-time indication of whether the generated code has encountered an error during execution.

```

rtwdemodbtype(file,'/* Real-time Model Data Structure */',...
 /* Block states (default storage) */',1,0)

/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
 const char_T *errorStatus;
};

```

When you modify model configuration parameters to suit your application, this structure can also contain other data that pertain to the entire model, such as scheduling information.

For the structure type that represents the real-time model data structure, the file `rtwdemo_roll_types.h` creates an alias (typedef) that the generated code later uses to allocate memory for the structure.

```

file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll_types.h');
rtwdemodbtype(file,'/* Forward declaration for rtModel */',...
 'RT_MODEL_rtwdemo_roll_T;',1,1)

```

```
/* Forward declaration for rtModel */
typedef struct tag_RTM_rtwdemo_roll_T RT_MODEL_rtwdemo_roll_T;
```

Using these structure types, the file `rtwdemo_roll.c` defines (allocates memory for) global structure variables that store input and output data for the generated algorithm. The file also defines variables that represent the real-time model data structure and a pointer to the structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,...
 /* External inputs (root inport signals with default storage) */,...
 '= &rtwdemo_roll_M;','1,1)
```

```
/* External inputs (root inport signals with default storage) */
ExtU_rtwdemo_roll_T rtwdemo_roll_U;
```

```
/* External outputs (root outports fed by signals with default storage) */
ExtY_rtwdemo_roll_T rtwdemo_roll_Y;
```

```
/* Real-time model */
static RT_MODEL_rtwdemo_roll_T rtwdemo_roll_M;
RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M = &rtwdemo_roll_M;
```

The file `rtwdemo_roll.h` declares these structure variables. Your external code can include (`#include`) this file, whose general name is `model.h` where `model` is the name of the model, to access data that participate in the model interface.

In `rtwdemo_roll.c`, the model `step` function, which represents the primary model algorithm, uses a `void void` interface (without arguments).

```
rtwdemodbtype(file,...
 /* Model step function */,'void rtwdemo_roll_step(void)',1,1)
```

```
/* Model step function */
void rtwdemo_roll_step(void)
```

In the function definition, the algorithm reads input data and writes output data by directly accessing the global structure variables. For example, near the end of the algorithm, the code for the `EngSwitch` block reads the value of the `AP_Eng` field (which represents an input) and, based on that value, conditionally writes a constant value to the `Ail_Cmd` field (which represents an output).

```
rtwdemodbtype(file,'if (rtwdemo_roll_U.AP_Eng) {' , ' }',1,1)
```

```
if (rtwdemo_roll_U.AP_Eng) {
 /* Outputs for Atomic SubSystem: '<Root>/BasicRollMode' */
 /* Saturate: '<S1>/CmdLimit' */
 if (rtwdemo_roll_Y.Ail_Cmd > 15.0F) {
 /* Sum: '<S1>/Sum2' incorporates:
 * Output: '<Root>/Ail_Cmd'
 */
 rtwdemo_roll_Y.Ail_Cmd = 15.0F;
 } else if (rtwdemo_roll_Y.Ail_Cmd < -15.0F) {
 /* Sum: '<S1>/Sum2' incorporates:
 * Output: '<Root>/Ail_Cmd'
 */
 }
}
```

```

 rtwdemo_roll_Y.Ail_Cmd = -15.0F;
}

/* End of Saturate: '<S1>/CmdLimit' */
/* End of Outputs for SubSystem: '<Root>/BasicRollMode' */
} else {
/* Sum: '<S1>/Sum2' incorporates:
 * Constant: '<Root>/Zero'
 * Outport: '<Root>/Ail_Cmd'
 */
 rtwdemo_roll_Y.Ail_Cmd = 0.0F;
}

/* End of Switch: '<Root>/EngSwitch' */
}

/* Model initialize function */
void rtwdemo_roll_initialize(void)
{
 /* Registration code */

 /* initialize error status */
 rtmSetErrorStatus(rtwdemo_roll_M, (NULL));

 /* states (dwork) */
 (void) memset((void *)&rtwdemo_roll_DW, 0,
 sizeof(DW_rtwdemo_roll_T));

 /* external inputs */
 (void)memset(&rtwdemo_roll_U, 0, sizeof(ExtU_rtwdemo_roll_T));

 /* external outputs */
 rtwdemo_roll_Y.Ail_Cmd = 0.0F;

 /* SystemInitialize for Atomic SubSystem: '<Root>/RollAngleReference' */
 /* InitializeConditions for UnitDelay: '<S4>/FixPt Unit Delay1' */
 rtwdemo_roll_DW.FixPtUnitDelay1_DSTATE = 0.0F;

 /* End of SystemInitialize for SubSystem: '<Root>/RollAngleReference' */

 /* SystemInitialize for Atomic SubSystem: '<Root>/BasicRollMode' */
 /* InitializeConditions for DiscreteIntegrator: '<S1>/Integrator' */
 rtwdemo_roll_DW.Integrator_DSTATE = 0.0F;
 rtwdemo_roll_DW.Integrator_PrevResetState = 0;

 /* End of SystemInitialize for SubSystem: '<Root>/BasicRollMode' */
}

/* Model terminate function */
void rtwdemo_roll_terminate(void)
{
 /* (no terminate code required) */
}

```

Due to the `void void` interface and the direct data access, the function is not reentrant. If you call the function multiple times in an application, each call reads and writes input and output data to the

same global structure variables, resulting in data corruption and unintentional interaction between the calls.

The model initialization function, `rtwdemo_roll_initialize`, initializes input and output data to zero. The function also initializes the error status. The function directly accesses the global variables, which means the function is not reentrant.

```
rtwdemodbtype(file, '/* Model initialize function */', ...
 'rtmSetErrorStatus(rtwdemo_roll_M, (NULL));', 1, 1)

/* Model initialize function */
void rtwdemo_roll_initialize(void)
{
 /* Registration code */

 /* initialize error status */
 rtmSetErrorStatus(rtwdemo_roll_M, (NULL));

rtwdemodbtype(file, ' /* external inputs */', ...
 '/* SystemInitialize for Atomic SubSystem:', 1, 0)

 /* external inputs */
 (void)memset(&rtwdemo_roll_U, 0, sizeof(ExtU_rtwdemo_roll_T));

 /* external outputs */
 rtwdemo_roll_Y.Ail_Cmd = 0.0F;
```

### Generate Reusable Code

You can configure the generated code as reentrant, which means that you can call the entry-point functions multiple times in an application. With this configuration, instead of directly accessing global variables, the entry-point functions exchange input, output, and other model data through formal parameters (pointer arguments). With these pointer arguments, each call can read inputs and write outputs to a set of separate global variables, preventing unintentional interaction between the calls.

In the model, set **Configuration Parameters > Code Generation > Interface > Code interface packaging** to Reusable function.

```
set_param('rtwdemo_roll', 'CodeInterfacePackaging', 'Reusable function')
```

Generate code from the model.

```
slbuild('rtwdemo_roll')

Starting build procedure for: rtwdemo_roll
Successful completion of build procedure for: rtwdemo_roll

Build Summary

Top model targets built:

Model Action Rebuild Reason
=====
rtwdemo_roll Code generated and compiled Generated code was out of date.

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 20.984s
```

Now, in `rtwdemo_roll.h`, the real-time model data structure contains pointers to the error indication, the input data, the output data, and additional data in the form of a `DWork` substructure (which stores, for example, block states such as the state of a Discrete-Time Integrator block).

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemobtype(file,'/* Real-time Model Data Structure */',...
 '/* External data declarations for dependent source files */',1,0)

/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
 const char_T *errorStatus;
 ExtU_rtwdemo_roll_T *inputs;
 ExtY_rtwdemo_roll_T *outputs;
 DW_rtwdemo_roll_T *dwork;
};
```

To call the generated code multiple times in an application, your code must allocate memory for a real-time model data structure per call. The file `rtwdemo_roll.c` defines a specialized function that allocates memory for a new real-time model data structure and returns a pointer to the structure. The function also allocates memory for the substructures that the fields in the model data structure point to, such as the input and output structures.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemobtype(file,'/* Model data allocation function */',...
 'RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)',1,1)

/* Model data allocation function */
RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)
```

In `rtwdemo_roll.c`, the model step function accepts an argument that represents the real-time model data structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemobtype(file,...
 '/* Model step function */','void rtwdemo_roll_step',1,1)

/* Model step function */
void rtwdemo_roll_step(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)
```

In the function definition, the algorithm first extracts each pointer from the real-time model data structure into a local variable.

```
rtwdemobtype(file,...
 '*rtwdemo_roll_DW =','rtwdemo_roll_M->outputs;',1,1)

 DW_rtwdemo_roll_T *rtwdemo_roll_DW = rtwdemo_roll_M->dwork;
 ExtU_rtwdemo_roll_T *rtwdemo_roll_U = (ExtU_rtwdemo_roll_T *)
 rtwdemo_roll_M->inputs;
 ExtY_rtwdemo_roll_T *rtwdemo_roll_Y = (ExtY_rtwdemo_roll_T *)
 rtwdemo_roll_M->outputs;
```

Then, to access the input and output data stored in global memory, the algorithm interacts with these local variables.

```

rtwdemodbtype(file, ' if (rtwdemo_roll_U->AP_Eng) {',...
 ' /* End of Switch: '<Root>/EngSwitch' */',1,1)

if (rtwdemo_roll_U->AP_Eng) {
 /* Outputs for Atomic SubSystem: '<Root>/BasicRollMode' */
 /* Saturate: '<S1>/CmdLimit' */
 if (rtwdemo_roll_Y->Ail_Cmd > 15.0F) {
 /* Sum: '<S1>/Sum2' incorporates:
 * Output: '<Root>/Ail_Cmd'
 */
 rtwdemo_roll_Y->Ail_Cmd = 15.0F;
 } else if (rtwdemo_roll_Y->Ail_Cmd < -15.0F) {
 /* Sum: '<S1>/Sum2' incorporates:
 * Output: '<Root>/Ail_Cmd'
 */
 rtwdemo_roll_Y->Ail_Cmd = -15.0F;
 }

 /* End of Saturate: '<S1>/CmdLimit' */
 /* End of Outputs for SubSystem: '<Root>/BasicRollMode' */
} else {
 /* Sum: '<S1>/Sum2' incorporates:
 * Constant: '<Root>/Zero'
 * Output: '<Root>/Ail_Cmd'
 */
 rtwdemo_roll_Y->Ail_Cmd = 0.0F;
}

```

Similarly, the model initialization function accepts the real-time model data structure as an argument.

```

rtwdemodbtype(file,...
 '/* Model initialize function */','void rtwdemo_roll_initialize',1,1)

/* Model initialize function */
void rtwdemo_roll_initialize(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)

```

Because each call that you make to an entry-point function interacts with a separate real-time model data structure, you avoid unintentional interaction between the calls.

## Configure Data Interface

To control the characteristics of the data interface in the generated code, see “Control Data and Function Interface in Generated Code” on page 33-44.

- “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49

## Control Data and Function Interface in Generated Code

To use the code that you generate from a model, you call generated entry-point functions such as `step` and `initialize`. The calling environment and the generated functions exchange input and output data through global variables or through formal parameters (arguments). This data and the exchange mechanisms constitute the interfaces of the entry-point functions. For information about the default interfaces for reentrant and nonreentrant models in the generated code, see “How Generated Code Exchanges Data with an Environment” on page 33-35.

By controlling the interfaces that appear in the generated code, you can:

- Minimize the modifications that you must make to existing code.
- Generate stable interfaces that do not change or minimally change when you make changes to the model.
- Generate code that exchanges data more efficiently (for example, by using pointers and pass-by-reference arguments for nonscalar data).

### Control Type Names, Field Names, and Variable Names of Standard I/O Structures (Embedded Coder)

By default, for nonreentrant code, Inport blocks at the root level of the model appear in the generated code as fields of a global structure variable. Similarly, Outport blocks appear in a different structure. For reentrant code, depending on your setting for model configuration parameter **Pass root-level I/O**, the code generator can also package input and output data into standard structures.

With Embedded Coder, you can control these names. See “Control Data Type Names in Generated Code” on page 35-2.

### Control Names of Generated Entry-Point Functions (Embedded Coder)

To use the generated code, you write code that calls generated entry-point functions. For example, entry-point functions include `model_step`, `model_initialize`, and top-level functions generated from an export-function model. To control the names of the model entry-point functions, use the Code Mappings editor (requires Embedded Coder) to apply a combination of these techniques:

- On the **Function Defaults** tab, specify default naming rules for categories of entry-point functions by applying function customization templates in the Code Mappings editor. With this technique, a naming rule applies to functions in a category. For more information, see “Configure Default Code Generation for Functions” on page 32-20.
- On the **Functions** tab, specify names for individual entry-point functions by either directly editing the **Function Name** column or through a configuration dialog box opened from the **Function Preview** column. Names that you specify override default naming rules specified by function customization templates. For more information, see “Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113

### Control Data Interface for Nonreentrant Code

When you set the model configuration parameter **Code interface packaging** to **Nonreusable function** (the default), generated entry-point functions are not reentrant. Typically, the functions exchange data with the calling environment through direct access to global variables.

### Configure Inport or Output Block as Separate Global Variable

To remove the block from the standard I/O structures by creating a separate global variable, apply a storage class, such as `ExportedGlobal` or `ExportToFile`, to the signal that the block represents. You can configure a default storage class for categories of data elements, such as Inport blocks. As you add such blocks to the model, they acquire the storage class that you specify. You can use the Code Mappings editor also to configure individual blocks. You might do this if a model has just a few data elements of a specific category or override the default configuration settings.

For an example, see “Design Data Interface by Configuring Inport and Outport Blocks”. For general information about configuring data for code generation, see “C Code Generation Configuration for Model Interface Elements” on page 32-2.

### Configure Generated Code to Read or Write to Global Variables Defined by External Code

If your calling code already defines a global variable that you want the generated code to use as input data or use to store output data, you can reuse the variable by preventing the code generator from duplicating the definition. Apply a storage class to the corresponding Inport or Outport block in the model. Choose a storage class that specifies an imported data scope, such as `ImportedExtern` or `ImportFromFile`. For information about applying storage classes, see “C Code Generation Configuration for Model Interface Elements” on page 32-2 and “Organize Parameter Data into a Structure by Using Struct Storage Class” on page 32-67.

### Package Multiple Inputs or Outputs into Custom Structure

You can configure a single Inport or Outport block to appear in the generated code as a custom structure that contains multiple input or output signals. You can also configure the block to appear as a substructure of the default I/O structures or as a separate structure variable.

Configure the block as a nonvirtual bus by using a `Simulink.Bus` object as the data type of the block. If your external code defines the structure type, consider using the `Simulink.importExternalCTypes` function to generate the bus object.

- To generate the bus signal as a substructure in the standard I/O structures, leave the block storage class at the default setting, `Auto`. If you have Embedded Coder, in the Code Mappings editor, on the **Data Defaults** tab, set the storage class for categories **Inports** and **Outports** to `Default`.
- To generate the bus signal as a separate global structure variable, apply a storage class such as `ExportedGlobal` or `ExportToFile`.

For more information about grouping signals into custom structures in the generated code, see “Organize Data into Structures in Generated Code” on page 33-145.

### Configure Inport or Output Block as Function Call (Embedded Coder)

If your external code defines a function that returns input data for the generated code or accepts output data that the generated code produces, you can configure an Inport or Outport block so that the generated code calls the function instead of accessing a global variable. Apply the Embedded Coder storage class `GetSet`. For more information, see “Access Data Through Functions with Storage Class `GetSet`” on page 37-25.

### Pass Inputs and Outputs Through Function Arguments (Embedded Coder)

With Embedded Coder, you can optionally configure the model step (execution) function to access root-level input and output through arguments instead of directly reading and writing to global

variables. Completely control the argument characteristics such as name, order, and passing mechanism (by reference or by value). This level of configuration can help to integrate generated code with your external code.

To pass inputs and outputs through arguments, in the Configure C Step Function interface dialog box, select **Configure arguments for Step function prototype**. Each Inport and Outport block at the root level of the model appears in the code as an argument of the execution function. For more information, see “Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113.

### Configure Referenced Model Inputs and Outputs as Global Variables (void-void)

By default, for a nonreentrant referenced model, the generated code passes root-level input and output through function arguments. A nonreentrant referenced model is one in which you set model configuration parameter **Total number of instances allowed per top model** to One.

To pass this data through global variables instead (for a void-void interface), in the referenced model, apply storage classes such as `ExportedGlobal` and `ExportToFile` to root-level Inport and Outport blocks.

- To apply a default storage class to such blocks, use the Code Mapping Editor. With this technique, as you add such blocks to the model, the blocks acquire the default storage class, preserving the void-void interface. For more information, see “Configure Default Code Generation for Data” on page 32-16.
- To override the default storage class, apply storage classes directly to individual blocks by using the Code Mapping editor. See “C Code Generation Configuration for Model Interface Elements” on page 32-2.
- For an example that requires Embedded Coder, see “Establish Data Ownership in a Model Hierarchy” on page 34-10.

### Control Data Interface for Reentrant Code

When you set **Code interface packaging** to `Reusable function`, generated entry-point functions are reentrant. The functions exchange data with the calling environment through formal parameters (arguments). By default, each root-level Inport and Outport block appears in the generated code as a separate argument instead of a field of the standard I/O structures.

- To reduce the number of arguments, see “Reduce Number of Arguments by Using Structures”.
- To control the data types of the arguments, see “Control Data Types of Arguments”.

### Prevent Unintended Changes to the Interface

Some changes that you make to a model change the entry-point function interfaces in the generated code. For example, if you change the name of the model, the names of the functions can change. If you configure the model code to exchange data through arguments, when you add or remove Inport or Outport blocks or change the names of the blocks, the corresponding arguments can change.

For easier maintenance of your calling code, prevent changes to the interfaces of the entry-point functions.

- If you exchange input and output data through arguments, configure the generated code to package Inport and Outport blocks into structures instead of allowing each block to appear as a

separate argument (the default). Then, when you add or remove Inport or Outport blocks, or change their properties such as name and data type, the fields of the structures change, but the function interfaces do not change. See “Reduce Number of Arguments by Using Structures” on page 33-47.

- Set the data types of Inport and Outport blocks explicitly instead of using an inherited data type setting (which these blocks use by default). Inherited data type settings can cause the blocks to use different data types depending on the data types of upstream and downstream signals. For more information about configuring data types, see “Control Data Types of Signals”.
- With Embedded Coder, specify function names that do not depend on the model name. If you specify a naming rule with a function customization template, do not use the token \$R in the rule. See “Control Names of Generated Entry-Point Functions (Embedded Coder)”.

## Reduce Number of Arguments by Using Structures

Reducing the number of arguments of a function can improve the readability of the code and reduce consumption of stack memory. To create a structure argument that can pass multiple pieces of data at one time, use these techniques:

- Manually combine multiple Inport or Outport blocks so that they appear in the generated code as fields of a structure or substructure of a standard data structure. The generated entry-point function or functions accept the address of the structure as a separate argument or as a substructure (field) of the standard I/O structures.

Replace the Inport or Outport blocks with a single block, and configure the new block as a nonvirtual bus by using a `Simulink.Bus` object as the data type of the block. If your external code defines the structure type, consider using the `Simulink.importExternalCTypes` function to generate the bus object. See “Organize Data into Structures in Generated Code” on page 33-145 and `Simulink.importExternalCTypes`.

- When you generate reentrant code with Embedded Coder, configure Inport and Outport blocks to appear in aggregated structures by default. Set model configuration parameter **Pass root-level I/O as** to a setting other than `Individual arguments`.
  - To package Inport and Outport blocks into the real-time model data structure, select `Part of model data structure`. The code generator aggregates the blocks into the default I/O structures to which the real-time model data structure points. The generated entry-point function or functions accept the real-time model data structure as a single argument. If you choose this setting, the function has the smallest number of arguments.
  - To aggregate Inport blocks into a structure and Outport blocks into a different structure, select `Structure reference`. The generated entry-point function or functions accept the address of each structure as an argument. Another argument accepts the real-time model data structure. If you choose this setting, the inputs and outputs are more identifiable in the function interfaces.

With this setting, if you remove the root-level Inport blocks or the root-level Outport blocks, the function signature can change. Similarly, the signature can change if you add a root-level Inport or Outport block to a model that does not include such blocks.

- For more control over the characteristics of the structures, set **Pass root-level I/O as** to `Part of model data structure`. Then, set the default storage class for Inport and Outport blocks to a structured storage class that you create. With this technique:

- You can create a single structure for the blocks or create two separate structures.
- You can control the names of the structure types.
- The structures appear as substructures of the real-time model data structure. You must set **Pass root-level I/O as** to Part of model data structure.

Create the storage class by using the Embedded Coder Dictionary (see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2). Apply the storage class by using the Code Mappings editor (see “Configure Default Code Generation for Data” on page 32-16).

For more information, see “Pass root-level I/O as”.

## Control Data Types of Arguments

You can configure the generated entry-point functions to exchange data through arguments. For a scalar or array argument, to control the name of the primitive data type, use a `Simulink.AliasType` object to either set the data type of the corresponding block or to configure data type replacements for the entire model. These techniques require Embedded Coder. For more information, see “Control Data Type Names in Generated Code” on page 35-2.

## Promote Data Item to the Interface

By default, the code generator assumes that Inport and Outport blocks at the root level of the model constitute the data interface of the model. You can promote an arbitrary signal, block parameter, or block state to the interface so that other systems and components can access it. See “Promote Internal Data to the Interface” on page 33-65.

## How Generated Code Stores Internal Signal, State, and Parameter Data

To calculate outputs from inputs, the generated code stores some internal data in global memory. A signal that does not connect to a root-level input or output (Inport or Outport block) is internal data.

Internal data can also include:

- A block state such as the state of a Unit Delay block. The algorithm must retain the state value between execution cycles, so the generated code typically stores states in global memory (for example, as a global variable or a field of a global structure variable).
- A block parameter, such as the **Gain** parameter of a Gain block, whose value the code generator cannot inline in the code. For example, the code generator cannot inline the value of a nonscalar parameter.
- The status indicator of a conditionally executed subsystem such as an enabled subsystem.

For more efficient code, you can configure optimizations such as **Configuration Parameters > Default parameter behavior** and **Configuration Parameters > Signal storage reuse** that attempt to eliminate storage for internal data. However, the optimizations cannot eliminate storage for some data, which consume memory in the generated code.

When you understand the default format in which the generated code stores internal data, you can:

- Make signals accessible and parameters tunable by default. You can then interact with and monitor the code during execution.
- Generate efficient production code by eliminating storage for internal data and, depending on your hardware and build toolchain, controlling the placement in memory of data that the optimizations cannot eliminate.
- Promote pieces of internal data to the model interface so that other components and systems can access that data.

For information about how the generated code exchanges data with a calling environment through interfaces, see “How Generated Code Exchanges Data with an Environment” on page 33-35.

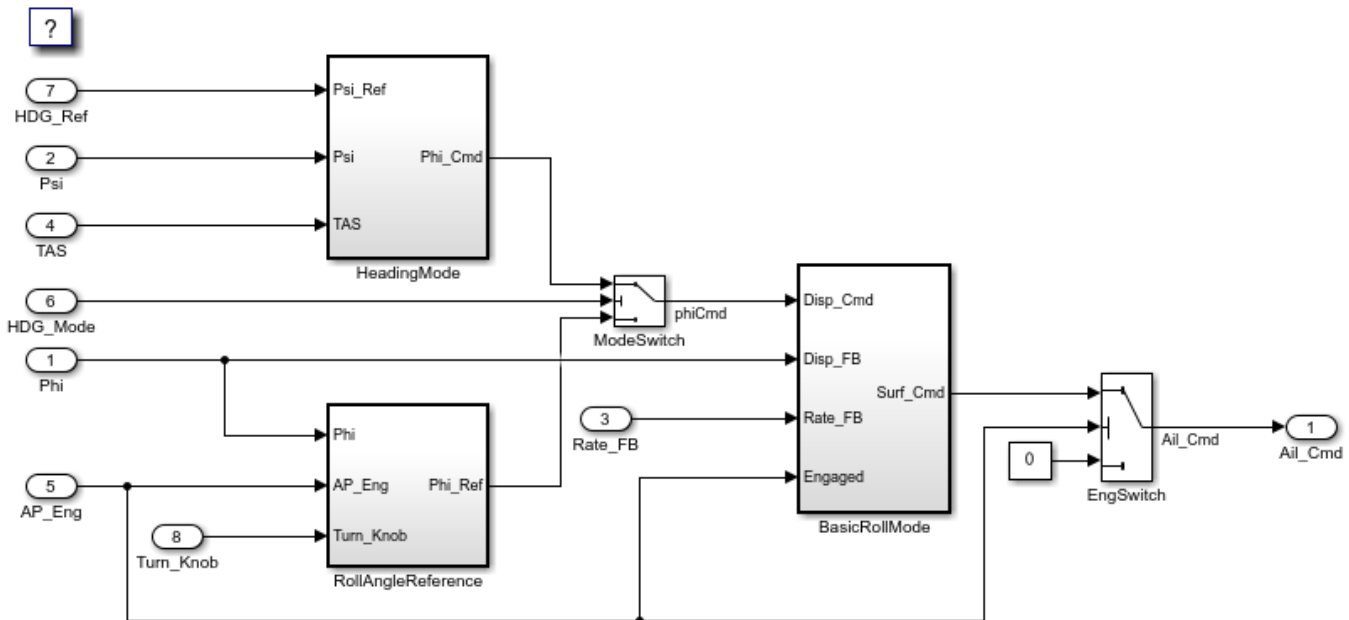

### Internal Data in the Generated Code

This example shows how the generated code stores internal data such as block states.

#### Explore Example Model

Open the example model `rtwdemo_roll`.

```
open_system('rtwdemo_roll')
```

Copyright 1990-2020 The MathWorks, Inc.

The model contains internal signals that do not connect to root-level Inport or Outport blocks. Some of the signals have a name, such as the `phiCmd` signal.

The model also contains some blocks that maintain state data. For example, in the `BasicRollMode` subsystem, a Discrete-Time Integrator block labeled `Integrator` maintains a state.

In the model, set **Configuration Parameters > Code Generation > System target file** to `grt.tlc`.

```
set_param('rtwdemo_roll', 'SystemTargetFile', 'grt.tlc')
```

Inspect the setting for **Configuration Parameters > Code Generation > Interface > Code interface packaging**. The setting `Nonreusable` function means that the generated code is not reusable (reentrant).

For this example, generate simpler code by clearing **Configuration Parameters > Code Generation > Interface > Advanced parameters > Mat-file logging**.

```
set_param('rtwdemo_roll', 'MatFileLogging', 'off')
```

### Generate Nonreusable Code

Set these configuration parameters:

- Set **Default parameter behavior** to `Tunable`.
- Clear **Signal storage reuse**.

```
set_param('rtwdemo_roll', 'DefaultParameterBehavior', 'Tunable', ...
 'OptimizeBlockIOStorage', 'off')
```

Generate code from the model.

```
slbuild('rtwdemo_roll')
```

```
Starting build procedure for: rtwdemo_roll
Successful completion of build procedure for: rtwdemo_roll
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_roll	Code generated and compiled	Generated code was out of date.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 13.735s
```

The file `rtwdemo_roll.h` defines several structure types that represent internal data. For example, the block input and output structure defines one field for each internal signal in the model. Each field name derives from the name of the block that generates the signal or, if you specify a name for the signal, from the name of the signal.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,...
 /* Block signals (default storage) */,' } B_rtwdemo_roll_T;',1,1)
```

```
/* Block signals (default storage) */
typedef struct {
 real32_T phiCmd; /* '<Root>/ModeSwitch' */
 real32_T hdgError; /* '<S2>/Sum' */
 real32_T DispGain; /* '<S2>/DispGain' */
 real32_T Product; /* '<S2>/Product' */
 real32_T Abs; /* '<S3>/Abs' */
 real32_T FixPtUnitDelay1; /* '<S4>/FixPt Unit Delay1' */
 real32_T Xnew; /* '<S4>/Enable' */
 real32_T TKSwitch; /* '<S3>/TKSwitch' */
 real32_T RefSwitch; /* '<S3>/RefSwitch' */
 real32_T Integrator; /* '<S1>/Integrator' */
 real32_T DispLimit; /* '<S1>/DispLimit' */
 real32_T Sum; /* '<S1>/Sum' */
 real32_T DispGain_f; /* '<S1>/DispGain' */
 real32_T RateLimit; /* '<S1>/RateLimit' */
 real32_T Sum1; /* '<S1>/Sum1' */
 real32_T RateGain; /* '<S1>/RateGain' */
 real32_T Sum2; /* '<S1>/Sum2' */
 real32_T CmdLimit; /* '<S1>/CmdLimit' */
 real32_T IntGain; /* '<S1>/IntGain' */
 boolean_T NotEngaged; /* '<S3>/NotEngaged' */
 boolean_T TKThreshold; /* '<S3>/TKThreshold' */
 boolean_T RefThreshold2; /* '<S3>/RefThreshold2' */
 boolean_T RefThreshold1; /* '<S3>/RefThreshold1' */
 boolean_T Or; /* '<S3>/Or' */
 boolean_T NotEngaged_e; /* '<S1>/NotEngaged' */
} B_rtwdemo_roll_T;
```

The file defines a structure type, the `DWork` structure, to represent block states such as the state of the Discrete-Time Integrator block.

```

rtwdemodbtype(file,...
 /* Block states (default storage) for system','} DW_rtwdemo_roll_T;',1,1)

/* Block states (default storage) for system '<Root>' */
typedef struct {
 real32_T FixPtUnitDelay1_DSTATE; /* '<S4>/FixPt Unit Delay1' */
 real32_T Integrator_DSTATE; /* '<S1>/Integrator' */
 int8_T Integrator_PrevResetState; /* '<S1>/Integrator' */
} DW_rtwdemo_roll_T;

```

The file defines a structure type to represent parameter data. Each tunable block parameter in the model, such as the **Gain** parameter of a Gain block, appears as a field of this structure. If a block parameter acquires its value from a MATLAB variable or a `Simulink.Parameter` object, the variable or object appears as a field, not the block parameter.

The file also defines a structure type, the *real-time model data structure*, whose single field represents a run-time indication of whether the generated code has encountered an error during execution.

```

rtwdemodbtype(file, /* Real-time Model Data Structure */',...
 /* Block parameters (default storage) */',1,0)

```

```

/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
 const char_T *errorStatus;
};

```

For the structure type that represents the real-time model data structure, the file `rtwdemo_roll_types.h` creates an alias that the generated code later uses to allocate memory for the structure.

```

file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll_types.h');
rtwdemodbtype(file, /* Forward declaration for rtModel */',...
 'RT_MODEL_rtwdemo_roll_T;',1,1)

```

```

/* Forward declaration for rtModel */
typedef struct tag_RTM_rtwdemo_roll_T RT_MODEL_rtwdemo_roll_T;

```

Using these structure types, the file `rtwdemo_roll.c` defines (allocates memory for) global structure variables that store internal data for the generated algorithm. The file also defines variables that represent the real-time model data structure and a pointer to the structure.

```

file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file, /* Block signals (default storage) */',...
 '= &rtwdemo_roll_M;',1,1)

```

```

/* Block signals (default storage) */
B_rtwdemo_roll_T rtwdemo_roll_B;

```

```

/* Block states (default storage) */
DW_rtwdemo_roll_T rtwdemo_roll_DW;

```

```

/* External inputs (root inport signals with default storage) */
ExtU_rtwdemo_roll_T rtwdemo_roll_U;

```

```

/* External outputs (root outputs fed by signals with default storage) */
ExtY_rtwdemo_roll_T rtwdemo_roll_Y;

/* Real-time model */
static RT_MODEL_rtwdemo_roll_T rtwdemo_roll_M;
RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M = &rtwdemo_roll_M;

```

The model `step` function, which represents the primary model algorithm, uses a `void void` interface (with no arguments).

```

rtwdemodbtype(file,...
 /* Model step function */,'void rtwdemo_roll_step(void)',1,1)

```

```

/* Model step function */
void rtwdemo_roll_step(void)

```

In the function definition, the algorithm performs calculations and stores intermediate results in the signal and state structures by directly accessing the global variables. The algorithm also reads parameter data from the corresponding global variable. For example, in the `BasicRollMode` subsystem, the code generated for the `Integrator` block reads and writes signal, state, and parameter data from the structures.

```

{
 /* Registration code */

 /* initialize error status */
 rtmSetErrorStatus(rtwdemo_roll_M, (NULL));

 /* block I/O */
 (void) memset(((void *) &rtwdemo_roll_B), 0,
 sizeof(B_rtwdemo_roll_T));

 /* states (dwork) */
 (void) memset((void *)&rtwdemo_roll_DW, 0,
 sizeof(DW_rtwdemo_roll_T));

 /* external inputs */
 (void)memset(&rtwdemo_roll_U, 0, sizeof(ExtU_rtwdemo_roll_T));

 /* external outputs */
 rtwdemo_roll_Y.Ail_Cmd = 0.0F;

 /* SystemInitialize for Atomic SubSystem: '<Root>/RollAngleReference' */
 /* InitializeConditions for UnitDelay: '<S4>/FixPt Unit Delay1' */
 rtwdemo_roll_DW.FixPtUnitDelay1_DSTATE = rtwdemo_roll_P.LatchPhi_vinit;
}

```

```

/* End of SystemInitialize for SubSystem: '<Root>/RollAngleReference' */

/* SystemInitialize for Atomic SubSystem: '<Root>/BasicRollMode' */
/* InitializeConditions for DiscreteIntegrator: '<S1>/Integrator' */
rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.Integrator_IC;
rtwdemo_roll_DW.Integrator_PrevResetState = 0;

/* End of SystemInitialize for SubSystem: '<Root>/BasicRollMode' */
}

/* Model terminate function */
void rtwdemo_roll_terminate(void)
{
/* (no terminate code required) */
}

```

Due to the `void void` interface and the direct data access, the function is not reentrant. If you call the function multiple times in an application, each call writes data to the global structure variables and the subsequent call can read that data, resulting in unintentional interference between the calls.

The model initialization function `rtwdemo_roll_initialize` initializes all of the internal data to zero. The function also initializes the error status by calling a specialized macro function. The initialization function directly accesses the global variables, which means that the function is not reentrant.

```

rtwdemodbtype(file, /* Model initialize function */ , ...
 'sizeof(DW_rtwdemo_roll_T);', 1, 1)

```

```

/* Model initialize function */
void rtwdemo_roll_initialize(void)
{
/* Registration code */

/* initialize error status */
rtmSetErrorStatus(rtwdemo_roll_M, (NULL));

/* block I/O */
(void) memset(((void *) &rtwdemo_roll_B), 0,
 sizeof(B_rtwdemo_roll_T));

/* states (dwork) */
(void) memset((void *)&rtwdemo_roll_DW, 0,
 sizeof(DW_rtwdemo_roll_T));
}

```

The function then initializes the block states in the `DWork` structure to the initial values that the block parameters in the model specify. Two of the three states in the model have tunable initial values, so the code initializes them by reading data from the parameters structure.

```

rtwdemodbtype(file, ...
 /* SystemInitialize for Atomic SubSystem: '<Root>/RollAngleReference' */ , ...
 /* Model terminate function */ , 1, 0)

/* SystemInitialize for Atomic SubSystem: '<Root>/RollAngleReference' */
/* InitializeConditions for UnitDelay: '<S4>/FixPt Unit Delay1' */
rtwdemo_roll_DW.FixPtUnitDelay1_DSTATE = rtwdemo_roll_P.LatchPhi_vinit;

```

```

/* End of SystemInitialize for SubSystem: '<Root>/RollAngleReference' */

/* SystemInitialize for Atomic SubSystem: '<Root>/BasicRollMode' */
/* InitializeConditions for DiscreteIntegrator: '<S1>/Integrator' */
rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.Integrator_IC;
rtwdemo_roll_DW.Integrator_PrevResetState = 0;

/* End of SystemInitialize for SubSystem: '<Root>/BasicRollMode' */
}

```

### Generate Reusable Code

You can configure the generated code as reentrant, which means you can call the entry-point functions multiple times in an application. With this configuration, instead of directly accessing global variables, the entry-point functions accept internal data through formal parameters (pointer arguments). With these pointer arguments, each call can maintain internal data in a set of separate global variables, preventing unintentional interaction between the calls.

In the model, set **Configuration Parameters > Code Generation > Interface > Code interface packaging** to Reusable function.

```
set_param('rtwdemo_roll','CodeInterfacePackaging','Reusable function')
```

Generate code from the model.

```
slbuild('rtwdemo_roll')
```

```
Starting build procedure for: rtwdemo_roll
Successful completion of build procedure for: rtwdemo_roll
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_roll	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 14.159s

Now, in `rtwdemo_roll.h`, the real-time model data structure contains pointers to the error indication, the internal data, and primary input and output data in the form of ExtU and ExtY substructures (the fields of which represent Inport and Outport blocks at the root level of the model).

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,'/* Real-time Model Data Structure */',...
 '/* External data declarations for dependent source files */',1,0)
```

```
/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
 const char_T *errorStatus;
 B_rtwdemo_roll_T *blockIO;
 ExtU_rtwdemo_roll_T *inputs;
 ExtY_rtwdemo_roll_T *outputs;
 DW_rtwdemo_roll_T *dwork;
};

```

```
};

/* Block parameters (default storage) */
extern P_rtwdemo_roll_T rtwdemo_roll_P;
```

To call the generated code multiple times in an application, your code must allocate memory for a real-time model data structure per call. The file `rtwdemo_roll.c` defines a specialized function that allocates memory for a new real-time model data structure and returns a pointer to the structure. The function also allocates memory for the substructures that the fields in the model data structure point to, such as the `DWork` structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Model data allocation function */',...
 'RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)',1,1)
```

```
/* Model data allocation function */
RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)
```

The model `step` function accepts an argument that represents the real-time model data structure.

```
rtwdemodbtype(file,'/* Model step function */','void rtwdemo_roll_step',1,1)
```

```
/* Model step function */
void rtwdemo_roll_step(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)
```

In the function definition, the algorithm first extracts each pointer from the real-time model data structure into a local variable.

```
rtwdemodbtype(file,'*rtwdemo_roll_B =','rtwdemo_roll_M->outputs;',1,1)
```

```
B_rtwdemo_roll_T *rtwdemo_roll_B = rtwdemo_roll_M->blockIO;
DW_rtwdemo_roll_T *rtwdemo_roll_DW = rtwdemo_roll_M->dwork;
ExtU_rtwdemo_roll_T *rtwdemo_roll_U = (ExtU_rtwdemo_roll_T *)
 rtwdemo_roll_M->inputs;
ExtY_rtwdemo_roll_T *rtwdemo_roll_Y = (ExtY_rtwdemo_roll_T *)
 rtwdemo_roll_M->outputs;
```

Then, to access the internal data stored in global memory, the algorithm interacts with these local variables.

```
rtwdemodbtype(file,'/* DiscreteIntegrator: '<S1>/Integrator' */',...
 '/* End of DiscreteIntegrator: '<S1>/Integrator' */',1,1)
```

```

/* external outputs */
{
 ExtY_rtwdemo_roll_T *rtwdemo_roll_Y = (ExtY_rtwdemo_roll_T *) malloc(sizeof
 (ExtY_rtwdemo_roll_T));
 rt_VALIDATE_MEMORY(rtwdemo_roll_M,rtwdemo_roll_Y);
 rtwdemo_roll_M->outputs = (rtwdemo_roll_Y);
}

{
 B_rtwdemo_roll_T *rtwdemo_roll_B = rtwdemo_roll_M->blockIO;
 DW_rtwdemo_roll_T *rtwdemo_roll_DW = rtwdemo_roll_M->dwork;
 ExtU_rtwdemo_roll_T *rtwdemo_roll_U = (ExtU_rtwdemo_roll_T *)
 rtwdemo_roll_M->inputs;
 ExtY_rtwdemo_roll_T *rtwdemo_roll_Y = (ExtY_rtwdemo_roll_T *)
 rtwdemo_roll_M->outputs;

 /* block I/O */
 (void) memset(((void *) rtwdemo_roll_B), 0,
 sizeof(B_rtwdemo_roll_T));

 /* states (dwork) */
 (void) memset((void *)rtwdemo_roll_DW, 0,
 sizeof(DW_rtwdemo_roll_T));

 /* external inputs */
 (void)memset(rtwdemo_roll_U, 0, sizeof(ExtU_rtwdemo_roll_T));

 /* external outputs */
 rtwdemo_roll_Y->Ail_Cmd = 0.0F;
}

return rtwdemo_roll_M;
}

```

Similarly, the model initialization function accepts the real-time model data structure as an argument.

```

rtwdemodbtype(file,...
 /* Model initialize function */,'void rtwdemo_roll_initialize',1,1)

/* Model initialize function */
void rtwdemo_roll_initialize(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)

```

Because each call that you make to an entry-point function interacts with a separate real-time model data structure, you avoid unintentional interaction between the calls.

### Eliminate Internal Data with Code Generation Optimizations

For more efficient code that consumes less memory, select the optimizations, such as **Default parameter behavior**, that you cleared earlier.

```

set_param('rtwdemo_roll','DefaultParameterBehavior','Inlined',...
 'OptimizeBlockIOStorage','on',...
 'LocalBlockOutputs','on')

```

In this example, for simpler code, set **Code interface packaging** to Nonreusable function.

```

set_param('rtwdemo_roll','CodeInterfacePackaging','Nonreusable function')

```

Generate code from the model.

```
slbuild('rtwdemo_roll')

Starting build procedure for: rtwdemo_roll
Successful completion of build procedure for: rtwdemo_roll
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_roll	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 12.188s

Now, `rtwdemo_roll.h` does not define a structure for block inputs and outputs. For all of the internal signals in the model, the optimizations either eliminated storage or created local function variables instead of global structure fields.

The optimizations were not able to eliminate storage for the three block states, so the file continues to define the `DWork` structure type.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,...
 /* Block states (default storage) for system','} DW_rtwdemo_roll_T;',1,1)

/* Block states (default storage) for system '<Root>' */
typedef struct {
 real32_T FixPtUnitDelay1_DSTATE; /* '<S4>/FixPt Unit Delay1' */
 real32_T Integrator_DSTATE; /* '<S1>/Integrator' */
 int8_T Integrator_PrevResetState; /* '<S1>/Integrator' */
} DW_rtwdemo_roll_T;
```

The code generated for the Discrete-Time Integrator block now stores state and output data only in the `DWork` structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,/* Update for DiscreteIntegrator: '<S1>/Integrator''',...
 /* End of Update for DiscreteIntegrator: '<S1>/Integrator' */',1,1)

/* Update for DiscreteIntegrator: '<S1>/Integrator' incorporates:
 * Gain: '<S1>/IntGain'
 */
rtwdemo_roll_DW.Integrator_DSTATE += 0.5F * rtb_TKSwitch * 0.025F;
if (rtwdemo_roll_DW.Integrator_DSTATE >= 5.0F) {
 rtwdemo_roll_DW.Integrator_DSTATE = 5.0F;
} else if (rtwdemo_roll_DW.Integrator_DSTATE <= -5.0F) {
 rtwdemo_roll_DW.Integrator_DSTATE = -5.0F;
}

rtwdemo_roll_DW.Integrator_PrevResetState = (int8_T)rtb_NotEngaged_f;
```

The optimizations also eliminated storage for the block parameters in the model. For example, in the Discrete-Time Integrator block, the **Upper saturation limit** and **Lower saturation limit** parameters are set to `intLim` and `-intLim`. `intLim` is a `Simulink.Parameter` object that stores the value 5. In the code generated for the Discrete-Time Integrator, these block parameters and `intLim` appear as inlined literal numbers `5.0F` and `-5.0F`.

If a model contains a parameter that the code generator cannot inline directly (for example, an array parameter), the code defines a structure type that represents the data. This *constant parameters* structure uses the `const` storage type qualifier, so some build toolchains can optimize the assembly code further.

The declaration of the structure, `ConstParam__model_`, is in `model.h`.

```
/* Constant parameters (auto storage) */
typedef struct {
 /* Expression: [1 2 3 4 5 6 7]
 * Referenced by: '<Root>/Constant'
 */
 real_T Constant_Value[7];

 /* Expression: [7 6 5 4 3 2 1]
 * Referenced by: '<Root>/Gain'
 */
 real_T Gain_Gain[7];
} ConstParam_model;
```

The declaration of the constant parameters, `model_ConstP`, is in `model_data.c` by default.

```
/* Constant parameters (auto storage) */
const ConstParam_model model_ConstP = {
 /* Expression: [1 2 3 4 5 6 7]
 * Referenced by: '<Root>/Constant'
 */
 { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0 },

 /* Expression: [7 6 5 4 3 2 1]
 * Referenced by: '<Root>/Gain'
 */
 { 7.0, 6.0, 5.0, 4.0, 3.0, 2.0, 1.0 }
};
```

`model_ConstP` is passed as an argument to referenced models.

## Local Variables in the Generated Code

When you select the optimization **Configuration Parameters > Enable local block outputs**, the code generator attempts to yield more efficient code by representing internal signals as local variables instead of fields of a global structure. If the memory consumed by local variables risks exceeding the stack space available on your target hardware, consider indicating the maximum stack size by setting **Configuration Parameters > Maximum stack size (bytes)**. For more information, see “Maximum stack size (bytes)”.

## Appearance of Test Points in the Generated Code

A *test point* is a signal that is stored in a unique memory location. For information about including test points in your model, see “Configure Signals as Test Points”.

When you generate code for models that include test points, the build process allocates a separate memory buffer for each test point. By default, test points are stored as members of a standard data structure such as `model_B`.

If you have Embedded Coder:

- You can control the default representation of test points by specifying code generation settings for the **Internal data** category of data in the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 32-16).
- You can specify that the build process ignore test points in the model, allowing optimal buffer allocation, by using the “Ignore test point signals” parameter. Ignoring test points facilitates transitioning from prototyping to deployment and avoids accidental degradation of generated code due to workflow artifacts. See “Ignore test point signals”.

Virtual buses do not appear in generated code, even when associated with a test point. To display a bus in generated code, use a nonvirtual bus or a virtual bus converted to a nonvirtual bus by a Signal Conversion block.

## Appearance of Workspace Variables in the Generated Code

Workspace variables are variables that you use to specify block parameter values in a model. Workspace variables include numeric MATLAB variables and `Simulink.Parameter` objects that you store in a workspace, such as the base workspace, or in a data dictionary.

When you set **Default parameter behavior** to `Tunable`, by default, workspace variables appear in the generated code as tunable fields of the global parameters structure. If you use such a variable to specify multiple block parameter values, the variable appears as a single field of the global parameters structure. The code does not create multiple fields to represent the block parameters. Therefore, tuning the field value during code execution changes the mathematical behavior of the model in the same way as tuning the value of the MATLAB variable or parameter object during simulation.

If you have Embedded Coder, you can control the default representation of workspace variables by specifying code generation settings for categories of parameter data in the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 32-16).

- The **Model parameters** category applies to variables that you store in a model workspace.
- The **External parameters** category applies to variables that you store in the base workspace or a data dictionary.

## Promote Internal Data to the Interface

By default, the code generator assumes that other systems and components in your application do not need to access internal data. For example, internal data are subject to optimizations that can eliminate them from the generated code. For prototyping and testing purposes, you can access internal data by clearing the optimizations or by configuring test points and applying storage classes

(see “Preserve Variables in Generated Code” on page 33-2). For optimized production code, configure individual data items to appear in the generated code as part of the model interface.

### Data That You Can Promote

Depending on the reentrancy of the generated code, that is, the setting that you choose for **Code interface packaging**, you can configure each data item in a model to participate in the interface by appearing in the code as one of these entities:

- A global symbol, such as a global variable or a call to a specialized function
- A formal parameter (argument) of the generated entry-point functions

The table shows the mechanisms that each category of data can use to participate in the interface.

Category of Data	Appear as Global Symbol	Appear as Argument of Entry-Point Function
Root-level Inport or Outport block	Only for a nonreentrant model.	Yes.
Signal connecting two blocks	Only for a nonreentrant model.	Only for a reentrant model and only as a field of a structure.  Alternatively, connect the signal to a root-level Outport block.
Block state	Only for a nonreentrant model.	Only for a reentrant model and only as a field of a structure.
Data store such as a Data Store Memory block	Yes.	Only for a reentrant model and only as a field of a structure.
Block parameter or parameter object such as <code>Simulink.Parameter</code>	Yes.	Only as a field of a structure.

### Single-Instance Algorithm

For a single-instance algorithm (you set **Code interface packaging** to `Nonreusable function`), apply storage classes directly to individual data items by using the Model Data Editor or the Property Inspector. With a directly applied storage class, a data item appears in the code as a global symbol such as a global variable. The storage class also prevents optimizations from eliminating storage for the data item.

You can apply storage classes to signals, block states, and block parameters. (For block parameters, you apply storage classes indirectly through parameter objects such as `Simulink.Parameter`). However, for a signal, consider connecting the signal to an Outport block at the root level of the model. Then, optionally, you can apply a storage class to the block. In the block diagram, the Outport block shows that the signal represents a system output.

For more information about storage classes, see “C Code Generation Configuration for Model Interface Elements” on page 32-2.

## Reentrant Algorithm

For a reentrant algorithm (you set **Code interface packaging** to `Reusable` function), use different techniques to configure data items to appear in the code as formal parameters (arguments) of the generated entry-point functions.

- For an internal signal, directly apply the storage class `Model default` (see “C Code Generation Configuration for Model Interface Elements” on page 32-2). If you have Embedded Coder, in the Code Mapping Editor, for the **Internal data** category, set the default storage class to `Default` or to a structured storage class that you define in an Embedded Coder Dictionary (see “Create Code Definitions for Use in the Code Mappings Editor” on page 31-2). Alternatively, configure the signal as a test point (see “Appearance of Test Points in the Generated Code” on page 33-65). By default, the signal appears as a field of one of the standard data structures (see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49). If you do not want the signal to appear in production code, use a test point so that you can later select the model configuration parameter **Ignore test point signals**.

Alternatively, connect the signal to an Outport block at the root level of the model. Connecting the signal to a root-level Outport block prevents optimizations from eliminating the signal from the code. To help with signal routing in a large model, use Goto and From blocks.

- For a block parameter, create a parameter object such as `Simulink.Parameter` and directly apply a storage class other than `Auto` to the object. The storage class prevents optimizations from inlining the parameter value in the code.

With the storage class, the parameter is shared between instances of the model, which are calls to the entry-point functions. The functions access the parameter data directly, as a global symbol, not an argument. You cannot configure a parameter to appear in the code as an argument, so you cannot enable each instance of the model to use a different value for the parameter.

For information about applying storage classes, see “C Code Generation Configuration for Model Interface Elements”.

## Control Default Representation of Internal Data (Embedded Coder)

By default, the code generator aggregates internal data that optimizations cannot eliminate, such as most state data, into standard structures such as the `DWork` structure. With Embedded Coder, you can control how the generated code stores this data.

### Control Placement of Data in Memory by Inserting Pragmas

Use the Code Mapping Editor to specify a default memory section for each category of data such as states and signals (**Internal data**). In the generated code, your custom pragmas or other decorations surround the data definitions and declarations.

You can also partition the structures according to atomic subsystems in your model so that you can specify different default memory sections for the data of subroutines and other algorithmic subcomponents.

For more information, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

### Control Names of Types, Fields, and Global Variables for Standard Data Structures

You can control some characteristics of the standard data structures. For more information, see “Control Data Type Names in Generated Code” on page 35-2.

For additional control over structure characteristics, such as placement in generated code files, create your own structured storage class by using the Embedded Coder Dictionary. Then, apply the storage class to categories of data by using the Code Mapping Editor. The storage class removes the data from the standard structures, creating other structures that you can more finely control. For more information about applying default storage classes to categories of data, see “Configure Default Code Generation for Data” on page 32-16. For more information about creating a storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2.

### Organize Data into Structures According to Subcomponents

- In the standard data structures, to create substructures that contain the data for a single-instance (nonreentrant) subroutine or subcomponent, use an atomic subsystem to encapsulate the corresponding blocks. In the subsystem parameters, set **Function packaging** to `Reusable function`. For more information, see “Generate Modular Function Code for Nonvirtual Subsystems” on page 40-2.

Alternatively, encapsulate the blocks in a model and use a Model block. In the referenced model, set **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** to `Multiple`. For more information, see “Generate Code for Model Reference Hierarchy” on page 5-2.

- To create separate, standalone structures that contain the data for a multi-instance (reentrant) subroutine or subcomponent, in the model, use an atomic subsystem to encapsulate the corresponding blocks. In the subsystem parameters, set **Function packaging** to `Nonreusable function` and select **Function with separate data**. For more information, see “Generate Modular Function Code for Nonvirtual Subsystems” on page 40-2.

Alternatively, encapsulate the blocks in a model and use a Model block. In the referenced model, choose one of these techniques:

- Set **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** to `One`. For more information, see “Generate Code for Model Reference Hierarchy” on page 5-2.
- Set **Total number of instances allowed per top model** to `Multiple` and create a structured storage class by using an Embedded Coder Dictionary. Then, apply the storage class to categories of data by using the Code Mapping Editor. To create a storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2. To apply the storage class to categories of data, see “Configure Default Code Generation for Data” on page 32-16.

### Organize Signal and Parameter Data into Meaningful, Custom Structures and Substructures

To organize arbitrary signals and parameters into custom structures and substructures, create nonvirtual bus signals and parameter structures. Optionally, to prevent optimizations from eliminating the data from the code, set the storage class of a bus signal or parameter structure to a value other than `Auto` (the default setting).

As you add blocks to the model, you must explicitly place each new signal and parameter into a bus or a structure.

For more information, see “Organize Data into Structures in Generated Code” on page 33-145.

### **Create Separate Global Variables Instead of Structure Fields**

To make a category of internal data appear in the generated code as separate, unstructured global variables instead of fields of a standard data structure, apply an unstructured storage class to the data category by using the Code Mapping Editor. For example, apply the storage class `ExportedGlobal`. However, if you generate multi-instance, reentrant code by setting the configuration parameter **Code interface packaging** to a value other than `Nonreusable function`, you cannot use this technique for some categories of data (see “Storage Classes and Reentrant, Multi-Instance Models and Components”).

To apply default storage classes to categories of data by using the Code Mapping Editor, see “Configure Default Code Generation for Data” on page 32-16. To choose a storage class, see “Choose Storage Class for Controlling Data Representation in Generated Code”.

## Choose Data Configuration Approach

When you generate code from a model, the code includes design data such as signals, states, and parameters, which your application code can read from and write to. When deciding how you want this data represented in the generated code, consider:

- What types of data elements do I want to use in my model?
- Where do I want to store the data?
- What are my code generation objectives?
- How can I configure the data to meet my code generation objectives?

The answers to these questions depend on your model architecture (standalone model, standalone hierarchy of referenced models, or a system of components), your application type (reentrant or single-instance), and whether you are integrating your code with existing external code.

### Data Element Categories

The possible data elements in your model fall under the data element types listed in this table.

Data Element Type	Description
Inports	Root-level input ports of a model, such as Inport and Bus Element In blocks.
Outports	Root-level output ports of a model, such as Outport and Bus Element Out blocks.
Model-scoped parameters	<ul style="list-style-type: none"> <li>• Model parameter arguments — Variables in the model workspace that you configure as model arguments. These parameters are exposed at the model block to enable the parent model to provide different values for each model instance.</li> <li>• Model parameters — Parameters that are defined in the model workspace. Unlike model arguments, these parameters are shared by each instance of the model.</li> </ul>
External parameters	Parameters that you define as objects in the base workspace or in a data dictionary. Multiple models in an application can use these parameters.

Data Element Type	Description
Data stores	<ul style="list-style-type: none"> <li>• Internal data (local data stores) — Data stores that are accessible from anywhere in a subsystem hierarchy that is at or below the level at which you define the data store. Defined graphically in a model by including a Data Store Memory block or by creating a signal object in the model workspace.</li> <li>• Global data stores — Data stores that are defined by a signal object in the base workspace or in a data dictionary. Multiple models in an application can use these data stores.</li> <li>• Shared local data stores — Data Store Memory blocks that have the block parameter <b>Share across model instances</b> set. These data stores are accessible only in the system where the Data Store Memory block is located. The data store value is shared across instances of the model.</li> </ul>
Internal data	Local data, such as internal signals and block states. Includes local data stores.
Constants	Constant parameters and constant-value block output in a model.

The code configuration options available for your data are dependent on the category of data that you are configuring. Where you store the data determines if you configure it by using a data object or by using a code mapping that is saved with the model.

## Where to Store Data Elements Used by Your Model

Where you store data for your model can depend on the type of model architecture that you are using and your modeling goals:

- MATLAB base workspace — Used for the temporary storage of data while experimenting with modeling techniques.
- Model workspace — Used to permanently store data that is local to a single model. Because the data is stored with the model, using this workspace can improve model portability. The model workspace is predominantly used to store parameters, arguments, and numeric variables. These elements are not typically stored in the model workspace:
  - Signal objects — You cannot configure a signal object in the model workspace for code generation. You do not need to define a signal object to configure a signal for code generation.
  - Data type objects.
- Simulink data dictionary — Used to permanently store global data, data types, and data that is shared between models.

For more information, see “Determine Where to Store Variables and Objects for Simulink Models”.

## When to Configure a Data Element for Code Generation

Whether you customize the generation of your data for code generation depends on your objectives for the generated code. If you choose not to configure customizations, the code generator determines whether to eliminate or change the representation of the data in generated code for optimization purposes.

There are many reasons you might choose to configure a data item. Configuring data prevents optimizations that might eliminate the data item from the generated code and enables you to configure how the generated code stores and defines the data item. For example, if you configure a data item, you can:

- Tune parameters.
- Monitor signals and states during execution.
- Configure data placement in memory.
- Exchange data with external code.
- Improve readability and traceability of generated code.

## Configure a Data Element for Code Generation

To configure your data for code generation, apply a storage class. A storage class is a code generation setting that enables you to control the appearance and placement of a data element in the generated code and prevents optimizations that might eliminate storage for that data element. You can use storage classes available with Simulink Coder and Embedded Coder. If you have special requirements that are not met by these storage classes and you are generating code for an ERT-based target, you can define and use a new storage class. For more information on storage classes and storage class properties, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.

### When to Configure Data by Using a Data Object

For most model-owned data, you can map a storage class directly to a data item by using the Code Mappings editor or code mapping API. You must configure some data that your model uses for code generation by using a data object, including:

- Parameters — Includes parameters in the base workspace, model workspace, or data dictionary. Configure parameters by using a `Simulink.Parameter` object.
- Global data stores — Configure by using a signal object.

Before configuring numeric variables for code generation, you must convert them to `Simulink.Parameter` objects.

### Configure Model-Owned Data by Using Code Mapping

Model-owned data consists of output blocks, signal lines, block states, data stores, and parameter objects in the model workspace. For this data, you can map a storage class to a data element in the coder app by using the Code Mappings editor or by using the code mappings API. For convenience, you can also configure external data objects in the Code Mappings editor, though for external data objects, the storage class is stored on the data object and not in the model. To see these objects, in the editor, click the **Refresh** link to the right of the category name.

To configure model-owned data, you first configure default code generation settings for categories of data elements. Using a default mapping saves time and reduces the risk of introducing errors in the code, especially when your model contains a significant number of elements in a particular category.

- In the **C Code** tab, select **Code Interface > Default Code Mappings**.
- On the **Data Defaults** tab, select a data category, then select a default storage class for that category. If you do not specify a storage class for a category, the `Default` storage class applies. In

this case, the code generator places the code for the category of data elements in standard structures. Other storage class options include:

- Relevant built-in storage classes, such as `ExportedGlobal`.
- Relevant storage classes in an available package, such as `ImportFromFile` (requires Embedded Coder).
- Storage classes defined in an Embedded Coder Dictionary (requires Embedded Coder). For more information on available storage classes, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.
- In the Property Inspector, configure the properties for that storage class. (For example, header and definition files).

For more information, see “C Code Generation Configuration for Model Interface Elements” on page 32-2.

For certain categories of data, including inports, outports, data stores, and block states, the default mapping is likely the only configuration you need to perform. But for data elements such as parameters and internal signals, you might need to specify an individual mapping to prevent the data from being optimized away. To apply a storage class to an individual data element:

- In the Code Mappings editor, find the data element on its corresponding category tab (for example, to configure an individual parameter, select the **Parameters** tab).
- Select a storage class for the data element. To apply the default configuration, select the storage class `Model default`.
- In the Property Inspector, configure the properties for that storage class. (For example, header and definition files).

For more information, see “C Code Generation Configuration for Model Interface Elements” on page 32-2.

### Configure External Data

Configure external data objects for code generation by using the Code Mappings editor or the Model Explorer. Select a data object in the **Contents** pane. Then, in the **Dialog** pane, on the **Code Generation** tab, select a storage class and set properties for that storage class. For convenience, you can also configure external data objects in the Code Mappings editor. To view and configure these objects, in the editor, click the **Refresh** link to the right of the category name.

You can configure external data objects programmatically. For example, to configure a `Simulink.Parameter` object for code generation by applying the storage class `ExportedGlobal`, you can use code similar to:

```
P = Simulink.Parameter;
P.Value = 5;
P.DataType = 'int32';
P.CoderInfo.StorageClass = 'ExportedGlobal';
```

### Load Storage Class Packages into Embedded Coder Dictionary

To apply a storage class from a storage class package other than Simulink (such as a package that you create):

- 1 Open the **Embedded Coder** app.

- 2 Open the Embedded Coder Dictionary. On the **C Code** tab, select **Code Interface > Embedded Coder Dictionary**.
- 3 In the Embedded Coder Dictionary, click **Storage Class**.
- 4 Below the **Storage Classes** table, click **Manage Packages**.
- 5 In the Manage Packages dialog box, select a package. If the package of interest is not in the list, click **Refresh**. Then, select your package.
- 6 Click **Load**.
- 7 Close the Embedded Coder Dictionary.
- 8 Use the Code Mappings editor or code mappings API to configure the model's interface elements.

For more information, see **Embedded Coder Dictionary**, **Code Mappings Editor - C**, and `coder.mapping.api.CodeMapping`.

To apply the storage class by using a data object (required parameters), instead of creating a `Simulink.Signal` or `Simulink.Parameter` object, create a `myPackage.Signal` or `myPackage.Parameter` object. To create data objects from your package, see “Create Data Objects from Another Data Class Package”. For an example that shows how to create and apply your own storage class, see “Create and Apply a Storage Class” on page 37-14.

## Choose Storage Class for Controlling Data Representation in Generated Code

A storage class is a code generation setting that you apply to data, such as parameters, signals, and states. During code configuration, use a storage class to control the appearance and placement of a data element in the generated code and to prevent optimizations from eliminating storage for that data element.

For model data, you can apply a storage class directly to a model data element by using the Code Mappings editor or code mappings API. Using either the editor or the API, apply a default storage class for categories of data, and then override that setting, as needed, for individual data elements.

For external data, you apply a storage class to a data object by using the Model Explorer or programmatically by using functions such as `get_param` and `set_param`.

Once you have specified a storage class for an element or category of elements, you can set properties for that storage class, such as header files, definition files, and memory sections.

### Storage Class Properties

The property settings for a storage class define how and where the code generator represents data in the generated code. The properties that the user of a storage class can configure vary depending on the storage class. For most individual elements, the user can configure an identifier for naming the data element in the code. To identify properties that the user can configure for predefined storage classes, see the following information on specific storage classes.

When you create a storage class by using the Custom Storage Class Designer, you can choose whether the user of the storage class can specify additional settings. See “Allow Users of Storage Class to Specify Property Value” on page 37-18.

### Default Storage Class

By default, the storage class for an individual data element is `Auto`. By using this default value, you are choosing to have the code generator handle storage class selection and application. In this case, the data element is subject to code generation optimizations, which can eliminate the element from the code or change the representation of the element. If optimizations do not eliminate the data element, the element appears as a field of a standard data structure in the generated code.

When using the Code Mappings editor or the code mappings API, a data element configured with storage class `Auto` that is not eliminated by optimizations acquires the default code generation settings for the corresponding data category. If you do not specify a code configuration for a category of data elements, the storage class is `Default`. When a data element category is using this storage class, data elements in that category appear as a field of a standard data structure in the generated code.

### Built-in and Predefined Storage Classes

To prevent optimizations from eliminating storage for a data element, you can choose a storage class for the element based on your code generation requirements. Available storage classes include built-in storage classes, predefined storage classes in the `Simulink` package, and might also include other project-specific storage classes defined in an Embedded Coder Dictionary. If you have special

requirements that are not met by the listed storage classes and you are generating code for an ERT-based target, you can define and use a new storage class. See “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2 and “Create Storage Classes by Using the Custom Storage Class Designer” on page 37-14.

For Simulink Coder, you can choose from these built-in and predefined storage classes.

<b>Requirements</b>	<b>Storage Class</b>
Enable optimizations, potentially generating more efficient code.	“Auto” on page 33-77 (Individual data elements)
For data elements that cannot be optimized away, represent data as a field of a standard data structure.	“Default” on page 33-77 (Default mapping)
Prevent optimizations from eliminating storage for a data element.	“Model Default” on page 33-77 (Individual mapping)
Access data from a standalone global variable. Generated code contains the variable declaration and definition.	“ExportedGlobal” on page 33-78
Access data from a standalone global variable. Generated code contains the variable declaration. Your external code provides the definition.	“ImportedExtern, ImportedExternPointer” on page 33-78

If you have Embedded Coder, you can choose from these additional predefined storage classes available in the Simulink package.

<b>Requirements</b>	<b>Storage Class</b>
Prevent optimizations from eliminating storage for a data element.	“Dictionary Default” on page 33-77 (Default mapping)
Generate standalone variables.	<ul style="list-style-type: none"> <li>• “ExportToFile” on page 33-80</li> <li>• “ImportFromFile” on page 33-82</li> <li>• “FileScope” on page 33-81</li> <li>• “Localizable” on page 33-82</li> <li>• “Reusable” on page 33-83</li> <li>• “Const, Volatile, and ConstVolatile” on page 33-79</li> </ul>
Generate variables as fields of a structure.	<ul style="list-style-type: none"> <li>• “Struct” on page 33-83</li> <li>• “Bitfield” on page 33-79</li> </ul>
Generate variables that have a value that is fixed during code compilation.	<ul style="list-style-type: none"> <li>• “Define, ImportedDefine” on page 33-80</li> <li>• “CompilerFlag” on page 33-79</li> </ul>
Generate variables that you access through a function call.	“GetSet” on page 33-81
Generate variables for single-instance data and generate structures for multi-instance data.	“MultiInstance” on page 33-83

These storage classes are examples of storage classes that you can add to an Embedded Coder Dictionary. These examples are defined and made available when you prepare a model for code generation by using the Quick Start tool.

Requirements	Storage Class
Generate global structures that contain parameter data and signal or state data.	"ParamStruct, SignalStruct" on page 33-84

## Auto

When you select this storage class, the code generator handles how to represent the data in the generated code and can enable optimizations to operate on the data element, potentially generating more efficient code.

**Auto** is the default storage class setting for each data element in a model. The data element is subject to code generation optimizations, which can eliminate the element from the code or change the representation of the element. For information about these optimizations, such as those on the **Configuration Parameters > Code Generation > Optimization** pane, see "How Generated Code Stores Internal Signal, State, and Parameter Data".

Optimizations cannot eliminate some data, such as most block states, from the code. The remaining data acquires a default storage class that you specify on the **Data Defaults** tab of the Code Mappings editor (see "Configure Default Code Generation for Data" on page 32-16). If a data element cannot be eliminated, the name of the element in the code is based on naming rules that you specify by using model configuration parameters. See "Identifier Format Control" on page 52-17—requires Embedded Coder.

## Default

On the **Data Defaults** tab of the Code Mappings editor, **Default** is the default storage class setting for each data element category. If you leave the storage class setting for a category at this value, data elements that are not subject to code generation optimizations appear as a field of a standard data structure. See "How Generated Code Stores Internal Signal, State, and Parameter Data" on page 33-49.

## Model Default

When you configure an individual data element for code generation, use the **Model Default** storage class to prevent optimizations from eliminating storage for a data element. See "How Generated Code Stores Internal Signal, State, and Parameter Data". With this storage class setting, the data element acquires the default storage class that you specify for the corresponding data category on the **Data Defaults** tab of the Code Mappings editor. The name of the data element in the code is the same as the name in the model.

## Dictionary Default

In Embedded Coder, if you link a model to a data dictionary, which includes a coder dictionary that configures default code definitions for categories of data, you can use the Code Mappings editor to apply the dictionary defaults. On the **Data Defaults** tab, select a category, then set the storage class to **Dictionary Default**. For more information on configuring a default code mapping in a coder dictionary, see "Configure Default Code Mapping in a Shared Dictionary" on page 31-10.

## ExportedGlobal

Use this built-in storage class to generate a global variable definition and declaration. By default, the name of the variable is the name of the data element. The code declares the variable in the generated file `model.h`, which you can include (`#include`) in your external code. The code generator does not optimize this global variable from the generated code.

When you use this storage class, you can also configure this property.

Property	Description
Identifier	Identifier string that the code generator uses to name the data element in the generated code.

For an example that uses this storage class, see “C Code Generation Configuration for Model Interface Elements”.

## ImportedExtern, ImportedExternPointer

To make a data element in a model represent a global variable that your external code defines, use the built-in storage class `ImportedExtern`. The generated algorithmic code uses the variable without defining it.

Generate code that reads from and writes to a global variable defined by your external code. The generated code declares the variable in the generated file `model_private.h` so that the model entry-point functions can read and write to the variable.

For example, you can apply the storage class `ImportedExtern` to a signal line, block state, or parameter object. For imported data:

- The generated code does not initialize parameter data. Your code must initialize imported parameter data.
- The generated initialization functions dynamically initialize some signal and state data. Unlike data that the generated code allocates, the code does not initialize imported signal or state data to a stored value of zero. Instead, the code immediately initializes the data to the real-world nonzero value that you specify in Simulink.

---

**Note** The code generator initializes zero values that you specify in an Initialize Function block, even if those values have imported scope.

---

When your external code defines a data element and provides a pointer for accessing that data, use `ImportedExternPointer`. The generated code reads from and writes to that pointer. The generated code declares the variable in the generated file `model_private.h` and reads and writes to the data by dereferencing the pointer.

When you use these storage classes, you can also configure this property.

Property	Description
Identifier	Identifier string that the code generator uses to name the data element in the generated code.

## Bitfield

Use this storage class to generate a structure that stores Boolean data in named bit fields.

When you use this storage class, you can also configure these properties.

Property	Description
Identifier	Identifier string that the code generator uses to name the data element in the generated code.
StructName	Name of the structure for the data element in the generated code.

For an example that uses this storage class, see “Bitfields” on page 25-69.

## CompilerFlag

Use this storage class to support preprocessor conditionals defined by using a compiler flag or option.

If you build the generated code by using Embedded Coder, to specify the compiler option, you can use the model configuration parameter **Configuration Parameters > Code Generation > Custom Code > Code information > Defines**. See Code Generation Pane: Custom Code: Additional Build Information: Defines.

When you use this storage class, you can also configure this property.

Property	Description
Identifier	Identifier string that the code generator uses to name the data element in the generated code.

For an example that uses this storage class, see “Generate Preprocessor Conditionals for Variant Systems” on page 26-32.

## Const, Volatile, and ConstVolatile

Use these storage classes to generate a global variable definition and declaration with the `const`, `volatile`, or `const` and `volatile` type qualifiers.

When you use these storage classes, you can also configure these properties.

Property	Description
Identifier	Identifier string that the code generator uses to name the data element in the generated code.
HeaderFile	Source header file that contains declarations for global data read by the data element and external code.
DefinitionFile	Source definition file that contains definitions for global data read by the data element and external code.
Owner	Owner of global data that is defined with the code generated for one of multiple components that use that data.

Property	Description
PreserveDimensions	When model configuration parameter <b>Array layout</b> is set to Row-major, a flag that indicates whether to preserve dimensions of a data element that is represented in generated code as a multidimensional array.

For an example that uses this storage class, see “Type Qualifiers” on page 25-12.

## Define, ImportedDefine

Use the Define storage class to generate a macro (`#define` directive) such as `#define myParam 5`.

Use ImportedDefine to generate code that uses a macro (`#define` directive) defined in a header file in your external code. For an example, see “Macro Definitions (`#define`)” on page 25-54.

When you use these storage classes, you can also configure these properties.

Property	Description
Identifier	Identifier string that the code generator uses to name the data element in the generated code.
HeaderFile	Source header file that contains declarations for global data that is read by the data element and external code.

For an example that uses this storage class, see “Macro Definitions (`#define`)” on page 25-54.

## ExportToFile

Generate a global variable definition and declaration to an external file. You can specify the name and placement of the files that define and declare the variable. See “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2.

When you use this storage class, you can also configure these properties.

Property	Description
Identifier	Identifier string that the code generator uses to name the data element in the generated code.
HeaderFile	Source header file where the code generator places the declarations for global data read by the data element and external code.
DefinitionFile	Source definition file where the code generator places the definitions for global data read by the data element and external code.  The code generator honors this setting only for single-instance models. The setting is ignored for reusable multi-instance models because the data definition is handled at the parent level.

Property	Description
Owner	A component in the model hierarchy where the code generator places a global data definition instead of placing it in the top component of the hierarchy. Requires that you set the model configuration parameter <b>Use owner from data object for data definition placement</b> .
PreserveDimensions	When model configuration parameter <b>Array layout</b> is set to Row-major, a flag that indicates whether to preserve dimensions of a data element that is represented in generated code as a multidimensional array.

For an example that uses this storage class, see “Definition, Initialization, and Declaration of Parameter Data” on page 25-5.

## FileScope

Use this storage class to generate a global variable definition and declaration that has the `static` type qualifier. In the generated code, the scope of the variable is limited to the current file, which is typically `model.c`.

In a model reference hierarchy, if a referenced model uses a parameter object (such as `Simulink.Parameter`) that you create in the base workspace or a data dictionary, you cannot apply `FileScope` to the object. As a workaround, move the parameter object into the model workspace of the referenced model. Then, you can use `FileScope`.

When you use this storage class, you can also configure these properties.

Property	Description
Identifier	Identifier string that the code generator uses to name the data element in the generated code.
PreserveDimensions	When model configuration parameter <b>Array layout</b> is set to Row-major, a flag that indicates whether to preserve dimensions of a data element that is represented in generated code as a multidimensional array.

## GetSet

Use this storage class to generate code that interacts with data by calling custom accessor functions. Your external code defines the data and provides the function definitions.

When you use this storage class, you can also configure these properties.

Property	Description
Identifier	Identifier string that the code generator uses to name the data element in the generated code.
HeaderFile	Source header file that contains declarations for global data that is read by the data element and external code.

Property	Description
GetFunction	Data element that appears in the generated code as a call to a specified <code>get</code> function
SetFunction	Data element that appears in the generated code as a call to a specified <code>set</code> function

For an example that uses this storage class, see “Access Data Through Functions with Storage Class `GetSet`” on page 37-25.

## ImportFromFile

Use this storage class to generate code that reads from and writes to a global variable defined by your external code. `ImportFromFile` is similar to `ExportToFile`, but the generated code does not define the variable.

When you use this storage class, you can also configure these properties.

Property	Description
Identifier	Identifier string that the code generator uses to name the data element in the generated code.
HeaderFile	Source header file that contains declarations for global data that is read by the data element and external code. To avoid linker errors, you must add include guards to the beginning of the header file.
PreserveDimensions	When model configuration parameter <b>Array layout</b> is set to <code>Row-major</code> , a flag that indicates whether to preserve dimensions of a data element that is represented in generated code as a multidimensional array.

For an example that uses this storage class, see “Integrate External Application Code with Code Generated from PID Controller” on page 37-45.

## Localizable

For signals, if possible, minimize the use of global storage by using local variables.

- If the variable is used in a single function, the variable is local to that function.
- If the variable is used in a single file, the variable is local to that file.
- If the variable is used in more than one function or file, the variable is a global.

Generating local variables prevents the code generator from removing the variables from the generated code.

When you use this storage class, you can also configure these properties.

Property	Description
Identifier	Identifier string that the code generator uses to name the data element in the generated code.

Property	Description
PreserveDimensions	When model configuration parameter <b>Array layout</b> is set to <b>Row-major</b> , a flag that indicates whether to preserve dimensions of a data element that is represented in generated code as a multidimensional array.

For an example that uses this storage class, see “Generate Local Variables with Localizable Storage Class” on page 37-62.

## Reusable

Use this storage class to reuse the same variable for multiple independent signals in a model. The code generator stores intermediate calculations of a data path (a series of connected blocks) in a single, reused global variable.

When you use this storage class, you can also configure this property.

Property	Description
Identifier	Identifier string that the code generator uses to name the data element in the generated code.

For an example that uses this storage class, see “Specify Buffer Reuse for Signals in a Path” on page 73-17.

## Struct

Use this storage class to generate a global structure with a name that you can specify.

When you use this storage class, you can also configure these properties.

Property	Description
Identifier	Identifier string that the code generator uses to name the data element in the generated code.
StructName	Name of the structure for the data element in the generated code.

For an example that uses this storage class, see “Organize Parameter Data into a Structure by Using Struct Storage Class” on page 32-67 and “Structures of Signals” on page 25-62.

## Multinstance

To generate unstructured variables for single-instance data and structures for multi-instance data, use this storage class. When you apply this storage class to a data item, the Embedded Coder Dictionary determines if it is a single-instance storage class or a multi-instance storage class. The dictionary determines the type of class by the type of data and by the context of the model within the model reference hierarchy. You can duplicate this storage class to create a copy that you can edit.

When you apply this storage class to an individual data element, you can also configure the **Identifier** property. The **Identifier** property is an identifier string that the code generator uses to name the data element in the generated code.

For an example that uses this storage class, see “Flexible Storage Class for Different Model Hierarchy Contexts” on page 31-28.

## ParamStruct, SignalStruct

Use these storage classes to generate global structures that contain parameter and signal or state data, respectively. In a hierarchy of components (referenced models or atomic subsystems), you can use these storage classes to create a corresponding hierarchy of structures. These storage classes appear in the Code Mappings editor only after preparing a model for code generation by using the Quick Start tool.

These storage classes are available only for model-owned data.

When you use these storage classes, you can also configure this property.

Property	Description
Identifier	Identifier string that the code generator uses to name the data element in the generated code.

## Storage Class Limitations

- When you use storage classes in the Code Mappings editor (Embedded Coder) or code mappings API, some limitations apply. See “Limitations” on page 32-11.
- Data objects cannot use an Embedded Coder storage class and a multiword data type.
- For Embedded Coder storage classes in models that use referenced models:
  - If you apply a grouped storage class, such as `Struct` or `Bitfield`, to multiple data items, you must set the storage class **Data scope** property to `Imported` and you must provide the data declaration in an external header file. Grouped storage classes use a single variable in the generated code to represent multiple data objects.
  - If a parameter object exists in the base workspace or a data dictionary, and a referenced model uses the object, you cannot apply the storage class `FileScope`. To apply this storage class to the parameter object, move the object into the model workspace of the referenced model.
- You cannot apply the storage class `FileScope` to data items used by a data exchange interface (C API, external mode, or ASAP2) or MAT-file logging. File-scoped data is not externally accessible.
- You cannot apply the storage class `FileScope` to data that is used in multiple files.

## Use Enumerated Data in Generated Code

### In this section...

“Enumerated Data Types” on page 33-85

“Specify Integer Data Type for Enumeration” on page 33-85

“Customize Enumerated Data Type” on page 33-86

“Control Enumerated Type Implementation in Generated Code” on page 33-90

“Type Casting for Enumerations” on page 33-91

“Enumerated Type Limitations” on page 33-91

## Enumerated Data Types

*Enumerated data* is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code. The following is a MATLAB class definition for an enumerated data type named `BasicColors`, which is used in the examples in this section.

```
classdef BasicColors < Simulink.IntEnumType
 enumeration
 Red(0)
 Yellow(1)
 Blue(2)
 end
end
```

For basic information about enumerated data types and their use in Simulink models, see “Use Enumerated Data in Simulink Models”. For information about enumerated data types in Stateflow charts, see “Define Enumerated Data Types” (Stateflow).

## Specify Integer Data Type for Enumeration

When you specify a data type for your enumeration, you can:

- Control the size of enumerated data types in the generated code by specifying a superclass.
- Reduce RAM/ROM usage.
- Improve code portability.
- Improve integration with legacy code.

You can specify these integer data types:

- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `Simulink.IntEnumType`. Specify values in the range of the signed integer for your hardware platform.

### Use a Class Definition in a MATLAB File

To specify an integer data type size, derive your enumeration class from the integer data type.

```
classdef Colors < int8
 enumeration
 Red(0)
 Green(1)
 Blue(2)
 end
end
```

The code generator generates this code:

```
typedef int8_T Colors;

#define Red ((Colors)0)
#define Green ((Colors)1)
#define Blue ((Colors)2)
```

### Use the Function `Simulink.defineIntEnumType`

To specify an integer data type size, specify the name-value pair `StorageType` as the integer data type.

```
Simulink.defineIntEnumType('Colors',{'Red','Green','Blue'},...
[0;1;2],'StorageType','int8')
```

The code generator generates this code:

```
typedef int8_T Colors;

#define Red ((Colors)0)
#define Green ((Colors)1)
#define Blue ((Colors)2)
```

### Customize Enumerated Data Type

When you generate code from a model that uses enumerated data, you can implement these static methods to customize the behavior of the type during simulation and in generated code:

- `getDefaultValue` — Specifies the default value of the enumerated data type.
- `getDescription` — Specifies a description of the enumerated data type.
- `getHeaderFile` — Specifies a header file where the type is defined for generated code.
- `getDataScope` — Specifies whether generated code exports or imports the enumerated data type definition to or from a separate header file.
- `addClassNameToEnumNames` — Specifies whether the class name becomes a prefix in generated code.

The first of these methods, `getDefaultValue`, is relevant to both simulation and code generation, and is described in “Specify a Default Enumerated Value”. The other methods are relevant only to code generation. To customize the behavior of an enumerated type, include a version of the method in the `methods(Static)` section of the enumeration class definition. If you do not want to customize the type, omit the `methods(Static)` section. The table summarizes the methods and the data to supply for each one.

Static Method	Purpose	Default Value Without Implementing Method	Custom Return Value
<code>getDefaultValue</code>	Specifies the default enumeration member for the class.	First member specified in the enumeration definition	A character vector containing the name of an enumeration member in the class (see “Instantiate Enumerations”).
<code>getDescription</code>	Specifies a description of the enumeration class.	' '	A character vector containing the description of the type.
<code>getHeaderFile</code>	Specifies the name of a header file. The method <code>getDataScope</code> determines the significance of the file.	' '	A character vector containing the name of the header file that defines the enumerated type.  By default, the generated <code>#include</code> directive uses the preprocessor delimiter " instead of < and >. To generate the directive <code>#include &lt;myTypes.h&gt;</code> , specify the custom return value as ' <code>&lt;myTypes.h&gt;</code> '.
<code>getDataScope</code>	Specifies whether generated code exports or imports the definition of the enumerated data type. Use the method <code>getHeaderFile</code> to specify the generated or included header file that defines the type.	'Auto'	One of: 'Auto', 'Exported', or 'Imported'.
<code>addClassNameToEnumNames</code>	Specifies whether to prefix the class name in generated code.	false	true or false.

### Specify a Description

To specify a description for an enumerated data type, include this method in the `methods(Static)` section of the enumeration class:

```
function retVal = getDescription()
% GETDESCRIPTION Optional description of the data type.
 retVal = 'description';
end
```

Substitute a MATLAB character vector for *description*. The generated code that defines the enumerated type includes the specified description.

### Import Type Definition in Generated Code

To prevent generated code from defining an enumerated data type, which allows you to provide the definition in an external file, include these methods in the `methods(Static)` section of the enumeration class:

```
function retVal = getHeaderFile()
% GETHEADERFILE Specifies the file that defines this type in generated code.
% The method getDataScope determines the significance of the specified file.
retVal = 'imported_enum_type.h';
end

function retVal = getDataScope()
% GETDATASCOPE Specifies whether generated code imports or exports this type.
% Return one of:
% 'Auto': define type in model_types.h, or import if header file specified
% 'Exported': define type in a generated header file
% 'Imported': import type definition from specified header file
% If you do not define this method, DataScope is 'Auto' by default.
retVal = 'Imported';
end
```

Instead of defining the type in `model_types.h`, which is the default behavior, generated code imports the definition from the specified header file using a `#include` statement like:

```
#include "imported_enum_type.h"
```

Generating code does not create the imported header file. You must provide the header file, using the file name specified by the method `getHeaderFile`, that defines the enumerated data type.

To create a Simulink enumeration that corresponds to your existing C-code enumeration, use the `Simulink.importExternalCTypes` function.

### Export Type Definition in Generated Code

To generate a separate header file that defines an enumerated data type, include these methods in the `methods(Static)` section of the enumeration class:

```
function retVal = getDataScope()
% GETDATASCOPE Specifies whether generated code imports or exports this type.
% Return one of:
% 'Auto': define type in model_types.h, or import if header file specified
% 'Exported': define type in a generated header file
% 'Imported': import type definition from specified header file
% If you do not define this method, DataScope is 'Auto' by default.
retVal = 'Exported';
end

function retVal = getHeaderFile()
% GETHEADERFILE Specifies the file that defines this type in generated code.
% The method getDataScope determines the significance of the specified file.
retVal = 'exported_enum_type.h';
end
```

Generated code exports the enumerated type definition to the generated header file `exported_enum_type.h`.

### Add Prefixes To Class Names

By default, enumerated values in generated code have the same names that they have in the enumeration class definition. Alternatively, your code can prefix every enumerated value in an enumeration class with the name of the class. You can use this technique to prevent identifier conflicts or to improve the readability of the code. To specify class name prefixing, include this method in the `methods(Static)` section of an enumeration class:

```

function retVal = addClassNameToEnumNames()
 % ADDCLASSNAME_TOENUMNAMES Specifies whether to add the class name
 % as a prefix to enumeration member names in generated code.
 % Return true or false.
 % If you do not define this method, no prefix is added.
 retVal = true;
end

```

Specify the return value as `true` to enable class name prefixing or as `false` to suppress prefixing. If you specify `true`, each enumerated value in the class appears in generated code as *EnumTypeName\_EnumName*. For the example enumeration class `BasicColors` in “Enumerated Data Types” on page 33-85, the data type definition in generated code might look like this:

```

#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef enum {
 BasicColors_Red = 0, /* Default value */
 BasicColors_Yellow = 1,
 BasicColors_Blue = 2,
} BasicColors;

#endif

```

The enumeration class name `BasicColors` appears as a prefix for each of the enumerated names.

### Control Use of Duplicate Enumeration Member Names

When you import the enumeration data from a header file, you can control the use of duplicate enumeration member names during code generation. Duplicate enumeration member names improve the readability of the code. Use the model configuration parameter **Duplicate enumeration member names** to allow duplicate enumeration member names in different enumeration types during code generation or to generate an error or a warning message. You can use duplicate enumeration member names only if two enumerations have the same `StorageType` and have these specifications:

- `DataScope` set to 'Imported'
- `StorageType` set to 'int8', 'int16', 'int32', 'uint8', or 'uint16'
- `Value` is the same

For example:

```

typedef int32_T enum {
 Red = 0,
 Yellow = 1,
 Blue = 2,
}A;

typedef int32_T enum {
 Black = 0,
 Yellow = 1,
 White = 2,
}B;

```

You can have a `Yellow` enumeration member in enumeration A and B without prefixing the member name with a class name to improve the readability of your code.

## Control Enumerated Type Implementation in Generated Code

Suppose that you define an enumerated type `BasicColors`. You can specify that the generated code implement the type definition by using:

- An `enum` block. The native integer type of your hardware is the underlying integer type for the enumeration members.
- A `typedef` statement and a series of `#define` macros. The `typedef` statement bases the enumerated type name on a specific integer data type, such as `int8`. The macros associate the enumeration members with the underlying integer values.

### Implement Enumerated Type by Using `enum` Block

To implement the type definition by using an `enum` block:

- In Simulink, define the enumerated type by using a `classdef` block in a script file. Derive the enumeration from the type `Simulink.IntEnumType`.
- Alternatively, use the function `Simulink.defineIntEnumType`. Do not specify the property `StorageType`.

When you generate code, the type definition appears in an `enum` block.

```
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef enum {
 Red = 0, /* Default value */
 Yellow,
 Blue,
} BasicColors;

#endif
```

### Implement Enumerated Type Using a Specific Integer Type

To implement the type definition using a `typedef` statement and `#define` macros:

- In Simulink, define the enumerated type using a `classdef` block in a script file. Derive the enumeration from a specific integer type such as `int8`.
- Alternatively, use the function `Simulink.defineIntEnumType`. Specify the property `StorageType` using a specific integer type such as `int8`.

When you generate code, the type definition appears as a `typedef` statement and a series of `#define` macros.

```
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef int8_T BasicColors;

#define Red ((BasicColors)0) /* Default value */
#define Yellow ((BasicColors)1)
#define Blue ((BasicColors)2)

#endif
```

By default, the generated file `model_types.h` contains enumerated type definitions.

## Type Casting for Enumerations

### Safe Casting

A Simulink Data Type Conversion block accepts a signal of integer type. The block converts the input to one of the underlying values of an enumerated type.

If the input value does not match an underlying value of an enumerated type value, Simulink inserts a safe cast to replace the input value with the enumerated type default value.

### Enable and Disable Safe Casting

You can enable or disable safe casting for enumerations during code generation for a Simulink Data Type Conversion block or a Stateflow block.

To control safe casting, enable or disable the **Saturate on integer overflow** block parameter. The parameter works as follows:

- **Enabled:** Simulink replaces a nonmatching input value with the default value of the enumerated values during simulation. The software generates a safe cast function during code generation.
- **Disabled:** For a nonmatching input value, Simulink generates an error during simulation. The software omits the safe cast function during code generation. In this case, the code is more efficient. However, the code may be more vulnerable to run-time errors.

### Safe Cast Function in Generated Code

This example shows how the safe cast function `int32_T ET08_safe_cast_to_BasicColors` for the enumeration `BasicColors` appears in generated code when generated for 32-bit hardware.

```
static int32_T ET08_safe_cast_to_BasicColors(int32_T input)
{
 int32_T output;
 /* Initialize output value to default value for BasicColors (Red) */
 output = 0;
 if ((input >= 0) && (input <= 2)) {
 /* Set output value to input value if it is a member of BasicColors */
 output = input;
 }
 return output;
}
```

Through this function, the enumerated type's default value is used if the input value does not match one of underlying values of the enumerated type's values.

If the block's **Saturate on integer overflow** parameter is disabled, this function does not appear in generated code.

## Enumerated Type Limitations

- Generated code does not support logging enumerated data.

### About Data Stores

A data store contains data that is accessible in a model hierarchy at or below the level in which the data store is defined. Data stores can allow subsystems and referenced models to share data without having to use I/O ports to pass the data from level to level. See “Data Stores with Data Store Memory Blocks” for information about data stores in Simulink. This section provides additional information about data store code generation.

### Generate Code for Data Store Memory Blocks

To control the code generated for a Data Store Memory block, apply a storage class to the data store. You can associate a Data Store Memory block with a signal object that you store in a workspace or data dictionary, and control code generation for the block by applying the storage class to the object:

- 1 On the **Modeling** tab, click **Model Data Editor**.
- 2 In the Model Data Editor, select the **Data Stores** tab.
- 3 Begin editing the name of the target Data Store Memory block by clicking the corresponding row in the **Name** column.
- 4 Next to the name, click the button  and select **Create and Resolve**.
- 5 In the Create New Data dialog box, set **Value** to `Simulink.Signal`. Optionally, use the **Location** drop-down list to choose a workspace for storing the resulting `Simulink.Signal` object.
- 6 Click **Create**. The `Simulink.Signal` object, which has the same name as the data store, appears in the target workspace. Simulink selects the block parameter **Data store name must resolve to Simulink signal object**.

When the property dialog box for the object opens, click **OK**.

- 7 In the **Simulink Coder** or **Embedded Coder** app, open the Code Mappings editor. In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
- 8 On the **Data Stores** tab, apply the target storage class.

---

**Note** When a Data Store Memory block is associated with a signal object, the mapping between the **Data store name** and the signal object name must be one-to-one. If two or more identically named entities map to the same signal object, the name conflict is flagged as an error at code generation time. See “Resolve Conflicts in Configuration of Signal Objects for Code Generation” for more information.

---

## Storage Classes for Data Store Memory Blocks

You can control how Data Store Memory blocks in your model are stored and represented in the generated code by assigning storage classes and type qualifiers. You do this in almost exactly the same way you assign storage classes and type qualifiers for block states.

Data Store Memory blocks, like block states, have `Auto` storage class by default, and their memory is stored within the `DWork` vector. The symbolic name of the storage location is based on the data store name.

You can generate code from multiple Data Store Memory blocks that have the same data store name, subject to the following restriction: *at most one* of the identically named blocks can have a storage class other than `Auto`. An error is reported if this condition is not met.

For blocks with `Auto` storage class, the code generator produces a unique symbolic name for each block to avoid name clashes. For Data Store Memory blocks with storage classes other than `Auto`, the generated code uses the data store name as the symbol.

In the following model, a Data Store Write block writes to memory declared by the Data Store Memory block `myData`:

To control the storage declaration for a Data Store Memory block, in the coder app, use the Code Mapping editor. On the **Data Stores** tab, select a **Storage Class** for the block.

Data Store Memory blocks are nonvirtual because code is generated for their initialization in `.c` and `.cpp` files and their declarations in header files. The following table shows how the code generated for the Data Store Memory block in the preceding model differs for different storage classes. The table gives the variable declarations and `MdlOutputs` code generated for the `myData` block.

Storage Class	Declaration	Code
Auto or Model default (when Code Mapping Editor specifies Default storage class)	<p>In <code>model.h</code></p> <pre>typedef struct D_Work_tag {     real_T myData; } D_Work;</pre> <p>In <code>model.c</code> or <code>model.cpp</code></p> <pre>/* Block states (auto storage) */ D_Work model_DWork;</pre>	<pre>model_DWork.myData = rtb_SineWave;</pre>

Storage Class	Declaration	Code
ExportedGlobal	In <i>model.c</i> or <i>model.cpp</i>  /* Exported block states */ real_T myData;  In <i>model.h</i>  extern real_T myData;	myData = rtb_SineWave;
ImportedExtern	In <i>model_private.h</i>  extern real_T myData;	myData = rtb_SineWave;
ImportedExternPointer	In <i>model_private.h</i>  extern real_T *myData;	(*myData) = rtb_SineWave;

For information about applying storage classes, see “C Code Generation Configuration for Model Interface Elements” on page 32-2.

For ERT models, you can preserve dimensions of multidimensional arrays in data stores. For more information, see “Preserve Dimensions of Multidimensional Arrays in Generated Code” on page 44-2.

## Data Store Buffering in Generated Code

A Data Store Read block is a nonvirtual block that copies the value of the data store to its output buffer when it executes. Since the value is buffered, downstream blocks connected to the output of the data store read utilize the same value, even if a Data Store Write block updates the data store in between execution of two of the downstream blocks.

The next figure shows a model that uses blocks whose priorities have been modified to achieve a particular order of execution:

```

/* local block i/o variables */
real_T rtb_DataStoreRead;

/* DataStoreRead: '<Root>/Data Store Read' */
rtb_DataStoreRead = A; Buffer the value of A

/* Abs: '<Root>/Abs1' incorporates:
 * DataStoreRead: '<Root>/Data Store Read'
 */
y1 = fabs(A); Use A (whose value equals
the buffered value at this point

/* DataStoreWrite: '<Root>/Data Store Write' incorporates:
 * Inport: '<Root>/In1'
 */
A = u1; Update the value of A

/* Abs: '<Root>/Abs' */
y2 = fabs(rtb_DataStoreRead); Consistently use the same buffered
value as before the update to A

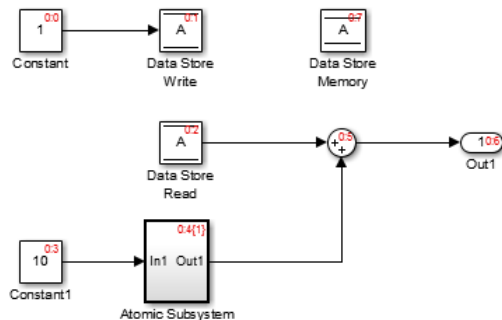

```

The following execution order applies:

- 1 The block Data Store Read buffers the current value of the data store A at its output.
- 2 The block Abs1 uses the buffered output of Data Store Read.
- 3 The block Data Store Write updates the data store.
- 4 The block Abs uses the buffered output of Data Store Read.

Because the output of Data Store Read is a buffer, both Abs and Abs1 use the same value: the value of the data store at the time that Data Store Read executes.

The next figure shows another example:

```

real_T rtb_DataStoreRead;

/* DataStoreWrite: '<Root>/Data Store Write' incorporates:
 * Constant: '<Root>/Constant'
 */
A = DoBufferDSMRead2_P.Constant_Value;

/* DataStoreRead: '<Root>/Data Store Read' */
rtb_DataStoreRead = A; Buffer the value of A

/* Outputs for atomic SubSystem: '<Root>/Atomic Subsystem' */
DoBufferDSMRead_AtomicSubsystem(); We don't do a global analysis to
detect if this function writes to A

/* end of Outputs for SubSystem: '<Root>/Atomic Subsystem' */

/* Output: '<Root>/Out1' incorporates:
 * Sum: '<Root>/Sum'
 */
Use the buffered value of A
DoBufferDSMRead2_Y.Out1 = rtb_DataStoreRead + DoBufferDSMRead2_B.Abs;

```

In this example, the following execution order applies:

- 1 The block Data Store Read buffers the current value of the data store A at its output.
- 2 Atomic Subsystem executes.
- 3 The Sum block adds the output of Atomic Subsystem to the output of Data Store Read.

Simulink assumes that Atomic Subsystem might update the data store, so Simulink buffers the data store. Atomic Subsystem executes after Data Store Read buffers its output, and the buffer provides a way for the Sum block to use the value of the data store as it was when Data Store Read executed.

In some cases, the code generator determines that it can optimize away the output buffer for a Data Store Read block, and the generated code refers to the data store directly, rather than a buffered value of it. The next figure shows an example:

```

/* Model step function */
void DONTbufferDSMRead_step(void)
{
 /* DataStoreWrite: '<Root>/Data Store Write' incorporates:
 * Inport: '<Root>/In1'
 */
 A = u1;

 /* Abs: '<Root>/Abs' incorporates:
 * DataStoreRead: '<Root>/Data Store Read'
 */
 y2 = fabs(A);
}

```

In the generated code, the argument of the `fabs()` function is the data store A rather than a buffered value.

## Data Stores Shared by Instances of a Reusable Model

You can use a data store to share a piece of data between the instances of a reusable referenced model (see “Share Data Among Referenced Model Instances”) or a model that you configure to generate reentrant code (by setting the configuration parameter **Code interface packaging** to `Reusable` function). If you implement the data store as a Data Store Memory block and select the **Share across model instances** parameter:

- By default, the data store appears in the generated code as a separate global symbol.
- If you have Embedded Coder, to restrict access such that only the code generated from the model can use the data store, configure the data store to appear as `static` by applying the storage class `FileScope`. For more information about `FileScope` and other storage classes, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.

## Structures in Generated Code Using Data Stores

If you use more than one data store to provide global access to multiple signals in generated code, you can combine the signals into a single structure variable by using one data store. This combination of signal data can help you integrate the code generated from a model with other existing code that requires the data in a structure format.

This example shows how to store several model signals in a structure in generated code using a single data store. To store multiple signals in a data store, you configure the data store to accept a composite signal, such as a nonvirtual bus signal or an array of nonvirtual bus signals.

### Explore Example Model

- 1 Open the example model `ex_bus_struct_in_code`.

The model contains three subsystems that perform calculations on the inputs from the top level of the model. In each subsystem, a Data Store Memory block stores an intermediate calculated signal.

- 2 Generate code with the model. In the code generation report, view the file `ex_bus_struct_in_code.c`. The code defines a global variable for each data store.

```
real_T BioBTURate;
real_T CoalBTURate;
real_T GasBTURate;
```

Suppose that you want to integrate code generated from the example model with other existing code. Suppose also that the existing code requires access to data from the three data stores in a single structure variable. You can use a data store to assemble the target data in a structure in generated code.

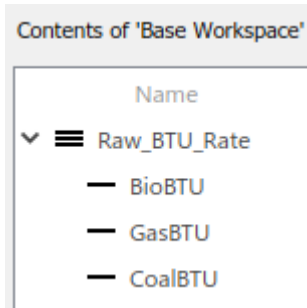

### Configure Data Store

Configure a data store to contain multiple signals by creating a bus type to use as the data type of the data store. Define the bus type using the same hierarchy of elements as the structure that you want to appear in generated code.

- 1 Open the Bus Editor tool.

buseditor

- 2 Define a new bus type Raw\_BTU\_Rate with one element for each of the three target signals. Name the elements BioBTU, GasBTU, and CoalBTU.

- 3 At the top level of the example model, add a Data Store Memory block.
- 4 On the **Modeling** tab, click **Model Data Editor**.
- 5 In the Model Data Editor, inspect the **Data Stores** tab.
- 6 For the new Data Store Memory block, use the **Name** column to set the data store name to Raw\_BTU\_Data.
- 7 Use the **Data Type** column to set the data type of the data store to Bus: Raw\_BTU\_Rate.
- 8 In the Code Mappings editor, on the **Data Stores** tab, apply the storage class ExportedGlobal to Raw\_BTU\_Data.

### Write to Data Store Elements

To write to a specific element of a data store, use a Data Store Write block. On the **Element Assignment** tab in the dialog box, you can specify to write to a single element, a collection of elements, or the entire contents of a data store.

- 1 Open the **Biomass Calc** subsystem.
- 2 Delete the Data Store Memory block BioBTURate.
- 3 In the block dialog box for the Data Store Write block, set **Data store name** to Raw\_BTU\_Data.
- 4 On the **Element Assignment** tab, under **Signals in the bus**, expand the contents of the data store Raw\_BTU\_Data. Click the element BioBTU, and then click **Select**. Click **OK**.

- 5 Modify the **Gas Calc** and **Coal Calc** subsystems similarly.
  - Delete the Data Store Memory block in each subsystem.
  - In each Data Store Write block dialog box, set **Data store name** to Raw\_BTU\_Data.
  - In the **Gas Calc** subsystem, use the Data Store Write block to write to the data store element GasBTU. In the **Coal Calc** subsystem, write to the element CoalBTU.

### Generate Code with Data Store Structure

- 1 Generate code for the example model.
- 2 In the code generation report, view the file `ex_bus_struct_in_code_types.h`. The code defines a structure that corresponds to the bus type Raw\_BTU\_Rate.

```
typedef struct {
 real_T BioBTU;
 real_T GasBTU;
 real_T CoalBTU;
} Raw_BTU_Rate;
```

- 3 View the file `ex_bus_struct_in_code.c`. The code represents the data store with a global variable Raw\_BTU\_Data of the structure type Raw\_BTU\_Rate. In the model step function, the code assigns the data from the calculated signals to the fields of the global variable Raw\_BTU\_Data.

## Specify Single-Precision Data Type for Embedded Application

When you want code that uses only single precision, such as when you are targeting a single-precision processor, you can use model configuration parameters and block parameters to prevent the introduction of `double` in the model.

To design and validate a single-precision model, see “Validate a Floating-Point Embedded Model”. If you have Fixed-Point Designer, you can use the Single Precision Converter app (see **Single Precision Converter**).

### Use single Data Type as Default for Underspecified Types

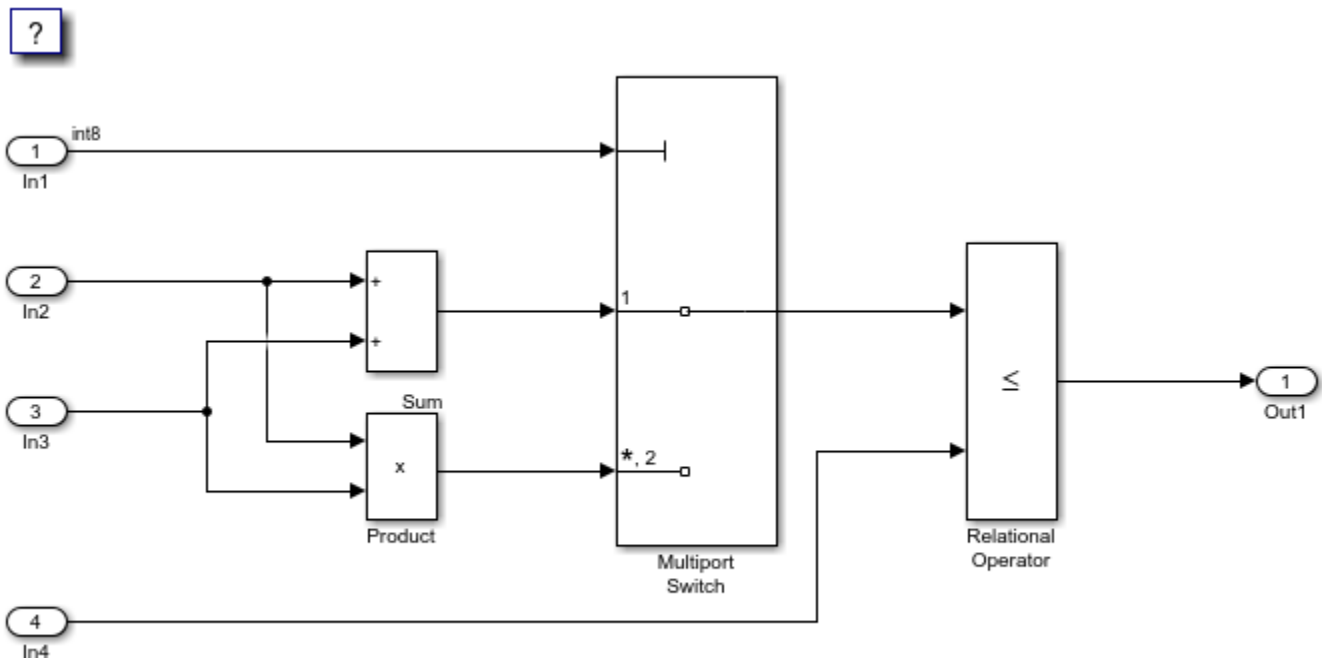

This example shows how to avoid introducing a double-precision data type in code generated for a single-precision hardware target.

If you specify an inherited data type for signals, but data type propagation rules cannot determine data types for the signals, the signal data types default to `double`. You can use a model configuration parameter to specify the default data type as `single`.

#### Explore Example Model

Open the example model `rtwdemo_underspecified_datatype` and configure it to show the generated names of blocks.

```
model = 'rtwdemo_underspecified_datatype';
load_system(model)
set_param(model, 'HideAutomaticNames', 'off')
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

The root inports In2, In3, and In4 specify `Inherit: Auto` for the **Data type** block parameter. The downstream blocks also use inherited data types.

### Generate Code with double as Default Data Type

The model starts with the configuration parameter **System target file** set to `ert.tlc`, which requires Embedded Coder. Set **System target file** to `grt.tlc` instead.

```
set_param(model, 'SystemTargetFile', 'grt.tlc')
```

Generate code from the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_underspecified_datatype
Successful completion of build procedure for: rtwdemo_underspecified_datatype
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_underspecified_datatype	Code generated and compiled	Code generation information file do

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 23.286s
```

In the code generation report, view the file `rtwdemo_underspecified_datatype.h`. The code uses the `double` data type to define the variables In2, In3, and In4 because the Inport data types are underspecified in the model.

```
cfile = fullfile('rtwdemo_underspecified_datatype_grt_rtw', ...
 'rtwdemo_underspecified_datatype.h');
rtwdemodbtype(cfile, ...
 /* External inputs (root inport signals with default storage) */ , ...
 /* External outputs (root outports fed by signals with default storage) */ , ...
 1, 0);
```

```
/* External inputs (root inport signals with default storage) */
typedef struct {
 int8_T In1; /* '<Root>/In1' */
 real_T In2; /* '<Root>/In2' */
 real_T In3; /* '<Root>/In3' */
 real_T In4; /* '<Root>/In4' */
} ExtU_rtwdemo_underspecified_d_T;
```

### Generate Code with single as Default Data Type

Open the Configuration Parameters dialog box. On the **Math and Data Types** pane, select `single` in the **Default for underspecified data type** drop-down list.

Alternatively, enable the optimization at the command prompt.

```
set_param(model, 'DefaultUnderspecifiedDataType', 'single');
```

Generate code from the model.

```

slbuild(model)

Starting build procedure for: rtwdemo_underspecified_datatype
Successful completion of build procedure for: rtwdemo_underspecified_datatype

Build Summary

Top model targets built:

## Tune Phase Parameter of Sine Wave Block During Code Execution

Under certain conditions, you cannot configure the **Phase** parameter of a Sine Wave block to appear in the generated code as a tunable global variable (for more information, see the block reference page). This example shows how to generate code so that you can tune the phase during execution.

Create the model `ex_phase_tunable` by using a Digital Clock block.

```
open_system('ex_phase_tunable')
```

Copyright 2021 The MathWorks, Inc.

Set **Default parameter behavior** to Tunable so that the parameters of the Sine Wave block appear in the generated code as tunable fields of the global parameter structure.

```
set_param('ex_phase_tunable','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```
slbuild('ex_phase_tunable')
```

```
Starting build procedure for: ex_phase_tunable
Successful completion of code generation for: ex_phase_tunable
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
ex_phase_tunable	Code generated	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 19.091s

In the code generation report, view the file `ex_phase_tunable.c`. The code algorithm in the model step function calculates the Sine Wave block output. The parameters of the block, including **Phase**, appear in the code as tunable structure fields.

```
file = fullfile('ex_phase_tunable_grt_rtw','ex_phase_tunable.c');
rtwdemodbtype(file,'/* Outport: '<Root>/Out1' incorporates:',...
 'ex_phase_tunable_P.SineWave_Bias;',1,1)

/* Outport: '<Root>/Out1' incorporates:
 * DigitalClock: '<Root>/Digital Clock'
 * Sin: '<Root>/Sine Wave'
 */
ex_phase_tunable_Y.Out1 = sin(ex_phase_tunable_P.SineWave_Freq *
 (((ex_phase_tunable_M->Timing.clockTick1+
```

```
ex_phase_tunable_M->Timing.clockTickH1* 4294967296.0)) * 1.0) +
ex_phase_tunable_P.SineWave_Phase) * ex_phase_tunable_P.SineWave_Amp +
ex_phase_tunable_P.SineWave_Bias;
```

During code execution, you can assign new values to the structure field that corresponds to the **Phase** parameter.

## Switch Between Output Waveforms During Code Execution for Waveform Generator Block

This example shows how to generate code that enables you to switch between stimulus waveforms during code execution.

For a Waveform Generator block, you cannot make the parameters of a waveform, such as amplitude and phase shift, tunable in the generated code. Instead, you can generate code that enables you to choose an active waveform from a set of waveform variants that you specify in the block. During execution of the code, you activate a variant by adjusting the value of a global structure field.

You must set the model configuration parameter **Default parameter behavior** to **Tunable**. Then, by default, block parameters in the model appear tunable in the generated code. These parameters can consume large amounts of memory for a large model.

Create the model `ex_switch_waveform`.

```
open_system('ex_switch_waveform')
```

Copyright 2021 The MathWorks, Inc.

In the Waveform Generator block, configure this waveform:

```
square(amp,10,0,dutyCycle)
```

In the base workspace, create the variables `amp` and `dutyCycle`.

```
amp = 2.71;
dutyCycle = 50;
```

This waveform represents the baseline stimulus that you want the application to use at the start of execution.

Suppose that, during execution, you want to observe the effects of changing the waveform frequency from 10 to 15 and the phase shift from 0 to 0.5. In the Waveform Generator block, add these waveform variants:

```
square(amp,10,0.5,dutyCycle)
square(amp,15,0,dutyCycle)
square(amp,15,0.5,dutyCycle)
```

Set the model configuration parameter **Default parameter behavior** to **Tunable**.

```
set_param('ex_switch_waveform','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```
slbuild('ex_switch_waveform')
```

```
Starting build procedure for: ex_switch_waveform
Successful completion of code generation for: ex_switch_waveform
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
ex_switch_waveform	Code generated	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 17.599s

The generated file `ex_switch_waveform.h` defines the standard structure type that stores tunable parameter data for the model. The structure contains a field whose value represents the active waveform.

```
file = fullfile('ex_switch_waveform_grt_rtw','ex_switch_waveform.h');
rtwdemodbtype(file,'/* Parameters (default storage) */',...
 '/* Real-time Model Data Structure */',1,0)

/* Parameters (default storage) */
struct P_ex_switch_waveform_T_ {
 real_T WaveformGeneratorStimulus_Select;
 /* Mask Parameter: WaveformGeneratorStimulus_Select
 * Referenced by: '<S1>/Switch'
 */
 real_T GainControlSystem_Gain; /* Expression: 3.5
 * Referenced by: '<Root>/Gain (Control System)'
 */
};
```

The file `ex_switch_waveform_data.c` defines a global structure variable and initializes the field value to 1. This value represents the baseline waveform.

```
file = fullfile('ex_switch_waveform_grt_rtw','ex_switch_waveform_data.c');
rtwdemodbtype(file,'/* Block parameters (default storage) */','};',1,1)

/* Block parameters (default storage) */
P_ex_switch_waveform_T ex_switch_waveform_P = {
 /* Mask Parameter: WaveformGeneratorStimulus_Select
 * Referenced by: '<S1>/Switch'
 */
 1.0,

 /* Expression: 3.5
 * Referenced by: '<Root>/Gain (Control System)'
 */
 3.5
};
```

The file `ex_switch_waveform.c` defines the model execution function. The function uses a `switch` statement to determine the value of the active waveform, and then calculates the value of the root-level Output block, `Out1`.

```

file = fullfile('ex_switch_waveform_grt_rtw','ex_switch_waveform.c');
rtwdemodbtype(file,'switch ((int32_T)',...
 'ex_switch_waveform_Y.Out1 =',1,1)

switch ((int32_T)ex_switch_waveform_P.WaveformGeneratorStimulus_Select) {
 case 1:
 temp = temp - floor(temp) <= 0.5 ? 2.71 : -2.71;
 break;

 case 2:
 temp = temp_0 - floor(temp_0) <= 0.5 ? 2.71 : -2.71;
 break;

 case 3:
 temp = temp_1 - floor(temp_1) <= 0.5 ? 2.71 : -2.71;
 break;

 default:
 temp = temp_2 - floor(temp_2) <= 0.5 ? 2.71 : -2.71;
 break;
}

/* End of MultiPortSwitch: '<S1>/MultiportSwitch' */

/* Output: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain (Control System)'
 */
ex_switch_waveform_Y.Out1 = ex_switch_waveform_P.GainControlSystem_Gain * temp;

```

During code execution, to change the active waveform, adjust the value of the structure field in the global parameters structure.

## Create Tunable Calibration Parameter in the Generated Code

A calibration parameter is a value stored in global memory that an algorithm reads for use in calculations but does not write to. Calibration parameters are tunable because you can change the stored value during algorithm execution. You create calibration parameters so that you can:

- Determine an optimal parameter value by tuning the parameter and monitoring signal values during execution.
- Efficiently adapt an algorithm to different execution conditions by overwriting the parameter value stored in memory. For example, you can use the same control algorithm for multiple vehicles of different masses by storing different parameter values in each vehicle's engine control unit.

In Simulink, create a `Simulink.Parameter` object to represent a calibration parameter. You use the parameter object to set block parameter values, such as the **Gain** parameter of a Gain block. To control the representation of the parameter object in the generated code, you apply a storage class to the object.

To make block parameters accessible in the generated code by default, for example for rapid prototyping, set **Default parameter behavior** (see “Default parameter behavior”) to `Tunable`. For more information, see “Preserve Variables in Generated Code” on page 33-2.

### Represent Block Parameter as Tunable Global Variable

This example shows how to create tunable parameter data by representing block parameters as global variables in the generated code.

#### Configure Block Parameter by Using Parameter Object

Open the example model `rtwdemo_paraminline` and configure it to show the generated names of blocks.

```
load_system('rtwdemo_paraminline')
set_param('rtwdemo_paraminline','HideAutomaticNames','off')
open_system('rtwdemo_paraminline')
```

Copyright 1994-2020 The MathWorks, Inc.

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

In the model, click the G1 Gain block. The Model Data Editor highlights the row that corresponds to the **Gain** parameter of the block.

In the Model Data Editor **Value** column, change the gain value from 2 to myGainParam.

Next to myGainParam, click the action button (with three vertical dots) and select **Create**.

In the Create New Data block dialog box, set **Value** to Simulink.Parameter(2). Click **Create**. A Simulink.Parameter object myGainParam stores the parameter value, 2, in the model workspace.

In the myGainParam dialog box, on the **Code Generation** tab, click **Configure in Coder App**.

In the Code Mappings editor, set **Storage Class** of myGainParam to ExportedGlobal. This storage class causes the parameter object to appear in the generated code as a tunable global variable.

Alternatively, to create the parameter object and configure the model, use these commands at the command prompt:

```
set_param('rtwdemo_paraminline/G1','Gain','myGainParam')
mws = get_param('rtwdemo_paraminline','modelworkspace');
mws.assignin('myGainParam',Simulink.Parameter(2));
cm = coder.mapping.utils.create('rtwdemo_paraminline');
setModelParameter(cm,'myGainParam','StorageClass','ExportedGlobal');
```

Use the Model Data Editor to create a parameter object, myOtherGain, for the G2 Gain block. Apply the storage class ExportedGlobal.

Alternatively, use these commands at the command prompt:

```
set_param('rtwdemo_paraminline/G2', 'Gain', 'myOtherGain')
mws.assignin('myOtherGain', Simulink.Parameter(-2));
setModelParameter(cm, 'myOtherGain', 'StorageClass', 'ExportedGlobal');
```

### Generate and Inspect Code

Generate code from the model.

```
slbuild('rtwdemo_paraminline')

Starting build procedure for: rtwdemo_paraminline
Successful completion of build procedure for: rtwdemo_paraminline
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_paraminline	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 9.502s

The generated file `rtwdemo_paraminline.h` contains extern declarations of the global variables `myGainParam` and `myOtherGain`. You can include (`#include`) this header file so that your code can read and write the value of the variable during execution.

```
file = fullfile('rtwdemo_paraminline_grt_rtw', 'rtwdemo_paraminline.h');
rtwdemodbtype(file, ...
 'extern real_T myGainParam;', 'Referenced by: '<Root>/G2'', 1, 1)
```

```
extern real_T myGainParam; /* Variable: myGainParam
 * Referenced by: '<Root>/G1'
 */
extern real_T myOtherGain; /* Variable: myOtherGain
 * Referenced by: '<Root>/G2'
```

The file `rtwdemo_paraminline.c` allocates memory for and initializes `myGainParam` and `myOtherGain`.

```
file = fullfile('rtwdemo_paraminline_grt_rtw', 'rtwdemo_paraminline.c');
rtwdemodbtype(file, ...
 '/* Exported block parameters */', 'Referenced by: '<Root>/G2'', 1, 1)
```

```
/* Exported block parameters */
real_T myGainParam = 2.0; /* Variable: myGainParam
 * Referenced by: '<Root>/G1'
 */
real_T myOtherGain = -2.0; /* Variable: myOtherGain
 * Referenced by: '<Root>/G2'
```

The generated code algorithm in the model step function uses `myGainParam` and `myOtherGain` for calculations.

```
rtwdemodbtype(file, ...
 '/* Model step function */', '/* Model initialize function */', 1, 0)
```

```

/* Model step function */
void rtwdemo_paraminline_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Gain: '<Root>/G1'
 * Gain: '<Root>/G2'
 * Inport: '<Root>/In1'
 * Sum: '<Root>/Sum'
 */
 rtwdemo_paraminline_Y.Out1 = myGainParam * rtwdemo_paraminline_U.In1 +
 myOtherGain * -75.0;
}

```

## Apply Storage Class When Block Parameter Refers to Numeric MATLAB Variable

If you use a numeric variable to set the value of a block parameter, you cannot apply a storage class to the variable. As a workaround, you can convert the variable to a parameter object, and then apply a storage class to the object. To convert the variable to a parameter object, choose one of these techniques:

- On the Model Data Editor **Parameters** tab, with **Change view** set to Code, find the row that corresponds to the variable. In the **Storage Class** column, from the drop-down list, select **Convert to parameter object**. The Model Data Editor converts the variable to a parameter object. Then, use the **Storage Class** column to apply a storage class to the object.

You can also use this technique in the Model Explorer.

- Use the Data Object Wizard (see “Create Data Objects for a Model Using Data Object Wizard”). In the Wizard, select the **Parameters** check box. The Wizard converts variables to objects. Then, apply storage classes to the objects, for example, by using the Model Data Editor or the Model Explorer.

## Create Storage Class That Represents Calibration Parameters (Embedded Coder)

This example shows how to create a storage class that yields a calibration parameter in the generated code. The storage class causes each parameter object (`Simulink.Parameter`) to appear as a global variable with special decorations such as keywords and pragmas.

In the generated code, the calibration parameters must appear as global variables defined in a file named `calPrms.c` and declared in `calPrms.h`. The variable definitions must look like these definitions:

```

#pragma SEC(CALPRM)

const volatile float param1 = 3.0F;
const volatile float param2 = 5.0F;
const volatile float param3 = 7.0F;

#pragma SEC()

```

The variables use the keywords `const` and `volatile`. The pragma `#pragma SEC(CALPRM)` controls the placement of the variables in memory. To implement the pragma, variable definitions must appear in a contiguous block of code.

Also, the generated code must include an ASAP2 (a2l) description of each parameter.

### Create Package for Storing Storage Class and Memory Section Definitions

Now, create a package in your current folder by copying the example package `+SimulinkDemos`. The package stores the definitions of `Parameter` and `Signal` classes that you later use to apply the storage class to data elements in models. Later, the package also stores the definitions of the storage class and an associated memory section.

- 1 Set your current MATLAB folder to a writable location.
- 2 Copy the `+SimulinkDemos` package folder into your current folder. Name the copy `+myPackage`.

```
copyfile(fullfile(matlabroot,...
 'toolbox','simulink','simdemos','dataclasses','+SimulinkDemos'),...
 '+myPackage','f')
```

- 3 Navigate inside the `+myPackage` folder to the file `Signal.m` to edit the definition of the `Signal` class.
- 4 Uncomment the methods section that defines the method `setupCoderInfo`. In the call to the function `useLocalCustomStorageClasses`, replace `'packageName'` with `'myPackage'`. When you finish, the section looks like this:

```
methods
 function setupCoderInfo(h)
 % Use custom storage classes from this package
 useLocalCustomStorageClasses(h, 'myPackage');
 end
end % methods
```

- 5 Save and close the file.
- 6 Navigate inside the `+myPackage` folder to the file `Parameter.m` to edit the definition of the `Parameter` class. Uncomment the methods section that defines the method `setupCoderInfo` and replace `'packageName'` with `'myPackage'`.
- 7 Save and close the file.

### Create Storage Class and Memory Section

- 1 Set your current folder to the folder that contains the package folder `+myPackage`.
- 2 Open the Custom Storage Class Designer.

```
cscdesigner('myPackage')
```

- 3 In the Custom Storage Class Designer, on the **Memory Sections** tab, click **New**.
- 4 For the new memory section, set properties according to the table.

Property	Value
<b>Name</b>	CalMem
<b>Statements Surround</b>	Group of variables
<b>Pre Statement</b>	<code>#pragma SEC(CALPRM)</code>
<b>Post Statement</b>	<code>#pragma SEC()</code>

Property	Value
<b>Is const</b>	Select
<b>Is volatile</b>	Select

- 5 Click **Apply**.
- 6 On the **Custom Storage Class** tab, click **New**.
- 7 For the new storage class, set properties according to the table.

Property	Value
<b>Name</b>	CalParam
<b>For signals</b>	Clear
<b>Data scope</b>	Exported
<b>Header File</b>	calPrms.h
<b>Definition File</b>	calPrms.c
<b>Memory Section</b>	CalMem

- 8 Click **OK**. In response to the message about saving changes, click **Yes**.

### Set Default Parameter Object to myPackage.Parameter

To make applying the storage class easier, use the Model Explorer to change the default parameter object from `Simulink.Parameter` to `myPackage.Parameter`.

- 1 At the command prompt, open the Model Explorer.
 

```
daexplr
```
- 2 In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
- 3 In the Model Explorer toolbar, click the arrow next to the **Add Simulink Parameter** button. In the drop-down list, select **Customize class lists**.
- 4 In the **Customize class lists** dialog box, under **Parameter classes**, select the check box next to **myPackage.Parameter**. Click **OK**.
- 5 In the Model Explorer toolbar, click the arrow next to the **Add Simulink Parameter** button. In the drop-down list, select **myPackage Parameter**.

A `myPackage.Parameter` object appears in the base workspace. You can delete this object.

Now, when you use tools such as the Model Data Editor to create parameter objects, Simulink creates `myPackage.Parameter` objects instead of `Simulink.Parameter` objects.

### Apply Storage Class

In the example model `rtwdemo_roll`, the `BasicRollMode` subsystem represents a PID controller. Configure the P, I, and D parameters as calibration parameters.

- 1 Open the model.
 

```
rtwdemo_roll
```
- 2 In the model, navigate into the `BasicRollMode` subsystem.
- 3 In the Apps gallery, click **Embedded Coder**.
- 4 Underneath the block diagram, open the Model Data Editor by selecting the **Model Data Editor** tab.
- 5 In the Model Data Editor, select the **Parameters** tab and update the block diagram.

Now, the data table contains rows that correspond to workspace variables used by the Gain blocks (which represent the P, I, and D parameters of the controller).

- 6 In the Model Data Editor, next to the **Filter contents** box, activate the **Filter using selection** button.
- 7 In the model, select the three Gain blocks.
- 8 In the **Filter contents** box, enter `model workspace`.

The variables that the Gain blocks use are in the model workspace.

- 9 In the data table, select the three rows and, in the **Storage Class** column for a row, select **Convert to parameter object**.

The Model Data Editor converts the workspace variables to `myPackage.Parameter` objects. Now, you can apply a storage class to the objects.

- 10 In the **Storage Class** column for a row, select **CalParam**.

### Generate and Inspect Code

- 1 Generate code from the model.
- 2 In the code generation report, inspect the `calPrms.c` file. The file defines the calibration parameters.

```
/* Exported data definition */
#pragma SEC(CALPRM)

/* Definition for custom storage class: CalParam */
const volatile real32_T dispGain = 0.75F;
const volatile real32_T intGain = 0.5F;
const volatile real32_T rateGain = 2.0F;

#pragma SEC()
```

The file `calPrms.h` declares the parameters.

- 3 Inspect the interface file `rtwdemo_roll.a2l`. The file contains information about each parameter, for example, for `dispGain`.

```
/begin CHARACTERISTIC
/* Name */ dispGain
/* Long Identifier */ ""
/* Type */ VALUE
/* ECU Address */ 0x0000 /* @ECU_Address@dispGain@ */
/* Record Layout */ Scalar_FLOAT32_IEEE
/* Maximum Difference */ 0
/* Conversion Method */ rtwdemo_roll_CM_single
/* Lower Limit */ -3.4E+38
/* Upper Limit */ 3.4E+38
/end CHARACTERISTIC
```

### Initialize Parameter Value From System Constant or Other Macro (Embedded Coder)

You can generate code that initializes a tunable parameter with a value calculated from some system constants (macros). For example, you can generate this code, which initializes a tunable parameter `totalVol` with a value calculated from macros `numVessels` and `vesInitVol`:

```
#define numVessels 16
#define vesInitVol 18.2
```

```
double totalVol = numVessels * vesInitVol;
```

This initialization technique preserves the mathematical relationship between the tunable parameter and the system constants, which can make the generated code more readable and easier to maintain. To generate this code:

- 1 Create parameter objects that represent the system constants.

```
numVessels = Simulink.Parameter(16);
vesInitVol = Simulink.Parameter(18.2);
```

- 2 Configure the objects to use the storage class `Define`, which yields a macro in the generated code.

```
numVessels.CoderInfo.StorageClass = 'Custom';
numVessels.CoderInfo.CustomStorageClass = 'Define';
```

```
vesInitVol.CoderInfo.StorageClass = 'Custom';
vesInitVol.CoderInfo.CustomStorageClass = 'Define';
```

- 3 Create another parameter object that represents the tunable parameter. Configure the object to use the storage class `ExportedGlobal`, which yields a global variable in the generated code.

```
totalVol = Simulink.Parameter;
totalVol.CoderInfo.StorageClass = 'ExportedGlobal';
```

- 4 Set the value of `totalVol` by using the expression `numVessels * vesInitVol`. To specify that the generated code preserve the expression, use the `slexpr` function.

```
totalVol.Value = slexpr('numVessels * vesInitVol');
```

- 5 Use `totalVol` to set block parameter values in your model. The code that you generate from the model initializes the tunable parameter with a value based on the system constants.

For more information and limitations about using an expression to set the value of a `Simulink.Parameter` object, see “Set Variable Value by Using a Mathematical Expression”.

## Code Generation Impact of Storage Location for Parameter Objects

You can create a parameter object in the base workspace, a model workspace, or a data dictionary. However, when you end your MATLAB session, variables in the base workspace are deleted. To determine where to store parameter objects and other variables that a model uses, see “Determine Where to Store Variables and Objects for Simulink Models”.

The location of a parameter object can impact the file placement of the corresponding data definition in the generated code.

- If you place a parameter object in the base workspace or a data dictionary, the code generator assumes that the corresponding parameter data (for example, a global variable) belongs to the system from which you generate code, not to a specific component in the system. For example, if a model in a model reference hierarchy uses a parameter object with a storage class other than `Auto`, the data definition appears in the code generated for the top model in the hierarchy, not in the code generated for the model that uses the object.

However, if you have Embedded Coder, some storage classes enable you to specify the name of the model that owns a piece of data. When you specify an owner model, the code generated for that

model defines the data. For more information about data ownership, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2.

- If you place a parameter object in a model workspace, the code generator assumes that the model owns the data. If you generate code from a reference hierarchy that includes the containing model, the data definition appears in the code generated for the containing model.

For more information about data ownership, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2.

- If you apply a storage class other than `Auto` to a parameter object, the object appears in the generated code as a global symbol. Therefore, in a model reference hierarchy, two such objects in different model workspaces or dictionaries cannot have the same name. The name of each object must be unique throughout the model hierarchy.

However, if you have Embedded Coder, you can use the storage class `FileScope` to prevent name clashes between parameter objects in different model workspaces. See “Organize Parameter Data into a Structure by Using Struct Storage Class” on page 32-67.

If you store an `AUTOSAR.Parameter` object in a model workspace, the code generator ignores the storage class that you specify for the object.

## Configure Accessibility of Signal Data

When you tune the value of a parameter during algorithm execution, you monitor or capture output signal values to analyze the results of the tuning. To represent signals in the generated code as accessible data, you can use techniques such as test points and storage classes. See “Preserve Variables in Generated Code” on page 33-2.

## Programmatic Interfaces for Tuning Parameters

You can configure the generated code to include:

- A C application programming interface (API) for tuning parameters independent of external mode. The generated code includes extra code so that you can write your own code to access parameter values. See “Exchange Data Between Generated and External Code Using C API” on page 59-2.
- A Target Language Compiler API for tuning parameters independently of external mode. See “Parameter Functions”.

## Set Tunable Parameter Minimum and Maximum Values

It is a best practice to specify minimum and maximum values for tunable parameters.

You can specify these minimum and maximum values:

- In the block dialog box that uses the parameter object. Use this technique to store the minimum and maximum information in the model.
- By using the properties of a `Simulink.Parameter` object that you use to set the parameter value. Use this technique to store the minimum and maximum information outside the model.

For more information, see “Specify Minimum and Maximum Values for Block Parameters”.

## Considerations for Other Modeling Goals

Goal	Considerations and More Information
Apply storage type qualifiers <code>const</code> and <code>volatile</code>	If you have Embedded Coder, to generate the storage type qualifiers, see “Protect Global Data with <code>const</code> and <code>volatile</code> Type Qualifiers” on page 42-13.
Prevent name clashes between parameters in different components by applying the keyword <code>static</code>	If you have Embedded Coder, use the storage class <code>FileScope</code> or a similar storage class that you create. See “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.
Generate ASAP2 (a2l) description	You can generate an a2l file that uses the ASAP2 standard to describe your calibration parameters. For more information, see “Define ASAP2 Information for Parameters and Signals” on page 60-3.
Generate AUTOSAR XML (ARXML) description	If you have Embedded Coder, you can generate an ARXML file that describes calibration parameters used by models that you configure for the AUTOSAR standard. See “Model AUTOSAR Calibration Parameters and Lookup Tables” (AUTOSAR Blockset).
Store lookup table data for calibration	<p>To store lookup table data for calibration according to the ASAP2 or AUTOSAR standards (for example, <code>STD_AXIS</code>, <code>COM_AXIS</code>, or <code>CURVE</code>), you can use <code>Simulink.LookupTable</code> and <code>Simulink.Breakpoint</code> objects in lookup table blocks.</p> <p>However, some limitations apply. See <code>Simulink.LookupTable</code>. To work around the limitations of <code>Simulink.LookupTable</code> and <code>Simulink.Breakpoint</code> objects, use <code>Simulink.Parameter</code> objects instead.</p> <p>For more information, see “Define ASAP2 Information for Parameters and Signals” on page 60-3 and “Configure Lookup Tables for AUTOSAR Calibration and Measurement” (AUTOSAR Blockset).</p>
Use pragmas to store parameter data in specific memory locations	If you have an Embedded Coder license, to generate code that includes custom pragmas, use storage classes and memory sections. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

## Limitations for Block Parameter Tunability in Generated Code

A block parameter, MATLAB variable, or `Simulink.Parameter` object is tunable if it appears in the generated code as data stored in memory, such as a global variable. For example, when you apply the storage class `ExportedGlobal` to a parameter object, the parameter object appears tunable in the generated code. When you set **Default parameter behavior** to `Tunable`, MATLAB variables and parameter objects appear tunable in the generated code. By definition, model arguments also appear tunable.

Under certain conditions, the code generator cannot maintain tunability of a parameter, variable, object, or expression. In this case, the code generator inlines the numeric value, preventing you from changing the value during code execution.

To detect these conditions in your model, set the model configuration parameter **Detect loss of tunability** (see “Detect loss of tunability”) to `warning` or `error`.

### Tunable Expression Limitations

You can specify block parameter values as expressions that use `Simulink.Parameter` objects or workspace variables. For example, you can use the expression `5 * gainParam`. For general information about using expressions to set block parameter values, see “Use Mathematical Expressions, MATLAB Functions, and Custom Functions”. For limitations with respect to expressions that you use to set the values of `Simulink.Parameter` objects, see “Code Generation of Parameter Objects With Expression Values”.

A tunable workspace variable is a `Simulink.Parameter` object or workspace variable that appears tunable in the generated code. For example, an object or variable is tunable if you apply a storage class other than `Auto` or if you set **Default parameter behavior** to `Tunable`.

An expression that contains one or more tunable workspace variables, model arguments, or tunable mask parameters is called a tunable expression. The expression is tunable because the code generator attempts to preserve the expression in the code. Because the code generator preserves the expression, you can change the values of the parameter data during code execution.

The code generator reduces certain expressions to an inlined numeric value in the generated code. The inlining renders workspace variables in the expression nontunable. To avoid loss of tunability due to unsupported expressions, observe these guidelines:

- Expressions involving complex (`i`) workspace variables or parameter objects are not supported.
- Certain operators and functions cause the code generator to reduce expressions and remove tunability. To determine whether an operator or function causes loss of tunability, use the information in this table.

Category	Operators or Functions
1	<code>+ - .* ./ &lt; &gt; &lt;= &gt;= == ~= &amp;  </code>
2	<code>* /</code>
3	<code>abs, acos, asin, atan, atan2, boolean, ceil, cos, cosh, exp, floor, log, log10, sign, sin, sinh, sqrt, tan, tanh, single, int8, int16, int32, uint8, uint16, uint32</code>
4	<code>: .^ ^ [] {} . \ .\ ' .' , ;</code>

- Use operators from category 1 without loss of tunability.
- Use operators from category 2 in expressions as long as at least one operand is a scalar. For example, scalar/scalar and scalar/matrix operand combinations are supported, but matrix/matrix combinations are not supported.
- You can use tunable workspace variables as arguments for the functions in category 3. If you use other functions, the code generator removes the tunability of the arguments.
- The operators in category 4 are not supported.
- The Fcn and If blocks do not support tunable expressions for code generation or in referenced models.
- You can write mask initialization code that creates and modifies variables. If you use those variables in an expression, the expression is not tunable in the generated code. This limitation also applies to Simulink library blocks with mask initialization code. For example, block parameters that specify bit operations for the Bitwise, Bit Set, and Bit Clear blocks are not tunable because the parameter is used in the mask initialization code for the block.
- You can specify a data type for the Simulink.Parameter objects or workspace variables that make up expressions. As long as the data type of these variables and objects and the data type of the corresponding block parameters are the same or `double`, the code generator can preserve tunability.

If the code generator preserves tunability of a parameter expression that includes at least one element of an integer type, simulation and execution of generated code can produce results that are numerically inconsistent. Evaluation of the expression in the generated code results in an overflow while the expression saturates during simulation. For more information, see “Numerical Consistency of Model and Generated Code Simulation Results”.

## Linear Block Parameter Tunability

These blocks have a `Realization` parameter that affects the tunability of their numeric parameters:

- Transfer Fcn
- State-Space
- Discrete State-Space

To set the `Realization` parameter, you must use the command prompt:

```
set_param(gcb, 'Realization', 'auto')
```

For the `Realization` parameter, you can choose these options:

- `general`: The block's numeric parameters appear tunable in the generated code.
- `sparse`: The generated code represents the block's parameters as transformed values that increase efficiency. The parameters are not tunable.
- `auto`: The default. If one or more of the block's parameters are tunable (for example, because you use a tunable parameter object to set a parameter value), then the block uses the `general` realization. Otherwise, the block uses the `sparse` realization.

To tune the parameter values of one of these blocks during an external mode simulation, the block must use the `general` realization.

## Parameter Structures

As described in “Organize Data into Structures in Generated Code” on page 33-145, you can create structures of parameter data in the generated code.

- If a parameter structure is tunable, the numeric fields of the structure are tunable in the generated code. However, if a field contains a nontunable entity, such as a multidimensional array, the structure fields are not tunable.
- You cannot declare individual substructures or fields within a parameter structure as tunable. You cannot use a `Simulink.Parameter` object as the value of a structure field. Instead, you must store the entire structure in the parameter object.

## Code Generation of Parameter Objects With Expression Values

As described in “Set Variable Value by Using a Mathematical Expression”, you can set the value of a `Simulink.Parameter` object to an expression involving other MATLAB variables or parameter objects. When you generate code from a model that uses such a parameter object, to achieve your goal, use the information in the table.

Goal	Technique and More Information
Generate code without Embedded Coder.	<p>For the parameter object that uses the expression, apply an available storage class (see “C Code Generation Configuration for Model Interface Elements”).</p> <p>For the parameter objects used in the expression, apply only the storage class <code>Auto</code>.</p>
Generate code that defines a global variable and initializes it by using an expression involving system constants and other macros (requires Embedded Coder).	See “Initialize Parameter Value From System Constant or Other Macro (Embedded Coder)” on page 33-116.
Generate code that defines a macro whose value is an expression involving other macros (requires Embedded Coder).	<p>For the parameter object that uses the expression, apply a storage class that yields a macro in the generated code, such as <code>Define</code> (see “Macro Definitions (<code>#define</code>)” on page 25-54).</p> <p>For the parameter objects used in the expression, apply storage classes that yield imported macros. For example, use the storage class <code>ImportedDefine</code>. Your external code must define these macros.</p>

### Considerations and Limitations

- To avoid errors that prevent code generation, if you apply a storage class other than `Auto` to the dependent parameter object (which uses the expression as its value), the parameter objects used in the expression must use either `Auto` or a storage class that yields a macro in the generated code.
- You cannot set the value of a parameter object that represents a symbolic dimension (see “Implement Dimension Variants for Array Sizes in Generated Code” on page 26-2) to an expression.
- With Embedded Coder, you can generate code that preserves the expression, but only for the purpose of statically initializing the value of a global variable or macro that corresponds to the dependent parameter object. Follow the guidelines in “Expression Preservation”.

### Expression Preservation

If you want Embedded Coder to preserve expressions in the generated code, adhere to these restrictions and guidelines.

- The dependent parameter object must use a storage class other than `Auto`. For example, to generate a global variable and initialize it by using the expression, use `ExportedGlobal` or `ExportToFile`.
- The parameter objects used in the expression must:
  - Use a storage class that yields a macro in the generated code, such as `Define`.
  - Have scalar, real values if the expression uses operators.
- The expression can use only these operators (in MATLAB syntax):
  - Mathematical: `+`, `-`, `*`
  - Relational: `==`, `~=`, `<`, `>`, `<=`, `>=`
- These data typing guidelines apply:
  - If possible, for a parameter object used in an expression, leave the `DataType` property at the default value, `auto`.

To use a value other than `auto`, you must set the `DataType` property of the object that uses the expression to the same value. Otherwise, the code generator does not preserve the expression.
  - If you want to use a parameter object in multiple different expressions, and the dependent parameter objects have different data types, leave the `DataType` property of the independent object at the default value, `auto`. In the generated code, the value of the macro is expressed as a floating-point number (with effective data type `double`), and the code initializes the dependent parameters by typecasting the result of each expression.

## Related Examples

- “Create Tunable Calibration Parameter in the Generated Code”
- “Share and Reuse Block Parameter Values by Creating Variables”

## Configure Packaging of Parameter Arguments in Generated Code

When you create a reusable component as a referenced model, configure block parameters to use the same value for instances of the component or a different value for each instance.

To customize the implementation of parameter arguments in the generated code, you can configure the packaging of these parameters in the model where they are defined.

Configure the default mapping for model parameter arguments by using one of these storage classes:

- **Default** — Each instance of the parameter is allocated a piece of memory in an exported structure whose attributes are defined by identifier naming rules.
- A structured storage class — Each instance of the parameter is allocated a piece of memory as defined by the code definition of that storage class.

Individually specify the storage class for model parameter arguments by using one of these storage classes:

- **Auto** — The parameter appears as an individual model function argument in the generated code. If a block in the model does not reference the parameter, it can be optimized away by the code generator.
- **Model default** — Each instance of the parameter is allocated a piece of memory as defined by the code definition of the default storage class. Specify this default storage class through the model default mapping.

If you use edit-time checking for code generation, you get an error for an invalid storage class.

For a parameter argument with a non-**Auto** storage class:

- On the **Model** block, you can specify the per-instance value as either a literal, a numeric MATLAB variable, or a `Simulink.Parameter` object.
- If the per-instance value is a `Simulink.Parameter` object, the object must have storage class **Auto**.
- If the per-instance value is a value expression, the evaluated value of the expression is used to statically initialize the parameter.

If you do not specify a default or individual storage class for a parameter argument, the code generator applies an internal storage class, `InstP`, to the parameter. The `InstP` storage class has these properties:

- Exported scope
- Type naming rule is `$R_InstP$M`
- Instance name is `InstP$R$M`

### Code Generation Behavior

For single-instance referenced models, the parameter arguments reside in a standalone global structure. The top model defines the structure. The referenced model declares and uses the structure.

For multi-instance referenced models, the parameter arguments are part of a hierarchically nested structure that the top model declares and defines. The referenced model has access to its parameter values through a pointer in its self structure. The self structure points to a substructure of the structure that the top model defines.

For parameter arguments defined in the top model, if the argument does not have a storage class, it is inlined. If it has a storage class, the resulting code depends on the value of the **Code interface packaging** parameter:

- **Nonreusable function** — The parameter is generated in a structure defined in the top model.
- **Reusable function** — The parameter is generated in a structure passed as part of the first argument of the function.

To understand the behavior of instance-specific parameters in the generated code, consider this referenced model that defines two parameter arguments, `gainArg` and `coeffArg`.

Model Data									
Parameters									
Source	Name	Value	Data Type	Min	Max	Dimensions	Unit	Argument	
Model Workspace	coeffArg	1.05	auto	[]	[]	[1 1]		<input checked="" type="checkbox"/>	
Model Workspace	gainArg	3.17	auto	[]	[]	[1 1]		<input checked="" type="checkbox"/>	

First consider the case where this model is configured to support only a single instance and the default mapping for model parameter arguments does not have a storage class. In the `ex_arg_code_ref.h` file, there is a type definition and a declaration for the instance-specific parameters.

```
/* instance parameters */
extern ex_arg_code_ref_InstP ex_arg_code_refrtInstP;
```

```

/* instance parameters, for model 'ex_arg_code_ref' */
typedef struct {
 real32_T coeffArg; /* Variable: coeffArg
 * Referenced by: synthesized block
 */
 real32_T gainArg; /* Variable: gainArg
 * Referenced by: synthesized block
 */
} ex_arg_code_ref_InstP;

```

When the top model references this model and supplies values for the instance-specific parameters, the code for the top model defines the instance-specific parameters by using the values provided by the top model.

```

/* Define buffer for instance parameters, Block: '<Root>/Model' */
ex_arg_code_ref_InstP ex_arg_code_refrtInstP = {
 1.98F,
 3.98F
};

```

Now consider if the referenced model is configured to support multiple instances. `ex_arg_code_ref.h` contains the same type definition as the single-instance, but the self for the model also contains a pointer to an instance of that data structure. There is no pointer declaration to a standalone global variable of that structure.

```

/* instance parameters, for model 'ex_arg_code_ref' */
typedef struct {
 real32_T coeffArg; /* Variable: coeffArg
 * Referenced by: synthesized block
 */
 real32_T gainArg; /* Variable: gainArg
 * Referenced by: synthesized block
 */
} ex_arg_code_ref_InstP;

/* Real-time Model Data Structure */
struct ex_arg_code_ref_tag_RTM {
 ex_arg_code_ref_InstP *ex_arg_code_ref_InstP_ref;
};

```

The top model declares a parent structure, including an instance of this substructure, and initializes the pointer in the self structure for the referenced model.

```
/* Assign pointer for instance parameters, Block: '<Root>/Model' */
ex_arg_code_DW->Model_InstanceData.rtm.ex_arg_code_ref_InstP_ref =
 &ex_arg_code_M->ex_arg_code_InstP_ref->InstP_Model;

/* Assign pointer for instance parameters, Block: '<Root>/Model1' */
ex_arg_code_DW->Model1_InstanceData.rtm.ex_arg_code_ref_InstP_ref =
 &ex_arg_code_M->ex_arg_code_InstP_ref->InstP_Model1;
}
```

## Limitations

When you configure an instance-specific parameter for code generation, these limitations apply:

- The default mapping for model parameter arguments cannot be reused for model parameters or external parameter objects.
- Instance-specific parameter values must be finite.
- Parameter arguments with a non-`Auto` storage class are not supported for C++ code generation with a C++ class code interface.

## Parameter Data Types in the Generated Code

The data type of a block parameter (such as the **Gain** parameter of a Gain block), numeric MATLAB variable, or `Simulink.Parameter` object determines the data type that the corresponding entity in the generated code uses (for example, a global variable or an argument of a function). To generate more efficient code, you can match parameter data types with signal data types or store parameters in smaller data types.

For basic information about setting block parameter data types in a model, see “Control Block Parameter Data Types”.

### Significance of Parameter Data Types

The data type that a block parameter, MATLAB variable, or parameter object uses determines the data type that the generated code uses to store the parameter value in memory. For example:

- If you set the model configuration parameter **Default parameter behavior** (see “Default parameter behavior”) to `Tunable`, the **Gain** parameter of a Gain block appears in the generated code as a field of a global structure that stores parameter data. If you apply the data type `single` to the block parameter in the model, the structure field in the code uses the corresponding data type, `real32_T`.
- If you apply the storage class `ExportedGlobal` to a `Simulink.Parameter` object, the object appears in the generated code as a separate global variable. If you set the `DataType` property of the object to `int8`, the global variable in the code uses the corresponding data type, `int8_T`.
- If you configure a `Simulink.Parameter` object in a model workspace as a model argument, the object appears in the generated code as a formal parameter (argument) of a model entry-point function, such as the `step` function. The `DataType` property of the object determines the data type of the formal parameter.

Other than determining the data type that the generated code uses to store parameter values in memory, the data type of a parameter, variable, or object can also:

- Cause the block to cast the value of the parameter prior to code generation. The cast can result in overflow, underflow, or quantization.
- Cause the generated code to include extra code, for example saturation code.

### Typecasts Due to Parameter Data Type Mismatches

When the data types of block parameters, workspace variables, and signals differ, blocks can use typecasts to reconcile the data type mismatches. These typecasts can cause the generated code algorithm, including the model `step` function, to include explicit casts to reconcile mismatches in storage data type and C bit shifts to reconcile mismatches in fixed-point scaling.

Parameter data type mismatches can occur when:

- The data type that you specify for a MATLAB variable or parameter object (`Simulink.Parameter`) differs from the data type of a block parameter. The block parameter typecasts the value of the variable or object.
- The data type that you specify for an initial value differs from the data type of the initialized signal or state.

- The data type that you specify for a block parameter differs from the data type of the signal or signals that the parameter operates on. Some blocks typecast the parameter to perform the operation. For example, the Gain block performs this typecast.

If you configure a variable or object to use bias or fractional fixed-point slope, the block parameter cannot perform the typecast. In this case, you must match the data type of the variable or parameter object with the data type of the block parameter. Use one of these techniques:

- Use context-sensitive data typing for the variable or parameter object. For a MATLAB variable, use a `double` number to set the value of the variable. For a parameter object, set the `DataType` property to `auto`.
- Use a `Simulink.AliasType` or `Simulink.NumericType` object to set the data type of the block parameter and the data type of a parameter object.

Use this technique when you cannot rely on context-sensitive data typing, for example, when you use the field of a structure to set the value of the block parameter.

- Manually specify the same data type for the block parameter and the variable or parameter object.

Use this technique to reduce the dependence of the model on inherited and context-sensitive data types and on external variables and objects.

For blocks that access parameter data through pointer or reference in the generated code, if you specify different data types for the workspace variable and the block parameter, the generated code implicitly casts the data type of the variable to the data type of the block parameter. Note, that an implicit cast requires a data copy which could significantly increase RAM consumption and slow down code execution speed for large data sets. For example, Lookup Table blocks often access large vectors or matrices through pointer or reference in the generated code.

For information about matching parameter data types when you use model arguments, see “Control Data Types of Model Arguments and Argument Values” on page 5-50.

### **Detect Downcast and Loss of Precision due to Data Type Mismatches**

You can configure diagnostic configuration parameters to detect unintentional data type mismatches that result in quantization and loss of parameter precision. See “Model Configuration Parameters: Data Validity Diagnostics”.

## **Considerations for Other Modeling Patterns**

When you use specific modeling patterns and constructs such as fixed-point data types, parameter structures, and lookup table objects, use different techniques to control parameter data types.

- “Tunable Parameters and Best-Precision Fixed-Point Scaling” on page 33-130
- “Control Data Types of Structure Fields” on page 33-131
- “Control Data Types of Lookup Table Objects” on page 33-131
- “Data Typing for Expressions in Parameter Objects” on page 33-132

### **Tunable Parameters and Best-Precision Fixed-Point Scaling**

To apply best-precision fixed-point scaling to a tunable block parameter or parameter object, you can use the Fixed-Point Tool to autoscale an entire system or use the Data Type Assistant to configure individual parameters or objects. See “Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters”.

If a tunable parameter uses best-precision fixed-point scaling, Simulink chooses a data type based on the minimum and maximum values that you specify for the parameter (see “Specify Minimum and Maximum Values for Block Parameters”). You can specify these values in the block dialog box that uses the parameter or in the properties of a `Simulink.Parameter` object.

If you do not specify a minimum or maximum, Simulink chooses a data type based on the value of the parameter. The chosen scaling might restrict the range of possible tuning values. Therefore, it is a best practice to specify minimum and maximum values for each tunable parameter.

A tunable parameter can use best-precision scaling even if you do not specify it in the parameter data type. For example, the Gain block can choose a best-precision scaling if the **Parameter data type** in the block dialog box is set to `Inherit: Inherit via internal rule`. This setting is the default for the block.

### Control Data Types of Structure Fields

When you use a structure as the value of a block parameter (for example to initialize a bus signal), or when you organize multiple block parameter values into a single structure, you can create a `Simulink.Bus` object to use as the data type of a `Simulink.Parameter` object. You can then control the data types of individual fields in the structure. See “Control Field Data Types and Characteristics by Creating Parameter Object” and “Control Data Types of Initial Condition Structure Fields”.

### Control Data Types of Lookup Table Objects

When you use `Simulink.LookupTable` and `Simulink.Breakpoint` objects to store table and breakpoint data for a lookup table block, to control the data types of the table and breakpoint data, use one of these techniques:

- Set the `Value` property of the embedded `Simulink.lookuptable.Table` and `Simulink.lookuptable.Breakpoint` objects by using untyped expressions such as `[1 2 3]`, which returns a `double` vector. If **Breakpoint specification** is set to `Explicit values`, use the MATLAB expression text box and tabular interface at the bottom of the property dialog box. To control the data type, set the `DataType` property to a value other than `auto`.

Use this technique to separate the value of the table or breakpoint data from the data type, which can improve readability and understanding of your design. You can then use a `Simulink.NumericType` or `Simulink.AliasType` object to:

- Customize the name of the data type in the generated code.
- Match the data type of the table or breakpoint data with the data type of a signal in the model.
- Set the `Value` property of the embedded objects by using typed expressions such as `single([1 2 3])`. To use a fixed-point data type, set the `Value` property with an `fi` object. If **Breakpoint specification** is set to `Explicit values`, use the MATLAB expression text box and tabular interface at the bottom of the property dialog box.

Set the `DataType` property of the embedded objects to the default value, `auto`. The table and breakpoint data then acquire the data type that you use to set the `Value` property.

Use this technique to store the data type information in the `Value` property, which can simplify the way you interact with the `Simulink.LookupTable` and `Simulink.Breakpoint` objects. You can leave the `DataType` property at the default value.

When you later change the breakpoint or table data in the `Value` property, preserve the data type information by using a typed expression. Alternatively, if you use a command at the command

prompt or a script to change the data, to avoid using a typed expression, use subscripted assignment, ( : ).

```
myLUTObject.Table.Value(:) = [4 5 6];
```

When you change the data stored in the `Value` property, if you do not use a typed expression or subscripted assignment, you lose the data type information.

When blocks in a subsystem use `Simulink.LookupTable` or `Simulink.Breakpoint` objects, you cannot set data type override (see “Control Fixed-Point Instrumentation and Data Type Override”) only on the subsystem. Instead, set data type override on the entire model.

### **Data Typing for Expressions in Parameter Objects**

You can use an expression to set the value of a parameter object (such as `Simulink.Parameter`). The expression encodes mathematical relationships between different objects. When you use this technique, different data typing rules apply. See “Set Variable Value by Using a Mathematical Expression”.

- “Control Data Types of Signals”
- “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49

## Generate Efficient Code by Specifying Data Types for Block Parameters

To generate more efficient code, match the data types of block parameters (such as the **Gain** parameter of a Gain block) with signal data types. Alternatively, you can store parameters in smaller data types.

### Eliminate Unnecessary Typecasts and Shifts by Matching Data Types

These examples show how to generate efficient code by configuring a block parameter to use the same data type as a signal that the block operates on.

#### Store Data Type Information in Model

Open the example model `rtwdemo_configrpinterface` and configure it to show the generated names of blocks.

```
open_system('rtwdemo_configrpinterface')
set_param('rtwdemo_configrpinterface','HideAutomaticNames','off')
```

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, select the Gain block. In the Model Data Editor, the **Data Type** column shows that the data type of the **Gain** parameter of the block is set to **Inherit: Same as input**. With this setting, the **Gain** parameter of this block uses the same data type as the input signal.

In the Code Mappings editor, under **Parameters**, set the storage class for K1 to `ExportedGlobal`.

In the Model Data Editor, set **Change view** to **Design**.

In the data table, for the row that represents K1, in the **Data Type** column, select **Auto**. With this setting, the parameter object acquires its data type from the block parameters that use the object (in this case, the **Gain** block parameter).

Alternatively, to create and configure the object, use these commands at the command prompt:

```
cm = coder.mapping.api.get('rtwdemo_configrpinterface');
setModelParameter(cm,'K1','StorageClass','ExportedGlobal');
hws = get_param(bdroot, 'modelworkspace');
hws.setVariablePart('K1.DataType','Auto');
```

Generate code from the model.

```
slbuild('rtwdemo_configrpinterface')

Starting build procedure for: rtwdemo_configrpinterface
Successful completion of code generation for: rtwdemo_configrpinterface
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
-------	--------	----------------

```

=====
rtwdemo_configrpinterface Code generated Code generation information file does not exist.

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 30.039s

```

The generated file `rtwdemo_configrpinterface.c` defines the global variable `K1` by using the data type `real_T`.

```
file = fullfile('rtwdemo_configrpinterface_grt_rtw','rtwdemo_configrpinterface.c');
rtwdemodbtype(file,'/* Exported block parameters */','real_T K1 = 2.0;',1,1)
```

```
/* Exported block parameters */
real_T K1 = 2.0; /* Variable: K1
```

The generated code algorithm in the model `step` function uses `K1` directly without typecasting.

```
rtwdemodbtype(file,'output =',...
 '10U',1,1)

 output = K1 * look1_binlc(*input2), rtCP_Table1_bp01Data,
 rtCP_Table1_tableData, 10U);
```

In the Code Mappings editor, under **Parameters**, you can optionally set the storage class for `K1` to `Inherit: Inherit via internal rule` (the default).

In this case, the block parameter chooses the same data type as the input signal, `double`. However, when you use `Inherit: Inherit via internal rule`, under other circumstances (for example, when you use fixed-point data types), the block parameter might choose a different data type.

### Store Data Type Information in Parameter Object

When you use a `Simulink.Parameter` object to export or import parameter data from the generated code to your external code, for example by applying the storage class `ImportedExtern`, you can specify data type information in the parameter object. To match the data type of the parameter object with a signal data type, create a `Simulink.NumericType` or `Simulink.AliasType` object. You can strictly control the data type that the parameter object uses in the generated code, eliminating the risk that Simulink chooses a different data type when you make changes to the model.

At the command prompt, create a `Simulink.NumericType` object that represents the data type `double`.

```
myType = Simulink.NumericType;
myType.DataTypeMode = 'Double';
```

Use the Model Data Editor **Data Type** column to set these data types to `myType`:

- The parameter object. Use the **Parameters** tab.
- The Inport block named `In2`. Use the **Inports/Outports** tab. Due to data type propagation, the input signal of the Gain block also uses `myType`.

Use the Model Data Editor **Parameters** tab to set the data type of the **Gain** block parameter to `Inherit: Inherit from 'Gain'`.

Use this data type object as the data type of the parameter object.

Alternatively, to configure the object and the blocks, use these commands at the command prompt:

```
K1.DataType = 'myType';
set_param('rtwdemo_configrpinterface/In2','OutDataTypeStr','myType')
set_param('rtwdemo_configrpinterface/Gain','ParamDataTypeStr','Inherit: Inherit from ''Gain'')
```

Generate code from the model.

```
slbuild('rtwdemo_configrpinterface')

Starting build procedure for: rtwdemo_configrpinterface
Successful completion of code generation for: rtwdemo_configrpinterface
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_configrpinterface	Code generated	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 22.541s

The global variable K1 continues to use the data type real\_T.

```
file = fullfile('rtwdemo_configrpinterface_grt_rtw','rtwdemo_configrpinterface.c');
rtwdemodbtype(file,'/* Exported block parameters */','real_T K1 = 2.0;',1,1)

/* Exported block parameters */
real_T K1 = 2.0; /* Variable: K1
```

Close the code generation report.

```
rtwdemoclean;
```

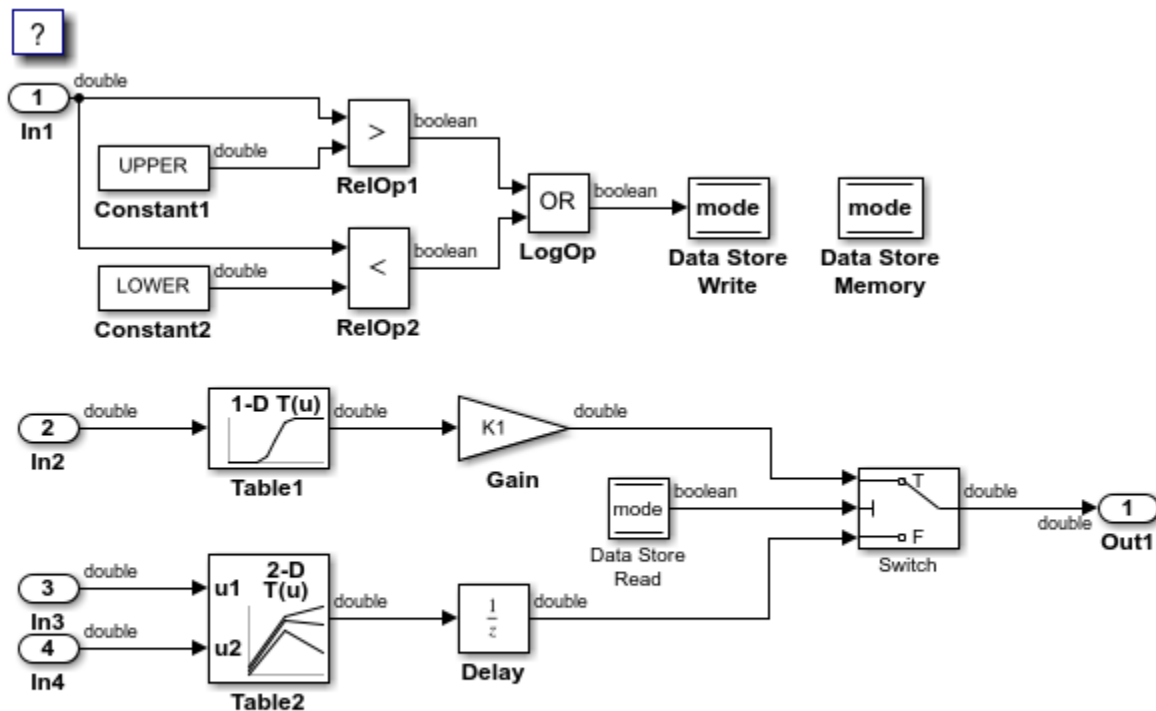

## Reduce Memory Consumption by Storing Parameter Value in Small Data Type

When you use a parameter object (for example, `Simulink.Parameter`) to set block parameter values, you can configure the object to appear in the generated code as a tunable global variable. By default, the parameter object and the corresponding global variable typically uses the same data type as the signal or signals on which the block operates. For example, if the input signal of a Gain block uses the data type `int16`, the parameter object typically use the same data type. To reduce the amount of memory that this variable consumes, specify that the variable use a smaller integer data type such as `int8`.

### Store Parameter Value in Integer Data Type

Open the model `rtwdemo_configrpinterface` and set the properties of the model.

```
open_system('rtwdemo_configrpinterface')
set_param('rtwdemo_configrpinterface','HideAutomaticNames','off')
set_param('rtwdemo_configrpinterface','ShowPortDataTypes','on')
set_param('rtwdemo_configrpinterface','SimulationCommand','Update')
```

Copyright 1994-2020 The MathWorks, Inc.

Many of the signals in the model use the data type `double`.

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

Click the **Show/refresh additional information** button.

Next to the **Filter contents** box, activate the **Filter using selection** button.

In the model, click the Gain block. The Model Data Editor shows one row that corresponds to the **Gain** parameter of the block and one row that corresponds to the MATLAB variable `K1`, which sets the parameter value to 2. `K1` resides in the model workspace.

In the C Code tab, select **Code Interface > Default Code Mappings**. In the Code Mappings editor, under **Parameters**, set the storage class for `K1` to `ExportedGlobal`.

```
cm = coder.mapping.api.get('rtwdemo_configrpiinterface');
setModelParameter(cm, 'K1', 'StorageClass', 'ExportedGlobal');
```

In the C Code tab, select **Code Interface > Default Code Mappings**. In the Model Data Editor, set **Change view** to **Design** and ensure that the **Data Type** column for `K1` is `int8`.

```
hws = get_param(bdroot, 'modelworkspace');
hws.setVariablePart('K1.DataType', 'int8');
```

For the row that represents the **Gain** block parameter, in the **Data Type** column, set the drop-down list to **Inherit: Inherit from 'Gain'**. With this setting, the **Gain** parameter of the block inherits the `int8` data type from the parameter object.

```
set_param('rtwdemo_configrpinterface/Gain','ParamDataTypeStr',...
 'Inherit: Inherit from ''Gain''')
```

Generate code from the model.

```
slbuild('rtwdemo_configrpinterface')

Starting build procedure for: rtwdemo_configrpinterface
Successful completion of code generation for: rtwdemo_configrpinterface
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_configrpinterface	Code generated	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 50.869s

The generated file `rtwdemo_configrpinterface.c` defines the global variable `K1` by using the data type `int8_T`, which corresponds to the data type `int8` in Simulink.

```
file = fullfile('rtwdemo_configrpinterface_grt_rtw','rtwdemo_configrpinterface.c');
rtwdemodbtype(file,'/* Exported block parameters */','int8_T K1 = 2;',1,1)
```

```
/* Exported block parameters */
int8_T K1 = 2; /* Variable: K1
```

The code algorithm in the model `step` function uses `K1` to calculate the output of the **Gain** block. The algorithm casts `K1` to the data type `real_T` (double) because the signals involved in the calculation use the data type `real_T`.

```
rtwdemodbtype(file,'output =',...
 '10U',1,1)

 output = (real_T)K1 * look1_binlc((*input2), rtCP_Table1_bp01Data,
 rtCP_Table1_tableData, 10U);
```

### Store Fixed-Point Parameter Value in Smaller Integer Data Type

Suppose you configure the signals in your model to use fixed-point data types. You want a gain parameter to appear in the generated code as a tunable global variable. You know the range of real-world values that you expect the parameter to assume (for example, between 0 and 4). If you can meet your application requirements despite reduced precision, you can reduce memory consumption by configuring the parameter to use a different data type than the input and output signals of the block.

Open the example model `fxpdemo_direct_form2` and configure it to show the generated names of blocks.

```
load_system('fxpdemo_direct_form2')
set_param('fxpdemo_direct_form2','HideAutomaticNames','off')
open_system('fxpdemo_direct_form2')
```

Update the block diagram. Signals in this model use signed fixed-point data types with a word length of 16 and binary-point-only scaling.

Open the Gain5 block dialog box. The **Gain** parameter is set to 1.85. Suppose you want to configure this parameter.

Set **Gain** to myGainParam and click **Apply**.

Click the action button (with three vertical dots) next to the parameter value. Select **Create**.

In the Create New Data dialog box, set **Value** to Simulink.Parameter(1.85) and click **Create**. The Simulink.Parameter object myGainParam appears in the base workspace.

Open the **Simulink Coder** app. In the C Code tab, select **Code Interface > Default Code Mappings**. In the Code Mappings editor, under **Parameters**, set the storage class for myGainParam to ExportedGlobal. With this setting, myGainParam appears in the generated code as a global variable.

In the block dialog box, on the **Parameter Attributes** tab, set **Parameter minimum** to 0 and **Parameter maximum** to 4.

Set **Parameter data type** to fixdt(0,8) and click **Apply**.

Click the **Show Data Type Assistant** button. The Data Type Assistant shows that the expression `fixdt(0,8)` specifies an unsigned fixed-point data type with a word length of 8 and best-precision scaling. When you simulate or generate code, the block parameter chooses a fraction length (scaling) that enables the data type to represent values between the parameter minimum and maximum (0 and 4) with the best possible precision.

In the Data Type Assistant, set **Scaling** to `Binary point`. Click **Calculate Best-Precision Scaling**, **Fixed-point details**, and **Refresh Details**. The information under **Fixed-point details** shows that a fraction length of 5 can represent the parameter values with a precision of 0.03125.

Set **Scaling** back to `Best precision` and click **OK**. In this example, when you simulate or generate code, the block parameter chooses a fraction length of 5.

Alternatively, you can use these commands at the command prompt to create the object and configure the block:

```
myGainParam = Simulink.Parameter(1.85);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
set_param('fxpdemo_direct_form2/Gain5','Gain','myGainParam')
set_param('fxpdemo_direct_form2/Gain5','ParamMin','0','ParamMax','4')
set_param('fxpdemo_direct_form2/Gain5','ParamDataTypeStr','fixdt(0,8)')
```

Configure the model to produce a code generation report. To reduce clutter in the Command Window, clear the configuration parameter **Verbose build**.

```
set_param('fxpdemo_direct_form2','GenerateReport','on',...
 'LaunchReport','on','RTWVerbose','off')
```

Generate code from the model.

```
evalc('slbuild(''fxpdemo_direct_form2'')');
```

The generated file `fxpdemo_direct_form2.c` defines the global variable `myGainParam` by using the data type `uint8_T`, which corresponds to the specified word length, 8. The code initializes the variable by using an integer value that, given the fraction length of 5, represents the real-world parameter value 1.85.

```
file = fullfile('fxpdemo_direct_form2_grt_rtw','fxpdemo_direct_form2.c');
rtwdemodbtype(file,'/* Exported block parameters */','uint8_T myGainParam = 59U;',1,1)
```

```
/* Exported block parameters */
uint8_T myGainParam = 59U; /* Variable: myGainParam
```

The code algorithm uses `myGainParam` to calculate the output of the Gain5 block. The algorithm uses a C shift to scale the result of the calculation.

```
rtwdemodbtype(file,'/* Gain: '<Root>/Gain5' incorporates:',...
 '/* Gain: '<Root>/Gain' incorporates:',1,0)
```

```
/* Gain: '<Root>/Gain5' incorporates:
 * UnitDelay: '<Root>/Unit Delay1'
 */
fxpdemo_direct_form2_B.Gain5 = (int16_T)((myGainParam *
 fxpdemo_direct_form2_B.UnitDelay1) >> 5);
```

```
rtwdemoclean;
```

- “Parameter Data Types in the Generated Code” on page 33-129
- “Reuse Parameter Data in Different Data Type Contexts” on page 33-141

## Reuse Parameter Data in Different Data Type Contexts

When you use a `Simulink.Parameter` object or a numeric MATLAB® variable to set two or more block parameter values, if the block parameters have different data types, you must explicitly specify the data type of the object or variable. For example, you cannot leave the data type of the parameter object at the default value, `auto`.

### Create and Configure Example Model

Create the model `ex_paramdt_contexts`.

`ex_paramdt_contexts`

Copyright 2021 The MathWorks, Inc.

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, on the **Imports/Outputs** tab, use the **Data Type** column to set the data type of the In1 Inport block to `single` and the data type of the In2 block to `int8`.

On the **Signals** tab, set the data types of the Gain block outputs to `Inherit: Same as input`.

On the **Parameters** tab, for the **Gain** parameters of the Gain blocks, set **Data Type** to `Inherit: Same as input`.

For the **Gain** parameters, set **Value** to `myGainParam`.

Alternatively, to configure the blocks, use these commands at the command prompt:

```
set_param('ex_paramdt_contexts/In1','OutDataTypeStr','single')
set_param('ex_paramdt_contexts/In2','OutDataTypeStr','int8')
set_param('ex_paramdt_contexts/Gain - single','Gain','myGainParam',...
 'OutDataTypeStr','Inherit: Same as input',...
 'ParamDataTypeStr','Inherit: Same as input')
set_param('ex_paramdt_contexts/Gain - int8','Gain','myGainParam',...
 'OutDataTypeStr','Inherit: Same as input',...
 'ParamDataTypeStr','Inherit: Same as input')
```

In the Model Data Editor, for either **Gain** block parameter, click the cell in the **Value** column. Next to `myGainParam`, click the action button (with three vertical dots) and select **Create**.

In the **Create New Data** dialog box, set **Value** to `Simulink.Parameter(3)` and click **Create**. A `Simulink.Parameter` object with value 3 appears in the model workspace.

In the **myGainParam** property dialog box, set **Data type** to `int8`.

On the Code Generation tab, click **Configure in Coder App**.

In the Code Mappings editor, set the storage class of `myGainParam` to `ExportedGlobal`. With the storage class `ExportedGlobal`, the object appears in the generated code as a global variable.

Alternatively, to create and configure the parameter object, use these commands at the command prompt:

```
mws = get_param('ex_paramdt_contexts', 'modelworkspace');
mws.assignin('myGainParam', Simulink.Parameter(3));
setVariablePart(mws, 'myGainParam.DataType', 'int8');
cm = coder.mapping.utils.create('ex_paramdt_contexts');
setModelParameter(cm, 'myGainParam', 'StorageClass', 'ExportedGlobal');
```

In this model, you use the parameter object `myGainParam` to set two block parameter values. The block parameters inherit different data types from the block input signals (`single` or `int8`). To use `myGainParam` in these different data type contexts, you explicitly specify the data type of the parameter object by setting the `DataType` property to `int8`.

### Match Parameter Object Data Type with Signal Data Type

Optionally, use a `Simulink.NumericType` or `Simulink.AliasType` object to set the parameter object data type and one of the signal data types. This technique eliminates unnecessary typecasts and shifts in the generated code due to a mismatch between the parameter object data type and the signal data type.

At the command prompt, create a `Simulink.NumericType` object to represent the data type `int8`.

```
sharedType_int8 = fixdt('int8');
```

In the Model Data Editor, on the **Inports/Outports** tab, set the data type of the In2 Inport block to `sharedType_int8`.

On the **Parameters** tab, update the block diagram. The data table now contains a row that represents the parameter object, `myGainParam`.

Use the **Data Type** column to set the data type of the parameter object to `sharedType_int8`.

Alternatively, to configure the block and the object, use these commands at the command prompt:

```
myGainParam.DataType = 'sharedType_int8';
set_param('ex_paramdt_contexts/In2', 'OutDataTypeStr', 'sharedType_int8')
```

The parameter object and the signal use the data type `int8`. To change this data type, adjust the properties of the data type object `sharedType_int8`.

### Generate and Inspect Code

Generate code from the model.

```
slbuild('ex_paramdt_contexts')
```

```
Starting build procedure for: ex_paramdt_contexts
Successful completion of build procedure for: ex_paramdt_contexts
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
ex_paramdt_contexts	Code generated and compiled	Code generation information file does not exist

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 21.087s
```

The generated file `ex_paramdt_contexts.c` defines the global variable `myGainParam` by using the data type `int8_T`, which corresponds to the data type `int8` in Simulink.

```
file = fullfile('ex_paramdt_contexts_grt_rtw','ex_paramdt_contexts.c');
rtwdemodbtype(file, /* Exported block parameters */,'int8_T myGainParam = 3;',1,1)
```

```
/* Exported block parameters */
int8_T myGainParam = 3; /* Variable: myGainParam
```

The generated code algorithm in the model `step` function uses `myGainParam` to calculate the outputs of the two Gain blocks. In the case of the Gain block whose input signal uses the data type `single`, the code algorithm casts `myGainParam` to the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```
rtwdemodbtype(file, /* Model step function */,...
 /* Model initialize function */,'1,0)

/* Model step function */
void ex_paramdt_contexts_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain - single'
 * Inport: '<Root>/In1'
 */
 ex_paramdt_contexts_Y.Out1 = (real32_T)myGainParam * ex_paramdt_contexts_U.In1;

 /* Output: '<Root>/Out2' incorporates:
 * Gain: '<Root>/Gain - int8'
 * Inport: '<Root>/In2'
 */
 ex_paramdt_contexts_Y.Out2 = (int8_T)(myGainParam * ex_paramdt_contexts_U.In2);
}
```

## Organize Data into Structures in Generated Code

In C code, you use structures (`struct`) to store data in contiguous locations in memory. You can organize data, such as signals and states, by using meaningful names. Each structure acts as a namespace, so you can reuse a name to designate multiple data items. Like arrays, with structures, you can write code that efficiently transfers and operates on large amounts of data by using pointers.

By default, the code generator aggregates data into standard structures (see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49). To control the characteristics of these structures or to override this default behavior by creating different structures, use the information in the table.

Goal	Technique
Control the characteristics of the standard data structures. For example, specify the names of the structure types, structure variables, and field names.	With Embedded Coder, see “Control Data Type Names in Generated Code” on page 35-2.
Control the placement of the structures in memory, for example, by inserting pragmas or other code decorations.	With Embedded Coder, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

Goal	Technique
<p>Aggregate data into structures whose names and other basic characteristics you can control. As you add blocks and signals to the model, the resulting new data appears in these structures by default.</p>	<p>With Embedded Coder, apply a structured storage class to a category of data by using the Code Mapping Editor.</p> <ul style="list-style-type: none"> <li>• When you generate nonreentrant, single-instance code by setting the model configuration parameter <b>Code interface packaging</b> to <b>Nonreusable function</b>, create flat, global structure variables by applying the built-in storage class <b>Struct</b>. Alternatively, use example storage classes created by Quick Start tool, <b>ParamStruct</b> and <b>SignalStruct</b>, or create and apply your own structured storage class.</li> <li>• When you generate multi-instance (reentrant) code from a model or a component, for example by setting <b>Code interface packaging</b> to a value other than <b>Nonreusable function</b>, in the Code Mappings editor, you cannot use the built-in storage class <b>Struct</b> or a structured storage class that you create in a package. Instead, create your own structured storage class by using an Embedded Coder Dictionary. If you use the Embedded Coder Quick Start tool to prepare the model for code generation (see “Generate Code by Using the Quick Start Tool” on page 50-9), you can use example storage classes <b>ParamStruct</b> and <b>SignalStruct</b>.</li> <li>• You cannot use this technique to aggregate global data stores or global parameters (which include parameter objects that you store in the base workspace or a data dictionary). For these kinds of data, use other techniques to create structures.</li> </ul> <p>For more information about the Code Mapping Editor, see “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15. To create your own storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2.</p>

Goal	Technique
Improve readability of the generated code by organizing individual data items into a custom structure whose characteristics you can finely control.	<p>Create a <code>Simulink.Bus</code> object that represents the structure type that you want. Use the bus object to set the data types of nonvirtual bus signals and parameter structures in your model.</p> <ul style="list-style-type: none"><li>• For an example that shows how to organize parameter data, see “Structures of Parameters” on page 33-150.</li><li>• For an example that shows how to organize signal data, see “Structures of Signals” on page 33-152.</li></ul> <p>To create an array of structures, see “Arrays of Structures” on page 33-158.</p>
Exchange structured data between generated code and your external code, for example, when the external code already defines a custom structure type and a corresponding global variable.	<p>Create a <code>Simulink.Bus</code> object that represents the structure type that you want. If your external code already defines the type, use the <code>Simulink.importExternalCTypes</code> function to generate the bus object. Use the bus object to set the data types of nonvirtual bus signals and parameter structures in your model. For an example, see “Exchange Structured and Enumerated Data Between Generated and External Code” on page 35-27.</p>

Goal	Technique
Reduce the number of arguments (formal parameters) for generated functions.	<ul style="list-style-type: none"> <li>• To reduce the number of arguments for the entry-point functions of the model from which you generate code, such as <code>model_step</code>, see “Reduce Number of Arguments by Using Structures” on page 33-47.</li> <li>• To reduce the number of arguments for the entry-point functions of a referenced model, in the referenced model: <ul style="list-style-type: none"> <li>• Configure root-level Inport and Outport blocks to appear in the code as structure fields. Replace multiple such blocks with a single block that you configure as a nonvirtual bus signal. With this technique, you have the greatest control over the structure characteristics. As you add blocks to the model, you must manually modify the bus definitions. See “Nonvirtual Buses and Parameter Structures” on page 33-150.</li> <li>• Organize model arguments into a custom structure (see “Specify Instance-Specific Parameter Values for Reusable Referenced Model” on page 5-28).</li> </ul> </li> <li>• To reduce the number of arguments for the entry-point functions of a masked, reentrant subsystem, aggregate mask parameters into a custom structure.</li> </ul>
Organize lookup table data into a structure.	Use <code>Simulink.LookupTable</code> and <code>Simulink.Breakpoint</code> objects. See <code>Simulink.LookupTable</code> .
Generate bit fields.	See “Bitfields” on page 25-69 and “Optimize Generated Code by Packing Boolean Data into Bitfields” on page 75-11.

## Techniques to Create Structures

To create structures in the generated code, you can use these techniques:

- Apply a structured storage class to categories of data by using the Code Mapping Editor. As you add blocks and signals to a model, new data elements acquire this storage class by default.
- Apply a structured storage class, such as the built-in storage class `Struct`, directly to individual data items by using the Model Data Editor.
- Create custom nonvirtual buses and parameter structures.

To decide which techniques to use, use the information in the table.

Capability	Default Application of Structured Storage Class	Direct Application of Structured Storage Class	Nonvirtual Buses and Parameter Structures
Aggregate new data items into a structure by default	Yes	No	No
Prevent elimination of the target data by optimizations (specify that the data appear in the generated code)	No	Yes	Only if you directly apply a storage class such as <code>ExportedGlobal</code> to the bus or structure
Aggregate data into a structure without changing the appearance of the block diagram	Yes	Yes	No
Place signal, state, and parameter data in the same structure	No	Yes	No
Include state data in a structure	Yes	Yes	No
Organize structures into nested structures	No	No	Yes
Organize structures into an array of structures	No	No	Yes
Control name of structure type	Yes	Yes, but the type name derives from the variable name, which you specify	Yes
Create a structure to reduce the number of arguments in a generated function	Yes, but you must create your own storage class by using an Embedded Coder Dictionary	No	Yes
Requires Embedded Coder	Yes	Yes	No

## Default Application of Structured Storage Class

You can apply a default storage class to a category of model data. As you add blocks and signals to the model, the associated data acquire the default storage class that you specify. To aggregate new data into structures by default, you can apply structured storage classes. You must use example storage classes `ParamStruct` and `SignalStruct` created by the Quick Start tool or create your own storage class by using an Embedded Coder Dictionary.

You cannot use default application to aggregate global data stores or global parameters (parameter objects that you store in the base workspace or a data dictionary).

To apply default storage classes, use the Code Mapping Editor. In a model window, in the Apps gallery, click **Embedded Coder**. Then, under **Code Mappings > Data Defaults**, apply storage classes by using the **Storage Class** column.

For more information about the Code Mapping Editor, see “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15. To create your own storage class by using an Embedded Coder Dictionary, see “Create Code Definitions for Use in the Code Mappings Editor” on page 31-2.

## Direct Application of Structured Storage Class

You can apply a structured storage class to individual data items. The direct application prevents code generation optimizations, such as **Default parameter behavior** and **Signal storage reuse**, from eliminating each data item from the generated code. The direct application also overrides the default storage classes that you specify with **Code Mappings > Data Defaults**.

To directly apply a storage class, use the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). Set **Change view** to Code and apply the storage class by using the **Storage Class** column.

For an example that shows how to use `Struct`, see “Configure Parameters for C Code Generation” on page 32-61. For more information about applying storage classes, see “Organize Parameter Data into a Structure by Using Struct Storage Class” on page 32-67.

## Nonvirtual Buses and Parameter Structures

- To create a nonvirtual bus signal, use a Bus Creator block to organize multiple signal lines into a single bus, or configure an Inport block or Outport block as a nonvirtual bus. You must create a `Simulink.Bus` object that represents the structure type. For an example, see “Structures of Signals” on page 33-152. For general information about nonvirtual buses, see “Group Signal Lines into Virtual Buses”.
- To create a parameter structure, use MATLAB commands or the Variable Editor to organize the values of multiple block parameters into a MATLAB structure. Optionally, create a `Simulink.Bus` object so that you can control the name of the structure type and other characteristics such as the data type and dimensions of each field. For an example, see “Structures of Parameters” on page 33-150. For general information about parameter structures, see “Organize Related Block Parameter Definitions in Structures”.

### Structures of Parameters

Create a structure in the generated code. The structure stores parameter data.

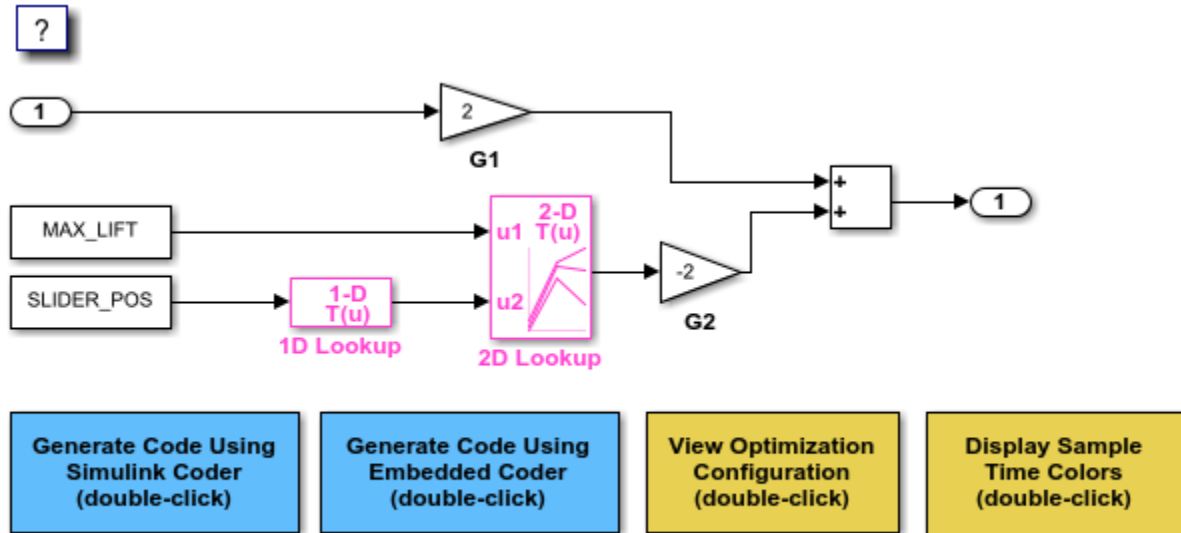

#### C Construct

```
typedef struct {
 double G1;
 double G2;
} myStructType;

myStructType myStruct = {
 2.0,
 -2.0
} ;
```

## Procedure

1. Open the example model `rtwdemo_paraminline`.

Copyright 1994-2020 The MathWorks, Inc.

2. On the **Modeling** tab, click **Model Data Editor**. In the Model Data Editor, select the **Parameters** tab.
3. In the model, click the Gain block labeled G1. In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to `myStruct.G1`.
4. Set the value of the **Gain** parameter in the G2 block to `myStruct.G2`.
5. Next to `myStruct.G2`, click the action button (with three vertical dots) and select **Create**.
6. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(struct)` and click **Create**. A `Simulink.Parameter` object named `myStruct` appears in the base workspace.
7. In the `Simulink.Parameter` property dialog box, next to the **Value** property, click the action button and select **Open Variable Editor**.
8. Right-click the white space under the **Field** column and select **New**. Name the new structure field `G1`. Use the **Value** column to set the value of the field to 2.
9. Add a field `G2` whose value is -2, and then close the Variable Editor.
10. In the `Simulink.Parameter` property dialog box, on the **Code Generation** tab, set **Storage class** to `ExportedGlobal`. The structure `myStruct` appears in the generated code as a global variable.
11. Generate code from the model.

## Results

The generated header file `rtwdemo_paraminline_types.h` defines a structure type that has a random name.

```
typedef struct {
 real_T G1;
 real_T G2;
} struct_6h72eH5WFuEIyQr5YrdGuB;
```

The source file `rtwdemo_paraminline.c` defines and initializes the structure variable `myStruct`.

```
/* Exported block parameters */
struct_6h72eH5WFuEIyQr5YrdGuB myStruct = {
 2.0,
 -2.0
};

/* Variable: myStruct
 * Referenced by:
 * '<Root>/G1'
 * '<Root>/G2'
 */
```

### Specify Name of Structure Type

1. Optionally, specify a name to use for the structure type definition (`struct`). At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object that represents the structure type.
2. The default name of the object is `slBus1`. Change the name by copying the object into a new MATLAB variable.
3. In the Model Data Editor, click the **Show/refresh additional information** button.
4. In the data table, find the row that corresponds to `myStruct`. Use the **Data Type** column to set the data type of `myStruct` to `Bus: myStructType`.
5. Generate code from the model.

The code generates the definition of the structure type `myStructType` and uses this type to define the global variable `myStruct`.

```
myStructType myStruct = {
 2.0,
 -2.0
};

/* Variable: myStruct
```

### Structures of Signals

This example shows how to create a structure of signal data in the generated code.

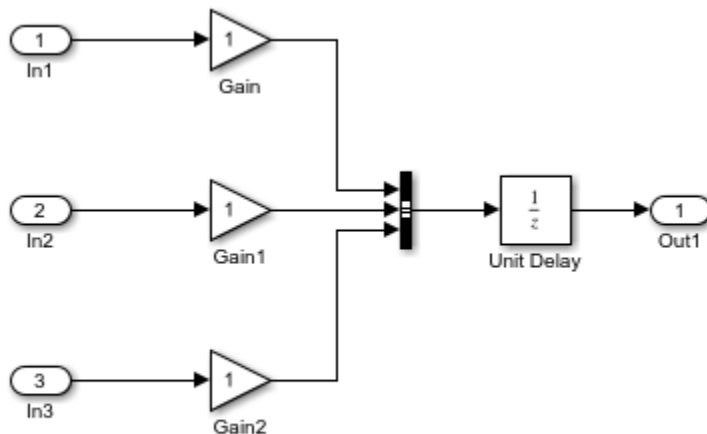

#### C Construct

```
typedef struct {
 double signal1;
 double signal2;
 double signal3;
} my_signals_type;
```

## Procedure

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of buses in your model.

1. Create the `ex_signal_struct` model by using Gain blocks, a Bus Creator block, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

Copyright 2021 The MathWorks, Inc.

2. To configure the Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.
3. In the toolstrip, on the **Modeling** tab, under **Design**, click **Bus Editor**.
4. In the Bus Editor toolstrip, in the **Add** gallery, click **Bus** to create a `Simulink.Bus` object. Then, name it `my_signals_type`. With `my_signals_type` selected, in the **Add** gallery, click **Bus Element** three times to add three elements. Name them `signal1`, `signal2`, and `signal3`. For more information, see Bus Editor.

Contents of 'Base Workspace' Filter contents

Name	DataType	Complexity	Dimensions	DimensionsMode	Min	Max	Unit	Description
my_signals_type								
— signal1	double	real	1	Fixed	[]	[]		
— signal2	double	real	1	Fixed	[]	[]		
— signal3	double	real	1	Fixed	[]	[]		

Property Inspector

Simulink.Bus: my\_signals\_type

**Properties**

Name:

Description:

5. Save the bus objects in your current folder as `ex_signal_struct_data.mat`.

This bus object represents the structure type that you want the generated code to use.

6. In the Bus Creator block dialog box, set **Output data type** to Bus: `my_signals_type`.
7. Select **Output as nonvirtual bus**. Click **OK**. A nonvirtual bus appears in the generated code as a structure.

8. Open the **Simulink Coder** app. In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
9. Open the **Signals/States** tab. In the model, select the output signal of the Bus Creator block and click the **Add selected signals to code mappings** button in the Code Mappings editor.
11. For the added signal, set **Storage Class** to `ExportedGlobal`.
12. In the Property Inspector, set the **Code > Identifier** property to `sig_struct_var`. The output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.
13. Generate code from the model.

### Results

The generated header file `ex_signal_struct_types.h` defines the structure type `my_signals_type`.

```
typedef struct {
 real_T signal1;
 real_T signal2;
 real_T signal3;
} my_signals_type;
```

The source file `ex_signal_struct.c` allocates memory for the global variable `sig_struct_var`, which represents the output of the Bus Creator block.

```
/* Exported block signals */
my_signals_type sig_struct_var; /* '<Root>/Bus Creator' */
```

In the same file, in the model `step` function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

### Nested Structures of Signals

You can create nested structures of signal data in the generated code.

#### C Construct

```
typedef struct {
 double signal1;
 double signal2;
 double signal3;
} B_struct_type;

typedef struct {
 double signal1;
 double signal2;
} C_struct_type;

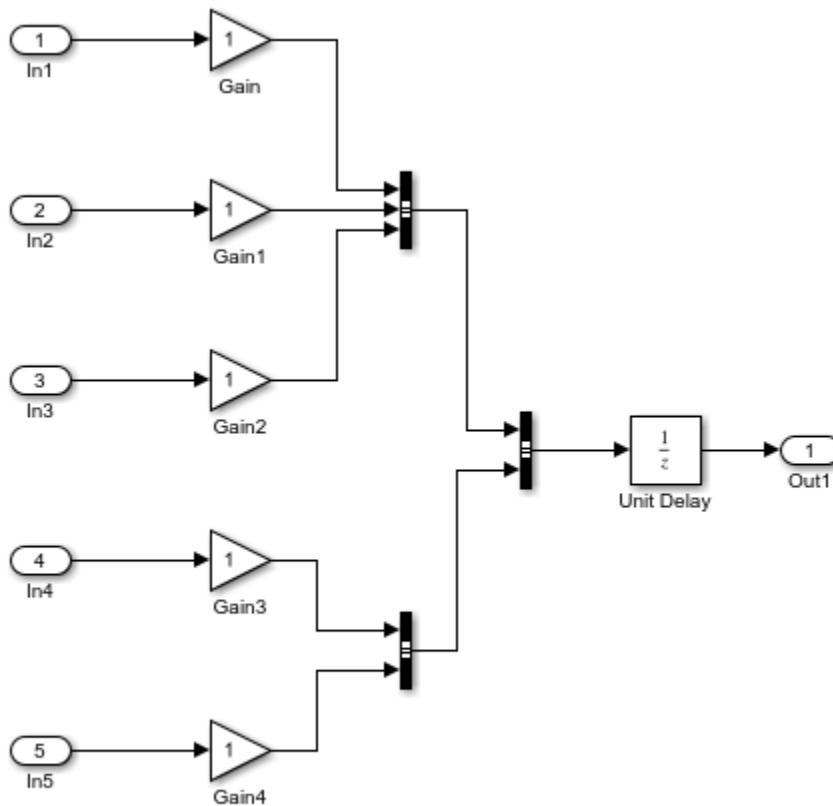

typedef struct {
 B_struct_type subStruct_B;
 C_struct_type subStruct_C;
} A_struct_type;
```

## Procedure

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of buses in your model.

To nest a structure inside another structure, use a bus object as the data type of an element in another bus object.

1. Create the `ex_signal_nested_struct` model with Gain blocks, Bus Creator blocks, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

Copyright 2021 The MathWorks, Inc.

2. To configure a Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.

3. In the toolstrip, on the **Modeling** tab, under **Design**, click **Bus Editor**.

In the Bus Editor toolstrip, in the **Add** gallery, click **Bus** to create a `Simulink.Bus` object. Then, name it `A_struct_type`. With `A_struct_type` selected, in the **Add** gallery, click **Bus Element** twice to add two elements. Name the elements `subStruct_B` and `subStruct_C`. For more information, see Bus Editor. This bus object represents the top-level structure type that you want the generated code to use.

4. Similarly, create `Simulink.Bus` objects `B_struct_type` (with three elements) and `C_struct_type` (with two elements).
5. In the `A_struct_type` object, for the `subStruct_B` element, set **Data Type** to `Bus: B_struct_type`. Similarly, for the `subStruct_C` element, set **Data Type** to `Bus: C_struct_type`.

The screenshot shows the 'Contents of Base Workspace' window on the left and the 'Property Inspector' on the right. The workspace window displays a tree view of Simulink.Bus objects:

Name	DataType	Complexity	Dimensions
▼ A_struct_type			
▼ subStruct_B	<b>Bus: B_struct_type</b>	real	1
— signal1	double	real	1
— signal2	double	real	1
— signal3	double	real	1
▼ subStruct_C	<b>Bus: C_struct_type</b>	real	1
— signal1	double	real	1
— signal2	double	real	1
▼ B_struct_type			
— signal1	double	real	1
— signal2	double	real	1
— signal3	double	real	1
▼ C_struct_type			
— signal1	double	real	1
— signal2	double	real	1

The Property Inspector on the right shows the selected object: `Simulink.Bus: A_struct_type`. Under the 'Properties' section, the 'Name' is set to `A_struct_type`. The 'Code Generation' section is also visible.

Each element in `A_struct_type` uses another bus object as a data type. These elements represent substructures.

6. In the dialog box of the Bus Creator block that collects the three Gain signals, set **Output data type** to `Bus: B_struct_type`. Click **Apply**.
7. Select **Output as nonvirtual bus** and click **OK**.
8. In the dialog box of the other subordinate Bus Creator block, set **Output data type** to `Bus: C_struct_type` and select **Output as nonvirtual bus**. Click **OK**.
9. In the last Bus Creator block dialog box, set **Output data type** to `Bus: A_struct_type` and select **Output as nonvirtual bus**. Click **OK**.
10. Open the **Simulink Coder** app. In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
11. Open the **Signals/States** tab. In the model, select the output signal of the `A_struct_type` Bus Creator block, which feeds the Unit Delay block. Click the **Add selected signals to code mappings** button in the Code Mappings editor.

12. For the added signal, set **Storage Class** to `ExportedGlobal`.

13. In the Property Inspector, set the **Code > Identifier** property to `sig_struct_var`. The output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

14. Generate code from the model.

## Results

The generated header file `ex_signal_nested_struct_types.h` defines the structure types. Each structure type corresponds to a `Simulink.Bus` object.

```
typedef struct {
 real_T signal1;
 real_T signal2;
 real_T signal3;
} B_struct_type;

typedef struct {
 real_T signal1;
 real_T signal2;
} C_struct_type;

typedef struct {
 B_struct_type subStruct_B;
 C_struct_type subStruct_C;
} A_struct_type;
```

The generated source file `ex_signal_nested_struct.c` allocates memory for the global structure variable `sig_struct_var`. By default, the name of the `A_struct_type` Bus Creator block is `Bus Creator2`.

```
/* Exported block signals */
A_struct_type sig_struct_var; /* '<Root>/Bus Creator2' */
```

In the same file, in the model step function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

## Combine Techniques to Work Around Limitations

To work around some of the limitations of each technique, you can combine structured storage classes with nonvirtual buses and parameter structures. For example, you can:

- Include a structure of signal data and a structure of parameter data in the same parent structure.
- Nest structures while aggregating new data by default.

In the generated code, a flat parent structure, which corresponds to the structured storage class, contains substructures, which correspond to each bus and parameter structure. Choose one of these combined techniques:

- Apply the structured storage class directly to each bus and parameter structure. For example, set the storage class of two nonvirtual bus signals to `Struct`. Each bus appears in the generated code as a field (substructure) of a single structure.

- Leave the storage class of each bus and parameter structure at the default setting, `Auto`, or at `Model default`, which prevents code generation optimizations from eliminating the bus or parameter structure. Then, configure default storage classes such that signal data and parameter data use the structured storage class by default.

## Arrays of Structures

You can further package multiple consistent bus signals or parameter structures into an array. The array of buses or parameter structures appears in the generated code as an array of structures. To create arrays of buses, see “Group Nonvirtual Buses in Arrays of Buses”. To create arrays of parameter structures, see “Group Multiple Parameter Structures into an Array”.

## Structure Padding

By default, the code generator does not explicitly add padding fields to structure types. Structure types can appear in the generated code through, for example, the standard data structures (see “Data Structures in the Generated Code” on page 33-31), `Simulink.Bus` objects, and parameter structures that you use in a model.

However, when you use a code replacement library with Embedded Coder, you can specify data alignment (including structure padding) as part of the replacement library. For more information, see “Provide Data Alignment Specifications for Compilers” on page 69-106.

## Limitations

- With built-in Simulink Coder and Embedded Coder features, you cannot generate or use a custom structure that contains a field whose value is a pointer. You can do so manually by creating an advanced storage class and writing accompanying TLC code (see “Finely Control Data Representation by Writing TLC Code for a Storage Class” on page 37-23).
- You cannot use the built-in storage class `Struct`, or a structured storage class that you create with the Custom Storage Class Designer (you set the storage class property **Type** to `FlatStructure`), to set data defaults in the Code Mapping Editor.

## Switch Between Sets of Parameter Values During Simulation and Code Execution

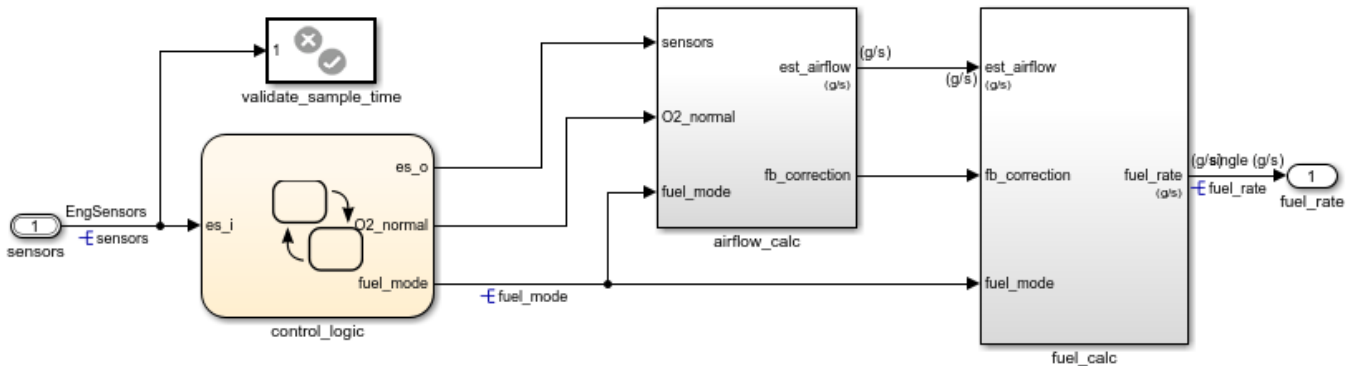

To store multiple independent sets of values for the same block parameters, you can use an array of structures. To switch between the parameter sets, create a variable that acts as an index into the array, and change the value of the variable. You can change the value of the variable during simulation and, if the variable is tunable, during execution of the generated code.

### Explore Example Model

Open the example model.

```
open_system('sldemo_fuelsys_dd_controller')
```

### Fuel Rate Controller

Copyright 1990-2017 The MathWorks, Inc.

This model represents the fueling system of a gasoline engine. The output of the model is the rate of fuel flow to the engine.

Navigate to the `switchable_compensation` nested subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/', ...
 'switchable_compensation'])
```

### Loop Compensation and Filtering

This subsystem corrects and filters noise out of the fuel rate signal. The subsystem uses different filter coefficients based on the fueling mode, which the control logic changes based on sensor failures in the engine. For example, the control algorithm activates the `low_mode` subsystem during normal operation. It activates the `rich_mode` subsystem in response to sensor failure.

Open the `low_mode` subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/', ...
 'switchable_compensation/low_mode'])
```

The Discrete Filter block filters the fuel rate signal. In the block dialog box, the **Numerator** parameter sets the numerator coefficients of the filter.

The sibling subsystem `rich_mode` also contains a Discrete Filter block, which uses different coefficients.

Update the model diagram to display the signal data types. The input and output signals of the block use the single-precision, floating-point data type `single`.

In the lower-left corner of the model, click the model data badge, then click the **Data Dictionary** link. The data dictionary for this model, `sldemo_fuelsys_dd_controller.sldd`, opens in the Model Explorer.

In the Model Explorer **Model Hierarchy** pane, select the **Design Data** node.

In the **Contents** pane, view the properties of the Simulink.NumericType objects, such as `s16En15`. All of these objects currently represent the single-precision, floating-point data type `single`. The model uses these objects to set signal data types, including the input and output signals of the Discrete Filter blocks.

Suppose that during simulation and execution of the generated code, you want each of these subsystems to switch between different numerator coefficients based on a variable whose value you control.

### Store Parameter Values in Array of Structures

Store the existing set of numerator coefficients in a Simulink.Parameter object whose value is a structure. Each field of the structure stores the coefficients for one of the Discrete Filter blocks.

```
lowBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
 'switchable_compensation/low_mode/Discrete Filter'];
richBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
 'switchable_compensation/rich_mode/Discrete Filter'];
params.lowNumerator = eval(get_param(lowBlock, 'Numerator'));
params.richNumerator = eval(get_param(richBlock, 'Numerator'));
params = Simulink.Parameter(params);
```

Copy the value of `params` into a temporary variable. Modify the field values in this temporary structure, and assign the modified structure as the second element of `params`.

```
temp = params.Value;
temp.lowNumerator = params.Value.lowNumerator * 2;
temp.richNumerator = params.Value.richNumerator * 2;
params.Value(2) = temp;
clear temp
```

The value of `params` is an array of two structures. Each structure stores one set of filter coefficients.

### Create Variable to Switch Between Parameter Sets

Create a Simulink.Parameter object named `Ctrl`.

```
Ctrl = Simulink.Parameter(2);
Ctrl.DataType = 'uint8';
```

In the `low_mode` subsystem, in the Discrete Filter block dialog box, set the **Numerator** parameter to the expression `params(Ctrl).lowNumerator`.

```
set_param(lowBlock, 'Numerator', 'params(Ctrl).lowNumerator');
```

In the Discrete Filter block in the `rich_mode` subsystem, set the value of the **Numerator** parameter to `params(Ctrl).richNumerator`.

```
set_param(richBlock, 'Numerator', 'params(Ctrl).richNumerator');
```

The expressions select one of the structures in `params` by using the variable `Ctrl`. The expressions then dereference one of the fields in the structure. The field value sets the values of the numerator coefficients.

To switch between the sets of coefficients, you change the value of `Ctrl` to the corresponding index in the array of structures.

### Use Bus Object as Data Type of Array of Structures

Optionally, create a `Simulink.Bus` object to use as the data type of the array of structures. You can:

- Control the shape of the structures.
- For each field, control characteristics such as data type and physical units.
- Control the name of the `struct` type in the generated code.

Use the function `Simulink.Bus.createObject` to create the object and rename the object as `paramsType`.

```
Simulink.Bus.createObject(params.Value)
paramsType = slBus1;
clear slBus1
```

You can use the `Simulink.NumericType` objects from the data dictionary to control the data types of the structure fields. In the bus object, use the name of a data type object to set the `DataType` property of each element.

```
paramsType.Elements(1).DataType = 's16En15';
paramsType.Elements(2).DataType = 's16En7';
```

Use the bus object as the data type of the array of structures.

```
params.DataType = 'Bus: paramsType';
```

### Use Enumerated Type for Switching Variable

Optionally, use an enumerated type as the data type of the switching variable. You can associate each of the parameter sets with a meaningful name and restrict the allowed values of the switching variable.

Create an enumerated type named `FilterCoeffs`. Create an enumeration member for each of the structures in `params`. Set the underlying integer value of each enumeration member to the corresponding index in `params`.

```
Simulink.defineIntEnumType('FilterCoeffs',{'Weak','Aggressive'},[1 2])
```

Use the enumerated type as the data type of the switching variable. Set the value of the variable to `Aggressive`, which corresponds to the index 2.

```
Ctrl.Value = FilterCoeffs.Aggressive;
```

### Add New Objects to Data Dictionary

Add the objects that you created to the data dictionary `sldemo_fuelsys_dd_controller.slidd`.

```
dictObj = Simulink.data.dictionary.open('sldemo_fuelsys_dd_controller.slidd');
sectObj = getSection(dictObj,'Design Data');
addEntry(sectObj,'Ctrl',Ctrl)
```

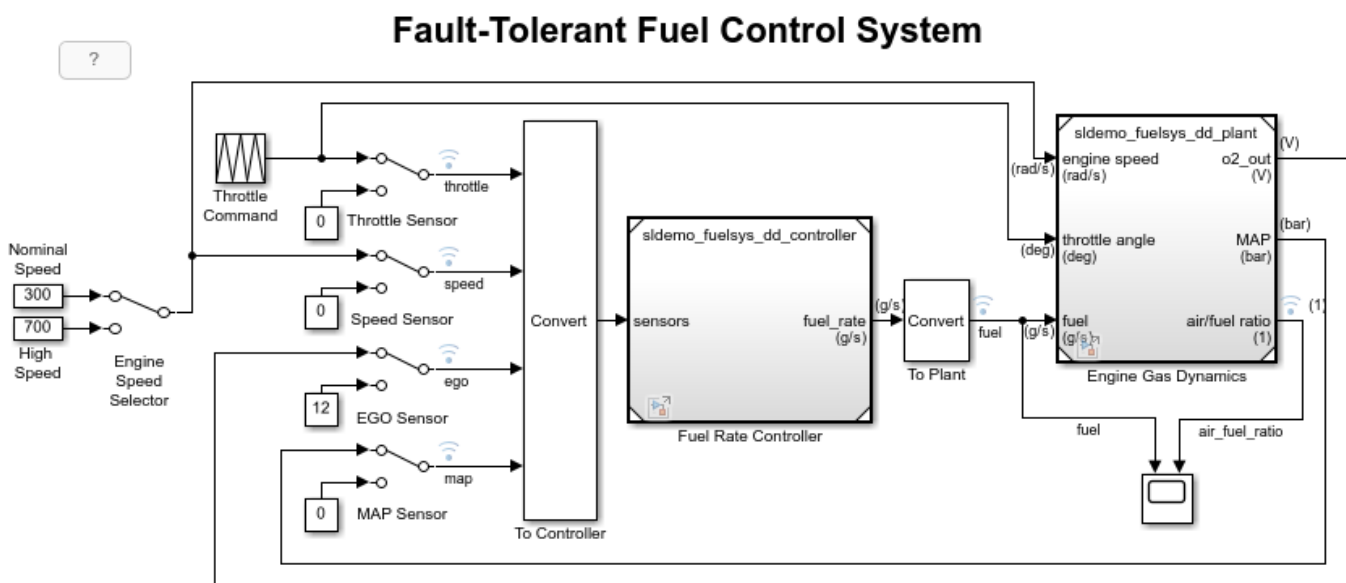

```
addEntry(sectObj, 'params', params)
addEntry(sectObj, 'paramsType', paramsType)
```

You can also store enumerated types in data dictionaries. However, you cannot import the enumerated type in this case because you cannot save changes to `sldemo_fuelsys_dd_controller.sldd`. For more information about storing enumerated types in data dictionaries, see “Enumerations in Data Dictionary”.

### Switch Between Parameter Sets During Simulation

Open the example model `sldemo_fuelsys_dd`, which references the controller model `sldemo_fuelsys_dd_controller`.

```
open_system('sldemo_fuelsys_dd')
```

The sensor switches simulate any combination of sensor failures.  
The Engine Speed Selector switch simulates different engine speeds (rad/s).

Copyright 1990-2017 The MathWorks, Inc.

Set the simulation stop time to `Inf` so that you can interact with the model during simulation.

Begin a simulation run and open the Scope block dialog box. The scope shows that the fuel flow rate (the `fuel` signal) oscillates with significant amplitude during normal operation of the engine.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. Set the value of `Ctrl` to `FilterCoeffs.Weak`.

Update the `sldemo_fuelsys_dd` model diagram. The scope shows that the amplitude of the fuel rate oscillations decreases due to the less aggressive filter coefficients.

Stop the simulation.

### Generate and Inspect Code

If you have Simulink Coder software, you can generate code that enables you to switch between the parameter sets during code execution.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. In the **Contents** pane, set **Column View** to **Storage Class**.

Use the **StorageClass** column to apply the storage class `ExportedGlobal` to `params` so that the array of structures appears as a tunable global variable in the generated code. Apply the same storage class to `Ctrl` so that you can change the value of the switching variable during code execution.

Alternatively, to configure the objects, use these commands:

```
tempEntryObj = getEntry(sectObj, 'params');
params = getValue(tempEntryObj);
params.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj, params);

tempEntryObj = getEntry(sectObj, 'Ctrl');
Ctrl = getValue(tempEntryObj);
Ctrl.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj, Ctrl);
```

Generate code from the controller model.

```
slbuild('sldemo_fuelsys_dd_controller')

Starting build procedure for: sldemo_fuelsys_dd_controller
Successful completion of code generation for: sldemo_fuelsys_dd_controller
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
sldemo_fuelsys_dd_controller	Code generated	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 1m 15.131s

In the code generation report, view the header file `sldemo_fuelsys_dd_controller_types.h`. The code defines the enumerated data type `FilterCoeffs`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw', ...
 'sldemo_fuelsys_dd_controller_types.h');
rtwmodbtype(file, '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_', ...
 '/* Forward declaration for rtModel */', 1, 0)

#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_
#define DEFINED_TYPEDEF_FOR_FilterCoeffs_

typedef enum {
 Weak = 1, /* Default value */
 Aggressive
} FilterCoeffs;

#endif
```

The code also defines the structure type `paramsType`, which corresponds to the `Simulink.Bus` object. The fields use the single-precision, floating-point data type from the model.

```
rtwdemodbtype(file, '#ifndef DEFINED_TYPEDEF_FOR_paramsType_', ...
 '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_', 1, 0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_paramsType_
#define DEFINED_TYPEDEF_FOR_paramsType_
```

```
typedef struct {
 real32_T lowNumerator[2];
 real32_T richNumerator[2];
} paramsType;
```

```
#endif
```

View the source file `sldemo_fuelsys_dd_controller.c`. The code uses the enumerated type to define the switching variable `Ctrl`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw', ...
 'sldemo_fuelsys_dd_controller.c');
rtwdemodbtype(file, 'FilterCoeffs Ctrl = Aggressive;', ...
 '/* Block signals (default storage) */', 1, 0)
```

```
FilterCoeffs Ctrl = Aggressive; /* Variable: Ctrl
 * Referenced by:
 * '<S12>/Discrete Filter'
 * '<S13>/Discrete Filter'
 */
```

The code also defines the array of structures `params`.

```
rtwdemodbtype(file, '/* Exported block parameters */', ...
 '/* Variable: params', 1, 1)
```

```
/* Exported block parameters */
paramsType params[2] = { {
 { 8.7696F, -8.5104F },

 { 0.0F, 0.2592F }
}, { { 17.5392F, -17.0208F },

 { 0.0F, 0.5184F }
} }; /* Variable: params
```

The code algorithm in the model `step` function uses the switching variable to index into the array of structures.

To switch between the parameter sets stored in the array of structures, change the value of `Ctrl` during code execution.

Close the connections to the data dictionary. This example discards unsaved changes. To save the changes, use the `'-save'` option.

```
Simulink.data.dictionary.closeAll('sldemo_fuelsys_dd_controller.sldd','-discard')
```

## Design Data Interface by Configuring Inport and Output Blocks

The data interface of a model is the means by which the model exchanges data (for example, signal values) with other, external models or systems. Customize the data interface of a model to:

- Enable integration of the generated code with your own code.
- Improve traceability and readability of the code.

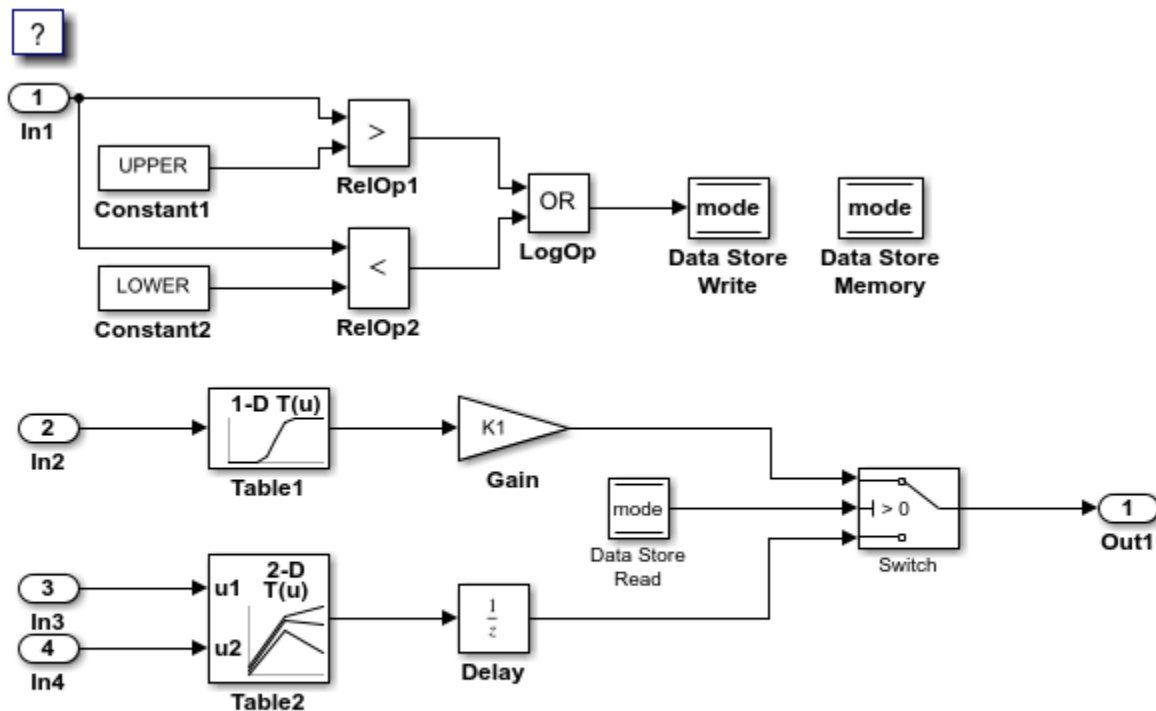

At the top level of a model, Inport and Output blocks represent the input and output signals of the model. To customize the data interface in the generated code, configure these blocks. Early in the design process, when a model can contain unconnected Inport and Output blocks, use this technique to specify the interface before developing the internal algorithm.

When you apply storage classes to Inport and Output blocks, each block appears in the generated code as a field of a global structure or as a separate global variable that the generated algorithm references directly. If you have Embedded Coder, you can use function prototype control instead of storage classes to pass data into and out of the model `step` function as formal parameters. For more information, see “Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113.

### Design Data Interface

Open the example model `rtwdemo_configrpinterface`.

```
open_system('rtwdemo_configrpinterface')
```

Copyright 1994-2020 The MathWorks, Inc.

Configure the model to show the generated names of blocks.

```
set_param('rtwdemo_configrpinterface', 'HideAutomaticNames', 'off')
```

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, select the **Inports/Outports** tab. Each row in the table represents an Output block or a signal that exits an Inport block.

For each of the signals that exit the Inport blocks, set **Data Type** to `single` or to a different data type. Due to the data type inheritance settings that the other blocks in the model use by default, downstream signals in the rest of the model use the same or a similar data type.

Optionally, configure other design attributes such as **Min** and **Max** (minimum and maximum values).

### Configure Default Storage Class

You can configure a default storage class for Inport blocks and Outport blocks then select the blocks that should use the specified default.

- 1 Open the **Simulink Coder** app.
- 2 In the C Code tab, select **Code Interface > Default Code Mappings**.
- 3 In the Code Mappings editor, under **Inports and Outports**, set the default storage class for both **Inports** and **Outports** to `ExportedGlobal`.

- 4 Next, on the **Inports** tab, select the data items that should use the default storage class. Press **Ctrl** and click each inport.
- 5 For the selected inports, set the storage class to `Model default: ExportedGlobal`.
- 6 Similarly, on the **Outputs** tab, set the storage class for the output to `Model default: ExportedGlobal`.

Alternatively, to configure the data defaults at the command prompt, use these commands:

```
cm = coder.mapping.api.get('rtwdemo_configrpinterface');
setDataDefault(cm,'Inports','StorageClass','ExportedGlobal');
setDataDefault(cm,'Outputs','StorageClass','ExportedGlobal');

setInport(cm,'In1','StorageClass','Model default');
setInport(cm,'In2','StorageClass','Model default');
setInport(cm,'In3','StorageClass','Model default');
setInport(cm,'In4','StorageClass','Model default');

setOutput(cm,'Out1','StorageClass','Model default','Identifier','output_sig');
```

Generate code from the model.

```
slbuild('rtwdemo_configrpinterface');

Starting build procedure for: rtwdemo_configrpinterface
Successful completion of code generation for: rtwdemo_configrpinterface
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_configrpinterface	Code generated	Code generation information file does not exist.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 41.226s
```

View the generated file `rtwdemo_configrpinterface.c`. Because you applied the storage class `ExportedGlobal` to the Inport and Output blocks, the code creates separate global variables that represent the inputs and the output.

```
file = fullfile('rtwdemo_configrpinterface_grt_rtw','rtwdemo_configrpinterface.c');
rtwdemodbtype(file,'/* Data with Exported storage */','real_T output_sig',1,1)

/* Data with Exported storage */
real_T input1; /* '<Root>/In1' */
real_T input2; /* '<Root>/In2' */
real_T input3; /* '<Root>/In3' */
real_T input4; /* '<Root>/In4' */
real_T output_sig; /* '<Root>/Out1' */
```

The generated algorithm in the model `step` function directly references these global variables to calculate and store the output signal value, `output_sig`.

### Route Signal Data to Multiple Outputs

Once you have configured the default storage classes for Inports and Outputs, you can choose to override this default and set the storage class for some data elements individually. For example, you

can route a single signal to multiple Outport blocks and apply a different storage class to each Outport. For example, use this technique to send signal data to a custom function (such as a device driver) and to a global variable that your custom algorithmic code can use:

- 1 Branch the target signal line to each Outport block.
- 2 For more efficient code, leave the storage class of the target signal line configured to Auto (the default). Optimizations can then eliminate the signal line from the generated code.
- 3 In the Code Mappings editor, on the **Outports** tab, apply the storage class `GetSet` to one Outport block and `ExportToFile` to the other Outport block.
- 4 In the Property Inspector, configure the properties associated with each applied storage class.

```
open_system('ex_route_sig')
```

Copyright 2021 The MathWorks, Inc.

## Limitations

You cannot apply a storage class to an Outport block if the input to the block has a variable size. Instead, apply the storage class to the signal line.

## Generate Efficient Code for Bus Signals

### In this section...

“Code Efficiency for Bus Signals” on page 33-171

“Set Bus Diagnostics” on page 33-171

“Optimize Virtual and Nonvirtual Buses” on page 33-172

In a model, you use bus signals to package multiple signals together into a single signal line. You can create virtual or nonvirtual bus signals. The representation in the generated code depends on:

- For a virtual bus, the generated code appears as if the bus did not exist.
- Generated code for a nonvirtual bus represents the bus data with a structure. When you want to trace the correspondence between the model and the code, the use of a structure in the generated code can be helpful. To generate structures using nonvirtual bus signals, see “Organize Data into Structures in Generated Code” on page 33-145.

For general information about buses, see and “Types of Composite Signals”.

To generate efficient code from models that contain bus signals, eliminate unnecessary data copies by following best practices as you construct the model.

### Code Efficiency for Bus Signals

When you use buses in a model for which you intend to generate code:

- Setting bus diagnostic configuration parameters can make model development easier.
- The bus implementation techniques, and the choice of a nonvirtual or virtual bus, can influence the speed, size, and clarity of the generated code.
- Some useful bus implementation techniques are not immediately obvious.

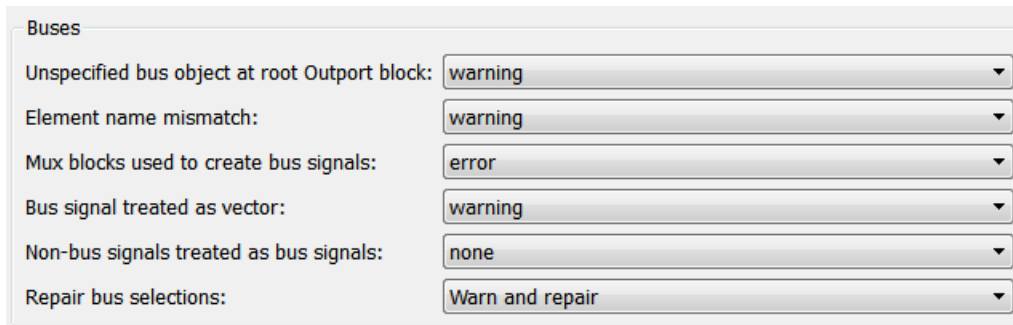

When you work with buses, these guidelines help you to improve the results. The guidelines describe techniques to:

- Simplify the layout of the model.
- Increase the efficiency of generated code.
- Define data structures for function (subsystem) interfaces.
- Define data structures that match existing data structures in external C code.

There are some trade-offs among speed, size, and clarity. For example, the code for nonvirtual buses is easier to read because the buses appear in the code as structures, but the code for virtual buses is faster because virtual buses do not require copying signal data. Apply some of the guidelines based on where you are in the application development process.

### Set Bus Diagnostics

Simulink provides diagnostics that you can use to optimize bus usage. Set the following values on the **Configuration Parameters > Diagnostics > Connectivity** pane.

## Optimize Virtual and Nonvirtual Buses

Virtual buses are graphical conveniences that do not affect generated code. As a result, the code generation engine is able to fully optimize the signals in the bus. Use virtual buses rather than nonvirtual buses wherever possible. You can convert between virtual and nonvirtual buses by using Signal Conversion blocks. In some cases, Simulink automatically converts a virtual bus to a nonvirtual bus when required. For example, a Stateflow chart converts an input virtual bus to a nonvirtual bus.

To bundle function-call signals, you must use a virtual bus.

You must use nonvirtual buses for:

- Nonauto storage classes
- Generating a specific structure from the bus
- Root-level Inport or Outport blocks when the bus has mixed data types

### Avoid Nonlocal Nested Buses in Nonvirtual Buses

Buses can contain subordinate buses. To generate efficient code, set the storage classes of subordinate buses to Auto. Setting the storage class to Auto eliminates:

- Allocation of redundant memory for the subordinate bus signal and for the parent bus signal
- Additional copy operations (copying data to the subordinate bus, and then copying from the subordinate bus to the final bus)

This model contains nonvirtual bus signals. The subordinate bus signals Sub\_Bus\_1 and Sub\_Bus\_2 use the storage class Auto.

The generated code algorithm efficiently assigns the input signal data to the bus signals.

```
void ex_nonvirtual_buses_step(void)
{
 Nonvirtual_In_One.SimpleBus_1.A1 = A1;
 Nonvirtual_In_One.SimpleBus_1.A2 = A2;
 Nonvirtual_In_One.SimpleBus_2.A3 = A3;
 Nonvirtual_In_One.SimpleBus_2.A4 = A4;
 Nonvirtual_In_One.A5 = A5;
}
```

## Control Signal and State Initialization in the Generated Code

To initialize signals and discrete states with custom values for simulation and code generation, you can use signal objects and block parameters. Data initialization increases application reliability and is a requirement of safety critical applications. Initializing signals for both simulation and code generation can expedite transitions between phases of Model-Based Design.

For basic information about specifying initial values for signals and discrete states in a model, see “Initialize Signals and Discrete States”.

### Signal and State Initialization in the Generated Code

The initialization behavior for code generation is the same as that for model simulation with the following exceptions:

- RSim executables can use the **Data Import/Export** pane of the Configuration Parameters dialog box to load input values from MAT-files. GRT and ERT executables cannot load input values from MAT-files.
- The initial value for a block output signal or root level input or output signal can be overwritten by an external (calling) program.
- Setting the initial value for persistent signals is relevant if the value is used or viewed by an external application.

When you generate code, initialization statements are placed in *model.c* or *model.cpp* in the model's initialize code.

For example, consider the model *rtwdemo\_sigobj\_iv*.

If you create and initialize signal objects in the base workspace, the code generator places initialization code for the signals in the file *rtwdemo\_sigobj\_iv.c* under the *rtwdemo\_sigobj\_iv\_initialize* function, as shown below.

```
/* Model initialize function */
void rtwdemo_sigobj_iv_initialize(void)
{
 .
 .
 .
/* exported global signals */
```

```

S3 = -3.0;
S2 = -2.0;
.
.
.
/* exported global states */
X1 = 0.0;
X2 = 0.0;

/* external inputs */
S1 = -4.5;
.
.
.

```

The following code shows the initialization code for the enabled subsystem's Unit Delay block state X1 and output signal S2.

```

void MdlStart(void) {
.
.
.
/* InitializeConditions for UnitDelay: '<S2>/Unit Delay' */
X1 = aa1;

/* Start for enable system: '<Root>/Enabled Subsystem (state X1 inside)' */

/* virtual outports code */

/* (Virtual) Output Block: '<S2>/Out1' */

S2 = aa2;
}

```

For an enabled subsystem, the initial value is also used as a reset value if the subsystem's Output block parameter **Output when disabled** is set to **reset**. The following code from `rtwdemo_sigobj_iv.c` shows the assignment statement for S3 as it appears in the model output function `rtwdemo_sigobj_iv_output`.

```

/* Model output function */
static void rtwdemo_sigobj_iv_output(void)
{
.
.
.
/* Disable for enable system: '<Root>/Enabled Subsystem (state X1 inside)' */

/* (Virtual) Output Block: '<S2>/Out1' */

S2 = aa2;
}

```

## Generate Tunable Initial Conditions

You can represent initial conditions for signals and states by creating tunable global variables in the generated code. These variables allow you to restart an application by using initial conditions that are stored in memory.

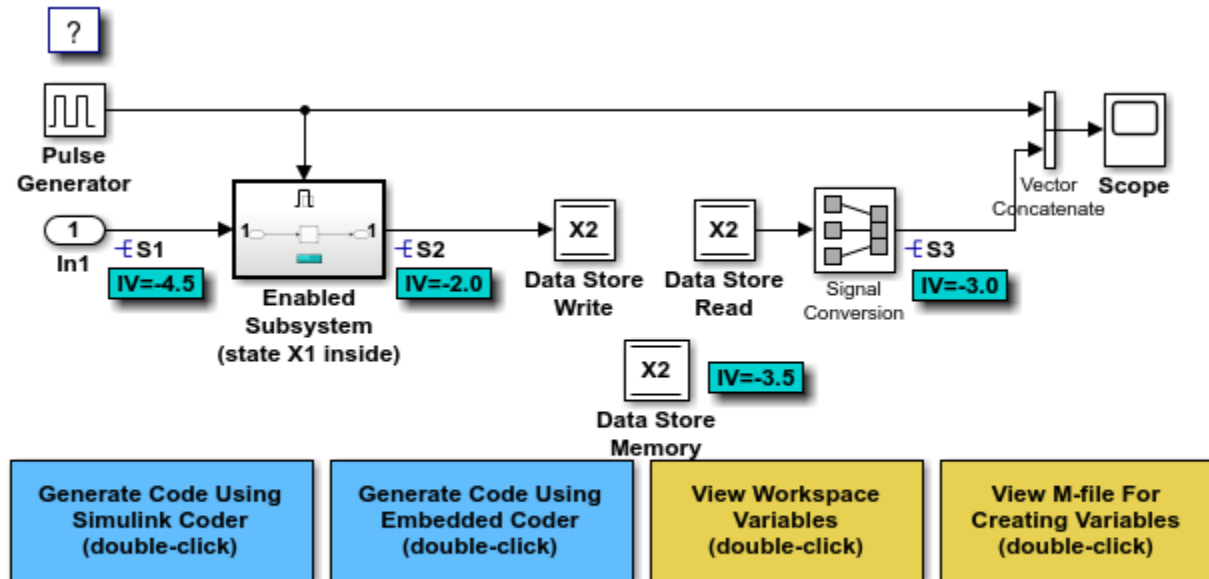

If you set **Configuration Parameters > Optimization > Default parameter behavior** to **Tunable**, initial conditions appear as tunable fields of the global parameters structure.

Whether you set **Default parameter behavior** to **Tunable** or **Inlined**, you can use a tunable parameter to specify the `InitialValue` property of a signal object or the **Initial condition** parameter of a block. For basic information about tunable parameters, see “Create Tunable Calibration Parameter in the Generated Code”.

This example shows how to use tunable parameters to specify initial conditions for signals and states.

### Explore Example Model

Open the example model `rtwdemo_sigobj_iv` and configure it to show the generated names of blocks. The signal `S2` uses a `Simulink.Signal` object in the base workspace.

Copyright 1994-2020 The MathWorks, Inc.

Double-click the `Simulink.Signal` object `S2` to view its properties. The **Initial value** property is set to `aa2`. The object uses the variable `aa2` to specify an initial condition for the signal `S2`. The **Storage class** property is set to `ExportedGlobal`. To use a `Simulink.Signal` object to initialize a signal, the signal object must use a storage class other than `Auto` or, if the corresponding data category in the Code Mapping Editor uses a storage class setting other than `Default`, `Model default`.

On the **Optimization** pane, in the Configuration Parameters dialog box, click **Configure**. The variable `aa2` is a tunable parameter that uses the storage class `ExportedGlobal`.

In the model, open the Enabled Subsystem. In the Output block dialog box, the parameter **Output when disabled** is set to `reset`. When the subsystem becomes disabled, the output signal `S2` resets to the initial value `aa2`.

Open the Unit Delay block dialog box. On the **State Attributes** tab, the **State name** box is set to `X1`.

Open the Enable block dialog box. The parameter **States when enabling** is set to `reset`. When the subsystem transitions from a disabled state to an enabled state, it resets internal block states, such as `X1`, to their initial values.

In the base workspace, double-click the `Simulink.Signal` object `X1` to view its properties. The **Initial value** property is set to `aa1`.

Double-click the `Simulink.Parameter` object `aa1` to view its properties. The **Storage class** property is set to `ExportedGlobal`. You can generate tunable initial conditions for block states by using tunable parameters such as `aa1` and `Simulink.Signal` objects such as `X1`.

## Generate and Inspect Code

Generate code with the example model.

```
Starting build procedure for: rtwdemo_sigobj_iv
Successful completion of build procedure for: rtwdemo_sigobj_iv
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_sigobj_iv	Code generated and compiled	Code generation information file does not exist.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 17.787s
```

In the code generation report, view the file `rtwdemo_sigobj_iv.c`. The code uses global variables to represent the block state `X1` and the signal `S2`.

```
/* Exported block states */
real_T X1; /* '<S1>/Unit Delay' */

/* Exported block signals */
real_T S1; /* '<Root>/In1' */
real_T S3; /* '<Root>/Signal Conversion' */
real_T S2; /* '<S1>/Unit Delay' */
```

The code uses global variable to represent the tunable parameter `aa1`.

```
/* Exported block parameters */
real_T aa1 = -2.5; /* Variable: aa1
```

The model initialization function uses the tunable parameter `aa1` to initialize the state `X1`. The function also uses the tunable parameter `aa2` to initialize the signal `S2`.

```
/* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem (state X1 inside)' */
/* InitializeConditions for UnitDelay: '<S1>/Unit Delay' */
X1 = aa1;

/* SystemInitialize for UnitDelay: '<S1>/Unit Delay' incorporates:
 * Output: '<S1>/Out1'
 */
S2 = 0.0;
```

In the model step function, when the Enabled Subsystem transitions from a disabled state to an enabled state, the Unit Delay block state `X1` resets to its initial value.

```
if (rtb_PulseGenerator > 0) {
 if (!rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M) {
 /* InitializeConditions for UnitDelay: '<S1>/Unit Delay' */
 X1 = aa1;
 }
}
```

```

 rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M = true;
}

/* UnitDelay: '<S1>/Unit Delay' */
S2 = X1;

/* Update for UnitDelay: '<S1>/Unit Delay' incorporates:
 * Inport: '<Root>/In1'
 */
X1 = S1;
} else if (rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M) {
/* Disable for UnitDelay: '<S1>/Unit Delay' incorporates:
 * Outport: '<S1>/Out1'
 */
S2 = 0.0;
rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M = false;
}

/* End of Outputs for SubSystem: '<Root>/Enabled Subsystem (state X1 inside)' */

/* DataStoreWrite: '<Root>/Data Store Write' */
X2 = S2;

/* SignalConversion: '<Root>/Signal Conversion' incorporates:
 * DataStoreRead: '<Root>/Data Store Read'
 */
S3 = X2;
}

/* Model initialize function */
void rtwdemo_sigobj_iv_initialize(void)
{
/* Registration code */

/* initialize error status */
rtmSetErrorStatus(rtwdemo_sigobj_iv_M, (NULL));

/* block I/O */

/* exported global signals */
S3 = -3.0;

/* states (dwork) */
(void) memset((void *)&rtwdemo_sigobj_iv_DW, 0,
 sizeof(DW_rtwdemo_sigobj_iv_T));

/* exported global states */
X1 = 0.0;
X2 = 0.0;

/* external inputs */
S1 = -4.5;

/* Start for DiscretePulseGenerator: '<Root>/Pulse Generator' */
rtwdemo_sigobj_iv_DW.clockTickCounter = -2;

/* Start for DataStoreMemory: '<Root>/Data Store Memory' */
X2 = -3.5;

```

```

/* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem (state X1 inside)' */
/* InitializeConditions for UnitDelay: '<S1>/Unit Delay' */
X1 = aa1;

/* SystemInitialize for UnitDelay: '<S1>/Unit Delay' incorporates:
 * Output: '<S1>/Out1'
 */
S2 = 0.0;

/* End of SystemInitialize for SubSystem: '<Root>/Enabled Subsystem (state X1 inside)' */
}

/* Model terminate function */
void rtwdemo_sigobj_iv_terminate(void)
{
 /* (no terminate code required) */
}

```

If the Enabled Subsystem becomes disabled during code execution, the algorithm uses the tunable initial condition `aa2` to set the value of the signal `S2`.

```

} else {

} else if (rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M) {
 /* Disable for UnitDelay: '<S1>/Unit Delay' incorporates:
 * Output: '<S1>/Out1'
 */
 S2 = 0.0;
 rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M = false;
}

```

## Generate Tunable Initial Condition Structure for Bus Signal

When you use a MATLAB® structure to specify initialization values for the signal elements in a bus, you can create a tunable global structure in the generated code.

If you set **Configuration Parameters > Optimization > Default parameter behavior** to **Tunable**, the initial condition appears as a tunable substructure of the global parameters structure.

Whether you set **Default parameter behavior** to **Tunable** or **Inlined**, you can specify the initial condition by using a tunable `Simulink.Parameter` object whose value is a structure. If you apply a storage class other than `Auto` to the parameter object, the structure is tunable in the generated code.

To generate efficient code by avoiding data type mismatches between the structure and the bus signal, use either:

- Typed expressions to specify the values of the structure fields. Match the data type of each field with the data type of the corresponding signal element.
- A `Simulink.Bus` object to control the data types of the structure fields and the signal elements.

For basic information about using structures to initialize bus signals, and to decide how to control field data types, see “Specify Initial Conditions for Bus Elements”.

### Generate Tunable Initial Condition Structure

This example shows how to use a tunable structure parameter to initialize a virtual bus signal.

Open the example model `rtwdemo_tunable_init_struct` and configure it to show the generated names of blocks.

Copyright 2015-2020 The MathWorks, Inc.

On the **Modeling** tab, click **Model Data Editor**.

On the **Inports/Outputs** tab, the **Data Types** column shows that each Inport block in the model uses a different output data type.

Open the Bus Creator block dialog box. The block output is a virtual bus.

In the Configuration Parameters dialog box, open the **Optimization** pane. The configuration parameter **Default parameter behavior** is set to **Tunable**. By default, block parameters, including initial conditions, appear in the generated code as tunable fields of the global parameters structure.

In the Model Data Editor, inspect the **States** tab.

For the Unit Delay block, set **Initial Value** to a structure that specifies an initial condition for each of the three signal elements. To generate efficient code, match the data types of the structure fields with the data types of the corresponding signal elements. For example, set **Initial Value** to the expression `struct('thermocpl',15.23,'magFlow',uint32(79),'posSwitch',false)`.

```
set_param('rtwdemo_tunable_init_struct/Unit Delay','InitialCondition',...
'struct('thermocpl',15.23,'magFlow',uint32(79),'posSwitch',false)')
```

Generate code from the example model.

```
Starting build procedure for: rtwdemo_tunable_init_struct
Successful completion of build procedure for: rtwdemo_tunable_init_struct
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_tunable_init_struct	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 26.532s

In the code generation report, view the file `rtwdemo_tunable_init_struct_types.h`. The code defines a structure type whose fields use the data types that you specified in the struct expression.

```
#ifndef DEFINED_TYPEDEF_FOR_struct_mqGiljsItE0G7cf1bNqMu_
#define DEFINED_TYPEDEF_FOR_struct_mqGiljsItE0G7cf1bNqMu_

typedef struct {
 real_T thermocpl;
 uint32_T magFlow;
 boolean_T posSwitch;
} struct_mqGiljsItE0G7cf1bNqMu;
```

View the file `rtwdemo_tunable_init_struct.h`. The struct type definition of the global parameters structure contains a substructure, `UnitDelay_InitialCondition`, which represents the **Initial condition** parameter of the Unit Delay block.

```
struct P_rtwdemo_tunable_init_struct_T {
 struct_mqGiljsItE0G7cf1bNqMu UnitDelay_InitialCondition;
```

View the file `rtwdemo_tunable_init_struct_data.c`. This source file allocates memory for the global parameters structure. The substructure `UnitDelay_InitialCondition` appears.

```
/* Block parameters (default storage) */
P_rtwdemo_tunable_init_struct_T rtwdemo_tunable_init_struct_P = {
 /* Mask Parameter: UnitDelay_InitialCondition
 * Referenced by:
 * '<Root>/Unit Delay'
 * '<Root>/Unit Delay'
 * '<Root>/Unit Delay'
 */
 {
 15.23,
 79U,
 0
 },
```

View the file `rtwdemo_tunable_init_struct.c`. The model initialization function uses the fields of the substructure to initialize the block states.

```
/* InitializeConditions for UnitDelay generated from: '<Root>/Unit Delay' */
rtwdemo_tunable_init_struct_DW.UnitDelay_1_DSTATE =
 rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.thermocpl;

/* InitializeConditions for UnitDelay generated from: '<Root>/Unit Delay' */
rtwdemo_tunable_init_struct_DW.UnitDelay_2_DSTATE =
```

```

rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.magFlow;

/* InitializeConditions for UnitDelay generated from: '<Root>/Unit Delay' */
rtwdemo_tunable_init_struct_DW.UnitDelay_3_DSTATE =
 rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.posSwitch;

```

### Use Bus Object to Specify Data Types

If you create a bus object, you can use it to specify the data type of the bus signal and the tunable initial condition structure. Before code generation, the `Simulink.Parameter` object casts the values of the structure fields to the data types of the signal elements. For basic information about creating bus objects and using them in models, see “Specify Bus Properties with Simulink.Bus Object Data Types”.

Open the example model `rtwdemo_init_struct_busobj` and configure it to show the generated names of blocks.

Copyright 2015-2020 The MathWorks, Inc.

In the base workspace, double-click the `Simulink.Bus` object `ComponentData`. The object defines three signal elements: `thermocpl`, `magFlow`, and `posSwitch`. The elements each use a different data type.

In the model, open the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). The **Inports/Outports** tab shows that for the Inport block `DataIn`, the output data type (**Data Type** column) is set to `Bus: ComponentData`.

At the command prompt, create the structure parameter `initStruct`. You can specify the field values by using untyped expressions. To improve readability, specify the field `posSwitch` with a Boolean value.

```

initStruct = struct(...
 'thermocpl',15.23,...
 'magFlow',79,...
 'posSwitch',false ...
);

```

```
initStruct = Simulink.Parameter(initStruct);
```

In the Model Data Editor, inspect the **Parameters** tab.

In the model, click the Unit Delay block. The Model Data Editor highlights the row that corresponds to the **Initial condition** parameter of the block.

In the Model Data Editor, set the parameter value (**Value** column) to `initStruct`.

Click the **Show/refresh additional information** button. The parameter object, `initStruct`, appears in the data table as a row.

Use the **Data Type** column to set the data type of `initStruct` to `Bus: ComponentData`.

```
initStruct.DataType = 'Bus: ComponentData';
```

Set the **Change View** drop-down list to `Code`.

Use the **Storage Class** column to apply the storage class `ExportedGlobal` to `initStruct`.

```
initStruct.StorageClass = 'ExportedGlobal';
```

Generate code from the example model.

```
Starting build procedure for: rtwdemo_init_struct_busobj
Successful completion of build procedure for: rtwdemo_init_struct_busobj
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_init_struct_busobj	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 20.062s

In the code generation report, view the file `rtwdemo_init_struct_busobj_types.h`. The code creates a structure type `ComponentData` whose fields use the data types in the bus object.

```
#ifndef DEFINED_TYPEDEF_FOR_ComponentData_
#define DEFINED_TYPEDEF_FOR_ComponentData_

typedef struct {
 real_T thermocpl;
 uint32_T magFlow;
 boolean_T posSwitch;
} ComponentData;
```

View the file `rtwdemo_init_struct_busobj.c`. The code creates a global variable to represent the tunable parameter object `initStruct`.

```
/* Exported block parameters */
ComponentData initStruct = {
 15.23,
```

```
 79U,
 0
} ; /* Variable: initStruct
```

The model initialization function uses the structure fields to initialize the block states.

```
/* InitializeConditions for UnitDelay generated from: '<Root>/Unit Delay' */
rtwdemo_init_struct_busobj_DW.UnitDelay_1_DSTATE = initStruct.thermocpl;

/* InitializeConditions for UnitDelay generated from: '<Root>/Unit Delay' */
rtwdemo_init_struct_busobj_DW.UnitDelay_2_DSTATE = initStruct.magFlow;

/* InitializeConditions for UnitDelay generated from: '<Root>/Unit Delay' */
rtwdemo_init_struct_busobj_DW.UnitDelay_3_DSTATE = initStruct.posSwitch;
```

To change the data type of a signal element, specify the new type in the bus object. The signal element in the model uses the new type. Before simulation and code generation, the parameter object `initStruct` casts the corresponding structure field to the new type.

## Initialization of Signal, State, and Parameter Data in the Generated Code

Signal lines, block parameters, and block states in a model can appear in the generated code as data, for example, as global variables. By default, the code initializes this data before execution of the primary algorithm. To match the numerics of simulation in Simulink, the code generator chooses the initial values based on specifications that you make in the model.

By understanding how the generated code initializes data, you can:

- Model a system that reinitializes states during execution, which means that the application can restart the entire system.
- Store initial values in memory as variables, which can persist between execution runs. You can then overwrite these values before starting or restarting a system.
- Generate efficient code by eliminating storage for invariant initial values and by preventing the generation of code that unnecessarily or redundantly initializes data.

For basic information about initializing signals and states in a model, see “Initialize Signals and Discrete States” and “Load State Information”.

### Static Initialization and Dynamic Initialization

To initialize a data item such as a global variable, an application can use static or dynamic initialization.

- Static initialization occurs in the same statement that defines (allocates memory for) the variable. The initialization does not occur inside a function definition.

The code can be more efficient because none of the generated model functions execute initialization statements.

- Dynamic initialization occurs inside a function. For each model or nonvirtual subsystem, the code generator typically creates one or more functions that are dedicated to initialization.

The generated code or your code can restart a system by calling an initialization function during execution.

### Real-World Ground Initialization Requiring Nonzero Bit Pattern

Each data item has a real-world ground value. This value can depend on the data type of the item. For example, for a signal whose data type is `double` or `int8`, the real-world ground value is zero. For an enumeration, the ground value is the default enumeration member.

For some kinds of data, to represent a real-world ground value, a computer stores zero in memory (all bits zero). However, for some other data, a computer stores a nonzero value in memory. This data includes, for example:

- Fixed-point data with bias. The code initializes such a data item to the stored integer value that, given the scaling and bias, represents real-world zero.
- An enumeration whose default member maps to an integer value other than zero. For example, if the default member is `High` with an underlying integer value of 3, the code initializes such a data item to `High`.

## Initialization of Signal and State Data

In a model, you can control signal and state initial values through block parameters. For example, to set the initial value of a Unit Delay block, you use the **Initial condition** parameter. In some cases, you can also use the `InitialValue` property of a `Simulink.Signal` object. For most of these block parameters, the default value is 0.

You can also initialize states by using State Writer blocks in Initialize Function subsystems and the **Initial states** model configuration parameter.

By default, the generated code dynamically initializes signal and state data (and other data, such as the model error status) in the generated initialization function. The function, named `model_initialize` by default, performs signal and state initialization operations in this order:

- 1 Initializes the signal and state data in the default generated structures, such as the `DWork` structure, to a stored value of zero.
- 2 Initializes additional signal and state data that are not in the default generated structures to the relevant real-world ground value.

This initialization applies only to data that meet both of these criteria:

- The generated code defines (allocates memory for) the data.
- The data use a storage class other than `Auto` (the default storage class) or `Model default` (when the Code Mapping Editor specifies the `Default` storage class, the default setting).

For example, the code applies this operation to data items that use the storage class `ExportedGlobal`.

- 3 Initializes each signal and state to the real-world value that the model specifies, for example, through the **Initial condition** parameter of a Unit Delay block.
- 4 Initializes each state to the real-world value that you assign by using a State Writer block. The function performs this initialization only if you use an Initialize Function subsystem in the model.
- 5 Initializes each state to the real-world value that you specify with the configuration parameter **Initial states**.

After this initialization function executes, each data item has the last real-world value that the function assigned. For example, if you use a State Writer block to initialize a block state to 5 while also using the **Initial states** configuration parameter to initialize the same state to 10, the state ultimately uses 10 as an initial value.

### memset for Bulk Initialization

To initialize signal or state data items that have contiguous storage to a stored value of zero, the generated code can call `memset` in an initialization function. Data items that have contiguous storage include the `DWork` structure, arrays, or data items that use a multiword data type.

If your application requires it, you can prevent the generated code from using `memset` for initializing floating-point data to stored zero. See “Use `memset` to initialize floats and doubles to 0.0”.

### Tunable Initial Values

You can configure the way that tunable block parameters, such as the **Gain** parameter of a Gain block, appear in the generated code. Most block parameters that set initial values (for example,

**Initial condition**) are tunable. For example, the configuration parameter **Default parameter behavior** can determine whether the initial values appear in the generated code as inlined constants or as tunable global data. You can also use parameter objects and storage classes to control the representation of these initial values.

For tunable initial values, in the model initialization function, the right-hand side of the assignment statement is a global variable, structure field, or other data whose value you can change in memory.

To make initial values tunable in the generated code, see “Control Signal and State Initialization in the Generated Code” on page 33-174.

## Initialization of Parameter Data

The generated code statically initializes parameter data to the values that you specify in Simulink.

To express the initial value of a tunable parameter (a global variable) as a mathematical expression involving system constants or other macros, which requires Embedded Coder, see “Initialization by Mathematical Expression (Embedded Coder)”.

### Kinds of Parameter Data

These model elements appear in the generated code as parameter data:

- Tunable block parameters, such as the **Gain** parameter of a Gain block, when you set **Default parameter behavior** to **Tunable**. Each parameter appears as a field of a dedicated global structure.
- Some tunable block parameters when you set **Default parameter behavior** to **Inlined**. When the code generator cannot inline the value of a parameter as a literal number, the parameter appears as a field of a dedicated global `const` structure.
- `Simulink.Parameter` objects to which you apply a storage class that has an exported data scope. For example, the built-in storage class `ExportedGlobal` has an exported data scope, but the storage class `ImportedExtern` does not.

### Initialization by Mathematical Expression (Embedded Coder)

You can set the value of a parameter object (such as `Simulink.Parameter`) to a mathematical expression involving numbers, MATLAB variables, and other parameter objects. See “Set Variable Value by Using a Mathematical Expression”.

If you use this technique with Embedded Coder, you can generate code that initializes the corresponding parameter data (global variable) by using the specified expression. For an example, see “Initialize Parameter Value From System Constant or Other Macro (Embedded Coder)” on page 33-116. For general information, including limitations, see “Code Generation of Parameter Objects With Expression Values”.

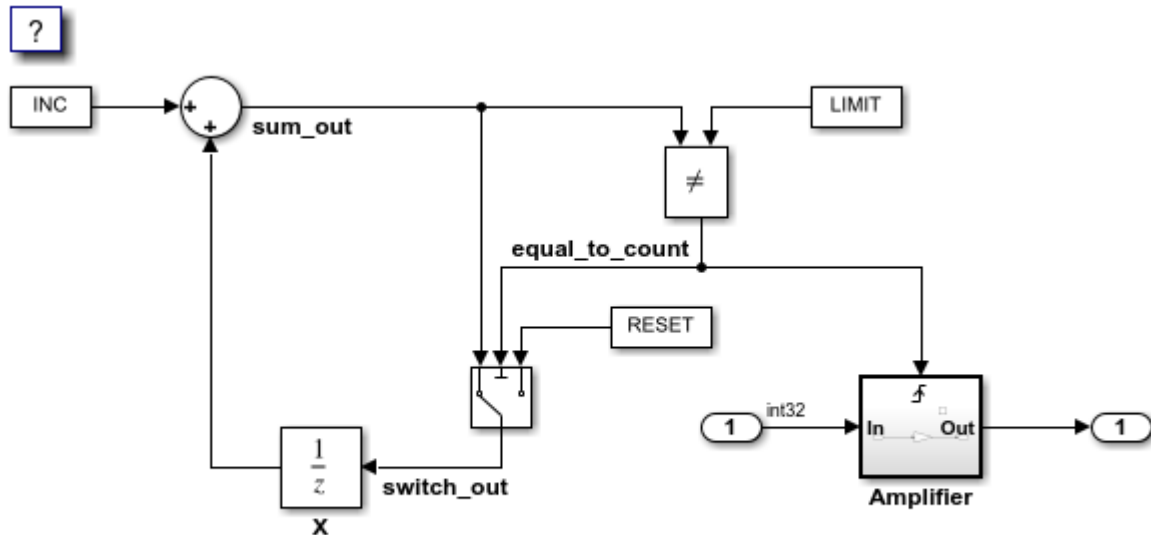

## Data Initialization in the Generated Code

This example shows how the generated code initializes signal, state, and parameter data.

### Explore Example Model

Open the example model, `rtwdemo_rtwintro`.

```
open_system('rtwdemo_rtwinintro')
```

Copyright 1994-2020 The MathWorks, Inc.

In the Apps gallery, click **Simulink Coder**.

Open the Model Data Editor. On the **Modeling** tab, click **Model Data Editor**.

Inspect the **States** tab. For the Unit Delay block state, the **Initial Value** is set to 0, the default, which means the initial value of the state is zero. The state is named X.

Set **Initial Value** to a nonzero number, for example, 5.

```
set_param('rtwdemo_rtwinintro/X', 'InitialCondition', '5')
```

Open the Code Mappings editor. In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.

On the **Signals/States** tab, under **States** set **Storage Class** for X to ExportedGlobal. With this setting, the block state appears in the generated code as a separate global variable.

```
coder.mapping.utils.create('rtwdemo_rtwinintro');
cm = coder.mapping.api.get('rtwdemo_rtwinintro');
setState(cm, 'rtwdemo_rtwinintro/X', 'StorageClass', 'ExportedGlobal');
```

In the model, open the Amplifier subsystem, which is a triggered subsystem.

In the Model Data Editor, inspect the **Parameters** tab. To set and inspect initial values of signals and states, you can use the **Parameters** tab instead of the **States** tab.

The Model Data Editor shows that for the Output block, the **Initial output** (InitialOutput) parameter is set to 0, the default. This subsystem output requires an initial value because the subsystem executes conditionally. Leave the initial value at the default.

In the model, clear **Configuration Parameters > Signal storage reuse**. When you clear this setting, signal lines appear in the generated code as fields of a generated structure whose purpose is

to store signal data. This representation of the signals makes it easier to see how the code generator initializes data.

```
set_param('rtwdemo_rtwintr', 'OptimizeBlockIOStorage', 'off')
```

In the model, inspect the configuration parameter **Configuration Parameters > Optimization > Default parameter behavior**. The configuration parameter is set to **Inlined**, which means block parameters, including initial values, appear in the generated code as inlined literals or as `const` data.

Navigate to the root level of the model.

In the Model Data Editor, click the **Show/refresh additional information** button.

Near the **Filter contents** box, click the **Filter using selection** button.

In the model, click the Constant block labeled **INC**. The Model Data Editor shows that the **Constant value** (Value) parameter of the block is set to **INC**. **INC** is a MATLAB variable in the base workspace.

For **INC**, set the value in the **Value** column to `Simulink.Parameter(uint8(1))`. MATLAB converts **INC** to a `Simulink.Parameter` object.

In the Code Mappings editor, on the **Parameters** tab, apply the storage class `ExportedGlobal` to **INC**. With this setting, the generated code defines **INC** as a global variable. Concerning initialization, **INC** is an item of parameter data.

```
INC = Simulink.Parameter(INC);
INC.StorageClass = 'ExportedGlobal';
```

### Generate and Inspect Code

To build the model and generate code, press **Ctrl+B**.

```
slbuild('rtwdemo_rtwintr');

Starting build procedure for: rtwdemo_rtwintr
Successful completion of build procedure for: rtwdemo_rtwintr
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_rtwintr	Code generated and compiled	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 21.641s

In the generated file `rtwdemo_rtwintr.c`, outside the definition of a function, the code statically initializes the parameter data **INC**. The value of **INC** is 1.

```
file = fullfile('rtwdemo_rtwintr_grt_rtw', 'rtwdemo_rtwintr.c');
rtwdemodbtype(file, '/* Exported block parameters */', 'uint8_T INC = 1U;', 1, 1)
```

```
/* Exported block parameters */
uint8_T INC = 1U; /* Variable: INC
```

In the same file, inspect the definition of the `rtwdemo_rtwinintro_initialize` function. First, the function uses `memset` to initialize the internal signals in the model to a stored value of 0.

```
rtwdemo_dbtype(file, '/* block I/O */', 'sizeof(B_rtwdemo_rtwinintro_T);', 1, 1)
```

```
/* block I/O */
(void) memset(((void *) &rtwdemo_rtwinintro_B), 0,
 sizeof(B_rtwdemo_rtwinintro_T));
```

The function then initializes the Unit Delay state, `X`, to a ground value. In this case, the ground value is zero.

```
rtwdemo_dbtype(file, '/* exported global states */', 'X = 0U;', 1, 1)
```

```
/* exported global states */
X = 0U;
```

The function also initializes other data, including the root-level inputs and outputs (Inport and Output blocks), to ground values.

```
rtwdemo_dbtype(file, '/* external inputs */', 'Amplifier_Trig_ZCE = POS_ZCSIG;', 1, 1)
```

```
/* external inputs */
rtwdemo_rtwinintro_U.Input = 0;

/* external outputs */
rtwdemo_rtwinintro_Y.Output = 0;
rtwdemo_rtwinintro_PrevZCX.Amplifier_Trig_ZCE = POS_ZCSIG;
```

The function then initializes `X` to the value that you specified in the **Initial condition** block parameter.

```
rtwdemo_dbtype(file, '/* InitializeConditions for UnitDelay: '<Root>/X' */', ...
 'X = 5U;', 1, 1)
```

```
/* InitializeConditions for UnitDelay: '<Root>/X' */
X = 5U;
```

Finally, the function initializes the output of the Amplifier subsystem.

```
rtwdemo_dbtype(file, 'SystemInitialize for Triggered SubSystem', ...
 'End of SystemInitialize for SubSystem', 1, 1)
```

```
/* SystemInitialize for Triggered SubSystem: '<Root>/Amplifier' */
/* SystemInitialize for Output: '<Root>/Output' incorporates:
 * Output: '<S1>/Out'
 */
rtwdemo_rtwinintro_Y.Output = 0;
```

## Inspect Difference Between Stored Value and Real-World Value

For some data, even if the real-world initial value is zero, a computer stores a nonzero value in memory. To observe this difference, apply a slope-bias fixed-point data type to the block state, X. To run this example, you must have Fixed-Point Designer™.

In the Model Data Editor, inspect the **Signals** tab.

In the model, click the output signal of the Switch block, `switch_out`.

Use the **Data Type** column of the Model Data Editor to set the signal data type to `fixdt(1,16,1,3)`. This expression represents a fixed-point data type with a slope of 1 and a bias of 3.

```
set_param('rtwdemo_rtwinintro/Switch','OutDataTypeStr',...
 'fixdt(1,16,1,3)')
```

In the model, select the Sum block. In the Property Inspector, under **Signal Attributes**, clear **Require all inputs to have the same data type**.

```
set_param('rtwdemo_rtwinintro/Sum','InputSameDT','off')
```

To prevent compilation errors on different platforms, select the model configuration parameter **Generate code only**. This setting causes the model to generate only code.

```
set_param('rtwdemo_rtwinintro','GenCodeOnly','on')
```

To build the model and generate code, press **Ctrl+B**.

```
slbuild('rtwdemo_rtwinintro')

Starting build procedure for: rtwdemo_rtwinintro
Successful completion of code generation for: rtwdemo_rtwinintro
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_rtwinintro	Code generated	Generated code was out of date.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 16.984s
```

The model initialization function first initializes X to a real-world ground value, 0. Due to the slope-bias data type, which has bias 3, this real-world value corresponds to a stored value of -3.

```
rtwdemodbtype(file,'/* exported global states */','X = -3;',1,1)
```

```
/* exported global states */
X = -3;
```

The function then initializes X to the real-world initial value that you specified in the **Initial condition** block parameter, 5. This real-world value corresponds to a stored value of 2.

```
rtwdemodbtype(file,'/* InitializeConditions for UnitDelay: '<Root>/X' */',...
 'X = 2;',1,1)
```

```
/* InitializeConditions for UnitDelay: '<Root>/X' */
X = 2;
```

## Modeling Goals

Goal	More Information
Explicitly model initialization behavior by using blocks	<p>You can explicitly model initialization and reset behavior by using Initialize Function and Reset Function subsystems. In the subsystems, use State Writer blocks to calculate and assign an initial value for a state dynamically. The corresponding code appears in the model initialization function.</p> <p>For more information, see “Startup, Reset, and Shutdown Function Interfaces” on page 2-25.</p>
Prevent generation of code that explicitly initializes data to zero	<p>If your application environment already initializes global variables to zero, for more efficient code, you can prevent the generation of statements that explicitly initialize global variables to zero. This optimization applies only to signals and states whose initial values are stored in memory as zero. For example, the code generator does not apply the optimization to:</p> <ul style="list-style-type: none"> <li>• Data for which you specify a nonzero initial value by using a block parameter.</li> <li>• Data whose real-world initial value is zero but whose corresponding stored value is not zero.</li> <li>• Enumerated data whose default member maps to a nonzero integer.</li> </ul> <p>The optimization requires Embedded Coder. For more information, see “Remove Zero Initialization Code” on page 74-3.</p>
Generate code that imports data from your external code	<p>You can generate code that reuses (imports) data that your external code defines. For example, you can apply the storage class <code>ImportedExtern</code> to a signal line, block state, or parameter object. For imported data:</p> <ul style="list-style-type: none"> <li>• The generated code does not initialize parameter data. Your code must initialize imported parameter data.</li> <li>• The generated initialization functions dynamically initialize some signal and state data. Unlike data that the generated code allocates, the code does not initialize imported signal or state data to a stored value of zero. Instead, the code immediately initializes the data to the real-world value that you specify in Simulink.</li> </ul> <p>For more information, including how to prevent the generated code from initializing imported data, see “Exchange Data Between External Calling Code and Generated Code”.</p>

## Declare Workspace Variables as Tunable Parameters Using the Model Parameter Configuration Dialog Box

You can use the Model Parameter Configuration dialog box to declare numeric MATLAB variables in the base workspace as tunable parameters. You can select code generation options, such as storage class, for each tunable parameter.

However, it is a best practice to instead use parameter objects to declare tunable parameters. Do not use the Model Parameter Configuration dialog box to select parameter objects in the base workspace. To use parameter objects, instead of the Model Parameter Configuration dialog box, to declare tunable parameters, see “C Code Generation Configuration for Model Interface Elements” on page 32-2.

---

**Note** You cannot use the Model Parameter Configuration dialog box to declare tunable parameters for a referenced model. Use `Simulink.Parameter` objects instead.

---

### Declare Existing Workspace Variables as Tunable Parameters

Use the Model Parameter Configuration dialog box to declare existing workspace variables as tunable parameters for a model.

- 1 In the Configuration Parameters dialog box, on the **Code Generation > Optimization** pane, set the **Default parameter behavior** parameter to **Tunable** and click **Configure**.
- 2 In the Model Parameter Configuration dialog box, under **Source list**, select a method to populate the list of available workspace variables.
  - Select **MATLAB workspace** to view numeric variables that are defined in the base workspace.
  - Select **Referenced workspace variables** to view only the numeric variables in the base workspace that the model uses. Selecting this option begins a diagram update and a search for used variables, which can take time for a large model.
- 3 In the Model Parameter Configuration dialog box, under **Source list**, select one or more workspace variables.
- 4 Click **Add to table**. The variables appear as tunable parameters under **Global (tunable) parameters**, and appear in italic font under **Source list**.
- 5 Optionally, select a parameter under **Global (tunable) parameters**, and adjust the code generation settings for the parameter. For more information about adjusting the code generation options for tunable parameters, see “Set Tunable Parameter Code Generation Options” on page 33-197
- 6 Click **OK** to apply your selection of tunable parameters and close the dialog box.

### Declare New Tunable Parameters

Use the Model Parameter Configuration dialog box to declare new tunable parameters. You can use this technique to declare the names of tunable parameters, and to adjust their code generation settings, before you create the corresponding workspace variables.

- 1 In the Configuration Parameters dialog box, on the **Optimization** pane, set the **Default parameter behavior** parameter to **Tunable** and click **Configure**.

- 2 In the Model Parameter Configuration dialog box, under **Global (tunable) parameters**, click **New**.
- 3 Under the **Name** column, specify a name for the new tunable parameter.
- 4 Optionally, adjust the code generation settings for the new parameter. For more information about adjusting the code generation options for tunable parameters, see “Set Tunable Parameter Code Generation Options” on page 33-197
- 5 Click **OK** to apply your changes and close the dialog box.

## Set Tunable Parameter Code Generation Options

To set the properties of tunable parameters listed under **Global (tunable) parameters** in the Model Parameter Configuration dialog box, select a parameter and specify a storage class and, optionally, a storage type qualifier.

Property	Description
<b>Storage class</b>	<p>Select one of the following to use for code generation:</p> <ul style="list-style-type: none"> <li>• Model default</li> <li>• ExportedGlobal</li> <li>• ImportedExtern</li> <li>• ImportedExternPointer</li> </ul> <p>For more information about tunable parameter storage classes, see “C Code Generation Configuration for Model Interface Elements” on page 32-2.</p>
<b>Storage type qualifier</b>	<p>For variables with a storage class other than Auto, you can add a qualifier (such as <code>const</code> or <code>volatile</code>) to the generated storage declaration. To do so, you can select a predefined qualifier from the list, or add qualifiers not in the list by typing them in. The code generator does not check the storage type qualifier for validity, and includes the qualifier text in the generated code without checking syntax .</p>

## Programmatically Declare Workspace Variables as Tunable Parameters

### Tune Parameters from the Command Line

When parameters are MATLAB workspace variables, the Model Parameter Configuration dialog box is the recommended way to see or set the properties of tunable parameters. In addition to that dialog box, you can also use MATLAB `get_param` and `set_param` commands.

**Note** You can also use `Simulink.Parameter` objects for tunable parameters. See “Create Tunable Calibration Parameter in the Generated Code” on page 33-110 for details.

The following commands return the tunable parameters and corresponding properties:

- `get_param(gcs, 'TunableVars')`

- `get_param(gcs, 'TunableVarsStorageClass')`
- `get_param(gcs, 'TunableVarsTypeQualifier')`

The following commands declare tunable parameters or set corresponding properties:

- `set_param(gcs, 'TunableVars', str)`

The argument `str` (character vector) is a comma-separated list of variable names.

- `set_param(gcs, 'TunableVarsStorageClass', str)`

The argument `str` (character vector) is a comma-separated list of storage class settings.

The valid storage class settings are

- `Auto`
- `ExportedGlobal`
- `ImportedExtern`
- `ImportedExternPointer`
- `set_param(gcs, 'TunableVarsTypeQualifier', str)`

The argument `str` (character vector) is a comma-separated list of storage type qualifiers.

The following example declares the variable `k1` to be tunable, with storage class `ExportedGlobal` and type qualifier `const`. The number of variables and number of specified storage class settings must match. If you specify multiple variables and storage class settings, separate them with a comma.

```
set_param(gcs, 'TunableVars', 'k1')
set_param(gcs, 'TunableVarsStorageClass', 'ExportedGlobal')
set_param(gcs, 'TunableVarsTypeQualifier', 'const')
```

# Share Data Between Code Generated from Simulink, Stateflow, and MATLAB

Stateflow® and MATLAB® Coder™ can fully define their data definitions, or they can inherit them from Simulink®. Data definition capabilities include:

- Inheriting input/output data types and sizes from Simulink.
- Parameterized data types and sizes. That is, data type and size may be specified as a function of another data's type and size, e.g., `type(y)=type(u)` and `size(y)=size(u)`.
- Inferred output size and type from Simulink via signal attribute back propagation.
- Parameter scoped data, which allows referencing Simulink parameters in Stateflow and MATLAB.

## Open Example Model

Open the example model `rtwdemo_dynamicio`.

```
open_system('rtwdemo_dynamicio')
```

Copyright 1994-2020 The MathWorks, Inc.

## Instructions

- 1 Compile the model (on the **Simulation** tab, under **Prepare**, click **Update Model**) and note the displayed signal types and sizes.
- 2 Change the data type and/or size of the Constant block and recompile the model. Note that the attributes of the signals automatically adapt to the Constant block specification.
- 3 Generate and inspect code using the blue buttons in the model. Note that `K` is shared by the Gain and `sfVerticalSum` block.

## Notes

- The data type and size of Stateflow and MATLAB data is inherited from Simulink.

- The Gain block and the Stateflow chart sfVerticalSum share the Simulink parameter K, which is defined in the MATLAB workspace as a Simulink.Parameter with Model default storage class (i.e., rtP.K in the generated code).

## Air-Fuel Ratio Control System with Fixed-Point Data

This example shows how to generate and optimize the code for a fixed-point air-fuel ratio control system designed with Simulink® and Stateflow®. For a detailed explanation of the model, see:

- “Modeling a Fault-Tolerant Fuel Control System”
- “Fixed-Point Fuel Rate Control System” (Fixed-Point Designer)

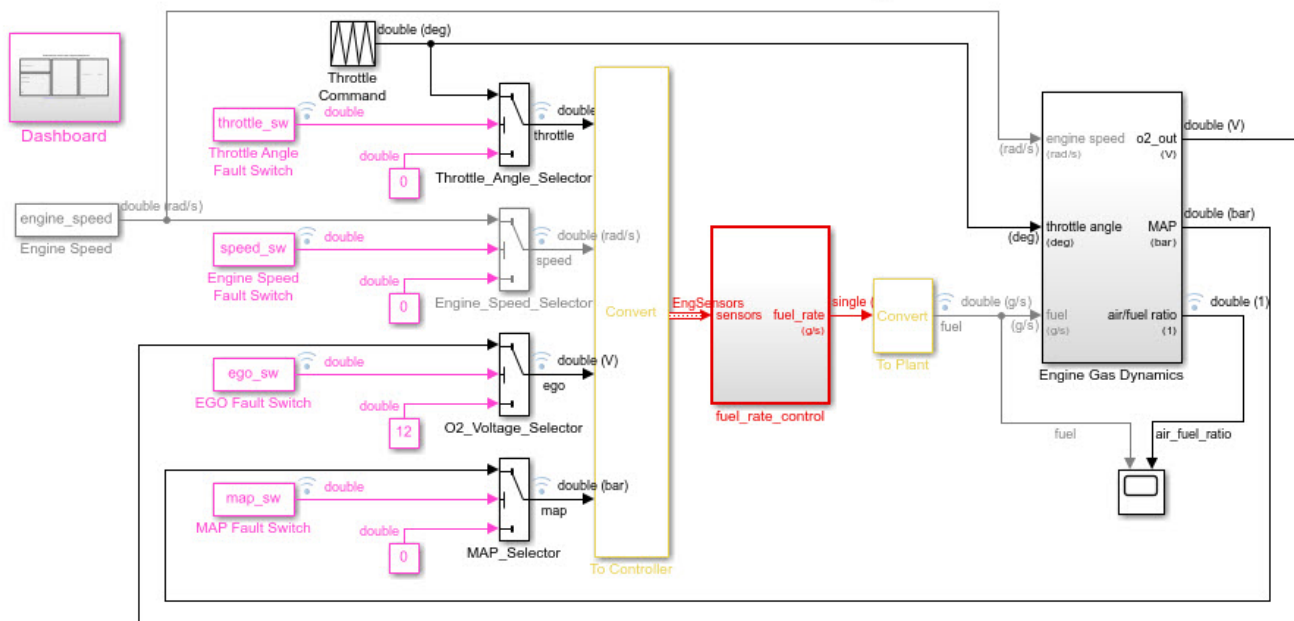

The example uses the Embedded Coder® system target file (ert.tlc).

### Relevant Portions of the Model

Figures 1-4 show relevant portions of the `sldemo_fuelsys` model, which is a closed-loop system containing a plant subsystem and a controller subsystem. The plant allows engineers to validate the controller through simulation early in the design cycle. In this example, generate code for the relevant controller subsystem, `fuel_rate_control`. Figure 1 shows the top-level simulation model.

```
% Open |sldemo_fuelsys|, set the parameters and update the model diagram
% to view the signal data types.
close_system('sldemo_fuelsys',0)
load_system('sldemo_fuelsys');
rtwconfiguredemo('sldemo_fuelsys','ERT','fixed');
sldemo_fuelsys_data('sldemo_fuelsys','switch_data_type','fixed');
sldemo_fuelsys_data('sldemo_fuelsys','set_info_text','rtwdemo_fuelsys_fxp_script');
sldemo_fuelsys_data('sldemo_fuelsys','top_level_logging','on');
set_param('sldemo_fuelsys','ShowPortDataTypes','on');
set_param('sldemo_fuelsys','SampleTimeColors','on');
set_param('sldemo_fuelsys','Dirty','off');
sldemo_fuelsys([],[],[],'compile');
sldemo_fuelsys([],[],[],'term');
```

### Fault-Tolerant Fuel Control System

**Figure 1: Top-level model of the plant and controller**

The air-fuel ratio control system is composed of Simulink® and Stateflow® blocks. It is the portion of the model for which to generate code.

```
open_system('sldemo_fuelsys/fuel_rate_control');
```

### Fuel Rate Control Subsystem

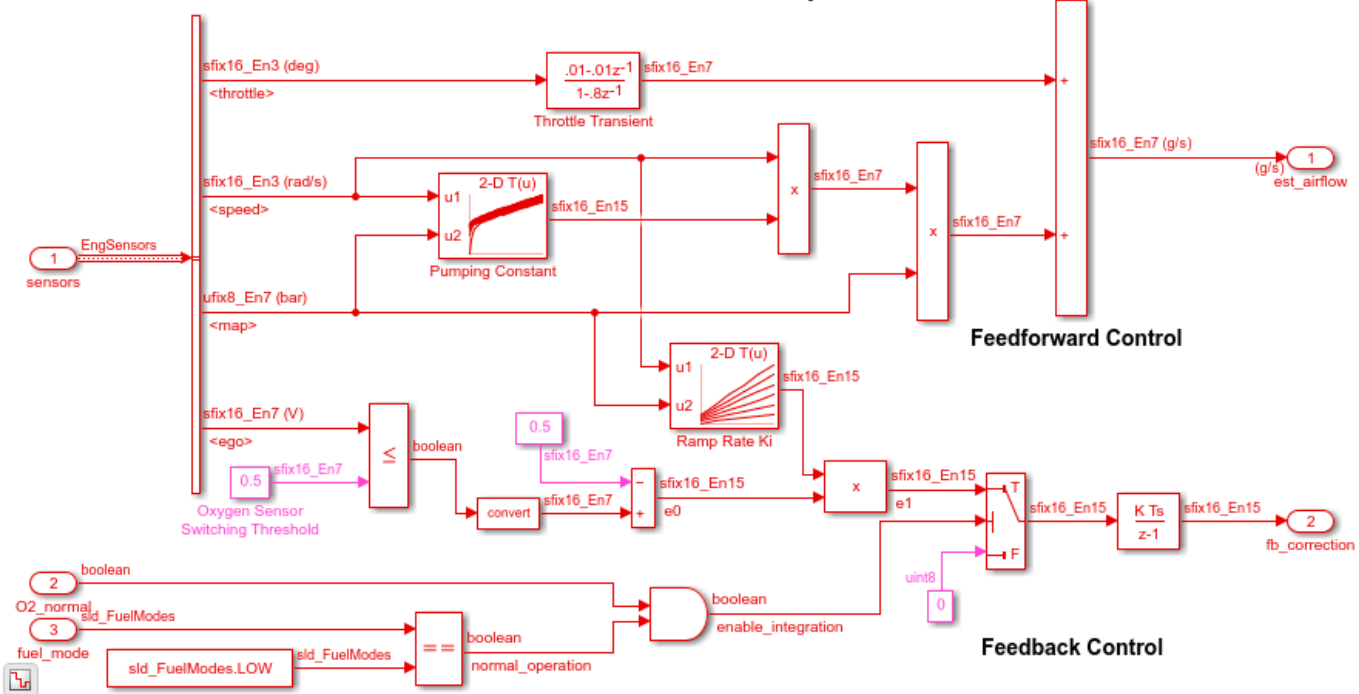

**Figure 2: The air-fuel ratio controller subsystem**

The intake airflow estimation and closed loop correction system contains two lookup tables, Pumping Constant and Ramp Rate Ki.

```
open_system('sldemo_fuelsys/fuel_rate_control/airflow_calc');
```

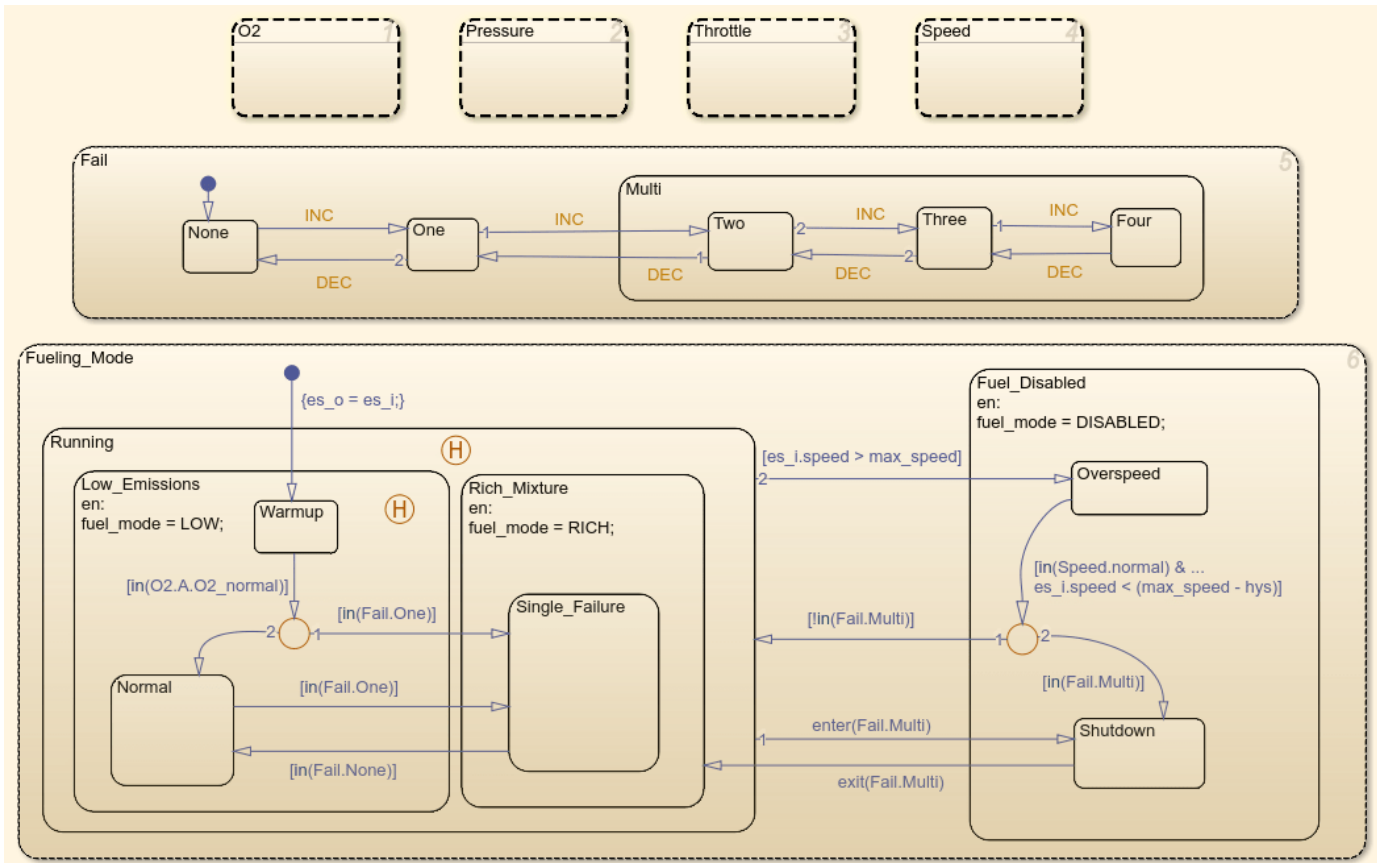

### Intake Airflow Estimation and Closed-Loop Correction

**Figure 3: The airflow\_calc subsystem**

The control logic is a Stateflow® chart that specifies the different modes of operation.

```
open_system('sldemo_fuelsys/fuel_rate_control/control_logic');
```

**Figure 4: Fuel ratio controller logic**

Remove the window clutter.

```
close_system('sldemo_fuelsys/fuel_rate_control/airflow_calc');
close_system('sldemo_fuelsys/fuel_rate_control/fuel_calc');
close_system('sldemo_fuelsys/fuel_rate_control/control_logic');
hDemo.rt=sfroot;hDemo.m=hDemo.rt.find('-isa','Simulink.BlockDiagram');
hDemo.c=hDemo.m.find('-isa','Stateflow.Chart','-and','Name','control_logic');
hDemo.c.visible=false;
close_system('sldemo_fuelsys/fuel_rate_control');
```

Build the air-fuel ratio control system only. Once the code generation process is complete, an HTML report detailing the generated code is displayed. The main body of the code is located in fuel\_rate\_control.c.

```
slbuild('sldemo_fuelsys/fuel_rate_control');

Starting build procedure for: fuel_rate_control
Successful completion of build procedure for: fuel_rate_control
```

## Build Summary

Top model targets built:

Model	Action	Rebuild Reason
fuel_rate_control	Code generated and compiled	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 54.715s

Figure 5 shows snippets of the generated code for the lookup table Pumping Constant.

To see the code for Pumping Constant, right-click the block and select **C/C++ Code > Navigate To C/C++ Code**.

```
rtwtrace('sldemo_fuelsys/fuel_rate_control/airflow_calc/Pumping Constant');
```

The code for the pumping constant contains two breakpoint searches and a 2D interpolation. The `SpeedVect` breakpoint is unevenly spaced, and while the `PressVect` breakpoint is evenly spaced, neither have power of two spacing. The current spacing leads to extra code (ROM), including a division, and requires all breakpoints to be in memory (RAM).

```
/* Lookup_n-D: '<S2>/Pumping Constant' */
bpIdx = plook_u32s16u32n31_linca_s(rtB.es_o.speed, &rtConstP.pooled2[0], 17U, &frac);
fractions[0U] = frac;

```

**Figure 5: Generated code for Pumping Constant lookup (contains unevenly spaced breakpoints)**

### Optimize Code with Evenly Spaced Power of Two Breakpoints

You can optimize the generated code performance by using evenly spaced power of two breakpoints. In this example, remap the lookup table data in the air-fuel ratio control system based on the existing measured data.

When you loaded the model, the model `PostLoadFcn` created the lookup table data in the model workspace. Retrieve the original table data via `sldemo_fuelsys_data`, modify it for evenly spaced power of two, and reassign it in the model workspace.

```
td = sldemo_fuelsys_data('sldemo_fuelsys', 'get_table_data');
```

Compute new table data for evenly spaced power of two breakpoints.

```

ntd.SpeedVect = 64 : 2^5 : 640; % 32 rad/sec
ntd.PressVect = 2*2^-5 : 2^-5 : 1-(2*2^-5); % 0.03 bar
ntd.ThrotVect = 0:2^1:88; % 2 deg
ntd.RampRateKiX = 128:2^7:640; % 128 rad/sec
ntd.RampRateKiY = 0:2^-2:1; % 0.25 bar

```

Remap table data.

```

ntd.PumpCon = interp2(td.PressVect,td.SpeedVect,td.PumpCon, ntd.PressVect',ntd.SpeedVect);
ntd.PressEst = interp2(td.ThrotVect,td.SpeedVect,td.PressEst,ntd.ThrotVect',ntd.SpeedVect);
ntd.SpeedEst = interp2(td.PressVect,td.ThrotVect,td.SpeedEst,ntd.PressVect',ntd.ThrotVect);
ntd.ThrotEst = interp2(td.PressVect,td.SpeedVect,td.ThrotEst,ntd.PressVect',ntd.SpeedVect);

```

Recompute Ramp Rate table data.

```

ntd.RampRateKiZ = (1:length(ntd.RampRateKiX))' * (1:length(ntd.RampRateKiY)) * td.Ki;

```

### Pumping Constant Power Of Two Spacing

```

figure('Tag','CloseMe');
mesh(td.PressVect,td.SpeedVect,td.PumpCon), hold on
mesh(ntd.PressVect,ntd.SpeedVect,ntd.PumpCon)
xlabel('PressVect'), ylabel('SpeedVect'), zlabel('PumpCon')
title(sprintf('Pumping Constant\nOriginal Spacing (%dx%d) vs. Power of Two Spacing (%dx%d)',...
 size(td.PumpCon,1),size(td.PumpCon,2),size(ntd.PumpCon,1),size(ntd.PumpCon,2)));

```

### Pressure Estimate Power Of Two Spacing

```

clf
mesh(td.ThrotVect,td.SpeedVect,td.PressEst), hold on
mesh(ntd.ThrotVect,ntd.SpeedVect,ntd.PressEst)
xlabel('ThrotVect'), ylabel('SpeedVect'), zlabel('PressEst')
title(sprintf('Pressure Estimate\nOriginal Spacing (%dx%d) vs. Power of Two Spacing (%dx%d)',...
 size(td.PressEst,1),size(td.PressEst,2),size(ntd.PressEst,1),size(ntd.PressEst,2)));

```

### Speed Estimate Power Of Two Spacing

```

clf
mesh(td.PressVect,td.ThrotVect,td.SpeedEst), hold on,
mesh(ntd.PressVect,ntd.ThrotVect,ntd.SpeedEst)
xlabel('PressVect'), ylabel('ThrotVect'), zlabel('SpeedEst')
title(sprintf('Speed Estimate\nOriginal Spacing (%dx%d) vs. Power of Two Spacing (%dx%d)',...
 size(td.SpeedEst,1),size(td.SpeedEst,2),size(ntd.SpeedEst,1),size(ntd.SpeedEst,2)));

```

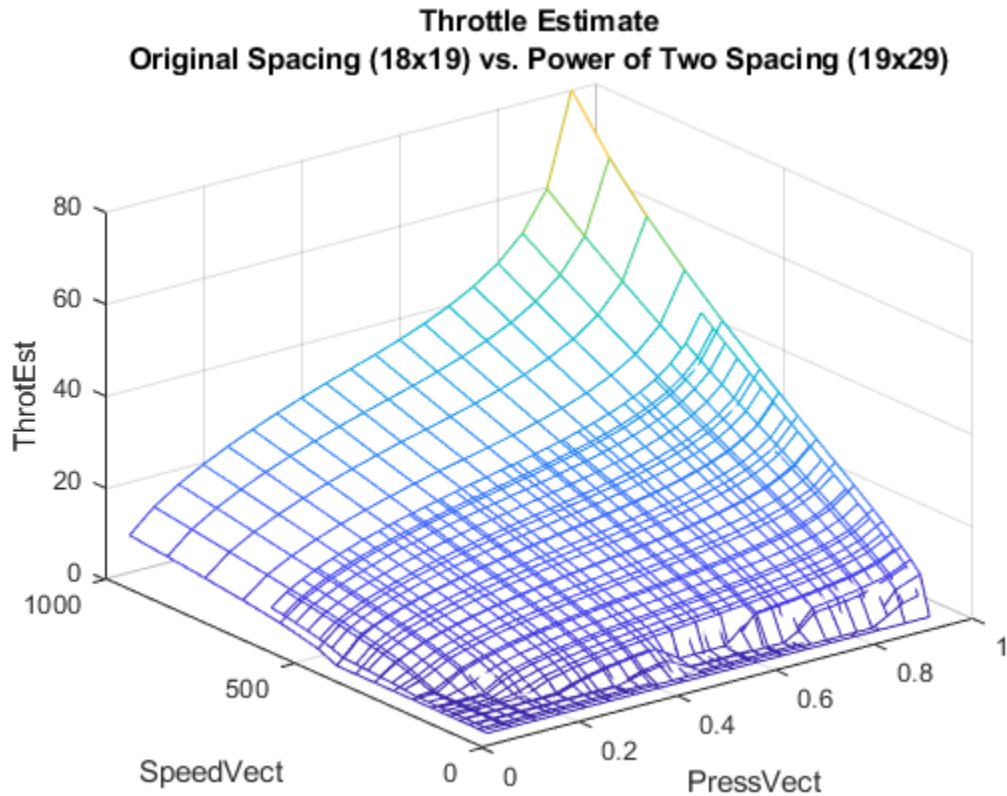

### Throttle Estimate Power Of Two Spacing

```

clf
mesh(td.PressVect,td.SpeedVect,td.ThrotEst), hold on
mesh(ntd.PressVect,ntd.SpeedVect,ntd.ThrotEst)
xlabel('PressVect'), ylabel('SpeedVect'), zlabel('ThrotEst')
title(sprintf('Throttle Estimate\nOriginal Spacing (%dx%d) vs. Power of Two Spacing (%dx%d)',...
 size(td.ThrotEst,1),size(td.ThrotEst,2),size(ntd.ThrotEst,1),size(ntd.ThrotEst,2)));

```

### Ramp Rate Ki Power Of Two Spacing

```

clf
mesh(td.RampRateKiX,td.RampRateKiY,td.RampRateKiZ'), hold on
mesh(ntd.RampRateKiX,ntd.RampRateKiY,ntd.RampRateKiZ'), hidden off
xlabel('RampRateKiX'), ylabel('RampRateKiY'), zlabel('RampRateKiZ')
title(sprintf('Ramp Rate Ki\nOriginal Spacing (%dx%d) vs. Power of Two Spacing (%dx%d)',...
 size(td.RampRateKiZ,1),size(td.RampRateKiZ,2),size(ntd.RampRateKiZ,1),size(ntd.RampRateKiZ,2)

```

The default configuration causes the model to log simulation data for the top-level signals. These simulation results are stored in the workspace variable `sldemo_fuelsys_output`. Before updating the model workspace with the new data, save the result of the simulation in `hDemo.orig_data` for later comparison with the evenly spaced power of two table simulation.

```
set_param('sldemo_fuelsys', 'StopTime', '8')
sim('sldemo_fuelsys')
hDemo.orig_data = sldemo_fuelsys_output;
```

Reassign the new table data in the model workspace.

```
hDemo.hWS = get_param('sldemo_fuelsys', 'ModelWorkspace');
hDemo.hWS.assignin('PressEst', ntd.PressEst);
hDemo.hWS.assignin('PressVect', ntd.PressVect);
hDemo.hWS.assignin('PumpCon', ntd.PumpCon);
hDemo.hWS.assignin('SpeedEst', ntd.SpeedEst);
hDemo.hWS.assignin('SpeedVect', ntd.SpeedVect);
hDemo.hWS.assignin('ThrotEst', ntd.ThrotEst);
hDemo.hWS.assignin('ThrotVect', ntd.ThrotVect);
hDemo.hWS.assignin('RampRateKiX', ntd.RampRateKiX);
hDemo.hWS.assignin('RampRateKiY', ntd.RampRateKiY);
hDemo.hWS.assignin('RampRateKiZ', ntd.RampRateKiZ);
```

Reconfigure lookup tables for evenly spaced data.

```
hDemo.lookupTables = find_system(get_param('sldemo_fuelsys', 'Handle'), ...
 'BlockType', 'Lookup_n-D');
```

```

for hDemo_blkIdx = 1 : length(hDemo.lookupTables)
 hDemo.blkH = hDemo.lookupTables(hDemo_blkIdx);
 set_param(hDemo.blkH, 'IndexSearchMethod', 'Evenly spaced points')
 set_param(hDemo.blkH, 'InterpMethod', 'None - Flat')
 set_param(hDemo.blkH, 'ProcessOutOfRangeInput', 'None')
end

```

Rerun the simulation for the evenly spaced power of two implementation, and store the result of the simulation in `hDemo.pow2_data`.

```

sim('sldemo_fuelsys')
hDemo.pow2_data = sldemo_fuelsys_output;

```

Compare the result of the simulation for the fuel flow rate and the air fuel ratio. The simulation exercised the Pumping Constant and Ramp Rate  $K_i$  lookup tables, and shows an excellent match for the evenly spaced power of two breakpoints relative to the original table data.

```

figure('Tag', 'CloseMe');

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 45.797s
```

Figure 6 shows the same snippets of the generated code for the 'Pumping Constant' lookup table. The generated code for evenly spaced power of two breakpoints is significantly more efficient than the unevenly spaced breakpoint case. The code consists of two simple breakpoint calculations and a direct index into the 2D lookup table data. The expensive division is avoided and the breakpoint data is not required in memory.

```
rtwtrace('sldemo_fuelsys/fuel_rate_control/airflow_calc/Pumping Constant');
```

```

/* Lookup_n-D: '<S2>/Pumping Constant' */
bpIdx = plook_u32s16_even8cka(rtB.es_o.speed, 512, 18U);
bpIndices_idx = bpIdx;
bpIdx = plook_u32u8_even2cka(rtb_map, 8U, 28U);

/* DiscreteFilter: '<S2>/Throttle Transient' */
rtDWork.ThrottleTransient_tmp = (int16_T)((rtb_throttle << 14) - -13107 *
 rtDWork.ThrottleTransient_DSTATE) >> 14);

/* Sum: '<S2>/Sum' incorporates:
 * Product: '<S2>/Product'
 * Product: '<S2>/Product2'
 */
rtb_Product2 = (int16_T)((rtConstP.PumpingConstant_tab[bpIdx * 19U + bpIndices_idx] *
 rtb_speed >> 11) * rtb_map >> 7) + ((20972 *
 rtDWork.ThrottleTransient_tmp + -20972 * rtDWork.ThrottleTransient_DSTATE) >>
 17));

```

Simple index calculation

Direct index into table data

```

uint32_T plook_u32s16_even8cka(int16_T u, int16_T bp0, uint32_T maxIndex)
(
 uint32_T bpIndex;
 uint16_T fbpIndex;

 /* Prelookup - Index only
 * Index Search method: 'even'
 * Process out of range input: 'Clip to range'
 * Use previous index: 'off'
 * Use last breakpoint for index at or above upper limit: 'on'
 */
 if (u < bp0) {
 bpIndex = 0U;
 } else {
 fbpIndex = (uint16_T)((uint32_T)u - (uint32_T)bp0) >> 8U;
 if ((uint32_T)fbpIndex >= maxIndex) {
 bpIndex = maxIndex;
 } else {
 bpIndex = (uint32_T)fbpIndex;
 }
 }

 return bpIndex;
}

```

**Figure 6: Generated code for Pumping Constant lookup (evenly spaced power of two breakpoints)**

Close the example.

```
close(findobj(0, 'Tag', 'CloseMe'));
clear hDemo* td ntd
close_system('sldemo_fuelsys',0);
rtwdemoclean;
```

### **Model Advisor for Code Efficiency**

Improving code efficiency by using evenly spaced power of two breakpoints is one of several important optimizations for fixed-point code generation. The Simulink® Model Advisor is a great tool for identifying other methods of improving code efficiency for a Simulink® and Stateflow® model. Make sure to run the checks under the Embedded Coder® folder or Simulink Coder®.

## Control Placement of Global Data Definitions and Declarations in Generated Files

The generated code can create standard, global structure variables whose fields represent the signal, state, and parameter data in a model. With storage classes, you can configure data to appear in the code as separate global variables or custom global structures. For information about the standard data structures, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49 and “How Generated Code Exchanges Data with an Environment” on page 33-35. For information about storage classes, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.

You can control the file placement of the variable definitions and declarations. Use the information in the table.

Goal	Details and Techniques
Generate a variable that external code can use	<p>Apply a storage class with exported data scope, such as <code>ExportToFile</code>. The generated code declares the variable in a file that your code can include (<code>#include</code>).</p> <p>To generate an <code>extern</code> declaration in <code>model.h</code>, consider using the storage class <code>ExportedGlobal</code>.</p> <p>Alternatively, to place the declaration in a file whose name you can specify, choose one of these techniques:</p> <ul style="list-style-type: none"> <li>• To aggregate multiple variable declarations into one or more specific header files by default, apply a storage class such as <code>ExportToFile</code> to a category of data by using the Code Mappings editor. As you add blocks and signals to the model, new data items are declared in the files that you specify.</li> <li>• To explicitly specify the placement for an individual data item, directly apply a storage class such as <code>ExportToFile</code> and specify a header file name by using the <b>Header file</b> property.</li> </ul> <p>See “Exchange Data Between External Calling Code and Generated Code” on page 55-69.</p>

Goal	Details and Techniques
<p>Generate code that uses a variable defined by external code</p>	<p>Apply a storage class with imported data scope, such as <code>ImportFromFile</code>, to a data element in a model that represents the variable. Then, the generated code does not define the variable, but instead includes (<code>#include</code>) an external header file whose name you can specify. The generated algorithm (for example, the model <code>step</code> function) reads and writes to the variable.</p> <p>Alternatively, if you do not have an external declaration header file or do not want the generated code to include a header file, apply the storage class <code>ImportedExtern</code>. Then, the generated code declares the variable in <code>model_private.h</code>.</p> <p>See “Exchange Data Between External Calling Code and Generated Code” on page 55-69.</p>
<ul style="list-style-type: none"> <li>• Reduce the size of a generated file by creating multiple smaller files</li> <li>• Organize data into different files to make generated code easier to understand</li> </ul>	<p>Depending on the setting of <b>Configuration Parameters &gt; File packaging format</b>, generated files such as <code>model.c</code> and <code>model_data.c</code> can contain many definitions of global variables. Corresponding header files can contain many declarations.</p> <ul style="list-style-type: none"> <li>• To make <code>model.c</code> smaller, consider setting <b>File packaging format</b> to Modular or Compact (with separate data file). Then, the generated code defines the standard structures that represent tunable and constant parameter data in <code>model_data.c</code> instead of <code>model.c</code>.</li> <li>• To place different categories of data (for example, external parameters, block states, and internal signals) in specific files by default, use the Code Mappings editor. For each category of data, use a storage class such as <code>ExportToFile</code> and specify the property <b>Header file</b>. See “Configure Default Code Generation for Data” on page 32-16.</li> <li>• For precise control over the file placement of data, apply storage classes such as <code>ExportToFile</code> to individual data items. Use the properties of the storage class, such as <b>Definition file</b> and <b>Header file</b>, to specify file placement for each data item. For an example, see “Definition and Declaration of Signal Data” on page 25-7.</li> </ul>

Goal	Details and Techniques
Combine multiple files into a single file	<ul style="list-style-type: none"> <li>• Consider setting the model configuration parameter <b>File packaging format</b> to <b>Compact</b>. Then, the code generator does not create the <i>model_data.c</i> file. Instead, the definitions of the standard structures that store tunable and constant parameter data appear in <i>model.c</i>.</li> <li>• When you apply a storage class such as <code>ExportToFile</code> to data elements, leave the properties <b>Definition file</b> and <b>Header file</b> blank, the default value. Also, set the model configuration parameter <b>Data definition</b> to <b>Data defined in source file</b>. Then, the data definitions appear in <i>model.c</i> with the definitions of other global data.</li> </ul>
Separate data definitions from function definitions	<p>By default, the generated file that defines the entry-point functions for a model or subsystem also defines the data for that model or subsystem. When you frequently make changes to data, especially initial values for tunable parameters, the changing source code files can impede verification and make change management more difficult. To separate the data from the functions:</p> <ul style="list-style-type: none"> <li>• Consider setting the model configuration parameter <b>File packaging format</b> to a value that results in the generation of the separate data file <i>model_data.c</i>. Then, the definitions of the standard structures that store tunable and constant parameter data appear in this file instead of in <i>model.c</i>.</li> <li>• Apply storage classes such as <code>ExportToFile</code> to data elements by using the Code Mappings editor. Use the properties of the storage class, such as <b>Definition file</b> and <b>Header file</b>, to specify file placement. For more information, see “Configure Default Code Generation for Data” on page 32-16 and “Organize Parameter Data into a Structure by Using Struct Storage Class” on page 32-67.</li> </ul>
Isolate data definitions in separate files for component-based, team-oriented model development	See “Organize Data to Support Component-Based, Team-Oriented Model Development” on page 34-5.

Goal	Details and Techniques
Aggregate definitions of variant control parameters ( <code>#define</code> macros) into a single header file	<p>As described in “Generate Preprocessor Conditionals for Variant Systems” on page 26-32, a variant control parameter is a parameter object such as <code>SimuLink.Parameter</code>. You apply a storage class that makes the object appear in the generated code as a macro. To control the file placement, choose one of these techniques:</p> <ul style="list-style-type: none"> <li>• For each variant control parameter that uses the storage class <code>Define</code>, set the <b>Header file</b> property to the same value. To configure these objects in a list that you can search, sort, and filter, you can use the Model Data Editor <b>Parameters</b> tab. For an example, see “Generate Variant Control Macros in Same Header File” on page 26-34.</li> <li>• Create one or more storage classes that represent variant control parameters. In the Custom Storage Class Designer, you can set <b>Header file</b> to a value that applies to all of the variant control parameters that use the storage class. With this technique, you do not need to manually specify a header file for each variant control parameter. For more information, see “Create Storage Classes by Using the Custom Storage Class Designer” on page 37-14.</li> </ul>

## Organize Data to Support Component-Based, Team-Oriented Model Development

Depending on your model configuration, data definitions can appear aggregated in large generated files. In a system of components (subsystems or referenced models), you can separate and organize the data definitions into manageable, meaningful files based on the component hierarchy.

Goal	Technique
<p>Establish ownership of global data by placing the data definitions with the code generated for specific components</p>	<p>When you divide a system into components by using referenced models and atomic subsystems, by default, global data is typically defined by the code generated for the top component in the hierarchy. Global data includes parameters, signals, and states to which you apply storage classes (see “C Code Generation Configuration for Model Interface Elements” on page 32-2).</p> <p>Instead, you can place global data definitions with other components in the hierarchy. For an example involving referenced models, see “Establish Data Ownership in a Model Hierarchy” on page 34-10.</p> <ul style="list-style-type: none"> <li>To place a data definition with the code generated for a referenced model, use a built-in storage class such as <code>ExportToFile</code>, or a storage class that you create in a package, and set the <b>Owner</b> property to the name of the referenced model.</li> </ul> <p>To use <b>Owner</b> in a model, you must select the model configuration parameter <b>Use owner from data object for data definition placement</b>. The default setting for this parameter, cleared, means the code generator ignores the setting that you specify for <b>Owner</b>.</p> <p>If only one referenced model uses a parameter object, consider storing the object in the model workspace of that model. Then, the code generated for that model defines the data. You do not need to specify an owner (<b>Owner</b>) for the object.</p> <ul style="list-style-type: none"> <li>In an atomic subsystem, use a storage class such as <code>ExportToFile</code> and explicitly specify the name of the definition file by using the <b>Definition file</b> property. However, you cannot place the definition file with the source files that belong to the subsystem. Instead, the definition file that you specify appears in the folder generated for the model.</li> </ul>

Goal	Technique
For an atomic subsystem, place the standard data structures for the subsystem with the subsystem code	<p>By default, the standard data structures for an atomic subsystem appear as substructures of the data structures for the entire model.</p> <p>To generate separate data structures for a subsystem, select the <b>Function with separate data</b> parameter in the subsystem block. Then, the subsystem data appear in separate structure variables that the subsystem code defines. See “Generate Modular Function Code for Nonvirtual Subsystems” on page 40-2.</p>

## Specify Default Placement

When you create data in a model by adding blocks and signal lines, by default, the data definitions appear in *model.c*. To specify a different default placement, use these tools and parameters:

- The model configuration parameter **File packaging format**. The setting that you choose determines whether the code generator places the standard structures that store tunable and constant parameter data in *model\_data.c* instead of *model.c*. See “File packaging format”.
- The Code Mappings editor. For each category of model data, you can specify a default storage class, which controls file placement. For example, apply the storage class `ExportToFile` to a data category and, in the Property Inspector, use the **DefinitionFile**, **HeaderFile**, and **Owner** properties to control file placement.
- The model configuration parameters **Data definition** and **Data declaration**. These configuration parameters specify the default file placement for data items that you apply storage classes to.
  - These configuration parameters do not affect data items that you apply these storage classes to:
    - `ExportedGlobal`
    - `ImportedExtern`
    - `ImportedExternPointer`
    - `BitField`
    - `FileScope`
    - `Localizable`
    - `Struct`
    - `CompilerFlag`

In the Embedded Coder Dictionary, the **Header File** value for unsupported storage classes is empty. You cannot specify default file placement for unsupported storage classes.

- If you apply a storage class that explicitly specifies definition and declaration files for a data element, those specifications override the **Data definition** and **Data declaration** configuration parameters.

For more information, see “Data definition” and “Data declaration”.

- The subsystem block parameter **Function with separate data**. When you select this parameter, the standard structures that store the subsystem data, such as the `DWork` structure, appear as

separate structure variables. By default, the variable definitions appear in the source file that defines the subsystem execution function. See “Generate Modular Function Code for Nonvirtual Subsystems” on page 40-2.

## Override Default Placement for Individual Data Items

For an individual data item, to override the default file placement, use the Code Mappings editor to apply a storage class directly. For example, to make a data item appear in the generated code as a global variable, apply the storage class `ExportToFile`. Then, use the **Definition file** and **Header file** properties to control file placement. To apply storage classes directly, see “Organize Parameter Data into a Structure by Using Struct Storage Class” on page 32-67.

## Prevent Name Clashes by Configuring Data Item as static

To apply the C keyword `static` to a global variable, which can help you avoid name clashes by limiting the scope of the variable name to the file that defines the variable, choose one of these techniques:

- Apply the built-in storage class `FileScope`. For more information, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.
- If `FileScope` does not satisfy your requirements, create your own storage class by using the Custom Storage Class Designer. In the Designer, set **Data scope** to `File` or `Auto`.
  - With `File`, the data element appears in the code as a `static` global variable.
  - With `Auto`, the code generator first attempts to represent the data element with a local variable in a function. If this attempt fails, the code generator uses a `static` global variable.

For an example that shows how to create your own storage class by using the Designer, see “Create and Apply a Storage Class” on page 37-14.

You cannot apply `static` to the standard data structures such as the `DWork` structure.

To access `static` data, you can configure the generated code to include an interface such as an `a2l` (ASAP2) file. For more information, see “Export ASAP2 File for Data Measurement and Calibration” on page 60-2. To place the data in a specific memory location by including pragmas or other decorations in the generated code, create your own memory section and storage class. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

## Code Generation Impact of Storage Location for Parameter Objects

You can create a parameter object (such as `Simulink.Parameter`) in the base workspace, a model workspace, or a data dictionary. However, when you apply a storage class to the object, the location of the object can impact the file placement of the corresponding data definition in the generated code. See “Code Generation Impact of Storage Location for Parameter Objects” on page 33-117.

## Specify Default `#include` Syntax for Data Header Files

To control the file placement of a data item, such as a signal line or block state, in the generated code, you can apply a storage class to the data item (see “Organize Parameter Data into a Structure by Using Struct Storage Class” on page 32-67). You then use the **Header file** property to specify the generated or external header file that contains the declaration of the data.

To reduce maintenance effort and data entry, when you specify **Header file**, you can omit delimiters (" or <>) and use only the file name. You can then control the default delimiters that the generated code uses for the corresponding `#include` directives. To use angle brackets by default, set **Configuration Parameters > Code Generation > Code Placement > #include file delimiters** to `#include <header.h>`.

## Establish Data Ownership in a Model Hierarchy

This example shows how to establish ownership of global data in the code generated from referenced models.

You can create a global variable in the generated code by applying a storage class to a data element in a referenced model (see “C Code Generation Configuration for Model Interface Elements” on page 32-2). Under certain conditions, the code generator places the variable definition with the code generated from the top model in the hierarchy. This default placement can make it more difficult to determine which model is responsible for the data and to manage code changes in a team-based development environment.

To establish ownership of a global variable by placing the definition with the code generated from the relevant model, apply a storage class such as `ExportToFile` and specify the **Owner** custom attribute. Alternatively, for parameter objects such as `Simulink.Parameter` that you use in only one model, you can establish ownership by storing the object in a model workspace instead of the base workspace or a data dictionary.

### Explore Example Model

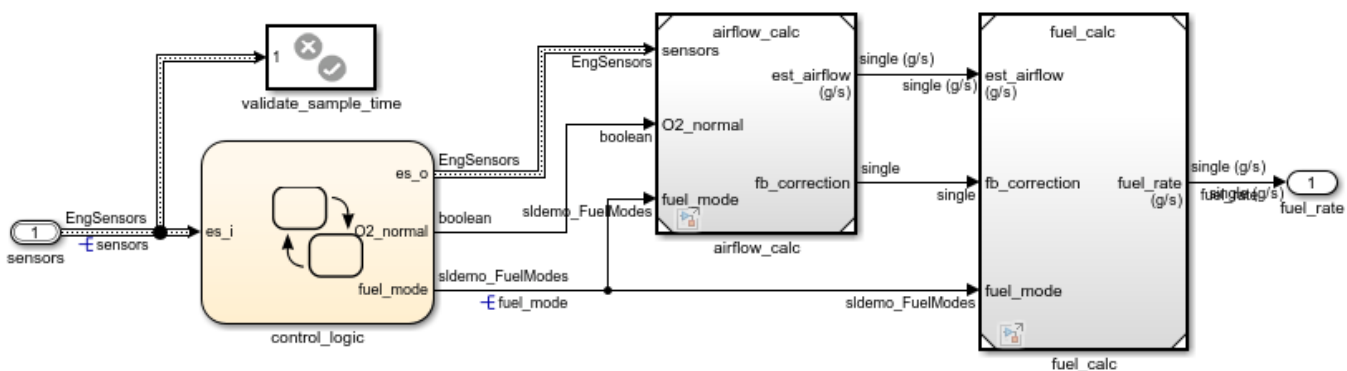

1. Copy the script file `prepare_sl-demo_fuelsys_dd_ctrl.m` to your current folder.

```
[~, ~] = copyfile(fullfile(matlabroot, 'examples', 'ecoder', 'main', 'prepare_sl-demo_fuelsys_dd_ctrl', 'prepare_sl-demo_fuelsys_dd_ctrl.m'), 'f');
```

2. Run the copy of the script in your current folder. The script opens the model `sl-demo_fuelsys_dd_controller` and prepares it for this example.

```
prepare_sl-demo_fuelsys_dd_ctrl
open_system('sl-demo_fuelsys_dd_controller')
```

### Fuel Rate Controller

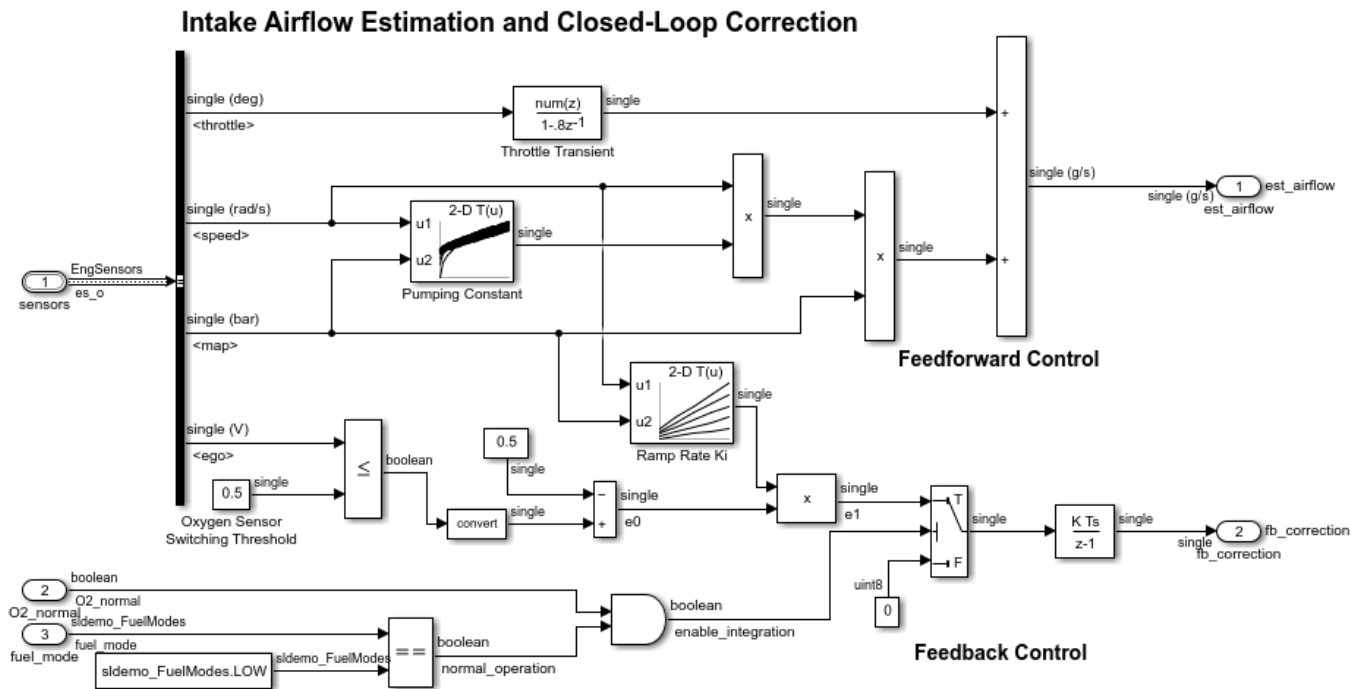

Copyright 1990-2017 The MathWorks, Inc.

This controller model contains two models, `airflow_calc` and `fuel_calc`. The two outputs of `airflow_calc`, `est_airflow` and `fb_correction`, are inputs of `fuel_calc`.

3. Open the `airflow_calc` model.

```
open_system('airflow_calc')
```

4. On the **Modeling** tab, click **Model Data Editor**.

5. In the Model Data Editor, set the **Change view** drop-down list to Code.

6. In the `airflow_calc` model, select the `est_airflow` Outport block.

7. In the Model Data Editor, inspect the value in the **Storage Class** column. The signal that this block represents, `est_airflow`, uses the storage class `ExportToFile`. With this setting, the signal appears in the generated code as a global variable. The Outport block labeled `fb_correction` also uses this setting.

8. In the Model Data Editor, select the **Parameters** tab and click the **Show/refresh additional information** button. The Model Data Editor now shows information about workspace variables and objects, such as `Simulink.Parameter` objects, that the model uses to set block parameter values.

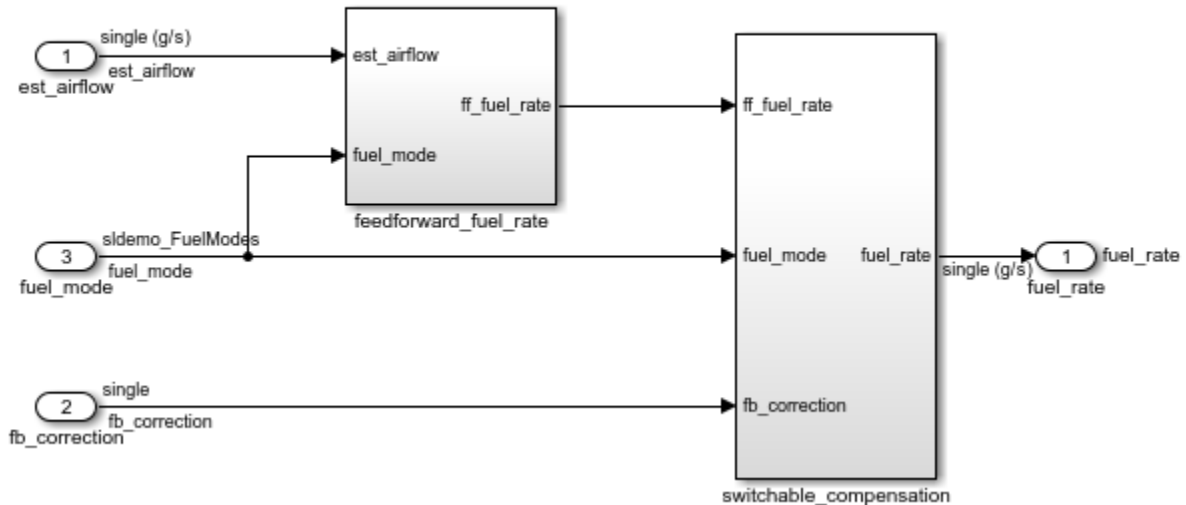

9. In the **Filter contents** box, enter `numerator`. The `Simulink.Parameter` object `numerator_param`, which is in the base workspace, sets the value of the **Numerator** parameter in the Discrete Filter block labeled **Throttle Transient**. The object uses the storage class `ExportToFile`.

10. Select the **Signals** tab. In the **Filter contents** box, enter `e0`. The signal `e0`, which is internal to the `airflow_calc` referenced model, also uses `ExportToFile`. The signal is internal because it is not a root-level input or output of the model.

11. Open the `fuel_calc` model.

```
open_system('fuel_calc')
```

## Fuel Rate Calculation

12. In the Model Data Editor for this model, on the **Imports/Outputs** tab, set **Change view** to Code. The Import blocks `est_airflow` and `fb_correction` use the same storage class, `ExportToFile`, as the corresponding Output blocks in `airflow_calc`. The Output block labeled `fuel_rate` also uses `ExportToFile`.

### Generate and Inspect Code

Generate code from the controller model, `sldemo_fuelsys_dd_controller`.

```
evalc('slbuild(''sldemo_fuelsys_dd_controller'')');
```

In the code generation report, under **Referenced Models**, click the hyperlink to inspect the code generated for `airflow_calc`.

The file `airflow_calc.c` defines the global variable that represents the signal `e0`. Because the blocks that write to and read from `e0` exist only in `airflow_calc`, the code generator assumes that this model owns the signal.

```
file = fullfile('slprj','ert','airflow_calc','airflow_calc.c');
rtwdemodbtype(file,'/* Definition for custom storage class: ExportToFile */',...
 'real32_T e0;',1,1)
```

```
/* Definition for custom storage class: ExportToFile */
real32_T e0; /* '<Root>/Sum1' */
```

In the code generation report, return to the code generated for `sldemo_fuelsys_dd_controller`.

The file `sldemo_fuelsys_dd_controller.c` defines the other global variables.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
 'sldemo_fuelsys_dd_controller.c');
rtwdemodbtype(file,...
 '/* Definition for custom storage class: ExportToFile */',...
 'real32_T numerator_param[2] = { 0.01F, -0.01F } ;',1,1);
```

```

/* Definition for custom storage class: ExportToFile */
real32_T est_airflow; /* '<Root>/airflow_calc' */
real32_T fb_correction; /* '<Root>/airflow_calc' */
real32_T fuel_rate; /* '<Root>/fuel_calc' */
real32_T numerator_param[2] = { 0.01F, -0.01F } ;

```

Because the signals `est_airflow` and `fb_correction` pass between the two models and through the top-level controller model, the code generator assumes that `sldemo_fuelsys_dd_controller` owns the signals. The code generator makes a similar assumption about `fuel_rate`. Because the parameter object `numerator_param` exists in the base workspace, any model in the hierarchy can use the object. Therefore, the code generator assumes that `sldemo_fuelsys_dd_controller` owns the parameter.

You can configure each shared signal and the parameter object so that the corresponding variable definition appears in the code generated for the relevant model.

### Configure Data Ownership

In this example, you configure code generation settings so that:

- The code generated for the `airflow_calc` model defines the signals that pass between the two models, `est_airflow` and `fb_correction`.
  - The code generated for `airflow_calc` defines the parameter data, `numerator_param`.
  - The code generated for `fuel_calc` defines the output signal that it calculates, `fuel_rate`.
1. In the `airflow_calc` model, on the **Modeling** tab, under **Design**, click **Property Inspector**.
  2. In the Model Data Editor, select the **Inports/Outports** tab.
  3. Select the row that corresponds to the Outport block `est_airflow`. The Property Inspector shows the properties of the Outport block.
  4. In the Property Inspector, under **Code**, set **Owner** to `airflow_calc`. The code generator places the definition of the global variable with the code generated for `airflow_calc`.
  5. For `fb_correction`, use the Model Data Editor and the Property Inspector to set **Owner** to `airflow_calc`.
  6. Select the **Parameters** tab.
  7. Find the row that corresponds to the parameter object, `numerator_param`. In the row, double-click the icon in the left column. The Model Explorer opens and displays the properties of `numerator_param`.
  8. In the **Model Hierarchy** pane, expand the `airflow_calc` node so that you can see the subordinate **Model Workspace** node.
  9. Use the Model Explorer to move `numerator_param` from the base workspace to the `airflow_calc` model workspace. For example, in the **Model Hierarchy** pane, select **Base Workspace**. Then, drag `numerator_param` from the **Contents** pane to the **Model Workspace** node in the **Model Hierarchy** pane. With this change, the code generator assumes that `airflow_calc` owns `numerator_param`, and places the variable definition in the code generated for `airflow_calc`.

10. In the `fuel_calc` model, on the **Modeling** tab, under **Design**, click **Property Inspector**.

11. For the Inport blocks `est_airflow` and `fb_correction`, use the Model Data Editor and the Property Inspector to set **Owner** to `airflow_calc`. With this configuration, the `fuel_calc` code does not define the variables.

12. For the Outport block, use the Model Data Editor and the Property Inspector to set **Owner** to `fuel_calc`.

Alternatively, to configure the data in the models, use these commands at the command prompt:

```
temp = Simulink.Signal;
temp.CoderInfo.StorageClass = 'Custom';
temp.CoderInfo.CustomStorageClass = 'ExportToFile';
temp.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

set_param('airflow_calc/est_airflow','SignalName','est_airflow')
set_param('airflow_calc/est_airflow','SignalObject',copy(temp))

set_param('airflow_calc/fb_correction','SignalName','fb_correction')
set_param('airflow_calc/fb_correction','SignalObject',copy(temp))

mdlwks = get_param('airflow_calc','ModelWorkspace');
assignin(mdlwks,'numerator_param',copy(numerator_param));

portHandles = get_param('fuel_calc/est_airflow','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'Name','est_airflow')
set_param(outportHandle,'SignalObject',copy(temp))

portHandles = get_param('fuel_calc/fb_correction','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'Name','fb_correction')
set_param(outportHandle,'SignalObject',copy(temp))

temp.CoderInfo.CustomAttributes.Owner = 'fuel_calc';

set_param('fuel_calc/fuel_rate','SignalName','fuel_rate')
set_param('fuel_calc/fuel_rate','SignalObject',copy(temp))

clear temp portHandles outportHandle numerator_param
```

13. In each of the three models, select **Configuration Parameters > Use owner from data object for data definition placement**. With this setting cleared (the default), the code generator ignores the values that you specify for **Owner**.

```
set_param('fuel_calc','EnableDataOwnership','on')
set_param('airflow_calc','EnableDataOwnership','on')
set_param('sldemo_fuelsys_dd_controller','EnableDataOwnership','on')
```

14. Save the referenced models.

```
save_system('fuel_calc')
save_system('airflow_calc')
```

### Generate Improved Code

Generate code from the controller model, `sldemo_fuelsys_dd_controller`.

```
evalc('slbuild(''sldemo_fuelsys_dd_controller''))');
```

Now, the file `sldemo_fuelsys_dd_controller.c` does not define any of the global variables.

In the code generation report, inspect the code generated for `airflow_calc`.

The file `airflow_calc.c` now defines the global variables that belong to `airflow_calc`.

```
file = fullfile('slprj','ert','airflow_calc','airflow_calc.c');
rtwdemodbtype(file,'/* Definition for custom storage class: ExportToFile */',...
 'real32_T numerator_param[2] = { 0.01F, -0.01F } ;',1,1)
```

```
/* Definition for custom storage class: ExportToFile */
real32_T e0; /* '<Root>/Sum1' */
real32_T est_airflow; /* '<Root>/Sum' */
real32_T fb_correction; /* '<Root>/Discrete Integrator' */
real32_T numerator_param[2] = { 0.01F, -0.01F } ;
```

Inspect the code generated for `fuel_calc`. The file `fuel_calc.c` defines the global variable `fuel_rate`.

```
file = fullfile('slprj','ert','fuel_calc','fuel_calc.c');
rtwdemodbtype(file,'/* Definition for custom storage class: ExportToFile */',...
 'real32_T fuel_rate;',1,1)
```

```
/* Definition for custom storage class: ExportToFile */
real32_T fuel_rate; /* '<S2>/Merge' */
```

### Create Single Point of Specification for Signals That Pass Between Models

The signal data elements `est_airflow` and `fb_correction` are represented by `Outport` blocks in `airflow_calc` and by `Inport` blocks in `fuel_calc`. If you want to change the configuration of one of these signals, you must make the change in both models. For example, if you want to change the storage class of `est_airflow` from `ExportToFile` to `Volatile`, you must change the storage class twice: once for the `Outport` block in `airflow_calc` and again for the `Inport` block in `fuel_calc`.

To make maintenance of each signal easier, store the code generation settings in a `Simulink.Signal` object, which can exist in the base workspace or a data dictionary.

1. In the Model Data Editor for `airflow_calc`, on the **Inports/Outports** tab, find the row that corresponds to `est_airflow`. For that row, in the **Signal Name** column, click the cell.
2. In the cell, next to the `est_airflow` text, click the action button (with three vertical dots). Select **Create and Resolve**.
3. In the **Create New Data** dialog box, set **Value** to `Simulink.Signal` and click **Create**. A `Simulink.Signal` object named `est_airflow` appears in the base workspace. In the Model Data Editor, for `est_airflow`, the check box in the **Resolve** check box is selected, which means the `Outport` block acquires code generation settings from the signal object in the base workspace.
4. In the `est_airflow` property dialog box, set **Storage class** to `ExportToFile`.
5. Set **Owner** to `airflow_calc`.
6. Use the Model Data Editor to create a similar signal object for `fb_correction`.

In the Model Data Editor for `fuel_calc`, on the **Inports/Outports** tab, in the **Resolve** column, select the check boxes for `est_airflow` and `fb_correction`. Now, each Inport block acquires code generation settings from the corresponding signal object.

Alternatively, to create the signal object and configure the blocks and lines in the model, at the command prompt, use these commands:

```
est_airflow = Simulink.Signal;
est_airflow.CoderInfo.StorageClass = 'Custom';
est_airflow.CoderInfo.CustomStorageClass = 'ExportToFile';
est_airflow.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

fb_correction = Simulink.Signal;
fb_correction.CoderInfo.StorageClass = 'Custom';
fb_correction.CoderInfo.CustomStorageClass = 'ExportToFile';
fb_correction.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

set_param('airflow_calc/est_airflow', 'StorageClass', 'Auto')
set_param('airflow_calc/est_airflow', 'MustResolveToSignalObject', 'on')

set_param('airflow_calc/fb_correction', 'StorageClass', 'Auto')
set_param('airflow_calc/fb_correction', 'MustResolveToSignalObject', 'on')

portHandles = get_param('fuel_calc/est_airflow', 'portHandles');
outputHandle = portHandles.Output;
set_param(outputHandle, 'StorageClass', 'Auto')
set_param(outputHandle, 'MustResolveToSignalObject', 'on')

portHandles = get_param('fuel_calc/fb_correction', 'portHandles');
outputHandle = portHandles.Output;
set_param(outputHandle, 'StorageClass', 'Auto')
set_param(outputHandle, 'MustResolveToSignalObject', 'on')

clear portHandles outputHandle
```

7. Save the models and generate code from `sldemo_fuelsys_dd_controller`. The code is the same as it was before you created the `Simulink.Signal` objects. Now, you can make changes to the signal objects instead of the corresponding blocks and lines in the models.

```
save_system('airflow_calc')
save_system('fuel_calc')
evalc('slbuild(''sldemo_fuelsys_dd_controller'')');
```

# Data Types in Embedded Coder

---

- “Control Data Type Names in Generated Code” on page 35-2
- “Control File Placement of Custom Data Types” on page 35-19
- “Replace and Rename Data Types to Conform to Coding Standards” on page 35-22
- “Exchange Structured and Enumerated Data Between Generated and External Code” on page 35-27
- “Specify Boolean and Data Type Limit Identifiers” on page 35-34

## Control Data Type Names in Generated Code

By default, the generated code uses Simulink Coder data type aliases to define scalar and array variables. For example, the Simulink Coder type `real32_T` corresponds to the Simulink type `single`. The code defines these types through `typedef` statements that build on C primitive types such as `float` and `short`. You can configure the code to use custom type names instead.

The code also aggregates signal, block parameter, and state data into structures (see “How Generated Code Exchanges Data with an Environment” on page 33-35 and “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49) by default. You can specify a naming rule for these structure types. You can also place data items into separate custom structures whose type names you can control.

Control these type names to help you to:

- Conform to coding standards. For an example, see “Replace and Rename Data Types to Conform to Coding Standards” on page 35-22.
- Integrate the generated code with your external code. For an example, see “Exchange Structured and Enumerated Data Between Generated and External Code” on page 35-27.
- Make the generated code more readable and meaningful.

For custom types, you can also specify that the generated code reuse type definitions, for example, `typedef` statements, from your external code.

For information about data type names that you cannot control and about custom data types that the generated code does not support, see “Limitations” on page 35-17.

To inform the code generator about the bit length of generic C types such as `int` and `short` for your target hardware, use **Hardware Implementation** configuration parameters. See “Configure Run-Time Environment Options” on page 9-2.

### Control Names of Primitive Data Types

To rename a Simulink Coder primitive data type such as `int8_T`, create a `Simulink.AliasType` object whose name matches the type name that you want the generated code to use. For example, to create a type named `myType`, at the command prompt, enter:

```
myType = Simulink.AliasType;
```

Set the `BaseType` property to the name of the Simulink data type that corresponds to the target Simulink Coder data type. For example, if the target type is `int8_T`, specify `int8`. To identify the Simulink data type, use the information in the table.

Simulink Coder Type Name	Corresponding Simulink Type Name
<code>real_T</code>	<code>double</code>
<code>real32_T</code>	<code>single</code>
<code>int32_T</code>	<code>int32</code>
<code>int16_T</code>	<code>int16</code>
<code>int8_T</code>	<code>int8</code>

Simulink Coder Type Name	Corresponding Simulink Type Name
uint32_T	uint32
uint16_T	uint16
uint8_T	uint8
boolean_T	boolean  For configuring data type replacement throughout an entire model ( <b>Configuration Parameters &gt; Code Generation &gt; Data Type Replacement</b> ), you can alternatively use one of these types: <ul style="list-style-type: none"> <li>• uint8</li> <li>• int8</li> <li>• intn*</li> </ul>
int_T	intn*
uint_T	uintn*
char_T	intn*
uint64_T	uint64
int64_T	int64

\* Replace  $n$  with the number of bits displayed in **Configuration Parameters > Hardware Implementation** for either **Number of bits: int** or **Number of bits: char**. Use the appropriate number of bits for the data type that you want to rename.

---

**Note** The `boolean_T` BaseType must promote to a signed `int`.

---

For example, to replace the type name `uint8_T` with `myType`, set the `BaseType` property of the `Simulink.AliasType` object to `'int8'`.

```
myType.BaseType = 'int8';
```

Then, use one or both of these techniques to apply the type to data items in a model:

- Configure data type replacements. Throughout the code that you generate from a model, you can replace a Simulink Coder data type name with the name of the `Simulink.AliasType` object. You configure data type replacements through model configuration parameters (**Configuration Parameters > Code Generation > Data Type Replacement**).

For an example that shows how to use data type replacement, see “Replace and Rename Data Types to Conform to Coding Standards” on page 35-22.

- Use the name of the `Simulink.AliasType` object to specify the data type of an individual signal, that is, a block output, or block parameter. By default, due to data type propagation and inheritance (see “Data Type Inheritance Rules”), the signals, states, and parameters of other downstream blocks typically inherit the same data type. Optionally, you can configure data items in upstream blocks to inherit the type (`Inherit: Inherit via back propagation`) or stop the propagation at an arbitrary block by specifying a noninherited data type setting.

To specify a data type for an individual data item, use the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). You can use the name of the same `Simulink.AliasType` object to specify the data types of multiple data items.

For an example that shows how to use a `Simulink.AliasType` object directly in a model, see “Create Data Type Alias in the Generated Code” on page 35-9.

Control Names of Primitive Types	Technique
<p>Change the name of a primitive type that the generated code uses to define variables by default (for example, <code>int8_T</code>).</p>	<p>Configure a data type replacement for an entire model.</p> <p>To replace a default Simulink Coder data type name with the corresponding Simulink type name, for example, to replace <code>int8_T</code> with <code>int8</code>, you do not need to create a <code>Simulink.AliasType</code> object. See “Use Simulink Data Type Names Instead of Simulink Coder Data Type Names” on page 35-5.</p> <p>To share data type replacements throughout a model reference hierarchy, use referenced configuration sets (see “Share a Configuration Across Referenced Models”).</p>
<p>Configure the generated code to define a particular data item, such as a variable, by using a specific, meaningful type name.</p>	<p>In the model, locate the data item that corresponds to the variable. For example, trace from the code generation report to the model. Use the name of the <code>Simulink.AliasType</code> object to set the data type of the item.</p> <p>If necessary, to prevent other data items in upstream and downstream blocks from using the same type name, configure those items to use a data type setting that is not inherited. By default, most signals use the inherited type <code>Inherit: Inherit via internal rule</code>.</p>
<p>Use the same type name for multiple signals and other data items in a data path, which is a series of connected blocks.</p>	<p>In the model, use the name of a <code>Simulink.AliasType</code> object to set the data type of one of the signals in the path, for example, a root-level Inport block or a Constant block. For example, if the path begins with an Inport block at the root level of the model, you can specify the type in that block. By default, due to data type propagation, the data items in the other blocks typically inherit the same type.</p> <p>Usually, no matter where on the data path you specify the type, downstream data items inherit the type. You can configure upstream data items to inherit the type, too. Consider specifying the type in a block that you do not expect to remove or change frequently.</p>

Control Names of Primitive Types	Technique
Configure the generated code to replace an implementation-dependent type, such as <code>char_T</code> or <code>boolean_T</code> , and another type of equivalent bit length with a single type name that you specify.	Use the name of the <code>Simulink.AliasType</code> object to configure multiple data type replacements simultaneously. See “Replace Implementation-Dependent Types with the Same Type Name” on page 35-6.

### Use Simulink Data Type Names Instead of Simulink Coder Data Type Names

For consistency between the data type names that you see in a model and in the generated code, you can configure data type replacements so the code uses Simulink type names instead of Simulink Coder names. For each Simulink Coder type that you want to rename, use the Simulink data type name to specify the replacement name. You do not need to create `Simulink.AliasType` objects.

Simulink Name	Code Generation Name	Replacement Name
double	<code>real_T</code>	<input type="text" value="&lt;empty&gt;"/>
single	<code>real32_T</code>	<input type="text" value="&lt;empty&gt;"/>
int32	<code>int32_T</code>	<input type="text" value="&lt;empty&gt;"/>
int16	<code>int16_T</code>	<input type="text" value="&lt;empty&gt;"/>
int8	<code>int8_T</code>	<input type="text" value="int8"/>
uint32	<code>uint32_T</code>	<input type="text" value="&lt;empty&gt;"/>
uint16	<code>uint16_T</code>	<input type="text" value="&lt;empty&gt;"/>
uint8	<code>uint8_T</code>	<input type="text" value="&lt;empty&gt;"/>
boolean	<code>boolean_T</code>	<input type="text" value="&lt;empty&gt;"/>
int	<code>int_T</code>	<input type="text" value="&lt;empty&gt;"/>
uint	<code>uint_T</code>	<input type="text" value="&lt;empty&gt;"/>
char	<code>char_T</code>	<input type="text" value="&lt;empty&gt;"/>
uint64	<code>uint64_T</code>	<input type="text" value="&lt;empty&gt;"/>
int64	<code>int64_T</code>	<input type="text" value="&lt;empty&gt;"/>

To replace `boolean_T`, `int_T`, or `uint_T`, use the information in the table.

Simulink Coder Type Name	Replacement Names to Use
boolean_T	One of these names: <ul style="list-style-type: none"> <li>• boolean</li> <li>• uint8</li> <li>• int8</li> <li>• intn*</li> </ul>
int_T	intn*
uint_T	uintn*
char_T	intn*

\* Replace  $n$  with the number of bits displayed in **Configuration Parameters > Hardware Implementation** for either **Number of bits: int** or **Number of bits: char**. Use the appropriate number of bits for the data type that you want to replace.

You cannot use this technique to replace `real_T` with `double` or `real32_T` with `single`.

### Replace Implementation-Dependent Types with the Same Type Name

Some Simulink Coder type names map to C primitives that are implementation-dependent. For example, the Simulink Coder type `int_T` maps to the C type `int`, whose bit length depends on the native integer size of your target hardware. Other implementation-dependent types include `boolean_T`, `char_T`, and `uint_T`.

For more readable, simpler code, you can use the same type name to replace multiple Simulink Coder types of the same size. For example, if the native integer size of your hardware is 32 bits, you can replace `int_T` and `int32_T` with the same type name, say, `myInt`.

- 1 Configure your target hardware settings in **Configuration Parameters > Hardware Implementation**.
- 2 Create a `Simulink.AliasType` object named `myInt`. In this case, because `int_T` and `int32_T` represent a 32-bit signed integer, set `BaseType` to `int32`.

```
myInt = Simulink.AliasType('int32')
```

- 3 Configure the same data type replacement for `int32_T` and `int_T`.

## Data type names

Simulink Name	Code Generation Name	Replacement Name
double	real_T	<empty>
single	real32_T	<empty>
int32	int32_T	myInt
int16	int16_T	<empty>
int8	int8_T	<empty>
uint32	uint32_T	<empty>
uint16	uint16_T	<empty>
uint8	uint8_T	<empty>
boolean	boolean_T	<empty>
int	int_T	myInt
uint	uint_T	<empty>
char	char_T	<empty>
uint64	uint64_T	<empty>
int64	int64_T	<empty>

**Note** Many-to-one data type replacement does not support the char (char\_T) built-in data type. Use char only in one-to-one data type replacements.

Many-to-one data type replacement is not supported for Simulink Coder data types of different sizes.

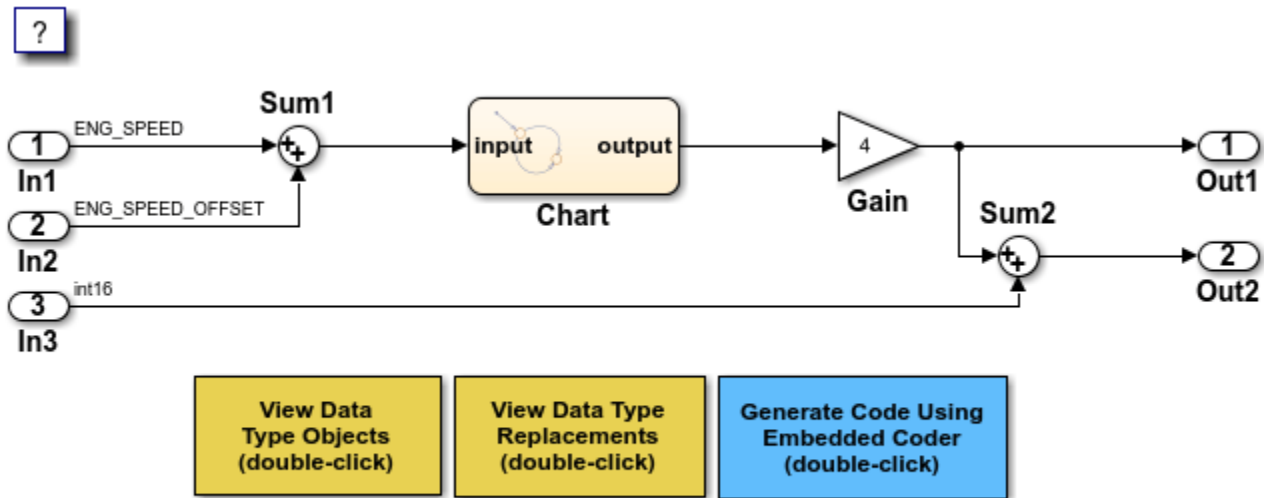

### Define Abstract Numeric Types and Rename Types

This model shows user-defined types, consisting of numeric and alias types. Numeric types allow you to define abstract numeric types, which is particularly useful for fixed-point types. Alias types allow you to rename types, which allows you create a relationship for types.

### Explore Example Model

Open the example model and configure it to show the generated names of blocks.

```
load_system('rtwdemo_udt')
set_param('rtwdemo_udt', 'HideAutomaticNames', 'off')
open_system('rtwdemo_udt')
```

Copyright 1994-2020 The MathWorks, Inc.

### Key Features of User-Defined Types

- Displayed and propagated on signal lines
- Used to parameterize a model by type (e.g., In1 specifies its **Output data type** as ENG\_SPEED)
- Types with a common ancestor can be mixed, whereby the common ancestor is propagated (e.g., output of Sum1)
- Intrinsically supported by the Simulink Model Explorer
- Include an optional header file attribute that is ideal for importing legacy types (ignored for GRT targets)
- Types used in the generated code (ignored for GRT targets)

### Instructions

- 1 Inspect the user-defined types in the Model Explorer by double-clicking the first yellow button below.
- 2 Inspect the replacement data type mapping by double-clicking the second yellow button below.
- 3 Compile the diagram to display the types in this model (Debug > Update Model > Update Model or **Ctrl+D**).
- 4 Generate code with the blue button below and inspect model files to see how user-defined types appear in the generated code.
- 5 Modify the attributes of ENG\_SPEED and ENG\_SPEED\_OFFSET and repeat steps 1-4.

### Notes

- User-defined types are a feature of Simulink that facilitate parameterization of the data types in a model. Embedded Coder preserves alias data type names (e.g., ENG\_SPEED) in the generated code, whereas Simulink Coder implements user-defined types as their base type (e.g., real32\_T).

- Embedded Coder also enables you to replace the built-in data types with user-defined data types in the generated code.

## Control Names of Structure Types

To control the names of the standard structures that Simulink Coder creates by default to store data (*model\_P* for parameter data, for example), use **Configuration Parameters > Code Generation > Identifiers > Global types** to specify a naming rule. For more information, see “Customize Generated Identifiers” on page 91-18.

When you use nonvirtual buses and parameter structures to aggregate signals and block parameters into a custom structure in the generated code, control the name of the structure type by creating a `Simulink.Bus` object. For more information, see “Organize Data into Structures in Generated Code” on page 33-145.

## Generate Code That Reuses Data Types From External Code

To generate code that reuses a data type definition from your external C code, specify the data scope of the corresponding data type object or enumeration in Simulink as `Imported`. With this setting, the generated code includes (`#include`) the definition from your code. For more information about controlling the file placement of a custom data type, see “Control File Placement of Custom Data Types” on page 35-19.

Instead of creating individual data type objects and enumerated types, and then configuring them, consider creating the objects and types by using the `Simulink.importExternalCTypes` function. By default, the function configures the new objects and types so that the generated code imports (reuses) the type definitions from your code. You can then use the objects and types to set data types in a model and to configure data type replacements. For more information, see `Simulink.importExternalCTypes` and “Exchange Structured and Enumerated Data Between Generated and External Code” on page 35-27.

## Create Data Type Alias in the Generated Code

This example shows how to configure the generated code to use a data type name (typedef) that you specify.

### Export Type Definition

When you integrate code generated from a model with code from other sources, your model code can create an exported typedef statement. Therefore, all of the integrated code can use the type. This example shows how to export the definition of a data type to a generated header file.

Create a `Simulink.AliasType` object named `mySingleAlias` that acts as an alias for the built-in data type `single`.

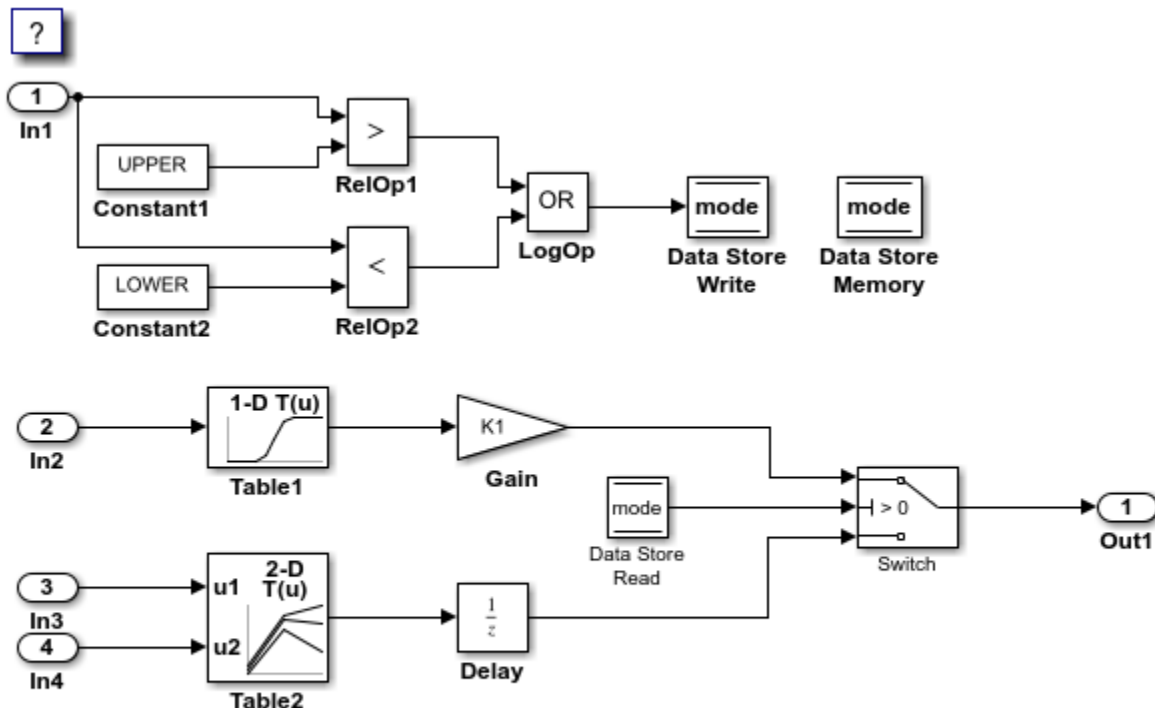

```
mySingleAlias = Simulink.AliasType('single');
```

Configure the object to export its definition to a header file called `myHdrFile.h`.

```
mySingleAlias.DataScope = 'Exported';
mySingleAlias.HeaderFile = 'myHdrFile.h';
```

Open the model `rtwdemo_configinterface`.

```
open_system('rtwdemo_configinterface')
```

Copyright 1994-2020 The MathWorks, Inc.

Configure the model to show the generated names of blocks.

```
set_param('rtwdemo_configinterface','HideAutomaticNames','off')
```

On the **Modeling** tab, click **Model Data Editor**.

In the model, select the Inport block labeled In1.

Use the **Data Type** column to set the data type to mySingleAlias.

```
set_param('rtwdemo_configinterface/In1','OutDataTypeStr','mySingleAlias')
```

Configure In1 to use default storage.

In the **C Code** tab, select **Code Interface > Default Code Mappings**.

In the Code Mappings editor, under **Inports and Outports**, select category **Inports**. Set the default storage class to Default.

On the **Inports** tab, set **Storage Class** to Model default.

```
cm = coder.mapping.api.get('rtwdemo_configinterface');
setDataDefault(cm,'Inports','StorageClass','Default');
setInport(cm,'In1','StorageClass','Model default');
```

Generate code from the model.

```
slbuild('rtwdemo_configinterface')
Starting build procedure for: rtwdemo_configinterface
tf =
 logical
 0
Successful completion of code generation for: rtwdemo_configinterface
Build Summary
Top model targets built:
Model Action Rebuild Reason
=====
rtwdemo_configinterface Code generated Code generation information file does not exist.
1 of 1 models built (0 models already up to date)
Build duration: 0h 1m 28.713s
```

In the code generation report, view the file `rtwdemo_configinterface_types.h`. The code creates a `#include` directive for the generated file `myHdrFile.h`.

```
file = fullfile('rtwdemo_configinterface_ert_rtw','rtwdemo_configinterface_types.h');
rtwdemodbtype(file,'#include "myHdrFile.h"',...
 '#include "myHdrFile.h"',1,1)
```

```
#include "myHdrFile.h"
```

View the file `myHdrFile.h`. The code uses the identifier `mySingleAlias` as an alias for the data type `real32_T`. By default, generated code represents the Simulink data type `single` by using the identifier `real32_T`.

The code also provides a macro guard of the form `RTW_HEADER_filename_h_`. When you export a data type definition to integrate generated code with code from other sources, you can use macro guards of this form to prevent unintentional identifier clashes.

```
file = fullfile('slprj','ert','_sharedutils','myHdrFile.h');
rtwdemodbtype(file,'#ifndef RTW_HEADER_myHdrFile_h_',...
 ' * File trailer for generated code.',1,0)

#ifndef RTW_HEADER_myHdrFile_h_
#define RTW_HEADER_myHdrFile_h_
#include "rtwtypes.h"

typedef real32_T mySingleAlias;
typedef creal32_T cmySingleAlias;

#endif /* RTW_HEADER_myHdrFile_h_ */

/*
```

View the file `rtwdemo_configinterface.h`. The code uses the data type alias `mySingleAlias` to define the structure field `input1`, which corresponds to the Inport block labeled In1.

```
file = fullfile('rtwdemo_configinterface_ert_rtw','rtwdemo_configinterface.h');
rtwdemodbtype(file,...
 /* External inputs (root inport signals with default storage) */,...
 '} ExtU_rtwdemo_configinterface_T;',1,1)

/* External inputs (root inport signals with default storage) */
typedef struct {
 mySingleAlias input1; /* '<Root>/In1' */
 MYTYPE input2; /* '<Root>/In2' */
 MYTYPE input3; /* '<Root>/In3' */
 MYTYPE input4; /* '<Root>/In4' */
} ExtU_rtwdemo_configinterface_T;
```

### Import Type Definition

When you integrate code generated from a model with code from other sources, to avoid redundant `typedef` statements, you can import a data type definition from the external code. This example shows how to import your own definition of a data type from a header file that you create.

Use a text editor to create a header file to import. Name the file `ex_myImportedHdrFile.h`. Place it in your working folder. Copy the following code into the file.

```
#ifndef HEADER_myImportedHdrFile_h_
#define HEADER_myImportedHdrFile_h_

typedef float myTypeAlias;

#endif
```

The code uses the identifier `myTypeAlias` to create an alias for the data type `float`. The code also uses a macro guard of the form `HEADER_filename_h`. When you import a data type definition to integrate generated code with code from other sources, you can use macro guards of this form to prevent unintentional identifier clashes.

At the command prompt, create a `Simulink.AliasType` object named `myTypeAlias` that creates an alias for the built-in type `single`. The Simulink data type `single` corresponds to the C data type `float`.

```
myTypeAlias = Simulink.AliasType('single')
```

```
myTypeAlias =
```

```
AliasType with properties:
```

```
Description: ''
DataScope: 'Auto'
HeaderFile: ''
BaseType: 'single'
```

Configure the object so that generated code imports the type definition from the header file `ex_myImportedHdrFile.h`.

```
myTypeAlias.DataScope = 'Imported';
myTypeAlias.HeaderFile = 'ex_myImportedHdrFile.h';
```

Open the model `rtwdemo_configinterface`.

```
open_system('rtwdemo_configinterface')
```

On the **Modeling** tab, click **Model Data Editor**.

In the model, select the Inport block labeled In1.

Use the **Data Type** column to set the data type to `myTypeAlias`.

```
set_param('rtwdemo_configinterface/In1','OutDataTypeStr','myTypeAlias')
```

Generate code from the model.

```
slbuild('rtwdemo_configinterface')
```

```
Starting build procedure for: rtwdemo_configinterface
Successful completion of code generation for: rtwdemo_configinterface
```

Build Summary

} Table2_Type;

#endif
#endif /* RTW_HEADER_rtwdemo_configinterface_types_h_ */

/*
 * File trailer for generated code.
 *
 * [EOF]
 */

```

View the file `rtwdemo_configinterface.h`. The code uses the data type alias `myTypeAlias` to define the structure field `input1`, which corresponds to the Inport block labeled In1.

```

file = fullfile('rtwdemo_configinterface_ert_rtw','rtwdemo_configinterface.h');
rtwdemodbtype(file,...
 '/* External inputs (root inport signals with default storage) */',...
 '} ExtU_rtwdemo_configinterface_T;',1,1)

/* External inputs (root inport signals with default storage) */
typedef struct {
 myTypeAlias input1; /* '<Root>/In1' */
 MYTYPE input2; /* '<Root>/In2' */
 MYTYPE input3; /* '<Root>/In3' */
 MYTYPE input4; /* '<Root>/In4' */
} ExtU_rtwdemo_configinterface_T;

```

### Display Base Data Types and Aliases on Model Diagram

When you display signal data types on the model diagram, you can choose to display aliases (such as `myTypeAlias`) and base data types (such as `int16`). To display aliases, on the **Debug** tab, select **Information Overlays > Alias Data Types**. To display the base types, select **Information Overlays > Base Data Types**. For more information, see “Port Data Types”.

### Create a Named Fixed-Point Data Type in the Generated Code

This example shows how to create and name a fixed-point data type in generated code. You can use the name of the type to specify parameter and signal data types throughout a model and in generated code.

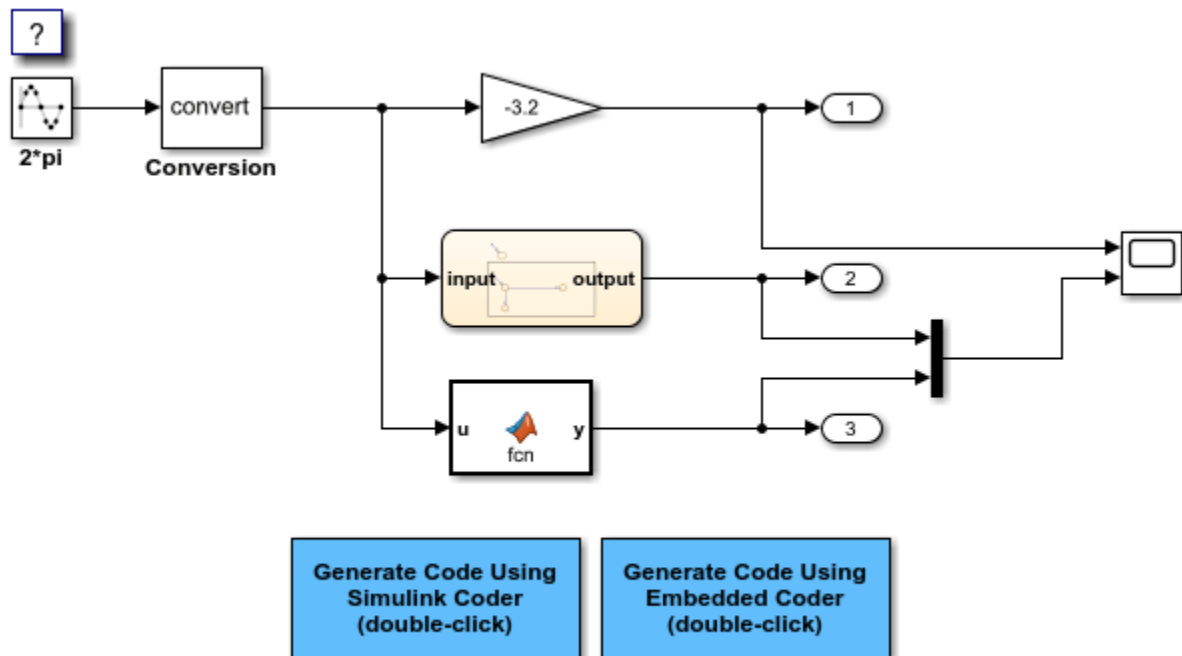

The example model `rtwdemo_fixpt1` uses fixed-point data types. So that you can more easily see the fixed-point data type in the generated code, in this example, you create a `Simulink.Parameter` object that appears in the code as a global variable.

Create a `Simulink.AliasType` object that defines a fixed-point data type. Name the object `myFixType`. The generated code uses the name of the object as a data type.

```
myFixType = Simulink.AliasType('fixdt(1,16,4)');
```

Open the model `rtwdemo_fixpt1`.

```
open_system('rtwdemo_fixpt1')
```

Copyright 1994-2020 The MathWorks, Inc.

Configure the model to show the generated names of the blocks.

```
set_param('rtwdemo_fixpt1', 'HideAutomaticNames', 'off')
```

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, select the Gain block.

In the Model Data Editor, for the row that represents the **Gain** parameter of the Gain block, in the **Value** column, specify myParam.

Click the action button (with three vertical dots) next to the parameter value. Select **Create**.

In the **Create New Data** dialog box, set **Value** to `Simulink.Parameter(8)`. In this example, for more easily readable code, you set the parameter value to 8 instead of -3.2. Click **Create**. A `Simulink.Parameter` object named myParam appears in the base workspace. The object stores the real-world value 8, which the Gain block uses for the value of the **Gain** parameter.

In the **Simulink.Parameter** property dialog box, set **Storage class** to `ExportedGlobal`. Click **OK**. With this setting, myParam appears in the generated code as a separate global variable.

In the Model Data Editor, use the **Data Type** column to set the data type of the **Gain** parameter of the Gain block to myFixType.

On the **Signals** tab, use the **Data Type** column to set the data type of the Gain block output to myFixType.

Use the **Data Type** column to set the data type of the Conversion block output to myFixType.

Alternatively, you can use these commands at the command prompt to configure the blocks and create the object:

```
set_param('rtwdemo_fixpt1/Gain','Gain','myParam','OutDataTypeStr','myFixType',...
'ParamDataTypeStr','myFixType')
myParam = Simulink.Parameter(8);
myParam.StorageClass = 'ExportedGlobal';
set_param('rtwdemo_fixpt1/Conversion','OutDataTypeStr','myFixType')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. With this setting, the code generator honors data type aliases such as `myFixType`.

```
set_param('rtwdemo_fixpt1','SystemTargetFile','ert.tlc')
```

Select the configuration parameter **Generate code only**.

```
set_param('rtwdemo_fixpt1','GenCodeOnly','on')
```

Generate code from the model.

```
slbuild('rtwdemo_fixpt1')

Starting build procedure for: rtwdemo_fixpt1
Successful completion of code generation for: rtwdemo_fixpt1
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_fixpt1	Code generated	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)

Build duration: 0h 1m 17.152s

In the code generation report, view the file `rtwdemo_fixpt1_types.h`. The code defines the type `myFixType` based on an integer type of the specified word length (16).

```
file = fullfile('rtwdemo_fixpt1_ert_rtw','rtwdemo_fixpt1_types.h');
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_myFixType_',...
'/* Forward declaration for rtModel */',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_myFixType_
#define DEFINED_TYPEDEF_FOR_myFixType_
```

```
typedef int16_T myFixType;
typedef cint16_T cmyFixType;
```

```
#endif
```

View the file `rtwdemo_fixpt1.c`. The code uses the type `myFixType`, which is an alias of the integer type `int16`, to define the variable `myParam`.

```
file = fullfile('rtwdemo_fixpt1_ert_rtw','rtwdemo_fixpt1.c');
rtwdemodbtype(file,'myFixType myParam = 128;', 'myFixType myParam = 128;',1,1)
```

```
myFixType myParam = 128; /* Variable: myParam
```

The stored integer value 128 of `myParam` is not the same as the real-world value 8 because of the scaling that the fixed-point data type `myFixType` specifies. For more information, see “Scaling” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

The line of code that represents the Gain block applies a right bit shift corresponding to the fraction length specified by `myFixType`.

```
rtwdemodbtype(file,...
 'rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);',...
 'rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);',1,1)

rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);
```

## Rename Data Type Object

To rename a data type object such as `Simulink.AliasType` or `Simulink.Bus` after you create it (for example, to rename an alias when coding standards change or when you encounter a naming conflict), you can allow Simulink to rename the object and correct all of the references to the object that appear in a model or models. In the Model Explorer, right-click the variable and select **Rename All**. For more information, see “Rename Variables”.

## Display Signal Data Types on Block Diagram

For readability, you can display signal data types directly on a block diagram. When you use custom names for primitive data types, you can choose to display the custom name (the alias), the underlying primitive, or both. See “Port Data Types”.

## Limitations

- You cannot configure the generated code to use these custom C data types:
  - Array types
  - Pointer types
  - `const` or `volatile` types
- You cannot configure the generated code to use generic C primitive types such as `int` and `short`.

## Data Type Replacement Limitations

When you select the model configuration parameter **Replace data type names in the generated code** on the **Code Generation > Data Type Replacement** pane of the Configuration Parameters dialog box, these limitations apply:

- Data type replacement does not support multiple levels of mapping. Each replacement data type name maps directly to one or more built-in data types.
- Data type replacement is not supported for simulation target code generation for referenced models.
- If you select the **Classic call interface** configuration parameter for your model, data type replacement is not supported.

- Code generation performs data type replacements while generating .c, .cpp, and .h files. Code generation places these files in build folders (including top and referenced model build folders) and in the `_sharedutils` folder. *Exceptions* are as follows:
  - `rtwtypes.h`
  - `multiword_types.h`
  - `model_reference_types.h`
  - `builtin_typeid_types.h`
  - `model_sf.c` or `.cpp` (ERT S-function wrapper)
  - `model_dt.h` (C header file supporting external mode)
  - `model_capi.c` or `.cpp`
  - `model_capi.h`
- Data type replacement is not supported for complex data types.
- Many-to-one data type replacement is not supported for the `char` data type. Attempting to use `char` as part of a many-to-one mapping to a custom data type represents a violation of the MISRA C specification. For example, if you map `char` (`char_T`) and either `int8` (`int8_T`) or `uint8` (`uint8_T`) to the same replacement type, the result is a MISRA C violation. If you try to generate C++ code, the code generator makes invalid implicit type casts, resulting in compile-time errors. Use `char` only in one-to-one data type replacements.

Many-to-one data type replacement is not supported for Simulink Coder data types of different sizes. For more information, see “Replace Implementation-Dependent Types with the Same Type Name” on page 35-6.
- For ERT S-functions, replace the `boolean` data type with only an 8-bit integer, `int8`, or `uint8`.
- Set the `DataScope` property of a `Simulink.AliasType` object to `Auto` (default) or `Imported`.

## Control File Placement of Custom Data Types

By default, when you use data type objects, such as `Simulink.AliasType` and `Simulink.Bus`, and custom enumerations to specify data types for signals and block parameters, the code generated from the model defines the types (for example, with `typedef` statements). To ease integration of the generated code with other existing code and to modularize the generated code, you can control the file placement of the type definitions by adjusting the properties of the objects and the enumerations.

### Data Scope and Header File

To control the file placement of a custom type definition in generated code, set the `DataScope` and `HeaderFile` properties of the data type object according to the table. Similarly, for an enumeration that you define in a MATLAB file, set the return arguments of the `getDataScope` and `getHeaderFile` methods.

- *typename* is the name of the custom data type.
- *filename* is the name of a header file.
- *model* is the name of the model.

Goal	Specify DataScope as	Specify HeaderFile as
Export type definition to <i>model_types.h</i>	Auto	Empty
Import type definition from a header file that you create, <i>filename</i>	Auto or Imported	<i>filename</i> (if necessary, include a .h extension)
Export type definition to a generated header file, <i>filename.h</i>	Exported	<i>filename</i> or <i>filename.h</i>
Export type definition to a generated header file, <i>typename.h</i>	Exported	Empty

When you import a data type definition (for example, by setting `DataScope` to `Imported`), the generated model code creates an `#include` directive for your header file in place of a type definition. You supply the header file that contains the definition. To avoid linker errors, you must add include guards, such as `#pragma once`, to the beginning of an imported header file.

### Considerations for Data Type Replacement

- If you use data type replacement to replace a built-in Simulink data type with your own data type in generated code (see “Model Configuration Parameters: Code Generation Data Type Replacement”), `typedef` statements and `#include` directives appear in `rtwtypes.h` instead of `model_types.h`.
- When a `Simulink.AliasType` or `Simulink.NumericType` object participates in data type replacements, you cannot set the `DataScope` property of the object to `Exported`. Therefore, if you want the code generator to generate the corresponding `typedef` statement, you cannot control the file placement of the statement. However, you can set `DataScope` to `Imported`, which means that you can configure the code to reuse the `typedef` statement that your external code provides.

As a workaround, instead of using the data type object as a data type replacement, use the object to set the data types of individual data items in a model. To configure many data items, you can use the Model Data Editor and take advantage of data type propagation and inheritance. For more information, see “Control Names of Primitive Data Types” on page 35-2.

### Import Definition of Numerically Complex Data Type

You can use a `Simulink.AliasType` object with numerically complex data (i). In this case, if you configure the generated code to import the type definition from your external code (for example, by setting the `DataScope` property to `Imported`), your code must provide two complementary `typedef` statements.

Suppose your external header file `myAliasTypes.h` defines the data type `IAT_int32` as an alias of a 32-bit integer. The file must define two types: `IAT_int32` and `cIAT_int32`:

```
#ifndef myAliasTypes_H_
#define myAliasTypes_H_

#include "rtwtypes.h"

typedef int32_T IAT_int32;
typedef cint32_T cIAT_int32;

#endif
```

You do not need to create two `Simulink.AliasType` objects. In this example, you create one object, `IAT_int32`. The generated code then creates complex data (variables) by using both `IAT_int32` and `cIAT_int32`.

### Macro Guards

When you export one or more data type definitions to a generated header file, the file contains a file-level macro guard of the form `RTW_HEADER_filename_h`.

Suppose that you use several `Simulink.AliasType` objects: `mySingleAlias`, `myDoubleAlias`, and `myIntAlias` with these properties:

- `DataScope` set to `Exported`
- `HeaderFile` set to `myTypes.h`

When you generate code, the guarded file `myTypes.h` contains the `typedef` statements:

```
#ifndef RTW_HEADER_myTypes_h_
#define RTW_HEADER_myTypes_h_
#include "rtwtypes.h"

typedef real_T myDoubleAlias;
typedef real32_T mySingleAlias;
typedef int16_T myIntAlias;

#endif
```

When you export data type definitions to `model_types.h`, the file contains a macro guard of the form `_DEFINED_TYPEDEF_FOR_typename_` for each `typedef` statement. Suppose that you use a `Simulink.AliasType` object `mySingleAlias` with these properties:

- DataScope set to Auto
- HeaderFile not specified

When you generate code, the file `model_types.h` contains the guarded typedef statement:

```
#ifndef _DEFINED_TYPEDEF_FOR_mySingleAlias_
#define _DEFINED_TYPEDEF_FOR_mySingleAlias_

typedef real32_T mySingleAlias;

#endif
```

### Related Examples

- “Control Data Type Names in Generated Code” on page 35-2

## Replace and Rename Data Types to Conform to Coding Standards

By default, the generated code uses data type aliases such as `real_T` and `int32_T`. The code uses these aliases to define global and local variables. If your coding standards require that you use other data type aliases, including aliases that your existing code defines, you can:

- Configure data type replacement for the entire model.
- Configure individual data items (such as signals, parameters, and states) to use specific data type aliases.

For information about controlling data types in a model, see “Control Data Types of Signals”.

### Inspect External C Code

Save this C code into a file named `my_types.h` in your current folder. This file represents a header file in your existing code that defines custom data type aliases by using `typedef` statements.

```
#include <stdbool.h>

typedef double my_dblPrecision;
typedef short my_int16;
typedef bool my_bool;
```

### Explore Example Model and Default Generated Code

- 1 Open the example model `ex_data_type_replacement`.
 

```
open_system(fullfile(docroot, 'toolbox', 'ecoder', 'examples', ...
'ex_data_type_replacement'))
```
- 2 On the **Modeling** tab, click **Model Data Editor**.
- 3 In the Model Data Editor, inspect the **Signals** tab.
- 4 Set the **Change view** drop-down list to **Code**. In the data table, the **Storage Class** column shows that named signal lines such as `temp` use the storage class `ExportedGlobal`. With this setting, the signal lines appear in the generated code as separate global variables.
- 5 Set the **Change view** drop-down list to **Design**.
- 6 Update the block diagram.

Simulink assigns a specific data type to each signal that uses an inherited data type setting such as `Inherit: Inherit via internal rule`.

- 7 In the data table, expand the width of the **Data Type** column. The column shows that the signals in the model use a mix of the data types `int16`, `double`, and `boolean`. You can also see these data types in the model.
- 8 Generate code from the model.
- 9 In the code generation report, inspect the shared utility file `rtwtypes.h`. The code uses `typedef` statements to rename the primitive C data types by using standard Simulink Coder aliases. For example, the code renames the primitive type `double` by using the alias `real_T`.

```
typedef double real_T;
```

- 10 Inspect the file `ex_data_type_replacement.c`. The code uses the default data type aliases to declare and define variables. For example, the code uses the data types `real_T`, `int16_T`, and `boolean_T` to define the global variables `flowIn`, `temp`, and `intlk`.

```
real_T flowIn; /* '<Root>/In3' */
int16_T temp; /* '<Root>/Add2' */
boolean_T intlk; /* '<S1>/Compare' */
```

The model step function defines local variables by using the same data type aliases.

```
real_T rtb_Add;
real_T rtb_FilterCoefficient;
```

## Reuse External Data Type Definitions

Configure the generated code to define variables by using the custom data types defined in `my_types.h` instead of the default type names.

- 1 At the command prompt, create a `Simulink.AliasType` object for each data type alias that your external code defines.

```
Simulink.importExternalCTypes('my_types.h');
```

In the base workspace, the `Simulink.importExternalCTypes` function creates the objects `my_dblPrecision`, `my_int16`, and `my_bool`.

For each object, the function sets the `DataScope` property to `'Imported'` and the `HeaderFile` property to `'my_types.h'`. With these settings, the code generator does not create a `typedef` statement for each object, but instead the generated code reuses the statements from `my_types.h` by including (`#include`) the file.

- 2 In the model, in the Configuration Parameters dialog box, on the **Code Generation > Data Type Replacement** pane, select **Replace data type names in the generated code**.
- 3 Specify the options in the **Replacement Name** column according to the table.

Simulink Name	Replacement Name
double	my_dblPrecision
int16	my_int16
boolean	my_bool

- 4 Generate code from the model.
- 5 In the code generation report, inspect the file `rtwtypes.h`. Now, the code uses an `#include` directive to import the contents of the external header file `my_types.h`, which contains the custom data type aliases.

```
#include "my_types.h" /* User defined replacement datatype for int16_T real_T boolean_T */
```

- 6 Inspect the file `ex_data_type_replacement.c`. The code uses the custom data type aliases `my_dblPrecision`, `my_int16`, and `my_bool` to define the global variables such as `flowIn`, `temp`, and `intlk`.

```
my_dblPrecision flowIn; /* '<Root>/In3' */
my_int16 temp; /* '<Root>/Add2' */
my_bool intlk; /* '<S1>/Compare' */
```

The model `step` function defines local variables by using the custom data type aliases.

```
my_dblPrecision rtb_Add;
my_dblPrecision rtb_FilterCoefficient;
```

## Create Meaningful Data Type Aliases for Individual Data Items

Suppose that your coding standards require that important data items use a data type whose name indicates the real-world significance. You can create more `Simulink.AliasType` objects to represent these custom data type aliases. Use the objects to set the data types of data items in the model.

- 1 In the Model Data Editor **Data Type** column, use the `Simulink.AliasType` objects to set the data types of these block outputs. You can select a signal line in the model, which highlights the corresponding row in the Model Data Editor, or search for the signals in the Model Data Editor by using the **Filter contents** box.

Block	Output Data Type
Flow Setpoint	flow_T
Add2 (which feeds the Compare block)	diffTemp_T

- 2 Use the Model Data Editor **Inports/Outports** tab to set the data type of the third Inport block to `flow_T`.
- 3 On the **Modeling** tab, under **Design**, click **Property Inspector**.
- 4 Select the block labeled Flow Controller. In the Property Inspector, click **Open** to open the block dialog box.
- 5 On the **Data Types** tab, set **Sum output** to `ctrl_T`. Click **OK**.

With these data type settings, some of the named signals, such as `temp` and `flowIn`, use data types that evoke real-world quantities, such as liquid flow rate and temperature.

- 6 At the command prompt, create `Simulink.AliasType` objects to represent these new custom data type aliases.

```
flow_T = Simulink.AliasType('double');
diffTemp_T = Simulink.AliasType('int16');
ctrl_T = Simulink.AliasType('double');
```

In the model, the signals `flowIn` and `flowSetPt` use the primitive data type `double`, so the data type alias `flow_T` maps to `double`.

- 7 Update the block diagram.

Due to data type inheritance, other signals also use the custom data type aliases. For example, the output data type of the Add block fed by the third Inport block is set to `Inherit: Inherit via internal rule`. The internal rule chooses the same data type that the block inputs use, `flow_T`.

- 8 Generate code from the model.
- 9 The file `ex_data_type_replacement_types.h` defines the new data types `flow_T`, `diffTemp_T`, and `ctrl_T` as aliases of `my_dblPrecision` and `my_int16`.

```
typedef my_dblPrecision flow_T;
typedef my_int16 diffTemp_T;
typedef my_dblPrecision ctrl_T;
```

- 10** In the file `ex_data_type_replacement.c`, the code defines global variables by using the new type names.

```

flow_T flowIn; /* '<Root>/In3' */
flow_T flowSetPt; /* '<Root>/Flow Setpoint' */
ctrl_T flowCtrl; /* '<Root>/Interlock' */
diffTemp_T temp; /* '<Root>/Add2' */

```

- 11** For blocks that do not use the new data types, the corresponding generated code continues to use the replacement types that you specified earlier. For example, in the file `ex_data_type_replacement.h`, the outputs of the blocks `In1` and `In2` appear as structure fields that use the replacement type `my_int16`.

```

/* External inputs (root inport signals with auto storage) */
typedef struct {
 my_int16 In1; /* '<Root>/In1' */
 my_int16 In2; /* '<Root>/In2' */
} ExtU_ex_data_type_replacement_T;

```

## Create Single Point of Definition for Primitive Types

The custom data type aliases `flow_T` and `ctrl_T` map to the primitive data type `double`. If you want to change this underlying data type from `double` to `single` (`float`), you must remember to modify the `BaseType` property of both `Simulink.AliasType` objects.

To more easily make this change, you can create a `Simulink.NumericType` object and configure both `Simulink.AliasType` objects to refer to it. Then, you need to modify only the `Simulink.NumericType` object. A `Simulink.NumericType` object enables you to share a data type without creating a data type alias.

- 1** At the command prompt, create a `Simulink.NumericType` object to represent the primitive data type `single`.

```

sharedType = Simulink.NumericType;
sharedType.DataTypeMode = 'Single';

```

- 2** Configure the `Simulink.AliasType` objects `flow_T` and `ctrl_T` to acquire an underlying data type from this new object.

```

flow_T.BaseType = 'sharedType';
ctrl_T.BaseType = 'sharedType';

```

- 3** On the **Debug** tab, select **Information Overlays > Base Data Types Information Overlays > Alias Data Types** and (see “Port Data Types”). Update the block diagram.

The data type indicators in the model show that the aliases `flow_T` and `ctrl_T` map to the primitive type `single`. To change this underlying primitive type, you can modify the `DataTypeMode` property of the `Simulink.NumericType` object, `sharedType`.

By default, the `Simulink.NumericType` object does not cause another `typedef` statement to appear in the generated code.

If you generate code from the model while the `Simulink.NumericType` object represents the data type `single`, the generated code maps `flow_T` and `ctrl_T` to the default Simulink Coder data type alias `real32_T`, which maps to the C data type `float`. You can replace `real32_T` in the same way that you replaced `real_T`, `int16_T`, and `boolean_T` (**Configuration Parameters > Code Generation > Data Type Replacement**).

## Permanently Store Data Type Objects

The `Simulink.NumericType` and `Simulink.AliasType` objects in the base workspace do not persist if you end your current MATLAB session. To permanently store these objects, consider migrating your model to a data dictionary. See “Migrate Models to Use Simulink Data Dictionary”.

## Create and Maintain Objects Corresponding to Multiple C typedef Statements

To create `Simulink.AliasType` objects for a large number of typedef statements in your external C code, consider using the `Simulink.importExternalCTypes` function.

## Exchange Structured and Enumerated Data Between Generated and External Code

This example shows how to generate code that exchanges data with external, existing code. Construct and configure a model to match data types with the external code and to avoid duplicating type definitions and memory allocation (definition of global variables). Then, compile the generated code together with the external code into a single application.

### Inspect External Code

Create the file `ex_cc_algorithm.c` in your current folder.

```
#include "ex_cc_algorithm.h"

inSigs_T inSigs;

float_32 my_alg(void)
{
 if (inSigs.err == TMP_HI) {
 return 27.5;
 }
 else if (inSigs.err == TMP_LO) {
 return inSigs.sig1 * calPrms.cal3;
 }
 else {
 return inSigs.sig2 * calPrms.cal3;
 }
}
```

The C code defines a global structure variable named `inSigs`. The code also defines a function, `my_alg`, that uses `inSigs` and another structure variable named `calPrms`.

Create the file `ex_cc_algorithm.h` in your current folder.

```
#ifndef ex_cc_algorithm_h
#define ex_cc_algorithm_h

typedef float float_32;

typedef enum {
 TMP_HI = 0,
 TMP_LO,
 NORM,
} err_T;

typedef struct inSigs_tag {
 err_T err;
 float_32 sig1;
 float_32 sig2;
} inSigs_T;

typedef struct calPrms_tag {
 float_32 cal1;
 float_32 cal2;
```

```

 float_32 cal3;
} calPrms_T;

extern calPrms_T calPrms;
extern inSigs_T inSigs;

float_32 my_alg(void);

#endif

```

The file defines `float_32` as an alias of the C data type `float`. The file also defines an enumerated data type, `err_T`, and two structure types, `inSigs_T` and `calPrms_T`.

The function `my_alg` is designed to calculate a return value by using the fields of `inSigs` and `calPrms`, which are global structure variables of the types `inSigs_T` and `calPrms_T`. The function requires another algorithm to supply the signal data that `inSigs` stores.

This code allocates memory for `inSigs`, but not for `calPrms`. Create a model whose generated code:

- Defines and initializes `calPrms`.
- Calculates values for the fields of `inSigs`.
- Reuses the type definitions (such as `err_T` and `float_32`) that the external code defines.

## Create Simulink Model

- 1 So that you can create enumerated and structured data in the Simulink model, first create Simulink representations of the data types that the external code defines. Store the Simulink types in a new data dictionary named `ex_cc_integ.sldd`.

```

Simulink.importExternalCTypes('ex_cc_algorithm.h',...
 'DataDictionary','ex_cc_integ.sldd');

```

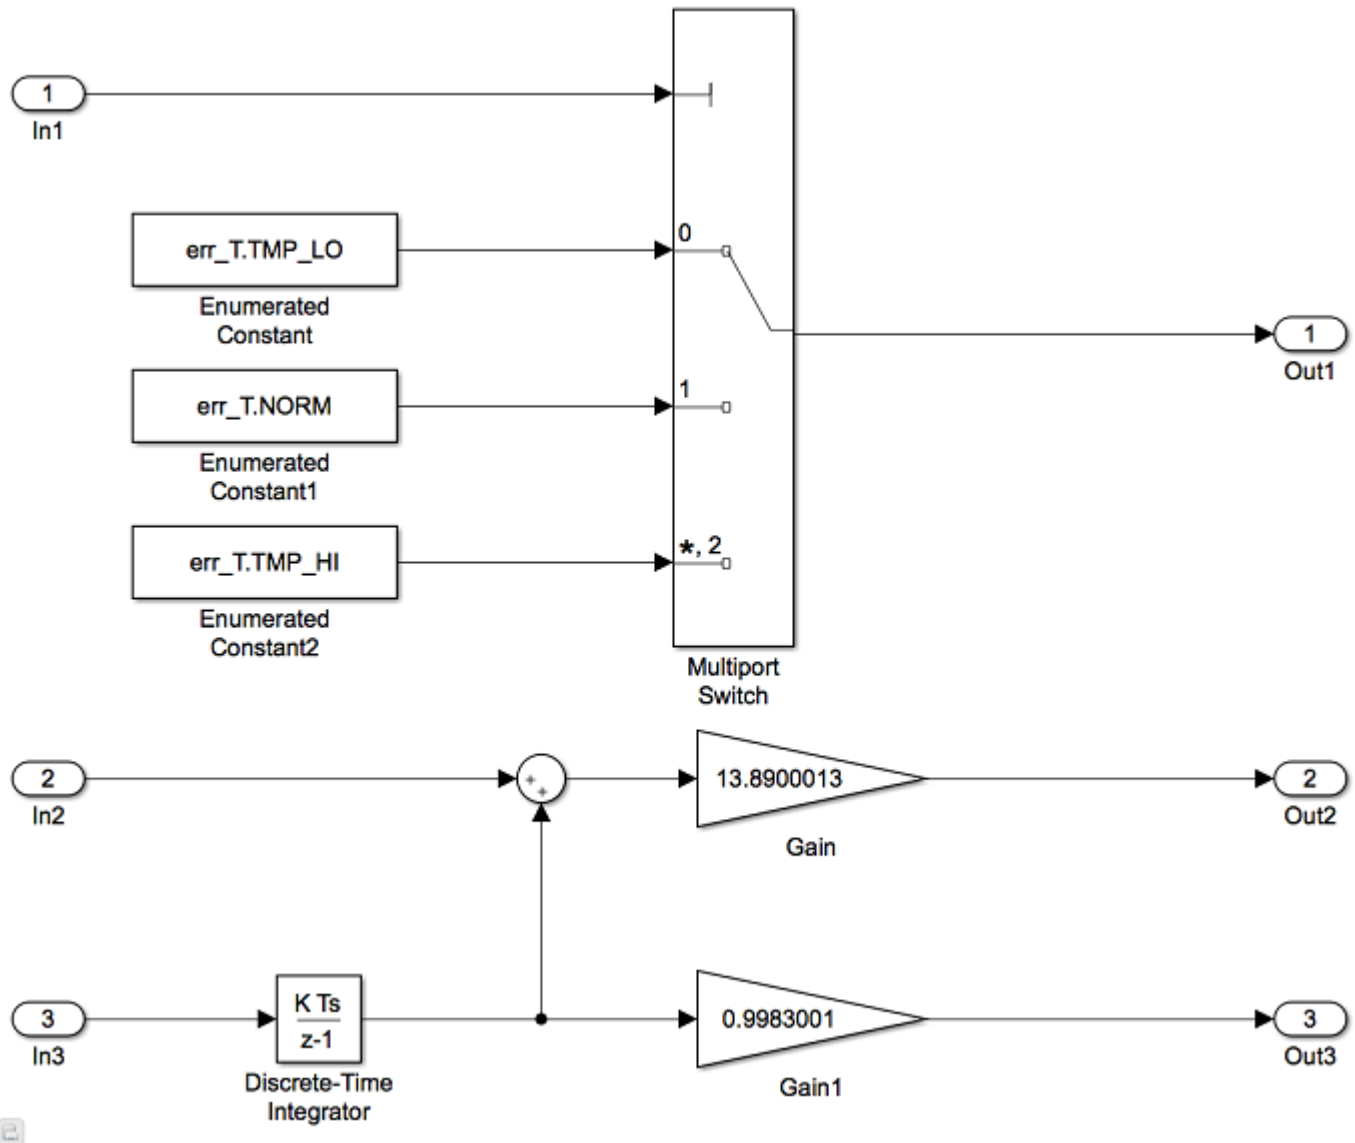

The data dictionary appears in your current folder.

- 2 To inspect the dictionary contents in the Model Explorer, in your current folder, double-click the file, `ex_cc_integ.sldd`.

The `Simulink.importExternalCTypes` function creates `Simulink.Bus`, `Simulink.AliasType`, and `Simulink.data.dictionary.EnumTypeDefinition` objects that correspond to the custom C data types from `ex_cc_algorithm.h`.

- 3 Create a new model and save it in your current folder as `ex_struct_enum_integ`.
- 4 Link the model to the data dictionary. On the **Modeling** tab, under **Design**, click **Data Dictionary**.
- 5 Add algorithmic blocks that calculate the fields of `inSigs`.

Now that you have the algorithm model, you must:

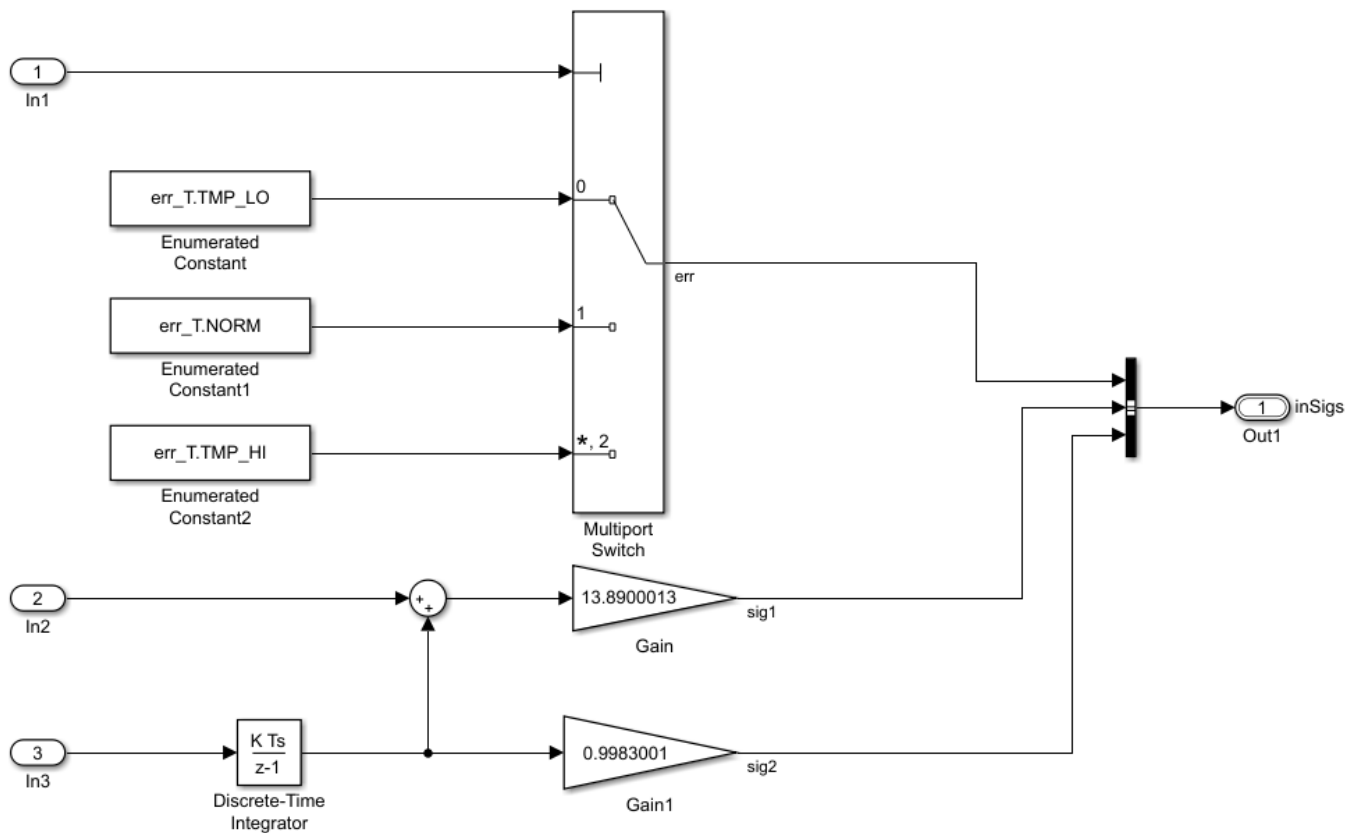

- Organize the output signals into a structure variable named `inSigs`.
- Create the structure variable `calPrms`.
- Include `ex_cc_algorithm.c` in the build process that compiles the code after code generation.

## Configure Generated Code to Write Output Data to Existing Structure Variable

- 1 Add a Bus Creator block near the existing Outputport blocks. The output of a Bus Creator block is a bus signal, which you can configure to appear in the generated code as a structure.
- 2 In the Bus Creator block, set these parameters:

- **Number of inputs** to 3
  - **Output data type** to Bus: inSigs\_T
  - **Output as nonvirtual bus** to selected
- 3 Delete the three existing Outport blocks (but not the signals that enter the blocks).
  - 4 Connect the three remaining signal lines to the inputs of the Bus Creator block.
  - 5 Add an Outport block after the Bus Creator block. Connect the output of the Bus Creator to the Outport.
  - 6 In the Outport block, set the **Data type** parameter to Bus: inSigs\_T.
  - 7 On the **Modeling** tab, click **Model Data Editor**.
  - 8 On the **Inports/Outports** tab, for the Inport blocks labeled In2 and In3, change **Data Type** from Inherit: auto to float\_32.
  - 9 Change the **Change View** drop-down list from Design to Code.
  - 10 For the Outport block, set **Signal Name** to inSigs.
  - 11 Set **Storage Class** to ImportFromFile.
  - 12 Set **Header File** to ex\_cc\_algorithm.h.
  - 13 Inspect the **Signals** tab.
  - 14 In the model, select the output signal of the Multiport Switch block.
  - 15 In the Model Data Editor, for the selected signal, set **Name** to err.
  - 16 Set the name of the output signal of the Gain block to sig1.
  - 17 Set the name of the output signal of the Gain1 block to sig2.

When you finish, the model stores output signal data (such as the signals err and sig1) in the fields of a structure variable named inSigs.

Because you set **Storage Class** to `ImportFromFile`, the generated code does not allocate memory for `inSigs`.

## Configure Generated Code to Define Parameter Data

Configure the generated code to define the global structure variable, `calPrms`, that the external code needs.

- 1 In the Model Explorer **Model Hierarchy** pane, under the dictionary node **ex\_cc\_integ**, select the **Design Data** node.
- 2 In the **Contents** pane, select the `Simulink.Bus` object named `calPrms_T`.
- 3 In the Dialog pane (the right pane), click **Launch Bus Editor**.
- 4 In the Bus Editor, select `calPrms_T`.
- 5 In the Bus Editor toolstrip, click **Simulink Parameter**.
- 6 In the MATLAB Editor, copy the generated MATLAB code and run the code at the command prompt. The code creates a `Simulink.Parameter` object in the base workspace.
- 7 In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
- 8 Use the Model Explorer to move the parameter object, `calPrms_T_Param`, from the base workspace to the Design Data section of the data dictionary.
- 9 With the data dictionary selected, in the **Contents** pane, rename the parameter object as `calPrms`.

- 10 In the Model Data Editor, select the **Parameters** tab.
- 11 Set the **Change view** drop-down list to **Design**.
- 12 For the Gain block, replace the value 13.8900013 with `calPrms.cal1`.
- 13 In the other Gain block, use `calPrms.cal2`.
- 14 While editing the value of the other Gain block, next to `calPrms.cal2`, click the action button  and select **calPrms > Open**.
- 15 In the `calPrms` property dialog box, next to the **Value** box, click the action button  and select **Open Variable Editor**.
- 16 Use the Variable Editor to set the field values in the parameter object.
  - For the fields `cal1` and `cal2`, use the numeric values that the Gain blocks in the model previously used.
  - For `cal3`, use a nonzero number such as 15.2299995.

When you finish, close the Variable Editor.

- 17 In the property dialog box, set **Storage class** to `ExportedGlobal`. Click **OK**.
- 18 Use the Model Explorer to save the changes that you made to the dictionary.

## Generate, Compile, and Inspect Code

- 1 Configure the model to include `ex_cc_algorithm.c` in the build process. Set **Configuration Parameters > Code Generation > Custom Code > Code information > Source files** to `ex_cc_algorithm.c`.
- 2 Generate code from the model.
- 3 Inspect the generated file `ex_struct_enum_integ.c`. The file defines and initializes `calPrms`.

```
/* Exported block parameters */
calPrms_T calPrms = {
 13.8900013F,
 0.998300076F,
 15.23F
};
/* Variable: calPrms
```

The generated algorithm in the model step function defines a local variable for buffering the value of the signal `err`.

```
err_T rtb_err;
```

The algorithm then calculates and stores data in the fields of `inSig`.

```
inSigs.err = rtb_err;
inSigs.sig1 = (rtU.In2 + rtDW.DiscreteTimeIntegrator_DSTATE) * calPrms.cal1;
inSigs.sig2 = (real32_T)(calPrms.cal2 * rtDW.DiscreteTimeIntegrator_DSTATE);
```

## Replace Data Type Names Throughout Model

To generate code that uses `float_32` instead of the default, `real32_T`, instead of manually specifying the data types of block output signals and bus elements, you can use data type replacement (**Configuration Parameters > Code Generation > Data Type Replacement**). For

more information, see “Replace and Rename Data Types to Conform to Coding Standards” on page 35-22.

## **See Also**

`Simulink.importExternalCTypes`

## **Related Examples**

- “Organize Data into Structures in Generated Code” on page 33-145

## Specify Boolean and Data Type Limit Identifiers

You can use command-line parameters to replace the default Boolean and data type limit identifiers. If you want to associate the data type limit identifiers with the data type names, consider replacing the default identifiers. You can also use command-line parameters to import a header file with the Boolean and data type limit identifier definitions.

### Data Type Limit Identifiers

You can control the data type limit identifiers in the generated code by using the command-line parameters in this table.

Data Type Limit	Default Identifier	Command-Line Parameter
64-bit integer maximum	MAX_int64_T	MaxIdInt64
16-bit integer maximum	MAX_int16_T	MaxIdInt16
32-bit integer maximum	MAX_int32_T	MaxIdInt32
8-bit integer maximum	MAX_int8_T	MaxIdInt8
64-bit unsigned integer maximum	MAX_uint64_T	MaxIdUInt64
16-bit unsigned integer maximum	MAX_uint16_T	MaxIdUInt16
32-bit unsigned integer maximum	MAX_uint32_T	MaxIdUInt32
8-bit unsigned integer maximum	MAX_uint8_T	MaxIdUInt8
64-bit integer minimum identifier	MIN_int64_T	MinIdInt64
16-bit integer minimum	MIN_int16_T	MinIdInt16
32-bit integer minimum	MIN_int32_T	MinIdInt32
8-bit integer minimum	MIN_int8_T	MinIdInt8

For example, to change the default identifiers for the 8-bit integer data limit minimum and maximum to `s4g_S4MIN` and `s4g_S4MAX`, respectively:

```
set_param(gcs, 'MinIdInt8', 's4g_S4MIN');
set_param(gcs, 'MaxIdInt8', 's4g_S4MAX');
```

If you do not import a header file, the generated file `rtwtypes.h` defines the 8-bit integer data minimum and maximum identifiers:

```
#define s4g_S4MAX ((int8_T)(127))
#define s4g_S4MIN ((int8_T)(-128))
```

If you do import a header file defining the data type limit identifiers, the header file is included in `rtwtypes.h`.

### Boolean Identifiers

You can control the Boolean identifiers in the generated code by using the command-line parameters in this table. When changing boolean identifiers, you must define `false` to be numerically equivalent to 0, and `true` to be numerically equivalent to 1.

Boolean	Default Identifier	Command-Line Parameter
True	true	BooleanTrueId
False	false	BooleanFalseId

For example, to change the default Boolean true and false identifiers:

```
set_param(gcs, 'BooleanTrueId', 'bTrue');
set_param(gcs, 'BooleanFalseId', 'bFalse')
```

If you do not import a header file, the generated file `rtwtypes.h` defines the Boolean identifiers:

```
#define bFalse (0U)
#define bTrue (1U)
```

If you do import a header file defining the Boolean identifiers, the header file is included in `rtwtypes.h`.

---

**Note** When changing boolean identifiers, you must define `false` to be numerically equivalent to 0, and `true` to be numerically equivalent to 1.

---

## Boolean and Data Type Limit Identifier Header Files

You can import a header file that defines Boolean and data type limit identifiers by using the configuration parameter **Type limit identifier replacement header file** or command-line parameter `TypeLimitIdReplacementHeaderFile`. The header file is included in `rtwtypes.h`. You must use the command-line parameters to specify the Boolean and data type limit identifiers that are included in the imported header file.

For example, if you have a header file `myfile.h` with data type limit definitions, use `TypeLimitIdReplacementHeaderFile` to include the definitions in the generated code:

```
set_param(gcs, 'TypeLimitIdReplacementHeaderFile', 'myfile.h');
```

The generated file `rtwtypes.h` includes `myfile.h`.

```
/* Import type limit identifier replacement definitions. */
#include "myfile.h"
```

## MPT Data Object Properties

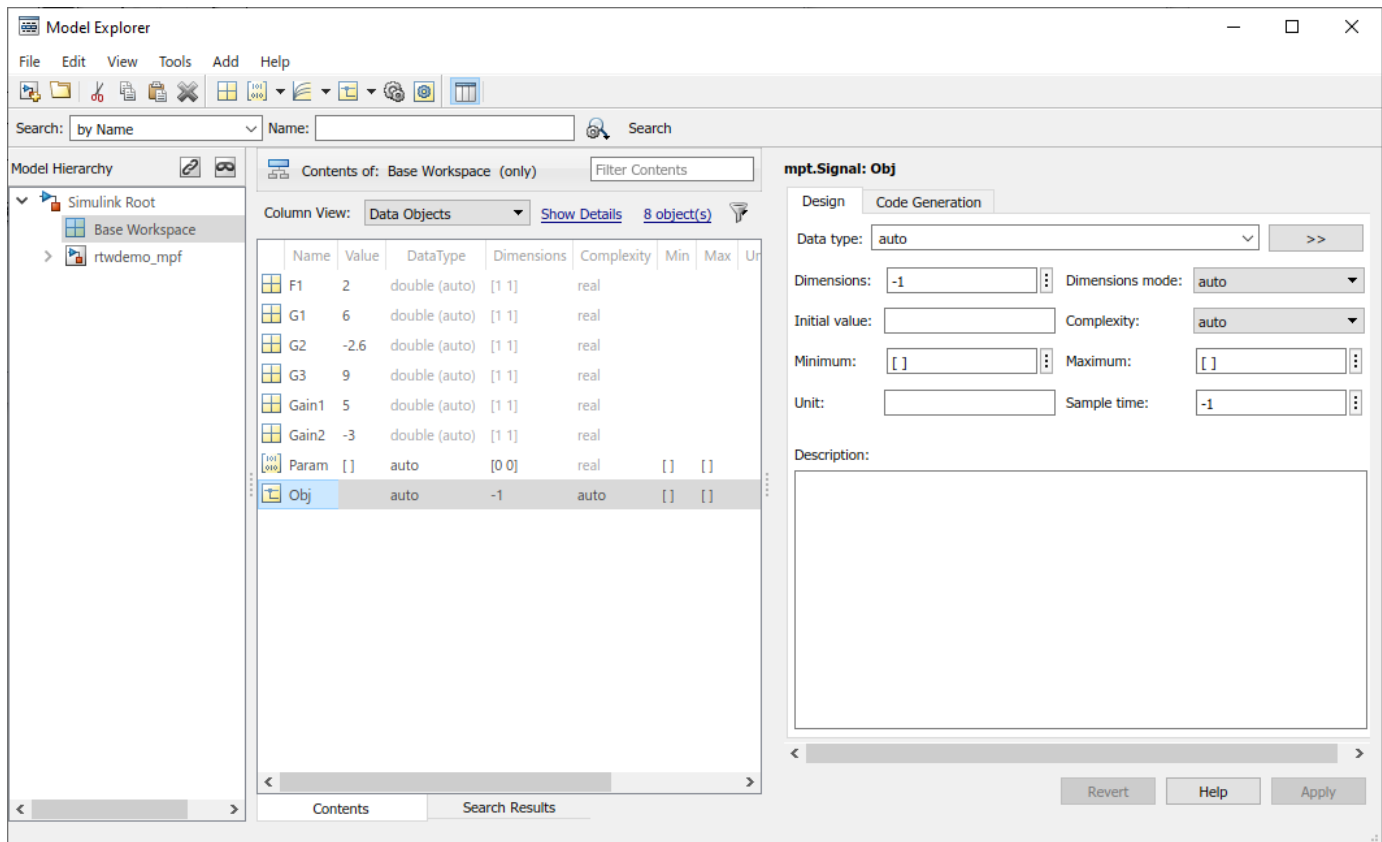

**Note** While `mpt.Signal` and `mpt.Parameter` objects continue to be supported for legacy applications, most of the advanced code generation capabilities that the objects provide are now also provided by `Simulink.Signal` and `Simulink.Parameter` objects.

The following table describes the properties and property values for `mpt.Parameter` and `mpt.Signal` data objects that appear in the Model Explorer.

**Note** You can create `mpt.Signal` and `mpt.Parameter` objects in the base MATLAB or model workspace. However, if you create a signal object in a model workspace, the object's storage class must be set to `Auto`.

The figure below shows an example of the Model Explorer. When you select an `mpt.Parameter` or `mpt.Signal` data object in the middle pane, its properties and property values display in the rightmost pane.

In the Properties column, the table lists the properties in the order in which they appear on the Model Explorer.

## Parameter and Signal Property Values

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Parameter	Value	*0	The data type and numeric value of the data object. For example, <code>int8(5)</code> . The numeric value is used as an initial parameter value in the generated code.
Both	Data type		Used to specify the data type for an <code>mpt.Signal</code> data object, but not for an <code>mpt.Parameter</code> data object. The data type for an <code>mpt.Parameter</code> data object is specified in the <b>Value</b> field above. See "About Data Types in Simulink".
Both	Unit	*null	Units of measurement of the signal or parameter. (Enter text in this field.)
Both	Dimensions	*-1	The dimension of the signal or parameter. For a parameter, the dimension is derived from its value.
Both	Complexity	*auto real complex	Complexity specifies whether the signal or parameter is a real or complex number. Select <code>auto</code> for the code generator to decide. For a parameter, the complexity is derived from its value.
Signal	Sample time	*-1	Model or block execution rate.
Signal	Sample mode	*auto	Determines how the signal propagates through the model. Select <code>auto</code> for the code generator to decide.
		Sample based	The signal propagates through the model one sample at a time.
		Frame based	The signal propagates through the model in batches of samples.
Both	Minimum	*0.0	The minimum value to which the parameter or signal is expected to be bound.
		Number within the minimum range of the parameter or signal. (Based on the data type and resolution of the parameter or signal.)	
Both	Maximum	*0.0	Maximum value to which the parameter or signal is expected to be bound. (Enter information using a dialog box.)
	Code generation options		

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
	Storage class		Note that an <code>auto</code> selection for a storage class tells the build process to decide how to declare and store the selected parameter or signal.
Both	Global (Custom)	Global is the default storage class for mpt data objects.	Specifies that a code generator not place a qualifier in the data object's declaration.
Both	Memory section	*Default	<b>Memory section</b> allows you to specify storage directives for the data object. <b>Default</b> specifies that the code generator not place a type qualifier and <code>pragma</code> statement with the data object's declaration.
Parameter		MemConst	Places the <code>const</code> type qualifier in the declaration.
Both		MemVolatile	Places the <code>volatile</code> type qualifier in the declaration.
Parameter		MemConstVolatile	Places the <code>const volatile</code> type qualifier in the declaration.
Both	Header file		Name of the file used to import or export the data object. This file contains the declaration ( <code>extern</code> ) to the data object.  Also, you can specify this header filename between the double-quotation or angle-bracket delimiter. You can specify the delimiter with or without the <code>.h</code> extension. For example, specify <code>"object.h"</code> or <code>"object"</code> . For the selected data object, this overrides the general delimiter selection in the <b>#include file delimiter</b> field on the Configuration Parameters dialog box.
Both	Owner	*Blank	The name of the module that owns this signal or parameter. This is used to help determine the ownership of a definition. For details, see "Control Placement of Global Data Definitions and Declarations in Generated Files" on page 34-2.
Both	Definition file	*Blank	Name of the file that defines the data object.
		Valid character vector	

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Both	Persistence level		The number you specify is relative to <b>Signal display level</b> or <b>Parameter tune level</b> on the <b>Code Placement</b> pane of the Configuration Parameters dialog box. For a signal, allows you to specify whether or not the code generator declares the data object as global data. For a parameter, allows you to specify whether or not the code generator declares the data object as tunable global data. See <b>Signal display level</b> and <b>Parameter tune level</b> in "Model Configuration Parameters: Code Generation Code Placement".
Both	Bitfield (Custom)		Embeds Boolean data in a named bit field.
	Struct name		Name of the <code>struct</code> into which the object's data will be packed.
Parameter	Const (Custom)		Places the <code>const</code> type qualifier in the declaration.
Parameter	Header file		See above.
Parameter	Owner		See above.
Parameter	Definition file		See above.
Parameter	Persistence level		See above.
Both	Volatile (Custom)		Places the <code>volatile</code> type qualifier in the declaration.
Both	Header file		See above.
Both	Owner		See above.
Both	Definition file		See above.
Both	Persistence level		See above.
Parameter	ConstVolatile (Custom)		Places the <code>const volatile</code> type qualifier in declaration.
Parameter	Header file		See above.
Parameter	Owner		See above.
Parameter	Definition file		See above.
Parameter	Persistence level		See above.
Parameter	Define (Custom)		Represents parameters with a <code>#define</code> macro.
Parameter	Header file		See above.
Both	ExportToFile (Custom)		Generates global variable definition, and generates a user-specified header ( <code>.h</code> ) file that contains the declaration ( <code>extern</code> ) to that variable.
Both	Memory section		See above.

<b>Class: Parameter, Signal, or Both</b>	<b>Property</b>	<b>Available Property Values (* Indicates Default)</b>	<b>Description</b>
Both	Header file		See above.
Both	Definition file		See above.
Both	ImportFromFile (Custom)		Includes predefined header files containing global variable declarations, and places the <code>#include</code> in a corresponding file. Assumes external code defines (allocates memory) for the global variable.
Both	Data access	*Direct	Allows you to specify whether the identifier that corresponds to the selected data object stores data of a data type ( <code>Direct</code> ) or stores the address of the data (a pointer).
Both		Pointer	If you select <code>Pointer</code> , the code generator places <code>*</code> before the identifier in the generated code.
	Header file		See above.
Both	Struct (Custom)		Embeds data in a named <code>struct</code> to encapsulate sets of data.
Both	Struct name		See above.
Signal	GetSet (Custom)		Reads (gets) and writes (sets) data using functions.
Signal	Header file		See above.
Signal	Get function		Specify the Get function.
Signal	Set function		Specify the Set function.
Both	Alias	*null	As explained in detail in “Apply Custom Naming Conventions to Identifiers” on page 52-11, for a Simulink or <code>mpt</code> data object (identifier), specifying a name in the <b>Identifier</b> field overrides the global naming rule selection you make on the Configuration Parameters dialog box.
		Valid ANSI <sup>a</sup> C/C++ variable name	
Both	Description	*null	Text description of the parameter or signal. Appears as a comment beside the signal or parameter's identifier in the generated code.
		Character vector	
Signal	Reusable		Allows the code generator to reuse a pair of root I/O signals when you specify the same name and the same storage class for both. The storage class is either <code>Reusable</code> or derived from <code>Reusable</code> .

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Signal	Data Scope	*Auto	You can specify the scope of symbols code generation generates for a data object of this class by selecting a value for <b>DataScope</b> . When you take the default of Auto, code generation determines the symbol scope internally. If possible, symbols have File scope. Otherwise, they have Exported scope.
		File	Code generation defines the scope of each symbol as the file that defines it. File scope requires each symbol to be used in a single file. If the same symbol is referenced in multiple files, code generation reports an error.
		Exported	Code generation exports symbols to external code in the header file specified by the <b>HeaderFile</b> field. If a <b>HeaderFile</b> is not specified, symbols are exported to external code in <i>model.h</i> .
		Imported	Code generation imports symbols from external code in the header file specified by the <b>HeaderFile</b> field. If you do not specify a header file, code generation generates an <code>extern</code> directive in <i>model_private.h</i> .
Signal	Header file		See above.
Signal	Owner		See above.
Signal	Definition file		See above.

a ANSI is a registered trademark of the American National Standards Institute, Inc.

**mpt Package Storage Classes**

<b>CSC Name</b>	<b>Purpose</b>	<b>Signals?</b>	<b>Parameters?</b>
BitField	Generate a <code>struct</code> declaration that embeds Boolean data in named bit fields.	Y	Y
CompilerFlag	Supports preprocessor conditionals defined via compiler flag. See “Generate Preprocessor Conditionals for Variant Systems” on page 26-32.	N	Y
Const	Generate a constant declaration with the <code>const</code> type qualifier.	N	Y
ConstVolatile	Generate declaration of volatile constant with the <code>const volatile</code> type qualifier.	N	Y
Define	Generate <code>#define</code> directive.	Y	Y
ExportToFile	Generate header ( <code>.h</code> ) file, with user-specified name, containing global variable declarations.	Y	Y
FileScope	Generate a static qualifier suffix for a variable declaration so that the scope of the variable is limited to the current file.	Y	Y
GetSet	Supports specialized function calls to read and write the memory associated with a Data Store Memory block. See “Access Data Through Functions with Storage Class GetSet” on page 37-25.	Y	Y
Global	The default storage class for the <code>mpt</code> package. Generate the declaration and definition of a data object in specified files, and use the specified memory section.	Y	Y
ImportedDefine	Supports preprocessor conditionals defined via legacy header file. See “Generate Preprocessor Conditionals for Variant Systems” on page 26-32.	N	Y
ImportFromFile	Generate directives to include predefined header files containing global variable declarations.	Y	Y
Reusable	Allows the code generator to reuse a pair of root I/O signals when you specify the same name and the same storage class for both. The storage class is either <code>Reusable</code> or derived from <code>Reusable</code> .	Y	N

<b>CSC Name</b>	<b>Purpose</b>	<b>Signals?</b>	<b>Parameters?</b>
Struct	Generate a <code>struct</code> declaration encapsulating parameter or signal object data.	Y	Y
StructConst	Generate a <code>struct</code> declaration, with a <code>const</code> type qualifier, encapsulating parameter object data.	N	Y
StructVolatile	Generate a <code>struct</code> declaration, with a <code>volatile</code> type qualifier, encapsulating parameter or signal object data.	Y	Y
Volatile	Use <code>volatile</code> type qualifier in declaration.	Y	Y

### Examples of Property Value Changes on Generated Code

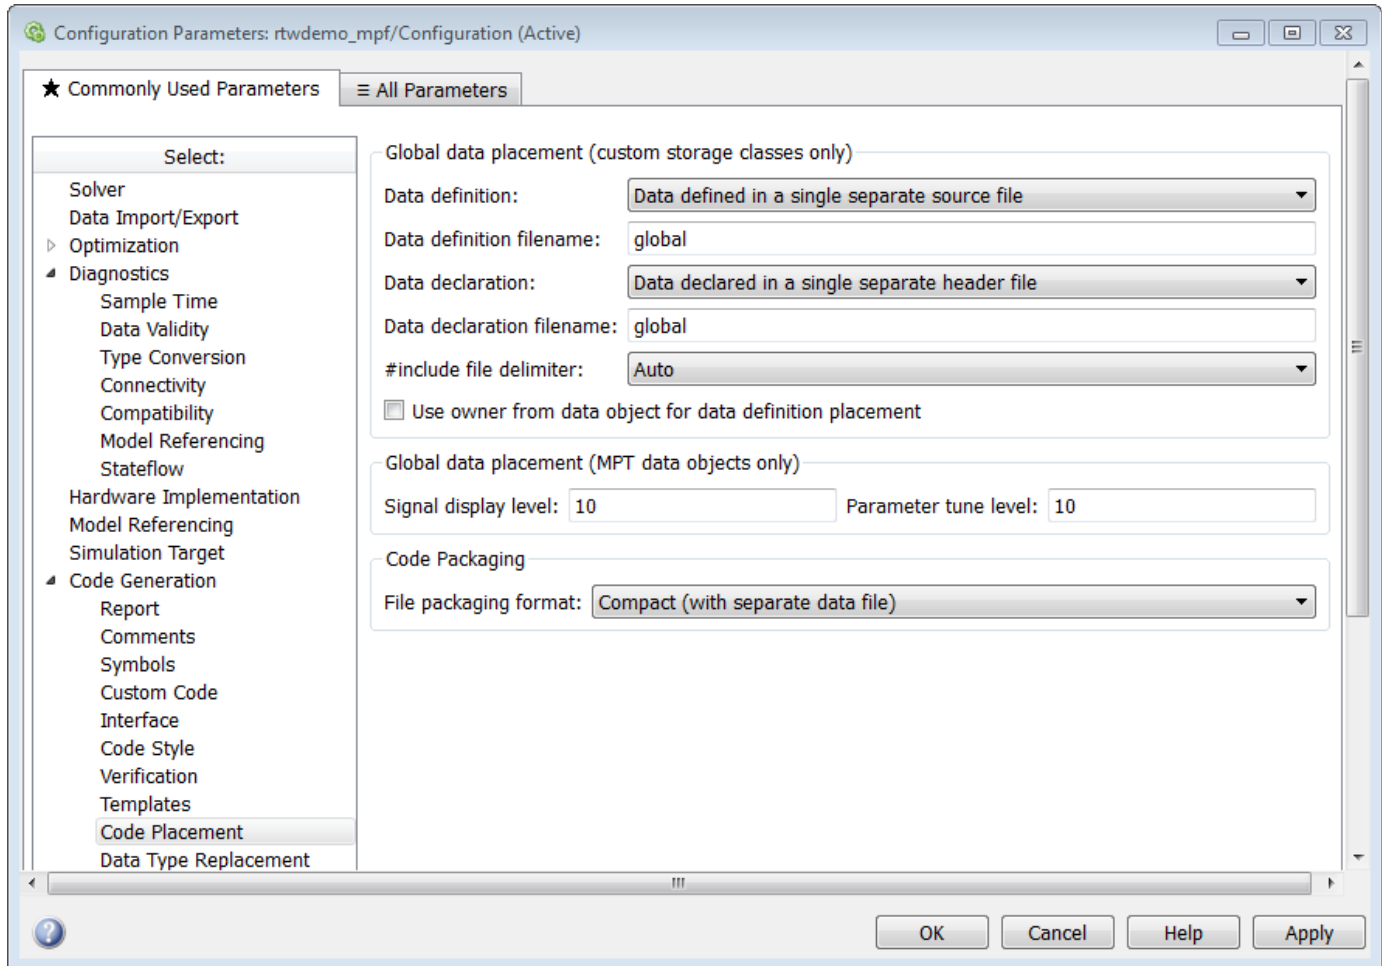

What I noticed when inspecting the .c/.cpp file	Change I made to property value settings	What I noticed after regenerating and reinspecting the file
<p>Example 1: Parameter data objects can be declared or defined as constants. I know that the data object GAIN is a parameter. I want this to be declared or defined in the .c file as a variable. But I notice that GAIN is declared as a constant by the statement <code>const real_T GAIN = 5.0;</code>. Also, this statement is in the constant section of the file.</p>	<p>In the Model Explorer, I clicked the data object GAIN. I noticed that the property value for its <b>Memory section</b> property is set at MemConst. I changed this to Default.</p>	<p>I notice two differences. One is that now GAIN is declared as a variable with the statement <code>real_T GAIN = 5.0;</code>. The second difference is that the declaration now is located in the MemConst memory section in the .c or .cpp file.</p>
<p>Example 2: I notice again the declaration of GAIN in the .c file mentioned in Example 1. It appears as <code>real_T GAIN = 5.0;</code>. But I have changed my mind. I want data object GAIN to be <code>#define</code>.</p>	<p>I changed the <b>Storage class</b> selection to Define.</p>	<p>GAIN is not declared in the .c file as a MemConst parameter. Rather, it is defined as a <code>#define</code> macro by the code <code>#define GAIN 5.0</code>, and this is located near the top of the .c file with the other preprocessor directives.</p>
<p>Example 3: I changed my mind again after doing Example 2. I do want GAIN defined using the <code>#define</code> preprocessor directive. But I do not want to include the <code>#define</code> in this file. I know it exists in another file and I want to reference that file.</p>	<p>On the Model Explorer, I notice that the property value for the <b>Header file</b> property is blank. I changed this to <code>filename.h</code>. (I chose the ANSI C/C++ + double quote mechanism for the <code>#include</code>, but could have chosen the angle bracket mechanism.) Also, I must make the user-defined <code>filename.h</code> available to the compiler, placing it either in the system path or local directory.</p>	<p><code>#define GAIN 5.0</code> is not present in this .c file. Instead, the <code>#include filename.h</code> code appears as a preprocessor directive at the top of the file.</p>
<p>Example 4: I have one more change I want to make. Let us say that we have declared the data object <code>data_in</code>, and that its declaration statement in the .c file reads <code>real_T data_in = 0.0;</code>. I want to replace this statement with an alias in the .c file.</p>	<p>In the Model Explorer, I selected the data object <code>data_in</code>. I noticed that the <b>Identifier</b> field is blank. I changed this to <code>data_in_alias</code>, which I know is a valid ANSI C/C++ variable name.</p>	<p>The identifier <code>data_in_alias</code> now appears in the .c file everywhere <code>data_in</code> appeared.</p>

### Specify Persistence Level for Signals and Parameters

With this procedure, you can control the persistence level of signal and parameter objects associated with a model. Persistence level allows you to make intermediate variables or parameters global during initial development. At the later stages of development, you can use this procedure to remove

these signals and parameters for efficiency. Use the **Persistence Level** property of `mpt.Signal` and `mpt.Parameter` data objects. For descriptions of the properties on the Model Explorer, see “MPT Data Object Properties” on page 36-2.

Notice also the **Signal display level** and **Parameter tune level** fields on the **Code Placement** pane of the Configuration Parameters dialog box, as illustrated in the next figure.

The **Signal display level** field allows you to specify whether or not the code generator defines a signal data object as global data in the generated code. The number you specify in this field is relative to the number you specify in the **Persistence level** field. The **Signal display level** number is for `mpt` (module packaging tool) signal data objects in the model. The **Persistence level** number is for a *particular* `mpt` signal data object. If the data object's **Persistence level** is equal to or less than the **Signal display level**, the signal appears in the generated code as global data with the custom attributes that you specified. For example, this would occur if **Persistence level** is 2 and **Signal display level** is 5.

Otherwise, the code generator automatically determines how the particular signal data object appears in the generated code. Depending on the settings on the **Optimization** pane of the Configuration Parameters dialog box, the signal data object could appear in the code as local data without the custom attributes you specified for that data object. Or, based on expression folding, the code generator could remove the data object so that it does not appear in the code.

The **Parameter tune level** field allows you to specify whether or not the code generator declares a parameter data object as tunable global data in the generated code.

The number you specify in this field is relative to the number you specify in the **Persistence level** field. The **Parameter tune level** number is for `mpt` parameter data objects in the model. The **Persistence level** number is for a *particular* `mpt` parameter data object. If the data object's **Persistence level** is equal to or less than the **Parameter tune level**, the parameter appears tunable in the generated code with the custom attributes that you specified. For example, this would occur if **Persistence level** is 2 and **Parameter tune level** is 5.

Otherwise, the parameter is inlined in the generated code, and the code generation settings determine its exact form.

Note that, in the initial stages of development, you might be more concerned about debugging than code size. Or, you might want one or more particular data objects to appear in the code so that you can analyze intermediate calculations of an equation. In this case, you might want to specify the **Parameter tune level (Signal display level for signals)** to be higher than **Persistence level** for some `mpt` parameter (or signal) data objects. This results in larger code size, because the code generator defines the parameter (or signal) data objects as global data, which have the custom properties you specified. As you approach production code generation, however, you might have more concern about reducing the size of the code and less need for debugging or intermediate analyses. In this stage of the tradeoff, you could make the **Parameter tune level (Signal display level for signals)** greater than **Persistence level** for one or more data objects, generate code and observe the results. Repeat until satisfied.

- 1 With the model open, in the Configuration Parameters dialog box, select **Code Generation > Code Placement**.
- 2 Type the desired number in the **Signal display level** or **Parameter tune level** field, and click **Apply**.
- 3 In the Model Explorer, type the desired number in the **Persistence** field for the selected signal or parameter, and click **Apply**.
- 4 Save the model and generate code.

## Reuse Parameter Data from External Code in the Generated Code

This example shows how to generate code that imports a parameter value from your external code.

### Create External Code Files

Suppose your external code defines a vector parameter `myGains` with three elements. Save the definition in your current folder in a file `ex_vector_import_src.c`.

```
#include "ex_vector_import_decs.h"

my_int8 myGains[3] = {
 2,
 4,
 6
};
```

Save the declaration in your current folder in a file called `ex_vector_import_decs.h`.

```
#include "ex_vector_import_cust_types.h"

extern my_int8 myGains[3];
```

Save the data type definition `my_int8` in your current folder in a file called `ex_vector_import_cust_types.h`.

```
typedef signed char my_int8;
```

### Import Parameter Value for Simulation

In your current folder, right-click the file `ex_vector_import_src.c` and select **Import Data**.

In the Import dialog box, set **Output Type** to **Numeric Matrix**.

Set the name of the generated MATLAB® variable to `tempVar`.

Select only the parameter values (2, 4, and 6) to import.

Import the data by clicking the green check mark. The MATLAB variable `tempVar` appears in the base workspace.

Alternatively, use the command prompt to manually create `tempVar`.

```
tempVar = [2;4;6];
```

At the command prompt, create a `Simulink.Parameter` object that represents `myGains`.

```
myGains = Simulink.Parameter(tempVar);
```

### Create and Configure Model

Create the model `ex_vector_import`.

```
open_system('ex_vector_import')
```

Copyright 2021 The MathWorks, Inc.

Open the **Embedded Coder** app.

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

Use the **Value** column to set the value of the **Gain** parameter in the Gain block to `myGains`.

Click the **Show/refresh additional information** button. The data table now contains a row that represents the parameter object, `myGains`.

Use the **Data Type** column to set the data type of `myGains` to `my_int8`.

For the other row (which represents the **Gain** parameter of the Gain block), set **Data Type** to **Inherit: Inherit from 'Gain'**. With this setting, the **Gain** parameter inherits the data type `my_int8` from `myGains`.

Set the **Change view** drop-down list to **Code**.

Set these properties for `myGains`:

- **Storage Class** to `ImportFromFile`
- **Header File** to `ex_vector_import_decs.h`

Alternatively, use these commands at the command prompt to configure the object and the block:

```
set_param('ex_vector_import/Gain','Gain','myGains',...
 'ParamDataTypeStr','Inherit: Inherit from ''Gain''')
myGains.DataType = 'my_int8';
myGains.CoderInfo.StorageClass = 'Custom';
myGains.CoderInfo.CustomStorageClass = 'ImportFromFile';
myGains.CoderInfo.CustomAttributes.HeaderFile = 'ex_vector_import_decs.h';
```

At the command prompt, create a `Simulink.AliasType` object to represent your custom data type `my_int8`. Set the `DataScope` and `HeaderFile` properties to import the type definition from your external code.

```
my_int8 = Simulink.AliasType('int8');
my_int8.DataScope = 'Imported';
my_int8.HeaderFile = 'ex_vector_import_cust_types.h';
```

Set model configuration parameter **Source files** to `ex_vector_import_src.c`.

```
set_param('ex_vector_import', 'CustomSource', 'ex_vector_import_src.c')
```

### Generate and Inspect Code

Generate code.

```
slbuild('ex_vector_import')
```

```
Starting build procedure for: ex_vector_import
Successful completion of build procedure for: ex_vector_import
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
ex_vector_import	Code generated and compiled	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 21.013s

The generated file `ex_vector_import.h` includes the external header files `ex_vector_import_decs.h` and `ex_vector_import_cust_types.h`, which contain the parameter variable declaration (`myGains`) and custom type definition (`my_int8`).

```
file = fullfile('ex_vector_import_ert_rtw', 'ex_vector_import.h');
rtwdemodtype(file, '#include "ex_vector_import_cust_types.h"', ...
 '#include "ex_vector_import_cust_types.h"', 1, 1)
rtwdemodtype(file, '/* Includes for objects with custom storage classes */', ...
 '#include "ex_vector_import_decs.h"', 1, 1)
```

```
/* Includes for objects with custom storage classes */
#include "ex_vector_import_decs.h"
```

The generated code algorithm in the model step function in the generated file `ex_vector_import.c` uses `myGains` for calculations.

```
file = fullfile('ex_vector_import_ert_rtw', 'ex_vector_import.c');
rtwdemodtype(file, '/* Model step function */', '/* Model initialize function */', 1, 0)
```

```
/* Model step function */
void ex_vector_import_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 */
}
```

```
* Inport: '<Root>/In1'
*/
rtY.Out1[0] = (real_T)myGains[0] * rtU.In1;
rtY.Out1[1] = (real_T)myGains[1] * rtU.In1;
rtY.Out1[2] = (real_T)myGains[2] * rtU.In1;
}
```

The generated code does not define (allocate memory for) or initialize the global variable `myGains` because the data scope of the corresponding parameter object is imported.

When you simulate the model in Simulink®, the model uses the value stored in the `Value` property of the parameter object. However, if you use external mode simulation, the external executable begins the simulation by using the value from your code. See “Considerations for Other Modeling Goals” on page 55-67.

## Import Parameter Data with Conditionally Compiled Dimension Length

Suppose your external code conditionally allocates memory for and initializes lookup table and breakpoint set data based on a dimension length that you specify as a `#define` macro. This example shows how to generate code that imports this external global data.

### Create External Code Files

Save the definition of the breakpoint set data `T1Break` and lookup table data `T1Data` in your current folder in a file called `ex_vec_symdim_src.c`. These global variables have either 9 or 11 elements depending on the value of the macro `bpLen`.

```
#include "ex_vec_symdim_decs.h"

#if bpLen == 11
double T1Break[bpLen] = {
 -5.0,
 -4.0,
 -3.0,
 -2.0,
 -1.0,

#endif
```

Save the declarations of the variables and the definition of the macro in your current folder in file `ex_vec_syndim_decs.h`.

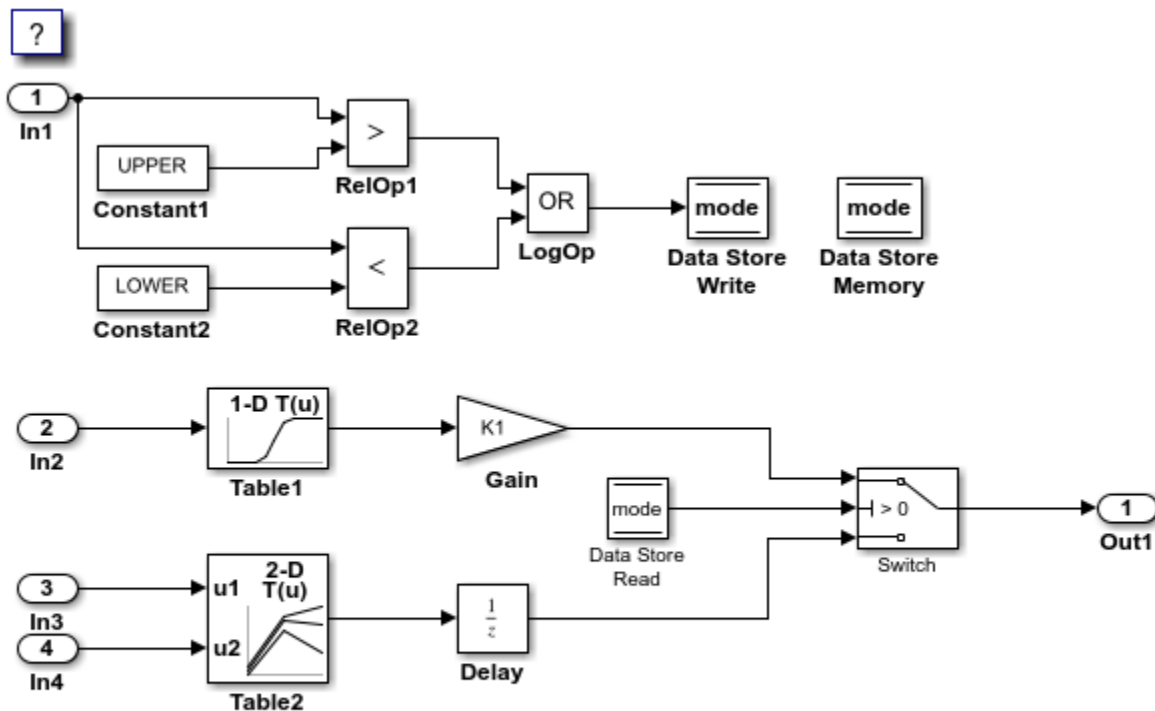

```
#define bpLen 11

extern double T1Break[bpLen];
extern double T1Data[bpLen];
```

### Explore and Configure Example Model

Open the example model `rtwdemo_configinterface`.

```
open_system('rtwdemo_configinterface')
set_param('rtwdemo_configinterface/Table1','DataSpecification','Table and breakpoints');
```

Copyright 1994-2020 The MathWorks, Inc.

Open the Table1 block dialog box. The block refers to variables, T1Data and T1Break, in the model workspace. These variables store the lookup table and breakpoint set data with 11 elements.

At the command prompt, convert the variables to Simulink.Parameter objects.

```
mws = get_param('rtwdemo_configinterface','modelworkspace');
T1Data = mws.getVariable('T1Data');
T1Break = mws.getVariable('T1Break');
T1Data = Simulink.Parameter(T1Data);
T1Break = Simulink.Parameter(T1Break);
```

At the command prompt, create a Simulink.Parameter object to represent the custom macro bpLen.

```
bpLen = Simulink.Parameter(11);
bpLen.Min = 9;
bpLen.Max = 11;
bpLen.DataType = 'int32';
bpLen.CoderInfo.StorageClass = 'Custom';
bpLen.CoderInfo.CustomStorageClass = 'ImportedDefine';
bpLen.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_syndim_decs.h';
```

Use bpLen to set the dimensions of the lookup table and breakpoint set data. Configure the model to enable symbolic dimensions by selecting the configuration parameter **Allow symbolic dimension specification**.

```
T1Data.Dimensions = '[1 bpLen]';
T1Break.Dimensions = '[1 bpLen]';
set_param('rtwdemo_configinterface', 'AllowSymbolicDim', 'on');
```

Set **Configuration Parameters > Code Generation > Custom Code > Code information > Source files** to `ex_vec_syndim_src.c`.

```
set_param('rtwdemo_configinterface', 'CustomSource', 'ex_vec_syndim_src.c')
```

Configure the objects to import the data definitions from your external code.

```
mws.assignin('T1Data', T1Data);
mws.assignin('T1Break', T1Break);
cm = coder.mapping.utils.create('rtwdemo_configinterface');
setDataDefault(cm, 'ModelParameters', 'StorageClass', 'Default');
setModelParameter(cm, 'Table1', 'StorageClass', 'Model default');
setModelParameter(cm, 'Table2', 'StorageClass', 'Model default');
setModelParameter(cm, 'T1Data', 'StorageClass', 'ImportFromFile', 'HeaderFile', 'ex_vec_syndim_decs.h');
setModelParameter(cm, 'T1Break', 'StorageClass', 'ImportFromFile', 'HeaderFile', 'ex_vec_syndim_decs.h');
```

### Generate and Inspect Code

Generate code from the model.

The generated code algorithm is in the model `step` function in the generated file `rtwdemo_configinterface.c`. The algorithm passes `T1Break`, `T1Data`, and `bpLen` as argument values to the function that performs the table lookup. In this case, `bpLen` controls the upper bound of the binary search that the function uses.

For more information about symbolic dimensions, see “Implement Dimension Variants for Array Sizes in Generated Code” on page 26-2.

- “Reuse Parameter Data from External Code in the Generated Code” on page 37-2

## Access Structured Data Through a Pointer That External Code Defines

This example shows how to generate code that uses global data that some handwritten code defines. In the handwritten code, a pointer variable points to one of three structure variables that contain parameter data. A handwritten function switches the pointer between the structures. The generated code accesses the parameter data by dereferencing the pointer variable.

### Explore External Code

Open the example source file `rtwdemo_importstruct_user.c`. The code defines a default data structure variable `ReferenceStruct` as constant (`const`) data and statically initializes each field. This structure represents the reference data set.

```
/* Constant default data structure (reference data set) */
const DataStruct_type ReferenceStruct =
{
 11, /* OFFSET */
 2 /* GAIN */
};
```

The code defines two other structure variables, `WorkingStruct1` and `WorkingStruct2`, as volatile (`volatile`) data.

```
/* Volatile data structures (working data sets) */
volatile DataStruct_type WorkingStruct1;
volatile DataStruct_type WorkingStruct2;
```

The code defines a function that can initialize:

- An inactive working structure from the active working structure.
- Both working structures from the reference structure.

```
/* Function to initialize inactive working structures from active structure */
void InitInactiveWorkingStructs(void)
{
 if (StructPointer == &WorkingStruct1) {
 /* Copy values from WorkingStruct1 to WorkingStruct2 */
 memcpy((void*)&WorkingStruct2, (void*)&WorkingStruct1, sizeof(ReferenceStruct));
 } else if (StructPointer == &WorkingStruct2) {
 /* Copy values from WorkingStruct2 to WorkingStruct1 */
 memcpy((void*)&WorkingStruct1, (void*)&WorkingStruct2, sizeof(ReferenceStruct));
 } else {
 /* Initialize both working structures from ReferenceStruct */
 memcpy((void*)&WorkingStruct1, &ReferenceStruct, sizeof(ReferenceStruct));
 memcpy((void*)&WorkingStruct2, &ReferenceStruct, sizeof(ReferenceStruct));
 }
}
```

The code defines `StructPointer`, which is a `const volatile` pointer to a structure. The code initializes the pointer to the address of `ReferenceStruct`.

```
/* Define structure pointer. Point to reference structure by default */
const volatile DataStruct_type *StructPointer = &ReferenceStruct;
```

Finally, the code defines a function that can dynamically set `StructPointer` to point to either `ReferenceStruct`, `WorkingStruct1`, or `WorkingStruct2`.

```
/* Function to switch between structures */
void SwitchStructPointer(Dataset_T Dataset)
{
 switch (Dataset) {
 case Working1:
 StructPointer = &WorkingStruct1;
 break;
 case Working2:
 StructPointer = &WorkingStruct2;
 break;
 default:
 StructPointer = &ReferenceStruct;
 }
}
```

The example header file `rtwdemo_importstruct_user.h` defines the enumeration `Dataset_T` and the structure type `Datastruct_type`. The file includes (`#include`) the built-in Simulink® Coder™ header file `rtwtypes.h`, which defines (`typedef`) Simulink Coder data types such as `int16_T`.

```
#include "rtwtypes.h"

typedef enum {
 Reference = 0,
 Working1,
 Working2
} Dataset_T;

typedef struct DataStruct_tag {
 int16_T OFFSET; /* OFFSET */
 int16_T GAIN; /* GAIN */
} DataStruct_type;
```

The file also declares the global variables and the functions.

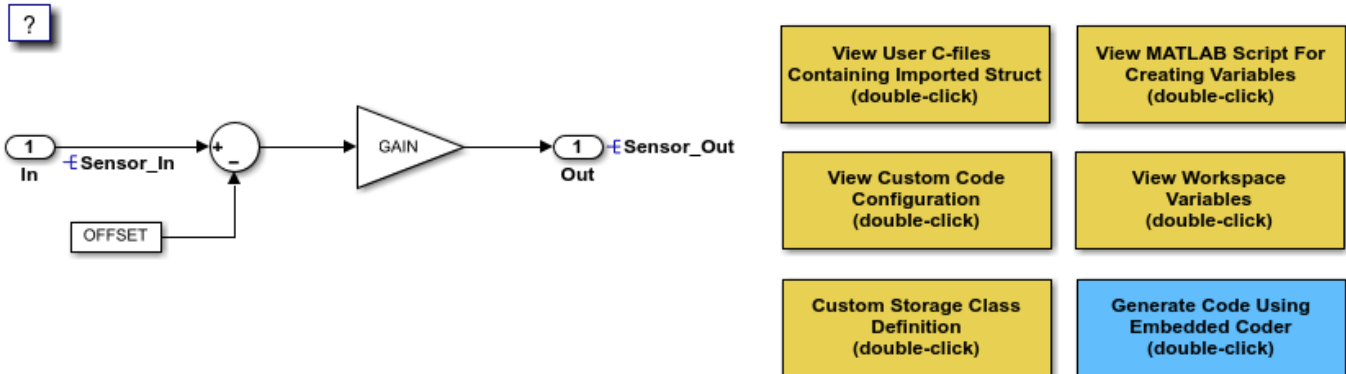

### Purpose of External Code

The code is designed so that the source code of a control algorithm (whether generated or handwritten) can read data from `ReferenceStruct`, `WorkingStruct1`, or `WorkingStruct2` by dereferencing (`->`) `StructPointer`. The two working structures (`WorkingStruct1` and `WorkingStruct2`) are located in volatile memory and are intended to be changed during runtime by an external calibration tool. The calibration engineer does not change the active working structure. Instead, the engineer changes the parameter values in the inactive working structure and then activates it by switching working structures.

If necessary for safety or in preparation for shutting down the application, the calibration tool can point `StructPointer` to `ReferenceStruct` instead. `ReferenceStruct` stores default parameter values that do not change during execution.

## Explore Example Model

Open the example model, `rtwdemo_importstruct`.

Copyright 2006-2020 The MathWorks, Inc.

The model creates variables and objects in the base workspace. The Constant block and the Gain block use the `ECodeuDemos.Parameter` objects `GAIN` and `OFFSET` to set the **Constant value** and **Gain** block parameters. `ECodeuDemos` is an example custom package that defines two classes, `Parameter` and `Signal`, and some custom storage classes.

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

Set the **Change view** drop-down list to Code.

Click the **Show/refresh additional information** button.

The Model Data Editor shows rows that correspond to the **Constant value** and **Gain** parameters of the blocks and rows that corresponds to `OFFSET` and `GAIN`, which set the parameter values. In the **Storage Class** column, `OFFSET` and `GAIN` use the custom storage class `StructPointer`, which the `ECodeuDemos` package defines.

Open the Custom Storage Class Designer and inspect the custom storage classes in the `ECodeuDemos` package. At the command prompt, use this command:

```
cscdesigner('ECodeuDemos')
```

This example package defines multiple custom storage classes, including `StructPointer`. You cannot edit the definitions. However, you can create your own packages and custom storage classes later. For an example that shows how to create a package and a custom storage class, see “Create and Apply a Storage Class” on page 37-14.

Under **Custom storage class definitions**, click `StructPointer`. The settings for this custom storage class enable the generated code to interact with the pointer variable, `StructPointer`, from the external code. For example, the custom storage class uses these settings:

- **Data scope** is set to `Imported` because the example external code defines (allocates memory for) `StructPointer`. With this setting, the code generator avoids generating unnecessary, duplicate

definitions for the data items, such as the `ECoderDemos.Parameter` objects, that use the custom storage class.

- **Data access** is set to `Pointer` because in the example external code, `StructPointer` is a pointer.
- **Memory section** is set to `ConstVolatile` because the example external code defines `StructPointer` as constant, volatile data (`const volatile`).
- **Type** is set to `FlatStructure` because in the example external code, `StructPointer` points to a structure. With this setting, the generated code treats each data item (`ECoderDemos.Parameter` object) as a field of a flat structure whose variable name and type name you can specify.
- On the **Structure Attributes** tab, **Struct name** is set to `StructPointer`. For a `FlatStructure` custom storage class, **Struct name** specifies the name of the structure variable in the generated code. In this example, `StructPointer` is the name of the variable that the external code defines.
- **Type name** is set to `DataStruct_type`, which is the name of the structure type that the example external code defines.

In the model, in the **Configuration Parameters** dialog box, inspect the **Code Generation > Custom Code** pane.

On the **Additional source code** tab, select **Initialize code**. This parameter value specifies the code to include in the generated model initialize function. In this model, the configuration parameter is set so that the generated code calls the `InitInactiveWorkingStructs` function.

`InitInactiveWorkingStructs` initializes the working structures with the values from `ReferenceStruct`. The initialization code then sets the pointer to the first working structure.

On the **Code information** tab, select **Source files**. This configuration parameter identifies the example external code file `rtwdemo_importstruct_user.c` for inclusion in the build process after code generation.

### Generate and Inspect Code

Generate code from the model.

In the generated file `rtwdemo_importstruct.c`, the model initialization function calls `InitInactiveWorkingStructs`. The algorithm in the model execution (`step`) function dereferences the pointer variable `StructPointer`.

## Create Storage Classes by Using the Custom Storage Class Designer

To control the appearance of data in the generated code, you can use built-in storage classes such as `ExportToFile` (see “Organize Parameter Data into a Structure by Using Struct Storage Class” on page 32-67). If the built-in storage classes do not meet your requirements, you can create your own storage classes. To create a storage class that you can apply to data objects, create the storage class in a package by using the Custom Storage Class Designer. See “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2.

To define a storage class that you can apply in a model by using the Code Mappings editor, use the **Embedded Coder Dictionary**. Or, create the storage class in a package and refer to the package from the Embedded Coder Dictionary.

A package also defines `Signal` and `Parameter` data classes. See “Data Objects”. A data object from a package such as `Simulink` can use storage classes defined in that package but not storage classes that are defined in other packages.

For information about using the Custom Storage Class Designer to create memory sections, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

### Create and Apply a Storage Class

This example shows how to control code generated from a model by creating and applying your own storage class for data objects.

#### Explore Example Model

Open the model `rtwdemo_cscpredef`. You can control code generated from this model by defining your own data classes and creating your own storage classes.

In this example, you export the declarations and definitions of multiple signals and parameters in the model to one declaration header file and one definition file.

#### Create Data Class Package

To create storage classes, you first create a data class package to contain the storage class definitions. Data objects that you create from your package can use the storage classes that the package defines.

- 1 Create your own data class package by copying the example package folder `+SimulinkDemos`. Navigate to the example package folder.

```
% Remember the current folder path
currentPath = pwd;

% Navigate to the example package folder
demoPath = '\toolbox\simulink\simdemos\dataclasses';
cd([matlabroot,demoPath])
```

- 2 Copy the `+SimulinkDemos` folder to your clipboard.
- 3 Return to your working folder.

```
cd(currentPath)
```

- 4 Paste the +SimulinkDemos folder from your clipboard into your working folder. Rename the copied folder to +myPackage.
- 5 Navigate inside the +myPackage folder to the file Signal.m to edit the definition of the Signal class.
- 6 Uncomment the methods section that defines the method setupCoderInfo. In the call to the function useLocalCustomStorageClasses, replace 'packageName' with 'myPackage'. When you finish, the section appears as follows:

```

methods
 function setupCoderInfo(h)
 % Use custom storage classes from this package
 useLocalCustomStorageClasses(h, 'myPackage');
 end
end % methods

```

The function useLocalCustomStorageClasses allows you to apply the storage classes that myPackage defines to data objects that you create from myPackage.

- 7 Save and close the file.
- 8 Navigate inside the +myPackage folder to the file Parameter.m to edit the definition of the Parameter class. Uncomment the methods section that defines the method setupCoderInfo and replace 'packageName' with 'myPackage'.
- 9 Save and close the file.

### Create Storage Class

You can use the Custom Storage Class Designer to create or to edit the storage classes that a data class package defines.

- 1 Set your current folder to the folder that contains the package myPackage.
- 2 Open the Custom Storage Class Designer.
 

```
cscdesigner('myPackage')
```
- 3 Select the storage class ExportToFile.
- 4 In the **Name** field, rename the storage class to ExportToGlobal.
- 5 In the **Header file** drop-down list, change the selection from Instance specific to Specify. In the new field, provide the header file name global.h.
- 6 In the **Definition file** drop-down list, change the selection from Instance specific to Specify. In the new field, provide the definition file name global.c.
- 7 Click **OK**. Click **Yes** to save changes to the data class package myPackage.

### Apply Storage Class

To apply your own storage class, you create data objects from your package and configure the objects to use your storage class.

- 1 Create data objects to represent some of the parameters and signals in the example model. Create the objects using the data class package myPackage.

```

% Parameters
templimit = myPackage.Parameter(202);
pressurelimit = myPackage.Parameter(45.2);
O2limit = myPackage.Parameter(0.96);

```

```
rpmlimit = myPackage.Parameter(7400);
```

```
% Signals
```

```
tempalarm = myPackage.Signal;
pressurealarm = myPackage.Signal;
O2alarm = myPackage.Signal;
rpmalarm = myPackage.Signal;
```

- 2 Set the storage class of each object to ExportToGlobal.

```
% Parameters
```

```
templimit.CoderInfo.StorageClass = 'Custom';
templimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
pressurelimit.CoderInfo.StorageClass = 'Custom';
pressurelimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
O2limit.CoderInfo.StorageClass = 'Custom';
O2limit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
rpmlimit.CoderInfo.StorageClass = 'Custom';
rpmlimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
```

```
% Signals
```

```
tempalarm.CoderInfo.StorageClass = 'Custom';
tempalarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
pressurealarm.CoderInfo.StorageClass = 'Custom';
pressurealarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
O2alarm.CoderInfo.StorageClass = 'Custom';
O2alarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
rpmalarm.CoderInfo.StorageClass = 'Custom';
rpmalarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
```

- 3 Select the **Signal name must resolve to Simulink signal object** option for each of the target signals in the model. You can select the option by using the Signal Properties dialog box, the **Resolve** column in the Model Data Editor, or by using the command line.

```
% Signal tempalarm
```

```
portHandles = get_param('rtwdemo_cscpredef/RelOp1', 'PortHandles');
outputPortHandle = portHandles.Outputport;
set_param(outputPortHandle, 'MustResolveToSignalObject', 'on')
```

```
% Signal pressurealarm
```

```
portHandles = get_param('rtwdemo_cscpredef/RelOp2', 'PortHandles');
outputPortHandle = portHandles.Outputport;
set_param(outputPortHandle, 'MustResolveToSignalObject', 'on')
```

```
% Signal O2alarm
```

```
portHandles = get_param('rtwdemo_cscpredef/RelOp3', 'PortHandles');
outputPortHandle = portHandles.Outputport;
set_param(outputPortHandle, 'MustResolveToSignalObject', 'on')
```

```
% Signal rpmalarm
```

```
portHandles = get_param('rtwdemo_cscpredef/RelOp4', 'PortHandles');
outputPortHandle = portHandles.Outputport;
set_param(outputPortHandle, 'MustResolveToSignalObject', 'on')
```

### Generate Code

- 1 Generate code for the example model.

```
slbuild('rtwdemo_cscpredef')
```

- 2 In the Code view for the model, view the generated header file `global.h`. The file contains the extern declarations of the model signals and parameters that use the storage class `ExportToGlobal`.

```
/* Declaration for custom storage class: ExportToGlobal */
extern boolean_T O2alarm;
extern real_T O2limit;
extern boolean_T pressurealarm;
extern real_T pressurelimit;
extern boolean_T rpmalarm;
extern real_T rpmlimit;
extern boolean_T tempalarm;
extern real_T templimit;
```

- 3 View the generated file `global.c`. The file contains the definitions of the model signals and parameters that use the storage class `ExportToGlobal`.

```
/* Definition for custom storage class: ExportToGlobal */
boolean_T O2alarm;
real_T O2limit = 0.96;
boolean_T pressurealarm;
real_T pressurelimit = 45.2;
boolean_T rpmalarm;
real_T rpmlimit = 7400.0;
boolean_T tempalarm;
real_T templimit = 202.0;
```

## Modify a Built-In Storage Class

You cannot directly modify a built-in storage class, such as `ExportToFile` from the Simulink package, but you can create a copy, and then modify the copy. When you create a new package with no `csc_registration.m` file, and then open the Custom Storage Class Designer for the first time in that package, Simulink copies the definitions of the built-in storage classes into the package. Then, in the Custom Storage Class Designer, you can modify the copied definitions. Alternatively, to keep the built-in storage classes available in your package, copy one of them by clicking **Copy**, then modify the resulting copy.

## Control Data Representation by Configuring Storage Class Properties

The Custom Storage Class Designer is a tool for creating and managing storage classes and memory sections. To open the Custom Storage Class Designer for a specific package, for example, `+mypkg`, at the command prompt, use the `cscdesigner` function:

```
cscdesigner('mypkg')
```

The name of the folder that represents a package begins with a `+`. When you use the function `cscdesigner`, omit the `+` from the name of the target package.

To control the effect that a storage class has on data in a model, you specify properties of the storage class in the Custom Storage Class Designer. To determine how to generate a particular kind of code, use the information in the table.

Kind of Data in Generated Code	Technique
Structure	Set <b>Type</b> to FlatStructure. See “Generate Structured Data” on page 37-19.
Macro	Set <b>Data initialization</b> to Macro and clear <b>For signals</b> . See “Generate a Macro” on page 37-18.
Pointer	Set <b>Data access</b> to Pointer and <b>Data scope</b> to Auto, Imported, or Instance specific. Your external code must define the pointer variable.
static data (file-scoped data)	Set <b>Data scope</b> to File.
const or volatile data	Set <b>Memory section</b> to a memory section that specifies const, volatile, or both. For example, use one of the built-in memory sections MemConst, MemVolatile, and MemConstVolatile. To create your own memory section, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.
Calls to external functions to read and write to data	See “Call Custom Accessor Functions or Macros Instead of Reading and Writing to Variables” on page 37-19.

### Allow Users of Storage Class to Specify Property Value

For some properties of a storage class, such as **Data scope**, instead of specifying a value in the Custom Storage Class Designer, you can allow users of the storage class to specify the value. You can create a single, flexible storage class instead of multiple storage classes that vary only by a few property values.

For example, suppose you create a storage class that yields a global variable in the generated code. You can configure the storage class so that a user can set the **Data scope** property to Exported for a signal in a model and set the property to Imported for a different signal.

In the Custom Storage Class Designer, for each property that you want to configure in this way, set the property value to Instance specific. Then, when a user applies the storage class to a data item, the property appears to the user as a custom attribute for that data item. For information about instance-specific custom attributes, see “Storage Class Properties” on page 33-75.

### Generate a Macro

To create a storage class that yields a macro in the generate code, set **Data initialization** to Macro and clear **For signals**.

When you set **Data initialization** to Macro, **Definition file** has no meaning. To prevent users of the storage class from specifying a meaningless definition file, in the Custom Storage Class Designer, set **Definition file** to Specify and leave the text box empty.

- To define the macro in a header file (`#define`), specify the name of the header file with the **Header file** property.
- To provide the macro definition as a compiler option or compiler flag, set **Data access** to Imported and **Header file** to Specify. Leave the **Header file** text box empty. Then, the generated code does not define the macro and does not include (`#include`) a header file.

To specify the compiler option or flag, use the model configuration parameter **Configuration Parameters > Code Generation > Custom Code > Code information > Defines**. See Code Generation Pane: Custom Code: Additional Build Information: Defines.

### Generate Structured Data

To create a storage class that aggregates data items into a flat structure (similar to the built-in storage class `Struct`), set **Type** to `FlatStructure`. The **Structure Attributes** tab appears.

- To control the name of the global structure variable that appears in the generated code, use the **Struct name** property and text box.
- If you set **Struct name** to `Instance specific`, users of the storage class specify the name of the structure variable. In this case, the code generator derives the name of the structure type from the name of the variable.

To more precisely control the name and other characteristics of the structure type, set **Struct name** to `Specify`. Control the type characteristics by using the additional properties that appear.

- To generate a structure with bit fields (similar to the built-in storage class `BitField`), select **Bit-pack booleans**. Data items that use the data type `boolean` appear in the generated code as bit fields of the structure.

### Control Assignment of Initial Value in Generated Code

- To use the default Simulink Coder initialization strategy, set **Data initialization** to the default value, `Auto`.
  - The generated code statically initializes parameter data with an assignment statement at the top of a `.c` or `.cpp` source file, outside of any function.
  - The generated code dynamically initializes signal and state data as part of the initialization function of the model (named `model_initialize` by default).
- To statically initialize the data, set **Data initialization** to `Static`.
- To dynamically initialize the data, set **Data initialization** to `Dynamic`.
- To prevent the generated code from initializing the data, set **Data initialization** to `None`. When your external code initializes the data, use this setting to prevent the generated code from overwriting your initialization. This setting does not apply to data that you specify in an Initialize Function block.

### Call Custom Accessor Functions or Macros Instead of Reading and Writing to Variables

Using the built-in storage class `GetSet`, you can generate code that calls your external, custom functions instead of directly interacting with variables. For general information about `GetSet`, see “Access Data Through Functions with Storage Class `GetSet`” on page 37-25.

To create a similar storage class, set **Type** to `AccessFunction`.

- Specify the names of the external functions.
  - To apply the same `get` or `set` function naming scheme to data items that use the storage class, set **Get function** and **Set function** to `Specify`. Then, in the text boxes, specify the function naming scheme, for example, `get_myData_$N`. Use the token `$N` in a naming scheme to represent the name of each data item. If you do not use the token, each data item uses the same specified `get` or `set` function name, so the model generates an error when you generate code.

- To specify a different `get` or `set` function name for each data item, set **Get function** or **Set function** to `Instance specific`. Later, when you create a data item and apply the storage class, specify the function name by configuring the custom attributes of the data item.
- Specify the name of the header file that declares the `get` and `set` functions with the **Header file** property. In this case, **Definition file** has no meaning. To prevent users of the storage class from specifying a meaningless definition file, set **Definition file** to `Specify` and leave the text box empty.
- If you implement the `get` mechanism for scalar or array data as a macro instead of a function, you can generate code that omits parentheses when reading that data. On the **Access Function Attributes** tab, select **Get data through macro (omit parentheses)**.

### Generate Code That Uses Data From External Code

When your external code defines data, to avoid generating a duplicate definition, you must configure the generated code to read and write to the existing data. In the Custom Storage Class Designer, set **Data scope** to `Imported`. The code generator does not generate a definition for the global variable or macro.

- If your code defines a pointer variable, to generate code that interacts with the pointer, set **Data access** to `Pointer`.
- If you generate structured data by setting **Type** to `FlatStructure`, your code must define the structure type and the global structure variable.
- If your code initializes state or signal data, you can prevent the generated code from overwriting your initialization by setting **Data initialization** to `None`. See “Prevent Duplicate Initialization Code for Global Variables” on page 55-70

### Generate Code Comments with Data Definitions and Declarations

To customize the comments that appear in the generated code, on the **Comments** tab, set **Comment rules** to `Specify`. To specify a comment that appears with the declaration of each data item, use the **Declaration comment** box. To specify a comment that appears with the definition, use the **Definition comment** box.

For structured data (you set **Type** to `FlatStructure`), to specify a comment that appears with the structure type definition, use the **Type comment** box.

## Avoid Errors During Code Generation by Validating Storage Class Configuration

As you configure a storage class in the Custom Storage Class Designer, to check for possible errors in the configuration, click **Validate**.

For example, validating the storage class warns you if you accidentally set **Data initialization** to `Macro` with **For signals** selected. A signal cannot appear in the generated code as a macro.

## Make Storage Classes Available Outside the Current Folder

To use a storage class that you create, you must make the defining package available. Either set your current folder to the folder that contains the package or add the folder containing the package folder to the MATLAB path (see “What Is the MATLAB Search Path?”). Adding the package to the MATLAB path enables you to use the storage classes no matter where you set your current folder.

## Make Storage Classes Available in the Code Mappings Editor

To use package-based storage classes in the Code Mappings editor, refer to the package from an Embedded Coder Dictionary. To configure an Embedded Coder Dictionary to refer to the package, see “Refer to Code Generation Definitions in a Package”.

## Share Storage Class Between Packages

When you create a package, you can refer to a storage class defined in another package such as the built-in package Simulink or a different package that you created. Then, the defining package and any referencing packages can use the storage class. When you want to make a change to the storage class, you make the change only once, in the defining package.

To configure a package to refer to a storage class that another package defines:

- 1 In the Custom Storage Class Designer, select the **Custom Storage Class** tab.
- 2 Use **Select Package** to select the referencing package. The package must be writable.
- 3 In the **Custom storage class definitions** pane, select the existing definition below which you want to insert the reference.
- 4 Click **New Reference**.

A new reference with a default name and properties appears below the previously selected definition. The new reference is selected and a **Reference** tab appears that shows the initial properties.

- 5 Use **Name** to specify a name for the new reference. The name must be unique in the importing package, but can duplicate the name in the source package. The name cannot be a TLC keyword.
- 6 Set **Refer to custom storage class in package** to specify the package that contains the storage class that you want to reference.
- 7 Set **Custom storage class to reference** to specify the storage class to be referenced.
- 8 Click **OK** or **Apply**. To save the changes permanently, click **Save**.

## Control Appearance of Storage Class Drop-Down List

When you apply a storage class to a data item, you select the storage class from a drop-down list.

- To control the order of the custom storage classes in the list, in the Custom Storage Class Designer, use the **Up** and **Down** buttons. The order of the storage classes in drop-down lists matches the order that you specify in the Custom Storage Class Designer.
- To prevent a user of a storage class from applying the storage class to parameter data or to signal and state data, use the **For parameters** and **For signals** check boxes. When you clear one of these properties, for the corresponding kind of data, the storage class does not appear in the drop-down list.

For example, if your storage class yields a macro in the generated code because you set **Data initialization** to Macro, to prevent users from applying the storage class to signal data, clear **For signals**.

## Protect Custom Storage Class Definitions

When you click **Save** in the Custom Storage Class Designer, the Designer saves memory section and storage class definitions into the `csc_registration.m` file in the package folder. To determine the location of this file, in the Custom Storage Class Designer, inspect the value of **Filename**.

You can prevent changes to the storage class definitions of an entire package by converting the `csc_registration.m` file from a MATLAB file to a P-file. Use the `pcode` function.

A best practice is to keep `csc_registration.m` and `csc_registration.p` in your package folder. That way, if you modify the storage classes by using the Designer, you can delete `csc_registration.p` and later regenerate it after you finish the modifications. Because the P-coded version of the file takes precedence, when both files exist in the package, the storage classes are protected and you cannot modify them in the Custom Storage Class Designer.

## Further Customize Generated Code by Writing TLC Code

If creating your own storage class by manipulating the properties in the Custom Storage Class Designer does not meet your requirements, you can finely control the generated code by writing TLC code for your storage class. Use an advanced mode of the Custom Storage Class Designer and, for the storage class, set **Type** to **Other**. See “Finely Control Data Representation by Writing TLC Code for a Storage Class” on page 37-23.

## Finely Control Data Representation by Writing TLC Code for a Storage Class

If creating your own storage class by using the properties in an Embedded Coder Dictionary or the Custom Storage Class Designer does not meet your requirements for controlling data representation in the generated code, you can write TLC code that explicitly controls the effect that a storage class has on the code. For example, to create a storage class that yields arbitrarily nested structures, you must write TLC code. In the Custom Storage Class Designer, these advanced storage classes have **Type** set to **Other**. You cannot create such a storage class in an Embedded Coder Dictionary, so to use the storage class in the Code Mappings editor, you must configure the dictionary of the model to refer to the package that contains the storage class, as described in “Refer to Code Generation Definitions in a Package”.

For an example, see “Generate Code That Dereferences Data from a Literal Memory Address” on page 68-15. For general information about TLC code, see “Why Use the Target Language Compiler?”.

### Create Custom Attributes Class for Storage Class

As described in “Allow Users of Storage Class to Specify Property Value” on page 37-18, instance-specific properties enable users of a storage class to control the effect that the storage class has on each data item. For example, the built-in storage class `ExportToFile` has several instance-specific properties such as **Header file** and **Definition file**.

When you create a storage class with **Type** set to **Other**, to add your own instance-specific properties that are not built into the Custom Storage Class Designer, create a custom attributes class for your package. A custom attributes class is a MATLAB class that you create as a subclass of `Simulink.CustomStorageClassAttributes`. Each property that you add to your custom attributes class appears to the user of the storage class as an instance-specific property.

To create your custom attributes class, see “Define Data Classes”.

### Write TLC Code for Storage Class

To control the effect of your storage class, write TLC code that specifies the code to generate for each data item.

- 1 In your package folder (for example, `+myPackage`), create a `tlc` folder.
- 2 Copy a TLC template such as `TEMPLATE_v2.tlc` from the folder `matlabroot/toolbox/rtw/targets/ecoder/csc_templates` (open) into your `tlc` folder.
- 3 Write your TLC code, following the comments in the template file. The comments describe how to specify, for example, how the generated code declares, defines, and accesses (by value or by reference) each data item.

### Create Storage Class by Using Custom Storage Class Designer

To create your storage class in your package, you open the Custom Storage Class Designer in an advanced mode.

- 1 At the command prompt, enter:

`cscdesigner` -advanced

- 2 Select your package and create a storage class.
- 3 For the storage class, set **Type** to **Other**. In the **Other Attributes** pane, specify the name of your TLC file and the name of your custom attributes class.
- 4 Set the properties on the **Other Attributes** pane.
  - **Is grouped**: Select this option if you intend to combine multiple data items into a single entity in the generated code. For example, the built-in storage classes `BitField` and `Struct` are grouped because they can aggregate multiple data items into a single structure variable.
  - **TLC file name**: Enter the name of your TLC file. The Custom Storage Class Designer assumes that the file exists in the package `tlc` folder, so specify only the name of the file, not the file path.
  - **CSC attributes class name**: (optional) If you created a custom attributes class, enter the full name of the class, including the package name. For example, specify `myPackage.myCustomAttsClass`. For more information, see “Create Custom Attributes Class for Storage Class” on page 37-23.
- 5 On the **General** and **Comments** panes, specify values for the remaining properties.

To apply the storage class to data objects, you create the data objects from your package and configure the objects to use your storage class. For more information on applying a custom storage class to data objects, see “Apply Storage Class” on page 37-15. To apply the storage class in a model by using the Code Mappings editor, you must configure the Embedded Coder Dictionary that the model uses to refer to your package. When you refer to the package, the storage class appears in the Embedded Coder Dictionary and becomes available in the Code Mappings editor. For more information, see “Refer to Code Generation Definitions in a Package”.

## Access Data Through Functions with Storage Class GetSet

To integrate the generated code with legacy code that uses specialized functions to read from and write to data, you can use the storage class `GetSet`. Signals, block parameters, and states that use `GetSet` appear in the generated code as calls to accessor functions. You provide the function definitions.

You can also create your own storage class in Embedded Coder Dictionary to access data through functions. Creating your own storage class in Embedded Coder Dictionary gives you the flexibility of customizing function names and return types. For more information, see “Access Data Through Functions by Using Storage Classes in Embedded Coder Dictionary” on page 37-41.

To generate code that conforms to the AUTOSAR standard by accessing data through Rte function calls, use the AUTOSAR code perspective. See “AUTOSAR Component Configuration” (AUTOSAR Blockset).

### Access Legacy Data Using Get and Set Functions

This example shows how to generate code that interfaces with legacy code by using specialized `get` and `set` functions to access data.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h', '/* ComponentData */', '} ComponentData;', 1, 1)

/* ComponentData */
typedef struct {
 ScalarData scalars;
 VectorData vectors;
 StructData structs;
 MatricesData matrices;
} ComponentData;
```

The field `scalars` is a substructure that uses the structure type `ScalarData`. The structure type `ScalarData` defines three scalar fields: `inSig`, `scalarParam`, and `outSig`.

```
rtwdemodbtype('ComponentDataHdr.h', '/* ScalarData */', '} ScalarData;', 1, 1)

/* ScalarData */
typedef struct {
 double inSig;
 double scalarParam;
 double outSig;
} ScalarData;
```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `scalars`.

```
rtwdemodbtype('getsetSrc.c', '/* Field "scalars" */', '/* End of "scalars" */', 1, 1)
```

```

/* Field "scalars" */
{
3.9,

12.3,

0.0
},
/* End of "scalars" */

```

The file also defines functions that read from and write to the fields of the substructure `scalars`. The functions simplify data access by dereferencing the leaf fields of the global structure variable `ex_getset_data`.

```

rtwdemodbtype('getsetSrc.c',...
 /* Scalar get() and set() functions */,'/* End of scalar functions */',1,1)

/* Scalar get() and set() functions */
double get_inSig(void)
{
 return ex_getset_data.scalars.inSig;
}

void set_inSig(double value)
{
 ex_getset_data.scalars.inSig = value;
}

double get_scalarParam(void)
{
 return ex_getset_data.scalars.scalarParam;
}

void set_scalarParam(double value)
{
 ex_getset_data.scalars.scalarParam = value;
}

double get_outSig(void)
{
 return ex_getset_data.scalars.outSig;
}

void set_outSig(double value)
{
 ex_getset_data.scalars.outSig = value;
}

```

View the example legacy header file `getsetHdrScalar.h`. The file contains the extern prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_scalar`. The model creates the data objects `inSig`, `outSig`, and `scalarParam` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_scalar')
```

Copyright 2015-2021 The MathWorks, Inc.

In the base workspace, double-click the object `inSig` to view its properties. The object uses the storage class `GetSet`. The `GetFunction` and `SetFunction` properties are set to the defaults, `get_$N` and `set_$N`. The generated code uses the function names that you specify in `GetFunction` and `SetFunction` to read from and write to the data. The code replaces the token `$N` with the name of the data object. For example, for the data object `inSig`, the generated code uses calls to the legacy functions `get_inSig` and `set_inSig`.

For the data object `inSig`, the `HeaderFile` property is set to `getsetHdrScalar.h`. This legacy header file contains the `get` and `set` function prototypes. The data objects `outSig` and `scalarParam` also use the storage class `GetSet` and the header file `getsetHdrScalar.h`.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, on the **Code information** tab, select **Source files**. The **Source files** box identifies the source file `getsetSrc.c` for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
slbuild('rtwdemo_getset_scalar');
```

```
Starting build procedure for: rtwdemo_getset_scalar
Successful completion of build procedure for: rtwdemo_getset_scalar
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_getset_scalar	Code generated and compiled	Code generation information file does not exist

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 1m 39.526s
```

In the code generation report, view the file `rtwdemo_getset_scalar.c`. The model step function uses the legacy `get` and `set` functions to execute the algorithm. The generated code accesses the legacy signal and parameter data by calling the custom, handwritten `get` and `set` functions.

```
rtwdemodbtype(fullfile('rtwdemo_getset_scalar_ert_rtw','rtwdemo_getset_scalar.c'),...
 /* Model step function */,'}',1,1)
```

```
/* Model step function */
```

```
void rtwdemo_getset_scalar_step(void)
{
 /* Gain: '<Root>/Gain' incorporates:
 * Inport: '<Root>/In1'
 */
 set_outSig(get_scalarParam() * get_inSig());
}
```

You can generate code that calls your custom `get` and `set` functions as long as the functions that you write accept and return the expected values. For scalar data, the functions must have these characteristics:

- The `get` function must return a single scalar numeric value of the appropriate data type, and must not accept any arguments (`void`).
- The `set` function must not return anything (`void`), and must accept a single scalar numeric value of the appropriate data type.

## Use GetSet with Vector Data

This example shows how to apply the storage class `GetSet` to signals and parameters that are vectors.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h', '/* ComponentData */', '}' ComponentData;', 1, 1)

/* ComponentData */

typedef struct {
 ScalarData scalars;
 VectorData vectors;
 StructData structs;
 MatricesData matrices;
} ComponentData;
```

The field `vectors` is a substructure that uses the structure type `VectorData`. The structure type `VectorData` defines three vector fields: `inVector`, `vectorParam`, and `outVector`. The vectors each have five elements.

```
rtwdemodbtype('ComponentDataHdr.h', '/* VectorData */', '}' VectorData;', 1, 1)

/* VectorData */

typedef struct {
 double inVector[5];
 double vectorParam[5];
 double outVector[5];
} VectorData;
```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `vectors`.

```
rtwdemodbtype('getsetSrc.c', '/* Field "vectors" */', '/* End of "vectors" */', 1, 1)
```

```

/* Field "vectors" */
{
 {5.7, 6.8, 1.2, 3.5, 10.1},

 {12.3, 18.7, 21.2, 28, 32.9},

 {0.0, 0.0, 0.0, 0.0, 0.0}
},
/* End of "vectors" */

```

The file also defines functions that read from and write to the fields of the substructure `vectors`. The functions simplify data access by dereferencing the leaf fields of the global structure variable `ex_getset_data`. To access the vector data, the functions accept an integer index argument. The `get` function returns the vector value at the input index. The `set` function assigns the input value to the input index.

```

rtwdemodbtype('getsetSrc.c',...
 /* Vector get() and set() functions */,'/* End of vector functions */',1,1)

/* Vector get() and set() functions */

double get_inVector(int index)
{
 return ex_getset_data.vectors.inVector[index];
}

void set_inVector(int index, double value)
{
 ex_getset_data.vectors.inVector[index] = value;
}

double get_vectorParam(int index)
{
 return ex_getset_data.vectors.vectorParam[index];
}

void set_vectorParam(int index, double value)
{
 ex_getset_data.vectors.vectorParam[index] = value;
}

double get_outVector(int index)
{
 return ex_getset_data.vectors.outVector[index];
}

void set_outVector(int index, double value)
{
 ex_getset_data.vectors.outVector[index] = value;
}

```

View the example legacy header file `getsetHdrVector.h`. The file contains the extern prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_vector`. The model creates the data objects `inVector`, `outVector`, and `vectorParam` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_vector')
```

Copyright 2015-2020 The MathWorks, Inc.

In the base workspace, double-click the object `inVector` to view its properties. The object uses the storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrVector.h`. This legacy header file contains the `get` and `set` function prototypes.

In the Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file `getsetSrc.c` is identified for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
slbuild('rtwdemo_getset_vector');
```

```
Starting build procedure for: rtwdemo_getset_vector
Successful completion of build procedure for: rtwdemo_getset_vector
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_getset_vector	Code generated and compiled	Code generation information file does not exist

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 17.58s
```

In the code generation report, view the file `rtwdemo_getset_vector.c`. The model step function uses the legacy `get` and `set` functions to execute the algorithm.

```
rtwdemodbtype(fullfile('rtwdemo_getset_vector_ert_rtw', 'rtwdemo_getset_vector.c'), ...
 /* Model step function */, '}', 1, 1)
```

```
/* Model step function */
void rtwdemo_getset_vector_step(void)
{
 int32_T i;
```

```

for (i = 0; i < 5; i++) {
 /* Gain: '<Root>/Gain' incorporates:
 * Inport: '<Root>/In1'
 */
 set_outVector(i, get_vectorParam(i) * get_inVector(i));
}

```

When you use the storage class `GetSet` with vector data, the `get` and `set` functions that you provide must accept an index input. The `get` function must return a single element of the vector. The `set` function must write to a single element of the vector.

## Use GetSet with Structured Data

This example shows how to apply the storage class `GetSet` to nonvirtual bus signals and structure parameters in a model.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```

rtwdemodbtype('ComponentDataHdr.h', ...
 /* ComponentData */,'} ComponentData;',1,1)

```

```

/* ComponentData */

```

```

typedef struct {
 ScalarData scalars;
 VectorData vectors;
 StructData structs;
 MatricesData matrices;
} ComponentData;

```

The field `structs` is a substructure that uses the structure type `StructData`. The structure type `StructData` defines three fields: `inStruct`, `structParam`, and `outStruct`.

```

rtwdemodbtype('ComponentDataHdr.h', /* StructData */,'} StructData;',1,1)

```

```

/* StructData */

```

```

typedef struct {
 SigBus inStruct;
 ParamBus structParam;
 SigBus outStruct;
} StructData;

```

The fields `inStruct`, `structParam`, and `outStruct` are also substructures that use the structure types `SigBus` and `ParamBus`. Each of these two structure types define three scalar fields.

```

rtwdemodbtype('ComponentDataHdr.h', /* SigBus */,'} ParamBus',1,1)

```

```

/* SigBus */

```

```

typedef struct {
 double cmd;
 double sensor1;
}

```

```
 double sensor2;
} SigBus;

/* ParamBus */

typedef struct {
 double offset;
 double gain1;
 double gain2;
} ParamBus;
```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `structs`.

```
rtwdemodbtype('getsetSrc.c',...
 /* Field "structs" */,'/* End of "structs" */',1,1)

 /* Field "structs" */
 {
 {1.3, 5.7, 9.2},

 {12.3, 9.6, 1.76},

 {0.0, 0.0, 0.0}
 },
 /* End of "structs" */
```

The file also defines functions that read from and write to the fields of the substructure `structs`. The functions simplify data access by dereferencing the fields of the global structure variable `ex_getset_data`. The functions access the data in the fields `inStruct`, `structParam`, and `outStruct` by accepting and returning complete structures of the types `SigBus` and `ParamBus`.

```
rtwdemodbtype('getsetSrc.c',...
 /* Structure get() and set() functions */,'...
 /* End of structure functions */',1,1)

/* Structure get() and set() functions */

SigBus get_inStruct(void)
{
 return ex_getset_data.structs.inStruct;
}

void set_inStruct(SigBus value)
{
 ex_getset_data.structs.inStruct = value;
}

ParamBus get_structParam(void)
{
 return ex_getset_data.structs.structParam;
}

void set_structParam(ParamBus value)
{
```

```

 ex_getset_data.structs.structParam = value;
}

SigBus get_outStruct(void)
{
 return ex_getset_data.structs.outStruct;
}

void set_outStruct(SigBus value)
{
 ex_getset_data.structs.outStruct = value;
}

```

View the example legacy header file `getsetHdrStruct.h`. The file contains the extern prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_struct`. The model creates the data objects `inStruct`, `structParam`, and `outStruct` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_struct')
```

Copyright 2015-2020 The MathWorks, Inc.

In the base workspace, double-click the object `inStruct` to view its properties. The object uses the storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrStruct.h`. This legacy header file contains the `get` and `set` function prototypes.

The model also creates the bus objects `ParamBus` and `SigBus` in the base workspace. The signals and parameter in the model use the bus types that these objects define. The property `DataScope` of each bus object is set to `Imported`. The property `HeaderFile` is set to `ComponentDataHdr.h`. The generated code imports these structure types from the legacy header file `ComponentDataHdr.h`.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file `getsetSrc.c` is identified for inclusion during the build process. This

legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
slbuild('rtwdemo_getset_struct');

Starting build procedure for: rtwdemo_getset_struct
Successful completion of build procedure for: rtwdemo_getset_struct

Build Summary

Top model targets built:

Model Action Rebuild Reason
=====
rtwdemo_getset_struct Code generated and compiled Code generation information file does not ex

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 18.65s
```

In the code generation report, view the file `rtwdemo_getset_struct.c`. The model step function uses the legacy `get` and `set` functions to execute the algorithm.

```
rtwdemodbtype(fullfile('rtwdemo_getset_struct_ert_rtw', ...
 'rtwdemo_getset_struct.c'), ...
 /* Model step function */,'}',1,1)

/* Model step function */
void rtwdemo_getset_struct_step(void)
{
 /* Bias: '<Root>/Bias' incorporates:
 * Inport: '<Root>/In1'
 */
 rtDW.BusCreator.cmd = (get_inStruct()).cmd + (get_structParam()).offset;

 /* Gain: '<Root>/Gain' incorporates:
 * Inport: '<Root>/In1'
 */
 rtDW.BusCreator.sensor1 = (get_structParam()).gain1 * (get_inStruct()).sensor1;

 /* Gain: '<Root>/Gain1' incorporates:
 * Inport: '<Root>/In1'
 */
 rtDW.BusCreator.sensor2 = (get_structParam()).gain2 * (get_inStruct()).sensor2;

 /* SignalConversion: '<Root>/Signal Conversion' */
 set_outStruct(rtDW.BusCreator);
}
```

When you use the storage class `GetSet` with structured data, the `get` and `set` functions that you provide must return and accept complete structures. The generated code dereferences individual fields of the structure that the `get` function returns.

The output signal of the Bus Creator block is a test point. This signal is the input for a Signal Conversion block. The test point and the Signal Conversion block exist so that the generated code

defines a variable for the output of the Bus Creator block. To provide a complete structure argument for the function `set_outStruct`, you must configure the model to create this variable.

## Use GetSet with Matrix Data

This example shows how to apply the storage class `GetSet` to signals and parameters that are matrices.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h',...
 /* ComponentData */,'} ComponentData;',1,1)

/* ComponentData */

typedef struct {
 ScalarData scalars;
 VectorData vectors;
 StructData structs;
 MatricesData matrices;
} ComponentData;
```

The field `matrices` is a substructure that uses the structure type `MatricesData`. The structure type `MatricesData` defines three fields: `matrixInput`, `matrixParam`, and `matrixOutput`. The fields store matrix data as serial arrays. In this case, the input and parameter fields each have 15 elements. The output field has nine elements.

```
rtwdemodbtype('ComponentDataHdr.h'...
 , /* MatricesData */,'} MatricesData;',1,1)

/* MatricesData */

typedef struct {
 double matrixInput[15];
 double matrixParam[15];
 double matrixOutput[9];
} MatricesData;
```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `matrices`.

```
rtwdemodbtype('getsetSrc.c',...
 /* Field "matrices" */,'/* End of "matrices" */',1,1)

/* Field "matrices" */
{
 {12.0, 13.9, 7.4,
 0.5, 11.8, 6.4,
 4.7, 5.3, 13.0,
 0.7, 16.1, 13.5,
 1.6, 0.5, 3.1},
```

```

 {8.3, 12.0, 11.5, 2.0, 5.7,
 7.5, 12.8, 11.1, 8.4, 9.9,
 10.9, 4.6, 2.7, 16.3, 3.8},

 {0.0, 0.0, 0.0,
 0.0, 0.0, 0.0,
 0.0, 0.0, 0.0}
 }
 /* End of "matrices" */

```

The input matrix has five rows and three columns. The matrix parameter has three rows and five columns. The matrix output has three rows and three columns. The file defines macros that indicate these dimensions.

```

rtwdemodbtype('getsetSrc.c',...
 /* Matrix dimensions */,'/* End of matrix dimensions */',1,1)

```

```

/* Matrix dimensions */

```

```

#define MATRIXINPUT_NROWS 5
#define MATRIXINPUT_NCOLS 3

```

```

#define MATRIXPARAM_NROWS 3
#define MATRIXPARAM_NCOLS 5

```

```

#define MATRIXOUTPUT_NROWS MATRIXPARAM_NROWS
#define MATRIXOUTPUT_NCOLS MATRIXINPUT_NCOLS

```

The file also defines functions that read from and write to the fields of the substructure matrices.

```

rtwdemodbtype('getsetSrc.c',...
 /* Matrix get() and set() functions */,'/* End of matrix functions */',1,1)

```

```

/* Matrix get() and set() functions */

```

```

double get_matrixInput(int colIndex)

}

double get_matrixOutput(int colIndex)
{
 int rowIndexGetOut = MATRIXOUTPUT_NCOLS * (colIndex % MATRIXOUTPUT_NROWS) + colIndex/MATRIXOUTPUT_NROWS;
 return ex_getset_data.matrices.matrixOutput[rowIndexGetOut];
}

void set_matrixOutput(int colIndex, double value)
{
 int rowIndexSetOut = MATRIXOUTPUT_NCOLS * (colIndex % MATRIXOUTPUT_NROWS) + colIndex/MATRIXOUTPUT_NROWS;
 ex_getset_data.matrices.matrixOutput[rowIndexSetOut] = value;
}

```

The code that you generate from a model represents matrices as serial arrays. Therefore, each of the `get` and `set` functions accept a single scalar index argument.

The generated code uses column-major format to store and to access matrix data. However, many C applications use row-major indexing. To integrate the generated code with the example legacy code, which stores the matrices `matrixInput` and `matrixParam` using row-major format, the custom `get` functions use the column-major index input to calculate an equivalent row-major index. The generated code algorithm, which interprets matrix data using column-major format by default, performs the correct matrix math because the `get` functions effectively convert the legacy matrices to column-major format. The `set` function for the output, `matrixOutput`, also calculates a row-major index so the code writes the algorithm output to `matrixOutput` using row-major format. Alternatively, to integrate the column-major generated code with your row-major legacy code, you can manually convert the legacy code to column-major format by transposing your matrix data and algorithms.

View the example legacy header file `getsetHdrMatrix.h`. The file contains the `extern` prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_matrix`. The model creates the data objects `matrixInput`, `matrixParam`, and `matrixOutput` in the base workspace. The objects correspond to the signals and parameter in the model.

```

load_system('rtwdemo_getset_matrix')
set_param('rtwdemo_getset_matrix','SimulationCommand','Update')
open_system('rtwdemo_getset_matrix')

```

Copyright 2015-2020 The MathWorks, Inc.

In the base workspace, double-click the object `matrixInput` to view its properties. The object uses the storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrMatrix.h`. This legacy header file contains the `get` and `set` function prototypes.

In the Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file `getsetSrc.c` is identified for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
slbuild('rtwdemo_getset_matrix');
```

```
Starting build procedure for: rtwdemo_getset_matrix
Successful completion of build procedure for: rtwdemo_getset_matrix
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_getset_matrix	Code generated and compiled	Code generation information file does not exist

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 17.761s
```

In the code generation report, view the file `rtwdemo_getset_matrix.c`. The model step function uses the legacy `get` and `set` functions to execute the algorithm.

```
rtwdemodbtype(fullfile('rtwdemo_getset_matrix_ert_rtw',...
 'rtwdemo_getset_matrix.c'), /* Model step function */', 1, 1)
```

```
/* Model step function */
void rtwdemo_getset_matrix_step(void)

 * Inport: '<Root>/In1'
 */
 matrixOutput_tmp = 3 * i_0 + i;
 set_matrixOutput(matrixOutput_tmp, 0.0);
 for (i_1 = 0; i_1 < 5; i_1++) {
 set_matrixOutput(matrixOutput_tmp, get_matrixParam(3 * i_1 + i) *
 get_matrixInput(5 * i_0 + i_1) + get_matrixOutput
 (matrixOutput_tmp));
 }
}

```

## Specify Header File or Function Naming Scheme for Data Items

By default, you specify a header file name, `get` function name, and `set` function name for each data item, such as a signal or parameter, that uses the storage class `GetSet`.

To configure a single header file, `get` function naming scheme, or `set` function naming scheme to use for every data item, you can use the Custom Storage Class Designer to create your own copy of `GetSet`. You can specify the header file or function names in a single location.

Follow these steps to create your own storage class by creating your own data class package, creating a copy of `GetSet`, and applying the new storage class to data items in your model.

- 1 Create your own data class package, `myPackage`, by copying the example package folder `+SimulinkDemos` and renaming the copied folder as `+myPackage`. Modify the `Parameter` and `Signal` class definitions so that they use the storage class definitions from `myPackage`. For an example, see “Create Data Class Package” on page 37-14.
- 2 Set your current folder to the folder that contains the package folder. Alternatively, add the folder containing the package folder to your MATLAB path.
- 3 Open the Custom Storage Class Designer.

```
cscdesigner('myPackage')
```

- 4 Select the storage class `GetSet`. Click **Copy** to create a copy called `GetSet_1`.
- 5 Select the new storage class `GetSet_1`. In the **General** tab, set **Name** to `myGetSet`.
- 6 Set the drop-down list **Header file** to `Specify`. In the new text box, set **Header file** to `myFcnHdr.h`. Click **Apply**.
- 7 On the **Access Function Attributes** tab, set the drop-down lists **Get function** and **Set function** to `Specify`.
- 8 In the new boxes, set **Get function** to `myGetFcn_$$N` and **Set function** to `mySetFcn_$$N`. Click **OK**. Click **Yes** in response to the message about saving changes.

When you generate code, the token `$$N` expands into the name of the data item that uses this storage class.

- 9 Apply the storage class `myGetSet` from your package to a data item. For example, create a `myPackage.Parameter` object in the base workspace.

```

myParam = myPackage.Parameter(15.23);
myParam.CoderInfo.StorageClass = 'Custom';
myParam.CoderInfo.CustomStorageClass = 'myGetSet';

```

- 10 Use the object to set a parameter value in your model. When you generate code, the code algorithm accesses the parameter through the functions that you specified. The code uses an `#include` directive to include the header file that you specified.

## Access Scalar and Array Data Through Macro Instead of Function Call

If you implement the `get` mechanism for scalar or array data as a macro instead of a function, you can generate code that omits parentheses when reading that data.

- For scalar data, your macro must yield the scalar value.
- For array data, your macro must yield the starting memory address.

Create your own `AccessFunction` storage class by using the Custom Storage Class Designer, as described in “Specify Header File or Function Naming Scheme for Data Items” on page 37-39. In the Designer, on the **Access Function Attributes** tab, select **Get data through macro (omit parentheses)**.

## GetSet Storage Class Restrictions

- GetSet does not support complex signals.
- Multiple data in the same model cannot use the same `GetFunction` or `SetFunction`.
- Some blocks do not directly support GetSet.
- Custom S-functions do not directly support GetSet.

To use GetSet with an unsupported block or a custom S-function:

- 1 Insert a Signal Conversion block at the output of the block or function.
- 2 In the Signal Conversion block dialog box, select **Exclude this block from 'Block reduction' optimization**.
- 3 Assign the storage class `GetSet` to the output of the Signal Conversion block.

## Access Data Through Functions by Using Storage Classes in Embedded Coder Dictionary

To replace the direct access to data in the generated code with your own or legacy functions that read and write data in a customized way, you can enable function access on your storage classes. You create these storage classes in the Embedded Coder Dictionary. Root-level inports, root-level outports, and model parameters that use your storage class appear in the generated code as calls to specified functions. You provide the function declarations and definitions in separate header and source files pointed to by the storage class.

### Access Legacy Data by Value

You can define and apply a storage class to root-level inports, root-level outports, and model parameters so they can be accessed by customizable `get` and `set` functions. Such customization can be useful, for example, to abstract layers of software, gain access to data from an external file or to control access to critical sections of code.

This example shows how to set up a storage class in the Embedded Coder Dictionary and map the storage class to root-level inports/outports and model parameters in the Code Mappings editor.

- 1 Open example model `rtwdemo_roll`. In the MATLAB command window, run this command:

```
addpath(fullfile(docroot, 'toolbox', 'ecoder', 'examples'))
```

Running the preceding command gives you these supporting files required for the example that define the `get` and `set` functions:

- `rtwdemo_roll_Value.h`
- `rtwdemo_roll_Value.c`
- `rtwdemo_roll_Pointer.h`
- `rtwdemo_roll_Pointer.c`

Save these files to your local path.

- 2 In the Apps gallery, under **Code Generation**, click **Embedded Coder**.
- 3 To open the Embedded Coder Dictionary, on the **C Code** tab, click **Code Interface > Embedded Coder Dictionary**.
- 4 On the left pane, click **Storage Class**.
- 5 The `rtwdemo_roll` model has two storage classes: `SignalStruct` and `ParamStruct`. They are already created by using the **Create** button. This example uses these storage classes. You can perform the following steps for a storage class that you create as well.
- 6 For the `SignalStruct` storage class, in the **Property Inspector** pane, update these property values:

- **Data Access** to `Function`
- **Header File** to `$R_Value.h`

Make sure that **Access Mode** is set to `Value`. **Data Scope** is set to `Imported` by default and cannot be changed.

The screenshot shows the Embedded Coder interface. The top window is the 'CODER DICTIONARY' with a 'Save' button and a 'View Model' button. Below it is a tree view with categories: General, Functions (with a sub-item 'Function Customization Template'), Memory (with sub-items 'Storage Class' and 'Memory Section'). The main area is a table of storage classes:

BitField	Simulink
Const	Simulink
Volatile	Simulink
ConstVolatile	Simulink
Define	Simulink
ImportedDefine	Simulink
ExportToFile	Simulink
ImportFromFile	Simulink
FileScope	Simulink
Localizable	Simulink
Struct	Simulink
GetSet	Simulink
CompilerFlag	Simulink
Reusable	Simulink
Multinstance	Simulink
SignalStruct	rtwdemo_roll
ParamStruct	rtwdemo_roll

Below the table are 'Manage Packages' and 'Create' buttons. To the right is the 'Property Inspector' for 'SignalStruct':

- Name: SignalStruct
- Description: A multi-instance storage class for signals. This is an exa
- Data Access: Function
- File Placement: (empty)
- Data Scope: Imported
- Header File: \$R\_value.h
- Access Function: (empty)
- Access Mode: Value

At the bottom is the 'Pseudocode Preview' window, showing code for single-instance data and multi-instance data. The multi-instance data tab is active, showing:

```

Type definition:
typedef struct {
 ...
 FIELDTYPE FIELDNAME;
 ...
} MODELNAME_Signals_T;

Declaration: imported from file: "MODELNAME_value.h"
extern MODELNAME_Signals_T MODELNAME_Signals;

Get Function:
DATATYPE get_DATANAME();

Set Function:
void set_DATANAME(const DATATYPE DATANAME);

```

For the ParamStruct storage class, in the **Property Inspector** pane, update these property values:

- **Data Access** to Function
- **Header File** to \$R\_Value.h

These properties are already set:

- **Access Mode** to Value
- **Data Initialization** to Static

Storage classes used for parameters can have **Data Initialization** set to Auto, Static, or None.

- 7 Open the Configuration Parameters dialog box. In the toolstrip, on the **C Code** tab, click **Settings**. Select **Code Generation** > **Custom Code** > **Code information** > **Source files** and specify:

rtwdemo\_roll\_Value.c

- 8 In the Embedded Coder app, open the Code Mappings editor. On the **Data Defaults** tab, map these model element categories:

- **Inports** to SignalStruct
- **Outports** to SignalStruct
- **Model parameters** to ParamStruct

Data Defaults		Function Defaults	Functions	Inports	Outports	Parameters	Data Stores	Signals/States	
Model Element Category		Storage Class							
▼	Inports and Outports								
	<input type="radio"/>	Inports						SignalStruct	
	<input checked="" type="radio"/>	Outports						SignalStruct	
>	Signals								
▼	Parameters								
	<input type="checkbox"/>	Model parameter arguments						Default	
	<input checked="" type="checkbox"/>	Model parameters	Prefer inlined parameters					ParamStruct	
	<input type="checkbox"/>	External parameter objects	Prefer inlined parameters					Default	

## 9 Build the model and generate code.

In the generated code, view the file `rtwdemo_roll.c`. The model `step` function uses the specified `get` and `set` functions to execute the algorithm. The generated code accesses the legacy data by calling the custom, handwritten `get` and `set` functions. For example, here is the code snippet for the `HDG_Ref` inport:

```
if (get_HDG_Mode()) {
 /* Outputs for Atomic SubSystem: '<Root>/HeadingMode' */
 rtb_Sum1 = (get_HDG_Ref() - get_Psi()) * 0.015F * get_TAS();

 /* End of Outputs for SubSystem: '<Root>/HeadingMode' */
} else {
 /* Outputs for Atomic SubSystem: '<Root>/RollAngleReference' */
 if ((real32_T)fabs(get_Turn_Knob()) >= 3.0F) {
 rtb_Sum1 = get_Turn_Knob();
 }
}
```

You can generate code that calls your custom `get` and `set` functions if the functions that you write accept and return the expected values.

## Access Legacy Data by Pointer

To access data using a pointer, follow all the preceding steps but make these changes:

- In the Embedded Coder Dictionary, for storage classes `SignalStruct` and `ParamStruct`, specify:
  - **Access Mode** to Pointer
  - **Header File** to `$R_Pointer.h`
- Select **Configuration Parameters > Code Generation > Custom Code > Code information > Source files** and replace `rtwdemo_roll_Value.c` with:

```
rtwdemo_roll_Pointer.c
```

With the pointer access, a `get` function now returns a pointer whose value must be dereferenced with the `*` before use. For example, the generated code for the HDG\_Ref inport now looks like this code:

```
if (*get_HDG_Mode()) {
 /* Outputs for Atomic SubSystem: '<Root>/HeadingMode' */
 rtb_Sum1 = (*get_HDG_Ref() - *get_Psi()) * 0.015F * *get_TAS();

 /* End of Outputs for SubSystem: '<Root>/HeadingMode' */
} else {
 /* Outputs for Atomic SubSystem: '<Root>/RollAngleReference' */
 if ((real32_T)fabs(tmp_1) >= 3.0F) {
 rtb_Sum1 = tmp_1;
 }
}
```

Creating your own storage class in Embedded Coder Dictionary gives you the flexibility of customizing function names and return types. You can also use the storage class `GetSet` to access data through `get` and `set` functions. For more information, see “Access Data Through Functions with Storage Class `GetSet`” on page 37-25.

- “Access Structured Data Through a Pointer That External Code Defines” on page 37-10

## Integrate External Application Code with Code Generated from PID Controller

This example shows how to generate C code from a control algorithm model and integrate that code with existing, external application code. In the complete application, which consists of three modules, the algorithm module must exchange data with other modules through global variables. In the example, you configure the generated code to interact with existing external variables, resemble the external code in appearance and organization, and conform to specific coding requirements.

### Inspect External Code

Set your current folder to a writable location.

Copy the script `prepare_ext_code` to your current folder and run the script. The script copies external code files into several folders.

```
try
copyfile(fullfile(matlabroot, 'examples', 'ecoder', 'main', 'prepare_ext_code.m'), ...
 'prepare_ext_code.m', 'f');
catch
end
run('prepare_ext_code.m');
```

In your current folder, open `ext_code_main.c`. This application code represents an embedded system with a trivial scheduling algorithm (a `while` loop) and three modules whose algorithms run in every execution cycle: `ex_ext_inputs_proc`, `ex_ext_ctrl_alg`, and `ex_ext_outputs_proc`.

```
type('ext_code_main.c')
```

In the shared folder, inspect `ex_ext_projTypes.h`. The file defines two custom data types (typedef) that the data in the modules use.

```
type(fullfile('shared', 'ex_ext_projTypes.h'))
```

In the `io_drivers` folder, inspect `ex_sensor_accessors.c`. This file defines functions, `get_fromSensor_flow` and `get_fromSensor_temp`, that return raw data recorded by a flow sensor and a temperature sensor. For this example, the functions return trivial sinusoidal stimuli for the control algorithm.

```
type(fullfile('io_drivers', 'ex_sensor_accessors.c'))
```

In the `ex_ext_inputs_proc` folder, inspect `ex_ext_inputs_proc.c`. The `ex_ext_inputs_proc` module reads the sensor data (by calling the accessor functions), filters the data, and stores it in two global variables, `PROC_INPUT_FLOW` and `PROC_INPUT_TEMP`. These global variables are defined in the file `ex_ext_proc_inputs.c` and declared in `ex_ext_proc_inputs.h`.

```
type(fullfile('ex_ext_inputs_proc', 'ex_ext_inputs_proc.c'))
```

The filter algorithm in this module and the algorithms in the other two modules require state data, which must persist between execution cycles of the application. Each module stores relevant state data as global variables. For example, in the `ex_ext_inputs_proc` module, `ex_ext_inputs_proc.c` defines these variables:

- `flowFilterIn_state_data`

- `tempFilterIn_state_data`
- `flowFilterIn_tmp_data`
- `tempFilterIn_tmp_data`

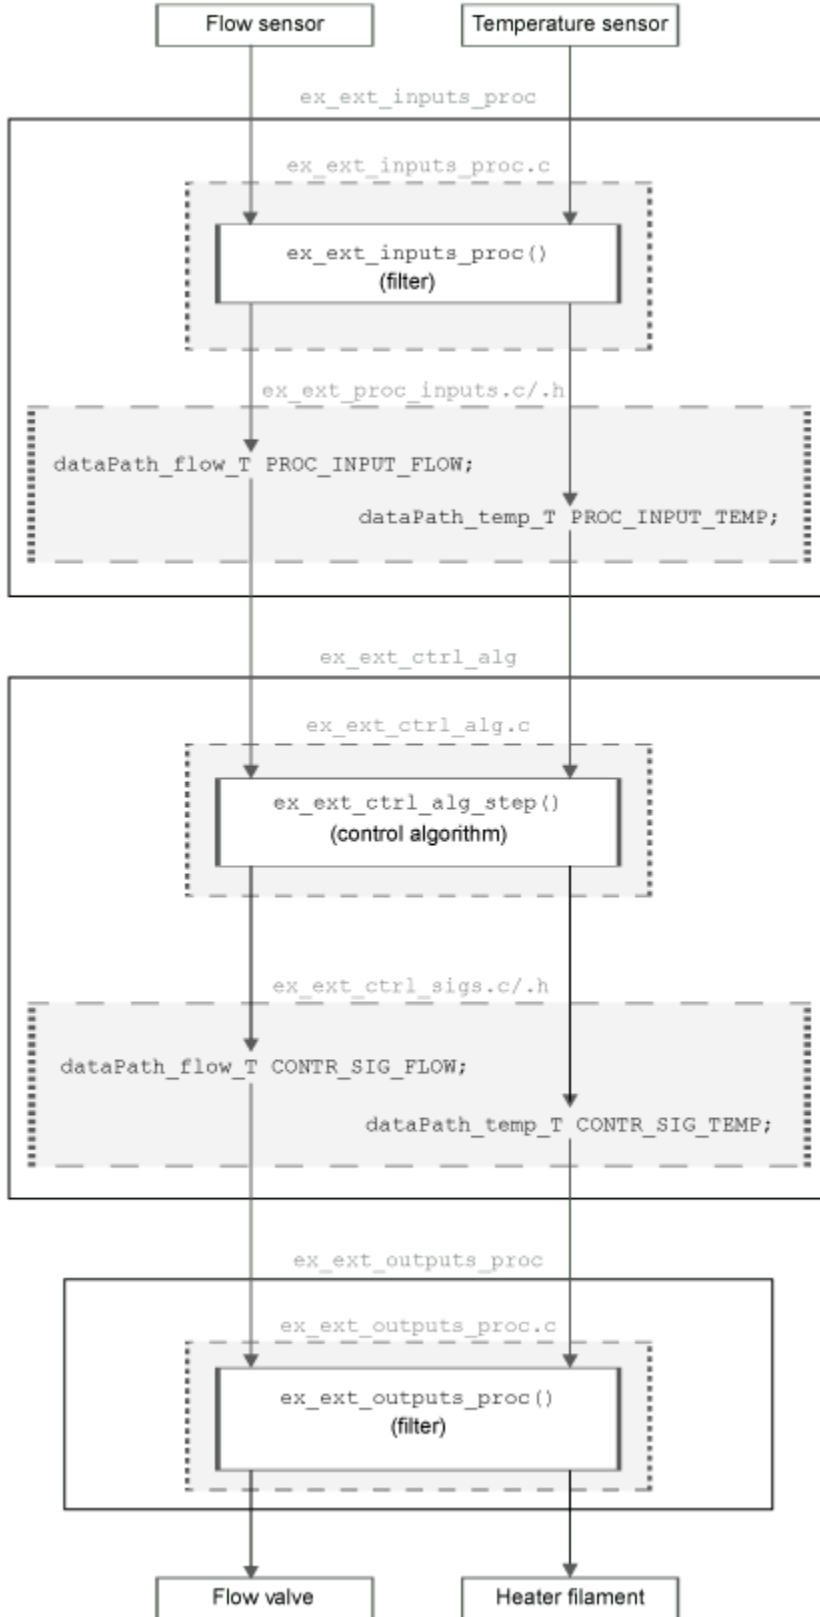

The empty `ex_ext_ctrl_alg` folder is a placeholder for the generated code. The `ex_ext_ctrl_alg` module must perform PID control on the filtered flow and temperature measurements. Later, you examine the requirements for this code, which are based on the code in the other modules.

In the `ex_ext_outputs_proc` folder, inspect `ex_ext_outputs_proc.c`. This module reads the PID output signals from global variables named `CONTR_SIG_FLOW` and `CONTR_SIG_TEMP`. The `ex_ext_ctrl_alg` module (the generated code) must define these variables. The `ex_ext_outputs_proc` module then filters these signals and passes the filtered values to functions that represent device drivers for actuators (for example, a valve and a heater filament).

```
type(fullfile('ex_ext_outputs_proc', 'ex_ext_outputs_proc.c'))
```

The actuator functions are defined in the `io_drivers` folder in the file `ex_actuator_accessors.c`.

The figure shows the intended flow of data through the system. The figure also shows the code files that define and declare the data (global variables) that cross the module boundaries.

## Inspect Simulink Model and Determine Requirements for Generated Code

Open the example model `ex_ext_ctrl_alg`.

```
open_system('ex_ext_ctrl_alg')
```

The blocks in the model implement the required PID control algorithm. The model uses default code generation settings for an ERT-based system target file (`ert.tlc`).

To complete the application by performing the function of the `ex_ext_ctrl_alg` module, the code generated from this model must:

- Use the custom data types `dataPath_flow_T` and `dataPath_temp_T` from the external file `ex_ext_projTypes.h`.
- Read filtered sensor data from the global variables `PROC_INPUT_FLOW` and `PROC_INPUT_TEMP`. The generated code must not define these variables because the module `ex_ext_inputs_proc` defines them, declaring them in `ex_ext_proc_inputs.h`.
- Write PID control signals to global variables named `CONTR_SIG_FLOW` and `CONTR_SIG_TEMP`. The generated code must define these variables and declare them in a file named `ex_ext_ctrl_sigs.h`. Then, the `ex_ext_outputs_proc` module can read the raw control signals from them.
- Conform to variable naming standards that govern the external application. For example, the generated code must store state data in global variables whose names end in `_data`. In addition, for this example, the names of local function variables must end in `_local`.
- Conform to standards that govern the organization of the code in each of the external files. For example, each file contains sections, delimited by comments, that aggregate similar code constructs such as type definitions, variable declarations, and function definitions.

So that you and others can interact with the control algorithm during execution, for this example, you also configure the generated code to define and declare `const` global variables named `PARAM_setpoint_flow` and `PARAM_setpoint_temp`, which represent the PID controller setpoints. The definitions must appear in a file named `ex_ext_ctrl_params.c` and the declarations must appear in a file named `ex_ext_ctrl_params.h`.

## Configure Model to Use Custom Data Types

Set your current folder to the shared folder.

Use the function `Simulink.importExternalCTypes` to generate `Simulink.AliasType` objects that represent the custom data types `dataPath_flow_T` and `dataPath_temp_T`.

```
cd('shared')
Simulink.importExternalCTypes('ex_ext_projTypes.h');
```

The objects appear in the base workspace.

In the `ex_ext_ctrl_alg` model, on the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, for the Inport block that represents `PROC_INPUT_FLOW`, set **Data Type** to `dataPath_flow_T`.

For the Inport block that represents `PROC_INPUT_TEMP`, set **Data Type** to `dataPath_temp_T`.

Select the **Signals** tab.

In the model, select the output signal of each Constant block. In the Model Data Editor, set **Data Type** to **Inherit: Inherit via back propagation**. With this setting, each Constant block inherits its output data type from the block immediately downstream, in this case, a Sum block.

Alternatively, to configure the data types, at the command prompt, use these commands.

```
set_param('ex_ext_ctrl_alg/In1','OutDataTypeStr','dataPath_flow_T')
set_param('ex_ext_ctrl_alg/In2','OutDataTypeStr','dataPath_temp_T')
set_param('ex_ext_ctrl_alg/Flow Setpt','OutDataTypeStr',...
 'Inherit: Inherit via back propagation')
set_param('ex_ext_ctrl_alg/Temp Setpt','OutDataTypeStr',...
 'Inherit: Inherit via back propagation')
```

Update the block diagram. The diagram shows that, due to data type inheritance and propagation, signals in the model use a custom data type.

### Configure Interface Data

Configure the model to generate code that accesses and defines the correct global variables such as PROC\_INPUT\_FLOW and CONTR\_SIG\_TEMP.

In the Model Data Editor, select the **Inports/Outports** tab and set the **Change view** drop-down list to **Code**.

Select the rows that correspond to the two Inport blocks.

For either row, set **Storage Class** to **ImportFromFile** and **Header File** to `ex_ext_proc_inputs.h`. With the storage class **ImportFromFile**, each Inport block appears in the generated code as a global variable. However, the generated code does not define the variable, instead including (`#include`) the variable declaration from `ex_ext_proc_inputs.h`.

For the rows that correspond to the Outport blocks, set:

- **Storage Class** to **ExportToFile**
- **Header file** to `ex_ext_ctrl_sigs.h`
- **Definition File** to `ex_ext_ctrl_sigs.c`

With **ExportToFile**, the generated code defines the global variable.

Alternatively, to configure the signals, at the command prompt, use these commands.

```
temp = Simulink.Signal;
temp.CoderInfo.StorageClass = 'Custom';
temp.CoderInfo.CustomStorageClass = 'ImportFromFile';
temp.CoderInfo.CustomAttributes.HeaderFile = 'ex_ext_proc_inputs.h';

portHandles = get_param('ex_ext_ctrl_alg/In1','portHandles');
outportHandle = portHandles.Output;
set_param(outportHandle,'SignalObject',copy(temp))

portHandles = get_param('ex_ext_ctrl_alg/In2','portHandles');
outportHandle = portHandles.Output;
set_param(outportHandle,'SignalObject',copy(temp))

temp.CoderInfo.CustomStorageClass = 'ExportToFile';
temp.CoderInfo.CustomAttributes.HeaderFile = 'ex_ext_ctrl_sigs.h';
```

```
temp.CoderInfo.CustomAttributes.DefinitionFile = 'ex_ext_ctrl_sigs.c';

set_param('ex_ext_ctrl_alg/Out1', 'SignalObject', copy(temp))
set_param('ex_ext_ctrl_alg/Out2', 'SignalObject', copy(temp))
```

To apply a storage class to a block parameter, such as the **Constant value** parameter of a Constant block, you must create a parameter object such as `Simulink.Parameter`. You can use the Model Data Editor to create parameter objects.

Select the **Parameters** tab and set **Change view** to Design.

In the model, select the Constant block labeled Flow Setpt.

In the Model Data Editor, set **Value** to `PARAM_setpoint_flow`.

Next to `PARAM_setpoint_flow`, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(3)`.

Set **Location** to Model Workspace and click **Create**.

In the `PARAM_setpoint_flow` property dialog box, set **Storage class** to `Const`.

Set **HeaderFile** to `ex_ext_ctrl_params.h` and **DefinitionFile** to `ex_ext_ctrl_params.c`.

For the other Constant block, use the Model Data Editor to create a `Simulink.Parameter` object named `PARAM_setpoint_temp` with value 2.

Alternatively, to configure the blocks, at the command prompt, use these commands.

```
PARAM_setpoint_flow = Simulink.Parameter(3);
PARAM_setpoint_flow.CoderInfo.StorageClass = 'Custom';
PARAM_setpoint_flow.CoderInfo.CustomStorageClass = 'Const';
PARAM_setpoint_flow.CoderInfo.CustomAttributes.HeaderFile = 'ex_ext_ctrl_params.h';
PARAM_setpoint_flow.CoderInfo.CustomAttributes.DefinitionFile = 'ex_ext_ctrl_params.c';

PARAM_setpoint_temp = copy(PARAM_setpoint_flow);
PARAM_setpoint_temp.Value = 2;

mdlwks = get_param('ex_ext_ctrl_alg', 'ModelWorkspace');
assignin(mdlwks, 'PARAM_setpoint_flow', copy(PARAM_setpoint_flow))
assignin(mdlwks, 'PARAM_setpoint_temp', copy(PARAM_setpoint_temp))

set_param('ex_ext_ctrl_alg/Flow Setpt', 'Value', 'PARAM_setpoint_flow')
set_param('ex_ext_ctrl_alg/Temp Setpt', 'Value', 'PARAM_setpoint_temp')

clear temp PARAM_setpoint_flow PARAM_setpoint_temp mdlwks portHandles outportHandle
```

### Configure Internal Data

In the external code, internal data that does not participate in the module interfaces, such as state data and local variables in functions, conform to naming schemes. In the model, configure internal data that appears in the generated code to mimic these naming schemes.

In the model Configuration Parameters dialog box, inspect the **Code Generation > Identifiers** pane. When you specify values for the naming schemes under **Identifier format control**:

- $\$R$  represents the name of the model, `ex_ext_ctrl_alg`.
- $\$N$  represents the name of each model element to which the scheme applies, such as a signal, block state, or standard data structure.
- $\$M$  represents name-mangling text that the code generator inserts, if necessary, to avoid name clashes. For most naming rules, this token is required.

Set **Global variables** to  $\$R\$N\_data\$M$ . This setting controls the names of global variables, such as those that represent state data. The naming scheme  $\$R\$N\_data\_\$M$  most closely approximates the scheme that the state variables in the external code use.

Set **Local temporary variables** and **Local block output variables** to  $\$N\_local\$M$ .

Alternatively, to set the configuration parameters, at the command prompt, use these commands.

```
set_param('ex_ext_ctrl_alg', 'CustomSymbolStrGlobalVar', 'RN_data$M')
set_param('ex_ext_ctrl_alg', 'CustomSymbolStrTmpVar', 'N_localM')
set_param('ex_ext_ctrl_alg', 'CustomSymbolStrBlkIO', 'N_localM')
```

Configure the state data in the model to appear in the generated code as separate global variables instead of fields of the standard DWork structure. Enable the Code perspective. In the Apps gallery, click **Embedded Coder**.

Underneath the block diagram, under **Code Mappings > Data Defaults**, for the **Internal data** row, in the **Storage Class** column select `ExportedGlobal`.

Alternatively, to configure this default storage class, use these commands at the command prompt:

```
coder.mapping.create('ex_ext_ctrl_alg');
coder.mapping.defaults.set('ex_ext_ctrl_alg', 'InternalData', ...
 'StorageClass', 'ExportedGlobal');
```

### Configure Organization of Code in Each Generated File

Set your current folder to the `ex_ext_ctrl_alg` folder.

```
cd(fullfile('.', 'ex_ext_ctrl_alg'))
```

At the command prompt, navigate to the folder that contains the built-in code generation template `ert_code_template.cgt`. By default, when you generate code with the system target file `ert.tlc`, this template governs the organization and, in part, the appearance of the code in each generated file.

```
currentFolder = pwd;
cd(fullfile(matlabroot, 'toolbox', 'rtw', 'targets', 'ecoder'))
```

Copy the `ert_code_template.cgt` file to your clipboard.

Return to the `ex_ext_ctrl_alg` folder. To avoid overwriting your clipboard, instead of using the command prompt to navigate to the folder, you can use the **Back** button in MATLAB®.

```
cd(currentFolder)
clear currentFolder
```

Paste the file into the `ex_ext_ctrl_alg` folder. Rename the file as `ex_my_code_template.cgt`.

Open the file and replace the contents with this code.

```
type(fullfile(matlabroot, 'examples', 'ecoder', 'data', 'ex_my_code_template.cgt'))
```

This new template conforms more closely to the organization of the external files. For example, the template organizes similar code constructs into named sections (delimited by comments) and, at the top of the template, specifies only minimal information about each generated file.

In the model, select **Configuration Parameters > Code Generation > Templates**.

Under **Code templates** and **Data templates**, set the four configuration parameters to `ex_my_code_template.cgt`.

Alternatively, to copy the file and set the parameters, at the command prompt, use these commands.

```
copyfile(fullfile(matlabroot, 'examples', 'ecoder', 'data', 'ex_my_code_template.cgt'), ...
 'ex_my_code_template.cgt', 'f')
set_param('ex_ext_ctrl_alg', 'ERTSrcFileBannerTemplate', 'ex_my_code_template.cgt')
set_param('ex_ext_ctrl_alg', 'ERTHdrFileBannerTemplate', 'ex_my_code_template.cgt')
set_param('ex_ext_ctrl_alg', 'ERTDataSrcFileTemplate', 'ex_my_code_template.cgt')
set_param('ex_ext_ctrl_alg', 'ERTDataHdrFileTemplate', 'ex_my_code_template.cgt')
```

### Generate and Inspect Code

Because the external code already defines a main function, select **Configuration Parameters > Generate code only** and clear **Configuration Parameters > Generate an example main program**.

```
set_param('ex_ext_ctrl_alg', 'GenCodeOnly', 'on')
set_param('ex_ext_ctrl_alg', 'GenerateSampleERTMain', 'off')
```

Generate code from the model.

```
slbuild('ex_ext_ctrl_alg')
```

In the code generation report, inspect the generated files. The code meets the requirements. For example, `ex_ext_ctrl_sigs.c` defines the control output signals, `CONTR_SIG_FLOW` and `CONTR_SIG_TEMP`.

```
file = fullfile('ex_ext_ctrl_alg_ert_rtw', 'ex_ext_ctrl_sigs.c');
rtwdemodbtype(file, 'dataPath_flow_T CONTR_SIG_FLOW;', ...
 'dataPath_temp_T CONTR_SIG_TEMP;', 1, 1)
```

The setpoint parameters appear in `ex_ext_ctrl_params.c`.

```
file = fullfile('ex_ext_ctrl_alg_ert_rtw', 'ex_ext_ctrl_params.c');
rtwdemodbtype(file, 'const dataPath_flow_T PARAM_setpoint_flow = 3.0;', ...
 'const dataPath_temp_T PARAM_setpoint_temp = 2.0;', 1, 1)
```

The file `ex_ext_ctrl_alg.c` defines global variables to store state data. The variables follow the naming scheme that you specified. Code is similar to the following:

```
dataPath_temp_T ex_ext_Integrator_DSTATE_datag;
dataPath_flow_T ex_ext_c_Integrator_DSTATE_data;
dataPath_temp_T ex_ext_ctrl_Filter_DSTATE_datad;
dataPath_flow_T ex_ext_ctrl_Filter_DSTATE_data;
```

In the same file, the model execution function, `ex_ext_ctrl_alg_step`, creates local function variables to store temporary calculations. The variables follow the naming scheme that you specified. Code is similar to the following:

```
dataPath_flow_T Diff_local;
dataPath_flow_T FilterCoefficient_local;
dataPath_temp_T Diff1_local;
dataPath_temp_T FilterCoefficient_local1;
```

Some of the global and local variable names contain extra mangling characters that prevent name clashes. These extra characters correspond to the  $\$M$  token that you specified in the naming schemes.

The generated code files are in the generated folders `ex_ext_ctrl_alg_ert_rtw` and `slprj`. You must configure file management systems and build tools to use these folders and files.

## Configure Generated Code According to Interface Control Document Specifications

This example shows how to configure code generation settings for a model according to specifications in an interface control document (ICD). The example also shows how to store shared Simulink® variables and data objects in a data dictionary.

An ICD describes the data interface between software components. To exchange and share data, the components declare and define global variables that store signal and parameter values according to the ICD. The ICD names the variables and lists characteristics such as data type, physical units, and parameter values. When you create component models in Simulink, you can configure the models such that the generated code conforms to the ICD. For example, you can use the ICD as a reference source while configuring models interactively or you can automate configuration by using a script to import data from an ICD.

### Explore Interface Control Document

In Microsoft® Excel® or another compatible program, open the `ex_ICD_PCG.xlsx` workbook and review the contents of the worksheets.

open `ex_ICD_PCG.xlsx`

- **Signals worksheet.** Each row represents a signal that crosses the interface boundary. Inspect the cell values in the worksheet. The `Owner` column identifies the name of the component that allocates memory for a signal. The `DataType` column names the signal data type in memory. For example, the worksheet uses the expression `Bus: EngSensors` to name the structure type `EngSensors`.
- **Parameters worksheet.** The `Value` column lists the value of each parameter. If the value of a parameter is nonscalar, the value is stored in its own separate worksheet, which has the same name as the parameter.
- **Numeric Types worksheet.** Each row represents a named numeric data type. In this ICD, the data uses fixed-point data types (Fixed-Point Designer). The `IsAlias` column indicates whether the C code uses the name of the data type (for example, `s16En3`) or uses the name of the primitive integer data type that corresponds to the word length (such as `short`). The `DataScope` column indicates whether the generated code exports or imports the data type definition.
- **Structure Types worksheet.** Each row represents a structure type or a field of a structure type. For structure types, the value in the `DataType` column is `struct`. Subsequent rows that do not use `struct` represent fields of the preceding structure type. This ICD defines structure type, `EngSensors`, with four fields: `throttle`, `speed`, `ego`, and `map`.
- **Enumerated Types worksheet.** Similar to the Structure Types worksheet, each row represents an enumerated type or an enumeration member. This ICD defines enumerated type `sldemo_FuelModes`.

### Explore External Code

Some data items in the ICD belong to `other_component`, which is a component that exists outside of MATLAB®. Open and explore the content of these example files, which define and declare the external data:

```
edit ex_inter_types.h
edit ex_inter_sigs.c
edit ex_inter_sigs.h
```

## Explore Example Model

In this example, you generate code from the controller model `rtwdemo_fuelsys_dd_controller`. Open your copy of the model.

```
open_system('rtwdemo_fuelsys_dd_controller')
```

Some signals in the controller model have names, for example, the input signal `sensors`. Some block parameters in the model refer to `Simulink.Parameter` objects in a data dictionary. For example, in the `airflow_calc` subsystem, the `Pumping Constant` block uses the parameter objects `PumpCon`, `SpeedVect`, and `PressVect`. These parameter objects set the values of the corresponding block parameters. You can apply code generation settings to the signals and parameter objects.

The controller model is linked to data dictionary `rtwdemo_fuelsys_dd_controller.sldd`. Explore the data dictionary.

- 1 In the lower-left corner of the controller model, click the model data badge.
- 2 Click the **External Data** link.
- 3 In the Model Explorer **Model Hierarchy** pane, expand the nodes **rtwdemo\_fuelsys\_dd\_controller**, **External data**, and **rtwdemo\_fuelsys\_dd\_controller**.
- 4 Select **Design Data**.

The dictionary stores:

- Parameter objects
- `Simulink.NumericType` objects, such as `u8En7`
- `Simulink.Bus` object, `EngSensors`

## Configure Model Design Data According to ICD

- 1 Open the ICD spreadsheet, if not open already.
- 2 In the Simulink Editor window for the controller model, navigate to the root level of the model.
- 3 On the **Modeling** tab, click **Model Data Editor**.
- 4 In the Model Data Editor, click the **Change scope** button. The Model Data Editor shows information about data items in the model subsystems.
- 5 Click the **Show/refresh additional information** button. The Model Data Editor shows information about data objects (the `Simulink.Parameter` objects in the data dictionary) that the model uses.

## Configure Design Settings for Signals

- 1 In the ICD, click the **Signals** tab.
- 2 In the Model Data Editor, click the **Inports/Outports** tab.
- 3 Make sure that the configuration settings for Inport block `sensors` match the ICD specification. **Data Type** must be set to `Bus: EngSensors`.
- 4 Make sure that the configuration settings for Outport block `fuel_rate` match the ICD specification. **Data Type** must be set to `s16En7`. **Min** must be set to `0.8000`. **Max** must be set to `1.7000`. **Unit** must be set to `g/s`.
- 5 Make sure that the configuration settings for signal `fuel_mode` match the ICD specification. Because `fuel_mode` is an output signal of a Stateflow® chart, you must use Model Explorer to

configure the design settings. In the model, navigate into the Stateflow chart. Open Model Explorer. In the Model Explorer **Contents** pane (the middle pane), select `fuel_mode`. **Data Type** must be set to `Enum:sld_FuelModes`.

### Configure Design Settings for Parameters

- 1 In the ICD, click the **Parameters** tab.
- 2 Navigate to the root level of the control model.
- 3 In the Model Data Editor, click the **Parameters** tab.
- 4 Use the **Filter contents** box to search for parameter `PressEst`. The Model Data Editor shows two rows: one row that corresponds to parameter object `PressEst` and one row that corresponds to the block parameter that uses `PressEst`.
- 5 Make sure that the configuration settings for parameter `PressEst` match the ICD specification. **Data Type** must be `u8En7`. **Value** must be a 19x45 matrix of numeric values.
- 6 Make sure that the **Data Type** and **Value** settings for parameters `PumpCon`, `SpeedEst`, `ThrotEst`, and `RampRateKiz` match the ICD specification.

### Configure Design Settings for Numeric Types

- 1 In the ICD, click the **Numeric Types** tab.
- 2 If the Model Explorer is not open, open it.
- 3 In the **Model Hierarchy** pane, navigate to the design data in the data dictionary for the controller model (`rtwdemo_fuelsys_dd_controller`> **External Data**>`rtwdemo_fuelsys_dd_controller`>**Design Data**).
- 4 In the **Contents** (middle) pane, select the `Simulink.NumericType` object `u8En7`. This object represents one of the typedef statements in `ex_inter_types.h`.
- 5 In the right pane, on the **Design** tab, confirm that the setting for **Data type mode** aligns with the ICD specification.
- 6 Make sure that the design configuration for numeric types `s16En3`, `s16En7`, and `s16En15` matches the ICD specification.

### Configure Design Settings for Structures

- 1 In the ICD, click the **Structure Types** tab.
- 2 In the Model Explorer **Contents** pane, select `EngSensors`. This `Simulink.Bus` object represents the structure type defined in `ex_inter_types.h`.
- 3 Confirm that the data type configuration aligns with the ICD specification. In the right pane, on the **Design** tab, or in the Bus Editor, adjust the bus signal configurations (for example, settings for **Min** and **Max**) to align with the ICD specification.

### Configure Design Settings for Enumerated Types

- 1 In the ICD, click the **Enumerated Types** tab.
- 2 Open the file `sld_FuelModes.m`, which defines the class for the enumerated type `sld_FuelModes`.
- 3 Confirm that the class definition aligns with the ICD specification. In the file `sld_FuelModes.m`, adjust member names and underlying integer values to align with the ICD specification.

## Configure Model for Code Generation According to ICD

- 1 Open the ICD spreadsheet, if not open already.
- 2 Open the Embedded Coder app.

## Configure Code Generation Settings for Inport and Outport Blocks

- 1 In the ICD, click the **Signals** tab. The Owner column in the ICD implies that a different component (`other_component`), not `rtwdemo_fuelsys_dd_controller`, provides the code definition of the `sensors` variable.
- 2 Include the C source code file that defines the variable `sensors`. In the Simulink Editor, on the C Code tab, select **Settings** > **C/C++ Code generation settings**. Make sure that the code generation custom code parameter **Source files** is set to `ex_inter_sigs.c`.
- 3 In the Simulink Editor, on the **C Code** tab, select **Code Interface** > **Individual Element Code Mappings**.
- 4 In the Code Mappings editor, click the **Inports** tab.
- 5 Select the row for `sensors`. Because the source code definition is provided in the external file `ex_inter_sigs.c`, which you configured in step 2, **Storage class** must be set to `ImportFromFile`.
- 6 Click the  icon. Check that the **HeaderFile** property setting matches the ICD specification, `ex_inter_sigs.h`. Make sure that a value is specified for the **Identifier** property. This property specifies the variable name for the data element in the generated code.
- 7 In the Code Mappings editor, click the **Outports** tab.
- 8 Select the row for `fuel_rate`. Because the ICD specifies `rtwdemo_fuelsys_dd_controller` as the owner of `fuel_rate`, **Storage Class** must be set to `ExportToFile`.
- 9 Click the  icon. Make sure that the settings for properties **HeaderFile**, **DefinitionFile**, and **Owner** match the ICD specifications `global_data.h`, `signals.c`, and `rtwdemo_fuelsys_dd_controller`, respectively. Make sure that a value is specified for the **Identifier** property.

## Configure Code Generation Settings for Signals

- 1 In the Code Mappings editor, click the **Signals/States** tab. The third signal listed on the **Signals** tab of the ICD is `fuel_mode`.
- 2 Add the `fuel_mode` signal to the model code mappings. In the model diagram, select signal `fuel_mode`. Place your cursor on the ellipsis that appears above or below the signal line to open the action bar. Click the **Add selected signals to code mappings** button. In the Code Mappings editor, the **Signals** node expands and lists the signal that you added. The Storage Class setting must indicate that the signal resolves to a signal object and that the storage class for the object is set to `ExportToFile`. Because the signal is associated with a signal object, you must use the Model Explorer to confirm that the code generation configuration aligns with the ICD specification.
- 3 Open the Model Explorer. In the Model Hierarchy pane, navigate to the design data in the data dictionary for the controller model (`rtwdemo_fuelsys_dd_controller` > **External Data** > `rtwdemo_fuelsys_dd_controller` > **Design Data**). In the **Contents** pane, select `fuel_mode`.
- 4 In the right pane, click the **Code Generation** tab. **Storage class** must be set to `ExportToFile`. Confirm that properties **HeaderFile**, **DefinitionFile**, and **Owner** match the ICD specifications `global_data.h`, `signals.c`, and `rtwdemo_fuelsys_dd_controller`, respectively.

### Configure Code Generation for Parameters

- 1 In the ICD, click the **Parameters** tab.
- 2 In the Code Mappings editor, click the **Parameters** tab.
- 3 Use the **Filter contents** box to search for parameter `PressEst`. The Code Mappings editor shows a row that corresponds to parameter object `PressEst`. Because the ICD specifies `rtwdemo_fuelsys_dd_controller` as the owner of `PressEst`, **Storage Class** should be set to `ExportToFile`.
- 4 Click the  icon. Check that the settings for properties **HeaderFile**, **DefinitionFile**, and **Owner** match the ICD specifications `global_data.h`, `params.c`, and `rtwdemo_fuelsys_dd_controller`, respectively. Also, make sure that a value is specified for the **Identifier** property.
- 5 Check the **Storage Class**, **HeaderFile**, **DefinitionFile**, **Identifier**, and **Owner** settings for parameters `PumpCon`, `SpeedEst`, `ThrotEst`, and `RampRateKiz`.

### Configure Code Generation for Numeric Types

- 1 In the ICD, click the **Numeric Types** tab.
- 2 If the Model Explorer is not open, open it.
- 3 In the **Model Hierarchy** pane, navigate to the design data in the data dictionary for the controller model (`rtwdemo_fuelsys_dd_controller` > **External Data** > `rtwdemo_fuelsys_dd_controller` > **Design Data**).
- 4 In the **Contents** pane, select the `Simulink.NumericType` object `u8En7`. This object represents one of the typedef statements in `ex_inter_types.h`.
- 5 In the right pane, click the **Code Generation** tab. Confirm that the settings for **Data scope** and **Header file** align with the ICD specifications, `Imported` and `ex_inter_types.h`, respectively.
- 6 Check and adjust the code generation configuration for numeric types `s16En3`, `s16En7`, and `s16En15`.

### Configure Code Generation for Structures

- 1 In the ICD, click the **Structure Types** tab.
- 2 In the Model Explorer **Contents** pane, select `EngSensors`. This `Simulink.Bus` object represents the structure type defined in `ex_inter_types.h`.
- 3 In the right pane, click the **Code Generation** tab. Confirm that the settings for **Data scope** and **Header file** align with the ICD specifications, `Imported` and `ex_inter_types.h`, respectively.

### Generate and Inspect Code

1. Generate code for the controller model.

```
slbuild('rtwdemo_fuelsys_dd_controller')

Starting build procedure for: rtwdemo_fuelsys_dd_controller
Successful completion of build procedure for: rtwdemo_fuelsys_dd_controller
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
-------	--------	----------------

```

=====
rtwdemo_fuelsys_dd_controller Code generated and compiled Code generation information file does
1 of 1 models built (0 models already up to date)
Build duration: 0h 3m 1.371s

```

2. Inspect the generated code. The generated header file `rtwdemo_fuelsys_dd_controller_types.h`:

- Includes (`#include`) the external header file `ex_inter_types.h`, which defines numeric data types `u8En7`, `s16En3`, and `s16En7` and the structure type `EngSensors`
- Defines the enumeration `sld_FuelModes`

```

file = fullfile('rtwdemo_fuelsys_dd_controller_ert_rtw',...
 'rtwdemo_fuelsys_dd_controller_types.h');
rtwdemodbtype(file,'#include "ex_inter_types.h"','} sld_FuelModes;',1,1)

#include "ex_inter_types.h"

/* Model Code Variants */
#ifndef DEFINED_TYPEDEF_FOR_sld_FuelModes_
#define DEFINED_TYPEDEF_FOR_sld_FuelModes_

typedef enum {
 LOW = 1, /* Default value */
 RICH,
 DISABLED
} sld_FuelModes;

```

The file `rtwdemo_fuelsys_dd_controller_private.h` includes the header file `ex_inter_sigs.h`. This external header file contains the extern declaration of the signal sensors, which a different software component owns.

The data header file `global_data.h` declares the exported parameters and signals that the ICD specifies. To share this data, other components can include this header file.

```

file = fullfile('rtwdemo_fuelsys_dd_controller_ert_rtw','global_data.h');
rtwdemodbtype(file,'/* Exported data declaration */',...
 'fuel_rate',1,1)

/* Exported data declaration */

/* Declaration for custom storage class: ExportToFile */
extern real32_T PressEst[855]; /* Referenced by: '<S6>/Pressure Estimation' */
extern real32_T PumpCon[551]; /* Referenced by: '<S1>/Pumping Constant' */
extern real32_T RampRateKiz[25]; /* Referenced by: '<S1>/Ramp Rate Ki' */
extern real32_T SpeedEst[1305]; /* Referenced by: '<S7>/Speed Estimation' */
extern real32_T ThrotEst[551]; /* Referenced by: '<S8>/Throttle Estimation' */
extern sld_FuelModes fuel_mode; /* '<Root>/control_logic' */
extern real32_T fuel_rate; /* '<Root>/fuel_rate' */

```

The algorithm code is in the model `step` function in the file `rtwdemo_fuelsys_dd_controller.c`. The algorithm uses the global data that the ICD identifies. For example, the algorithm uses the value of the signal `fuel_mode` in a switch block to control the flow of execution.

```

file = fullfile('rtwdemo_fuelsys_dd_controller_ert_rtw',...
 'rtwdemo_fuelsys_dd_controller.c');

```

```

rtwdemodbtype(file, '/* End of MultiPortSwitch: '<S9>/Multiport Switch' */', ...
 '/* Output: '<Root>/fuel_rate' incorporates:', 0, 0)

/* SwitchCase: '<S10>/Switch Case' */
switch (fuel_mode) {
case LOW:
 /* Outputs for IfAction SubSystem: '<S10>/low_mode' incorporates:
 * ActionPort: '<S12>/Action Port'
 */
 /* DiscreteFilter: '<S12>/Discrete Filter' incorporates:
 * DiscreteIntegrator: '<S1>/Discrete Integrator'
 */
 denAccum = rtDWork.DiscreteIntegrator_DSTATE - -0.7408F *
 rtDWork.DiscreteFilter_states_g;

bdclose('rtwdemo_fuelsys_dd_controller')
Simulink.data.dictionary.closeAll('rtwdemo_fuelsys_dd_controller.sldd', '-discard')

```

### Import ICD Specifications into Simulink

You can use a MATLAB script to import data settings from the ICD into variables in the Simulink base workspace.

1. Open and inspect the example script `ex_importICD_PCG.m`.

```
edit ex_importICD_PCG
```

The script:

- Imports the data from each worksheet of the ICD into variables in the base workspace.
- Uses the imported data to configure design and code generation properties of `Simulink.Signal` and `Simulink.Parameter` objects in the base workspace.

If the base workspace already contains a data object that corresponds to a data element in the ICD, the script configures properties of the existing object. If the object does not exist, the script creates the object.

2. Load the model and run the script.

```
load_system('rtwdemo_fuelsys_dd_controller')
run('ex_importICD_PCG')
```

3. Regenerate and inspect the code.

```
slbuild('rtwdemo_fuelsys_dd_controller')

Starting build procedure for: rtwdemo_fuelsys_dd_controller
Successful completion of build procedure for: rtwdemo_fuelsys_dd_controller
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_fuelsys_dd_controller	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 1m 36.732s

### Considerations

- When you make changes to an ICD, you can reuse your import script to reconfigure the model.
- If you use a script to import data from an ICD to the base workspace, consider migrating the data objects and variables to a data dictionary. A data dictionary permanently stores and tracks changes to data objects and variables. For example, you can import the definition of enumerated type `sld_FuelModes` into the controller model dictionary. See “Import and Export Dictionary Data” and “Enumerations in Data Dictionary”.
- You can store configuration settings for signal and state data elements, such as data types, minimum and maximum values, and physical units inside or outside of model files. `Simulink.Signal` objects store the configuration settings outside of a model file. Alternatively, you can store the configuration settings in the model file by using block and port parameters that you can access through the Model Data Editor, Property Inspector, and other dialog boxes. See “Store Design Attributes of Signals and States”.

## Generate Local Variables with Localizable Storage Class

For signals, if possible, generate variables that are local to functions rather than in global storage. Generating local variables prevents the code generator from implementing optimizations that remove these variables from the generated code. Local variables improve observability, readability, and are helpful in debugging the generated code.

Minimizing the use of global variables by using local variables interacts with stack usage control. For example, stack size can determine the number of local and global variables that the code generator can allocate in the generated code. For more information, see “Customize Stack Space Allocation”.

### Example Model

The model `rtwdemo_localizable_csc` contains two signals that have a `Localizable` storage class. In the `Latching` subsystem, the signal with the label `Latch` has a `Localizable` storage class. In the `Debug` subsystem, the signal with the label `Debug` has a `Localizable` storage class.

Copyright 2017 The MathWorks, Inc.

### Generate Code with Localizable Storage Class

- 1 Open the model.

```
model='rtwdemo_localizable_csc';
open_system(model);
```

- 2 To observe the specification, open the Code Mappings editor. On the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
- 3 On the **Signals/States** tab, expand **Signals**. The storage class for signals **Latch** and **Debug** is set to **Localizable**.
- 4 Generate and view the code. The **Debug\_b** function contains this code:

```
static void Debug_b(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T
 rtd_A[6])
{
 real_T Debug;
 int32_T i;
 for (i = 0; i < 6; i++) {
 Debug = rtu_In1[i] * rtu_In2[i];
 rtd_A[i] += Debug;
 }
}
```

The **Latching** function contains this code:

```
static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T
 rty_Out2[6], real_T rtd_A[6])
{
 real_T Latch[6];
 int32_T i;
 int32_T i_0;
 for (i = 0; i < 6; i++) {
 Latch[i] = rtd_A[i];
 rty_Out2[i] = -Latch[i];
 }

 for (i = 0; i < 6; i++) {
 rty_Out1[i] = 0.0;
 for (i_0 = 0; i_0 < 6; i_0++) {
 rty_Out1[i] += rtu_In1[6 * i_0 + i] * Latch[i_0];
 }
 }
}
```

Both functions contain variables for holding intermediate values. The **Debug\_b** function contains the variable **Debug**. The **Latching** function contains the variable **Latch**.

## Generate Code Without Localizable Storage Class

- 1 Change the signal storage class from **Localizable** to **ExportToFile**. In the Code Mappings editor, for each signal, set the storage class to **ExportToFile**.
- 2 Generate and view the code. The `rtwdemo_localizable_csc.c` file contains these two global variable declarations:

```
real_T Debug[6];
real_T Latch[6];
```

The **Debug\_b** function contains this code:

```
static void Debug_b(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T
 rtd_A[6])
{
 int32_T i;
 for (i = 0; i < 6; i++) {
 Debug[i] = rtu_In1[i] * rtu_In2[i];
 rtd_A[i] += Debug[i];
 }
}
```

The **Latching** function contains this code:

```

static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T
 rty_Out2[6], real_T rtd_A[6])
{
 int32_T i;
 int32_T i_0;
 for (i = 0; i < 6; i++) {
 Latch[i] = rtd_A[i];
 rty_Out2[i] = -Latch[i];
 }

 for (i = 0; i < 6; i++) {
 rty_Out1[i] = 0.0;
 for (i_0 = 0; i_0 < 6; i_0++) {
 rty_Out1[i] += rtu_In1[6 * i_0 + i] * Latch[i_0];
 }
 }
}

```

The code readability and observability is the same as with the `Localizable` storage class specification except the labeled signals are global variables.

- 3 Remove the `Debug` and `Latch` signals from the code mappings. In the Code Mappings editor, select each signal and click the **Remove Signal** button.
- 4 Save the model.
- 5 Generate and review the code. The `Debug_b` function contains this code:

```

static void Debug(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T
 rtd_A[6])
{
 int32_T i;
 for (i = 0; i < 6; i++) {
 rtd_A[i] += rtu_In1[i] * rtu_In2[i];
 }
}

```

The `Latching` function contains this code:

```

static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T
 rty_Out2[6], real_T rtd_A[6])
{
 int32_T i;
 int32_T i_0;
 for (i = 0; i < 6; i++) {
 rty_Out2[i] = -rtd_A[i];
 rty_Out1[i] = 0.0;
 for (i_0 = 0; i_0 < 6; i_0++) {
 rty_Out1[i] += rtu_In1[6 * i_0 + i] * rtd_A[i_0];
 }
 }
}

```

Without the `Localizable` or `ExportToFile` storage classes, the code generator removes the `Debug` and `Latch` variables. Without these variables, the readability and observability of the generated code decreases.

## Additional Information

- For the code generator to localize signals with the `Localizable` storage class specification, select model configuration parameter **Enable Local Block Outputs**. This parameter is on by default.
- You can specify the same `Localizable` storage class on two signals that are in different reusable subsystems. Therefore, you can create a library block from a reusable subsystem with a `Localizable` storage class specification.
- The code generator does not create a local variable for a signal that must stay global. A few cases in which the code generator cannot localize a signal are:

- Input and output signals of a nonreusable subsystem even when the **Function interface** parameter is set to **Allow arguments (Optimized)**.
- Signal is holding a state because its receiver and drive blocks execute at different rates.
- **Localizable** specification is on a signal that crosses the boundary of a conditionally executed subsystem.

# **Data Object Wizard in Embedded Coder**

---

## Create Data Objects for Code Generation with Data Object Wizard

To specify code generation options for signal lines, block parameters, and states in a model, you can use data objects that you store in a workspace or data dictionary. For basic information about data objects, see “Data Objects”.

You can use the Data Object Wizard to create data objects for:

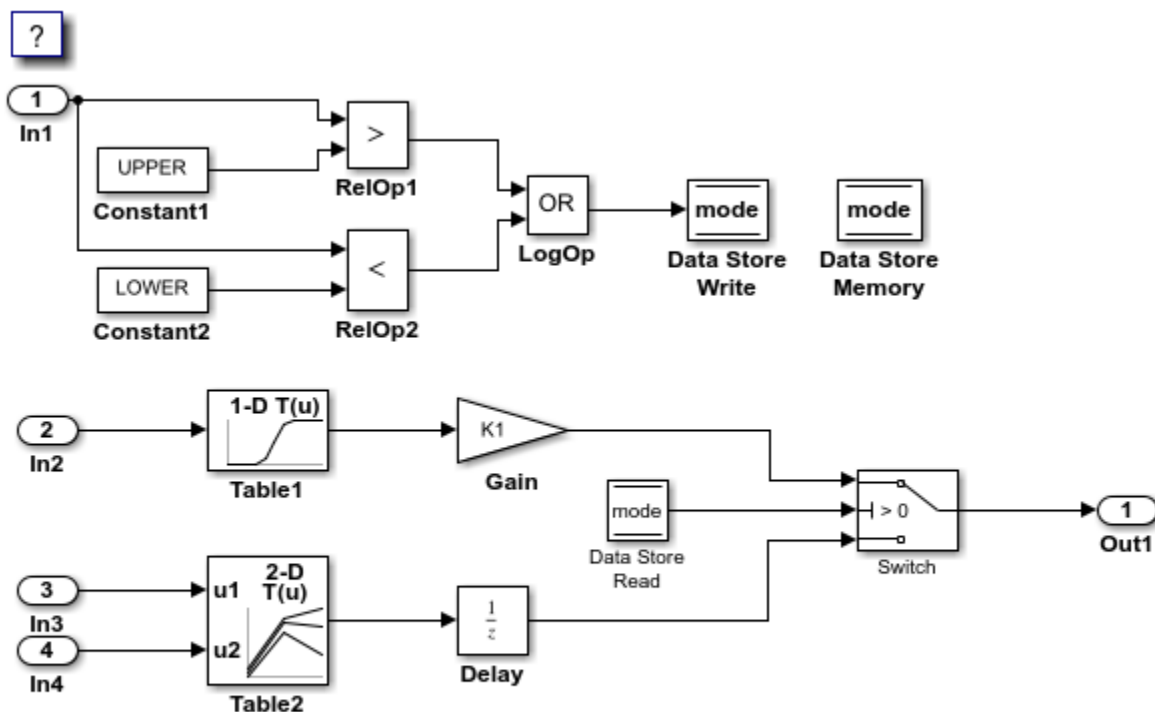

- New or existing models that do not use data objects.
- Existing models to which you have added signal lines or blocks.

This example shows how to use the Data Object Wizard to create and configure data objects for code generation from the built-in package Simulink.

### Create Data Objects

Open the example model `rtwdemo_configinterface`.

```
open_system('rtwdemo_configinterface')
```

Copyright 1994-2020 The MathWorks, Inc.

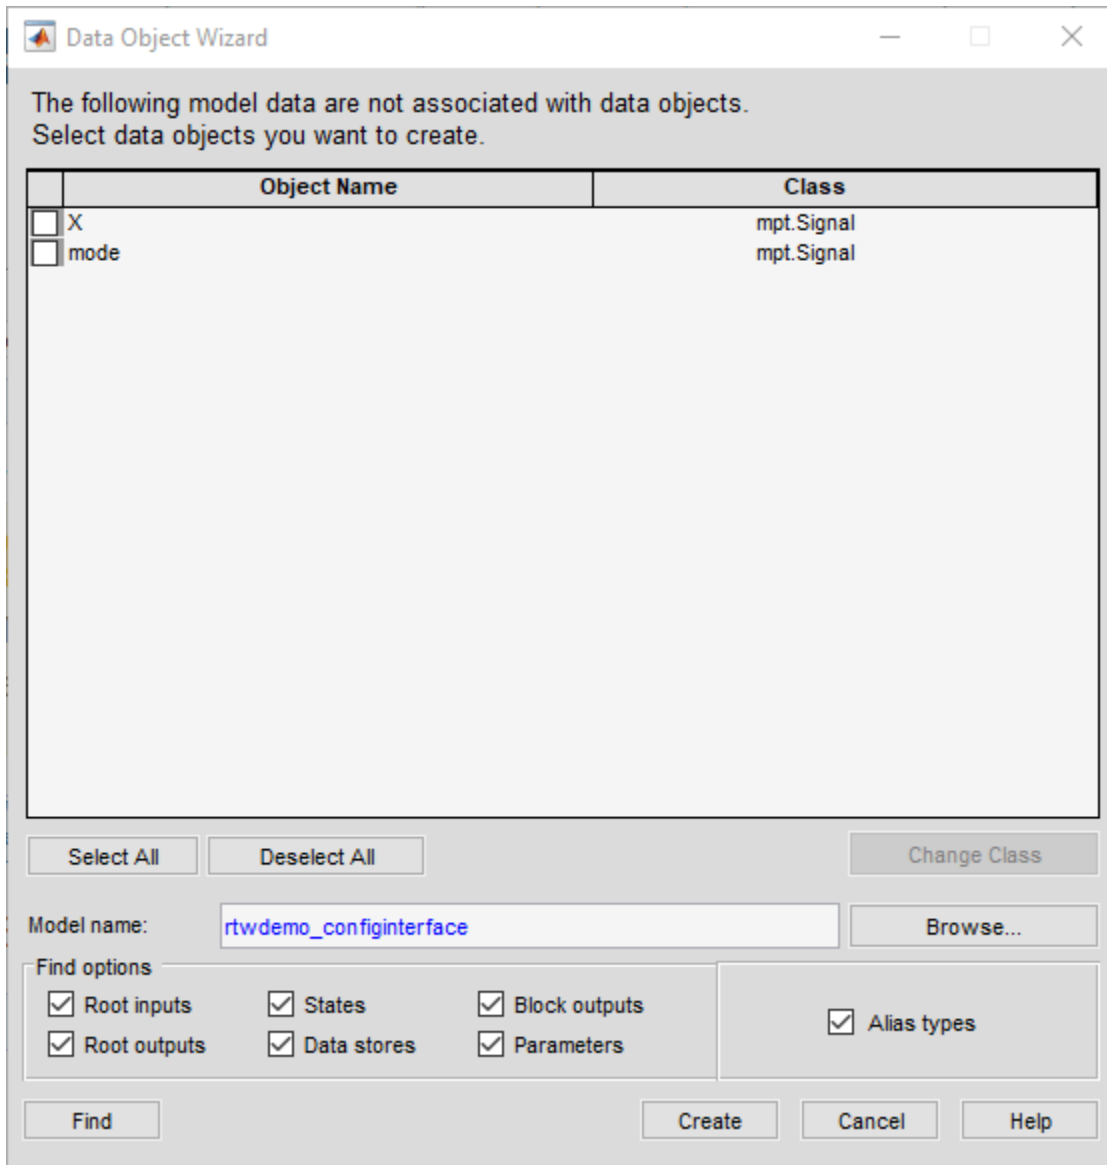

The model creates numeric variables in the base workspace. Blocks in the model use these variables to set parameter values (such as the **Gain** parameter of a Gain block). Some of the signals and block states in the model have explicit names, such as `input1`.

On the **Modeling** tab, under **Design**, click **Data Object Wizard**.

In the Data Object Wizard, click **Find**. The wizard proposes the creation of `Simulink.Parameter` objects to replace the variables and the creation of `Simulink.Signal` objects to represent the signals and states.

The wizard finds only signals, parameters, data stores, and states whose storage class is set to Auto. For example, if you use the Signal Properties dialog box to specify a storage class other than Auto for a signal line, the wizard does not propose a data object.

Click **Select All**.

Click **Create**. The data objects appear in the base workspace.

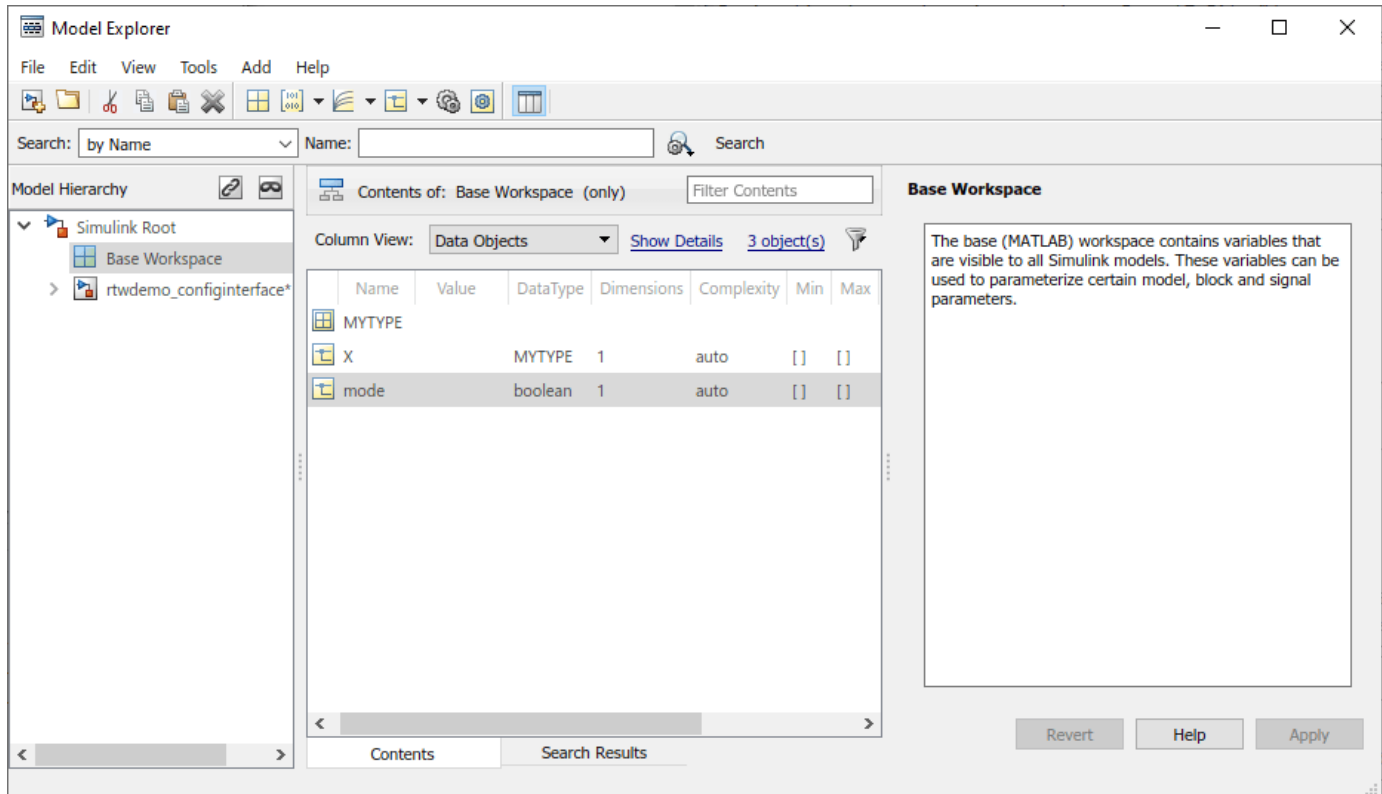

For detailed information about the options that you can choose in the Data Object Wizard, see “Create Data Objects for a Model Using Data Object Wizard”.

### Set Storage Class for Data Objects

Storage classes determine how the generated code uses variables to represent signals, parameters, and states. For data objects from the built-in package Simulink, the default storage class is Auto. To specify storage classes for the new data objects, use the Model Explorer.

Open the Model Explorer.

In the **Model Hierarchy** pane, select **Base Workspace**.

In the **Contents** pane, from the drop-down list **Column View**, select **Storage Class**.

Select all of the new data objects. For example, select the object `input1`, hold **Shift**, and select the object `X`.

Set the property **StorageClass** for all of the data objects to **ExportToFile**. To change the storage class for all of the selected objects, in the **StorageClass** column, click any of the objects. In the drop-down list, select **ExportToFile**. The change that you make propagates to all of the selected objects.

Specify the **HeaderFile** property for all of the objects as `myExportedHdrFile.h`.

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. With this setting, the code generator honors storage classes such as **ExportToFile**.

### Generate and Inspect Code

Generate code from the model.

```
Starting build procedure for: rtwdemo_configinterface

tf =

 logical

 0
```

```
tf =
 logical
 0

Successful completion of code generation for: rtwdemo_configinterface

Build Summary

Top model targets built:

Model Action Rebuild Reason
=====
```

Model	Action	Rebuild Reason
rtwdemo_configinterface	Code generated	Code generation information file does not exist.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 1m 0.7s
```

In the code generation report, view the generated file `myExportedHdrFile.h`. The file contains extern declarations for the global variables that correspond to the data objects.

```
/* Exported data declaration */
/* Declaration for custom storage class: ExportToFile */
extern real_T X;
```

View the file `rtwdemo_configinterface.c`. The file contains the definitions for the global variables. The code assigns numeric values for the variables that correspond to parameter objects.

```
/* Exported data definition */

/* Definition for custom storage class: ExportToFile */
real_T X;
```

# Entry-Point Functions and Scheduling in Simulink Coder

---

- “Configure Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-2
- “Generate C++ Class Interface to Model or Subsystem Code” on page 39-9
- “Execution of Code Generated from a Model” on page 39-12
- “Rapid Prototyping Model Functions” on page 39-21

## Configure Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks

With Embedded Coder, you can customize the generated C and C++ function interfaces for Simulink Function and Function Caller blocks. Function code interface configuration supports easier integration of generated code with functions or function calls in external code and customizations for coding standards or design requirements.

You can customize generated C and C++ function interfaces for:

- Global Simulink functions
- Exported scoped Simulink functions

You cannot customize the generated function interface for a scoped Simulink Function block that is not located at the root level of a model. For more information, see “Scoped, Global, and Port-Scoped Simulink Function Blocks Overview”.

By opening a dialog box from a selected Simulink Function or Function Caller block, you can customize the function prototype generated for that block. Your changes for the selected block also update other corresponding Simulink Function and Function Caller blocks in the model. The function visibility, global or scoped, set in the function Trigger Port block determines which function attributes you can modify:

- For a global function, you can change the function name, and the names, type qualifiers, and order of function arguments.
- For an exported scoped function, you can change the argument type qualifiers and the order of arguments. You cannot change the function and argument names.

Your changes do not graphically alter the model and do not affect the Simulink function prototype defined in the block.

Embedded Coder supports Simulink function code interface configuration for models configured with ERT-based system target files, except for AUTOSAR system target files.

### Configure Generated C Function Interface for Global Simulink Function Block

This example shows how to customize the C function interface that the code generator produces for a global Simulink Function block.

- 1 Open example model `rtwdemo_functions`. Save a copy of the model to a writable location.
- 2 In the apps gallery, open the **Embedded Coder** app.
- 3 On the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
- 4 In the Code Mappings editor, click the **Functions** tab.
- 5 In the row for Simulink Function: `f3`, click the function preview hyperlink. The C/C++ Function Interface dialog box shows **Simulink function prototype** as `y = f3(u)` and **C/C++ function prototype** as `void f3(rtu_u, * rty_y)`. The preview for **C/C++ function prototype** is updated as you make changes.

## 6 Configure the function name and arguments.

- Modify the function and argument identifier names. Model configuration parameter **Subsystem method arguments** defines the default naming rule for Simulink Function arguments. Changes that you make in the C/C++ Function Interface dialog box override the default naming rule.

In the **C/C++ function name** field, and in the **C/C++ Identifier Name** column for each Simulink function argument, enter a custom name or naming rule. Specify valid C-identifier characters, identifier format macros, or a combination of characters and macros. For this example, name the function `function3` and, for the arguments, enter naming rule `$N$M`.

To see tips about available macros, place your cursor over **C/C++ function name** and **C/C++ Identifier Name**. For more information about identifier naming rules, see “Identifier Format Control” on page 52-17.

- For argument `u`, set **C/C++ Type Qualifier** to `Pointer` to `const`.
- Reorder the arguments. Drag the `y` argument row above the `u` argument row.

- 7 Verify your changes by checking the function prototype preview.
- 8 Click **Apply**. Your modifications, whether made to a Simulink Function block or a Function Caller block, affect code generation for the Simulink Function block and corresponding Function Caller blocks in the model.

Optionally, you can change **C/C++ return argument** from `void` to `y`. In that case, the C function prototype is `y = function3(const * u)`.

- 9 Save your changes by clicking **OK**.
- 10 Save the model.
- 11 Make sure that the Simulink Function block is not selected. Then, generate code for the model.
- 12 In the **Code** view, open the generated file `rtwdemo_functions.c` and search for `function3`. The generated function code reflects the changes to the generated C function prototype.

```
void function3(real_T *y, const real_T *u)
{
 rtY.TicToc10 = rtDWork.Delay_DSTATE;

 rtDWork.Delay_DSTATE = (int8_T)(int32_T)-(int32_T)rtY.TicToc10;

 adder(rtB.Subtract, rtU.U2, *u, &rtB.FunctionCaller);

 *y = rtB.FunctionCaller;
}
```

## Configure Generated C Function Interface for Exported Scoped Simulink Function Block

This example shows how to customize the C function interface that the code generator produces for an exported, scoped Simulink Function block.

For an exported, scoped function, you can modify the generated return argument, the argument type qualifiers, and the order of arguments. You cannot change the generated function name and argument names.

- 1 Open the model `rtwdemo_functions`. Save it to a writable location.
- 2 Change the visibility of the global function `f3` from global to scoped. Open the Simulink Function block `f3`. Inside the function block, double-click the Trigger Port block `f3`. In the block parameters dialog box, set **Function visibility** to `scoped`. Click **Apply** and **OK**.
- 3 In the apps gallery, open the **Embedded Coder** app.
- 4 In the **C Code** tab, click the **Code Mappings - C** tab.
- 5 In the Code Mappings editor, click the **Functions** tab.
- 6 In the row for function `f3`, click the function preview hyperlink. The C/C++ Function Interface dialog box shows **Simulink function prototype** as `y = f3(u)` and **C/C++ function prototype** as `y = rtwdemo_functions_f3(rtu_u)`. The preview for **C/C++ function prototype** is updated as you make changes.

For models that you configure for C multi-instantiable code, the interface preview for scoped Simulink functions includes a `self` argument. The `self` argument is a pointer to a version of the real-time model (`RT_MODEL`) data structure that stores multi-instance data associated with reusable functions.

If model configuration parameter **Code interface packaging** is set to `Reusable function` and **Total number of instances allowed per top model** is set to `Multiple`, the argument appears as `self`, indicating that the code generator produces a `self` structure.

If model configuration parameter **Code interface packaging** is set to `Reusable function` or **Total number of instances allowed per top model** is set to `Multiple`, the argument appears as `[self]`, indicating that the argument is optional. The code generator produces a `self` structure only if you use the model as a top model and **Code interface packaging** is set to `Reusable function` or if you use the model as a referenced model and **Total number of instances allowed per top model** is set to `Multiple`.

For more information about configuring a model for multi-instantiable code generation, see “Generate Reentrant Code from Simulink Function Blocks” on page 7-23.

- 7 Configure the arguments. For this example, configure the `u` argument. Set **C/C++ type Qualifier** to `Pointer to const`.

- 8 Verify your change by checking the function prototype preview.
- 9 Click **Apply**. Your modifications, whether made to a Simulink Function block or a Function Caller block, affect code generation for the Simulink Function block and corresponding Function Caller blocks in the model.

Optionally, you can change **C/C++ return argument** from `y` to `void`. In that case, the C function prototype is `void = rtwdemo_functions_f3(* rty_y, const * rtu_u)`.

- 10 Save your change by clicking **OK**.
- 11 Save the model.
- 12 Make sure that the Simulink Function block is not selected. Then, generate code for the model.
- 13 In the **Code** view, open the generated file `rtwdemo_functions.c` and search for `rtwdemo_functions_f3`. The generated function code reflects the changes to the generated C function prototype.

```
real_T rtwdemo_functions_f3(const real_T *rtu_u)
{
 real_T rty_y_0;

 rtY.TicToc10 = rtDWork.Delay_DSTATE;
 rtDWork.Delay_DSTATE = (int8_T)(int32_T)-(int32_T)rtY.TicToc10;
 adder(rtB.Subtract, rtU.U2, *rtu_u, &rtB.FunctionCaller);
 rty_y_0 = rtB.FunctionCaller;

 return rty_y_0;
}
```

## Configure Generated C++ Function Interface for Exported Scoped Simulink Function Block

This example shows how to customize the C++ function interface that the code generator produces for an exported scoped Simulink Function block.

For an exported scoped function, you can modify the generated return argument, the argument type qualifiers, and the order of arguments. You cannot change the generated function name and argument names.

- 1 Open the model `rtwdemo_functions`. Save it to a writable work area.
- 2 Change the visibility of the global function `f3` from `global` to `scoped`. Open the Simulink Function block `f3`. Inside the function block, double-click the Trigger Port block `f3`. In the block parameters dialog box, set **Function visibility** to `scoped`. Click **Apply** and **OK**.
- 3 In the apps gallery, open the **Embedded Coder** app.
- 4 Set the model configuration parameter **Language** to `C++`.
- 5 Open the Configure C/C++ Function Interface dialog box. Right-click the Simulink Function block `f3`. In the context menu, select **C/C++ Code > Configure C/C++ Function Interface**. The dialog box shows **Simulink function prototype** as `y = f3(u)` and **C/C++ function prototype** as `y = rtwdemo_functions_f3(rtu_u)`. The preview for **C/C++ function prototype** is updated as you make changes.

- 6 Configure the arguments. For this example, configure the `u` argument. Set **C/C++ type Qualifier** to **Pointer to const**.
- 7 Click **Apply**. Your modifications, whether made to a Simulink Function block or a Function Caller block, affect code generation for the Simulink Function block and corresponding Function Caller blocks in the model.

Optionally, you can change **C/C++ return argument** from `y` to `void`. In that case, the C++ function prototype is `void = rtdemo_functions_f3(* rty_y, const * rtu_u)`.

- 8 Save your change by clicking **OK**.
- 9 Save the model.
- 10 Make sure that the Simulink Function block is not selected. Then, generate code for the model.
- 11 In the **Code** view, open the generated file `rtdemo_functions.cpp` and search for function `f3`. The generated function code reflects the changes to the generated C++ function prototype.

```
real_T rtdemo_functionsModelClass::f3(const real_T *rtu_u)
{
 real_T rty_y_0;

 rtY.TicToc10 = rtDWork.Delay_DSTATE;

 rtDWork.Delay_DSTATE = static_cast<int8_T>(static_cast<int32_T>
 (-static_cast<int32_T>(rtY.TicToc10)));

 adder(rtB.Subtract, rtU.U2, *rtu_u, &rtB.FunctionCaller);

 rty_y_0 = rtB.FunctionCaller;

 return rty_y_0;
}
```

## Simulink Function Code Interface Limitations

- For C++ code generation, global Simulink functions are incompatible with C++ class interfaces for model entry-point functions.
- Simulink function code interface configuration does not support Simulink functions and function callers in Stateflow.

- The Argument Outport block cannot be a return argument for a Simulink function when its data type is set to one of the following types:
  - Complex types
  - Bus types
  - Image types
  - Non-scalar types
  - Multiword types

## Generate C++ Class Interface to Model or Subsystem Code

To generate a C++ class interface to model code, set model configuration parameter “Code interface packaging” to C++ class. The generated interface encapsulates required model data into C++ class attributes and model entry point functions into C++ class methods. The benefits of C++ class encapsulation include:

- Greater control over access to model data
- Ability to create multiple instances of model classes
- Easier integration of model code into C++ programming environments

C++ class encapsulation also works for right-click builds of nonvirtual subsystems. (For information on requirements that apply, see “Generate C++ Class Interface to Nonvirtual Subsystem Code” on page 39-10.)

### Generate C++ Class Interface to Model Code

To generate encapsulated C++ class code from a model:

- 1 Set model configuration parameter **Language** to C++. This selection also enables C++ class code interface packaging for the model.
- 2 Verify that model configuration parameter **Code interface packaging** is set to C++ class.
- 3 Examine the setting of **Multi-instance code error diagnostic**. Leave the parameter at its default value Error unless you need to alter the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code.

- 4 Generate code for the model.
- 5 Examine the C++ model class code in the generated files *model.h* and *model.cpp*. For example, the following code excerpt from the H file generated for the example model *rtwdemo\_secondOrderSystem* shows the C++ class declaration for the model.

```
/* Class declaration for model rtwdemo_secondOrderSystem */
class rtwdemo_secondOrderSystemModelClass {
 /* public data and function members */
public:
 /* External outputs */
 ExtY_rtwdemo_secondOrderSystem_T rtwdemo_secondOrderSystem_Y;

 /* Model entry point functions */

 /* model initialize function */
 void initialize();

 /* model step function */
 void step();

 /* model terminate function */
 void terminate();

 /* Constructor */
 rtwdemo_secondOrderSystemModelClass();

 /* Destructor */
 ~rtwdemo_secondOrderSystemModelClass();
};
```

```

/* Real-Time Model get method */
RT_MODEL_rtwdemo_secondOrderS_T * getRTM();
...
};

```

For more information about generating and calling model entry-point functions, see “Configure Generated C Function Interface for Model Entry-Point Functions”.

---

**Note** If you have an Embedded Coder license and you have selected an ERT-based system target file for your model, use additional **Code Generation > Interface** pane parameters to customize the generated C++ class interface.

---

## Generate C++ Class Interface to Nonvirtual Subsystem Code

You can generate C++ class interfaces for right-click builds of nonvirtual subsystems, if the following requirements are met:

- The model is configured for the C++ language and C++ class code interface packaging.
- The subsystem is convertible to a Model block using the function `Simulink.SubSystem.convertToModelReference`. For referenced model conversion requirements, see the Simulink reference page `Simulink.SubSystem.convertToModelReference`.

To configure C++ class interfaces for a subsystem that meets the requirements:

- 1 Open the containing model and select the subsystem block.
- 2 Right-click the subsystem and select **C/C++ Code > Build This Subsystem**.
- 3 When the subsystem build completes, examine the C++ class interfaces in the generated files and the HTML code generation report. For more information about generating and calling model entry-point methods, see “Configure Generated C Function Interface for Model Entry-Point Functions”.

If you have an Embedded Coder license and you have selected an ERT-based system target file for your model, you can use the MATLAB command `RTW.configSubsystemBuild` to customize the generated C++ class interface to subsystem code.

## C++ Class Interface Limitations

- Among the data exchange interfaces available on the **Interface** pane of the Configuration Parameters dialog box, only the C API interface is supported for C++ class code generation. If you select **External mode** or **ASAP2 interface**, code generation fails with a validation error.
- If a model root inport value connects to a Simscape conversion block, you must insert a Simulink Signal Conversion block between the root inport and the Simscape conversion block. On the Simulink Signal Conversion block parameter dialog box, select **Exclude this block from 'Block reduction' optimization**.
- You cannot use a C++ class interface in cases when a referenced model cannot have a combined output/update function. Cases include a model that
  - Has a continuous sample time
  - Saves states

- “Configure Generated C Function Interface for Model Entry-Point Functions”
- “Execution of Code Generated from a Model”
- “Rapid Prototyping Model Functions”

## Execution of Code Generated from a Model

The code generator produces algorithmic code as defined by your model. You can include external (for example, custom or legacy) code in a model by using techniques explained in “Choose an External Code Integration Workflow”.

The code generator also provides an interface that executes the generated model code. The interface and model code are compiled together to create an executable program. The next figure shows a high-level object-oriented view of the executable.

### The Object-Oriented View of a Real-Time Program

In general, the conceptual design of the model execution driver does not change between the rapid prototyping and embedded style of generated code. The following sections describe model execution for single-tasking and multitasking environments both for simulation (non-real-time) and for real time. For most model code, the multitasking environment provides the most efficient model execution (that is, fastest sample rate).

The following concepts are useful in describing how model code executes.

- **Initialization:** `model_initialize` initializes the interface code and the model code.
- **ModelOutputs:** Calls blocks in your model that have a sample hit at the current time and has them produce their output. `model_output` can be done in major or minor time steps. In major time steps, the output is a given simulation time step. In minor time steps, the interface integrates the derivatives to update the continuous states.
- **ModelUpdate:** `model_update` calls blocks that have a sample hit at the current point in time and has them update their discrete states or similar type objects.
- **ModelDerivatives:** Calls blocks in your model that have continuous states and has them update their derivatives. `model_derivatives` is only called in minor time steps.
- **ModelTerminate:** `model_terminate` terminates the program if it is designed to run for a finite time. It destroys the real-time model data structure, deallocates memory, and can write data to a file.

### Program Execution

A real-time program cannot require 100% of the CPU time. This requirement provides an opportunity to run background tasks during the free time.

Background tasks include operations such as writing data to a buffer or file, allowing access to program data by third-party data monitoring tools, or updating program parameters.

It is important, however, that the program be able to preempt the background task so the model code can execute in real time.

The way the program manages tasks depends on capabilities of the environment in which it operates.

## Program Timing

Real-time programs require careful timing of the task invocations (either by using an interrupt or a real-time operating system tasking primitive) so that the model code executes to completion before another task invocation occurs. The timing includes time to read and write data to and from external hardware.

The next figure illustrates interrupt timing.

## Task Timing

The sample interval must be long enough to allow model code execution between task invocations.

In the figure above, the time between two adjacent vertical arrows is the sample interval. The empty boxes in the upper diagram show an example of a program that can complete one step within the interval and still allow time for the background task. The gray box in the lower diagram indicates what happens if the sample interval is too short. Another task invocation occurs before the task is complete. Such timing results in an execution error.

If the real-time program is designed to run forever (that is, the final time is 0 or infinite so that the `while` loop never exits), then the shutdown code does not execute.

For more information on how the timing engine works, see "Absolute and Elapsed Time Computation".

## External Mode Communication

External mode allows communication between the Simulink block diagram and the standalone program that is built from the generated code. In this mode, the real-time program functions as an interprocess communication server, responding to requests from the Simulink engine.

## Data Logging in Single-Tasking and Multitasking Model Execution

“Configure Model for Debugging” on page 45-34 explains how you can save system states, outputs, and time to a MAT-file at the completion of the model execution. The LogTXY function, which performs data logging, operates differently in single-tasking and multitasking environments.

If you examine how LogTXY is called in the single-tasking and multitasking environments, notice that for single-tasking LogTXY is called after ModelOutputs. During this ModelOutputs call, blocks that have a hit at time  $t$  execute, whereas in multitasking, LogTXY is called after ModelOutputs(tid=0), which executes only the blocks that have a hit at time  $t$  and that have a task identifier of 0. This results in differences in the logged values between single-tasking and multitasking logging. Specifically, consider a model with two sample times, the faster sample time having a period of 1.0 second and the slower sample time having a period of 10.0 seconds. At time  $t = k*10$ ,  $k=0,1,2\dots$  both the fast (tid=0) and slow (tid=1) blocks execute. When executing in multitasking mode, when LogTXY is called, the slow blocks execute, but the previous value is logged, whereas in single-tasking the current value is logged.

Another difference occurs when logging data in an enabled subsystem. Consider an enabled subsystem that has a slow signal driving the enable port and fast blocks within the enabled subsystem. In this case, the evaluation of the enable signal occurs in a slow task, and the fast blocks see a delay of one sample period; thus the logged values will show these differences.

To summarize differences in logged data between single-tasking and multitasking, differences will be seen when

- A root output block has a sample time that is slower than the fastest sample time
- A block with states has a sample time that is slower than the fastest sample time
- A block in an enabled subsystem where the signal driving the enable port is slower than the rate of the blocks in the enabled subsystem

For the first two cases, even though the logged values are different between single-tasking and multitasking, the model results are not different. The only real difference is where (at what point in time) the logging is done. The third (enabled subsystem) case results in a delay that can be seen in a real-time environment.

## Non-Real-Time Single-Tasking Systems

This pseudocode shows the execution of a model for a non-real-time single-tasking system.

```
main()
{
 Initialization
 While (time < final time)
 ModelOutputs -- Major time step.
 LogTXY -- Log time, states and root outputs.
 ModelUpdate -- Major time step.
 Integrate -- Integration in minor time step for
 -- models with continuous states.

 ModelDerivatives
 Do 0 or more
 ModelOutputs
 ModelDerivatives
 EndDo -- Number of iterations depends upon the solver
 Integrate derivatives to update continuous states.
```

```

 EndIntegrate
 EndWhile
 Termination
}

```

The initialization phase begins first. This consists of initializing model states and setting up the execution engine. The model then executes, one step at a time. First `ModelOutputs` executes at time  $t$ , then the workspace I/O data is logged, and then `ModelUpdate` updates the discrete states. Next, if your model has continuous states, `ModelDerivatives` integrates the continuous states' derivatives to generate the states for time  $t_{new} = t + h$ , where  $h$  is the step size. Time then moves forward to  $t_{new}$  and the process repeats.

During the `ModelOutputs` and `ModelUpdate` phases of model execution, only blocks that reach the current point in time execute.

## Non-Real-Time Multitasking Systems

This pseudocode shows the execution of a model for a non-real-time multitasking system.

```

main()
{
 Initialization
 While (time < final time)
 ModelOutputs(tid=0) -- Major time step.
 LogTXY -- Log time, states, and root
 -- outputs.
 ModelUpdate(tid=0) -- Major time step.
 Integrate -- Integration in minor time step for
 -- models with continuous states.
 ModelDerivatives
 Do 0 or more
 ModelOutputs(tid=0)
 ModelDerivatives
 EndDo (Number of iterations depends upon the solver.)
 Integrate derivatives to update continuous states.
 EndIntegrate
 For i=1:NumTids
 ModelOutputs(tid=i) -- Major time step.
 ModelUpdate(tid=i) -- Major time step.
 EndFor
 EndWhile
 Termination
}

```

Multitasking operation is more complex than single-tasking execution because the output and update functions are subdivided by the *task identifier* (`tid`) that is passed into these functions. This allows for multiple invocations of these functions with different task identifiers using overlapped interrupts, or for multiple tasks when using a real-time operating system. In simulation, multiple tasks are emulated by executing the code in the order that would occur if preemption did not exist in a real-time system.

Multitasking execution assumes that task rates are multiples of the base rate. The Simulink product enforces this when you create a fixed-step multitasking model. The multitasking execution loop is very similar to that of single-tasking, except for the use of the task identifier (`tid`) argument to `ModelOutputs` and `ModelUpdate`.

You cannot use `tid` values from code generated by a target file and not by Simulink Coder. Simulink Coder tracks the use of `tid` when generating code for a specific subsystem or function type. When you generate code in a target file, this argument cannot be tracked because the scope does not have subsystem or function type. Therefore, `tid` becomes an undefined variable and your target file fails to compile.

## Real-Time Single-Tasking Systems

This pseudocode shows the execution of a model in a real-time single-tasking system where the model is run at interrupt level.

```
rtOneStep()
{
 Check for interrupt overflow
 Enable "rtOneStep" interrupt
 ModelOutputs -- Major time step.
 LogTXY -- Log time, states and root outputs.
 ModelUpdate -- Major time step.
 Integrate -- Integration in minor time step for models
 -- with continuous states.
 ModelDerivatives
 Do 0 or more
 ModelOutputs
 ModelDerivatives
 EndDo (Number of iterations depends upon the solver.)
 Integrate derivatives to update continuous states.
 EndIntegrate
}

main()
{
 Initialization (including installation of rtOneStep as an
 interrupt service routine, ISR, for a real-time clock).
 While(time < final time)
 Background task.
 EndWhile
 Mask interrupts (Disable rtOneStep from executing.)
 Complete any background tasks.
 Shutdown
}
```

Real-time single-tasking execution is very similar to non-real-time single-tasking execution, except that instead of free-running the code, the `rt_OneStep` function is driven by a periodic timer interrupt.

At the interval specified by the program's base sample rate, the interrupt service routine (ISR) preempts the background task to execute the model code. The base sample rate is the fastest in the model. If the model has continuous blocks, then the integration step size determines the base sample rate.

For example, if the model code is a controller operating at 100 Hz, then every 0.01 seconds the background task is interrupted. During this interrupt, the controller reads its inputs from the analog-to-digital converter (ADC), calculates its outputs, writes these outputs to the digital-to-analog converter (DAC), and updates its states. Program control then returns to the background task. These steps must occur before the next interrupt.

## Real-Time Multitasking Systems

This pseudocode shows how a model executes in a real-time multitasking system where the model is run at interrupt level.

```

rtOneStep()
{
 Check for interrupt overflow
 Enable "rtOneStep" interrupt
 ModelOutputs(tid=0) -- Major time step.
 LogTXY -- Log time, states and root outputs.
 ModelUpdate(tid=0) -- Major time step.
 Integrate -- Integration in minor time step for
 -- models with continuous states.

 ModelDerivatives
 Do 0 or more
 ModelOutputs(tid=0)
 ModelDerivatives
 EndDo (Number of iterations depends upon the solver.)
 Integrate derivatives and update continuous states.
EndIntegrate
For i=1:NumTasks
 If (hit in task i)
 ModelOutputs(tid=i)
 ModelUpdate(tid=i)
 EndIf
EndFor
}

main()
{
 Initialization (including installation of rtOneStep as an
 interrupt service routine, ISR, for a real-time clock).
 While(time < final time)
 Background task.
 EndWhile
 Mask interrupts (Disable rtOneStep from executing.)
 Complete any background tasks.
 Shutdown
}

```

Running models at interrupt level in a real-time multitasking environment is very similar to the previous single-tasking environment, except that overlapped interrupts are employed for concurrent execution of the tasks.

The execution of a model in a single-tasking or multitasking environment when using real-time operating system tasking primitives is very similar to the interrupt-level examples discussed above. The pseudocode below is for a single-tasking model using real-time tasking primitives.

```

tSingleRate()
{
 MainLoop:
 If clockSem already "given", then error out due to overflow.
 Wait on clockSem
 ModelOutputs -- Major time step.
 LogTXY -- Log time, states and root
 -- outputs
}

```

```

 ModelUpdate -- Major time step
 Integrate -- Integration in minor time step
 -- for models with continuous
 -- states.

 ModelDerivatives
 Do 0 or more
 ModelOutputs
 ModelDerivatives
 EndDo (Number of iterations depends upon the solver.)
 Integrate derivatives to update continuous states.
EndIntegrate
EndMainLoop
}

main()
{
 Initialization
 Start/spawn task "tSingleRate".
 Start clock that does a "semGive" on a clockSem semaphore.
 Wait on "model-running" semaphore.
 Shutdown
}

```

In this single-tasking environment, the model executes as real-time operating system tasking primitives. In this environment, create a single task (tSingleRate) to run the model code. This task is invoked when a clock tick occurs. The clock tick gives a clockSem (clock semaphore) to the model task (tSingleRate). The model task waits for the semaphore before executing. The clock ticks occur at the fundamental step size (base rate) for your model.

## Multitasking Systems Using Real-Time Tasking Primitives

This pseudocode is for a multitasking model using real-time tasking primitives.

```

tSubRate(subTaskSem,i)
{
 Loop:
 Wait on semaphore subTaskSem.
 ModelOutputs(tid=i)
 ModelUpdate(tid=i)
 EndLoop
}

tBaseRate()
{
 MainLoop:
 If clockSem already "given", then error out due to overflow.
 Wait on clockSem
 For i=1:NumTasks
 If (hit in task i)
 If task i is currently executing, then error out due to
 overflow.
 Do a "semGive" on subTaskSem for task i.
 EndIf
 EndFor
 ModelOutputs(tid=0) -- major time step.
 LogTXY -- Log time, states and root outputs.
 ModelUpdate(tid=0) -- major time step.
 Loop: -- Integration in minor time step for
}

```

```

-- models with continuous states.
ModelDerivatives
Do 0 or more
 ModelOutputs(tid=0)
 ModelDerivatives
EndDo (number of iterations depends upon the solver).
Integrate derivatives to update continuous states.
EndLoop
EndMainLoop
}
main()
{
 Initialization
 Start/spawn task "tSubRate".
 Start/spawn task "tBaseRate".

 Start clock that does a "semGive" on a clockSem semaphore.
 Wait on "model-running" semaphore.
 Shutdown
}

```

In this multitasking environment, the model is executed using real-time operating system tasking primitives. Such environments require several model tasks (tBaseRate and several tSubRate tasks) to run the model code. The base rate task (tBaseRate) has a higher priority than the subrate tasks. The subrate task for tid=1 has a higher priority than the subrate task for tid=2, and so on. The base rate task is invoked when a clock tick occurs. The clock tick gives a clockSem to tBaseRate. The first thing tBaseRate does is give semaphores to the subtasks that have a hit at the current point in time. Because the base rate task has a higher priority, it continues to execute. Next it executes the fastest task (tid=0), consisting of blocks in your model that have the fastest sample time. After this execution, it resumes waiting for the clock semaphore. The clock ticks are configured to occur at the fundamental step size for your model.

## Rapid Prototyping and Embedded Model Execution Differences

The rapid prototyping program framework provides a common application programming interface (API) that does not change between model definitions.

The Embedded Coder product provides a different framework called the embedded program framework. The embedded program framework provides an optimized API that is tailored to your model. When you use the embedded style of generated code, you are modeling how you would like your code to execute in your embedded system. Therefore, the definitions defined in your model should be specific to your embedded targets. Items such as the model name, parameter, and signal storage class are included as part of the API for the embedded style of code.

One major difference between the rapid prototyping and embedded style of generated code is that the latter contains fewer entry-point functions. The embedded style of code can be configured to have only one function, *model\_step*.

Thus, model execution code eliminates Loop...EndLoop statements and groups ModelOutputs, LogTXY, and ModelUpdate into a single statement, *model\_step*.

For more information about how generated embedded code executes, see "Configure Generated C Function Interface for Model Entry-Point Functions" on page 32-113.

## Rapid Prototyping Model Functions

Rapid prototyping code defines the following functions that interface with the main program (`main.c` or `main.cpp`):

- `Model()`: The model registration function. This function initializes the work areas (for example, allocating and setting pointers to various data structures) used by the model. The model registration function calls the `MdlInitializeSizes` and `MdlInitializeSampleTimes` functions. These two functions are very similar to the S-function `mdlInitializeSizes` and `mdlInitializeSampleTimes` methods.
- `MdlStart(void)`: After the model registration functions `MdlInitializeSizes` and `MdlInitializeSampleTimes` execute, the main program starts execution by calling `MdlStart`. This routine is called once at startup.

The function `MdlStart` has four basic sections:

- Code to initialize the states for each block in the root model that has states. A subroutine call is made to the “initialize states” routines of conditionally executed subsystems.
- Code generated by the one-time initialization (start) function for each block in the model.
- Code to enable the blocks in the root model that have enable methods, and the blocks inside triggered or function-call subsystems residing in the root model. Simulink blocks can have enable and disable methods. An enable method is called just before a block starts executing, and the disable method is called just after the block stops executing.
- Code for each block in the model whose output value is constant. The block code appears in the `MdlStart` function only if the block parameters are not tunable in the generated code and if the code generator cannot eliminate the block code through constant folding.
- `MdlOutputs(int_T tid)`: `MdlOutputs` updates the output of blocks. The `tid` (task identifier) parameter identifies the task that in turn maps when to execute blocks based upon their sample time. This routine is invoked by the main program during major and minor time steps. The major time steps are when the main program is taking an actual time step (that is, it is time to execute a specific task). If your model contains continuous states, the minor time steps will be taken. The minor time steps are when the solver is generating integration stages, which are points between major outputs. These integration stages are used to compute the derivatives used in advancing the continuous states.
- `MdlUpdate(int_T tid)`: `MdlUpdate` updates the states and work vector state information (that is, states that are neither continuous nor discrete) saved in work vectors. The `tid` (task identifier) parameter identifies the task that in turn indicates which sample times are active, allowing you to conditionally update only states of active blocks. This routine is invoked by the interface after the major `MdlOutputs` has been executed. The solver is also called, and `model_Derivatives` is called in minor steps by the solver during its integration stages. All blocks that have continuous states have an identical number of derivatives. These blocks are required to compute the derivatives so that the solvers can integrate the states.
- `MdlTerminate(void)`: `MdlTerminate` contains any block shutdown code. `MdlTerminate` is called by the interface, as part of the termination of the real-time program.

The contents of the above functions are directly related to the blocks in your model. A Simulink block can be generalized to the following set of equations.

$$y = f_0(t, x_c, x_d, u)$$

Output  $y$  is a function of continuous state  $x_c$ , discrete state  $x_d$ , and input  $u$ . Each block writes its specific equation in a section of `MdlOutputs`.

$$x_{d+1} = f_u(t, x_d, u)$$

The discrete states  $x_d$  are a function of the current state and input. Each block that has a discrete state updates its state in `MdlUpdate`.

$$\dot{x} = f_d(t, x_c, u)$$

The derivatives  $\dot{x}$  are a function of the current input. Each block that has continuous states provides its derivatives to the solver (for example, `ode5`) in `model_Derivatives`. The derivatives are used by the solver to integrate the continuous state to produce the next value.

The output,  $y$ , is generally written to the block I/O structure. Root-level Output blocks write to the external outputs structure. The continuous and discrete states are stored in the states structure. The input,  $u$ , can originate from another block's output, which is located in the block I/O structure, an external input (located in the external inputs structure), or a state. These structures are defined in the `model.h` file that the Simulink Coder software generates.

The next example shows the general contents of the rapid prototyping style of C code written to the `model.c` file.

```
/*
 * Version, Model options, TLC options,
 * and code generation information are placed here.
 */
<includes>
void MdlStart(void)
{
 /*
 * State initialization code.
 * Model start-up code - one time initialization code.
 * Execute any block enable methods.
 * Initialize output of any blocks with constant sample times.
 */
}

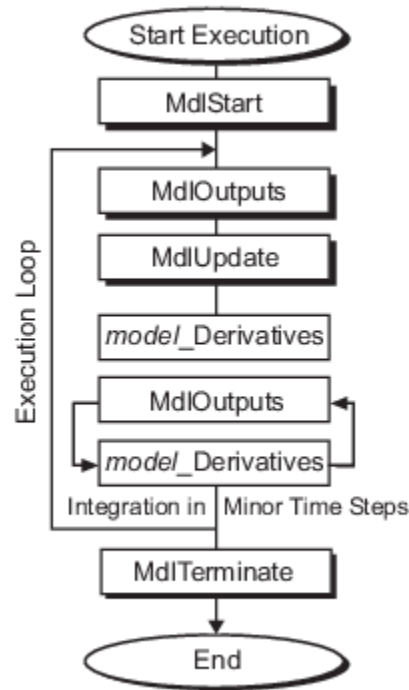

void MdlOutputs(int_T tid)
{
 /* Compute: y = f0(t,xc,xd,u) for each block as needed. */
}

void MdlUpdate(int_T tid)
{
 /* Compute: xd+1 = fu(t,xd,u) for each block as needed. */

 /* Compute: dxc = fd(t,xc,u) for each block in model_derivatives
 as needed. */
}

void MdlTerminate(void)
{
 /* Perform shutdown code for any blocks that
 have a termination action */
}
}
```

This figure shows a flow chart describing the execution of the rapid prototyping generated code.

### Rapid Prototyping Execution Flow Chart

Each block places code in specific Mdl routines according to the algorithm that it is implementing. Blocks have input, output, parameters, and states, as well as other general items. For example, in general, block inputs and outputs are written to a block I/O structure (*model\_B*). Block inputs can also come from the external input structure (*model\_U*) or the state structure when connected to a state port of an integrator (*model\_X*), or ground (*rtGround*) if unconnected or grounded. Block outputs can also go to the external output structure (*model\_Y*). This figure shows the general mapping between these items.

### Data View of the Generated Code

The following list defines the structures shown in the preceding figure:

- Block I/O structure (*model\_B*): This structure consists of persistent block output signals. The number of block output signals is the sum of the widths of the data output ports of the nonvirtual blocks in your model. If you activate block I/O optimizations, the Simulink and Simulink Coder products reduce the size of the *model\_B* structure by
  - Reusing the entries in the *model\_B* structure
  - Making other entries local variables

See “How Generated Code Stores Internal Signal, State, and Parameter Data” for more information on these optimizations.

Structure field names are determined either by the block's output signal name (when present) or by the block name and port number when the output signal is left unlabeled.

- Block states structures: The continuous states structure (*model\_X*) contains the continuous state information for blocks in your model that have continuous states. Discrete states are stored in a data structure called the *DWork vector* (*model\_DWork*).
- Block parameters structure (*model\_P*): The parameters structure contains block parameters that can be changed during execution (for example, the parameter of a Gain block).
- External inputs structure (*model\_U*): The external inputs structure consists of the root-level Inport block signals. Field names are determined by either the block's output signal name, when present, or by the Inport block's name when the output signal is left unlabeled.
- External outputs structure (*model\_Y*): The external outputs structure consists of the root-level Outport blocks. Field names are determined by the root-level Outport block names in your model.
- Real work, integer work, and pointer work structures (*model\_RWork*, *model\_IWork*, *model\_PWork*): Blocks might have a need for real, integer, or pointer work areas. For example, the Memory block uses a real work element for each signal. These areas are used to save internal states or similar information.

## Generate Modular Function Code for Nonvirtual Subsystems

### About Nonvirtual Subsystem Code Generation

By default, when producing code for a nonvirtual subsystem, the code generator places internal data associated with a nonvirtual subsystem in the same data structure as internal data for the parent model. This can make it difficult to trace and test code, particularly for nonreusable subsystems. Also, in large models containing nonvirtual subsystems, data structures can become large and potentially difficult to compile.

To generate modular function code for nonvirtual subsystems, including atomic subsystems and conditionally executed subsystems, use the subsystem block parameter **Function with separate data**. This block parameter instructs the code generator to produce a block I/O and DWork data structure for the nonvirtual subsystem function that is independent from the parent model data structures. As a result, generated code for the subsystem:

- Is easier to trace.
- Is easier to test.
- Reduces the size of a model's global data structures.

To use the **Function with separate data** parameter,

- Configure the model with an ERT-based system target file.
- Configure the subsystem to be atomic or conditionally executed.
- Set the subsystem block parameter **Function packaging** to `Nonreusable function`.

To configure your subsystem for generating modular function code, invoke the Subsystem Parameters dialog box and make a series of selections to display and enable the **Function with separate data** option. See “Configure Subsystem for Generating Modular Function Code” on page 40-2 and “Modular Function Code for Nonvirtual Subsystems” on page 40-5 for details. For limitations that apply, see “Nonvirtual Subsystem Modular Function Code Limitations” on page 40-17.

For more information about generating code for atomic subsystems, see “Generate Subsystem Code as Separate Function and Files” and “Generate Code and Executables for Individual Subsystems”.

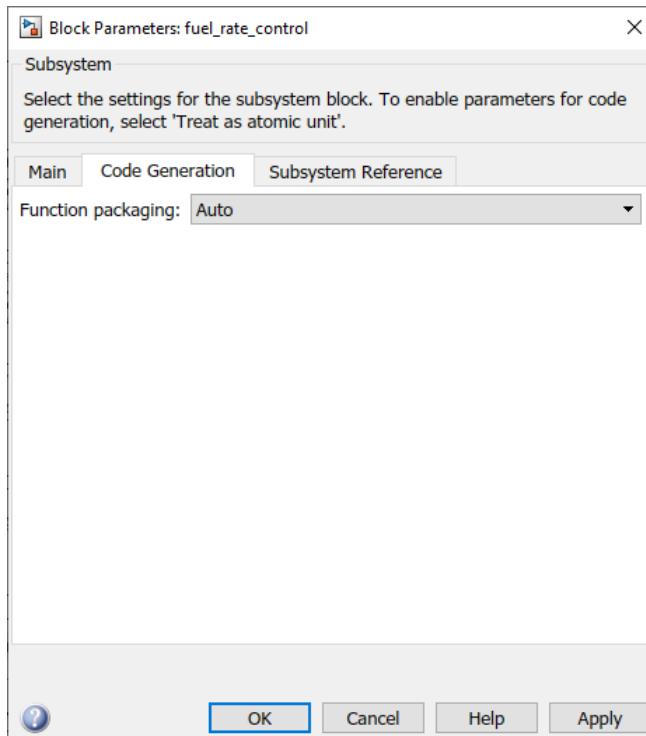

### Configure Subsystem for Generating Modular Function Code

- 1 Verify that the model containing the subsystem uses an ERT-based system target file.
- 2 Select the subsystem for which you want to generate modular function code and open the Subsystem Parameters dialog box. The dialog box for an atomic subsystem is shown below. (In the dialog box for a conditionally executed subsystem, the dialog box option **Treat as atomic unit** is greyed out, and you can skip Step 3.)

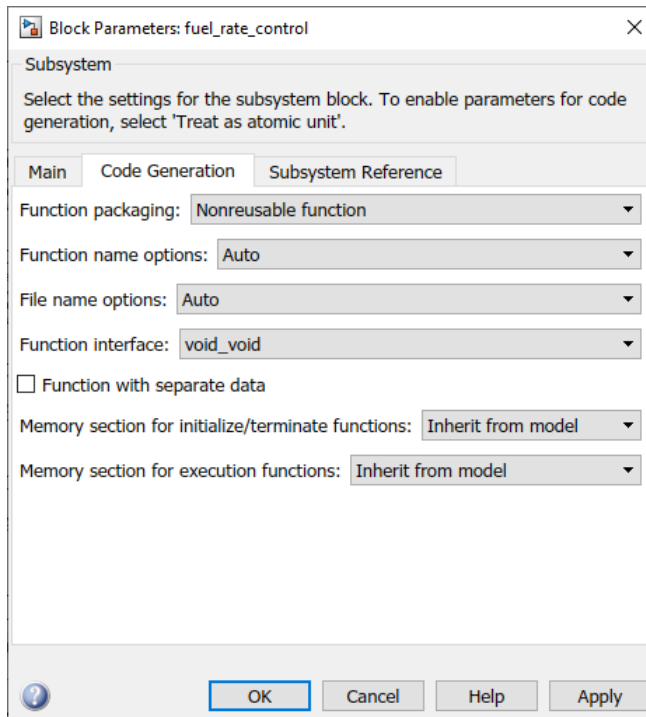

- 3 If the block parameter **Treat as atomic unit** is available for selection but not selected, the subsystem is neither atomic nor conditionally executed. Select the parameter **Treat as atomic unit**, which enables the **Function packaging** parameter on the **Code Generation** tab. Select the **Code Generation** tab.

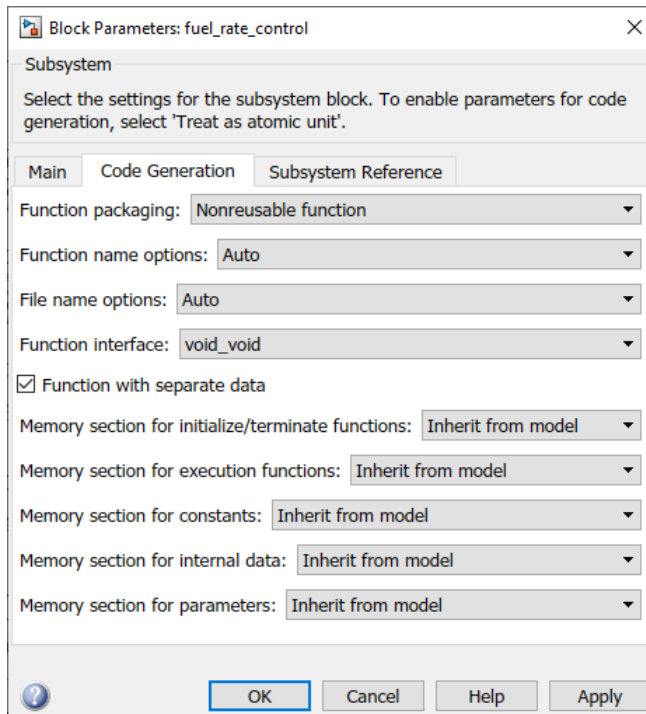

- 4 For the **Function packaging** parameter, select `Nonreusable` function. After you make this selection, the **Function with separate data** parameter is displayed.

Before you generate code for the nonvirtual subsystem with the **Function with separate data** parameter selected, consider generating function code with the parameter cleared and save the generated function .c and .h files in a separate directory for later comparison.

- 5 Select the **Function with separate data** parameter. Additional parameters appear.

To control the naming of the generated subsystem function and the subsystem files, modify subsystem parameters **Function name options** and **File name options**.

- 6 Save your subsystem parameter changes and exit the dialog box by clicking **OK**.
- 7 Generate code for the subsystem and examine the generated files, including the function .c and .h files named according to your subsystem parameter specifications.

For more information on generating code for nonvirtual subsystems, see “Generate Subsystem Code as Separate Function and Files” on page 3-7. For examples of generated subsystem function code, see “Modular Function Code for Nonvirtual Subsystems” on page 40-5.

## Modular Function Code for Nonvirtual Subsystems

This example shows how to generate nonvirtual subsystem function code with the **Function with separate data** parameter cleared and selected and compares the results.

- 1 Open example model `rtwdemo_atomic`. Then, open the **Embedded Coder** app. Change the system target file to `ert.tlc`.

This model shows how to preserve the boundary of a virtual subsystem. When you select subsystem block parameter **Treat as atomic unit**, the code that the code generator produces for the subsystem executes as an atomic unit. When configured as atomic, you can specify how the code generator represents the subsystem by setting the **Function Packaging** parameter on the **Code Generation** tab. You can specify that the subsystem is translated to one of these types of implementation:

- **Inline**: Inlined subsystem code at call sites.
- **Function**: void/void function with I/O and internal data in the model global data structure.
- **Reusable Function**: Reentrant function with data passed in as function arguments.
- **Auto**: Code generator optimizes the implementation based on context.

- 2 Double-click the SS1 subsystem and examine the contents.

Then, close the subsystem window.

- 3 Right-click the SS1 subsystem, select **Block Parameters (Subsystem)** from the context menu, and examine the settings. Simulink and the code generator can avoid "artificial" algebraic loops when

you make the subsystem atomic with subsystem parameter **Minimize algebraic loop occurrences**.

- 4 Create a variant of `rtwdemo_atomic` that shows function code *without* data separation.
  - a In the Subsystem Parameters dialog box,
    - In the **Main** tab, select **Treat as atomic unit**.
    - In the **Code Generation** tab:
      - Set **Function packaging** to Nonreusable function.
      - Set **Function name options** to User specified.
      - Set **Function name** to `myfun`.
      - Set **File name options** to Use function name. This setting is optional but simplifies the later task of code comparison by causing the atomic subsystem function code to be generated into files `myfun.c` and `myfun.h`.

Do *not* select the **Function with separate data** parameter.

- b Click **Apply** to apply the changes and click **OK** to exit the dialog box.
  - c Save the model variant with a unique file name (for example, `rtwdemo_atomic1`) to a writable location.
- 5 Create a variant of `rtwdemo_atomic` that shows function code *with* data separation.
  - a Open model `rtwdemo_atomic`.
  - b Open the **Embedded Coder** app. Change the system target file to `ert.tlc`.
  - c In the model canvas, right-click the SS1 subsystem and select **Block Parameters (Subsystem)**. In the Subsystem Parameters dialog box,
    - In the **Main** tab, select **Treat as atomic unit**.
    - In the **Code Generation** tab:
      - Set **Function packaging** to Nonreusable function.
      - Set **Function name options** to User specified.
      - Set **Function name** to `myfun`.
      - Set **File name options** to Use function name.
      - Select **Function with separate data**.
  - d Click **Apply** to apply the change and click **OK** to exit the dialog box.
  - e Save the model variant with a unique file name (for example, `rtwdemo_atomic2`) to a writable location.
- 6 Generate code for each model (for example, `rtwdemo_atomic1` and `rtwdemo_atomic2`).
- 7 Compare the `model.c/.h` and `myfun.c/.h` files generated for the two models. For code comparison discussion, see “H File Differences for Nonvirtual Subsystem Function Data Separation” on page 40-7 and “C File Differences for Nonvirtual Subsystem Function Data Separation” on page 40-7.

In this example, there are not significant differences in the generated variants of `ert_main.c`, `model_private.h`, `model_types.h`, or `rtwtypes.h`.

## H File Differences for Nonvirtual Subsystem Function Data Separation

- Selecting **Function with separate data** causes the code generator to place type definitions for subsystem data in the `myfun.h` file for `rtwdemo_atomic2`:

```
/* Block states (default storage) for system '<Root>/SS1' */
typedef struct {
 real_T Integrator_DSTATE; /* '<S1>/Integrator' */
} DW_myfun_T;
```

For `rtwdemo_atomic1`, type definitions for subsystem data belong to the model and appear in `rtwdemo_atomic1.h`:

```
/* Block signals (default storage) */
typedef struct {
 real_T Sum; /* '<Root>/Sum' */
} B_rtwdemo_atomic_1_T;

/* Block states (default storage) for system '<Root>' */
typedef struct {
 real_T Integrator_DSTATE; /* '<S1>/Integrator' */
} DW_rtwdemo_atomic_1_T;
```

- Selecting **Function with separate data** generates the following external declarations in the `myfun.h` file for `rtwdemo_atomic2`:

```
/* Extern declarations of internal data for system '<Root>/SS1' */
extern DW_myfun_T myfun_DW;
extern void myfun_Update(void);
extern void myfun(void);
```

By contrast, the generated code for `rtwdemo_atomic1` contains model-level external declarations for the subsystem BlockIO and D\_Work data, in `rtwdemo_atomic1.h`:

```
/* Block signals (default storage) */
extern B_rtwdemo_atomic_1_T rtwdemo_atomic_1_B;

/* Block states (default storage) */
extern DW_rtwdemo_atomic_1_T rtwdemo_atomic_1_DW;
```

## C File Differences for Nonvirtual Subsystem Function Data Separation

- Selecting **Function with separate data** causes a separate subsystem initialize function, `myfun_initialize`, to be generated in the `myfun.c` file for `rtwdemo_atomic2`:

```
void myfun_initialize(void) {
 {
 ((real_T*)&rtwdemo_atomic2_myfunB.Integrator)[0] = 0.0;
 }
 rtwdemo_atomic2_myfunDW.Integrator_DSTATE = 0.0;
}
```

The subsystem initialize function in `myfun.c` is invoked by the model initialize function in `rtwdemo_atomic2.c`:

```
/* Model initialize function */

void rtwdemo_atomic2_initialize(void)
{
 ...
}
```

```

 /* Initialize subsystem data */
 myfun_initialize();
}

```

By contrast, for `rtwdemo_atomic1`, subsystem data is initialized by the model initialize function in `rtwdemo_atomic1.c`:

```

/* Model initialize function */

void rtwdemo_atomic1_initialize(void)
{
 ...
 /* block I/O */
 {
 ...
 ((real_T*)&rtwdemo_atomic1_B.Integrator)[0] = 0.0;
 }

 /* states (dwork) */

 rtwdemo_atomic1_DWork.Integrator_DSTATE = 0.0;
 ...
}

```

- Selecting **Function with separate data** generates the following declarations in the `myfun.c` file for `rtwdemo_atomic2`:

```

/* Declare variables for internal data of system '<Root>/SS1' */
DW_myfun_T myfun_DW;

```

By contrast, the generated code for `rtwdemo_atomic1` contains model-level declarations for the subsystems `BlockIO` and `D_Work` data, in `rtwdemo_atomic1.c`:

```

/* Block signals (default storage) */
B_rtwdemo_atomic_1_T rtwdemo_atomic_1_B;

/* Block states (default storage) */
DW_rtwdemo_atomic_1_T rtwdemo_atomic_1_DW;

```

- Selecting **Function with separate data** generates identifier naming that reflects the subsystem orientation of data items. The references to subsystem data in subsystem functions, such as `myfun` and `myfun_update`, are in the model `model_step` function. For example, compare this code from `myfun` for `rtwdemo_atomic2`

```

/* DiscreteIntegrator: '<S1>/Integrator' */
rtwdemo_atomic_2_Y.Out1 = myfun_DW.Integrator_DSTATE;

```

to the corresponding code from `myfun` for `rtwdemo_atomic1`.

```

/* DiscreteIntegrator: '<S1>/Integrator' */
rtwdemo_atomic_1_Y.Out1 = rtwdemo_atomic_1_DW.Integrator_DSTATE;

```

## Partition Functions in Generated Code

This example shows how to associate subsystems in a model with function names and files.

Learn how to:

- Specify function and file names in the generated code.
- Identify the parts of the generated code that are required for integration.
- Generate code for atomic subsystems.
- Identify data that are required to execute a generated function.

For information about the example model and other examples in this series, see “Prepare a Control Algorithm Model for C Code Generation” on page 50-18.

### **Atomic and Virtual Subsystems**

The example models in “Prepare a Control Algorithm Model for C Code Generation” on page 50-18 and “Configure Data Interface in the Generated Code” on page 50-29 use *virtual subsystems*. Virtual subsystems visually organize blocks but do not affect the model functionality. *Atomic subsystems* evaluate the blocks included in a model as a unit. With atomic subsystems, you can specify additional function partitioning information. In a model, atomic subsystems appear with a bold border.

### **View Changes in Model Architecture**

Open the example model `rtwdemo_PCG_Eval_P3`.

Save a copy of the model to a writable folder.

This example shows how to replace the virtual subsystems with *function-call subsystems*. Function-call subsystems:

- Are atomic subsystems
- Enable you to control subsystem execution order
- Execute when a *function call signal* triggers

By controlling the execution order of the subsystems, you can match the model with an existing system that has a specific execution order.

The figure identifies the function call subsystems (1) `PI_ctrl_1`, `PI_ctrl_2`, and `Pos_Command_Arbitration`.

This version of the model contains the new subsystem `Execution_Order_Control` (2), which contains a Stateflow® chart that models the calling functionality of a scheduler. The subsystem controls the execution order of the function call subsystems through function call signals (3). Later in this example, you examine how changing the execution order can change the simulation results.

This version of the model contains new Signal Conversion blocks (4) at the outputs of the PI controllers. With these additional blocks in place, the code generator can generate a single reentrant function for the PI controllers.

### Control Function Location and File Placement in the Generated Code

In “Prepare a Control Algorithm Model for C Code Generation” on page 50-18 and “Configure Data Interface in the Generated Code” on page 50-29, the code generator creates a single `model_step` function that contains the control algorithm code. However, many applications require a greater level of control over the file placement of functions. By modifying the parameters of atomic subsystems, you can specify multiple functions within a single model.

The figure shows the subsystem parameters for `PI_ctrl_1`.

### Treat as atomic unit

- Enables other submenus. For atomic subsystems, this parameter is automatically selected and disabled.

### Sample time

- Specifies a sample time for execution. Not available for function-call subsystems.

### Function packaging options

- `Auto` -- Determines how the subsystem appears in the generated code. This value is the default.
- `InLine` -- Places the subsystem code inline with the rest of the model code.
- `Function` -- Generates the code for the subsystem as a function.
- `Reusable function` -- Generates a reusable (reentrant) function from the subsystem. The function passes all input and output data through formal parameters. The function does not directly access global variables.

### Function name options

- Selecting `Function` or `Reusable function` for **Function packaging** enables function name options.
- `Auto` -- Determines the function.
- `Use subsystem name` -- Bases the function on the subsystem name.
- `User specified` -- Applies the specified file name.

### File name options

- Selecting `Function` or `Reusable function` for **Function packaging** enables file name options.
- `Auto` -- Places the function definition in the module generated for the parent system, or, if the model root is the parent, in `model.c`.

- Use subsystem name -- Generates a separate file. The name of the file is the name of the subsystem or library block.
- Use function name -- Generates a separate file. The name of the file is the name that you specify with **Function name options**.
- User specified -- Applies the specified, unique file name.

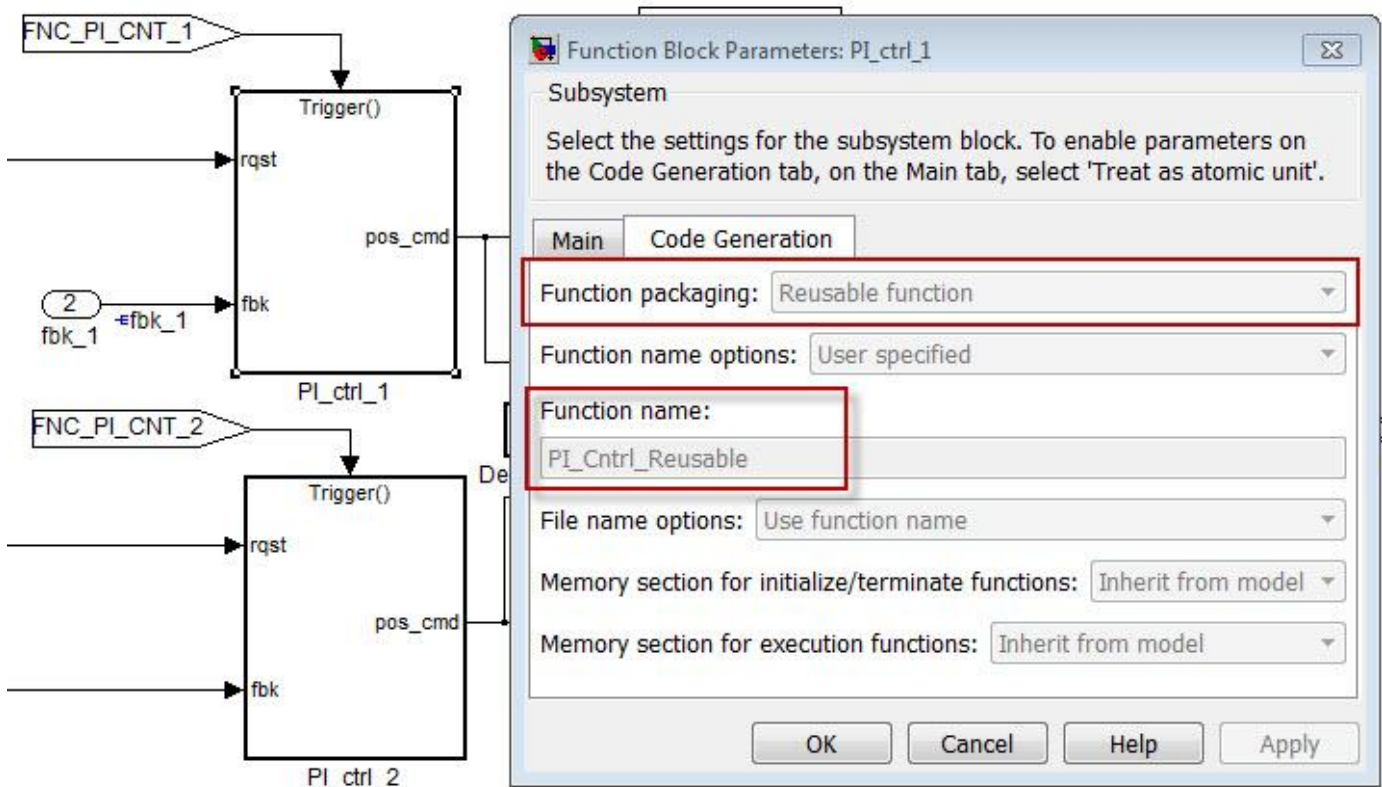

**Function with separate data**

- Enabled when you set **Function packaging** to Function. When selected, the code generator separates the internal data of the subsystem (for example, signals) from the data of the parent model. The subsystem owns this separate data.

**Generate Reentrant Code**

Embedded Coder® supports *reentrant code*. Reentrant code is a reusable programming routine that multiple programs can use simultaneously. Reentrant code is used in operating systems and other system software that uses multithreading to handle concurrent events. Reentrant code does not maintain state data, so there are no persistent variables in the function. Calling programs maintain state variables and must pass the state data into the function. Multiple users or processes can share one copy of a reentrant function.

To generate reentrant code, you must first specify the subsystem as reusable by configuring the subsystem parameter **Function packaging**.

In some cases, the configuration of the model prevents reusable code. The table lists common issues.

Cause	Solution
-------	----------

Subsystem output feeds global signal data

Add a Signal Conversion block between the subsystem and the global signal.

Generated function receives data (formal parameters) through pointers

Select Configuration Parameters > Model Referencing > Pass fixed-size scalar root inputs by value for code generation.

Subsystem uses global signal data in internal algorithm

Use a port to pass the global data in and out of the subsystem.

### Use a Mask to Pass Parameter Values into Library Subsystem

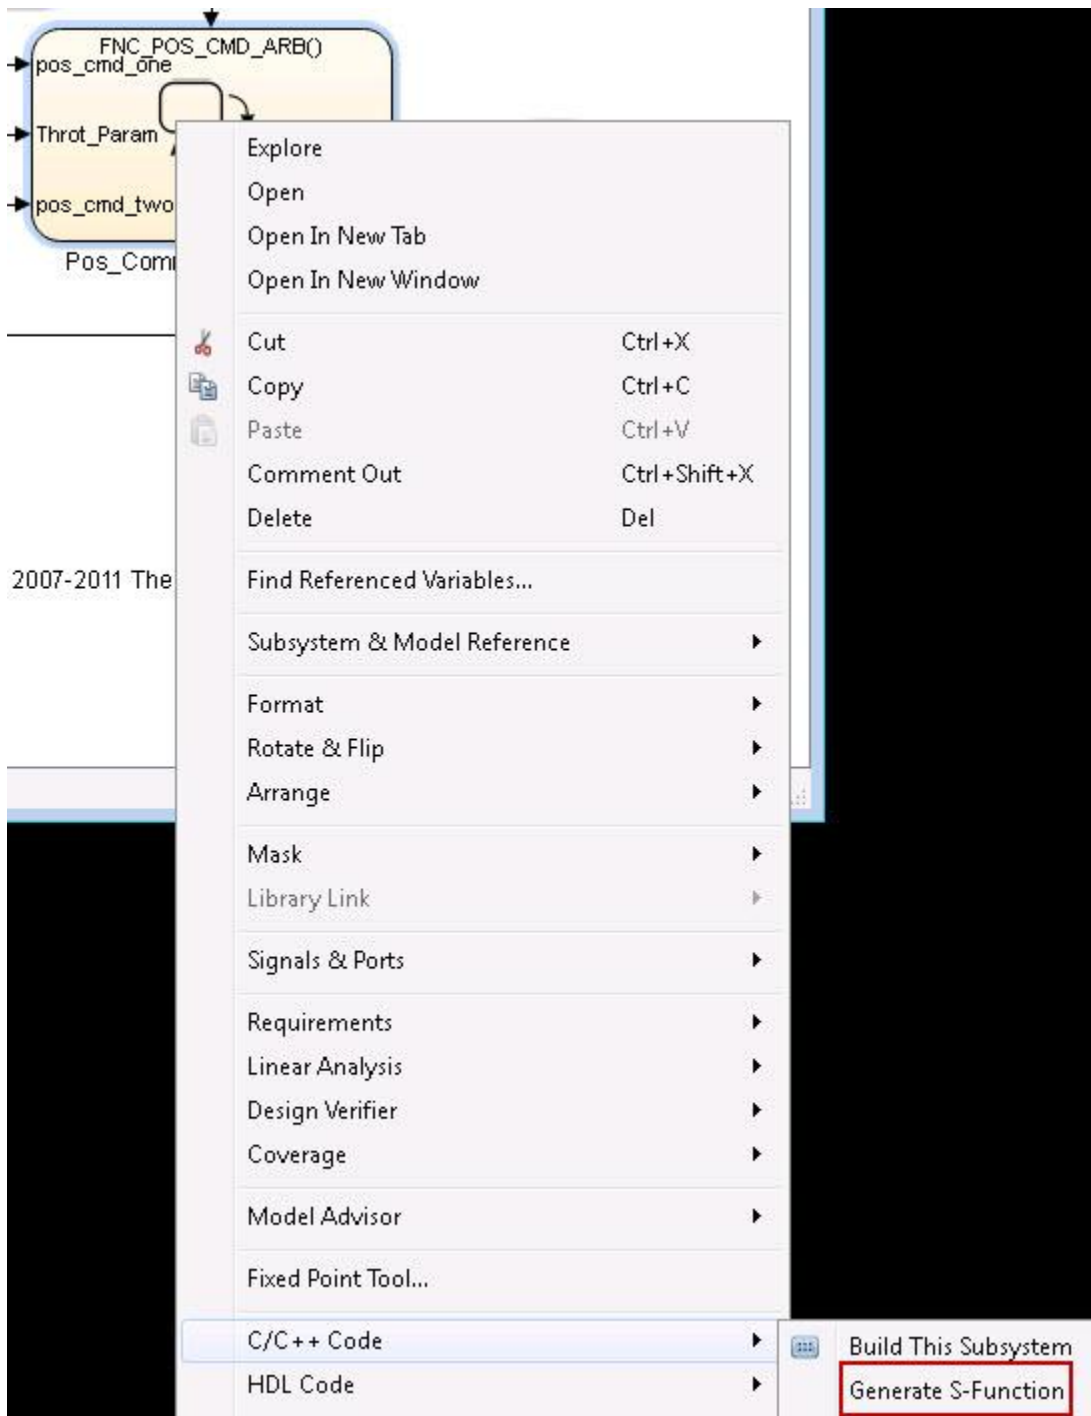

To define algorithmic parameter data (such as a gain or coefficient) outside the scope of a reusable library block or subsystem, you can apply a *mask* to the block or subsystem and create a mask parameter. You can then specify a different parameter value for each instance of the block or subsystem. Each mask parameter appears in the generated code as a formal parameter of the reentrant function.

In this version of the model, the subsystems PI\_ctrl\_1 and PI\_ctrl\_2 are masked. In each mask, the values of the P and I gains are set by data objects such as I\_Gain\_2 and P\_Gain\_2.

### Generate Code for Atomic Subsystem

In “Prepare a Control Algorithm Model for C Code Generation” on page 50-18 and “Configure Data Interface in the Generated Code” on page 50-29, you generate code at the root level of the model. Alternatively, you can build a specific subsystem.

To initiate a subsystem build, use the context menu. You can choose from these options:

- 1 **Build This Subsystem:** Treats the subsystem as a separate mode and creates the full set of source C files and header files. This option does not support function-call subsystems.
- 2 **Generate S-Function:** Generates C code for the subsystem and creates an S-Function wrapper. You can then simulate the code in the original model. This option does not support function-call subsystems.

- 3 Export Functions:** Generates C code without the scheduling code that comes with the **Build This Subsystem** option. Use this option to build subsystems that use triggers, such as function-call subsystems.

Alternatively, open the **Embedded Coder** app, select the subsystem and on the **C Code** tab, click **Build**.

### Examine Generated Code

This example compares the files that are generated for the full system build with the files that are generated for exported functions. You also examine how the masked data appears in the code.

Run the build script for the three options. Then, examine the generated files by clicking the hyperlinks.

- 1 Generate code from the entire model.
- 2 Export the function `PI_ctrl_1`.
- 3 Export the function `Pos_Command_Arbitration`.

#### **rtwdemo\_PCG\_Eval\_P3.c**

- Full Build: Yes, Step function
- `PI_ctrl_1`: No
- `Pos_Command_Arbitration`: No

#### **PI\_ctrl\_1.c**

- Full Build: No
- `PI_ctrl_1`: Yes, Trigger function
- `Pos_Command_Arbitration`: No

#### **Pos\_Command\_Arbitration.c**

- Full Build: No
- `PI_ctrl_1`: No
- `Pos_Command_Arbitration`: Yes, Init and Function

#### **PI\_Ctrl\_Reusable.c**

- Full Build: Yes
- `PI_ctrl_1`: Yes
- `Pos_Command_Arbitration`: No

#### **ert\_main.c**

- Full Build: Yes
- `PI_ctrl_1`: Yes
- `Pos_Command_Arbitration`: Yes

#### **eval\_data.c**

- Full Build: Yes(1)
- PI\_ctrl\_1: Yes(1)
- Pos\_Command\_Arbitration: No, Eval data not used in diagram

(1) `eval_data.c` has different content in the full and export function builds. The full build includes all of the parameters that the model uses. The export function contains only the variables that the subsystem uses.

### Masked Data in the Generated Code

In the file `rtwdemo_PCG_Eval_P3.c`, the call sites of the reentrant function use the data objects `P_Gain`, `I_Gain`, `P_Gain_2`, and `I_Gain_2` as arguments.

```
PI_Cntrl_Reusable(*pos_rqst, fbk_1, &rtwdemo_PCG_Eval_P3 B->PI_ctrl_1,
 &rtwdemo_PCG_Eval_P3_DWork->PI_ctrl_1, I_Gain, P_Gain);
PI_Cntrl_Reusable(*pos_rqst, fbk_2, &rtwdemo_PCG_Eval_P3 B->PI_ctrl_2,
 &rtwdemo_PCG_Eval_P3_DWork->PI_ctrl_2, I_Gain_2, P_Gain_2);
```

### Effect of Execution Order on Simulation Results

By default, Simulink® executes the subsystems in this order:

- 1 PI\_ctrl\_1
- 2 PI\_ctrl\_2
- 3 Pos\_Command\_Arbitration

For this example, you can specify one of two alternative orders of execution. You can then use the test harness to observe the effect of the execution order on the simulation results. The subsystem `Execution_Order_Control` has two configurations that control the execution order. To choose a configuration, use the subsystem context menu.

Change the execution order and observe the results.

- 1 Set the execution order to `PI_ctrl_1`, `PI_ctrl_2`, `Pos_Command_Arbitration`.
- 2 Open the test harness.
- 3 Run the test harness.
- 4 Change the execution order to `Pos_Command_Arbitration`, `PI_ctrl_1`, `PI_ctrl_2`.
- 5 Run the test harness.

The simulation results (throttle position over time) vary slightly depending on the order of execution. You can see the difference most clearly when the throttle request changes.

For the next example in this series, see “Call External C Code from Model and Generated Code” on page 50-47.

## Nonvirtual Subsystem Modular Function Code Limitations

Nonvirtual subsystem block parameter **Function with separate data** has the following limitations:

- The parameter is available for models configured with an ERT-based system target file.
- The nonvirtual subsystem to which the parameter is applied cannot have multiple sample times or continuous sample times; that is, the subsystem must be single-rate with a discrete sample time.
- The nonvirtual subsystem cannot contain continuous states.
- The nonvirtual subsystem cannot output function call signals.
- The nonvirtual subsystem cannot contain noninlined S-functions.
- The generated files for the nonvirtual subsystem will reference model-wide header files, such as *model.h* and *model\_private.h*.
- The parameter is incompatible with the **Classic call interface** parameter. Selecting both parameters generates an error.
- The parameter is incompatible with the **Reusable function** setting for model configuration parameter **Code interface packaging**. Selecting both parameters generates an error.
- When you select the parameter for a subsystem, the model that contains the subsystem cannot contain a Data Store Memory block with **Share across model instances** selected. See Data Store Memory.

## Generate Reentrant, Multi-Instance Code

This example shows you how to configure a model for reentrant, multi-instance code generation. Multiple programs can use reentrant code simultaneously. When you configure a model for reentrancy, the execution (step) entry-point function uses root-level input and output arguments instead of global data structures. After examining the configuration settings, generate and review the generated code.

### Open the Model

Open the model `rtwdemo_reusable`. The model contains two root Inport blocks and a root Outport block.

```
model='rtwdemo_reusable';
open_system(model);
```

Copyright 1994-2020 The MathWorks, Inc.

Save a copy of the model to a writable location.

```
currentDir=pwd;
[~,cgDir] = rtwdemodir();
```

### Examine Relevant Model Configuration Parameter Settings

1. Open the **Embedded Coder** app.
2. Open the Model Configuration Parameters dialog box.
3. Model configuration parameter **System target file** is set to `ert.tlc`. Although you can generate reentrant code for a model configured with **System target file** set to `grt.tlc`, ERT and ERT-based system target files provide more control over how the code passes root-level I/O.
4. Open the **Code Generation > Interface** pane and explore relevant model configuration parameter settings.
  - **Code interface packaging** is set to `Reusable` function. This parameter setting instructs the code generator to produce reusable, multi-instance code.
  - Setting of `Reusable` function displays parameter **Multi-instance code error diagnostic**. That parameter is set to `Error`, indicating that the code generator abort if the model violates requirements for generating multi-instance code.

- **Pass root-level I/O as** is set to Part of model data structure. This setting packages root-level model input and output into the real-time model data structure (`rtModel`), which is an optimized data structure that replaces `SimStruct` as the top-level data structure for a model.
- **Remove error status field in real-time model data structure** is selected. This parameter setting reduces memory usage by omitting the error status field from the generated real-time model data structure.

### Generate and Review Code

```
slbuild(model);
```

```
Starting build procedure for: rtwdemo_reusable
Successful completion of build procedure for: rtwdemo_reusable
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_reusable	Code generated and compiled	Code generation information file does not exist.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 17.385s
```

### Review the Generated Code

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point function `rtwdemo_reusable_step`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_reusable.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_reusable.h` declare model data structures and a public interface to the model entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

### Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework.

1. Include the generated header file by adding directive `#include rtwdemo_reusable.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for the model Outport block.

Input ports:

- `<Root>/In1` of data `real_T` with dimension of 1
- `<Root>/In2` of data `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_reusable_initialize(RT_MODEL *const rtM)`. At startup, call this function once.
- Output and update (step) entry-point function, `void rtwdemo_reusable_step(RT_MODEL *const rtM)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.

Output port:

- `<Root>/Out1` of data type `real_T` with dimension of 1

### Examine the Step Function

Examine the `rtwdemo_reusable_step` function code in `rtwdemo_reusable.c`.

```
cfile = fullfile(cgDir, 'rtwdemo_reusable_ert_rtw', 'rtwdemo_reusable.c');
rtwdemodbtype(cfile, '/* Model step function', '/* Model initialize function ', 1, 0);
```

```
/* Model step function */
void rtwdemo_reusable_step(RT_MODEL *const rtM)
{
 D_Work *rtDWork = rtM->dwork;
 ExternalInputs *rtU = (ExternalInputs *) rtM->inputs;
 ExternalOutputs *rtY = (ExternalOutputs *) rtM->outputs;

 /* Output: '<Root>/Out1' incorporates:
 * UnitDelay: '<Root>/Delay'
 */
 rtY->Out1 = rtDWork->Delay_DSTATE;

 /* Gain: '<Root>/Gain' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 * Sum: '<Root>/Sum'
 * UnitDelay: '<Root>/Delay'
 */
 rtDWork->Delay_DSTATE = (rtU->In1 + rtU->In2) * rtP.k1;
}
```

The code generator passes model data to the `rtwdemo_reusable_step` function as part of the real-time model data structure. Try different settings for model configuration parameters **Code interface packaging** and **Pass root-level I/O** and regenerate code. Observe how the function prototype changes.

### Close the Model and Report

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Generate Code for String Blocks by Using the Standard C++ String Library

Optimize generated code for Simulink® string blocks by using standard C++ library string functions and string objects. The C++ string library provides consistent C++ code and improves functionality, such as string length retrieval, concatenation, string copy, string swapping, string comparison, and substring computations.

### Example Model

In the model `matlab:mStrfindSubStr`, a string constant block that has the value "Hello!" connects to the `str` port of a String Find block. An inport connects to the `sub` port of the same String Find block.

```
model = 'mStrfindSubStr';
open_system(model);
```

Copyright 2021 The MathWorks, Inc.

In your system's temporary folder, create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

### Generate Code by Using C++ String Libraries

In the Configuration Parameters dialog box, set the **Language** parameter to C++.

```
set_param(model, 'TargetLang', 'C++');
```

In the Configuration Parameters dialog box, set the **Code interface packaging** parameter to C++ class.

```
set_param(model, 'CodeInterfacePackaging', 'C++ class');
```

In the Configuration Parameters dialog box, set the **Standard math library** parameter to C++03 (ISO).

```
set_param(model, 'TargetLangStandard', 'C++03 (ISO)');
```

Build the model.

```
evalc('slbuild(model)');
```

View the generated code with C++ string library objects. Here is a portion of `mStrfindSubStr.h`. The code instantiates a `std::string` object `In1`.

```
cfile = fullfile(cgDir, 'mStrfindSubStr_ert_rtw', 'mStrfindSubStr.h');
rtwdemodbtype(cfile, 'External inputs', 'External outputs', 0, 0);
```

```
struct ExtU_mStrfindSubStr_T {
 std::string In1; // '<Root>/In1'
};
```

View the generated code with C++ string library functions. Here is a portion of `mStrfindSubStr.cpp`. The code uses the `find` function to look for the first character match, which is present in the C++ string library.

```
cfile = fullfile(cgDir, 'mStrfindSubStr_ert_rtw', 'mStrfindSubStr.cpp');
rtwdemodbtype(cfile, 'Model step function', 'Model initialize function', 0, 0);
```

```
void untitled1ModelClass::step()
{
 uint32_T tmpOut;

 // StringFind: '<Root>/String Find' incorporates:
 // Inport: '<Root>/In1'
 // StringConstant: '<Root>/String Constant'

 tmpOut = mStrfindSubStr_P.StringConstant_String.find(mStrfindSubStr_U.In1);
 if (tmpOut == (uint32_T)std::string::npos) {
 // Outport: '<Root>/Out1'
 mStrfindSubStr_Y.Out1 = -1;
 } else {
 // Outport: '<Root>/Out1'
 mStrfindSubStr_Y.Out1 = static_cast<int32_T>(tmpOut) + 1;
 }

 // End of StringFind: '<Root>/String Find'
}
```

This code executes faster and is easier to read. Close the model and the code generation report.

```
bdclose(model);
rtwdemoclean;
cd(currentDir);
```

### Limitations:

An array of a bus that contains `std:string` is not supported in software-in-loop (SIL) and processor-in-loop (PIL) simulations.

## Configure Deployment Types for Model Hierarchy

When you develop a complex system by using Model-Based Design, models have different requirements for the resulting code to run on the target platform. A *deployment type* indicates how the generated code for a model interacts with the platform and code generated from other models. The deployment type also indicates the role of a model in the system and determines the composition rules for using the model in a hierarchy with other models. You can set the deployment type of each model in a system by using the Embedded Coder app or the code mappings programmatic interface. The deployment types are:

- **Component** — The top model from which the code generator produces code. The code generator produces a standalone algorithm that runs on the target platform. The component code exposes its interface to other components in the system and to platform services.
- **Subcomponent** — A model reference that a component model uses. The generated code entry points are symbolically scoped to the parent component and are not exposed to the platform.
- **Automatic** — Embedded Coder determines the deployment type based on the model hierarchy context.
- **Simulation only** — A model intended for simulation only. For example, for a plant model that you use for testing a component model, set the deployment type to simulation only.

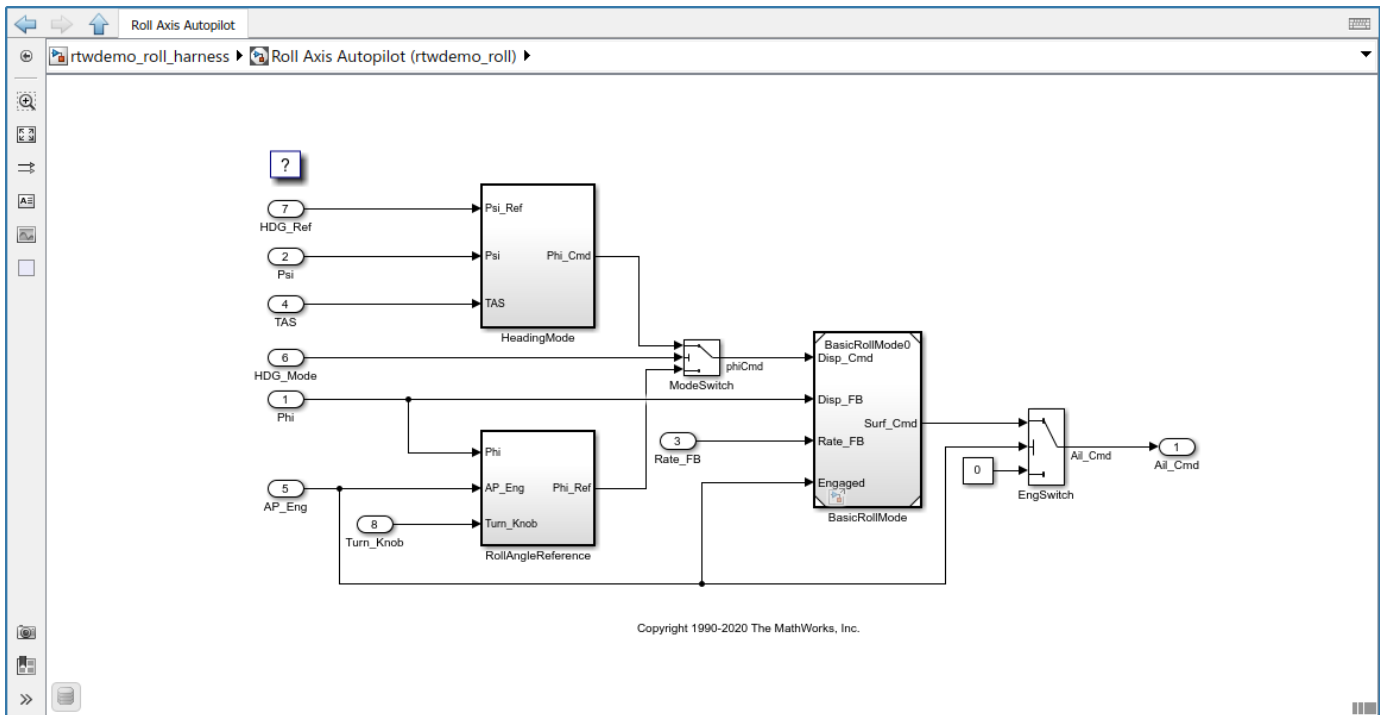

Embedded Coder uses the deployment type of a model to determine whether or not to generate code for the model and, if the model is for code generation, how to map elements of the model to code interfaces for the platform. This example shows you how to configure the deployment types for several models in a system and generate code to run on the target platform.

### Set Up Test Harness and Model Hierarchy

The model `rtwdemo_roll_harness` is a harness model that generates test inputs for the component model `rtwdemo_roll`. The harness model is for simulation only. You generate code for the model `rtwdemo_roll`. For this example, you add a referenced model to the `rtwdemo_roll` model to represent a subcomponent in the generated code.

- 1 Open the model `rtwdemo_roll_harness`. At the command line, enter `rtwdemo_roll_harness`.
- 2 View the component model `rtwdemo_roll` by double-clicking the Model block.
- 3 Convert the subsystem `BasicRollMode` to a referenced model. Right-click the Subsystem block and click **Subsystem & Model Reference > Convert to > Referenced Model**. Click **Convert**.

The model hierarchy now contains these models:

- `rtwdemo_roll_harness` — The test harness that generates inputs for `rtwdemo_roll`. You simulate this model. You do not generate code from this model.
- `rtwdemo_roll` — The component model from which the code generator generates code for the target platform.
- `BasicRollMode` — A subcomponent for which the code generator produces code in the context of the component model `rtwdemo_roll`.

To generate code according to this hierarchy, configure the deployment types for these models.

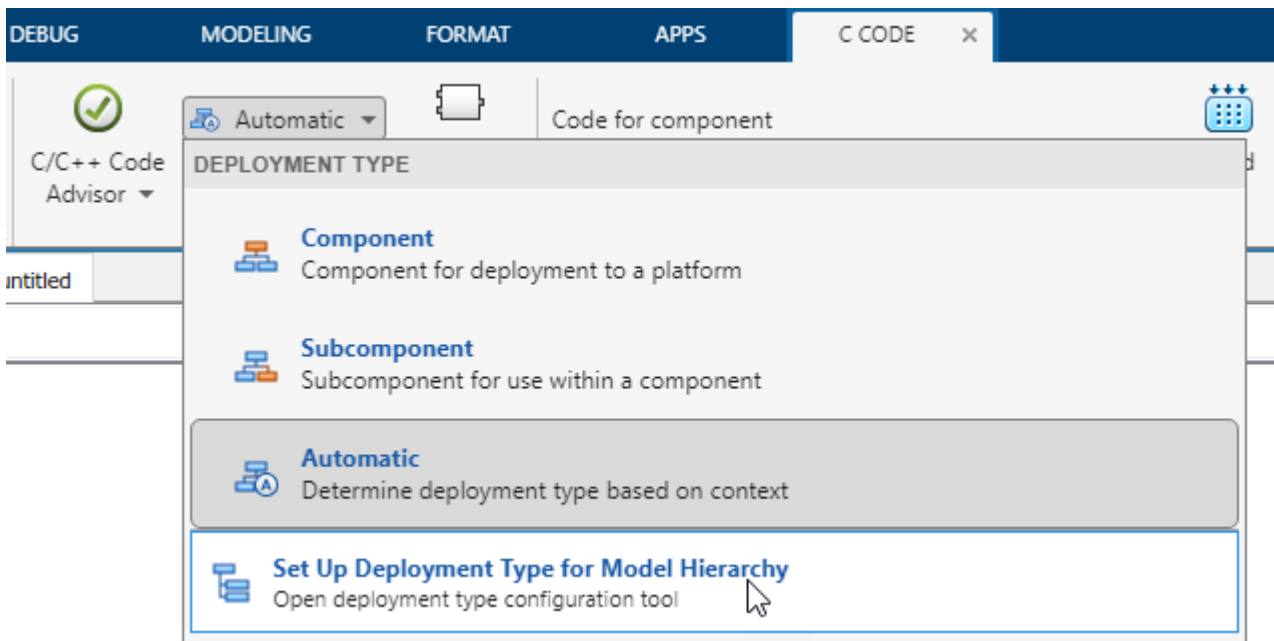

## Specify Deployment Types for the Models

You specify the deployment types of the models in one of these ways:

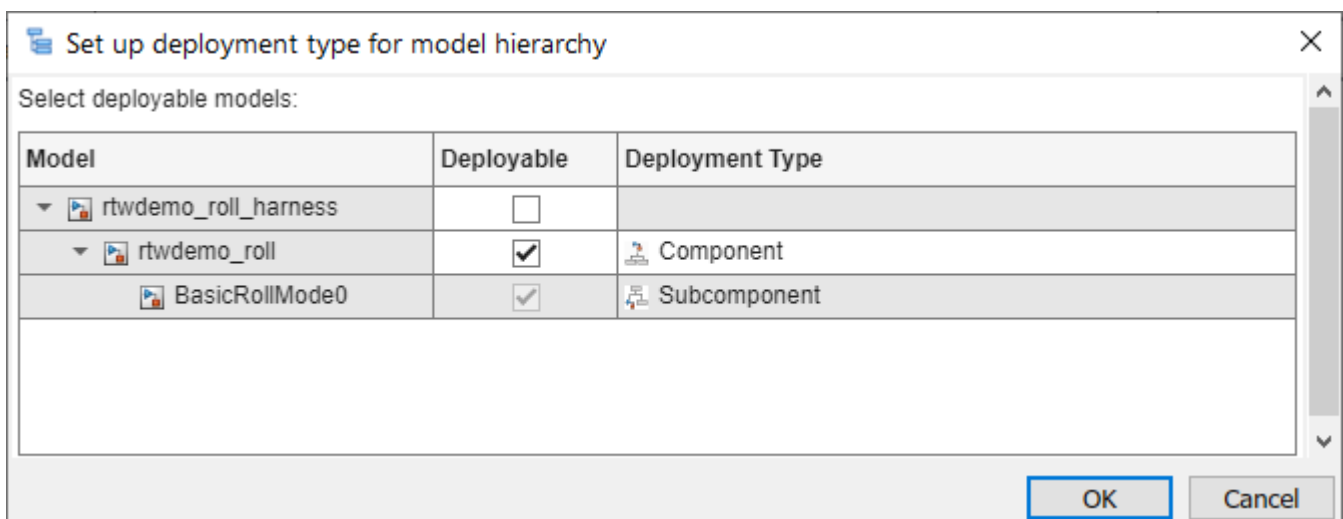

- For each model, on the **C Code** tab, select the deployment type from the deployment type options. Select the **Simulation only** option from the **Output** menu or select a deployment type from the **Deployment Type** menu.
- Configure the models in a hierarchy by using the deployment configuration tool.
- Use the code mappings programmatic interface.

For this example, use the deployment configuration tool and set the deployment types for the whole model hierarchy.

- 1 With the `rtwdemo_roll_harness` model open, open the **Embedded Coder** app.
- 2 On the **C Code** tab, in the **Prepare** section, click the **Automatic** button. This button shows the deployment type for the model that is in the canvas. **Automatic** indicates that Embedded Coder determines the deployment type based on the model context.

- 3 From the **Deployment Type** menu, select **Set Up Deployment Type for Model Hierarchy**.
- 4 In the Set up deployment type for model hierarchy dialog box, expand the `rtwdemo_roll_harness` and `rtwdemo_roll` models to see the model hierarchy.
- 5 Specify the `rtwdemo_roll_harness` model as simulation only. In the row for the model, clear the check box for the **Deployable** column. This configures the model for simulation only. The code generator does not produce code from this model.
- 6 Specify the `rtwdemo_roll` model as a component. In the row for the model, in the **Deployment Type** column, double-click the box and from the drop-down select **Component**. This configures the model for top-level model code generation.
- 7 Because `rtwdemo_roll` is a component model, the `BasicRollMode` model is automatically configured as a subcomponent. For this model, the code generator produces subcomponent code, which is scoped to the component code for `rtwdemo_roll`.

- 8 Click **OK**. On the **C Code** tab, the **Code for component** field shows the component model for which you generate code.

## Generate and Inspect Code

Generate code for the models. On the **C Code** tab, click **Build**. The Code view displays the generated code next to the model. To view code for a specific model, navigate to the model in the canvas. The Code view is updated to show the code for the currently displayed model. If you navigate to a simulation only model, such as `rtwdemo_roll_harness`, the Code view continues to show code from the component model.

View the code for the component model `rtwdemo_roll`. This code snippet shows some of the component interface that is generated for the model.

```
#include "rtwdemo_roll.h"
#include <math.h>
#include "rtwtypes.h"
#include "BasicRollMode.h"

/* Block signals and states (default storage) */
DW rtDW;

/* External inputs (root inport signals with default storage) */
ExtU rtU;

/* External outputs (root outports fed by signals with default storage) */
ExtY rtY;

/* Model step function */
void rtwdemo_roll_step(void)
{
 /* local block i/o variables */
 real32_T rtb_BasicRollMode;
 real32_T rtb_FixPtUnitDelay1;

 /* Outputs for Atomic SubSystem: '<Root>/RollAngleReference' */
 /* UnitDelay: '<S3>/FixPt Unit Delay1' */
 rtb_FixPtUnitDelay1 = rtDW.FixPtUnitDelay1_DSTATE;
}
```

View the code for the subcomponent model `BasicRollMode`. This code snippet shows some of the subcomponent interface that is generated for the model.

```
#include "BasicRollMode.h"
#include "rtwtypes.h"

/* Disable for referenced model: 'BasicRollMode' */
void BasicRollMode_Disable(BasicRollMode_DW_f *localDW)
{
 /* Disable for DiscreteIntegrator: '<Root>/Integrator' */
 localDW->Integrator_DSTATE = localDW->Integrator;
}

/* Output and update for referenced model: 'BasicRollMode' */
void BasicRollMode(const real32_T *rtu_Disp_Cmd, const real32_T *rtu_Disp_FB,
 const real32_T *rtu_Rate_FB, const boolean_T *rtu_Engaged,
 real32_T *rty_Surf_Cmd, BasicRollMode_DW_f *localDW)
{
 real32_T rtb_Sum;
 real32_T u0;
 boolean_T rtb_NotEngaged;
}
```

To further customize the interface of the generated code, use the Code Mappings editor to map model element categories and individual model elements to code definitions. The Code Mappings editor shows code definitions that are available to the model based on the deployment type.

## Interactively Configure C++ Interface

To streamline the integration of C++ code generated from Simulink applications, components, and subsystems with external C or C++ code, configure a customized C++ class interface. When you generate C++ code from a model, the model appears as a class, the data elements appear as class members, and the model functions appear as class methods in the generated code. Configuring a C++ class interface enables you to customize the following aspects of the generated C++ code:

- Class information — Class name and namespace
- Class member information — Class member access and visibility
- Class method information — Class method names and arguments

A customized C++ class interface enables the generated classes to meet specific code standards or interface requirements so that the generated code can compile and integrate into larger architectures with minimal post-generation customization.

### Interactive Workflow Overview

The interactive workflow provides quick, intuitive, and complete configuration of a customized C++ class interface by using tools accessible directly from the **C++ Code** tab. From the tab, you can click **Code Interface** and access the **Class Name & Namespace** configuration dialog box and Code Mappings editor (with Property Inspector) to configure an interface.

To interactively configure a customized C++ interface:

- 1 “Open Environment” on page 41-2
- 2 “Configure Model as Class” on page 41-4
- 3 “Configure Model Data Elements as Class Members” on page 41-5
- 4 “Configure Model Functions as Class Methods” on page 41-14
- 5 “Generate C++ Class Interface” on page 41-22

### Open Environment

Open the environment for configuring a customized C++ class interface:

- 1 Open the Embedded Coder app. In the Apps gallery, click **Embedded Coder**.
- 2 Set the language to C++. On the **C++ Code** tab, click **Output** and select **Embedded C++ Code**.

- Set the model configuration parameters. To open the Configuration Parameters dialog box, on the **C++ Code** tab, click **Settings**, and select **C/C++ Code generation settings**. These parameters configure model-wide code generation behavior. To configure parameters specific to generating a customized C++ class interface, you can set these parameters (located on the **Interface** pane):

Code interface

Code interface packaging: C++ class      Multi-instance code error diagnostic: Error

Remove error status field in real-time model data structure

Include model types in model class

Configuration Parameter	Description
<b>Code interface packaging</b>	Selects output language for generated code. For more information, see “Code interface packaging”.
<b>Multi-instance code error diagnostic</b>	Specifies the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code. For more information, see “Multi-instance code error diagnostic”.

Configuration Parameter	Description
<b>Remove error status field in real-time model data structure</b>	Specifies whether to omit the error status field from the generated real-time model data structure <code>rtModel</code> . For more information, see “Remove error status field in real-time model data structure”.
<b>Include model types in model class</b>	Specifies to include model type definitions within the class namespace of the model. For more information, see “Include model types in model class”.

Interface parameters that are related but are less commonly used appear under **Advanced parameters**.

Configuration Parameter	Description
<b>Terminate function required</b>	Specifies whether to generate the <code>model_terminate</code> method. For more information, see “Terminate function required”.
<b>Combine signal/state structures</b>	Specifies whether to combine global block signals and global state data into one data structure in the generated code. For more information, see “Combine signal/state structures”.
<b>Generate destructor</b>	Specifies whether to generate a destructor for the C++ model class. For more information, see “Generate destructor”.
<b>Use dynamic memory allocation for model block instantiation</b>	Specifies memory allocation for model hierarchies. For more information, see “Use dynamic memory allocation for model block instantiation”.

## Configure Model as Class

Configure the class name and namespace. When you generate C++ code from a model, that model appears as a class in the generated code. To ease integration and comply with code and interface requirements, you can customize the generated class name. Optionally, you can scope the generated code and prevent symbol clashes within a project by specifying a namespace for the generated class. In modeled systems constructed as a model hierarchy, you can specify a different namespace for each model in the hierarchy.

The generated C++ class interface, declared in the model header file, incorporates the customized name and namespace:

```
// File: rtdemo_cppclass_workflow.h

namespace CustomizedNamespace
{
 class customized_ModelClass {
 // public data and function members
 }
}
```

```

public:

 // private data and function members
private:

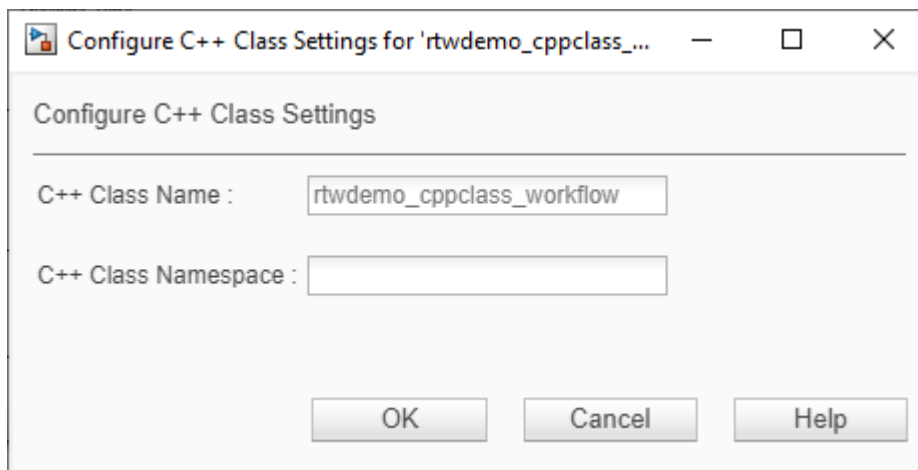

};
}

```

## Workflow

To configure the class name and namespace for a customized C++ class interface:

- 1 On the **C++ Code** tab, click **Code Interface** and select **Class Name & Namespace**.

- 2 To configure the class name, edit the **C++ Class Name** field.
- 3 To configure the class namespace, edit the **C++ Class Namespace** field.

You can configure a nested namespace for the model by delimiting the namespaces by using the scope resolution operator `::` in the form `ns1::ns2::ns3`.

- 4 Click **OK**. Validation is performed interactively with field warnings that alert you if you enter an invalid name or namespace.

## Configure Model Data Elements as Class Members

Configure the visibility and access of class members. When you generate C++ code from a model, Simulink data elements appear as class members in the generated code. To adjust the encapsulation of the class data to meet code standards, security, or performance requirements, you can customize the visibility and access of the generated class members. Simulink data elements can be grouped into these categories of modeling elements:

Model Element Category	Description
Inports	Root-level data input ports of a model, such as Inport and In Bus Element blocks. For more information, see Inport.
Outports	Root-level data output ports of a model, such as Outport and Out Bus Element blocks. For more information, see Outport.

Model Element Category	Description
Model parameter arguments	Workspace variables that appear as instance (nonstatic) class data members.
Model parameters	Workspace variables that are shared across instances of the model class that are generated as static class data members.
Signals, states, and internal data	Data elements that are internal to a model, such as block output signals, discrete block states, data stores, and zero-crossing signals.

For each model element category, you can configure the data visibility to control the access modifier (access specifier) of the generated class members. Each option and its impact on the generated C++ class interface, declared in the model header file, is outlined in this table.

Data Visibility Options	Description
public	<p>If you configure data elements as <b>public</b>, they appear as public members of the generated class:</p> <p>File: <code>rtwdemo_cppclass_workflow.h</code></p> <pre> <b>namespace</b> CustomizedNamespace {   <b>class</b> customized_ModelClass {     <b>public:</b>        // example inport       ExtU rtU;        // example outport       ExtY rtY;        // example block signals and states       DW rtDW;        // Other data, methods, and types (not shown)       <b>private:</b>       ...   }; } </pre>

Data Visibility Options	Description
private	<p>If you configure elements as <code>private</code>, they appear as private members of the generated class:</p> <p>File: <code>rtwdemo_cppclass_workflow.h</code></p> <pre> namespace CustomizedNamespace {   class customized_ModelClass {   public:    private:     // example inport     ExtU rtU;      // example outputport     ExtY rtY;      // example block signals and states     DW rtDW;      // Other data, methods, and types (not shown)   }; } </pre>
Individual arguments (Model parameter arguments only)	<p>If you configure data elements as <code>Individual arguments</code>, the elements do not appear as members of the class, but are instead passed as arguments to class methods:</p> <p>File: <code>rtwdemo_cppclass_workflow.h</code></p> <pre> namespace CustomizedNamespace {   class customized_ModelClass {   public:      // model step function     void step1(real_T rty_engineState,               const real_T modelParameterArgument);      // Other data, methods, and types (not shown)   private:     ""   }; } </pre>

After you set the data visibility of a model element category, you can configure the model access method to determine how the get and set methods are generated for the data elements. This configuration controls how application code can view and modify the class member data. Each option and its impact on the generated C++ class interface, declared in the model header file, is outlined in this table.

Member Access Method Options	Description
Method	<p>If you configure inports as <b>Method</b>, a set method appears for each inport. If you configure outports as <b>Method</b>, a get method appears for each outport in the model. If you configure the other model element categories as <b>Method</b>, an aggregate structure-based get and set method appears for the data element category.</p> <p>File: rtwdemo_cppclass_workflow.h</p> <pre> namespace CustomizedNamespace {   class customized_ModelClass {   public:     // example inport     void setInport(real_T localArgInput);      // example outport     real_T getOutport() const;      // example of model parameter arguments configured with     // 'DataAccess' 'Direct'     real_T const &amp;getInstP() const;      // example of model parameter arguments configured with     // 'DataAccess' 'Pointer'     // real_T const *getInstP() const;      // example Block parameters get and set methods     const P &amp;getBlockParameters() const;      void setBlockParameters(const P *pP) const;      // example Block states get and set methods     const DW &amp;getDWork() const;      void setDWork(const DW *pDW);    private:     ...   }; } </pre>

Member Access Method Options	Description
Inlined method	<p>If you configure inports as <code>Inlined method</code>, a set method defined in its declaration appears for each inport. If you configure outports as <code>Inlined method</code>, a get method defined in its declaration appears for each output in the model. If you configure the other model element categories as <code>Inlined method</code>, an aggregate structure-based get and set method defined in its declaration appears for the data element category.</p> <p>File: <code>rtwdemo_cppclass_workflow.h</code></p> <pre> namespace CustomizedNamespace {   class customized_ModelClass {   public:     // example inport set method     void setkeyState(real_T localArgInput) {       rtU.keyState = localArgInput;     }      // example output get method     const real_T *getengineState() const {       return rtY.engineState;     }      // example Block parameters get and set method     const P &amp;getBlockParameters() const {       return rtP;     }      void setBlockParameters(const P *pP) const {       rtP = *pP;     }      // example Block states get and set methods     const DW &amp;getDWork() const {       return rtDW;     }      void setDWork(const DW *pDW) {       rtDW = *pDW;     }    private:     ""   }; } </pre>

Member Access Method Options	Description
Structure-based method	<p>If you configure the inports as Structure-based method, the inports appear as an aggregate structure-based set method for the model element category. If you configure the outports as Structure-based method, the outports appear as an aggregate structure-based get method for the model element category. This configuration option does not apply to the other model element categories.</p> <p>File: rtwdemo_cppclass_workflow.h</p> <pre> namespace CustomizedNamespace {   class customized_ModelClass {      // public data and function members     public:      // External inputs (root inport signals with default storage)     struct ExtU {       real_T keyState;           // '&lt;Root&gt;/keyState'     };      // External outputs (root outports fed by signals with default storage)     struct ExtY {       real_T engineState[3];     // '&lt;Root&gt;/engineState'       real_T cycleTime;         // '&lt;Root&gt;/cycleTime'     };     ...      // example inport     void setExternalInputs(const ExtU *pExtU);      // example outport     const ExtY &amp;getExternalOutputs() const;      // Other model element categories may not be configured as 'Structure-based method'      private:     ...   }; } </pre>

Member Access Method Options	Description
Inlined structure-based method	<p>If you configure the inports as <code>Inlined structure-based method</code>, the inports appear as an aggregate structure-based set method defined in its declaration for the model element category. If you configure the outports to <code>Inlined structure-based method</code>, the outports appear as an aggregate structure-based get method defined in their declaration for the model element category. This configuration option does not apply to the other model element categories.</p> <p>File: <code>rtwdemo_cppclass_workflow.h</code></p> <pre> namespace CustomizedNamespace { class customized_ModelClass { public:  // External inputs (root inport signals with default storage) struct ExtU {     real_T keyState;                // '&lt;Root&gt;/keyState' };  // External outputs (root outports fed by signals with default storage) struct ExtY {     real_T engineState[3];         // '&lt;Root&gt;/engineState'     real_T cycleTime;             // '&lt;Root&gt;/cycleTime' }; ...  // example inport void setExternalInputs(const ExtU *pExtU);  // example output const ExtY &amp;getExternalOutputs() const;  // example inport void setExternalInputs(const ExtU *pExtU) {     rtU = *pExtU; }  // example output const ExtY &amp;getExternalOutputs() const {     return rtY; } // Other model element categories may not be configured as 'Inlined structure-based  private: ... }; } </pre>

Member Access Method Options	Description
None	<p>If you configure the access of a model element category as <b>None</b>, get and set methods do not appear in the generated class and data can be accessed directly by application code.</p> <p>File: rtwdemo_cppclass_workflow.h</p> <pre> namespace CustomizedNamespace {   class customized_ModelClass {   public:     // External inputs (root inport signals with default storage)     struct ExtU {       real_T keyState;           // '&lt;Root&gt;/keyState'     };      // External outputs (root outports fed by signals with default storage)     struct ExtY {       real_T engineState[3];    // '&lt;Root&gt;/engineState'       real_T cycleTime;        // '&lt;Root&gt;/cycleTime'     };     ...      // External inputs     ExtU rtU;      // External outputs     ExtY rtY;    private:     ...   }; } </pre>

For each model element category, valid data visibility and member access method combinations are outlined in this table.

Model Element Category	Data Visibility	Member Access Method
Inports	private	Method Inlined method Structure-based method Inlined structure-based method

<b>Model Element Category</b>	<b>Data Visibility</b>	<b>Member Access Method</b>
	public	None Method Inlined method Structure-based method Inlined structure-based method
Outports	private	Method Inlined method Structure-based method Inlined structure-based method
	public	None Method Inlined method Structure-based method Inlined structure-based method
Model parameter arguments	Individual arguments	None
	private	Method Inlined method
Model parameters	private	None Method Inlined method
	public	None Method Inlined method
Signals, states, and internal data	private	None Method Inlined method
	public	None Method Inlined method

## Workflow

To configure the class members of a customized C++ class interface:

- 1 Open the Code Mappings editor. On the **C++ Code** tab, click **Code Interface** and select **Code Mappings**.
- 2 Open the **Data** pane. In the Code Mappings editor, click the **Data** tab.

The screenshot displays the MATLAB/Simulink C++ Code interface. The main window shows a Simulink model for 'rtwdemo\_cppclass\_workflow'. The model includes blocks for 'initialize', 'terminate', 'keyState', 'K Ts z-1', 'engineLogic', 'engineState', and 'gtsqSwitch'. The 'engineLogic' block is highlighted with a green border. The 'Code Mappings - Component Interface' window is open, showing the 'Data' tab. The table below shows the configuration for various model element categories.

Model Element Category	Data Visibility	Member Access Method	...
Inports	private	Inlined structure-based method	
Outports	private	Inlined structure-based method	
Model parameter arguments	private	Method	
Model parameters	private	None	
Signals, states, and internal data	private	None	

- 3 Configure the visibility. To configure the visibility of a category of Simulink data elements in the generated code, from the **Data Visibility** column, select an access specifier from the given options. Options vary depending on the **Model Element Category**.
- 4 Configure the access. To configure the access of a category of Simulink data elements in the generated code, from the **Member Access Method** column, select how to generate get and set methods from the given options. Options vary depending on the **Model Element Category** and the selected **Data Visibility**.

## Configure Model Functions as Class Methods

Configure the class method names and arguments. When you generate C++ code from a model, model functions appear as class methods in the generated code. To integrate with external code or interface requirements, you can customize the name of the generated class methods. Additionally, for base-rate periodic functions and Simulink Functions, you can configure the name, order, and identifier of the generated arguments.

The generated class methods are referred to as entry-point methods and are locations in code where a transfer of program control (execution) occurs. Entry-point methods vary depending on the type of Simulink model and can be grouped into the following types:

Model Type	Type of Model Function	Description	Name of Model Function	Expected Method Name
Export-Function Models	Exported function	The exported function for a subsystem.	ExportedFunction: <i>slIdentifier</i> , where <i>slIdentifier</i> is the name of the function-call Inport block in the model	<i>function-call-inport-block-name</i> or <i>signal-label</i> (if specified)
	Simulink Function	The exported function for a Simulink Function block.	Simulink Function: <i>slIdentifier</i> , where <i>slIdentifier</i> is the name of the Simulink Function block in the model	<i>function-name</i> for a global Simulink Function block or <i>model_function-name</i> for a scoped Simulink Function block
Export-Function or Rate-based Models	Initialize function	Initialization code for a model. At the start of the application code, call the function <i>once</i> . Do not use this function to reset the real-time model data structure (rtM).	Initialize	<i>model_initialize</i>
	Partition function	For a model partition, output and update code. Model configuration parameter <b>Single output/update function</b> is selected (the default).	Partition: <i>slIdentifier</i> , where <i>slIdentifier</i> is a partition that was created explicitly from a block in the model and shown in the Simulink® Schedule Editor (for example, P1)	<i>model_stepn</i> , where <i>n</i> uniquely identifies the function generated for one of the model sample periods

Model Type	Type of Model Function	Description	Name of Model Function	Expected Method Name
	Periodic multitasking function	For blocks in a rate-based model configured for multitasking, output and update code. The code generator produces a function for each sample period. Model configuration parameter <b>Single output/update function</b> is selected (the default).	Periodic: <i>slIdentifier</i> , where <i>slIdentifier</i> is an annotation that corresponds to the sample time period for a periodic or continuous rate of a multitasking model (for example, D1)	<i>model_stepn</i> , where <i>n</i> uniquely identifies the function generated for one of the model sample periods
	Periodic single-tasking function	For blocks in a rate-based model configured for single-tasking, output and update code. Model configuration parameter <b>Single output/update function</b> is selected (the default).	Periodic	<i>model_step</i>
	Reset function	If the model includes a Reset Function block, reset code generated. To reset conditions or state, call the function from the application code.	Reset: <i>slIdentifier</i> , where <i>slIdentifier</i> is the name of the reset function in the model	<i>model_reset-function-name</i>

Model Type	Type of Model Function	Description	Name of Model Function	Expected Method Name
	Terminate function	Code for turning off a system. For ERT-based models, you can suppress generation of this function by clearing the model configuration parameter <b>Terminate function required</b> (set by default).	Terminate	<i>model_terminate</i>

The generated C++ class interface, declared in the model header file, incorporates the function name and argument customizations in the generated entry-point methods:

File: `rtwdemo_cppclass_workflow.h`

```
namespace CustomizedNamespace
{
 class customized_ModelClass {
 public:
 // model initialize function- customized name
 void customized_initialize();

 // model step function- customized name & arguments
 void customized_step(customArg1, const* customArg2);

 // model terminate function- customized name
 void customized_terminate();

 // Constructor
 customized_ModelClass();

 // Destructor
 ~customized_ModelClass();

 private:
 ...
 };
}
```

### Workflow

- 1 Open the Code Mappings editor. On the **C++ Code** tab, click **Code Interface** and select **Code Mappings**.
- 2 Open the **Functions** pane. In the Code Mappings editor, click the **Functions** tab. To view a complete list of entry-point functions for your model, click the **Update Diagram** button.

The screenshot displays the MATLAB/Simulink environment. The main workspace shows a Simulink model for 'rtwdemo\_cppclass\_workflow'. The model includes blocks for 'initialize', 'terminate', 'keyState', 'cycleTime', 'engineState', and 'engineLogic'. A 'Discrete-Time Integrator' block is also present. The 'Code Mappings - Component Interface' window is open, showing a table of mappings between Simulink components and C++ methods.

Source	Method Name	Method Preview
Initialize		void initialize()
Periodic:D1 [Sample Time: 0.01s]		void step0()
Periodic:D2 [Sample Time: 0.1s]		void step1()
Simulink Function:f	f	void f(rtu_cycleTime, * rty_y)
Terminate		void terminate()

### 3 Configure method names.

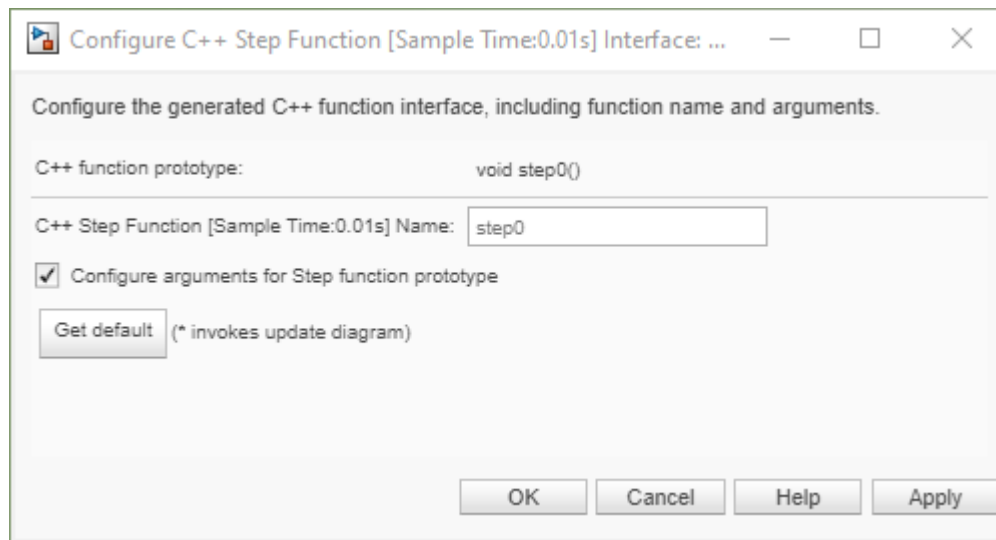

- a To configure the name of an entry-point method in the generated code, from the **Method Name** column, click and directly edit the spreadsheet. You can enter a custom name or you can use identifier format parameters to control a dynamically generated name. For more information about identifier format parameters, see “Identifier Format Control” on page 52-17.

- b Verify the name in the **Method Preview** column.

### 4 Configure method arguments. For base-rate periodic functions and Simulink Functions, you can configure the name, order, and identifiers of the method arguments.

To configure the arguments of a base-rate periodic function:

- a Open the Step Function Interface configuration dialog box. From the Code Mappings editor, on the **Functions** tab, in the **Method Preview** column, click the method preview hyperlink of a base-rate periodic function:

- b** In the dialog box, select **Configure arguments for Step function prototype** and click **Get default**. This action launches a view of the method arguments.

- c To change the order of the arguments, click and drag the argument rows in the viewer.
- d To change the identifier, in the **C++ Type Qualifier** column, select the appropriate identifier from the drop-down list:

Identifier Option	Preview
Value (Inports only)	myPeriodicFunction(argInport)
Const Reference (Inports only)	myPeriodicFunction(const & argInport)
Pointer to Const	myPeriodicFunction(const * argInport)
Pointer	myPeriodicFunction(* argInport)
Const Pointer to const	myPeriodicFunction(const * const argInport)

- e To change the name of an argument, in the **C++ Identifier Name** column, click and directly edit the name. You can enter a custom name or you can use identifier format parameters to

control a dynamically generated name. For more information about identifier format parameters, see “Identifier Format Control” on page 52-17.

- i If you enter the same name for an inport argument and an outport argument the inport and outport appear as one parameter in the generated method. For example, if you specify an inport as `argInport` and an outport argument as `argOutport`, the generated method would be:

```
myStepFunction(argInport, argOutport);
```

If you specify an inport argument as `argIO` and an outport argument as `argIO`, the generated method would be:

```
myStepFunction(argIO);
```

- f To verify the arguments selections, click **Validate**.
- g To apply changes and exit the dialog box, click **OK**.

To configure the arguments of a Simulink Function:

- a Open the Simulink Function Interface configuration dialog box. From the Code Mappings editor, on the **Functions** tab, in the **Method Preview** column, click the method preview hyperlink of a Simulink Function:

- b To change the return argument, select a return argument option from the **C/C++ return argument** drop-down list.
- c To change the order of the arguments, click and drag the argument rows in the viewer.
- d To change the identifier, in the **C++ Type Qualifier** column, select the identifier from the drop-down list:

Identifier Option	Preview
Auto	mySimulinkFunction(argInport)
Const Reference	mySimulinkFunction(const & argInport)
Pointer to Const	mySimulinkFunction(const * argInport)
Pointer	mySimulinkFunction(* argInport)
Const Pointer to const	mySimulinkFunction(const * const argInport)

- e To change the name of the argument, in the **C++ Identifier name** column, click and directly edit the name. You can enter a custom name or you can use identifier format parameters to control a dynamically generated name. For more information about identifier format parameters, see “Identifier Format Control” on page 52-17.
- f To verify changes to the Simulink Function arguments, review the **Simulink function prototype** field to view the expected method prototype.
- g To apply changes and exit the dialog box, click **OK**.

## Generate C++ Class Interface

Generate the customized C++ class interface by generating code from the model. To verify your C++ class interface configurations, build the model and view the generated class, class member, and class method representations.

- 1 Generate code. To generate a C++ class interface, on the **C++ Code** tab, click **Build**.
- 2 View code. To view the generated code, on the tab click **View Code**. The generated code appears beside the model in the model workspace.

Model Element Category	Data Visibility	Member Access Method
Inports	private	Inlined structure-based method
Outports	private	Inlined structure-based method
Model parameter arguments	private	Method
Model parameters	private	None
Signals, states, and internal data	private	None

- Iterate. If the generated interface does not meet code requirements, make configuration adjustments until requirements are satisfied.

If the generated code representation does not meet your requirements, reconfigure the interface and generate code again until code generations requirements are satisfied. For guidance on understanding the generated code, see “Analyze the Generated Code Interface” on page 51-13.

## Considerations and Limitations

- Instance-Specific Parameter Support** — You can use model parameter arguments to configure workspace variables that have been specified as arguments. You can configure these arguments as private members of your class or as individual arguments defined outside the class. To configure within the class, you can set the data visibility to private and configure the generation of the get and set methods. Optionally, you can configure the class member values as defined within the class (in the Property Inspector, set **Data Access** to **Direct**) or passed-by-reference through the class constructor (in the Property Inspector, set **Data Access** to **Pointer**). The data access setting is supported for top model builds. For reference model builds, the code is generated as references in the model class. To configure instance-specific parameters outside the class, set the data visibility to individual arguments.

Instance-specific parameter limitations include:

- MATLAB variables marked as model arguments are not able to be configured as private class members.

- Model parameter arguments are not supported by right-click builds.
- Interface Code Generation Behavior — The I/O arguments style of step method specification supports single-rate models and multirate single-tasking models. Multirate multitasking models are not supported. Additionally, the C++ encapsulation interface is not the default, the value is ignored for the **Pass fixed-size scalar root inputs by value for code generation** parameter.
- Stateflow considerations — If you have a Stateflow license, for a Stateflow chart that resides in a root model configured to use the I/O arguments step method function specification, and that uses a model root inport value or calls a subsystem that uses a model root inport value, do one of the following to generate code:
  - In the Stateflow chart, clear the **Execute (enter) Chart At Initialization** check box.
  - Insert a Simulink Signal Conversion block immediately after the root inport. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- Simscape Considerations — If a model root inport value connects to a Simscape block, insert a Simulink Signal Conversion block between the root inport and the Simscape conversion block. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- Referenced Model Considerations — When building a referenced model that is configured to generate a C++ class interface:
  - Do not use a C++ class interface in cases when a referenced model cannot have a combined output/update function. Cases include a model that has a continuous sample time or saves states.
  - Do not use virtual buses as inputs or outputs to the referenced model when the referenced model uses the I/O arguments step method. When bus signals cross referenced model boundaries, either use nonvirtual buses or use the Default step method.

## Programmatically Configure C++ Interface

To streamline the integration of C++ code generated from Simulink applications, components, and subsystems with external C or C++ code, configure a customized C++ class interface. When you generate C++ code from a model, the model appears as a class, the data elements appear as class members, and the model functions appear as class methods in the generated code. Configuring a C++ class interface enables you to customize the following aspects of the generated C++ code:

- Class information — Class name and namespace
- Class member information — Class member access and visibility
- Class method information — Class method names and arguments

A customized C++ class interface enables the generated classes to meet specific code standards or interface requirements so that the generated code can compile and integrate into larger architectures with minimal post-generation customization.

### Programmatic Workflow Overview

The programmatic workflow uses a programmatic interface that you can call into by using the MATLAB command line or a MATLAB script to configure a customized C++ class interface. Additionally, you can use the functions to facilitate scripting, automated testing, and developing or utilizing downstream features. The programmatic interface is composed of the following functions:

- To create or retrieve the Code Mappings object to configure a customized C++ Class interface, you can use the functions `coder.mapping.utils.create` and `coder.mapping.api.get`.
- To configure the class name and namespace, you can use the functions `getClassName`, `setClassName`, `getClassNamespace`, and `setClassNamespace`.
- To configure how data elements appear as class members, you can use the functions `getData` and `setData`.
- To configure how model functions appear as class methods, you can use the functions `find`, `getFunction`, and `setFunction`.

To programmatically configure a customized C++ interface, follow the outlined workflow:

- 1 “Open Environment” on page 41-25
- 2 “Configure Model as Class” on page 41-27
- 3 “Configure Model Data Elements as Class Members” on page 41-28
- 4 “Configure Model Functions as Class Methods” on page 41-37
- 5 “Generate C++ Class Interface” on page 41-42

### Open Environment

Open the environment for configuring a customized C++ class interface:

- 1 Open the model and the MATLAB command prompt. Alternatively, you can create a MATLAB configuration script.

```
model='rtwdemo_cppclass_workflow'
open_system(model)
```

- 2 Set model configuration parameters. These parameters configure model-wide code generation behavior. To configure parameters specific to generating a customized C++ class interface, you can use the `set_param` function to set these parameters:

Configuration Parameter	Description
<b>Code interface packaging</b>	Selects output language for generated code. For more information, see “Code interface packaging”.
<b>Multi-instance code error diagnostic</b>	Specifies the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code. For more information, see “Multi-instance code error diagnostic”.
<b>Remove error status field in real-time model data structure</b>	Specifies whether to omit the error status field from the generated real-time model data structure <code>rtModel</code> . For more information, see “Remove error status field in real-time model data structure”.
<b>Include model types in model class</b>	Specifies to include model type definitions within the class namespace of the model. For more information, see “Include model types in model class”.

Interface parameters that are related, but are less commonly used:

Configuration Parameter	Description
<b>Terminate function required</b>	Specifies whether to generate the <code>model_terminate</code> method. For more information, see “Terminate function required”.
<b>Combine signal/state structures</b>	Specifies whether to combine global block signals and global state data into one data structure in the generated code. For more information, see “Combine signal/state structures”.
<b>Generate destructor</b>	Specifies whether to generate a destructor for the C++ model class. For more information, see “Generate destructor”.
<b>Use dynamic memory allocation for model block instantiation</b>	Specifies memory allocation for model hierarchies. For more information, see “Use dynamic memory allocation for model block instantiation”.

- 3 To configure a customized C++ class interface for a model, create a Code Mappings object. To create a new Code Mappings object for a model, use the function `coder.mapping.utils.create`. If a Code Mappings object already exists for the model, the function returns the existing object.

```
% Create a new Code Mappings object for a model
cm = coder.mapping.utils.create(model);
```

## Configure Model as Class

Configure the class name and namespace. When you generate C++ code from a model, that model appears as a class in the generated code. To ease integration and comply with code and interface requirements, you can customize the generated class name. Optionally, you can scope the generated code and prevent symbol clashes within a project by specifying a namespace for the generated class. In modeled systems that use a model hierarchy, you can specify a different namespace for each model in the hierarchy.

The generated C++ class interface, declared in the model header file, incorporates the customized name and namespace:

```
// File: rtwdemo_cppclass_workflow.h

namespace CustomizedNamespace
{
 class customized_ModelClass {
 // public data and function members
 public:

 // private data and function members
 private:

 };
}
```

### Workflow

To programmatically configure the class name and namespace, get the Code Mappings object for your model and set the name and namespace:

- 1 Get the Code Mappings object for your model. To get the object, use the function `coder.mapping.api.get`.

```
% Get the Code Mappings object for a model
cm = coder.mapping.api.get(model);
```

- 2 Configure the class name. To set the class name, use the function `setClassName`.

```
% Set the class name
setClassName(cm, 'customized_ModelClass');
```

To verify the new class name before generating code, use the function `getClassName`.

```
% Get the class name
getClassName(cm);
```

- 3 Configure the class namespace. To set the namespace, use the function `setClassNamespace`.

```
% Set the class namespace
setClassNamespace(cm, 'customized_namespace');
```

To configure a nested namespace, use the scope resolution operator `::` to specify scope.

```
% Set a nested namespace
setClassNamespace(cm, 'customized_namespace1::customized_namespace2');
```

To verify the new namespace before generating code, use the function `getClassNamespace`.

```
% Get the class namespace
getClassNamespace(cm);
```

## Configure Model Data Elements as Class Members

Configure the visibility and access of class members. When you generate C++ code from a model, Simulink data elements appear as class members in the generated code. To adjust the encapsulation of the class data to meet code standards, security, or performance requirements, you can customize the visibility and access of the generated class members. Simulink data elements can be grouped into the following categories of modeling elements:

Model Element Category	Description
Inports	Root-level data input ports of a model, such as Inport and In Bus Element blocks. For more information, see Inport.
Outports	Root-level data output ports of a model, such as Outport and Out Bus Element blocks. For more information, see Outport.
Model parameter arguments	Workspace variables that appear as instance (nonstatic) class data members.
Model parameters	Workspace variables that are shared across instances of the model class that are generated as static class data members.
Signals, states, and internal data	Data elements that are internal to a model, such as block output signals, discrete block states, data stores, and zero-crossing signals.

For each model element category, you can configure the data visibility to control the access modifier (access specifier) of the generated class members. Each option and its impact on the generated C++ class interface, declared in the model header file, is outlined in this table.

Data Visibility Options	Description
public	<p>If you configure data elements as <b>public</b>, they appear as public members of the generated class:</p> <p>File: rtwdemo_cppclass_workflow.h</p> <pre> <b>namespace</b> CustomizedNamespace {   <b>class</b> customized_ModelClass {     <b>public:</b>      // example inport     ExtU rtU;      // example outport     ExtY rtY;      // example block signals and states     DW rtDW;      // Other data, methods, and types (not shown)     <b>private:</b>     ...   }; }</pre>
protected	<p>If you configure data elements as <b>protected</b>, they appear as protected members of the generated class:</p> <p>File: rtwdemo_cppclass_workflow.h</p> <pre> // Class declaration for model example_model <b>namespace</b> CustomizedNamespace {   <b>class</b> customized_ModelClass {     <b>public:</b>      <b>protected:</b>      // example inport     ExtU rtU;      // example outport     ExtY rtY;      // example block signals and states     DW rtDW;      // Other data, methods, and types (not shown)     <b>private:</b>     ...   }; }</pre>

Data Visibility Options	Description
private	<p>If you configure elements as <code>private</code>, they appear as private members of the generated class:</p> <p>File: <code>rtwdemo_cppclass_workflow.h</code></p> <pre> namespace CustomizedNamespace {   class customized_ModelClass {   public:    private:     // example inport     ExtU rtU;      // example outputport     ExtY rtY;      // example block signals and states     DW rtDW;      // Other data, methods, and types (not shown)   }; } </pre>
Individual arguments (Model parameter arguments only)	<p>If you configure data elements as <code>Individual arguments</code>, the elements do not appear as members of the class, but are instead passed as arguments to class methods:</p> <p>File: <code>rtwdemo_cppclass_workflow.h</code></p> <pre> namespace CustomizedNamespace {   class customized_ModelClass {   public:      // model step function     void step1(real_T rty_engineState,               const real_T modelParameterArgument);      // Other data, methods, and types (not shown)   private:     ""   }; } </pre>

After you set the data visibility of a model element category, you can configure the data access method to determine how the get and set methods are generated for the data elements. This configuration controls how application code can view and modify the class member data. Each option and its impact on the generated C++ class interface, declared in the model header file, is outlined in this table.

Member Access Method Options	Description
Method	<p>If you configure inports as <b>Method</b>, a set method appears for each inport. If you configure outports as <b>Method</b>, a get method appears for each outport in the model. If you configure the other model element categories as <b>Method</b>, an aggregate structure-based get and set method appears for the data element category.</p> <p>File: rtwdemo_cppclass_workflow.h</p> <pre> <b>namespace</b> CustomizedNamespace {   <b>class</b> customized_ModelClass {   <b>public:</b>     // example inport     void setInport(real_T localArgInput);      // example outport     real_T getOutput() const;      // example of model parameter arguments configured with     // 'DataAccess' 'Direct'     real_T const &amp;getInstP() const;      // example of model parameter arguments configured with     // 'DataAccess' 'Pointer'     // real_T const *getInstP() const;      // example Block parameters get and set methods     const P &amp;getBlockParameters() const;      void setBlockParameters(const P *pP) const;      // example Block states get and set methods     const DW &amp;getDWork() const;      void setDWork(const DW *pDW);    <b>private:</b>     ...   }; } </pre>

Member Access Method Options	Description
Inlined method	<p>If you configure inports as <code>Inlined method</code>, a set method defined in its declaration appears for each inport. If you configure outports as <code>Inlined method</code>, a get method defined in its declaration appears for each outport in the model. If you configure the other model element categories as <code>Inlined method</code>, an aggregate structure-based get and set method defined in its declaration appears for the data element category.</p> <p>File: <code>rtwdemo_cppclass_workflow.h</code></p> <pre> namespace CustomizedNamespace {   class customized_ModelClass {   public:     // example inport set method     void setkeyState(real_T localArgInput) {       rtU.keyState = localArgInput;     }      // example outport get method     const real_T *getengineState() const {       return rtY.engineState;     }      // example Block parameters get and set method     const P &amp;getBlockParameters() const {       return rtP;     }      void setBlockParameters(const P *pP) const {       rtP = *pP;     }      // example Block states get and set methods     const DW &amp;getDWork() const {       return rtDW;     }      void setDWork(const DW *pDW) {       rtDW = *pDW;     }    private:     ""   }; } </pre>

Member Access Method Options	Description
Structure-based method	<p>If you configure the inports as <b>Structure-based method</b>, the inports appear as an aggregate structure-based set method for the model element category. If you configure the outports as <b>Structure-based method</b>, the outports appear as an aggregate structure-based get method for the model element category. This configuration option does not apply to the other model element categories.</p> <p>File: rtwdemo_cppclass_workflow.h</p> <pre> namespace CustomizedNamespace {   class customized_ModelClass {     // public data and function members     public:      // External inputs (root inport signals with default storage)     struct ExtU {       real_T keyState;           // '&lt;Root&gt;/keyState'     };      // External outputs (root outports fed by signals with default storage)     struct ExtY {       real_T engineState[3];     // '&lt;Root&gt;/engineState'       real_T cycleTime;         // '&lt;Root&gt;/cycleTime'     };     ...      // example inport     void setExternalInputs(const ExtU *pExtU);      // example outport     const ExtY &amp;getExternalOutputs() const;      // Other model element categories may not be configured as 'Structure-based method'      private:     ...   }; } </pre>

Member Access Method Options	Description
Inlined structure-based method	<p>If you configure the inports as <code>Inlined structure-based method</code>, the inports appear as an aggregate structure-based set method defined in its declaration for the model element category. If you configure the outports to <code>Inlined structure-based method</code>, the outports appear as an aggregate structure-based get method defined in their declaration for the model element category. This configuration option does not apply to the other model element categories.</p> <p>File: <code>rtwdemo_cppclass_workflow.h</code></p> <pre> namespace CustomizedNamespace { class customized_ModelClass { public:  // External inputs (root inport signals with default storage) struct ExtU {     real_T keyState;                // '&lt;Root&gt;/keyState' };  // External outputs (root outports fed by signals with default storage) struct ExtY {     real_T engineState[3];        // '&lt;Root&gt;/engineState'     real_T cycleTime;            // '&lt;Root&gt;/cycleTime' }; ...  // example inport void setExternalInputs(const ExtU *pExtU);  // example output const ExtY &amp;getExternalOutputs() const;  // example inport void setExternalInputs(const ExtU *pExtU) {     rtU = *pExtU; }  // example output const ExtY &amp;getExternalOutputs() const {     return rtY; } // Other model element categories may not be configured as 'Inlined structure-based  private: ... }; } </pre>

Member Access Method Options	Description
None	<p>If you configure the access of a model element category as <b>None</b>, get and set methods do not appear in the generated class and data can be accessed directly by application code.</p> <p>File: <code>rtwdemo_cppclass_workflow.h</code></p> <pre> namespace CustomizedNamespace {   class customized_ModelClass {   public:     // External inputs (root inport signals with default storage)     struct ExtU {       real_T keyState;           // '&lt;Root&gt;/keyState'     };      // External outputs (root outports fed by signals with default storage)     struct ExtY {       real_T engineState[3];    // '&lt;Root&gt;/engineState'       real_T cycleTime;        // '&lt;Root&gt;/cycleTime'     };     ...      // External inputs     ExtU rtU;      // External outputs     ExtY rtY;    private:     ...   }; } </pre>

For each model element category, valid data visibility and member access method combinations are outlined in this table.

Model Element Category	Data Visibility	Member Access Method
Inports	private	Method Inlined method Structure-based method Inlined structure-based method

<b>Model Element Category</b>	<b>Data Visibility</b>	<b>Member Access Method</b>
	public	None Method Inlined method Structure-based method Inlined structure-based method
Outports	private	Method Inlined method Structure-based method Inlined structure-based method
	public	None Method Inlined method Structure-based method Inlined structure-based method
Model parameter arguments	Individual arguments	None
	private	Method Inlined method
Model parameters	private	None Method Inlined method
	public	None Method Inlined method
Signals, states, and internal data	private	None Method Inlined method
	public	None Method Inlined method

## Workflow

To programmatically configure class member visibility and access, get the Code Mappings object for the model and set the data access and visibility properties:

- 1 Get the Code Mappings object for the model. To get the object, use the function `coder.mapping.api.get`.

```
% Get the Code Mappings object
cm = coder.mapping.api.get(model);
```

- 2 Configure the visibility. To set the data visibility of a category of Simulink data elements in the generated code, use the function `setData`. When you use the `setData` function, specify the Code Mappings object, model element category, data visibility property, and data visibility option. Valid data visibility options vary depending on the model element category.

```
% Set the data visibility of Simulink model data elements by category
% setData(Code Mappings object, model element category, 'DataVisibility', data visibility option)
setData(cm, 'Outports', 'DataVisibility', 'private');
```

To verify the data visibility setting before generating code, use the function `getData`:

```
% Get the data visibility of Simulink model data elements by category
% getData(code mappings object, model element category, 'DataVisibility')
getData(cm, 'Outports', 'DataVisibility');
```

- 3 Configure the access. To set the member access method of a category of Simulink data elements in the generated code, use the function `setData`. When you use the `setData` function, specify the Code Mappings object, model element category, member access method property, and member access method option. Valid member access method options vary depending on the model element category and selected data visibility option.

```
% Set the access of Simulink model data elements by category
% setData(Code Mappings object, model element category, ...
% 'MemberAccessMethod', member access method option)
setData(cm, 'Inports', 'MemberAccessMethod', 'Method');
```

To verify the member access method setting before generating code, use the function `getData`:

```
% Get the visibility of Simulink model data elements by category
% getData(code mappings- C++ object, model element category, 'MemberAccessMethod')
getData(cm, 'Inports', 'MemberAccessMethod');
```

## Configure Model Functions as Class Methods

Configure the class method names and arguments. When you generate C++ code from a model, model functions appear as class methods in the generated code. To integrate with external code or interface requirements, you can customize the name of the generated class methods. Additionally, for base-rate periodic functions and Simulink Functions, you can configure the name, order, and identifier of the generated arguments.

The generated class methods are referred to as entry-point methods and are locations in code where a transfer of program control (execution) occurs. Entry-point methods vary depending on the type of Simulink model and can be grouped into the following types:

Model Type	Type of Model Function	Description	Name of Model Function	Expected Method Name
Export-Function Models	Exported function	The exported function for a subsystem.	ExportedFunction: <i>slIdentifier</i> , where <i>slIdentifier</i> is the name of the function-call Inport block in the model	<i>function-call-inport-block-name</i> or <i>signal-label</i> (if specified)
	Simulink Function	The exported function for a Simulink Function block.	Simulink Function: <i>slIdentifier</i> , where <i>slIdentifier</i> is the name of the Simulink Function block in the model	<i>function-name</i> for a global Simulink Function block or <i>model_function-name</i> for a scoped Simulink Function block
Export-Function or Rate-based Models	Initialize function	Initialization code for a model. At the start of the application code, call the function <i>once</i> . Do not use this function to reset the real-time model data structure (rtM).	Initialize	<i>model_initialize</i>
	Partition function	For a model partition, output and update code. Model configuration parameter <b>Single output/update function</b> is selected (the default).	Partition: <i>slIdentifier</i> , where <i>slIdentifier</i> is a partition that was created explicitly from a block in the model and shown in the Simulink® Schedule Editor (for example, P1)	<i>model_stepn</i> , where <i>n</i> uniquely identifies the function generated for one of the model sample periods

Model Type	Type of Model Function	Description	Name of Model Function	Expected Method Name
	Periodic multitasking function	For blocks in a rate-based model configured for multitasking, output and update code. The code generator produces a function for each sample period. Model configuration parameter <b>Single output/update function</b> is selected (the default).	<code>Periodic:slIdentifier</code> , where <code>slIdentifier</code> is an annotation that corresponds to the sample time period for a periodic or continuous rate of a multitasking model (for example, D1)	<code>model_stepn</code> , where <code>n</code> uniquely identifies the function generated for one of the model sample periods
	Periodic single-tasking function	For blocks in a rate-based model configured for single-tasking, output and update code. Model configuration parameter <b>Single output/update function</b> is selected (the default).	<code>Periodic</code>	<code>model_step</code>
	Reset function	If the model includes a Reset Function block, reset code generated. To reset conditions or state, call the function from the application code.	<code>Reset:slIdentifier</code> , where <code>slIdentifier</code> is the name of the reset function in the model	<code>model_reset-function-name</code>

Model Type	Type of Model Function	Description	Name of Model Function	Expected Method Name
	Terminate function	Code for turning off a system. For ERT-based models, you can suppress generation of this function by clearing the model configuration parameter <b>Terminate function required</b> (set by default).	Terminate	<i>model_terminate</i>

The generated C++ class interface, declared in the model header file, incorporates the function name and argument customizations in the generated entry-point methods:

File: `rtwdemo_cppclass_workflow.h`

```
namespace CustomizedNamespace
{
 class customized_ModelClass {
 public:
 // model initialize function- customized name
 void customized_initialize();

 // model step function- customized name & arguments
 void customized_step(customArg1, const* customArg2);

 // model terminate function- customized name
 void customized_terminate();

 // Constructor
 customized_ModelClass();

 // Destructor
 ~customized_ModelClass();

 private:
 ...
 };
}
```

### Workflow

To programmatically configure class method names and arguments, get the Code Mappings object for the model and set the function properties:

- 1 Get the Code Mappings object for the model. To get the object, use the function `coder.mapping.api.get`.

```
% Get the Code Mappings object
cm = coder.mapping.api.get(model);
```

- 2 To view the available entry-point methods for the model, use the function `find`. When you use the `find` function, specify the Code Mappings object and the function category you would like to view for the model. Valid function category options are the following:

- Functions
- PeriodicFunctions
- PartitionFunctions
- ExportedFunctions
- ResetFunctions
- SimulinkFunctions

```
% View entry-point methods for a model by category
% This example shows how to view the entry-point functions for a model
% find(Code Mappings object, function category')
find(cm, 'Functions');
```

- 3 Configure method names. To configure the method name of an entry-point method, use the function `setFunction`. When you use the `setFunction` function, specify the Code Mappings object, model function name, the method name property, and the custom name. Valid model function names are specified in the following way:

- `Initialize` — Initialize function.
- `Terminate` — Terminate function.
- `Periodic:sIdentifier` — Periodic function (implicit task), where `sIdentifier` is the annotation (for example, D1) corresponding to the sample time period. `Periodic` is sufficient for a single-tasking periodic function.
- `Partition:sIdentifier` — Partition function (explicit task), where `sIdentifier` is the partition name in Schedule Editor.
- `Reset:sIdentifier` — Reset function where `sIdentifier` is name of the reset function in model.
- `ExportedFunction:sIdentifier` — Exported function where `sIdentifier` is the name of function-call inport block.
- `ExportedFunction:sIdentifier` — Simulink function where `sIdentifier` is the name of Simulink function in model.

```
% Set the name of individual entry-point methods
% This examples shows how to customize the name of a periodic function
% setFunction(Code Mappings object, model function, 'MethodName', custom name)
setFunction(cm, 'Periodic', 'MethodName', 'custom_Periodic');
```

To verify the method name before generating code, use the function `getFunction`:

```
% Get method name
% getFunction(code mappings object, model function, 'MethodName')
getData(cm, 'Periodic', 'MethodName');
```

- 4 Configure method arguments. For base-rate periodic functions and Simulink Functions, you can use the function `setFunction` to configure the generated method arguments. When you use the `setFunction` function, specify the Code Mappings object, model function name, the arguments property, and the method prototype. Valid model function names are specified in the following way:

- `Initialize` — Initialize function.
- `Terminate` — Terminate function.
- `Periodic:sIdentifier` — Periodic function (implicit task), where `sIdentifier` is the annotation (for example, D1) corresponding to the sample time period. `Periodic` is sufficient for a single-tasking periodic function.
- `Partition:sIdentifier` — Partition function (explicit task), where `sIdentifier` is the partition name in Schedule Editor.
- `Reset:sIdentifier` — Reset function where `sIdentifier` is name of the reset function in model.
- `ExportedFunction:sIdentifier` — Exported function where `sIdentifier` is the name of function-call inport block.
- `ExportedFunction:sIdentifier` — Simulink function where `sIdentifier` is the name of Simulink function in model.

Valid identifier options for parameters are the following:

Identifier Option	Preview
Value (Inports only)	<code>myPeriodic(argInport)</code>
Const Reference (Inports only)	<code>myPeriodic(const &amp; argInport)</code>
Pointer to Const	<code>myPeriodic(const * argInport)</code>
Pointer	<code>myPeriodic(* argInport)</code>
Const Pointer to const	<code>myPeriodic(const * const argInport)</code>

In the below example, the periodic function, `foo`, is configured to generate a method where `y` is the return argument and its parameter `u1` is passed as a scalar and `u2` is passed as a constant pointer:

```
% Configure method arguments
% setFunction(Code Mappings object, function, 'Arguments', function prototype)
setFunction(cm, 'Periodic:foo', 'Arguments', 'y=(u1, const *u2)');
```

To verify the method arguments before generating code, use the function `getFunction`:

```
% Get method name
% getFunction(Code Mappings object, model function, 'Arguments')
getData(cm, 'Periodic:foo', 'Arguments');
```

## Generate C++ Class Interface

Generate the customized C++ class interface by generating code from the model. To verify your customized C++ class interface configurations, build the model and view the generated class, class member, and class method representations.

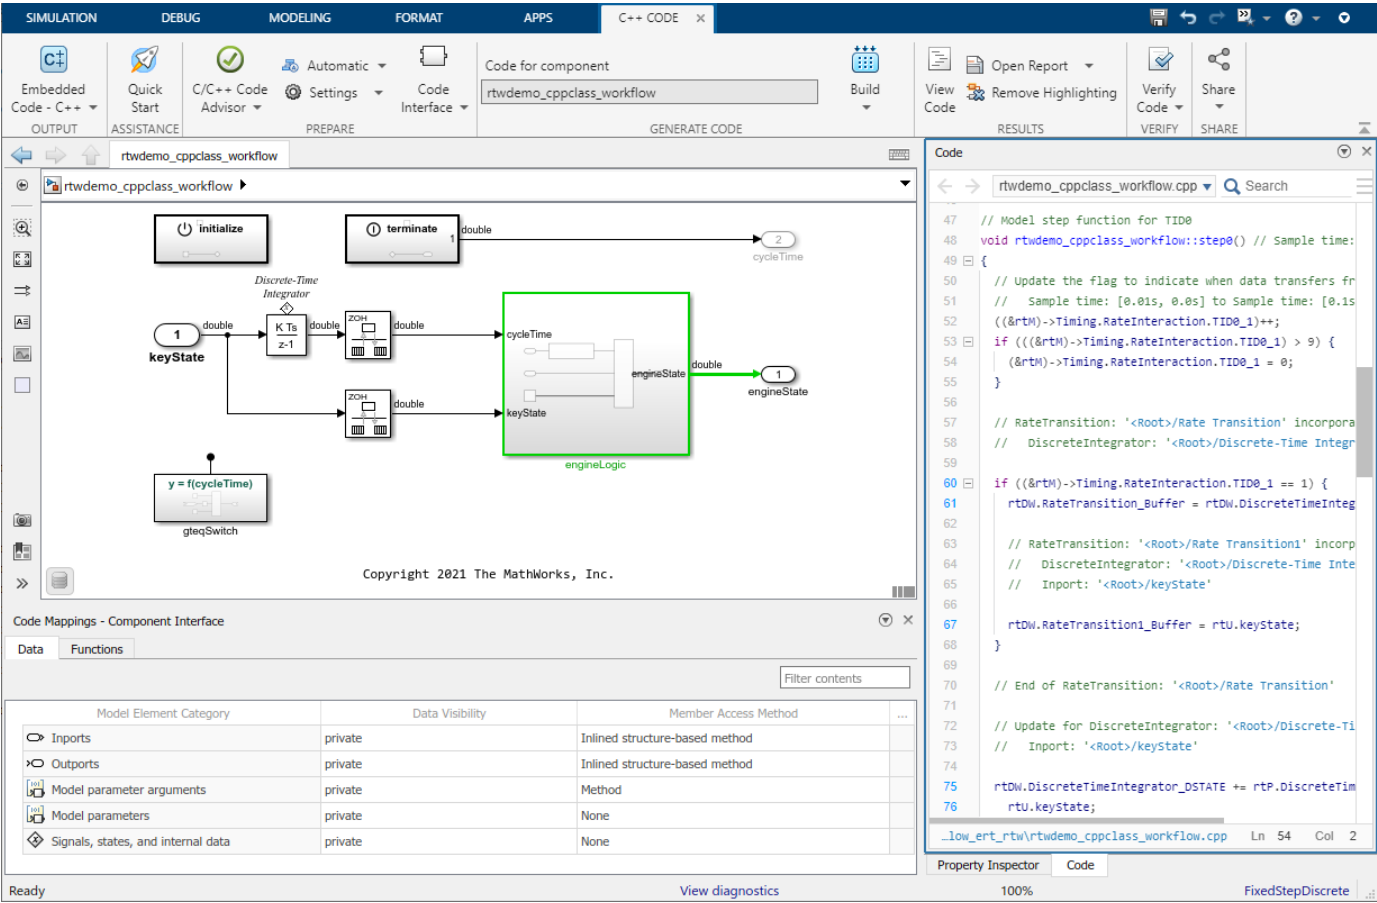

- 1 Generate code. To generate a C++ class interface, build the model with the command `slbuild`.

```
slbuild example_model
```

- 2 View code. To view the generated code, open the model in the Embedded Coder app.

```
open example_model
```

To open the **Code** view, on the **C++ Code** tab, click **View Code**. The generated code appears beside the model in the model workspace.

- 3 Iterate. If the generated interface does not meet code requirements, make configuration adjustments until requirements are satisfied.

If the generated code representation does not meet your requirements, reconfigure the interface and generate code again until code generations requirements are satisfied. For guidance on understanding the generated code, see “Analyze the Generated Code Interface” on page 51-13.

### Considerations and Limitations

- Instance-Specific Parameter Support — You can use model parameter arguments to configure workspace variables that have been specified as arguments. You can configure these arguments as private members of your class or as individual arguments defined outside the class. To configure within the class, you can set the data visibility setting to private and configure the generation of the get and set methods. Optionally, you can configure the class member values as defined within the class (setData(cm, 'ModelParameterArguments', 'DataAccess', 'Direct')) or passed-by-reference through the class constructor (setData(cm, 'ModelParameterArguments', 'DataAccess', 'Pointer')). The data access setting is supported for top model builds. For reference model builds, the code is generated as references in the model class. To configure instance-specific parameters outside the class, set the data visibility to individual arguments.

Instance-specific parameter limitations include:

- MATLAB variables marked as model arguments are not able to be configured as private class members.
- Model parameter arguments are not supported by right-click builds.
- Interface Code Generation Behavior — The I/O arguments style of step method specification supports single-rate models and multirate single-tasking models. Multirate multitasking models are not supported. Additionally, the C++ encapsulation interface is not the default, the value is ignored for the **Pass fixed-size scalar root inputs by value for code generation** parameter.
- Stateflow considerations — If you have a Stateflow license, for a Stateflow chart that resides in a root model configured to use the I/O arguments step method function specification, and that uses a model root input value or calls a subsystem that uses a model root input value, do one of the following to generate code:
  - In the Stateflow chart, clear the **Execute (enter) Chart At Initialization** check box.
  - Insert a Simulink Signal Conversion block immediately after the root input. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- Simscape Considerations — If a model root input value connects to a Simscape block, insert a Simulink Signal Conversion block between the root input and the Simscape conversion block. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- Reference Model Considerations — When building a referenced model that is configured to generate a C++ class interface:
  - Do not use a C++ class interface in cases when a referenced model cannot have a combined output/update function. Cases include a model that has a continuous sample time or saves states.
  - Do not use virtual buses as inputs or outputs to the referenced model when the referenced model uses the I/O arguments step method. When bus signals cross referenced model boundaries, either use nonvirtual buses or use the Default step method.

## Configure C++ Class Interface for Rate-Based Models

This example shows how to configure a C++ class interface for a rate-based model. In Simulink you can create and generate code for a rate-based modeling system that enables you to control the scheduling of model components. This example shows you how to customize the generated class name, namespace, class members, and class methods for an example model. This example, `rtwdemo_cppclass`, simulates whether a vehicle engine is on or off depending if the ignition has been turned on.

### Interface Goals and Requirements

A primary goal for configuring a C++ class interface for a rate-based model is to customize the generated code so that it easily integrates with your task scheduler. For this example, the goal is to update the name and namespace of the class to more meaningful values, distinguish the varied sample rates, and to simplify and encapsulate the remaining data and functions in the interface.

- To better reflect that this model is an engine status model, update the class name to `engine_status`.
- To prevent clashes with other symbols in a project and indicate that the generated code is from Simulink, update the class namespace to `sl`.
- To enable the configuration of the name and arguments of the base-rate periodic function, configure the inports and outports of the model as public class members without a get/set method.
- To enable the calibrate of shared values across multiple instances of the generated model class, configure the model parameters as private class members with a get/set method.
- To simplify the interface, configure parameter arguments and internal data as private without a get/set method.
- To make the other entry-point names more meaningful, update the names of the initialize and terminate entry-rate methods.

### Interactive Example

#### Configure Model Class Name and Namespace

1. On the **C++ Code** tab, click **Code Interface** and select **Class Name & Namespace**.
2. To configure the class name, in the **C++ Class Name** field, update the name to `engine_status`.
3. To configure the class namespace, in the **C++ Class Namespace** field, update the name to `sl`.
4. Click **OK**.

#### Configure Model Data Elements as Class Members

1. Open the Code Mappings editor. On the **C++ Code** tab, click **Code Interface** and select **Code Mappings**.
2. Configure the data visibility. For the model element categories:
  - Set the **Inports** and **Outports** to `public` and `None`.
  - Set the **Model parameters** to `private` and `Method`.
  - Set the **Model parameter arguments** and **Signals, states, and internal data** to `private` and `None`.

#### Configure Model Functions as Class Methods

1. Open the **Functions** pane. In the Code Mappings editor, click the **Functions** tab.
2. To view a complete list of entry-point functions for your model, click the **Update Diagram** button.
3. Configure the periodic functions to distinguish the sample rates.
  - To configure the base-rate periodic function, in the **Method Preview** column, click its method preview hyperlink.
  - Configure the function name. In the Step Function Interface configuration dialog box **C++ Step Function Name** field, update the function name to `EngineEntrypoint`.
  - Open the arguments viewer. In the dialog box, select **Configure arguments for Step function prototype** and click **Get default**.
  - Configure the argument names. In the **C++ Identifier Name** column, click and edit the names to `keyState arg_keyState`, `engineState arg_engineState`, `cycleTime arg_cycleTime`.
  - Configure the argument identifiers. In the **C++ Type Qualifier** column, select the appropriate identifier from the drop-down options. Configure `keyState arg_keyState` as `value`, `engineState arg_engineState` as `Pointer`, and `cycleTime arg_cycleTime` as `Pointer`.
  - Change the order of the arguments. Click and drag the argument rows in the viewer to the following order: `keyState arg_keyState`, `engineState arg_engineState`, and `cycleTime arg_cycleTime`.
  - Verify the arguments selections. Click **Validate**.
  - To apply changes and exit the dialog box, click **OK**.
4. Configure the other entry-point methods.
  - Configure the Initialize function name. In the **Method Name** column, click and edit the spreadsheet to change the name to `initIntegrator`.

- Configure the Terminate function name. In the **Method Name** column, click and edit the spreadsheet to change the name to terminateReadIntegrator.
5. Verify the method prototypes for all entry-point functions in the **Method Preview** column.

### Generate the Interface

1. Generate code. To generate a C++ class interface, on the **C++ Code** tab, click **Build**.
2. View code. To view the generated code, on the tab click **View Code**. The generated code appears beside the model in the model workspace.

### Programmatic Example

To programmatically configure a C++ class interface for the `rtwdemo_cppclass` model, use this workflow:

#### Open the example model

```
model = 'rtwdemo_cppclass';
open_system(model);

% Get the C++ mapping object
cm = coder.mapping.api.get(model);
```

#### Configure Model Class Name and Namespace

```
% Configure the C++ class name
setClassName(cm, 'engine_status');
% Configure the enclosing namespace
setClassNamespace(cm, 'sl');
```

#### Configure Model Data Elements as Class Members

```
% Configure the inports and outport to pass external data directly to
% the base-rate periodic function in the modeled application. This
% configuration enables you to later configure the name and arguments for
% the base-rate periodic function
setData(cm, 'Inports', 'DataVisibility', 'public');
setData(cm, 'Outports', 'DataVisibility', 'public');
setData(cm, 'Inports', 'MemberAccessMethod', 'None');
setData(cm, 'Outports', 'MemberAccessMethod', 'None');

% Configure model parameters so that you can adjust calibration values
setData(cm, 'ModelParameters', 'DataVisibility', 'private');
setData(cm, 'ModelParameters', 'MemberAccessMethod', 'Method');

% Configure Model Parameter Arguments and Internal data as encapsulated and simple
setData(cm, 'ModelParameterArguments', 'DataVisibility', 'private');
setData(cm, 'ModelParameterArguments', 'MemberAccessMethod', 'None');
setData(cm, 'InternalData', 'DataVisibility', 'private');
setData(cm, 'InternalData', 'MemberAccessMethod', 'None');
```

#### Configure Model Functions as Class Methods

```
% To configure the periodic functions, use the find function to
% retrieve the periodic functions for the model
periodic_functions = find(cm, 'PeriodicFunctions');
```

```
% Configure the base-rate periodic function method name
setFunction(cm, periodic_functions, 'MethodName', 'EngineEntrypoint');

% Configure the base-rate periodic function arguments
setFunction(cm, periodic_functions, 'Arguments', ...
 '(const & keyState arg_keyState, * engineState arg_engineState, * cycleTime arg_cycleTime)')

% Configure the initialize and terminate function names
setFunction(cm, 'Initialize', 'MethodName', 'initIntegrator');
setFunction(cm, 'Terminate', 'MethodName', 'terminateReadIntegrator');
```

### Generate The Interface

Build the application model to generate the C++ class interface.

## Configure C++ Class Interface for Export-Function Models

This example shows how to configure a C++ class interface for an export-function model. Export-function modeling enables you to generate code for event-triggered functions that can be integrated with an external environment or a scheduler. Functions are defined using Function-Call Subsystem, function-call Model, Simulink Function, and S-Function blocks. This example shows you how to customize the generated class name, namespace, class members, and class methods for an example model. This example, `rtwdemo_cppclass_expfcn`, provides a set of functions you might customize in a typical export-function model.

### Interface Goals and Requirements

A primary goal for configuring the generated C++ code from an export-function model is to be able to customize event-driven behavior. For this example, the goal is to update the name and namespace of the class to more meaningful values, customize the export functions, and to simplify and encapsulate the remaining data and functions in the interface.

- To better reflect the event-driven behavior in the model, update the class name to `triggered_events`.
- To prevent clashes with other symbols in a project and to indicate that the generated code is from Simulink, update the class namespace to `sl`.
- To simplify and encapsulate the data, set the model elements to private with a `get/set` method.
- To customize the functions, customize the names of the export-functions.
- To make the other entry-point names more meaningful, update the names of the `initialize` and `terminate` entry-point methods.

### Interactive Example

#### Configure Model Class Name and Namespace

1. On the **C++ Code** tab, click **Code Interface** and select **Class Name & Namespace**.
2. To configure the class name, in the **C++ Class Name** field, update the name to `triggered_events`.
3. To configure the class namespace, in the **C++ Class Namespace** field, update the name to `sl`.
4. Click **OK**.

#### Configure Model Data Elements as Class Members

1. Open the Code Mappings editor. On the **C++ Code** tab, click **Code Interface** and select **Code Mappings**.
2. Configure the data visibility. For the model element categories:
  - Set the **Inports** and **Outports** to private and Method.
  - Set the **Model parameters** to private and Method.
  - Set the **Model parameter arguments** to private and Method.
  - Set the **Signals, states, and internal data** to private and Method.

#### Configure Model Functions as Class Methods

1. Open the **Functions** pane. In the Code Mappings editor, click the **Functions** tab.
2. Configure the export function names.
  - For the export function, `Export Function: event 1`, from the **Method Name** column, click and edit the spreadsheet to update the name to `subsystemEvent1`.
  - For the export function, `Export Function: event 2`, from the **Method Name** column, click and edit the spreadsheet to update the name to `subsystemEvent2`.
3. Configure the Initialize function name. In the **Method Name** column, click and edit the spreadsheet to change the name to `initIntegrator`.
4. Configure the Terminate function name. In the **Method Name** column, click and edit the spreadsheet to change the name to `terminateReadIntegrator`.
5. Verify the method prototypes for all entry-point functions in the **Method Preview** column.

#### Generate the Interface

1. Generate code. To generate a C++ class interface, on the **C++ Code** tab, click **Build**.
2. View code. To view the generated code, on the tab, click **View Code**. The generated code appears beside the model in the model workspace.

#### Programmatic Example

To programmatically configure a C++ class interface for the `rtwdemo_cppclass_expfcn` model, use this workflow:

**Open the example model**

```
model = 'rtwdemo_cppclass_expfcn';
open_system(model);

% Get the C++ mapping object
cm = coder.mapping.api.get(model);
```

**Configure Model Class Name and Namespace**

```
% Configure the C++ class name
setClassName(cm, 'event_triggered');
% Configure the enclosing namespace
setClassNamespace(cm, 'sl');
```

**Configure Model Data Elements as Class Members**

```
% Configure the inports and outports for the model
setData(cm, 'Inports', 'DataVisibility', 'private');
setData(cm, 'Outports', 'DataVisibility', 'private');
setData(cm, 'Inports', 'MemberAccessMethod', 'Method');
setData(cm, 'Outports', 'MemberAccessMethod', 'Method');

% Configure the model parameters
% static model parameters (shared across all instances)
setData(cm, 'ModelParameters', 'DataVisibility', 'private');
setData(cm, 'ModelParameters', 'MemberAccessMethod', 'Method');

% Configure the model parameter arguments
setData(cm, 'ModelParameterArguments', 'DataVisibility', 'private');
setData(cm, 'ModelParameterArguments', 'MemberAccessMethod', 'Method');

% Configure the internal data
setData(cm, 'InternalData', 'DataVisibility', 'private');
setData(cm, 'InternalData', 'MemberAccessMethod', 'Method');
```

**Configure Model Functions as Class Methods**

```
% To configure the export functions, use the find function to
% retrieve all the export functions for the model
exported_functions = find(cm, 'ExportedFunctions');

% Configure the Exported Function names
setFunction(cm, exported_functions{1}, 'MethodName', 'subsystemEvent1');
setFunction(cm, exported_functions{2}, 'MethodName', 'subsystemEvent2');

% Configure the initialize and terminate function names
setFunction(cm, 'Initialize', 'MethodName', 'initIntegrator');
setFunction(cm, 'Terminate', 'MethodName', 'terminateReadIntegrator');
```

**Generate The Interface**

Build the application model to generate the C++ class interface.

# Memory Sections in Embedded Coder

---

- “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2
- “Protect Global Data with const and volatile Type Qualifiers” on page 42-13

## Control Data and Function Placement in Memory by Inserting Pragmas

For some applications, you can use pragmas and other code decorations to control the placement of data (global variables) and function definitions in memory. For example, a linker configuration file can define named sections in a `SECTIONS` directive and map each section to a range of memory addresses. In the C code, you include pragmas that assign global variables and functions to these named sections and, by extension, to the memory ranges. By controlling memory placement, you can:

- Generate code that is more efficient for your hardware.
- Modularize your application code for easier maintenance and modification later in the development process and after deployment.

With Embedded Coder and memory sections, you can:

- Apply default pragmas or other decorations to categories of model data and entry-point functions. To configure these defaults, use the Code Mappings editor. For example, you can:
  - Apply a default pragma to internal data, which includes block states that the code generator cannot eliminate through optimizations. You can apply a different default pragma to constant parameters, such as nonscalar parameters that the generated code must store in memory.
  - Apply a default pragma to categories of generated functions, including entry-point functions such as `model_step`.
- Override the default pragmas for individual data items such as block parameters, states, and signals. To do so, create your own storage class.
- Override the default pragmas for individual functions that correspond to atomic subsystems, which you can configure to appear in the generated code as separate functions with separate data. Use the subsystem parameters dialog box.

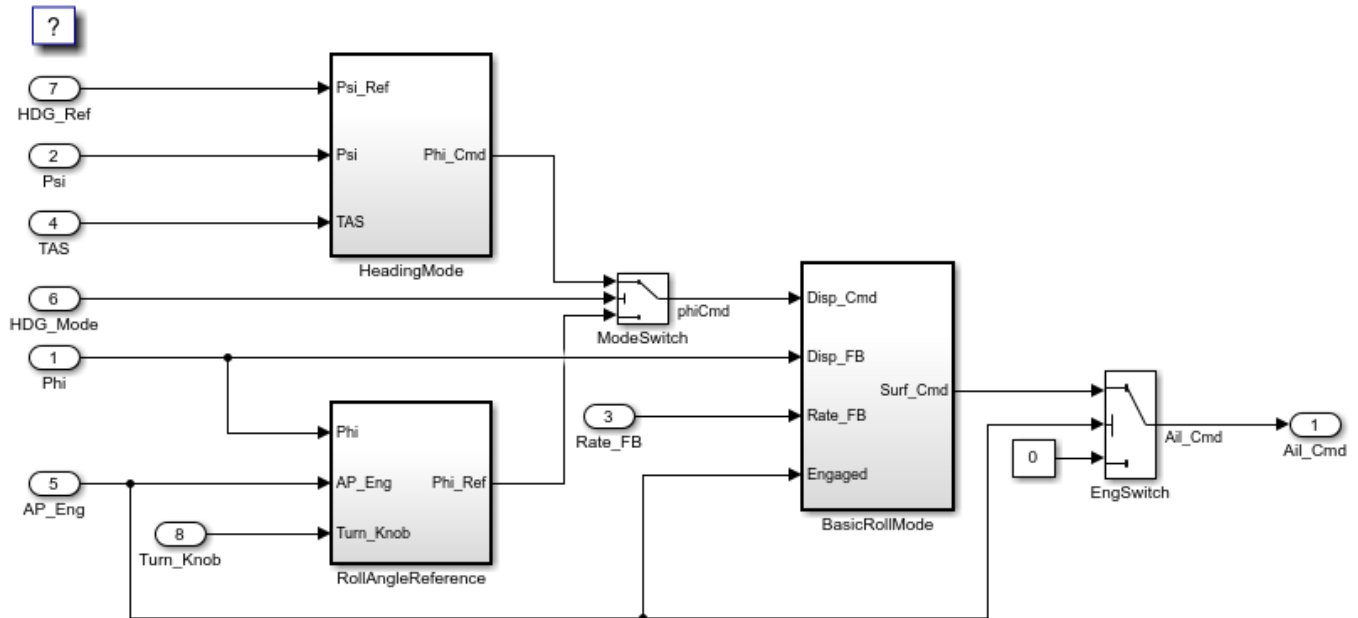

### Insert Pragmas by Using Memory Sections

In this example, you configure the default memory placement for all of the data and functions of the algorithm represented by the example model `rtwdemo_roll`. Then, for some signal data, you override the default placement.

#### Explore Example Model and Inspect Default Generated Code

- 1 Open the example model.

```
open_system('rtwdemo_roll')
```

The model is configured to generate efficient production code. For example, the configuration parameter **Default parameter behavior** is set to **Inlined**.

- 2 In the **Apps** gallery, under **Code generation**, click **Embedded Coder**. The **C Code** tab opens. Generate code from the model.
- 3 In the code generation report, inspect the file `rtwdemo_roll.h`. The file defines structure types that represent data that the algorithm needs. For example, the file defines a structure type that represents block states such as the states of Discrete-Time Integrator blocks.

```
/* Block signals and states (default storage) for system '<Root>' */
typedef struct {
 real32_T FixPtUnitDelay1_DSTATE; /* '<S7>/FixPt Unit Delay1' */
 real32_T Integrator_DSTATE; /* '<S1>/Integrator' */
 int8_T Integrator_PrevResetState; /* '<S1>/Integrator' */
} DW;
```

The file also declares entry-point functions for the model.

```
/* Model entry point functions */
extern void rtwdemo_roll_initialize(void);
extern void rtwdemo_roll_step(void);
```

- 4 Inspect `rtwdemo_roll.c`. This file defines global structure variables to store the data. The file also defines the functions.

In this example, assume your linker configuration file defines named sections `MYALGORITHM_DATA` and `MYALGORITHM_CODE` in a `SECTIONS` directive. You can configure the model so that the generated code includes pragmas, placing the memory allocated for the data and functions in these named sections.

- For a global variable named `myVar`, the pragma syntax is:

```
#pragma SEC_MYALGORITHM_DATA("myVar")

double myVar;
```

- For a function named `myFunction`, the pragma syntax is the same except for the section name:

```
#pragma SEC_MYALGORITHM_CODE("myFunction")

void myFunction(void)
```

### Create Memory Sections

In this example, you use two pragmas with different syntaxes, so you must create two memory sections.

- 1 Open the Embedded Coder app. On the **C Code** tab, select **Code Interface > Embedded Coder Dictionary**.
- 2 In the **Embedded Coder Dictionary** dialog box, select the **Memory Sections** tab and click the **Create** button.
- 3 For the new memory section, set these options:
  - **Name** to `MYALGORITHM_DATA`.
  - **Statements Surround** to `Each variable`.
  - **Pre Statement** to `#pragma SEC_MYALGORITHM_DATA("$N")`. The token `$N` stands for the name of each variable that uses the memory section.
- 4 Create another, similar memory section that corresponds to `MYALGORITHM_CODE`.
- 5 Click **Save** and close the Embedded Coder Dictionary.

### Configure Default Pragmas for Data and Functions

- 1 On the **C Code** tab, select **Code Interface > Default Code Mappings** or **Code Interface > Individual Element Code Mappings**.
- 2 In the **Data Defaults** tab, expand **Inports and Outports, Signals and Parameters**.
- 3 In the table, select the **Inports** row.
- 4 Click the  icon and set **Memory Section** to `MYALGORITHM_DATA`.
- 5 For the other rows in the table, set **Memory Section** to `MYALGORITHM_DATA`.
- 6 Under **Function Defaults**, for each row in the table, set **Memory Section** to `MYALGORITHM_CODE`.
- 7 In your current folder, delete the existing `slprj` folder.
- 8 Configure the model to generate only code. Select the configuration parameter **Configuration Parameters > Generate code only**.
- 9 Click **Generate Code**.

Now, the `rtwdemo_roll.c` file applies the pragmas to the definitions of the structure variables and the functions. For each category of data and functions that you configured in the Code Mappings editor, the code applies a pragma. For example, the code applies the `MYALGORITHM_DATA` pragma to each of the structures that store block states, root-level inputs, and root-level outputs.

```
/* Block signals and states (default storage) */
#pragma SEC_MYALGORITHM_DATA("rtDW")

DW rtDW;

/* External inputs (root inport signals with default storage) */
#pragma SEC_MYALGORITHM_DATA("rtU")

ExtU rtU;

/* External outputs (root outports fed by signals with default storage) */
#pragma SEC_MYALGORITHM_DATA("rtY")

ExtY rtY;
```

## Retain Default Memory Section After Applying a Default Storage Class or Function Template

In the Code Mappings editor, you can use the **Storage Class** and **Function Customization Template** columns to control the default appearance of data and functions in the generated code. When you use these columns to apply a setting other than **Default**, the Code Mappings editor discards the memory section that you applied in the Property Inspector. To retain the memory section, use the Embedded Coder Dictionary to create a storage class or function template, then apply the memory section to that storage class or function template.

In this example, you configure the nonparameter data of the model, such as signals and states, to appear in the same structure by creating a storage class. To retain the MYALGORITHM\_DATA memory section, you apply the memory section to the storage class.

- 1 In the Embedded Coder Dictionary for the model, select the **Storage Classes** tab and click the **Create** button.
- 2 For the new storage class, set:
  - **Name** to STRUCT\_DATA.
  - **Storage Type** to Structured.
  - **Memory Section** to MYALGORITHM\_DATA.
- 3 In the Code Mappings editor, under **Data Defaults**, in the **Storage Class** column, select STRUCT\_DATA for these rows:
  - **Inports**
  - **Outports**
  - **Signals, states and internal data**
- 4 Generate code from the model.
- 5 Inspect rtwdemo\_roll.c. Now, the file defines a single structure variable that contains the nonparameter data, applying the pragma to that variable.

```
/* Storage class 'STRUCT_DATA' */
#pragma SEC_MYALGORITHM_DATA("STRUCT_DATA_rtwdemo_roll")

rtwdemo_roll_STRUCT_DATA STRUCT_DATA_rtwdemo_roll;
```

## Incorporate Default Memory Section into a Storage Class for Individual Mapping

To override the default storage classes that you specify in **Code Mappings > Data Defaults**, apply a storage class directly to a data item by using the Code Mappings editor. Directly applying a storage class other than **Auto** or **Model default** bypasses the default memory section that you specify in **Data Defaults**. To retain the memory section, create a storage class in the Embedded Coder Dictionary and apply the desired memory section to it. Then, apply the storage class to individual data items in the Code Mappings editor. Other models cannot access the storage class and memory section that you define in the Embedded Coder Dictionary. To share the storage class and memory section sections among other models, store the Embedded Coder Dictionary in a Simulink Data Dictionary data (sldd) outside of your model. Then, share the dictionary between the target models. For more information, see “Migrate Definitions from Model File to Shared Data Dictionary” on page 31-14.

In rtwdemo\_roll, in the BasicRollMode subsystem, the three Gain blocks represent the parameters of a PID control algorithm. In the “Retain Default Memory Section After Applying a Default Storage Class or Function Template” on page 42-5 section, configure the nonparameter data of the model, such as signals and states, to appear in the same structure by applying the default

storage class `STRUCT_DATA`. In this example, you configure the output signals of the Gain blocks so that the generated code allocates memory for them in the `MYALGORITHM_DATA` section but does not appear in the default storage class structure. Define a new storage class `myStore` in the Embedded Coder Dictionary and apply the desired memory section `MYALGORITHM_DATA` to it. Then, directly apply the storage class to the output signals of the Gain blocks.

- 1 In the Embedded Coder Dictionary of the model, select the **Storage Classes** tab and click the **Create** button.
- 2 For the new storage class, set:
  - **Name** to `myStore`.
  - **Storage Type** to `Structured`.
  - **Memory Section** to `MYALGORITHM_DATA`.
- 3 In the model, navigate into the `BasicRollMode` subsystem. The signals of the subsystem are not automatically populated into the Code Mappings editor. You need to manually add signals by pausing on the ellipsis that appears above or below a signal line to open the action bar. Click the **Add Signal** button. The button is also available in the Code Mappings editor on the **Signals/States** tab.
- 4 After you add the output signals of the Gain blocks, the signal rows appear in the **Code Mappings > Signals/States** tab. Open the Property Inspector by selecting the signal rows. In the Code section, set these properties:
  - **Storage Class** to `myStore`.
  - **Identifier** to the block names.
- 5 Generate code from the model.
- 6 Inspect the generated file `rtwdemo_roll.c`. The file defines a structure variable `myStore_rtwdemo_roll` and applies the pragma to the variable.

```
/* Storage class 'myStore' */
#pragma SEC_MYALGORITHM_DATA("myStore_rtwdemo_roll")
```

```
rtwdemo_roll_myStore myStore_rtwdemo_roll;
```

- 7 Inspect the generated file `rtwdemo_roll.h`. The structure variable contains the output signals of the Gain blocks. The output signals are now in a different structure but stored in the same `MYALGORITHM_DATA` memory section.

```
/* Storage class 'myStore', for system '<Root>' */
typedef struct {
 real32_T DispGain; /* '<S1>/DispGain' */
 real32_T RateGain; /* '<S1>/RateGain' */
 real32_T IntGain; /* '<S1>/IntGain' */
} rtwdemo_roll_myStore;
```

## Configure Pragma to Surround Groups of Definitions

If your build toolchain requires that a pragma or other decoration surround multiple definitions of variables or functions at once, in an Embedded Coder Dictionary or the Custom Storage Class Designer, set **Statements surround** to `Group of variables` (the default in the Custom Storage Class Designer).

## Override Default Memory Placement for Individual Data Elements

After you configure memory section defaults in the Code Mappings editor (see “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15), to override these

default settings for individual data elements (signals, parameters, and states), create a storage class and any required memory sections by using the Embedded Coder Dictionary. For more information see, “Choose Where to Create and Store Memory Section Definition” on page 42-7. When you create the storage class, set the **Memory section** property to the appropriate memory section. Then, use the Code Mappings editor to apply the storage class to individual data elements.

## Choose Where to Create and Store Memory Section Definition

To define a memory section, you must choose where to create it: in an Embedded Coder Dictionary or in a Simulink Shared Dictionary.

- If you need to use the memory section only in the Code Mappings editor, define the memory section in an Embedded Coder Dictionary.

If you need to use the memory section only in the Code Mappings editor and want to share it with other models, define the memory section in a Simulink® data dictionary (sldd). For more information, see “Share Embedded Coder Dictionary Definition Between Models” on page 31-12.

- If you need to use the memory section outside of the Code Mappings editor, define the memory section in a package. For example, define memory sections in a package to configure memory sections of an atomic Subsystem. For more information, see “Override Memory Section for Atomic Subsystem” on page 42-7.

## Share Memory Section Definition Between Models

- If you define the memory section in the Embedded Coder Dictionary of a model, you cannot use the memory section in other models. To share the memory section, migrate the definition to a Simulink data dictionary (sldd). Then, share the dictionary between the target models. For more information, see “Migrate Definitions from Model File to Shared Data Dictionary” on page 31-14.
- If you define the memory section in a package by using the Custom Storage Class Designer, any model can use the memory section. For more information, see “Create Storage Class by Using Custom Storage Class Designer” on page 37-23. Add the folder containing the package folder to the MATLAB path (see “What Is the MATLAB Search Path?”).

## Override Default Memory Placement for Subsystem Functions and Data

When you use atomic subsystems to partition the generated code into functions (see “Generate Subsystem Code as Separate Function and Files” on page 3-7), you can apply different memory sections to the functions and data of each subsystem. You can also specify that a subsystem not use a memory section.

- To use different memory sections to override the model-level defaults that you set in the Code Mappings editor, see “Override Memory Section for Atomic Subsystem” on page 42-7.
- To specify that a subsystem not use a memory section (in other words, to prevent the subsystem from inheriting the model-level defaults), see “Specify That Atomic Subsystem Does Not Use a Memory Section” on page 42-8.

### Override Memory Section for Atomic Subsystem

The memory sections that you specify for a subsystem override the model-level defaults that you set in the Code Mappings editor. Use this technique to aggregate the data and instruction code for

subroutines or subcomponents (represented by subsystems) into different regions of memory. To apply a memory section directly to an atomic subsystem, define the memory section in a package by using the Custom Storage Class Designer. You cannot use a memory section that you define in an Embedded Coder Dictionary. Then, load the package into the model and configure the subsystem block parameters to specify the memory section.

To create the memory section:

- 1 In your current folder, create a folder named `+myPackage`. The folder defines a package named `myPackage`. For more information, see “Create Data Class Package” on page 37-14.

To make the package available outside of your current folder, optionally, you can add the folder containing the `+myPackage` folder to the MATLAB path.

- 2 Open the Custom Storage Class designer.

```
cscdesigner('myPackage');
```

- 3 In the Custom Storage Class Designer, select the **Memory Section** tab.

- 4 Click **New**.

- 5 For the new memory section, set these options:

- **Name** to `MYALGORITHM_DATA`.
- **Statements surround** to `Each variable`.
- **Pre statement** to `#pragma SEC_MYALGORITHM_DATA("$N")`.

- 6 Click **Apply** and **Save**.

- 7 Set your current folder to the folder that contains the `+myPackage` folder.

To apply the memory section in an atomic subsystem:

- 1 Configure the Embedded Coder Dictionary of the model to load the target package as described in “Refer to Code Generation Definitions in a Package”.

- 2 To configure the target subsystem to specify the memory section, open the subsystem parameters dialog box. On the **Code Generation** tab:

- Set **Function packaging** to `Nonreusable function` or `Reusable function` (for reentrant code).
- If you set **Function packaging** to `Nonreusable function`, to enable configuration of memory sections for the subsystem data, select **Function with separate data**. If you do not select **Function with separate data**, the subsystem data inherits memory sections from the model or, if applicable, a parent subsystem.
- To apply the `MYALGORITHM_DATA` memory section directly to the subsystem functions and data, use these block parameters:
  - **Memory section for initialize/terminate functions**
  - **Memory section for execution functions**
  - **Memory section for constants**
  - **Memory section for internal data**
  - **Memory section for parameters**

### Specify That Atomic Subsystem Does Not Use a Memory Section

By default, subsystem functions and data inherit the model-level memory sections that you specify for relevant function and data categories in the Code Mappings editor. For example, if you specify a

function customization template for the **Execution** category, and that template carries a memory section, the memory section applies to subsystem execution functions as well as model entry-point execution functions.

To specify that a subsystem does not use a memory section, open the subsystem parameters dialog box. On the **Code Generation** tab, set these parameters to Default:

- **Memory section for initialize/terminate functions**
- **Memory section for execution functions**
- **Memory section for constants**
- **Memory section for internal data**
- **Memory section for parameters**

With these settings, the subsystem does not use a memory section for the data or functions that each parameter represents.

### Limitations and Other Considerations

- The settings that you specify for an atomic, nonreusable subsystem with separate data apply only to the data and functions of that subsystem, not to data in similarly configured child subsystems. Atomic, nonreusable child subsystems with separate data can inherit memory sections from the containing model, not from the parent subsystem.
- If you use **Build This Subsystem** or **Build Selected Subsystem** to generate code for an atomic subsystem that specifies memory sections, the code generator ignores the subsystem-level specifications and uses the model-level specifications instead. For information about building subsystems, see “Generate Code and Executables for Individual Subsystems”.

## Share Memory Section Between Packages (Package Memory Sections Only)

Packages can access and use memory sections that are defined in other packages, including custom packages and built-in packages such as Simulink. Only one copy of the memory section exists, in the package that defines it. Other packages refer to the memory section by pointing to it in its original location. Changes to the memory section, including changes to a built-in memory section in later MathWorks product releases, are immediately available in every referencing package.

To configure a package to refer to a memory section that is defined in another package:

- 1 Open the Custom Storage Class Designer. At the command prompt, enter `cscdesigner`.
- 2 Select the **Memory Section** tab.
- 3 Use **Select Package** to select the package in which you want to reference a class or section defined in some other package.
- 4 In the **Memory section definitions** pane, select the existing definition below which you want to insert the reference.
- 5 Click **New Reference**.

A new reference with a default name and properties appears below the previously selected definition. The new reference is selected, and a **Reference** tab appears that shows the reference's initial properties.

- 6 Use the **Name** field to enter a name for the new reference. The name must be unique in the importing package, but can duplicate the name in the source package.
- 7 Set **Refer to memory section in package** to specify the package that contains the memory section that you want to reference.
- 8 Set **Memory section to reference** to specify the memory section to be referenced.
- 9 Click **OK** or **Apply** to save the changes to memory. To save the changes permanently, click **Save**.

## Control Appearance of Memory Section Drop-Down List (Package Memory Sections Only)

When you apply a package memory section, you select the memory section from a drop-down list. To control the order of the memory sections in the list, in the Custom Storage Class Designer, use the **Up** and **Down** buttons. The order of memory sections in drop-down lists matches the order in the Custom Storage Class Designer.

## Protect Definitions of Package Memory Sections (Package Memory Sections Only)

When you click **Save** in the Custom Storage Class Designer, the Designer saves memory section and custom storage class definitions into the `csc_registration.m` file in the package folder. To determine the location of this file, in the Custom Storage Class Designer, inspect the value of **Filename**.

You can prevent changes to the memory section definitions of an entire package by converting the `csc_registration.m` file from a MATLAB file to a P-file. Use the `pcode` function.

A best practice is to keep `csc_registration.m` and `csc_registration.p` in your package folder. That way, if you need to modify the memory sections by using the Designer, you can delete `csc_registration.p` and later regenerate it after you finish the modifications. Because the P-coded version of the file takes precedence, while both files exist in the package, the memory sections are protected.

## Limitations

- The code generator does not apply memory sections to data that uses these built-in storage classes:
  - `ExportedGlobal`
  - `ImportedExtern`
  - `ImportedExternPointer`
- In the Custom Storage Class Designer, the storage type qualifier that you specify for a memory section by using the **Qualifier** text box affects only data items that use a storage class setting other than these built-in storage classes:
  - `ExportedGlobal`
  - `ImportedExtern`

- ImportedExternPointer

The code generator omits the qualifier from other data categories.

- When you create a subsystem in a custom block library, you cannot specify memory sections for the subsystem definition in the library. Instead, specify memory sections for the subsystem instances that you place in your models.

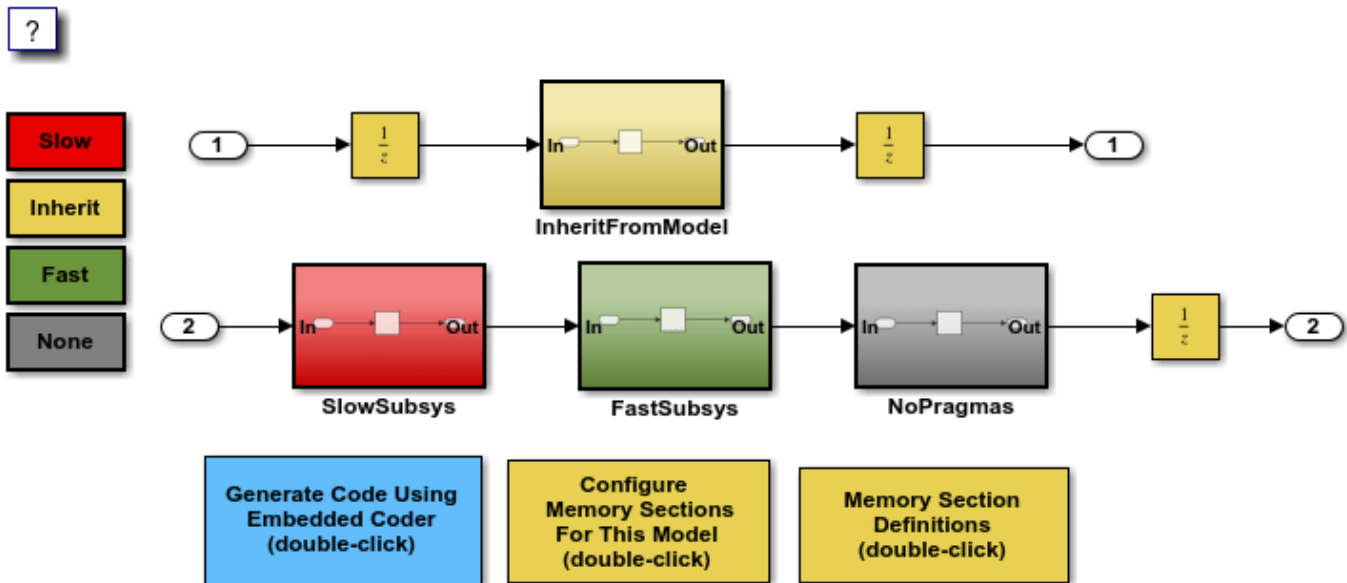

## Insert Pragmas for Functions and Data in Generated Code

This example shows how to insert pragmas in generated code to control the placement of data and functions in memory. To configure memory placement for subsystem functions, use the memory sections that you define in a package. This example illustrates how to use memory sections defined in a package to insert pragmas for functions and data in the generated code.

### Explore Example Model

Open the example model.

```
open_system('rtwdemo_memsec')
```

Copyright 1994-2020 The MathWorks, Inc.

- 1 To view the memory sections in the ECoderDemos package, click the **Memory Section Definitions** button in the model and then select the **Memory Sections** tab.
- 2 To configure the memory sections for functions and data, click the **Configure Memory Sections For This Model** button. In the Code Mappings editor, select the appropriate row, and then specify memory sections in the Property Inspector.
- 3 The model-level settings are the default settings for atomic subsystems. Open the subsystem parameter drop-down lists to see the memory section settings for each of the atomic subsystems in the model. You can override the default model-level setting by configuring the subsystem block parameters.

- 4 To generate code, click the **Generate Code Using Embedded Coder** button. A code generation report opens automatically. Inspect the data and function definitions in the .c files and observe how the generated pragmas correspond to the specified memory sections.

- “Protect Global Data with const and volatile Type Qualifiers” on page 42-13
- “Data Structures in the Generated Code” on page 33-31

## Protect Global Data with const and volatile Type Qualifiers

In C, you use the type qualifier `const` to prevent code in an application from assigning a new value to a variable. In an application where an external actor (for example, a hardware device) can manipulate the value of a variable, you use the keyword `volatile` to prevent a compiler from optimizing the assembly code in a way that compromises the integrity of the variable value. You can also use `volatile` to prevent a compiler from eliminating storage for `const` data, such as a parameter that has a value that you want to tune during execution.

- To apply the qualifiers to an individual data item in a model, including a custom structure that you create by using a nonvirtual bus or a parameter structure, apply the appropriate predefined storage class directly to the data item. The storage class prevents optimizations such as **Default parameter behavior** from eliminating storage for the data item. For an example, see “Type Qualifiers” on page 25-12. For information about optimizations that a directly applied storage class prevents, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49.

If the predefined storage classes do not meet your requirements, you can create your own custom storage class. To make your custom storage class apply the qualifiers, in the Custom Storage Class Designer, set **Memory section** to the appropriate built-in memory section or to a memory section that you create. For more information, see “Create Storage Classes by Using the Custom Storage Class Designer” on page 37-14.

- You can apply the qualifiers to a category of model data by default, such as parameters or states. As you add blocks to a model, new data items in these categories carry the qualifiers that you specify. For more information, see “Configure Default Code Generation for Data” on page 32-16.

If the predefined storage classes do not meet your requirements, you can create your own by using an Embedded Coder Dictionary. In the Dictionary, for your new storage class, select the appropriate check boxes under **Qualifiers**. For more information, see “Create Code Definitions for Use in the Code Mappings Editor” on page 31-2.

### Maintain const Correctness for Arguments of Entry-Point Functions

When your external code calls a generated entry-point function and passes `const` data through an argument (formal parameter) of the function, to make the corresponding argument in the function definition `const`, customize the execution (step) entry-point function interface.

- To configure the step entry-point function interface for a model, see “Configure Name and Arguments for Individual Step Functions” on page 32-119.
- To configure the step entry-point function interface for a Simulink Function block, see “Configure Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-2.

### Incorrect Results or Undefined Behavior When Passing Volatile Data to a Generated Function

The generated code can define and call functions other than model entry-point functions. For example, you can configure an atomic subsystem to appear in the code as a separate function. Also, lookup table blocks, such as n-D Lookup Table, typically yield separate utility functions.

When the generated code defines a function that has an argument (formal parameter), the function definition does not apply `volatile` to the argument. Therefore, when other generated code or your

external code calls the function and passes a volatile variable as the value of the argument, the called function implicitly casts away the volatility.

If your application executes the called function while the value of the volatile data changes, the function can yield incorrect results or undefined behavior. In particular, for lookup table data that you prepare for calibration, by applying `const` and `volatile`, make sure that you do not calibrate the data while your application executes the lookup utilities.

# Array Layout

---

## Column-Major Layout to Row-Major Layout Conversion of Models with Lookup Table Blocks

Simulink® Coder™ supports row-major array layout for code generation. You can integrate existing applications that use row-major array layout with the generated code in row-major array layout. When you switch an existing model with lookup table (LUT) blocks from the column-major array layout to the row-major array layout, it is recommended to convert the LUT blocks from the column-major algorithm to the row-major algorithm. The code generated by using row-major algorithm performs with the best speed and memory usage when operating on table data with row-major array layout. The code generated by using column-major algorithm performs best with column-major array layout.

This example shows the workflow of converting a model with LUT blocks from column-major layout to row-major layout to achieve the best performance on a row-major array layout.

In this example, you:

- Identify the array layout and select the optimized algorithm.
- Preserve semantics through table permutation.
- Generate code by using a row-major algorithm and an array layout.

### Simulate and Generate Code by Using Column-Major Algorithms

1. Open the example model `rtwdemo_row_lutcol2row_workflow`.

```
open_system('rtwdemo_row_lutcol2row_workflow');
```

?

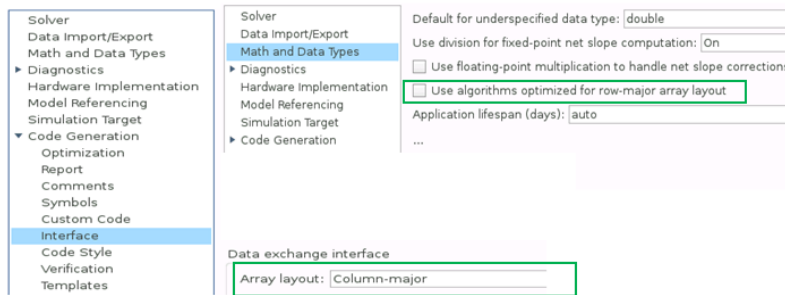

Copyright 2018-2020 The MathWorks, Inc.

By default, Simulink configures a model to use column-major algorithms and a column-major array layout. These parameters are the configuration parameters in the Configuration Parameters dialog box.

- Math and Data Types > “Use algorithms optimized for row-major array layout” — This parameter affects simulation and code generation.
- Code Generation > Interface > “Array layout” — This parameter affects only code generation.

2. On the **Modeling** tab, click **Run** to simulate the model and observe the output logged in workspace variable `yout`.

3. Change your current folder in MATLAB® to a writable folder. On the **C Code** tab, click **Build** to generate C code.

### Select Optimized Algorithms for Row-Major Array Layout

Table data with row-major array layout is frequently used in the field of calibration. To interface the row-major table data with the existing model, update the column-major model to operate efficiently on row-major table data.

Use the algorithm that is optimized for the specified array layout to achieve the best performance. For example, use row-major algorithms when **Array layout** is set as `Row-major` during code generation.

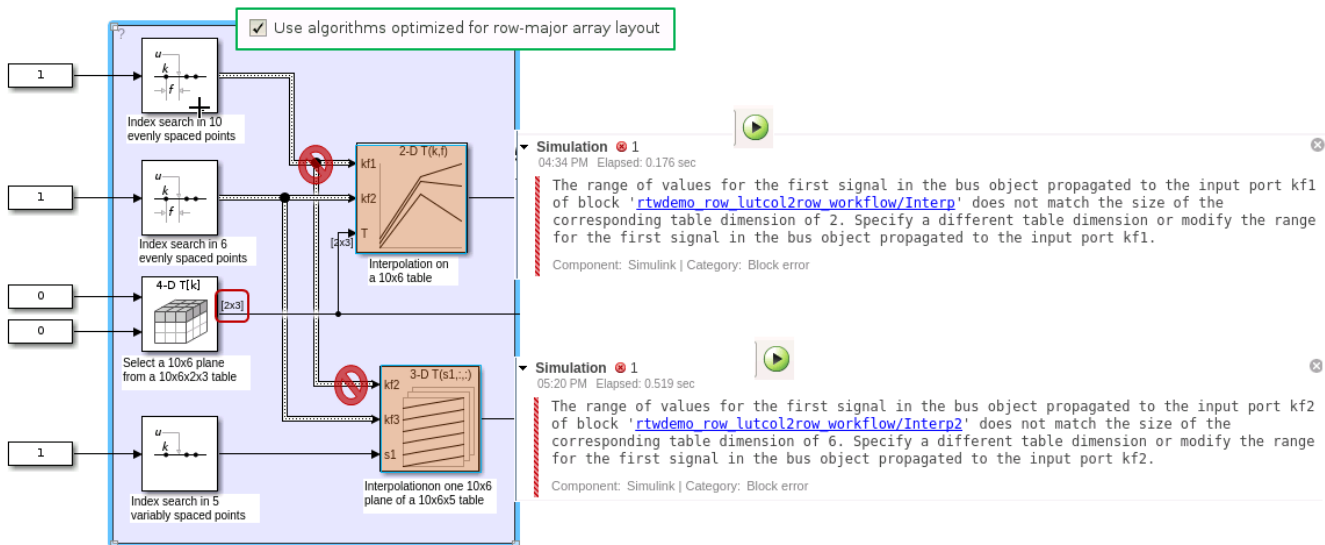

Array Layout	Algorithm	Cache-Friendly Algorithm
Column-major	Column-major	✓ (Recommended)
Row-major	Row-major	✓ (Recommended)
Row-major	Column-major	⚠ (Not recommended)
Column-major	Row-major	⚠ (Not recommended)

1. To enable row-major algorithms, open the Configuration Parameters dialog box. On the **Math and Data Types** pane, select the configuration parameter **Use algorithms optimized for row-major array layout**. Alternatively, in the MATLAB Command Window, enter:

```
set_param('rtwdemo_row_lutcol2row_workflow','UseRowMajorAlgorithm','on');
```

2. Click **Run** to simulate the model. Simulink reports errors because it encounters inconsistent breakpoint and table data between prelookup and interpolation blocks. The causes of this error are the two semantic changes that occur when you switch from column-major algorithms to row-major algorithms, that is, when you:

- Select a plane from a 3-D table in interpolation block.
- Select a plane from a 4-D table through a direct lookup table block.

Dimension of the Selected Plane (Semantic Changes)

	Column-major algorithm	Row-major algorithm
Select a plane from a 4-D table (10x6x2x3)	10x6	2x3
Select a plane from a 3-D table (10x6x5)	10x6	6x5

### Preserve Semantics by Using Table Permutation

1. For subtable selection before interpolation, or direct lookup that outputs a vector or 2-D matrix, the model semantics change when you switch from a column-major algorithm to a row-major algorithm by selecting the configuration parameter **Use algorithms optimized for row-major array layout**. To preserve the semantics and fix the previous errors, permute the table data by using these commands:

```
T4d_str = get_param('rtwdemo_row_lutcol2row_workflow/Direct LUT','Table');
set_param('rtwdemo_row_lutcol2row_workflow/Direct LUT','Table',...
['permute(' ,T4d_str,',[3,4,1,2]]');
```

```
T3d_str = get_param('rtwdemo_row_lutcol2row_workflow/Interp2','Table');
set_param('rtwdemo_row_lutcol2row_workflow/Interp2','Table',...
['permute(' ,T3d_str,',[3,1,2]]');
```

2. Before you import table data from a file, you must permute the table data in the file. This permutation keeps the table tunable throughout the simulation and code generation workflow.

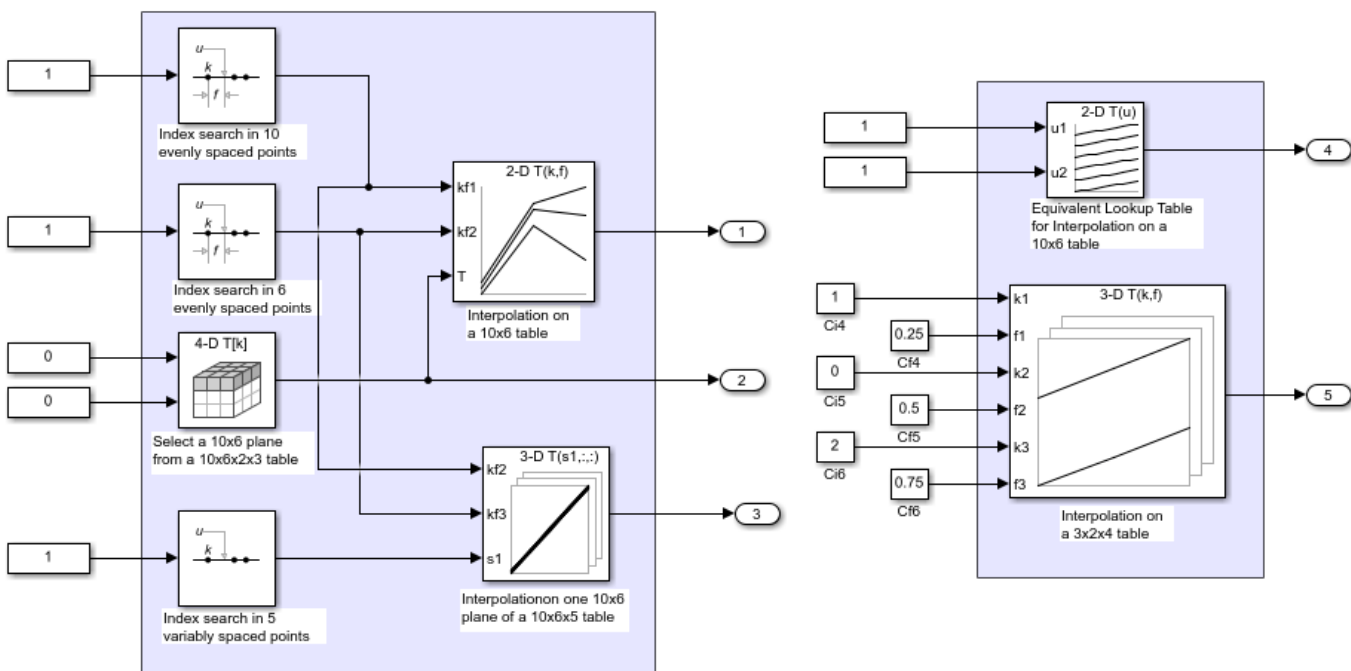

### Code Generation by Using Row-Major Algorithm and Array Layout

After permuting the table data, Simulink configures the model `rtwdemo_row_lutcol2row_workflow` for row-major simulation. The model is equivalent to the preconfigured model `rtwdemo_row_lutcol2row_workflow_rowrow` that has permuted table data and uses a row-major algorithm.

1. Open the example model `rtwdemo_row_lutcol2row_workflow_rowrow`.

```
open_system('rtwdemo_row_lutcol2row_workflow_rowrow');
```

?

Copyright 2018-2020 The MathWorks, Inc.

2. To set up these models for row-major code generation, open the Configuration Parameters dialog box. In addition to enabling the **Use algorithms optimized for row-major array layout** configuration parameter, on the **Code Generation > Interface** pane, set the configuration parameter **Array Layout** to Row-Major option. The **Array Layout** parameter enables the model for row-major code generation. Alternatively, in the MATLAB Command Window, enter:

```
% For model 'rtwdemo_row_lutcol2row_workflow_rowrow'
set_param('rtwdemo_row_lutcol2row_workflow_rowrow', 'ArrayLayout', 'Row-major');
% For model 'rtwdemo_row_lutcol2row_workflow'
set_param('rtwdemo_row_lutcol2row_workflow', 'ArrayLayout', 'Row-major');
```

3. In the block dialog boxes, examine the permuted 3-D table.

4. Change your current folder in MATLAB to a writable folder. On the **C Code** tab, click **Build** to generate C code. In the generated code, observe the table data with row-major array layout

```

21 /* Block parameters (default storage) */
22 P rtP = {
23 /* Variable: Tbl_1
24 * Referenced by: '<Root>/2-D Lookup Table'
25 */
26 { 1.0, 11.0, 21.0, 31.0, 41.0, 51.0, 2.0, 12.0, 22.0, 32.0, 42.0, 52.0, 3.0,
27 13.0, 23.0, 33.0, 43.0, 53.0, 4.0, 14.0, 24.0, 34.0, 44.0, 54.0, 5.0, 15.0,
28 25.0, 35.0, 45.0, 55.0, 6.0, 16.0, 26.0, 36.0, 46.0, 56.0, 7.0, 17.0, 27.0,
29 37.0, 47.0, 57.0, 8.0, 18.0, 28.0, 38.0, 48.0, 58.0, 9.0, 19.0, 29.0, 39.0,
30 49.0, 59.0, 10.0, 20.0, 30.0, 40.0, 50.0, 60.0 }
31 };

```

In the generated code, the memcpy function replaces the for loops. Using memcpy reduces the amount of memory for storing data. This optimization improves execution speed.

```

83 /* Model step function */
84 void rtwdemo_row_lutcol2row_workflow_rowrow_step(void)
85 {
86 uint32_T rtb_Prelookup_Index;

101 * 4-dimensional Direct Look-Up returning a 2-D Matrix,
102 * which is contiguous for row-major array
103 */
104 memcpy(&rtY.Out2[0], &rtCP_DirectLUT_table[0], 60U * sizeof(real_T));
105
106 /* PreLookup: '<Root>/PreLookup' incorporates:
107 * Constant: '<Root>/Constant1'
108 */
109 rtb_Prelookup_Index = plook_evenca(1.0, rtCP_Prelookup_BreakpointsData[0],
110 rtCP_Prelookup_BreakpointsData[1] - rtCP_Prelookup_BreakpointsData[0], 9U,
111 &rtb_Prelookup_Fraction);

```

Observe the algorithms optimized for row-major data.

```

17 real_T intrp2d_la(const uint32_T bpIndex[], const real_T frac[], const real_T
18 table[], const uint32_T stride, const uint32_T maxIndex[])
19 {
20 real_T y;
21 real_T yR_1d;
22 uint32_T offset_1d;
23
24 /* Row-major Interpolation 2-D
25 Interpolation method: 'Linear point-slope'
26 Use last breakpoint for index at or above upper limit: 'on'
27 Overflow mode: 'wrapping'
28 */
29 offset_1d = bpIndex[1U] * stride + bpIndex[0U];
30 if (bpIndex[0U] == maxIndex[0U]) {
31 y = table[offset_1d];
32 } else {
33 y = (table[offset_1d + 1U] - table[offset_1d]) * frac[0U] + table[offset_1d];
34 }
35
36 if (bpIndex[1U] == maxIndex[1U]) {
37 } else {
38 offset_1d += stride;
39 if (bpIndex[0U] == maxIndex[0U]) {
40 yR_1d = table[offset_1d];
41
42 close_system('rtwdemo_row_lutcol2row_workflow',0);
43 close_system('rtwdemo_row_lutcol2row_workflow_rowrow',0);

```

## Interpolation Algorithm for Row-Major Array Layout

This example illustrates the interpolation algorithm in 2-D and 3-D Lookup Table that is optimized for row-major array layout. The interpolation algorithm that is optimized for column-major array layout is also presented as a reference. The code generated by using row-major interpolation algorithm performs with the best speed and memory usage when operating on table data with row-major array layout. The code generated by using column-major interpolation algorithm performs best with column-major array layout.

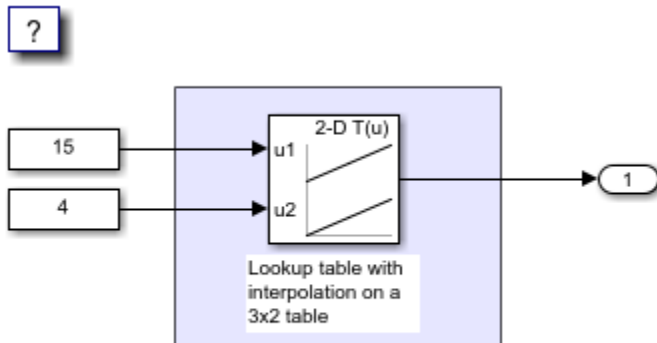

In this example, you:

- Interpolate on a 2-D Lookup Table with column-major and row-major algorithm.
- Generate code with a row-major algorithm and an array layout.
- Identify the array layout and select the optimized algorithm.
- Interpolate on a 3-D Lookup Table with column-major and row-major algorithm.

### Simulate with 2-D Row-Major Algorithm

1. Open the example model `rtwdemo_row_lut2d`.

```
model = 'rtwdemo_row_lut2d';
open_system(model);
```

Copyright 2018-2020 The MathWorks, Inc.

2. By default, Simulink configures a model with column-major algorithm and column-major array layout. The model `rtwdemo_row_lut2d` is configured to use column-major algorithm. Simulate the model. To observe the output, open the Data Inspector from the **Simulation** tab. The output value is 4.

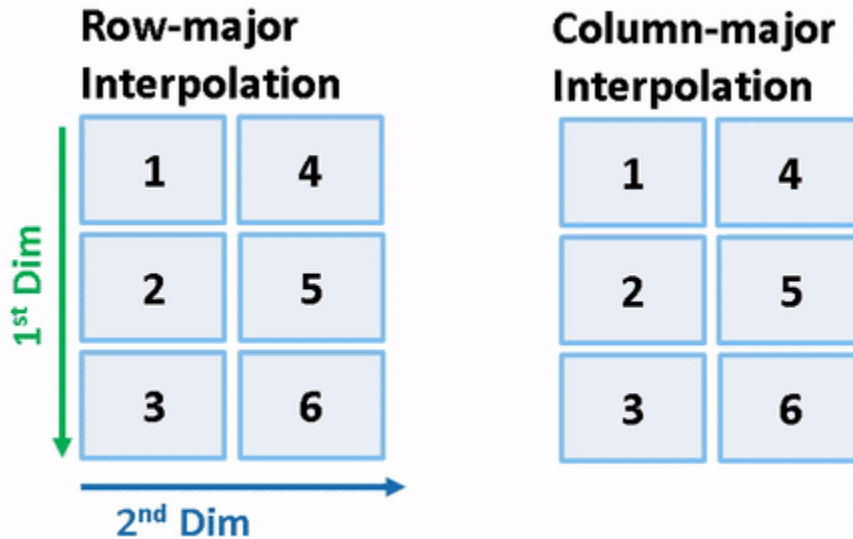

3. To enable row-major algorithms, open the Configuration Parameters dialog box. On the **Math and Data Types** pane, enable the configuration parameter "Use algorithms optimized for row-major array layout". Alternatively, in the MATLAB Command Window, enter:

```
set_param(model, 'UseRowMajorAlgorithm', 'on');
```

4. Simulate the model and observe those results in the Data Inspector. The output value is 4.

The column-major and row-major algorithms differ only in the interpolation order. In some cases, due to different operation order on the same data set, you might experience minor numeric differences in

the outputs of column-major and row-major algorithms. For the 2-D Lookup Table used in the example model, the interpolation algorithm is illustrated here.

### Generate Code by Using Row-Major Algorithm and Array Layout

The 2-D table data used in model `rtwdemo_row_lut2d` is:

`Table_3by2.Value`

`ans =`

1	4
2	5
3	6

1. Open the Configuration Parameters dialog box. In addition to enabling the **Use algorithms optimized for row-major array layout** configuration parameter, on the **Code Generation > Interface** pane, set the configuration parameter "Array layout" to Row-Major option. This configuration parameter enables the model for row-major code generation. Alternatively, in the MATLAB Command Window, enter:

```
set_param(model, 'ArrayLayout', 'Row-major');
```

2. Change your current folder in MATLAB® to a writable folder. On the **C Code** tab, click **Build** to generate C code.

3. In the generated code, observe the table data with row-major array layout. For comparison, here is the table data in the generated code for column-major array layout.

**2-D Table with row-major array layout**

```

/* Block parameters (default storage) */
P_rtdemo_row_lut2d_T rtdemo_row_lut2d_P = {
 /* Variable: Table_3by2
 * Referenced by: '<Root>/2-D Lookup Table'
 */
 { 1.0, 4.0, 2.0, 5.0, 3.0, 6.0 }
};

```

**2-D Table with column-major array layout**

```

/* Block parameters (default storage) */
P_rtdemo_row_lut2d_T rtdemo_row_lut2d_P = {
 /* Variable: Table_3by2
 * Referenced by: '<Root>/2-D Lookup Table'
 */
 { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0 }
};

```

In the generated code, the table data is in row-major order and the interpolation algorithm is optimized for row-major array layout. The row-major algorithm operates on table data that is contiguous in memory. This leads to faster cache access, making these algorithms cache-friendly.

This table summarizes the relationship between array layout and cache-friendly algorithms. It is recommended to use the algorithm that is optimized for the specified array layout to achieve good performance. For example, use row-major interpolation algorithm when the array layout is set to Row-Major for code generation.

Array Layout	Algorithm	Cache-Friendly Algorithm
Column-major	Column-major	✓ (Recommended)
Row-major	Row-major	✓ (Recommended)
Row-major	Column-major	⚠ (Not recommended)
Column-major	Row-major	⚠ (Not recommended)

**Interpolation on a 3-D Table**

1. Open the example model `rtdemo_row_interpalg`.

```
open_system('rtdemo_row_interpalg');
```

Copyright 2018-2020 The MathWorks, Inc.

2. Generate code for the model by using the preceding procedure. Simulate and generate code from the model by repeating the steps performed on `rtwdemo_row_lut2d` model.

The row-major and column-major interpolations on the 3-D table used in the example model are illustrated here.

```
close_system('rtwdemo_row_lut2d',0);
close_system('rtwdemo_row_interpalg', 0);
```

- "Interpolation with Subtable Selection Algorithm for Row-Major Array Layout" on page 43-15

## Interpolation with Subtable Selection Algorithm for Row-Major Array Layout

This example illustrates the algorithm for interpolating a subtable that the interpolation block selects from a higher dimension table. The interpolation algorithm with subtable selection is optimized for row-major array layout. As a reference, see the interpolation algorithm with subtable selection that is optimized for column-major array layout. The code generated by using row-major interpolation algorithm performs with the best speed and memory usage when operating on table data with row-major array layout. The code generated by using column-major algorithm performs best with column-major array layout.

In this example, you:

- Interpolate on a selected subtable with column-major and row-major algorithm.
- Preserve block semantics through table permutation.
- Generate code with row-major algorithm and array layout.

### Simulate by Using Row-Major Algorithm

1. Open example model `rtwdemo_col_interpselectsubtable` and `rtwdemo_row_interpselectsubtable`.

```
open_system('rtwdemo_col_interpselectsubtable');
open_system('rtwdemo_row_interpselectsubtable');
```

Copyright 2018-2020 The MathWorks, Inc.

2. By default, Simulink configures a model with column-major algorithm and column-major array layout. The model `rtwdemo_col_interpselsubtable` is configured to use a column-major algorithm. Run the model and observe the output stored in workspace variable `yout`.

3. To enable row-major algorithms, open the Configuration Parameters dialog box. On the **Math and Data Types** pane, select the configuration parameter “Use algorithms optimized for row-major array layout” Alternatively, in the MATLAB Command Window, enter:

```
set_param('rtwdemo_col_interpselsubtable', 'UseRowMajorAlgorithm', 'on');
```

4. Simulate the model and observe the error.

The range of values for the first signal in the bus object propagated to the input port `kf2` of block '`rtwdemo_col_interpselsubtable/Interp`' does not match the size of the corresponding table dimension of 2. Specify a different table dimension or modify the range for the first signal in the bus object propagated to the input port `kf2`.

Component: Simulink | Category: Block error

The column-major and row-major algorithms differ in terms of subtable selection and interpolation order. The subtable selection is performed inside the original table. No extra memory is allocated for the subtable. The selected subtable is contiguous in memory. The interpolation order is cache-friendly for column-major algorithms with column-major array layouts and row-major algorithms with row-major array layouts. This illustration compares the row-major and column-major interpolations with subtable selection.

Due to a change in semantics, column-major and row-major interpolations are performed on different subtables or data sets. This interpolation leads to different numeric outputs or an error.

### Preserve Semantics Through Table Permutation

With subtable selection, the model semantics change when switching from a column-major algorithm to a row-major algorithm. To preserve the semantics or ensure that the same subtable is selected for interpolation, you need to permute the table data. Otherwise, Simulink might report error if it encounters inconsistent breakpoint and table data between prelookup and interpolation blocks.

1. The block `rtwdemo_col_interpselfsubtable/Interp` has 3-D table data given as **T3d = reshape([1:24], 3,2,4)** and one selection port with input **2** (0-based index). The selected subtable is

**T3d(:, :, 3)** (1-based index in MATLAB) for the column-major algorithm. To preserve the semantics for the row-major algorithm on the same model, that is, select the same subtable with same index and selection port inputs, permute the table as **T3d\_p = permute(T3d, [3,1,2])**. The selected subtable is **T3d\_p(3, :, :)** (1-based index) for the row-major algorithm.

```
T3d_str = get_param('rtwdemo_col_interpselsubtable/Interp','Table');
set_param('rtwdemo_col_interpselsubtable/Interp','Table', ...
 ['permute(' ,T3d_str, ',',[3,1,2])']);
```

2. When you import table data from a file, you must permute the table data in the file before importing it. This permutation keeps the table tunable throughout the simulation and code generation workflow.

### Generate Code by Using Row-Major Algorithm and Array Layout

After permuting the table data, model `rtwdemo_col_interpselsubtable` is configured for row-major simulation. The model is equivalent to the preconfigured model `rtwdemo_row_interpselsubtable` that uses a row-major algorithm.

1. To set up the model for row-major code generation, open the Configuration Parameters dialog box. In addition to selecting the **Use algorithms optimized for row-major array layout** configuration parameter, on the **Code Generation > Interface** pane, set the configuration parameter “Array layout” to Row-Major option. This configuration parameter enables the model for row-major code generation. Alternatively, in the MATLAB Command Window, enter:

```
set_param('rtwdemo_col_interpselsubtable', 'ArrayLayout', 'Row-major');
```

2. In the dialog box, examine the permuted 3-D table data and the selected 2-D subtable.

Block Parameters: Interp ×

**Interpolation\_n-D**

Perform interpolation (or extrapolation) on an n-dimensional table using pre-calculated indices and fraction values.

Use 'Number of table dimensions' and 'Table data' to specify an n-dimensional table that represents a function of 'n' variables.

'Number of subtable selection dimensions' lets you specify that the block interpolates only a subset of table data. If you specify 'k' as its value, the block displays 'n-k' pairs of index and fraction inputs and 'k' subtable selection inputs. Its default value is 0, i.e., interpolate the entire table. Use the selection inputs to specify the indices of the subtable to be interpolated.

You may use Prelookup blocks to compute the index, fraction, and selection inputs.

Main Data Types

**Table data**

Number of dimensions:   Require index and fraction as bus

Specification	Source	Value
<input type="text" value="Explicit values"/>	<input type="text" value="Dialog"/>	<input type="text" value="permute(reshape([1:24], 3,2,4), [3,1,2])"/> <input type="button" value="Edit..."/>

**Algorithm**

## Direct Lookup Table Algorithm for Row-Major Array Layout

This example shows how Simulink selects a vector or a 2-D matrix from table data. In a 2-D table, the output vector can be a column or a row depending on the model configuration setting **Use algorithms optimized for row-major array layout**. In this example, the Direct Lookup Table algorithm is optimized for row-major array layout. The Direct Lookup Table algorithm that is optimized for column-major array layout is also presented as a reference. The code generated by using row-major interpolation algorithm performs with the best speed and memory usage when operating on table data with row-major array layout. The code generated by using column-major algorithm performs best with column-major array layout.

In this example, you:

- Output a vector or a plane by using direct lookup with a column-major or a row-major algorithm.
- Preserve semantics when switching from a column-major algorithm to a row-major algorithm.
- Generate code by using a row-major algorithm and an array layout.

### Simulate by Using Row-Major Algorithm — Output a Vector from 3-D Table

Open example models `rtwdemo_row_dlut3d_selvector` and `rtwdemo_col_dlut3d_selvector`.

```
open_system('rtwdemo_row_dlut3d_selvector');
open_system('rtwdemo_col_dlut3d_selvector');
```

Copyright 2018-2020 The MathWorks, Inc.

Copyright 2018-2020 The MathWorks, Inc.

1. By default, Simulink configures a model with column-major algorithm and column-major array layout. The model `rtwdemo_col_dlut3d_selvector` is preconfigured to use column-major algorithms. Simulate the model and observe the output stored in workspace variable `yout`.

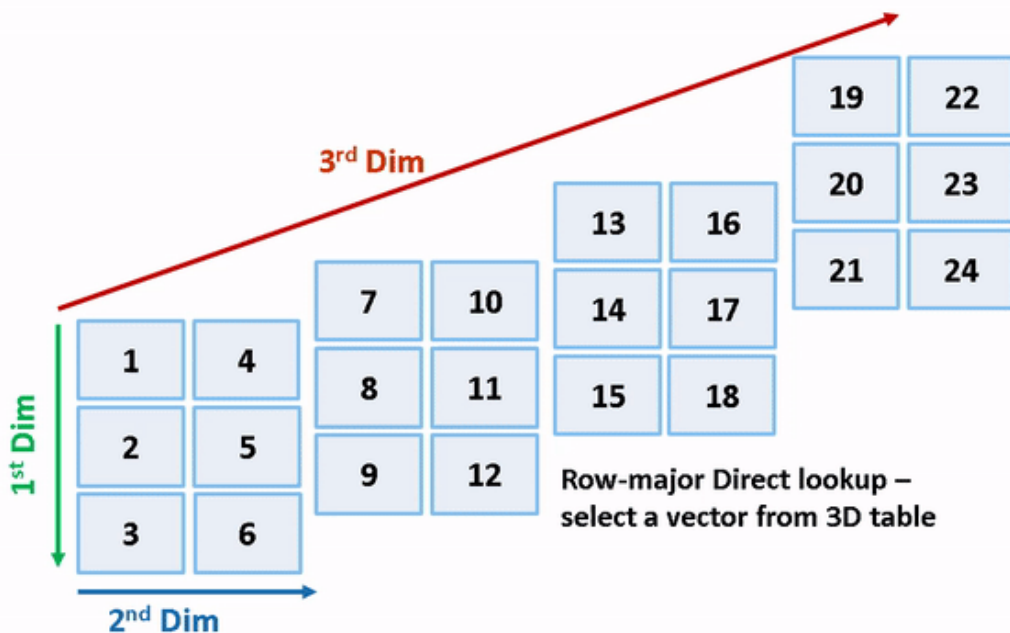

2. To enable row-major algorithms, open the Configuration Parameters dialog box. On the **Math and Data Types** pane, select the configuration parameter “Use algorithms optimized for row-major array layout” Alternatively, in the MATLAB Command Window, enter:

```
set_param('rtwdemo_col_dlut3d_selvector', 'UseRowMajorAlgorithm', 'on');
```

3. On the **Simulation** tab, click **Run** to simulate the model. Observe the change in output dimension and numeric values logged in workspace variable `yout`.

The column-major and row-major algorithms differ semantically in the selection of output vector. For example, in a 2-D table, Simulink selects a column vector as output for column-major algorithm and a row vector for row-major algorithm. In a table with a 3-D or higher dimension, Simulink selects the output vector from the first dimension of the table for a column-major algorithm and from the last dimension of the table for a row-major algorithm. The elements of the selected vector are contiguous in the table storage memory. In this example, the last dimension is the third dimension of the 3-D table. Due to semantic change, column-major and row-major direct lookup table algorithms output different vector size and numeric values.

These illustrations compare the vector output of row-major and column-major direct lookup table algorithms in a 3-D table.

### Preserve Semantics by Using Table Permutation

For a direct lookup table that outputs a vector or 2-D matrix, the model semantics change when you switch from a column-major algorithm to a row-major algorithm. To preserve the semantics or ensure the same output given the same block I/O connections, you must permute the table data. Otherwise, Simulink propagates incorrect dimensions to downstream blocks.

1. The block `rtwdemo_col_dlut3d_selvector/Direct Lookup Table (n-D)` has 3-D table data  $\mathbf{T3d} = \text{reshape}([1:24], 3,2,4)$  and two input ports with value **0** and **1** (both are 0-based indices). The selected output vector is  $\mathbf{T3d}(:,1,2)$  (1-based index) for a column-major algorithm. To preserve the semantics for a row-major algorithm on the same model, that is, select the same vector with same index port inputs, permute the table as  $\mathbf{T3d}_p = \text{permute}(\mathbf{T3d}, [2,3,1])$ . For a row-major algorithm, the selected vector is  $\mathbf{T3d}_p(1,2,:)$ .

```
T3d_str = get_param('rtwdemo_col_dlut3d_selvector/Direct Lookup Table (n-D)', 'Table');
set_param('rtwdemo_col_dlut3d_selvector/Direct Lookup Table (n-D)', 'Table', ...
['permute(', T3d_str, ', [2,3,1]')]);
```

2. When you import table data from a file, you must permute the table data in the file before importing it. This permutation keeps the table tunable throughout the simulation and code generation workflow.

### Code Generation by Using Row-Major Algorithm and Array Layout

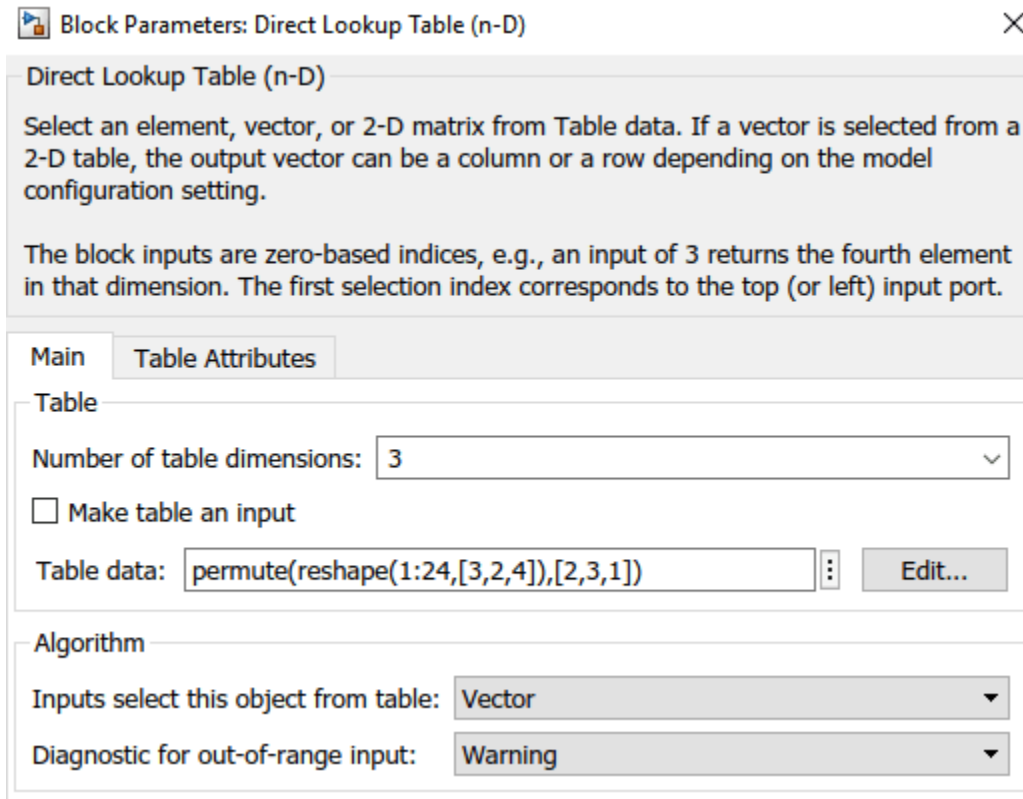

After permuting the table data, Simulink configures the model `rtwdemo_col_dlut3d_selvector` for row-major simulation. The model is equivalent to the preconfigured model `rtwdemo_row_dlut3d_selvector` that has permuted table data and uses a row-major algorithm.

1. To set up these models for row-major code generation, open the Configuration Parameters dialog box. In addition to enabling the **Use algorithms optimized for row-major array layout** configuration parameter, on the **Code Generation > Interface** pane, set the configuration

parameter “Array layout” to the Row-Major option. This configuration parameter enables the model for row-major code generation. Alternatively, in the MATLAB Command Window, enter:

```
% For model 'rtwdemo_col_dlut3d_selvector'
set_param('rtwdemo_col_dlut3d_selvector', 'ArrayLayout', 'Row-major');
% For model 'rtwdemo_row_dlut3d_selvector'
set_param('rtwdemo_row_dlut3d_selvector', 'ArrayLayout', 'Row-major');
```

2. In the Direct Lookup Table (n-D) block dialog box, examine the permuted 3-D table data.

3. Change your current folder in MATLAB® to a writable folder. On the **C Code** tab, click **Build** to generate C code. In the generated code, the `memcpy` function replaces the `for` loops. Using `memcpy` reduces the amount of memory for storing data. This optimization improves execution speed.

```
34 void rtwdemo_row_dlut3d_selvector_step(void)
35 {
36 /* Outport: '<Root>/Out2' incorporates:
37 * LookupNDDirect: '<Root>/Direct Lookup Table (n-D)'
38 *
39 * About '<Root>/Direct Lookup Table (n-D)':
40 * 3-dimensional Direct Look-Up returning a Vector,
41 * which is contiguous for row-major array
42 */
43 memcpy(&rtY.Out2[0], &rtCP_DirectLookupTablenD_table[3], 3U * sizeof(real_T));
44 }
```

**Simulate by Using Row-Major Algorithm – Output a Plane from 3-D Table**

```
open_system('rtwdemo_row_dlut3d_selplane');
open_system('rtwdemo_col_dlut3d_selplane');
```

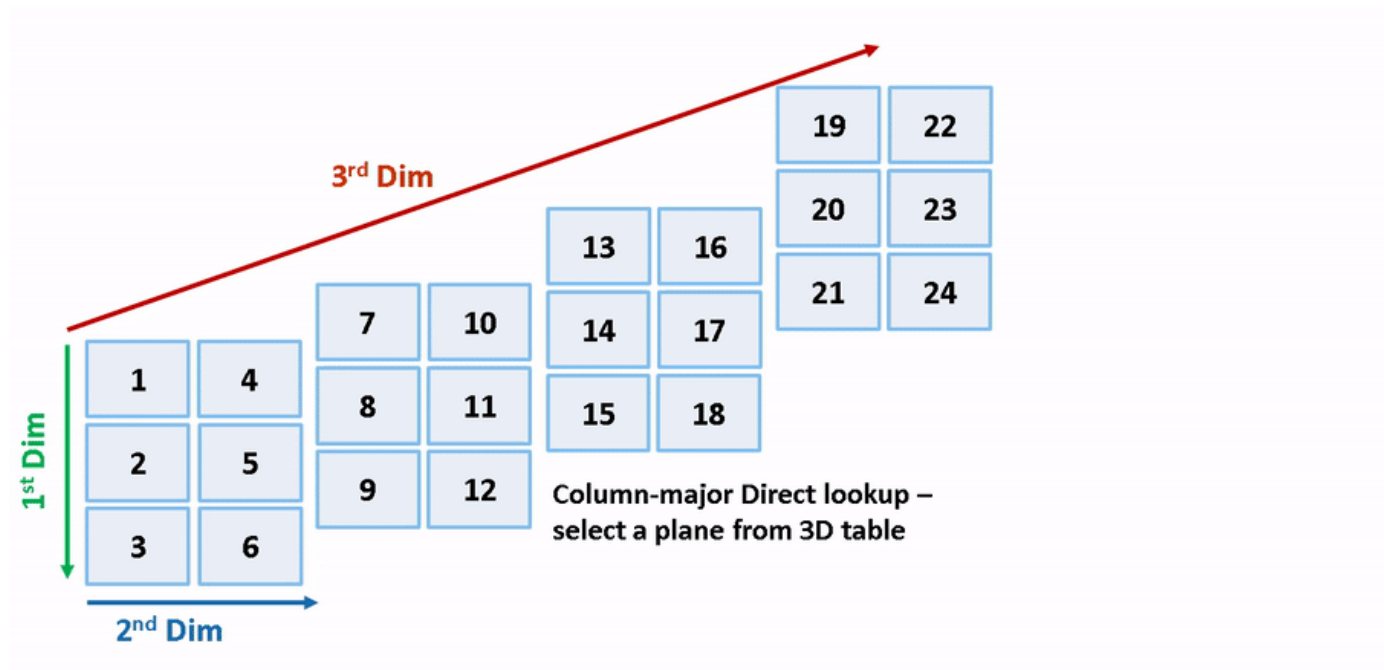

Copyright 2018-2020 The MathWorks, Inc.

Copyright 2018-2020 The MathWorks, Inc.

1. Open the example model `rtwdemo_row_dlut3d_selplane` that outputs a plane or 2-D matrix from a 3-D table.
2. Simulate and generate code from the model by repeating the steps performed on `rtwdemo_col_dlut3d_selvector`. The row-major and column-major direct lookup algorithms that output a 2-D matrix from a 3-D table are illustrated here.

```
close_system('rtwdemo_row_dlut3d_selvector',0);
close_system('rtwdemo_col_dlut3d_selvector',0);
close_system('rtwdemo_row_dlut3d_selplane',0);
close_system('rtwdemo_col_dlut3d_selplane',0);
```

## Generate Row-Major Code for S-Functions

You can generate row-major code for models that contain S-functions. By default, the code generator generates column-major code. To learn more about row-major code generation, see “Code Generation of Matrices and Arrays”.

For an existing model that contains S-functions, when you set the configuration parameter “Array layout” as Row-major, the configuration parameter “External functions compatibility for row-major code generation” is enabled and set to error by default. When you try to build the existing model, you get an error because the S-functions are not enabled for row-major code generation by default. You can test the compatibility of your S-function for row-major code generation by using the **External functions compatibility for row-major code generation** configuration parameter.

This workflow is also applicable to C Caller blocks in a model.

### Example

1. Open example model `ex_sfcn_rowmajor_unset`. The model needs these additional files:

- S-function: `ex_sfcn_rowmajor.c`
- TLC: `ex_sfcn_rowmajor.tlc`.

Save these files to your local folder.

```
open_system('ex_sfcn_rowmajor_unset');
```

Copyright 2021 The MathWorks, Inc.

2. The model is configured with **Array layout** set to Column-major. To enable row-major code generation, set **Array layout** to Row-major.

3. When you build the model, the code generator terminates the build and you see this error message:

```
Build procedure for model: 'ex_sfcn_rowmajor_unset' aborted due to an error.
S-function "ex_sfcn_rowmajor" with SSArrayLayout set to 'SS_UNSET' does not support row major code
generation. To test this S-function, set the configuration parameter 'External functions
compatibility for row-major code generation' to 'warning' or 'none'.
Component: Simulink | Category: Block diagram error
```

4. To proceed, do one of the following:

- If you want to test your existing S-functions with the row-major code for the model, change the setting of the configuration parameter **External functions compatibility for row-major code**

**generation** to warning or none. The code generator completes the build without generating row-major code for the S-functions.

- If you want to update your S-functions so that they are compatible with row-major array layout, use the S-function API to enable the S-function for row-major code generation.

To test your model for S-functions with unspecified array layout, you can also run the Model Advisor checks on the model. Select the **Identify TLC S-functions with unset array layout** check and click the **Run This Check** button. If the model includes S-functions with unspecified array layout, you see a warning such as:

The screenshot shows a dialog box titled "Identify TLC S-Functions with unset array layout". It contains a "Run This Check" button and a "View by" dropdown menu set to "Recommended Action". The result is a warning icon and the text "Warning". Below this, a message states: "List all S-Functions which have SSArrayLayout set to SS\_UNSET. These S-Functions can have numerical implications in the generated code." A "Warning" section follows, stating: "The following TLC S-Functions have SSArrayLayout set to SS\_UNSET whose algorithms need evaluation." A bullet point lists a link: "ex\_sfcn\_rowmajor\_unset/S-Function".

To specify the array layout of the user-defined S-function, use the `ssSetArrayLayoutForCodeGen` function of the SimStruct API. You can set the enumerated type `SSArrayLayout` to:

- `SS_UNSET` - This setting is the default setting that disables the block for row-major code generation.
- `SS_COLUMN_MAJOR` - Specify the block for column-major code generation only.
- `SS_ROW_MAJOR` - Specify the block for row-major code generation only.
- `SS_ALL` - Specify the block as allowed for code generation regardless of the array layout.

5. Update the `ex_sfcn_rowmajor.c` file by adding the `ssSetArrayLayoutForCodeGen` in the `mdlInitializeSizes` method:

```
static void mdlInitializeSizes(SimStruct *S)
{
 /* Specify array layout of the S-function */
 ssSetArrayLayoutForCodeGen(S, SS_ROW_MAJOR);
 .
 .
 .
}
```

If your S-function is not affected by an array layout, set `SSArrayLayout` to `SS_ALL`.

6. Compile the S-function by using this command in the MATLAB Command Window:

```
mex ex_sfcn_rowmajor.c
```

```
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
```

7. To build the model and generate code, press **Ctrl+B**.

If you generate S-functions by using S-Function Builder, use the parameter **Array layout** to specify the majority of the S-function. For more information, see “Build S-Functions Automatically Using S-Function Builder”. If you use the Legacy Code Tool to integrate C functions, use the `convertNDArrayToRowMajor` option in `legacy_code`. The S-Function Builder and Legacy Code Tool apply preceding transposes when the S-function is set to row-major array layout during simulation in normal mode.

## Row-Major Algorithms for Row-Major Array Layout

This example shows how to use row-major algorithms to generate efficient code. You can enable the “Use algorithms optimized for row-major array layout” configuration parameter to enable efficient row-major algorithms that are optimized for row-major array layout. The code that you generate by using row-major algorithms performs with better speed and efficient memory usage when operating on data with row-major array layout.

In this example, you operate on row-major data by first using the default column-major algorithms, and then using the row-major algorithms. This comparison helps in identifying the appropriate algorithm settings to achieve different requirements.

### Generate Code by Using the Default Column-Major Algorithms for Row-Major Array Layout

Open the example model `ex_rowmajor_algorithm`.

```
model = 'ex_rowmajor_algorithm';
open_system(model);
```

Copyright 2021 The MathWorks, Inc.

The model contains a Sum of Elements block and the input of the block is an array. By default, Simulink configures a model with column-major algorithms and column-major array layout. In this example, you configure the array layout of this model as row-major. To specify the array layout, open the **Embedded Coder** app, and then open the Configuration Parameters dialog box. On the **Code Generation > Interface** pane, set the configuration parameter **Array layout** to Row-Major option. Alternatively, in the MATLAB Command Window, enter:

```
set_param(model, 'ArrayLayout', 'Row-major');
```

Change your current folder in MATLAB to a writable folder. Then generate code from the model by using the `slbuild` function or by pressing **Ctrl+B**.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
% Generate code and capture the code generation information to Value
Value=evalc('slbuild(''ex_rowmajor_algorithm'')');
```

Inspect the generated `ex_rowmajor_algorithm_step` step function in the `ex_rowmajor_algorithm.c`.

```
file = fullfile('ex_rowmajor_algorithm_ert_rtw', 'ex_rowmajor_algorithm.c');
rtwdemodbtype(file, '/* Model step function */', '/* Model initialize function', 1, 1);
```

```

/* Model step function */
void ex_rowmajor_algorithm_step(void)
{
 int32_T i;
 int32_T i_0;

 /* Sum: '<Root>/Sum of Elements Dim1' incorporates:
 * Constant: '<Root>/Constant1'
 */
 ex_rowmajor_algorithm_Y.Out2 = -0.0F;
 for (i = 0; i < 2; i++) {
 for (i_0 = 0; i_0 < 3; i_0++) {
 int32_T tmp;
 tmp = (i_0 << 1) + i;
 ex_rowmajor_algorithm_Y.Out2 =
 ((ex_rowmajor_algorithm_ConstP.Constant1_Value[tmp] +
 ex_rowmajor_algorithm_Y.Out2) +
 ex_rowmajor_algorithm_ConstP.Constant1_Value[tmp + 6]) +
 ex_rowmajor_algorithm_ConstP.Constant1_Value[tmp + 12]) +
 ex_rowmajor_algorithm_ConstP.Constant1_Value[tmp + 18];
 }
 }

 /* End of Sum: '<Root>/Sum of Elements Dim1' */
}

```

When **Array layout** is set to Row-major and the **Use algorithms optimized for row-major array layout** configuration parameter is set to off, the code generator uses column-major algorithms. The algorithms traverse the data in column-major order though the data is in row-major order. This process requires some extra operations in the generated code, which makes the code less efficient but at the same time results in higher accuracy of numeric results. If you need higher accuracy of numeric results where less efficient code is not a concern, it is recommended that you use the column-major algorithms for row-major array layout. When the **Use algorithms optimized for row-major array layout** parameter is set to off, the code generator does not include other vectorization optimizations such as single-instance, multiple-data (SIMD) optimizations.

### Generate Code by Using the Row-Major Algorithms for Row-Major Array Layout

To enable the row-major algorithms, on the **Math & Data Types** pane, select the configuration parameter “Use algorithms optimized for row-major array layout” check box. This parameter enables the algorithms that are optimized for row-major array layout. Alternatively, in the MATLAB Command Window, enter:

```
set_param(model, 'UseRowMajorAlgorithm', 'on');
```

After enabling the row-major algorithms, generate code.

```
Value=evalc('slbuild(''ex_rowmajor_algorithm'')');
```

Inspect the generated `ex_rowmajor_algorithm_step` step function in the `ex_rowmajor_algorithm.c`.

```
file = fullfile('ex_rowmajor_algorithm_ert_rtw', 'ex_rowmajor_algorithm.c');
rtwdemodbtype(file, '/* Model step function */', '/* Model initialize function', 1, 1);
```

```
/* Model step function */
void ex_rowmajor_algorithm_step(void)
{
 int32_T i;

 /* Sum: '<Root>/Sum of Elements Dim1' incorporates:
 * Constant: '<Root>/Constant1'
 */
 ex_rowmajor_algorithm_Y.Out2 = -0.0F;
 for (i = 0; i < 24; i++) {
 ex_rowmajor_algorithm_Y.Out2 +=
 ex_rowmajor_algorithm_ConstP.Constant1_Value[i];
 }

 /* End of Sum: '<Root>/Sum of Elements Dim1' */
}
```

In comparison to the previous code, when the **Array layout** is set to Row-major and the **Use algorithms optimized for row-major array layout** configuration parameter is set to on, the code generator generates efficient code. The code generator uses row-major algorithms that traverse the data in row-major order, which reduces the number of operations in the generated code. But the accuracy of numeric results might not be as high as the previous example. So, you might experience minor numeric differences in the output of column-major and row-major algorithms. If you need an efficient code where numeric accuracy is not a concern, it is recommended that you use the row-major algorithms for row-major array layout.

## Generate Row-Major Code for Model That Contains a MATLAB Function Block

Programming languages and environments assume a single array layout for all data. MATLAB and Fortran use column-major layout by default, whereas C and C++ use row-major layout. With Simulink Coder, you can generate C/C++ code that uses row-major layout or column-major layout.

To learn more about row-major code generation, see “Code Generation of Matrices and Arrays” on page 49-60.

MATLAB Function blocks enable you to define custom functionality in Simulink models by using the MATLAB language. You can generate row-major code for models that contain a MATLAB Function block by using row-major or column-major data. For more information on MATLAB Function blocks, see “Implement MATLAB Functions in Simulink with MATLAB Function Blocks”.

By default, the code generator generates column-major code. For C/C++ code generation, you can specify the array layout at the model level by using the **Array layout** model configuration parameter. Setting this parameter to Row-major enables the model for row-major code generation. To enable the MATLAB Function block in your model for row-major code generation, use the `coder.rowMajor` function at the function level inside the block.

### Row-Major Code Generation

For certain algorithms, row-major layout provides more efficient memory access. You get efficient code when you generate code for a model that uses row-major array layout and the model contains a MATLAB Function block that uses an algorithm for row-major data.

- 1 Consider an example model `ex_row_major_MLFB`.

This model contains a Constant block that has a [5 4] matrix. To specify the matrix, set **Constant value** to:

```
reshape(1:20,5,4)
```

The Inport block also specifies a [5 4] matrix. To specify the matrix, set the **Port dimensions** to [5 4].

- 2 In the Configuration Parameters dialog box, set **Array layout** to Row-major.
- 3 Write a function for matrix addition called `addMatrix`. The MATLAB Function block inherits the array layout setting from the model configuration parameter **Array layout** unless specified otherwise.

Optionally, you can use `coder.rowMajor` to explicitly set the array layout of the MATLAB Function block to row-major layout.

```
function S = addMatrix(A,B)
S = zeros(size(A));
for row = 1:size(A,1)
 for col = 1:size(A,2)
 S(row,col) = A(row,col) + B(row,col);
 end
end
```

- 4 Generate code for the model. From the **C Code** tab, click **Build**.

The code generator produces this C code:

```
for (b_row = 0; b_row < 5; b_row++) {
 for (b_col = 0; b_col < 4; b_col++) {
 rtb_S_tmp = (b_row << 2) + b_col;
 rtb_S[rtb_S_tmp] = ex_row_major_MLFB_P.Constant_Value[rtb_S_tmp] +
 ex_row_major_MLFB_U.Inport1[rtb_S_tmp];
 }
}
```

The generated code has two `for` loops. The first `for` loop accesses the rows and the second `for` loop accesses the columns. When the array layout of the MATLAB Function block and the model is the same, the generated code is efficient because no transposes or conversion are required.

## Mixed-Majority Code Generation

You can generate mixed-majority code when you have a model that operates on row-major data and a MATLAB Function block that operates on column-major data. When you generate code for a model that uses column-major layout, and the model contains a MATLAB Function block that uses row-major layout, then the code generator converts the block input data to row-major and the block output data back to column-major data, as needed. You can also generate mixed majority code when you have a model that operates on column-major data and a MATLAB Function block that operates on row-major data.

Array layout conversions can affect performance.

- 1 Consider the example model `ex_row_major_MLFB`. For more information on the example model, see “Row-Major Code Generation” on page 43-34.

In the Configuration Parameters dialog box, set **Array layout** to Row-major.

- 2 Update the `addMatrix` function in the MATLAB Function block for column-major data by using the `coder.columnMajor` function.

```
function S = addMatrix(A,B)
coder.columnMajor;
S = zeros(size(A));
for row = 1:size(A,1)
 for col = 1:size(A,2)
 S(row,col) = A(row,col) + B(row,col);
 end
end
```

You can generate mixed-majority code by using the MATLAB Function block. In this case, you configure the model for row-major array layout and the MATLAB Function block for column-major array layout.

- 3 Generate code for the model. From the **C Code** tab, click **Build**.

The code generator produces this C code:

```
for (b_row = 0; b_row < 4; b_row++) {
 for (b_col = 0; b_col < 5; b_col++) {
 B_tmp = (b_col << 2) + b_row;
 B_tmp_0 = b_col + 5 * b_row;
 B[B_tmp_0] = ex_row_major_MLFB_19b_U.Inport1[B_tmp];
 A[B_tmp_0] = ex_row_major_MLFB_19b_P.Constant_Value[B_tmp];
 }
}

for (b_row = 0; b_row < 5; b_row++) {
 /* Output: '<Root>/Output' */
 for (b_col = 0; b_col < 4; b_col++) {
 B_tmp = 5 * b_col + b_row;
 ex_row_major_MLFB_19b_Y.Outport[b_col + (b_row << 2)] = A[B_tmp] + B[B_tmp];
 }
}
```

The inputs to the MATLAB Function block exist in a row-major environment. The code generator performs a conversion operation on inputs before they are fed to the MATLAB Function block because the block is column-major layout. After processing the algorithm in the MATLAB Function block, the code generator converts the data back to row-major data before passing the data to an Output.

# Preserve Dimensions

---

- “Preserve Dimensions of Multidimensional Arrays in Generated Code” on page 44-2
- “Preserve Dimensions of Bus Elements in Generated Code” on page 44-6

## Preserve Dimensions of Multidimensional Arrays in Generated Code

By default, the generated code contains one-dimensional arrays for multidimensional model data. In the Configuration Parameters dialog box, if you set the **Array layout** parameter to **Row-major**, you can preserve dimensions of multidimensional arrays in the generated code. Preserving array dimensions in the generated code enhances integration with external code.

MATLAB and C organize multidimensional data in different ways. For more details, see “Dimension Preservation of Multidimensional Arrays” on page 32-110.

In the generated code, you can preserve dimensions of root-level inports and outports, parameters, signals, states, lookup tables, and data stores.

### Configure Default Model Data Elements to Preserve Dimensions

In the **Code Mappings > Data Defaults** tab, you can configure these model data elements categories. You specify a storage class to preserve dimensions.

- **Inports**
- **Outports**
- **Signals, states, and internal data**
- **Shared local data stores**
- **Global data stores**
- **Model parameters**
- **External parameters**

Then, when you set the **Storage class** to **Auto** or **Model default** on individual model data elements, by default, the code generator applies the configuration that you set up for the respective model data elements in the **Data Defaults** tab.

An example workflow that is applicable to the preceding model data element categories is:

- 1 Open the `rtwdemo_preservedimensions` example model.
- 2 In the Configuration Parameters dialog box, verify that parameter **Array layout** is set to **Row-major**.
- 3 Open the **Embedded Coder** app.
- 4 In the **C Code** tab, open the Code Mappings editor. Select **Code Interface > Default Code Mappings**. This option pins the Code Mappings editor.
- 5 On the **Data Defaults** tab, select the **Inports** category. The **Storage Class** specified is

`ExportToFile`. Click the  icon and select the **PreserveDimensions** property.

To configure the **PreserveDimensions** property programmatically, use the `coder.mapping.defaults.set` function in the MATLAB command window:

```
coder.mapping.defaults.set('rtwdemo_preservedimensions', 'Inports', ...
 'Storageclass', 'ExportToFile', ...
 'PreserveDimensions', 'off')
```

You can create a new storage class in Embedded Coder, and then specify that class to preserve dimensions. For more details, see “Preserve Dimensions for New Storage Classes” on page 44-4.

For a list of supported storage classes, see “Storage Classes Supported to Preserve Dimensions” on page 44-4.

- 6 Generate and review code. The generated code preserves the dimensions of the root-level Inports.

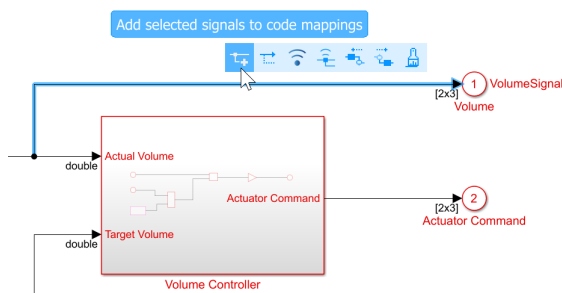

```
real_T rtPressure[2][3];
real_T rtTargetVolume[2][3];
real_T rtTemperature[2][3];
```

## Configure Individual Model Data Elements to Preserve Dimensions

You can override the default configurations specified in the **Data Defaults** tab by configuring individual model data element sources in other tabs such as **Inports**, **Outports**, **Parameters**, **Data Stores**, and **Signals/States**. Here is an example workflow that is applicable to the model data element categories.

- 1 From the **C Code** tab, open **Code Interface > Individual Element Code Mappings**.
- 2 In the Code Mappings editor, select the **Signals/States** tab. The **Signals** section is currently empty. There can be multiple signals in a given model. Some of these signals might not be important when configuring code generation. You can mark signals as signals of interest that are relevant to your code generation configuration. When you add a signal explicitly, it gets added to the Code Mappings editor.

In the Code Mappings editor, open the **Signals/States** tab. Select the signal in the Simulink Editor that you want to add to the Code Mappings editor. Pause on the ellipsis (...) that appears above or below the signal line to open the action bar. Click the **Add selected signals to code mappings** button. The signal is populated in the **Signals** table in the Code Mappings editor.

For this example, select the signal going from the subsystem Volume Controller to the output Actuator Command and click the **Add selected signals to code mappings** button.

- 3 As per the configurations in the **Data Defaults** tab, the default storage class for signals is **Localizable**. The default configuration for signals also specifies to preserve dimensions of multidimensional arrays.

By default the **Storage Class** of the individually added signal is configured as **Auto**. You can override the default configuration for the individual signal by changing the specification of the added signal under **Signals/States** tab.

If you want to apply the default settings, in the **Signals/States** tab, set the **Storage Class** to `Model default: Localizable`. If you want to maintain the same storage class, `Localizable`, but not preserve dimensions for the selected signal, specify **Storage Class** as `Localizable` and clear the **PreserveDimensions** property.

---

**Note** If you specify the **Storage Class** as `Model default`, you cannot override the default configurations specified in **Data Defaults** tab. To override the default specifications for the default storage class, select that storage class and change the configurations for the individual modeling element.

---

- 4 Click the  icon, specify a signal name in the **Identifier** property, such as `VolumeController`.
- 5 Generate and review code. The generated code does not preserve dimensions of the individual signal but does for other signals.

```
/* Definition for custom storage class: Localizable */
static real_T LogSignal[11][9]; /* '<S2>/Log volume difference' */
real_T VolumeController[6]; /* '<S3>/Gain' */
static real_T rtIterationCount[2][3]; /* '<S2>/IterationCount' */
static real_T rtIterationCount_g[2][3]; /* '<S2>/PreviousVolumeErrorAverage' */
static real_T rtVolumedifference[2][3]; /* '<S1>/Volume difference' */
```

## Storage Classes Supported to Preserve Dimensions

You can preserve dimensions in the generated code for these storage classes:

- `Const`
- `Volatile`
- `ConstVolatile`
- `ExportToFile`
- `ImportFromFile`
- `FileScope`
- `Localizable`

## Preserve Dimensions for New Storage Classes

To preserve dimensions when you design your own storage class, in the Embedded Coder Dictionary, in the Property Inspector, set **Storage Type** to `Unstructured` and select the **Preserve array dimensions** property. Selecting this property preserves dimensions for instances of your storage class. To use the storage class, in the Code Mappings editor, configure the model element categories by specifying **Storage Class** to the new storage class that you created.

To preserve dimensions when you design your own storage class in the Custom Storage Class Designer, specify **Type** as `Unstructured` and select the **Preserve array dimensions** property. **Preserve array dimensions** has these options:

- `No` (default) — Flattens the multidimensional array to one dimension in the generated code.
- `Yes` — Preserves array dimensions for parameters of the specified storage class.
- `Instance Specific` — If you want to preserve array dimensions for each instance of the storage class, enable the **Preserve array dimensions** property on the parameter object. For the Simulink package, this property setting is `Instance Specific` by default.

## Limitations

- The code generator does not preserve dimensions for parameters without data objects.

## Related Examples

- “Code Generation of Matrices and Arrays” on page 49-60
- “Select Array Layout for Matrices in Generated Code” (Stateflow)
- “Preserve Dimensions of Bus Elements in Generated Code” on page 44-6
- “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75
- “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2

## Preserve Dimensions of Bus Elements in Generated Code

By default, the generated code contains one-dimensional arrays for multidimensional model data. In the Configuration Parameters dialog box, if you set the “Array layout” parameter to Row-major, you can preserve dimensions of multidimensional arrays in the generated code. See “Preserve Dimensions of Multidimensional Arrays in Generated Code” on page 44-2.

In the generated code, you can preserve dimensions of root-level inports and outports, parameters, signals, states, lookup tables, and data stores by configuring storage classes in the Embedded Coder Dictionary and Code Mappings editor. The **Preserve array dimensions** property that you configure for storage classes is applicable to data elements in the model. You cannot use the storage class property to preserve dimensions of bus elements because the bus objects are global types usually shared between multiple data elements such as states, signals, and so on.

To preserve dimensions of bus objects that contain multidimensional bus elements, use the **Preserve element dimensions** property in the Bus Editor. You can preserve dimensions of bus objects for ERT models only.

### Open Example Model

1. Open the model `rtwdemo_preservedimensions_slbus`.

```
rtwdemo_preservedimensions_slbus;
```

Copyright 2020 The MathWorks, Inc.

2. Open the **Embedded Coder** app.
3. In the Configuration Parameters dialog box, verify that parameter **Array layout** is set to Row-major.

### Configure Bus Elements

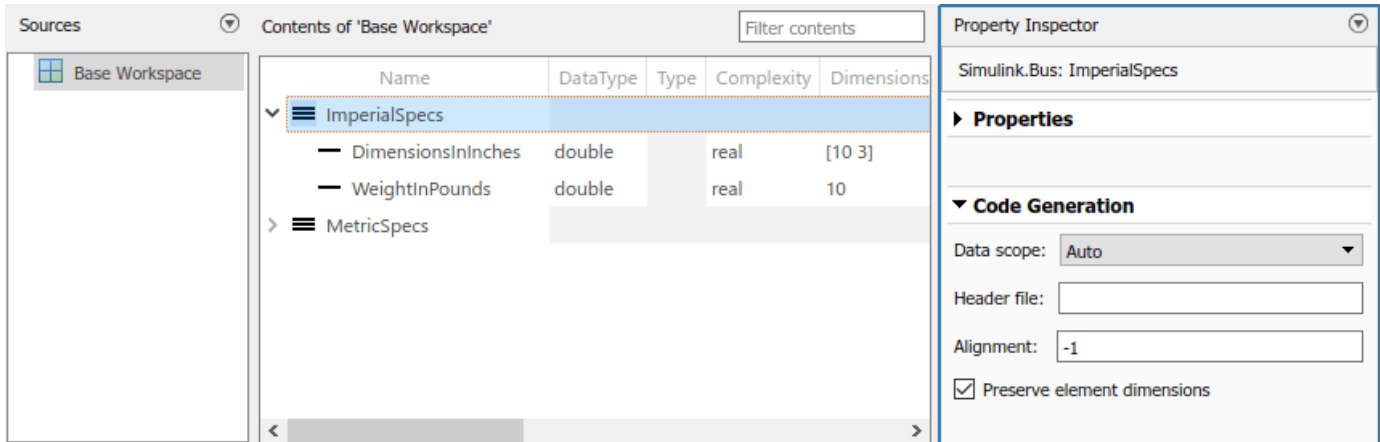

The model includes these Simulink.Bus objects in the base workspace:

- ImperialSpecs
- MetricSpecs

1. In the Simulink Toolstrip, on the **Modeling** tab, in the **Design** gallery, click **Bus Editor**. Alternatively, at the MATLAB command prompt, enter `buseditor`.

2. Select the bus object named `ImperialSpecs`. In the **Property Inspector** pane, expand the **Code Generation** section and select **Preserve element dimensions**. When you select this property, you configure the bus object to preserve dimensions of all elements within the bus object.

Alternatively, at the MATLAB command prompt, enter:

```
ImperialSpecs.PreserveElementDimensions = 1;
```

3. Close the Bus Editor.

### Generate and Review Code

Generate code for the model. On the **C Code** tab, click **Build**.

```
currentDir = pwd;
[~,cgDir] = rtwmoddir();
evalc('slbuild(''rtwdemo_preservedimensions_slbus'')');
```

The generated code preserves the dimensions of the multidimensional element. In the `ImperialSpecs` bus object, the element named `DimensionsInInches` is a multidimensional array of [10 3] whereas the element named `WeightInPounds` is a vector of [10]. The **Preserve element dimensions** property is applied for multidimensional arrays.

```
file = fullfile('rtwdemo_preservedimensions_slbus_ert_rtw',...
 'rtwdemo_preservedimensions_slbus.h');
rtwdemodbtype(file,'#define DEFINED_TYPEDEF_FOR_ImperialSpecs_', ...
 '} ImperialSpecs;',0,1);
```

```
typedef struct {
 real_T DimensionsInInches[10][3];
 real_T WeightInPounds[10];
} ImperialSpecs;
```

## Code Generation Configuration

When you are ready to generate code for a model, you can modify the model configuration parameters specific to code generation. The code generation parameters determine how the code generator produces code and builds an executable program from your model.

The model configuration parameters for code generation are in the **Code Generation** pane in the Configuration Parameters dialog box. The content of the **Code Generation** pane and its subpanes can change depending on the target that you specify. Some configuration options are available only with the Embedded Coder product.

Your application objectives can include a combination of these code generation objectives: debugging, traceability, execution efficiency, and safety precaution. There are tradeoffs associated with these configuration choices, such as execution speed and memory usage. To help configure a model to achieve your application objectives, use the Model Advisor and the Code Generation Advisor.

### Open the Model Configuration for Code Generation

To modify the model configuration parameters for code generation, open the **Code Generation** pane. There are several different ways to open the **Code Generation** pane from the Simulink editor:

- To open the Configuration Parameters dialog box, click the model configuration parameters icon.

Then, click **Code Generation** in the left pane.

- On the **C Code** tab, select **Settings > Code Generation Settings**.
- On the **Modeling** tab, click **Model Explorer**, or from the MATLAB command line, type `daexplr` and press **Enter**. In the left pane of the Model Explorer, expand the node for the current model and click the Configurations node. In the **Contents** pane, right-click the configuration and select **Open** from the context menu. Then click **Code Generation** in the left pane.

---

**Note** In the Configuration Parameters dialog box, when you change the value of a check box, menu selection, or edit field, the white background of the element changes color to indicate that you made an unsaved change. When you click **OK**, **Cancel**, or **Apply**, the background resets to white.

---

## Configuration Tools

To help you configure your model for code generation and to check your configuration against your code generation objectives, Simulink Coder and Embedded Coder provide several tools.

Goal	Approach	More Information
Automate configuration.	At the MATLAB command line, use the <code>set_param</code> function	“Configure Code Generation Parameters for Model Programmatically” on page 45-4

- “Model Configuration Sets”
- “Configure Code Generation Parameters for Model Programmatically”
- “Application Objectives Using Code Generation Advisor” on page 45-18

## Configure Code Generation Parameters for Model Programmatically

You can modify code generation parameters for the active configuration set in the Configuration Parameters dialog box or from the MATLAB command line. Use the command-line approach for creating a script that automates setting parameters for an established model configuration.

### Modify Parameters to Support Execution efficiency

In this example, you modify the configuration parameters to support the Code Generation Advisor application objective, Execution efficiency.

#### Step 1. Open a model.

```
openExample('slexAircraftExample')
```

#### Step 2. Get the active configuration set.

```
cs = getActiveConfigSet(model);
```

#### Step 3. Select the Generic Real-Time (GRT) target.

```
switchTarget(cs, 'grt.tlc', []);
```

#### Step 4. To optimize execution speed, modify parameters.

If your application objective is Execution efficiency, use `set_param` to modify these parameters:

```
set_param(cs, 'MatFileLogging', 'off');
set_param(cs, 'SupportNonFinite', 'off');
set_param(cs, 'RTWCompilerOptimization', 'on');
set_param(cs, 'OptimizeBlockIOStorage', 'on');
set_param(cs, 'EnhancedBackFolding', 'on');
set_param(cs, 'ConditionallyExecuteInputs', 'on');
set_param(cs, 'DefaultParameterBehavior', 'Inlined');
set_param(cs, 'BooleanDataType', 'on');
set_param(cs, 'BlockReduction', 'on');
set_param(cs, 'ExpressionFolding', 'on');
set_param(cs, 'LocalBlockOutputs', 'on');
set_param(cs, 'EfficientFloat2IntCast', 'on');
set_param(cs, 'BufferReuse', 'on');
```

#### Step 5. Save the model configuration to a file.

Save the model configuration to a file, 'Exec\_efficiency\_cs.m', and view the parameter settings.

```
saveAs(cs, 'Exec_Efficiency_cs');
dbtype Exec_Efficiency_cs 1:50
```

### More About

- “Code Generation Configuration” on page 45-2
- “Application Objectives Using Code Generation Advisor” on page 45-18

## Configure Model from Command Line

The code generator provides model configuration parameters for customizing generated code. Depending on how you use and interact with the generated code, you make configuration decisions. You choose a configuration that best matches your needs for debugging, traceability, code efficiency, and safety precaution.

It is common to automate the model configuration process by using a MATLAB® script once you have decided upon a desired configuration.

The example describes:

- Concepts of working with configuration parameters
- Documentation to understand the code generation options
- Tools and scripts to automate the configuration of a model

### Configuration Parameter Workflows

There are many workflows for Configuration Parameters that include persistence within a single model or persistence across multiple models. Depending on your needs, you can work with configuration sets as copies or references. This example shows the basics steps for working directly with the active configuration set of a model. For a comprehensive description of configuration set features and workflows, see “Manage Configuration Sets for a Model” in the Simulink® documentation.

### Configuration Set Basics

Load a model into memory.

```
model='rtwdemo_configwizard';
load_system(model)
```

Obtain the model's active configuration set.

```
cs = getActiveConfigSet(model);
```

Simulink® Coder™ exposes a subset of the code generation options. If you are using Simulink® Coder™, select the Generic Real-Time (GRT) target.

```
switchTarget(cs, 'grt.tlc', []);
```

Embedded Coder® exposes the complete set of code generation options. If you are using Embedded Coder®, select the Embedded Real-Time (ERT) target.

```
switchTarget(cs, 'ert.tlc', []);
```

To automate configuration of models built for GRT- and ERT-based targets, the configuration set **IsERTTarget** attribute is useful.

```
isERT = strcmp(get_param(cs, 'IsERTTarget'), 'on');
```

You can interact with code generation options via the model or the configuration set. This example gets and sets options indirectly via the model.

```
deftParamBehvr = get_param(model, 'DefaultParameterBehavior'); % Get
set_param(model, 'DefaultParameterBehavior', deftParamBehvr) % Set
```

This example gets and sets options directly via the configuration set.

```
if isERT
 lifespan = get_param(cs,'LifeSpan'); % Get LifeSpan
 set_param(cs,'LifeSpan',lifespan) % Set LifeSpan
end
```

### Configuration Option Summary

The full list of code generation options are documented with tradeoffs for debugging, traceability, code efficiency, and safety precaution. For Simulink® Coder™, see the Simulink® Coder™ version of “Recommended Settings Summary for Model Configuration Parameters”. For Embedded Coder®, see the Embedded Coder® version of “Recommended Settings Summary for Model Configuration Parameters”.

Use Code Generation Advisor to obtain a model configuration optimized for your goals. In the Set Objectives dialog box, you can set and prioritize objectives.

You can find documentation about the Code Generation Advisor in “Application Objectives Using Code Generation Advisor”. You can find additional documentation specific to Embedded Coder® in “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 46-2.

### Parameter Configuration Scripts

Simulink® Coder™ provides an example configuration script that you can use as a starting point for your application. A list of the most relevant GRT and ERT code generation options is contained in `rtwconfiguremodel.m`.

Alternatively, you can generate a MATLAB function that contains the complete list of model configuration parameters by using the configuration set `saveAs` function.

```
% Go to a temporary writable directory.
currentDir = pwd;
rtwdemodir();

% Save the model's configuration parameters to file 'MyConfig.m'.
saveAs(cs,'MyConfig')

% Display the first 50 lines of MyConfig.m.
dbtype MyConfig 1:50
```

```
1 function cs = MyConfig()
```

```

2 % MATLAB function for configuration set generated on 27-Feb-2022 03:32:53
3 % MATLAB version: 9.12.0.1884302 (R2022a)
4
5 cs = Simulink.ConfigSet;
6
7 % Original configuration set version: 22.0.0
8 if cs.versionCompare('22.0.0') < 0
9 error('Simulink:MFileVersionViolation', 'The version of the target configuration set is
10 end
11
12 % Character encoding: UTF-8
13
14 % Do not change the order of the following commands. There are dependencies between the pa
15 cs.set_param('Name', 'Configuration'); % Name
16 cs.set_param('Description', ''); % Description
17
18 % Original configuration set target is ert.tlc
19 cs.switchTarget('ert.tlc', '');
20
21 cs.set_param('HardwareBoard', 'None'); % Hardware board
22
23 cs.set_param('TargetLang', 'C'); % Language
24
25 cs.set_param('CodeInterfacePackaging', 'Nonreusable function'); % Code interface packagin
26
27 cs.set_param('GenerateAllocFcn', 'off'); % Use dynamic memory allocation for model initi
28
29 cs.set_param('Solver', 'FixedStepDiscrete'); % Solver
30
31 % Solver
32 cs.set_param('StartTime', '0.0'); % Start time
33 cs.set_param('StopTime', '48'); % Stop time
34 cs.set_param('SampleTimeConstraint', 'STIndependent'); % Periodic sample time constraint
35 cs.set_param('SolverType', 'Fixed-step'); % Type
36 cs.set_param('ConcurrentTasks', 'off'); % Allow tasks to execute concurrently on target
37 cs.set_param('AllowMultiTaskInputOutput', 'off'); % Allow multiple tasks to access input
38
39 % Data Import/Export
40 cs.set_param('Decimation', '1'); % Decimation
41 cs.set_param('LoadExternalInput', 'off'); % Load external input
42 cs.set_param('SaveFinalState', 'off'); % Save final state
43 cs.set_param('LoadInitialState', 'off'); % Load initial state
44 cs.set_param('LimitDataPoints', 'off'); % Limit data points
45 cs.set_param('SaveFormat', 'StructureWithTime'); % Format
46 cs.set_param('SaveOutput', 'off'); % Save output
47 cs.set_param('SaveState', 'off'); % Save states
48 cs.set_param('SignalLogging', 'on'); % Signal logging
49 cs.set_param('DSMLogging', 'on'); % Data stores
50 cs.set_param('StreamToWks', 'on'); % Stream To Workspace blocks

```

Each parameter setting in the generated file includes a comment for the corresponding parameter string in the Configuration Parameters dialog box.

```

% Return to previous working directory.
cd(currentDir)

```

## Configuration Wizard Blocks

Embedded Coder® provides a set of Configuration Wizard blocks to obtain an initial configuration of a model for a specific goal. For more information, see “Configure and Optimize Model with Configuration Wizard Blocks” on page 46-15.

The predefined blocks provide configuration for:

- ERT optimized for fixed point
- ERT optimized for floating point
- GRT optimized for fixed and floating point
- GRT debug settings for fixed and floating point
- Custom (you provide the script)

Put the block into a model and double-click it to configure the model. Open model `rtwdemo_configwizard` and click **Open Configuration Wizard Library** to interact with the blocks.

```
open_system(model)
```

[Open Configuration Parameters](#)

[Open Configuration Wizard Library](#)

Copyright 1994-2020 The MathWorks, Inc.

To use configuration wizard blocks in the `rtwdemo_configwizard` model follow these steps:

- Open the Configuration Wizard Library by clicking the link provided in the model.
- Open the Model's Configuration Parameters by clicking the link provided in the model.
- Drag and drop a Configuration Wizard Block, for example ERT (optimized for fixed point), from the wizard library into the model.
- Double-click the wizard block.

The Configuration Parameter options are modified automatically.

```
% cleanup
rtwdemoclean;
close_system(model,0)
```

**Summary**

Simulink provides a rich set of MATLAB functions to automate the configuring a model for simulation and code generation. Simulink Coder and Embedded Coder® provide additional functionality specific for code generation. The Code Generation Advisor optimizes the model configuration based on a set of prioritized goals. You can save the optimal configuration to a MATLAB file by using the configuration set saveAs function, and reuse it across models and projects.

- “Code Generation Configuration” on page 45-2
- “Application Objectives Using Code Generation Advisor” on page 45-18

## Use Configuration Reference to Select Code Generation Target

This example shows how to use a configuration reference to select a code generation target for a model reference hierarchy without modifying individual models.

### Open Example Model

Open the example model `slexConfigSetRefExample`.

```
open_system('slexConfigSetRefExample');
```

### Sharing and Switching Configurations with Configuration Reference

This model and its referenced model use the same configuration set stored in data dictionary.

Copyright 2017 The MathWorks, Inc.

To open the active configuration set for the model `slexConfigSetRefExample`, on the **Modeling** tab, click the **Model Configuration Parameters** button.

Because the model is using a referenced configuration, the Configuration Reference dialog box opens and displays a read-only view of the referenced configuration set. Information at the top of the dialog box indicates that the model is using the configuration set, Reference, located in the data dictionary, `slxConfigSetRefData.slidd`. In this example, Reference is another configuration reference, Configuration\_ERT.

In the model editor, right-click the Model block, Amplifier, and select **Open As Top Model**.

```
open_system('slxConfigSetRefExample/Amplifier');
```

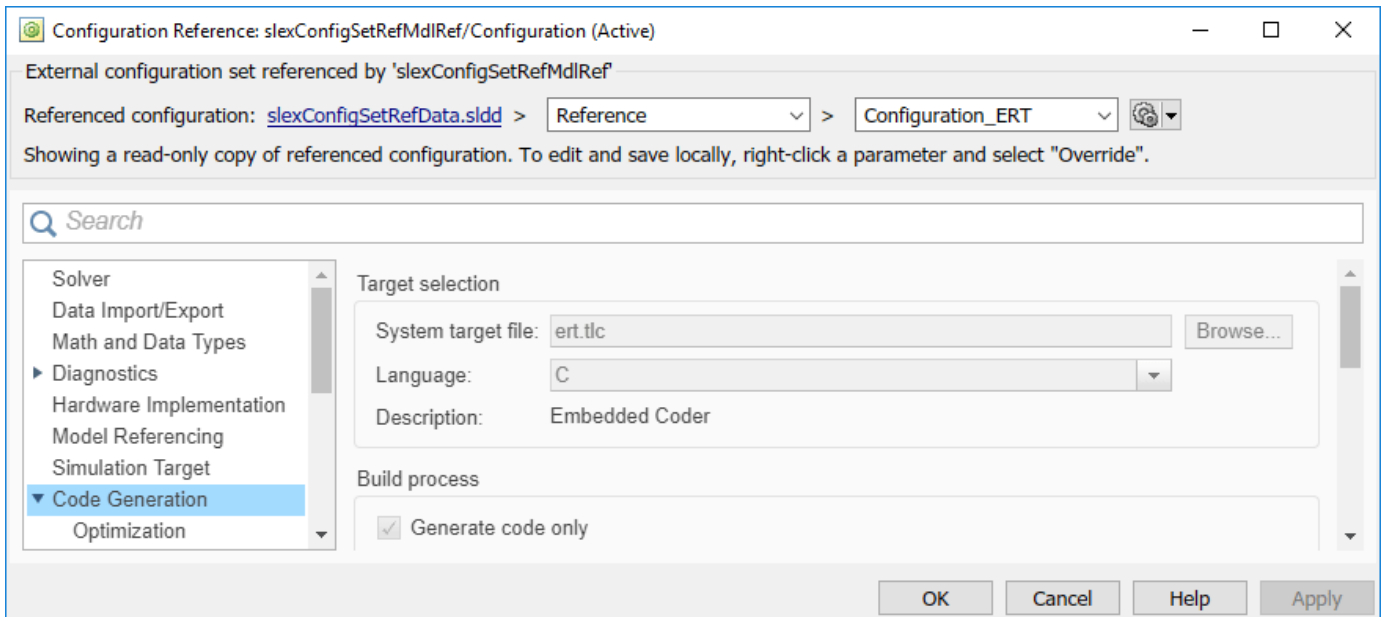

## Sharing and Switching Configurations with Configuration Reference

This model and its parent model use the same configuration set stored in data dictionary.

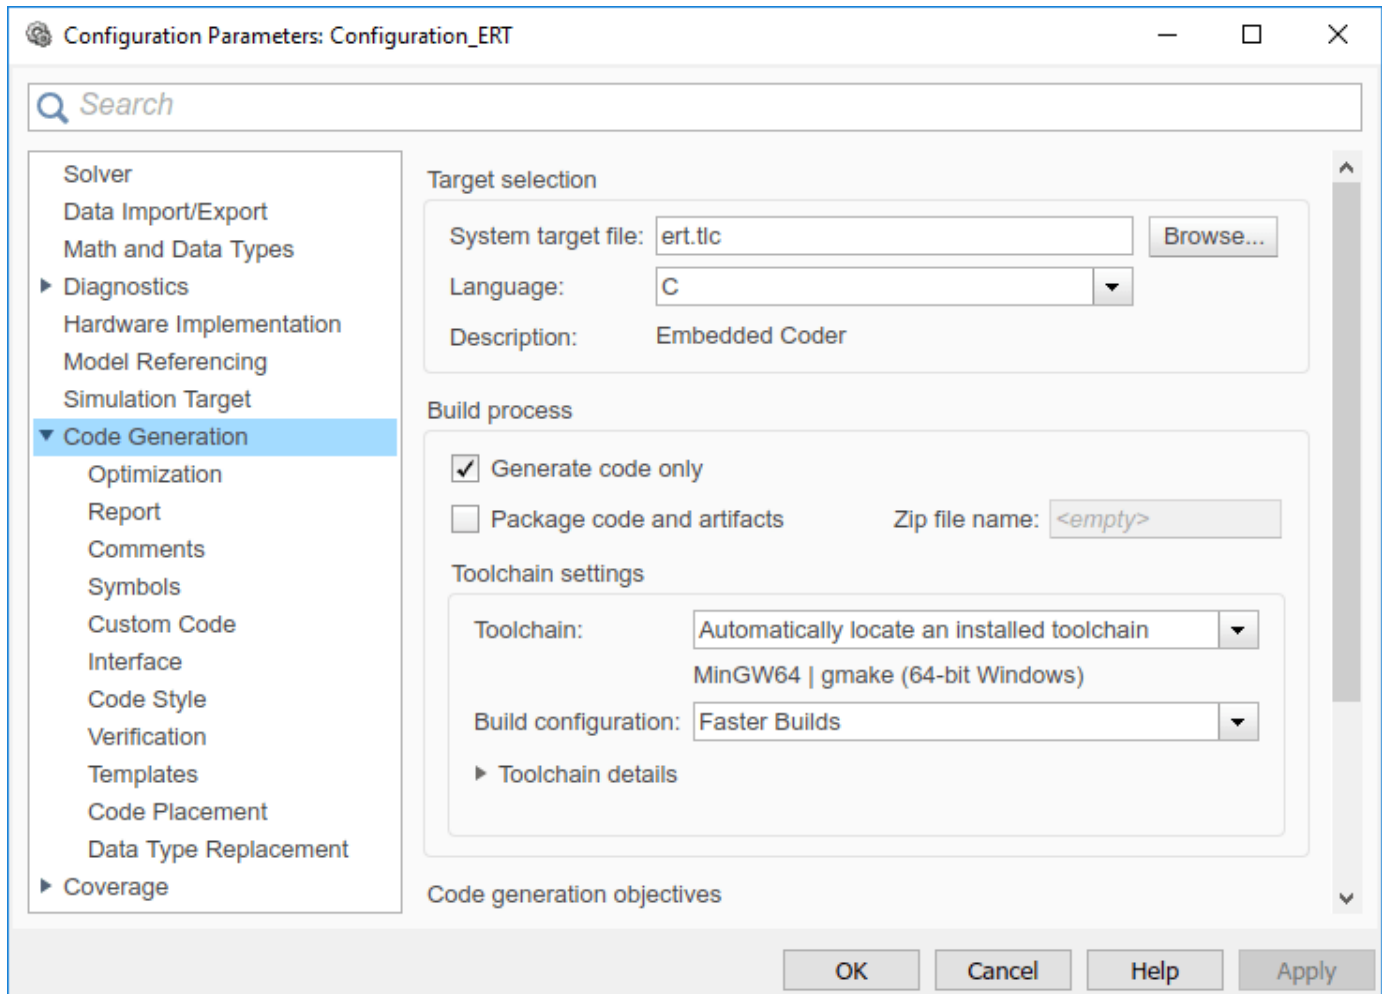

Open the active configuration set for this model. The name and location for the referenced configuration is the same as in `slxConfigSetRefExample`.

### Open the Referenced Configuration Set

If you need to change and apply parameter values in the configuration set, open Configuration\_ERT for edit in the Configuration Parameters dialog box by clicking the Model Configuration Parameters icon at the top of either of the Configuration Reference dialog boxes.

### Generate Code for ERT Target

The referenced configuration set is customized for ERT code generation. To generate code, press **Ctrl +B**.

```
slbuild('slexConfigSetRefExample');
```

```
Starting serial model reference code generation build
Starting build procedure for: slexConfigSetRefMdlRef
Successful completion of code generation for: slexConfigSetRefMdlRef
Starting build procedure for: slexConfigSetRefExample
Successful completion of code generation for: slexConfigSetRefExample
```

Build Summary

Code generation targets built:

Model	Action	Rebuild Reason
slexConfigSetRefMdlRef	Code generated	slexConfigSetRefMdlRef.c does not exist.

Top model targets built:

Model	Action	Rebuild Reason
slexConfigSetRefExample	Code generated	Code generation information file does not exist.

2 of 2 models built (0 models already up to date)  
Build duration: 0h 0m 35.66s

The code generation report displays once code generation is complete.

### Switch Targets and Generate Code for AUTOSAR Target

For this model there is another configuration set, Configuration\_AUTOSAR, that is customized for AUTOSAR code generation. At the top of the Configuration Reference dialog box, in the rightmost drop-down list, select Configuration\_AUTOSAR. slexConfigSetRefExample and its referenced model, slexConfigSetMdlRef, now both use the configuration set, Configuration\_AUTOSAR.

Because you edited the configuration reference, the data dictionary has unsaved changes. The configurations are stored outside of the models so the models do not have unsaved changes.

If you have downloaded the AUTOSAR package, you can now generate code for an AUTOSAR target. In the model editor window, press **Ctrl+B**.

## Check Model and Configuration for Code Generation

You can use the Model Advisor checks to assess model readiness to generate code. To check and configure your model for code generation application objectives such as traceability or debugging, use the Code Generation Advisor.

For information about	See
Model Advisor	"Run Model Advisor Checks"
Code Generation Advisor	"Application Objectives Using Code Generation Advisor"
Checks available with Simulink Coder	"Simulink Coder Checks"
Checks available with Embedded Coder	"Embedded Coder Checks"

### Check Model for Code Efficiency with Model Advisor

To check model `rtwdemo_throttlecntrl` for code efficiency, use the Model Advisor.

- 1 Open `rtwdemo_throttlecntrl`. Save a copy as `throttlecntrl` in a writable location on your MATLAB path.
- 2 To start the Model Advisor, on the **Modeling** tab, click **Model Advisor**. A dialog box opens showing the model system hierarchy.
- 3 Click `throttlecntrl` and then click **OK**. The Model Advisor window opens.
- 4 Expand **By Task > Code Generation Efficiency**. To check your model for code generation efficiency, use the checks in the folder. By default, checks that do not trigger an Update Diagram are selected. The checks available for code generation efficiency depend on whether you have a Simulink Coder or Embedded Coder license.
- 5 In the left pane, select the remaining checks. Right-click on the **Code Generation Efficiency** folder and select **Run Selected Checks**.

The results shows a **Run Summary** that flags check warnings. The warnings identify issues that impact code efficiency. For more information about the report, see "View Model Advisor Check Reports".

### Check Model During Code Generation by using the Code Generation Advisor

To review a model as part of the code generation process, use the Code Generation Advisor.

- 1 To specify your code generation objectives, on the **Configuration Parameters > Code Generation** pane, choose a value for the **Select objective** parameter.
- 2 Select one of the following values for the parameter **Check model before generating code**:
  - On (proceed with warnings)
  - On (stop for warnings)
- 3 If you want to only generate code, select **Generate code only**. Otherwise clear the check box to build an executable.
- 4 Apply your changes, and press **Ctrl+B** to generate code. The Code Generation Advisor starts and reviews the top model and subsystems.

If the Code Generation Advisor issues failures or warnings, and you specified:

- On (proceed with warnings) — The Code Generation Advisor window opens while the build process proceeds. After the build process is complete, you can review the results.
  - On (stop for warnings) — The build process halts and displays the Diagnostic Viewer. To continue, you must review and resolve the Code Generation Advisor results or clear the **Check model before generating code** parameter.
- 5 In the Code Generation Advisor dialog box, review the results by selecting a check from the left pane. The results for that check display in the right pane.
  - 6 After reviewing the check results, you can choose to fix warnings and failures as described in “Fix a Model Advisor Check Warning or Failure”.

---

**Note** When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

---

For more information, see “Set Objectives — Code Generation Advisor Dialog Box”

## See Also

### Related Examples

- “Check Your Model Using the Model Advisor”
- “Application Objectives Using Code Generation Advisor” on page 45-18

## Application Objectives Using Code Generation Advisor

### In this section...

“High-Level Code Generation Objectives” on page 45-18

“Configure Model for Code Generation Objectives Using Code Generation Advisor” on page 45-19

“Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box” on page 45-19

Consider how your application objectives, such as efficiency or debugging, map to code generation options in a model configuration set. Parameters that you set in the Configuration Parameters dialog box specify the behavior of a model in simulation and the code generated for the model.

Before generating code, or as part of the code generation process, you can use the Code Generation Advisor to review a model. When you choose to review a model before generating code, you specify which model, subsystem, or referenced model the Code Generation Advisor reviews. When you choose to review a model as part of the code generation process, the Code Generation Advisor reviews the entire system. The Code Generation Advisor uses the information presented in “Recommended Settings Summary for Model Configuration Parameters” to determine the parameter values that meet your objectives. To configure objectives for a model with an ERT-based target, see “Configure Model for Code Generation Objectives Using Code Generation Advisor” on page 45-19.

Setting a code generation objective, and then running the Code Generation Advisor provides information on how to meet the code generation objective for your model. The Code Generation Advisor does not alter the generated code. You can use the Code Generation Advisor to make the suggested changes to your model. The generated code is changed only after you modify your model and regenerate code. When you use the Code Generation Advisor to set the code generation objective and check your model, the generated code includes comments identifying which objective you specified, the checks the Code Generation Advisor ran on the model, and the results of running the checks.

If a model uses a configuration reference, you can run the Code Generation Advisor to review your configuration parameter settings. However, the Code Generation Advisor cannot modify the configuration parameter settings.

### High-Level Code Generation Objectives

Depending on the type of application that your model represents, you are likely to have specific high-level code generation objectives. For example, debugging might be more critical than efficient execution. If you have a specific objective, you can quickly configure your model to meet that objective by selecting from these code generation objectives:

- Execution efficiency — Configure code generation settings to achieve fast execution time.
- Debugging — Configure code generation settings to debug the code generation build process.

For a list of objectives that are available for models with ERT-based targets, see “High-Level Code Generation Objectives” on page 46-2.

## Configure Model for Code Generation Objectives Using Code Generation Advisor

This example shows how to use the Code Generation Advisor to check and configure your model to meet code generation objectives:

- 1 On the **C Code** tab, click **C/C++ Code Advisor**.
- 2 In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.
- 3 In the Code Generation Advisor, on the **Code Generation Objectives** pane, select a code generation objective from the drop-down list (GRT-based targets). As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it will run on your model. If your model is configured with an ERT-based target, more objectives are available.
- 4 Click **Run Selected Checks** to run the checks listed in the left pane of the Code Generation Advisor.
- 5 In the Code Generation Advisor window, review the results for **Check model configuration settings against code generation objectives** by selecting it from the left pane. The results for that check are displayed in the right pane.

**Check model configuration settings against code generation objectives** triggers a warning for these issues:

- Parameters are set to values other than the value recommended for the specified code generation objective.
- The selected code generation objective differs from the objective set in the model.

Click **Modify Parameters** to set:

- Parameters to the value recommended for the specified code generation objective.
  - Code generation objective in the model to the objective specified in the Code Generation Advisor.
- 6 In the Code Generation Advisor window, review the results for the remaining checks by selecting them from the left pane. The results for the checks display in the right pane.
  - 7 After reviewing the check results, you can choose to fix warnings and failures, as described in “Fix a Model Advisor Check Warning or Failure”.

When you specify a the execution efficiency objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

## Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box

This example shows how to check and configure the code generation objectives in the Configuration Parameters dialog box:

- 1 Open the Configuration Parameters dialog box and select **Code Generation**.
- 2 Select or confirm selection of a System target file.
- 3 Specify the objective using the **Select objectives** drop-down list.

- 4** Click **Check Model** to run the model checks.
- 5** In the System Selector window, select the model or subsystem that you want to review, and then click **OK**. The Code Generation Advisor dialog box opens. The Code Generation Advisor uses the code generation objective to determine which model checks to run.
- 6** On the left pane, the Code Generation Advisor lists the checks run on the model and the results. Click each warning to see the suggestions for changes that you can make to your model to pass the check.
- 7** Determine which changes to make to your model. On the right pane of the Code Generation Advisor, follow the instructions listed for each check to modify the model.

## Simulink Coder Model Advisor Checks for Standards and Code Efficiency

To check that your model meets standards and is ready to generate code, you can use the Model Advisor checks available with Simulink Coder.

- On the **Modeling** tab, click **Model Advisor**.
- In the Model Advisor window, expand the **By Product** folder. The **Simulink Coder** folder contains Model Advisor checks that you can run.

For more information about the Model Advisor, see “Run Model Advisor Checks”.

The table summarizes the Simulink Coder Model Advisor checks that are available in the **By Task** folders.

<b>By Task folder</b>	<b>Model Advisor checks</b>
<b>Code Generation Efficiency</b>	“Identify blocks using one-based indexing”
<b>Modeling Standards for DO-178C/DO-331</b>	“Check solver for code generation” “Check for blocks that have constraints on tunable parameters” “Check sample times and tasking mode”
<b>Model Referencing</b>	“Check for model reference configuration mismatch” “Check for code generation identifier formats used for model reference”

## Configure Code Comments

Configure how the code generator inserts comments into generated code by modifying parameters on the **Code Generation > Comments** pane.

Goal	Action
Include comments in generated code	<b>Include comments.</b> Selecting this parameter allows you to select one or more autogenerated comment types to be placed in the code.
Include comments that describe a Simulink block's code	<b>Simulink block comments.</b> Selecting this parameter includes the comments before the Simulink block's code in the generated code. In Embedded Coder, use <b>Trace to model using</b> to select <code>Block path</code> or <code>Simulink identifier</code> as the comment format.
Include comments that describe Stateflow objects	<b>Stateflow object comments.</b> Selecting this parameter includes the comments describing Stateflow objects in the generated code. In Embedded Coder, use <b>Trace to model using</b> to select <code>Block path</code> or <code>Simulink identifier</code> as the comment format.
Include MATLAB source code as comments	<b>MATLAB source code as comments.</b> Selecting this parameter inserts these comments preceding the associated generated code. The function signature is included in the function banner.
Include comments for eliminated blocks	<b>Show eliminated blocks.</b> Selecting this parameter includes comments for blocks that were eliminated as the result of optimizations, such as inlining parameters.
Include parameter comments regardless of the number of parameters	<b>Verbose comments for 'Model default' storage class.</b> Selecting this parameter includes comments for parameter variable names and names of source blocks in the model parameter structure declaration in <code>model_prm.h</code> .  If you do not select this parameter, parameter comments are generated if less than 1000 parameters are declared. This reduces the size of the generated file for models with a large number of parameters.
Include MATLAB user comments	<b>MATLAB user comments.</b> Selecting this parameter includes function description comments and other user comments from MATLAB code as comments in the generated code.
Specify comment style	<b>Comment style.</b> Select <code>Auto</code> , <code>Multi-line</code> or <code>Single-line</code> as the style of comments in the generated code.

**Note** When you configure the code generator to produce code that includes comments, the code generator includes text for model parameters, block names, signal names, and Stateflow object names in the generated code comments. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter `ア` with the escape sequence `&#x30A2;`. For more information, see “Internationalization and Code Generation”.

#### More About

- “Model Configuration Parameters: Comments”

## Include MATLAB Code as Comments in Generated Code

If you have Simulink Coder, you can include MATLAB source code as comments in the code generated for a MATLAB Function block. Including this information in the generated code enables you to:

- Correlate the generated code with your source code.
- Understand how the generated code implements your algorithm.
- Evaluate the quality of the generated code.

When you select the **MATLAB source code as comments** parameter, the generated code includes:

- The source code as a comment immediately after the traceability tag. When you enable traceability and generate code for ERT targets (requires Embedded Coder), the traceability tags are hyperlinks to the source code. For more information, see “Use Traceability in MATLAB Function Blocks” on page 79-35.

For examples and information on the location of the comments in the generated code, see “Location of Comments in Generated Code” on page 45-23.

- The function help text in the function body in the generated code. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it.

---

**Note** With Embedded Coder, you can also include the function help text in the generated code function banner. For more information, see “Include MATLAB User Comments in Generated Code” on page 45-25.

---

## Include MATLAB Code as Comments in the Generated Code

To include MATLAB source code as comments in the code generated for a MATLAB Function block:

- 1 On the **C Code** tab, click **Configuration Parameters**.
- 2 In the **Code Generation > Comments** pane, select **MATLAB source code as comments** and click **Apply**.

## Location of Comments in Generated Code

The comments containing the source code appear after the traceability tag in the generated code as follows.

```
/* '<S2>:1:18' for y = 1 : 2 : (HEIGHT-4) */
```

Selecting the **Stateflow object comments** parameter generates the traceability comment '`<S2>:1:18`'. Selecting the **MATLAB source code as comments** parameter generates the `for y = 1 : 2 : (HEIGHT-4)` comment.

### Straight-Line Source Code

The comment containing the source code precedes the generated code that implements the source code statement. This comment appears after comments that you add, which precede the generated

code. The comments are separated from the generated code because the statements are assigned to function outputs.

#### MATLAB Code

```
function [x y] = straightline(r,theta)
%#codegen
% Convert polar to Cartesian
x = r * cos(theta);
y = r * sin(theta);
```

#### Commented C Code

```
/* MATLAB Function 'straightline': '<S1>:1' */
/* Convert polar to Cartesian */
/* '<S1>:1:4' x = r * cos(theta); */
/* '<S1>:1:5' y = r * sin(theta); */
straightline0_Y.x = straightline0_U.r * cos(straightline0_U.theta);

/* Output: '<Root>/y' incorporates:
 * Inport: '<Root>/r'
 * Inport: '<Root>/theta'
 * MATLAB Function Block: '<Root>/straightline'
 */
straightline0_Y.y = straightline0_U.r * sin(straightline0_U.theta);
```

#### If Statements

The comment for the `if` statement immediately precedes the code that implements the statement. This comment appears after comments that you add, which precede the generated code. The comments for the `elseif` and `else` clauses appear immediately after the code that implements the clause and before the code generated for statements in the clause.

#### MATLAB Code

```
function y = ifstmt(u,v)
%#codegen
if u > v
 y = v + 10;
elseif u == v
 y = u * 2;
else
 y = v - 10;
end
```

#### Commented C Code

```
/* MATLAB Function 'MLFcn': '<S1>:1' */
/* '<S1>:1:3' if u > v */
if (MLFcn_U.u > MLFcn_U.v) {
 /* Output: '<Root>/y' */
 /* '<S1>:1:4' y = v + 10; */
 MLFcn_Y.y = MLFcn_U.v + 10.0;
} else if (MLFcn_U.u == MLFcn_U.v) {
 /* Output: '<Root>/y' */
 /* '<S1>:1:5' elseif u == v */
 /* '<S1>:1:6' y = u * 2; */
 MLFcn_Y.y = MLFcn_U.u * 2.0;
} else {
```

```

/* Output: '<Root>/y' */
/* '<S1>:1:7' else */
/* '<S1>:1:8' y = v - 10; */
MLFcn_Y.y = MLCfn_U.v - 10.0;

```

### For Statements

The comment for the `for` statement header immediately precedes the generated code, which implements the header. This comment appears after comments that you add, which precede the generated code.

#### MATLAB Code

```

function y = forstmt(u)
%#codegen
y = 0;
for i=1:u
 y = y + 1;
end

```

#### Commented C Code

```

/* MATLAB Function 'MLFcn': '<S1>:1' */
/* '<S1>:1:3' y = 0; */
rtb_y = 0.0;

/* '<S1>:1:5' for i=1:u */
for (i = 1.0; i <= MLCfn_U.u; i++) {
 /* '<S1>:1:6' y = y + 1; */
 rtb_y++;
}

```

### While Statements

The comment for the `while` statement header immediately precedes the generated code, which implements the statement header. This comment appears after comments that you add, which precede the generated code.

### Switch Statements

The comment for the `switch` statement header immediately precedes the generated code that implements the statement header. This comment appears after comments that you add that precede the generated code. The comments for the `case` and `otherwise` clauses appear immediately after the generated code that implements the clause, and before the code generated for statements in the clause.

## Include MATLAB User Comments in Generated Code

MATLAB user comments include the function help text and other comments. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it. You can include the MATLAB user comments in the code generated for a MATLAB Function block.

- 1 On the **C Code** tab, click **Configuration Parameters**.
- 2 In the **Code Generation > Comments** pane, select “MATLAB user comments” and click **Apply**.

## Limitations of MATLAB Source Code as Comments

For including MATLAB source code as comments, the MATLAB Function block has these limitations :

- You cannot include MATLAB source code as comments for:
  - MathWorks toolbox functions
  - P-code
  - Simulation targets
  - Stateflow Truth Table blocks
- The appearance or location of comments can vary depending on these conditions:
  - Comments might still appear in the generated code even if the implementation code is eliminated, for example, due to constant folding.
  - Comments might be eliminated from the generated code if a complete function or code block is eliminated.
  - For certain optimizations, the comments might be separated from the generated code.
  - The generated code includes legally required comments from the MATLAB source code, even if you do not choose to include source code comments in the generated code.

## Construction of Generated Identifiers

For GRT and RSim targets, the code generator automatically constructs identifiers for variables and functions in the generated code. These identifiers represent:

- Signals and parameters that have `Auto` storage class
- Subsystem function names that are not user-defined
- Stateflow names

The components of a generated identifier include

- The root model name, followed by
- The name of the generating object (signal, parameter, state, and so on), followed by
- Unique *name-mangling* text

The code generator conditionally generates the name-mangling text to resolve potential conflicts with other generated identifiers.

To configure how the code generator names identifiers and objects, see:

- “Specify Identifier Length to Avoid Naming Collisions” on page 45-29
- “Specify Reserved Names for Generated Identifiers” on page 45-30

The code generator reserves certain words for its own use as keywords of the generated code language. For more information, see “Reserved Keywords” on page 45-31.

With an Embedded Coder license, you can specify parameters to control identifier formats, mangle length, scalar inlined parameters, and Simulink data object naming rules. For more information, see “Customize Generated Identifier Naming Rules” on page 52-10.

## Identifier Name Collisions and Mangling

In identifier generation, a circumstance that would cause generation of two or more identical identifiers is called a *name collision*. When a potential name collision exists, unique *name-mangling* text is generated and inserted into each of the potentially conflicting identifiers. Each set of name-mangling characters is unique for each generated identifier.

### Identifier Name Collisions with Referenced Models

Referenced models can introduce additional naming constraints. Within a model that uses referenced models, collisions between the names of the models cannot exist. When you generate code from a model that includes referenced models, the **Maximum identifier length** parameter must be large enough to accommodate the root model name and name-mangling text. A code generation error occurs if **Maximum identifier length** is too small.

When a name conflict occurs between an identifier within the scope of a higher-level model and an identifier within the scope of a referenced model, the identifier from the referenced model is preserved. Name mangling is performed on the identifier from the higher-level model.

For more information on referenced models, see “Parameterize Instances of a Reusable Referenced Model”.

## Specify Identifier Length to Avoid Naming Collisions

The length of a generated identifier is limited by the **Maximum identifier length** parameter specified on the **Identifiers** pane of the Configuration Parameters dialog box. The **Maximum identifier length** field allows you to limit the number of characters in function, type definition, and variable names. The default is 31 characters. This is also the minimum length you can specify. The maximum is 256 characters.

When there is a potential name collision between two identifiers, name-mangling text is generated. The text has the minimum number of characters required to avoid the collision. The other symbol components are then inserted. If **Maximum identifier length** is not large enough to accommodate full expansions of the other components, they are truncated. To avoid this outcome, it is good practice to:

- Avoid name collisions by not using default block names (for example, `Gain1`, `Gain2...`) when the model includes multiple blocks of the same type.
- For subsystems, make them atomic and reusable.
- Increase the **Maximum identifier length** parameter to accommodate the length of the identifier you expect to generate.

## Specify Reserved Names for Generated Identifiers

You can specify a set of reserved keywords that the code generation process should not use, facilitating code integration where functions and variables from external environments are unknown in the Simulink model. To create a list of reserved names, open the Configuration Parameters dialog box. On the **Code Generation > Identifiers** pane, enter the keywords in the “Reserved names” field.

If your model contains MATLAB Function or Stateflow blocks, the code generation process can use the reserved names specified for those blocks if you select **Use the same reserved names as Simulation Target** on the **Code Generation > Identifiers** pane.

## Reserved Keywords

### In this section...

“C Reserved Keywords” on page 45-31

“C++ Reserved Keywords” on page 45-31

“Reserved Keywords for Code Generation” on page 45-32

“Code Generation Code Replacement Library Keywords” on page 45-32

Generator keywords are reserved for internal use. Do not use them in models as identifiers or function names. Also avoid using C reserved keywords in models as identifiers or function names. If your model contains reserved keywords, code generation does not complete and an error message appears. To address the error, modify your model to use identifiers or names that are not reserved.

If you use the code generator to produce C++ code, your model must not contain the “Reserved Keywords for Code Generation” on page 45-32 nor the “C++ Reserved Keywords” on page 45-31.

**Note** You can register additional reserved identifiers in the Simulink environment. For more information, see “Specify Reserved Names for Generated Identifiers” on page 45-30.

### C Reserved Keywords

auto	double	int	struct
break	else	long	switch
case	enum	register	typedef
char	extern	return	union
const	float	short	unsigned
continue	for	signed	void
default	goto	sizeof	volatile
do	if	static	while

### C++ Reserved Keywords

catch	friend	protected	try
class	inline	public	typeid
const_cast	mutable	reinterpret_cast	typename
delete	namespace	static_cast	using
dynamic_cast	new	template	virtual
explicit	operator	this	wchar_t
export	private	throw	

## Reserved Keywords for Code Generation

abs	int8_T	MAX_uint8_T*	rtInf
asm	int16_T	MAX_uint16_T*	rtMinusInf
bool	int32_T	MAX_uint32_T*	rtNaN
boolean_T	int64_T	MAX_uint64_T	SeedFileBuffer
byte_T	INTEGER_CODE	MIN_int8_T*	SeedFileBufferLen
char_T	LINK_DATA_BUFFER_SIZE	MIN_int16_T*	single
cint8_T	LINK_DATA_STREAM	MIN_int32_T*	TID01EQ
cint16_T	localB	MIN_int64_T	time_T
cint32_T	localC	MODEL	true
creal_T	localDWork	MT	uint_T
creal32_T	localP	NCSTATES	uint8_T
creal64_T	localX	NULL	uint16_T
cuint8_T	localXdis	NUMST	uint32_T
cuint16_T	localXdot	pointer_T	uint64_T
cuint32_T	localZCE	PROFILING_ENABLED	UNUSED_PARAMETER
ERT	localZCSV	PROFILING_NUM_SAMPLES	USE_RTMODEL
false	matrix	real_T	VCAST_FLUSH_DATA
fortran	MAX_int8_T*	real32_T	vector
HAVESTDIO	MAX_int16_T*	real64_T	
id_t	MAX_int32_T*	RT	
int_T	MAX_int64_T	RT_MALLOC	
*Not reserved if you specify a replacement identifier.			

## Code Generation Code Replacement Library Keywords

The list of code replacement library reserved keywords for your development environment varies depending on which libraries are registered. The list of available code replacement libraries varies depending on other installed products (for example, a target product), or if you used Embedded Coder to create and register custom code replacement libraries.

To generate a list of reserved keywords for libraries currently registered in your environment, use the following MATLAB function:

```
lib_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers()
```

This function returns an array of library keywords. Specifying the input argument is optional.

---

**Note** To list the libraries currently registered in your environment, use the MATLAB command `crviewer`.

---

To generate a list of reserved keywords for a specific library that you are using to generate code, call the function passing the name of the library as displayed in the **Code replacement library** menu on the **Code Generation > Interface** pane of the Configuration Parameters dialog box. For example,

```
lib_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU C99 extensions')
```

Here is a partial example of the function output:

```
>> lib_ids = ...
 RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU C99 extensions')

lib_ids =

 'exp10'
 'exp10f'
 'acosf'
 'acoshf'
 'asinf'
 'asinhf'
 'atanf'
 'atanhf'
 ...
 'rt_lu_cplx'
 'rt_lu_cplx_sgl'
 'rt_lu_real'
 'rt_lu_real_sgl'
 'rt_mod_boolean'
 'rt_rem_boolean'
 'strcpy'
 'utAssert'
```

---

**Note** Some of the returned keywords appear with the suffix `$N`, for example, `'rt_atan2$N'`. `$N` expands into the suffix `_snf` only if nonfinite numbers are supported. For example, `'rt_atan2$N'` represents `'rt_atan2_snf'` if nonfinite numbers are supported and `'rt_atan2'` if nonfinite numbers are not supported. As a precaution, you should treat both forms of the keyword as reserved.

---

## Configure Model for Debugging

In the Configuration Parameters dialog box, use parameters on the **Diagnostics** pane and debugging parameters to configure a model such that the generated code and the build process are set for debugging. You can set parameters that apply to the model compilation phase, the target language code generation phase, or both.

Parameters in the following table will be helpful if you are writing TLC code for customizing targets, integrating legacy code, or developing new blocks.

To...	Select...
Display progress information during code generation in the MATLAB Command Window	"Verbose build". Compiler output also displays.
Prevent the build process from deleting the <i>model.rtw</i> file from the build folder at the end of the build	"Retain .rtw file". This parameter is useful if you are modifying the target files, in which case you need to look at the <i>model.rtw</i> file.
Instruct the TLC profiler to analyze the performance of TLC code executed during code generation and generate a report	"Profile TLC". The report is in HTML format and can be read in your web browser.
Start the TLC debugger during code generation	"Start TLC debugger when generating code". Alternatively, enter the argument <code>-dc</code> for the "System target file" parameter on the <b>Code Generation</b> pane. To start the debugger and run a debugger script, enter <code>-df filename</code> for <b>System target file</b> .
Generate a report containing statistics indicating how many times the code generator reads each line of TLC code during code generation	"Start TLC coverage when generating code". Alternatively, enter the argument <code>-dg</code> for the <b>System Target File</b> parameter on the <b>Code Generation</b> pane.
Halt a build if a user-supplied TLC file contains an <code>%assert</code> directive that evaluates to <code>FALSE</code>	<p>"Enable TLC assertion". Alternatively, you can use MATLAB commands to control TLC assertion handling.</p> <p>To set the flag on or off, use the <code>set_param</code> command. The default is off.</p> <pre>set_param(model, 'TLCAssertion', 'on off')</pre> <p>To check the current setting, use <code>get_param</code>.</p> <pre>get_param(model, 'TLCAssertion')</pre>

To...	Select...
Detect loss of tunability	<p>“Detect loss of tunability” on the <b>Diagnostics &gt; Data Validity</b> pane. You can use this parameter to report loss of tunability when an expression is reduced to a numeric expression. This can occur if a tunable workspace variable is modified by Mask Initialization code, or is used in an arithmetic expression with unsupported operators or functions. Possible values are:</p> <ul style="list-style-type: none"><li>• <b>none</b> — Loss of tunability can occur without notification.</li><li>• <b>warning</b> — Loss of tunability generates a warning (default).</li><li>• <b>error</b> — Loss of tunability generates an error.</li></ul> <p>For a list of supported operators and functions, see “Tunable Expression Limitations”</p>

To...	Select...
Enable model verification (assertion) blocks	<p>“Model Verification block enabling”. Use this parameter to enable or disable model verification blocks such as Assert, Check Static Gap, and related range check blocks. The diagnostic applies to generated code and simulation behavior. For example, simulation and code generation ignore this parameter when model verification blocks are inside an S-function. Possible values are:</p> <ul style="list-style-type: none"> <li>• User local settings</li> <li>• Enable All</li> <li>• Disable All</li> </ul> <p>For Assertion blocks not disabled, generated code for a model includes one of the following statements, depending on the blocks input signal type (Boolean, real, or integer, respectively).</p> <pre>utAssert(input_signal); utAssert(input_signal != 0.0); utAssert(input_signal != 0);</pre> <p>If the model contains variant blocks with the <code>Variant</code> activation time parameter set to <code>startup</code> and the <code>Allow zero active variant controls</code> parameter set to <code>off</code>, the <code>model_initialize</code> function in the generated code contains this assertion.</p> <pre>utAssert(&lt;variant condition expression on the block&gt;);</pre> <p>This statement checks that at least one variant choice is active for such variant blocks.</p> <p>By default, <code>utAssert</code> does not change generated code. For assertions to abort execution, you must enable them by specifying the following <code>make_rtw</code> command for <b>Code Generation</b> &gt; “Make command” parameter:</p> <pre>make_rtw OPTS="-DDOASSERTS"</pre> <p>Use the following variant if you want triggered assertions to print the assertion statement instead of aborting execution:</p> <pre>make_rtw OPTS="-DDOASSERTS -DPRINT_ASSERTS"</pre> <p><code>utAssert</code> is defined as <code>#define utAssert(exp) assert(exp)</code>.</p> <p>To customize assertion behavior, provide your own definition of <code>utAssert</code> in a handwritten header file that overrides the default <code>utAssert.h</code>. For details on how to include a customized header file in generated code, see “Integrate External Code by Using Model Configuration Parameters”.</p> <p>When running a model in accelerator mode, the Simulink engine calls back to itself to execute assertion blocks instead of using generated code. Thus, user-defined callbacks are still called when assertions fail.</p>

For more information about the TLC debugging options, see Debugging on “Target Language Compiler”. Also, consider using the Model Advisor as a tool for troubleshooting model builds. For more information about the Model Advisor, see “Run Model Advisor Checks”.

## Configure Model for Code Generation Objectives by Using Code Generation Advisor

### In this section...

“High-Level Code Generation Objectives” on page 46-2

“Specify Objectives in Referenced Models” on page 46-3

“Configure Model Using Code Generation Advisor” on page 46-3

“Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box” on page 46-4

Consider how your application objectives, such as efficiency, traceability, and safety, map to code generation parameters in a model configuration set. Parameters that you set in the Configuration Parameters dialog box specify the behavior of a model in simulation and the code generated for the model.

Before generating code, or as part of the code generation process, you can use the Code Generation Advisor to review a model. When you choose to review a model before generating code, you specify which model, subsystem, or referenced model the Code Generation Advisor reviews. When you choose to review a model as part of the code generation process, the Code Generation Advisor reviews the entire system. The Code Generation Advisor uses the information presented in “Recommended Settings Summary for Model Configuration Parameters” to determine the parameter values that meet your objectives. When there is a conflict between multiple objectives, the higher-priority objective takes precedence.

Setting code generation objectives, and then running the Code Generation Advisor provides information on how to meet code generation objectives for your model. The Code Generation Advisor does not alter the generated code. You can use the Code Generation Advisor to make the suggested changes to your model. The generated code is changed only after you modify your model and regenerate code. When you use the Code Generation Advisor to set code generation objectives and check your model, the generated code includes comments identifying which objectives you specified, the checks that the Code Generation Advisor ran on the model, and the results of running the checks.

If a model uses a configuration reference, you can run the Code Generation Advisor to review your configuration parameter settings. However, the Code Generation Advisor cannot modify the configuration parameter settings.

### High-Level Code Generation Objectives

Depending on the type of application that your model represents, you are likely to have specific high-level code generation objectives. For example, safety and traceability are more critical than efficient use of memory. If you have specific objectives, you can quickly configure your model to meet those objectives by selecting and prioritizing from these code generation objectives:

- Execution efficiency (all targets) — Configure code generation settings to achieve fast execution time.
- ROM efficiency (ERT-based targets) — Configure code generation settings to reduce ROM usage.
- RAM efficiency (ERT-based targets) — Configure code generation settings to reduce RAM usage.
- Traceability (ERT-based targets) — Configure code generation settings to provide mapping between model elements and code.

- Safety precaution (ERT-based targets) — Configure code generation settings to increase clarity, determinism, robustness, and verifiability of the code.
- Debugging (all targets) — Configure code generation settings to debug the code generation build process.
- MISRA C:2012 guidelines (ERT-based targets) — Configure code generation settings to increase compliance with MISRA C:2012 guidelines.
- Polyspace (ERT-based targets) — Configure code generation settings to prepare the code for Polyspace analysis.

If you select the MISRA C:2012 guidelines code generation objective, the Code Generation Advisor:

- Checks the model configuration settings for compliance with the MISRA C:2012 configuration setting recommendations.
- Checks for blocks that are not supported or recommended for MISRA C:2012 compliant code generation.

## Specify Objectives in Referenced Models

When you check a model during the code generation process, you must specify the same objectives in the top model and referenced models. If you specify different objectives for the top model and referenced model, the build process generates an error.

To specify different objectives for the top model and each referenced model, review the models separately without generating code.

## Configure Model Using Code Generation Advisor

This example shows how to use the Code Generation Advisor to check and configure your model to meet code generation objectives:

- 1 On the **C Code** tab, click **C/C++ Code Advisor**.
- 2 In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.
- 3 In the Code Generation Advisor, on the **Code Generation Objectives** pane, select the code generation objectives. As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it runs on your model. If your model is configured with an ERT-based target, more objectives are available. For this example, the model is configured with an ERT-based target. If your objectives are execution efficiency and traceability, in that priority, do the following:
  - a In **Available objectives**, double-click Execution efficiency. Execution efficiency is added to **Selected objectives - prioritized**.
  - b In **Available objectives**, double-click Traceability. Traceability is added to **Selected objectives - prioritized** under Execution efficiency.

- 4 To run the checks listed in the left pane of the Code Generation Advisor, right-click on the **Code Generation Advisor** folder and select **Run Selected Checks**.
- 5 In the Code Generation Advisor window, review the results for **Check model configuration settings against code generation objectives** by selecting it from the left pane. The results for that check are displayed in the right pane.

**Check model configuration settings against code generation objectives** triggers a warning for these issues:

- Parameters are set to values other than the value recommended for the specified code generation objectives.
- Selected code generation objectives differ from the objectives set in the model.

Click **Modify Parameters** to set:

- Parameters to the value recommended for the specified code generation objectives.
  - Code generation objectives in the model to the objectives specified in the Code Generation Advisor.
- 6 In the Code Generation Advisor window, review the results for the remaining checks by selecting them from the left pane. The results for the checks display in the right pane.
  - 7 After reviewing the check results, you can choose to fix warnings and failures, as described in “Fix a Model Advisor Check Warning or Failure”.

When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

## Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box

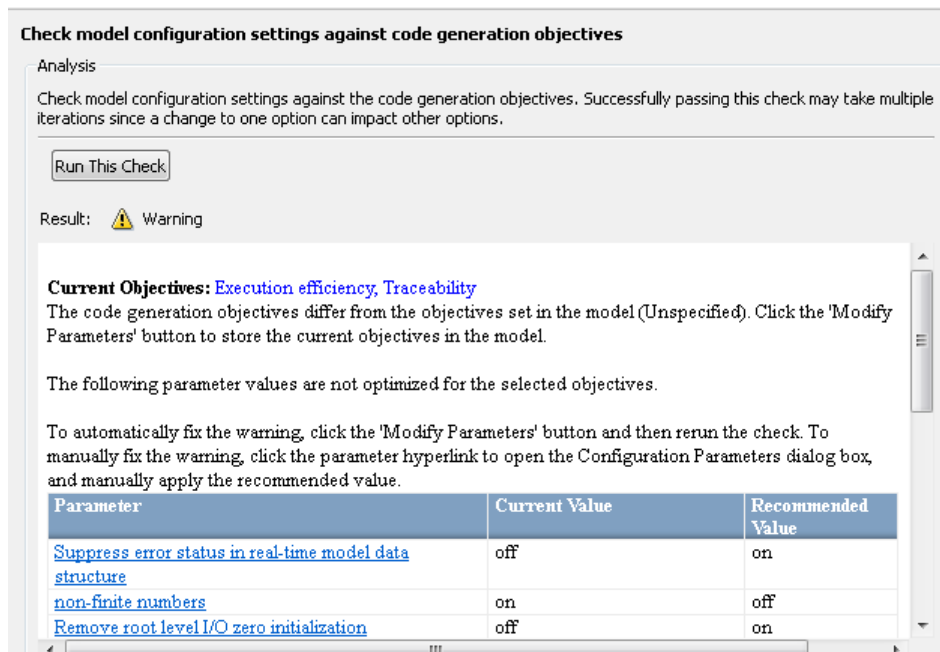

This example shows how to configure and check your model to meet code generation objectives via the Configuration Parameters dialog box:

- 1 Open the Configuration Parameters dialog box. Select **Code Generation**.
- 2 Specify a system target file. If you specify an ERT-based target, more objectives are available. For this example, choose an ERT-based target such as `ert.tlc`.
- 3 Click **Set Objectives**.
- 4 In the “Set Objectives — Code Generation Advisor Dialog Box”, specify your objectives. For example, if your objectives are execution efficiency and traceability, in that priority, do the following:

- a In **Available objectives**, double-click Execution efficiency. Execution efficiency is added to **Selected objectives - prioritized**.
- b In **Available objectives**, double-click Traceability. Traceability is added to **Selected objectives - prioritized** under Execution efficiency.

- c To accept the objectives, click **OK**. In the Configuration Parameters dialog box, **Code Generation > Prioritized objectives** is updated.
- 5 On the **Code Generation** pane, click **Check Model**.
  - 6 In the System Selector window, select the model or subsystem that you want to review, and then click **OK**. The Code Generation Advisor opens and reviews the model or subsystem that you specified.
  - 7 In the Code Generation Advisor window, review the results by selecting a check from the left pane. The results for that check display in the right pane.

- 8 After reviewing the check results, you can choose to fix warnings and failures, as described in “Fix a Model Advisor Check Warning or Failure”.

When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

For more information, see “Set Objectives — Code Generation Advisor Dialog Box”

## Configure Code Generation Objectives Programmatically

This example shows how to configure code generation objectives by writing a MATLAB script or entering commands at the command line.

- 1 Specify a system target file. If you specify an ERT-based target, more objectives are available. For this example, specify `ert.tlc`. *model\_name* is the name or handle to the model.

```
set_param(model_name, 'SystemTargetFile', 'ert.tlc');
```

- 2 Specify your objectives. For example, if your objectives are execution efficiency and traceability, in that priority, enter:

```
set_param(model_name, 'ObjectivePriorities', ...
{'Execution efficiency', 'Traceability'});
```

- 3 Execute the Code Generation Advisor, by using either the Code Generation Advisor or in the Configuration Parameters dialog box. For more information, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 46-2.

When you specify a GRT-based system target file, you can specify an objective at the command line. If you specify ROM efficiency, RAM efficiency, Traceability, MISRA C:2012 guidelines, Polyspace, or Safety precaution, the build process changes the objective to Unspecified because you have specified a value that is invalid when using a GRT-based target.

## Check Model and Configuration for Code Generation

By using Embedded Coder, you can assess whether your model is ready to generate code and also satisfies the intended code generation objectives. These capabilities are provided in:

- Code Generation Advisor — Evaluate whether your model satisfies the intended code generation objectives, such as execution efficiency, traceability, and MISRA C:2012 compliance. For a complete list of high-level objectives, see “High-Level Code Generation Objectives” on page 46-2. By using the advisor interface, you can update the model to satisfies the code generation objectives. For more information, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 46-2.
- Model Advisor — If you have Embedded Coder or Simulink Coder , you use Model Advisor checks to assess the readiness of your model for generating code, including configuration parameter settings and compliance with standards. You can use the advisor interface to modify configuration parameters. For more information, see:
  - “Embedded Coder Model Advisor Checks for Standards, Guidelines, and Code Efficiency” on page 46-9
  - “Simulink Coder Model Advisor Checks for Standards and Code Efficiency” on page 45-21

### Check Model During Code Generation by Using the Code Generation Advisor

To review a model as part of the code generation process, use the Code Generation Advisor.

- 1 To select and prioritize your code generation objectives, on the **Configuration Parameters > Code Generation** pane, click **Set Objectives**.
- 2 On the **Configuration Parameters > Code Generation > General** pane, select one of the following from **Check model before generating code**:
  - On (proceed with warnings)
  - On (stop for warnings)
- 3 If you want to only generate code, select **Generate code only**. Otherwise clear the check box to build an executable.
- 4 Apply your changes. Press **Ctrl+B** to generate code or build the model.

If the Code Generation Advisor issues failures or warnings, and you specified:

- On (proceed with warnings) — The Code Generation Advisor window opens while the build process proceeds. After the build process is complete, you can review the results.
  - On (stop for warnings) — The build process halts and displays the Diagnostic Viewer. To continue, you must review and resolve the Code Generation Advisor results or clear the **Check model before generating code** parameter.
- 5 In the Code Generation Advisor window, review the results by selecting a check from the left pane. The results for that check display in the right pane.
  - 6 After reviewing the check results, you can choose to fix warnings and failures as described in “Fix a Model Advisor Check Warning or Failure”.

---

**Note** When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

---

For more information, see “Set Objectives — Code Generation Advisor Dialog Box”

## Embedded Coder Model Advisor Checks for Standards, Guidelines, and Code Efficiency

To check that your model meets guidelines, standards, and is ready to generate code, you can use the Model Advisor checks available with Embedded Coder.

- On the **Modeling** tab, select **Model Advisor**.
- In the Model Advisor window, expand the **By Product** folder. The **Embedded Coder** folder contains Model Advisor checks that you can run. For a complete list of checks, see “Embedded Coder Checks”.

For more information about the Model Advisor, see “Check Your Model Using the Model Advisor”.

This example shows the use of the Model Advisor to check model `rtwdemo_throttlecntl` for code efficiency.

- 1 Open `rtwdemo_throttlecntl`. Save a copy as `throttlecntl` in a writable location on your MATLAB path.
- 2 On the **Modeling** tab, click **Model Advisor**. A dialog box opens showing the model system hierarchy.
- 3 Click `throttlecntl` and then click **OK**. The Model Advisor window opens.
- 4 Expand **By Task > Code Generation Efficiency**. To check your model for code generation efficiency, use the checks in the folder. By default, checks that do not trigger an Update Diagram are selected. The checks available for code generation efficiency depend on whether you have a Simulink Coder or Embedded Coder license.
- 5 In the left pane, select the remaining checks. Right-click on the **Code Generation Efficiency** folder and select **Run Selected Checks**.

The results shows a **Run Summary** that flags check warnings. The warnings identify issues that impact code efficiency. For more information about the report, see “View Model Advisor Check Reports”.

## Create Custom Code Generation Objectives

### In this section...

“Specify Parameters in Custom Objectives” on page 46-10

“Specify Checks in Custom Objectives” on page 46-10

“Determine Checks and Parameters in Existing Objectives” on page 46-11

“Steps to Create Custom Objectives” on page 46-12

The Code Generation Advisor reviews your model based on objectives that you specify. If the predefined efficiency, traceability, Safety precaution, and debugging objectives do not meet your requirements, you can create custom objectives.

To create custom objectives:

- Create an objective and add parameters and checks to this new objective.
- Create an objective based on an existing objective, then add, modify, and remove the parameters and checks within that new objective.

### Specify Parameters in Custom Objectives

When you create a custom objective, you specify the values of configuration parameters that the Code Generation Advisor reviews. You can use the following methods:

- `addParam` — Add parameters and specify the values that the Code Generation Advisor reviews in **Check model configuration settings against code generation objectives**.
- `modifyInheritedParam` — Modify inherited parameter values that the Code Generation Advisor reviews in **Check model configuration settings against code generation objectives**.
- `removeInheritedParam` — Remove inherited parameters from a new objective that is based on an existing objective. When you select multiple objectives, if another selected objective includes this parameter, the Code Generation Advisor reviews the parameter value in **Check model configuration settings against code generation objectives**.

### Specify Checks in Custom Objectives

Objectives include the **Check model configuration settings against code generation objectives** check by default. When you create a custom objective, you specify the list of additional checks that are associated with the custom objective. You can use the following methods:

- `addCheck` — Add checks to the Code Generation Advisor. When you select the custom objective, the Code Generation Advisor displays the check, unless you specify an additional objective with a higher priority that excludes the check.

For example, add a check to the Code Generation Advisor to include a custom check in the automatic model checking process.

- `excludeCheck` — Exclude checks from the Code Generation Advisor. When you select multiple objectives, if you specify an additional objective that includes this check as a higher priority objective, the Code Generation Advisor displays this check.

For example, exclude a check from the Code Generation Advisor when a check takes a long time to process.

- `removeInheritedCheck` — Remove inherited checks from a new objective that is based on an existing objective. When you select multiple objectives, if another selected objective includes this check, the Code Generation Advisor displays the check.

For example, remove an inherited check, rather than exclude the check, when the check takes a long time to process, but the check is important for another objective.

## Determine Checks and Parameters in Existing Objectives

When you base a new objective on an existing objective, you can determine what checks and parameters the existing objective contains. The Code Generation Advisor contains the list of checks in each objective.

For example, the Efficiency objective includes checks that you can see in the Code Generation Advisor.

- 1 Open the `rtwdemo_rtweccintro` model.
- 2 Specify an ERT-based target.
- 3 On **C Code** tab, click **C/C++ Code Advisor**.
- 4 In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.
- 5 In the Code Generation Advisor, on the **Code Generation Objectives** pane, select the code generation objectives. As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it runs on your model. For this example, select **Execution efficiency**. In **Available objectives**, double-click **Execution efficiency**. **Execution efficiency** is added to **Selected objectives - prioritized**.

In the left pane, the Code Generation Advisor lists the checks for the **Execution efficiency** objective. The first check, **Check model configuration settings against code generation objectives**, lists parameters and values specified by the objective. For example, the Code Generation Advisor displays the list of parameters and the recommended values in the **Execution efficiency** objective. To see the list of parameters and values:

- 1 Run **Check model configuration settings against code generation objectives**.
- 2 Click **Modify Parameters**.
- 3 Rerun the check.

In the check results, the Code Generation Advisor displays the list of parameters and recommended values for the **Execution efficiency** objective.

Passed

Current Objectives: **Execution efficiency**

The following parameters have been checked and confirmed with the recommended value

Parameter	Value
<a href="#">non-inlined S-functions</a>	off
<a href="#">Suppress error status in real-time model data structure</a>	on
<a href="#">MAT-file logging</a>	off
<a href="#">Classic call interface</a>	off
<a href="#">continuous time</a>	off
<a href="#">non-finite numbers</a>	off
<a href="#">Single output/update function</a>	on
<a href="#">Minimize algebraic loop occurrences</a>	off

## Steps to Create Custom Objectives

To create a custom objective:

- 1 Create an `sl_customization.m` file.
  - Specify custom objectives in a single `sl_customization.m` file only or the software generates an error. This issue is true even if you have more than one `sl_customization.m` file on your MATLAB path.
  - Except for the `matlabroot/work` folder, do not place an `sl_customization.m` file in your root MATLAB folder or its subfolders. Otherwise, the software ignores the customizations that the file specifies.
- 2 Create an `sl_customization` function that takes a single argument. When the software invokes the function, the value of this argument is the Simulink customization manager. In the function:
  - To create a handle to the code generation objective, use the `ObjectiveCustomizer` constructor.
  - To register a callback function for the custom objectives, use the `ObjectiveCustomizer.addCallbackObjFcn` method.
  - To add a call to execute the callback function, use the `ObjectiveCustomizer.callbackFcn` method.

For example:

```
function sl_customization(cm)
%SL_CUSTOMIZATION objective customization callback

objCustomizer = cm.ObjectiveCustomizer;
index = objCustomizer.addCallbackObjFcn(@addObjectives);
objCustomizer.callbackFcn{index}();

end
```

- 3 Create a MATLAB callback function that:
  - Creates code generation objective objects by using the `rtw.codegenObjectives.Objective` constructor.
  - Adds, modifies, and removes configuration parameters for each objective by using the `addParam`, `modifyInheritedParam`, and `removeInheritedParam` methods.
  - Includes and excludes checks for each objective by using the `addCheck`, `excludeCheck`, and `removeInheritedCheck` methods.
  - Registers objectives by using the `register` method.

The following example shows how to create an objective Reduce RAM Example. Reduce RAM Example includes five parameters and three checks that the Code Generation Advisor reviews.

```
function addObjectives

% Create the custom objective
obj = rtw.codegenObjectives.Objective('ex_ram_1');
setObjectiveName(obj, 'Reduce RAM Example');

% Add parameters to the objective
addParam(obj, 'DefaultParameterBehavior', 'Inlined');
addParam(obj, 'BooleanDataType', 'on');
addParam(obj, 'OptimizeBlockIOStorage', 'on');
addParam(obj, 'EnhancedBackFolding', 'on');
```

```

addParam(obj, 'BooleansAsBitfields', 'on');

% Add additional checks to the objective
% The Code Generation Advisor automatically includes 'Check model
% configuration settings against code generation objectives' in every
% objective.
addCheck(obj, 'mathworks.design.UnconnectedLinesPorts');
addCheck(obj, 'mathworks.design.Update');

%Register the objective
register(obj);

end

```

The following example shows you how to create an objective `My Traceability Example` based on the existing `Traceability` objective. The custom objective modifies, removes, and adds parameters that the Code Generation Advisor reviews. It also adds and removes checks from the Code Generation Advisor.

```

function addObjectives

% Create the custom objective from an existing objective
obj = rtw.codegenObjectives.Objective('ex_my_trace_1', 'Traceability');
setObjectiveName(obj, 'My Traceability Example');

% Modify parameters in the objective
modifyInheritedParam(obj, 'GenerateTraceReportSf', 'Off');
removeInheritedParam(obj, 'ConditionallyExecuteInputs');
addParam(obj, 'MatFileLogging', 'On');

% Modify checks in the objective
addCheck(obj, 'mathworks.codegen.SWEnvironmentSpec');
removeInheritedCheck(obj, 'mathworks.codegen.CodeInstrumentation');

%Register the objective
register(obj);

end

```

- 4 If you previously opened the Code Generation Advisor, close the model from which you opened the Code Generation Advisor.
- 5 Refresh the customization manager. At the MATLAB command line, enter `sl_refresh_customizations`.
- 6 Open your model and review the new objectives.

## Configuration Variations

Every model contains one or more named configuration sets that specify model parameters such as solver options, code generation options, and other choices. A model can contain multiple configuration sets, but only one configuration set is active at a time. For more information on configuration sets and how to view and edit them in the Configuration Parameters dialog box, see “Manage Configuration Sets for a Model”.

A configuration set includes parameters that specify code generation in general. For more information, see “Configure Model and Generate Code” on page 49-11. With Embedded Coder and an ERT system target file, more parameters are available for fine-tuning to optimize and customize the appearance of the generated code.

Multiple configuration sets can be useful in embedded systems development. By defining multiple configuration sets in a model, you can easily retarget code generation from that model. For example, one configuration set can specify the default ERT target with external mode support enabled for rapid prototyping. Another configuration set can specify the ERT-based target for Visual C++ to generate production code for deployment of the application. Activation of either configuration set fully reconfigures the model for that type of code generation.

## Configure and Optimize Model with Configuration Wizard Blocks

The Embedded Coder software provides a library of Configuration Wizard blocks and scripts to help you configure and optimize code generation from your models.

### In this section...

“Configuration Wizard Block Library” on page 46-15

“Add a Configuration Wizard Block” on page 46-16

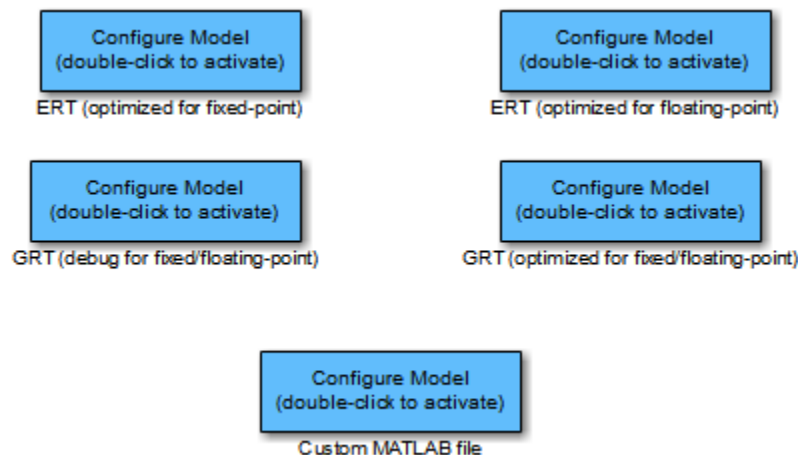

“Use Configuration Wizard Blocks to Configure Your Model” on page 46-17

“Create a Custom Configuration Wizard Block” on page 46-17

### Configuration Wizard Block Library

The library provides a Configuration Wizard block that you can customize. It also provides four preset Configuration Wizard blocks that update the active configuration parameters for a specified goal.

Block	Description
Custom MATLAB file	Update active configuration parameters of parent model by using a custom file
ERT (optimized for fixed-point)	Update active configuration parameters of parent model for ERT fixed-point code generation
ERT (optimized for floating-point)	Update active configuration parameters of parent model for ERT floating-point code generation
GRT (debug for fixed/floating-point)	Update active configuration parameters of parent model for GRT fixed- or floating-point code generation with debugging enabled
GRT (optimized for fixed/floating-point)	Update active configuration parameters of parent model for GRT fixed- or floating-point code generation

When you add one of the preset Configuration Wizard blocks to your model and double-click it, a predefined MATLAB file script configures parameters of the active configuration set without manual intervention. The preset blocks optimally configure the parameters for one of the following cases:

- Fixed-point code generation with the ERT target
- Floating-point code generation with the ERT target
- Fixed-point or floating-point code generation with TLC debugging parameters enabled, with the GRT target.
- Fixed-point or floating-point code generation with the GRT target

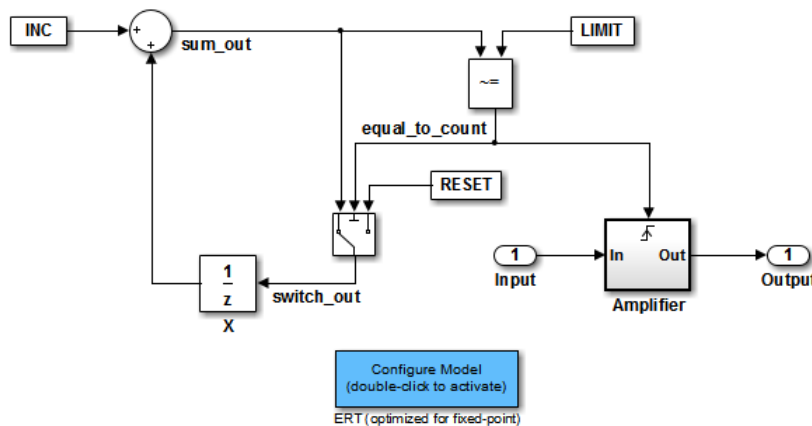

The Custom block provides an example MATLAB file script that you can adapt to your requirements.

You can also set up the Configuration Wizard blocks to invoke the build process after configuring the model.

## Add a Configuration Wizard Block

The Configuration Wizard blocks are available in the Embedded Coder block library. To use a Configuration Wizard block:

- 1 Open the model that you want to configure.
- 2 Open the Embedded Coder block library by typing the command `rtweclib`.
- 3 Double-click the Configuration Wizards icon. The Configuration Wizards sublibrary opens.
- 4 Select the Configuration Wizard block that you want to use and drag it into your model. This model contains the ERT (optimized for fixed-point) Configuration Wizard block.

- 5 If you want the Configuration Wizard block to invoke the build process after configuration, right-click the Configuration Wizard block in your model, and select **Mask > Mask Parameters** from the context menu. Then, select the **Invoke build process after configuration** parameter. Do not change the **Configure the model for** block parameter, unless you want to create a custom block and script. In that case, see “Create a Custom Configuration Wizard Block” on page 46-17.
- 6 Click **Apply** and close the Mask Parameters dialog box.
- 7 Save the model.

## Use Configuration Wizard Blocks to Configure Your Model

After you add a Configuration Wizard block to your model, to configure your model, double-click the block. The script associated with the block sets parameters of the active configuration set that are relevant to code generation (including selection of the target). You can see that the parameters have changed by opening the Configuration Parameters dialog box and examining the parameter settings.

If you selected the **Invoke build process after configuration** block parameter, the script also initiates the code generation and build process.

---

**Note** To provide a quick way to switch between configurations, you can add more than one Configuration Wizard block to your model.

---

## Create a Custom Configuration Wizard Block

The Custom Configuration Wizard block and the associated MATLAB file script, *matlabroot/toolbox/coder/simulinkcoder\_core/rtwsampleconfig.m*, provide a starting point for customization.

### Set Up a Configuration Wizard Block

Set up a custom Configuration Wizard block and link it to a script. If you want to use the block in more than one mode, it is advisable to create a Simulink library to contain the block.

To begin, make a copy of the example script for later customization:

- 1 To store your custom script, create a folder. This folder must not be anywhere inside the MATLAB folder structure (that is, it must not be under *matlabroot*).

The example refers to this folder as */my\_wizards*.

- 2 Add the folder to the MATLAB path. Save the path for future sessions.
- 3 Copy the example script *rtwsampleconfig.m* in the folder *matlabroot/toolbox/rtw/rtw* (open) to the */my\_wizards* folder that you created. Then, rename the script. This example uses the name *my\_configscript.m*.
- 4 Open the example script into the MATLAB editor. Scroll to the end of the file and enter the following line of code:

```
disp('Custom Configuration Wizard Script completed.');
```

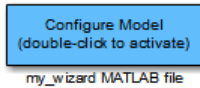

This statement is used later as a test to see that your custom block has executed the script.

- 5 Save your script and close the MATLAB editor.

The next task is to create a Simulink library and add a custom block to it.

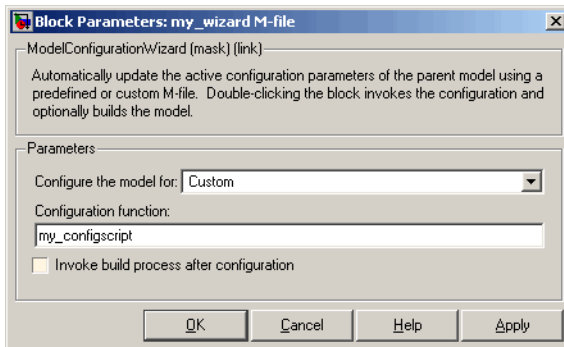

- 1 Open the Embedded Coder block library and the Configuration Wizards sublibrary, as described in “Add a Configuration Wizard Block” on page 46-16.
- 2 On the **Library** tab, select **New > Library**. From the Simulink Start Page, choose a Blank Library. An empty library window opens.
- 3 Select the Custom MATLAB file block from the Configuration Wizards sublibrary and drag it into the empty library window.

- 4 To distinguish your custom block from the original, edit the Custom MATLAB file label under the block.
- 5 On the **Library** tab, select **Save > Save as**. Save the library to the `/my_wizards` folder, under your library name of choice. In this figure, the library is saved as `ex_custom_button` and the block is labeled `my_wizard MATLAB-file`.

The next task is to link the custom block to the custom script:

- 1 Right-click the block in your model and select **Mask > Mask Parameters** from the context menu. The **Configure the model for** menu is set to `Custom`. When `Custom` is selected, the **Configuration function** edit field is enabled so that you can enter the name of a custom script.
- 2 In the **Configuration function** field, enter the name of your custom script. (Do not enter the `.m` file name extension, which is implicit.)

- 3 By default, the **Invoke build process after configuration** parameter is cleared. You can change the default for your custom block by selecting this option. For now, leave this parameter cleared.
- 4 Click **Apply** and close the Mask Parameters dialog box.
- 5 Save the library.
- 6 Close the Embedded Coder block library and the Configuration Wizards sublibrary. Leave your custom library open for use in the next task.

Test your block and script in a model.

- 1 Open the `vdp` model by typing the command:
 

```
vdp
```
- 2 Open the Configuration Parameters dialog box and view the parameters by clicking **Code Generation** in the list in the left pane of the dialog box.
- 3 Observe that `vdp` is configured, by default, for the GRT target. Close the Configuration Parameters dialog box.
- 4 Select your custom block from your custom library. Drag the block into the `vdp` model.
- 5 In the `vdp` model, double-click your custom block.
- 6 In the MATLAB window, you see the test message that you previously added to your script:
 

```
Custom Configuration Wizard Script completed.
```

The test message indicates that the custom block executed the script.

- 7 Reopen the Configuration Parameters dialog box and view the **Code Generation** pane again. The model is now configured for the ERT target.

Before applying further edits to your custom script, proceed to the next section to learn about the operation and conventions of Configuration Wizard scripts.

### Create a Configuration Wizard Script

Create your custom Configuration Wizard script by copying and modifying the example script, `rtwsampleconfig.m`.

#### The Configuration Function

The example script implements a single function without a return value. The function takes a single argument `cs`:

```
function rtwsampleconfig(cs)
```

The argument `cs` is a handle to a proprietary object that contains information about the active configuration set. The Simulink software obtains this handle and passes it in to the configuration function when you double-click a Configuration Wizard block.

Your custom script must conform to this prototype. Your code must use `cs` as a “black-box” object that transmits information to and from the active configuration set.

#### Access Configuration Set Parameters

To set parameters or obtain parameter values, use the Simulink `set_param` and `get_param` functions.

Option names are passed in to `set_param` and `get_param` as character vectors specifying an *internal option name*. The internal option name can be different from the option label on the UI (for example, the Configuration Parameters dialog box). The example configuration accompanies each `set_param` and `get_param` call with a comment that correlates internal option names to UI option labels. For example:

```
set_param(cs, 'LifeSpan', '1'); % Application lifespan (days)
```

To obtain the current setting of an option in the active configuration set, call `get_param`. Pass in the `cs` object as the first argument, followed by the internal option name. For example, the following code excerpt tests the setting of the **Create code generation report** option:

```
if strcmp(get_param(cs, 'GenerateReport'), 'on')
 ...
end
```

To set an option in the active configuration set, call `set_param`. Pass in the `cs` object as the first argument, followed by one or more parameter/value pairs that specify the internal option name and its value. For example, the following code excerpt turns off the **Support absolute time** option:

```
set_param(cs, 'SupportAbsoluteTime', 'off');
```

#### Select a Target

A Configuration Wizard script must select a target configuration. The example script uses the ERT target as a default. The script first stores character vector variables that correspond to the required **System target file**, **Template makefile**, and **Make command** settings:

```
stf = 'ert.tlc';
tmf = 'ert_default_tmf';
mc = 'make_rtw';
```

You select the system target file by passing the `cs` object and the `stf` character vector to the `switchTarget` function:

```
switchTarget(cs,stf,[]);
```

Set the template makefile and make command options by using `set_param` calls:

```
set_param(cs,'TemplateMakefile',tmf);
set_param(cs,'MakeCommand',mc);
```

To select a target, your custom script must set up the character vector variables `stf`, `tmf`, and `mc` and pass them to the calls.

### Obtain Target and Configuration Set Information

The following utility functions and properties are provided so that your code can obtain information about the current target and configuration set with the `cs` object:

- `isValidParam(cs, 'option')`: The `option` argument is an internal option name. `isValidParam` returns true if `option` can be accessed by using the `get_param` function in the context of the active configuration set.
- `getPropEnabled(cs, 'option')`: The `option` argument is an internal option name. Returns true if this `option` is enabled (that is, writable).
- `IsERTTarget` property: Your code can detect whether the currently selected target is derived from the ERT target by checking the `IsERTTarget` property, as follows:

```
isERT = strcmp(get_param(cs,'IsERTTarget'),'on');
```

You can use this information to determine whether the script must configure ERT-specific parameters, for example:

```
if isERT
 set_param(cs,'ZeroExternalMemoryAtStartup','off');
 set_param(cs,'ZeroInternalMemoryAtStartup','off');
 set_param(cs,'InitFltsAndDblsToZero','off');
 set_param(cs,'NoFixptDivByZeroProtection','on')
end
```

### Invoke a Configuration Wizard Script from the Command Line

Configuration Wizard scripts can be run from the MATLAB command line.

Before invoking the script, you must open a model and instantiate a `cs` object to pass in as an argument to the script. After running the script, you can invoke the build process with the `slbuild` command. The following example opens, configures, and builds a model.

```
open my_model;
cs = getActiveConfigSet ('my_model');
rtwsampleconfig(cs);
slbuild('my_model');
```

## Aircraft Position Radar Model

This model shows the code generated for a Simulink model containing a MATLAB script.

The model contains an Extended Kalman Filter that estimates aircraft position from radar measurements. The MATLAB script `rtwdemo_eml_aero_radar.m` contains data for running the model. The estimated and actual positions are saved to the workspace and are plotted at the end of the simulation by the program `rtwdemo_aero_radplot` (called from the simulation automatically).

### Review and Simulate the Model

In this section you should review the model and perform a simulation.

Open the Simulink model.

```
model='rtwdemo_eml_aero_radar';
open_system(model)
rtwdemo_eml_aero_radar([],[],[],'compile');
rtwdemo_eml_aero_radar([],[],[],'term');
```

Open the MATLAB Function block `RadarTracker` in the MATLAB Editor.

```
open_system([model, '/RadarTracker'])
```

```

Block: rtwdemo_eml_aero_radar/RadarTracker

### Generate Code for the Model

In this section you will generate code for the Kalman Filter portion of the model using the subsystem build functionality provided by Simulink Coder. In the first build, the model is configured to generate code using Simulink Coder. In the second build, the model is configured to generate code using Embedded Coder.

```
% Create a temporary folder (in your system's temporary folder) for the
% build and inspection process.
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Configure and build the model using Simulink Coder.

```
rtwconfiguredemo(model, 'GRT')
slbuild([model, '/RadarTracker'])
```

```
Starting build procedure for: RadarTracker
Successful completion of build procedure for: RadarTracker
```

## Build Summary

Top model targets built:

Model	Action	Rebuild Reason
RadarTracker	Code generated and compiled	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 47.489s

Configure and build the model using Embedded Coder.

```
rtwconfiguredemo(model, 'ERT')
slbuild([model, '/RadarTracker'])
```

```
Starting build procedure for: RadarTracker
Successful completion of build procedure for: RadarTracker
```

# System Target File Configuration

---

- “Configure a System Target File” on page 47-2
- “Configure STF-Related Code Generation Parameters” on page 47-5
- “Configure a Code Replacement Library” on page 47-12
- “Configure Standard Math Library for Target System” on page 47-13
- “Compare System Target File Support Across Products” on page 47-16

## Configure a System Target File

To configure a model for code generation, follow the steps in “Select a Solver That Supports Code Generation” and “Select a System Target File from STF Browser”. When you select a system target file, other model configuration parameters change to serve requirements of the execution environment. For example:

- Code interface parameters
- Build process parameters, such as the toolchain or template makefile
- Target hardware parameters, such as word size and byte ordering

After selecting a system target file, you can modify model configuration parameter settings.

You can switch between different system target files in a single workflow for different code generation purposes (for example, rapid prototyping versus production code deployment). To switch, set up different configuration sets for the same model and switch the active configuration set for the current operation. For more information on how to set up configuration sets and change the active configuration set, see “Manage Configuration Sets for a Model”.

### Select a Solver That Supports Code Generation

To build a model, the model configuration must specify a solver that is compatible with code generation for the system target file. Few system target files support code generation with variable-step solvers or for models with a nonzero start time.

- For GRT, ERT, and ERT-based system target files, set the **Type** configuration parameter to **Fixed-step**.
- For Rapid Simulation (Rsim) or S-Function (rtwsfcn) system target files, set the **Type** configuration parameter to **Fixed-step** or **Variable-step**.

For more information about the requirement that you use a fixed-step solver to generate code for a realtime system target file, see “Time-Based Scheduling and Code Generation” on page 28-2.

The Rapid Simulation (RSim) system target file supports a nonzero start time when the **Solver selection** configuration parameter is set to **Use Simulink solver module**. Other system target files do not support a nonzero start time -- the code generator does not produce code and the build process produces an error.

### Select a System Target File from STF Browser

After you select a solver (see “Select a Solver That Supports Code Generation”), specify a value for the **System target file** configuration parameter. Enter the name of your system target file directly in the field or use the System Target File Browser to select a file.

To use the System Target File Browser:

- 1 In the configuration parameters dialog box, next to the **System target file** field, click the **Browse** button. The browser displays a list of available system target files, including customizations.
- 2 From the list, select your file, for example, the GRT system target file (`grt.tlc`). The background of the list box turns yellow to indicate that the choice is not applied. Click **Apply** or **OK**.

### System Target File Browser

You also can select a system target file programmatically from MATLAB code, as described in “Select a System Target File Programmatically” on page 47-3.

After selecting a system target file, you can modify model configuration parameter settings. Selecting a system target file for your model selects either the toolchain approach or template makefile approach for build process control. For more information about these approaches, see “Configure Toolchain or Template Makefile Build Process” on page 56-12.

If you want to switch between different system target files in a single workflow for different code generation purposes, set up different configuration sets for the same model. Switch the active configuration set for the current operation. This approach is useful for switching between rapid prototyping and production code deployment. For more information on how to set up configuration sets and change the active configuration set, see “Manage Configuration Sets for a Model”.

## Select a System Target File Programmatically

Simulink models store model-wide parameters and system target file-specific data in *configuration sets*. Every configuration set contains a component that defines the structure of a particular system target file and the current values of relevant options. Simulink loads some of this information from the system target file that you specify. You can configure models to generate alternative code by copying and modifying old or adding new configuration sets and browsing to select a new system target file. Then, you can interactively select an active configuration from among these sets (only one configuration set can be active at a given time).

Scripts that automate system target file selection must emulate this process.

To program system target file selection:

- 1 Obtain a handle to the active configuration set with a call to the `getActiveConfigSet` function.
- 2 Define character vector variables that correspond to the required system target file, toolchain or template makefile, and/or make command settings. For example, for the ERT system target file, you would define variables for the character vectors `'ert.tlc'`, `'ert_default_tmf'`, and `'make_rtw'`.
- 3 Select the system target file with a call to the `switchTarget` function. In the function call, specify the handle for the active configuration set and the system target file.
- 4 Set the `TemplateMakefile` and `MakeCommand` configuration parameters to the corresponding variables created in step 2.

For example:

```
cs = getActiveConfigSet(model);
stf = 'ert.tlc';
tmf = 'ert_default_tmf';
mc = 'make_rtw';
switchTarget(cs,stf,[]);
set_param(cs,'TemplateMakefile',tmf);
set_param(cs,'MakeCommand',mc);
```

For more information about selecting system target files programmatically, see `switchTarget`.

## Develop Custom System Target Files

You can create your own system target files that interface with external code or operating environments.

For more information on how to make custom system target files appear in the System Target File Browser and display relevant controls, see “Custom Targets” and the topics it references.

## Configure STF-Related Code Generation Parameters

Many model configuration parameters for code generation are specific to GRT, ERT, or ERT-based system target files.

### Specify Generated Code Interfaces

Use interface model configuration parameters to control which libraries to use when generating code, whether to include support for an API in generated code, and other interface options.

To...	Select or Enter...
Specify the language standard that the code generator uses when generating code.	<p>Select C89/C90 (ANSI), C99 (ISO), or C++03 (ISO) for the <b>Language standard</b> parameter.</p> <p>Selecting C89/C90 (ANSI) provides the ANSI<sup>a</sup> C set of library functions. For example, selecting C89/C90 (ANSI) results in generated code that calls <code>sin()</code> whether the input argument is double precision or single precision. However, if you select C99 (ISO), the generated code calls the function <code>sinf()</code> when the input argument is single precision. If your compiler supports the ISO<sup>b</sup> C math extensions, selecting the ISO C library can result in more efficient code.</p> <p>For more information, see “Language standard”.</p> <p>The options for this parameter have dependencies. See Interface Dependencies.</p>
Specify an application-specific library that the code generator uses when generating code.	<p>If you generate application-specific C or C++ code for math functions or operations, select a value for <b>Code replacement library</b>. Otherwise, specify <b>None</b>.</p> <p>For more information about code replacement libraries, see “Choose a Code Replacement Library” on page 53-6 and “Code replacement library”.</p> <p>The options for this parameter have dependencies. See Interface Dependencies.</p>
Direct where the code generator places fixed-point and other utility code.	<p>Select <b>Auto</b> or <b>Shared</b> location for <b>Shared code placement</b>. The shared location directs code for utilities to be placed within the <code>slprj</code> folder in your working folder, which is used for building referenced models. If you select <b>Auto</b>,</p> <ul style="list-style-type: none"> <li>• When the model contains Model blocks, places utility code within the <code>slprj/target/_sharedutils</code> folder.</li> <li>• When the model does not contain Model blocks, places utility code in the build folder (generally, in <code>model.c</code> or <code>model.cpp</code>).</li> </ul>
Specify text to be added to the variable names used when logging data to MAT-files and to distinguish logging data from code generation and simulation applications.	<p>Enter a prefix or suffix, such as <code>rt_</code> or <code>_rt</code>, for the <b>MAT-file variable name modifier</b> parameter. The code generator prefixes or appends the text to the variable names for system outputs, states, and simulation time specified in the <b>Data Import/Export</b> pane. See “Log Program Execution Results” on page 58-2 for information on MAT-file data logging.</p>

To...	Select or Enter...
Specify data exchange APIs to be included in generated code.	<p>Select one or more <b>C API</b> options, the <b>ASAP2 interface</b> option, or the <b>External mode</b> option. When you select <b>External mode</b>, other options appear. The data exchange APIs are independent, and you can select combinations of these APIs. For example, you could choose C API and external mode.</p> <p>For more information on working with these interfaces, see “Exchange Data Between Generated and External Code Using C API” on page 59-2, “Export ASAP2 File for Data Measurement and Calibration” on page 60-2, and “External Mode Simulations for Parameter Tuning and Signal Monitoring”.</p> <p>The options for this parameter have dependencies. See Interface Dependencies.</p>

a ANSI is a registered trademark of the American National Standards Institute, Inc.

b ISO is a registered trademark of the International Organization for Standardization.

---

**Note** Before setting **Language standard** or **Code replacement library**, verify that your compiler supports the library you want to use. If you select a parameter value that your toolchain does not support, compiler errors can occur. For example, if you select the language standard C99 (ISO) and your compiler does not support the ISO C math extensions, compile-time errors could occur.

---

When the Embedded Coder product is installed on your system, the **Code Generation > Interface** pane expands to include several additional options. For descriptions of **Code Generation > Interface** pane parameters, see “Model Configuration Parameters: Code Generation Interface”.

Several interface parameters have dependencies on settings of other parameters. The following table summarizes the dependencies.

## Interface Dependencies

Parameter	Dependencies?	Dependency Details
<b>Language standard</b>	Yes	Available values depend on <b>Language</b> selection.
<b>Code replacement library</b>	Yes	Available values depend on product licensing and other parameters. For more information, see “Code replacement library”.
<b>Shared code placement</b>	No	
<b>Support: floating-point numbers</b> (ERT system target files only)	No	
<b>Support: non-finite numbers</b>	Yes (ERT) No (GRT)	For ERT system target files, enabled by <b>Support floating-point numbers</b>
<b>Support: complex numbers</b> (ERT system target files only)	No	
<b>Support: absolute time</b> (ERT system target files only)	No	
<b>Support: continuous time</b> (ERT system target files only)	Yes	Requires that you disable <b>Remove error status field in real-time model data structure</b> .
<b>Support: non-inlined S-functions</b> (ERT system target files only)	Yes	Requires that you enable <b>Support floating-point numbers</b> and <b>Support non-finite numbers</b>
<b>Classic call interface</b>	Yes	Requires that you disable <b>Single output/update function</b> . For ERT system target files, requires that you enable <b>Support floating-point numbers</b> .
<b>Single output/update function</b>	Yes	Disable for <b>Classic call interface</b>
<b>Terminate function required</b> (ERT system target files only)	Yes	
<b>Code interface packaging</b>	Yes	Available values depend on <b>Language</b> selection.
<b>Multi-instance code error diagnostic</b>	Yes	Set <b>Code interface packaging</b> to Reusable function or C++ class
<b>Pass root-level I/O as</b> (ERT system target files only)	Yes	Set <b>Code interface packaging</b> to Reusable function
<b>Use dynamic memory allocation for model initialization</b> (ERT system target files only)	Yes	Set <b>Code interface packaging</b> to Reusable function
<b>MAT-file logging</b>	Yes	For GRT system target files, requires that you enable <b>Support non-finite numbers</b> ; for ERT system target files, requires that you enable <b>Support floating-point numbers</b> , <b>Support non-finite numbers</b> , and <b>Terminate function required</b>

Parameter	Dependencies?	Dependency Details
<b>MAT-file file variable name modifier</b>	Yes	Enabled by <b>MAT-file logging</b>
<b>Remove error status field in real-time model data structure</b> (ERT system target files only)	Yes	Requires that you disable <b>Support: continuous time</b> .
<b>Generate C API for: signals</b>	No	
<b>Generate C API for: parameters</b>	No	
<b>Generate C API for: states</b>	No	
<b>Generate C API for: root-level I/O</b>	No	
<b>ASAP2 interface</b>	No	
<b>External mode</b>	No	
<b>Transport layer</b>	Yes	Enable <b>External mode</b>
<b>MEX-file arguments</b>	Yes	Enable <b>External mode</b>
<b>Static memory allocation</b>	Yes	Enable <b>External mode</b>
<b>Static memory buffer size</b>	Yes	Enable <b>Static memory allocation</b>

## Configure Numeric Data Support

By default, ERT system target files support code generation for integer, floating-point, nonfinite, and complex numbers.

To Generate Code That Supports...	Do...
Integer data only	Clear <b>Support floating-point numbers</b> . If noninteger data or expressions are encountered during code generation, an error message reports the offending blocks and parameters.
Floating-point data	Select <b>Support floating-point numbers</b> .
Nonfinite values (for example, NaN, Inf)	Select <b>Support floating-point numbers</b> and <b>Support non-finite numbers</b> .
Complex data	Select <b>Support complex numbers</b> .

For more information, see “Model Configuration Parameters: Code Generation Interface”.

## Configure Time Value Support

Certain blocks require the value of absolute time, elapsed time, or continuous time. Absolute time is the time from the start of program execution to the present time. Elapsed time is the time elapsed between two trigger events. Depending on the blocks used, your model could require adjustment of the configuration settings for supported time values.

To...	Select...
Generate code that creates and maintains integer counters for blocks that use absolute or elapsed time values (default).	<b>Support absolute time.</b> For further information on the allocation and operation of absolute and elapsed timers, see “Absolute and Elapsed Time Computation”. If you do not select this parameter and the model includes a block that uses absolute or elapsed time values, the build process generates an error.
Generate code for blocks that rely on continuous time.	<b>Support continuous time.</b> If you do not select this parameter and the model includes continuous-time blocks, the build process generates an error.

For more information, see “Model Configuration Parameters: Code Generation Interface”.

## Configure Noninlined S-Function Support

To generate code for noninlined S-Functions in a model, select **Support noninlined S-functions**. The generation of noninlined S-functions requires floating-point and nonfinite numbers. Thus, when you select **Support non-inlined S-functions**, the ERT system target file selects **Support floating-point numbers** and **Support non-finite numbers**.

When you select **Support non-finite numbers** and the model includes a C MEX S-function that does not have a corresponding TLC implementation (for inlining code generation), the build process generates an error.

Inlining S-functions is highly advantageous in production code generation, for example in implementing device drivers. To enforce the use of inlined S-functions for code generation, clear **Support non-inlined S-functions**.

When generating code for a model that contains noninlined S-functions with an ERT system target file, there can be a mismatch between the simulation and code generation results when either of the following is true:

- Model configuration parameter `GenCodeOnly` is set to off.
- Model configuration parameter `ProdEqTarget` is set to off.

To avoid such a mismatch, set `ProdEqTarget` to on or set `GenCodeOnly` to on.

## Configure Model Function Generation and Argument Passing

For ERT system target files, you can configure model for how functions are generated and how arguments are passed to the functions.

To...	Do...
Generate model function calls that are compatible with the main program module of the pre-R2012a GRT system target file ( <code>grt_main.c</code> or <code>.cpp</code> ).	Select <b>Classic call interface</b> and <b>MAT-file logging</b> . In addition, clearing <b>Remove error status field in real-time model data structure</b> . <b>Classic call interface</b> provides a quick way to use code generated in R2012a or higher with a pre-R2012a GRT-based custom system target file by generating wrapper function calls that interface to the generated code.

To...	Do...
Reduce overhead and use more local variables by combining the output and update functions in a single <i>model_step</i> function.	Select <b>Single output/update function</b> Errors or unexpected behavior can occur if a Model block is part of a cycle and the model configuration enables “Single output/update function” (the default). For more information about direct feed through, see “Algebraic Loop Concepts”.
Generate a <i>model_terminate</i> function for a model not designed to run indefinitely.	Select <b>Terminate function required</b> . For more information, see the description of <i>model_terminate</i> .
Generate reusable, reentrant code from a model or subsystem.	Select <b>Generate reusable code</b> . See “Configure Code Reuse Support” on page 47-10 for details.
Statically allocate model data structures and access them directly in the model code.	Clear <b>Generate reusable code</b> . The generated code is not reusable or reentrant. See “Configure Generated C Function Interface for Model Entry-Point Functions” for information on the calling interface generated for model functions in this case.
Suppress the generation of an error status field in the real-time model data structure, <i>rtModel</i> , for example, if you do not require to log or monitor error messages.	Select <b>Remove error status field in real-time model data structure</b> . Selecting this parameter can also cause the code generator to omit the <i>rtModel</i> structure from the generated code.  When generating code for multiple integrated models, set this parameter the same for all of the models. Otherwise, the integrated application could exhibit unexpected behavior. For example, if you select the option in one model but not in another, it is possible that the integrated application could not register the error status.  Do not select this parameter if you select the <b>MAT-file logging</b> option. The two options are incompatible.
Open the Configure C Step Function Interface dialog box and modify the <i>model_step</i> function prototype.	In the Code Mapping Editor, on the <b>Entry-Point Functions</b> tab, click in the Function Name column for the base-rate step function. Click the three vertical dots that appear. Then click <b>Configure Prototype</b> . Unless a function prototype was previously configured, the dialog box opens showing a preview of the step function interface without arguments ( <i>void-void</i> ). The dialog box also shows the current function name. If arguments have previously been configured for the model, the dialog box displays the current settings. You can change the name and argument settings for the step function. For more information, see “Configure Name and Arguments for Individual Step Functions” on page 32-119.

For more information, see “Model Configuration Parameters: Code Generation Interface”.

## Configure Code Reuse Support

For GRT, ERT, GRT-based, and ERT-based system target files, you can configure how a model reuses code by setting the **Code interface packaging** configuration parameter value to **Reusable function**.

The **Pass root-level I/O as** configuration parameter provides options that control how model inputs and outputs at the root level of the model are passed to the *model\_step* function.

To...	Select...
Pass each root-level model input and output argument to the <i>model_step</i> function individually (the default)	<b>Code interface packaging</b> > Reusable function and <b>Pass root-level I/O as</b> > Individual arguments.
Pack root-level input arguments and root-level output arguments into separate structures that are then passed to the <i>model_step</i> function	<b>Code interface packaging</b> > Reusable function and <b>Pass root-level I/O as</b> > Structure reference.
Pack root-level input arguments and root-level output arguments into the model data structure to support reentrant multi-instance code from a model for ERT system target file	<b>Code interface packaging</b> > Reusable function and <b>Pass root-level I/O as</b> > Part of model data structure.

If using the **Code interface packaging** > Reusable function selection, consider using the **Use dynamic memory allocation for model initialization** option to control whether an allocation function is generated. This option applies for ERT system target files.

Sometimes, selecting **Code interface packaging** as Reusable function can generate code that compiles but is not reentrant. For example, if a signal, DWork structure, or parameter data has a storage class other than Auto, global data structures are generated. To handle such cases, use the **Multi-instance code error diagnostic** parameter to choose the severity levels for diagnostics.

Sometimes, the code generator is unable to generate valid and compilable code. For example, if the model contains one of the following, the generated code is invalid.

- An S-function that is not code-reuse compliant
- A subsystem triggered by a wide function-call trigger

In these cases, the build terminates after reporting the problem.

For more information, see “Generate Reentrant Code from Top Models” on page 7-18 and “Model Configuration Parameters: Code Generation Interface”.

- “Configure a Code Replacement Library” on page 47-12
- “Configure Standard Math Library for Target System” on page 47-13
- “Compare System Target File Support Across Products” on page 47-16

## Configure a Code Replacement Library

You can configure the code generator to change the code that it generates for functions and operators such that the code meets application requirements. Configure the code generator to apply a code replacement library (CRL) during code generation. If you have Embedded Coder, you can develop and apply custom code replacement libraries.

For more information about replacing code, using code replacement libraries that MathWorks provides, see “What Is Code Replacement?” on page 54-2 and “Code Replacement Libraries”. For information about developing code replacement libraries, see “What Is Code Replacement Customization?” on page 69-3.

- “Configure Standard Math Library for Target System” on page 47-13
- “Compare System Target File Support Across Products” on page 47-16
- “Specify Generated Code Interfaces” on page 47-5

## Configure Standard Math Library for Target System

Specify standard library extensions that the code generator uses for math operations. When you generate code for a new model or with a new configuration set object, the code generator uses the ISO®/IEC 9899:1999 C (C99 (ISO)) library by default. For preexisting models and configuration set objects, the code generator uses the library specified by the **Standard math library** parameter.

If your compiler supports the ISO®/IEC 9899:1990 (C89/C90 (ANSI)), ISO/IEC 14882:2003(C++03 (ISO) or ISO/IEC 14882:2011(C++11 (ISO)) math library extensions, you can change the standard math library setting. The C++03 (ISO) or C++11 (ISO) library is an option when you select C++ for the programming language.

The C99 library leverages the performance that a compiler offers over standard ANSI C. When using the C99 library, the code generator produces calls to ISO C functions when possible. For example, the generated code calls the function `sqrtf()`, which operates on single-precision data, instead of `sqrt()`.

To change the library setting, use the **Configuration Parameters>Standard math library** parameter. The command-line equivalent is `TargetLangStandard`.

### Generate and Inspect ANSI C Code

1. Open the example model `rtwdemo_clibsup`.

Copyright 1994-2020 The MathWorks, Inc.

2. Generate code.

```
Starting build procedure for: rtwdemo_clibsup
Successful completion of code generation for: rtwdemo_clibsup
```

## Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_clibsup	Code generated	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 32.567s

3. Examine the code in the generated file `rtwdemo_clibsup.c`. Note that the code calls the `sqrt` function.

```
if (rtb_Abs2 < 0.0F) {
 rtb_Abs2 = -(real32_T)sqrt((real32_T)fabs(rtb_Abs2));
} else {
 rtb_Abs2 = (real32_T)sqrt(rtb_Abs2);
}
```

**Generate and Inspect ISO C Code**

1. Change the setting of **Standard math library** to C99 (ISO). Alternatively, at the command line, set `TargetLangStandard` to C99 (ISO).

2. Regenerate the code.

```
Starting build procedure for: rtwdemo_clibsup
Successful completion of code generation for: rtwdemo_clibsup
```

## Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_clibsup	Code generated	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 39.814s

3. Reexamine the code in the generated file `rtwdemo_clibsup.c`. Now the generated code calls the function `sqrtf` instead of `sqrt`.

```
if (rtb_Abs2 < 0.0F) {
 rtb_Abs2 = -sqrtf(fabsf(rtb_Abs2));
} else {
 rtb_Abs2 = sqrtf(rtb_Abs2);
}
```

## Compare System Target File Support Across Products

When you select a system target file (such as `grt.tlc`), the selection defines the run-time environment and the code generation features. Identify the system target file features that match your code generation workflow goals.

The code generator uses the system target file to produce code intended for execution on certain target hardware or on a certain operating system. The system target file invokes other run-time environment-specific files. For more information on configuring model code generation parameters for target hardware, see “Configure Run-Time Environment Options”.

Different types of system target files support a selection of generated code features. In the system target file, the value of the `CodeFormat` TLC variable and corresponding `rtwgensettings.DerivedFrom` field value identify the system target file type and generated code features. These selections apply your code generation control decisions at several points in the code generation process. Your selections include whether and how the model build generates:

- Certain data structures (for example, `SimStruct` or `rtModel`)
- Static or dynamic memory allocation code
- Calling interface for generated model functions

For custom system target file development, the `CodeFormat` value differs among code generation targets:

- If the system target file does not include a value for the `CodeFormat` TLC variable, the default value is `RealTime` for generic real-time target (GRT). The corresponding `rtwgensettings.DerivedFrom` field value is `grt.tlc` (default value).
- If you are developing a custom system target file and you have Embedded Coder software, consider setting the `CodeFormat` TLC variable value to `Embedded-C` for embedded real-time target (ERT). The corresponding `rtwgensettings.DerivedFrom` field value is `ert.tlc`. The ERT system target file supports more generated code features than the GRT system target file.

This example shows how the value for the `CodeFormat` TLC variable and corresponding `rtwgensettings.DerivedFrom` field value are set in `ert.tlc`.

```
%assign CodeFormat = "Embedded-C"

/%
BEGIN_RTW_OPTIONS
 rtwgensettings.DerivedFrom = 'ert.tlc';
END_RTW_OPTIONS
%/
```

---

**Note** Use the value for the `CodeFormat` TLC variable with its corresponding `rtwgensettings.DerivedFrom` field value to generate code for the model. If you do not select a value explicitly, the default values apply. For the `rtwgensettings.DerivedFrom` field, use `'ert.tlc'` or `'grt.tlc'`. For more information, see “System Target File Structure”.

---

For a description of the optimized call interface generated by default for the GRT and ERT system target files, see “Configure Generated C Function Interface for Model Entry-Point Functions”.

Code generation with the GRT and ERT system target files uses the real-time model data structure (`rtModel`). This structure encapsulates model-specific information in a much more compact form

than the simulation structure, `SimStruct`. Many efficient features of generated code depend on generation of `rtModel` rather than `SimStruct`, including:

- Integer absolute and elapsed timing services
- Independent timers for asynchronous tasks
- Generation of improved C API code for signal, state, and parameter monitoring
- Pruning the data structure to minimize its size (ERT-derived system target files only)

For a description of the `rtModel` data structure, see “Real-Time Model Data Structure” on page 33-32.

## Compare Product System Target Files

You can select from a range of system target files by using the System Target File Browser. This selection lets you experiment with configuration options and save your model with different configurations.

You cannot build or generate code for non-GRT system target files, unless you have the required software on your system. For example, you require Embedded Coder for ERT system target files, Simulink Desktop Real-Time for SLDRT system target files, and so on.

Selecting a system target file for your model selects either the toolchain approach or the template makefile approach for build process control. For more information about these approaches, see “Approaches for Building Code Generated from Simulink Models” on page 56-11.

**Note** To create and build a Visual C++ Solution (.sln) file with Debug configuration, select RTW.MSVCCBuild in the “Template makefile” field.

## Compare Code Styles and STF Support

The code generator produces two styles of code. One code style is suitable for rapid prototyping (and simulation by using code generation). The other style is suitable for embedded applications. This table maps system target files to corresponding code styles.

### Code Styles Listed by System Target File

System Target File	Code Style	Purpose
Embedded Coder embedded real-time (ERT)	Embedded	A starting point for embedded application development of C/C++ generated code.
Simulink Coder generic real-time (GRT)	Rapid prototyping	A starting point for creating a rapid prototyping target hardware that does not use real-time operating system tasking primitives and for verifying the generated C/C++ code on your desktop computer.
Rapid simulation (RSim)	Rapid prototyping	Provides non-real-time simulation on your desktop computer and a high-speed or batch simulation tool.
S-function	Rapid prototyping	Creates a C MEX S-function for simulation within another Simulink model.
Simulink Desktop Real-Time	Rapid prototyping	Runs a model in real time at interrupt level while your desktop computer runs Microsoft Windows in the background.
Simulink Real-Time	Rapid prototyping	Runs a model in real time on a desktop computer running the Simulink Real-Time kernel.

Third-party vendors supply additional system target files to support code generation for their products. For more information about third-party products, see the vendor website or the MathWorks Connections program web page: <https://www.mathworks.com/products/connections>.

## **Compare Generated Code Features by Product**

The code generation process for real-time system target files (such as GRT) provides many embedded code optimizations. Selecting an ERT-based system target file offers more extensive features than GRT. The system target file selection determines the available features for the code generation product. As you select the code generation target that matches your development process, use this table to compare code generation features available with Simulink Coder and features available with Embedded Coder.

**Compare Code Generation Features for Simulink Coder Versus Embedded Coder**

Feature	Simulink Coder	Embedded Coder
rtModel data structure	<ul style="list-style-type: none"> <li>Full rtModel structure generated</li> <li>GRT variable declaration: rtModel_model model_M_;</li> </ul>	<ul style="list-style-type: none"> <li>rtModel is optimized for the model</li> <li>Optional suppression of error status field and data logging fields</li> <li>ERT variable declaration: RT_MODEL_model model_M_;</li> </ul>
Custom storage classes (CSCs)	Code generation ignores CSCs. Objects are assigned a CSC default to Auto storage class.	Code generation with CSCs is supported
HTML code generation report	Basic HTML code generation report	Enhanced report with additional detail and hyperlinks to the model
Symbol formatting	Symbols (for signals, parameters, and so on) are generated in accordance with hard-coded default	Detailed control over generated symbols
User-defined maximum identifier length for generated symbols	Supported	Supported
Generation of terminate function	Generated	Option to suppress the terminate function
Combined output/update function	Separate output/update functions are generated	Option to generate combined output/update function
Optimized data initialization	Not available	Options to suppress generation of unnecessary initialization code for zero-valued memory, I/O ports, and so on
Comments generation	Basic options to include or suppress comment generation	Options to include Simulink block descriptions, Stateflow object descriptions, and Simulink data object descriptions in comments
Module Packaging Features (MPF)	Not supported	Extensive code customization features See "Control Data Type Names in Generated Code" on page 35-2 and "MPT Data Object Properties" on page 36-2.
System target file-optimized data types header file	Requires full tmwtypes.h header file	Generates optimized rtwtypes.h header file, including definitions required by the system target file
User-defined types	User-defined types default to base types in code generation	User-defined data type aliases are supported in code generation
Rate grouping	Not supported	Supported
Auto-generation of main program module	Not supported. Static main program module is provided.	Automated and customizable generation of main program module is supported (static main program also available)
Reusable (multi-instance) code generation	Option to generate reusable code with dynamic memory allocation	Option to generate reusable code with static or dynamic memory allocation

Feature	Simulink Coder	Embedded Coder
Software constraint options	Support for floating-point, complex, and nonfinite numbers is enabled	Options to enable or disable support for floating-point, complex, and nonfinite numbers
Application life span	Defaults to <code>inf</code>	User-specified. Determines most efficient word size for integer timers
ANSI-C/C++ code generation	Supported	Supported
ISO-C/C++ code generation	Supported	Supported
GNU <sup>®</sup> -C/C++ code generation	Supported	Supported
Generate scalar inlined parameters as <code>#DEFINE</code> statements	Not supported	Supported
MAT-file variable name modifier	Supported	Supported
Data exchange: C API, ASAP2, external mode	Supported	Supported

## Compare Generated Code Features by STF

The code generator supports a selection of generated code features for different types of system target files. In each system target file, the value of the `CodeFormat` TLC variable identifies the set of features.

This table summarizes how different system target files support applications.

Application	System Target File (STF)
Fixed- or variable-step acceleration	RSIM, S-Function, Model Reference
Fixed-step real-time deployment	GRT, ERT, Simulink Real-Time, Simulink Desktop Real-Time, ...

This table summarizes the various options available for each **System target file** selection, with the exceptions noted.

## Features Supported in Code Generated for System Target Files (STF)

Feature	System Target Files (STF)							
	grt.tlc (See note 1.)	ert.tlc (See note 1.)	ert_shrlib.tlc (See note 1.)	rtwsfcn.tlc (See note 1.)	rsim.tlc (See note 1.)	sldrt.tlc (See note 1.)	sirealtime.tlc (See note 1.)	Other (See note 1.)
Static memory allocation	X	X				X	X	X
Dynamic memory allocation	X (See notes 4, 5.)	X (See notes 4, 5.)		X	X		X	
Continuous time	X	X		X	X	X	X	
C/C++ MEX S-functions (noninlined)	X	X		X	X	X	X	
S-function (inlined)	X	X		X	X	X	X	X
Minimize RAM/ROM usage		X					X <sup>2</sup>	X
Supports external mode	X	X			X	X	X	
Rapid prototyping	X					X	X	X
Production code		X					X <sup>2</sup>	X (See note 3.)
Batch parameter tuning and Monte Carlo methods			X		X			
System-level Simulator			X					
Executes in hard real time	X (See note 3.)	X (See note 3.)				X	X	X <sup>5</sup>
Non-real-time executable included	X	X			X			

Feature	System Target Files (STF)							
	grt.tlc (See note 1.)	ert.tlc (See note 1.)	ert_shrlib.tlc (See note 1.)	rtwsfcn.tlc (See note 1.)	rsim.tlc (See note 1.)	sldrt.tlc (See note 1.)	srealtime.tlc (See note 1.)	Other (See note 1.)
Multiple instances of model	X  (See notes 4, 5.)	X  (See notes 4, 5.)		X <sup>4</sup>			X  (See notes 4, 5.)	X  (See notes 4, 5.)
Supports variable-step solvers				X	X			
Supports SIL/PIL	X	X						X

**Notes**

**1** System Target Files:

- **grt.tlc** - generic real-time target
- **ert.tlc** - embedded real-time target
- **ert\_shrlib.tlc** - embedded real-time target shared library
- **rtwsfcn.tlc** - S-Function
- **rsim.tlc** - rapid simulation
- **sldrt.tlc** - Simulink Desktop Real-Time
- **srealtime.tlc** - Simulink Real-Time
- **Other** - The embedded real-time capabilities in Simulink Coder support other system target files

**2** Does not apply to GRT-based system target files. Applies to only ERT-based system target files.

**3** The default GRT and ERT `rt_main` files emulate execution of hard real time. When explicitly connected to a real-time clock, they execute in hard real time.

**4** You can generate code for multiple instances of a Stateflow chart or subsystem containing a chart, except when the chart contains exported graphical functions or the Stateflow model contains machine-parented events.

**5** In the Configuration Parameters dialog box, for the **Code interface packaging** field, select Reusable function.

# Internationalization Support in Embedded Coder

---

## Internationalization and Code Generation

Internationalization support in software development tooling is vital to enabling efficient globalization. If there is a remote possibility that you could collaborate in the future with others across locales, consider internationalization from project inception. Internationalization can prevent rework or having to develop a new model design. The relevant requirement concerns locale settings.

### In this section...

“Locale Settings” on page 48-2

“Prepare to Generate Code for Mixed Languages and Locales” on page 48-2

“Character Set Limitations” on page 48-2

“XML Escape Sequence Replacements” on page 48-3

“CGT Files and XML Escape Sequence Replacements” on page 48-3

“Generate and Review Code with Mixed Languages and Mixed Locales” on page 48-3

### Locale Settings

On a computer, a locale setting defines the language (character set encoding) for the user interface and the display formats for information such as time, date, and currency. The encoding dictates the number of characters that a locale can render. For example, the US-ASCII coded character set (codeset) defines 128 characters. A Unicode<sup>®</sup> codeset, such as UTF-8, defines more than 1,100,000 characters.

For code generation, the locale setting determines the character set encoding of generated file content. To avoid garbled text or incorrectly displayed characters, the locale setting for your MATLAB session must be compatible with the setting for your compiler and operating system. For information on finding and changing the operating system setting, see “Internationalization” or see the operating system documentation.

### Prepare to Generate Code for Mixed Languages and Locales

To prepare to generate code for a model, identify:

- The operating system locale.
- The locale of the MATLAB session.
- Code generation requirements for:
  - Target Language Compiler files
  - Code generation template files that include comments (requires Embedded Coder)

### Character Set Limitations

Target language compiler files support user default encoding only. To produce international, custom generated code that is portable, use the 7-bit ASCII character set.

Before using this example, see “Internationalization and Code Generation” or “Internationalization and Code Generation” on page 48-2.

The `rtwdemo_unicode` model configuration uses the Embedded Coder® `ert.tlc` system target file. To see internationalization and localization support with Simulink® Coder™, configure the model to use the `grt.tlc` system target file. The example indicates the support that is specific to Embedded Coder (for example, code generation templates).

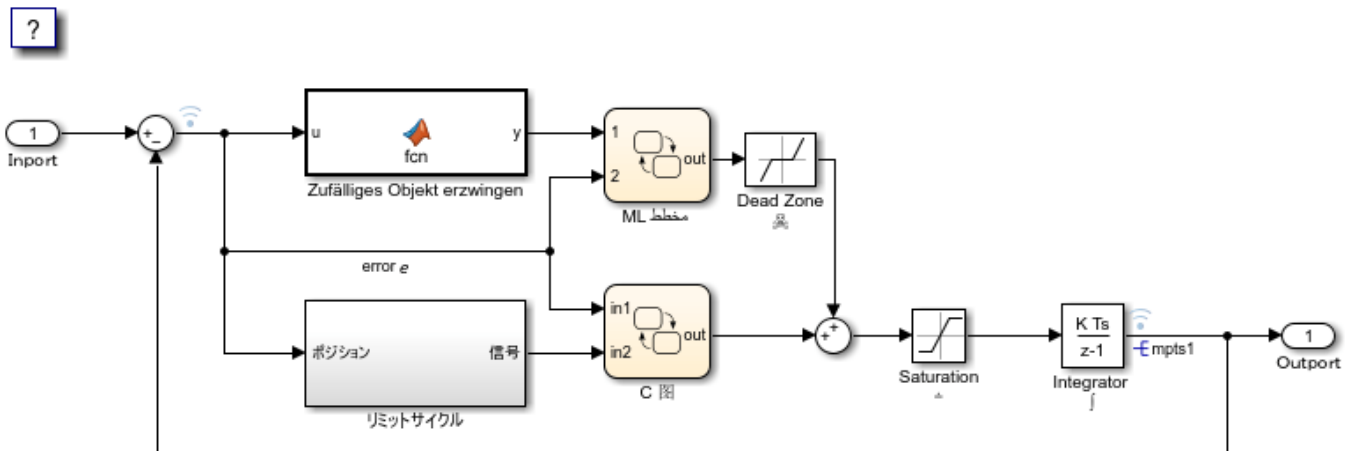

The model configuration specifies files and settings that control how the code generator handles localization for:

- C and C++ API interfaces
- Code generation template (CGT) files (requires Embedded Coder)
- Target Language Compiler (TLC) files that apply code customizations (requires Embedded Coder)

### Open the Example Model `rtwdemo_unicode`.

Open example model `rtwdemo_unicode`. Labels in the model appear in multiple languages (Arabic, Chinese, English, German, and Japanese) and various Unicode symbols.

```
model = 'rtwdemo_unicode';
open_system(model);
%
```

Copyright 2015-2020 The MathWorks, Inc.

### Open the Embedded Coder App

In the Apps tab, select **Embedded Coder**.

### Verify Locale Settings

Verify that the locale setting for your MATLAB® software is compatible with your compiler. See the documentation for your operating system or the following MATLAB documentation:

- “Set Locale on Microsoft Windows Platforms”
- “Set Locale on Linux Platforms”

- “Set Locale on macOS Platforms”

### Code Generation Template Files

To use a code generation template file with unicode characters when generating code, complete these steps (requires Embedded Coder). Otherwise, go to the next section.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code generation template file `rtwdemo_unicode.cgt`. That file adds comments to the top of generated code files. For the code generator to apply escape sequence replacements for the `.cgt` file, enable replacements by specifying:

```
<encodingIn = "encoding-name">
```

3. Open the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

```
edit rtwdemo_unicode.cgt
```

4. Find the line of code that enables escape sequence replacements for the character set encoding UTF-8.

```
<encodingIn = "UTF-8">
```

5. Close the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

### Generated File Customization Template

To use file customization templates with unicode characters when generating code, complete these steps (requires Embedded Coder). Otherwise, go to the next section.

You can specify customizations to generated code files by using TLC code. TLC files support user default encoding only. To produce international custom generated code that is portable, use the 7-bit ASCII character set.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code customization file `example_file_process.tlc`. That file customizes the generated code just before the code generator writes the code files. For example, the file adds a C source file, corresponding include file, and `#define` and `#include` statements.

3. Open the file `/toolbox/rtw/rtwdemos/example_file_process.tlc`.

```
edit example_file_process.tlc
```

4. Before generating code, uncomment the following line of code:

```
%% %assign ERTCustomFileTest = TLC_TRUE%
```

5. Close the file `/toolbox/rtw/rtwdemos/example_file_process.tlc`.

### Generate C Code and a Report

Generate C code and a code generation report.

```
evalc('slbuild(''rtwdemo_unicode'')');
```

### Review the Generated Code

For characters that are not in the current MATLAB character set encoding, the code generator uses escape sequence replacements to render characters correctly in the code generation report.

1. If the code generation report for model `rtwdemo_unicode` is not open, in the Command Window, type:

```
coder.report.open('rtwdemo_unicode')
```

2. Review the generated code in `rtwdemo_unicode.c` and `rtwdemo_unicode.h`. Names of model elements appear in code comments as replacement names in the local language.

3. Open the Traceability Report. The report maintains traceability information, even when the name contains characters that are not represented in the current encoding. Names of model elements appear in the report as replacement names in the local language.

4. Scroll down to and click the code location link for the first Chart (State 'Selection' <S2>:23). The report view changes to show the corresponding code in `rtwdemo_unicode.c`.

5. In the code comment, click the <S2>:23 link. The model window shows the chart in a new tab.

6. In the model window, right-click that chart. From the context menu, select **C/C++ Code > Navigate to C/C++ Code**. The report view changes to show the named constant section of code for that chart.

7. Close the code generation report, Model Advisor, and model. In the Command Window, type:

```
coder.report.close();
bdclose('all');
```

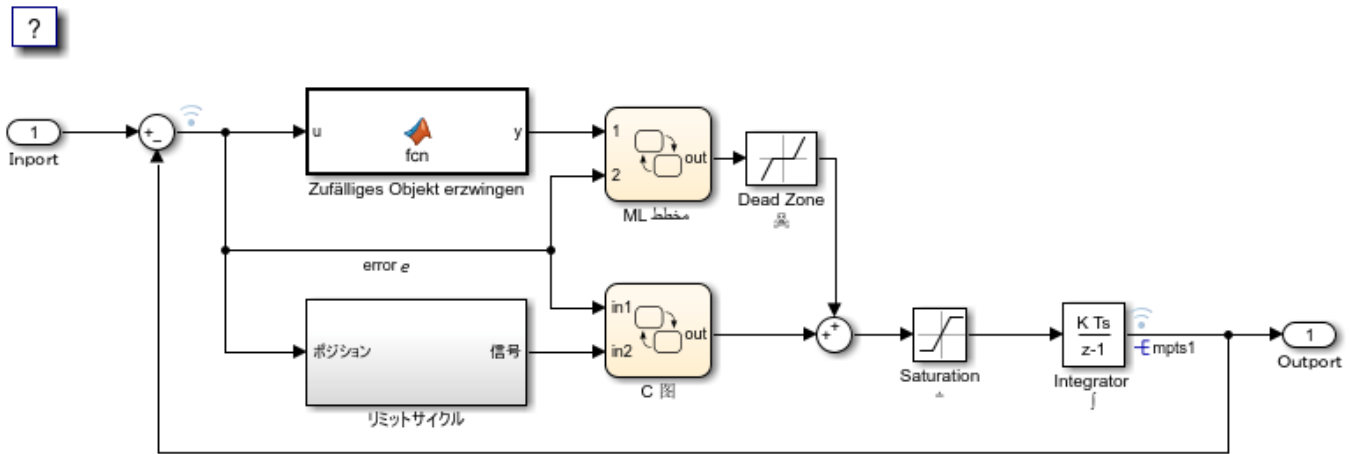

### Generate C++ Code

Generate C++ code and a code generation report.

1. Open the model.

```
model = 'rtwdemo_unicode';
open_system(model);
```

Copyright 2015-2020 The MathWorks, Inc.

2. Set model configuration parameter **Language** to C++. Or, in the Command Window, type:

```
set_param('rtwdemo_unicode', 'TargetLang', 'C++');
```

3. Set model configuration parameter **Code interface packaging** to C++ class. Or, in the Command Window, type:

```
set_param('rtwdemo_unicode', 'CodeInterfacePackaging', 'C++ class');
```

4. Generate C++ code and a code generation report.

```
evalc('rtwrebuild(''rtwdemo_unicode'')');
```

5. To see internationalization and localization support, review the generated code. See **Review the Generated Code**.

6. Close the code generation report and model. In the Command Window, type:

```
coder.report.close();
bdclose('all');
```

“Key Points” on page 49-9  
“Learn More” on page 49-10

### About This Example

#### Learning Objectives

- Learn about the functional behavior of the example model.
- Learn about the role of the example test harness and its components.
- Run simulation tests on a model.

#### Prerequisites

- Ability to open and modify Simulink models and subsystems.
- Understand subsystems and how to view subsystem details.
- Understand referenced models and how to view referenced model details.
- Ability to set model configuration parameters.

#### Required Files

Before you use each example model file, place a copy in a writable location and add it to your MATLAB path.

- `rtwdemo_throttlecntrl` model file
- `rtwdemo_throttlecntrl_testharness` model file

### Functional Design of the Model

This example uses a simple, but functionally complete, example model of a throttle controller. The model features redundant control algorithms. The model highlights a standard model structure and a set of basic blocks in algorithm design.

### View the Top Model

Open `rtwdemo_throttlecntrl` and save a copy as `throttlecntrl` in a writable location on your MATLAB path.

**Note** This model uses Stateflow software.

The top level of the model consists of the following elements:

Subsystems	PI_ctrl_1 PI_ctrl_2 Define_Throt_Param Pos_Command_Arbitration
Top-level input	pos_rqst fbk_1 fbk_2
Top-level output	pos_cmd_one pos_cmd_two ThrotComm1
Signal routing	
Omit blocks that change the value of a signal, such as Sum and Integrator	

The layout uses a basic architectural style for models:

- Separation of calculations from signal routing (lines and buses)
- Partitioning into subsystems

You can apply this style to a wide range of models.

## View the Subsystems

Explore two of the subsystems in the top model.

- 1 If not already open, open `throttlectrl`.

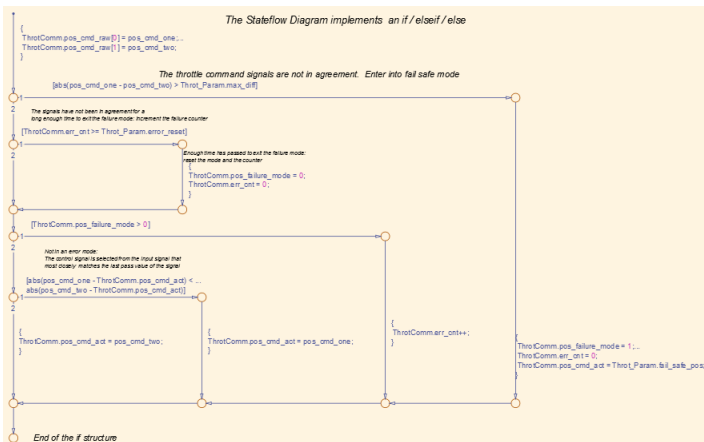

Two subsystems in the top model represent proportional-integral (PI) controllers, `PI_ctrl_1` and `PI_ctrl_2`. At this stage, these identical subsystems, use identical data.

- 2 Open the `PI_ctrl_1` subsystem.

The PI controllers in the model are from a *library*, a group of related blocks or models for reuse. Libraries provide one of two methods for including and reusing models. The second method, model referencing, is described in “Simulation Test Environment” on page 49-4. You cannot edit a block that you add to a model from a library. Edit the block in the library so that instances of the block in different models remain consistent.

- Open the Pos\_Command\_Arbitration subsystem. This Stateflow chart performs basic error checking on the two command signals. If the command signals are too far apart, the Stateflow diagram sets the output to a fail\_safe position.

- Close throttlecntrl.

## Simulation Test Environment

To test the throttle controller algorithm, incorporate it into a test harness. A test harness is a model that evaluates the control algorithm and offers the following benefits:

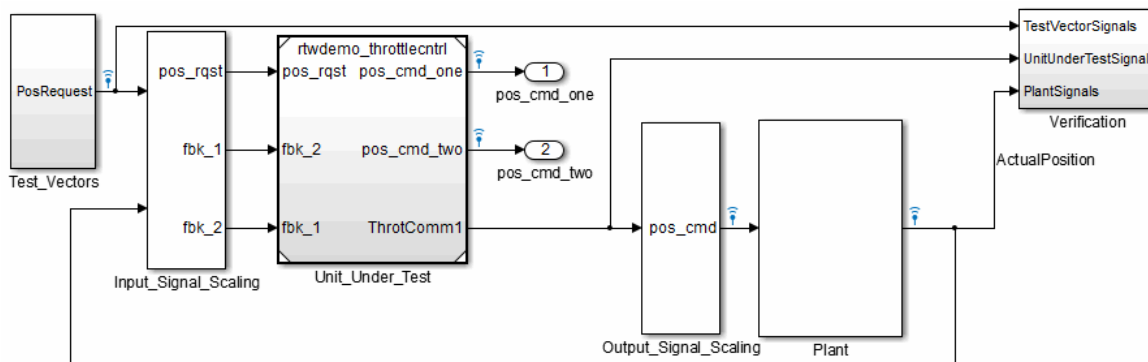

- Separates test data from the control algorithm.
- Separates the plant or feedback model from the control algorithm.
- Provides a reusable environment for multiple versions of the control algorithm.

The test harness model for this example implements a common simulation testing environment consisting of the following parts:

- Unit under test
- Test vector source
- Evaluation and logging
- Plant or feedback system
- Input and output scaling

Explore the simulation testing environment.

- 1 Open the test harness model `rtwdemo_throttlecntrl_testharness` and save a copy as `throttlecntrl_testharness` in a writable location on your MATLAB path.

Copyright 2007-2011 The MathWorks, Inc.

- 2 Set up your `throttlecntrl` model as the control algorithm of the test harness.
  - a Open the `Unit_Under_Test` block and view the control algorithm.
  - b View the model reference parameters by right-clicking the `Unit_Under_Test` block and selecting **Block Parameters (ModelReference)**.

rtwdemo\_throttlecntrl appears as the name of the referenced model.

- c Change the value of **Model name** to throttlecntrl.
- d Update the test harness model diagram by clicking **Simulation > Update Diagram**.

The control algorithm is the unit under test, as indicated by the name of the Model block, Unit\_Under\_Test.

The Model block provides a method for reusing components. From the top model, it allows you to reference other models (directly or indirectly) as compiled functions. By default, Simulink software recompiles the model when the referenced models change. Compiled functions have the following advantages over libraries:

- Simulation time is faster for large models.
  - You can directly simulate compiled functions.
  - Simulation requires less memory. Only one copy of the compiled model is in memory, even when the model is referenced multiple times.
- 3 Open the test vector source, implemented in this test harness as the Test\_Vectors subsystem.

The subsystem uses a Signal Builder block for the test vector source. The block has data that drives the simulation (PosRequest) and provides the expected results used by the Verification subsystem. This example test harness uses only one set of test data. Typically, create a test suite that fully exercises the system.

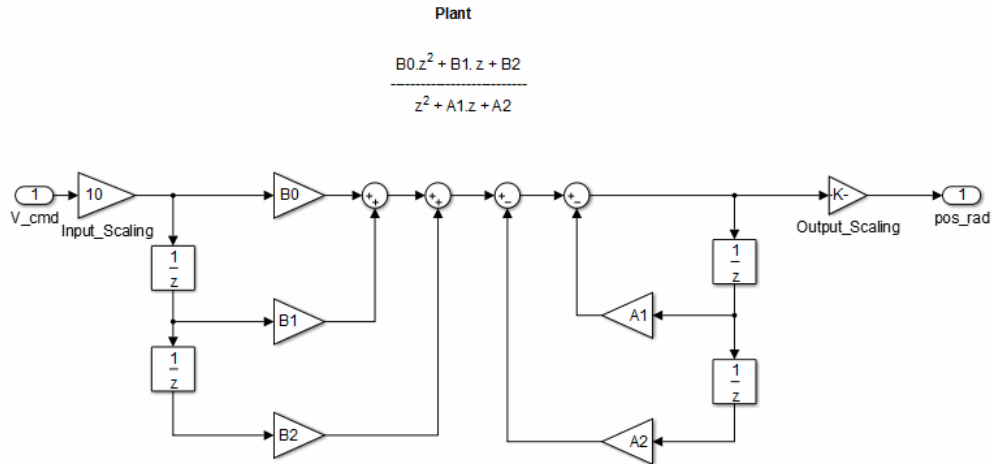

- 4 Open the evaluation and logging subsystem, implemented in this test harness as subsystem Verification.

A test harness compares control algorithm simulation results against golden data — test results that exhibit the desired behavior for the control algorithm as certified by an expert. In the Verification subsystem, an Assertion block compares the simulated throttle value position from the plant against the golden value from the test harness. If the difference between the two signals is greater than 5%, the test fails and the Assertion block stops the simulation.

Alternatively, you can evaluate the simulation data after the simulation completes execution. Perform the evaluation with either MATLAB scripts or third-party tools. Post-execution evaluation provides greater flexibility in the analysis of data. However, it requires waiting until execution is complete. Combining the two methods can provide a highly flexible and efficient test environment.

- 5 Open the plant or feedback system, implemented in this test harness as the Plant subsystem.

The Plant subsystem models the throttle dynamics with a transfer function in canonical form. You can create plant models to varying levels of fidelity. It is common to use different plant models at different stages of testing.

- Open the input and output scaling subsystems, implemented in this test harness as Input\_Signal\_Scaling and Output\_Signal\_Scaling.

The subsystems that scale input and output perform the following primary functions:

- Select input signals to route to the unit under test.
- Select output signals to route to the plant.
- Rescale signals between engineering units and units that are writable for the unit under test.
- Handle rate transitions between the plant and the unit under test.

- Save and close throttlecntrl\_testharness.

## Run Simulation Tests

- Check that your working folder is set to a writable folder, such as the folder into which you placed copies of the example model files.
- Open your copy of the test harness model, throttlecntrl\_testharness.

- 3 Start a test harness model simulation. When the simulation is complete, the following results appear.

The lower-right hand plot shows the difference between the expected (golden) throttle position and the throttle position that the plant calculates. If the difference between the two values is greater than  $\pm 0.05$ , the simulation stops.

- 4 Save and close throttle controller and test harness models.

## Key Points

- A basic model architecture separates calculations from signal routing and partitions the model into subsystems
- Two options for model reuse include block libraries and model referencing.
- If you represent your control algorithm in a test harness as a Model block, specify the name of the control algorithm model in the Model Reference Parameters dialog box.
- A test harness is a model that evaluates a control algorithm. Typically, a harness consists of a unit under test, a test vector source, evaluation and logging, a plant or feedback system, and input and output scaling components.
- The unit under test is the control algorithm being tested.
- The test vector source provides the data that drives the simulation which generates results used for verification.
- During verification, the test harness compares control algorithm simulation results against golden data and logs the results.
- The plant or feedback component of a test harness models the environment that is being controlled.

- When developing a test harness,
  - Scale input and output components.
  - Select input signals to route to the unit under test.
  - Select output signals to route to the plant.
  - Rescale signals between engineering units and units that are writable for the unit under test.
  - Handle rate transitions between the plant and the unit under test.

# Configure Model and Generate Code

## In this section...

“About This Example” on page 49-11  
 “Configure the Model for Code Generation” on page 49-11  
 “Save Your Model Configuration as a MATLAB Function” on page 49-12  
 “Check Model Conditions and Configuration Settings” on page 49-13  
 “Generate Code for the Model” on page 49-13  
 “Review the Generated Code” on page 49-13  
 “Generate an Executable” on page 49-14  
 “Key Points” on page 49-14

## About This Example

### Learning Objectives

- Configure a model for code generation.
- Use model checking tools to discover conditions and configuration settings resulting in generation of inaccurate or inefficient code.
- Generate code from a model.
- Locate and identify generated code files.
- Review generated code.

### Prerequisites

- Ability to open and modify Simulink models and subsystems.
- Ability to set model configuration parameters.
- Ability to use the Code Generation Advisor.
- Ability to read C code.
- An installed, supported C compiler.

### Required Files

rtwdemo\_throttlecntrl model file

## Configure the Model for Code Generation

Model configuration parameters determine the method for generating the code and the resulting format.

- 1 Open `rtwdemo_throttlecntrl` and save a copy as `throttlecntrl` in a writable location on your MATLAB path. Then, open the **Simulink Coder** app.
- 2 Open the Configuration Parameters dialog box, **Solver** pane. To generate code for a model, you must configure the model to use a fixed-step solver. The following table shows the solver configuration for this example.

Parameter	Setting	Effect on Generated Code
<b>Type</b>	Fixed-step	Maintains a constant (fixed) step size, which is required for code generation
<b>Solver</b>	discrete (no continuous states)	Applies a fixed-step integration technique for computing the state derivative of the model
<b>Fixed-step size</b>	.001	Sets the base rate; must be the lowest common multiple of the rates in the system

Solver options

Type:  Solver:

► Additional options

- Set model configuration parameter **System target file** to `grt.tlc`.

**Note** The GRT (Generic Real-Time Target) configuration requires a fixed-step solver. However, the `rsim.tlc` system target file supports variable step code generation.

The system target file defines an environment for generating and building code for execution on a certain hardware or operating system platform. For example, one property of a system target file is the value for the `CodeFormat` TLC variable. The GRT configuration requires a fixed step solver and the `rsim.tlc` supports variable step code generation.

- Set model configuration parameter **Include directories** as follows:

```
"$matlabroot$\toolbox\rtw\rtwdemos\EmbeddedCoderOverview\"
```

This folder includes files that are required to build an executable for the model.

- Close the Model Configuration Parameters dialog box.

## Save Your Model Configuration as a MATLAB Function

You can save the settings of model configuration parameters as a MATLAB function by using the `getActiveConfigSet` function. In the MATLAB Command Window, enter:

```
thcntrlAcs = getActiveConfigSet('throttlecntrl');
thcntrlAcs.saveAs('throttlecntrlModelConfig');
```

You can then use the resulting function (for example, `throttlecntrlModelConfig`) to:

- Archive the model configuration.
- Compare different model configurations by using differencing tools.
- Set the configuration of other models.

For example, you can set the configuration of model `myModel` to match the configuration of the throttle controller model by opening `myModel` and entering:

```
myModelAcs = throttlecntrlModelConfig;
attachConfigSet('myModel', myModelAcs, true);
setActiveConfigSet('myModel', myModelAcs.Name);
```

For more information, see “Save a Configuration Set” and “Load a Saved Configuration Set”.

## Check Model Conditions and Configuration Settings

Before generating code for a model, use the Code Generation Advisor to check the model conditions and configuration settings. The check identifies issues that can result in inaccurate or inefficient code.

- 1 Open model `throttlecntrl`. Then, open the **Simulink Coder** app.
- 2 In the **C Code** tab, click **C/C++ Code Advisor**. A dialog box opens showing the model system hierarchy.
- 3 Click `rtwdemo_throttlecntrl` and then click **OK**. The Code Generation Advisor window opens.
- 4 Right-click on the **Code Generation Advisor** folder and select **Run Selected Checks**.
- 5 To review the results for check **Check model configuration settings against code generation objectives**, select the check in the left pane. The results are displayed in the right pane.
- 6 After reviewing the check results, you can choose to fix warnings and failures as described in “Fix a Model Advisor Check Warning or Failure”.

## Generate Code for the Model

- 1 Open `throttlecntrl`. Then, open the **Simulink Coder** app.
- 2 Select model configuration parameter **Generate code only**.
- 3 Select model configuration parameter **Create code generation report** and click **Apply**.
- 4 Generate code.

Messages appear in the Diagnostics Viewer. The code generator produces standard C and header files, and an HTML code generation report. The code generator places the files in a *build folder*, a subfolder named `throttlecntrl_grt_rtw` under your current working folder.

## Review the Generated Code

- 1 In the code generation report, click the link for the generated C model file and review the generated code. Look for these items in the report:
  - Identification, version, timestamp, and configuration comments.
  - Links to help you navigate within and between files
  - Data definitions
  - Scheduler code
  - Controller code
  - Model initialization and termination functions

- Call interface for the GRT system target file — output, update, initialization, start, and terminate
- 2 Save and close model `throttlecntrl`.

Consider examining the following files. In the code generation report **Contents** pane, click the links.

File	Description
<code>throttlecntrl.c</code>	C file that contains the scheduler, controller, initialization, and interface code
<code>throttlecntrl_data.c</code>	C file that assigns values to generated data structures
<code>throttlecntrl.h</code>	Header file that defines data structures
<code>throttlecntrl_private.h</code>	Header file that defines data used only by the generated code
<code>throttlecntrl_types.h</code>	Header file that defines the model data structure

For more information, see “Manage Build Process File Dependencies”.

At this point, consider logging data to a MAT-file. For an example, see “Log Data for Analysis”.

## Generate an Executable

- 1 Open `throttlecntrl`. Then, open the **Simulink Coder** app.
- 2 Clear model configuration parameter **Generate code only** and click **Apply**.
- 3 Build the model. Watch the messages in the Diagnostics Viewer. The code generator uses a template make file associated with your system target file selection to create an executable file. You can run this program on your workstation, independent of external timing and events.
- 4 Check your working folder for the file `throttlecntrl.exe`.
- 5 Run the executable. In the Command Window, enter `!throttlecntrl`. The `!` character passes the command that follows it to the operating system, which runs the standalone program.

The program produces one line of output in the Command Window:

```
** starting the model **
```

At this point, consider logging data to a MAT-file. For an example, see “Log Data for Analysis”.

---

**Tip** For UNIX platforms, run the executable program in the Command Window with the syntax `!./executable_name`. If preferred, run the executable program from an OS shell with the syntax `./executable_name`. For more information, see “Run External Commands, Scripts, and Programs”.

---

## Key Points

- To generate code, change the model configuration to specify a fixed-step solver then select a system target file. Using the `grt.tlc` file requires a fixed-step solver. If the model contains continuous time blocks, you can use a variable-step solver with the `rsim.tlc` system target file.
- After debugging a model, consider configuring a model with parameter inlining enabled.

- Use the `getActiveConfigSet` function to save a model configuration for future use or to apply it to another model.
- Before generating code, consider checking a model with the Code Generation Advisor.
- The code generator places generated files in a subfolder (*model\_grt\_rtw*) of your working folder.

- [“Code Generation”](#)
- [“Model Configuration Sets”](#)
- [“Check Your Model Using the Model Advisor”](#)

## Configure Data Interface

### About This Example

#### Learning Objectives

- Configure the data interface for code generated for a model.
- Control the name, data type, and data storage class of signals and parameters in generated code.

#### Prerequisites

- Understanding ways to represent and use data and signals in models.
- Familiarity with representing data constructs as data objects.
- Ability to read C code.

#### Required File

rtwdemo\_throttlenctrl\_datainterface model file

### Declare Data

Most programming languages require that you declare data before using it. The declaration specifies the following information:

Data Attribute	Description
Scope	The region of the program that has access to the data
Duration	The period during which the data is resident in memory
Data type	The amount of memory allocated for the data
Initialization	An initial value, a pointer to memory, or NULL. If you do not provide an initial value, most compilers assign a zero value or a null pointer.

The following data types are supported for code generation.

#### Supported Data Types

Name	Description
double	Double-precision floating point
single	Single-precision floating point
int8	Signed 8-bit integer
uint8	Unsigned 8-bit integer
int16	Signed 16-bit integer
uint16	Unsigned 16-bit integer
int32	Signed 32-bit integer
uint32	Unsigned 32-bit integer
Fixed-point data types	8-, 16-, 32-bit word lengths

A storage class is the scope and duration of a data item. For more information about storage classes, see “C Code Generation Configuration for Model Interface Elements” on page 32-2.

## Use Data Objects

In Simulink models and Stateflow charts, the following methods are available for declaring data: data objects and direct specification. This example uses the data object method. Both methods allow full control over the data type and storage class. You can mix the two methods in a single model.

In the MATLAB and Simulink environment, you can use data objects in various ways. This example focuses on the following types of data objects:

- Signal
- Parameter
- Bus

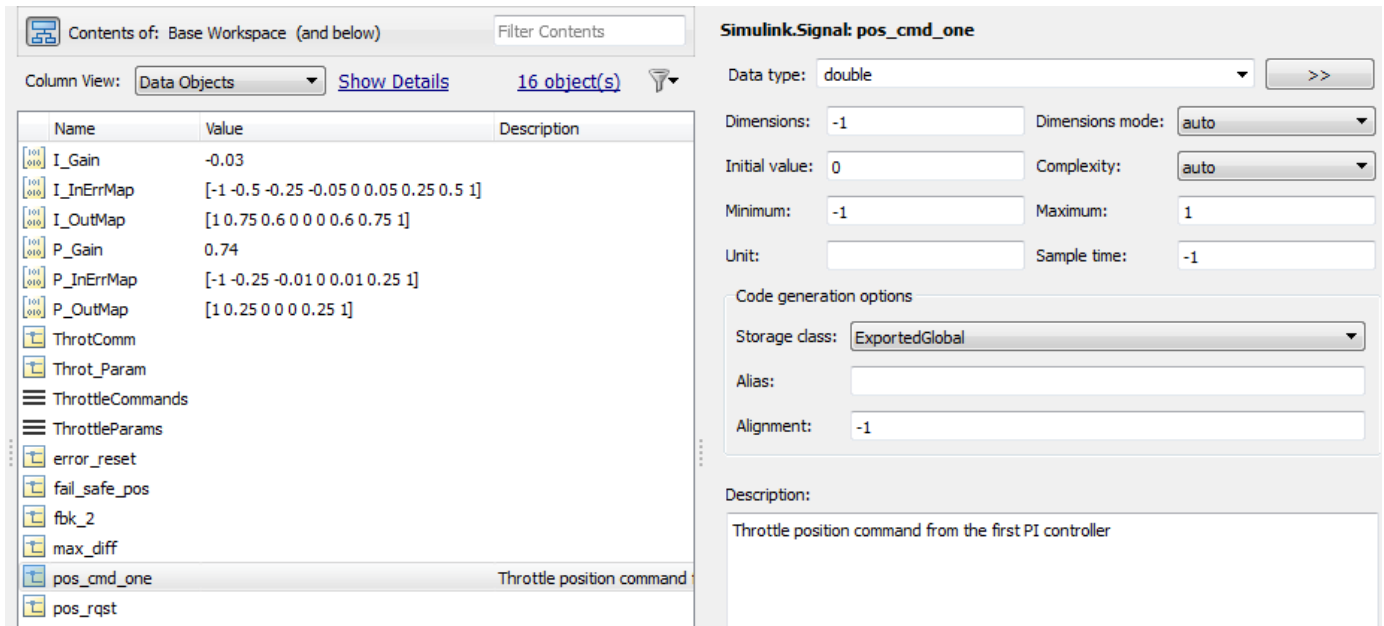

To configure the data interface for your model using the data object method, in the MATLAB base workspace, you define data objects. Then, associate them with your Simulink model or embedded Stateflow chart. When you build your model, the build process uses the associated base workspace data objects in the generated code.

You can set the values of the data object properties, which include:

- Data type
- Storage class
- Value (parameters)
- Initial value (signals)
- Identifier (define a different name in the generated code)
- Dimension (typically inherited for parameters)
- Complexity (inherited for parameters)
- Unit (physical measurement unit)
- Minimum value
- Maximum value
- Description (used to document your data objects — does not affect simulation or code generation)

You can create and inspect base workspace data objects by entering commands in the MATLAB Command Window or by using Model Explorer. To explore base workspace signal data objects, use these steps:

- 1 Open `rtwdemo_throttlectrl_datainterface` and save a copy as `throttlectrl_datainterface` in a writable location on your MATLAB path.
- 2 Open Model Explorer.
- 3 Select **Base Workspace**.
- 4 Select the `pos_cmd_one` signal object for viewing.

You can also view the definition of a signal object. In the MATLAB Command Window, enter `pos_cmd_one`:

```
pos_cmd_one =
Signal with properties:
 CoderInfo: [1x1 Simulink.CoderInfo]
 Description: 'Throttle position command from the first PI controller'
 DataType: 'double'
 Min: -1
 Max: 1
 Unit: ''
 Dimensions: -1
 DimensionsMode: 'auto'
 Complexity: 'auto'
 SampleTime: -1
 InitialValue: '0'
```

- To view other signal objects, in Model Explorer, click the object name or in the MATLAB Command Window, enter the object name. This table summarizes object characteristics for some of the data objects in this model.

Object Characteristics	pos_cmd_one	pos_rqst	P_InErrMap	ThrotComm*	ThrottleCommands*
Description	Top-level output	Top-level input	Calibration parameter	Top-level output structure	Bus definition
Data type	Double	Double	Auto	Auto	Structure
Storage class	Exported global	Imported extern pointer	Constant	Exported global	None

\* `ThrottleCommands` defines a Bus object; `ThrotComm` is an instantiation of the bus. If the bus is a nonvirtual bus, the signal generates a structure in the C code.

You can use a bus definition (`ThrottleCommands`) to instantiate multiple instances of the structure. In a model diagram, a bus object appears as a wide line with central dashes, as shown.

## Add New Data Objects

You can create data objects for named signals, states, and parameters. To associate a data object with a construct, the construct must have a name.

To find constructs for which you can create data objects, use the Data Object Wizard. This tool finds the constructs and then creates the objects for you. The model includes two signals that are not associated with data objects: `fbk_1` and `pos_cmd_two`.

To find the signals and create data objects for them:

- 1 In the Simulink Editor, in the **Modeling** tab, under **Design**, click **Data Object Wizard**. The Data Object Wizard dialog box opens.
- 2 To find candidate constructs, click **Find**. Constructs `fbk_1` and `pos_cmd_two` appear in the dialog box.
- 3 To select both constructs, click **Select All**.
- 4 In the table, under **Class**, make sure that each proposed data object uses the class `Simulink.Signal`. To change the class of the objects, click **Change Class**.
- 5 To create the data objects, click **Create**. Constructs `fbk_1` and `pos_cmd_two` are removed from the dialog box.
- 6 Close the Data Object Wizard.
- 7 In the **Contents** pane of the Model Explorer, find the newly created objects `fbk_1` and `pos_cmd_two`.

## Enable Data Objects for Generated Code

- 1 Enable a signal to appear in generated code.
  - a In the Simulink Editor, right-click the `pos_cmd_one` signal line and select **Properties**. A Signal Properties dialog box opens.
  - b Make sure that you select the **Signal name must resolve to Simulink signal object** parameter.

- 2 Enable signal object resolution for the signals in the model. In the MATLAB Command Window, enter:

```
disableimplicitsignalresolution('throttlecntrl_datainterface')
```

- 3 Save and close throttlecntrl\_datainterface.

## Effects of Simulation on Data Typing

In the throttle controller model, the data types are set to `double`. Because Simulink software uses the `double` data type for simulation, do not expect changes in the model behavior when you run the generated code. You verify this effect by running the test harness.

Before you run your test harness, update it to include the `throttlecntrl_datainterface` model.

---

**Note** The following procedure requires a Stateflow license.

---

- 1 Open `throttlecntrl_datainterface`.
- 2 Open your copy of test harness, `throttlecntrl_testharness`.
- 3 Right-click the `Unit_Under_Test Model` block and select **Block Parameters (ModelReference)**.
- 4 Set **Model name** to `throttlecntrl_datainterface`. Click **OK**.
- 5 Update the test harness model diagram.
- 6 Simulate the test harness.

The resulting plot shows that the difference between the golden and simulated versions of the model remains zero.

7 Save and close `throttlecntrl_testharness`.

## Manage Data

Data objects exist in a separate file from the model in the base workspace. To save the data manually, in the MATLAB Command Window, enter `save`.

The separation of data from the model provides the following benefits:

- One model, multiple data sets:
  - Use of different parameter values to change the behavior of the control algorithm (for example, for reusable components with different calibration values)
  - Use of different data types to change targeted hardware (for example, for floating-point and fixed-point targeted hardware)
- Multiple models, one data set:
  - Sharing data between models in a system
  - Sharing data between projects (for example, transmission, engine, and wheel controllers can use the same CAN message data set)

## Key Points

- You can declare data in Simulink models and Stateflow charts by using data objects or direct specification.
- From the Model Explorer or from the command line in the MATLAB Command Window, manage (create, view, configure, and so on) base workspace data.
- The Data Object Wizard provides a quick way to create data objects for constructs such as signals, buses, and parameters.
- Configure data objects explicitly to appear by name in generated code.
- Separation of data from model provides several benefits.

- “Key Points” on page 49-27

## About This Example

### Learning Objectives

- Evaluate a C function as part of a model simulation.
- Call an external C function from generated code.

### Prerequisites

- Ability to open and modify Simulink models and subsystems.
- Ability to set model configuration parameters.
- Ability to read C code.
- An installed, supported C compiler.

### Required Files

- `rtwdemo_throttlecntrl_extfuncall` model file
- `rtwdemo_ValidateLegacyCodeVrsSim` model file
- `/toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files/SimpleTable.c`
- `/toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files/SimpleTable.h`

## Include External C Functions in a Model

Simulink models are one part of Model-Based Design. For many applications, a design also includes a set of pre-existing C functions created, tested (verified), and validated outside of a MATLAB and Simulink environment. You can integrate these functions easily into a model and the generated code. You can use external C code in the generated code to access hardware devices and external data files during rapid simulation runs.

This example shows you how to create a custom block that calls an external C function. When the block is part of the model, you can take advantage of the simulation environment to test the system further.

## Create a Block That Calls a C Function

To specify a call to an external C function, use an S-Function block. You can automate the process of creating the S-Function block by using the Simulink Legacy Code Tool. Using this tool, specify an

interface for your external C function. The tool then uses that interface to automate creation of an S-Function block.

- 1 Make copies of the files `SimpleTable.c` and `SimpleTable.h`, located in the folder `matlabroot/toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files` (open). Put the copies in your working folder.
- 2 Create an S-Function block that calls the specified function at each time step during simulation:

- a In the MATLAB Command Window, create a function interface definition structure:

```
def=legacy_code('initialize')
```

The data structure `def` defines the function interface to the external C code.

```
def =
```

```

 SFunctionName: ''
InitializeConditionsFcnSpec: ''
 OutputFcnSpec: ''
 StartFcnSpec: ''
 TerminateFcnSpec: ''
 HeaderFiles: {}
 SourceFiles: {}
 HostLibFiles: {}
 TargetLibFiles: {}
 IncPaths: {}
 SrcPaths: {}
 LibPaths: {}
 SampleTime: 'inherited'
 Options: [1x1 struct]
```

- b Populate the function interface definition structure by entering the following commands:

```
def.OutputFcnSpec=['double y1 = SimpleTable(double u1, ...,
 'double p1[], double p2[], int16 p3)'];
def.HeaderFiles = {'SimpleTable.h'};
def.SourceFiles = {'SimpleTable.c'};
def.SFunctionName = 'SimpTableWrap';
```

- c Create the S-function:

```
legacy_code('sfcn_cmex_generate', def)
```

- d Compile the S-function:

```
legacy_code('compile', def)
```

- e Create the S-Function block:

```
legacy_code('slblock_generate', def)
```

A new model window opens that contains the `SimpTableWrap` block.

---

**Tip** Creating the S-Function block is a one-time task. Once the block exists, you can reuse it in multiple models.

---

- 3 Save the model to your working folder as: `s_func_simpltablewrap`.
- 4 Create a Target Language Compiler (TLC) file for the S-Function block:

```
legacy_code('sfcn_tlc_generate', def)
```

The TLC file is the component of an S-function that specifies how the code generator produces the code for a block.

For more information on using the Legacy Code Tool, see:

- “Integrate C Functions Using Legacy Code Tool”
- “Import Calls to External Code into Generated Code with Legacy Code Tool”

## Validate External Code in the Simulink Environment

When you integrate external C code with a Simulink model, before using the code, validate the functionality of the external C function code as a standalone component.

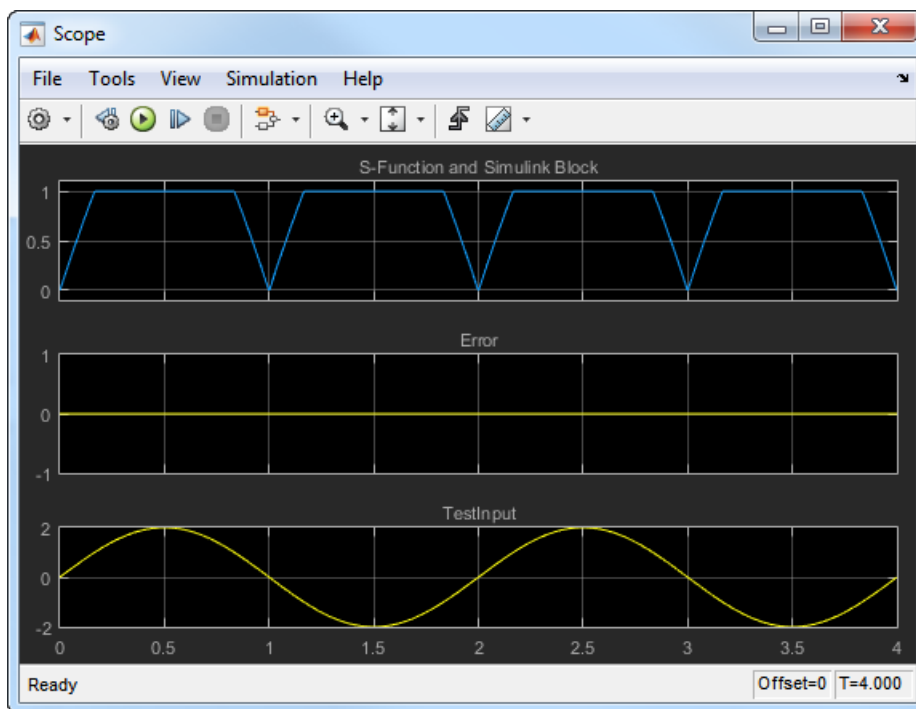

- 1 Open the model `rtwdemo_ValidateLegacyCodeVrsSim`. This model validates the S-function block that you created.

Copyright 2007-2011 The MathWorks, Inc.

- The Sine Wave block produces output values from [-2 : 2].
  - The input range of the lookup table is from [-1 : 1].
  - The output from the lookup table is the absolute value of the input.
  - The lookup table output clips the output at the input limits.
- 2 Simulate the model.
  - 3 View the validation results by opening the `Validation` subsystem and, in that subsystem, clicking the Scope block.

The following figure shows the validation results. The external C code and the Simulink Lookup table block provide the same output values.

- 4 Close the validation model.

## Validate C Code as Part of a Model

After you validate the functionality of the external C function code as a standalone component, validate the S-function in the model. Use the test harness model to complete the validation.

---

**Note** The following procedure requires a Stateflow license.

---

- 1 Open `rtwdemo_throttlectrl_extfunccall` and save a copy to `throttlectrl_extfunccall` in a writable folder on your MATLAB path.
- 2 Examine the `PI_ctrl_1` and `PI_ctrl_2` subsystems.
  - a Lookup blocks have been replaced with the block you created using the Legacy Code Tool.
  - b Examine the block parameter settings for `SimpTableWrap` and `SimpTableWrap1`.
  - c Close the Block Parameter dialog boxes and the PI subsystem windows.
- 3 Open the test harness model, right-click the `Unit_Under_Test Model` block, and select **Block Parameters (ModelReference)**.
- 4 Set **Model name** to `throttlectrl_extfunccall`. Click **OK**.
- 5 Update the test harness model diagram.
- 6 Simulate the test harness.

The simulation results match the expected golden values.

- 7 Save and close `throttlecntrl_extfunccall` and `throttlecntrl_testharness`.

## Call a C Function from Generated Code

The code generator uses a TLC file to process the S-Function block. Calls to C code embedded in an S-Function block:

- Can use data objects.
- Are subject to expression folding, an operation that combines multiple computations into a single output calculation.

- 1 Open `throttlecntrl_extfunccall`.
- 2 Generate code for the model.
- 3 Examine the generated code in the file `throttlecntrl_extfunccall.c`.
- 4 Close `throttlecntrl_extfunccall` and `throttlecntrl_testharness`.

## Key Points

- You can easily integrate external functions into a model and generated code by using the Legacy Code Tool.
- Validate the functionality of external C function code which you integrate into a model as a standalone component.
- After you validate the functionality of external C function code as a standalone component, validate the S-function in the model.

## **See Also**

### **More About**

- “Integrate C Functions Using Legacy Code Tool”

## Reload Generated Code

You can reload the code generated for a model from the Model Explorer.

- 1 Click the **Code for *model*** node in the **Model Hierarchy** pane.
- 2 In the **Code** pane, click the **Refresh** link.

The code generator reloads the code for the model from the build folder.

## Manage Build Process Folders

The build process places generated files from Simulink diagram updates and model builds into a hierarchy of folders that is specified by default. You can change the default specification for build process folders, if, for example:

- Your company does not use the current working folder as the location for the code generation folder or the simulation cache folder.
- You place the code generation folder under version control, but do not place the simulation cache folder under version control.

The MATLAB session parameters `CacheFolder`, `CodeGenFolder`, and `CodeGenFolderStructure` are file generation control parameters that specify the folder locations for the build process. At the start of a MATLAB session, these Simulink preferences determine the values of the parameters:

**Simulation cache folder** - `CacheFolder`

**Code generation folder** - `CodeGenFolder`

**Code generation folder structure** - `CodeGenFolderStructure`

To modify the parameters during a MATLAB session, use `Simulink.fileGenControl`. The parameter values that you set expire at the end of the MATLAB session.

## File Generation Control Parameters

This table provides information about how you can use the parameters to manage build process folders.

MATLAB Session Parameter	Simulink Preference	Description
CacheFolder	<b>Simulation cache folder</b>	<p>The build process places generated files from Simulink diagram updates and model build artifacts for simulation and code generation in the simulation cache folder <i>simulationCacheFolder</i>. The folder is a root folder.</p> <p>By default (<code>CacheFolder = ''</code>), <i>simulationCacheFolder</i> is the current working folder, <code>pwd</code>.</p> <p>You can use the parameter to specify another folder. For example, if you want to:</p> <ul style="list-style-type: none"> <li>• Separate generated files from the models and other source material.</li> <li>• Reuse or share previously built simulation targets without having to set the current working folder back to a previous working folder.</li> </ul>

MATLAB Session Parameter	Simulink Preference	Description
CodeGenFolder	<b>Code generation folder</b>	<p>The build process, which uses system target files to generate production code from a Simulink model, places the production code in the code generation folder <i>codeGenerationFolder</i>. The folder is a root folder.</p> <p>If you choose to generate an executable program file, the build process writes the file <i>model.exe</i> (Windows) or <i>model</i> (UNIX) to the folder.</p> <p>By default (<code>CodeGenFolder = ''</code>), <i>codeGenerationFolder</i> is the current working folder, <code>pwd</code>.</p> <p>You can use the parameter to specify another folder. For example, if you want to separate generated production code from:</p> <ul style="list-style-type: none"> <li>• Models and other source material.</li> <li>• Generated simulation and code generation artifacts.</li> </ul> <p>If you specify the root folder of a drive as the code generation folder, the build process cannot generate code for your model. For example, <code>C:\</code>.</p>
CodeGenFolderStructure	<b>Code generation folder structure</b>	<p>To specify the folder structure within the code generation folder, use the parameter. For example, if you configure models for different target environments, you can specify a separate subfolder for the generated code from each model.</p>

## Build Process Folders

This table provides information about how `CodeGenFolderStructure` controls the folder structure within the simulation cache folder and the code generation folder.

Folder Name when CodeGenFolderStructure = 'ModelSpecific'	Folder Name when CodeGenFolderStructure = 'TargetEnvironmentSubfolder'	Description
<p><i>codeGenerationFolder/model_target_rtw</i></p> <p>The default for <i>target</i> is the name of the selected system target file, for example, <i>grt</i>, <i>ert</i>, and <i>rsim</i>. You can change <i>target</i> with the <i>rtwgensettings.BuildDirSuffix</i> field in the system target file.</p>	<p><i>codeGenerationFolder/targetSpecific/model</i></p> <p>The build process uses configuration information for the system target file and the hardware device to produce a unique label for the subfolder, <i>targetSpecific</i>.</p>	<p>Build folder, which stores generated source code and other files created by the build process.</p> <p>Contains the generated code modules, <i>model.c</i> and <i>model.h</i>, and generated makefile, <i>model.mk</i>.</p> <p><i>model.mk</i> is for compiling and linking code generated from model components.</p> <p><i>model</i> is the name of the source model.</p>
<p><i>codeGenerationFolder/model_target_rtw/html</i></p>	<p><i>codeGenerationFolder/targetSpecific/model/html</i></p>	<p>Code generation report folder that contains report files generated by the build process.</p>
<p><i>codeGenerationFolder/slprj/target/model</i></p>	<p><i>codeGenerationFolder/targetSpecific/_ref/model</i></p>	<p>Model reference target files.</p>
<p><i>codeGenerationFolder/slprj/target/model/referenced_model_includes</i></p>	<p><i>codeGenerationFolder/targetSpecific/_ref/model/referenced_model_includes</i></p>	<p>Header files from models referenced by <i>model</i>.</p>
<p><i>codeGenerationFolder/slprj/target/model/tmwinternal</i></p>	<p><i>codeGenerationFolder/targetSpecific/_ref/model/tmwinternal</i></p>	<p>MAT-files used during code generation.</p>
<p><i>codeGenerationFolder/slprj/target/_sharedutils</i></p>	<p><i>codeGenerationFolder/targetSpecific/_shared</i></p>	<p>Utility functions for model reference system target files, which are shared across models.</p> <p>Folder also contains <i>rtwshared.mk</i> for compiling generated shared utility code</p>
<p><i>simulationCacheFolder/slprj/sim/model</i></p>	<p><i>simulationCacheFolder/slprj/sim/model</i></p>	<p>Simulation target files for referenced models.</p>
<p><i>simulationCacheFolder/slprj/sim/model/tmwinternal</i></p>	<p><i>simulationCacheFolder/slprj/sim/model/tmwinternal</i></p>	<p>MAT-files used during code generation.</p>
<p><i>simulationCacheFolder/slprj/sim/_sharedutils</i></p>	<p><i>simulationCacheFolder/slprj/sim/_sharedutils</i></p>	<p>Utility functions for simulation system target files, which are shared across models.</p>

If the system target file is ERT-based, then these model configuration parameters also control the location of shared utility code:

- Shared code placement (`UtilityFuncGeneration`)
- Existing shared code (`ExistingSharedCode`)

You can use `RTW.getBuildDir` to display build folder information for the model.

## Manage Build Process Files

To apply generated code source and header files from the build process, it is helpful to understand the files that the build process generates and the conditions that control file generation. This information provides access to generated code resources, such as:

- Public interface to the model entry points
- Enumerated types corresponding to built-in data types
- Data structures that describe the model signals, states, and parameters

The code generator creates *model*.*\** files during the code generation and build process. You can customize the file names for generated header, source, and data files. For more information, see “Customize Generated File Names” on page 52-59. The code generator creates additional folders and dependency files to support shared utilities and model references. For more information about the folders that the build process creates, see “Manage Build Process Folders”. For an example that shows how to use a project to manage build process folders, see “Generate Code and Simulate Models in a Project”.

Depending on model architectures and code generation options, the build process for a GRT-based system target file can produce files that the build process does not generate for an ERT-based system target file. Also, for ERT-based system target files, the build process packages generated files differently than for GRT-based system target files. See “Manage File Packaging of Generated Code Modules” on page 50-12.

---

**Note** By default, the build process deletes foreign (not generated) source files in the build folder. It is possible to preserve foreign source files in the build folder by following the guidelines in “Preserve External Code Files in Build Folder”.

---

The table describes the principal generated files. Within the generated file names shown in the table, the *model* represents the name of the model for which you are generating code. The *subsystem* represents the name of a subsystem within the model. When you select the **Create code generation report** parameter, the code generator produces a set of HTML files. There is one HTML file for each source file plus a *model\_contents.html* index file in the *html* subfolder within your build folder. The source and header files in the table have dependency relationships. For descriptions of other file dependencies, see “Manage Build Process File Dependencies” and “Add Build Process Dependencies”.

File	Description
<code>builtin_typeid_types.h</code>	<p>Defines an enumerated type corresponding to built-in data types.</p> <p>A model build generates this file when one or more of these conditions apply:</p> <ul style="list-style-type: none"> <li>• Your model contains a Stateflow chart that uses messages.</li> <li>• Your model configuration enables <b>MAT-file logging</b>.</li> <li>• Your model configuration enables C API options in <b>Code Generation &gt; Interface</b>.</li> </ul>

File	Description
<i>model.bat</i>	<p>Contains Windows batch file commands that set the compiler environment and invoke the make utility.</p> <p>For more information about using this file, see “model.bat” on page 49-38.</p>
<i>model.c</i> <i>model.cpp</i>	<p>Corresponds to the model file.</p> <p>The Target Language Compiler generates this C or C++ source code file. The file contains:</p> <ul style="list-style-type: none"> <li>• Include files <i>model.h</i> and <i>model_private.h</i></li> <li>• Data, except data placed in <i>model_data.c</i></li> <li>• Model-specific scheduler code</li> <li>• Model-specific solver code</li> <li>• Model registration code</li> <li>• Algorithm code</li> <li>• Optional GRT wrapper functions</li> </ul>
<i>model.exe</i> (Windows platform)	Executable program file.
<i>model</i> (UNIX and Macintosh platforms)	A model build generates this file unless you explicitly specify that the code generator produce code only. The build generates the executable in the current folder (not the build folder) under control of the make utility of your development system.
<i>model.h</i>	<p>Defines model data structures and a public interface to the model entry points and data structures. Provides an interface to the real-time model data structure (<i>model_rtM</i>) via access macros.</p> <p>Subsystem .c or .cpp files in the model include <i>model.h</i>. This file includes:</p> <ul style="list-style-type: none"> <li>• Exported Simulink data symbols</li> <li>• Exported Stateflow machine parented data</li> <li>• Model data structures, including <i>rtM</i></li> <li>• Model entry-point functions</li> </ul> <p>For more information, see “model.h”.</p>
<i>model.mk</i>	<p>Generated makefile that controls compiling and linking the generated code into the final binary file by the make utility of your development system.</p> <p>If you set the MAKEFLAGS environment variable, do not select options with this variable that conflict with the current make utility used by the build process.</p>
<i>model.rtw</i>	<p>Represents the compiled model.</p> <p>By default, the build process deletes this ASCII file when the build process is complete. You can choose to retain the file for inspection.</p>

File	Description
<i>model_capi.h</i> <i>model_capi.c</i>	(optional files) Contain data structures that describe the model signals, states, and parameters without using external mode.  For more information, see “Exchange Data Between Generated and External Code Using C API”.
<i>model_data.c</i>	Contains (if conditionally generated) declarations for the parameters data structure and the constant block I/O data structure, and zero representations for structure data types that the model uses.  A model build generates this file when the model uses these data structures. The <code>extern</code> declarations for structures appear in <i>model.h</i> . When present, this file contains: <ul style="list-style-type: none"> <li>• Constant block I/O parameters</li> <li>• Include files <i>model.h</i> and <i>model_private.h</i></li> <li>• Definitions for the zero representations for user-defined structure data types that the model uses</li> <li>• Constant parameters</li> </ul>
<i>model_dt.h</i>	(optional file) Declares structures that contain data type and data type transition information for generated model data structures for supporting external mode.
<i>model_private.h</i>	Contains local <code>define</code> constants and local data for the model and subsystems.  The generated source files from the model build include this file. When you interface external code with generated code from a model, include <i>model_private.h</i> . The file contains: <ul style="list-style-type: none"> <li>• Imported Simulink data symbols</li> <li>• Imported Stateflow machine parented data</li> <li>• Stateflow entry points</li> <li>• Simulink Coder details (various macros, enums, and so forth, that are private to the code)</li> </ul> For more information, see “Manage Build Process File Dependencies”.
<i>model_reference_types.h</i>	Contains type definitions for timing bridges.  A model build generates this file for a referenced model or a model containing model reference blocks.
<i>model_targ_data_map.m</i>	(optional file) Contains MATLAB language commands that external mode uses to initialize the external mode connection.
<i>model_types.h</i>	Provides forward declarations for the real-time model data structure and the parameters data structure.  The generated header files from the model build include this file. Function declarations of reusable functions can use these structures.

File	Description
multiword_types.h	<p>Contains type definitions for multiple-word wide data types and their word-size chunks. If your code uses multiword data types, include this header file.</p> <p>A model build generates this file when one or more of these conditions apply:</p> <ul style="list-style-type: none"> <li>• Your model uses multiword data types.</li> <li>• Your model configuration enables <b>MAT-file logging</b>.</li> <li>• Your model configuration enables <b>Code Generation &gt; Interface &gt; External mode</b>.</li> </ul>
rtGetInf.c rtGetInf.h rtGetNaN.c rtGetNaN.h rt_nonfinite.c rt_nonfinite.h	<p>Declares and initializes global nonfinite values for inf, minus inf, and nan. Provides nonfinite comparison functions.</p> <p>A model build generates these files when one or more of these conditions apply:</p> <ul style="list-style-type: none"> <li>• The model contains S-functions.</li> <li>• The generated code from the model requires nonfinite numbers.</li> <li>• Your model configuration enables <b>MAT-file logging</b>.</li> <li>• Your model configuration selects <code>grt.tlc</code> as the <b>System target file</b> and enables the <b>Classic call interface</b>.</li> </ul>
rtmodel.h	<p>Contains <code>#include</code> directives required by static main program modules such as <code>rt_main.c</code>.</p> <p>The build process does not create these modules at code generation time. The modules include <code>rtmodel.h</code> to access model-specific data structures and entry points. If you create your own main program module, make sure to include <code>rtmodel.h</code>.</p>
rtwtypes.h	<p>Provides the essential type definitions, <code>#define</code> statements, and enumerations.</p> <p>For ERT-based system target files that do not generate a GRT interface and do not have noninlined S-functions, <code>rtwtypes.h</code> does not include <code>simstruc_types.h</code>.</p> <p>For more information, see “<code>rtwtypes.h</code>” and “Manage Build Process File Dependencies”.</p>
rtw_proj.tmw sl_proj.tmw	<p>Marker files.</p> <p>The build process generates these files to help the make utility determine when to recompile and link the generated code.</p>
rt_defines.h	<p>Contains type definitions for special mathematical constants (such as <math>\pi</math> and <math>e</math>) and defines the <code>UNUSED_PARAMETER</code> macro.</p> <p>A model build generates this file when the generated code requires a mathematical constant definition or when the function body does not access a required model function argument.</p>

File	Description
rt_sfcn_helper.h rt_sfcn_helper.c	(optional files) Provide functions that the noninlined S-functions use in a model.  The noninlined S-functions use functions <code>rt_CallSys</code> , <code>rt_enableSys</code> , and <code>rt_DisableSys</code> to call downstream function-call subsystems.
<i>subsystem.c</i>	(optional file) Contains C source code for each noninlined nonvirtual subsystem or copy the code when the subsystem is configured to place code in a separate file.
<i>subsystem.h</i>	(optional file) Contains exported symbols for noninlined nonvirtual subsystems.

## model.bat

This file contains Windows batch file commands that set the compiler environment and invoke the make utility.

If you are using the toolchain approach for the build process, you also can use this batch file to extract information from the generated makefile, *model.mk*. The information includes macro definitions and values that appear in the makefile, such as `CFLAGS` (C compiler flags) and `CPP_FLAGS` (C++ compiler flags). With the folder containing *model.bat* selected as the current working folder, in the Command Window, type:

```
>> system('model.bat info')
```

On UNIX and Macintosh platforms, the code generator does not create the *model.bat* file. To extract information for toolchain approach builds from the generated makefile on these systems, in the Command Window, type:

```
>> system('gmake -f model.mk info')
```

## model.h

The header file *model.h* declares model data structures and a public interface to the model entry points and data structures. This header file also provides an interface to the real-time model data structure (*model\_M*) by using access macros. If your code interfaces to model functions or model data structures, include *model.h*:

- Exported global signals

```
extern int32_T INPUT; /* '<Root>/In' */
```
- Global structure definitions

```
/* Block parameters (auto storage) */
extern Parameters_mymodel mymodel_P;
```
- Real-time model (RTM) macro definitions

```
#ifndef rtmGetSampleTime
define rtmGetSampleTime(rtm, idx)
((rtm)->Timing.sampleTimes[idx])
#endif
```

- Model entry point functions (ERT example)

```
extern void mymodel_initialize(void);
extern void mymodel_step(void);
extern void mymodel_terminate(void);
```

The `main.c` (or `.cpp`) file includes `model.h`. If the model build generates the `main.c` (or `.cpp`) file from a TLC script, the TLC source can include `model.h`.

```
#include "%<CompiledModel.Name>.h"
```

If `main.c` is a static source file, you can use the fixed header file name `rtmodel.h`. This file includes the `model.h` header file:

```
#include "model.h" /* If main.c is generated */

or

#include "rtmodel.h" /* If static main.c is used */
```

Other external source files can require to include `model.h` to interface to model data, for example exported global parameters or signals. The `model.h` file itself can have additional header dependencies due to requirements of generated code. See “System Header Files” and “Code Generator Header Files”.

To reduce dependencies and reduce the number of included header files, see “Manage Build Process File Dependencies”.

## rtwtypes.h

The header file `rtwtypes.h` defines data types, structures, and macros required by the generated code. You include `rtwtypes.h` for GRT and ERT system target files, instead of including `tmwtypes.h`.

Often, the generated code requires that integer operations overflow or underflow at specific values. For example, when the code expects a 16-bit integer, the code does not accept an 8-bit or a 32-bit integer type. The C language does not set a standard for the number of bits in types such as `char`, `int`, and others. So, there is no universally accepted data type in C to use for sized-integers.

To accommodate this feature of the C language, the generated code uses sized integer types, such as `int8_T`, `uint32_T`, and others, which are not standard C types. In `rtwtypes.h`, the generated code maps these sized-integer types to the corresponding C keyword base type using information in the **Hardware Implementation** pane of the configuration parameters.

The code generator produces the optimized version of `rtwtypes.h` for ERT-based system target files when these conditions apply:

- **Configuration Parameters > Code Generation > Interface > Advanced parameters > Classic call interface** is not selected.
- The model does not contain noninlined S-functions.

Include `rtwtypes.h`. If you include it for GRT system target files, for example, it is easier to use your code with ERT-based system target files.

For GRT and ERT system target files, the location of `rtwtypes.h` depends on whether the build process uses the *shared utilities* location. If it uses a shared location, the code generator places

`rtwtypes.h` in `slprj/target/_sharedutils`; otherwise, it places `rtwtypes.h` in the build folder (`model_target_rtw`). See “Specify Generated Code Interfaces”.

Source files include the `rtwtypes.h` header file when the source files use code generator type names or other code generator definitions. A typical example is for files that declare variables by using a code generator data type, for example, `uint32_T myvar`.

A source file that the code generator and an S-function use can use the preprocessor macro `MATLAB_MEX_FILE`. The macro definition comes from the `mex` function:

```
#ifndef MATLAB_MEX_FILE
#include "tmwtypes.h"
#else
#include "rtwtypes.h"
#endif
```

A source file for the code generator `main.c` (or `.cpp`) file includes `rtwtypes.h` without preprocessor checks.

```
#include "rtwtypes.h"
```

Custom source files that the Target Language Compiler generates can also emit these `include` statements into their generated file.

See “Control Placement of `rtwtypes.h` for Shared Utility Code”.

## Manage Build Process File Dependencies

An important control of the size of generated code is managing the number and size of included files (dependencies). To reduce the number of system header files and generated header files that generated code requires, it is helpful to understand the dependencies that the build process generates and the conditions that lead to dependencies.

The dependency relationships among generated source and header files appear in the figure. Arrows coming from a file point to files it includes. Other dependencies exist, for example, on Simulink header files `tmwtypes.h` and `simstruc_types.h`, plus C or C++ library files. The figure maps inclusion relations between only those files that are generated in the build folder. These files can reference utility and model reference code located in a code generation folder. For more information about the folders and files that the build process creates, see “Manage Build Process Folders” and “Manage Build Process Files”.

The two tables identify the conditions that control creation of dependency files for GRT and ERT targets. To manage build-related dependencies, consider how these conditions apply to your model and code generation process. Then, configure model parameters and code generation options to manage build process file dependencies.

Due to differences in file packaging options for code generated with ERT-based system target files, the file dependencies differ slightly from file packaging for code generated with GRT-based system target files. See “Manage File Packaging of Generated Code Modules” on page 50-12.

The parent system header files (`model.h`) include child subsystem header files (`subsystem.h`). In more layered models, subsystems similarly include their children's header files in the model hierarchy. As a consequence, subsystems are able to view recursively into their descendant subsystems and view into the root system because every `subsystem.c` or `subsystem.cpp` includes `model.h` and `model_private.h`.

In the figure, files `model.h`, `model_private.h`, and `subsystem.h` depend on the header file `rtwtypes.h`. If you use system target files that are not based on the ERT system target file, the source files that you generate can have additional dependencies on `tmwtypes.h` and `simstruc_types.h`.

## System Header Files

The system header files make function declarations, type definitions, and macro definitions available to the legacy or external code. Some code generation scenarios require including header files that are specific to the code generator product.

The code generator includes some system header files for broadly defined cases. For example, generated code includes `<stddef.h>` when the model contains a utility function that requires this header file. This approach helps identify header file dependencies:

- 1 Set model configuration parameter **Shared code placement** to 'Shared location' and build the model. The code generator places the utility functions in `__sharedutils` folder.
- 2 Use a find-in-file utility (for example, `grep` utility) to search the `.c` and `.h` files in the `__sharedutils` folder for `#include`. The search results list the utilities with header file dependencies.
- 3 Use this information to identify utilities to remove from the model and reduce header file dependencies in the generated code.

For more information, see “Generate Shared Utility Code for Fixed-Point Functions”.

System Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
<math.h>	<p>Defines math constants</p> <p>GRT—Generated code does not include this file.</p> <p>ERT—Generated code includes this file when the code honors your model configuration for solver <b>Stop time</b> and either:</p> <ul style="list-style-type: none"> <li>• Your model configuration enables parameter <b>MAT-file logging</b>. See “MAT-file logging”.</li> <li>• Your model configuration enables parameter <b>External mode</b>.</li> </ul>
<float.h>	<p>Provides floating-point math functions</p> <p>GRT—Generated code includes this file when your model contains a floating-point math function.</p> <p>ERT—Generated code includes this file when your model contains a floating-point math function, unless a code replacement library entry overrides the function. For more information, see “Choose a Code Replacement Library”.</p>

To omit calls to <code>memset()</code> from model initialization code, select model configuration parameters <b>Remove root level I/O zero initialization</b> and <b>Remove internal data zero initialization</b>.</p>

## Code Generator Header Files

Dependencies in the table for generated header files apply to the system target files `grt.tlc` and `ert.tlc`. System target files derived from these base system target files can have additional header dependencies. Code generation for blocks from blocksets, embedded targets, and custom S-functions can introduce additional header dependencies.

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
<code>builtin_typeid_types.h</code>	<p>Defines an enumerated type corresponding to built-in data types</p> <p>GRT and ERT—Generated code includes this file when one or more of these conditions apply:</p> <ul style="list-style-type: none"> <li>Your model contains a Stateflow chart that uses messages.</li> <li>Your model configuration enables: <b>MAT-file logging</b>. See “MAT-file logging”.</li> <li>Your model configuration selects C API options at <b>Code Generation &gt; Interface</b>.</li> </ul>
<code>dt_info.h</code>	<p>Defines data structures for external mode</p> <p>GRT and ERT—Generated code includes this file when your model configuration enables external mode.</p>
<code>ext_work.h</code>	<p>Defines external mode functions</p> <p>GRT and ERT—Generated code includes this file when your model configuration enables external mode.</p>

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
fixedpoint.h	<p>Provides fixed-point support for noninlined S-functions</p> <p>GRT—Generated code includes this file.</p> <p>ERT—Generated code includes this file when either:</p> <ul style="list-style-type: none"> <li>• Your model uses noninlined S-functions.</li> <li>• Your model configuration selects parameter <b>Classic call interface</b>.</li> </ul>
model_reference_types.h	<p>Contains type definitions for timing bridges</p> <p>GRT and ERT—Generated code includes this file when building a reference model or building a model that contains model blocks.</p>
model_types.h	<p>Defines model-specific data types</p> <p>GRT and ERT—Generated code includes this file.</p>
multiword_types.h	<p>Contains type definitions for multiword-wide data types and their word-size chunks</p> <p>GRT and ERT—Generated code includes this file when one or more of these conditions apply:</p> <ul style="list-style-type: none"> <li>• Your model uses multiword data types.</li> <li>• Your model configuration selects parameter <b>MAT-file logging</b>. See “MAT-file logging”.</li> <li>• Your model configuration selects <b>External mode</b>.</li> </ul> <p>For a model that uses multiword data types, the code generator overwrites the file if the data types are greater in length than those of the model for which code was last generated. To avoid overwriting this file, set:</p> <ul style="list-style-type: none"> <li>• <code>MultiwordTypeDef</code> to 'User defined'</li> <li>• <code>MultiwordLength</code> to the biggest length that is required by your models.</li> </ul>

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
rtGetInf.h rtGetNaN.h rt_nonfinite.h	<p>Support nonfinite numbers</p> <p>GRT—Generated code includes this file when one or more of these conditions apply:</p> <ul style="list-style-type: none"> <li>• Your model contains S-functions.</li> <li>• The generated code requires nonfinite numbers.</li> <li>• Your model configuration selects parameter <b>MAT-file logging</b>. ## Add Build Process Dependencies

When you specify a system target file for code generation, the code generator can build a standalone executable program that can run on the development computer. To build the executable program, the code generator uses the selected compiler and the makefile generated by the toolchain or template makefile (TMF) build process approach. Part of the makefile generation process is to add source file, header file, and library file information (the dependencies) in the generated makefile for a compilation. Or, for a specific application, you can add the generated files and file dependencies through a configuration management system.

The generated code for a model consists of a small set of files. (See “Manage Build Process Files”.) These files have dependencies on other files, which occur due to:

- Header file inclusions
- Macro declarations
- Function calls
- Variable declarations

The model or external code introduces dependencies for various reasons:

- Blocks in a model generate code that makes function calls. These calls can occur in several forms:
  - Included source files (not generated) declare the called functions. In cases such as a blockset, manage these source file dependencies by compiling them into a library file.
  - The generated code makes calls to functions in the run-time library provided by the compiler.
  - Some function dependencies also are generated files, which are referred to as shared utilities. Some examples are fixed-point utilities and non-finite support functions. These dependencies are referred to as shared utilities. The generated functions can appear in files in the build folder for standalone models or in the `_sharedutils` folder under the `slprj` folder for builds that involve model reference.
- Models with continuous time require solver source code files.
- Code generator options such as external mode, C API, and MAT-file logging.
- External code specifies dependencies.

### File Dependency Information for the Build Process

The code generator provides several mechanisms to input file dependency information into the build process. The mechanisms depend on whether your dependencies are block-based or are model- or system target file-based.

For block dependencies, consider using:

- S-functions and blocksets
  - Add folders that contain S-function MEX-files that the model uses to the header include path.
  - Create makefile rules for these folders to allow for finding source code.
  - Specify additional source file names with the S-Function block parameter `SFunctionModules`.
  - Specify additional dependencies with the `rtwmakecfg.m` mechanism. See “Use `rtwmakecfg.m` API to Customize Generated Makefiles”.

For more information on applying these approaches to legacy or external code integration, see “Import Calls to External Code into Generated Code with Legacy Code Tool”.

- S-Function Builder block, which provides its own UI for specifying dependency information

For model- or system target file-based dependencies, such as external header files, consider using:

- The **Code Generation > Custom Code** pane in the Configuration Parameters dialog box. You can specify additional libraries, source files, and include folders.
- TLC functions `LibAddToCommonIncludes()` and `LibAddToModelSources()`. You can specify dependencies during the TLC phase. See “`LibAddToCommonIncludes(incFileName)`” and “`LibAddSourceFileCustomSection(file, builtInSection, newSection)`”. The Embedded Coder product also provides a TLC-based customization template for generating additional source files.

### Generated Makefile Dependencies

For toolchain approach or template makefile (TMF) approach build processes, the code generator generates a makefile. For TMFs, the generated makefile provides token expansion in which the build process expands different tokens in the makefile to include the additional dependency information. The resulting makefile contains the complete dependency information. See “Customize Template Makefiles”.

The generated makefile contains:

- Names of the source file dependencies
- Folders where source files are located
- Location of the header files
- Precompiled library dependencies
- Libraries that the make utility compiles and creates

A property of make utilities is that you do not have to specify the specific location for a given source C or C++ file. If a rule exists for that folder and the source file name is a prerequisite in the makefile, the make utility can find the source file and compile it. The C or C++ compiler (preprocessor) does not require absolute paths to the headers. The compiler finds header file with the name of the header file by using an `#include` directive and an include path. The generated C or C++ source code depends on this standard compiler capability.

Libraries are created and linked against, but occlude the specific functions that the program calls.

These properties can make it difficult to determine the minimum list of file dependencies manually. You can use the makefile as a starting point to determine the dependencies in the generated code.

Another approach to determining the dependencies is using linker information, such as a linker map file, to determine the symbol dependencies. The map file provides the location of code generator and blockset source and header files to help in locating the dependencies.

### Code Generator Static File Dependencies

Several locations in the MATLAB folder tree contain static file dependencies specific to the code generator:

- `matlabroot/rtw/c/src` (open)

This folder has subfolders and contains additional files must be compiled. Examples include solver functions (for continuous time support), external mode support files, C API support files, and S-

function support files. Include source files in this folder into the build process with the SRC variables of the makefile.

- Header files in the folder `matlabroot/extern/include`
- Header files in the folder `matlabroot/simulink/include`

These folders contain additional header file dependencies such as `tmwtypes.h`, `simstruc_types.h`, and `simstruc.h`.

---

**Note** For ERT-based system target files, you can avoid several header dependencies. ERT-based system target files generate the minimum set of type definitions, macros, and so on, in the file `rtwtypes.h`.

---

### Blockset Static File Dependencies

Blockset products with S-function code apply the `rtwmakecfg.m` mechanism to provide the code generator with dependency information. The `rtwmakecfg.m` file from the blockset contains the list of include path and source path dependencies for the blockset. Typically, blocksets create a library from the source files to which the generated model code can link. The libraries are created and identified when you use the `rtwmakecfg.m` mechanism.

To locate the `rtwmakecfg.m` files for blocksets in your MATLAB installed tree, use the following command:

```
>> which -all rtwmakecfg.m
```

If the model that you are compiling uses one or more of the blocksets listed by the `which` command, you can determine folder and file dependency information from the respective `rtwmakecfg.m` file.

### Folder Dependency Information for the Build Process

You can add `#include` statements to generated code. Such references can come from several sources, including TLC scripts for inlining S-functions, custom storage classes, bus objects, and data type objects. The included files consist of header files for external code or other customizations. You can specify compiler include paths with the `-I` compiler option. The build process uses the specified paths to search for included header files.

Usage scenarios for the generated code include, but are not limited to, the following:

- A custom build process compiles generated code that requires an environment-specific set of `#include` statements.

In this scenario, the build process invokes the code generator when you select model configuration parameter **Generate code only**. Consider using fully qualified paths, relative paths, or just the header file names in the `#include` statements. Use include paths.

- The build process compiles the generated code.

In this case, you can specify compiler include paths (`-I`) for the build process in several ways:

- Specify additional include paths on the **Code Generation > Custom Code** pane in the Configuration Parameters dialog box. The code generator propagates the include paths into the generated makefile.

- The `rtwmakecfg.m` mechanism allows S-functions to introduce additional include paths into the build process. The code generator propagates the include paths into the generated makefile.
- When building a model that uses a custom system target file and is makefile-based, you can directly add the include paths into the template makefile that the system target file uses.
- Use the `make` command to specify a `USER_INCLUDES` make variable that defines a folder in which the build process searches for included files. For example:

```
make_rtw USER_INCLUDES=-Id:\work\feature1
```

The build process passes the custom includes to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler.

### Use #include Statements and Include Paths

Consider the following approaches for using `#include` statements and include paths with the build process to generate code that remains portable and minimizes compatibility problems with future versions.

Assume that additional header files are:

```
c:\work\feature1\foo.h
c:\work\feature2\bar.h
```

- An approach is to include in the `#include` statements only the file name, such as:

```
#include "foo.h"
#include "bar.h"
```

Then, the include path passed to the compiler contains folders in which the headers files exist:

```
cc -Ic:\work\feature1 -Ic:\work\feature2 ...
```

- Another approach is to use relative paths in `#include` statements and provide an anchor folder for these relative paths using an include path, for example:

```
#include "feature1\foo.h"
#include "feature2\bar.h"
```

Then, specify the anchor folder (for example `\work`) to the compiler:

```
cc -Ic:\work ...
```

### Avoid These Folder Dependencies

When using the build process, avoid dependencies on folders in the build process “Code generation folder”, such as the `model_ert_rtw` folder or the `slprj` folder. Do not use paths in `#include` statements that are relative to the location of the generated source file. For example, if your MATLAB code generation folder is `c:\work`, the build process generates the `model.c` source file into a subfolder such as:

```
c:\work\model_ert_rtw\model.c
```

The `model.c` file has `#include` statements of the form:

```
#include "..\feature1\foo.h"
#include "..\feature2\bar.h"
```

It is preferable to use one of the other suggested approaches because the relative path creates a dependency on the code generator folder structure.

# Build Process Support for Folder Names

## Folder Names with Spaces

On a Windows system, the code generator maps a drive corresponding to the MATLAB installation folder for either of these conditions:

- The `matlabroot` folder is a UNC location.
- The path the `matlabroot` folder contains spaces, and the system has no alternative name support.

These folder paths can contain spaces:

- The path to your MATLAB installation folder (`matlabroot`). For example, `C:\Program Files\MATLAB\R2015b`
- The path to the current working folder where you start the build (`pwd`). For example, `C:\Users\username\Documents\My Work`.
- The path to the installation folder for a compiler that the build process uses.

If your work environment includes one or more of the preceding scenarios, use the following support mechanisms for the build process:

- If you are using the toolchain approach to build generated code, the system support for spaces in folder names influences toolchain operation:
  - For Linux<sup>®</sup> systems and Windows systems with 8.3 name creation enabled, the toolchain manages spaces in folder names by using alternative names from the operating system. The toolchain uses the `TransformPathsWithSpaces` attribute to manage these names.

```
addAttribute(toolchainObject, 'TransformPathsWithSpaces', true);
```

The security permissions of drives and folders can determine whether the toolchain transforms the path. For example, if the path contains a folder with a security configuration that forbids 8.3 path transformations, the toolchain does not transform the path and the build process produces a warning.

- For Windows systems with 8.3 name creation disabled, the toolchain manages spaces in folder names by mapping a network drive using a batch file (.bat). This operation requires adding the `RequiresBatchFile` attribute to the toolchain definition.

```
addAttribute(toolchainObject, 'RequiresBatchFile', true);
```

When developing a toolchain for a Windows system, set both attributes. For more information about the toolchain attributes, see `addAttribute`.

- If you are using the template makefile approach to build generated code, the template makefile (.tmf) requires code to manage spaces in folder names. When the alternative folder names (Windows short names) differ from the file system folder names (Windows long names), add this code to the makefile.

```
ALT_MATLAB_ROOT = |>ALT_MATLAB_ROOT<|
ALT_MATLAB_BIN = |>ALT_MATLAB_BIN<|
!if "$(MATLAB_ROOT)" != "$(ALT_MATLAB_ROOT)"
MATLAB_ROOT = $(ALT_MATLAB_ROOT)
!endif
!if "$(MATLAB_BIN)" != "$(ALT_MATLAB_BIN)"
```

```
MATLAB_BIN = $(ALT_MATLAB_BIN)
!endif
```

When the values of the location tokens are not equal, this code replaces `MATLAB_ROOT` with `ALT_MATLAB_ROOT`. The replacement indicates that the path to your MATLAB installation folder includes spaces. This code applies the same type of replacement for `MATLAB_BIN` with `ALT_MATLAB_BIN`. The preceding code is specific to `nmake`. For platform-specific examples, see the supplied template makefiles.

With either build approach, when there is an issue with support for creation of alternate names (short names), build errors can occur on Windows. If a build generates an error message similar to the following message, see “Troubleshooting Errors When Folder Names Have Spaces” on page 49-57.

```
NMAKE : fatal error U1073: don't know how to make ' ...
```

When using operating system commands, such as `system` or `dos`, enclose paths that specify executable files or command parameters in double quotes ( " "). For example:

```
system('dir "D:\Applications\Common Files"')
```

This table provides a summary of build folder support and limitations for Windows.

Build Process Folders	Approach for Paths with UNC or Spaces	Support for Windows
<p><code>matlabroot</code> folder</p> <p>The <code>matlabroot</code> value is derived from the MATLAB installation location.</p>	<p>During a build, a UNC location such as:  <code>\\networkdrive\matlab\R20xxb</code>                      could be remapped as:  <code>T:\</code></p> <p>During a build on a Windows system with short file name (8.3) support (default for Windows using NTFS), the build process uses the Windows API <code>getShortPathName()</code> for the folder location.</p> <p>During a build on a Windows system without short file name (8.3) support (systems using ReFS or using NTFS with 8.3 support disabled), a location with spaces in the path such as:  <code>C:\Program Files\MATLAB\R20xxb</code>                      could be remapped as:  <code>T:\R20xxb</code></p>	<p>Build process folder support available independent of file system (NTFS or ReFS) or file system configuration for short file name support.</p> <p><b>Limitations:</b></p> <p>On systems that require drive mapping for the installation location, the build process requires that a drive letter is available for mapping.</p> <p>On systems without short file name (8.3) support (using ReFS or using NTFS with 8.3 support disabled), the final folder in the installation location cannot contain spaces. For example, a final folder name:  <code>C:\Program Files\MATLAB\R20xxb sp1</code>                      is not supported.</p>
<p>Code generation folder</p> <p>Simulation cache folder</p>	<p>For UNC locations, build process temporarily maps a drive by using the shell commands <code>pushd</code> and <code>popd</code>.</p>	<p>Build process folder support is available independent of file system (NTFS or ReFS) or file system configuration for short path name support.</p>

Build Process Folders	Approach for Paths with UNC or Spaces	Support for Windows
Custom code source file locations—among others, these locations include folders specified by: <ul style="list-style-type: none"> <li>• <code>rtwmakecfg.m</code></li> <li>• Model configuration parameter</li> </ul> <b>Additional build information</b> <ul style="list-style-type: none"> <li>• Code replacement library</li> </ul>	For paths with spaces, build process uses the Windows short path name (8.3) by using the Windows API: <pre>getShortPathName()</pre>	Build process folder support depends on NTFS file system and requires Windows default support. Registry sets value of 2 or 0 for: <pre>NtfsDisable8dot3NameCreation</pre> <p><b>Limitations:</b> Build process does not support spaces in the path to these folders for:</p> <ul style="list-style-type: none"> <li>• NTFS file system with short path name support disabled</li> <li>• ReFS file system (this file system does not support short path names)</li> </ul>

## Troubleshooting Errors When Folder Names Have Spaces

On Windows, when there is an issue with support for creation of short file names, build process errors can occur. When this issue affects a build, you see an error message similar to:

```
NMAKE : fatal error U1073: don't know how to make 'C:\Work\My'
```

This message can occur if a space in the folder name (`C:\Work\My Models`) prevents the build process from finding the model or a file to build. For descriptions of the build-related folders that are sensitive to a space in the folder name or path, see “Folder Names with Spaces” on page 49-55.

To avoid issues from folder names with spaces when Windows short file name support for file names is disabled, do not use paths with spaces. For example, install third-party software to paths without spaces. Do not use paths with spaces for folders containing your models, source files, or libraries.

An issue can occur with builds that use folder names with spaces, because it is possible to disable Windows alternate name support. The build process uses this alternate name support on Windows systems. There are many terms for this file, folder, and path alternate name support:

- 8.3 name
- DOS path
- short file name (SFN, ShortFileName)
- long name alias
- Windows path alias

Verify the type of file system that the drive uses. In Windows Explorer, right-click the drive icon and select properties.

- If the file system is ReFS (Resilient File System), it is an issue. The ReFS does not provide short file name support. Except for the MATLAB installation folder, the build process does not support

folder names with spaces for the ReFS file system. If your work environment requires short file name support for the build folder or for additional external code folders, do not use ReFS.

- If the file system is NTFS (New Technology File System), it is possible that the build error is related to a registry setting incompatibility. Continue with troubleshooting steps.

The error could stem from an issue with short file name support on a system using NTFS. Check the Windows registry setting that enables the creation of short names for files, folders, and paths.

- 1 Open the Windows command prompt, running as administrator. For example, from the Windows Start menu, type `cmd`, right-click the `cmd.exe` icon, and select `Run as administrator`.
- 2 Change to the `windows\system32` folder and query the `NtfsDisable8dot3NameCreation` status by typing:

```
> fsutil 8dot3name query
```

- 3 If the registry state of `NtfsDisable8dot3NameCreation` is not 2, the default (Volume level setting), change the value to 2 by typing:

```
> fsutil 8dot3name set 2
```

For more information about enabling creation of short names. See [https://docs.microsoft.com/en-us/previous-versions/windows/it-pro/windows-server-2012-R2-and-2012/ff621566\(v=ws.11\)](https://docs.microsoft.com/en-us/previous-versions/windows/it-pro/windows-server-2012-R2-and-2012/ff621566(v=ws.11)).

Changing the registry setting enables creation of short names only for files and folders that are created after the change.

- 4 To create short names for files created while short name creation was disabled, at the Windows command line, use the `fsutil` utility.

To set the short name, the syntax is:

```
> fsutil file setshortname <FileName> <ShortName>
```

For example, to create the short name `PROGRA~1` for the long name `C:\Program Files`, type:

```
> fsutil file setshortname "C:\Program Files" PROGRA~1
```

The `C:\Program Files` folder name is in quotations because it has spaces.

- 5 To verify that the short name was created, use the `dir` command with `/x` option to show short names.

```
> dir C:\ /x
```

## Folder Names with Special Characters

The build process might produce an error if a build-related folder path contains:

- Unicode characters that do not belong to the system locale. This limitation does not apply if the build process uses a Microsoft Visual C++ compiler.
- A Japanese (multibyte) character where the final byte is equal to the 5C hexadecimal character. The make and compiler tools might incorrectly interpret the final byte as the `'\'` (backslash) character.

## Very Long Folder Paths

For the MinGW® compiler, the build process produces an error when the command line length exceeds the Windows limit of 32,767 characters. If this error occurs, check the length of include

paths. You can reduce the command line length by building the generated code in a code generation folder that has a shorter name

## Code Generation of Matrices and Arrays

MATLAB stores matrix data and arrays (1-D, 2-D, ...) in column-major format as a vector. Simulink and the code generator can store array data in column-major or row-major format. For an array stored in column-major layout, the elements of the columns are contiguous in memory. In row-major layout, the elements of the rows are contiguous. Array layout is also referred to as order, format, and representation. The order in which elements are stored can be important for integration, usability, and performance. Certain algorithms perform better on data stored in a particular order.

Programming languages and environments assume a single array layout for all data. MATLAB and Fortran use column-major layout by default, whereas C and C++ use row-major layout. With Simulink Coder, you can generate C/C++ code that uses row-major layout or column-major layout.

### Array Storage in Computer Memory

Computer memory stores data in terms of one-dimensional arrays. For example, when you declare a 3-by-3 matrix, the software stores this matrix as a one-dimensional array with nine elements. By default, MATLAB stores these elements with a column-major array layout. The elements of each column are contiguous in memory.

Consider the matrix A:

```
A =
 1 2 3
 4 5 6
 7 8 9
```

A translates to an array of length 9 in this order:

```
A(1) = A(1,1) = 1;
A(2) = A(2,1) = 4;
A(3) = A(3,1) = 7;
A(4) = A(1,2) = 2;
A(5) = A(2,2) = 5;
```

and so on.

In column-major format, the next element of an array in memory is accessed by incrementing the first index of the array. For example, these element pairs are stored sequentially in memory:

- $A(i)$  and  $A(i+1)$
- $B(i, j)$  and  $B(i+1, j)$
- $C(i, j, k)$  and  $C(i+1, j, k)$

The matrix A is represented in memory by default with this arrangement:

```
1 4 7 2 5 8 3 6 9
```

In row-major array layout, the programming language stores row elements contiguously in memory. In row-major layout, the elements of the array are stored as:

```
1 2 3 4 5 6 7 8 9
```

You can store the N-dimensional arrays in column-major or row-major layout. In column-major layout, the elements from the first (leftmost) dimension or index are contiguous in memory. In row-major layout, the elements from the last (rightmost) dimension or index are contiguous.

For more information on the internal representation of MATLAB data, see “MATLAB Data”.

Code generation software uses column-major format by default for several reasons:

- The world of signal and array processing is largely in column-major array layout: MATLAB, LAPack, Fortran90, and DSP libraries.
- A column is equivalent to a channel in frame-based processing. In this case, column-major storage is more efficient.
- A column-major array is self-consistent with its component submatrices:
  - A column-major 2-D array is a simple concatenation of 1-D arrays.
  - A column-major 3-D array is a simple concatenation of 2-D arrays.
  - The stride is the number of memory locations to index to the next element in the same dimension. The stride of the first dimension is one element. The stride of the nth dimension element is the product of the sizes of the lower dimensions.
  - Row-major n-D arrays have their stride of 1 for the highest dimension. Submatrix manipulations are typically accessing a scattered data set in memory, which does not allow for efficient indexing.

C uses row-major format. MATLAB and Simulink use column-major format by default. You can configure the code generation software to generate code with a row-major array layout. If you are integrating external C code with the generated code, see the considerations listed in this table.

<b>Action</b>	<b>Consider</b>
Configure array layout of the model for code generation.	In the Configuration Parameters dialog box, set model configuration parameter <b>Array layout</b> to Column-major or Row-major.
Enable efficient row-major algorithms for simulation and code generation.	Select model configuration parameter <b>Use algorithms optimized for row-major array layout</b> .

Action	Consider
Integrate external C code functions in row-major array layout with the generated code.	<p>Create S-functions that integrate external code functions with the generated code by using:</p> <ul style="list-style-type: none"> <li>• The SimStruct function <code>ssSetArrayLayoutForCodeGen</code>.</li> <li>• The “Set Array Layout” setting in the S-Function Builder block.</li> <li>• The Legacy Code Tool option <code>convert2DMatrixToRowMajor</code> in <code>legacy_code</code>. Using <code>convert2DMatrixToRowMajor</code> impacts code efficiency.</li> </ul> <p>Use the C Caller block to call external C functions into Simulink. Specify array layout of custom C functions by using model configuration parameter <b>Default function array layout</b>.</p> <p>You can also use <code>coder.ceval</code> in a MATLAB Function block. See “Interface with Row-Major Data in MATLAB Function Block”.</p>

## Code Generator Matrix Parameters

The compiled model file, `model.rtw`, represents matrices as character vectors in MATLAB syntax, without an implied storage format. This format enables you to copy the character vector out of an `.rtw` file, paste it into a MATLAB file, and have MATLAB recognize it.

### Column-Major Layout

For example, the 3-by-3 matrix in the Constant block

```

1 2 3
4 5 6
7 8 9

```

is stored in `model.rtw` as

```

Parameter {
 Identifier "Constant_Value"
 LogicalSrc P0
 Protected no
 Value [1.0, 4.0, 7.0, 2.0, 5.0, 8.0, 3.0, 6.0, 9.0]
 CGTypeIdx 18
 ContainerCGTypeIdx 19
 ReferencedBy Matrix(1,4)
 GraphicalRef Matrix(1,2)
 BHMPrmIdx 0
 GraphicalSource [0, 1]
 OwnerSysIdx [0, -1]
 VarGroupIdx [1, 0]
}
[[0, -1, 0, 0];]
[[0, 1];]

```

```

 WasAccessedAsVariable 1
}

```

The `model_data.c` file declares the actual storage for the matrix parameter. You can see that the format is in column-major layout.

```

Parameters model_P = {
 /* Expression: [[1,2,3] ; [4,5,6] ; [7,8,9]]
 * Referenced by: '<Root>/Constant '
 */
 { 1.0, 4.0, 7.0, 2.0, 5.0, 8.0, 3.0, 6.0, 9.0 }
};

```

### Row-Major Layout

For example, the 3-by-3 matrix in the Constant block

```

1 2 3
4 5 6
7 8 9

```

is stored in `model.rtw` as

```

Parameter {
 Identifier "Constant_Value"
 LogicalSrc P0
 Protected no
 Value [1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0]
 CGTypeIdx 18
 ContainerCGTypeIdx 19
 ReferencedBy Matrix(1,4)
 GraphicalRef Matrix(1,2)
 GraphicalSource [0, 1]
 OwnerSysIdx [0, -1]
 VarGroupIdx [1, 0]
 WasAccessedAsVariable 1
}

```

The `model_data.h` file declares the actual storage for the matrix parameter. You can see that the format is in row-major layout.

```
Parameters model_P = {
 /* Expression: [[1,2,3] ; [4,5,6] ; [7,8,9]]
 * Referenced by: '<Root>/Constant '
 */
 { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0 }
};
```

## Internal Data Storage for Complex Number Arrays

Simulink and code generator internal data storage formatting differs from MATLAB internal data storage formatting only in the storage of complex number arrays. In MATLAB, the real and imaginary parts are stored in separate arrays. In Simulink and the code generator, the parts are stored in an interleaved format. The numbers in memory alternate real, imaginary, real, imaginary, and so forth. This convention allows efficient implementations of small signals on Simulink lines, for Mux blocks, and other virtual signal manipulation blocks. For example, the signals do not actively copy their inputs, just the references.

## Unsupported Blocks for Row-Major Code Generation

The code generator does not support these blocks for code generation in row-major array layout.

## Cross-Release Shared Utility Code Reuse

### In this section...

“Workflow to Reuse Shared Utility Code” on page 49-66

“Required Editing for Shared Utility Code Reuse” on page 49-67

When you generate code for a model, the code generator by default creates shared utility files that the model requires. When you generate code with different releases, the code generators can produce functionally identical shared files that contain some nonfunctional differences. For example, different comments and different coding style. When you use the same release to generate code for different models in different folders, you can also produce shared files with nonfunctional differences. For example, if you specify different `ParenthesesLevel` or `ExpressionFolding` values for the models, the code generator can produce shared files that contain different comments or different coding styles.

Integrated code that includes functionally identical shared files:

- Is more expensive to verify because each shared file requires verification.
- Produces compilation errors if the shared files define duplicate symbols.

If you have an Embedded Coder license, you can avoid these issues by specifying the reuse of shared code from an existing folder, for example, a read-only library of verified code. In this case, the code generator does not create new shared utility files. The build process uses external code or previously generated shared utility code from the folder. An administrator maintains and updates the read-only library.

### Workflow to Reuse Shared Utility Code

- 1 In the Configuration Parameters dialog box:
  - a In the **Existing shared code** field, enter the full path to your shared code folder.
  - b Verify that the **Use only existing shared code** diagnostic is set to error (default).
- 2 Remove the `slprj` folder or move to a new working folder.
- 3 Build your model. If you do not see an error, your shared code folder contains the required shared utility files.
- 4 If files are missing from the existing shared code folder, you see an error. To continue code generation with a locally generated version of the missing shared utility files:
  - a Set the **Use only existing shared code** diagnostic to warning.
  - b Rebuild your model. The code generation process uses a locally generated version of the missing shared utility files.
  - c Provide the administrator of the verified code library with your model and information about missing shared utility files. With the model, the administrator generates the required shared utility files. Using `sharedCodeUpdate`, the administrator adds the files to the existing shared code folder.

If you require reuse of shared code for a component exported from a previous release, provide the administrator with information about the build folder location for the component. The administrator can use `sharedCodeUpdate` to copy the shared code for the component to the existing shared code folder.

- d When the files are available in the existing shared code folder, repeat steps 1-3.

If the shared utility code is generated from library subsystems that are shared across models, you cannot reuse the code *across* releases because the code is release-specific—the symbol name and file name mangling includes the release number. The administrator must add the shared utility code generated for each release to the shared code folder.

The `sharedCodeUpdate` function can add files to the shared code folder that have identical content but different file and function names. This behavior is useful when you have different model components that require their own shared utility functions. Although some code is duplicated, the different model components can access the shared utility functions with which they were verified. To force model components to have their own versions of shared utility functions, configure naming rules to insert the model name into shared utility identifiers.

## Required Editing for Shared Utility Code Reuse

For most shared utility code files, you can specify master copies that you can reuse across releases without modifying the files. With some files, for example, `rtwtypes.h`, and `zero_crossing_types.h`, there are situations where manual editing is required to produce master copies that you can use with generated code from different releases. For example:

- The `rtwtypes.h` file generated by releases up to and including R2013a contains a checksum.

```
/* This ID is used to detect inclusion
 of an incompatible rtwtypes.h */
#define RTWTYPES_ID_C08S16I32L64N64F0
```

For each version of this `rtwtypes.h` file that you want to include in your integration, copy the corresponding `#define` statement into your master copy of `rtwtypes.h`.

- In R2015a, the zero-crossing definitions moved from `rtwtypes.h` into `zero_crossing_types.h`. To create an `rtwtypes.h` file that is compatible with generated model code from different releases, in your master copy of `rtwtypes.h`, insert this statement.

```
#include "zero_crossing_types.h"
```

Remove definitions from `rtwtypes.h` that `zero_crossing_types.h` provides.

“Use Multiple Instances of Code Generated from Reusable Referenced Model” on page 49-76

“Compare Simulation Behavior of Model Component in Current Release and Generated Code from Previous Release” on page 49-77

“Import AUTOSAR Code from Previous Releases” on page 49-78

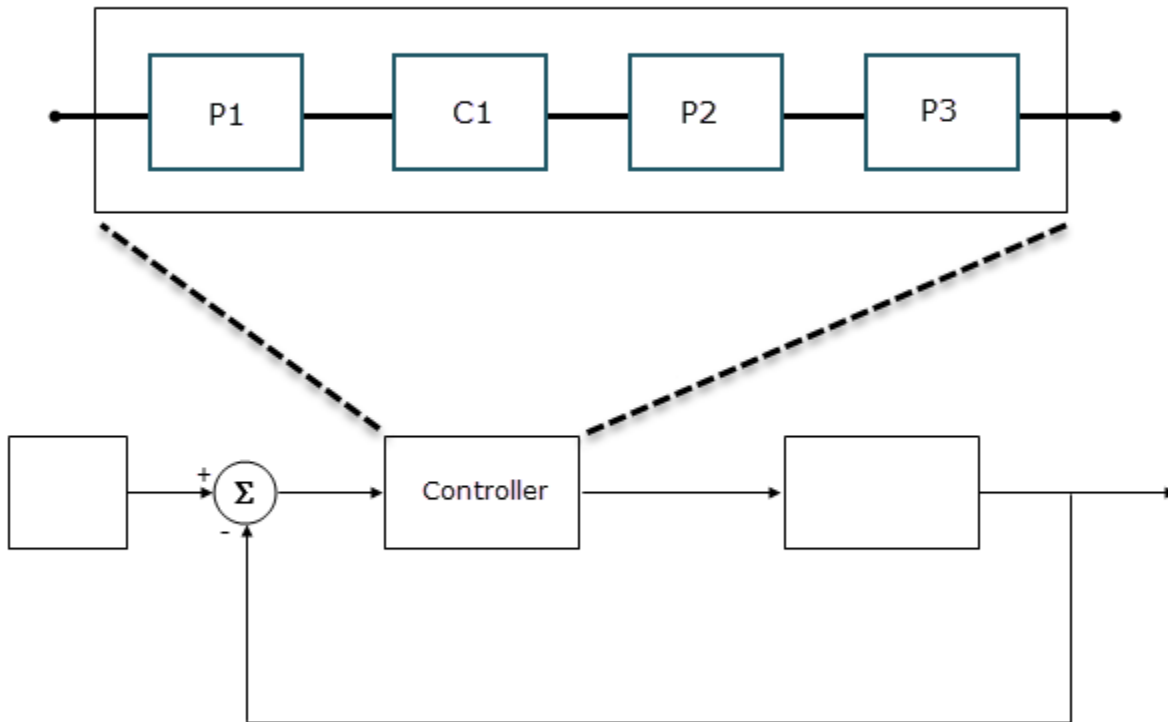

If you have an Embedded Coder license, you can integrate generated C code from previous releases (R2010a and later) with generated code from the current release when the source models are single-rate and the generated C code is from:

- Top-model or subsystem build processes that use the nonreusable function code interface.
- Single or multiple instance model reference build processes that suppress error status monitoring (`SuppressErrorStatus` is on).

If you can reuse existing code without modification, you can reduce the cost of reverification.

### Workflow

Consider this control system model.

The Controller Model block references a model that consists of three components:

- P1 is a Model block, which references a model developed with a previous release, for example, R2015b. The generated model code, with the standalone code interface, is in the folder P1\_ert\_rtw.
- C1 is a Model block, which references a model that you are developing in the current release.
- P2 is a subsystem block developed with a previous release, for example, R2016a. The generated subsystem code is in the folder P2\_ert\_rtw.
- P3 is a Model block, which references a model developed with a previous release, for example, R2016b. The generated model code, with the model reference code interface, is in the folder slprj/ert/P3.

To integrate code from previous releases with generated code from the current release, use this workflow:

### 1 Specify an existing shared code folder

You can specify the reuse of shared code from an existing folder, for example, a library of verified code that an administrator maintains and updates. Specify the shared code folder for model components that require code generation in the current release, for example, Controller and C1.

In the Configuration Parameters dialog box, in the **Existing shared code** field, enter the full path to the shared code folder.

## 2 Import components into current release

From the current release, import generated component code from previous releases as software-in-the-loop (SIL) blocks or processor-in-the-loop (PIL) blocks. For example:

```
crossReleaseImport(folderPathForP1_ert_rtw, 'Controller', ...
'SimulationMode', 'SIL');
crossReleaseImport(folderPathForP2_ert_rtw, 'Controller', ...
'SimulationMode', 'SIL');
crossReleaseImport(folderPathForP3, 'Controller', ...
'SimulationMode', 'SIL');
```

In the current working folder, the `crossReleaseImport` function creates the `xrel` subfolder that contains software-in-the-loop (SIL) blocks and subfolders:

- P1\_R2015b\_sil and P1\_R2015b\_sil\_resources
- P2\_R2016a\_sil and P2\_R2016a\_sil\_resources
- P3\_R2016b\_sil and P3\_R2016b\_sil\_resources

## 3 Incorporate components into current release model

To replace components with SIL or PIL blocks, use the Simulink Editor or the `pil_block_replace` command. For example, replace:

- P1 with P1\_R2015b\_sil.
- P2 with P2\_R2016a\_sil.
- P3 with P3\_R2016b\_sil.

When you run a model simulation, the simulation runs the previous release code through the SIL or PIL blocks.

When you build the `Controller` model (`slbuild('Controller')`), the code generator does not generate new code for the components represented by the SIL or PIL blocks. The model code calls code generated by previous releases.

The Simulink Code Inspector supports call-site validation for a cross-release SIL or PIL block. The block provides a specification of the expected function call, which is derived from the generated code. During analysis, the Simulink Code Inspector compares the expected function call with the block behavior. For information about analysis limitations, see “S-Function” (Simulink Code Inspector).

## Limitations

The cross-release code integration workflow does not support:

- Export-function models for ERT code.
- Simulink Function and Function Caller blocks across the boundaries of ERT code generated by different releases.
- The integration of generated code from releases before R2010a.
- The import of generated code from the current release into a previous release (forward compatibility).

- The export of files located in the MATLAB root folder of the previous release, for example, blockset library files.
- The export and import of generated code from models with noninlined S-functions.
- C-API on page 59-2.

At the end of the model build process, the code generation report displays shared files that are directly used by the integration model, for example, `Controller`. The report does not display shared files used by the components of the model, for example, `P1` and `P2`.

If your model has:

- A cross-release SIL or PIL block, you cannot run rapid accelerator mode simulations.
- A Model block that references a model containing a cross-release SIL or PIL block, you cannot run accelerator mode or rapid accelerator mode simulations.

You can run:

- Top-model SIL simulations of models that contain cross-release SIL or PIL blocks. The models must not contain cross-release AUTOSAR Model blocks.
- Model block SIL simulations of referenced models that contain cross-release SIL or PIL blocks. The referenced models must not contain cross-release AUTOSAR Model blocks.

For information about other cross-release AUTOSAR code integration limitations, see “Import AUTOSAR Code from Previous Releases” on page 49-78.

## Simulink.Bus Support

To use a bus object as a data type in cross-release ERT code integration, use one of these approaches.

Approach	Code Export	Code Import
Automatic	<p>In the previous release, before generating code, set the <code>DataScope</code> property of the <code>Simulink.Bus</code> object to <code>Auto</code>. Do not assign a value to the <code>HeaderFile</code> property.</p> <p>The code generator creates the <code>Simulink.Bus</code> data type definition in the default header file on page 50-14, which is located in the code generation folder for the model.</p>	<p>In the current release, before running <code>crossReleaseImport</code>, set the <code>DataScope</code> property of the <code>Simulink.Bus</code> object to <code>Auto</code>.</p> <p>When you build the integration model, the build process uses the <code>Simulink.Bus</code> data type from the header file in the imported code.</p>

Approach	Code Export	Code Import
Exported bus	<p>In the previous release, before generating code, specify these properties of the <code>Simulink.Bus</code> object:</p> <ul style="list-style-type: none"> <li>• <code>DataScope</code> — Set to <code>Exported</code>.</li> <li>• <code>HeaderFile</code> — Specify a file name, for example, <code>prevRelBusType</code>.</li> </ul> <p>The code generator creates <code>prevRelBusType.h</code> in the shared utility code folder. This header file contains the definition for the <code>Simulink.Bus</code> data type. Use <code>sharedCodeUpdate</code> to add <code>prevRelBusType.h</code> to the shared code folder that <code>ExistingSharedCode</code> specifies.</p> <p>For R2010a and R2010b, the <code>DataScope</code> property is not available. Do not assign a value to the <code>HeaderFile</code> property. The code generator creates the <code>Simulink.Bus</code> data type definition in <code>modelName_types.h</code>, which is located in the code generation folder for the model.</p>	<p>In the current release, before running <code>crossReleaseImport</code>, set the <code>DataScope</code> property of the <code>Simulink.Bus</code> object to <code>Imported</code>.</p> <p>When you build the integration model that incorporates the imported SIL or PIL block, the build process uses the <code>Simulink.Bus</code> data type definition in <code>prevRelBusType.h</code>.</p> <p>If the imported code is from R2010a or R2010b, specify these properties of the <code>Simulink.Bus</code> object:</p> <ul style="list-style-type: none"> <li>• <code>DataScope</code> — Set to <code>Imported</code>.</li> <li>• <code>HeaderFile</code> — Set to file path for <code>modelName_types.h</code>, which is in the imported code folder.</li> </ul> <p>When you build the integration model, the build process uses the <code>Simulink.Bus</code> data type definition in <code>modelName_types.h</code>.</p>
Imported bus	<p>In the previous release, before generating code, specify these properties of the <code>Simulink.Bus</code> object:</p> <ul style="list-style-type: none"> <li>• <code>DataScope</code> — Set to <code>Imported</code>.</li> <li>• <code>HeaderFile</code> — Specify a path to a file that contains the <code>Simulink.Bus</code> data type definition, for example, <code>aBusType.h</code>.</li> </ul> <p>For R2010a and R2010b, the <code>DataScope</code> property is not available. For the <code>HeaderFile</code> property, specify a path to a file that contains the <code>Simulink.Bus</code> data type definition, for example, <code>aBusType.h</code>.</p>	<p>In the current release, after importing generated code, you do not have to change the <code>Simulink.Bus</code>.</p> <p>When you build the integration model that incorporates the imported SIL or PIL block, the build process uses the <code>Simulink.Bus</code> data type definition from <code>aBusType.h</code>.</p> <p>If the imported code is from R2010a or R2010b, specify these properties of the <code>Simulink.Bus</code> object:</p> <ul style="list-style-type: none"> <li>• <code>DataScope</code> — Set to <code>Imported</code>.</li> <li>• <code>HeaderFile</code> — Set to <code>aBusType.h</code>.</li> </ul> <p>When you build the integration model, the build process uses the <code>Simulink.Bus</code> data type definition in <code>aBusType.h</code>.</p>

## Root-Level I/O Through Global Variables in Generated Code

When imported ERT code from a previous release implements an input or output port through a global variable, the code that is generated from the integration model depends on the properties of the signal connected to the port in the integration model.

If the integration model signal does not map to a generated code variable that has the same name as the signal in the imported code, the generated code:

- Defines the variable if it is declared but undefined in the imported code.
- Creates additional code to copy data between the variable generated from the integration model and the variable in the imported code.

If the integration model signal maps to a variable with the same name as the signal in the imported code, the variable used by the imported code is also used by the code generated from the integration model. You must use a compatible storage class for the signal.

Storage Class Property	Property Value Support
<b>Type</b>	Unstructured only
<b>Data access</b>	<p>Cannot connect a port implemented as a <code>Pointer</code> variable in the imported code to a signal of the same name that is implemented through a <code>Direct</code> storage class in the integration model</p> <p>Cannot connect a port implemented as a <code>Direct</code> variable in the imported code to a signal of the same name that is implemented as a <code>Pointer</code> in the integration model</p>

Storage Class Property	Property Value Support
<b>Data scope</b>	<p>If the imported code declares but does not define the variable (i.e. code is generated from a signal that uses the Imported value), then one of the following is required:</p> <ul style="list-style-type: none"> <li>• The integration model uses the Exported value.</li> <li>• External code defines the variable.</li> </ul> <p>If the imported code defines the variable (i.e. code is generated from a signal that uses the Exported value):</p> <ul style="list-style-type: none"> <li>• For signals in the integration model that are connected to root-level I/O ports: <ul style="list-style-type: none"> <li>• Set the <code>EnableDataOwnership</code> configuration parameter to on.</li> <li>• Use a custom storage class with these properties: <ul style="list-style-type: none"> <li>• <b>Type</b> - Unstructured</li> <li>• <b>Data access</b> - Direct</li> <li>• <b>Data scope</b> - Exported</li> <li>• <b>Owner</b> - Non-empty value that is not the name of the integration model. For example, the value can be the name of the imported component.</li> </ul> </li> </ul> </li> <li>• For signals in the integration model that are not connected to root-level I/O ports, use a custom storage class with these property values: <ul style="list-style-type: none"> <li>• <b>Data scope</b> - Imported</li> <li>• <b>Data access</b> - Direct</li> </ul> </li> </ul>

## Communicate Between Current and Previous Release Components Through Global Data Stores

Current and previous release components can communicate through global data stores associated with `Simulink.Signal` objects in the MATLAB base workspace or a Simulink data dictionary. The workflow described here applies to cross-release ERT code integration.

### Code Generation Configuration

Before generating model component code in the old release, configure data store memory to use a storage class that imports external code.

If a top-model or subsystem build process generates the code, set the **Storage class** property of the `Simulink.Signal` objects to one of these classes:

- `ImportedExtern`
- `ImportedExternPointer`
- `ImportFromFile` custom storage class

If a model reference build process generates the code, you can also use these classes:

- `ExportedGlobal`
- `ExportToFile` custom storage class

### Import Configuration

In the current release, before you run `crossReleaseImport`, define a `Simulink.Signal` object in the MATLAB base workspace or a Simulink data dictionary for each global data store of the component that you want to import:

- 1 For the object name and the **Data type**, **Complexity**, and **Dimensions** object properties, specify values that match values of the corresponding object in the component that you want to import.
- 2 For the **Storage class** property, specify a value that is compatible. If the previous release value is `ImportedExtern`, specify one of these values for the current release:
  - `ImportedExtern`
  - `ExportedGlobal`
  - `ImportFromFile` or `ExportToFile` custom storage class.

If the previous release value is `ImportedExternPointer`, then specify `ImportedExternPointer` for the current release.

- 3 For the **Identifier** property, specify a matching value only if the property is specified for the object in the component that you want to import.
- 4 Save the `Simulink.Signal` objects. The objects are required each time you simulate or build the imported SIL or PIL block.

For more information, see “Data Stores in Generated Code”.

### Parameter Tuning

The cross-release ERT code integration workflow supports parameter tuning in an integration model that contains component code with tunable parameters from previous releases.

In the current release, before you run `crossReleaseImport`, for each tunable parameter of the component that you want to import:

- 1 Define a `Simulink.Parameter` object in the MATLAB base workspace or a Simulink data dictionary.
- 2 For the object name and the **Data type**, **Complexity**, and **Dimensions** object properties, specify values that match the previous release object values. If the variable in the imported source code does not have the same name as the object, for the **Identifier** property, specify a value that matches the variable name.
- 3 If the previous release object uses the `GetSet` custom storage class, specify:
  - A matching value for the **Storage class** object property.

- The header file that defines the `get` and `set` access functions. For details, see “Control Data Representation by Configuring Storage Class Properties” on page 37-17 and “Access Data Through Functions with Storage Class GetSet” on page 37-25.

Support of the `GetSet` custom storage class from a previous release applies only for R2011a and later releases.

For code generated by a top-model or subsystem build process in a previous release, these limitations apply:

- If a tunable parameter specified by a `Simulink.Parameter` object in the previous release has storage class set to `ExportedGlobal` and the storage class of the `Simulink.Parameter` object in the current release is also `ExportedGlobal`, an error occurs when you build the integration model.
- On a Mac operating system, if a tunable parameter specified by a `Simulink.Parameter` object in the previous release has storage class set to `ExportedGlobal`, you cannot build the integration model if the storage class of the `Simulink.Parameter` object in the current release (with the same name or alias) is `ImportedExtern`. To work around this limitation, modify the default settings:

- 1 Get the build tool from the default toolchain.

```
tc = coder.make.getDefaultToolchain;
cComp = tc.getBuildTool('C Compiler');
```

- 2 Extract the C compiler standard options.

```
stdMaps = cComp.SupportedStandard.getLangStandardMaps;
optionValues = stdMaps.getCompilerOptions('*');
```

- 3 Remove `-fno-common` from the standard options for the C and C++ compilers.

```
optionToRemove = '-fno-common';
optionsToKeep = strrep(optionValues, optionToRemove, '');
c_standard_opts_id = '$(C_STANDARD_OPTS)';

custToolChainOpts = get_param(model, 'CustomToolchainOptions');
custToolChainOpts{2} = ...
 strrep(custToolChainOpts{2}, c_standard_opts_id, optionsToKeep);

set_param(model, 'CustomToolchainOptions', custToolChainOpts);
```

## Use Multiple Instances of Code Generated from Reusable Referenced Model

Using a reusable referenced model, you can specify unique model argument values for each instance of the referenced model in a parent model. Import previously generated code for the reusable referenced model into the current release as a parameterized cross-release SIL or PIL block, and then insert multiple instances of the block into an integration model. For each block instance, you can specify unique model argument values.

- 1 Update existing shared code folder.

```
sharedCodeUpdate(sourceFolder, destinationFolder)
```

- 2 Import generated code for the reusable referenced model into the current release as a parameterized cross-release block, for example, a SIL block.

```
handleSILBlock = crossReleaseImport(reusableReferencedModelcodeLocation, ...
 configSetIntegrationModel, 'SimulationMode', 'SIL');
```

- 3 In the integration model, replace, for example, two instances of the referenced model with instances of the cross-release SIL block.

```
open_system(integrationModel);

blockInstanceName1 = 'refModelInstanceName1';
blockInstanceName2 = 'refModelInstanceName2';

SILBlockFullName = getfullname(handleSILBlock);
replace_block(integrationModel, 'Name', blockInstanceName1, ...
 SILBlockFullName, 'noprompt');
replace_block(integrationModel, 'Name', blockInstanceName2, ...
 SILBlockFullName, 'noprompt');
```

- 4 Suppose the reusable referenced model has model arguments *paramA* and *paramB*, and the values for the referenced model instances, *refModelInstanceName1* and *refModelInstanceName2*, are workspace variables. In this case, you can specify argument values for the cross-release block instances that are workspace variables.

```
pathToBlockInstanceName1 = [integrationModel, '/', blockInstanceName1];
pathToBlockInstanceName2 = [integrationModel, '/', blockInstanceName2];

set_param(pathToBlockInstanceName1, 'paramA', 'paramA_instName1');
set_param(pathToBlockInstanceName1, 'paramB', 'paramB_instName1');

set_param(pathToBlockInstanceName2, 'paramA', 'paramA_instName2');
set_param(pathToBlockInstanceName2, 'paramB', 'paramB_instName2');
```

- 5 To specify unique model argument values for the block instances in the integration model, assign values to the workspace variables, *paramA\_instName1*, *paramB\_instName1*, *paramA\_instName2*, and *paramB\_instName2*.

## Compare Simulation Behavior of Model Component in Current Release and Generated Code from Previous Release

In a previous release, suppose that you developed a model component, generated code for the component, and tested and deployed the generated code. Now, in the current release, you want to add features to the model component and use the model component in system development and code generation. Before you proceed, you can compare the functional behavior of the model component and the generated code from the previous release.

To test the numerical equivalence between the model component and the generated code from the previous release, use Simulink Test. With the Test Manager (Simulink Test), you can perform back-to-back tests and output comparisons:

- 1 Bring the model component into the current release as a Model block with the **Simulation mode** block parameter set to **Normal**.
- 2 With the Model block, create a top model that specifies test input data.
- 3 Import the code generated in the previous release into the current release as a SIL block.
- 4 With the SIL block, create another top model that specifies the same the test input data.
- 5 In the Test Manager, create an equivalence test case that runs simulations of the top models and compares outputs.
- 6 Run the test case and review results.

For more information, see “Test Two Simulations for Equivalence” (Simulink Test).

**Note** If you want to compare the behavior of generated code from the current and previous release, in step 1, specify these Model block parameters:

- Set **Simulation mode** to `Software-in-the-loop (SIL)` or `Processor-in-the-loop (PIL)`.
  - Set **Code interface** to `Top model`.
- 

## Import AUTOSAR Code from Previous Releases

If you install the Embedded Coder Support Package for AUTOSAR Standard, you can import into the current release AUTOSAR component code that you generated in a previous release.

When you run `crossReleaseImport`, the function imports the AUTOSAR code as a cross-release Model block instead of a SIL or PIL block. The **Simulation mode** parameter of the Model block is set to `Software-in-the-loop (SIL)` or `Processor-in-the-loop (PIL)`. Incorporate the Model block into the current release model.

These limitations apply:

- The cross-release workflow does not support per-instance memory that accesses NVRAM.
- Tunable parameters must be mapped to AUTOSAR calibration parameters or AUTOSAR internal calibration parameters.
- If the original model uses variants or symbolic dimensions (dimension variants), the imported model can use only the same variant and symbolic dimension configuration that was used when generating the code in the previous release.

## Integration of Code from Multiple Folders

To help you to integrate generated code from multiple code generation folders, this table provides information about actions you can take.

Action	Information	Type of Integration Supported
Use consistent configuration parameters across models	<p>If you want to integrate a group of models, aim to use a configuration set that is consistent across the models.</p> <p>For each model, you can create a hash table from the shared utilities checksum file, <code>checksummap.mat</code>. The key-value pairs in the hash table give you information about model parameters. This information can help you to determine the parameter values that you must use across the models. For more information, see “Manage the Shared Utility Code Checksum” on page 7-59</p> <p>To determine whether parameter values are consistent across the models, for each model, you can run checks for compliance with modeling guidelines that specify parameter values. For more information, see “Model Advisor Checks for High-Integrity Modeling Guidelines”.</p> <p>You can specify the same configuration parameters for a group of models. For example, for each model, use a configuration reference to access the same configuration set from a data dictionary. When you use the same configuration set, the generated data types for each model are the same and the corresponding <code>rtwtypes.h</code> files are equivalent except for comments. To integrate code from the different models, you can choose a single <code>rtwtypes.h</code> file. For more information, see:</p> <ul style="list-style-type: none"> <li>• “Share a Configuration with Multiple Models”</li> <li>• “What Is a Data Dictionary?”</li> </ul>	Same-release, cross-release

Action	Information	Type of Integration Supported
Reuse shared utility code	<p>You can reuse data and functions across software components by specifying a shared utilities folder for your models. In the Configuration Parameters dialog box, set <b>Shared code placement</b> to Shared location.</p> <p>If you want software components to share a utilities folder, generate code from a common working folder or specify the same code generation folder through the file generation control parameter, <code>CodeGenFolder</code>. For more information, see “Manage Build Process Folders” on page 49-30.</p> <p>Identically-named utility files generated in different releases are functionally equivalent even if file style or comments differ. For cross-release code integration, you can use the <code>ExistingSharedCode</code> parameter to specify the reuse of shared utility code from an existing folder. For more information, see:</p> <ul style="list-style-type: none"> <li>• “Workflow to Reuse Shared Utility Code” on page 49-66</li> <li>• “Existing shared code”</li> </ul>	Same release, cross-release
Avoid generated header file updates	<p>In general, when you build a model, existing header files (and source files) in the <code>_sharedutils</code> or <code>_shared</code> folder are not regenerated. However, there are instances when the code generator overwrites existing header files in the folder. The table in “Code Generator Header Files” on page 49-44, which describes header file generation dependencies, provides information about how you can avoid overwriting some header files, for example, <code>rtwtypes.h</code> and <code>multiword_types.h</code>.</p> <p>For more information, see:</p> <ul style="list-style-type: none"> <li>• “Build Process Folders” on page 49-31</li> <li>• “Control Placement of <code>rtwtypes.h</code> for Shared Utility Code” on page 7-58</li> </ul>	N/A

Action	Information	Type of Integration Supported
Use cross-release SIL or PIL block	You can use the cross-release SIL or PIL block to integrate generated code from previous releases (R2010a and later) with generated code from the current release. For more information, see “Cross-Release Code Integration” on page 49-68.	Same release, cross-release
Use CRL and ExistingSharedCode	<p>You can use the code replacement library (CRL) and ExistingSharedCode parameter approaches either separately or jointly:</p> <ul style="list-style-type: none"> <li>• The CRL approach supports customization of code generation and eliminates the generation of some shared utility files. You must manage the use of utility files that are not replaced by CRL. For more information, see “Develop a Code Replacement Library” on page 69-20.</li> <li>• The <b>ExistingSharedCode</b> approach, which is based on previously generated utility files, also supports customization and suppresses regeneration of utility files. If customization is not required, the ExistingSharedCode approach is simpler to set up and manage. For more information, see “Cross-Release Shared Utility Code Reuse” on page 49-66.</li> </ul>	Same release, cross-release

## Integrate Generated Code by Using Cross-Release Workflow

This example shows how to reuse previously generated code by creating a cross-release software-in-the-loop (SIL) block and incorporating the block within an integration model. For more information about the workflow, see “Cross-Release Code Integration” on page 49-68.

### Generate Code from a Model

In the cross-release code integration workflow, you create a software-in-the-loop (SIL) or processor-in-the-loop (PIL) block from code that you previously generated.

This example uses generated code from the current release.

```
model = 'rtwdemo_crossrelease_counter';
close_system(model,0)
load_system(model)
set_param(model, 'SimulationCommand', 'update');
open_system(model)
slbuild(model);

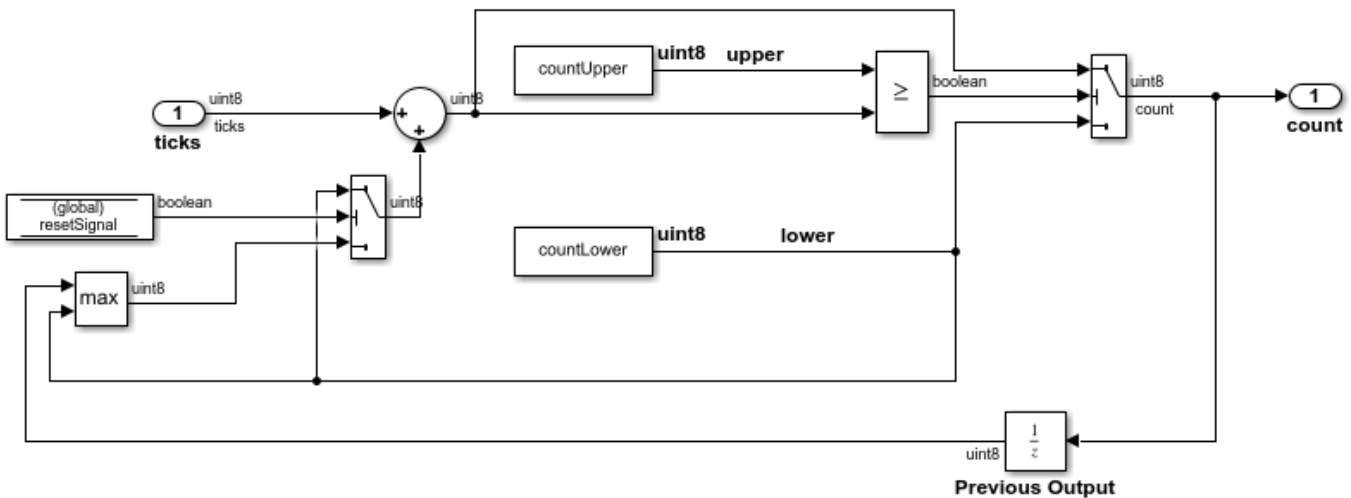

Starting build procedure for: rtwdemo_crossrelease_counter
Successful completion of code generation for: rtwdemo_crossrelease_counter
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_crossrelease_counter	Code generated	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 1m 51.523s

Copyright 2017-2020 The MathWorks, Inc.

Identify the build folder that contains the generated code.

```
buildFolder = RTW.getBuildDir(model).BuildDirectory;
```

Identify the folder that contains code for shared utilities associated with the generated code.

```
previousSharedCodeFolder = RTW.getBuildDir(model).SharedUtilsTgtDir;
```

To reuse generated code from a previous release:

- 1 On the **Simulation** tab, in the **File** section, select **Save > Previous Version**.
- 2 In the **Save as type field**, specify the release and model type.
- 3 Click **Save**.
- 4 Use the previous release to open the saved model, and then generate code.
- 5 Set the value of `buildFolder` to the location of the code generated in the previous release.
- 6 Set the value of `previousSharedCodeFolder` to the location of the shared utilities generated in the previous release.

### Manage Shared Code

Add the generated shared source code files to a repository folder that is used by the integration model.

```
sharedCodeRepo = 'SharedCodeRepo';
mkdir(sharedCodeRepo);
sharedCodeUpdate(previousSharedCodeFolder, sharedCodeRepo, 'Interactive', false);
```

The following files will be copied from `slprj\ert\_sharedutils` to `SharedCodeRepo\R2022a`:

```
rtwtypes.h
```

Files copied from `slprj\ert\_sharedutils` to `SharedCodeRepo\R2022a`.

### Import Code

Load the integration model.

```
integrationModel = 'rtwdemo_crossrelease_integration';
close_system(integrationModel, 0);
load_system(integrationModel);
```

Modify the Simulink configuration set so that it references the existing shared code library.

```
cs = getActiveConfigSet(integrationModel);
set_param(cs, 'ExistingSharedCode', fullfile(pwd, sharedCodeRepo));
```

Create the cross-release SIL block.

```
blockHandle = crossReleaseImport(buildFolder, cs, 'SimulationMode', 'SIL');

Starting import process for component: rtwdemo_crossrelease_counter_R2022a
Starting build process for SIL block: rtwdemo_crossrelease_counter_R2022a
```

### Incorporate Cross-Release SIL Block into Integration Model

To replace a block in the integration model with the cross-release block, use `pil_block_replace`. This function preserves the block size, line connections, and priority.

```
srcBlock = getfullname(blockHandle);
dstBlock = [integrationModel, '/', 'Counter'];
pil_block_replace(srcBlock, dstBlock)
open_system(integrationModel)
```

Successfully swapped the following blocks:

```
untitled/rtwdemo_crossrelease_counter_R2022a_sil
rtwdemo_crossrelease_integration/Counter
```

Copyright 2017-2020 The MathWorks, Inc.

### Simulate Integration Model

Run a simulation of the integration model.

```
sim(integrationModel)
```

```
Preparing to start SIL block simulation: <a href="matlab: targets_hyperlink_manager('run',1)
Starting SIL simulation for component: rtwdemo_crossrelease_counter_R2022a_sil
Application stopped
Stopping SIL simulation for component: rtwdemo_crossrelease_counter_R2022a_sil
```

### Tune Parameters

The source model for the cross-release SIL block references two tunable parameters, which are controlled by Simulink.Parameter objects in the base workspace. Use these parameters to modify the behavior of the SIL simulation.

```
countUpper.Value = 30;
countLower.Value = 20;
yout_returned = sim(integrationModel, 'ReturnWorkspaceOutputs', 'on');
```

```
Preparing to start SIL block simulation: <a href="matlab: targets_hyperlink_manager('run',1)
Starting SIL simulation for component: rtwdemo_crossrelease_counter_R2022a_sil
Application stopped
Stopping SIL simulation for component: rtwdemo_crossrelease_counter_R2022a_sil
```

### Configure Storage Class for Signals in Integration Model

Configure:

- Signal names in the integration model to match the names used in the imported code.
- Complementary storage classes.

In this case, the `ticks` input and `count` output are implemented through the `ImportedExtern` storage class in the imported code. If the storage class for the signals connected to the input and output ports of the cross-release block in the integration model is `ExportedGlobal`, the integration model must provide the definitions for the variables.

If the signal names do not match, the integration model generates additional code to copy data between the signal implemented by the integration model and the signal implemented by the imported code.

```
hLines = get_param(dstBlock, 'LineHandles');
```

```
% Use the code mappings API to configure the storage class on the signals.
cm = coder.mapping.api.get(integrationModel);
```

```

ticksPortHandle = get(hLines.Inport(1), 'SrcPortHandle');
set(ticksPortHandle, 'Name', 'ticks');
addSignal(cm, ticksPortHandle);
setSignal(cm, ticksPortHandle, 'StorageClass', 'ExportedGlobal');

countPortHandle = get(hLines.Outport(1), 'SrcPortHandle');
set(countPortHandle, 'Name', 'count');
addSignal(cm, countPortHandle);
setSignal(cm, countPortHandle, 'StorageClass', 'ExportedGlobal');

```

### Configure Storage Class for Parameters and Data Store Memory in Integration Model

The parameters and data stores are implemented through the ImportedExtern storage class in the imported code. If you configure the parameters and data stores to use the ExportedGlobal storage class, the integration model must provide the definitions for the variables.

```

resetSignal.CoderInfo.StorageClass = 'ExportedGlobal';
countLower.CoderInfo.StorageClass = 'ExportedGlobal';
countUpper.CoderInfo.StorageClass = 'ExportedGlobal';

```

### Generate Code from Integration Model

Once the required shared code is in the shared code repository, remove the previously generated shared utilities folder.

```

if isfolder(RTW.getBuildDir(integrationModel).SharedUtilsTgtDir)
 rmdir(RTW.getBuildDir(integrationModel).SharedUtilsTgtDir, 's');
end

```

Delete the scope and connecting line that do not affect code generation.

```

scopeBlock = [integrationModel, '/', 'Scope'];
hScopeLines = get_param(scopeBlock, 'LineHandles');
hScopeLine = hScopeLines.Inport(1);
assert(strcmp(get(hScopeLine, 'SegmentType'), 'branch'));
delete_line(hScopeLine);
delete_block(scopeBlock);

```

Generate code.

```

slbuild(integrationModel);

Starting build procedure for: rtwdemo_crossrelease_integration
Successful completion of code generation for: rtwdemo_crossrelease_integration

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_crossrelease_integration	Code generated	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 52.095s

### Examine Call to Imported Code

To examine the cross-release block code within the integration model code, use the `rtwtrace` utility.

```
rtwtrace(dstBlock);
```

### Test Code Generated from Integration Model

Run a top-model software-in-the-loop (SIL) simulation of the integration model. The simulation runs the code generated from the integration model, which calls the imported code.

Log the simulation output in the workspace.

```
set_param(integrationModel, 'SimulationMode', 'software-in-the-loop (sil)');
yout_SIL = sim(integrationModel, 'ReturnWorkspaceOutputs', 'on');
plot(yout_SIL.yout{1}.Values);
```

```
Starting build procedure for: rtwdemo_crossrelease_integration
Successful completion of build procedure for: rtwdemo_crossrelease_integration
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_crossrelease_integration	Code generated and compiled	S-function rtwdemo_crossrelease_c

```
1 of 1 models built (0 models already up to date)
```

```
Build duration: 0h 0m 30.649s
```

```
Preparing to start SIL simulation ...
```

```
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
```

```
Updating code generation report with SIL files ...
```

```
Starting SIL simulation for component: rtwdemo_crossrelease_integration
```

```
Application stopped
```

```
Stopping SIL simulation for component: rtwdemo_crossrelease_integration
```

### Compare Simulation Outputs

Compare the outputs from the simulation where only the imported code ran in SIL mode with the outputs from the simulation where the integration model ran as a top-model in SIL mode.

```
max(abs(yout_SIL.yout{1}.Values.Data - yout_returned.yout{1}.Values.Data))
```

```
ans =
```

```
uint8
```

```
0
```

## Use Protected Models from Previous Releases to Perform SIL Testing and Generate Code

This example shows how you can use a protected model from a previous release (R2018b onwards) to:

- Test numerical equivalence between the protected model and its previously generated code.
- Generate new code in the current release.

The workflow in this example supports only protected models that specify these system target file types:

- ERT
- ERT-based
- AUTOSAR Classic
- GRT (Embedded Coder required)
- GRT-based (Embedded Coder required)

### Protected Model

Use the pregenerated protected model `rtwdemo_crossrelease_protected_counter.slxp`, which was created in R2018b.

The protected model allows the user to:

- Open a read-only view of the model.
- Run simulations.
- Use generated code.

The protected model supports the ERT system target file, and the code that it contains is "Readable source code" and supports the "Model reference" code interface.

If you want to re-create the protected model with different settings, you can export the model `rtwdemo_crossrelease_unprotected_counter` from the current release into a format that can be used in MATLAB R2018b. In the current release, run these commands:

```
load_system('rtwdemo_crossrelease_unprotected_counter');
Simulink.exportToVersion('rtwdemo_crossrelease_unprotected_counter', ...
 'rtwdemo_crossrelease_protected_counter.slx', ...
 'R2018b');
close_system('rtwdemo_crossrelease_unprotected_counter', 0);
```

The protected model was created in MATLAB R2018b by running this command:

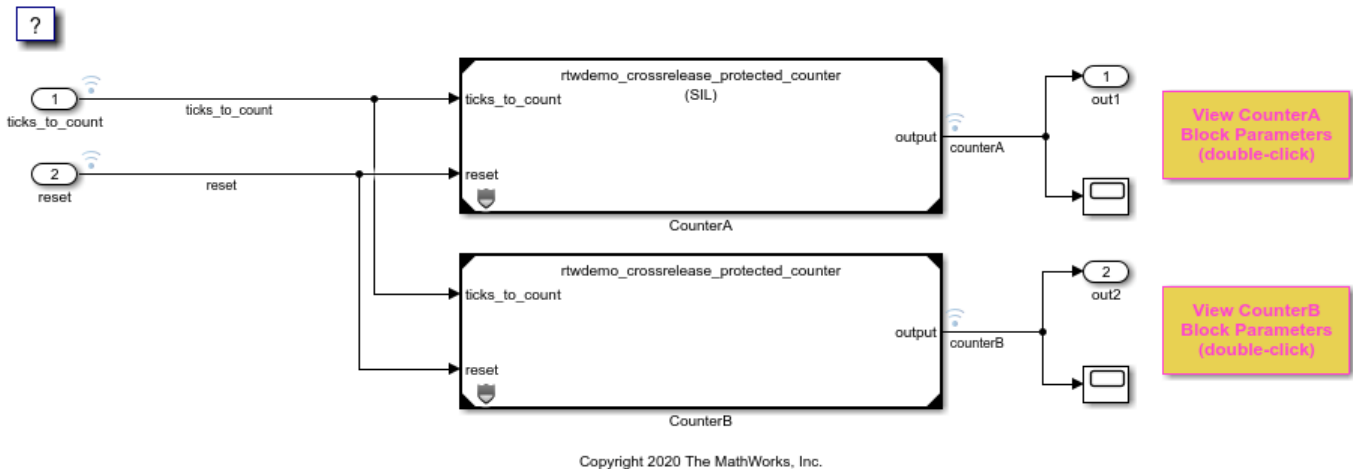

```
Simulink.ModelReference.protect('rtwdemo_crossrelease_protected_counter', ...
 'Mode', 'CodeGeneration', ...
 'OutputFormat', 'MinimalCode', ...
 'ObfuscateCode', false, ...
 'WebView', true, ...)
```

```
'Report', true)
```

## Open Top Model

Open `rtwdemo_crossrelease_protected_model`, the top model that references the protected model.

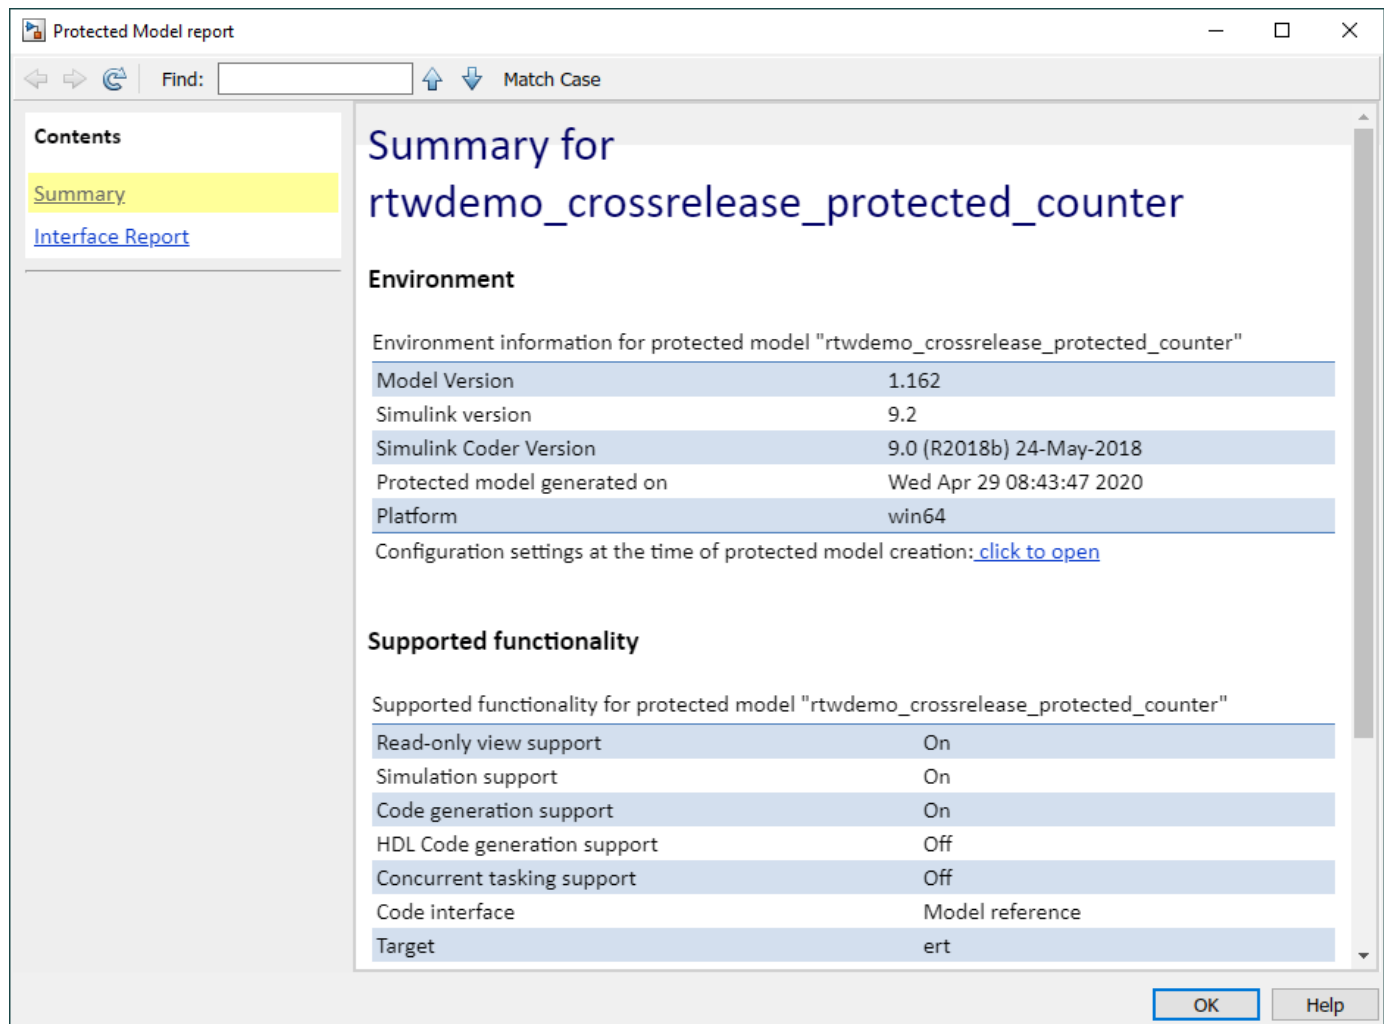

```
model = 'rtwdemo_crossrelease_protected_model';
open_system(model);
```

## Open Protected Model Report

To open the protected model report, on one of the Model blocks, right click the protected-model badge icon and then click "Display report". Or, open the report from the command line.

```
protectedModel = 'rtwdemo_crossrelease_protected_counter';
Simulink.ModelReference.ProtectedModel.displayReport(protectedModel);
```

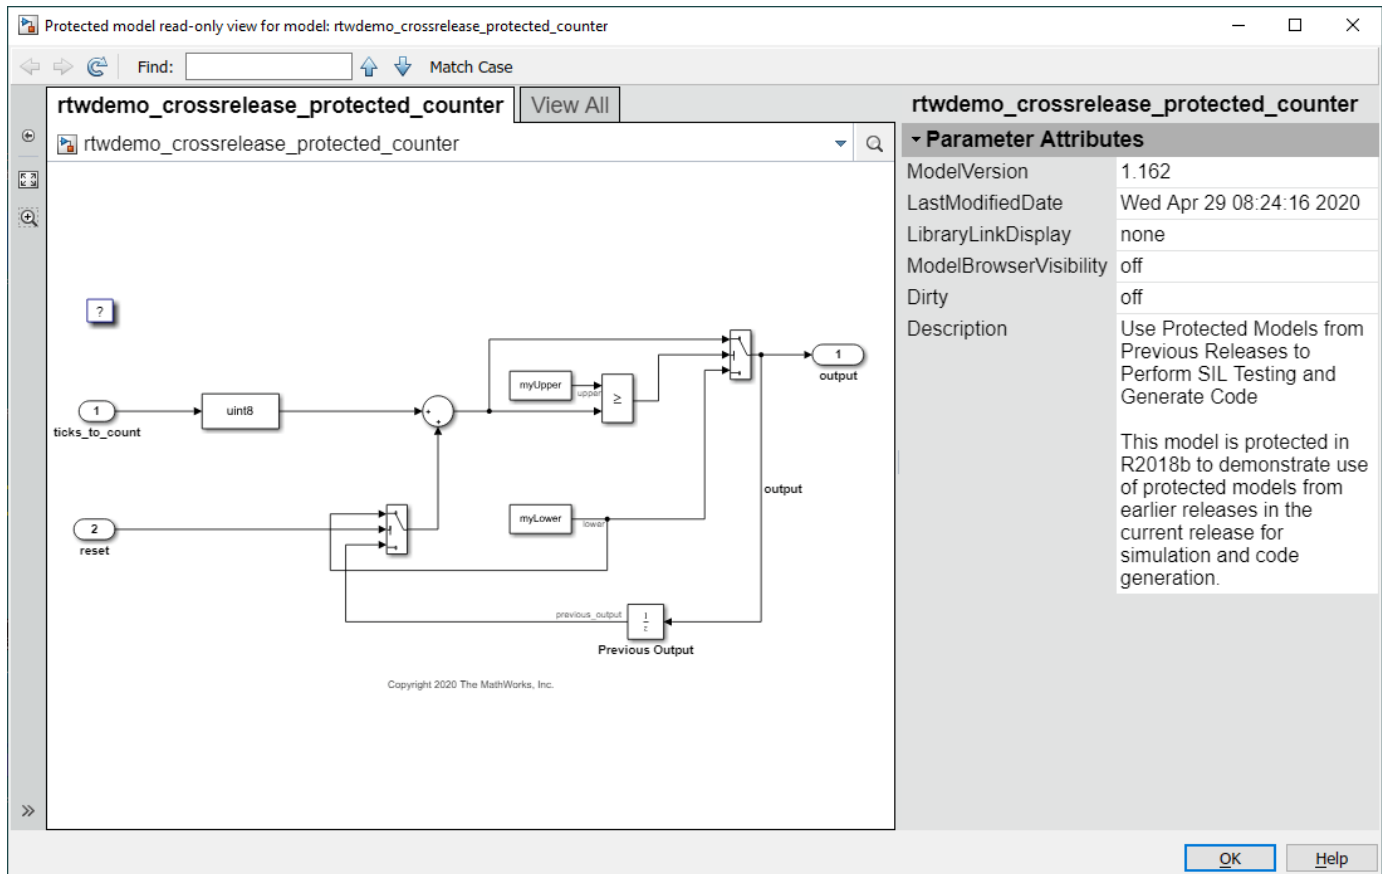

The report shows that the protected model was generated by using Simulink Coder 9.0 (R2018b).

### Open Read-Only View

To open a read-only view of the protected model, right click the protected-model badge icon and then click "Show web view". Or, open the read-only view from the command line.

```
Simulink.ModelReference.ProtectedModel.displayWebview(protectedModel);
```

## Merge Shared Utility Code

When you integrate code from multiple releases, you can specify the shared utility code that the final build uses.

Specify the shared code folder for the top model.

```
mkdir('sharedCode');
set_param(model, 'ExistingSharedCode', fullfile(pwd, 'sharedCode'));
```

Use `sharedCodeUpdate` to merge protected model shared utility files with the shared code folder content.

```
Simulink.ModelReference.ProtectedModel.CurrentTarget.clear(protectedModel);
sharedCodeUpdate('rtwdemo_crossrelease_protected_counter.slxp', 'sharedCode', 'Interactive', false);
```

The following files will be copied from `rtwdemo_crossrelease_protected_counter.slxp:slprj\vert\sharedutils` to `sharedCode`:

```
rtwtypes.h
```

Files copied from `rtwdemo_crossrelease_protected_counter.slxp:slprj\vert\sharedutils` to `sharedCode`:

## Test the Code in the Protected model

The top model references two instances of the protected model. The **Simulation mode** Model block parameter for "CounterA" and "CounterB" are Software-in-the-loop (SIL) and Accelerator

respectively. When you run a top-model simulation, "CounterA" runs generated code from the protected model while "CounterB" runs the protected model.

```
simOut = sim(model);
Simulink.sdi.view;
```

```
Preparing to start SIL simulation ...
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Starting SIL simulation for component: rtwdemo_crossrelease_protected_counter
Application stopped
Stopping SIL simulation for component: rtwdemo_crossrelease_protected_counter
```

### Compare Outputs from Both Model Blocks

To view the simulation output and compare the values of the signals from the Model blocks, use the Simulation Data Inspector.

```
simulationRunObj = Simulink.sdi.getCurrentSimulationRun(model);
counterASignal = getSignalsByName(simulationRunObj, 'counterA');
counterBSignal = getSignalsByName(simulationRunObj, 'counterB');
Simulink.sdi.compareSignals(counterASignal.ID, counterBSignal.ID);
Simulink.sdi.view(Simulink.sdi.GUITabType.CompareRuns);
```

## Generate Code from Top Model

You can generate code from the top model, referencing the code that is contained in the protected model.

```
slbuild(model);

Starting build procedure for: rtwdemo_crossrelease_protected_model
Successful completion of build procedure for: rtwdemo_crossrelease_protected_model
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_crossrelease_protected_model	Code generated and compiled	Code generation information f

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 53.228s

## Compile Code in Another Development Environment

This example shows how you can relocate generated code and compile it in another development environment. Use packNGo to create a ZIP file that contains generated source code, build information, and CMake configuration files. In your target development environment, use the codebuild function to build the final library or executable file.

### Configure the Model

Open the model.

```
rtwdemo_codebuild
```

Copyright 2016-2020 The MathWorks, Inc.

Do not automatically compile the code, generate a makefile, or package generated code and artifacts.

```
set_param('rtwdemo_codebuild', 'GenerateMakefile', 'off');
set_param('rtwdemo_codebuild', 'PackageGeneratedCodeAndArtifacts', 'off');
```

### Generate Code and CMake Configuration Files

Run code generation command.

```
slbuild('rtwdemo_codebuild');

Starting serial model reference code generation build
Starting build procedure for: rtwdemo_codebuild
Generated code for 'rtwdemo_codebuild' is up to date because no structural, parameter or code
Successful completion of code generation for: rtwdemo_codebuild
```

Build Summary

```
0 of 2 models built (2 models already up to date)
Build duration: 0h 0m 27.479s
```

Generate the CMakeLists.txt configuration files.

```
buildFolder = RTW.getBuildDir('rtwdemo_codebuild').BuildDirectory;
codebuild(buildFolder, 'BuildMethod', 'cmake');
```

## Package Generated Code and CMake Configuration Files

Run packNGo, packaging the files hierarchically.

```
packNGo(buildFolder, 'packType', 'hierarchical', 'nestedZipFiles', false);
```

## Switch to Another Development Environment

This is an optional step. For example, if your current development environment is a Linux computer, you can copy the zip file to a Windows computer and then perform the subsequent steps on that computer.

## Unzip Source Code and Build Information Files

Unzip the files.

```
rtwdemo_codebuild_files = unzip('rtwdemo_codebuild.zip');
```

```
Warning: Permission denied to overwrite file "matlab/extern/include/tmwtypes.h".
Warning: Permission denied to overwrite file
"matlab/simulink/include/rtw_continuous.h".
Warning: Permission denied to overwrite file
"matlab/simulink/include/rtw_solver.h".
Warning: Permission denied to overwrite file "matlab/rtw/c/src/rt_logging.h".
Warning: Permission denied to overwrite file
"matlab/rtw/c/src/common/rt_main.c".
Warning: Permission denied to overwrite file
"matlab/rtw/c/src/ext_mode/common/ext_work.h".
```

Identify folder containing unzipped code for the top component.

```
rtwdemo_codebuild_top_component_folder = fileparts(rtwdemo_codebuild_files{1});
```

## Build Executable File Using Default Toolchain

Identify the default toolchain (based on compiler selected by mex -setup).

```
defaultToolchain = coder.make.getDefaultToolchain;
```

Build the executable file.

```
codebuild(rtwdemo_codebuild_top_component_folder, 'BuildMethod', defaultToolchain);
```

Check that executable file is produced.

```
dir(fullfile(rtwdemo_codebuild_top_component_folder, '..', 'rtwdemo_codebuild*'))
```

```
rtwdemo_codebuild
rtwdemo_codebuild_grt_rtw
```

## Build Executable File Using Default Template Makefile

Select a template makefile for the current platform.

```
if ispc
 % With ert_vcx64.tmf, you must have Microsoft Visual C++ installed. If
 % it is not installed, specify ert_lcc64.tmf to use lcc-win64 instead.
```

```

 templateMakefile = 'ert_vcx64.tmf';
else
 templateMakefile = 'ert_unix.tmf';
end

```

Build the executable file.

```
codebuild(rtwdemo_codebuild_top_component_folder, 'BuildMethod', templateMakefile);
```

### Build Shared Library

On Windows, create a definition file that specifies exported symbols.

```

if ispc
 exportsFile = fullfile...
 (rtwdemo_codebuild_top_component_folder, 'rtwdemo_codebuild.def');
 fid = fopen(exportsFile, 'w');
 fwrite(fid, ['EXPORTS' newline]);
 fwrite(fid, ['rtwdemo_codebuild_initialize' newline]);
 fwrite(fid, ['rtwdemo_codebuild_step' newline]);
 fwrite(fid, ['rtwdemo_codebuild_terminate' newline]);
 fclose(fid);
end

```

Build the shared library.

```
codebuild(rtwdemo_codebuild_top_component_folder, 'BuildVariant', 'SHARED_LIBRARY');
```

### Build Static Library

```
codebuild(rtwdemo_codebuild_top_component_folder, 'BuildVariant', 'STATIC_LIBRARY');
```

### Use CMake Configuration Files

With the CMakeLists.txt files, you can use the third-party tool CMake to generate makefiles or workspaces for a compiler environment of your choice.

```

% Compute the CMake command for the current platform.
if ispc
 cmakeCommand = fullfile(matlabroot, 'bin', computer('arch'), 'cmake', 'bin', 'cmake.exe');
else
 cmakeCommand = fullfile(matlabroot, 'bin', computer('arch'), 'cmake', 'bin', 'cmake');
end

```

Using CMake, build the executable file.

```

cd(rtwdemo_codebuild_top_component_folder)
[status1, cmdout1] = system([cmakeCommand ' .']);
[status2, cmdout2] = system([cmakeCommand ' --build .']);

```

- “Code Compilation Customization”

## Generate Code and Simulate Models in a Project

This example shows how to use the code generation template for a new Project. The code generation project template for Project includes multiple models. The project template also provides utilities (.m scripts) that help you generate controller code and run simulations of the harness model.

To see the Project API functions for each operation in this example, view the example code.

### Create a Project

Create a new Project from the code generation project template.

To create this project from the Simulink start page, in the Command Window, type:

```
simulink
```

Select the Code Generation template from the start page, and create the `exampleCodeGen` project.

### Generate Code

Generate controller code for the `feedback_control.slx` model.

To generate controller code, select the **Project Shortcuts** tab and select the **Generate Controller Code** shortcut.

This shortcut runs the `generate_controller_code.m` script in the utilities folder of the project. The script builds the `feedback_control.slx` model in the controller folder of the project.

Copyright 2012-2017 The MathWorks, Inc.

### Simulate Models

Simulate the top-level harness `feedback_harness.slx` model.

To open the harness model for simulation, select the **Project Shortcuts** tab and select the **Feedback Harness** shortcut. This shortcut opens the `feedback_harness.slx` model in the harnesses folder of the project.

To simulate the model, click **Run**.

Copyright 2012 The MathWorks, Inc.

### Observe Simulation Output

Open the Scope block in the model and observe the simulation output.

To open the scope and observe simulation, in the Simulink window, double-click the Scope block.

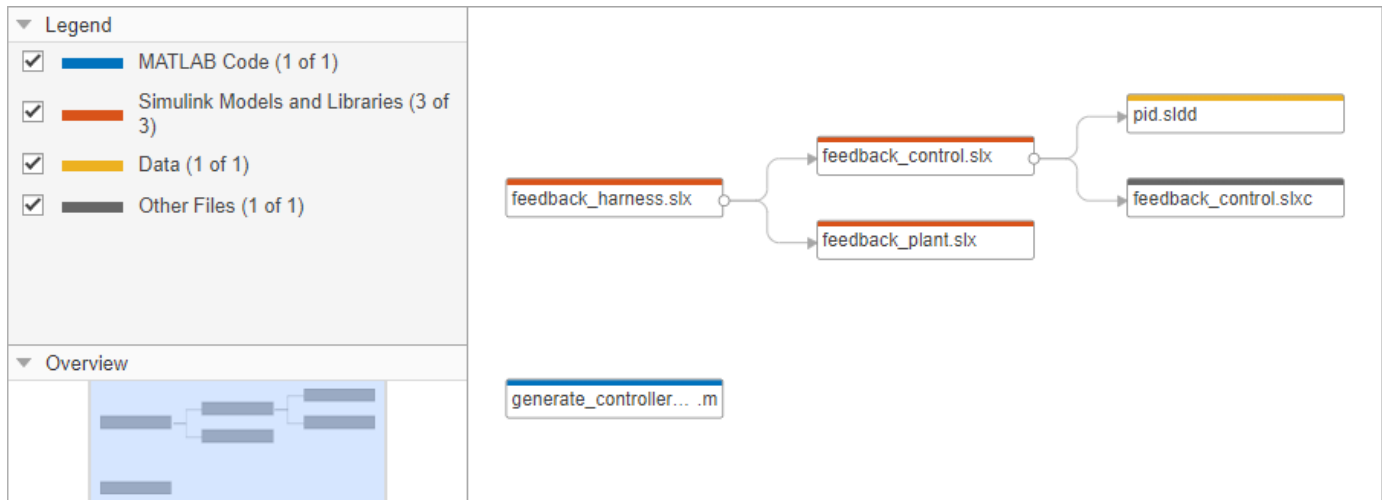

### Use the Dependency Analyzer View

To view file dependencies, use the **Dependency Analyzer** view of the project.

From the **Dependency Analyzer** view, you can:

- Observe file dependencies.
- Hover over the dependency arrows to examine the dependency type.
- Double-click on a file or a model to open it.

### More Information

- “Work with Project Files”
- `Simulink.createFromTemplate`
- “Automate Startup Tasks”
- “Automate Shutdown Tasks”

### Related Examples

## Generate Code and Simulate Models Programmatically with Project

This example shows how to use the Project API to create a new project and automate project tasks for manipulating files. It covers how to programmatically create a blank project, add files and folders, set up the project path, define project shortcuts, generate code, and simulate the harness model.

Project helps you organize large designs by managing and sharing files and settings, finding required files, and interacting with source control.

### Manage a Model-Based Design Project

The example models provide a controller that positions a camera fixed to a DC motor that tracks a green ball.

The MBD approach leads to modeling the controller operations:

- Model plant: The plant is a DC motor that rotates to reposition the camera.
- Model controller: The design uses a PID controller with feedback on angular position for positioning the DC motor.
- Model high-level ball tracking scheduler: The scheduler checks for validity of the position of the green ball and the saturation of the reference angle. The scheduler handles the instances of no ball on the screen to track.

The design and Project have the following folders.

**Plant** -- The plant provides:

- Models with continuous-time dynamic systems that use basic Simulink blocks.
- Models with linear time invariant (LTI) systems that use the LTI system block.
- Import and export of simulation data to and from the workspace
- Loading of parameters into the base workspace that use data dictionary and model callbacks.

**Controller** -- The controller provides:

- Models with discrete-time dynamic systems that use basic Simulink blocks.
- Models with discrete-time dynamic systems that use the PID Controller Block.
- Enforcement of signal saturation that use a PWM Conversion subsystem.

**Ball Tracking** -- The ball tracking provides:

- The basic ball tracking algorithm.
- The terminator and ground blocks as placeholders.
- A hybrid controller that generates motor reference angles using Stateflow.

**Harnesses** -- The harnesses provide top-level simulation of the full system.

### Create a Blank Project and Add Files

1. Create a blank project. On the **Home** tab, click **New > Project > Blank Project**.

Alternatively, create this project and use `currentProject` to get a project object to manipulate the project from the Command Window:

```
matlab.project.createProject('modelBasedDesignCodeGenProject');
proj_modelBasedDesignCodeGen = currentProject

proj_modelBasedDesignCodeGen =
 Project with properties:

 Name: "modelBasedDesignCodeGenProject"
 SourceControlIntegration: ""
 RepositoryLocation: ""
 SourceControlMessages: [1x0 string]
 ReadOnly: 0
 TopLevel: 1
 Dependencies: [1x1 digraph]
 Categories: [1x1 matlab.project.Category]
 Files: [1x0 matlab.project.ProjectFile]
 Shortcuts: [1x0 matlab.project.Shortcut]
 ProjectPath: [1x0 matlab.project.PathFolder]
 ProjectReferences: [1x0 matlab.project.ProjectReference]
 StartupFiles: [1x0 string]
 ShutdownFiles: [1x0 string]
 DefinitionFileType: FixedPathMultiFile
 Description: ""
 RootFolder: "C:\workSpace\modelBasedDesignCodeGenProject"
 SimulinkCacheFolder: ""
 ProjectStartupFolder: "C:\workSpace\modelBasedDesignCodeGenProject"
 SimulinkCodeGenFolder: ""
```

## 2. Copy the example files to folders within the Project.

Alternatively, in the Command Window, type:

```
copyfile(fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'slproject_codegen_demo'), ...
fullfile(pwd), 'f');
```

## 3. Add existing files to the project:

- Click the **Project Files View** button and select **All files View**.
- Select the folders `ball_tracking`, `controller`, `harnesses`, `plant`, and `utilities`, right-click the icon for one of the folders, and select **Add Folder to Project (Including Child Files)**.

Alternatively, add these files to the project programmatically from the Command Window:

```
addFolderIncludingChildFiles(proj_modelBasedDesignCodeGen, 'ball_tracking');
addPath(proj_modelBasedDesignCodeGen, 'ball_tracking');
addFolderIncludingChildFiles(proj_modelBasedDesignCodeGen, 'controller');
addPath(proj_modelBasedDesignCodeGen, 'controller');
addFolderIncludingChildFiles(proj_modelBasedDesignCodeGen, 'harnesses');
addPath(proj_modelBasedDesignCodeGen, 'harnesses');
addFolderIncludingChildFiles(proj_modelBasedDesignCodeGen, 'plant');
addPath(proj_modelBasedDesignCodeGen, 'plant');
addFolderIncludingChildFiles(proj_modelBasedDesignCodeGen, 'utilities');
addPath(proj_modelBasedDesignCodeGen, 'utilities');
```

## 4. Select the work folder, right-click the icon for one of the folders, and select **Project Path > Add to the Project Path (Including Subfolders)**. If you choose to add this folder to the path, generated

files (artifacts) from simulation and code generation are available on the project path. If you choose not to include the generated files in the project, the dependency graph does not display these files.

Alternatively, add this folder to the project path from the Command Window:

```
addPath(proj_modelBasedDesignCodeGen, 'work');
```

**5.** To make the project more accessible, define and set properties for project shortcuts. In the **Files** View, select the **Project** tab. Open the utilities folder node.

**6.** Select the files `clean_up_project.m`, `generate_controller_code.m`, and `set_up_project.m`, right-click the icon for one of the files, and select **Create Shortcut**.

**7.** To set the current working folder, set the simulation cache folder, and run other setup scripts when you open the project:

- Select the `set_up_project.m` script.
- Right-click the file.
- Select **Run at Startup**.

Alternatively, add this setup script to project startup from the Command Window:

```
addStartupFile(proj_modelBasedDesignCodeGen, fullfile(pwd, '/utilities/set_up_project.m'));
```

**8.** To restore previous settings and run other clean-up scripts when you close the project:

- Select the `clean_up_project.m` script.
- Right-click the file.
- Select **Run at Shutdown**.

Alternatively, add the clean-up script to project shutdown programmatically from the Command Window:

```
addShutdownFile(proj_modelBasedDesignCodeGen, fullfile(pwd, '/utilities/clean_up_project.m'));
```

**9.** Reopen the project to run the **Startup** shortcut.

Alternatively, reload the project and run the `set_up_project` from the Command Window:

```
reload(proj_modelBasedDesignCodeGen);
run('set_up_project');
```

### Generate Code for the Controller from the Dependency Graph

**1.** On the **Project** tab, click **Dependency Analyzer** to run a dependency analysis on all the files in your project.

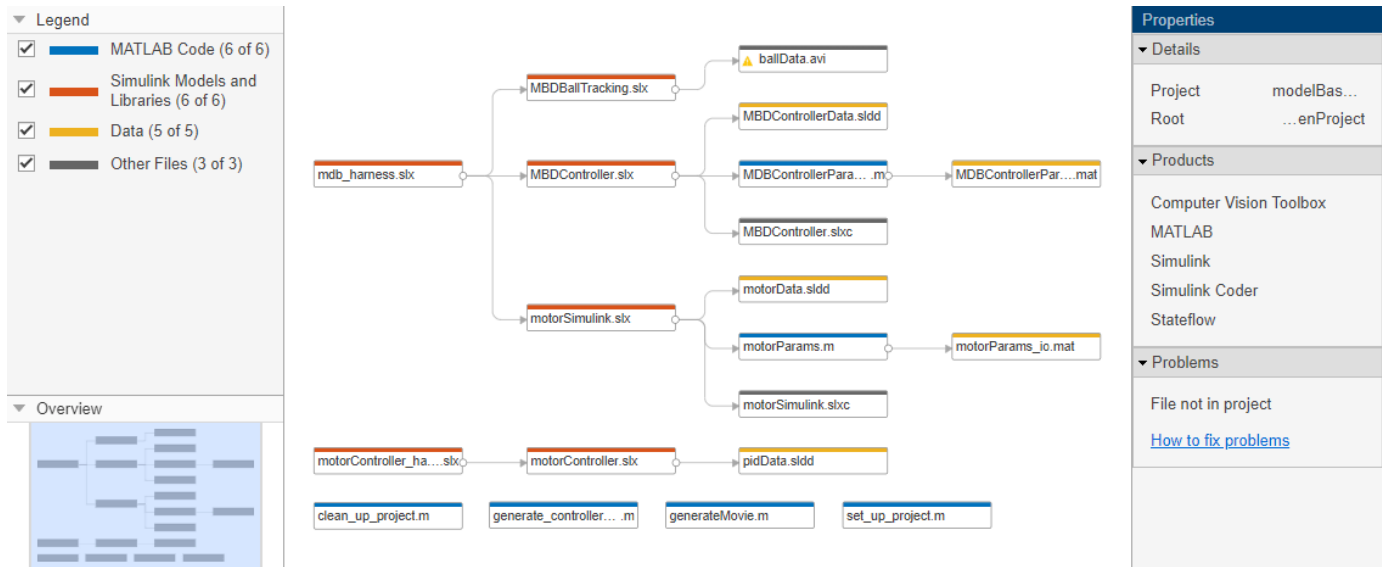

The dependency graph displays your project structure and the files dependencies. It shows how files relate to each other. Each item in the graph represents a file, and each arrow is a dependency.

The contents of the `work` folder do not appear in the dependency graph. This setup simplifies the view to indicate the dependencies in model files and `.m` script file.

**a.** Examine the **Properties** pane on the right for useful information about your project, such as required products and problem files.

**b.** Use the **Zoom In** button to zoom into the dependencies map. Use arrow keys or click-drag with the mouse roller wheel to move around in the map.

**c.** Hover over the dependency arrows to examine the dependency type. For example, the MATLAB scripts and functions are being run by model callbacks.

**2.** Select the `MBDController.slx` model on the dependency map. Right-click the model and select **Open**.

**3.** When the model opens in Simulink, click the **Build** button to generate code for the model. Or, use the `generate_controller_code` shortcut in the project to generate code.

Alternatively, generate code for the model from the Command Window. For the sake of this example, set write permissions to `MBDController.slxc` then generate code for the model:

```
fileattrib('MBDController.slxc', '+w');
eval('slbuild(''MBDController'')');
```

**4.** Close the project from the Project window.

Alternatively, close this project and run `clean_up_project` from the Command Window:

```
run('clean_up_project');
close(proj_modelBasedDesignCodeGen);
```

## Code Generation for Deep Learning Simulink Model That Performs Lane and Vehicle Detection

This example shows how to generate C++ code from a Simulink® model that performs lane and vehicle detection by using convolutional neural networks (CNNs). The example takes the frames of a traffic video as an input, outputs two lane boundaries that correspond to the left and right lanes of the ego vehicle, and detects vehicles in the frame. This example uses a pretrained lane detection network and a pretrained vehicle detection network from the *Object Detection Using YOLO v2 Deep Learning* example of the Computer Vision Toolbox™. For more information, see “Object Detection Using YOLO v2 Deep Learning” (Computer Vision Toolbox).

This example illustrates the following concepts:

- Model the lane detection application in Simulink. First you process the traffic video by resizing to 227-by-227-by-3 and multiplying by a constant factor of 255. Subsequently, you process the traffic video by using the pretrained network loaded in the Predict block from Deep Learning Toolbox™. Finally, if the left and right lane boundaries are detected, the parabolic coefficients to model the trajectories of the lane boundaries are obtained.
- Model the vehicle detection application in Simulink by processing the traffic video using a pretrained YOLO v2 detector. This network detects vehicles in the video and outputs the coordinates of the bounding boxes for these vehicles and their confidence score.
- Configure the model for code generation.

### Prerequisites

- Intel Math Kernel Library for Deep Neural Networks (MKL-DNN).
- Refer to MKLDNN CPU Support for the list of processors that support MKL-DNN library.
- Deep Learning Toolbox™ for using the DAGNetwork object.
- Computer Vision Toolbox™ for video I/O operations.

### Algorithmic Workflow

The block diagram for the algorithmic workflow of the Simulink model follows.

## Get Pretrained Lane and Vehicle Detection Networks

This example uses the `trainedLaneNet` and `yolov2ResNet50VehicleExample` MAT files containing the pretrained networks. The files are approximately 143 MB and 98 MB in size, respectively. Download the files.

```
lanenetFile = matlab.internal.examples.downloadSupportFile('gpcoder/cnn_models/lane_detection',
vehiclenetFile = matlab.internal.examples.downloadSupportFile('vision/data','yolov2ResNet50VehicleExample');
```

## Download Test Traffic Video

To test the model, the example uses the Caltech lanes data set. The file is approximately 16 MB in size. Download this file.

```
mediaFile = matlab.internal.examples.downloadSupportFile('gpcoder/media','caltech_washington1.avi');
```

## Lane and Vehicle Detection Simulink Model

The following diagram shows the Simulink model for performing lane and vehicle detection on the traffic video. When the model runs, the Video Viewer block displays the traffic video with lane and vehicle annotations.

```
model='laneAndVehicleDetection';
open_system(model);
```

Set the file paths of the downloaded network model in the Predict and Detector blocks of the Simulink model.

```
set_param('laneAndVehicleDetection/Lane Detection','NetworkFilePath',lanenetFile)
set_param('laneAndVehicleDetection/Vehicle Detector','DetectorFilePath',vehiclenetFile)
```

Set the location of the test video that you load to the Simulink model.

```
set_param('laneAndVehicleDetection/Traffic Video','inputFileName',mediaFile)
```

## Lane Detection

The Predict block loads the pretrained lane detection network from the `trainedLaneNet.mat` file. This network takes an image as an input and outputs two lane boundaries that correspond to the left and right lanes of the ego vehicle. Each lane boundary is represented by the parabolic equation:

$$y = ax^2 + bx + c$$

Here,  $y$  is the lateral offset and  $x$  is the longitudinal distance from the vehicle. The network outputs the three parameters  $a$ ,  $b$ , and  $c$  per lane. The LaneDetectionCoordinates MATLAB Function block defines a function `lane_detection_coordinates` that takes the output from the predict block and outputs three parameters: `laneFound`, `ltPts`, and `rtPts`. The block uses thresholding to determine if both left and right lane boundaries are both found. If are found, `laneFound` is set to be true and the trajectories of the boundaries are calculated and stored in `ltPts` and `rtPts`.

```
type lane_detection_coordinates
```

```
function [laneFound,ltPts,rtPts] = lane_detection_coordinates(laneNetOut)

% Copyright 2020 The MathWorks, Inc.

persistent laneCoeffMeans;
if isempty(laneCoeffMeans)
 laneCoeffMeans = [-0.0002 0.0002 1.4740 -0.0002 0.0045 -1.3787];
end

persistent laneCoeffStds;
if isempty(laneCoeffStds)
 laneCoeffStds = [0.0030 0.0766 0.6313 0.0026 0.0736 0.9846];
end

params = laneNetOut .* laneCoeffStds + laneCoeffMeans;

isRightLaneFound = abs(params(6)) > 0.5; %c should be more than 0.5 for it to be a right lane
isLeftLaneFound = abs(params(3)) > 0.5;

persistent vehicleXPoints;
if isempty(vehicleXPoints)
 vehicleXPoints = 3:30; %meters, ahead of the sensor
end

ltPts = coder.nullcopy(zeros(28,2,'single'));
rtPts = coder.nullcopy(zeros(28,2,'single'));

if isRightLaneFound && isLeftLaneFound
 rtBoundary = params(4:6);
 rt_y = computeBoundaryModel(rtBoundary, vehicleXPoints);
 ltBoundary = params(1:3);
 lt_y = computeBoundaryModel(ltBoundary, vehicleXPoints);

 % Visualize lane boundaries of the ego vehicle
 tform = get_tformToImage;
 % map vehicle to image coordinates
 ltPts = tform.transformPointsInverse([vehicleXPoints', lt_y]);
 rtPts = tform.transformPointsInverse([vehicleXPoints', rt_y]);
 laneFound = true;
else
 laneFound = false;
end
end
```

## Vehicle Detection

A YOLO v2 object detection network is composed of two subnetworks: a feature extraction network followed by a detection network. This pretrained network uses a ResNet -50 for feature extraction. The detection sub-network is a small CNN compared to the feature extraction network and is composed of a few convolutional layers and layers specific to YOLO v2. The Simulink model performs vehicle detection using the Object Detector block. This block takes an image as input and outputs the bounding box coordinates along with the confidence scores for vehicles in the image.

## Annotation of Vehicle Bounding Boxes and Lane Trajectory in Traffic Video

The LaneVehicleAnnotation MATLAB Function block defines a function `lane_vehicle_annotation`, which annotates the vehicle bounding boxes with the confidence scores. Also, if `laneFound` is true, then the left and right lane boundaries stored in `ltPts` and `rtPts` are annotated in the traffic video.

```
type lane_vehicle_annotation

function In = lane_vehicle_annotation(laneFound, ltPts, rtPts, bboxes, scores, In)

% Copyright 2020 The MathWorks, Inc.

if ~isempty(bboxes)
 In = insertObjectAnnotation(In, 'rectangle', bboxes, scores);
end

pts = coder.nullcopy(zeros(28, 4, 'single'));
if laneFound
 prevpt = [ltPts(1,1) ltPts(1,2)];
 for k = 2:1:28
 pts(k,1:4) = [prevpt ltPts(k,1) ltPts(k,2)];
 prevpt = [ltPts(k,1) ltPts(k,2)];
 end
 In = insertShape(In, 'Line', pts, 'LineWidth', 2);
 prevpt = [rtPts(1,1) rtPts(1,2)];
 for k = 2:1:28
 pts(k,1:4) = [prevpt rtPts(k,1) rtPts(k,2)];
 prevpt = [rtPts(k,1) rtPts(k,2)];
 end
 In = insertShape(In, 'Line', pts, 'LineWidth', 2);
 In = insertMarker(In, ltPts);
 In = insertMarker(In, rtPts);
end

end
```

## Get Pretrained Lane and Vehicle Detection Networks

This function downloads the `yolov2ResNet50VehicleExample.mat` file.

```
getVehicleDetectionAndLaneDetectionNetworks()
```

## Run Simulation

Open Configuration Parameters dialog box. On the **Simulation Target** pane, in the **Deep Learning** group, select the Target library as MKL - DNN.

```
set_param(model, 'SimDLTargetLibrary', 'MKL-DNN');
```

On the **Interface** pane, in the **Deep Learning** group, select the **Target library** as MKL - DNN.

```
set_param(model, 'DLTargetLibrary', 'MKL-DNN');
```

To verify the lane and vehicle detection algorithms and display the lane trajectories, vehicle bounding boxes, and scores for the traffic video loaded in the Simulink model, run the simulation.

```
set_param('laneAndVehicleDetection', 'SimulationMode', 'Normal');
sim('laneAndVehicleDetection');
```

## Generate and Build Simulink Model

In the **Code Generation** pane, select the **Language** as **C++**.

```
set_param(model, 'TargetLang', 'C++');
```

Generate and build the Simulink model using the `slbuild` command. The code generator places the files in the `laneAndVehicleDetection_grt_rtw` build subfolder under your current working folder.

```
currentDir = pwd;
status = evalc("slbuild('laneAndVehicleDetection')");
```

## Generated C++ Code

The subfolder named `laneAndVehicleDetection_grt_rtw` contains the generated C++ code corresponding to the different blocks in the Simulink model and the specific operations being performed in those blocks. For example, the file `trainedLaneNet0_0.h` contains the C++ class, which contains attributes and member functions representing the pretrained lane detection network.

```
hfile = fullfile(currentDir, 'laneAndVehicleDetection_grt_rtw',...
 'trainedLaneNet0_0.h');
rtwdemodbtype(hfile, '#ifndef RTW_HEADER_trainedLaneNet0_0_h',...
 '#endif')
```

```
#ifndef RTW_HEADER_trainedLaneNet0_0_h_
#define RTW_HEADER_trainedLaneNet0_0_h_
#include "rtwtypes.h"
#include "MWMkldnnTargetNetworkImpl.hpp"
#include "MWTensorBase.hpp"
#include "MWTensor.hpp"
#include "MWCNNLayer.hpp"
#include "MWInputLayer.hpp"
#include "MWElementwiseAffineLayer.hpp"

#include "MWActivationFunctionType.hpp"
#include "MWRNNParameterTypes.hpp"
#include "MWTargetTypes.hpp"
#include "MWMkldnnUtils.hpp"

```

```

#include "MWMkldnnCustomLayerBase.hpp"

class yolov2ResNet50VehicleExample0_0
{
public:
 yolov2ResNet50VehicleExample0_0();
 void setSize();
 void resetState();
 void setup();
 void predict();
 void activations(int32_T layerIdx);
 void cleanup();
 real32_T *getLayerOutput(int32_T layerIndex, int32_T portIndex);
 int32_T getLayerOutputSize(int32_T layerIndex, int32_T portIndex);
 real32_T *getInputDataPointer(int32_T index);
 real32_T *getInputDataPointer();
 real32_T *getOutputDataPointer(int32_T index);
 real32_T *getOutputDataPointer();
 int32_T getBatchSize();
 ~yolov2ResNet50VehicleExample0_0();
private:
 int32_T numLayers;
 boolean_T isInitialized;
 MWTensorBase *inputTensors;
 MWTensorBase *outputTensors;
 MWCNNLayer *layers[57];
 MWMkldnnTarget::MWTargetNetworkImpl *targetImpl;
 void allocate();
 void postsetup();
 void deallocate();
};

```

**Note:** If the **System target file** parameter is set to `grt.tlc`, you must select the **Generate code only** model configuration parameter. If you set the **System target file** to `ert.tlc`, you can clear the **Generate code only** parameter, but to create an executable file, you must generate an example main program.

### Cleanup

Close the Simulink model.

```
close_system('laneAndVehicleDetection');
```

## Generate Code Using Embedded Coder

This example shows how to select a system target file for a Simulink® model, configure model parameters, generate C code for embedded systems, and view generated files.

The model represents an 8-bit counter that feeds a triggered subsystem that is parameterized by constant blocks INC, LIMIT, and RESET. Input and Output represent I/O for the model. The Amplifier subsystem amplifies the input signal by gain factor K, which updates when signal `equal_to_count` is true.

1. Open the model.

```
model='rtwdemo_rtwecontrol';
open_system(model)
```

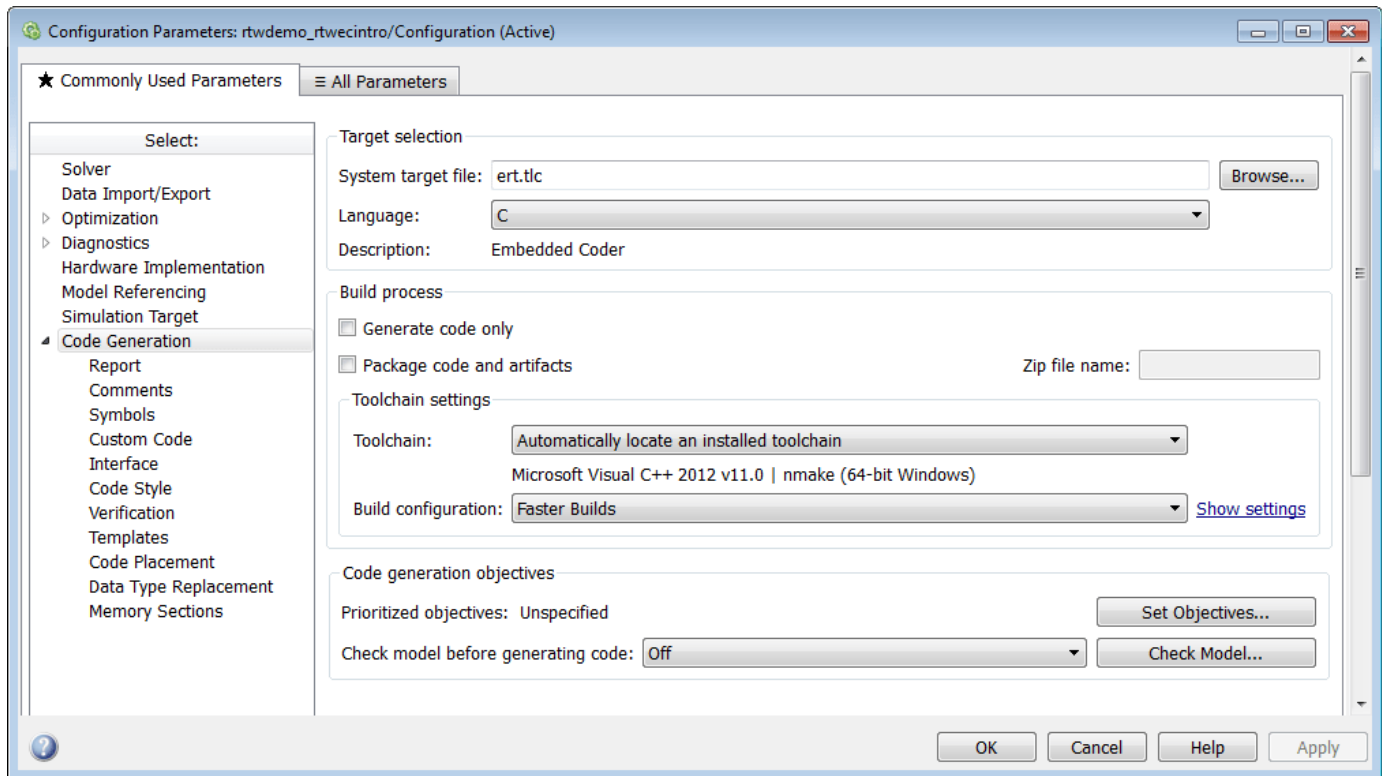

Copyright 1994-2020 The MathWorks, Inc.

2. Open the Model Configuration Parameters dialog box.

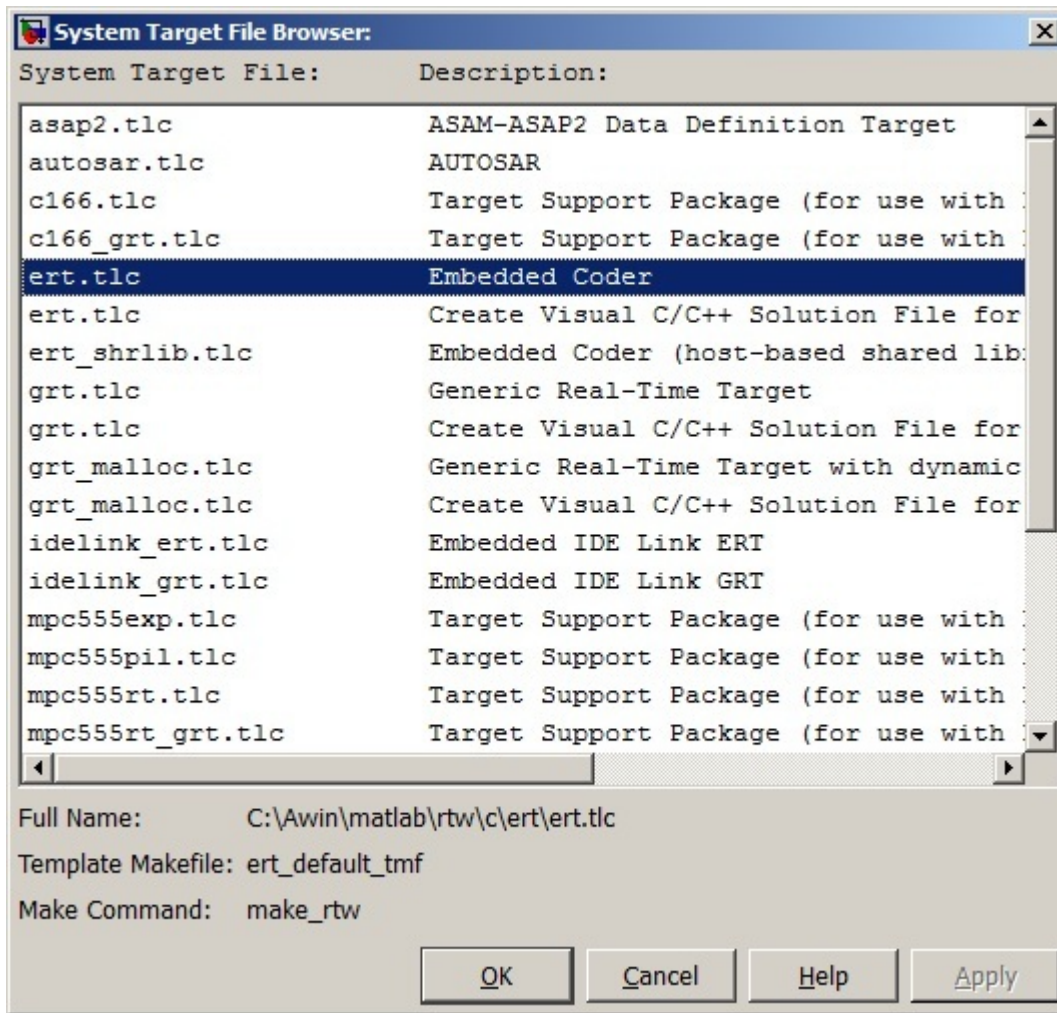

```
cs = getActiveConfigSet(model);
openDialog(cs);
```

3. Select the **Code Generation** tab.

4. To select a system target file, in the **Target Selection** pane, click **Browse**. You can generate code for a specific target environment or purpose. Some built-in targeting options are provided by system target files, which control the code generation process for a target environment.

5. Select the **Embedded Real-Time (ERT)** system target file and click **Apply**.

The ERT system target file supports a utility that you can use to specify and prioritize code generation settings based on your application objectives.

6. In the **Code Generation Advisor** pane, click **Set Objectives**.

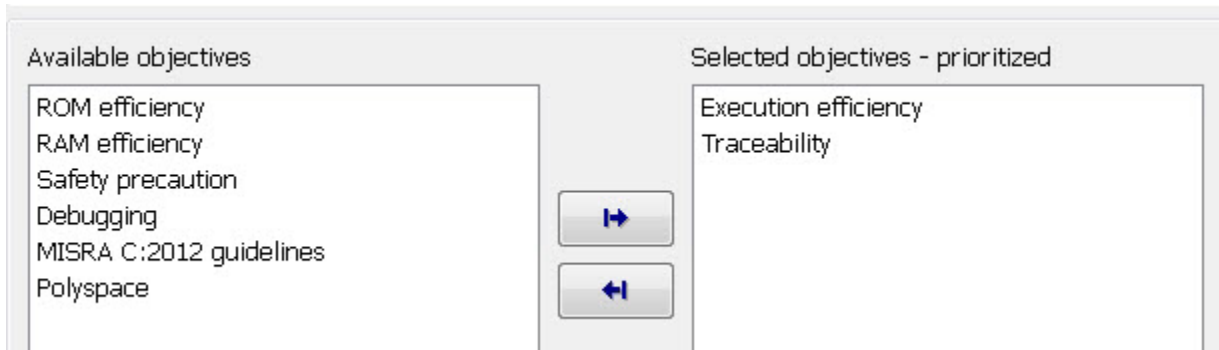

You can set and prioritize objectives for the generated code. For example, while code traceability might be a very important criterion for your application, you might not want to prioritize it at the cost of code execution efficiency.

7. In the **Set Objectives** pane, select **Execution efficiency** and **Traceability**. Click **OK**.

You can select and prioritize a combination of objectives before generating code.

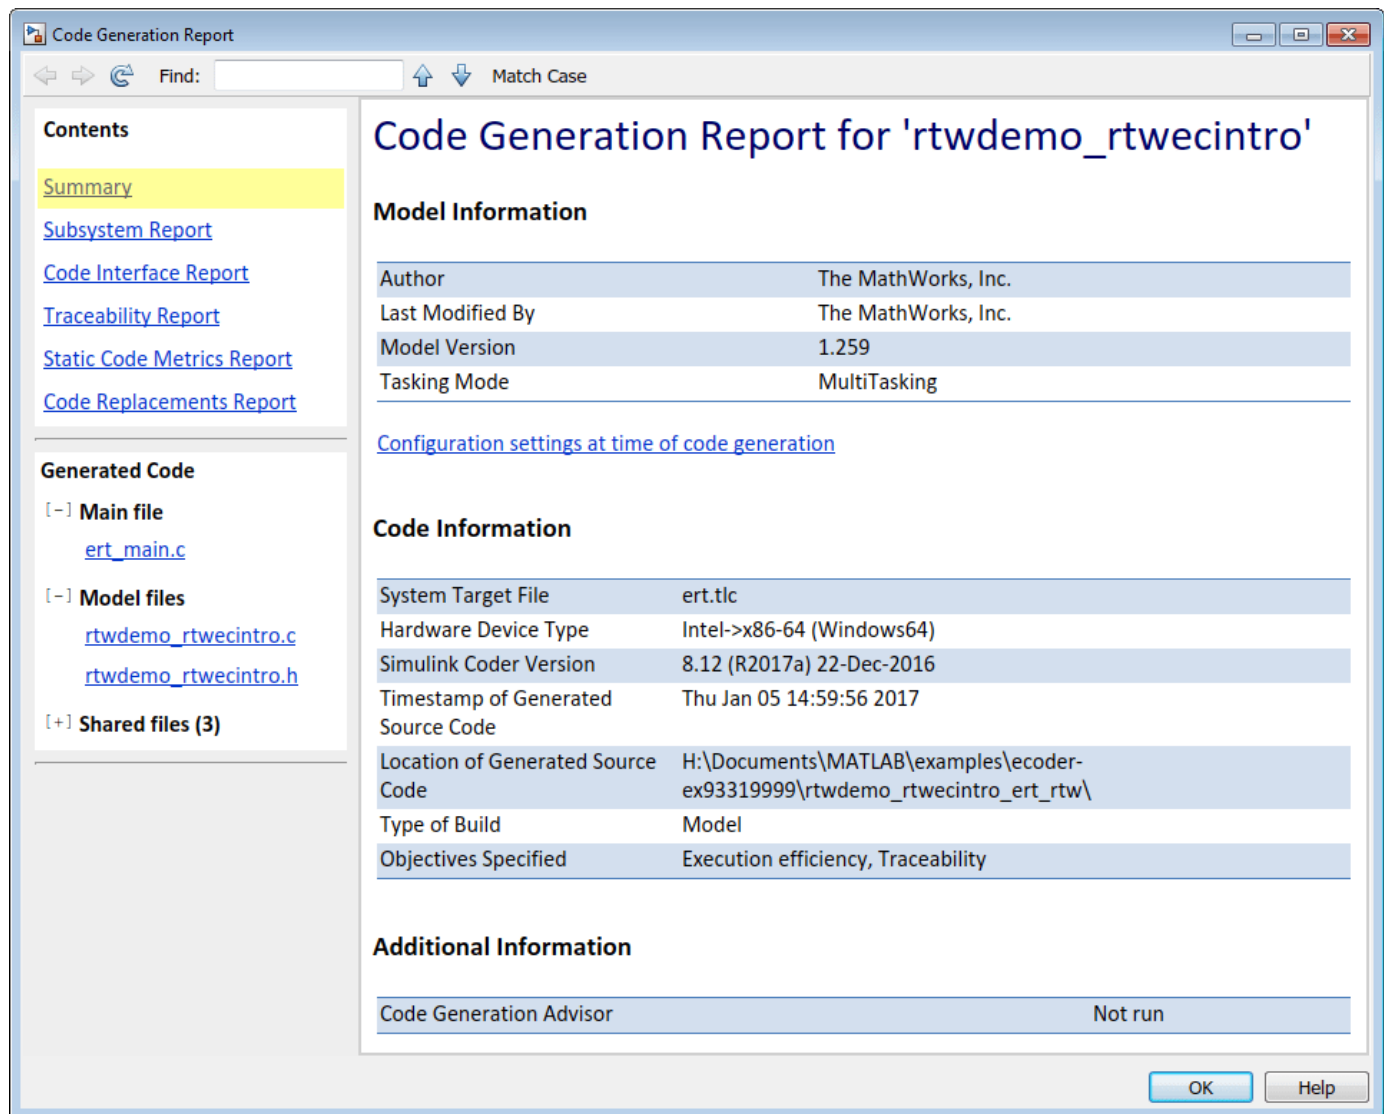

**8.** In the model window, initiate code generation and the build process for the model by using one of these options:

- Click the Build Model button.
- Press **Ctrl+B**.
- Invoke the `slbuild` command from the MATLAB command line.
- Invoke the `slbuild` command from the MATLAB command line.

**9.** View the code generation report.

The report includes `rtwdemo_rtwecintro.c`, associated utility and header files, and traceability and validation reports.

This figure contains a portion of `rtwdemo_rtweintro.c`

```

Step function for model: rtwdemo_rtwecintro
File: rtwdemo_rtwecintro.c

1 /* Model step function */
2 void rtwdemo_rtwecintro_step(void)
3 {
4 boolean_T rtb_equal_to_count;
5
6 /* Sum: '<Root>/Sum' incorporates:
7 * Constant: '<Root>/INC'
8 * UnitDelay: '<Root>/X'
9 */
10 rtDWork.X = (uint8_T) (1U + (uint32_T)rtDWork.X);
11
12 /* RelationalOperator: '<Root>/RelOpt' incorporates:
13 * Constant: '<Root>/LIMIT'
14 */
15 rtb_equal_to_count = (rtDWork.X != 16);
16
17 /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
18 * TriggerPort: '<S1>/Trigger'
19 */
20 if (rtb_equal_to_count && (rtPrevZCSigState.Amplifier_Trig_ZCE != POS_ZCSIG))
21 {
22 /* Outport: '<Root>/Output' incorporates:
23 * Gain: '<S1>/Gain'
24 * Inport: '<Root>/Input'
25 */
26 rtY.Output = rtU.Input << 1;
27 }
28
29 rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T) (rtb_equal_to_count ? (int32_T)
30 POS_ZCSIG : (int32_T)ZERO_ZCSIG);
31
32 /* End of Outputs for SubSystem: '<Root>/Amplifier' */
33
34 /* Switch: '<Root>/Switch' */
35 if (!rtb_equal_to_count) {
36 /* Update for UnitDelay: '<Root>/X' incorporates:
37 * Constant: '<Root>/RESET'
38 */
39 rtDWork.X = 0U;
40 }
41
42 /* End of Switch: '<Root>/Switch' */
43 }

```

10. Close the model.

```

bdclose(model)
rtwdemoclean;

```

## Generate Code by Using the Quick Start Tool

The Quick Start tool helps you prepare a model for generating readable, efficient code. To start the tool, open the Embedded Coder app. On the **C Code** tab, click **Quick Start**.

After you start the tool, you must answer these questions about the code that you want to generate:

- What is the model or subsystem for code generation?
- What is the type of code output for your generated code?
- Does your application require reentrant, multi-instance code?
- What is the target hardware processor type?
- What is your primary code generation objective?

The tool validates your choices against the model and presents the parameter changes required to generate code. If you choose to generate code, the tool applies the parameter changes to your configuration set and generates the code. After code generation, you can view the code generation report and find information on building, customizing, optimizing, and packaging the code. For more information about the code generation report, see “Reports for Code Generation” on page 51-2.

To further customize your generated code, click **Finish**, and then use the Embedded Coder app with the Code perspective environment. The Code perspective provides the tools to control the names and representation of the model data and functions in the generated code. For more information, see “C Code Generation Configuration for Model Interface Elements” on page 32-2.

### Quick Start Model Analysis

At each step of the quick start process, the tool validates your model against your selections. The tool checks for model conditions that prevent you from proceeding with code generation. During the analysis step, the tool must also examine your model or subsystem for answers to the following questions. The answers help determine the best configuration for the deployment of your code.

#### How many sample rates are in your system?

The Quick Start tool evaluates your model to determine the number of periodic sample rates in your system.

<b>Single rate</b>	Your model has only one periodic sample rate. The generated code has a single-entry point function that runs at the time interval of the sample rate.
<b>Multirate</b>	<p>Your model has more than one periodic sample rate. It is possible that the generated code does not execute at the same time intervals. After the analysis step, you can choose to generate a single-entry point function for each of the sample rates or generate a different entry point function for each sample rate.</p> <p>If you choose to generate multitasking code, the code generator produces multiple entry-point functions. These functions run as multiple tasks. Each entry-point function is called at an interval defined by the sample rate that is configured in the model.</p>

If your model contains an asynchronous rate, an additional entry-point function is generated to run at the specific interrupt time.

For more information about sample rates, see “Time-Based Scheduling and Code Generation”.

**Does your system contain continuous states?**

The Quick Start tool evaluates your model for continuous blocks to determine the correct solver to use.

<b>No</b>	If your system does not contain continuous states, the Quick Start tool configures your model to use a fixed-step discrete solver for code generation if you have not selected one.
<b>Yes</b>	If your system does contain continuous states, the Quick Start tool configures your model to use a fixed-step continuous solver for code generation if you have not selected one. The tool also selects the <code>SupportContinuous</code> configuration parameter.

For more information on solvers, see “Solver Selection Criteria”.

**Did you configure your system for export function calls?**

The Quick Start tool evaluates your model to see if scheduler code must be generated.

<b>No</b>	If you did not configure your system for export function calls, the generated code includes code for the system algorithm and the scheduler code.
<b>Yes</b>	If you configured your system for export function calls, the generated code includes code for the system algorithm. You can manually write the scheduler code or generate it from other models.

For more information, see “Export-Function Models Overview”.

**Does your system contain referenced models?**

The Quick Start tool evaluates your model to see if it depends on code from other models.

<b>No</b>	If your system does not contain referenced models, the generated code does not depend on code from other models.
<b>Yes</b>	If your system contains referenced models, the generated code for your model depends on other modules generated from referenced models. The code generator can optimize the generated code because it is aware of the relationship between your model and the referenced models. When the Quick Start tool applies configuration parameter changes to your model, it also applies the changes to the referenced models.

For more information, see “Generate Code for Model Reference Hierarchy”.

**Configuration Parameter Changes for Models That Have a Configuration Reference**

To apply configuration parameter changes to a model that has an active configuration reference, the Quick Start tool:

- Creates a `Simulink.ConfigSet` object `QuickStart_timestamp` in the workspace or data dictionary that contains the original configuration set. The new object is a copy of the original configuration set that has the parameter changes applied.
- Creates a `Simulink.ConfigSetRef` object that points to the new configuration set object.
- Attaches the new configuration reference to the model and makes it the active configuration.

- If your system contains referenced models that share your original configuration set, the tool attaches the new configuration reference to the referenced models and makes the new configuration reference the active configuration.

To restore the original configuration set, activate the original `Simulink.ConfigSetRef` object.

---

**Note** If the Quick Start tool creates the configuration set object in the MATLAB workspace, you must save the object to preserve the configuration set after the MATLAB session ends. For more information, see “Save a Configuration Set”.

---

## Next Steps

After you generate code by using Quick Start tool, possible next steps are:

- “Preserve Variables in Generated Code” on page 33-2
- “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 46-2
- “Generated Code Compilation”
- “Manage Configuration Sets for a Model”
- “Build and Run a Program” on page 56-29
- “Relocate or Share Generated Code”

To control the names and representation of the model data and functions in the generated code, use the Code Mappings editor and the Model Data Editor in the Embedded Coder app. For more information, see “C Code Generation Configuration for Model Interface Elements” on page 32-2.

## Manage File Packaging of Generated Code Modules

The code generator produces code modules. The file packaging configuration controls where the code generator places code into code modules and header files.

To locate and examine the generated code files, use the **Code** view or the HTML code generation report. The code generation report provides hyperlinks in the comments that you can click to view the generated code in the MATLAB Help browser. For more information, see “Traceability in Generated Code” on page 79-3.

### In this section...

“Generated Code Modules” on page 50-12

“User-Written Code Modules” on page 50-14

“Customize Generated Code Modules” on page 50-14

## Generated Code Modules

The code generator creates a build folder in your working folder to store generated source code. The build folder contains object files, a makefile, and other files created during the code generation process. The default name of the build folder is *model\_ert\_rtw*.

Code Modules and Header Files Affected by File Packaging summarizes the structure of source code that the code generator produces.

You can customize the generated set of files in several ways:

- **File packaging formats:** Manage the number of source files generated for your model. Select model configuration parameter **File packaging format**. For more information, see “Customize Generated Code Modules” on page 50-14.
- **Nonvirtual subsystem code generation:** Instruct the code generator to produce separate functions within separate code files for nonvirtual subsystems. You can control the names of the functions and of the code files. For more information, see “Generate Subsystem Code as Separate Function and Files” on page 3-7.
- **Storage classes:** Define and use storage classes that partition generated data structures into different files based on file names that you specify. For more information, see “Organize Parameter Data into a Structure by Using Struct Storage Class” on page 32-67.
- **Module packaging:** Direct the generated code into a required set of `.c` or `.cpp` and `.h` files, and control the internal organization of the generated files. For details, see “Code Interface Configuration”.

**Code Modules and Header Files Affected by File Packaging**

<b>File</b>	<b>Description</b>
<i>model.c</i> or <i>.cpp</i>	Contains entry points for code implementing the model algorithm (for example, <i>model_step</i> , <i>model_initialize</i> , and <i>model_terminate</i> ).
<i>model_private.h</i>	Contains local macros and local data that the model and subsystems require. This file is included in the <i>model.c</i> file as a <code>#include</code> statement. You do not need to include <i>model_private.h</i> when interfacing handwritten code to the generated code of a model.
<i>model.h</i>	<p>Declares model data structures and a public interface to the model entry-points and data structures. Provides an interface to the real-time model data structure (<i>model_M</i>) with accessor macros.</p> <p>The code generator:</p> <ul style="list-style-type: none"> <li>• Produces a separate header file for each Simulink Function block in a model.</li> <li>• Includes <i>model.h</i> in the subsystem <i>.c</i> or <i>.cpp</i> files of a model.</li> </ul> <p>If you interface handwritten code to generated code for one or more models, include <i>model.h</i> for each of those models.</p>
<i>model_data.c</i> or <i>.cpp</i>	Contains (if conditionally generated) the declarations for the parameters data structure, the constant block I/O data structure, and any zero representations for the model structure data types. If the model does not use these data structures and zero representations, <i>model_data.c</i> or <i>.cpp</i> is not generated. These structures and zero representations are declared extern in <i>model.h</i> .
<i>model_types.h</i>	Provides forward declarations for the real-time model data structure and the parameters data structure. Function declarations of reusable functions can require these declarations. Provides type definitions for user-defined types that the model uses.
<i>rtwtypes.h</i>	Defines data types, structures, and macros required by generated code. For more information, see “Control Placement of <i>rtwtypes.h</i> for Shared Utility Code”.
<i>multiword_types.h</i>	<p>Contains type definitions for wide data types and their chunks. File is generated when multiword data types are used or when you select one or more of these model configuration parameters:</p> <ul style="list-style-type: none"> <li>• <b>MAT-file logging</b></li> <li>• <b>External mode</b></li> </ul>
<i>model_reference_types.h</i>	Contains type definitions for timing bridges. File is generated for a referenced model or a model containing Model blocks.
<i>builtin_typeid_types.h</i>	<p>Defines an enumerated type corresponding to built-in data types. File is generated when your model contains a Stateflow chart that uses messages or when you select one or more of these configuration parameters:</p> <ul style="list-style-type: none"> <li>• <b>MAT-file logging</b></li> <li>• C API model configuration parameter</li> </ul>

File	Description
zero_crossing_types.h	Contains zero-crossing definitions for models with triggered subsystems where the trigger is rising, falling, or either. File is generated only if required by the model.
ert_main.c or .cpp	(optional file) If you select model configuration parameter <b>Generate an example main program</b> , this file is generated. For more information, see “Generate an example main program”.
rtmodel.h	(optional file) If you clear model configuration parameter <b>Generate an example main program</b> , this file is generated. For more information, see “Generate an example main program”.  Contains #include directives required by the rt_main.c or rt_cppclass_main.cpp static main program module. Includes rtmodel.h to access model-specific data structures and entry points, because the static main program module is not created at code generation time.  For more information, see “Static Main Program Module” on page 68-8.
model_capi.c or .cpp model_capi.h	(optional file) Provides data structures that enable a running program to access model signals, states, and parameters without external mode. To learn how to generate and use the model_capi.c or .cpp and .h files, see “Exchange Data Between Generated and External Code Using C API”.

## User-Written Code Modules

Code that you write to interface with generated model code usually includes a customized main module. Base this module on a main program produced by the code generator. This customized main module can also include interrupt handlers, device driver blocks and other S-functions, and other supervisory or supporting code. Steps to set up the development environment to support a customized main module include:

- 1 Establish a working folder for your own code modules.
- 2 Put your working folder on the MATLAB path.
- 3 At minimum, inform the build process about the location of your source and object files with model configuration parameter **Additional build information**.
- 4 Your development process could require generating code for a particular microprocessor or development board and deploying the code on target hardware with a cross-development system. To accomplish these goals, make more extensive modifications to the ERT-based system target file.

For information on how to customize your ERT-based system target file for your production requirements, see “Target Development”.

## Customize Generated Code Modules

Model configuration parameter **File packaging format** specifies how the code generator packages generated source code into files. You can set the parameter to **Modular**, **Compact (with separate data file)**, and **Compact**. This table describes the generated files and the removed files for each file packaging format.

**Generated Files According to File Packaging Format**

File Packaging Format	Generated Files	Removed Files
Modular (default)	<i>model.c</i> subsystem files (optional) <i>model.h</i> <i>model_types.h</i> <i>model_private.h</i> <i>model_data.c</i> (conditional)	None
Compact (with separate data file)	<i>model.c</i> <i>model.h</i> <i>model_data.c</i> (conditional)	<i>model_private.h</i> <i>model_types.h</i> (conditional, see Removed Files According to File Packaging Format)
Compact	<i>model.c</i> <i>model.h</i>	<i>model_data.c</i> <i>model_private.h</i> <i>model_types.h</i> (conditional, see Removed Files According to File Packaging Format)

This table describes content placement from the removed files.

**Removed Files According to File Packaging Format**

Removed File	Generated Content In File
<i>model_private.h</i>	<i>model.c</i> and <i>model.h</i>
<i>model_types.h</i>	<i>model.h</i>
<i>model_data.c</i>	<i>model.c</i>

You can specify a different file packaging format for each referenced model.

Model configuration parameter **Shared code placement** interacts with file packaging operations. If you set **Shared code placement** to `Shared location`, the code generator produces separate files for utility code in a shared location, regardless of the file packaging format. If you set **Shared code placement** to `Auto`, the code generator generates code for utilities according to the file packaging format selection.

- Modular: Some shared utility files are in the build folder.
- Compact (with separate data file): Utility code is generated in *model.c*.
- Compact: Utility code is generated in *model.c*.

File packaging formats Compact and Compact (with separate data file) generate *model\_types.h* for models containing:

- A Variant Subsystem block. The *model\_types.h* file includes preprocessor directives defining the variant objects associated with a variant block.
- Storage classes generating a separate header file.

File packaging formats Compact and Compact (with separate data file) are not compatible with:

- A model containing a subsystem, which is configured to generate separate source files
- A model containing a noninlined S-function
- A model for which **Shared code placement** is set to Auto, which uses data objects for which **Data scope** is set to Exported

# Tutorial for Generating C Code from a Control Algorithm for an Embedded System

This guided tutorial uses a series of examples to show the workflow of generating code from a control algorithm for an embedded system. In each example, you learn how to perform a specific aspect of code generation or integration. The examples are based on a shared model. Each example has a unique version of that model and corresponding data set so that you can use the examples independently. You do not have to run the examples in a specific order. When you transition between examples, you save the current model so that each example captures your modifications to the model and model data.

To recover a model in its original state, delete your local copy of the model and model data. The model data is saved as `PCG_Demo_#_data.mat`.

Use these hyperlinks to navigate to the examples in the tutorial.

- 1 “Prepare a Control Algorithm Model for C Code Generation” on page 50-18
- 2 “Configure Data Interface in the Generated Code” on page 50-29
- 3 “Partition Functions in Generated Code” on page 50-38
- 4 “Call External C Code from Model and Generated Code” on page 50-47
- 5 “Build Integrated Code Outside the Simulink Environment” on page 50-52
- 6 “Test Generated Code” on page 50-57
- 7 “Evaluate Performance of the Generated Code” on page 50-63
- 8 “Install and Use Cygwin and Eclipse” on page 50-67

## Third-Party Software

Some of the examples use the Eclipse™ IDE and the Cygwin™/gcc compiler. Instructions to install and use Eclipse™ and Cygwin™/gcc are available in “Install and Use Cygwin and Eclipse” on page 50-67.

## See Also

## Prepare a Control Algorithm Model for C Code Generation

Generate code for a control algorithm model, integrate the generated code with an existing system, and validate simulation and executable results.

### Understand the Model

This example shows and describes the model from behavioral and structural perspectives. The example also shows how to configure a model for code generation and how to generate code. You learn how to:

- Understand the functional behavior of the example model.
- Understand how to validate the model.
- Become familiar with model-checking tools.
- Become familiar with configuration options that affect code generation.
- Generate code from a model.

### Understand the Functional Design of the Model

This example uses a simple model of a throttle controller. The model features redundancy, which safety-critical, drive-by-wire applications commonly use. The model highlights a standard model structure and a set of basic blocks in algorithm design.

In the current configuration, the code that the model generates is not configured for a production target system. In this example, you change the target configuration and observe the resulting changes to the format of the generated code.

### Inspect the Top-Level Model

Open the example model.

The top-level model consists of:

- Four subsystems: `PI_ctrl_1`, `PI_ctrl_2`, `Define_Throt_Param`, and `Pos_Command_Arbitration`.
- Top-level inputs: `pos_rqst`, `fbk_1`, and `fbk_2`.
- Top-level outputs: `pos_cmd_one`, `pos_cmd_two`, and `ThrotComm`.
- Signal routing.
- No transformative blocks. Transformative blocks change the value of a signal, for example, `Sum` and `Integrator` blocks.

The layout shows a basic model architectural style.

- Separation of calculations from signal routing (lines and buses)
- Partitioning into subsystems

This style suits many types of models.

## Inspect Subsystems

Two subsystems represent PI controllers: `PI_ctrl_1` and `PI_ctrl_2`. The subsystems have identical content and, for now, use identical data. Later, you use the subsystems to learn how the code generator can create reusable functions.

The PI controllers come from a *library*, which is a group of related blocks or models that you intend to reuse. Libraries provide one of two methods for including and reusing models. You see the second method, model referencing, later in this series.

When you use a library block in a model, you cannot edit the instance of the block in the model. Instead, edit the block definition in the library. Then, instances of the block in different models remain consistent.

Open the subsystem `PI_ctrl_1`.

The Stateflow® chart `Pos_Command_Arbitration` performs basic error checking on the two command signals. If the command signals are too far apart, the chart sets the output to a `fail_safe` position.

Open `Pos_Command_Arbitration`.

## Inspect Model Configuration Parameter Settings for Code Generation

To prepare a model for code generation, open the **Embedded Coder** app. Then, set code generation model configuration parameters. The parameters determine the method that the code generator uses to generate the code and the resulting code format.

### Code Generation Objectives

You can manually configure the model configuration parameters. Alternatively, you can choose from predefined objectives to automatically configure the model configuration parameters.

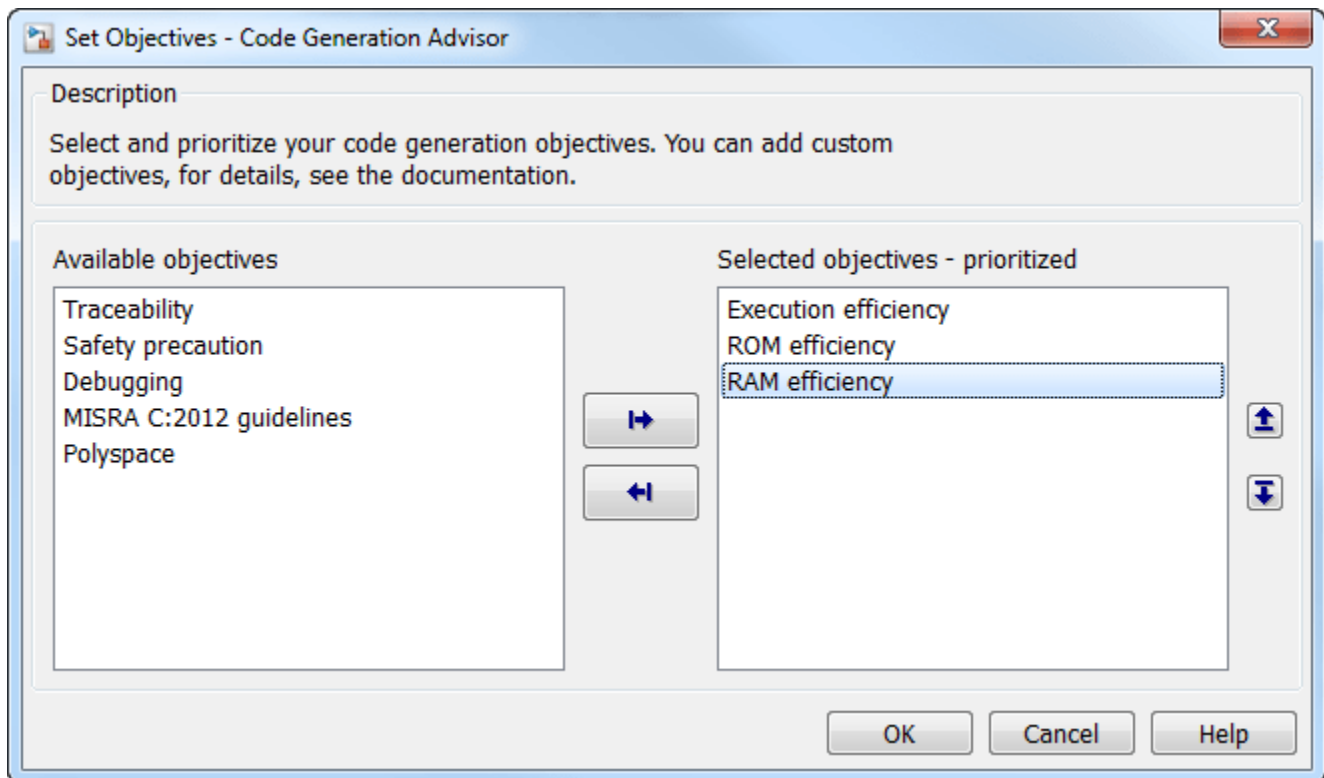

You can choose from these high-level code generation objectives:

- Execution efficiency
- ROM efficiency
- RAM efficiency
- Traceability
- Safety precaution
- Debugging

Each objective checks the current model configuration parameters against the recommended values of the objectives. Each objective also includes a set of Code Generation Advisor checks. You can use these additional checks to verify that the model configuration parameters are set to create code that meets the objectives.

Some of the recommendations that the objectives make conflict with the Code Generation Advisor checks. The order in which you select objectives determines the result. Simulink® resolves conflicts by satisfying objectives that have a higher priority.

The figure shows how to set the priority to `Execution efficiency > ROM efficiency > RAM efficiency`. To open the dialog box, in the Configuration Parameters dialog box, select the **Code Generation** pane. Then, click **Set objectives**.

You can run the Code Generation Advisor to check the model based on the specified objectives. To open the Code Generation Advisor, in the **C Code** tab, click **C/C++ Code Advisor**.

The Code Generation Advisor creates a list of checks based on the objectives that you select. The first check reviews current values of the model configuration parameters and suggests alternative values based on the objectives. The check provides an automated method for setting the parameters to recommended values.

### Manual Configuration Options

In the Model Configuration Parameters dialog box, these panes are relevant to code generation:

- Solver
- Hardware Implementation
- Code Generation

### Solver

Open the **Solver** pane.

- To generate code for a model, you must set model configuration parameter **Type** to Fixed-step.
- Parameter **Fixed-step size** sets the base rate of the system. Set the parameter to the lowest common multiple of rates in the system.

- Parameter **Solver** controls the integration algorithms that the code generator uses.
- To generate an entry-point function for each rate in the system, select parameter **Treat each discrete rate as a separate task**.

### **Hardware Implementation**

Open the **Hardware Implementation** pane.

Use hardware implementation parameters to specify a hardware board. Simulink® adjusts other settings on the pane, including hidden microprocessor device details, based on your board selection. To view or adjust the hidden parameter settings, such as the word size and byte ordering, click **Device details**.

### **Code Generation**

Open the **Code Generation** pane.

Use the **Code Generation** pane to specify the system target file and optimizations. This example uses the Embedded Coder® system target file (`ert.tlc`). You can extend that system target file to create a customized configuration. Some of the basic parameters on the **Code Generation** pane and its subpanes include:

#### **System target file**

- `ert.tlc` - "Base" Embedded Coder®
- `grt.tlc` - "Base" Generic Real-Time Target
- Hardware-specific targets

#### **Make file**

#### **Code optimizations**

- Remove unused branches from the code and control the creation of temporary variables.
- Control which signals have explicit initialization code.
- Enable and disable use of overflow and division-by-zero protection code.

#### **Code formatting options**

- Use of parentheses
- Header file information
- Variable naming conventions

#### **Inclusion of custom code**

- C files
- H files
- Object files
- Folder paths

#### **Generation of ASAP2 files**

## Save Model Configuration Parameters

You can save the values of model configuration parameters as a MATLAB® function. At the command prompt, enter:

```
hCs = getActiveConfigSet('rtwdemo_PCG_Eval_P1');
hCs.saveAs('ConfiguredData');
```

The MATLAB® function saves a textual representation of the configuration parameter object. You can use the generated file for archiving or comparing different versions of the files by using traditional diff tools. You can also visually inspect the content of the file.

You can run the function to set the configuration parameters of other models.

```
hCs2 = ConfiguredData;
attachConfigSet('myModel', hCs2, true);
setActiveConfigSet('myModel', hCs2.Name);
```

## Understand the Simulation Testing Environment

You test the throttle controller model in a separate model called a *test harness*. A test harness is a model that evaluates the control algorithm. Using a test harness:

- Separates the test data from the control algorithm
- Separates the plant or feedback model from the control algorithm
- Provides a reusable environment for multiple versions of the control algorithm

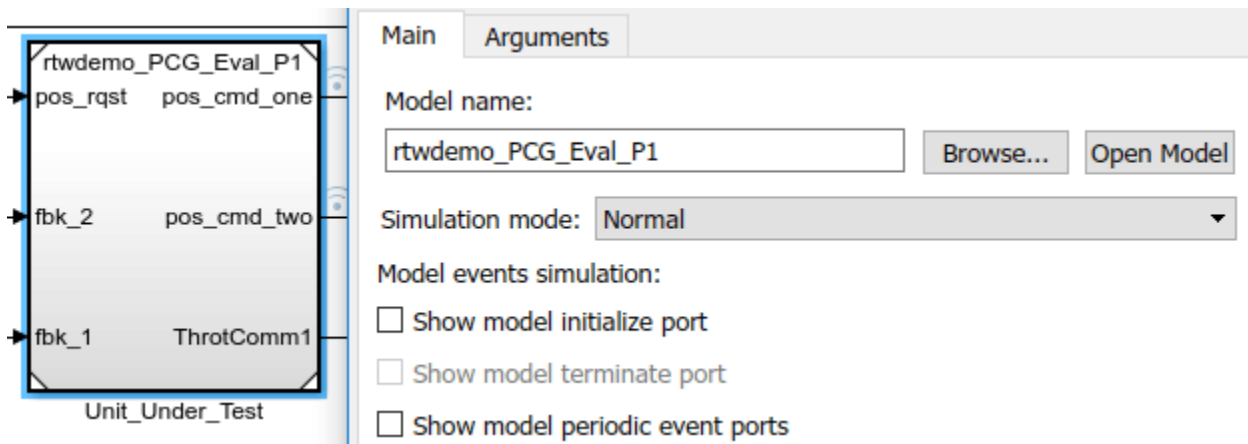

Open the test harness.

A typical simulation testing environment consists of these parts:

- Unit under test
- Test vector source
- Evaluation and logging
- Plant or feedback system
- Input and output scaling

Highlight the unit under test.

The control algorithm is the *unit under test*. The test harness model references the control algorithm through a Model block. With Model blocks, you can reuse components. The Model block refers to the control algorithm by name (rtwdemo\_PCG\_Eval\_P1).

The Model block enables inclusion (referencing) of a model in another model as a *compiled function*. By default, Simulink® compiles the referenced model when you change it. Compiled functions have these advantages over libraries:

- Large models simulate faster.
- You can simulate compiled functions directly.
- The simulation requires less memory. When you add multiple instances of the model (multiple Model blocks), only one copy of the compiled model exists in memory.

Highlight the test vector source.

The model uses a Signal Builder block as the test vector source. The block has data that drives the simulation (`pos_rqst`) and the expected results that the Verification subsystem uses. This example uses only one set of test data, though in a typical application you create a test suite that fully exercises the system.

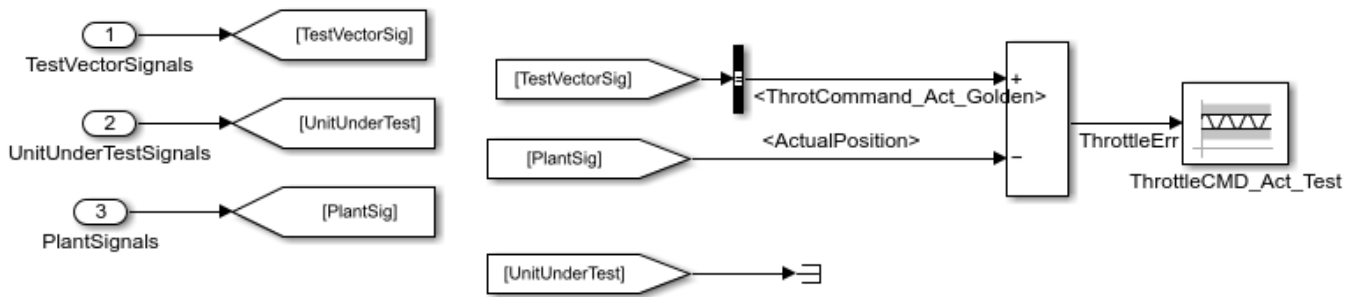

Highlight Verification.

The test harness compares the simulation results against *golden data*, which is a set of test results that indicate the desired behavior for the model. In this model, the V&V Assertion block compares the simulated throttle value position from the plant against the golden value that the test harness provides. If the difference between the two signals is greater than 5%, the test fails and the Assertion block stops the simulation.

Alternatively, you can evaluate the simulation data after the simulation completes execution. You can use either MATLAB® scripts or third-party tools to perform the evaluation. Post-execution evaluation provides greater flexibility in the analysis of the data, though you must wait until execution finishes. Combining the two methods can yield a highly flexible and efficient test environment.

```
load_system('rtwdemo_PCGEvalHarness')
open_system('rtwdemo_PCGEvalHarness/Verification')
```

Highlight the plant/feedback system.

This example models the throttle dynamics by breaking a transfer function down into a canonical form. You can create plant models to model a specific level of fidelity. Many applications use a different plant model at each stage of testing.

Highlight scaled input and output.

The subsystems that scale input and output perform these primary functions:

- Select signals to route to the unit under test and to the plant.
- Rescale signals between engineering units and units that the unit under test requires.
- Handle rate transitions between the plant and the unit under test.

### Run Simulation Tests

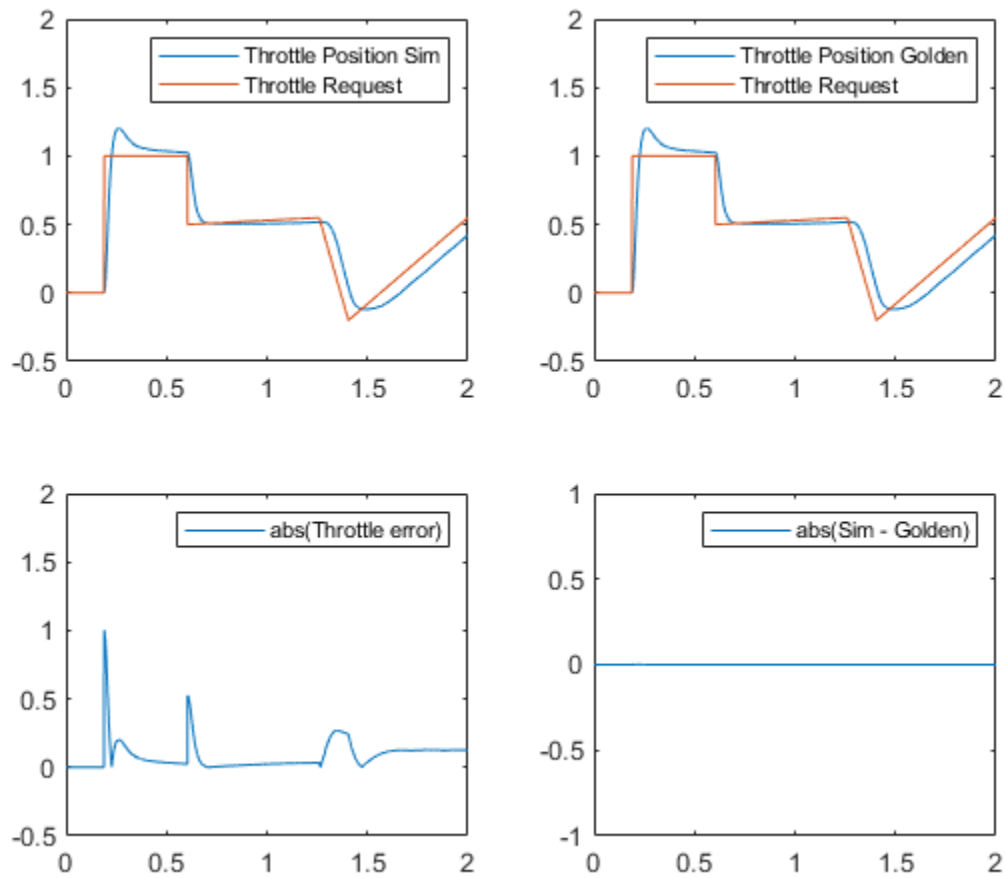

To run the test harness model simulation, click **Start** or click this hyperlink.

Run the test harness.

The first time the test harness runs, Simulink® must compile the referenced model. You can monitor the compilation progress in the Command Window.

When the model simulation is complete, Simulink® displays the results in a plot figure.

```
sim('rtwdemo_PCGEvalHarness')
```

The lower-right plot shows the difference between the expected (golden) throttle position and the throttle position that the plant calculated.

### Generate Code

To generate code, open the **Embedded Coder** app. Then, using one of these techniques:

- In the model, press **Ctrl+B**.
- In the **C Code** tab, select **Build** or **Generate Code**.
- Click this hyperlink:

Generate code for the model.

The code generator produces several files. The resulting code, though computationally efficient, is not yet organized for integration into the production environment.

## Examine the Generated Code

The code generator creates multiple files that you can view from the **Code** view or code generation report. In addition to the standard C definition and header files, the code generator creates a set of HTML files. The HTML files provide hyperlinks between the code and the model.

In the Model Explorer, open the HTML Code Browser.

In the generated code, observe that:

- The controller code exists in one function called *modelName\_step*, which is in the file *rtwdemo\_PCG\_Eval\_P1.c*.
- The code generator folds the operations of multiple blocks into one statement of code.
- The function *modelName\_initialize* initializes variables.
- Data structures define model data (for example, *rtwdemo\_PCG\_Eval\_P1\_U.pos\_rqst*).

```
/* Model step function */
void rtwdemo_PCG_Eval_P1_step(void)
{
 real_T rtb_Sum3;
 real_T rtb_IntegralGainShape;
 real_T Discrete_Time_Integrator1;
 real_T Discrete_Time_Integrator1_i;

 /* Sum: '<S2>/Sum2' incorporates:
 * Inport: '<Root>/fbk_1'
 * Inport: '<Root>/pos_rqst'
 */
 rtb_IntegralGainShape = rtwdemo_PCG_Eval_P1_U.pos_rqst -
 rtwdemo_PCG_Eval_P1_U.fbk_1;
}
```

- *rtwdemo\_PCG\_Eval\_P1.c*: C file that defines step and initialization functions
- *ert\_main.c*: Example Main file that includes a simple scheduler
- *rtwdemo\_PCG\_Eval\_P1.h*: H file that contains type definitions of the Simulink® Coder™ data structures
- *PCG\_Eval\_p1\_private.h*: File that declares data that only the generated code uses
- *rtwdemo\_PCG\_Eval\_P1\_types.h*: H file that declares the real-time model data structure

For the next example in this series, see “Configure Data Interface in the Generated Code” on page 50-29.

## Configure Data Interface in the Generated Code

Specify signals, states, and parameters for inclusion in generated code.

Learn how to control these attributes of data in the generated code:

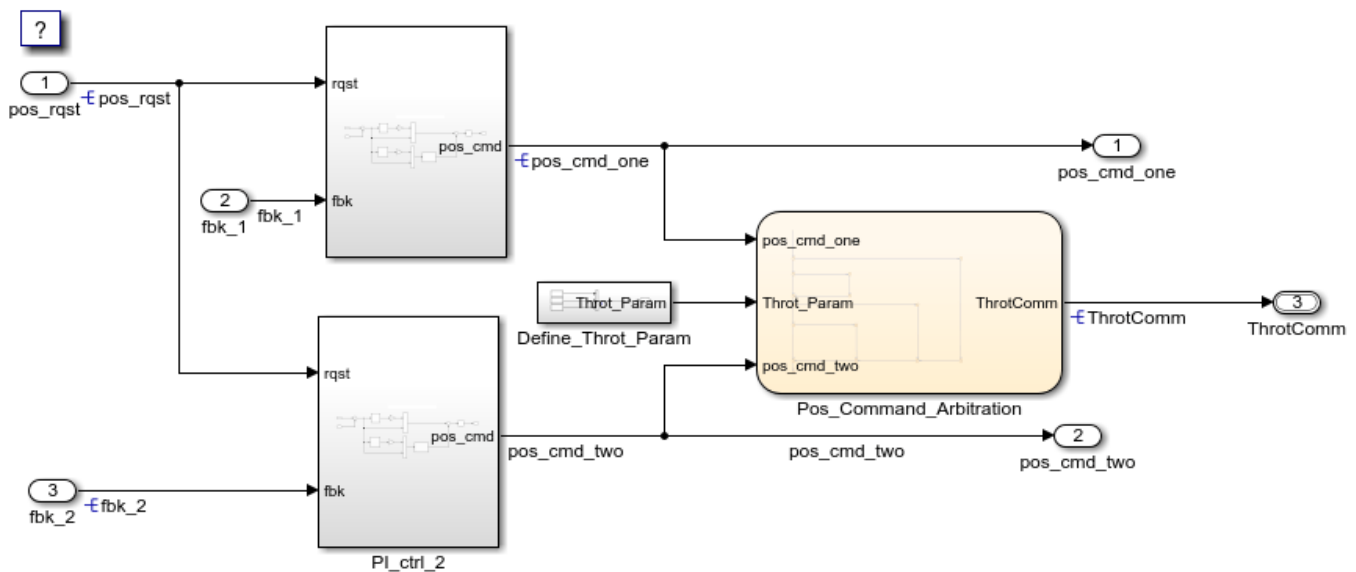

- Name
- Data type
- Data storage class

For information about the example model, see “Prepare a Control Algorithm Model for C Code Generation” on page 50-18.

### Open Example Model

Open the example model, `rtwdemo_PCG_Eval_P2`.

```
open_system('rtwdemo_PCG_Eval_P2')
```

Copyright 2007-2020 The MathWorks, Inc.

### Data Declaration

Most programming languages require that you declare data and functions before using them. The declaration specifies:

- Scope: The region of the program that has access to the data
- Duration: The period during which the data exist in memory
- Data type: The amount of memory allocated for the data
- Initialization: A value, a pointer to memory, or NULL

The combination of scope and duration is the storage class. If you do not provide an initial value, most compilers assign a zero value or a null pointer.

Supported data types include:

- `double`: Double-precision floating point
- `single`: Single-precision floating point
- `int8`: Signed 8-bit integer
- `uint8`: Unsigned 8-bit integer
- `int16`: Signed 16-bit integer
- `uint16`: Unsigned 16-bit integer
- `int32`: Signed 32-bit integer
- `uint32`: Unsigned 32-bit integer
- Fixed Point: 8-, 16-, 32-bit word lengths

With storage classes you can:

- Generate exported files, with custom names, that contain global variable declarations and definitions.
- Import custom header files that contain global variable declarations.
- Generate `const` or `volatile` type qualifiers in declarations.
- Represent a parameter as a macro (`#define` or compiler option).
- Package signals or parameters into flat structures or bit fields.

### Control Data in Simulink® and Stateflow®

This example uses data objects to specify code generation settings for data. Alternatively, you can store the settings in the model by using dialog boxes. Both methods allow full control over the data type and storage class. You can use both methods in a single model.

This example focuses on these types of data objects:

- Signal
- Parameter
- Bus

The code generator uses the objects from the MATLAB base workspace or a Simulink data dictionary. You can create and inspect the objects with commands at the command prompt or by using the Model Data Editor or the Model Explorer with the Code Mappings Editor.

As an example, inspect the definition of the Simulink.Signal object `pos_cmd_one`, which the model created in the base workspace:

- 1 Open the **Embedded Coder** app.
- 2 On the **Modeling** tab, click **Model Data Editor**.
- 3 In the Model Data Editor, inspect the **Signals** tab.
- 4 Click the **Show/refresh additional information** button.
- 5 Next to the **Filter contents** box, toggle the **Filter using selection** button.
- 6 In the model, select the `pos_cmd_one` signal line. Now, the data table contains two rows: One that corresponds to the signal line in the model and one that corresponds to the signal object in

the base workspace. For the row that corresponds to the signal line, the **Resolve** check box is selected, which means the signal line acquires settings from the signal object.

- 7 Optionally, to inspect other properties of the signal object, adjust the setting for the **Change view** drop-down list.
- 8 In the model, select the `pos_cmd_one` signal line and pause on the ellipsis that appears above or below the signal line to open the action bar. Click the Add Signal button.
- 9 Open the **Code Mappings Editor**, click the **Signals** tab. Inspect the `pos_cmd_one` signal storage class.

Return to the Model Data Editor, toggle the **Filter using selection button**. Now, the data table shows these signal lines and signal objects:

- `pos_cmd_one`
- `pos_rqst`
- `P_InErrMap`
- `ThrotComm`

`ThrotComm` is a bus signal, which is an instantiation of the `Simulink.Bus` object `ThrottleCommands`. If a bus signal is nonvirtual, the signal appears as a structure in the C code. Bus objects do not appear in the Model Data Editor. However, you can inspect the object in the Model Explorer (**View > Model Explorer**).

As in C, you can use a bus definition (`ThrottleCommands`) to create multiple instances of the structure. In a model diagram, a bus signal appears as a wide line with central dashes.

A data object has properties that you configure for simulation and for code generation, including:

- `DataType` (numeric data type for storage in the generated code)
- `StorageClass` (storage class for code generation)
- `Value` (parameter value)
- `InitialValue` (initial value for signal)
- `Alias` (alternative name for the data, which the code generator uses)
- `Dimensions` (size and number of dimensions of parameter or signal value)
- `Complexity` (numeric complexity)
- `Unit` (physical units such as cm)
- `Min` (minimum value)
- `Max` (maximum value)

Use the property `Description` to specify custom documentation for data objects.

## Add New Data Objects

You can create data objects for named signals, states, and parameters. To associate a data object with a construct, the construct must have a name.

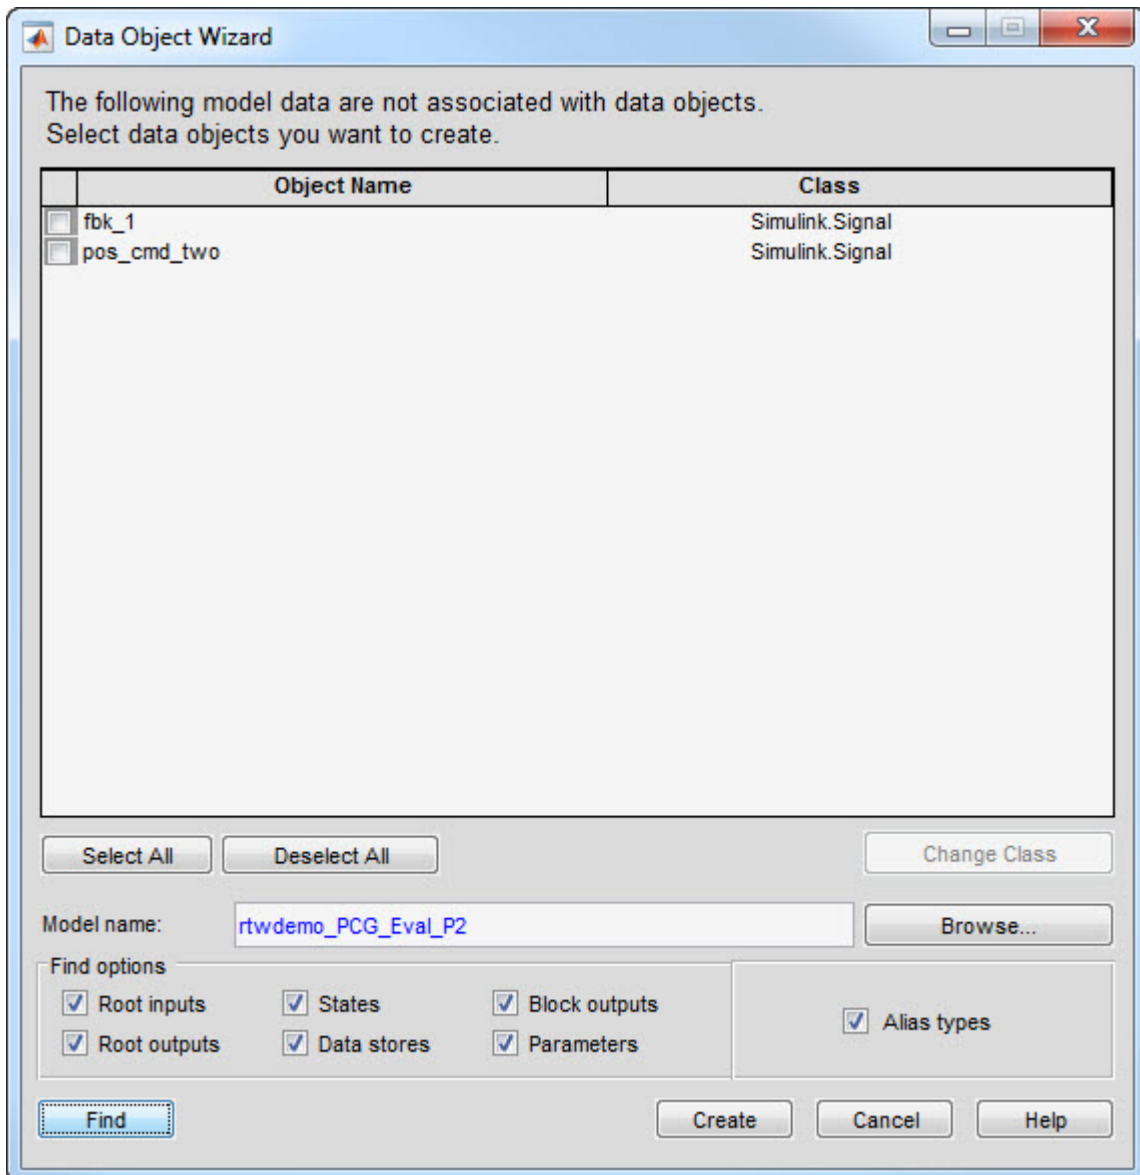

The Data Object Wizard tool finds constructs for which you can create data objects, and then creates the objects for you. The example model includes two signals that are not associated with data objects: `fbk_1` and `pos_cmd_two`.

To find the signals and create data objects for them:

1. Open the Data Object Wizard.

```
dataobjectwizard('rtwdemo_PCG_Eval_P2')
```

2. Click **Find** to find candidate constructs.

3. Click **Select All** to select all candidates.

4. Click **Create** to create the data objects.

The Data Object Wizard performs the equivalent of the following commands:

```
fbk_1 = Simulink.Signal;
fbk_1.Dimensions = 1;
fbk_1.DataType = 'double';
output = get_param('rtwdemo_PCG_Eval_P2/fbk_1','PortHandles');
output = output.Output;
set_param(output,'MustResolveToSignalObject','on')

pos_cmd_two = Simulink.Signal;
pos_cmd_two.Dimensions = 1;
pos_cmd_two.DataType = 'double';
output = get_param('rtwdemo_PCG_Eval_P2/PI_ctrl_2','PortHandles');
output = output.Output;
set_param(output,'MustResolveToSignalObject','on')
```

### Configure Data Objects

Set the data type and storage class for each data object. To configure data object properties, inspect the appropriate tab in the Model Data Editor. Use the **Change view** drop-down list to show design properties (such as data type) and code generation settings (such as storage class).

In the Model Data Editor, inspect the **Signals** tab and click the **Show/refresh additional information** button to display information for the signal objects that the Data Object Wizard created. Then, configure these properties for the objects:

- fbk\_1: Data type double, storage class ImportedExtern
- pos\_cmd\_two: Data type double, storage class ExportedGlobal

Alternatively, you can use these commands at the command prompt to configure the objects:

```
fbk_1.DataType = 'double';
fbk_1.StorageClass = 'ImportedExtern';

pos_cmd_two.DataType = 'double';
pos_cmd_two.StorageClass = 'ExportedGlobal';
```

### Control File Placement of Parameter Data

With Embedded Coder®, you can control the file placement of definitions for parameters and constants. The example model writes the parameter definitions to the file `eval_data.c`.

To change the placement of parameter and constant definitions, set the data placement options for the model configuration. In the Configuration Parameters dialog box, configure the options on the **Code Generation > Code Placement** pane.

In the example model, inspect the **Code Placement** pane in the Configuration Parameters dialog box. The model places data definitions in the file `eval_data.c` and declarations in the file `eval_data.h`.

### Declare Block Parameters Tunable or Inlined

You can control the default tunability of block parameters in the generated code by setting model configuration parameter **Default parameter behavior**.

For the example model, the default parameter behavior is set to `Inlined`. By default, block parameters appear in the code as numeric literal values, not as variables stored in memory. You can use `Simulink.Parameter` objects to override inlining and preserve tunability for individual parameters.

### Enable Signal Data Objects in Generated Code

Make sure that the signal data objects (`Simulink.Signal`) appear in the generated code. For individual signal lines in the model, select the option **Signal name must resolve to Simulink signal object** to explicitly resolve the signal name to a `Simulink.Signal` object in a workspace or data dictionary. In the Model Data Editor, set **Change view** to `Code` and select the check box in the **Resolve** column.

Alternatively, you can select the option for all signals in a model. At the command prompt, use the `disableimplicitsignalresolution` function.

### View Data Objects in Generated Code

Generate code from the example model.

```
slbuild('rtwdemo_PCG_Eval_P2');
Starting build procedure for: rtwdemo_PCG_Eval_P2
tf =
 logical
 0
Successful completion of code generation for: rtwdemo_PCG_Eval_P2
Build Summary
Top model targets built:
Model Action Rebuild Reason
=====
rtwdemo_PCG_Eval_P2 Code generated Code generation information file does not exist.

1 of 1 models built (0 models already up to date)
Build duration: 0h 1m 0.415s
```

Create a code generation report to more easily view the generated files. In the Simulink Editor, select model configuration parameter **Open Model Report**.

You can access these generated files:

- `rtwdemo_PCG_Eval_P2.c`: Defines the step and initialization functions. Uses the defined data objects.
- `eval_data.c`: Assigns initial values to the defined parameters. The model configuration specifically sets the file name.
- `eval_data.h`: Provides extern declarations of parameter data. The model configuration specifically sets the file name.
- `ert_main.c`: Defines scheduling functions.

- `rtwdemo_PCG_Eval_P2.h`: Contains the type definitions of the default structures that store signal, state, and parameter data. Due to the data object settings, some data appear in `eval_data.c` instead.
- `PCG_Eval_p2_private.h`: Declares private (local) data for the generated functions.
- `rtwdemo_PCG_Eval_P2_types.h`: Declares the real-time model data structure.
- `rtwtypes.h`: Provides mapping to the data types that Simulink® Coder™ defines (typedef). Used for integration with external systems.

For example, view the file `eval_data.c`, which allocates `const` memory for global variables that correspond to the Simulink.Parameter objects in the base workspace.

```
cfile = fullfile('rtwdemo_PCG_Eval_P2_ert_rtw','eval_data.c');
rtwdemodbtype(cfile,'/* Exported data definition */','* [EOF]',1,1)

/* Exported data definition */

/* Const memory section */
/* Definition for custom storage class: Const */
const real_T I_Gain = -0.03;
const real_T I_InErrMap[9] = { -1.0, -0.5, -0.25, -0.05, 0.0, 0.05, 0.25, 0.5,
 1.0 } ;

const real_T I_OutMap[9] = { 1.0, 0.75, 0.6, 0.0, 0.0, 0.0, 0.6, 0.75, 1.0 } ;

const real_T P_Gain = 0.74;
const real_T P_InErrMap[7] = { -1.0, -0.25, -0.01, 0.0, 0.01, 0.25, 1.0 } ;

const real_T P_OutMap[7] = { 1.0, 0.25, 0.0, 0.0, 0.0, 0.25, 1.0 } ;

/*
 * File trailer for generated code.
 *
 * [EOF]
```

View the code algorithm in the model `step` function in the file `rtwdemo_PCG_Eval_P2.c`. The algorithm uses the data object names directly.

```
cfile = fullfile('rtwdemo_PCG_Eval_P2_ert_rtw','rtwdemo_PCG_Eval_P2.c');
rtwdemodbtype(cfile,'/* Model step function */',...
 '/* Sum: '<S2>/Sum3' incorporates:',1,0);

/* Model step function */
void rtwdemo_PCG_Eval_P2_step(void)
{
 real_T Discrete_Time_Integrator1;
 real_T Discrete_Time_Integrator1_i;
 real_T rtb_IntegralGainShape;

 /* Sum: '<S2>/Sum2' incorporates:
 * Inport: '<Root>/fbk_1'
 * Inport: '<Root>/pos_rqst'
 */
 rtb_IntegralGainShape = *pos_rqst - fbk_1;
```

```

/* DiscreteIntegrator: '<S2>/Discrete_Time_Integrator1' */
if (rtwdemo_PCG_Eval_P2_DWork.Discrete_Time_Integrator1_SYSTE != 0) {
/* DiscreteIntegrator: '<S2>/Discrete_Time_Integrator1' */
Discrete_Time_Integrator1 =
 rtwdemo_PCG_Eval_P2_DWork.Discrete_Time_Integrator1_DSTAT;
} else {
/* DiscreteIntegrator: '<S2>/Discrete_Time_Integrator1' incorporates:
 * Gain: '<S2>/Int Gain1'
 * Lookup_n-D: '<S2>/Integral Gain Shape'
 * Lookup_n-D: '<S3>/Integral Gain Shape'
 * Product: '<S2>/Product3'
 */
Discrete_Time_Integrator1 = I_Gain * look1_binlx(rtb_IntegralGainShape,
 &I_InErrMap[0], &I_OutMap[0], 8U) * rtb_IntegralGainShape * 0.001 +
 rtwdemo_PCG_Eval_P2_DWork.Discrete_Time_Integrator1_DSTAT;
}

/* End of DiscreteIntegrator: '<S2>/Discrete_Time_Integrator1' */

```

Without storage classes and other code generation settings that the data objects specify, the generated code:

- Inlines invariant signals and block parameters when you select these optimizations in the model configuration parameters
- Places model input and output signals, block states, and tunable parameters in global data structures
- Does not create global variables that correspond to MATLAB® variables

In contrast, the example code shows that most of the default data structures have been replaced with user-defined data objects. For example, these signals and parameters appear as global variables in the code:

- pos\_rqst
- fbk\_1
- I\_Gain
- I\_OutMap
- I\_InErrMap

However, the local variable `rtb_IntegralGainShape` and the state variable `rtwdemo_PCG_Eval_P2_DWork.Discrete_Time_Integrator1_DSTAT` still use code generator data structures. Data objects do not exist for these entities.

### Store Model Data in Data Dictionary

When you end your MATLAB session, variables that you create in the base workspace do not persist. To permanently store data objects and bus objects, consider linking the model to a data dictionary.

- 1 In the example model, on the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
- 2 In the Model Properties dialog box, click **New**.
- 3 In the Create a New Data Dictionary dialog box, set **File name** to `rtwdemo_PCG_Eval_dict` and click **Save**.
- 4 In the Model Properties dialog box, click **Apply**.

- 5 Click **Migrate data**.
- 6 Click **Migrate** in response to message about copying referenced variables.
- 7 Click **OK**.

Alternatively, to manually migrate the objects into a data dictionary, you can use programmatic commands:

```
% Create a list of the variables and objects that the target
% model uses.
usedVars = {Simulink.findVars('rtwdemo_PCG_Eval_P2').Name};
% Create a new data dictionary in your current folder. Link the model to
% this new dictionary.
dictObj = Simulink.data.dictionary.create('rtwdemo_PCG_Eval_dict.sldd');
set_param('rtwdemo_PCG_Eval_P2','DataDictionary','rtwdemo_PCG_Eval_dict.sldd')
% Import only the target variables from the base workspace to the data
% dictionary.
importFromBaseWorkspace(dictObj,'clearWorkspaceVars',true,'varList',usedVars);
saveChanges(dictObj);
```

The data dictionary permanently stores the objects that the model uses. To view the contents of the dictionary, click the model data badge in the lower-left corner of the model, then click the **Data Dictionary** link. In the Model Explorer **Model Hierarchy** pane, select the **Design Data** node.

The separation of data from the model provides these benefits:

#### One model, multiple data sets

- Use of different data types to change the targeted hardware (for example, for floating-point and fixed-point targets)
- Use of different parameter values to change the behavior of the control algorithm (for example, for reusable components with different calibration values)

#### Multiple models, one data set

- Sharing of data between Simulink® models in a system
- Sharing of data between projects (for example, transmission, engine, and wheel controllers might all use the same CAN message data set)

## Partition Functions in Generated Code

This example shows how to associate subsystems in a model with function names and files.

Learn how to:

- Specify function and file names in the generated code.
- Identify the parts of the generated code that are required for integration.
- Generate code for atomic subsystems.
- Identify data that are required to execute a generated function.

For information about the example model and other examples in this series, see “Prepare a Control Algorithm Model for C Code Generation” on page 50-18.

### Atomic and Virtual Subsystems

The example models in “Prepare a Control Algorithm Model for C Code Generation” on page 50-18 and “Configure Data Interface in the Generated Code” on page 50-29 use *virtual subsystems*. Virtual subsystems visually organize blocks but do not affect the model functionality. *Atomic subsystems* evaluate the blocks included in a model as a unit. With atomic subsystems, you can specify additional function partitioning information. In a model, atomic subsystems appear with a bold border.

### View Changes in Model Architecture

Open the example model `rtwdemo_PCG_Eval_P3`.

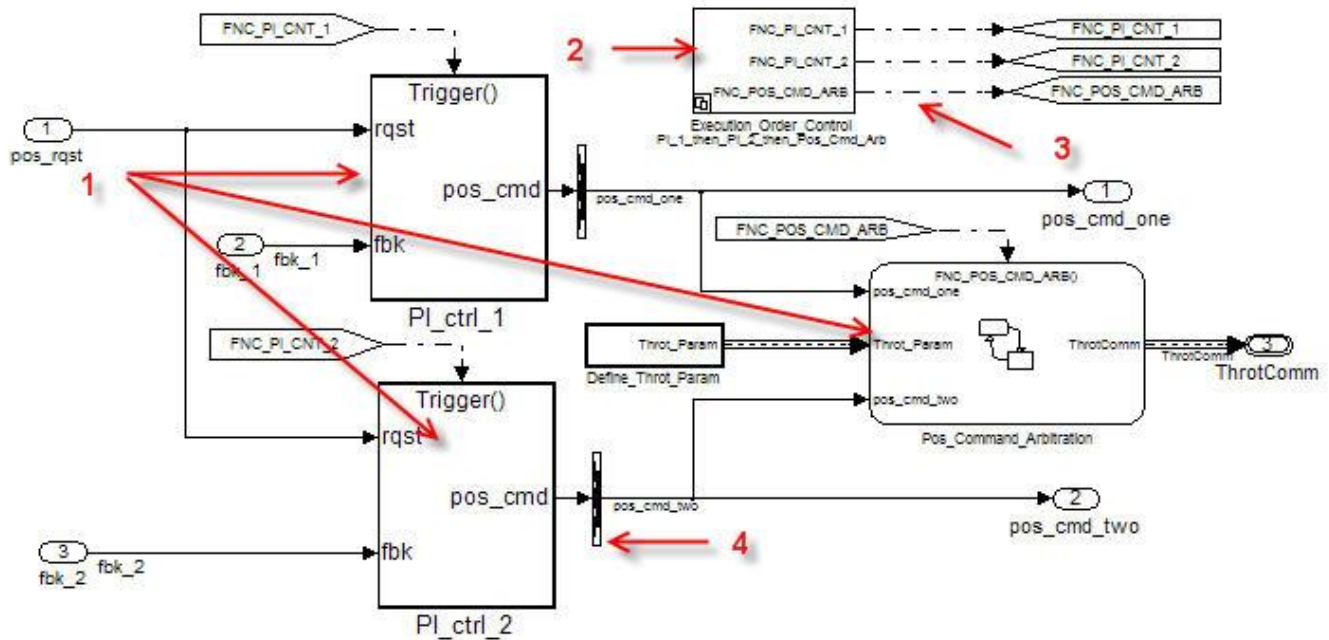

Save a copy of the model to a writable folder.

This example shows how to replace the virtual subsystems with *function-call subsystems*. Function-call subsystems:

- Are atomic subsystems
- Enable you to control subsystem execution order
- Execute when a *function call signal* triggers

By controlling the execution order of the subsystems, you can match the model with an existing system that has a specific execution order.

The figure identifies the function call subsystems (1) `PI_ctrl_1`, `PI_ctrl_2`, and `Pos_Command_Arbitration`.

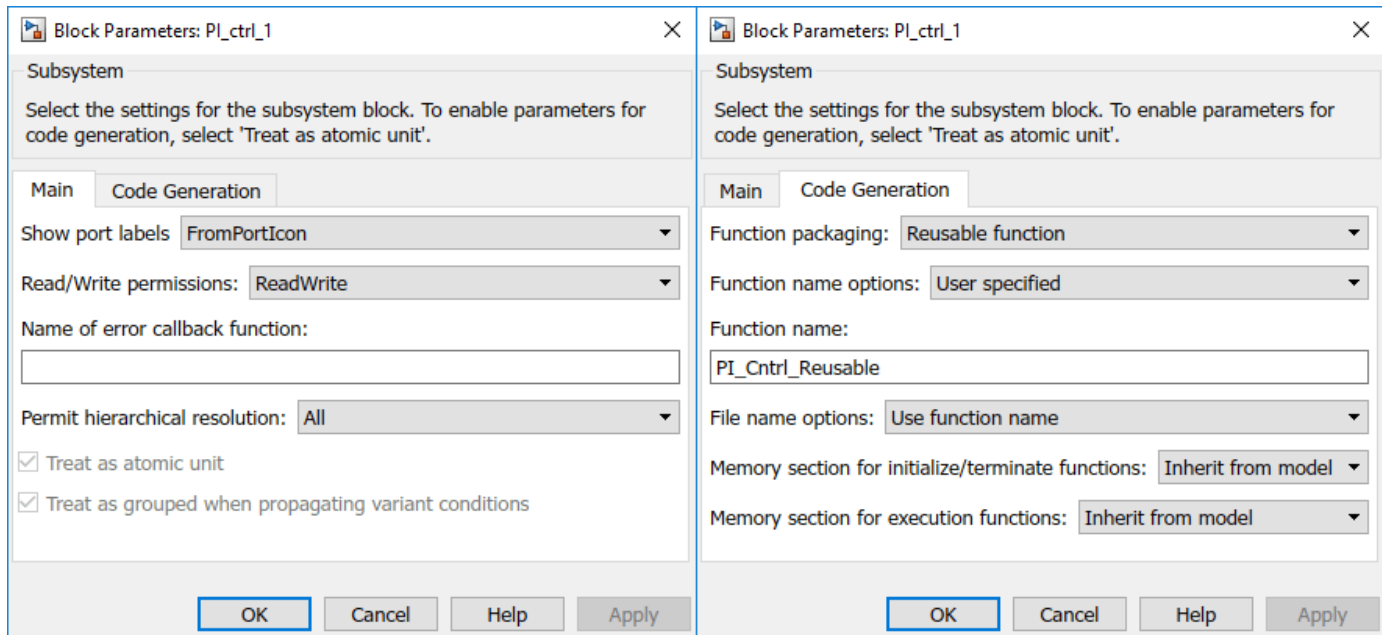

This version of the model contains the new subsystem `Execution_Order_Control` (2), which contains a Stateflow® chart that models the calling functionality of a scheduler. The subsystem controls the execution order of the function call subsystems through function call signals (3). Later in this example, you examine how changing the execution order can change the simulation results.

This version of the model contains new Signal Conversion blocks (4) at the outputs of the PI controllers. With these additional blocks in place, the code generator can generate a single reentrant function for the PI controllers.

### Control Function Location and File Placement in the Generated Code

In “Prepare a Control Algorithm Model for C Code Generation” on page 50-18 and “Configure Data Interface in the Generated Code” on page 50-29, the code generator creates a single `model_step` function that contains the control algorithm code. However, many applications require a greater level of control over the file placement of functions. By modifying the parameters of atomic subsystems, you can specify multiple functions within a single model.

The figure shows the subsystem parameters for `PI_ctrl_1`.

### Treat as atomic unit

- Enables other submenus. For atomic subsystems, this parameter is automatically selected and disabled.

### Sample time

- Specifies a sample time for execution. Not available for function-call subsystems.

### Function packaging options

- `Auto` -- Determines how the subsystem appears in the generated code. This value is the default.
- `InLine` -- Places the subsystem code inline with the rest of the model code.
- `Function` -- Generates the code for the subsystem as a function.
- `Reusable function` -- Generates a reusable (reentrant) function from the subsystem. The function passes all input and output data through formal parameters. The function does not directly access global variables.

### Function name options

- Selecting `Function` or `Reusable function` for **Function packaging** enables function name options.
- `Auto` -- Determines the function.
- `Use subsystem name` -- Bases the function on the subsystem name.
- `User specified` -- Applies the specified file name.

### File name options

- Selecting `Function` or `Reusable function` for **Function packaging** enables file name options.
- `Auto` -- Places the function definition in the module generated for the parent system, or, if the model root is the parent, in `model.c`.

- Use subsystem name -- Generates a separate file. The name of the file is the name of the subsystem or library block.
- Use function name -- Generates a separate file. The name of the file is the name that you specify with **Function name options**.
- User specified -- Applies the specified, unique file name.

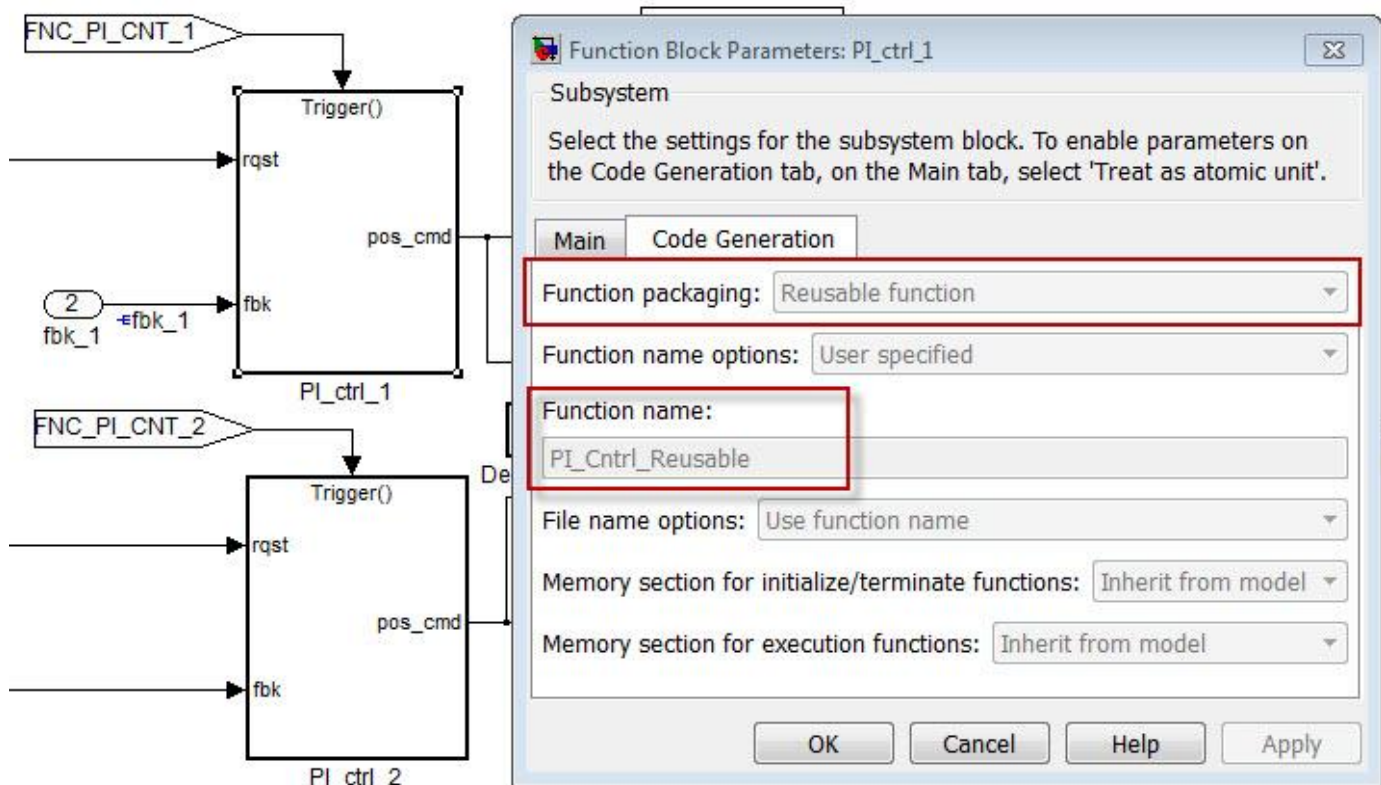

### Function with separate data

- Enabled when you set **Function packaging** to Function. When selected, the code generator separates the internal data of the subsystem (for example, signals) from the data of the parent model. The subsystem owns this separate data.

### Generate Reentrant Code

Embedded Coder® supports *reentrant code*. Reentrant code is a reusable programming routine that multiple programs can use simultaneously. Reentrant code is used in operating systems and other system software that uses multithreading to handle concurrent events. Reentrant code does not maintain state data, so there are no persistent variables in the function. Calling programs maintain state variables and must pass the state data into the function. Multiple users or processes can share one copy of a reentrant function.

To generate reentrant code, you must first specify the subsystem as reusable by configuring the subsystem parameter **Function packaging**.

In some cases, the configuration of the model prevents reusable code. The table lists common issues.

Cause	Solution
-------	----------

Subsystem output feeds global signal data

Generated function receives data (formal parameters) through pointers

Subsystem uses global signal data in internal algorithm

Add a Signal Conversion block between the subsystem and the global signal.

Select Configuration Parameters > Model Referencing > Pass fixed-size scalar root inputs by value for code generation.

Use a port to pass the global data in and out of the subsystem.

### Use a Mask to Pass Parameter Values into Library Subsystem

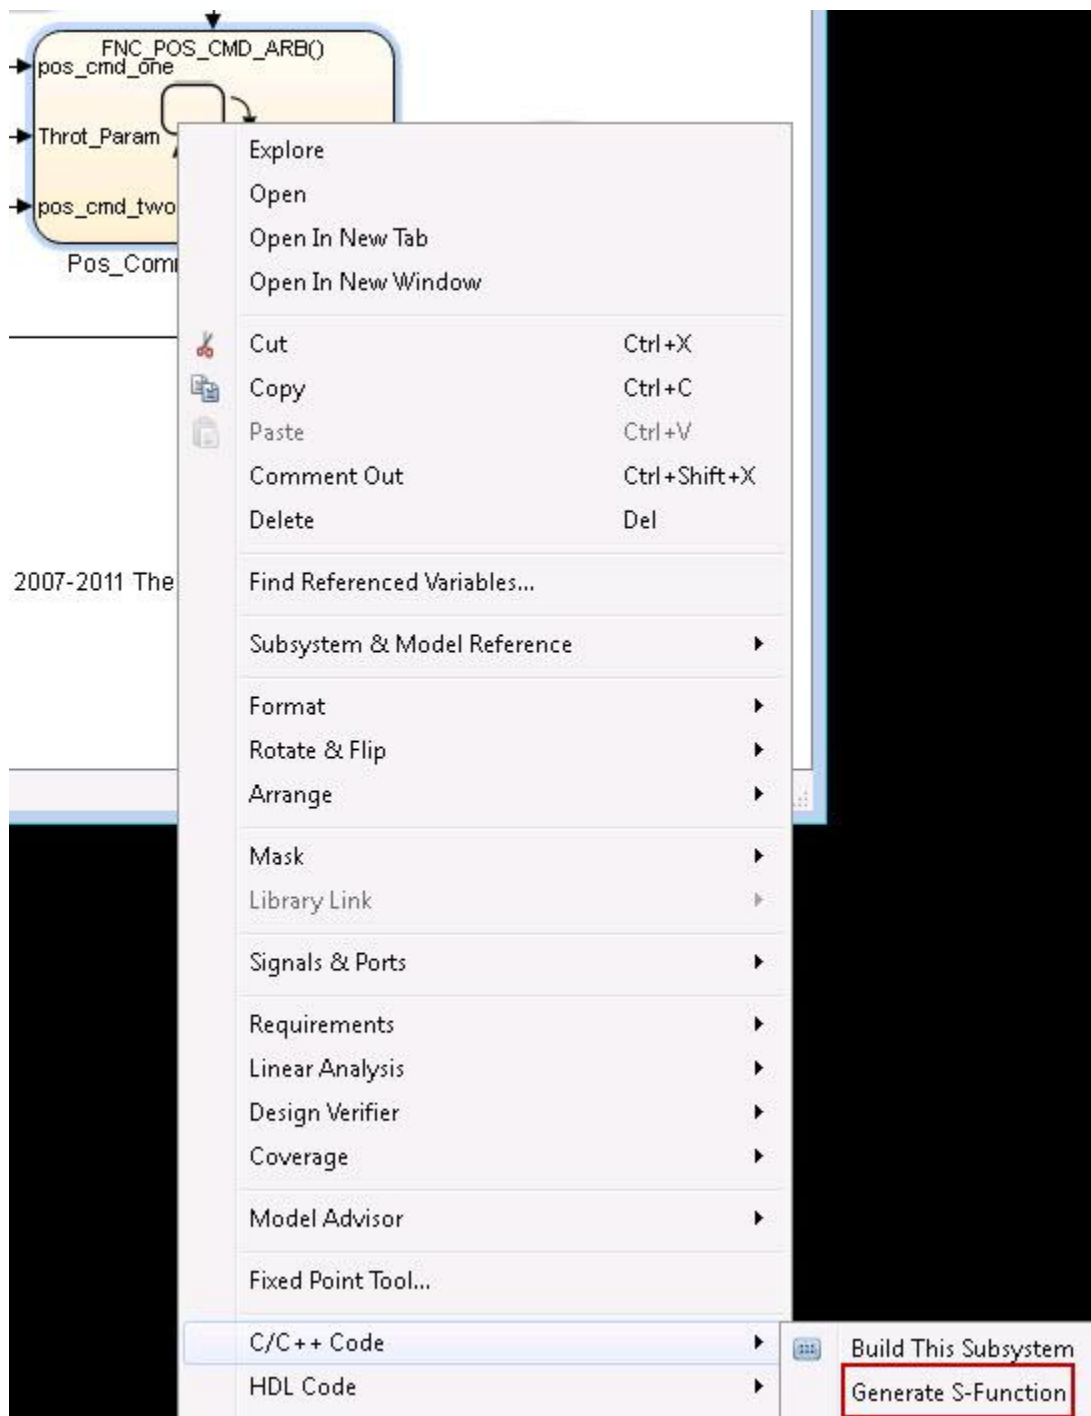

To define algorithmic parameter data (such as a gain or coefficient) outside the scope of a reusable library block or subsystem, you can apply a *mask* to the block or subsystem and create a mask parameter. You can then specify a different parameter value for each instance of the block or subsystem. Each mask parameter appears in the generated code as a formal parameter of the reentrant function.

In this version of the model, the subsystems PI\_ctrl\_1 and PI\_ctrl\_2 are masked. In each mask, the values of the P and I gains are set by data objects such as I\_Gain\_2 and P\_Gain\_2.

### Generate Code for Atomic Subsystem

In “Prepare a Control Algorithm Model for C Code Generation” on page 50-18 and “Configure Data Interface in the Generated Code” on page 50-29, you generate code at the root level of the model. Alternatively, you can build a specific subsystem.

To initiate a subsystem build, use the context menu. You can choose from these options:

- 1 **Build This Subsystem:** Treats the subsystem as a separate mode and creates the full set of source C files and header files. This option does not support function-call subsystems.
- 2 **Generate S-Function:** Generates C code for the subsystem and creates an S-Function wrapper. You can then simulate the code in the original model. This option does not support function-call subsystems.

- 3 Export Functions:** Generates C code without the scheduling code that comes with the **Build This Subsystem** option. Use this option to build subsystems that use triggers, such as function-call subsystems.

Alternatively, open the **Embedded Coder** app, select the subsystem and on the **C Code** tab, click **Build**.

### Examine Generated Code

This example compares the files that are generated for the full system build with the files that are generated for exported functions. You also examine how the masked data appears in the code.

Run the build script for the three options. Then, examine the generated files by clicking the hyperlinks.

- 1 Generate code from the entire model.
- 2 Export the function `PI_ctrl_1`.
- 3 Export the function `Pos_Command_Arbitration`.

#### **rtwdemo\_PCG\_Eval\_P3.c**

- Full Build: Yes, Step function
- `PI_ctrl_1`: No
- `Pos_Command_Arbitration`: No

#### **PI\_ctrl\_1.c**

- Full Build: No
- `PI_ctrl_1`: Yes, Trigger function
- `Pos_Command_Arbitration`: No

#### **Pos\_Command\_Arbitration.c**

- Full Build: No
- `PI_ctrl_1`: No
- `Pos_Command_Arbitration`: Yes, Init and Function

#### **PI\_Ctrl\_Reusable.c**

- Full Build: Yes
- `PI_ctrl_1`: Yes
- `Pos_Command_Arbitration`: No

#### **ert\_main.c**

- Full Build: Yes
- `PI_ctrl_1`: Yes
- `Pos_Command_Arbitration`: Yes

#### **eval\_data.c**

- Full Build: Yes(1)
- PI\_ctrl\_1: Yes(1)
- Pos\_Command\_Arbitration: No, Eval data not used in diagram

(1) `eval_data.c` has different content in the full and export function builds. The full build includes all of the parameters that the model uses. The export function contains only the variables that the subsystem uses.

### Masked Data in the Generated Code

In the file `rtwdemo_PCG_Eval_P3.c`, the call sites of the reentrant function use the data objects `P_Gain`, `I_Gain`, `P_Gain_2`, and `I_Gain_2` as arguments.

```
PI_Cntrl_Reusable(*pos_rqst, fbk_1, &rtwdemo_PCG_Eval_P3 B->PI_ctrl_1,
 &rtwdemo_PCG_Eval_P3_DWork->PI_ctrl_1, I_Gain, P_Gain);
PI_Cntrl_Reusable(*pos_rqst, fbk_2, &rtwdemo_PCG_Eval_P3 B->PI_ctrl_2,
 &rtwdemo_PCG_Eval_P3_DWork->PI_ctrl_2, I_Gain_2, P_Gain_2);
```

### Effect of Execution Order on Simulation Results

By default, Simulink® executes the subsystems in this order:

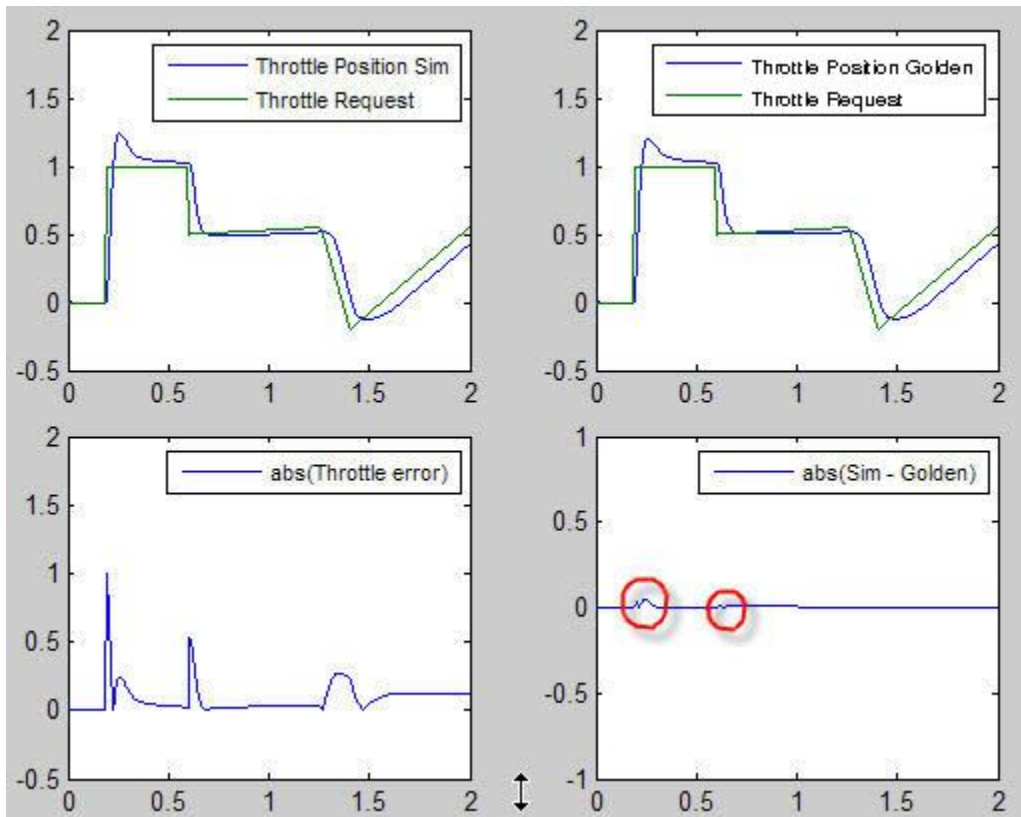

- 1 PI\_ctrl\_1
- 2 PI\_ctrl\_2
- 3 Pos\_Command\_Arbitration

For this example, you can specify one of two alternative orders of execution. You can then use the test harness to observe the effect of the execution order on the simulation results. The subsystem `Execution_Order_Control` has two configurations that control the execution order. To choose a configuration, use the subsystem context menu.

Change the execution order and observe the results.

- 1 Set the execution order to `PI_ctrl_1`, `PI_ctrl_2`, `Pos_Command_Arbitration`.
- 2 Open the test harness.
- 3 Run the test harness.
- 4 Change the execution order to `Pos_Command_Arbitration`, `PI_ctrl_1`, `PI_ctrl_2`.
- 5 Run the test harness.

The simulation results (throttle position over time) vary slightly depending on the order of execution. You can see the difference most clearly when the throttle request changes.

For the next example in this series, see “Call External C Code from Model and Generated Code” on page 50-47.

## Call External C Code from Model and Generated Code

Call existing, external functions from a simulation or from the generated code by using the Legacy Code Tool.

Learn how to:

- Evaluate a C function as part of a Simulink® model simulation.
- Call a C function from the code that you generate from a model.

For information about the example model, see “Prepare a Control Algorithm Model for C Code Generation” on page 50-18.

### Replacement Process

Open the example model, `rtwdemo_PCG_Eval_P4`.

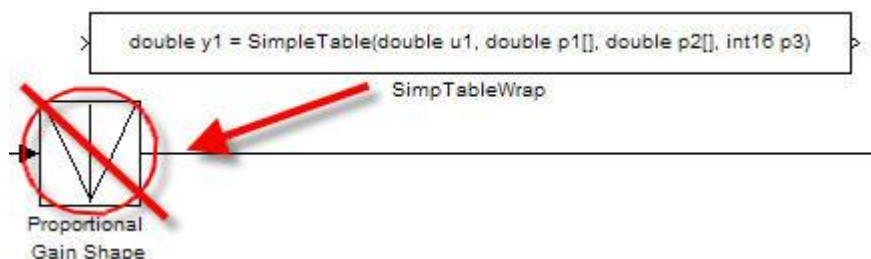

For many Model-Based Design applications, in addition to Simulink® models, a design includes a set of existing C functions that have been tested and validated. You can integrate these functions into a Simulink® model and generate code that uses the functions.

In this example, you create a custom Simulink® block that calls an existing C function. You then include the block in a model and test the overall system through model simulation in Simulink®.

In the example model, you can replace the Lookup blocks (lookup tables) in the PI controllers with calls to an existing C function. The function is defined in files `SimpleTable.c` and `SimpleTable.h`.

View `SimpleTable.c`.

View `SimpleTable.h`.

### Create Block That Calls C Function

To specify a call to an existing C function, use an S-Function block. You can automate the creation of the S-Function block by using the Legacy Code Tool. In the tool, you first specify an interface for your existing C function. The tool then uses that interface to create an S-Function block.

Use the Legacy Code Tool to create an S-Function block for the existing C function in `SimpleTable.c`.

1. Create a structure to contain the definition of the function interface.

```
def = legacy_code('initialize')
```

You can use the structure `def` to define the function interface to the existing C code.

2. Populate the fields of the structure.

```

% Defines the function interface, inputs, return values and parameters
def.OutputFcnSpec = ['double y1 = SimpleTable(double u1, ...,
 'double p1[], double p2[], int16 p3)'];

% the C and H files where the external code is defined
def.HeaderFiles = {'SimpleTable.h'};
def.SourceFiles = {'SimpleTable.c'};
% The name of the created S-Function
def.SFunctionName = 'SimpTableWrap';

```

3. Create the S-function.

```
legacy_code('sfcn_cmex_generate',def)
```

4. Compile the S-function.

```
legacy_code('compile',def)
```

5. Create the S-Function block.

```
legacy_code('slblock_generate',def)
```

The generated S-Function block calls the C function in `SimpleTable.c`. You can now use this S-Function block in models.

6. Create the TLC file.

```
legacy_code('sfcn_tlc_generate',def)
```

This command creates a TLC file, which is the component of an S-Function that specifies how to generate code for the block.

### Validate External Code Through Simulation

When you integrate existing C code in a Simulink® model, validate the generated S-Function block.

To validate the replacement of the Lookup blocks, compare the simulation results produced by the Lookup blocks with the results produced by the new S-Function block.

1. Open the validation model.

- The Sine Wave block produces output values from [-2 : 2].
- The input range of the lookup table is from [-1 : 1].
- The lookup table outputs the absolute value of the input.
- The lookup table clips the output at the input limits.

2. Run the validation model.

The figure shows the validation results. The existing C code and the Simulink® table block produce the same output values.

**Validate C Code as Part of Simulink® Model**

After validating the existing C function code as a standalone component, validate the S-function in the model. To complete the validation, use a test harness model.

1. Open the test harness.
2. Run the test harness.

The simulation results match the golden values.

### Call C Function from the Generated Code

The code generator uses the TLC file to process the S-Function block like any other block. The code generator can implement *expression folding* with the S-Function block, an operation that combines multiple computations into a single output calculation.

1. Build the full model.
2. Examine the generated code in `PI_Control_Reusable.c`.

The generated code now calls the `SimpleTable` C function.

The figures show the generated code before and after the C code integration. Before the integration, the code calls a generated lookup routine. After the integration, the generated code calls the C function `SimpleTable`.

```
Discrete_Time_Integrator1 = rtp_Masked_I_Gain * look1_binlx(rtb_Sum2,
 (&(I_InErrMap[0])), (&(I_OutMap[0])), 8U) * rtb_Sum2 * 0.001 +
 localDW->Discrete_Time_Integrator1_DSTAT;
```

```
/* DiscreteIntegrator: '<S3>/Discrete_Time_Integrator1' incorporates:
 * Gain: '<S3>/Int_Gain1'
 * Product: '<S3>/Product3'
 * S-Function (SimpTableWrap): '<S3>/SimpTableWrap1'
 */
Discrete_Time_Integrator1 = I_Gain * SimpleTable(rtb_Sum2, (real_T*)
 (&(I_InErrMap[0])), (real_T*)(&(I_OutMap[0])), 7) * rtb_Sum2 * 0.001 +
 localDW->Discrete_Time_Integrator1_DSTAT;
```

## Build Integrated Code Outside the Simulink Environment

Identify required files and interfaces for calling generated code in an external build process.

Learn how to:

- Collect files required for building integrated code outside of Simulink®.
- Interface with external variables and functions.

For information about the example model and related examples, see “Prepare a Control Algorithm Model for C Code Generation” on page 50-18.

### Collect and Build Required Data and Files

The code that Embedded Coder® generates requires support files that MathWorks® provides. To relocate the generated code to another development environment, such as a dedicated build system, you must relocate these support files. You can package these files in a zip file by using the `packNGo` utility. This utility finds and packages the files that you need to build an executable image. The utility uses tools for customizing the build process after code generation, which include a `buildinfo_data` structure, and a `packNGo` function. These files include external files that you identify in the **Code Generation > Custom Code** pane in the Model Configuration Parameters dialog box. The utility saves the `buildinfo` MAT-file in the `model_ert_rtw` folder.

Open the example model, `rtwdemo_PCG_Eval_P5`.

This model is configured to run `packNGo` after code generation.

Generate code from the entire model.

To generate the zip file manually:

- 1 Load the file `buildInfo.mat` (located in the `rtwdemo_PCG_Eval_P5_ert_rtw` subfolder).
- 2 At the command prompt, enter the command `packNGo(buildInfo)`.

The number of files in the zip file depends on the version of Embedded Coder® and on the configuration of the model that you use. The compiler might require a subset of the files in the zip file. The compiled executable size (RAM/ROM) depends on the linking process. The linker likely includes only the object files that are necessary.

### Integrating the Generated Code into an Existing System

This example shows how to integrate the generated code into an existing code base. The example uses the Eclipse™ IDE and the Cygwin™/gcc compiler. The required integration tasks are common to integration environments.

#### Overview of Integration Environment

A full embedded controls system consists of multiple hardware and software components. Control algorithms are just one type of component. Other components can be:

- An operating system (OS)
- A scheduling layer
- Physical hardware I/O

- Low-level hardware device drivers

Typically, you do not use the generated code in these components. Instead, the generated code includes interfaces that connect with these components. MathWorks® provides hardware interface block libraries for many common embedded controllers. For examples, see the Embedded Targets block library.

This example provides files to show how you can build a full system. The main file is `example_main.c`, which contains a simple main function that performs only basic actions to exercise the code.

View `example_main.c`.

```
int_T main(void)
{
 /* Initialize model */
 rt_Pos_Command_Arbitration_Init(); /* Set up the data structures for chart*/
 rtwdemo_PCG_Define_Throt_Param(); /* SubSystem: '<Root>/Define_Throt_Param' */
 defineImportData(); /* Defines the memory and values of inputs */

 do /* This is the "Schedule" loop.
 Functions would be called based on a scheduling algorithm */
 {
 /* HARDWARE I/O */

 /* Call control algorithms */
 PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
 &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
 PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
 &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
 pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
 pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;

 rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
 &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
 }
}
```

The file:

- Defines function interfaces (function prototypes).
- Includes files that declare external data.
- Defines extern data.
- Initializes data.
- Calls simulated hardware.
- Calls algorithmic functions.

The order of function execution matches the order of subsystem execution in the test harness model and in `rtwdemo_PCG_Eval_P5.h`. If you change the order of execution in `example_main.c`, results that the executable image produces differ from simulation results.

## Match System Interfaces

Integration requires matching the *Data* and *Function* interfaces of the generated code and the existing system code. In this example, the `example_main.c` file imports and exports the data through `#include` statements and `extern` declarations. The file also calls the functions from the generated code.

## Connect Input Data

The system has three input signals: `pos_rqst`, `fbk_1`, and `fbk_2`. The generated code accesses the two feedback signals through direct reference to imported global variables (storage class `ImportedExtern`). The code accesses the position signal through an imported pointer (storage class `ImportedExternPointer`).

The handwritten file `defineImportedData.c` defines the variables and the pointer. The generated code does not define the variables and the pointer because the handwritten code defines them. Instead, the generated code declares the imported data (`extern`) in the file `rtwdemo_PCG_Eval_P5_Private.h`. In a real system, the data typically comes from other software components or from hardware devices.

View `defineImportedData.c`.

```
/* Define imported data */
#include "rtwtypes.h"
#include "defineImportedData.h"

real_T fbk_1;
real_T fbk_2;
real_T dummy_pos_value = 10.0;
real_T *pos_rqst;
void defineImportData(void)
{
 pos_rqst = &dummy_pos_value;
}
```

View `rtwdemo_PCG_Eval_P5_Private.h`.

```
/* Imported (extern) block signals */
extern real_T fbk_1; /* '<Root>/fbk_1' */
extern real_T fbk_2; /* '<Root>/fbk_2' */

/* Imported (extern) pointer block signals */
extern real_T *pos_rqst; /* '<Root>/pos_rqst' */
```

## Connect Output Data

In this example, you do not access the output data of the system. The example “Test Generated Code” on page 50-57 shows how you can save the output data to a standard log file. You can access the output data by referring to the file `rtwdemo_PCG_Eval_P5.h`.

View `rtwdemo_PCG_Eval_P5.h`.

## Access Additional Data

The generated code contains several structures that store commonly used data including:

- Block state values (integrator, transfer functions)
- Local parameters
- Time

The table lists the common data structures. Depending on the configuration of the model, a combination of these structures appear in the generated code. The data is declared in the file `rtwdemo_PCG_Eval_P5.h`, but in this example, you do not access this data.

Data Type	Data Name	Data Purpose
Constants	model_cP	Constant parameters
Constants	model_cB	Constant block I/O
Output	model_U	Root and atomic subsystem input
Output	model_Y	Root and atomic subsystem output
Internal data	model_B	Value of block output
Internal data	model_D	State information vectors
Internal data	model_M	Time and other system level data
Internal data	model_Zero	Zero-crossings
Parameters	model_P	Parameters

## Match Function Call Interfaces

By default, functions that the code generator generates have a `void Func(void)` interface. If you configure the model or atomic subsystem to generate reentrant code, the code generator creates a more complex function prototype. In this example, the `example_main` function calls the generated functions with valid input arguments.

```
PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
 &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
 &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;

rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
 &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
```

Calls to the function `PI_Cntrl_Reusable` use a mixture of separate, unstructured global variables and Simulink® Coder™ data structures. The handwritten code defines these variables. The structure types are defined in `rtwdemo_PCG_Eval_P5.h`.

## Build Project in Eclipse™ Environment

This example uses the Eclipse™ IDE and the Cygwin™ GCC debugger to build the embedded system. The example provides installation files for both programs. Software components and versions numbers are:

- Eclipse™ SDK 3.2
- Eclipse™ CDT 3.3

- Cygwin™/GCC 3.4.4-1
- Cygwin™/GDB 20060706-2

To install and use Eclipse™ and GCC, see “Install and Use Cygwin and Eclipse” on page 50-67.

You can install the files for this example by clicking this hyperlink:

Set up the build folder.

Alternatively, to install the files manually:

- 1** Create a build folder (Eclipse\_Build\_P5).
- 2** Unzip the file `rtwdemo_PCG_Eval_P5.zip` into the build folder.
- 3** Delete the files `rtwdemo_PCG_Eval_P5.c`, `ert_main.c` and `rt_logging.c`, which are replaced by `example_main.c`.

You can use the Eclipse™ debugger to step through and evaluate the execution behavior of the generated C code. See the example “Install and Use Cygwin and Eclipse” on page 50-67.

To exercise the model with input data, see “Test Generated Code” on page 50-57.

## Test Generated Code

Validate generated code by using system-level S-functions or by running the code in an external environment.

Learn about:

- Different methods for testing the generated code
- How to test generated code in Simulink®
- How to test generated code outside of Simulink

For information about the example model and other examples in this series, see “Prepare a Control Algorithm Model for C Code Generation” on page 50-18.

### Validation Methods

Simulink® supports multiple system testing methods for validating the behavior of generated code.

**Windows® run-time executable:** Generate a Microsoft® Windows® executable and run the executable from the command prompt.

- Benefit: Easy to create and enables use of a C debugger to evaluate code
- Drawback: Partial emulation of target hardware

**Software-in-the-loop (SIL) testing:** Use an S-function to include the generated code in the Simulink model.

- Benefit: Easy to create, enables reuse of the Simulink test environment, and enables use of a C debugger to evaluate code
- Drawback: Partial emulation of target hardware

**Processor in the loop (PIL) testing:** Run a non-real-time cosimulation. Simulink executes a portion of the model (typically a plant model) while the target processor runs a different portion of the model (typically a controller). After you download code to the target processor, the processor-in-the-loop technology handles the communication of signals between Simulink and the target during the cosimulation.

- Benefit: Enables reuse of the Simulink test environment, enables use of a C debugger with the simulation, and involves the target processor
- Drawback: Requires additional steps to set up the test environment and the processor does not run in real time

**On-target rapid prototyping:** Run the generated code on the target processor as part of the full system.

- Benefit: You can determine actual hardware constraints and test the component within the full system. The processor runs in real time
- Drawback: Requires hardware and requires additional steps to set up the test environment

**External Mode:** Run the generated code on the target processor as part of the full system.

- Benefit: You can determine actual hardware constraints and test the component within the full system

- Drawback: Requires hardware and requires additional steps to set up the test environment

### Reuse Test Data Outside of Simulink®

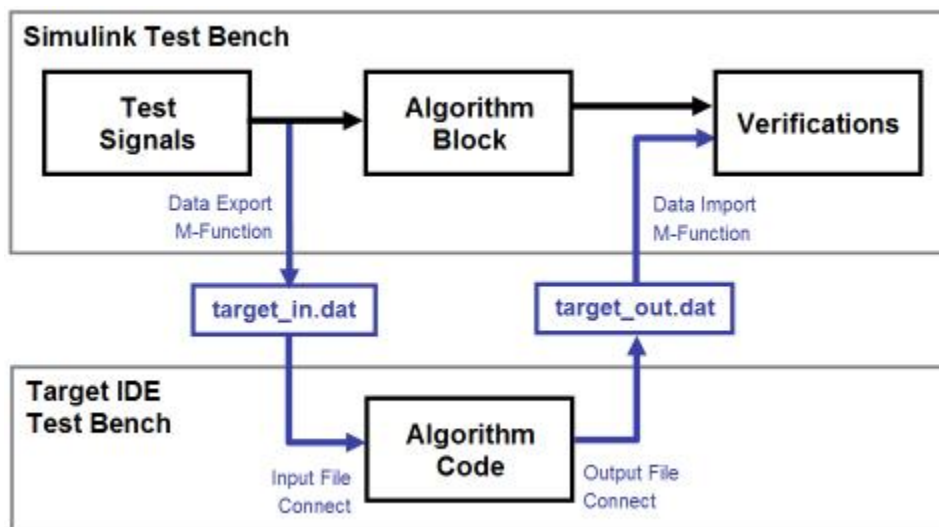

In other examples in this series, you test the system through simulation in Simulink. The test input data come from a Signal Builder block in the test harness model.

To test the system outside of Simulink®, you can reuse the test input data.

- 1 Save the Simulink test data into a file.
- 2 Format the data in a way that the system code can access.
- 3 Read the data file as part of the system code procedures.

To use Simulink to perform verification, you can save the test output data from the external environment in a format that MATLAB® can read.

In this example, the file `hardwareInputs.c` contains the data from the Signal Builder block in the test harness model.

### Test via Software-in-the-Loop (Model Block SIL)

#### Create and Configure Model Block for SIL

Simulink can generate code from a Model block, wrap the code into an S-Function, and add the S-Function back into the model for software-in-the-loop testing.

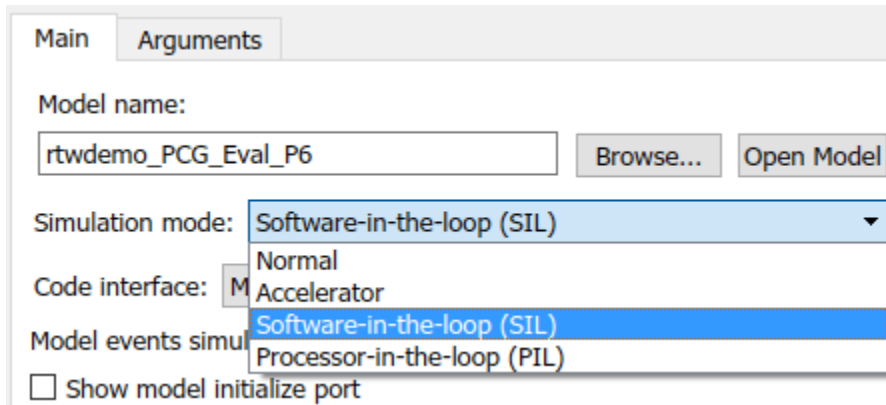

Open the example model, `rtwdemo_PCG_Eval_P6`.

Open the test harness model.

The test harness uses a Model block to access the example model. In this example, you run a software-in-the-loop test on the example model.

- 1 Right-click the Model block and select **Block Parameters (ModelReference)**.
- 2 Set **Model name** to the name of the model that you want to test.

- 3 Set **Simulation mode** to Software-in-the-loop (SIL).

The Model block now shows a (SIL) tag.

**Configure Models for SIL**

Configure the example model, `rtwdemo_PCG_Eval_P6`, and the test harness model, `rtwdemo_PCGEvalHarnessHTGSIL`, for SIL simulation by adjusting the hardware implementation parameters.

Open the example model.

For both models, in the Configuration Parameters dialog box, select the **Support long long** check box.

Save a copy of the example model, `rtwdemo_PCG_Eval_P6`, in your current folder.

### Run Model Block SIL

In this example, the test harness model contains a Model block that is configured for SIL simulation.

Open the test harness.

Run the test harness.

The generated code and the simulation yield the same results.

### Configure System for Testing via Test Vector Import and Export

This example extends the integration example in "Build Integrated Code Outside the Simulink Environment" on page 50-52. In this case, `example_main.c` uses simulated hardware I/O.

The augmented `example_main.c` file now uses this execution order:

1. Initialize data (one time)

```
while < endTime
```

2. Read the simulated hardware inputs

3. `PI_cnrl_1`

4. `PI_ctrl_2`

5. `Pos_Command_Arbitration`

6. Write the simulated hardware outputs

```
end while
```

View `example_main.c`.

Two functions, `plant` and `hardwareInputs`, supply the input test data.

`Plant.c`: This function, which was generated from the plant portion of the test harness, simulates the throttle body response to throttle commands.

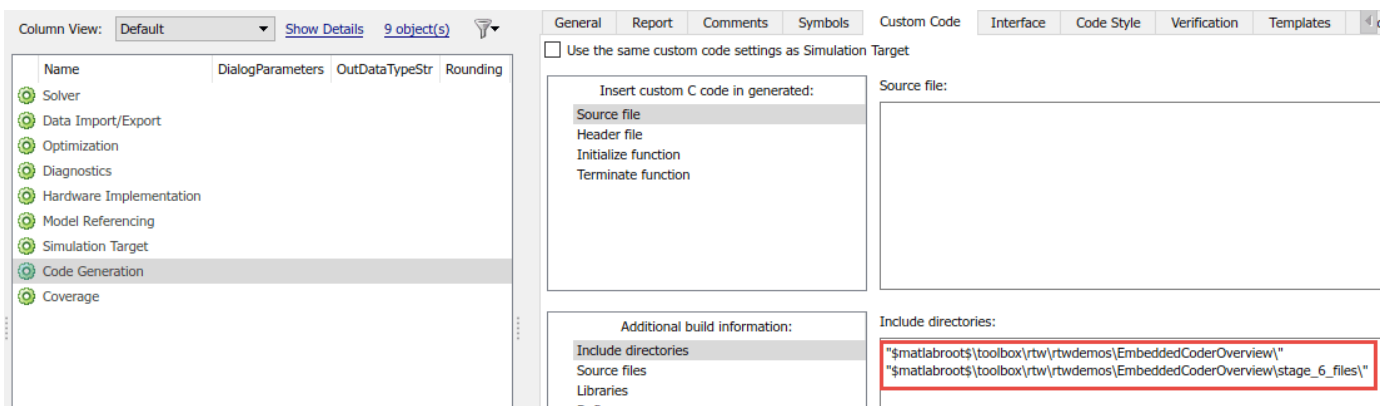

```
void Plant(void)
```

`HardwareInputs.c`: This function provides the `pos_req` signal and adds noise from the `Input_Signal_Scaling` subsystems into the plant feedback signal.

```
void hardwareInputs(void)
```

The handwritten function in `WriteDataForEval.c` logs output data from the test. After the test is finished, the function executes and writes the data to the file `PCG_Eval_ExternSimData.m`. You can run this script file in MATLAB to access the data. You can then compare the data to the simulated data from Simulink®.

To enable these additional files, identify them by using **Configuration Parameters > Code Generation > Custom Code > Additional build information**.

### **Test via Test Vector Import and Export (Eclipse™ Environment)**

Before building an executable in the Eclipse™ environment, regenerate the code without the S-function interface.

Build C code for integration.

To learn how to install and use Eclipse™ and GCC, see “Install and Use Cygwin and Eclipse” on page 50-67.

To install the files for this example automatically, click the hyperlink.

Automatically set up the build folder.

Alternatively, to manually install the files:

- 1** Create a build folder (`Eclipse_Build_P6`).
- 2** Unzip the file `rtwdemo_PCG_Eval_P6.zip` into the build folder.
- 3** Delete the files `rtwdemo_PCG_Eval_P6.c`, `ert_main.c`, and `rt_logging.c`, which are replaced by `example_main.c`.

Run the control code in Eclipse™. The function in `writeDataForEval.c` creates the file `eclipseData.m`, which contains the output test data. In MATLAB®, load this Eclipse™ data by running the script file. Then, compare this data with the data from the Simulink® test harness model by using `plot`.

For the next example in this series, see “Evaluate Performance of the Generated Code” on page 50-63.

### **See Also**

#### **More About**

- “SIL and PIL Simulations” on page 82-2

## Evaluate Performance of the Generated Code

Learn how characteristics of generated code and RAM/ROM data affect the RAM/ROM metric.

For information about the example model and other examples in this series, see “Prepare a Control Algorithm Model for C Code Generation” on page 50-18.

### Code Evaluation

You can evaluate the generated code based on two primary metrics: *execution speed* and *memory usage*. In some cases, improvement in one metric implies a sacrifice in the other metric. For example, you can often gain faster execution by consuming more memory.

You can further classify memory usage as ROM (read-only memory) and RAM (random access memory).

- Accessing data from RAM is faster than accessing data from ROM.
- Executables and data must be stored on ROM because RAM does not maintain data between power cycles.

This example evaluates memory requirements and divides the memory usage into function and data components. The example does not evaluate execution speed.

### Compiler Information

This evaluation uses the Freescale™ CodeWarrior® compiler.

- **Compiler:** Freescale™ CodeWarrior®
- **Version:** 5.5.1.1430
- **Target Processor:** Power PC 565

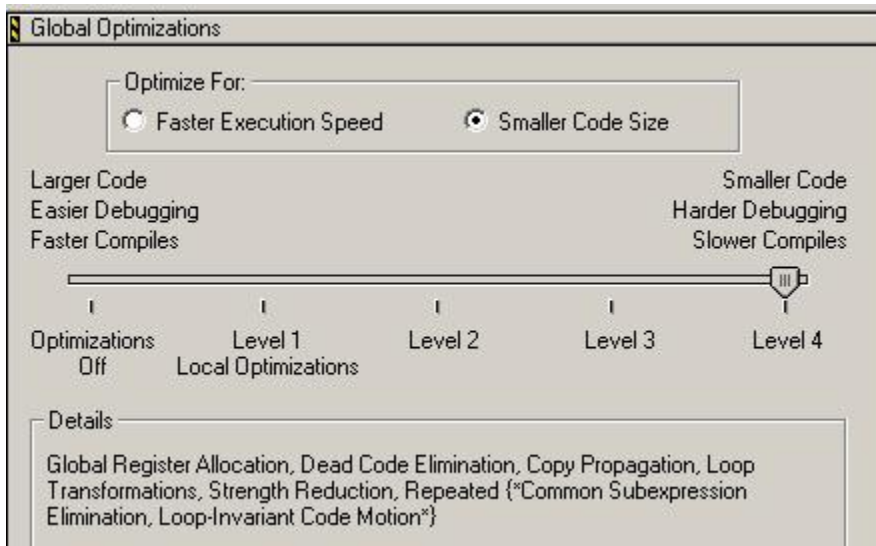

### View Code Metrics

As described in “Build Integrated Code Outside the Simulink Environment” on page 50-52 and “Test Generated Code” on page 50-57, the generated code can require the use of utility functions. The utility functions incur a one-time, fixed cost of memory. Due to this fixed overhead, the data in this example show memory usage for:

- **Algorithms:** The C code generated from the Simulink® block diagrams plus the data definition functions
- **Utilities:** Functions that are part of the Simulink® Coder™ library source
- **Full:** The sum of both the algorithm and utilities

### Build Options Configuration

The three evaluations in this example use the same build configuration. Freescale™ CodeWarrior® was configured to minimize memory usage and apply all applicable optimizations.

### Configuration 1: Reusable Functions with Data Type Double

- **Source files:** PCG\_Eval\_File\_1.zip
- **Data Type:** All doubles
- **Included Data:** The project includes all data that the build requires (including data declared as extern: pos\_rqst, fbk\_1, and fbk\_2)
- **Main Function:** A modified version of example\_main from "Build Integrated Code Outside the Simulink Environment" on page 50-52
- **Function Call Method:** Reusable functions for the PI controllers

definelImportedData.c	12	28	•
definelImportedData.h	0	0	
eval_data.c	0	288	•
eval_data.h	0	0	
example_main.c	260	88	•
PCG_Eval_Fil_Define_Throt_Param.c	52	8	•
PCG_Eval_Fil_Define_Throt_Param.h	0	0	
PCG_Eval_File_1.c	464	92	•
PCG_Eval_File_1.h	0	0	
PCG_Eval_File_1_private.h	0	0	
PCG_Eval_File_1_types.h	0	0	
PI_Cntrl_Reusable.c	384	44	•
PI_Cntrl_Reusable.h	0	0	
rt_look1d.c	220	20	•
rt_look.c	372	20	•

Utilities

Func | Data

### Memory Usage

	Function	Data
Algorithms	1172 bytes	549 bytes
Utilities	592 bytes	40 bytes
Full	1764 bytes	589 bytes

## Configuration 2: Reusable Functions with Data Type Single

In this configuration, the model data use a single-precision floating-point data type instead of double precision.

### Model Configuration

- **Source files:** PCG\_Eval\_File\_2.zip
- **Data Type:** All singles
- **Included Data:** The project includes all data that the build requires (including data declared as extern: pos\_rqst, fbk\_1, and fbk\_2)
- **Main Function:** A modified version of `example_main` from “Build Integrated Code Outside the Simulink Environment” on page 50-52
- **Function Call Method:** Reusable functions for the PI controllers

### Memory Usage

	Function	Data
Algorithms	800 bytes	308 bytes
Utilities	592 bytes	40 bytes
Full	1392 bytes	348 bytes

This configuration uses only 56% of the data memory from the first configuration: 308 bytes instead of 549 bytes. This configuration also uses 68% of the function memory: 800 bytes instead of 1172 bytes. For this system, using single precision instead of double precision does not affect the accuracy of the control algorithm, so you can use this configuration to achieve more efficient code.

## Configuration 3: Nonreusable Functions with Data Type Single

- **Source files:** PCG\_Eval\_File\_3.zip
- **Data Type:** All singles
- **Included Data:** The project includes all data that the build requires (including data declared as extern: pos\_rqst, fbk\_1, and fbk\_2)
- **Main Function:** A modified version of `example_main` from “Build Integrated Code Outside the Simulink Environment” on page 50-52
- **Function Call Method:** The function interface is `void void` so data exchange occurs through global variables

### Memory Usage

	Function	Data
Algorithms	948 bytes	348 bytes
Utilities	592 bytes	40 bytes
Full	1540 bytes	388 bytes

This configuration consumes more data and function memory than the previous configuration.

## See Also

### More About

- “Generate Static Code Metrics Report for Simulink Model” on page 51-26

- “Optimize Generated Code with Code Efficiency Tools and Techniques” on page 71-7

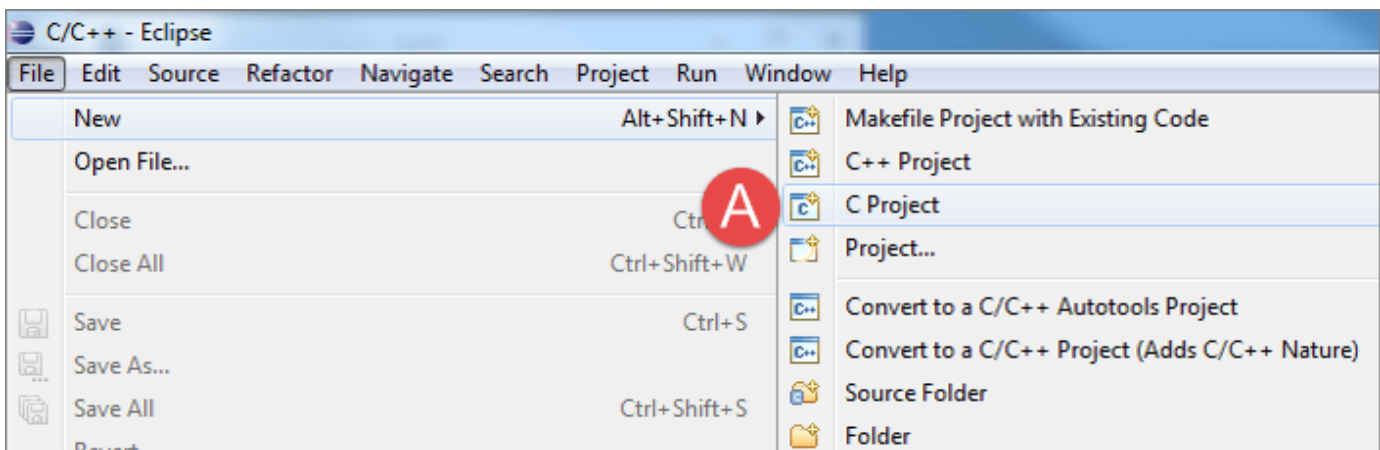

## Install and Use Cygwin and Eclipse

Use Eclipse™ and Cygwin™, a free software integration development environment (IDE) and free compiler, for the examples “Build Integrated Code Outside the Simulink Environment” on page 50-52 and “Test Generated Code” on page 50-57.

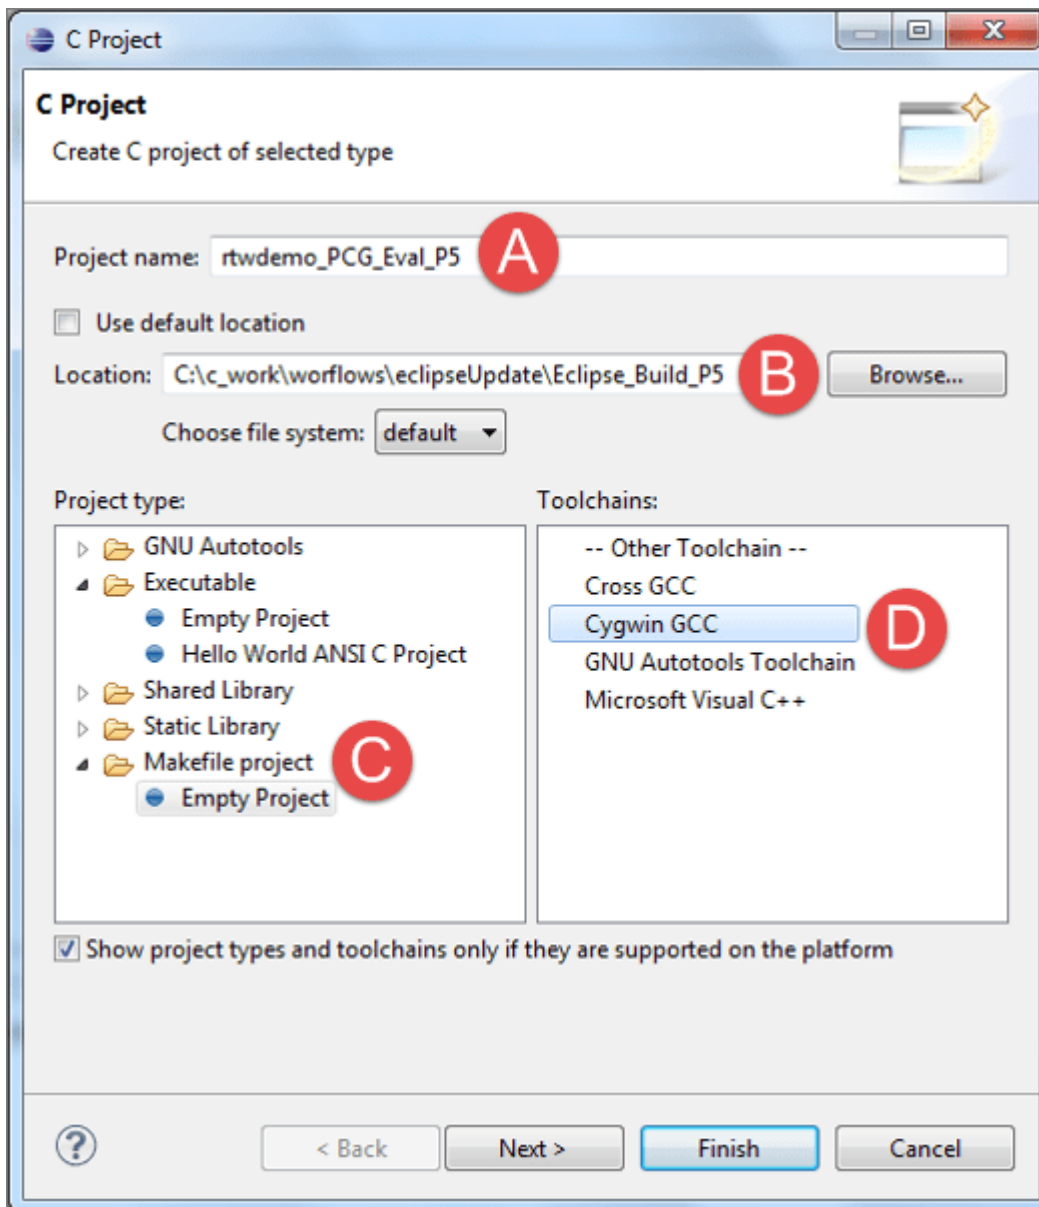

For information about the example model and other examples in this series, see “Prepare a Control Algorithm Model for C Code Generation” on page 50-18.

### Create an Eclipse CDT Managed Make C Project

1. Open Eclipse.
2. Select **File > New > C Project**.

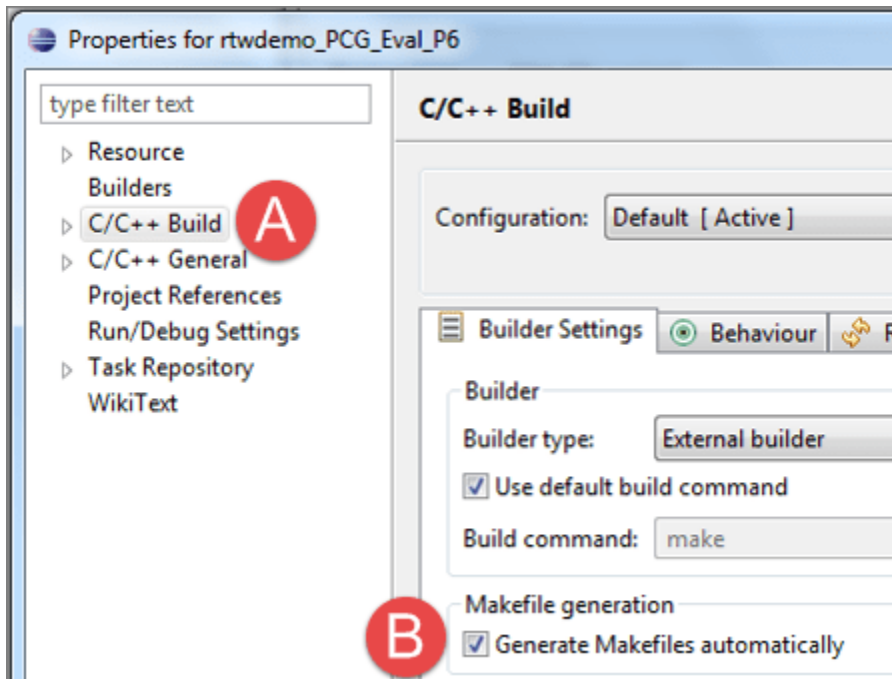

3. Use the **C Project** dialog box to configure the project.
  - a. Specify the project name.
  - b. Select the project location.
  - c. Select the project type as **Makefile**.
  - d. Select the Cygwin GCC toolchain and click **Finish**.

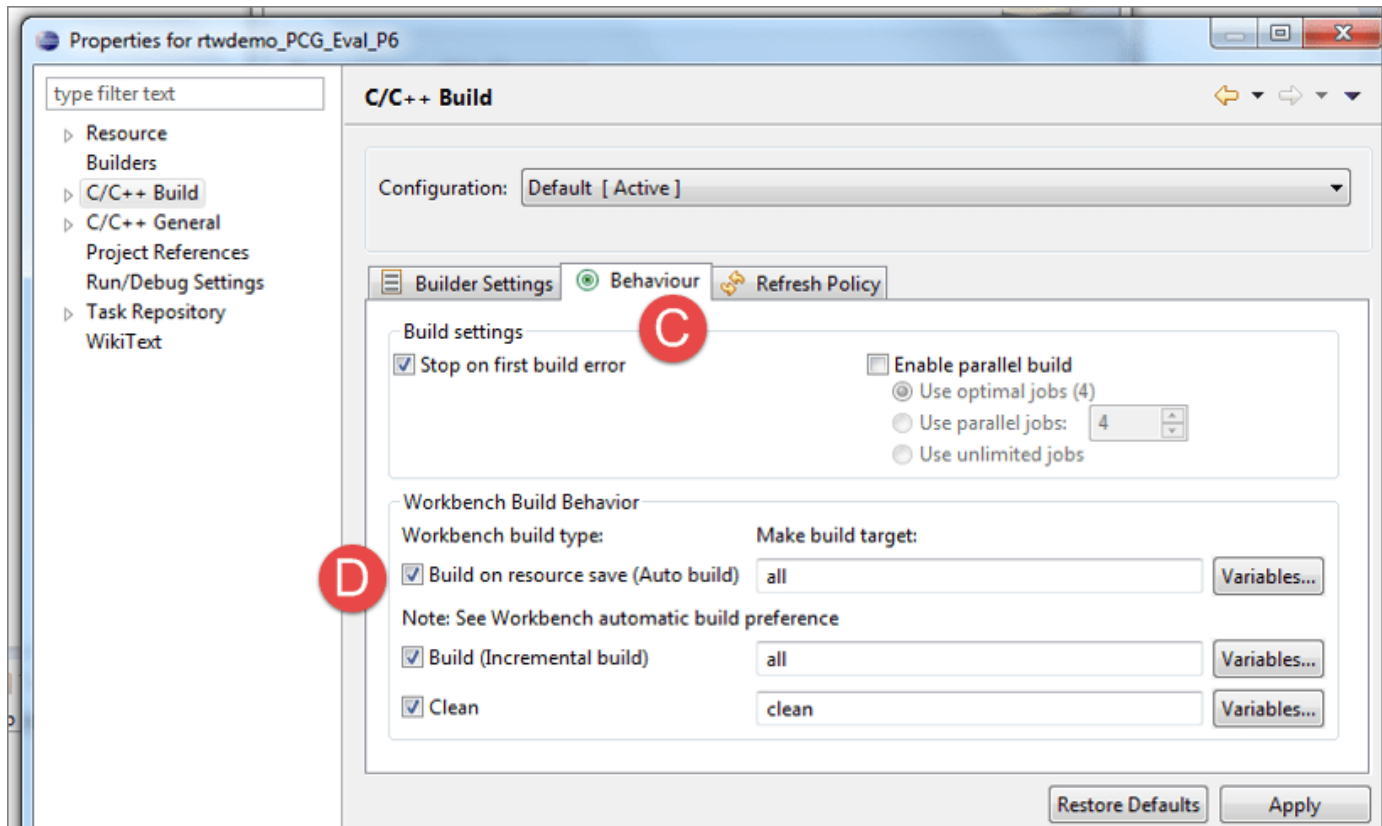

4. Select **Project > Properties**. Use **Advanced settings** to fully configure the project.
  - a. Select the **C/C++ Build** properties.
  - b. On the **Builder Settings** tab, select **Generate Makefiles automatically**.

c. View the **Behaviour** tab.

d. Select **Build on resource save (Auto build)**.

## 5. Compile the generated code with Eclipse.

After you define the files, Eclipse determines the main function and builds the project with the managed make environment. The build details appear in the Console window.

```
CDT Build Console [Eclipse_Build_P5]

Building file: ../rtwdemo_PCG_Define_Throt_Param.c
Invoking: Cygwin C Compiler
gcc -O2 -g -Wall -c -fmessage-length=0 -MMD -MP -MF"rtwdemo_PCG_Define_Throt_Param.d" -MT"rtwdemo_PCG_Define_Throt_Param.d" -o "rtwdemo_PCG_
Finished building: ../rtwdemo_PCG_Define_Throt_Param.c

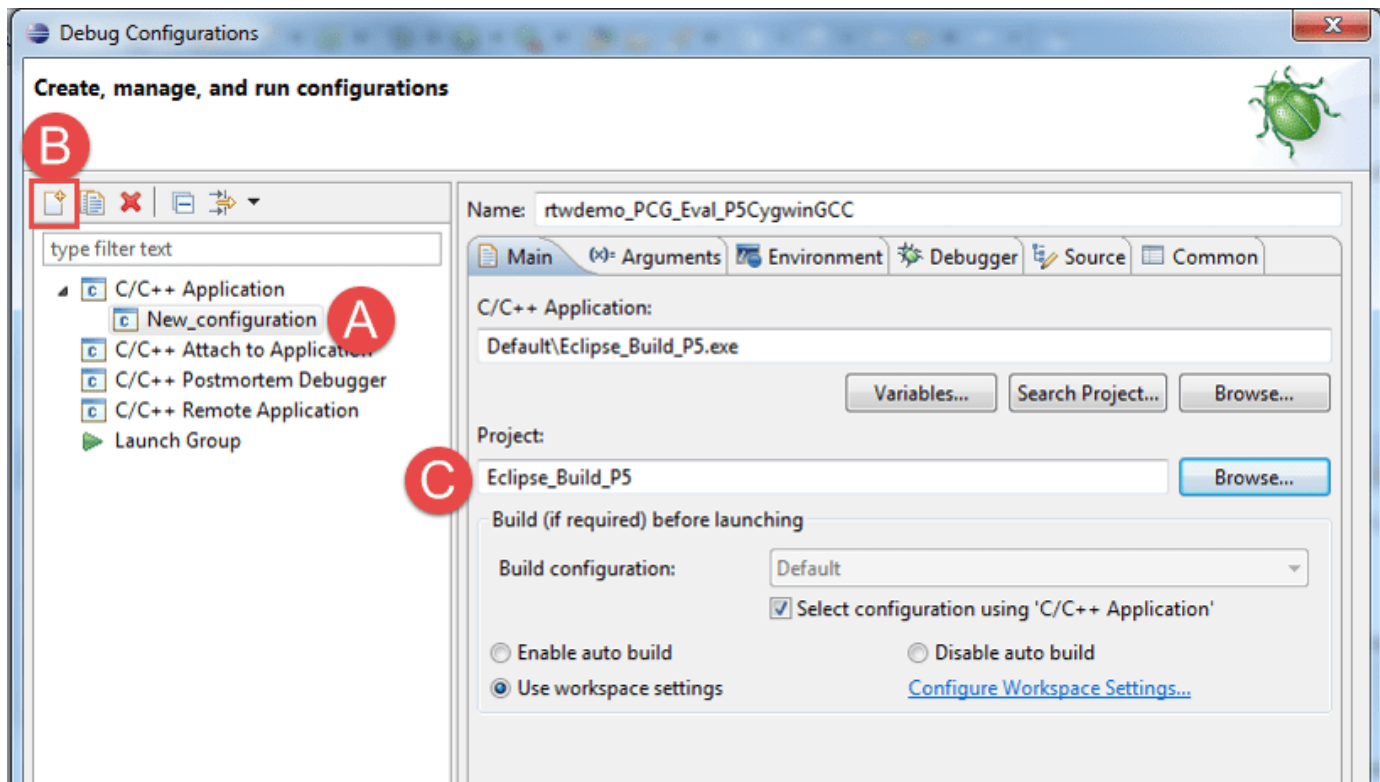

Building file: ../rtwdemo_Pos_Command_Arbitration.c
Invoking: Cygwin C Compiler
gcc -O2 -g -Wall -c -fmessage-length=0 -MMD -MP -MF"rtwdemo_Pos_Command_Arbitration.d" -MT"rtwdemo_Pos_Command_Arbitration.d" -o "rtwdemo_Pos_C
Finished building: ../rtwdemo_Pos_Command_Arbitration.c

Building target: Eclipse_Build_P5
Invoking: Cygwin C Linker
gcc -o "Eclipse_Build_P5" ./PI_Cntrl_Reusable.o ./defineImportedData.o ./eval_data.o ./example_main.o ./look1_binlx.o ./rtwdemo_PCG_Define_T
Finished building target: Eclipse_Build_P5

15:45:11 Build Finished (took 1s.762ms)
```

### Use Eclipse Debugger with the Generated Code

1. Select **Run > Debug Configurations**.
2. Use the **Debug Configurations** dialog box to configure the debugger.
  - a. Select **C/C++ Application**.
  - b. Click the new configuration button.
  - c. Select the project.

d. Click **Apply**. Do not click **Run**.

If required, select the executable. Eclipse automatically finds the `exe` file.

3. To start the debugger, from the primary Eclipse window, select **Run > Debug**.

During the build process, Cygwin creates a virtual drive, `/cygdrive/c/`. To run the debugger, Eclipse either remaps the drive or locates the files. After locating the first file, Eclipse finds the remaining files.

4. Run the debugger on the generated code.

```

example_main.c

static BlockIO_rtwdemo_PCG_Eval_P5 rtwdemo_PCG_Eval_P5_B; /* Observable sign
static D_Work_rtwdemo_PCG_Eval_P5 rtwdemo_PCG_Eval_P5_DWork; /* Observable s

real_T pos_cmd_one; /* '<Root>/Signal Conversion1' */
real_T pos_cmd_two; /* '<Root>/Signal Conversion2' */
ThrottleCommands ThrotComm; /* '<Root>/Pos_Command_Arbitration'
ThrottleParams Throt_Param; /* '<S1>/Bus Creator' */

int simulationLoop = 0;

int_T main(void)
{
 /* Initialize model */
 rt Pos Command Arbitration Init(): /* Set up the data structures for char
 system: '<Root>/Define_Throt_Param
 nes the memory and values of in

 scheduling algorithm */

 Toggle Breakpoint Ctrl+Shift+B
 Add Breakpoint... Ctrl+Double Click
 Disable Breakpoint Shift+Double Click
 Breakpoint Properties... Ctrl+Double Click

```

## Use Eclipse Debugger Commands

You can use these commands from the debugger context menu:

- **F5**: Step into
- **F6**: Step over
- **F7**: Step out
- **F8**: Resume
- **Ctrl+Shift+B**: Toggle break point
- **Ctrl+Shift+R**: Run to line
- **Shift+F5**: Use Step Filters

## Reports for Code Generation

### In this section...

“HTML Code Generation Report Content” on page 51-2

“HTML Code Generation Report Location” on page 51-2

“HTML Code Generation Report for Referenced Models” on page 51-2

“HTML Code Generation Report Extensions” on page 51-3

The code generator software produces an HTML code generation report so that you can view and analyze the generated code. When you build your model, the code generation process produces an HTML file that is displayed in an HTML browser or in the Model Explorer. For an example, see “Generate Code Generation Report” on page 51-5.

If you have Simulink Report Generator, you can document your code generation project in multiple formats, including HTML, PDF, RTF, Microsoft Word, and XML. For an example of how to create a Microsoft Word report, see “Document Generated Code with Simulink Report Generator” on page 51-35.

### HTML Code Generation Report Content

The code generation report includes:

- The **Summary** section that contains model and code information, including **Author**, **Tasking Mode**, **System Target File**, **Hardware Device Type**, and code generation objectives information. The **Configuration settings at the time of code generation** link opens a noneditable view of the Configuration Parameters dialog box. The dialog box shows the Simulink model settings at the time of code generation, including TLC options.
- The **Subsystem Report** section that contains information on nonvirtual subsystems in the model.
- The **Code Interface Report** section that provides information about the generated code interface, including model entry-point functions and input/output data. For more information, see “Analyze the Generated Code Interface”.
- In the **Code** section on the **Contents** pane, you can click the names of source code files generated from your model to view their contents.

### HTML Code Generation Report Location

The default location for the code generation report files is in the `html` subfolder of the build folder, `model_target_rtw/html/`. *target* is the name of the **System target file** specified on the **Code Generation** pane. The default name for the top-level HTML report file is `index.html`. For more information on the location of the build folder, see “Manage Build Process Folders”.

### HTML Code Generation Report for Referenced Models

To generate a code generation report for a top model and code generation reports for each referenced model, you need to specify the **Create code generation report** on the **Code Generation > Report** pane for the top model and each referenced model. You can open the code generation report of a referenced model in one of two ways:

- From the top-model code generation report, you can access the referenced model code generation report by clicking the name of the top model above the generated code. In the drop-down list of the model reference hierarchy, click the referenced model. To navigate back to the top model code generation report, use the **Back** button at the top of the left navigation pane or use the model reference hierarchy context menu.
- In the referenced model diagram window, on the **C Code** tab, click **Open Report**.

For more information, see “Generate Code for Model Reference Hierarchy”.

## HTML Code Generation Report Extensions

If you have Embedded Coder, the code generator enhances the HTML code generation report. Configure your model to include these sections in the report:

- The **Traceability Report** section enables you to account for **Eliminated / Virtual Blocks** that are untraceable versus the listed **Traceable Simulink Blocks / Stateflow Objects / MATLAB Scripts**. This section provides a complete mapping between model elements and code. For more information, see “Customize Traceability Reports” on page 79-30.
- The **Static Code Metrics Report** section provides generated code statistics. Metrics are estimated from static analysis of the generated code. To generate a static code metrics report without generating a code generation report, use the function `coder.report.generateCodeMetrics`. For more information, see “Static Code Metrics” on page 51-23.
- The **Code Replacements Report** section enables you to account for code replacement library (CRL) functions that were used during code generation, providing a mapping between each replacement instance and the Simulink block that triggered the replacement. For more information, see “Analyze Code Replacements in Generated Code” on page 51-33.
- The **Coder Assumptions** section provides a list of:
  - Code generation assumptions for your target hardware that you can check.
  - Expected results for the assumption checks.

For more information, see “Check Code Generation Assumptions” on page 55-12.

- The model web view displays an interactive model diagram within the code generation report and supports traceability between the source code and the model. You can then share your model and generated code outside of the MATLAB environment. For more information, see “Web View of Model in Code Generation Report” on page 51-10.

On the **Contents** pane, in the **Generated Files** section, you can click the names of source code files generated from your model to view their contents in a MATLAB web browser window. In the displayed source code:

- If you enable code-to-model traceability, hyperlinks within the displayed source code navigate to the blocks or subsystems from which the code is generated. For more information, see “Code-to-Model Traceability” on page 79-8.
- If you enable model-to-code traceability, you can navigate to the generated code for a block in the model. For more information, see “Model-to-Code Traceability” on page 79-10.
- If you set the **Code coverage tool** parameter on the **Code Generation > Verification** pane, you can view the code coverage data and annotations. For more information, see “Configure Code Coverage with Third-Party Tools” on page 85-9.

- If you select the **Generate static code metrics** check box on the **Code Generation > Report** pane, you can view code metrics information and navigate to code definitions and declarations in the generated code. For more information, see “View Static Code Metrics and Definitions Within the Generated Code” on page 51-25.

---

**Note** To view the contents of your generated code and navigate between model and code, you can also use the Code view in the Code perspective. In the perspective, click the **Code** tab in the bottom-right corner.

---

### See Also

### Related Examples

- “Verify Generated Code by Using Code Tracing” on page 79-2

## Generate Code Generation Report

You can configure a model to generate a code generation report when you build the model. If you want to separate report generation from code generation, you can manually generate a report after generating code. If you do not change the model after generating code, you can generate a report without regenerating the code.

If you have Embedded Coder, you can include optional sections in the report, such as reports on traceability and code replacement. For more information, see “Reports for Code Generation” on page 51-2.

### Configure Model

Configure a model to generate code without generating a report.

- 1 Open a model, for example, `rtwdemo_sum`.  

```
model = 'rtwdemo_sum';
open_system(model);
```
- 2 On the **C Code** tab, from the **Open Report** list, select **Report Options**. The Configuration Parameters dialog box opens with the **Code Generation > Report** pane visible.
- 3 Clear the **Create code generation report** parameter. When you generate code, the report is not generated. Instead, you generate the report manually.
- 4 If you have Embedded Coder, verify that “**Eliminated / virtual blocks**” is selected. This parameter enables an optional **Traceability Report** section in the code generation report.
- 5 Generate code.

### Generate Report

On the **C Code** tab, select **Open Report**. The report generation process writes the code generation report files to the `html` subfolder of the build folder (see “HTML Code Generation Report Location” on page 51-2) without regenerating the code. Next, a MATLAB web browser window opens and displays the code generation report.

If you selected **Eliminated / virtual blocks**, the code generation report includes a **Traceability Report** section.

To open the code generation report at any time after generating code, on the **C Code** tab, select **Open Report**. If a report already exists, it opens without regenerating the code or report.

### Share Report

To share the code generation report, you can package the code generation report files and supporting files into a ZIP file for transfer.

- 1 In the **Current Folder** browser, select these folders:
  - `/slprj`
  - `model_target_rtw`
- 2 To open the context menu, right click one of the selected folders.

- 3** In the context menu, select **Create Zip File**. A file appears in the **Current Folder** browser.
- 4** Name the ZIP file.

If your model is part of a project, you can include the code generation report when archiving the project. For more information, see “Archive Projects”.

## Limitation

After building your model or generating the code generation report, if you modify legacy or custom code, you must rebuild your model or regenerate the report for the code generation report to include the updated legacy source files. For example, if you modify your legacy code, and then use the **Open Report** button to open an existing report, the software does not check if the legacy source file is out of date compared to the generated code. The code generation report is not regenerated and the report includes the out-of-date legacy code.

To reflect changes to legacy or custom code in the code generation report, rebuild the model before using the **Open Report** button.

## See Also

### More About

- “Reports for Code Generation” on page 51-2
- “Generate Code Generation Report Programmatically” on page 51-7

## Generate Code Generation Report Programmatically

You can programmatically generate, open, and close an HTML code generation report at the MATLAB command line using the `coder.report.generate` function. When you generate the report, you can configure it rather than tie the report configuration to the model configuration set. If you do not change the model after generating code, you can generate a code generation report without regenerating the code.

### Configure Model

Open the model.

```
model='rtwdemo_sum';
open_system(model)
```

Clear the `GenerateReport` configuration parameter programmatically. When you build the code, the report is not generated. Instead, you generate the report manually at the command line.

```
set_param(model, 'GenerateReport', 'off');
```

Build the model.

```
slbuild(model);

Starting build procedure for: rtwdemo_sum
Successful completion of build procedure for: rtwdemo_sum
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_sum	Code generated and compiled	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)

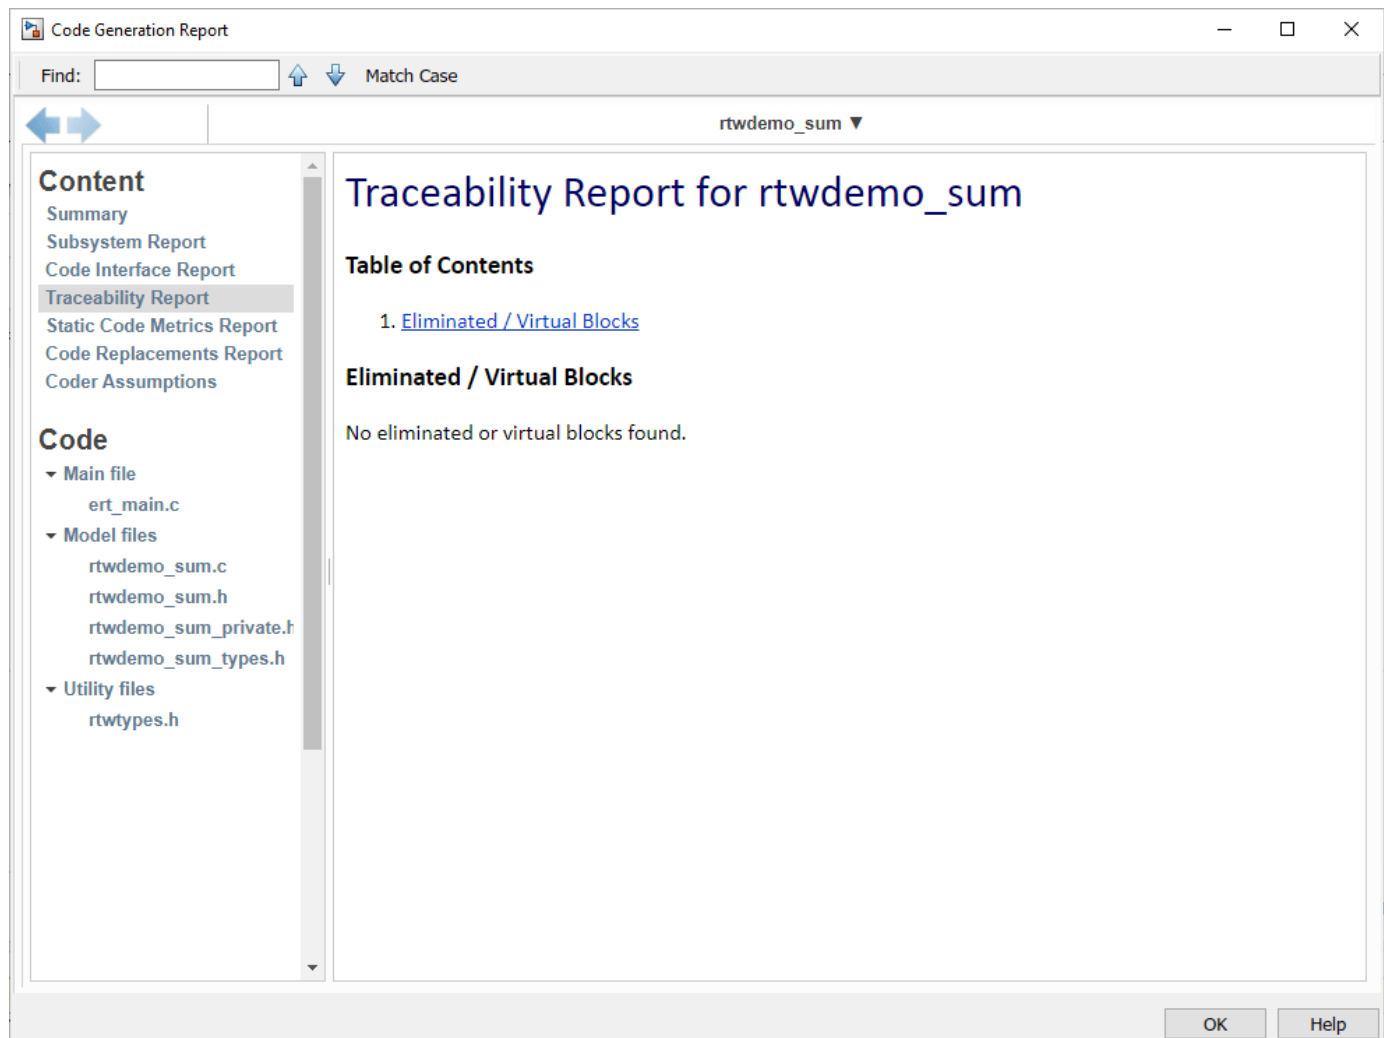

Build duration: 0h 0m 16.589s

### Generate Report

When you generate the report at the command line, you can use name-value arguments to configure the report without changing the model configuration set. Generate the report with `GenerateTraceReport` set to 'on'.

```
coder.report.generate(model, GenerateTraceReport='on');
```

The code generation report includes a **Traceability Report** section.

Verify that `GenerateTraceReport` is not selected in the model configuration set.

```
get_param(model, 'GenerateTraceReport')
```

```
ans =
'off'
```

Close the code generation report.

```
coder.report.close();
```

To reopen the report programmatically, use `coder.report.open`.

```
coder.report.open(model);
```

### Share Report

To share the code generation report, package the code generation report files and supporting files into a ZIP file for transfer.

```
zip('myzip', {'s\prj', 'rtwdemo_sum_ert_rtw'});
```

If your model is part of a project, you can include the code generation report when archiving the project. For more information, see “Archive Projects”.

### **Limitation**

After building your model or generating the code generation report, if you modify legacy or custom code, you must rebuild your model or regenerate the report for the code generation report to include the updated legacy source files. For example, if you modify your legacy code, and then use `coder.report.open` to open an existing report, the software does not check if the legacy source file is out of date compared to the generated code. The code generation report is not regenerated and the report includes the out-of-date legacy code.

To reflect changes to legacy or custom code in the code generation report, before using `coder.report.open`, rebuild the model.

## Web View of Model in Code Generation Report

### In this section...

“Generate HTML Code Generation Report with Model Web View” on page 51-10

“Model Web View Limitations” on page 51-12

To review and analyze the generated code, it is helpful to navigate between the code and model. If you have a Simulink Report Generator license, you can include a Web view of the model within the HTML code generation report. You can then share your model and generated code outside of the MATLAB environment. When you generate the report, the Web view includes the block diagram attributes displayed in the Simulink Editor, such as, block sorted execution order, signal properties, and port data types. You can display the generated Web views in a supported Web browser. See “Web Views” (Simulink Report Generator) for browser requirements and to read more about Web views.

### Generate HTML Code Generation Report with Model Web View

This example shows how to create an HTML code generation report which includes a Web view of the model diagram.

- 1 Open the `rtwdemo_mdleftop` model.
- 2 Open the Configuration Parameters dialog box and navigate to the **Code Generation** pane.
- 3 Specify `ert.tlc` for the **System target file** parameter.
- 4 Open the **Code Generation > Report** pane.
- 5 Select the following parameters:
  - **Create code generation report**
  - **Open report automatically**
  - **Generate model Web view**
- 6 Select the parameters **Code-to-model** and **Model-to-code**.

---

**Note** These settings specify only the top model, not referenced models.

- 7 Open the Configuration Parameters for the referenced model, `rtwdemo_mdleftbot` and perform steps 3–6.
- 8 Save the models, `rtwdemo_mdleftop` and `rtwdemo_mdleftbot`.
- 9 From the top model diagram, press Ctrl+B. After building the model and generating code, the code generation report for the top model opens in a MATLAB Web browser.
- 10 In the left navigation pane, select a source code file. The corresponding source code is displayed in the right pane and includes hyperlinks.

The screenshot displays the 'Code Generation Report' interface. On the left, a 'Content' pane lists various reports and code files, with 'rtwdemo\_mdireftop.c' selected. The main area is split into two panes. The top pane shows the source code for 'rtwdemo\_mdireftop.c', with lines 51-71 visible. The bottom pane shows a Simulink model diagram for 'rtwdemo\_mdireftop' with three sub-models: 'rtwdemo\_mdireftop\_upper', 'rtwdemo\_mdireftop\_bot', and 'rtwdemo\_mdireftop\_bot'. The 'rtwdemo\_mdireftop\_bot' block is highlighted in green, and its corresponding code in the top pane is also highlighted. A 'Parameter Attributes' panel on the right shows details for the selected model, including ModelVersion (4.0), LastModifiedDate (Tue Feb 23 14:02:40 2021), and a description: 'This model shows how to use Model Reference to provide system interface encapsulation and incremental code'.

- 11 Click a link in the code. The model Web view displays and highlights the corresponding block in the model.
- 12 To highlight the generated code for a Model block in your model, click CounterB. The corresponding code is highlighted in the source code pane.

**Note** You cannot open the referenced model diagram in the Web view by double-clicking the Model block in the top model.

- 13 To open the code generation report for a referenced model, at the top of the report, click **rtwdemo\_mdireftop**. In the drop-down, click **rtwdemo\_mdireftop\_bot**. The source files for the referenced model are displayed along with the Web view of the referenced model.
- 14 To go back to the code generation report for the top model, at the top of the left navigation pane, click the **Back** button until the top model's report is displayed.

For more information about exploring a model in a Web view, see "Navigate a Web View" (Simulink Report Generator).

For more information about navigating between the generated code and the model diagram, see "Trace Simulink Model Elements in Generated Code" on page 79-8.

## Model Web View Limitations

The HTML code generation report includes the following limitations when using the model Web view:

- Code is not generated for virtual blocks. In the model Web view of the code generation report, when tracing between the model and the code, when you click a virtual block, it is highlighted yellow.
- In the model Web view, you cannot open a referenced model diagram by double-clicking the Model block in the top model. Instead, open the code generation report for the referenced model by using the drop-down menu at the top of the report.
- Stateflow truth tables, events, and links to library charts are not supported in the model Web view.
- Searching in the code generation report does not find or highlight text in the model Web view.
- If you navigate from the actual model diagram (not the model Web view in the report), to the source code in the HTML code generation report, the model Web view is disabled and not visible. To enable the model Web view, open the report again.
- For a subsystem build, the traceability hyperlinks of the root level inport and outport blocks are disabled.
- “Traceability Limitations” on page 79-7 that apply to tracing between the code and the actual model diagram.

## Analyze the Generated Code Interface

### In this section...

“Code Interface Report Overview” on page 51-13  
 “Generating a Code Interface Report” on page 51-13  
 “Navigating Code Interface Report Subsections” on page 51-15  
 “Interpreting the Entry-Point Functions Subsection” on page 51-16  
 “Interpreting the Inports and Outports Subsections” on page 51-19  
 “Interpreting the Interface Parameters Subsection” on page 51-20  
 “Interpreting the Data Stores Subsection” on page 51-21  
 “Code Interface Report Limitations” on page 51-21

### Code Interface Report Overview

When you select the **Create code generation report** option, a **Code Interface Report** section is automatically included in the generated HTML report. The **Code Interface Report** section provides documentation of the generated code interface, including model entry-point functions and interface data, for consumers of the generated code. The information in the report can help facilitate code review and code integration.

The code interface report includes the following subsections:

- **Entry-Point Functions** — interface information about each model entry-point function, including `model_initialize`, `model_step`, and (if applicable) `model_reset` and `model_terminate`.
- **Inports and Outports** — interface information about each model inport and outport.
- **Interface Parameters** — interface information about tunable parameters that are associated with the model.
- **Data Stores** — interface information about global data stores and data stores with non-auto storage that are associated with the model.

For limitations that apply to code interface reports, see “Code Interface Report Limitations” on page 51-21.

For illustration purposes, this section uses the following models:

- `rtwdemo_configinterface` (with the **ExportedGlobal Storage Class** button selected in the model window) for examples of report subsections
- `rtwdemo_mrmtbb` for examples of timing information
- `rtwdemo_fcncnprotoctrl` for examples of function argument and return value information

### Generating a Code Interface Report

To generate a code interface report for your model:

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Code Generation > Report** pane, select **Create code generation report**. The `rtwdemo_configinterface`, `rtwdemo_mrmtbb`, and `rtwdemo_fcncnprotoctrl` models used in this section select multiple other **Report** pane options by default.

Alternatively, you can programmatically select the option by issuing the following MATLAB command:

```
set_param(bdroot, 'GenerateReport', 'on')
```

If your model uses an ERT-based target, you can select the **Code-to-model** parameter. In this case, the generated report contains hyperlinks to the model.

- 3** Build the model. On the **C Code** tab, click **Open Report**.
- 4** To display the code interface report for your model, on the **Contents** pane of the HTML report, click the **Code Interface Report** link. For example, here is the generated code interface report for the model `rtwdemo_configinterface` (with the **ExportedGlobal Storage Class** button selected in the model window).

Code Interface Report for `rtwdemo_configinterface`

## Table of Contents

- [Entry-Point Functions](#)
- [Inports](#)
- [Outports](#)
- [Interface Parameters](#)
- [Data Stores](#)

## Entry-Point Functions

Function: [rtwdemo\\_configinterface\\_initialize](#)

Prototype	<code>void rtwdemo_configinterface_initialize(void)</code>
Description	Initialization entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_configinterface.h</a>

Function: [rtwdemo\\_configinterface\\_step](#)

Prototype	<code>void rtwdemo_configinterface_step(void)</code>
Description	Output entry point of generated code
Timing	Must be called periodically, every 1 second
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_configinterface.h</a>

Function: [rtwdemo\\_configinterface\\_terminate](#)

Prototype	<code>void rtwdemo_configinterface_terminate(void)</code>
Description	Termination entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_configinterface.h</a>

## Inports

## Navigating Code Interface Report Subsections

To help you navigate code interface descriptions, the code interface report provides collapse/expand tokens and hyperlinks, as follows:

- For a large subsection, the report provides [-] and [+] symbols that allow you to collapse or expand that section. In the example in the previous section, the symbols are provided for the **Inports** and **Interface Parameters** sections.

- Several forms of hyperlink navigation are provided in the code interface report. For example:
  - The **Table of Contents** located at the top of the code interface report provides links to each subsection.
  - You can click each function name to go to its definition in *model.c*.
  - You can click each function's header file name to go to the header file source listing.
  - If you selected the **Code-to-model** parameter for your model, to go to the corresponding location in the model display, you can click hyperlinks for any of the following:
    - Function argument
    - Function return value
    - Inport
    - Outport
    - Interface parameter (if the parameter source is a block)
    - Data store (if the data store source is a Data Store Memory block)

For backward and forward navigation within the HTML code generation report, use the **Back** and **Forward** buttons above the **Contents** section in the upper-left corner of the report.

## Interpreting the Entry-Point Functions Subsection

The **Entry-Point Functions** subsection of the code interface report provides the following interface information about each model entry-point function, including `model_initialize`, `model_step`, and (if applicable) `model_reset` and `model_terminate`.

Field	Description
<b>Function:</b>	Lists the function name. You can click the function name to go to its definition in <i>model.c</i> .
<b>Prototype</b>	Displays the function prototype, including the function return value, name, and arguments.
<b>Description</b>	Provides a text description of the function's purpose in the application.
<b>Timing</b>	Describes the timing characteristics of the function, such as how many times the function is called, or if it is called periodically, and at what time interval. For a multirate timing example, see the following <code>rtwdemo_mrmtbb</code> report excerpt.
<b>Arguments</b>	If the function has arguments, displays the number, name, data type, and Simulink description for each argument. If you select the <b>Code-to-model</b> parameter for your model, you can click the hyperlink in the description to go to the block corresponding to the argument in the model display. For argument examples, see the <code>rtwdemo_fcncnprotoctrl</code> report excerpt below.
<b>Return value</b>	If the function has a return value, this field displays the return value data type and Simulink description. If you selected the <b>Code-to-model</b> parameter for your model, you can click the hyperlink in the description to go to the block corresponding to the return value in the model display. For a return value example, see the following <code>rtwdemo_fcncnprotoctrl</code> report excerpt.

Field	Description
<b>Header file</b>	Lists the name of the header file for the function. You can click the header file name to go to the header file source listing.

For example, here is the **Entry-Point Functions** subsection for the model `rtwdemo_configinterface`.

#### Entry-Point Functions

Function: [rtwdemo\\_configinterface\\_initialize](#)

Prototype	<code>void rtwdemo_configinterface_initialize(void)</code>
Description	Initialization entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_configinterface.h</a>

Function: [rtwdemo\\_configinterface\\_step](#)

Prototype	<code>void rtwdemo_configinterface_step(void)</code>
Description	Output entry point of generated code
Timing	Must be called periodically, every 1 second
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_configinterface.h</a>

Function: [rtwdemo\\_configinterface\\_terminate](#)

Prototype	<code>void rtwdemo_configinterface_terminate(void)</code>
Description	Termination entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_configinterface.h</a>

To illustrate how timing information might be listed for a multirate model, here are the **Entry-Point Functions** and **Inports** subsections for the model `rtwdemo_mrmtbb`. This multirate, discrete-time, multitasking model contains Inport blocks 1 and 2, which specify 1-second and 2-second sample times, respectively. The sample times are constrained to the specified times by the **Periodic sample time constraint** option on the **Solver** pane of the Configuration Parameters dialog box.

**Entry-Point Functions**Function: [rtwdemo\\_mrmtbb\\_initialize](#)

Prototype	<b>void rtwdemo_mrmtbb_initialize(void)</b>
Description	Initialization entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_mrmtbb.h</a>

Function: [rtwdemo\\_mrmtbb\\_step0](#)

Prototype	<b>void rtwdemo_mrmtbb_step0(void)</b>
Description	Output entry point of generated code
Timing	Must be called periodically, every 1 second
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_mrmtbb.h</a>

Function: [rtwdemo\\_mrmtbb\\_step1](#)

Prototype	<b>void rtwdemo_mrmtbb_step1(void)</b>
Description	Output entry point of generated code
Timing	Must be called periodically, every 2 seconds
Arguments	None
Return value	None
Header file	<a href="#">rtwdemo_mrmtbb.h</a>

**Inports**

Block Name	Code Identifier	Data Type	Dimension
<a href="#">&lt;Root&gt;/In1_1s</a>	rtU.In1_1s	real_T	1
<a href="#">&lt;Root&gt;/In2_2s</a>	rtU.In2_2s	real_T	1

To illustrate how function arguments and return values are displayed in the report, here is the entry-point function description of the model step function for model `rtwdemo_fcncnprotctrl`.

Function: [rtwdemo\\_fcncnprotctrl\\_step\\_custom](#)

Prototype	<b>boolean_T rtwdemo_fcncnprotctrl_step_custom(const real_T argIn1, const BusObject *const argIn2, BusObject *argOut2, const BusObject *const argIn3, uint8_T *argIn4)</b>		
Description	Output entry point of generated code		
Timing	Can be called at any time		
Arguments	[-]		
	<b># Name</b>	<b>Data Type</b>	<b>Description</b>
	1 argIn1	const real_T	<a href="#">&lt;Root&gt;/In1</a>
	2 argIn2	const BusObject *const	<a href="#">&lt;Root&gt;/In2</a>
	3 argOut2	BusObject *	<a href="#">&lt;Root&gt;/Out2</a>
	4 argIn3	const BusObject *const	<a href="#">&lt;Root&gt;/In3</a>
	5 argIn4	uint8_T *	<a href="#">&lt;Root&gt;/In4</a>
Return value	<b>Data Type</b>	<b>Description</b>	
	<b>boolean_T</b>	<a href="#">&lt;Root&gt;/Out1</a>	
Header file	<a href="#">rtwdemo_fcncnprotctrl.h</a>		

## Interpreting the Inports and Outports Subsections

The **Inports** and **Outports** subsections of the code interface report provide the following interface information about each inport and output in the model.

Field	Description
<b>Block Name</b>	Displays the Simulink block name of the inport or output. If you selected the <b>Code-to-model</b> parameter for your model, you can click on each inport or output <b>Block Name</b> value to go to its location in the model display.
<b>Code Identifier</b>	Lists the identifier associated with the inport or output data in the generated code, as follows: <ul style="list-style-type: none"> <li>• If the data is defined in the generated code, the field displays the identifier text.</li> <li>• If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label 'Imported data:'.</li> <li>• If the data is neither defined nor declared in the generated code — for example, if model configuration parameter <b>Code interface packaging</b> is set to <b>Reusable function</b> — the field displays the text 'Defined externally'.</li> </ul>
<b>Data Type</b>	Lists the data type of the inport or output.
<b>Scaling</b>	For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation. <p><b>Note</b> You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).</p>
<b>Dimension</b>	Lists the dimensions of the inport or output (for example, 1 or [4, 5]).

For example, here are the **Inports** and **Outports** subsections for the model `rtwdemo_configinterface`.

### Inports

[ - ]

Block Name	Code Identifier	Data Type	Dimension
<a href="#">&lt;Root&gt;/In1</a>	Imported data: input1	MYTYPE	1
<a href="#">&lt;Root&gt;/In2</a>	Imported data: input2	MYTYPE	1
<a href="#">&lt;Root&gt;/In3</a>	Imported data: input3	MYTYPE	1
<a href="#">&lt;Root&gt;/In4</a>	Imported data: input4	MYTYPE	1

### Outports

Block Name	Code Identifier	Data Type	Dimension
<a href="#">&lt;Root&gt;/Out1</a>	output	MYTYPE	1

## Interpreting the Interface Parameters Subsection

The **Interface Parameters** subsection of the code interface report provides the following interface information about tunable parameters that are associated with the model.

Field	Description
<b>Parameter Source</b>	Lists the source of the parameter value, as follows: <ul style="list-style-type: none"> <li>If the source of the parameter value is a block, the field displays the block name, such as &lt;Root&gt;/Gain2 or &lt;S1&gt;/Lookup1. If you selected the <b>Code-to-model</b> parameter for your model, you can click the <b>Parameter Source</b> value to go to the parameter's location in the model display.</li> <li>If the source of the parameter value is a workspace variable, the field displays the name of the workspace variable.</li> </ul>
<b>Code Identifier</b>	Lists the identifier associated with the tunable parameter data in the generated code, as follows: <ul style="list-style-type: none"> <li>If the data is defined in the generated code, the field displays the identifier text.</li> <li>If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label 'Imported data:'.</li> <li>If the data is neither defined nor declared in the generated code — for example, if model configuration parameter <b>Code interface packaging</b> is set to Reusable function — the field displays the text 'Defined externally'.</li> </ul>
<b>Data Type</b>	Lists the data type of the tunable parameter.
<b>Scaling</b>	For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation. <p><b>Note</b> You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).</p>
<b>Dimension</b>	Lists the dimensions of the tunable parameter (for example, 1 or [4, 5, 6]).

For example, here is the **Interface Parameters** subsection for the model `rtwdemo_configinterface` (with the **ExportedGlobal Storage Class** button selected in the model window).

### Interface Parameters

[ - ]

Parameter Source	Code Identifier	Data Type	Dimension
synthesized block	Table1	const volatile Table1_Type	1
synthesized block	Table2	const volatile Table2_Type	1
synthesized block	K1	const volatile int8_T	1

## Interpreting the Data Stores Subsection

The **Data Stores** subsection of the code interface report provides the following interface information about global data stores and data stores with non-auto storage that are associated with the model.

Field	Description
<b>Data Store Source</b>	Lists the source of the data store memory, as follows: <ul style="list-style-type: none"> <li>If the data store is defined using a Data Store Memory block, the field displays the block name, such as &lt;Root&gt;/DS1. If you selected the <b>Code-to-model</b> parameter for your model, you can click on the <b>Data Store Source</b> value to go to the data store's location in the model display.</li> <li>If the data store is defined using a Simulink.Signal object, the field displays the name of the Simulink.Signal object.</li> </ul>
<b>Code Identifier</b>	Lists the identifier associated with the data store data in the generated code, as follows: <ul style="list-style-type: none"> <li>If the data is defined in the generated code, the field displays the identifier text.</li> <li>If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label 'Imported data:'.</li> <li>If the data is neither defined nor declared in the generated code — for example, if model configuration parameter <b>Code interface packaging</b> is set to Reusable function — the field displays the text 'Defined externally'.</li> </ul>
<b>Data Type</b>	Lists the data type of the data store.
<b>Scaling</b>	For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation. <p><b>Note</b> You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).</p>
<b>Dimension</b>	Lists the dimensions of the data store (for example, 1 or [1, 2]).

For example, here is the **Data Stores** subsection for the model `rtwdemo_configinterface` (with the **ExportedGlobal Storage Class** button selected in the model window).

### Data Stores

Data Store Source	Code Identifier	Data Type	Dimension
<a href="#">&lt;Root&gt;/Data Store Memory</a>	mode	volatile boolean_T	1

## Code Interface Report Limitations

The following limitations apply to the code interface section of the HTML code generation reports.

- The code interface report does not support the GRT interface with an ERT target or **C++ class** code interface packaging. For these configurations, the code interface report is not generated and does not appear in the HTML code generation report **Contents** pane.
- The code interface report supports data resolved with most storage classes, except when the storage class properties are set in any of the following ways:
  - The storage class property **Type** is set to **FlatStructure**. For example, the **BitField** and **Struct** storage classes in the Simulink package have **Type** set to **FlatStructure**.
  - The storage class property **Type** is set to **Other**. For example, the **GetSet** storage class in the Simulink package has **Type** set to **Other**.
  - The storage class property **Data access** is set to **Pointer**, indicating that imported symbols are declared as pointer variables rather than simple variables. This property is accessible only when the storage class property **Data scope** is set to **Imported** or **Instance-specific**.

In these cases, the report displays empty **Data Type** and **Dimension** fields.

- For outputs, the code interface report cannot describe the associated memory (data type and dimensions) if the memory is optimized. In these cases, the report displays empty **Data Type** and **Dimension** fields.
- The code interface report does not support data type replacement using the **Code Generation > Data Type Replacement** pane of the Configuration Parameters dialog box. The data types listed in the report will link to built-in data types rather than their specified replacement data types.

## Static Code Metrics

### In this section...

“Static Code Metrics” on page 51-23

“Static Code Metrics Analysis” on page 51-23

“View Static Code Metrics and Definitions Within the Generated Code” on page 51-25

“Static Code Metrics Report Limitations” on page 51-25

### Static Code Metrics

The code generator performs static analysis on page 51-23 of the generated C or C++ code and provides these metrics in the **Static Code Metrics Report** section of the HTML Code Generation Report. When you place your cursor over a function or a variable in the generated code, you can also see metrics.

You can use the information in the report to:

- Find the number of files and lines of code in each file.
- Estimate the number of lines of code and stack usage per function.
- Compare the difference in terms of how many files, functions, variables, and lines of code are generated every time you change the model or MATLAB algorithm.
- Determine a target platform and allocation of RAM to the stack, based on the size of global variables plus the estimated stack size.
- Determine possible performance slow points, such as the largest global variables or the most costly call path in terms of stack usage.
- View the cyclomatic complexity of a function, which counts the number of linearly independent paths through a function.
- View the function call tree. Determine the longest call path to estimate the worst case execution timing.
- View how target functions, provided by the selected code replacement library, are used in the generated code.

For examples, see:

- “Generate Static Code Metrics Report for Simulink Model” on page 51-26
- “Generating a Static Code Metrics Report for Code Generated from MATLAB Code” on page 51-30

### Static Code Metrics Analysis

Static analysis of the generated code is performed only on the source code without executing the program. The results of the static code metrics analysis are included in the **Static Code Metrics** section of the HTML Code Generation Report. The report is not available if you generate a MEX function from MATLAB code.

Static analysis of the generated source code files:

- Uses the specified C data types. For Simulink models, you specify these data types in the **Hardware Implementation > Production hardware** pane of the Configuration Parameters dialog box. For code generation from MATLAB code, you specify them in the **Hardware** tab of the MATLAB Coder project settings dialog box or using a code generation configuration object. Actual object code metrics might differ due to target-specific compiler and platform settings.
- Includes custom code only if you specify it. For Simulink models, you specify custom code on the **Code Generation > Custom Code** pane in the model configuration. For code generation from MATLAB code, you specify it on the **Debugging** tab of the MATLAB Coder project settings dialog box or using a code generation configuration object. An error report is generated if the generated code includes platform-specific files not contained in the standard C run-time library.
- For Simulink models, includes the generated code from referenced models.
- Uses 1-byte alignment for all members of a structure for estimating global and local data structure sizes. The size of a structure is calculated by summing the sizes of all of its fields. This estimation represents the smallest possible size for a structure.
- Calculates the self stack size of a function as the size of local data within a function, excluding input arguments. The accumulated stack size of a function is the self stack size plus the maximum of the accumulated stack sizes of its called functions. For example, if the accumulated stacks sizes for the called functions are represented as `accum_size1...accum_sizeN`, then the accumulated stack size for a function is

$$\text{accumulated\_stack\_size} = \text{self\_stack\_size} + \max(\text{accum\_size1}, \dots, \text{accum\_sizeN})$$

For example consider this piece of generated code:

```
/* Real-time model */
RT_MODEL rtM_;
RT_MODEL *const rtM = &rtM_;
static void Debug_b(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T
 rtd_A[6], real_T rtd_B[6]);
```

Now consider the code metrics shown below:

Static Code Metrics reported stack sizes

Function Name	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code
(-) local_demo_step	12	0	1
Debug_b	12	12	6
local_demo_initialize	0	0	0

The accumulated stack size is 12 bytes because the self stack size of the function `Debug_b` is 12 bytes and the 4 input arguments do not contribute to the calculation of accumulated stack size.

- When estimating the stack size of a function, static analysis stops at the first instance of a recursive call. The **Function Information** table indicates when recursion occurs in a function call path. Code generation generates only recursive code for Stateflow event broadcasting and for graphical functions if it is written as a recursive function.
- Calculates the cyclomatic complexity of a function as the number of decisions plus one:

$$CC = \text{Number of decisions} + 1$$

The following constructs add a decision:

- If statement
- Else-If statement
- Switch statement (1 decision for each case branch)
- Loop statements: While, For, Do-while

---

**Note** Boolean operators in the preceding constructs do not add extra decisions.

---

- Does not include `ert_main.c`, because you have the option to provide your own `main.c`.

## View Static Code Metrics and Definitions Within the Generated Code

When you view code in the Code view or in the code generation report, place your cursor over the global variables and functions to see code metrics information.

```

44
45 /* D Integrator' */
46 if (Integrator_PrevResetState != 0)) {
47 | rt rtDWork;
48 |
49 |
50 if (rtDWork.Integrator_DSTATE >= 5.0) {
51 | rtDWork.Integrator_DSTATE = 5.0;
52 | } else if (rtDWork.Integrator_DSTATE <= -5.0) {
53 | rtDWork.Integrator_DSTATE = -5.0;
54 | }

```

The tooltip provides a link to the definition for the variable or function.

```

21 /* Block signals and states (default storage) */
22 D_work rtDWork;
23
24 /* External inputs (root inport signals with default storage) */
25 ExternalInputs rtU;

```

## Static Code Metrics Report Limitations

Static code metrics are not available if the target configuration for a model results in generated code that:

- Includes a header file that is not generated by the model hierarchy and is not a system header file
- Uses a macro that is not recognized

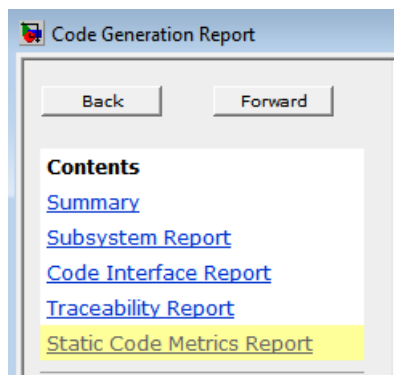

## Generate Static Code Metrics Report for Simulink Model

The **Static Code Metrics Report** is a section included in the HTML Code Generation Report. For more information on the static analysis of the generated code, see “Static Code Metrics Analysis” on page 51-23.

- 1 To generate the static code metrics report in the HTML Code Generation Report, open the Configuration Parameters dialog box for your model. On the **Code Generation > Report** pane, select the “Generate static code metrics” check box. If your model includes referenced models, select the **Generate static code metrics** check box in each referenced model’s configuration set. Otherwise, you cannot view a separate static code metrics report for a referenced model.

Alternatively, after you generate code, generate only the static code metrics report by using the function `coder.report.generateCodeMetrics`.

- 2 Press **Ctrl+B** to build your model and generate the HTML code generation report. For more information, see “Generate Code Generation Report” on page 51-5.
- 3 If the HTML Code Generation Report is not already open, open the report. On the left navigation pane, in the **Contents** section, select **Static Code Metrics Report**.

If you generated only the static code metrics report, open the report. By default, the static code metrics report file `metrics.html` is generated in the current folder.

- 4 To see the generated files and how many lines of code are generated per file, look at the **File Information** section.

**1. File Information** [\[hide\]](#)

[-] Summary (excludes ert\_main.c)

Number of .c files : 2  
 Number of .h files : 4  
 Lines of code : 1,132  
 Lines : 1,958

[-] File details

File Name	Lines of Code	Lines	Generated On
<a href="#">fuel_rate_control.c</a>	665	1,107	06/10/2016 4:17 PM
<a href="#">fuel_rate_control_data.c</a>	253	342	06/10/2016 4:17 PM
<a href="#">rtwtypes.h</a>	97	177	06/10/2016 4:17 PM
<a href="#">fuel_rate_control.h</a>	88	249	06/10/2016 4:17 PM
<a href="#">fuel_rate_control_types.h</a>	22	52	06/10/2016 4:17 PM
<a href="#">fuel_rate_control_private.h</a>	7	31	06/10/2016 4:17 PM

- 5 Hover your cursor over column titles and some column values to see a description of the corresponding data.
- 6 If your model includes referenced models, the File information section includes a **Referenced Model** column. In this column, click the referenced model name to open its static code metrics report. If the static code metrics report is not available for a referenced model, specify the **Generate static code metrics** parameter in the referenced model's configuration set and rebuild your model.
- 7 To view the global variables in the generated code, their size, and the number of accesses, see the **Global Variables** section.

**2. Global Variables** [\[hide\]](#)

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[+] <a href="#">fuel_rate_control_DW</a>	23	175	78
[+] <a href="#">fuel_rate_control_B</a>	21	42	26
[+] <a href="#">fuel_rate_control_U</a>	16	27	24
[+] <a href="#">fuel_rate_control_M</a>	8	0*	0*
[+] <a href="#">fuel_rate_control_Y</a>	4	4	3
<b>Total</b>	<b>72</b>	<b>248</b>	

\* The global variable is not directly used in any function.

The **Reads/Writes** column displays the total number of read and write accesses to the global variable. The **Reads/Writes in a Function** column displays the maximum number of read and write accesses to the global variable within a function. You use this information to estimate the benefit of turning on optimizations, which reduce the number of global references. For more information, see "Optimize Global Variable Usage" on page 73-2.

Click [+] to expand structures.

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
<a href="#">[-] fuel_rate_control_DW</a>	23	175	78
DiscreteIntegrator_DSTATE	4	5	4
ThrottleTransient_states	4	4	3
DiscreteFilter_states	4	4	3

fuel_rate	4	4	3
<b>Total</b>	<b>72</b>	<b>248</b>	

\* The global variable is not directly used in any function.

- 8 To navigate from the report to the source code, click a global variable or function name. These names are hyperlinks to their definitions.
- 9 To view the function call tree of the generated code, in the **Function Information** section, click **Call Tree** at the top of the table.

### 3. Function Information [\[hide\]](#)

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View: Call Tree | [Table](#)

Function Name	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
<a href="#">[-] fuel_rate_control_step</a>	52	16	272	504	43
<a href="#">.look2_iff_linlca</a>	36	36	55	100	12
<a href="#">[-] fuel_rate_control_Fail</a>	4	4	67	103	13
<a href="#">fuel_rate_control_Fueling_Mode</a>	0	0	166	240	19
<a href="#">fuel_rate_control_Fueling_Mode</a>	0	0	166	240	19
<a href="#">[+] fuel_rate_control_initialize</a>	0	0	43	67	1
<a href="#">fuel_rate_control_terminate</a>	0	0	0	4	1

ert\_main.c is not included in the code metrics analysis, therefore it is not shown in the call tree format. The **Complexity** column includes the cyclomatic complexity of each function.

- 10 To view the functions in a table format, click **Table**.

### 3. Function Information [\[hide\]](#)

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View: [Call Tree](#) | [Table](#)

Function Name	Called By (number of call sites)	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
<a href="#">fuel_rate_control_Fail</a>	<a href="#">fuel_rate_control_step</a> (9)	4	4	67	103	13
<a href="#">fuel_rate_control_Fueling_Mode</a>	<a href="#">fuel_rate_control_step</a> <a href="#">fuel_rate_control_Fail</a> (2)	0	0	166	240	19
<a href="#">fuel_rate_control_initialize</a>		0	0	43	67	1
<a href="#">fuel_rate_control_step</a>		52	16	272	504	43
<a href="#">fuel_rate_control_terminate</a>		0	0	0	4	1
<a href="#">look2_iff_linlca</a>	<a href="#">fuel_rate_control_step</a> (5)	36	36	55	100	12
memset	<a href="#">fuel_rate_control_initialize</a> (2)	<i>Not available</i>	-	-	-	-

The second column, **Called By**, lists functions that call the function listed in the first column, using the following criteria:

- If a function is called by multiple functions, all functions are listed.
- If a function has no called function, this column is empty.

For example, `Fueling_Mode` is called by `Fail` and `fuel_rate_control_step`. The number of call sites is included in parentheses. `Fail` calls `Fueling_Mode` twice.

### More About

- “Static Code Metrics Analysis” on page 51-23
- “Reports for Code Generation” on page 51-2
- “Generate Code Generation Report” on page 51-5
- “Generate Code Generation Report Programmatically” on page 51-7

## Generating a Static Code Metrics Report for Code Generated from MATLAB Code

The static code metrics report contains the results of static analysis of the generated C/C++ code, including generated file information, number of lines, and memory usage. For more information, see “Static Code Metrics” on page 51-23. To produce a static code metrics report, you must use Embedded Coder to generate standalone C/C++ code and produce a code generation report. See “Code Generation Reports”.

By default, static code metrics analysis does not run at code generation time. Instead, if and when you want to run the analysis and view the results, click **Code Metrics** on the **Summary** tab of the code generation report.

### Example Static Code Metrics Report

This example runs static code metrics analysis and examines a static code metrics report.

Create the example function `averaging_filter`.

```
function y = averaging_filter(x) %#codegen
% Use a persistent variable 'buffer' that represents a sliding window of
% 16 samples at a time.
persistent buffer;
if isempty(buffer)
 buffer = zeros(16,1);
end
y = zeros(size(x), class(x));
for i = 1:numel(x)
 % Scroll the buffer
 buffer(2:end) = buffer(1:end-1);
 % Add a new sample value to the buffer
 buffer(1) = x(i);
 % Compute the current average value of the window and
 % write result
 y(i) = sum(buffer)/numel(buffer);
end
```

Create sample data.

```
v = 0:0.00614:2*pi;
x = sin(v) + 0.3*rand(1,numel(v));
```

Enable production of a code generation report by using a configuration object for standalone code generation (static library, dynamically linked library, or executable program).

```
cfg = coder.config('lib', 'ecoder', true);
cfg.GenerateReport=true;
```

Alternatively, use the `codegen -report` option.

Generate code by using `codegen`. Specify the type of the input argument by providing an example input with the `-args` option. Specify the configuration object by using the `-config` option.

```
codegen averaging_filter -config cfg -args {x}
```

To open the code generation report, click **View report**.

To run the static code metrics analysis and view the code metrics report, on the **Summary** tab of the code generation report, click **Code Metrics**.

Explore the code metrics report.

- 1 To see the generated files and the number of lines of code per file, click **File Information**.

averaging\_filter.m Code Metrics x

**1. File Information** [\[hide\]](#)

[ - ] Summary

Number of .c files : 3  
 Number of .h files : 5  
 Lines of code : 86  
 Lines : 281

[ - ] File details

File Name	Lines of Code	Lines
<a href="#">averaging_filter.c</a>	24	65
<a href="#">rtwtypes.h</a>	22	46
<a href="#">averaging_filter.h</a>	9	30
<a href="#">averaging_filter_initialize.h</a>	8	29
<a href="#">averaging_filter_terminate.h</a>	8	29
<a href="#">averaging_filter_initialize.c</a>	6	30
<a href="#">averaging_filter_terminate.c</a>	5	30
<a href="#">averaging_filter_types.h</a>	4	22

- 2 To see the global variables in the generated code, go to the **Global Variables** section.

**2. Global Variables** [\[hide\]](#)

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
<a href="#">buffer</a>	128	5	4
<b>Total</b>	<b>128</b>	<b>5</b>	

To navigate from the report to the source code, click a global variable name.

- 3 To view the function call tree of the generated code, in the **Function Information** section, click **Call Tree**.

**3. Function Information** [\[hide\]](#)

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View: [Call Tree](#) | [Table](#)

Function Name	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
[ - ] <a href="#">averaging_filter</a>	136	136	14	24	3
<a href="#">double_to_uint64_helper</a>	8	8	6	8	1
[ + ] <a href="#">averaging_filter_initialize</a>	0	0	1	4	1
<a href="#">averaging_filter_terminate</a>	0	0	0	4	1

To navigate from the report to the function code, click a function name.

- 4 To view the functions in a table format, click **Table**.

**3. Function Information** [\[hide\]](#)

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View: [Call Tree](#) | [Table](#)

Function Name	Called By (number of call sites)	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
<a href="#">averaging_filter</a>		136	136	14	24	3
<a href="#">averaging_filter_init</a>	<a href="#">averaging_filter_initialize</a>	0	0	1	4	1
<a href="#">averaging_filter_initialize</a>		0	0	1	4	1
<a href="#">averaging_filter_terminate</a>		0	0	0	4	1

The second column, **Called By**, lists functions that call the function listed in the first column. If multiple functions call that function, all functions are listed. If no functions call that function, this column is empty.

## Requirements for Running Static Code Metrics Analysis After Code Generation

By default, static code metrics analysis does not run at code generation time. Instead, you can run the analysis later by clicking **Code Metrics** in the code generation report. Running static code metrics analysis after code generation has these requirements and limitations:

- You must have Embedded Coder and use the platform that you used for code generation. Once you run the static code metrics analysis, you can open the code metrics report without Embedded Coder or open it on a different platform.
- If you make the code generation report read-only before you run the analysis, each time that you click **Code Metrics**, the analysis runs.

## Running Static Code Metrics at Code Generation Time

If you want the code generator to run static code metrics analysis and produce the code metrics report at code generation time:

- In an Embedded Coder code generation configuration object, set `GenerateCodeMetricsReport` to `true`.
- In the MATLAB Coder app, on the **Debugging** tab, set **Static code metrics** to **Yes**.

## See Also

- “Code Generation Reports”

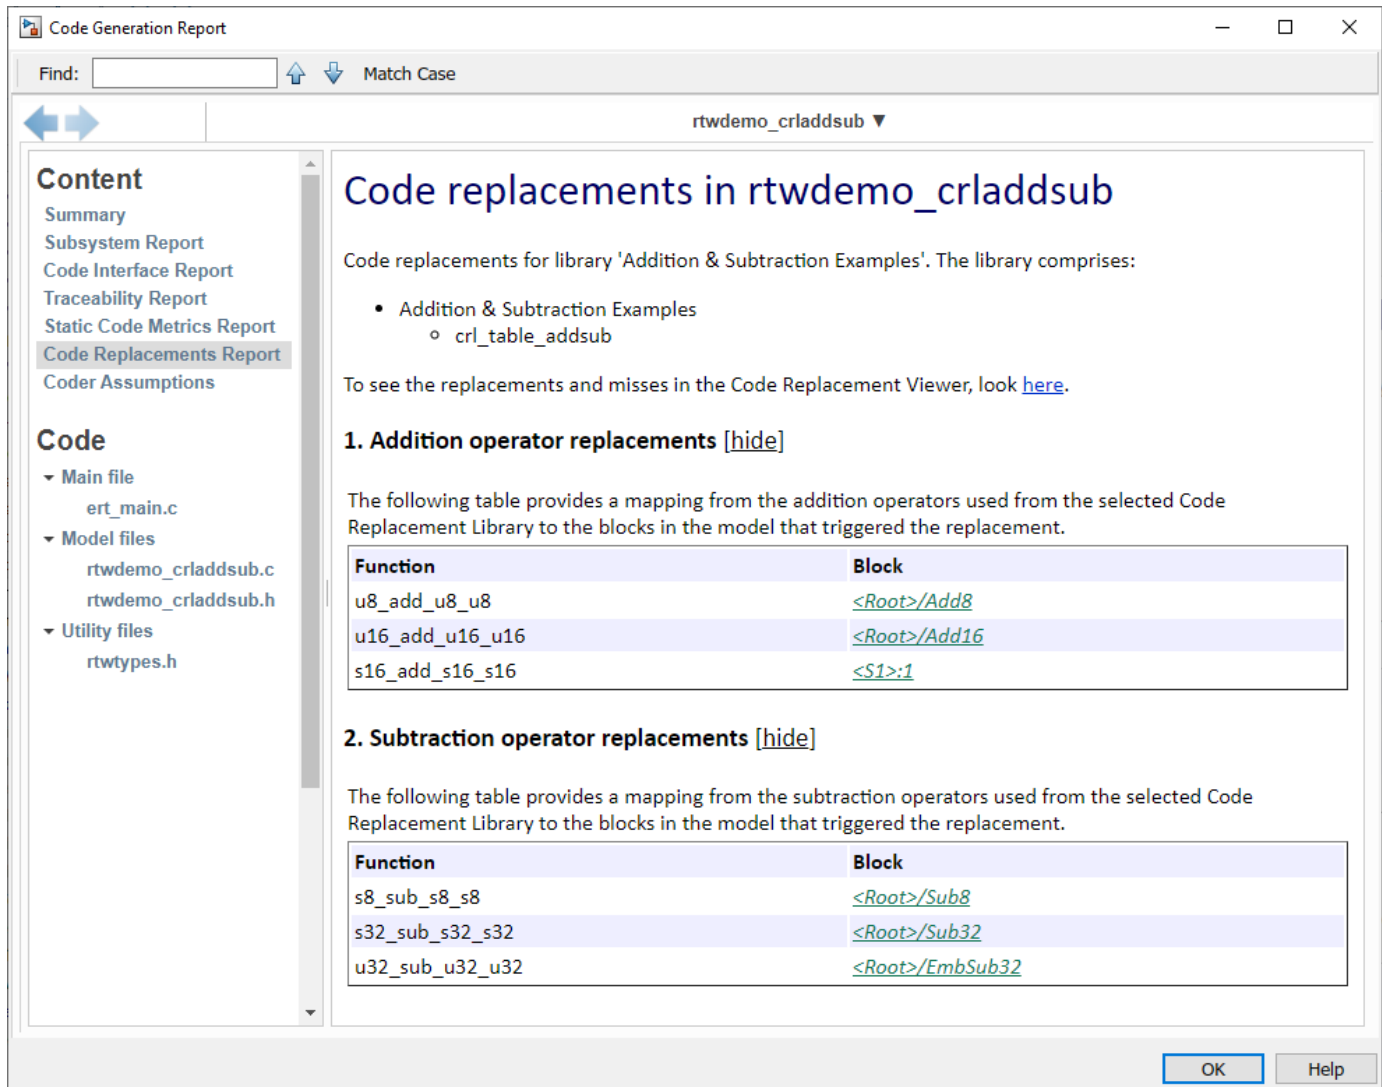

## Analyze Code Replacements in Generated Code

When you select the check box **Summarize which blocks triggered code replacements** for an ERT-based model, a Code Replacements Report section is automatically included in the generated HTML report. The Code Replacements Report section documents the SIMD instruction sets and code replacement library (CRL) functions that were used for code replacements during code generation, providing a mapping between each replacement instance and the Simulink block that triggered the replacement. To enable display of the Simulink block information, select the **Code Generation > Comments** check box **Include comments**. On the same pane, select either the **Simulink block comments** checkbox or the **Simulink block descriptions** check box if present, or both.

You can use the report to:

- Determine which replacement functions were used in the generated code.
- Trace each replacement instance back to the block that triggered the replacement.

The figure below shows a Code Replacements Report generated for the CRL model `rtwdemo_crladdsub`. Each replacement function used is listed with a link to the block that triggered the replacement.

If you click a block path in the report, the block that triggered the replacement is highlighted in the model diagram. If the replacement was triggered by a Stateflow chart or a MATLAB function, a window opens to display the chart or function.

For more information, see “Verify Code Replacement Library” on page 69-55.

## Document Generated Code with Simulink Report Generator

In this section...
“Generate Code for the Model” on page 51-35
“Open the Report Generator” on page 51-36
“Set Report Name, Location, and Format” on page 51-38
“Include Models and Subsystems in a Report” on page 51-39
“Customize the Report” on page 51-39
“Generate the Report” on page 51-40

The Simulink Report Generator software creates documentation from your model in multiple formats, including HTML, PDF, RTF, Microsoft Word, and XML. This example shows one way to document a code generation project in Microsoft Word. The generated report includes:

- System snapshots (model and subsystem diagrams)
- Block execution order list
- Simulink Coder and model version information for generated code
- List of generated files
- Optimization configuration parameter settings
- System target file selection and build process configuration parameter settings
- Subsystem map
- File name, path, and generated code listings for the source code

To adjust Simulink Report Generator settings to include custom code and then generate a report for a model, complete the following tasks:

- 1 “Generate Code for the Model” on page 51-35
- 2 “Open the Report Generator” on page 51-36
- 3 “Set Report Name, Location, and Format” on page 51-38
- 4 “Include Models and Subsystems in a Report” on page 51-39
- 5 “Customize the Report” on page 51-39
- 6 “Generate the Report” on page 51-40

A Simulink Report Generator license is required for the following report formats: PDF, RTF, Microsoft Word, and XML. For more information on generating reports in these formats, see the Simulink Report Generator documentation.

### Generate Code for the Model

Before you use the Report Generator to document your project, generate code for the model.

- 1 In the MATLAB Current Folder browser, navigate to a folder where you have write access.
- 2 Create a working folder from the MATLAB command line by typing:

```
mkdir report_ex
```

- 3 Make `report_ex` your working folder:

```
cd report_ex
```

- 4 Open the `slexAircraftExample` model. In the Command Window, enter:

```
openExample('slexAircraftExample')
```

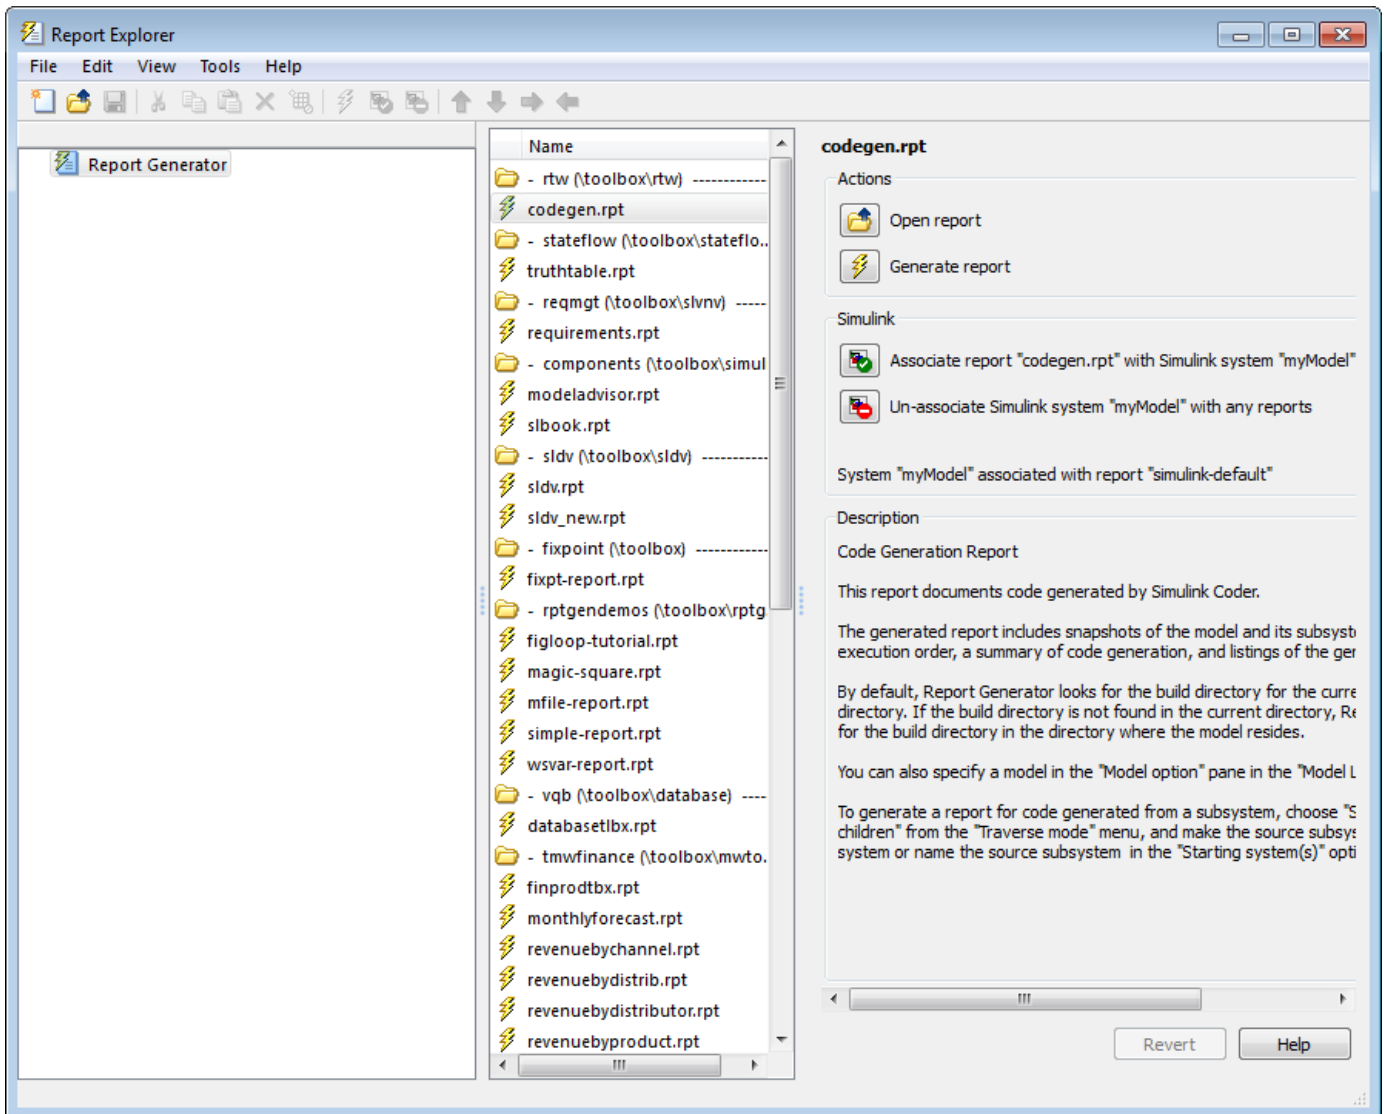

- 5 On the **Simulation** tab, in the **Save** list, select **Save as**. Navigate to the working folder, `report_ex`, and save a copy of the `slexAircraftExample` model as `myModel`.
- 6 Open the Configuration Parameters dialog box. Set the **Solver > Solver selection > Type** parameter to `Fixed-step`.
- 7 Select the **Code Generation** pane. Select **Generate code only**.
- 8 Click **Apply**.
- 9 In the model window, press **Ctrl+B**. The build process generates code for the model.

## Open the Report Generator

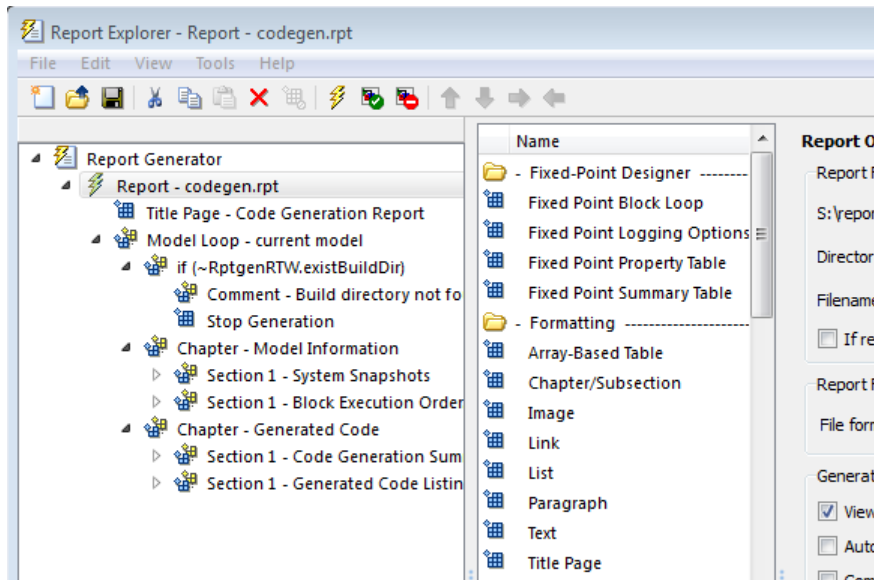

After you generate the code, open the Report Generator.

- 1 Open the Report Generator app. In the model diagram window, in the **Apps** gallery, click **Report Generator**.
- 2 In the Report Explorer window, in the options pane (center), click the folder **rtw (\toolbox\rtw)**. Click the setup file that it contains, **codegen.rpt**.

- 3 Double-click **codegen.rpt** or select it and click the **Open report** button. The Report Explorer displays the structure of the setup file in the outline pane (left).

## Set Report Name, Location, and Format

Before generating a report, you can specify report output options, such as the folder, file name, and format. For example, to generate a Microsoft Word report named `MyCGModelReport.rtf`:

- 1 In the properties pane, under **Report Options**, review the options listed.

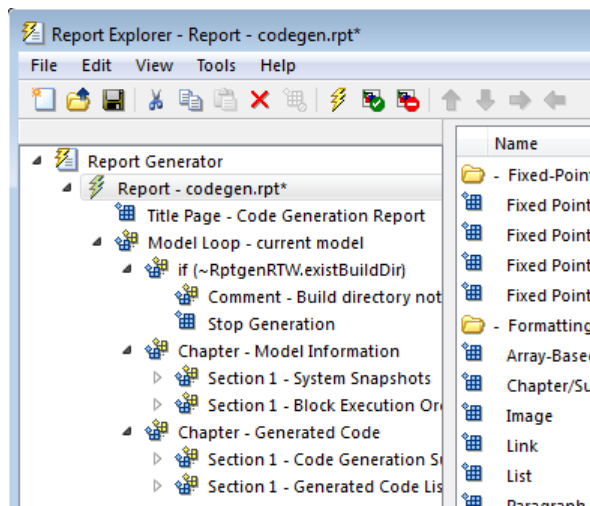

- 2 Leave the **Directory** field set to Present working directory.
- 3 For **Filename**, select Custom: and replace index with the name MyModelCGReport.
- 4 For **File format**, specify Rich Text Format and replace Standard Print with Numbered Chapters & Sections.

## Include Models and Subsystems in a Report

Specify the models and subsystems that you want to include in the generated report by setting options in the Model Loop component.

- 1 In the outline pane (left), select **Model Loop**. Report Generator displays Model Loop component options in the properties pane.
- 2 If not already selected, select Current block diagram for the **Model name** option.
- 3 In the outline pane, click **Report - codegen.rpt\***.

## Customize the Report

After specifying the models and subsystems to include in the report, you can customize the sections included in the report.

- 1 In the outline pane (left), expand the node **Chapter - Generated Code**. By default, the report includes two sections, each containing one of two report components.
- 2 Expand the node **Section 1 — Code Generation Summary**.
- 3 Select **Code Generation Summary**. Options for the component are displayed in the properties pane.
- 4 Click **Help** to review the report customizations that you can make with the Code Generation Summary component. For this example, do not customize the component.
- 5 In the Report Explorer window, expand the node **Section 1 — Generated Code Listing**.
- 6 Select **Import Generated Code**. Options for the component are displayed in the properties pane.
- 7 Click **Help** to review the report customizations that you can make with the Import Generated Code component.

## Generate the Report

After you adjust the report options, from the **Report Explorer** window, generate the report by clicking **File > Report**. A **Message List** dialog box opens, which displays messages that you can monitor as the report is generated. Model snapshots also appear during report generation. The **Message List** dialog box might be hidden behind other dialog boxes.

When the report is complete, open the report, `MyModelCGReport.rtf` in the folder `report_ex` (in this example).

## Get Code Description of Generated Code

You can use the code descriptor API to obtain meta-information about the generated code. For each model build, the code generator, by default, creates a `codedescriptor.dmr` file in the build folder. When simulating the model in Accelerator and Rapid Accelerator modes, the `codedescriptor.dmr` is not generated.

You can use the code descriptor API once the code is generated. Use the code descriptor API to describe these items in the generated code:

- Data Interfaces: inports, outports, parameters, data stores, and internal data.
- Function Interfaces: initialize, output, update, and terminate.
- Run-time information of the data and function interfaces, such as timing requirements of each interface entity.
- Model hierarchy information and code description of referenced models.

### Get Data Interface Information

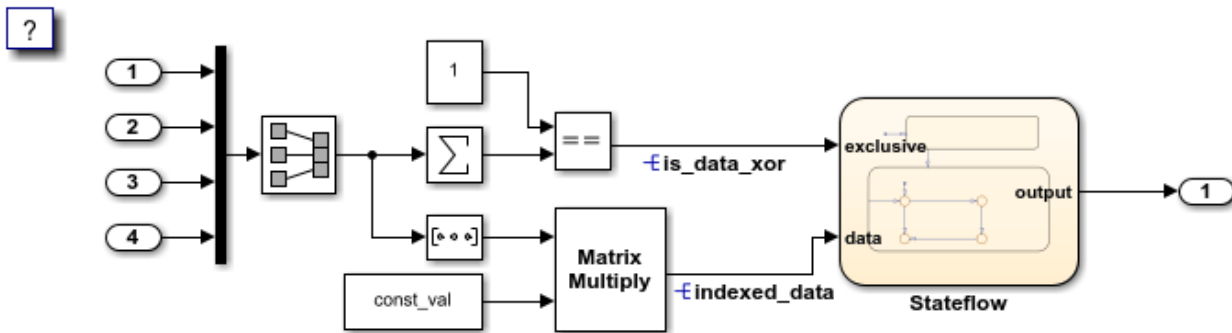

The `coder.descriptor.DataInterface` object describes various properties for a specified data interface in the generated code. In the model `rtwdemo_comments`, there are four inports, one outport, and a tunable external parameter. For more information about the data interfaces in your model, use the `coder.codedescriptor.CodeDescriptor` object and its methods.

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

2. Open and build the model.

```
open_system('rtwdemo_comments');
evalc('slbuild(''rtwdemo_comments'')');
```

Generate Code Using  
Embedded Coder  
(double-click)

DOC  
Text  
History

Copyright 1994-2020 The MathWorks, Inc.

3. Create a `coder.codedescriptor.CodeDescriptor` object for the required model by using the `getCodeDescriptor` function.

```
codeDescriptor = coder.getCodeDescriptor('rtwdemo_comments');
```

4. To obtain a list of all the data interface types in the generated code, use the `getDataInterfaceTypes` method.

```
dataInterfaceTypes = codeDescriptor.getDataInterfaceTypes()
```

```
dataInterfaceTypes =
```

```
5x1 cell array
```

```
{'Inports' }
{'Outports' }
{'Parameters' }
{'ExternalParameterObjects'}
{'InternalData' }
```

To obtain a list of all the supported data interfaces, use the `getAllDataInterfaceTypes` method.

5. To obtain more information about a particular data interface type, use the `getDataInterfaces` method.

```
dataInterface = codeDescriptor.getDataInterfaces('Inports');
```

This method returns properties of the Inport blocks in the generated code.

6. Because this model has four inports, `dataInterface` is an array of `coder.descriptor.DataInterface` objects. Obtain the details of the first Inport of the model by accessing the first location in the array.

```
dataInterface(1)
```

```
ans =
```

```
DataInterface with properties:
 Type: [1x1 coder.descriptor.types.Type]
 SID: 'rtwdemo_comments:99'
 GraphicalName: 'In1'
 VariantInfo: [1x0 coder.descriptor.VariantInfo]
 Implementation: [1x1 coder.descriptor.DataImplementation]
 Timing: [1x1 coder.descriptor.TimingInterface]
 Unit: ''
 Range: [1x0 coder.descriptor.Range]
```

### Get Function Interface Information

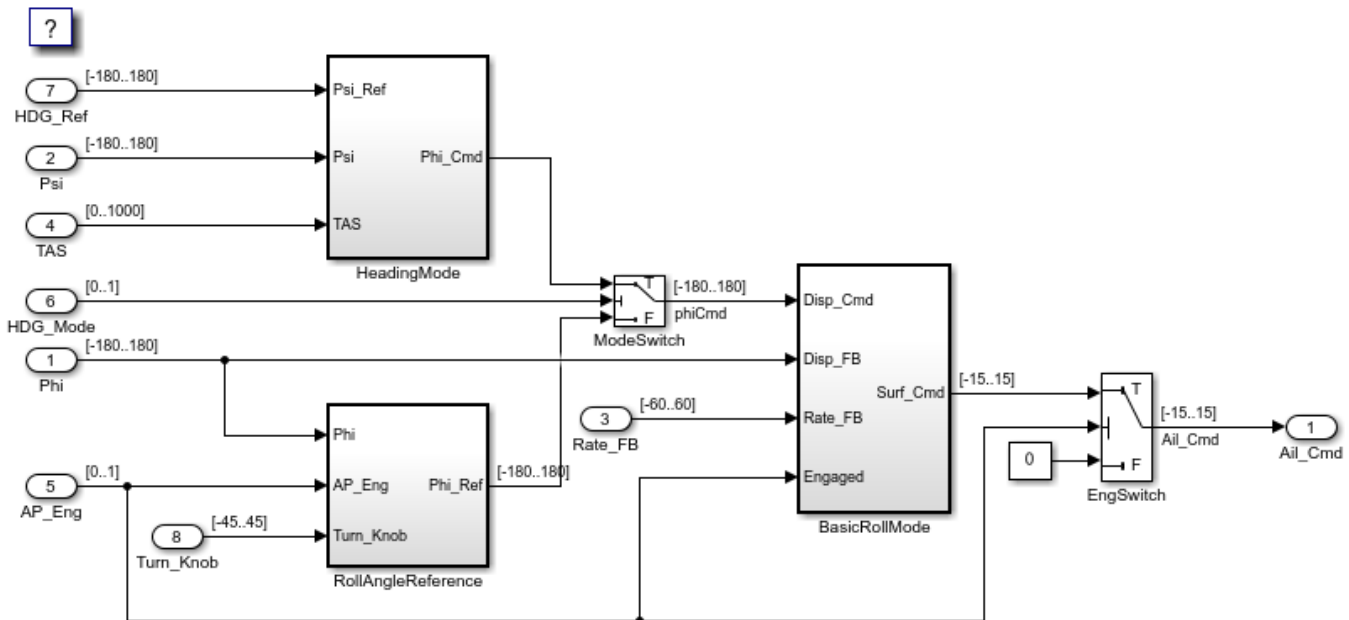

The function interfaces are the entry-point functions in the generated code. In the model `rtwdemo_roll`, the entry-point functions are `model_initialize`, `model_step`, and `model_terminate`. For more information about the function interfaces in your model, use the `coder.descriptor.FunctionInterface` object.

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

2. Open and build the model.

```
open_system('rtwdemo_roll');
evalc('slbuild(''rtwdemo_roll'')');
```

Copyright 1990-2020 The MathWorks, Inc.

3. Create a `coder.codeDescriptor.CodeDescriptor` object for the required model by using the `getCodeDescriptor` function.

```
codeDescriptor = coder.getCodeDescriptor('rtwdemo_roll');
```

4. To obtain a list of all the function interface types in the generated code, use the `getFunctionInterfaceTypes` method.

```
functionInterfaceTypes = codeDescriptor.getFunctionInterfaceTypes()
```

```
functionInterfaceTypes =
```

```
2x1 cell array
```

```
 {'Initialize'}
 {'Output' }
```

To obtain a list of all the supported function interfaces, use the `getAllFunctionInterfaceTypes` method.

5. To obtain more information about a particular function interface type, use the `getFunctionInterfaces` method.

```
functionInterface = codeDescriptor.getFunctionInterfaces('Initialize')
```

```
functionInterface =
```

```
FunctionInterface with properties:
 Prototype: [1x1 coder.descriptor.types.Prototype]
```

```

ActualReturn: [1x0 coder.descriptor.DataInterface]
VariantInfo: [1x0 coder.descriptor.VariantInfo]
FunctionOwner: [1x0 coder.descriptor.TypedRegion]
 Timing: [1x1 coder.descriptor.TimingInterface]
ActualArgs: [1x0 coder.descriptor.DataInterface Sequence]

```

6. You can further expand on the properties to obtain detailed information. To get the function return value, name, and arguments:

```
functionInterface.Prototype
```

```
ans =
```

```

Prototype with properties:
 Name: 'rtwdemo_roll_initialize'
 Return: [1x0 coder.descriptor.types.Argument]
 HeaderFile: 'rtwdemo_roll.h'
 SourceFile: 'rtwdemo_roll.c'
 Arguments: [1x0 coder.descriptor.types.Argument Sequence]

```

### Get Model Hierarchy Information

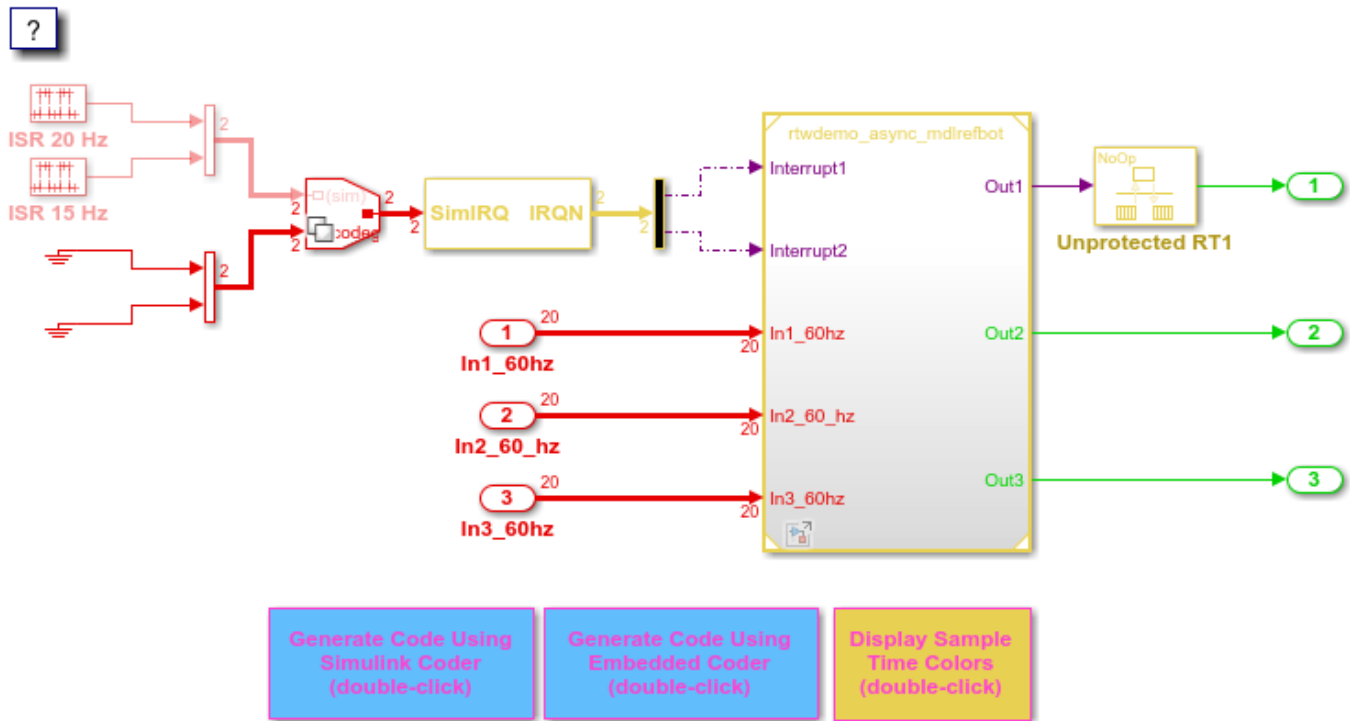

Use the `coder.codedescriptor.CodeDescriptor` object to get the entire model hierarchy information. The model `rtwdemo_async_mdltreftop` has model `rtwdemo_async_mdltreftop` as the referenced model.

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

2. Open and build the model.

```
open_system('rtwdemo_async_mdltreftop');
evalc('slbuild(''rtwdemo_async_mdltreftop'')');
```

Copyright 2010-2020 The MathWorks, Inc.

3. Create a `coder.CodeDescriptor` object for the required model by using the `getCodeDescriptor` function.

```
codeDescriptor = coder.getCodeDescriptor('rtwdemo_async_mdrefbot');
```

4. Get a list of all the referenced models by using the `getReferencedModelNames` method.

```
refModels = codeDescriptor.getReferencedModelNames()
```

```
refModels =
```

```
1x1 cell array
```

```
 {'rtwdemo_async_mdrefbot'}
```

5. To obtain the `coder.CodeDescriptor` object for the referenced model, use the `getReferencedModelCodeDescriptor` method.

```
refCodeDescriptor = codeDescriptor.getReferencedModelCodeDescriptor('rtwdemo_async_mdrefbot');
```

You can now use the `refCodeDescriptor` object to obtain more information about the referenced model by using all the available methods in the Code Descriptor API.

## See Also

### Related Examples

- “Analyze the Generated Code Interface” on page 51-13
- `coder.codedescriptor.CodeDescriptor`
- “Get Generated Type and Name of Inport Structures” on page 51-48

## Get Generated Type and Name of Inport Structures

To obtain the generated type and name of inport and outport structures, use the code descriptor API. The code generator stores this information within a `DataImplementation` object field on a `DataInterface` object when it generates the code.

To interface your generated code with other components of your application, use the code descriptor API.

### Open and Build Model

Open the model.

```
open_system('rtwdemo_sum');
```

Copyright 2015-2018 The MathWorks, Inc.

Build the model.

```
evalc('slbuild(''rtwdemo_sum'')');
```

The generated code includes a structure representing the inports.

```
/* External inputs (root inport signals with default storage) */
ExtU rtU;
```

### Get Code Descriptor and Inport Structure Names and Types

Get the code descriptor object.

```
codeDescObj = coder.getCodeDescriptor('rtwdemo_sum')
```

```
codeDescObj =
```

```
CodeDescriptor with properties:
```

```
ModelName: 'rtwdemo_sum'
```

```
BuildDir: 'C:\TEMP\Bdoc22a_1891349_13144\ibC86E06\26\tp3a8018bf\simulinkcoder-ex78186698\rt'
```

Get the list of data interface types in the generated code.

```
dataInterfaceTypes = codeDescObj.getDataInterfaceTypes()
```

```
dataInterfaceTypes = 2x1 cell
 {'Inports' }
```

```
{'Outports'}
```

Get the `DataInterface` object that represents the inports.

```
inports = codeDescObj.getDataInterfaces('Inports')
```

```
inports =
 1x2 DataInterface array with properties:
```

```

 Type
 SID
 GraphicalName
 VariantInfo
 Implementation
 Timing
 Unit
 Range
```

Get the `Implementation` object that represents the first inport. In this example, the inports are each represented as a `StructExpression`, which is a subclass of `DataImplementation`.

```
impl = inports(1).Implementation
```

```
impl =
 StructExpression with properties:
 Type: [1x1 coder.descriptor.types.Type]
 BaseRegion: [1x1 coder.descriptor.TypedRegion]
 ElementIdentifier: 'In1'
 Variant: ''
```

Get the `Type` of the first inport. The `Type` of the inport is `real_T`.

```
implType = impl.Type
```

```
implType =
 Double with properties:
 Identifier: 'real_T'
 Name: 'double'
 ReadOnly: 0
 Volatile: 0
 WordLength: 64
 Signedness: 1
```

Get the `BaseRegion` of the first inport. `BaseRegion` represents the structure that contains the inport. The `BaseRegion` is `rtU`.

```
baseRegion = impl.BaseRegion
```

```
baseRegion =
 Variable with properties:
 Type: [1x1 coder.descriptor.types.Type]
 Identifier: 'rtU'
 VarOwner: 'rtwdemo_sum'
 StorageSpecifier: ''
```

Get the Type of the BaseRegion. The Type of the BaseRegion is ExtU.

```
baseRegionType = baseRegion.Type
```

```
baseRegionType =
 Struct with properties:
 Identifier: 'ExtU'
 Name: 'ExtU'
 ReadOnly: 0
 Volatile: 0
 Elements: [1x2 coder.descriptor.types.AggregateElement Sequence]
 Checksum: [1x0 Integer Sequence]
```

### **Close Model**

```
bdclose('all');
```

### More About

- “Model Configuration Parameters: Comments”

## Add Custom Comments for Variables in the Generated Code

To control code generation options for signals, states, and parameters in a model, you can create data objects in a workspace or data dictionary. You can generate comments in the code that help you to document the purpose and properties of the data in each object. Associate handwritten comments with each object, or write a function that generates comments based on the properties of the object.

For more information about data objects, see “Data Objects”.

### Embed Handwritten Comments for Signals or Parameters

To embed handwritten comments in the generated code near the definition of a signal, state, or parameter:

- 1 Open a Simulink model.

```
openExample('ex_param_array');
```

- 2 Create a data object to represent a signal, state, or parameter. You can use a data object from any package such as Simulink. For example, use a data object of the classes `Simulink.Signal` or `Simulink.Parameter`, which are defined in the package `Simulink`.

```
myParam = Simulink.Parameter(15.23);
```

- 3 In the model, under the **PREPARE** section select **Property Inspector**. Click the target Gain block. Set its parameter value to `myParam`.
- 4 Set the storage class of the data object so that optimizations do not eliminate the signal or parameter from the generated code. For example, use the storage class `ExportedGlobal`.

```
myParam.StorageClass = 'ExportedGlobal';
```

- 5 Set the **Description** property of the object. The description that you specify appears in the generated code as lines of comments.

```
myParam.Description = 'This parameter represents multiplication';
```

- 6 In the **Model Configuration Parameters** select **Simulink data object descriptions**.
- 7 Generate code from the model. In the code, the data object description appears near the definition of the corresponding variable.

```
/* Exported block parameters */
real_T myParam = 15.23; /* Variable: myParam
 * Referenced by: '<S1>/Gain'
 * This parameter represents multiplication.
 */
```

### Generate Dynamic Comments Based on Data Properties

You can generate dynamic comments that include the properties of a data object such as data type, units, and dimensions. If you change the properties of the data object in Simulink, the code generator maintains the accuracy of the comments. For example, this comment displays some of the property values for a data object named `MAP` for the Simulink model in the previous example:

- 1 Create a data object from the package `mpt` and apply a custom storage class to the object. The default storage class is the custom storage class `Global (Custom)`.

```
myParam = mpt.Parameter;
```

To generate dynamic comments, you must use a data object from the package `mpt` and you must apply a custom storage class to the object.

- 2 Write a MATLAB or TLC function that generates the comment text. For an example MATLAB function, see the function `matlabroot/toolbox/rtw/rtwdemos/rtwdemo_comments_mptfun.m`.

The function must accept three input arguments that correspond to `objectName`, `modelName`, and `request`. If you write a TLC file, you can use the library function `LibGetSLDataObjectInfo` to get the property values of the data object.

- 3 Save the function as a MATLAB file or a TLC file. Place the file in a folder that is on your MATLAB path.
- 4 In the **Model Configuration Parameters** select **Custom comments (MPT objects only)**.
- 5 Set **Custom comments function** to the name of the MATLAB file or TLC file that you created.
- 6 Generate code from the model. The comments that your function generates appear near the code that represents each data object.

```
/* Object: myParam - user description:
 DataType -- auto
 Units --
 CSC -- Global */
```

### Limitations

- To generate comments by using the **Custom comments (MPT objects only)** and **Custom comments function** options, you must create data objects from the package `mpt`. The data objects must use a custom storage class.
- Only the custom storage classes from the `mpt` package that create unstructured variables support the custom comments function.

## Add Global Comments in the Generated Code

### In this section...

“Use a Simulink DocBlock to Add a Comment” on page 52-5

“Use a Simulink Annotation to Add a Comment” on page 52-7

“Use Sorted Notes to Add Comments” on page 52-8

“Limitations” on page 52-9

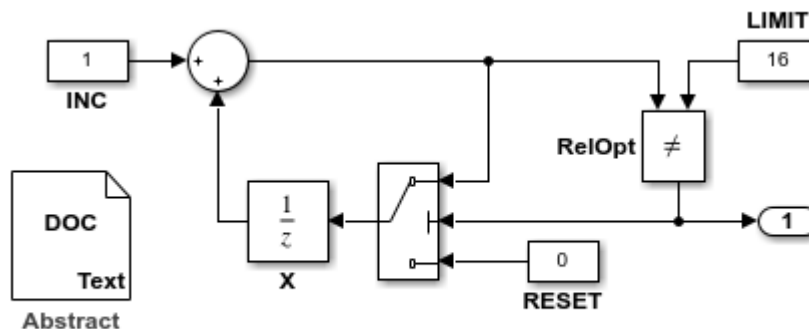

These examples show how to add a global comment to a Simulink model so that the comment text appears in the generated file or files. Specify a template symbol name with a Simulink DocBlock, a Simulink annotation, or a Stateflow note. You can also use a sorted-notes capability that works with Simulink annotations or Stateflow notes, but not DocBlocks. For more information about template symbols, see “Template Symbols and Rules” on page 52-80.

**Note** Template symbol names **Description** and **Model Information** are fields in the **Property Inspector** dialog box. If you use one of these symbol names for global comment text and its **Property Inspector** fields also has text in it, both names appear in the generated files.

### Use a Simulink DocBlock to Add a Comment

- 1 Open a Simulink model.

```
model='rtwdemo_codetemplate';
open_system(model)
```

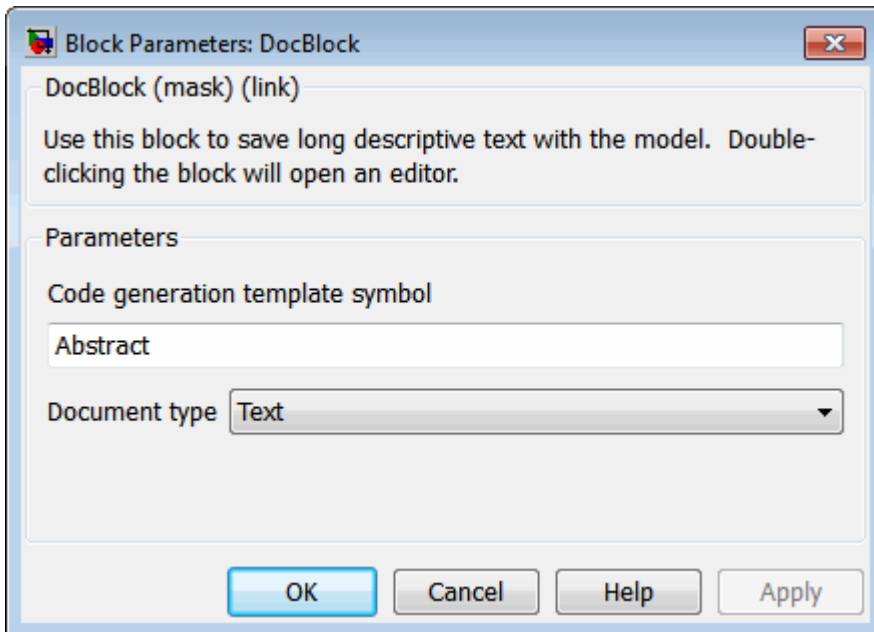

<S:Note>This Simulink annotation maps to the code template %<Note> symbol.

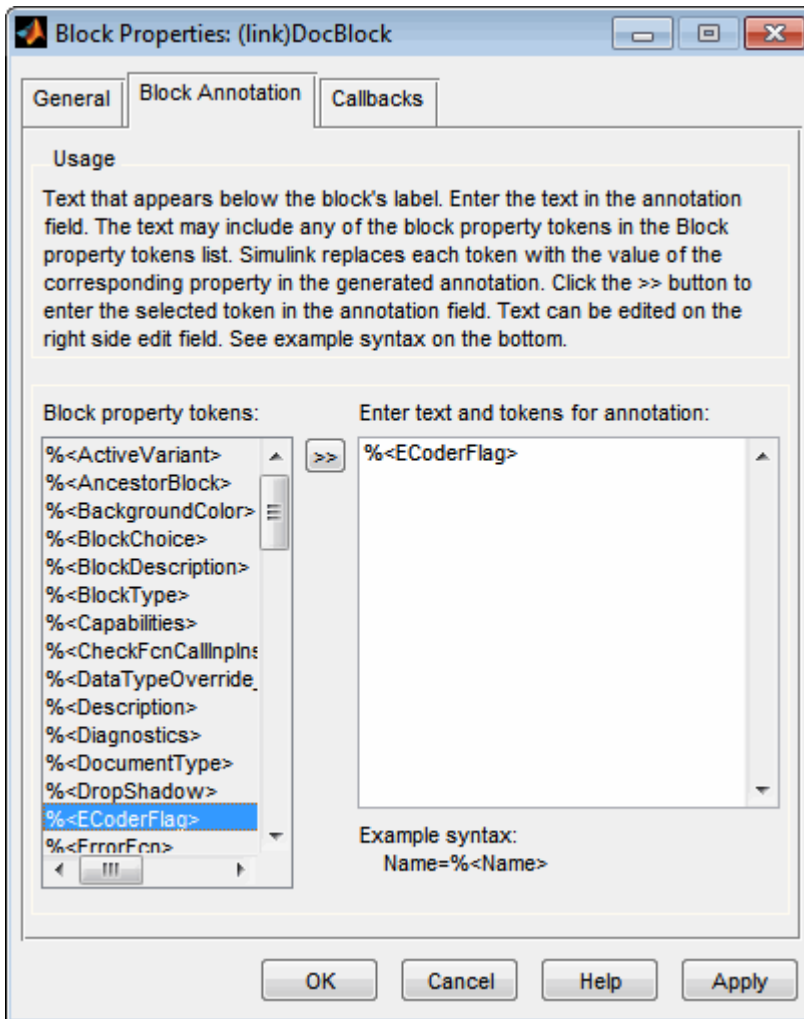

- 2 Under Configuration Parameters, set the **Code templates** to `rtwdemocodetemplate.cgt`. This code template contains the required customizations to generate global comments.
- 3 Right-click the DocBlock and select **Mask > Mask Parameters**.
- 4 In the **Code generation template symbol** box, type one of the following:
  - Abstract
  - Description
  - History
  - Notes

Click **OK**. Template symbol names are case-sensitive.

If you are using a DocBlock to add comments to your code, set the **Document type** to **Text**. If you set **Document type** to **RTF** or **HTML**, your comments do not appear in the code.

- 5 In the Block Properties dialog box, on the **Block Annotation** tab, select `%<ECoderFlag>` and click **OK**. The symbol name that you typed in the previous step now appears under the DocBlock in the model.

- 6 Save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you designated. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file.

The relevant fragment from the generated file for this model is:

```
*
* ABSTRACT:
* This text maps to the code template %<Abstract> symbol.
```

- 7 To add more comments to the generated files, repeat steps 2-6.

## Use a Simulink Annotation to Add a Comment

- 1 Open the model `rtwdemo_codetemplate`.
- 2 Double-click the unoccupied area on the model where you want to place the comment. See “Describe Models Using Notes and Annotations”.
- 3 Type `<S:Symbol_name>` followed by the comment. `Symbol_name` is one of the following:

- Abstract
- Description
- History
- Notes

For example, type `<S:Description>This is the description I want`. Template symbol names are case-sensitive. If you want the code generator to sort multiple comments for the **Notes** symbol name, replace the next step with “Use Sorted Notes to Add Comments” on page 52-8.

- 4 Click outside the annotation rectangle and save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you assigned. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file. If you want the code generator to sort multiple comments for the **Notes** symbol name, replace the next step with “Use Sorted Notes to Add Comments” on page 52-8.
- 5 To add one or more other comments to the generated files, repeat steps 2-4.

## Use Sorted Notes to Add Comments

The sorted-notes capability enables you to add sorted comments to the generated files. The code generator places these comments in each generated file at the location that corresponds to where the **Notes** symbol is located in the template file.

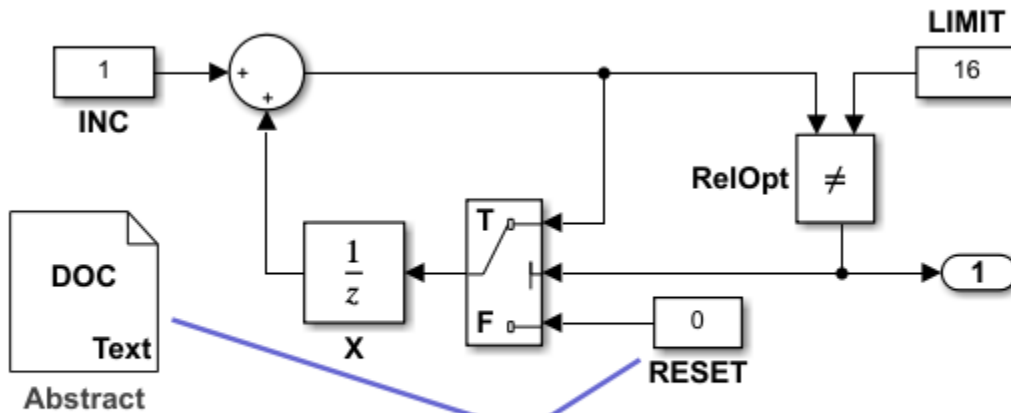

The code generator uses this sorting order:

- Numbers before letters.
- Among numbers, zero is placed first.
- Among letters, uppercase letters are placed before lowercase letters.

You can use sorted notes for a Simulink annotation or a Stateflow note, but not with a DocBlock.

- In the Simulink annotation or the Stateflow note, type `<S:NoteY>` followed by the first comment. Y is a number or a letter.
- Repeat this process for as many additional comments you want. Replace Y with a subsequent number or letter.

This figure illustrates sorted notes on a model. It shows where the code generator places each note in a generated file.

<S:Note>This Simulink annotation maps to the code template %<Note> symbol.

<S:Note1>Another Simulink annotation .

The relevant fragment from the generated file for this model is:

```
*
* NOTES:
* Note: This Simulink annotation maps to the code template %<Note> symbol.
* Note1: Another Simulink annotation .
*
```

## Limitations

You cannot generate global comments using template symbol names inside a Simulink DocBlock, when the **Language** for code generation is C++.

## Customize Generated Identifier Naming Rules

### In this section...

“Apply Naming Rules to Identifiers Globally” on page 52-10

“Apply Custom Naming Conventions to Identifiers” on page 52-11

For GRT and RSim targets, the code generator constructs identifiers for variables and functions in the generated code. For ERT targets, you can customize the naming of identifiers in the generated code by specifying parameters on the **Code Generation > Identifiers** pane in the Configuration Parameters dialog box. You can also specify parameters that control identifiers generated from Simulink data objects. For detailed information about these parameters, see “Model Configuration Parameters: Code Generation Identifiers”.

### Apply Naming Rules to Identifiers Globally

Goal	Specification
Set the maximum number of characters that the code generator uses for function, typedef, and variable names (default 31).	An integer value for the “Maximum identifier length” parameter. For more information, see “Specify Identifier Length to Avoid Naming Collisions”. If you expect your model to generate lengthy identifiers (due to use of long signal or parameter names, for example), or if identifiers are mangled more than you expect, increase the value of this parameter.
Define a macro that specifies certain text included within generated identifiers for: <ul style="list-style-type: none"> <li>• Global variables</li> <li>• Global types</li> <li>• Field names of global types</li> <li>• Subsystem methods</li> <li>• Subsystem method arguments</li> <li>• Local temporary variables</li> <li>• Local block output variables</li> <li>• Constant macros</li> <li>• Shared utilities identifier format</li> </ul>	A macro for the <b>Identifier format control</b> parameters. For more information, see “Identifier Format Control” on page 52-17. See also “Exceptions to Identifier Formatting Conventions” on page 52-27 and “Identifier Format Control Parameters Limitations” on page 52-28.
Set the minimum number of characters that the code generator uses for the mangling text.	An integer value for the “Minimum mangle length” parameter. For more information, see “Control Name Mangling in Generated Identifiers” on page 52-24

Goal	Specification
Control whether the software uses shortened names for system-generated identifiers.	Shortened for the “System-generated identifiers” parameter. This setting: <ul style="list-style-type: none"> <li>• Provides more space for user names.</li> <li>• Provides a more predictable and consistent naming system that uses camel case.</li> <li>• Does not include underscores or plurals.</li> <li>• Provides consistent abbreviations for both a type and a variable.</li> </ul>
Control whether the generated code expresses scalar inlined parameter values as literal values or as macros.	The value <code>Literals</code> or <code>Macros</code> for the “Generate scalar inlined parameters as” parameter. <ul style="list-style-type: none"> <li>• <b>Literals:</b> If you set <b>Default parameter behavior</b> to <code>Inlined</code>, parameters are expressed as numeric constants.</li> <li>• <b>Macros:</b> Parameters are expressed as variables (with <code>#define</code> macros). This setting makes code more readable.</li> </ul>

## Apply Custom Naming Conventions to Identifiers

This example shows how to apply uniform naming rules for Simulink® data objects, including signals, parameters, and data store memory variables.

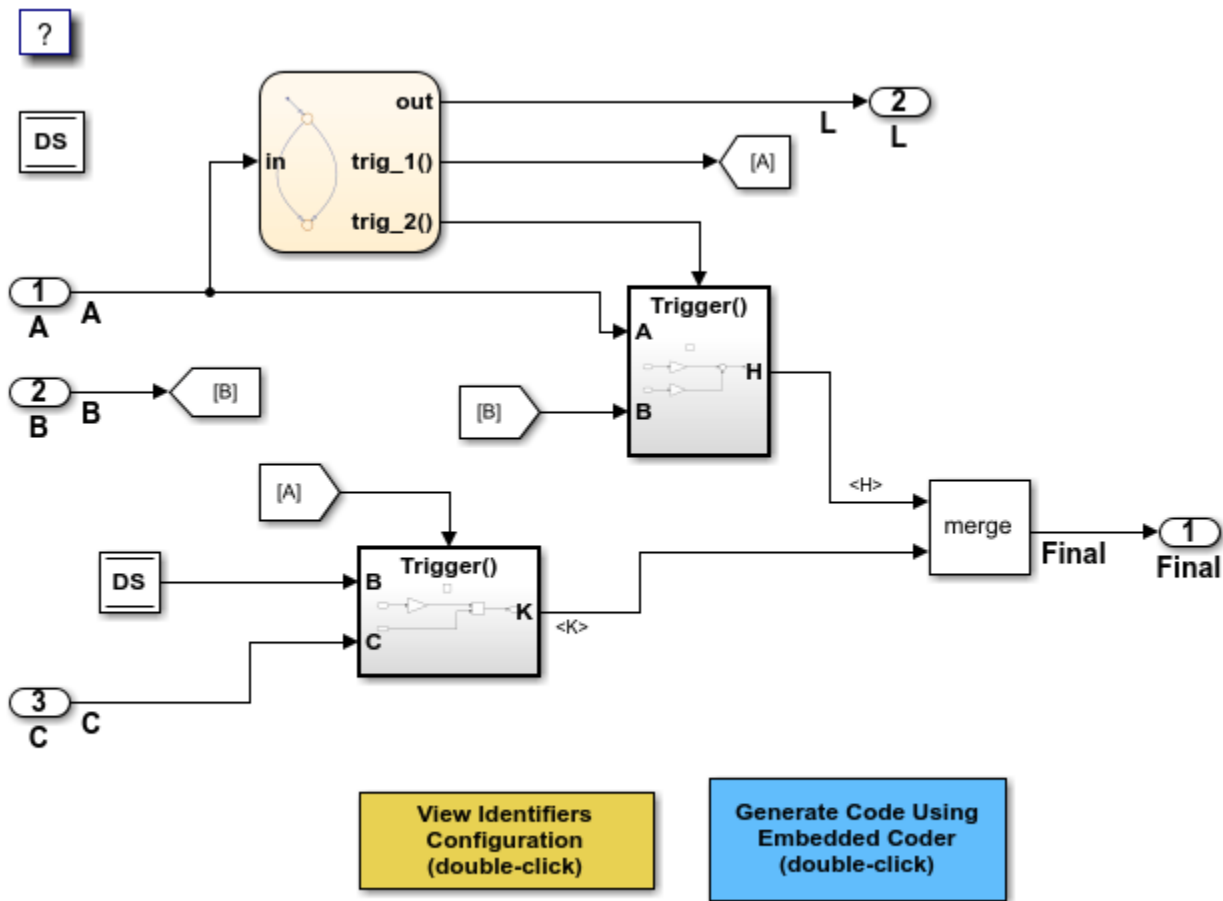

When your model uses Simulink data objects from the `Simulink` package, identifiers in the generated code copy the names of the objects by default. For example, a `Simulink.Signal` object named `Speed` appears as the identifier `Speed` in generated code.

You can control these identifiers by specifying naming rules that are specific to Simulink data objects. When you specify naming rules for generated code, follow ANSI® C/C++ rules for naming identifiers.

### Apply Lowercase Naming Rule

1. Open the model.

```
model='rtwdemo_namerules';
open_system(model)
```

2. Open the **C Code** tab and click **View Code**.

3. In the **Model Configuration Parameters**, navigate to **Identifiers > Advanced parameters > Simulink data object naming rules**. In this model, all three rules are set to Force lower case.

Simulink data object naming rules

Signal naming:	Force lower case	
M-function:	<empty>	Browse... Edit...
Parameter naming:	Force lower case	
M-function:	<empty>	Browse... Edit...
#define naming:	Force lower case	
M-function:	<empty>	Browse... Edit...

4. Generate code for the model. The generated file `rtwdemo_namerules.c` uses lowercase identifiers for parameters.

```
/* Exported block parameters */
real_T f1 = 2.0; /* Variable: F1
 * Referenced by: '<Root>/Chart'
 */
real_T g1 = 3.0; /* Variable: G1
 * Referenced by:
 * '<Root>/Chart'
 * '<S3>/Gain1'
 */
real_T g2 = 4.0; /* Variable: G2
 * Referenced by: '<S3>/Gain2'
 */
real_T g3 = 5.0; /* Variable: G3
 * Referenced by: '<S2>/Gain'
 */
```

### Apply Naming Rule Using a Function

You can customize identifiers in generated code by defining a MATLAB® function.

1. Write a MATLAB function that returns an identifier by modifying a data object name, then save the function in your working folder. For example, the following function returns an identifier name by appending a data object's data type to that data object's name.

```
function revisedName = append_text(name, object)
% APPEND_TEXT: Returns an identifier for generated
% code by appending text to a data object name.
%
% Input arguments:
% name: data object name as spelled in model
% object: information about model
%
% Output arguments:
% revisedName: altered identifier returned for use in
% generated code.
%
%
DataType = Simulink.data.evalinGlobal(object.modelName,[name, '.DataType']);

revisedName = [name, '_', DataType];
```

2. In the **Model Configuration Parameters**, navigate to **Identifiers > Advanced parameters > Simulink data object naming rules**. From the **Parameter naming** drop-down list, select Custom M-function.

3. In the **M-function** field under **Parameter naming**, type the name of the file that defines the MATLAB function, `append_text.m`, then click **Apply**.

Simulink data object naming rules

Signal naming:	Force lower case	
M-function:	<empty>	Browse... Edit...
Parameter naming:	Custom M-function	
M-function:	append_text.m	Browse... Edit...
#define naming:	Force lower case	
M-function:	<empty>	Browse... Edit...

4. Generate code for the model. The generated code implements the parameter object naming rule in `rtwdemo_namerules.c`.

```

/* Exported block parameters */
real_T F1_auto = 2.0;
real_T G1_auto = 3.0;
real_T G2_auto = 4.0;
real_T G3_auto = 5.0;
/* Variable: F1
 * Referenced by: '<Root>/Chart'
 */
/* Variable: G1
 * Referenced by:
 * '<Root>/Chart'
 * '<S3>/Gain1'
 */
/* Variable: G2
 * Referenced by: '<S3>/Gain2'
 */
/* Variable: G3
 * Referenced by: '<S2>/Gain'
 */

```

### Specify Naming Rule for Storage Class `define`

You can specify a naming rule that applies only to Simulink data objects whose storage class you set to `Define`.

1. Open the **Code Mappings Editor**. On the **C Code** tab, select **Code Interface > Default Code Mappings**.
2. In the **Parameters** tab of the **Code Mappings Editor**, find the data table row labeled **External Parameter Objects**. Click the **Refresh** button in that row.
3. Find the row in the data table that corresponds to the `Simulink.Parameter` object `G1`, which resides in the base workspace. From the drop-down menu, set the Storage Class for `G1` to `Define`.

External Parameter Objects (5)		Refresh
 F1	ExportedGlobal	
 G1	Define	
 G2	ExportedGlobal	
 G3	ExportedGlobal	
 K1	Define	

4. In the **Model Configuration Properties**, navigate to **Identifiers > Advanced parameters > Simulink data object naming rules**. From the #define naming drop-down list, select **Custom M-function**.

5. In the **M-function** field under #define naming, type the name of the file that defines the MATLAB function, `append_text.m`.

6. From the **Parameter naming** drop-down list, select **Force lower case**, then click **Apply**.

Simulink data object naming rules

Signal naming:	Force lower case	
M-function:	<empty>	Browse... Edit...
Parameter naming:	Force lower case	
M-function:	append_text.m	Browse... Edit...
#define naming:	Custom M-function	
M-function:	append_text.m	Browse... Edit...

7. Generate code for the model. The generated file `rtwdemo_namerules.h` represents G1 with G1\_auto and K1 with K1\_auto.

```
/* Definition for custom storage class: Define */
#define G1_auto 3.0 /* Referenced by:
 * '<Root>/Chart'
 * '<S3>/Gain1'
 */
#define K1_auto 6.0 /* Referenced by: '<Root>/Chart
```

### Override Data Object Naming Rules

You can override data object naming rules for individual data objects by specifying the **Identifier** property. Generated code uses the text that you specify as the identifier to represent the data object, regardless of naming rules.

1. In the **Parameters** tab of the **Code Mappings Editor**, find the row in the data table that corresponds to the Simulink.Parameter object G2. Right click the row and select **Open**.

2. In the Property Inspector, go to the **Code Generation** tab. Specify the **Identifier** property as `myIdentifier`. Click **Apply**.

3. Generate code for the model. The generated file `rtwdemo_namerules.c` represents G2 with the variable `myIdentifier`.

```
/* Exported block parameters */
real_T f1 = 2.0; /* Variable: F1
 * Referenced by: '<Root>/Chart'
 */
real_T myIdentifier = 4.0; /* Variable: G2
 * Referenced by: '<S3>/Gain2'
 */
real_T g3 = 5.0; /* Variable: G3
```

```
* Referenced by: '<S2>/Gain'
*/
```

**See Also**

“Signal naming”

## Identifier Format Control

You can customize generated identifiers by specifying the **Identifier format control** parameters on the **Code Generation > Identifiers** pane in the Configuration Parameters dialog box. For each parameter, you can enter a macro that specifies whether, and in what order, certain text is included within generated identifiers. For example, you can specify that the root model name be inserted into each identifier using the \$R token.

The macro can include:

- Valid tokens, which are listed in Identifier Format Tokens. You can use or omit tokens depending on what you want to include in the identifier name. The **Shared utilities identifier format** parameter requires you to specify the checksum token, \$C. The other parameters require the mangling token, \$M. For more information, see “Control Name Mangling in Generated Identifiers” on page 52-24. The mangling token is subject to the use and ordering restrictions noted in Identifier Format Control Parameter Values.
- Token decorators, which are listed in “Control Case by Using Token Decorators” on page 52-20. You can use token decorators to control the case of generated identifiers for each token.
- Valid C or C++ language identifier characters (a-z, A-Z, \_ , 0-9).

The build process generates each identifier by expanding tokens and inserting the resultant text into the identifier. The tokens are expanded in the order listed in Identifier Format Tokens. Groups of characters are inserted in the positions that you specify around tokens directly into the identifier. Contiguous token expansions are separated by the underscore (\_) character.

### Identifier Format Tokens

Token	Description
\$C	This token is required for <b>Shared utilities identifier format</b> . If the identifier exceeds the <b>Maximum identifier length</b> , the code generator inserts an 8-character checksum to avoid naming collisions. The position of the \$C token in the <b>Identifier format control</b> parameter specification determines the position of the checksum in the generated identifier. For example, if you use the specification \$N\$C, the checksum is appended to the end of the identifier. This token is available only for shared utilities.
\$M	This token is required. If necessary, the code generator inserts name-mangling text to avoid naming collisions. Modify checksum character length by using <b>Shared checksum length</b> parameter. The position of the \$M token in the <b>Identifier format control</b> parameter specification determines the position of the name-mangling text in the generated identifier. For example, if you use the specification \$R\$N\$M, the name-mangling text is appended (if required) to the end of the identifier. For more information, see “Control Name Mangling in Generated Identifiers” on page 52-24.
\$U	Insert text that you specify for the \$U token. Use the <b>Custom token text</b> parameter to specify this text.
\$F	Insert method name (for example, <code>_Update</code> for update method). This token is available only for subsystem methods.
\$N	Insert name of object (block, signal or signal object, state, parameter, shared utility function or parameter object) for which identifier is being generated.
\$R	Insert root model name into identifier, replacing unsupported characters with the underscore ( <code>_</code> ) character. When you use referenced models, this token is required in addition to \$M (see “Avoid Identifier Name Collisions with Referenced Models” on page 52-25).  <b>Note:</b> This token replaces the <b>Prefix model name to global identifiers</b> option in previous releases.
\$H	Insert tag indicating system hierarchy level. For root-level blocks, the tag is the text <code>root_</code> . For blocks at the subsystem level, the tag is of the form <code>sN_</code> . N is a unique system number assigned by the Simulink software. This token is available only for subsystem methods and field names of global types.  <b>Note:</b> This token replaces the <b>Include System Hierarchy Number in Identifiers</b> option in previous releases.
\$A	Insert data type acronym (for example, <code>i32</code> for integers) to signal and work vector identifiers. This token is available for local block output variables, local temporary variables, and field names of global types.  <b>Note:</b> This token replaces the <b>Include data type acronym in identifier</b> option in previous releases.

Token	Description
\$I	<ul style="list-style-type: none"> <li>• Insert <code>u</code> if the argument is an input.</li> <li>• Insert <code>y</code> if the argument is an output.</li> <li>• Insert <code>uy</code> if the argument is an input and output.</li> </ul> <p>For example, <code>rtu_</code> for an input argument, <code>rty_</code> for an output argument, and <code>rtuy_</code> for an input and output argument. This token is available only for subsystem method arguments.</p>
\$G	<p>Insert the name of a storage class that is associated with the data item. This token is also available in the naming rule that you specify for the <b>Header File</b> for a storage class in the Embedded Coder Dictionary.</p>
\$E	<p>Insert the file type. <code>\$E</code> represents these instances of file types:</p> <ul style="list-style-type: none"> <li>• <code>capi</code></li> <li>• <code>capi_host</code></li> <li>• <code>dt</code></li> <li>• <code>testinterface</code></li> <li>• <code>private</code></li> <li>• <code>types</code></li> </ul> <p>This token is required for <b>Header files</b> and <b>Source files</b>.</p>

Identifier Format Control Parameter Values lists the default macro value, the supported tokens, and the applicable restrictions for each **Identifier format control** parameter.

### Identifier Format Control Parameter Values

Parameter	Default Value	Supported Tokens	Restrictions
Global variables	\$R\$N\$M	\$M, \$R, \$G,\$N,\$U	\$F, \$H, \$A, \$E, and \$I are not allowed.
Global types	\$N\$R\$M_T	\$M, \$R, \$G,\$N,\$U	\$F, \$H, \$A, \$E, and \$I are not allowed.
Field name of global types	\$N\$M	\$M, \$N, \$H, \$A, \$U	\$R, \$F, \$G, \$E, and \$I are not allowed.
Subsystem methods	\$R\$N\$M\$F	\$M, \$R, \$N, \$H, \$F, \$U	\$F and \$H are empty for Stateflow functions; \$A, \$G, \$E, and \$I are not allowed.
Subsystem method arguments	rt\$I\$N\$M	\$M, \$N, \$I, \$U	\$R, \$F, \$H, \$G, \$E, and \$A are not allowed.
Local temporary variables	\$N\$M	\$M, \$R, \$N, \$A, \$U	\$F, \$H, \$G, \$E, and \$I are not allowed.
Local block output variables	rtb_-\$N\$M	\$M, \$N, \$A, \$U	\$R, \$F, \$H, \$G, \$E, and \$I are not allowed.
Constant macros	\$R\$N\$M	\$M, \$R, \$N, \$U	\$F, \$H, \$A, \$G, \$E, and \$I are not allowed.
Shared utilities identifier format	\$N\$C	\$N, \$C, \$R, \$U	\$C is required. \$M, \$F, \$H, \$A, \$G, \$E, and \$I are not allowed.
EMX array utility functions identifier format	emx\$M\$N	\$M, \$N,\$R	\$C, \$U, \$F, \$H, \$A, \$G, \$E, and \$I are not allowed.
EMX array types identifier format	emxArray_-\$M\$N	\$M, \$N,\$R	\$C, \$U, \$F, \$H, \$A, \$G, \$E, and \$I are not allowed.
Header files	\$R\$E	\$R,\$U,\$E	\$C, \$M, \$N, \$F, \$H, \$A, \$G, and \$I are not allowed.
Source files	\$R\$E	\$R,\$U,\$E	\$C, \$M, \$N, \$F, \$H, \$A, \$G, and \$I are not allowed.
Data files	\$R_data	\$R,\$U	\$C, \$M, \$N, \$F, \$H, \$A, \$G, \$E, and \$I are not allowed.

Non-ERT-based targets (such as the GRT target) implicitly use a default \$R\$N\$M specification. This default specification consists of the root model name, followed by the name of the generating object (signal, parameter, state, and so on), followed by name-mangling text.

For limitations that apply to **Identifier format control** parameters, see “Exceptions to Identifier Formatting Conventions” on page 52-27 and “Identifier Format Control Parameters Limitations” on page 52-28.

### Control Case by Using Token Decorators

On the **Code Generation > Identifiers** pane, you can use token decorators to control the case of generated identifiers. Place a decorator immediately after the target token and enclose the decorator

in square brackets [ ]. For example, you can set **Global variables** to `$R[uL]$N$M`, which capitalizes the first letter of the model name and forces the remaining characters in the model name to lowercase.

The table shows how to manipulate the expansion of the `$R` token for a model whose name is `modelName`.

Desired Expansion	Description	Token and Decorator
<code>ModelName</code>	First letter of model name is uppercase. Remaining characters are not modified.	<code>\$R[u]</code>
<code>Modelname</code>	First letter of model name is uppercase. Remaining characters are lowercase.	<code>\$R[uL]</code>
<code>MODELNAME</code>	All characters are uppercase.	<code>\$R[U]</code>
<code>modelname</code>	All characters are lowercase.	<code>\$R[L]</code>
<code>mODELNAME</code>	First letter of model name is lowercase. Remaining characters are uppercase.	<code>\$R[lU]</code>
<code>modelName</code>	First letter of model name is lowercase. Remaining characters are not modified.	<code>\$R[l]</code>

When you use a decorator, the code generator removes the underscore character (`_`) that appears between tokens by default. However, you can append each decorator with an underscore: `$R[U_] $N`. For example, if you set the **Global variables** parameter to `$R[u_] $N[uL] $M` for a model named `modelName` and a `DWork` structure represented by `DW`, the result is `ModelName_Dw`.

## Modify Identifiers by Using Regular Expression Decorators

To modify identifiers in ways other than by case, you can use regular expressions. To use a regular expression, enclose the decorator in double quotes. A regular expression decorator contains two regular expressions separated by a forward slash. The code generator searches for substrings of the token that match the first regular expression and replaces those substrings using the second regular expression. For example, the following identifier naming rule takes the root model name `$R` and replaces instances of `a` with `b`: `$R["a/b"]`. The code generator interprets regular expression syntax in a way that is consistent with the `regexp` function, except regular expression decorators do not support dynamic expressions, which use MATLAB commands.

You can configure a regular expression decorator by appending a list of options to the end of the decorator. Separate the options from the second regular expression by using a forward slash and separate the options from each other by using the pipe character. For example, the following identifier naming rule takes the root model name `$R` and replaces only the first instance of `a` with `b`, ignoring case: `$R["a/b/once|ignorecase"]`.

Category	Option	Description	Example Decorator	Example Input	Example Output
Match/replace occurrence	<code>all</code> (default)	Match and replace the expression as many times as possible.	<code>["a/-/all"]</code>	<code>afabcswwbc</code>	<code>-f-bcswwbc</code>

Category	Option	Description	Example Decorator	Example Input	Example Output
	once	Match and replace the expression only once.	["a/-/once"]	a-fab-cswbc	-fab-cswbc
	N	Where N is an integer, match and replace the Nth occurrence of a match.	["a/-/2"]	a-fab-cswbc	af-b-cswbc
Case matching	matchcase (default)	Match letter case.	["aBCD/wXyZ/matchcase"]	abcdABCD	abcdABCD
	ignorecase	Ignore letter case.	["aBCD/wXyZ/ignorecase"]	wXyZwXyZ	wXyZwXyZ
	preservecase	Ignore letter case while matching but preserve the case of corresponding characters in the original text while replacing.	["aBCD/wXyZ/preservecase"]	wxyzWXYZ	wxyzWXYZ
Empty matching	noemptymatch (default)	Ignore zero-length matches.	["^/prefix/noemptymatch"]	abcdABCD	abcdABCD
	emptymatch	Include zero-length matches.	["^/prefix/emptymatch"]	prefixabcdABCD	prefixabcdABCD

If a regular expression decorator results in uncompileable code, the code generator produces an error before building the code.

### Regular Expression Limitations

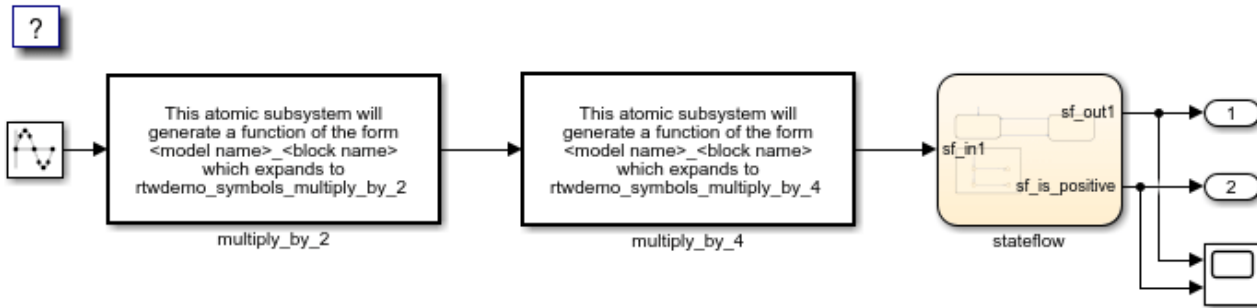

- Regular expression decorators are applicable only to \$G, \$N, and \$R tokens.
- Unlike `regexprep`, regular expression decorators do not support dynamic expressions, which use MATLAB commands.
- Regular expression decorators are not supported for function mappings in the **Code Mappings** editor.
- The code generator cannot evaluate whether a regular expression is valid. An invalid regular expression does not result in a change to the affected token and does not produce a warning.

### Control Formatting of Identifiers

This example shows how to customize generated identifiers by specifying the **Identifier format control** parameters on the **Code Generation > Identifiers** pane in the Configuration Parameters dialog box. To maintain model traceability, it is important that incremental revisions to a model have minimal impact on the identifier names that appear in the generated code. This example shows how

to use name mangling by specifying the **Identifier format control** parameters to minimally impact the identifier names.

```
model='rtwdemo_symbols';
open_system(model)
```

▶ Double-click to view identifier format

▶ Double-click to view mangle settings

Global variable names  
contain model name.

## Control Name Mangling in Generated Identifiers

The position of the \$M token in the **Identifier format control** parameter specification determines the position of the name-mangling text in the generated identifiers. For example, if you use the specification \$R\$N\$M, the name-mangling text is appended (if required) to the end of the identifier. For more information, see “Identifier Format Control” on page 52-17.

### Name-Mangling Text Per Object

Object Type	Source of Mangling Text
Block diagram	Name of block diagram
Simulink block	Simulink identifier (for details, see “Simulink Identifiers”)
Simulink parameter	Full name of parameter owner (model or block) and parameter name
Simulink signal	Signal name, full name of source block, and port number
Stateflow objects	Complete path to Stateflow block and Stateflow computed name (unique within chart)

The length of the name-mangling text is specified by the “Minimum mangle length” parameter. The default value is 1, but this automatically increases during code generation as a function of the number of collisions. To minimize disturbance to the generated code during development, specify a larger **Minimum mangle length**. A **Minimum mangle length** of 4 is a conservative value. A value of 4 allows for over 1.5 million collisions for a particular identifier before the mangle length is increased.

### Minimize Name Mangling

The length of generated identifiers is limited by the **Maximum identifier length** parameter. When a name collision exists, the \$M token is expanded to the minimum number of characters required to avoid the collision. Other tokens are expanded in the order listed in Identifier Format Tokens. If the **Maximum identifier length** is not large enough to accommodate full expansions of the other tokens, partial expansions are used. To avoid partial expansions, it is good practice to:

- Avoid name collisions. One way to avoid name collisions is to not use default block names (for example, Gain1, Gain2. . .) when there are many blocks of the same type in the model.
- Where possible, increase the **Maximum identifier length** to accommodate the length of the identifiers that you expect to generate.
- Set the **Maximum identifier length** parameter to reserve at least three characters for the name-mangling text. The length of the name-mangling text increases as the number of name collisions increases.

If changes to the model create more or fewer collisions, existing name-mangling text increases or decreases in length. If the length of the name-mangling text increases, additional characters are appended to the existing text. For example, the mangling text 'xyz' can change to 'xyzQ'. For fewer collisions, the name-mangling text 'xyz' changes to 'xy'.

## Avoid Identifier Name Collisions with Referenced Models

Within a model that uses referenced models, collisions between the names of the models are not allowed. When generating code from a model that uses model referencing:

- You must include the \$R token in the **Identifier format control** parameter specifications (in addition to the \$M token).
- The **Maximum identifier length** must be large enough to accommodate full expansions of the \$R and \$M tokens. If **Maximum identifier length** is too small, a code generation error occurs.

When a name conflict occurs between an identifier within the scope of a higher-level model and an identifier within the scope of a referenced model, the identifier from the referenced model is preserved. Name mangling is performed on the identifier from the higher-level model.

If your model contains two referenced models with the same input or output port names, and one of the referenced models contains an atomic subsystem with “Function packaging” set to `Nonreusable function`, a name conflict can occur and the build process produces an error.

### Use Model Advisor to Detect Identifier Names Changed During Code Generation

For a referenced model, if the following parameters do not have specifications that do not contain a \$R token (which represents the name of the reference model), code generation prepends the \$R token to the identifier format.

- “Global variables”
- “Global types”
- “Subsystem methods”
- “Constant macros”

You can use the Model Advisor to identify referenced models in a model referencing hierarchy for which code generation changes these configuration parameter settings.

- 1 In the **Modeling** tab, click **Model Advisor**.
- 2 Select **By Task**.
- 3 Run the **Check code generation identifier formats used for model reference** check.

## Maintain Traceability for Generated Identifiers

To verify your model, you can trace back and forth between generated identifiers and corresponding entities within the model. To maintain traceability, it is important that incremental revisions to a model have minimal impact on the identifier names that appear in generated code. There are two ways to minimally impact the identifier names:

- Choose unique names for Simulink objects (blocks, signals, states, and so on) as much as possible.
- Use name mangling when conflicts cannot be avoided.

The position of the name-mangling text is specified by the placement of the \$M token in the **Identifier format control** parameters. Mangle characters consist of alphanumeric characters that are unique to each object. For more information, see “Control Name Mangling in Generated Identifiers” on page 52-24.

## Exceptions to Identifier Formatting Conventions

There are some exceptions to the identifier formatting conventions described in “Identifier Format Control” on page 52-17.

- Type name generation: name mangling conventions do not apply to type names (that is, typedef statements) generated for global data types. If the \$R token is included in the **Identifier format control** parameter specification, the model name is included in the typedef. When generating type definitions, the **Maximum identifier length** parameter is not respected.
- Non-Auto storage classes: the **Identifier format control** parameters specification does not affect objects (such as signals and parameters) that have a storage class other than Auto (such as ImportedExtern or ExportedGlobal).
- For shared utilities, code generation inserts the checksum specified by \$C to prevent name collisions in the following situations:
  - \$C is specified without \$N.
  - The length of \$N plus the length of the text that you specify exceeds the **Maximum identifier length**. Code generation truncates \$N and inserts an 8-character checksum where you specified \$C in the formatting scheme.

## Identifier Format Control Parameters Limitations

The following limitations apply to the **Identifier format control** parameters:

- The following autogenerated identifiers currently do not fully comply with the setting of the **Maximum identifier length** parameter on the **Code Generation > Identifiers** pane of the Configuration Parameters dialog box.
  - Model methods
    - The applicable format scheme is \$R\$F, and the longest \$F is `_derivatives`, which is 12 characters long. The model name can be up to 19 characters without exceeding the default **Maximum identifier length** of 31.
  - Local functions generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - Local variables generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - DW identifiers generated by S-functions in referenced models
  - Fixed-point shared utility macros or shared utility functions
  - Simulink `rtm` macros
    - Most are within the default **Maximum identifier length** of 31, but some exceed the limit. Examples are `RTMSpecAccsGetStopRequestedValStoredAsPtr`, `RTMSpecAccsGetErrorStatusPointer`, and `RTMSpecAccsGetErrorStatusPointerPointer`.
  - Define protection guard macros
    - Header file guards, such as `_RTW_HEADER_(filename)_h_`, which can exceed the default **Maximum identifier length** of 31 given a filename such as `$R_private.h`.
    - Include file guards, such as `_$R_COMMON_INCLUDES_`.
    - `typedef` guards, such as `_CSCI_$R_CHARTSTRUCT_`.
- In some situations, the following identifiers potentially can conflict with others.
  - Model methods
  - Reentrant model function arguments
  - Local functions generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - Local variables generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - Fixed-point shared utility macros or shared utility functions
  - Include header guard macros
- The following external identifiers that are unknown to the Simulink software might conflict with autogenerated identifiers.
  - Identifiers defined in custom code
  - Identifiers defined in custom header files
  - Identifiers introduced through a non-ANSI C standard library

- Identifiers defined by custom TLC code
- Identifiers generated for simulation targets might exceed the **Maximum identifier length**. Simulation targets include the model reference simulation target, the accelerated simulation target, the RSim target, and the S-function target.
- Identifiers generated using a model name and bus object data type name, which are both long names, might exceed the **Maximum identifier length**. For example, a ground value variable name is generated as *<model\_name>\_rtZ<bus\_name>*. If the *model\_name* and *bus\_name* are close to the maximum identifier length, the name exceeds the maximum identifier length.

## Control Parentheses in Generated Code

C code contains some syntactically required parentheses, and can contain additional parentheses that change semantics by overriding default operator precedence. C code can also contain optional parentheses that have no functional significance, but only increase the readability of the code. Optional C parentheses vary between two stylistic extremes:

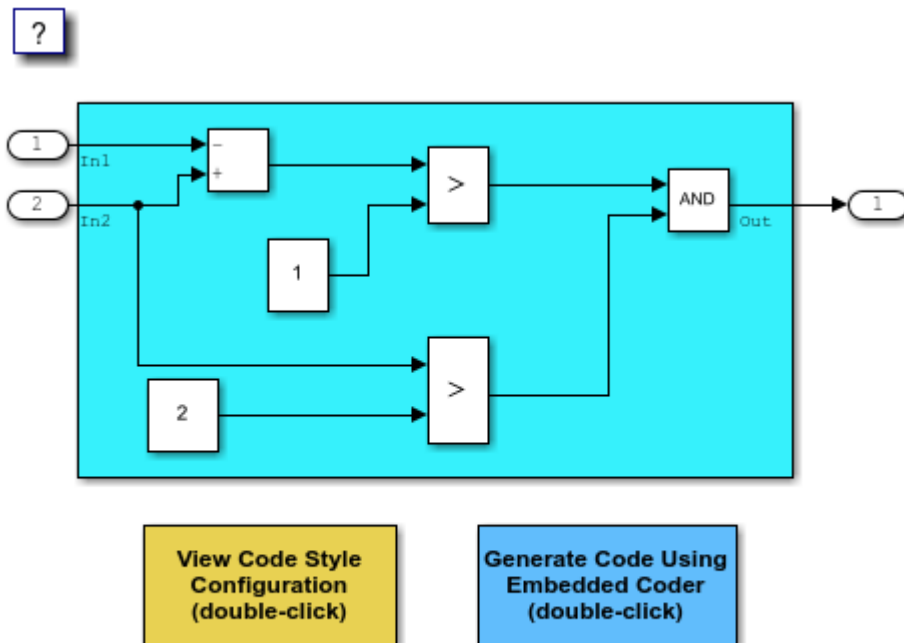

- Include the minimum parentheses required by C syntax and precedence overrides so that C precedence rules specify all semantics unless overridden by parentheses.
- Include the maximum parentheses that can exist without duplication so that C precedence rules become irrelevant. Parentheses alone completely specify all semantics.

Understanding code with minimum parentheses can require applying nonobvious precedence rules. Maximum parentheses can hinder code reading by belaboring obvious precedence rules. Various parenthesization standards exist that specify one or the other extreme, or define an intermediate style useful to people who read code.

### Control Use of Parentheses

This example shows that Embedded Coder® provides three levels of control for parentheses in the generated code.

```
model='rtwdemo_parentheses';
open_system(model)
```

## Optimize Code by Reordering Commutable Operands

This example shows how to reorder commutable operands to make expressions left-recursive. Left-recursive reordering saves stack space in memory. This optimization improves code efficiency.

### Example Model

To reorder commutable operands, create this model and name it `operand_order`. The output signal is the result of multiplying the signal from Inport block In1 by the sum of the signals from Inport blocks In2 and In3.

### Generate Code

- 1 Open the Model Configuration Parameters dialog box. On the **Code Style** tab, select the **Preserve operand order in expression** parameter.
- 2 Generate code for the model.

In the `operand_order.c` file, the `operand_order_step` function contains this code:

```
operand_order_Y.Out1 = operand_order_U.In1 * (operand_order_U.In2 +
operand_order_U.In3);
```

The code generator preserves the specified expression order in the model, which increases the readability of the code for code traceability.

### Generate Code with Optimization

- 1 Open the Model Configuration Parameters dialog box. On the **Code Style** tab, clear the **Preserve operand order in expression** parameter.
- 2 Generate code for the model.

In the `operand_order.c` file, the `operand_order_step` function contains this code:

```
operand_order_Y.Out1 = (operand_order_U.In2 + operand_order_U.In3) *
operand_order_U.In1;
```

The code generator optimizes the code by reordering the commutable operands to make the expression left-recursive, which improve code efficiency.

## Suppress Generation of Default Cases for Unreachable Stateflow Switch Statements

This example shows how to specify whether to generate default cases for switch-case statements in the code for Stateflow charts. Generated code that does not contain default cases conserves ROM consumption and enables better code coverage because every branch in the generated code is falsifiable.

Some coding standards, such as MISRA, require the default case for switch-case statements. If you want to increase your chances of producing MISRA C compliant code, generate default cases for unreachable Stateflow switch statements.

### Example

Figures 1, 2, and 3 show relevant portions of the `sldemo_fuelsys` model, a closed-loop system containing a plant and controller. The Air-fuel rate controller logic is a Stateflow chart that specifies the different operation modes.

**Figure 1: Top-level model of the plant and controller**

### Fuel Rate Control Subsystem

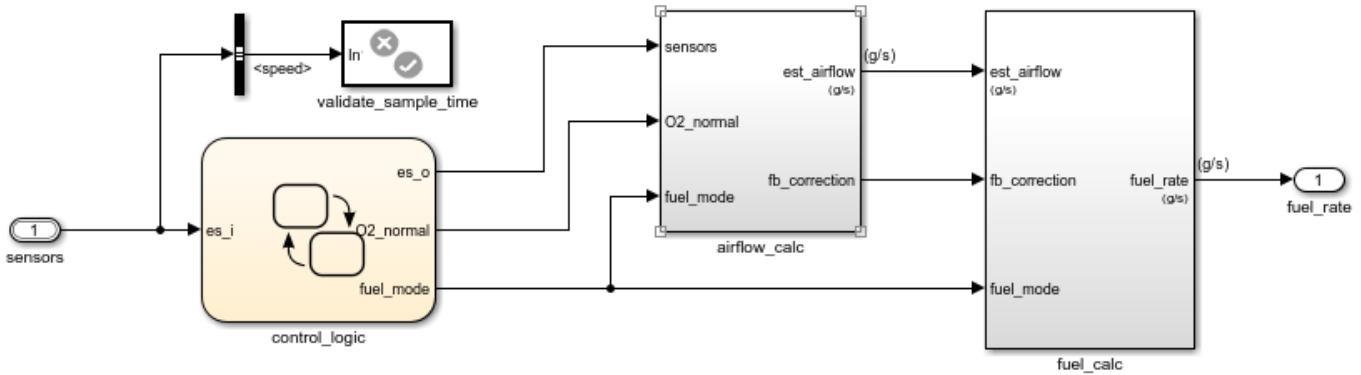

Figure 2: Fuel rate controller subsystem

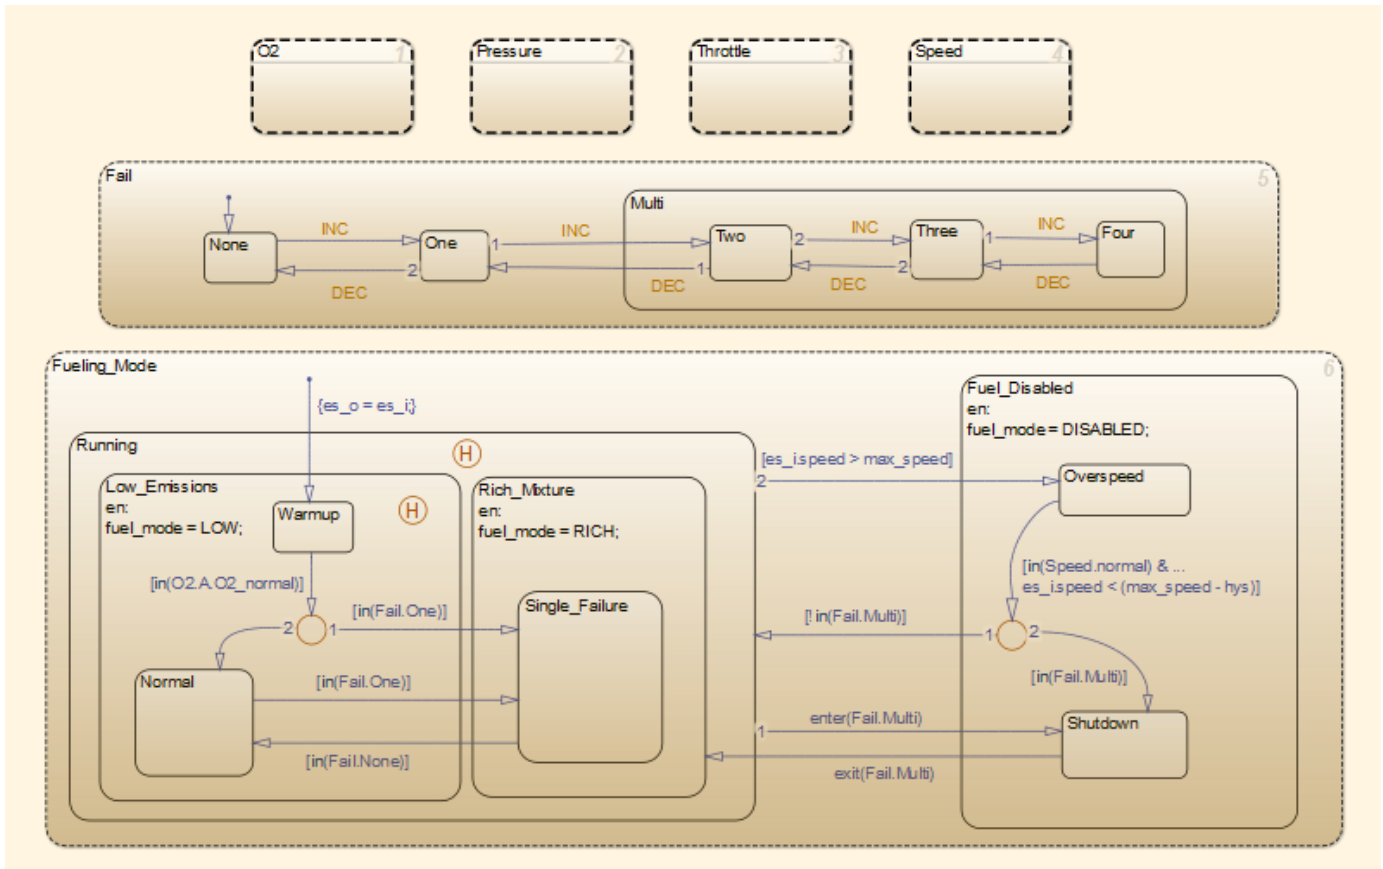

Figure 3: Fuel rate controller logic

## Generate Code with Default Cases for Unreachable Stateflow Switch Statements

- 1 In the MATLAB Command Window, to open `sldemo_fuelsys` enter:

```
openExample('sldemo_fuelsys');
```

- 2 Open the Model Configuration parameters dialog box. On the **Code Generation > Code Style** tab, clear the **Suppress generation of default cases for Stateflow switch statements if unreachable** parameter.

- 3 In the MATLAB Command Window, to build the model, enter:

```
slbuild('sldemo_fuelsys/fuel_rate_control');
```

For the different operation modes, the `fuel_rate_control.c` file contains default cases for unreachable switch statements. For example, for the Shutdown operation mode, the generated code contains this default statement:

```
default:
/* Unreachable state, for coverage only */
rtDWork.bitsForTID0.is_Fuel_Disabled = IN_NO_ACTIVE_CHILD;
break;
```

For the Warmup operation mode, the generated code contains this default statement:

```
default:
/* Unreachable state, for coverage only */
rtDWork.bitsForTID0.is_Low_Emissions = IN_NO_ACTIVE_CHILD;
break;
```

## Suppress Default Cases for Unreachable Stateflow Switch Statements

- 1 Open the Configuration Parameters dialog box. On the **Code Generation > Code Style** tab, select the **Suppress generation of default cases for Stateflow switch statements if unreachable** parameter.
- 2 Build the model.

Read through the `fuel_rate_control.c` file. The default cases for unreachable switch statements are not in the generated code.

## Replace Multiplication by Powers of Two with Signed Bitwise Shifts

This example shows how to generate code that replaces multiplication by powers of two with signed bitwise shifts. Code that contains bitwise shifts executes faster than the code containing multiplication by powers of two.

Some coding standards, such as MISRA, do not allow bitwise operations on signed integers. If you want to increase your chances of producing MISRA C compliant code, do not replace multiplication by powers of two with bitwise shifts.

### Example

To replace multiplication by powers of two with bitwise shifts, create the following model. In this model, a signal of **Data type** `int16` feeds into a Shift Arithmetic block. In the Shift Arithmetic Block Parameters dialog box, the **Bits to shift** > **Direction** parameter is set to Left. The **Bits to shift** > **Number** parameter is set to 3. This parameter corresponds to a value of 8, or raising 2 to the power of 3.

### Generate Code with Signed Bitwise Shifts

- 1 Open the Model Configuration Parameters dialog box and select the **Code Style** tab. The **Replace multiplications by powers of two with signed bitwise shifts** parameter is on by default.
- 2 Generate code for the model.

In the `bitwise_multiplication.c` file, the `bitwise_multiplication` step function contains this code:

```
bitwise_multiplication_Y.Out1 = (int16_T)(bitwise_multiplication_U.In1 << 3);
```

The signed integer, `bitwise_multiplication_U.In1`, is shifted three bits to the left.

### Generate Code with Multiplication by Powers of Two

- 1 Open the Model Configuration Parameters dialog box and select the **Code Style** tab.
- 2 Clear the **Replace multiplications by powers of two with signed bitwise shifts** parameter.
- 3 Generate code for the model.

In the `bitwise_multiplication.c` file, the `bitwise_multiplication` step function contains this code:

```
bitwise_multiplication_Y.Out1 = (int16_T)(bitwise_multiplication_U.In1 * 8);
```

The signed integer `bitwise_multiplication_U.In1` is multiplied by 8.

## **See Also**

### **Related Examples**

- “Replace multiplications by powers of two with signed bitwise shifts”
- “Model Configuration Parameters: Code Style”

## Generate Code Containing Right Shifts on Signed Integers

This example shows how to control whether the generated code contains right shifts on signed integers. Generated code that does not contain right shifts on signed integers first casts the signed integers to unsigned integers, and then right shifts the unsigned integers.

Some coding standards, such as MISRA, do not allow right shifts on signed integers because different hardware can store negative integers differently. For negative integers, you can get different answers depending on the hardware. If you want to increase your chances of producing MISRA C compliant code, do not allow right shifts on signed integers.

### Example Model

To generate code with right shifts on signed integers, create this model. A signal of **Data type** `int16` feeds into a Shift Arithmetic block. In the Shift Arithmetic Block Parameters dialog box, the **Bits to shift** > **Direction** parameter is set to Right. The **Bits to shift** > **Number** parameter is set to 3.

### Generate Code Containing Right Shifts on Signed Integers

- 1 Open the Model Configuration Parameters dialog box and select the **Code Style** tab. The **Allow right shifts on signed integers** parameter is on by default.
- 2 Generate code for the model.

In the `rightshift.c` file, the `rightshift_step` function contains this code:

```
rightshift_Y.Out1 = (int16_T)(rightshift_U.In1 >> 3);
```

The signed integer `rightshift_U.In1` is shifted three bits to the right.

### Generate Code That Does Not Allow Right Shifts on Signed Integers

- 1 Open the Model Configuration Parameters dialog box and select the **Code Style** tab. Clear the **Allow right shifts on signed integers** parameter.
- 2 Generate code for the model.

In the `rightshift.c` file, the `rightshift_step` function contains this code:

```
rightshift_Y.Out1 = (int16_T)asr_s32(rightshift_U.In1, 3U);
```

When you clear the **Allow right shifts on signed integers** parameter, the generated code contains a function call instead of a right shift on a signed integer. The function `asr_s32` contains this code:

```
int32_T asr_s32(int32_T u, uint32_T n)
{
```

```
int32_T y;
if (u >= 0) {
 y = (int32_T)((uint32_T)u >> n);
} else {
 y = -(int32_T)((uint32_T)-(u + 1) >> n) - 1;
}

return y;
}
```

The `asr_s32` function casts a signed integer to an unsigned integer, and then right shifts the unsigned integer.

## Control Cast Expressions in Generated Code

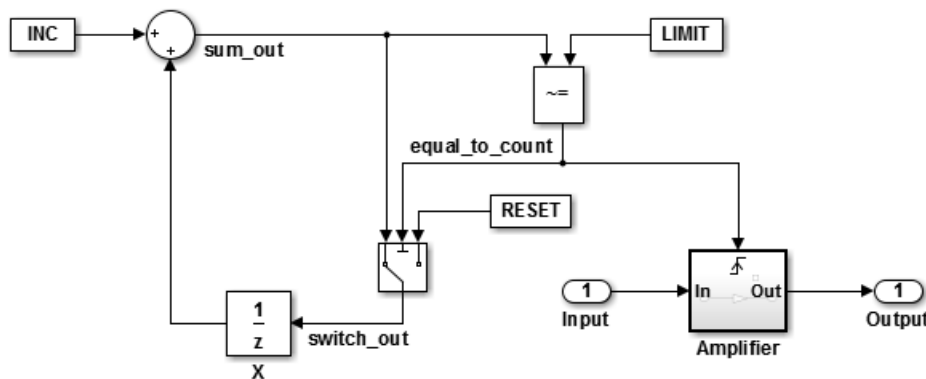

You can choose how the code generator specifies data type casts in the generated code. In the Configuration Parameters dialog box, select **Code Generation > Code Style**. From the **Casting modes** drop-down list, three parameter options control how the code generator casts data types.

- **Nominal** instructs the code generator to generate code that has minimal data type casting. When you do not have special data type information requirements, choose **Nominal**.
- **Standards Compliant** instructs the code generator to cast data types to conform to MISRA standards when it generates code. The MISRA data type casting eliminates common MISRA standard violations, including address arithmetic and assignment. It reduces 10.1, 10.2, 10.3, and 10.4 violations.

For more information, see “MISRA C” on page 22-10.

- **Explicit** instructs the code generator to cast data type values explicitly when it generates code. You can see how a value is stored, which tells you how much memory space the code uses for the variable. The data type informs you how much precision is possible in calculations involving the variable.

Open the example model `rtwdemo_rtwecintro`.

### Enable Nominal Casting Mode and Generate Code

When you choose **Nominal** casting mode, the code generator does not create data type casts for variables in the generated code.

- 1 On the **Code Generation > Code Style** pane, from the **Casting modes** drop-down list, select **Nominal**.
- 2 On the **Code Generation > Report** pane, select **Create code generation report**.
- 3 On the **Code Generation** pane, select **Generate code only**.
- 4 Click **Apply**.
- 5 In the model window, press **Ctrl+B** to generate code.
- 6 In the Code Generation report left pane, click `rtwdemo_rtwecintro.c` to see the code.

```
/* Model step function */
void rtwdemo_rtwecintro_step(void)
{
 boolean_T rtb_equal_to_count;
```

```

/* Sum: 'XRootX/Sum' incorporates:
 * Constant: 'XRootX/INC'
 * UnitDelay: 'XRootX/X'
 */
rtDWork.X++;

/* RelationalOperator: 'XRootX/RelOpt' incorporates:
 * Constant: 'XRootX/LIMIT'
 */
rtb_equal_to_count = (rtDWork.X != 16);

/* Outputs for Triggered SubSystem: 'XRootX/Amplifier' incorporates:
 * TriggerPort: 'XS1X/Trigger'
 */
if (rtb_equal_to_count && (rtPrevZCSigState.Amplifier_Trig_ZCE != POS_ZCSIG))
{
 /* Output: 'XRootX/Output' incorporates:
 * Gain: 'XS1X/Gain'
 * Inport: 'XRootX/Input'
 */
 rtY.Output = rtU.Input << 1;
}

rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)
 POS_ZCSIG : (int32_T)ZERO_ZCSIG);

/* End of Outputs for SubSystem: 'XRootX/Amplifier' */

/* Switch: 'XRootX/Switch' */
if (!rtb_equal_to_count) {
 /* Update for UnitDelay: 'XRootX/X' incorporates:
 * Constant: 'XRootX/RESET'
 */
 rtDWork.X = 0U;
}

/* End of Switch: 'XRootX/Switch' */
}

```

## Enable Standards Compliant Casting Mode and Generate Code

When you choose Standards Compliant casting mode, the code generator creates MISRA standards compliant data type casts for variables in the generated code.

- 1 On the **Code Style** pane, from the **Casting modes** drop-down list, select Standards Compliant.
- 2 On the **Code Generation** pane, click **Apply**.
- 3 In the model window, press **Ctrl+B** to generate code.
- 4 In the Code Generation report left pane, click `rtwdemo_rtwecintro.c` to see the code.

```

void rtwdemo_rtwecintro_step(void)
{
 boolean_T rtb_equal_to_count;

 /* Sum: '<Root>/Sum' incorporates:
 * Constant: '<Root>/INC'
 * UnitDelay: '<Root>/X'
 */
 rtDWork.X++;

 /* RelationalOperator: '<Root>/RelOpt' incorporates:
 * Constant: '<Root>/LIMIT'
 */
 rtb_equal_to_count = (boolean_T)(int32_T)((int32_T)rtDWork.X != (int32_T)16);

 /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
 * TriggerPort: '<S1>/Trigger'
 */
 if (((int32_T)rtb_equal_to_count) && (rtPrevZCSigState.Amplifier_Trig_ZCE !=
 POS_ZCSIG)) {
 /* Output: '<Root>/Output' incorporates:
 * Gain: '<S1>/Gain'
 */
 }
}

```

```

 * Inport: '<Root>/Input'
 */
 rtY.Output = (int32_T)(uint32_T)((uint32_T)rtU.Input << (uint32_T)(int8_T)1);
}

rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(int32_T)(rtb_equal_to_count ?
(int32_T)(uint8_T)POS_ZCSIG : (int32_T)(uint8_T)ZERO_ZCSIG);

/* End of Outputs for SubSystem: '<Root>/Amplifier' */

/* Switch: '<Root>/Switch' */
if (!rtb_equal_to_count) {
 /* Update for UnitDelay: '<Root>/X' incorporates:
 * Constant: '<Root>/RESET'
 */
 rtDWork.X = 0U;
}

/* End of Switch: '<Root>/Switch' */
}

```

## Enable Explicit Casting Mode and Generate Code

When you choose **Explicit** casting mode, the code generator creates explicit data type casts for variables in the generated code.

- 1 On the **Code Style** pane, from the **Casting modes** drop-down list, select **Explicit**.
- 2 On the **Code Generation** pane, click **Apply**.
- 3 In the model window, press **Ctrl+B** to generate code.
- 4 In the Code Generation report left pane, click `rtwdemo_rtwecintro.c` to see the code.

```

/* Model step function */
void rtwdemo_rtwecintro_step(void)
{
 boolean_T rtb_equal_to_count;

 /* Sum: '<Root>/Sum' incorporates:
 * Constant: '<Root>/INC'
 * UnitDelay: '<Root>/X'
 */
 rtDWork.X = (uint8_T)(1U + (uint32_T)(int32_T)rtDWork.X);

 /* RelationalOperator: '<Root>/RelOpt' incorporates:
 * Constant: '<Root>/LIMIT'
 */
 rtb_equal_to_count = (boolean_T)((int32_T)rtDWork.X != 16);

 /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
 * TriggerPort: '<S1>/Trigger'
 */
 if (((int32_T)rtb_equal_to_count) && ((int32_T)((int32_T)
rtPrevZCSigState.Amplifier_Trig_ZCE != (int32_T)POS_ZCSIG)) {
 /* Output: '<Root>/Output' incorporates:
 * Gain: '<S1>/Gain'
 * Inport: '<Root>/Input'
 */
 rtY.Output = rtU.Input << 1;
 }

 rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)
POS_ZCSIG : (int32_T)ZERO_ZCSIG);

 /* End of Outputs for SubSystem: '<Root>/Amplifier' */

 /* Switch: '<Root>/Switch' */
 if (!(int32_T)rtb_equal_to_count) {
 /* Update for UnitDelay: '<Root>/X' incorporates:
 * Constant: '<Root>/RESET'
 */
 rtDWork.X = 0U;
 }

 /* End of Switch: '<Root>/Switch' */
}

```

## Customize Code Organization and Format

### In this section...

“Custom File Processing Components” on page 52-45

“Custom File Processing Configuration” on page 52-46

Custom file processing (CFP) tools allow you to customize the organization and formatting of generated code. With these tools, you can:

- Generate a source (.c or .cpp) or header (.h) file. If you configure the **Code interface packaging** for a model to be `Reusable function` or `Nonreusable function` (not C++ class), you can use a *custom file processing template* to control how the code generator:
  - Emits code to standard generated files---*model.c* or *.cpp* and *model.h*
  - Produces files that are independent of model code
- Organize generated code into sections (such as includes, typedefs, functions, and more). Your CFP template can emit code (for example, functions), directives (such as `#define` or `#include` statements), or comments into each section.
- Generate custom *file banners* (comment sections) at the start and end of generated code files and custom *function banners* that precede functions in the generated code.
- Generate code to call model functions, such as *model\_initialize*, *model\_step*, and so on.
- Generate code to read and write model inputs and outputs.
- Generate a main program module.
- Obtain information about the model and the generated files from the model.

### Custom File Processing Components

The custom file processing features are based on the following interrelated components:

- *Code generation template* (CGT) files: a CGT file defines the top-level organization and formatting of generated code. See “Code Generation Template (CGT) Files” on page 52-48.
- The *code template API*: a high-level Target Language Compiler (TLC) API that provides functions with which you can organize code into named sections and subsections of generated source and header files. The code template API also provides utilities that return information about generated files, generate standard model calls, and perform other functions. See “Code Template API Summary” on page 52-70.
- *Custom file processing (CFP) templates*: a CFP template is a TLC file that manages the process of custom code generation. A CFP template assembles code to be generated into buffers. A CFP template also calls the code template API to emit the buffered code into specified sections of generated source and header files. A CFP template interacts with a CGT file, which defines the ordering of major sections of the generated code. See “Custom File Processing (CFP) Templates” on page 52-54.

To use CFP templates, you must understand TLC programming, for more information, see “Target Language Compiler”.

## Custom File Processing Configuration

Customize generated code by specifying code and data templates on the **Code Generation > Templates** pane:

Goal	Action
Specify a template that defines the top-level organization and formatting of generated source code (.c or .cpp) files	Enter a code generation template (CGT) file for the <b>Source file (*.c) template</b> parameter.
Specify a template that defines the top-level organization and formatting of generated header (.h) files	Enter a CGT file for the <b>Header file (*.h) template</b> parameter. This template file can be the same template file that you specify for <b>Source file (.c) template</b> . If you use the same template file, source and header files contain identical banners. The default template is <i>matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt</i> .
Specify a template that organizes generated code into sections (such as includes, typedefs, functions, and more)	Enter a custom file processing (CFP) template file for the “File customization template” parameter. A CFP template can emit code, directives, or comments into each section. For more information, see “Custom File Processing (CFP) Templates” on page 52-54.
Generate a model-specific example main program module	Select <b>Generate an example main program</b> . For more information, see “Generate a Standalone Program” on page 68-2.

---

**Note** Place the template files that you specify on the MATLAB path.

---

## Specify Templates For Code Generation

To use custom file processing features, create CGT files and CFP templates. These files are based on default templates provided by the code generation software. Once you have created your templates, you must integrate them into the code generation process.

Select and edit CGT files and CFP templates, and specify their use in the code generation process in the **Code Generation > Templates** pane of a model configuration set. The following figure shows options configured for their defaults.

The options related to custom file processing are:

- The **Source file (.c) template** field in the **Code templates** and **Data templates** sections. This field specifies the name of a CGT file to use when generating source (.c or .cpp) files. You must place this file on the MATLAB path.
- The **Header file (.h) template** field in the **Code templates** and **Data templates** sections. This field specifies the name of a CGT file to use when generating header (.h) files. You must place this file on the MATLAB path.

By default, the template for both source and header files is `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.

- The **File customization template** edit field in the **Custom templates** section. This field specifies the name of a CFP template file to use when generating code files. You must place this file on the MATLAB path. The default CFP template is `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`.

In each of these fields, click **Browse** to navigate to and select an existing CFP template or CGT file. Click **Edit** to open the specified file into the MATLAB editor where you can customize it.

## Code Generation Template (CGT) Files

Code Generation Template (CGT) files define the top-level organization and formatting of generated source code and header files. CGT files have the following applications:

- Generation of custom banners (comments sections) in code files. See “Generate Custom File and Function Banners” on page 52-73.
- Generation of custom code using a CFP template requires a CGT file. To use CFP templates, you must understand the CGT file structure. In many cases, however, you can use the default CGT file without modifying it.

### Default CGT file

The code generation software provides a default CGT file, *matlabroot/toolbox/rtw/targets/ecoder/ert\_code\_template.cgt*. Base your custom CGT files on the default file.

### CGT File Structure

A CGT file consists of one required section and four optional sections:

#### Code Insertion Section

(Required) This section contains tokens that define an ordered partitioning of the generated code into a number of sections (such as `Includes` and `Defines` sections). Tokens have the form of:

```
%<SectionName>
```

For example,

```
%<Includes>
```

The code generation software defines a minimal set of required tokens. These tokens generate C or C++ source or header code. They are *built-in* tokens (see “Built-In Tokens and Sections” on page 52-49). You can also define custom tokens on page 52-66 and custom sections on page 52-65.

Each token functions as a placeholder for a corresponding section of generated code. The ordering of the tokens defines the order in which the corresponding sections appear in the generated code. If you do not include a token, then the corresponding section is not generated. To generate code into a given section, explicitly call the code template API from a CFP template, as described in “Custom File Processing (CFP) Templates” on page 52-54.

The CGT tokens define the high-level organization of generated code. Using the code template API, you can partition each code section into named subsections, as described in “Subsections” on page 52-50.

In the code insertion section, you can also insert C or C++ comments between tokens. Such comments emit directly into the generated code.

#### File Banner Section

(Optional) This section contains comments and tokens you use in generating a custom file banner.

## Function Banner Section

(Optional) This section contains comments and tokens for use in generating a custom function banner.

## Shared Utility Function Banner Section

(Optional) This section contains comments and tokens for use in generating a custom shared utility function banner.

## File Trailer Section

(Optional) This section contains comments for use in generating a custom trailer banner.

For more information on these sections, see “Generate Custom File and Function Banners” on page 52-73.

## Built-In Tokens and Sections

The following code extract shows the required code insertion section of the default CGT file with the required built-in tokens.

```

%%
%% Code insertion section (required)
%% These are required tokens. You can insert comments and other tokens in
%% between them, but do not change their order or remove them.
%%
%<Includes>
%<Defines>
%<Types>
%<Enums>
%<Definitions>
%<Declarations>
%<Functions>

```

Note the following requirements for customizing a CGT file:

- Do not remove required built-in tokens.
- Built-in tokens must appear in the order shown because each successive section has dependencies on previous sections.
- Only one token per line.
- Do not repeat tokens.
- You can add custom tokens and comments to the code insertion section as long as you do not violate the previous requirements.

---

**Note** If you modify a CGT file and then rebuild your model, the code generation process does not force a top model build. To regenerate the code, see “Force Regeneration of Top Model Code”.

---

The following table summarizes the built-in tokens and corresponding section names, and describes the code sections.

**Built-In CGT Tokens and Corresponding Code Sections**

Token and Section Name	Description
Includes	<code>#include</code> directives section
Defines	<code>#define</code> directives section
Types	<code>typedef</code> section. Typedefs can depend on a previously defined type
Enums	Enumerated types section
Definitions	Data definitions (for example, <code>double x = 3.0;</code> )
Declarations	Data declarations (for example, <code>extern double x;</code> )
Functions	C or C++ functions

**Subsections**

You can define one or more named subsections for any section. Some of the built-in sections have predefined subsections summarized in table Subsections Defined for Built-In Sections.

---

**Note** Sections and subsections emit to the source or header file in the order listed in the CGT file.

---

Using the custom section feature, you can define additional sections. See “Generate a Custom Section” on page 52-65.

**Subsections Defined for Built-In Sections**

<b>Section</b>	<b>Subsections</b>	<b>Subsection Description</b>
Includes	N/A	
Defines	N/A	
Types	IntrinsicTypes	Intrinsic typedef section. Intrinsic types depend only on intrinsic C or C++ types.
Types	PrimitiveTypedefs	Primitive typedef section. Primitive typedefs depend only on intrinsic C or C++ types and on typedefs previously defined in the IntrinsicTypes section.
Types	UserTop	You can place any type of code in this section, including code that has dependencies on the previous sections.
Types	Typedefs	typedef section. Typedefs can depend on previously defined types
Enums	N/A	
Definitions	N/A	
Declarations	N/A	
Functions		C or C++ functions
Functions	CompilerErrors	<code>#error</code> directives
Functions	CompilerWarnings	<code>#warning</code> directives
Functions	Documentation	Documentation (comment) section
Functions	UserBottom	You can place any code in this section.

## Format Generated Code Files by Using Templates

This example shows how to use code generation templates to add custom code banners, rearrange data and functions, and insert additional code segments and documentation into generated code files.

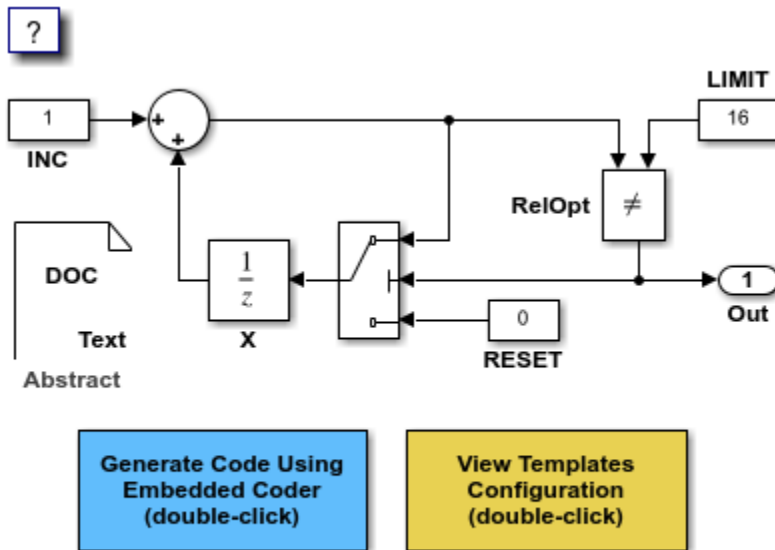

The model extracts text from the Model Description, a DOC block, and a Simulink® annotation. The Simulink annotation maps to the code template %<Note> symbol.

The templates provide consistent file layout and elaboration for your organization's coding standards. Embedded Coder® provides extensible code generation templates for formatting generated code. The layout and format of the code template file controls the output of the generated code.

Code generation templates (.cgt files) enable you to add custom code banners, rearrange data and functions, and insert additional code segments and documentation into the generated code files. Code generation templates are imported automatically from the MATLAB® path. For this model, the code generation template `rtwdemocodetemplate.cgt` is used.

1. Open model `rtwdemo_codetemplate`.

```
model='rtwdemo_codetemplate';
open_system(model)
```

Copyright 1994-2020 The MathWorks, Inc.

2. In the Configuration Parameters dialog box, open **Code Generation > Templates** pane.

3. In the **Code templates** section, click the **Edit** button beside **Source file template**. The `rtwdemocodetemplate.cgt` template opens in the MATLAB Command Window. Inspect the code template.

4. Build the model and generate code. On the **C Code** tab, click **Build**.

5. Open `rtwdemo_codetemplate.c` to inspect the generated code.

```
rtwdemoclean;
close_system(model,0)
```

## Custom File Processing (CFP) Templates

The files provided to support custom file processing are:

- `matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc`: A TLC function library that implements the code template API. `codetemplatelib.tlc` also provides the comprehensive documentation of the API in the comments headers preceding each function.
- `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`: An example custom file processing (CFP) template, which you should use as the starting point for creating your own CFP templates. Guidelines and examples for creating a CFP template are provided in “Generate Source and Header Files with a Custom File Processing (CFP) Template” on page 52-61.
- TLC files supporting generation of single-rate and multirate main program modules (see “Customizing Example Main Program Module Generation” on page 52-64).

Once you have created a CFP template, you must integrate it into the code generation process, using the **File customization template** edit field. See “Specify Templates For Code Generation” on page 52-47.

### Custom File Processing (CFP) Template Structure

A custom file processing (CFP) template imposes a simple structure on the code generation process. The template, a code generation template (CGT) file, partitions the code generated for each file into a number of sections. These sections are summarized in Built-In CGT Tokens and Corresponding Code Sections and Subsections Defined for Built-In Sections.

Code for each section is assembled in buffers and then emitted, in the order listed, to the file being generated.

To generate a file section, your CFP template must first assemble the code to be generated into a buffer. Then, to emit the section, your template calls the TLC function

```
LibSetSourceFileSection(fileH, section, tmpBuf)
```

where

- `fileH` is a file reference to a file being generated.
- `section` is the code section or subsection to which code is to be emitted. `section` must be one of the section or subsection names listed in Subsections Defined for Built-In Sections.

Determine the `section` argument as follows:

- If Subsections Defined for Built-In Sections does not define subsections for a given section, use the section name as the `section` argument.
- If Subsections Defined for Built-In Sections defines one or more subsections for a given section, you can use either the section name or a subsection name as the `section` argument.
- If you have defined a custom token denoting a custom section, do not call `LibSetSourceFileSection`. Special API calls are provided for custom sections (see “Generate a Custom Section” on page 52-65).
- `tmpBuf` is the buffer containing the code to be emitted.

There is no requirement to generate all of the available sections. Your template need only generate the sections you require in a particular file.

Note that legality or syntax checking is not performed on the custom code within each section.

See “Generate Source and Header Files with a Custom File Processing (CFP) Template” on page 52-61, for typical usage examples.

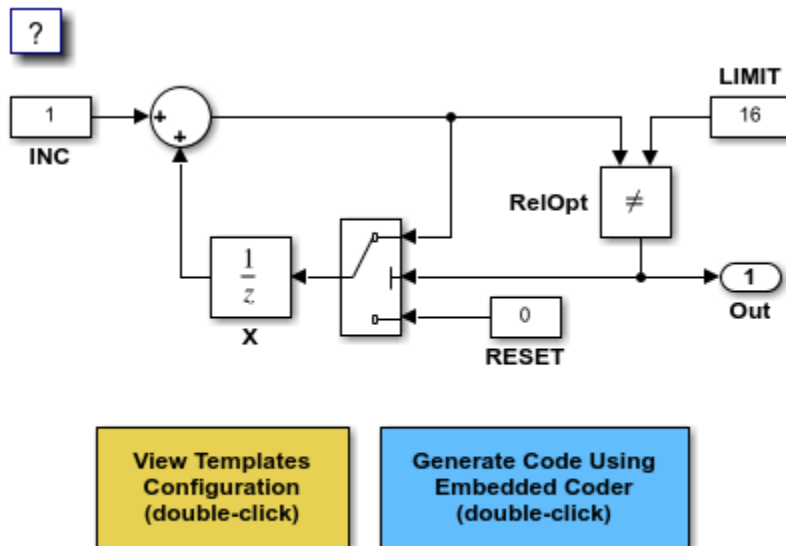

## Generate Additional Files Required to Interface with an Application

Embedded Coder® provides an extensible API to augment generated code and to generate additional files. The model configuration parameter **File customization template** specifies a custom Target Language Compiler (TLC) script that executes at the end of the code generation process. Using this script, you can generate additional code to interface with application code.

In this example, the TLC script file `rtwdemofileprocess.tlc` creates an additional entry-point function, `rtwdemo_fileprocess`, which calls the step function and initializes the model, if necessary. The initialization function is transparent to the caller.

1. Open the example model `rtwdemo_fileprocess`.

```
open_system('rtwdemo_fileprocess');
```

Copyright 1994-2020 The MathWorks, Inc.

2. Verify the model configuration parameter **File customization template** is set to `rtwdemofileprocess.tlc` by double-clicking the yellow button labeled **View Templates Configuration**.

3. Generate code.

4. Inspect the generated code. An additional function, `rtwdemo_fileprocess`, appears at the end of the generated file `rtwdemo_fileprocess.c`. The entry point is declared `extern` in `rtwdemo_fileprocess.h` as the `rtwdemofileprocess.tlc` script specifies.

## Change the Organization of a Generated File

The files created during code generation are organized according to the general code generation template. This template has the filename `ert_code_template.cgt`, and is specified by default in **Code Generation > Templates** pane of the Configuration Parameters dialog box.

The following fragment shows the `rtwdemo_configinterface.c` file header that is generated using this default template:

```

/*
 * File: rtwdemo_configinterface.c
 *
 * Code generated for Simulink model 'rtwdemo_configinterface'.
 *
 * Model version : 1.387
 * Simulink Coder version : 9.4 (R2020b) 19-May-2020
 * C/C++ source code generated on : Thu Jun 11 14:31:07 2020
 *
 * Target selection: ert.tlc
 * Embedded hardware selection: Intel->x86-64 (Windows64)
 * Code generation objectives: Unspecified
 * Validation result: Not run
 */

```

You can change the organization of generated files using code templates and data templates. Code templates organize the files that contain functions, primarily. Data templates organize the files that contain identifiers. In this procedure, you organize the generated files, using the supplied code and data templates:

- 1 In the Configuration Parameters dialog box, open the **Code Generation > Templates** pane.
- 2 In the **Code templates** section, in the **Source file template** box, type `code_c_template.cgt`.
- 3 In the **Header file template** box, type `code_h_template.cgt`.
- 4 In the **Data templates** section, in the **Source file template** box, type `data_c_template.cgt`.
- 5 In the **Header file template** box, type `data_h_template.cgt`.
- 6 Click **Apply**.
- 7 In the model window, press **Ctrl+B**. Now the files are organized using the templates you specified. For example, the `rtwdemo_configinterface.c` file header now is organized like this:

```

/**

** FILE INFORMATION:
** Filename: rtwdemo_configinterface.c
** File Creation Date: 11-Jun-2020
**
** ABSTRACT:
**
**
** NOTES:
**
**
** MODEL INFORMATION:
** Model Name: rtwdemo_configinterface
** Model Description: Data Dictionary Driven Modeling Using
** Simulink(R) Data Objects

```

This model shows how to use Simulink data objects to define data independently from the diagram which supports a data dictionary

```
driven modeling style.
** Model Version: 1.387
** Model Author: The MathWorks, Inc. - Mon Nov 27 14:36:56 2000
**
** MODIFICATION HISTORY:

**
**

**/
```

## Customize Generated File Names

The code generator creates *model.\** files during the code generation and build process. When you generate C/C++ code for ERT-based models, you can customize the names of the generated header, source, and data files. You cannot customize the generated files for referenced models. Custom file names enable you to:

- Comply with naming standards of the company or industry.
- Integrate with external code.

In the Configuration Parameters dialog box, on the **Code Generation > Code Placement** pane, use the **Auto-generated file naming rules** group to customize the names of generated files. When you use Modular or Compact(with separate date file) file packaging, you can specify custom names for generated header, source, and data files. When you use Compact file packaging, you can specify custom names for generated header and source files.

- 1 Open any ERT-based model, for example, `rtwdemo_dynamicio`. In the Configuration Parameters dialog box, change the **System target file** to `ert.tlc`.
- 2 On the **Code Generation > Code Placement** pane, select **File packaging format** as `Compact(with separate date file)`.
- 3 Specify custom file names by using the naming rules for these parameters:
  - **Header files:** `$R$E_header`
  - **Source files:** `$R$E_source`
  - **Data files:** `$R_data`

`$E` is mandatory for **Header files** and **Source files**. `$E` represents these instances of file types:

- `capi`
  - `capi_host`
  - `dt`
  - `testinterface`
  - `private`
  - `types`
- 4 To build the model, press **Ctrl + B**. In the code generation report, the generated files are listed on the left pane under **Model files** and **Data files** section.

**Generated Code**[-] **Main file**[ert\\_main.c](#)[-] **Model files**[rtwdemo\\_dynamicicio\\_header.h](#)[rtwdemo\\_dynamicicio\\_private\\_header.h](#)[rtwdemo\\_dynamicicio\\_source.c](#)[rtwdemo\\_dynamicicio\\_types\\_header.h](#)[-] **Data files**[rtwdemo\\_dynamicicio\\_data.c](#)

In this example, \$E resolves to `private` and `types`. The generated header files resolve to the model name with the value for \$E and custom text header. The generated source files resolve to the model name with custom text `source`. The generated data file resolves to the model name with custom text `data`. Here is a summary of naming rules applied and the corresponding generated files:

Type of File	Token Specification	Custom Text	Generated File Name
Header file	\$R\$E	header	rtwdemo_dynamicicio_header.h
Header file	\$R\$E	header	rtwdemo_dynamicicio_private_header.h
Source file	\$R\$E	source	rtwdemo_dynamicicio_source.c
Header file	\$R\$E	header	rtwdemo_dynamicicio_types_header.h
Data file	\$R	data	rtwdemo_dynamicicio_data.c

## Generate Source and Header Files with a Custom File Processing (CFP) Template

### In this section...

“Generate Code with a CFP Template” on page 52-61

“Analysis of the Example CFP Template and Generated Code” on page 52-62

“Generate a Custom Section” on page 52-65

“Custom Tokens” on page 52-66

This example shows you the process of generating a simple source (.c or .cpp) and header (.h) file using the example CFP template. Then, it examines the template and the code generated by the template.

The example CFP template, `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`, demonstrates some of the capabilities of the code template API, including

- Generation of simple source (.c or .cpp) and header (.h) files
- Use of buffers to generate file sections for includes, functions, and so on
- Generation of includes, defines, into the standard generated files (for example, `model.h`)
- Generation of a main program module

### Generate Code with a CFP Template

This section sets up a CFP template and configures a model to use the template in code generation. The template generates (in addition to the standard model files) a source file (`timestwo.c` or `.cpp`) and a header file (`timestwo.h`).

Follow the steps below to become acquainted with the use of CFP templates:

- 1 Copy the example CFP template, `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`, to a folder outside of the MATLAB folder structure (that is, not under `matlabroot`). If the folder is not on the MATLAB path or the TLC path, then add it to the MATLAB path. It is good practice to locate the CFP template in the same folder as your system target file, which is on the TLC path.
- 2 Rename the copied `example_file_process.tlc` to `test_example_file_process.tlc`.
- 3 Open `test_example_file_process.tlc` into the MATLAB editor.
- 4 Uncomment the following line:

```
% %assign ERTCustomFileTest = TLC_TRUE
```

It now reads:

```
%assign ERTCustomFileTest = TLC_TRUE
```

If `ERTCustomFileTest` is not assigned as shown, the CFP template is ignored in code generation.

- 5 Save your changes to the file. Keep `test_example_file_process.tlc` open, so you can refer to it later.

- 6 Open the `rtwdemo_udt` model.
- 7 Open the Simulink Model Explorer. Select the active configuration set of the model, and open the **Code Generation** pane of the active configuration set.
- 8 On the **Templates** tab, in the **File customization template** field, specify `test_example_file_process.tlc`. This is the file you previously edited and is now the specified CFP template for your model.
- 9 On the **General** tab, select the **Generate code only** check box.
- 10 Click **Apply**.
- 11 In the model window, press **Ctrl+B**. During code generation, notice the following message in the **Diagnostic Viewer**:

Warning: Overriding example ert\_main.c!

This message is displayed because `test_example_file_process.tlc` generates the main program module, overriding the default action of the ERT target. This is explained in greater detail below.

- 12 The `rtwdemo_udt` model is configured to generate an HTML code generation report. After code generation is complete, view the report.

Notice that the **Generated Code** list contains the following files:

- Under **Main file**, `ert_main.c`.
- Under **Other files**, `timestwo.c` and `timestwo.h`.

The files were generated by the CFP template. The next section examines the template to learn how this was done.

- 13 Keep the model, the code generation report, and the `test_example_file_process.tlc` file open so you can refer to them in the next section.

## Analysis of the Example CFP Template and Generated Code

This section examines excerpts from `test_example_file_process.tlc` and some of the code it generates. Refer to the comments in `matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc` while reading the following discussion.

### Generating Code Files

Source (`.c` or `.cpp`) and header (`.h`) files are created by calling `LibCreateSourceFile`, as in the following excerpts:

```
%assign cFile = LibCreateSourceFile("Source", "Custom", "timestwo")
...
%assign hFile = LibCreateSourceFile("Header", "Custom", "timestwo")
```

Subsequent code refers to the files by the file reference returned from `LibCreateSourceFile`.

### File Sections and Buffers

The code template API lets you partition the code generated to each file into sections, tagged as **Definitions**, **Includes**, **Functions**, **Banner**, and so on. You can append code to each section as many times as required. This technique gives you a great deal of flexibility in the formatting of your custom code files.

Subsections Defined for Built-In Sections describes the available file sections and their order in the generated file.

For each section of a generated file, use `%openfile` and `%closefile` to store the text for that section in temporary buffers. Then, to write (append) the buffer contents to a file section, call `LibSetSourceFileSection`, passing in the desired section tag and file reference. For example, the following code uses two buffers (`typesBuf` and `tmpBuf`) to generate two sections (tagged "Includes" and "Functions") of the source file `timestwo.c` or `.cpp` (referenced as `cFile`):

```
%openfile typesBuf

#include "rtwtypes.h"

%closefile typesBuf

%<LibSetSourceFileSection(cFile,"Includes",typesBuf)>

 %openfile tmpBuf

 /* Times two function */
 real_T timestwofcn(real_T input) {
 return (input * 2.0);
 }

%closefile tmpBuf

%<LibSetSourceFileSection(cFile,"Functions",tmpBuf)>
```

These two sections generate the entire `timestwo.c` or `.cpp` file:

```
#include "rtwtypes.h"

/* Times two function */
FLOAT64 timestwofcn(FLOAT64 input)
{
 return (input * 2.0);
}
```

### Adding Code to Standard Generated Files

The `timestwo.c` or `.cpp` file generated in the previous example was independent of the standard code files generated from a model (for example, `model.c` or `.cpp`, `model.h`, and so on). You can use similar techniques to generate custom code within the model files. The code template API includes functions to obtain the names of the standard models files and other model-related information. The following excerpt calls `LibGetMdlPubHdrBaseName` to obtain the name for the `model.h` file. It then obtains a file reference and generates a definition in the `Defines` section of `model.h`:

```
%% Add a #define to the model's public header file model.h

%assign pubName = LibGetMdlPubHdrBaseName()
%assign modelH = LibCreateSourceFile("Header", "Simulink", pubName)

%openfile tmpBuf

 #define ACCELERATION 9.81

%closefile tmpBuf

%<LibSetSourceFileSection(modelH,"Defines",tmpBuf)>
```

Examine the generated `rtwdemo_udt.h` file to see the generated `#define` directive.

### Customizing Example Main Program Module Generation

ERT-based system target files determine whether and how to generate an example main program module (`ert_main.c` or `ert_main.cpp`) based on the settings of the model configuration parameters **Generate an example main program** and **Target operating system**. You can override the default behavior and generate a main program customized for your target environment.

Two TLC files support generation of an example main program module:

- `bareboard_srmain.tlc`: TLC code for generating a single-rate example main program module for a bare-board target environment. TLC function `FcnSingleTaskingMain` generates the code.
- `bareboard_mrmain.tlc`: TLC code for generating a multirate example main program module for a bare-board target environment. TLC function `FcnMultiTaskingMain` generates the code.

In the example CFP template file `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`, this code generates a single- or multitasking example main program module. The logic depends on information obtained from the code template calls to `LibIsSingleRateModel` and `LibIsSingleTasking`.

```
%% Create a simple main. Files are located in MATLAB/rtw/c/tlc/mw.

%if LibIsSingleRateModel() || LibIsSingleTasking()
 %include "bareboard_srmain.tlc"
 %<FcnSingleTaskingMain()>
%else
 %include "bareboard_mrmain.tlc"
 %<FcnMultiTaskingMain()>
%endif
```

Files `bareboard_srmain.tlc` and `bareboard_mrmain.tlc` use the code template programming interface to generate the example main program modules `ert_main.c` or `ert_main.cpp`.

By default, the code generator produces an example main program module. To disable generation of that module, set the TLC variable `OverrideSampleERTMain` to `TLC_TRUE`.

For example:

```
%if GenerateSampleERTMain
 %assign CompiledModel.OverrideSampleERTMain = TLC_TRUE
 %warning Overriding example ert_main.c!
%endif
```

Alternatively, you can implement a `SelectCallback` function for your target. A `SelectCallback` function is a MATLAB function that is triggered when you:

- Load the model.
- Update model configuration parameter settings.
- Build the model.

Your `SelectCallback` clears the model configuration parameter **Generate an example main program**. Clearing the parameter prevents TLC variable `GenerateSampleERTMain` from being set to `TLC_TRUE`.

For information on how to create a `SelectCallback` function, see “`rtwgensettings` Structure”.

This code shows how to clear the **Generate an example main program** parameter in the context of a `SelectCallback` function.

```
slConfigUISetVal(hDlg, hSrc, 'GenerateSampleERTMain', 'off');
slConfigUISetEnabled(hDlg, hSrc, 'GenerateSampleERTMain', 0);
hSrc.refreshDialog;
```

Creation of a main program for your target environment requires customization. For example, in a bare-board environment, you need to attach `rt_OneStep` to a timer interrupt and customize the generated code, the generating TLC code, or both. For more information, see “Guidelines for Modifying the Main Program” on page 68-3 and “Guidelines for Modifying `rt_OneStep`” on page 68-7.

## Generate a Custom Section

You can define custom tokens on page 52-66 in a CGT file and direct generated code into an associated built-in section. This feature gives you additional control over the formatting of code within each built-in section. For example, you could add subsections to built-in sections that do not already define subsections. Custom sections must be associated with one of the built-in sections: `Includes`, `Defines`, `Types`, `Enums`, `Definitions`, `Declarations`, or `Functions`. To create custom sections, you must

- Add a custom token to the code insertion section of your CGT file.
- In your CFP file:
  - Assemble code to be generated to the custom section into a buffer.
  - Declare an association between the custom section and a built-in section, with the code template API function `LibAddSourceFileCustomSection`.
  - Emit code to the custom section with the code template API function `LibSetSourceFileCustomSection`.

The following code examples illustrate the addition of a custom token, `Myincludes`, to a CGT file, and the subsequent association of the custom section `Myincludes` with the built-in section `Includes` in a CFP file.

---

**Note** If you have not already created custom CGT and CFP files for your model, copy the default template files `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt` and `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc` to a work folder that is outside the MATLAB folder structure but on the MATLAB or TLC path, rename them (for example, add the prefix `test_` to each file), and update the **Templates** pane of the Configuration Parameters dialog box to reference them.

---

First, add the token `Myincludes` to the code insertion section of your CGT file. For example:

```
%<Includes>
%<Myincludes>
%<Defines>
%<Types>
%<Enums>
%<Definitions>
%<Declarations>
%<Functions>
```

Next, in the CFP file, add code to generate include directives into a buffer. For example, in your copy of the example CFP file, you could insert the following section between the `Includes` section and the `Create a simple main` section:

```
%% Add a custom section to the model's C file model.c

%openfile tmpBuf
#include "moretables1.h"
#include "moretables2.h"
%closefile tmpBuf

%<LibAddSourceFileCustomSection(modelC,"Includes","Myincludes")>
%<LibSetSourceFileCustomSection(modelC,"Myincludes",tmpBuf)>
```

The `LibAddSourceFileCustomSection` function call declares an association between the built-in section `Includes` and the custom section `Myincludes`. `Myincludes` is a subsection of `Includes`. The `LibSetSourceFileCustomSection` function call directs the code in the `tmpBuf` buffer to the `Myincludes` section of the generated file. `LibSetSourceFileCustomSection` is syntactically identical to `LibSetSourceFileSection`.

In the generated code, the include directives generated to the custom section appear after other code directed to `Includes`.

```
#include "rtwdemo_udt.h"
#include "rtwdemo_udt_private.h"

/* #include "mytables.h" */
#include "moretables1.h"
#include "moretables2.h"
```

---

**Note** The placement of the custom token in this example CGT file is arbitrary. By locating `%<Myincludes>` after `%<Includes>`, the CGT file specifies only that the `Myincludes` code appears after `Includes` code.

---

## Custom Tokens

Custom tokens are automatically translated to TLC syntax as a part of the build process. To escape a token, that is to prepare it for normal TLC expansion, use the `!` character. For example, the token `%<!TokenName>` is expanded to `%<TokenName>` by the template conversion program. You can specify valid TLC code, including TLC function calls: `%<!MyTLCFcn()>`.

Custom tokens are not supported when you generate C++ code.

## Comparison of a Template and Its Generated File

This figure shows part of a user-modified custom file processing (CFP) template and the resulting generated code. The figure illustrates how you can use a template to:

- Define what code the code generation software should add to the generated file
- Control the location of code in the file
- Optionally insert comments in the generated file

Notice %<Includes>, for example, on the template. The term Includes is a symbol name. A percent sign and brackets (%< >) must enclose every symbol name. You can add the desired symbol name (within the %< > delimiter) at a particular location in the template. This is how you control where the code generator places an item in the generated file.

### Template and Generated File

## Mapping Template Specification to Code Generation

This part of the template...		Generates in the file...		Explanation
		Line	Description	
(1)	<code>/*#INCLUDES*/ %&lt;Includes&gt;</code>	26-28	An <code>/*#INCLUDES*/</code> comment, followed by <code>#include</code> statements	The code generator adds the C/C++ comment as a header, and then interprets the <code>%&lt;Includes&gt;</code> template symbol to list the required <code>#include</code> statements in the file. This code is first in this section of the file because the template entries are first.
(2)	<code>/*#DEFINES*/ %&lt;Defines&gt;</code>	30	A <code>/*#DEFINES*/</code> comment, but no <code>#define</code> statements	Next, the code generator places the comment as a header for <code>#define</code> statements, but the file does not need <code>#define</code> . No code is added.
(3)	<code>#pragma string1</code>	31	<code>#pragma</code> statements	While the code generator requires <code>%&lt;&gt;</code> delimiters for template symbols, it can also interpret C/C++ statements in the template without delimiters. In this case, the generator adds the specified statements to the code, following the order in which the statements appear in the template.
(5)	<code>#pragma string2</code>	42		
(4)	<code>/*DEFINITIONS*/ %&lt;Definitions&gt;</code>	32-41	<code>/*DEFINITIONS*/</code> comment, followed by definitions	The code generator places the comment and definitions in the file between the <code>#pragma</code> statements, according to the order in the template. It also inserts comments (lines 33 and 36) that are preset in the model's Configuration Parameters dialog box.
(6)	<code>%&lt;Declarations&gt;</code>	43	No declarations	The file needs no declarations, so the code generator does not generate declarations for this file. The template does not have a comment to provide a header. Line 43 is left blank.
(7)	<code>%&lt;Functions&gt;</code>	44-74	Functions	Finally, the code generator adds functions from the model, plus comments that are preset in the Configuration Parameters dialog box. But it adds no comments as a header for the functions, because the template does not have one. This code is last because the template entry is last.

For a list of template symbols and the rules for using them, see “Template Symbol Groups” on page 52-80, “Template Symbols” on page 52-82, and “Rules for Modifying or Creating a Template” on

page 52-84. To set comment options, in the Configuration Parameters dialog box, select the **Code Generation > Comments** pane. For details, see "Configure Code Comments".

## Code Template API Summary

Code Template API Functions summarizes the code template API. See the source code in *matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc* for detailed information on the arguments, return values, and operation of these calls.

## Code Template API Functions

Function	Description
LibClearFileSectionContents	Clears a file section with custom values before writing file to disk.
LibGetNumSourceFiles	Returns the number of created source files (.c or .cpp and .h).
LibGetSourceFileTag	Returns <filename>_h and <filename>_c for header and source files, respectively, where filename is the name of the model file.
LibCreateSourceFile	Creates a new C or C++ file and returns its reference. If the file already exists, simply returns its reference.
LibGetFileRecordName	Returns a model file name (including the path) without the extension.
LibGetSourceFileFromIdx	Returns a model file reference based on its index. This is useful for a common operation on all files, such as to set the leading file banner of all files.
LibSetSourceFileSection	Adds to the contents of a specified section within a specified file (see also "Custom File Processing (CFP) Template Structure" on page 52-54).
LibIndentSourceFile	Indents a file (from within the TLC environment).
LibCallModelInitialize	Returns code for calling the model's <i>model_initialize</i> function (valid for ERT only).
LibCallModelStep	Returns code for calling the model's <i>model_step</i> function (valid for ERT only).
LibCallModelTerminate	Returns code for calling the model's <i>model_terminate</i> function (valid for ERT only).
LibCallSetEventForThisBaseStep	Returns code for calling the model's set events function (valid for ERT only).
LibWriteModelData	Returns data for the model (valid for ERT only).
LibSetRTModelErrorStatus	Returns the code to set the model error status.
LibGetRTModelErrorStatus	Returns the code to get the model error status.
LibIsSingleRateModel	Returns true if model is single rate and false otherwise.
LibGetModelName	Returns name of the model (without an extension).
LibGetMdlSrcBaseName	Returns the name of model's main source file (for example, <i>model.c</i> or <i>.cpp</i> ).
LibGetMdlPubHdrBaseName	Returns the name of model's public header file (for example, <i>model.h</i> ).
LibGetMdlPrvHdrBaseName	Returns the name of the model's private header file (for example, <i>model_private.h</i> ).
LibIsSingleTasking	Returns true if the model is configured for single-tasking execution.

<b>Function</b>	<b>Description</b>
<code>LibWriteModelInput</code>	Returns the code to write to a particular root input (that is, a model inport block). (valid for ERT only).
<code>LibWriteModelOutput</code>	Returns the code to write to a particular root output (that is, a model outport block). (valid for ERT only).
<code>LibWriteModelInputs</code>	Returns the code to write to root inputs (that is, all model inport blocks). (valid for ERT only)
<code>LibWriteModelOutputs</code>	Returns the code to write to root outputs (that is, all model outport blocks). (valid for ERT only).
<code>LibNumDiscreteSampleTimes</code>	Returns the number of discrete sample times in the model.
<code>LibSetSourceFileCodeTemplate</code>	Set the code template to be used for generating a specified source file.
<code>LibSetSourceFileOutputDirectory</code>	Set the folder into which a specified source file is to be generated.
<code>LibAddSourceFileCustomSection</code>	Add a custom section to a source file. The custom section must be associated with one of the built-in (required) sections: <code>Includes</code> , <code>Defines</code> , <code>Types</code> , <code>Enums</code> , <code>Definitions</code> , <code>Declarations</code> , or <code>Functions</code> .
<code>LibSetSourceFileCustomSection</code>	Adds to the contents of a specified custom section within a specified file. The custom section must have been previously created with <code>LibAddSourceFileCustomSection</code> .

## Generate Custom File and Function Banners

Using code generation template (CGT) files, you can specify custom file banners and function banners for the generated code files. File banners are comment sections in the header and trailer sections of a generated file. Function banners are comment sections for each function in the generated code. Use these banners to add a company copyright statement, specify a special version symbol for your configuration management system, remove time stamps, and for many other purposes. These banners can contain characters, which propagate to the generated code.

To specify banners, create a custom CGT file with customized banner sections. The build process creates an executable TLC file from the CGT file. The code generation process then invokes the TLC file.

You do not need to be familiar with TLC programming to generate custom banners. You can modify example files that are supplied with the ERT target.

---

**Note** Prior releases supported direct use of customized TLC files as banner templates. You specified these with the **Source file (.c) banner template** and **Header file (.h) banner template** options of the ERT target. You can still use a custom TLC file banner template, however, you can now use CGT files instead.

---

ERT template options on the **Code Generation > Templates** pane of a configuration set, in the **Code templates** section, support banner generation.

The options for function and file banner generation are:

- “Code templates: Source file (\*.c) template”: CGT file to use when generating source (.c or .cpp) files. Place this file on the MATLAB path.
- “Code templates: Header file (\*.h) template”: CGT file to use when generating header (.h) files. You must place this file on the MATLAB path. This file can be the same template specified in the **Code templates: Source file (\*.c) template** field, in which case identical banners are generated in source and header files.

By default, the template for both source and header files is *matlabroot/toolbox/rtw/targets/ecoder/ert\_code\_template.cgt*.

- In each of these fields, click **Browse** to navigate to and select an existing CGT file for use as a template. Click **Edit** to open the specified file into the MATLAB editor, where you can customize it.

### Create a Custom File and Function Banner Template

To customize a CGT file for custom banner generation, make a local copy of the default code template and edit it, as follows:

- 1 Activate the configuration set that you want to work with.
- 2 Open the **Code Generation** pane of the active configuration set.
- 3 Click the **Templates** tab.
- 4 By default, the code template specified in the **Code templates: Source file (\*.c) template** and **Code templates: Header file (\*.h) template** fields is *matlabroot/toolbox/rtw/targets/ecoder/ert\_code\_template.cgt*.

- 5 If you want to use a different template as your starting point, click **Browse** to locate and select a CGT file.
- 6 Click **Edit** button to open the CGT file into the MATLAB editor.
- 7 Save a local copy of the CGT file. Store the copy in a folder that is outside of the MATLAB folder structure, but on the MATLAB path. If required, add the folder to the MATLAB path.
- 8 If you intend to use the CGT file with a custom target, locate the CGT file in a folder under your target root folder.
- 9 Rename your local copy of the CGT file. When you rename the CGT file, update the associated **Code templates: Source file (\*.c) template** or **Code templates: Header file (\*.h) template** field to match the new file name.
- 10 Edit and customize the local copy of the CGT file for banner generation, using the information provided in “Customize a Code Generation Template (CGT) File for File and Function Banner Generation” on page 52-74.
- 11 Save your changes to the CGT file.
- 12 Click **Apply** to update the configuration set.
- 13 Save your model.
- 14 Generate code. Examine the generated source and header files to confirm that they contain the banners specified by the template or templates.

## Customize a Code Generation Template (CGT) File for File and Function Banner Generation

This section describes how to edit a CGT file for custom file and function banner generation. For a description of CGT files, see “Code Generation Template (CGT) Files” on page 52-48.

### Components of the File and Function Banner Sections in the CGT file

In a CGT file, you can modify the following sections: file banner, function banner, shared utility function banner, and file trailer. Each section is defined by open and close tags. The tags specific to each section are shown in the following table.

CGT File Section	Open Tag	Close Tag
File Banner on page 52-76	<FileBanner>	</FileBanner>
Function Banner on page 52-77	<FunctionBanner>	</FunctionBanner>
Shared-utility Banner on page 52-78	<SharedUtilityBanner>	</SharedUtilityBanner>
File Trailer on page 52-78	<FileTrailer>	</FileTrailer>

You can customize your banners by including tokens and comments between the open and close tag for each section. Tokens are typically TLC variables, for example <ModelVersion>, which are replaced with values in the generated code.

**Note** Including C comment indicators, '/\*' or a '\*/', in the contents of your banner might introduce an error in the generated code.

An open tag includes tag attributes. Enclose the value of the attribute in double quotes. The attributes available for an open tag are:

- `width`: specifies the width of the file or function banner comments in the generated code. The default value is 80.
- `style`: specifies the boundary for the file or function banner comments in the generated code.

The open tag syntax is as follows:

```
<OpenTag style = "style_value" width = "num_width">
```

---

**Note** If the **Configuration Parameters > Code Generation > Language** parameter is set to C++, to select a comment style that uses C comment notation (`/*...*/`), you must also set the **Configuration Parameters > Comments > Comment style** parameter to Multi-line.

---

The built-in style options for the `style` attribute are:

- `classic`

```
/* single line comments */
/*
 * multiple line comments
 * second line
 */
```

- `classic_cpp`

```
// single line comments
//
// multiple line comments
// second line
//
```

- `box`

```
/******
/* banner contents */
/******
```

- `box_cpp`

```
////////////////////////////////////
// banner contents //
////////////////////////////////////
```

- `open_box`

```
/******
 * banner contents

```

- `open_box_cpp`

```
////////////////////////////////////
// banner contents
////////////////////////////////////
```

- `doxygen`

```

/** single line comments */

/**
 * multiple line comments
 * second line
 */

```

- `doxygen_cpp`

```

/// single line comments

///
/// multiple line comments
/// second line
///

```
- `doxygen_qt`

```

/*! single line comments */

/*!
 * multiple line comments
 * second line
 */

```
- `doxygen_qt_cpp`

```

//! single line comments

//!
//! multiple line comments
//! second line
//!

```

### File Banner

This section contains comments and tokens for use in generating a custom file banner. The file banner precedes C or C++ code generated by the model. If you omit the file banner section from the CGT file, then no file banner emits to the generated code.

---

**Note** If you customize your file banner, the software does not emit the customized banner for the file `const_params.c`.

---

The following section is the file banner section provided with the default CGT file, `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.

```

%%
% Custom file banner section (optional)
%
<FileBanner style="classic">
File: %<FileName>

Code generated for Simulink model %<ModelName>.

Model version : %<ModelVersion>
Simulink Coder version : %<RTWFileVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
%<CodeGenSettings>
</FileBanner>

```

## Summary of Tokens for File Banner Generation

FileName	Name of the generated file (for example, "rtwdemo_udt.c").
FileType	Either "source" or "header". Designates whether generated file is a .c or .cpp file or an .h file.
FileTag	Given file names file.c or .cpp and file.h; the file tags are "file_c" and "file_h", respectively.
ModelName	Name of generating model.
ModelVersion	Version number of model.
Description	Description of the model specified in the CGT file or the text specified in the <b>Descripton</b> tab in <b>Model Properties (Modeling &gt; Model Settings)</b> . This token is not supported for referenced models in a model reference hierarchy.
RTWFileVersion	Version number of <i>model.rtw</i> file.
RTWFileGeneratedOn	Timestamp of <i>model.rtw</i> file.
TLCVersion	Version of Target Language Compiler.
SourceGeneratedOn	Timestamp of generated file.
CodeGenSettings	Code generation settings for model: target language, target selection, production hardware selection, test hardware selection, code generation objectives (in priority order), and Code Generation Advisor validation result.

## Function Banner

This section contains comments and tokens for use in generating a custom function banner. The function banner precedes C or C++ function generated during the build process. If you omit the function banner section from the CGT file, the default function banner emits to the generated code. The following section is the default function banner section provided with the default CGT file, *matlabroot/toolbox/rtw/targets/ecoder/ert\_code\_template.cgt*.

```

%%
%% Custom function banner section (optional)
%% Customize function banners by using the following predefined tokens:
%% %<ModelName>, %<FunctionName>, %<FunctionDescription>, %<Arguments>,
%% %<ReturnType>, %<GeneratedFor>, %<BlockDescription>.
%%
<FunctionBanner style="classic">
%<FunctionDescription>
%<BlockDescription>
</FunctionBanner>

```

### Summary of Tokens for Function Banner Generation

FunctionName	Name of function
Arguments	List of function arguments
ReturnType	Return type of function
ModelName	Name of generating model
FunctionDescription	Short abstract about the function
GeneratedFor	Full block path for the generated function
BlockDescription	User input from the <b>Block Description</b> parameter of the block properties dialog box. <b>BlockDescription</b> contains an optional token attribute, <b>style</b> . The only valid value for <b>style</b> is <b>content_only</b> , which is case-sensitive and enclosed in double quotes. Use the <b>content_only</b> style when you want to include only the block description content that you entered in the block parameter dialog. The syntax for the token attribute <b>style</b> is:  %<BlockDescription style = "content_only">

### Shared Utility Function Banner

The shared utility function banner section contains comments and tokens for use in generating a custom shared utility function banner. The shared utility function banner precedes C or C++ shared utility function generated during the build process. If you omit the shared utility function banner section from the CGT file, the default shared utility function banner emits to the generated code. The following section is the default shared utility function banner section provided with the default CGT file, *matlabroot/toolbox/rtw/targets/ecoder/ert\_code\_template.cgt*.

```

%%
%% Custom shared utility function banner section (optional)
%% Customize banners for functions generated in shared location by using the
%% following predefined tokens: %<FunctionName>, %<FunctionDescription>,
%% %<Arguments>, %<ReturnType>.
%%
<SharedUtilityBanner style="classic">
%<FunctionDescription>
</SharedUtilityBanner>

```

### Summary of Tokens for Shared Utility Function Banner Generation

FunctionName	Name of function
Arguments	List of function arguments
ReturnType	Return type of function
FunctionDescription	Short abstract about function

### File Trailer

The file trailer section contains comments for generating a custom file trailer. The file trailer follows C or C++ code generated from the model. If you omit the file trailer section from the CGT file, no file trailer emits to the generated code. The following section is the default file trailer provided in the default CGT file.

```

%%
%% Custom file trailer section (optional)
%%
<FileTrailer style="classic">

```

File trailer for generated code.

```
[EOF]
</FileTrailer>
```

Tokens available for the file banner are available for the file trailer. See Summary of Tokens for File Banner Generation.

## Template Symbols and Rules

### In this section...

“Introduction” on page 52-80

“Template Symbol Groups” on page 52-80

“Template Symbols” on page 52-82

“Rules for Modifying or Creating a Template” on page 52-84

### Introduction

“Template Symbol Groups” on page 52-80 and “Template Symbols” on page 52-82 describe custom file processing (CFP) template symbols and rules for using them. The location of a symbol in one of the supplied template files (`code_c_template.cgt`, `code_h_template.cgt`, `data_c_template.cgt`, or `data_h_template.cgt`) determines where the items associated with that symbol are located in the corresponding generated file. “Template Symbol Groups” on page 52-80 identifies the symbol groups, starting with the parent (“Base”) group, followed by the children of each parent. “Template Symbols” on page 52-82 lists the symbols alphabetically.

**Note** If you are using custom CGT sections, for files generated to the `_sharedutils` folder, you can only use symbol names in the Base symbol group.

### Template Symbol Groups

Symbol Group	Symbol Names in This Group
Base (Parents)	Declarations Defines Definitions Documentation Enums Functions Includes Types
Declarations	ExternalCalibrationLookup1D ExternalCalibrationLookup2D ExternalCalibrationScalar ExternalVariableScalar

<b>Symbol Group</b>	<b>Symbol Names in This Group</b>
Defines	LocalDefines LocalMacros
Definitions	FilescopeCalibrationLookup1D FilescopeCalibrationLookup2D FilescopeCalibrationScalar FilescopeVariableScalar GlobalCalibrationLookup1D GlobalCalibrationLookup2D GlobalCalibrationScalar GlobalVariableScalar
Documentation	Abstract Banner Created Creator Date Description FileName History LastModifiedDate LastModifiedBy ModelName ModelVersion ModifiedBy
	Notes ToolVersion
Functions	CFunctionCode
Types	This parent has no children.

## Template Symbols

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
Abstract	Documentation	N/A	User-supplied description of the model or file. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**
Banner	Documentation	N/A	Comments located near top of the file. Contains information that includes model and software versions, and date file was generated.
CFunctionCode	Functions	File	C/C++ functions. Must be at the bottom of the template.
Created	Documentation	N/A	Date when model was created. From <b>Created on</b> field on Model Properties dialog box.
Creator	Documentation	N/A	User who created model. From <b>Created by</b> field on Model Properties dialog box.
Date	Documentation	N/A	Date file was generated. Taken from computer clock.
Declarations	Base		Data declaration of a signal or parameter. For example, <code>extern real_T globalvar;</code>
Defines	Base	File	Required <code>#defines</code> of <code>.h</code> files.
Definitions	Base	File	Data definitions of signals or parameters.
Description	Documentation	N/A	Description of model. From <b>Model description</b> field on Model Properties dialog box.**
Documentation	Base	N/A	Comments about how to interpret the generated files.
Enums	Base	File	Enumerated data type definitions.
ExternalCalibrationLookup1D	Declarations	External	***
ExternalCalibrationLookup2D	Declarations	External	***
ExternalCalibrationScalar	Declarations	External	***
ExternalVariableScalar	Declarations	External	***
FileName	Documentation	N/A	Name of the generated file.
FilescopeCalibrationLookup1D	Definitions	File	***

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
FilescopeCalibrationLookup2D	Definitions	File	***
FilescopeCalibrationScalar	Definitions	File	***
FilescopeVariableScalar	Definitions	File	***
Functions	Base	File	Generated function code.
GlobalCalibrationLookup1D	Definitions	Global	***
GlobalCalibrationLookup2D	Definitions	Global	***
GlobalCalibrationScalar	Definitions	Global	***
GlobalVariableScalar	Definitions	Global	***
History	Documentation	N/A	User-supplied revision history of the generated files. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**
Includes	Base	File	#include preprocessor directives.
LastModifiedDate	Documentation	N/A	Date when model was last saved. From <b>Last saved on</b> field on Model Properties dialog box.
LastModifiedBy	Documentation	N/A	User who last saved model. From <b>Last saved by</b> field on Model Properties dialog box.
LocalDefines	Defines	File	#define preprocessor directives from code-generation data objects.
LocalMacros	Defines	File	C/C++ macros local to the file.
ModelName	Documentation	N/A	Name of the model.
ModelVersion	Documentation	N/A	Number incremented by 1 each time you save the model.
ModifiedBy	Documentation	N/A	Name of user who last modified the model.
Notes	Documentation	N/A	User-supplied miscellaneous notes about the model or generated files. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**
ToolVersion	Documentation	N/A	A list of the versions of the toolboxes used in generating the code.
Types	Base		Data types of generated code.

\* Symbol names must be enclosed between %< >. For example, %<Functions>.

\*\* This symbol can be used to add a comment to the generated files. See “Add Global Comments in the Generated Code” on page 52-5. The code generator places the comment in each generated file whose template has this symbol name. The code generator places the comment at the location that corresponds to where the symbol name is located in the template file.

\*\*\* The description can be deduced from the symbol name. For example, `GlobalCalibrationScalar` is a symbol that identifies a scalar. It contains data of global scope that you can calibrate.

## Rules for Modifying or Creating a Template

The following are the rules for creating an MPF template. “Comparison of a Template and Its Generated File” on page 52-67 illustrates several of these rules.

- 1 Place a symbol on a template within the `%< >` delimiter. For example, the symbol named `Includes` should look like this on a template: `%<Includes>`. *Note that symbol names are case-sensitive.*
- 2 Place a symbol on a template where desired. Its location on the template determines where the item associated with this symbol is located in the generated file. If no item is associated with it, the symbol is ignored.
- 3 Place a C/C++ statement outside of the `%< >` delimiter, and on a different line than a `%< >` delimiter, for that statement to appear in the generated file. For example, `#pragma message ("my text")` in the template results in `#pragma message ("my text")` at the corresponding location in the generated file. Note that the statement must be compatible with your C/C++ compiler.
- 4 Use the `.cgt` extension for every template filename. (“cgt” stands for code generation template.)
- 5 Note that `%% $Revision: 1.1.4.10.4.1 $` appears at the top of the MathWorks supplied templates. This is for internal MathWorks use only. It does not need to be placed on a user-defined template and does not show in a generated file.
- 6 Place a comment on the template between `/* */` as in standard ANSI C<sup>5</sup>. This results in `/*comment*/` on the generated file.
- 7 Each MPF template must have all of the Base group symbols, in predefined order. They are listed in “Template Symbol Groups” on page 52-80. Each symbol in the Base group is a parent. For example, `Declarations` is a parent symbol.
- 8 Each symbol in a non-Base group is a child. For example, `LocalMacros` is a child.
- 9 Except for Documentation children, children must be placed after their parent, before the next parent, and before the `Functions` symbol.
- 10 Documentation children can be located before or after their parent in any order anywhere in the template.
- 11 If a non-Documentation child is missing from the template, the code generator places the information associated with this child at its parent location in the generated file.
- 12 If a Documentation child is missing from the template, the code generator omits the information associated with that child from the generated file.

---

5 ANSI is a registered trademark of the American National Standards Institute, Inc.

## Annotate Code for Justifying Polyspace Checks

This example shows how to turn on comments in the generated code that suppress error detection through Polyspace®.

### Polyspace Checks

With the Polyspace Code Prover™ software you can apply Polyspace verification to Embedded Coder® generated code. The software detects run-time errors in the generated code and helps you to locate and fix model faults. Polyspace might highlight overflows for certain operations that are legitimate because of the way the code generator implements these operations. These legitimate overflows should not be flagged by Polyspace. Generate comments in the code that suppress this error detection.

### Code Generation

1. Open the example Simulink® model mSatAddSub.

```
model='mSatAddSub';
open_system(model);
```

2. In the Embedded Coder app on the **Configuration Parameters** dialog box, turn off **Operator annotations**.

```
set_param('mSatAddSub','OperatorAnnotations','off');
```

3. To build the model and generate code, press **Ctrl+B**.

```
evalc('slbuild(''mSatAddSub'')');
```

*%The generated code is:*

```
file = fullfile('mSatAddSub_ert_rtw','mSatAddSub.c');
rtwdemodbtype(file,'/* Model step function */',...
 'End of Sum',1,1);
```

```
/* Model step function */

 /* (no terminate code required) */
}

/*
 * File trailer for generated code.
 *
 * [EOF]
 */

```

4. Run the Polyspace check. The code generator recognizes that the largest built-in data type is 32-bit. It is not possible to saturate all the results of the subtractions using 0U and a bigger single-word integer data type. Instead the software detects the results overflow and the direction of the overflow, and saturates the result. The operation is flagged by Polyspace because it fails to recognize the saturation.

5. In the Embedded Coder app on the **Configuration Parameters** dialog box, turn off **Operator annotations**.

```

set_param('mSatAddSub','OperatorAnnotations','on');
evalc('slbuild(''mSatAddSub'')');

```

6. The generated code is:

 { 0, SS_UINT32, SS_UINT32, 0, 0, 0, 1.0, 0, 0.0 }
};

static RTWLogSignalInfo rt_LoggedOutputSignalInfo[] = {
 {
 1,

```

```

 rt_LoggedOutputWidths,
 rt_LoggedOutputNumDimensions,
 rt_LoggedOutputDimensions,
 rt_LoggedOutputIsVarDims,
 rt_LoggedCurrentSignalDimensions,
 rt_LoggedCurrentSignalDimensionsSize,
 rt_LoggedOutputDataTypeIds,
 rt_LoggedOutputComplexSignals,
 (NULL),
 rt_LoggingPreprocessingFcnPtrs,

 { rt_LoggedOutputLabels },
 (NULL),
 (NULL),
 (NULL),

 { rt_LoggedOutputBlockNames },

 { (NULL) },
 (NULL),
 rt_RTWLogDataTypeConvert
 }
};

 rtwSetLogYSignalInfo(mSatAddSub_M->rtwLogInfo, rt_LoggedOutputSignalInfo);

 /* set currSigDims field */
 rt_LoggedCurrentSignalDimensions[0] = &rt_LoggedOutputWidths[0];
}

 rtwSetLogY(mSatAddSub_M->rtwLogInfo, "yout");
}

/* block I/O */

/* exported global signals */
Usub = 0U;

/* external inputs */
U1 = 0U;
U2 = 0U;

/* external outputs */
mSatAddSub_Y.Out3 = 0U;

/* Matfile logging */
rtwStartDataLoggingWithStartTime(mSatAddSub_M->rtwLogInfo, 0.0, rtmGetTFinal
 (mSatAddSub_M), mSatAddSub_M->Timing.stepSize0, (&rtmGetErrorStatus
 (mSatAddSub_M)));
}

/* Model terminate function */
void mSatAddSub_terminate(void)
{
 /* (no terminate code required) */
}

/*

```

```
* File trailer for generated code.
*
* [EOF]
*/
```

The code generator inserts the `/*MW:0vSat0k*/` comment that suppresses the error detected by Polyspace.

7. Close the model.

```
bdclose(model)
rtwdemoclean;
```

## Enhance Readability of Code for Flow Charts

### In this section...

“Appearance of Generated Code for Flow Charts” on page 52-94

“Convert If-Elseif-Else Code to Switch-Case Statements” on page 52-96

“Example of Converting Code to Switch-Case Statements” on page 52-98

### Appearance of Generated Code for Flow Charts

If you have Embedded Coder and you generate code for models that include Stateflow objects, the code from a flow chart resembles the samples that follow.

The following characteristics apply:

- By default, the generated code uses `if-elseif-else` statements to represent switch patterns. To convert the code to use `switch-case` statements, see “Convert If-Elseif-Else Code to Switch-Case Statements” on page 52-96.
- By default, variables that appear in the flow chart do not retain their names in the generated code. Modified identifiers make sure that no naming conflicts occur.
- Traceability comments for the transitions appear between each set of `/*` and `*/` markers. To learn more about traceability, see “Trace Stateflow Elements in Generated Code” on page 79-12.

```
if (modelName_U.In1 == 1.0) {
 /* Transition: '<S1>:11' */
 /* Transition: '<S1>:12' */
 modelName_Y.Out1 = 10.0;

 /* Transition: '<S1>:15' */
 /* Transition: '<S1>:16' */
} else {
 /* Transition: '<S1>:10' */
```

```

if (modelname_U.In1 == 2.0) {
 /* Transition: '<S1>:13' */
 /* Transition: '<S1>:14' */
 modelname_Y.Out1 = 20.0;

 /* Transition: '<S1>:16' */
} else {
 /* Transition: '<S1>:17' */
 modelname_Y.Out1 = 30.0;
}
}

```

### Sample Code for a Decision Logic Pattern

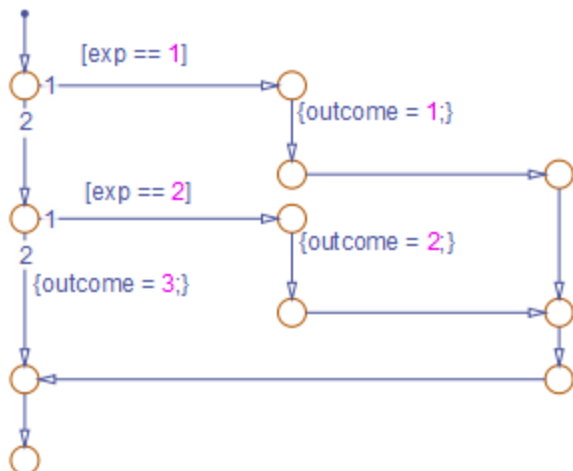

```

for (sf_i = 0; sf_i < 10; sf_i++) {
 /* Transition: '<S1>:40' */
 /* Transition: '<S1>:41' */
 modelname_B.y = modelname_B.y +
 modelname_U.In1;

 /* Transition: '<S1>:39' */
}

```

### Sample Code for an Iterative Loop Pattern

```

if (modelname_U.In1 == 1.0) {
 /* Transition: '<S1>:149' */
 /* Transition: '<S1>:150' */
 modelname_Y.Out1 = 1.0;

 /* Transition: '<S1>:151' */
 /* Transition: '<S1>:152' */
 /* Transition: '<S1>:158' */
 /* Transition: '<S1>:159' */
} else {
 /* Transition: '<S1>:156' */
 if (modelname_U.In1 == 2.0) {
 /* Transition: '<S1>:153' */
 /* Transition: '<S1>:154' */
 modelname_Y.Out1 = 2.0;

 /* Transition: '<S1>:155' */
 /* Transition: '<S1>:158' */
 /* Transition: '<S1>:159' */
 } else {
 /* Transition: '<S1>:161' */
 modelname_Y.Out1 = 3.0;
 }
}
}

```

### Sample Code for a Switch Pattern

## Convert If-Elseif-Else Code to Switch-Case Statements

When you generate code for embedded real-time targets, you can choose to convert `if-elseif-else` code to `switch-case` statements. This conversion can enhance readability of the code. For example, when a flow chart contains a long list of conditions, the `switch-case` structure:

- Reduces the use of parentheses and braces
- Minimizes repetition in the generated code

### How to Convert If-Elseif-Else Code to Switch-Case Statements

Step	Task	Reference
1	Verify that your flow chart follows the rules for conversion.	"Verify the Contents of the Flow Chart" on page 52-99
2	Enable the conversion and generate code for your model.	"Enable the Conversion" on page 52-100
3	Troubleshoot the generated code. <ul style="list-style-type: none"> <li>• If you see <code>switch-case</code> statements for your flow chart, you can stop.</li> <li>• If you see <code>if-elseif-else</code> statements for your flow chart, update the chart and repeat the previous step.</li> </ul>	"Troubleshoot the Generated Code" on page 52-100

## Rules of Conversion

For the conversion to occur, following these guidelines. LHS and RHS refer to the left-hand side and right-hand side of a condition, respectively.

Construct	Rules to Follow
Flow chart	Must have a default and two or more <i>unique</i> conditions. For more information, see “Duplicate Conditions” on page 52-97.
Each condition	Must test equality only. Must use the same variable or expression for the LHS. You can reverse the LHS and RHS.
Each LHS	Must be a single variable or expression. Cannot be a constant. Must have an integer or enumerated data type. Cannot have any side effects on simulation. For example, the LHS can read from but not write to global variables.
Each RHS	Must be a constant or a parameter. Must have an integer or enumerated data type.

## Duplicate Conditions

If a flow chart has duplicate conditions, the conversion preserves only the first condition. The code discards the other instances of duplicate conditions.

After removal of duplicates, two or more unique conditions must exist. If not, the conversion does not occur and the code contains all duplicate conditions.

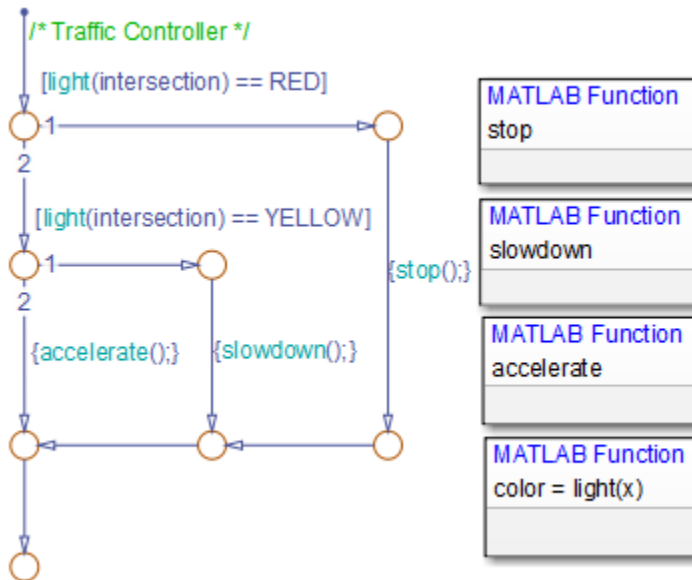

Example of Generated Code	Code After Conversion
<pre>if (x == 1) {     block1 } else if (x == 2) {     block2 } else if (x == 1) { // duplicate     block3 } else if (x == 3) {     block4 } else if (x == 1) { // duplicate     block5 } else {     block6 }</pre>	<pre>switch (x) {     case 1:         block1; break;     case 2:         block2; break;     case 3:         block4; break;     default:         block6; break; }</pre>
<pre>if (x == 1) {     block1 } else if (x == 1) { // duplicate     block2 } else {     block3 }</pre>	No change, because only one unique condition exists

## Example of Converting Code to Switch-Case Statements

Suppose that you have this model containing a single chart.

The chart contains a flow chart and four MATLAB functions.

The MATLAB functions in the chart contain the code listed in the table. In each case, the **Function Inline Option** is Auto. For more information about function inlining, see “Specify Properties of Graphical Functions” (Stateflow).

MATLAB Function	Code
stop	function stop %#codegen coder.extrinsic('disp'); disp('Not moving.')
slowdown	function slowdown %#codegen coder.extrinsic('disp') disp('Slowing down.')
	traffic_speed = 0;
	traffic_speed = 1;

MATLAB Function	Code
accelerate	<pre>function accelerate %#codegen coder.extrinsic('disp'); disp('Moving along.')  traffic_speed = 2;</pre>
light	<pre>function color = light(x) %#codegen if (x &lt; 20)     color = TrafficLights.GREEN; elseif (x &gt;= 20 &amp;&amp; x &lt; 25)     color = TrafficLights.YELLOW; else     color = TrafficLights.RED; end</pre>

The output `color` of the function `light` uses the enumerated type `TrafficLights`. The enumerated type definition in `TrafficLights.m` is:

```
classdef TrafficLights < Simulink.IntEnumType
 enumeration
 RED(0)
 YELLOW(5)
 GREEN(10)
 end
end
```

For more information, see “Define Enumerated Data Types” (Stateflow).

### Verify the Contents of the Flow Chart

Check that the flow chart in your Stateflow chart follows the rules in “Rules of Conversion” on page 52-97.

Construct	How the Construct Follows the Rules
Flow chart	<p>A default condition and two unique conditions exist:</p> <ul style="list-style-type: none"> <li>• <code>[light(intersection) == RED]</code></li> <li>• <code>[light(intersection) == YELLOW]</code></li> </ul>
Each condition	<p>Each condition:</p> <ul style="list-style-type: none"> <li>• Tests equality</li> <li>• Uses the same function call <code>light(intersection)</code> for the LHS</li> </ul>
Each LHS	<p>Each LHS:</p> <ul style="list-style-type: none"> <li>• Contains a single expression</li> <li>• Is the output of a function call, not a constant</li> <li>• Is of enumerated type <code>TrafficLights</code>, which you define in <code>TrafficLights.m</code> on the MATLAB path. See “Define Enumerated Data Types” (Stateflow).</li> <li>• Uses a function call that does not have side effects</li> </ul>

Construct	How the Construct Follows the Rules
Each RHS	Each RHS: <ul style="list-style-type: none"> <li>• Is an enumerated value and therefore a constant</li> <li>• Is of enumerated type TrafficLights</li> </ul>

### Enable the Conversion

- 1 Open the Model Configuration Parameters dialog box.
- 2 In the **Code Generation** pane, select `ert.tlc` for the **System target file** for an ERT-based target for your model.
- 3 In the **Code Generation > Code Style** pane, select the **Convert if-elseif-else patterns to switch-case statements** check box.

If you select this check box, the conversion applies to:

- Flow charts in all charts of a model
  - MATLAB functions in all charts of a model
  - All MATLAB Function blocks in that model
- 4 In the model, on the **C Code** tab, click **Build** to generate source code from the model.

### Troubleshoot the Generated Code

The generated code for the flow chart appears like this code:

```

if (sf_color == RED) {
 /* Transition: '<S1>:11' */
 /* Transition: '<S1>:12' */
 /* MATLAB Function 'stop': '<S1>:23' */
 /* '<S1>:23:6' */
 rtb_traffic_speed = 0;

 /* Transition: '<S1>:15' */
 /* Transition: '<S1>:16' */
} else {
 /* Transition: '<S1>:10' */
 /* MATLAB Function 'light': '<S1>:19' */
 if (ifelse_using_enums_U.In1 < 20.0) {
 /* '<S1>:19:3' */
 /* '<S1>:19:4' */
 sf_color = GREEN;
 } else if ((ifelse_using_enums_U.In1 >= 20.0) &&
 (ifelse_using_enums_U.In1 < 25.0)) {
 /* '<S1>:19:5' */
 /* '<S1>:19:6' */
 sf_color = YELLOW;
 } else {
 /* '<S1>:19:8' */
 sf_color = RED;
 }
}

if (sf_color == YELLOW) {
 /* Transition: '<S1>:13' */
 /* Transition: '<S1>:14' */

```

```

/* MATLAB Function 'slowdown': '<S1>:24' */
/* '<S1>:24:6' */
rtb_traffic_speed = 1;

/* Transition: '<S1>:16' */
} else {
/* Transition: '<S1>:17' */
/* MATLAB Function 'accelerate': '<S1>:25' */
/* '<S1>:25:6' */
rtb_traffic_speed = 2;
}
}
}

```

Because the MATLAB function `light` appears inlined, inequality comparisons appear in these lines of code:

```

if (ifelse_using_enums_U.In1 < 20.0) {
....
} else if ((ifelse_using_enums_U.In1 >= 20.0) &&
 (ifelse_using_enums_U.In1 < 25.0)) {
....

```

Because inequalities appear in the body of the `if-elseif-else` code for the flow chart, the conversion to `switch-case` statements does not occur. Do one of the following:

- Specify that the function `light` does not appear inlined. See “Change the Inlining Property for the Function” on page 52-101.
- Modify the flow chart. See “Modify the Flow Chart to Ensure Switch-Case Statements” on page 52-102.

### Change the Inlining Property for the Function

If you do not want to modify your flow chart, change the inlining property for the function `light`:

- 1 Right-click the function box for `light` and select **Properties**.
- 2 In the properties dialog box, for **Function Inline Option**, select **Function**.
- 3 Click **OK** to close the dialog box.

---

**Note** You do not have to change the inlining property for the other three MATLAB functions in the chart. Because the flow chart does not call those functions during evaluation of conditions, the inlining property for those functions can remain **Auto**.

---

When you regenerate code for your model, the code for the flow chart now appears like this code:

```

switch (ifelse_using_enums_light(ifelse_using_enums_U.In1)) {
case RED:
/* Transition: '<S1>:11' */
/* Transition: '<S1>:12' */
/* MATLAB Function 'stop': '<S1>:23' */
/* '<S1>:23:6' */
ifelse_using_enums_Y.Out1 = 0.0;

/* Transition: '<S1>:15' */
/* Transition: '<S1>:16' */

```

```
 break;

case YELLOW:
 /* Transition: '<S1>:10' */
 /* Transition: '<S1>:13' */
 /* Transition: '<S1>:14' */
 /* MATLAB Function 'slowdown': '<S1>:24' */
 /* '<S1>:24:6' */
 ifelse_using_enums_Y.Out1 = 1.0;

 /* Transition: '<S1>:16' */
 break;

default:
 /* Transition: '<S1>:17' */
 /* MATLAB Function 'accelerate': '<S1>:25' */
 /* '<S1>:25:6' */
 ifelse_using_enums_Y.Out1 = 2.0;
 break;
}
```

Because the MATLAB function `light` no longer appears inlined, the conversion to switch-case statements occurs. To enhance readability, the switch-case statements provide these benefits:

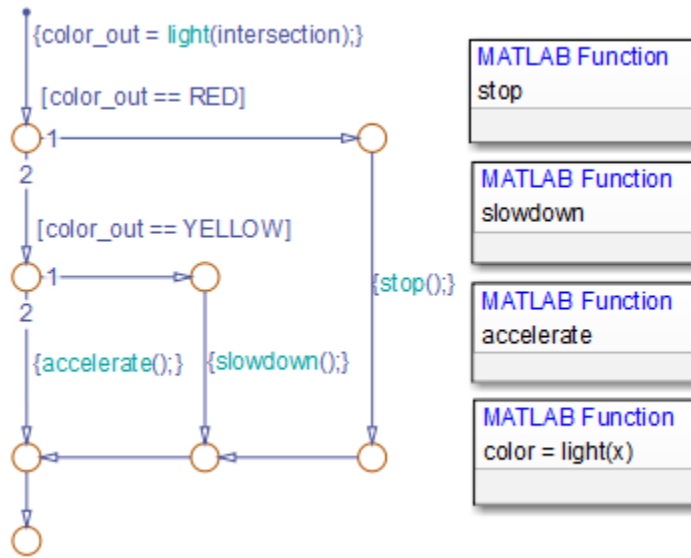

- The code reduces the use of parentheses and braces.
- The LHS expression `ifelse_using_enums_light(ifelse_using_enums_U.In1)` appears only once, minimizing repetition in the code.

### Modify the Flow Chart to Ensure Switch-Case Statements

If you do not want to change the inlining property for the function `light`, modify your flow chart:

- 1 Add chart local data `color_out` with the enumerated type `TrafficLights`.
- 2 Replace each instance of `light(intersection)` with `color_out`.
- 3 Add the action `{color_out = light(intersection)}` to the default transition of the flow chart.

The chart now looks similar to this chart:

When you regenerate code for your model, the code for the flow chart uses switch-case statements.

## Enhance Code Readability for MATLAB Function Blocks

### In this section...

“Requirements for Using Readability Optimizations” on page 52-104

“Converting If-Elseif-Else Code to Switch-Case Statements” on page 52-104

“Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements” on page 52-106

### Requirements for Using Readability Optimizations

To use readability optimizations in your code, you must have an Embedded Coder license. These optimizations appear only in code that you generate for an embedded real-time (ert) target.

**Note** These optimizations do not apply to MATLAB files that you call from the MATLAB Function block.

For more information, see “Configure a System Target File” on page 47-2.

### Converting If-Elseif-Else Code to Switch-Case Statements

When you generate code for embedded real-time targets, you can choose to convert `if-elseif-else` decision logic to `switch-case` statements. This conversion can enhance readability of the code.

For example, when a MATLAB Function block contains a long list of conditions, the `switch-case` structure:

- Reduces the use of parentheses and braces
- Minimizes repetition in the generated code

#### How to Convert If-Elseif-Else Code to Switch-Case Statements

The following procedure describes how to convert generated code for the MATLAB Function block from `if-elseif-else` to `switch-case` statements.

Step	Task	Reference
1	Verify that your block follows the rules for conversion.	“Verifying the Contents of the Block” on page 52-107
2	Enable the conversion.	“Enabling the Conversion” on page 52-108
3	Generate code for your model.	“Generating Code for Your Model” on page 52-108

#### Rules for Conversion

For the conversion to occur, the following rules must hold. LHS and RHS refer to the left-hand side and right-hand side of a condition, respectively.

Construct	Rules to Follow
MATLAB Function block	Must have two or more <i>unique</i> conditions, in addition to a default. For more information, see “How the Conversion Handles Duplicate Conditions” on page 52-105.
Each condition	Must test equality only.
	Must use the same variable or expression for the LHS.
	<b>Note</b> You can reverse the LHS and RHS.
Each LHS	Must be a single variable or expression, not a compound statement.
	Cannot be a constant.
	Must have an integer or enumerated data type.
	Must not have side effects on simulation. For example, the LHS can read from but not write to global variables.
Each RHS	Must be a constant.
	Must have an integer or enumerated data type.

### How the Conversion Handles Duplicate Conditions

If a MATLAB Function block has duplicate conditions, the conversion preserves only the first condition. The generated code discards other instances of duplicate conditions.

After removal of duplicates, two or more unique conditions must exist. Otherwise, a conversion does not occur and the generated code contains instances of duplicate conditions.

The following examples show how the conversion handles duplicate conditions.

Example of Generated Code	Code After Conversion
<pre>if (x == 1) {     block1 } else if (x == 2) {     block2 } else if (x == 1) { // duplicate     block3 } else if (x == 3) {     block4 } else if (x == 1) { // duplicate     block5 } else {     block6 }</pre>	<pre>switch (x) {     case 1:         block1; break;     case 2:         block2; break;     case 3:         block4; break;     default:         block6; break; }</pre>
<pre>if (x == 1) {     block1 } else if (x == 1) { // duplicate     block2 } else {     block3 }</pre>	Does not change, because only one unique condition exists

## Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements

Suppose that you have the following model with a MATLAB Function block. Assume that the output data type is double and the input data type is Controller, an enumerated type that you define.

The block contains the following code:

```
function system = fcn(type)
%#codegen

if (type == Controller.P)
 system = 0;
elseif (type == Controller.I)
 system = 1;
elseif (type == Controller.PD)
 system = 2;
elseif (type == Controller.PI)
 system = 3;
elseif (type == Controller.PID)
 system = 4;
else
 system = 10;
end
```

The enumerated type definition in Controller.m is:

```
classdef Controller < Simulink.IntEnumType
 enumeration
 P(0)
 I(1)
 PD(2)
 PI(3)
 PID(4)
 UNKNOWN(10)
 end
end
```

If you generate code for an embedded real-time target using default settings, you see something like this:

```
if (if_to_switch_eml_blocks_U.In1 == P) {
 /* '<S1>:1:4' */
 /* '<S1>:1:5' */
 if_to_switch_eml_blocks_Y.Out1 = 0.0;
} else if (if_to_switch_eml_blocks_U.In1 == I) {
 /* '<S1>:1:6' */
 /* '<S1>:1:7' */
```

```

 if_to_switch_eml_blocks_Y.Out1 = 1.0;
} else if (if_to_switch_eml_blocks_U.In1 == PD) {
 /* '<S1>:1:8' */
 /* '<S1>:1:9' */
 if_to_switch_eml_blocks_Y.Out1 = 2.0;
} else if (if_to_switch_eml_blocks_U.In1 == PI) {
 /* '<S1>:1:10' */
 /* '<S1>:1:11' */
 if_to_switch_eml_blocks_Y.Out1 = 3.0;
} else if (if_to_switch_eml_blocks_U.In1 == PID) {
 /* '<S1>:1:12' */
 /* '<S1>:1:13' */
 if_to_switch_eml_blocks_Y.Out1 = 4.0;
} else {
 /* '<S1>:1:15' */
 if_to_switch_eml_blocks_Y.Out1 = 10.0;
}

```

The LHS variable `if_to_switch_eml_blocks_U.In1` appears multiple times in the generated code.

---

**Note** By default, variables that appear in the block do not retain their names in the generated code. Modified identifiers prevent naming conflicts.

---

Traceability comments appear between each set of `/*` and `*/` markers. To learn more about traceability, see “Use Traceability in MATLAB Function Blocks” on page 79-35.

### Verifying the Contents of the Block

Check that the block follows the rules in “Rules for Conversion” on page 52-104.

Construct	How the Construct Follows the Rules
MATLAB Function block	Five unique conditions exist, in addition to the default: <ul style="list-style-type: none"> <li>• (type == Controller.P)</li> <li>• (type == Controller.I)</li> <li>• (type == Controller.PD)</li> <li>• (type == Controller.PI)</li> <li>• (type == Controller.PID)</li> </ul>
Each condition	Each condition: <ul style="list-style-type: none"> <li>• Tests equality</li> <li>• Uses the same input for the LHS</li> </ul>

Construct	How the Construct Follows the Rules
Each LHS	Each LHS: <ul style="list-style-type: none"> <li>• Contains a single variable</li> <li>• Is the input to the block and therefore not a constant</li> <li>• Is of enumerated type <code>Controller</code>, which you define in <code>Controller.m</code> on the MATLAB path</li> <li>• Does not impact simulation</li> </ul>
Each RHS	Each RHS: <ul style="list-style-type: none"> <li>• Is an enumerated value and therefore a constant</li> <li>• Is of enumerated type <code>Controller</code></li> </ul>

### Enabling the Conversion

- 1 Open the Configuration Parameters dialog box.
- 2 In the **Code Generation** pane, select `ert.tlc` for the **System target file**.

This step specifies an embedded real-time target for your model.

- 3 In the **Code Generation > Code Style** pane, select the **Convert if-elseif-else patterns to switch-case statements** check box.

---

**Tip** This conversion works on a per-model basis. If you select this check box, the conversion applies to:

- MATLAB Function blocks in a model
- MATLAB functions in Stateflow charts of that model
- Flow charts in Stateflow charts of that model

For more information, see “Enhance Readability of Code for Flow Charts” on page 52-94.

---

### Generating Code for Your Model

In the model window, press **Ctrl+B**.

The code for the MATLAB Function block uses switch-case statements instead of if-elseif-else code:

```
switch (if_to_switch_eml_blocks_U.In1) {
case P:
 /* '<S1>:1:4' */
 /* '<S1>:1:5' */
 if_to_switch_eml_blocks_Y.Out1 = 0.0;
 break;

case I:
 /* '<S1>:1:6' */
 /* '<S1>:1:7' */
 if_to_switch_eml_blocks_Y.Out1 = 1.0;
 break;
}
```

```
case PD:
 /* '<S1>:1:8' */
 /* '<S1>:1:9' */
 if_to_switch_eml_blocks_Y.Out1 = 2.0;
 break;

case PI:
 /* '<S1>:1:10' */
 /* '<S1>:1:11' */
 if_to_switch_eml_blocks_Y.Out1 = 3.0;
 break;

case PID:
 /* '<S1>:1:12' */
 /* '<S1>:1:13' */
 if_to_switch_eml_blocks_Y.Out1 = 4.0;
 break;

default:
 /* '<S1>:1:15' */
 if_to_switch_eml_blocks_Y.Out1 = 10.0;
 break;
}
```

The switch-case statements provide the following benefits to enhance readability:

- The code reduces the use of parentheses and braces.
- The LHS variable `if_to_switch_eml_blocks_U.In1` appears only once, minimizing repetition in the code.

## Improve Data Coherency in Generated Code

For models containing read and write operations for Data Store Memory blocks, you can generate code that contains a single variable to hold the value for each Data Store Read and Write operation. Generating one variable for each operation improves data access coherency.

### Example Model

The `data_store_latching` model contains a single Data Store Memory block that is accessed by two different Data Store Memory Read and two Data Store Memory Write blocks. Two Sum blocks perform addition on the input generated by the Data Store Read blocks and output the data to the Data Store Write blocks.

### Generate Code Without Parameter Enabled

Building the model with the **Implement each data store block as a unique access point** parameter turned off by default, generates this code:

```
void data_store_latching_step(void)
{
 /* DataStoreWrite: '<Root>/Data Store Write' incorporates:
 * DataStoreRead: '<Root>/Data Store Read'
 * Sum: '<Root>/Add'
 */
 data_store_latching_DW.A += data_store_latching_DW.A +
 data_store_latching_DW.A;

 /* DataStoreWrite: '<Root>/Data Store Write1' incorporates:
 * DataStoreRead: '<Root>/Data Store Read1'
 * Sum: '<Root>/Add1'
 */
}
```

```

 */
 data_store_latching_DW.A += data_store_latching_DW.A +
 data_store_latching_DW.A;
}

```

For both data read and write operations, the code contains the global variable `data_store_latching_DW.A`.

## Generate Code With Parameter Enabled

In the Configuration Parameters dialog box, on the **Interface** pane, select the **Implement each data store block as a unique access point** parameter. Click **Apply**.

The generated code is now:

```

void data_store_latching_step(void)
{
 real_T rtb_DataStoreRead;
 real_T rtb_DataStoreRead1;

 /* DataStoreRead: '<Root>/Data Store Read' */
 rtb_DataStoreRead = data_store_latching_DW.A;

 /* DataStoreWrite: '<Root>/Data Store Write' incorporates:
 * Sum: '<Root>/Add'
 */
 data_store_latching_DW.A = (rtb_DataStoreRead + rtb_DataStoreRead) +
 rtb_DataStoreRead;

 /* DataStoreRead: '<Root>/Data Store Read1' */
 rtb_DataStoreRead1 = data_store_latching_DW.A;

 /* DataStoreWrite: '<Root>/Data Store Write1' incorporates:
 * Sum: '<Root>/Add1'
 */
 data_store_latching_DW.A = (rtb_DataStoreRead1 + rtb_DataStoreRead1) +
 rtb_DataStoreRead1;
}

```

For each data store read operation, the code contains a variable. The variables are `rtb_DataStoreRead` and `rtb_DataStoreRead1`. These separate variables improve data access coherency.

# Code Replacement in Simulink Coder

---

- “What Is Code Replacement?” on page 53-2
- “Choose a Code Replacement Library” on page 53-6
- “Replace Code Generated from Simulink Models” on page 53-8

## What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of `math.h`.
  - Elimination of system header files.
  - Elimination of calls to `memcpy` or `memset`.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks provides and that you create and register by using the Embedded Coder product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, language standard, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

### Code Replacement Libraries

A code replacement library consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A code replacement table contains one or more code replacement entries, with each entry representing a potential replacement for a function or operator. Each entry maps a conceptual representation of a function or operator to an implementation representation and priority.

Table Entry Component	Description
Conceptual representation	<p>Identifies the table entry and contains match criteria for the code generator. Consists of:</p> <ul style="list-style-type: none"> <li>Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name 'cos' and operator key 'RTW_OP_ADD'.</li> <li>Conceptual arguments that observe code generator naming ('y1', 'u1', 'u2', ...), with corresponding I/O types (output or input) and data types.</li> <li>Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.</li> </ul>
Implementation representation	<p>Specifies replacement code. Consists of:</p> <ul style="list-style-type: none"> <li>Function name. For example, 'cos_dbl' or 'u8_add_u8_u8'.</li> <li>Implementation arguments, with corresponding I/O types (output or input) and data types.</li> <li>Parameters that provide additional implementation details, such as header and source file names and paths of build resources.</li> </ul>
Priority	<p>Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority.</p>

When the code generator looks for a match in a code replacement library, it creates and populates a call site object with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

## Code Replacement Terminology

Term	Definition
Cache hit	A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.
Cache miss	A conceptual representation of a function or operator for which the code generator does not find a match.
Call site object	Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.
Code replacement library	One or more code replacement tables that specify application-specific implementations of functions and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.
Code replacement table	One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.
Code replacement entry	Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.
Conceptual argument	Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions ('y1', 'u1', 'u2', ...) and data types familiar to the code generator.
Conceptual representation	Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of: <ul style="list-style-type: none"> <li>• Function or operator name or key</li> <li>• Conceptual arguments with type, dimension, and complexity specification for inputs and output</li> <li>• Attributes, such as an algorithm and fixed-point saturation and rounding modes</li> </ul>
Implementation argument	Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.

Term	Definition
Implementation representation	Specifies C or C++ replacement function prototype. Consists of: <ul style="list-style-type: none"> <li>• Function name (for example, 'cos_dbl' or 'u8_add_u8_u8')</li> <li>• Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output</li> <li>• Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags</li> </ul>
Key	Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key RTW_OP_ADD identifies the addition operator.
