Priority	Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.

## Code Replacement Limitations

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

Code replacement for matrices — Code replacement libraries do not support Dynamic and Symbolic sized matrices.

## Choose a Code Replacement Library

### In this section...

“About Choosing a Code Replacement Library” on page 53-6

“Explore Available Code Replacement Libraries” on page 53-6

“Explore Code Replacement Library Contents” on page 53-6

### About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

- 1 Explore available libraries. Identify one that best meets your application needs.
  - Consider the lists of application code replacement requirements and libraries that MathWorks provides in “What Is Code Replacement?” on page 54-2.
  - See “Explore Available Code Replacement Libraries” on page 53-6.
- 2 Explore the contents of the library. See “Explore Code Replacement Library Contents” on page 53-6.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

### Explore Available Code Replacement Libraries

Select the “Code replacement library” to use for code generation from the **Configuration Parameters > Code Generation > Interface** pane. To view a description of a library, select and hover your cursor over the library name. A tooltip describes the library and lists the tables that it contains. The tooltip lists the tables in the order that the code generator searches for a function or operator match.

### Explore Code Replacement Library Contents

Use the **Code Replacement Viewer** to explore the content of a code replacement library.

- 1 At the command prompt, type `crviewer`.

```
>> crviewer
```

The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```

- 2 In the left pane, select the name of a library. The viewer displays information about the library in the right pane.
- 3 In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.

- 4 In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.TfLCOperationEntryGenerator` or `RTW.TfLCOperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See **Code Replacement Viewer** for details on what the viewer displays.

## Replace Code Generated from Simulink Models

This example shows how to replace generated code, using a code replacement library. Code replacement is a technique you can use to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as elimination of `math.h`, system header files, or calls to `memcpy` or `memset`, or use of BLAS.

### Prepare for Code Replacement

1. Make sure that MATLAB®, Simulink®, Simulink Coder™, and a C compiler are installed on your system. Some code replacement libraries available in your development environment can require Embedded Coder®.

To install MathWorks® products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the Command Window, enter `ver`.

2. Identify an existing Simulink model or create a model for which you want the code generator to replace code.

### Choose a Code Replacement Library

By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks® provides and that you create and register by using the Embedded Coder® product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder® product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Depending on the product licenses that you have, other libraries might be available. If you have an Embedded Coder license, you can view and choose from other libraries and you can create custom code replacement libraries.

### Configure Code Generator to Use Code Replacement Library

1. Configure the code generator to apply a code replacement library during code generation for the model. Do one of the following:

- In the Configuration Parameters dialog box, on the **Code Generation > Interface** pane, select a library for the “Code replacement library” parameter.

- Set the `CodeReplacementLibrary` parameter at the command line or programmatically.
2. Configure the code generator to produce code only (not build an executable program) so you can verify your code replacements before building an executable program. Do one of the following:
    - In the Configuration Parameters dialog box, on the **Code Generation** pane, select “Generate code only”.
    - Set the `GenCodeOnly` parameter at the command line or programmatically.

### **Include Code Replacement Information in Code Generation Report**

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information can help you verify code replacements.

1. Configure the code generator to generate a report. In the Configuration Parameters dialog box, on the **Code Generation > Report** pane, select “Create code generation report”. Consider having the report open automatically. Select `Open report automatically`.
2. Include the code replacement section in the report. Select “Summarize which blocks triggered code replacements”.

### **Generate Replacement Code**

Generate C/C++ code from the model and, if you configured the code generator accordingly, a code generation report. For example, in the model window, press **Ctrl+B**.

The code generator produces the code and displays the report.

### **Verify Code Replacements**

Verify code replacements by examining the generated code. It is possible that code replacement behaves differently than you expect. For example, data types that you observe in the code generator input might not match what the code generator uses as intermediate data types during an operation.

## What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of `math.h`.
  - Elimination of system header files.
  - Elimination of calls to `memcpy` or `memset`.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks provides and that you create and register by using the Embedded Coder product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, language standard, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

### Code Replacement Libraries

A code replacement library consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A code replacement table contains one or more code replacement entries, with each entry representing a potential replacement for a function or operator. Each entry maps a conceptual representation of a function or operator to an implementation representation and priority.

Table Entry Component	Description
Conceptual representation	<p>Identifies the table entry and contains match criteria for the code generator. Consists of:</p> <ul style="list-style-type: none"> <li>Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name 'cos' and operator key 'RTW_OP_ADD'.</li> <li>Conceptual arguments that observe code generator naming ('y1', 'u1', 'u2', ...), with corresponding I/O types (output or input) and data types.</li> <li>Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.</li> </ul>
Implementation representation	<p>Specifies replacement code. Consists of:</p> <ul style="list-style-type: none"> <li>Function name. For example, 'cos_dbl' or 'u8_add_u8_u8'.</li> <li>Implementation arguments, with corresponding I/O types (output or input) and data types.</li> <li>Parameters that provide additional implementation details, such as header and source file names and paths of build resources.</li> </ul>
Priority	<p>Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority.</p>

When the code generator looks for a match in a code replacement library, it creates and populates a call site object with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

## Code Replacement Terminology

Term	Definition
Cache hit	A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.
Cache miss	A conceptual representation of a function or operator for which the code generator does not find a match.
Call site object	Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.
Code replacement library	One or more code replacement tables that specify application-specific implementations of functions and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.
Code replacement table	One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.
Code replacement entry	Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.
Conceptual argument	Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions ('y1', 'u1', 'u2', ...) and data types familiar to the code generator.
Conceptual representation	Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of: <ul style="list-style-type: none"> <li>• Function or operator name or key</li> <li>• Conceptual arguments with type, dimension, and complexity specification for inputs and output</li> <li>• Attributes, such as an algorithm and fixed-point saturation and rounding modes</li> </ul>
Implementation argument	Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.

Term	Definition
Implementation representation	Specifies C or C++ replacement function prototype. Consists of: <ul style="list-style-type: none"> <li>• Function name (for example, 'cos_dbl' or 'u8_add_u8_u8')</li> <li>• Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output</li> <li>• Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags</li> </ul>
Key	Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key RTW_OP_ADD identifies the addition operator.
Priority	Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.

## Code Replacement Limitations

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

Code replacement for matrices — Code replacement libraries do not support Dynamic and Symbolic sized matrices.

## Choose a Code Replacement Library

### In this section...

“About Choosing a Code Replacement Library” on page 54-6

“Explore Available Code Replacement Libraries” on page 54-6

“Explore Code Replacement Library Contents” on page 54-6

### About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

- 1 Explore available libraries. Identify one that best meets your application needs.
  - Consider the lists of application code replacement requirements and libraries that MathWorks provides in “What Is Code Replacement?” on page 54-2.
  - See “Explore Available Code Replacement Libraries” on page 54-6.
- 2 Explore the contents of the library. See “Explore Code Replacement Library Contents” on page 54-6.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

### Explore Available Code Replacement Libraries

Select the “Code replacement library” to use for code generation from the **Configuration Parameters > Code Generation > Interface** pane. To view a description of a library, select and hover your cursor over the library name. A tooltip describes the library and lists the tables that it contains. The tooltip lists the tables in the order that the code generator searches for a function or operator match.

### Explore Code Replacement Library Contents

Use the **Code Replacement Viewer** to explore the content of a code replacement library.

- 1 At the command prompt, type `crviewer`.
 

```
>> crviewer
```

The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```
- 2 In the left pane, select the name of a library. The viewer displays information about the library in the right pane.
- 3 In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.

- 4 In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.TfLCOperationEntryGenerator` or `RTW.TfLCOperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See **Code Replacement Viewer** for details on what the viewer displays.

## Replace Code Generated from Simulink Models

This example shows how to replace generated code, using a code replacement library. Code replacement is a technique you can use to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as elimination of `math.h`, system header files, or calls to `memcpy` or `memset`, or use of BLAS.

### Prepare for Code Replacement

1. Make sure that MATLAB®, Simulink®, Simulink Coder™, and a C compiler are installed on your system. Some code replacement libraries available in your development environment can require Embedded Coder®.

To install MathWorks® products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the Command Window, enter `ver`.

2. Identify an existing Simulink model or create a model for which you want the code generator to replace code.

### Choose a Code Replacement Library

By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks® provides and that you create and register by using the Embedded Coder® product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder® product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Depending on the product licenses that you have, other libraries might be available. If you have an Embedded Coder license, you can view and choose from other libraries and you can create custom code replacement libraries.

### Configure Code Generator to Use Code Replacement Library

1. Configure the code generator to apply a code replacement library during code generation for the model. Do one of the following:

- In the Configuration Parameters dialog box, on the **Code Generation > Interface** pane, select a library for the “Code replacement library” parameter.

- Set the `CodeReplacementLibrary` parameter at the command line or programmatically.
2. Configure the code generator to produce code only (not build an executable program) so you can verify your code replacements before building an executable program. Do one of the following:
    - In the Configuration Parameters dialog box, on the **Code Generation** pane, select “Generate code only”.
    - Set the `GenCodeOnly` parameter at the command line or programmatically.

### **Include Code Replacement Information in Code Generation Report**

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information can help you verify code replacements.

1. Configure the code generator to generate a report. In the Configuration Parameters dialog box, on the **Code Generation > Report** pane, select “Create code generation report”. Consider having the report open automatically. Select `Open report automatically`.
2. Include the code replacement section in the report. Select “Summarize which blocks triggered code replacements”.

### **Generate Replacement Code**

Generate C/C++ code from the model and, if you configured the code generator accordingly, a code generation report. For example, in the model window, press **Ctrl+B**.

The code generator produces the code and displays the report.

### **Verify Code Replacements**

Verify code replacements by examining the generated code. It is possible that code replacement behaves differently than you expect. For example, data types that you observe in the code generator input might not match what the code generator uses as intermediate data types during an operation.

# External Code Integration in Simulink Coder

---

The code generator includes multiple approaches for integrating legacy or custom code with generated code. Legacy code is existing handwritten code or code for environments that you integrate with code produced by the code generator. Custom code is legacy code or other user-specified lines of code that you include in the code generator build process. Collectively, legacy and custom code are called external code.

You integrate external code by importing existing external code into code produced by the code generator, exporting generated code into an existing external code base, or you can do both. For example, you can import code by calling an external function, by using the Legacy Code Tool, or place external code at specific locations in generated code by including Custom Code blocks in a model. When you import external code, the resulting generated code interfaces with generated scheduling code.

You can export generated code as a plug-in function for use in an external development environment. When you export generated code, you intend to interface that code manually with a scheduling mechanism in your application run-time environment.

For guidance on choosing an approach based on your application, see “Choose an External Code Integration Workflow” .

- “Choose an External Code Integration Workflow” on page 55-2

## Choose an External Code Integration Workflow

### In this section...

“Choose a Software Execution Framework for Scheduling Code Execution” on page 55-3

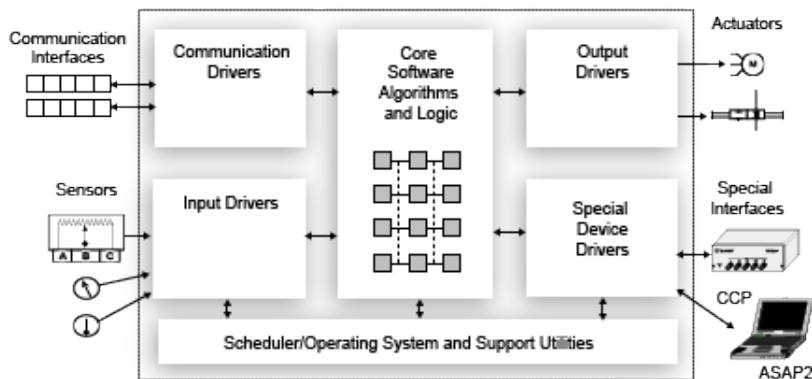

“Evaluate Characteristics of External Code” on page 55-4

“Identify Integration Requirements” on page 55-6

“Choose a Workflow” on page 55-7

Software projects typically involve combining code from multiple sources. A typical system structure for a code generation application consists of a framework that combines code from multiple sources, including external code and code generated from Simulink models.

This figure shows an application that requires integration of existing driver code for hardware devices. The core software algorithms and logic can be a combination of code modules for external reusable algorithms integrated into the Simulink environment and code generated as part of an overall model design.

Completing these tasks helps you choose external code integration workflows and tooling that align with your project.

Task	Action	More Information
1	Partition your application, map algorithms to components, and identify integration points.	“Software Deployment Concepts” on page 1-2, “Decompose Software Problem” on page 1-28, and “Map Embedded System Architecture to Simulink Modeling Environment” on page 1-29
2	Determine whether you can rely on scheduling code that the code generator produces, or whether you must integrate generated code with scheduling mechanisms that are specific to your run-time environment.	“Choose a Software Execution Framework for Scheduling Code Execution” on page 55-3
3	Evaluate the characteristics of the external code that you are importing.	“Evaluate Characteristics of External Code” on page 55-4

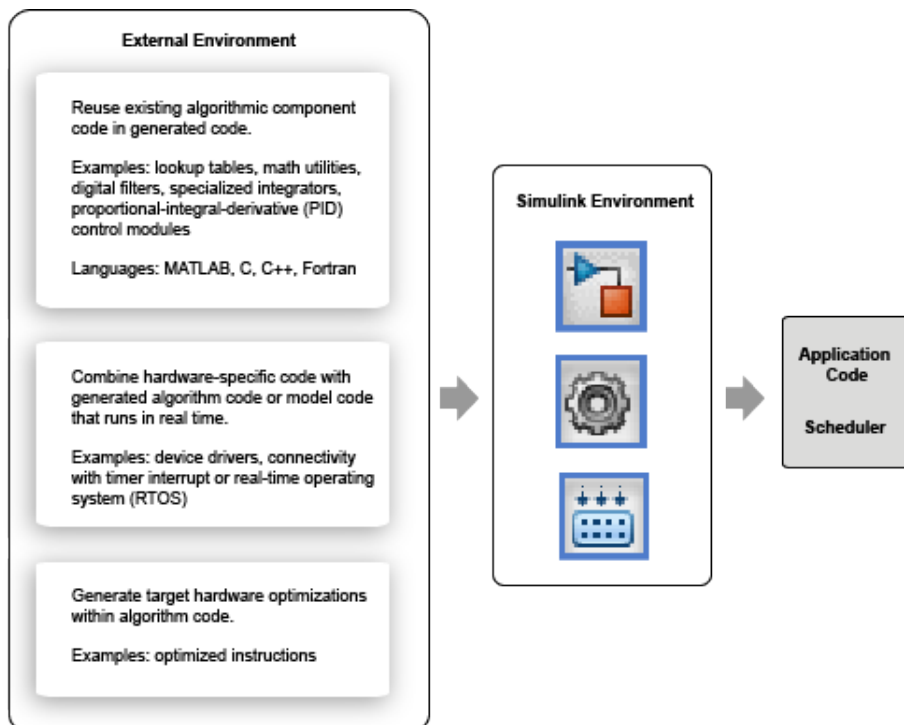

Task	Action	More Information
4	Identify integration requirements, which assists with choosing optimal tooling for your integration.	“Identify Integration Requirements” on page 55-6
5	Based on the results of tasks 1-4, choose a workflow.	“Choose a Workflow” on page 55-7

## Choose a Software Execution Framework for Scheduling Code Execution

The code generator supports two types of software execution frameworks—single top model and multiple top-level. The first question to answer concerns which of the two frameworks meets the scheduling and other needs of your project. For example, you can import external code into a single, rate-based top model. You can export code from a single top model or multiple top-level models for integration with custom (external) scheduling mechanisms.

- Single top model

Generate one set of application code files from external code and code that the Simulink C/C++ code generator produces. The generated code includes a scheduler. In this case, you *import* code into the Simulink code generation environment.

- Single top model or multiple top-level models

Integrate C or C++ code that the code generator produces from model components with external application code and an external scheduler. You *export* generated code from the Simulink code generation environment.

Importing calls to external device driver code into a model and generating code for that model for export involves importing and exporting code.

Based on goals and requirements, external code integration is characterized in several ways, requiring different workflows and integration tooling:

- Import existing external code into generated code.
  - Call reusable external algorithm code for simulation and code generation.
  - Place external C/C++ code in generated code.
  - Call external device drivers.
  - Apply function and operator code replacements.
  - Interface with external timer interrupt or scheduler.
  - Generate replacement code for specific run-time environment.
- Export generated code for inclusion in external code base. Requires Embedded Coder .
  - Generate component source code for export.
  - Generate shared library for export.

For more information on exporting generated code, see “Callable Function Integration”.

Next, see “Evaluate Characteristics of External Code” on page 55-4.

## Evaluate Characteristics of External Code

Before choosing an external integration workflow, evaluate these characteristics of the external code. To interface with external code, generated C or C++ code handles one or more of the external code

characteristics. An understanding of these characteristics and your requirements for modeling, simulation, and code generation helps you choose the optimal workflow for your integration scenario. (See “Identify Integration Requirements” on page 55-6.)

Characteristic	What to Consider
Hardware dependency	<p>Is the external code hardware-dependent? Utility functions, lookup tables, and filters are examples of hardware-independent code.</p> <p>Device drivers interact directly with hardware. They depend on characteristics of the hardware. For example, a device driver for an analog-to-digital converter initializes, reads data from, and writes data to hardware registers. Hardware differences and dependencies concern data type size, endianness, shift operations, compiler directives, and optimized function and operator support. Other code interfaces with device drivers by using an API and data mapped to specific memory addresses. Typically, simulation on a development computer is not possible. Reading from and writing to a register during simulation on a development computer produces unexpected and unwanted results.</p>
Reusable	<p>Is the external code a reusable software module? Examples include utility functions, lookup tables, filters, specialized integrators, and proportional-integral-derivative (PID) control modules.</p>
Dependency on data persistence between function calls	<p>Does the external code require persistent data? For example, a call to a first order filter function uses the output of the previous call to the function to calculate a new output value. You have the option of defining the data as global or using shared memory outside the context of the function.</p>
Data typing and interface	<p>How complex is the data that the external code uses? What does the data interface look like? It consists of arguments, a return value, global variables, and access functions. What data types does the code use? Are the types limited to basic ANSI C integers, floating-point types, arrays of integers or floating-point types, and pointers to these types? Does the interface include structures or pointers to structures?</p>
Fixed-point code	<p>Is the external code designed to run on integer-only processors? If yes, the code exchanges and uses data represented as integers only. Data can be associated with fixed-point scaling or offsets.</p>
External resource dependencies	<p>Does the external code use data, functions, or macros defined outside the scope of the code? For example, the function can use a standard ANSI function, a shared library, or predefined constants. In these cases, you must inform the compiler and linker of the paths and file names of the external resources.</p>
External solver required	<p>Are you using the external function for advanced development or rapid prototyping to describe a system with a continuous transfer function or a set of differential equations? If yes, the external code relies on an external solver.</p>

Next, see “Identify Integration Requirements” on page 55-6.

## Identify Integration Requirements

Before choosing an external integration workflow, review these integration requirements. An understanding of these requirements and the characteristics of your external code helps you choose the optimal workflow for your integration scenario. (See “Evaluate Characteristics of External Code” on page 55-4.)

Requirement	What to Consider
Effort	What level of effort is planned for the integration project—low, medium, or high?
Learning effort	What is the programming experience of assigned project resources? How much experience do assigned resources have with Simulink and MathWorks C/C++ code generation products?
Simulation and code generation behaviors	Do you want to take advantage of Model-Based Design? To take full advantage of Model-Based Design, convert code to modeling elements, which you can then use in the Simulink and Stateflow simulation environment. Then, simulate and generate code for the integrated component. Use software-in-the-loop (SIL) or processor-in-the-loop (PIL) testing to verify whether algorithm behavior is the same in both environments.
Data interface and typing	<ul style="list-style-type: none"> <li>• Does your model or generated code need to exchange data with the external function? If so, map inputs, outputs, and parameters to the external function interface. Typical function interfaces involve function arguments and return values, global variables, and access functions, such as <code>getRPM</code>.</li> <li>• Do you want to represent arrays, structures, or enumerated types? In the Simulink environment, you can represent these types as vectors, buses, and <code>IntEnum</code>, respectively.</li> <li>• Is fixed-point support required? If you use the Simulink fixed-point interface, you can scale and specify offsets.</li> <li>• Does the external code use company-specific data types? If yes and you have Embedded Coder software, create alias types to represent those external types. The code generator uses the alias types in the code that it produces. For example, once defined, you can specify an alias type in a function prototype, for a temporary variable, or for block output.</li> <li>• Does the code exchange data with shared memory? If yes, define and use memory sections.</li> </ul>
Direct function call	Do you want to call C external code directly from a model? You can choose from mechanisms, such as the C Function block, the C Caller block, Legacy Code Tool, Stateflow external code interface and chart action language, and the MATLAB Function block.
Insertion of external code into generated code	Do you want to control the placement of external code within generated code? Do you want to insert code into generated entry-point functions? You can place code within generated code by using model configuration parameters or custom code blocks.

Requirement	What to Consider
Code generation optimization support	Do you want to optimize the code that the code generator produces? If so, you can configure the model for the code generator to optimize the code it produces based on application objectives, such as execution, ROM, and RAM efficiency. You also have the option of using code replacement libraries.
Files required	Do you want to minimize the number of files that you maintain? Some external code integration tools require that you maintain separate files for defining simulation and code generation.

Next, see “Choose a Workflow” on page 55-7.

## Choose a Workflow

To choose a workflow for integrating external code into the Simulink environment, use the following table with links to more information.

Goal	Action	More Information
Call hardware-independent reusable external algorithmic code from generated code. For example: utility functions, lookup tables, and digital filters.	Choose an approach for integrating external code into the Simulink environment for code generation based on your programming language and other integration requirements.	“Call Reusable External Algorithm Code for Simulation and Code Generation” on page 55-15
Call hardware-dependent external reusable external algorithmic code from generated code. For example: device drivers.	Call external driver code from the Simulink environment.	“Call External Device Drivers” on page 55-31
Place external C/C++ code in generated code.	Augment functions with external code using model configuration parameters or custom code blocks.	“Place External C/C++ Code in Generated Code” on page 55-23
Change the code that the code generator produces for functions and operators to meet application code requirements.	Use code replacements to specify application-specific implementations of functions and operators.	“Apply Function and Operator Code Replacements” on page 55-32

## Configure Target Hardware Characteristics

Simulink® allows you to configure the hardware implementation characteristics of your target system. Failure to do so can result in code that is incorrect or inefficient.

### Open Example Model

Open the example model `rtwdemo_targetsettings`.

```
open_system('rtwdemo_targetsettings');
```

?

View Hardware Configuration (double-click)

Generate Code Using Simulink Coder (double-click)

Generate Code Using Embedded Coder (double-click)

My microprocessor is not listed ...

Open the **Hardware Implementation** pane of the Configuration Parameters dialog box by double-clicking the yellow button in the model.

## Hardware Board Configuration

By default, the model is configured for the code generator to determine the hardware board configuration based on the specified system target file. The default system target file setting is `grt.tlc`.

If you have installed support for a hardware board, that board should appear in the **Hardware board** menu. If you select it, the dialog box displays parameters that are relevant to your hardware board.

### My Hardware Board is Not Listed

If you are using a hardware board that is not listed, add it to the menu by installing the corresponding target support package. Start the Support Package Installer by setting **Hardware board** to `Get hardware Support Packages`, or by entering `supportPackageInstaller` in the MATLAB® Command Window.

After installing support for a hardware board, reopen the Configuration Parameters dialog box and select the hardware board.

### Cross-Development Systems that Include Source Level Debuggers

If you use a cross-development system that includes a source level debugger:

1. Configure the model for your hardware board.
2. Generate code and build an executable using your target development system. For details about retrieving file and path information, see the documentation on the Simulink Coder® Build Information API.
3. Download the executable to the target hardware and set breakpoints at the model output code for each output of the model.
4. Run a debugging session and observe the behavior of the code as it executes on the target hardware. As you step through the code, it computes the values for target hardware device characteristics.

If your target development system does not support source level debugging, generate code and add `printf` statements or other code that gets the results.

5. On the **Hardware Implementation** pane of the Configuration Parameters dialog box, set **Device vendor** to `Custom processor`, click the **Device details** arrow, and adjust the microprocessor device settings manually.

## Check Code Generation Assumptions

The code generator implements assumptions that depend, for example, on the hardware implementation settings for your model. It is important to check that the assumptions are valid for your target hardware. Use the `buildStandaloneCoderAssumptions` function to create an application that performs assumption checks on your target hardware.

When you configure your model, try to specify hardware implementation and build configuration settings that match your target hardware. Then, to check code generator assumptions for your target hardware, use this workflow:

- 1 With `GenerateReport` set to 'on', build (**Ctrl+B**) your model.
- 2 To view the list of code generator assumptions that you can check, open the code generation report and click the **Coder Assumptions** link.

For more information, see “Coder Assumptions List” on page 55-13.

- 3 Run `buildStandaloneCoderAssumptions`, which uses the generated code in the build folder to create an application that runs code generation assumption checks.
- 4 Download the application onto the target hardware or target environment, and then run the application.
- 5 While the application runs, use a debug tool to view check results that are in a data structure.

### Check Code Generator Assumptions for Development Computer

If the target hardware is, for example, your Windows development computer, you can use Microsoft Visual Studio® to run and debug the application:

- 1 To open a model, in the Command Window, enter `rtwdemo_sil_topmodel`.
- 2 In the Model Configuration Parameters dialog box, in the **Hardware Implementation** pane, specify settings to match the target hardware. For example, for a 64-bit Windows computer specify these parameter settings:
  - **Device vendor** -- Intel
  - **Device type** -- x86-64 (Windows 64)
- 3 Clear model configuration parameter **Enable portable word sizes**.
- 4 Build the model (**Ctrl+B**).
- 5 To view the list of code generator assumptions, open the code generation report and click the **Coder Assumptions** link.
- 6 From the Command Window, in the working folder, run:

```
buildStandaloneCoderAssumptions('rtwdemo_sil_topmodel_ert_rtw')
```

In the build folder, the function creates the `coderassumptions\standalone` subfolder, which contains the target application, `rtwdemo_sil_topmodel_ca`.

- 7 Open Microsoft Visual Studio and select **File > Open > Project/Solution**
- 8 Using the Open Project dialog box, navigate to the `coderassumptions\standalone` subfolder and select `rtwdemo_sil_topmodel_ca`. Then, click **Open**.
- 9 Select **File > Open > File**. Using the Open File dialog box, select `coderassumptions\standalone\rtwdemo_sil_topmodel_ca.c`

- 10 At the return statement, insert a break point.
- 11 Select **Debug > Start Debugging**.
- 12 To verify code generator assumptions, use a Watch window to inspect the Results data structure:
  - a In the `rtwdemo_sil_topmodel_ca.c` code, right-click Results.
  - b From the context menu, select **Add Watch**.

The variables in the data structure contain:

- Check outcomes (TestResults)
- Target hardware truths (ActualValues)
- Code generator assumptions (ExpectedValues)

For example, if the code generator assumption for `bitsPerChar` is accurate, you see the `CA_PASS` value in the `status` variable.

## Coder Assumptions List

The contents section of the code generation report has a link to the Coder Assumptions page. The page provides a list of:

- Code generation assumptions that you can check
- Expected results for the assumption checks

This table describes the labels that you see in the list.

Category	Label	Assumption You Can Check
C/C++ Language Configuration for Target Hardware or Development Computer	BitPerChar	Number of bits per char (ProdBitPerChar)
	BitPerShort	Number of bits per short (ProdBitPerShort)
	BitPerInt	Number of bits per int (ProdBitPerInt)
	BitPerLong	Number of bits per long (ProdBitPerLong)
	BitPerFloat	Size of float (Only if PurelyIntegerCode is 'off')

Category	Label	Assumption You Can Check
	BitPerDouble	Size of double (Only if PurelyIntegerCode is 'off')
	BitPerPointer	Number of bits per pointer (ProdBitPerPointer)
	BitPerSizeT	Number of bits per size_t (ProdBitPerSizeT)
	BitPerPtrDiffT	Number of bits per ptrdiff_t (ProdBitPerPtrDiffT)
	Endianness	Byte ordering (ProdEndianness)
	Shift right for signed integer is arithmetic shift	Sign bit behavior (ProdShiftRightIntArith)
	Signed integer division rounds to	Rounding behavior for integer division (ProdIntDivRoundTo)
C/C++ Language Standard	Initial value of a global integer variable and dynamically allocated memory is zero	Zero initialization of memory (ZeroExternalMemoryAtStartup, ZeroInternalMemoryAtStartup, and GenerateAllocFcn)
Floating-Point Numbers	Flush-to-zero computed subnormal values (FTZ)	Flush-to-zero subnormal number processing
	Flush-to-zero incoming subnormal values (DAZ)	Denormals-are-zero subnormal number processing

## Call Reusable External Algorithm Code for Simulation and Code Generation

Code reuse offers business and technological advantages. From a business perspective, code reuse saves time and resources. From a technological perspective, code reuse promotes consistency and reduces memory requirements. Other considerations include:

- Modularizing an application
- Reusing an optimized algorithm
- Interfacing with a predefined dataset
- Developing application variants

Examples of reusable hardware-independent algorithmic code to consider importing into the Simulink environment for simulation and code generation include:

- Utility functions
- Lookup tables
- Digital filters
- Specialized integrators
- Proportional-integral-derivative (PID) control modules

### Workflow

To call reusable external algorithm code for simulation and code generation, iterate through the tasks listed in this table.

Task	Action	More Information
1	Review your assessment of external code characteristics and integration requirements.	"Choose an External Code Integration Workflow" on page 55-2
2	Based on the programming language of the external code, choose an integration approach to add the external code to a Simulink model.	"Choose an Integration Approach" on page 55-16
3	Verify algorithm behavior and performance by simulating the model.	"Simulation"
4	Define the representation of model data for code generation.	"Code Interface Configuration" and "Exchange Data Between External C/C++ Code and Simulink Model or Generated Code" on page 55-61
5	Configure the model for code generation.	"Model Configuration Set Customization"
6	Generate code and a code generation report.	"Code Generation"
7	Review the generated code interface and static code metrics.	"Analyze the Generated Code Interface" on page 51-13 and "Static Code Metrics" on page 51-23

Task	Action	More Information
8	Build an executable program from the model.	“Build Integrated Code Within the Simulink Environment” on page 55-33
9	Verify that executable program behaves as expected.	“Verification, Testing, and Certification”

## Choose an Integration Approach

Several approaches are available for integrating reusable algorithmic code into the Simulink environment for code generation. Some approaches integrate external code directly. Other approaches convert the external code to Simulink or Stateflow modeling elements for simulation, and later for code generation from the modeled design. The integration approach that you choose depends on:

- Programming language of the external code — MATLAB, C, C++, or Fortran
- Your programming language experience and preference
- Performance requirements
- Whether the algorithm must model continuous time dynamics or you are integrating the algorithm into an application that uses discrete and continuous time
- Whether you want to take advantage of Model-Based Design
- Level of control required over the code that the code generator produces

To choose an approach for a reusable algorithm, see the subsection that matches the programming language of your external algorithm code.

- “Integration Approaches for External MATLAB Code” on page 55-16
- “Integration Approaches for External C or C++ Code” on page 55-18
- “Integration Approaches for External Fortran Code” on page 55-21

### Integration Approaches for External MATLAB Code

Multiple approaches are available for integrating external MATLAB code into the Simulink environment. The following table helps you choose the best integration approach for your application based on integration requirements.

Condition or Requirement	Action	More Information
<ul style="list-style-type: none"> <li>• External code complies with the MATLAB code generation subset</li> <li>• You want to call MATLAB code from a Simulink model</li> </ul>	Add a MATLAB Function block to the model. Embed the MATLAB code in that block.	<ul style="list-style-type: none"> <li>• “Integrate C Code by Using the MATLAB Function Block”</li> <li>• MATLAB Function</li> </ul>

Condition or Requirement	Action	More Information
<ul style="list-style-type: none"> <li>External code complies with the MATLAB code generation subset</li> <li>You want to call MATLAB code from a Simulink model</li> <li>Your algorithm includes iterative computations that process large streams of data</li> </ul>	<p>Add a MATLAB System block to the model. Embed the MATLAB code in that block as a System object™.</p>	<ul style="list-style-type: none"> <li>“Integrate C Code by Using the MATLAB Function Block”</li> <li>MATLAB System</li> </ul>
<ul style="list-style-type: none"> <li>External code complies with the MATLAB code generation subset</li> <li>You want to call MATLAB code from a Simulink model</li> <li>Your algorithm includes design logic that is based on state machines and flow charts</li> </ul>	<p>Add a Stateflow chart to the model. Call the external code from the chart, using MATLAB as the action language.</p>	<ul style="list-style-type: none"> <li>“Chart Programming Basics” (Stateflow)</li> <li>“Insert External Code into Stateflow Charts” on page 55-21</li> </ul>
<p>You want to use the <code>parfor</code> function for parallel computing or interface data types that are available to MATLAB Coder, Simulink Coder, and Embedded Coder. To use <code>parfor</code>, Parallel Computing Toolbox must be installed.</p>	<p>Use software to generate C code. Then, call that generated code as external C code.</p>	<ul style="list-style-type: none"> <li>“Generate C Code by Using the MATLAB Coder App”</li> <li>“Get Started with MATLAB Coder”</li> </ul>
<p>You have C or C++ programming experience and the external MATLAB code is compact and primarily uses C or C++ constructs.</p>	<p>Manually convert the MATLAB code to C or C++ code. ### Integration Approaches for External C or C++ Code

Multiple approaches are available for integrating external C or C++ code into the Simulink environment. The following table helps you choose the best integration approach for your application based on integration requirements.

Condition or Requirement	Action	More Information
You want to integrate external C code with generated C++ code or conversely	Match the language choice for the generated code by modifying the language of the external code.	“Modify Programming Language of External Code to Match Generated Code” on page 55-20
<ul style="list-style-type: none"> <li>• You have existing C code that models custom functionality. You want to integrate the code into Simulink blocks.</li> <li>• Your functions do not read or write global/static variables.</li> <li>• You want to easily integrate with Simulink Coverage, Simulink Test, and Simulink Design Verifier™</li> </ul>	For simple algorithms written in C, consider using the Simulink C Caller block.	“Integrate C Code Using C Caller Blocks”
<ul style="list-style-type: none"> <li>• You have existing C code that models custom functionality. You want to call multiple C functions from a Simulink block, or call C functions conditionally.</li> <li>• You want to include C code to preprocess and postprocess data before and after calling C functions.</li> <li>• You want to specify different code for simulation and code generation.</li> </ul>	Add a C Function block to your model.	“Integrate C Code by Using the MATLAB Function Block”

Condition or Requirement	Action	More Information
<ul style="list-style-type: none"> <li>The algorithm must model discrete and continuous state dynamics for simulation and rapid prototyping.</li> <li>The external code requires a fixed-point interface.</li> <li>Programming experience is limited. You want ease of use with basic flexibility for controlling what code the code generator produces for rapid prototyping.</li> </ul>	Generate S-function and TLC files by using the S-Function Builder. If necessary, refine the generated code manually to meet application requirements. (If you change the generated code, you lose the changes if you regenerate the S-function and TLC files.)	<ul style="list-style-type: none"> <li>“Use a Bus Signal with S-Function Builder to Create an S-Function”</li> <li>“Generate S-Function from Subsystem” on page 12-64</li> </ul>
<ul style="list-style-type: none"> <li>You want to simulate and generate external code for a discrete time application. Optimizing generated code is essential.</li> <li>You want ease of use with moderate flexibility for controlling what code the code generator produces.</li> <li>You have C or C++ programming experience, but you prefer to generate the files for adding the code to a model.</li> </ul>	Generate S-function and TLC files by using the Legacy Code Tool. If necessary, refine the generated code manually to meet application requirements. (If you change the generated code, you lose the changes if you regenerate the S-function and TLC files.)	<ul style="list-style-type: none"> <li>“Integrate C Functions Using Legacy Code Tool”</li> <li>“Import Calls to External Code into Generated Code with Legacy Code Tool”</li> <li>“Integrate C Code Using C Caller Blocks”</li> </ul>
<ul style="list-style-type: none"> <li>The application requires more entry-point functions than the code generator typically produces—for example, more than <i>model_step</i>, <i>model_initialize</i>, and <i>model_terminate</i>.</li> </ul> <p>You want maximum flexibility for controlling what code the code generator produces.</p>	Manually write an S-function and TLC file.	<ul style="list-style-type: none"> <li>“C/C++ S-Function Basics”</li> <li>“S-Functions and Code Generation” on page 12-2</li> <li>“C S-Function Examples” and “C++ S-Function Examples”</li> </ul>

Condition or Requirement	Action	More Information
Your algorithm includes design logic that is based on state machines and flow charts. Or, a function that you want to integrate must exchange data with a model by using global variables. The function defines the global variables and uses them to write output rather than returning a value (return) or writing output to an argument.	Add a Stateflow chart to the model. Call the external code from the chart, using C as the action language. In the chart, write code that calls the external function and reads from and writes to the global variables. To perform calculations with output of the external code, the model must read from the global variable during execution.	"Insert External Code into Stateflow Charts" on page 55-21
You want to include external C or C++ code in a Stateflow chart for simulation and code generation.	Configure the model that contains the chart to apply the external C or C++ code.	<ul style="list-style-type: none"> <li>• "Custom Code" (Stateflow)</li> <li>• "Call C Library Functions in C Charts" (Stateflow)</li> <li>• "Insert External Code into Stateflow Charts" on page 55-21</li> </ul>
You quickly want to embed a call to external C or C++ code in a model. Performance is not an issue.	Call the C or C++ code with the <code>coder.ceval</code> function from within a MATLAB Function block.	<ul style="list-style-type: none"> <li>• <code>coder.ceval</code> function</li> <li>• "Integrate C Code by Using the MATLAB Function Block"</li> <li>• MATLAB Function block</li> </ul>

### Modify Programming Language of External Code to Match Generated Code

To integrate external C code with generated C++ code or conversely, modify the language of the external code to match the programming language choice for the generated code. Options for making the programming language match include:

- Writing or rewriting the external code in the language choice for the generated code.
- If you are generating C++ code and the external code is C code, for each C function, create a header file that prototypes the function. Use this format:

```
#ifdef __cplusplus
extern "C" {
#endif
int my_c_function_wrapper();
#ifdef __cplusplus
}
#endif
```

The prototype serves as a function wrapper. If your compiler supports C++ code, the value `__cplusplus` is defined. The linkage specification `extern "C"` specifies C linkage without name mangling.

- If you are generating C code and the external code is C++ code, include an `extern "C"` linkage specification in each `.cpp` file. For example, the following example shows C++ code in the file `my_func.cpp`:

```
extern "C" {

int my_cpp_function()
{
```

```

} ...
}

```

## Integration Approaches for External Fortran Code

To integrate external Fortran code:

- 1 Write an S-function and corresponding TLC file.
- 2 Add the S-function to your model.
- 3 If necessary, add support files and control model code generation and builds within the Simulink environment.

See “C/C++ S-Function Basics”, “Implement Algorithms Using Fortran Code”, “S-Functions and Code Generation” on page 12-2, and “Fortran S-Function Examples”.

## Insert External Code into Stateflow Charts

- “Integrate External Code for Library Charts” on page 55-21
- “Integrate External Code for All Charts” on page 55-21

### Integrate External Code for Library Charts

To integrate external code that applies only to Stateflow library charts for code generation, for each library model that contributes a chart to your main model, complete these steps. Then, generate code.

- 1 In the Stateflow Editor, open the Model Configuration Parameters dialog box. Select parameter **Use local custom code settings (do not inherit from main model)**,

The library model retains its own custom code settings during code generation.

- 2 Specify your custom code in the subpanes.

Follow the guidelines in “Specify Relative Paths to Your Custom Code” (Stateflow).

If you specified custom code settings for simulation, you can apply these settings to code generation. To avoid entering the same information twice, select **Use the same custom code settings as Simulation Target**.

- 3 Click **OK**.

After completing these steps for each library model, generate code.

### Integrate External Code for All Charts

To integrate external code that applies to all charts for code generation:

- 1 Specify custom code options for code generation of your main model.
  - a In the Model Configuration Parameters dialog box, select **Code Generation > Custom Code**.
  - b In the custom code text fields, specify your custom code.

Follow the guidelines in “Specify Relative Paths to Your Custom Code” (Stateflow).

If you specified custom code settings for simulation, you can apply these settings to code generation. To avoid entering the same information twice, select **Use the same custom code settings as Simulation Target**.

- 2 Configure code generation for each library model that contributes a chart to your main model. In the Stateflow Editor, open the Model Configuration Parameters dialog box. Clear parameter **Use local custom code settings (do not inherit from main model)**. The library charts inherit the custom code settings of your main model. Click **OK**.
- 3 Generate code.

## Place External C/C++ Code in Generated Code

In this section...
“Workflow” on page 55-23
“Choose an Integration Approach” on page 55-24
“Integrate External Code by Using Custom Code Blocks” on page 55-25
“Integrate External Code by Using Model Configuration Parameters” on page 55-27
“Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters” on page 55-28

You can customize code that the code generator produces for a model by specifying external code with custom code blocks or model configuration parameters.

- Place code at the start and end of the generated code for the root model.
- Place declaration, body, and exit code in generated function code for blocks in the root model or nonvirtual subsystems.

The functions that you can augment with external code depends on the functions that the code generator produces for blocks that are in the model. For example, if a model or atomic subsystem includes blocks that have states, you can specify code for a disable function. Likewise, if you need the code for a block to save data, free memory, or reset target hardware, specify code for a terminate function. For more information, see “Block Target File Methods”.

### Workflow

To place external C or C++ code at specific locations in code that the code generator produces for root models and subsystems, iterate through the tasks listed in this table.

Task	Action	More Information
1	If you want to integrate external C code with generated C++ code or conversely, modify the language of the external code to match the language choice for the generated code.	“Modify Programming Language of External Code to Match Generated Code”
2	Review your assessment of external code characteristics and integration requirements.	“Choose an External Code Integration Workflow” on page 55-2
3	If necessary, rewrite code in C or C++.	
4	Choose an integration approach to add the external code to a Simulink model.	“Choose an Integration Approach” on page 55-24
5	Define the representation of model data for code generation.	“Exchange Data Between External C/C++ Code and Simulink Model or Generated Code” on page 55-61
6	Configure the model for code generation.	“Model Configuration Set Customization”
7	Generate code and a code generation report.	“Code Generation”

Task	Action	More Information
8	Review the generated code interface and static code metrics.	“Analyze the Generated Code Interface” on page 51-13 and “Static Code Metrics” on page 51-23
9	Build an executable program from the model.	“Build Integrated Code Within the Simulink Environment” on page 55-33
10	Verify that executable program performs as expected.	“Verification, Testing, and Certification”

## Choose an Integration Approach

Within the Simulink modeling environment, two approaches are available for placing external C or C++ code into sections of code that the code generator produces:

- Add blocks from the Custom Code library to a root model or atomic subsystem.
- Set model configuration parameters on the **Code Generation > Custom Code** pane.

The following table compares the two approaches. Choose the approach that aligns best with your integration requirements. For more information about how to apply each approach, see “Integrate External Code by Using Custom Code Blocks” on page 55-25 and “Integrate External Code by Using Model Configuration Parameters” on page 55-27.

Requirement	Blocks	Model Configuration Parameters
Include a representation of your external code in the modeling canvas	✓	
Place code in functions generated for root models	✓	✓
Place code in functions generated for atomic subsystems	✓	
Save code placement in a model configuration set		✓
Place code at the top and bottom of the header and source files generated for a model	✓	✓
Place code within declaration, execution, and exit sections of the <code>SystemInitialize</code> and <code>SystemTerminate</code> functions that the code generator creates	✓	✓
Place code within declaration, execution, and exit sections of the <code>SystemStart</code> , <code>SystemEnable</code> , <code>SystemDisable</code> , <code>SystemOutputs</code> , <code>SystemUpdate</code> , or <code>SystemDerivatives</code> functions that the code generator creates	✓	
Add preprocessor macro definitions to generated code		✓
Use the custom code settings that are specified for the simulation target		✓
Configure a library model to use custom code settings of the parent model to which the library is linked		✓

## Integrate External Code by Using Custom Code Blocks

- “Custom Code Block Library” on page 55-25
- “Add Custom Code Blocks to the Modeling Canvas” on page 55-26
- “Add External Code to Generated Start Function” on page 55-26

### Custom Code Block Library

The Custom Code block library contains blocks that you can use to place external C or C++ code into specific locations and functions within code that the code generator produces. The library consists of 10 blocks that add your code to the model header (*model.h*) and source (*model.c* or *model.cpp*) files that the code generator produces.

The Model Header and Model Source blocks add external code at the top and bottom of header and source files that the code generator produces for a root model. These blocks display two text fields into which you can type or paste code. One field specifies code that you want to place at the top of the generated header or source file. The second field specifies code that you want to place at the bottom of the file.

The remaining blocks add external code to functions that the code generator produces for the root model or atomic subsystem that contains the block. The blocks display text fields into which you can type or paste code that customizes functions that the code generator produces. The text fields correspond to the declaration, execution, and exit sections of code for a given function.

To Customize Code That	Use This Block
Computes continuous states	System Derivatives
Disables state	System Disable
Enables state	System Enable
Resets state	System Initialize
Produces output	System Outputs
Executes once	System Start
Saves data, free memory, reset target hardware	System Terminate
Requires updates at each major time step	System Update

The block and its location within a model determines where the code generator places the external code. For example, if the System Outputs block is at the root model level, the code generator places the code in the model **Outputs** function. If the block resides in a triggered or enabled subsystem, the code generator places the code in the subsystem **Outputs** function.

If the code generator does not need to generate a function that corresponds to a Custom Code block that you include in a model, the code generator does one of the following:

- Omits the external code that you specify in the Custom Code block.
- Returns an error, indicating that the model does not include a relevant block. In this case, remove the Custom Code block from the model.

For more information, see “Block Target File Methods”.

**Note** To avoid a potential mismatch between simulation and code generation results, do not use custom code blocks to read from and write to global Simulink data (signals, states, and block

parameters). Instead, use the proper modeling pattern (for example, Data Store Read, Data Store Write, State Reader, and State Writer blocks.)

### Add Custom Code Blocks to the Modeling Canvas

To add the Custom Code library blocks to a model:

- 1 In the Simulink Library Browser, expand the Simulink Coder node then select the Custom Code block library.
- 2 Drag the blocks that you want into your model or subsystem. Drag Model Header and Model Source blocks into root models only. Drag function-based Custom Code blocks into root models or atomic subsystems.

You can use models that contain Custom Code blocks as referenced models. The code generator ignores the blocks when producing code for a simulation target. When producing code for a code generation target, the code generator includes and compiles the custom code.

### Add External Code to Generated Start Function

This example shows how to use the System Start block to place external C code in the code that the code generator produces for a model that includes a discrete filter.

- 1 Create the following model.

- 2 Configure the model for code generation.
- 3 Double-click the System Start block.
- 4 In the block parameters dialog box, in the **System Start Function Declaration Code** field, enter this code:

```
unsigned int *ptr = 0xFFEE;
```

- 5 In the **System Start Function Execution Code** field, enter this code:

```
/* Initialize hardware */
*ptr = 0;
```

- 6 Click **OK**.
- 7 Generate code and a code generation report.
- 8 View the generated *model.c* file. Search for the string `start` function. You should find the following code, which includes the external code that you entered in steps 4 and 5.

```
{
{
/* user code (Start function Header) */
/* System '<Root>' */
unsigned int *ptr = 0xFFEE;
}
```

```

 /* user code (Start function Body) */
 /* System '<Root>' */
 /* Initialize hardware */
 *ptr = 0;
 }
}

```

For another example, see “Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters” on page 55-28.

## Integrate External Code by Using Model Configuration Parameters

Model configuration parameters provide a way to place external C or C++ code into specific locations and functions within code that the code generator produces.

To	Select
Insert external code near the top of the generated <i>model.c</i> or <i>model.cpp</i> file	<b>Additional code</b> , and enter the external code to insert.  If you generate subsystem code into separate files, that code does not have access to external code that you specify with the <b>Additional code</b> parameter. For example, if you specify an include file as a <b>Additional code</b> setting, the code generator inserts the <code>#include</code> near the top of the <i>model.c</i> or <i>model.cpp</i> file. The subsystem code that the code generator places in a separate file does not have access to declarations inside your included file. In this case, consider specifying your external code with the <b>Include headers</b> parameter.
Insert external code near the top of the generated <i>model.h</i> file	<b>Include headers</b> , and enter the external code to insert.
Insert external code inside the model initialize function in the <i>model.c</i> or <i>model.cpp</i> file	<b>Initialize code</b> , and enter the external code to insert.
Insert external code inside the model terminate function in the <i>model.c</i> or <i>model.cpp</i> file	<b>Terminate code</b> , and enter the external code to insert. Also select the <b>Terminate function required</b> parameter on the <b>Interface</b> pane.
Add preprocessor macro definitions	<b>Defines</b> , and enter a space-separated list of preprocessor macro definitions to add to the generated code. The list can include simple definitions (for example, <code>-DEF1</code> ) and definitions with a value (for example, <code>-DDEF2=1</code> ). Definitions can omit the <code>-D</code> (for example, <code>-DF00=1</code> and <code>F00=1</code> are equivalent). If a definition includes <code>-D</code> , the toolchain can override the flag if the toolchain uses a different flag for defines.
Use the same custom code parameter settings as the settings specified for simulation of MATLAB Function blocks, Stateflow charts, and Truth Table blocks	<b>Use the same custom code settings as Simulation Target</b>  This parameter refers to the <b>Simulation Target</b> pane in the Configuration Parameters dialog box.

To	Select
Enable a library model to use custom code settings unique from the parent model to which the library is linked	<p><b>Use local custom code settings (do not inherit from main model)</b></p> <p>This parameter is available only for library models that contain MATLAB Function blocks, Stateflow charts, or Truth Table blocks.</p>

To include a header file in an external header file, add `#ifndef` code. Using this code avoids multiple inclusions. For example, in `rtwtypes.h`, the following `#include` guards are added:

```
#ifndef RTW_HEADER_rtwtypes_h_
#define RTW_HEADER_rtwtypes_h_
...
#endif /* RTW_HEADER_rtwtypes_h_ */
```

For more information on how to add file names and locations of header, source, and shared library files to the build process, see “Build Integrated Code Within the Simulink Environment” on page 55-33.

---

**Note** The code generator includes external code that you include in a configuration set when generating code for software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations. However, the code generator ignores external code that you include in a configuration set when producing code with the S-function, rapid simulation, or simulation system target file.

---

For more information about **Custom Code** parameters, see “Model Configuration Parameters: Code Generation Custom Code”. For an example, see “Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters” on page 55-28.

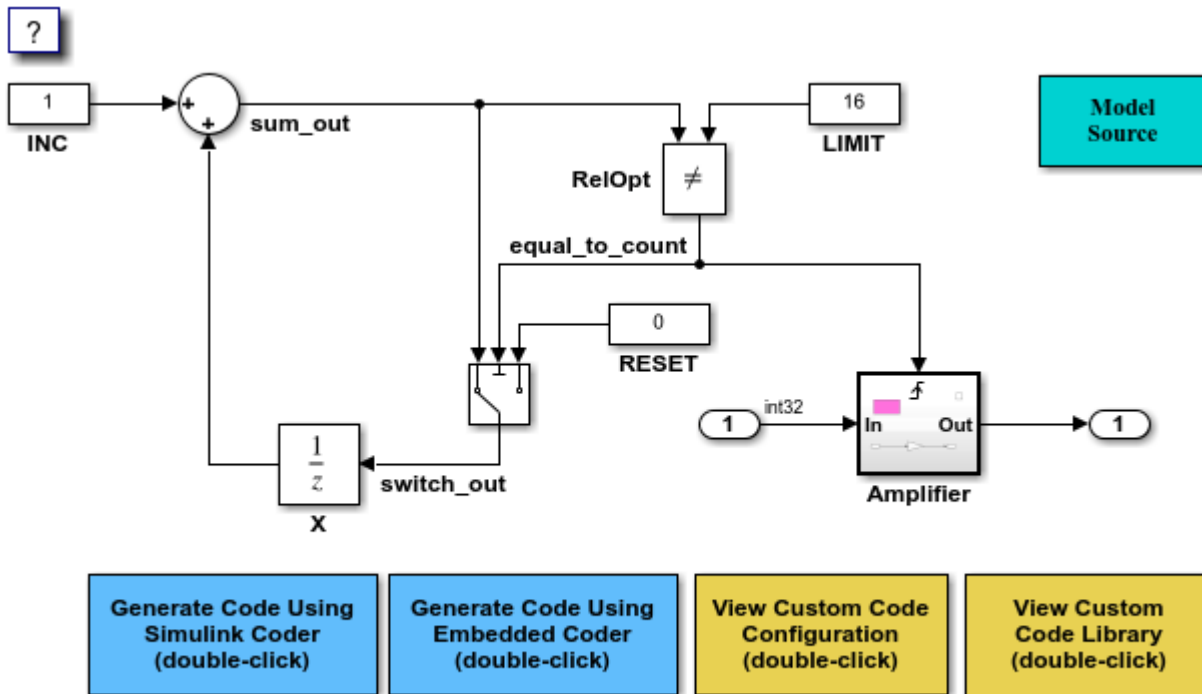

## Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model `rtwdemo_slcustcode`.

```
open_system('rtwdemo_slcustcode')
```

Copyright 1994-2020 The MathWorks, Inc.

2. Open the **Simulink Coder** or **Embedded Coder** app.
3. Open the Model Configuration Parameters dialog box and navigate to the **Custom Code** pane.
4. On the **Additional source code** tab, examine the settings for model configuration parameters **Additional code** and **Initialize code**.
  - **Additional code** specifies a comment and sets the variable GLOBAL\_INT2 to -1.
  - **Initialize code** initializes the variable GLOBAL\_INT2 to 1.
5. Close the dialog box.
6. Double-click the Model Source block. Block parameter **Top of Model Source** specifies that the code generator declare the variable GLOBAL\_INT1 and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.
7. Open the triggered subsystem **Amplifier**. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the **Amplifier** subsystem. The external code:
  - Declares the pointer variable `*intPtr` and initializes it with the value of variable GLOBAL\_INT1.
  - Sets the pointer variable to -1 during execution.
  - Resets the pointer variable to 0 before exiting.
8. Generate code and a code generation report.

9. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Additional code** configuration parameter and the second declaration with the Model Source block.

```
int_T GLOBAL_INT2 = -1;
```

```
int_T GLOBAL_INT1 = 0;
```

The Output function for the `Amplifier` subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Outputs block in the `Amplifier` subsystem.

```
int_T *intPtr = &GLOBAL_INT1;
```

```
*intPtr = -1;
```

```
rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;
```

```
*intPtr = 0;
```

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the **Initialize code** configuration parameter.

```
GLOBAL_INT2 = 1;
```

## Call External Device Drivers

Device drivers for protocols and target hardware are essential to many real-time development projects. For example, you can have a working device driver that you want to integrate with algorithmic code that has to read data from and write data to the I/O device that the driver supports. The code generator can produce a single set of application source files from an algorithm model and integrated driver code written in C or C++.

To call external device driver code from the Simulink environment, iterate through the tasks in this table.

Task	Action	More Information
1	Review your assessment of external code characteristics and integration requirements.	“Choose an External Code Integration Workflow” on page 55-2
2	Define the representation of model data for code generation.	“Exchange Data Between External C/C++ Code and Simulink Model or Generated Code” on page 55-61
3	Generate S-function and TLC files by using the Legacy Code Tool. If necessary, refine the generated code manually to meet application requirements.	<ul style="list-style-type: none"> <li>• “Integrate C Functions Using Legacy Code Tool”</li> <li>• “Import Calls to External Code into Generated Code with Legacy Code Tool”</li> </ul>
4	Verify algorithm behavior and performance by simulating the model.	“Simulation”
5	Configure the model for code generation.	“Model Configuration Set Customization”
6	Generate code and a code generation report.	“Code Generation”
7	Review the generated code interface and static code metrics.	“Analyze the Generated Code Interface” on page 51-13 and “Static Code Metrics” on page 51-23
8	Build an executable program from the model.	“Build Integrated Code Within the Simulink Environment” on page 55-33
9	Verify that executable program behaves and performs as expected.	“Verification, Testing, and Certification”

## Apply Function and Operator Code Replacements

If your generated code must use functions and operators that are consistent with external code, configure the code generator to use a code replacement library (CRL). By default, the code generator does not apply a code replacement library. You can choose from several libraries that MathWorks provides, including GNU C99 extensions, AUTOSAR 4.0, and several Intel platform-specific IPP and IPP/SSE libraries. Depending on the products that you have, other libraries might be available. If you have Embedded Coder software, you can view and choose from additional libraries and you can create custom code replacement libraries.

# Build Integrated Code Within the Simulink Environment

## Workflow

To build executable programs that integrate generated code and external C or C++ code, iterate through the tasks in this table.

Task	Action	More Information
1	Choose a build approach.	<p>“Approaches for Building Code Generated from Simulink Models” on page 56-11</p> <p>For an example, see “Build Process Workflow for Real-Time Systems” on page 56-26.</p>
2	Configure build process support for your external code.	“Configure Parameters for Integrated Code Build Process” on page 55-33
3	Configure S-Function build support for your external code.	<p>“Build Support for S-Functions” on page 55-35</p> <p>“Use makecfg to Customize Generated Makefiles for S-Functions” on page 87-15</p> <p>For examples, see “Call External C Code from Model and Generated Code” on page 50-47 and “Call Reusable External Algorithm Code for Simulation and Code Generation” on page 55-15.</p>
4	Configure build process to find the external code source, library, and header files.	<p>“Manage Build Process File Dependencies” on page 49-41</p> <p>“Control Library Location and Naming During Build” on page 87-3</p>
5	Set up custom build processing required for your external code integration.	<p>For the build process customization workflow, see “Customize Post-Code-Generation Build Processing” on page 87-7.</p> <p>To automate applying build customizations to a toolchain approach build, see “Customize Build Process with sl_customization.m” on page 87-39.</p> <p>To automate applying build customizations to a template makefile approach build, see “Customize Build Process with STF_make_rtw_hook File” on page 87-35.</p>

## Configure Parameters for Integrated Code Build Process

The table provides a guide to model configuration parameters on **Code Generation > Custom Code** pane of the Model Configuration Parameters dialog box that support the build process for external code integration. For information about folders for your external code, see “Manage Build Process Folders” on page 49-30. If you choose to place your external code in the “Code generation folder”, see “Preserve External Code Files in Build Folder” on page 55-34.

To	Select
Add include folders, which contain header files, to the build process	<p><b>Code information &gt; Include directories</b>, and enter the absolute or relative paths to the folders.</p> <p>If you specify relative paths, the paths must be relative to the folder containing your model files, not relative to the build folder. The order in which you specify the folders is the order in which they are searched for header, source, and library files.</p>
Add source files to be compiled and linked	<p><b>Code information &gt; Source files</b>, and enter the full paths or just the file names for the files.</p> <p>Enter just the file name if the file is in the current MATLAB folder or in one of the include folders. For each additional source that you specify, the build process expands a generic rule in the template makefile for the folder in which the source file is located. For example, if a source file is located in folder <code>inc</code>, the build process adds a rule similar to the following:</p> <pre>%.obj: builddir\inc\%.c     \$(CC) -c -Fo\$(@F) \$(CFLAGS) \$&lt;</pre> <p>The build process adds the rules in the order that you list the source files.</p>
Add libraries to be linked	<p><b>Code information &gt; Libraries</b>, and enter the full paths or just the file names for the libraries.</p> <p>Enter just the file name if the library is located in the current MATLAB folder or in one of the include folders.</p>
Use the same custom code settings as those specified for simulation of MATLAB Function blocks, Stateflow charts, and Truth Table blocks	<p><b>Use the same custom code settings as Simulation Target</b></p> <p>This parameter refers to the <b>Simulation Target</b> pane in the Configuration Parameters dialog box.</p>
Enable a library model to use custom code settings unique from the parent model to which the library is linked	<p><b>Use local custom code settings (do not inherit from main model)</b></p> <p>This parameter is available only for library models that contain MATLAB Function blocks, Stateflow charts, or Truth Table blocks.</p>

## Preserve External Code Files in Build Folder

By default, the build process deletes foreign source files. You can preserve foreign source files by following these guidelines.

If you put a `.c/.cpp` or `.h` source file in a build folder, and you want to prevent the code generator from deleting it during the TLC code generation process, insert the text `target specific file` in the first line of the `.c/.cpp` or `.h` file. For example:

```
/* COMPANY-NAME target specific file
 *
 * This file is created for use with the
```

```
* COMPANY-NAME target.
* It is used for ...
*/
...
```

Make sure that you spell the text “target specific file” as shown in the preceding example, and that the text is in the first line of the source file. Other text can appear before or after this text.

Flagging user files in this manner prevents postprocessing these files to indent them with generated source files. Auto-indenting occurred in previous releases to build folder files with names having the pattern *model\_\*.c/.cpp* (where \* was text). The indenting is harmless, but can cause differences detected by source control software that can potentially trigger unnecessary updates.

## Build Support for S-Functions

User-written S-Function blocks provide a powerful way to incorporate external code into the Simulink development environment. In most cases, you use S-functions to integrate existing external code with generated code. Several approaches to writing S-functions are available:

- “Write Noninlined S-Function” on page 12-95
- “Write Wrapper S-Function and TLC Files” on page 12-97
- “Write Fully Inlined S-Functions” on page 12-104
- “Write Fully Inlined S-Functions with mdlRTW Routine” on page 12-106
- “S-Functions for Code Reuse” on page 12-85
- “S-Functions for Multirate Multitasking Environments” on page 12-90

S-functions also provide the most flexible and capable way of including build information for legacy and custom code files in the build process.

There are different ways of adding S-functions to the build process.

### Implicit Build Support

When building models with S-functions, the build process adds rules, include paths, and source file names to the generated makefile. The source files (.h, .c, and .cpp) for the S-function must be in the same folder as the S-function MEX-file. Whether using the toolchain approach or template makefile approach for builds, the build process propagates this information through the toolchain or template makefile.

- If the file *sfcname.h* exists in the same folder as the S-function MEX-file (for example, *sfcname.mexext*), the folder is added to the include path.
- If the file *sfcname.c* or *sfcname.cpp* exists in the same folder as the S-function MEX-file, the build process adds a makefile rule for compiling files from that folder.
- When an S-function is not inlined with a TLC file, the build process must compile the S-function source file. To determine the name of the source file to add to the list of files to compile, the build process searches for *sfcname.cpp* on the MATLAB path. If the source file is found, the build process adds the source file name to the makefile. If *sfcname.cpp* is not found on the path, the build process adds the file name *sfcname.c* to the makefile, whether or not it is on the MATLAB path.

---

**Note** For the Simulink engine to find the MEX-file for simulation and code generation, it must exist on the MATLAB path or exist in our current MATLAB working folder.

---

## Specify Additional Source Files for an S-Function

If your S-function has additional source file dependencies, you must add the names of the additional modules to the build process. Specify the file names:

- In the **S-function modules** field in the S-Function block parameter dialog box
- With the `SFunctionModules` parameter in a call to the `set_param` function

For example, suppose you build your S-function with multiple modules.

```
mex sfun_main.c sfun_module1.c sfun_module2.c
```

You can then add the modules to the build process by doing one of the following:

- In the S-function block dialog box, specify `sfun_main`, `sfun_module1`, and `sfun_module2` in the **S-function modules** field.
- At the MATLAB command prompt, enter:

```
set_param(sfun_block, 'SFunctionModules', 'sfun_module1 sfun_module2')
```

Alternatively, you can define a variable to represent the parameter value.

```
modules = 'sfun_module1 sfun_module2'
set_param(sfun_block, 'SFunctionModules', modules)
```

The **S-function modules** field and `SFunctionModules` parameter do not support complete source file path specifications. To use the parameter, the code generator must find the additional source files when executing the makefile. For the code generator to locate the additional files, place them in the same folder as the S-function MEX-file. You can then leverage the implicit build support described in “Implicit Build Support” on page 55-35.

When you are ready to generate code, force the code generator to rebuild the top model, as described in “Control Regeneration of Top Model Code”.

For more complicated S-function file dependencies, such as specifying source files in other locations or specifying libraries or object files, use the `rtwmakecfg.m` API, as described in “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 87-17.

## Use TLC Library Functions

If you inline your S-function by writing a TLC file, you can add source file names to the build process by using the TLC library function `LibAddToModelSources`. For details, see “`LibAddSourceFileCustomSection(file, builtInSection, newSection)`”.

---

**Note** This function does not support complete source file path specifications. The function assumes that the code generator can find the additional source files when executing the makefile.

---

Another useful TLC library function is `LibAddToCommonIncludes`. Use this function in a `#include` statement to include S-function header files in the generated `model.h` header file. For details, see “`LibAddToCommonIncludes(incFileName)`”.

For more complicated S-function file dependencies, such as specifying source files in other locations or specifying libraries or object files, use the `rtwmakecfg.m` API, as described in “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 87-17.

## Precompile S-Function Libraries

You can precompile new or updated S-function libraries (MEX-files) for a model by using the MATLAB language function `rtw_precompile_libs`. Using a specified model and a library build specification, this function builds and places the libraries in a precompiled library folder.

By precompiling S-function libraries, you can optimize system builds. Once your precompiled libraries exist, the build process can omit library compilation from subsequent builds. For models that use numerous libraries, the time savings for build processing can be significant.

To use `rtw_precompile_libs`:

- 1 Set the library file suffix, including the file type extension, based on your system platform.

Consider determining the type of platform, and then use the `TargetLibSuffix` parameter to set the library suffix accordingly. For example, when applying a suffix for a GRT target, you can set the suffix to `_std.a` for a UNIX platform and `_vcx64.lib` for a Windows platform.

```
if isunix
 suffix = '_std.a';
else
 suffix = '_vcx64.lib';
end

set_param(my_model, 'TargetLibSuffix', suffix);
```

There are a number of factors that influence the precompiled library suffix and extension. The following table provides examples for typical selections of system target file, the compiler toolchain, and other options that affect your choice of suffix and extension. For more information, examine the template make files in the `matlab/rtw/c/grt` folder or `matlab/rtw/c/ert` folder.

TMF File	COMPILER _TOOL_CHAIN Value	Precompiler Libraries (PRECOMP_LIBRARIES)			
		Library Suffix S-Function (EXPAND _LIBRARY _NAME Value)	Library Suffix Integer- Only Code (EXPAND _LIBRARY _NAME Value)	Library Suffix Optimize for Speed (EXPAND _LIBRARY _NAME Value)	Library Extension (EXPAND _LIBRARY _NAME Value)
ert_lcc64.tmf	lcc	_rtwsfcn_lcc	_int_ert_lcc	_ert_lcc	.lib
ert_vcx64.tmf	vcx64	_rtwsfcn_vcx64	_int_ert_vcx64	_ert_vcx64	.lib
ert_unix.tmf	unix	_rtwsfcn	_int_ert	_ert	.a
grt_lcc64.tmf	lcc	n/a	n/a	_lcc	.lib
grt_vcx64.tmf	vcx64	n/a	n/a	_vcx64	.lib
grt_unix.tmf	unix	n/a	n/a	_std	.a

- 2 Set the precompiled library folder.

Use one of the following methods to set the precompiled library folder:

- Set the `TargetPreCompLibLocation` parameter, as described in “Specify the Location of Precompiled Libraries” on page 87-4.
- Set the `makeInfo.precompile` field in an `rtwmakecfg.m` function file. (For more information, see “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 87-17.)

If you set `TargetPreCompLibLocation` and `makeInfo.precompile`, the setting for `TargetPreCompLibLocation` takes precedence.

The following command sets the precompiled library folder for model `my_model` to folder `lib` under the current working folder.

```
set_param(my_model,'TargetPreCompLibLocation', fullfile(pwd,'lib'));
```

---

**Note** If you set both the target folder for the precompiled library files and a target library file suffix, the build process detects whether any precompiled library files are missing while processing builds.

---

### 3 Define a build specification.

Set up a structure that defines a build specification. The following table describes fields that you can define in the structure. These fields are optional, except for `rtwmakecfgDirs`.

Field	Description
<code>rtwmakecfgDirs</code>	<p>A cell array of character vectors that name the folders containing <code>rtwmakecfg</code> files for libraries to be precompiled. The function uses the <code>Name</code> and <code>Location</code> elements of <code>makeInfo.library</code>, as returned by <code>rtwmakecfg</code>, to specify the name and location of the precompiled libraries. If you set the <code>TargetPreCompLibLocation</code> parameter to specify the library folder, that setting overrides the <code>makeInfo.library.Location</code> setting.</p> <p><b>Note:</b> The specified model must contain blocks that use precompiled libraries specified by the <code>rtwmakecfg</code> files because the TMF-to-makefile conversion generates the library rules only if the build process uses the libraries.</p>
<code>libSuffix</code>	<p>A character vector that specifies the suffix, including the file type extension, to be appended to the name of each library (for example, <code>.a</code> or <code>_vc.lib</code>). The character vector must include a period (<code>.</code>). You must set the suffix with either this field or the <code>TargetLibSuffix</code> parameter. If you specify a suffix with both mechanisms, the <code>TargetLibSuffix</code> setting overrides the setting of this field.</p>
<code>intOnlyBuild</code>	<p>A Boolean flag. When set to true, the flag indicates the libraries are to be optimized such that they are compiled from integer code only. This field applies to ERT targets only.</p>
<code>makeOpts</code>	<p>A character vector that specifies an option to be included in the <code>rtwMake</code> command line.</p>
<code>addLibs</code>	<p>A cell array of structures that specify libraries to be built that are not specified by an <code>rtwmakecfg</code> function. Each structure must be defined with two fields that are character arrays:</p> <ul style="list-style-type: none"> <li><code>libName</code> — the name of the library without a suffix</li> <li><code>libLoc</code> — the location for the precompiled library</li> </ul> <p>The target makefile (TMF) can specify other libraries and how those libraries are built. Use this field to precompile those libraries.</p>

The following commands set up build specification `build_spec`, which indicates that the files to be compiled are in folder `src` under the current working folder.

```
build_spec = [];
build_spec.rtwmakecfgDirs = {fullfile(pwd,'src')};
```

**4** Issue a call to `rtw_precompile_libs`.

The call must specify the model for which you want to build the precompiled libraries and the build specification. For example:

```
rtw_precompile_libs(my_model,build_spec);
```

## Generate Component Source Code for Export to External Code Base

### In this section...

“Modeling Options” on page 55-40

“Requirements” on page 55-40

“Limitations for Export-Function Subsystems” on page 55-42

“Workflow” on page 55-42

“Choose an Integration Approach” on page 55-43

“Generate C Function Code for Export-Function Model” on page 55-44

“Generate C++ Function and Class Code for Export-Function Model” on page 55-47

“Generate Code for Export-Function Subsystems” on page 55-52

If you have Embedded Coder software, you can generate function source code from modeling components to use in an external code base. The generated code does not include supporting scheduling code (for example, a step function). Controlling logic outside of the Simulink environment invokes the generated function code.

### Modeling Options

You can generate function code to export for these modeling components:

- Export-function models (model containing functional blocks that consist exclusively of function-call subsystems, function-call model blocks, or other export-function models, as described in “Export-Function Models Overview”)
- Export-function subsystems (virtual subsystem that contains function-call subsystems)

To export code that the code generator produces for these modeling components, the modeling components must meet specific requirements on page 55-40.

For models designed in earlier releases, the code generator can export functions from triggered subsystems. The requirements stated for export-function subsystems also apply to exporting functions from triggered subsystems, with the following exceptions:

- Encapsulate triggered subsystems from which you intend to export functions in a top-level virtual subsystem.
- Triggered subsystems do not have to meet requirements and limitations identified for virtual subsystems that contain function-call subsystem.
- “Export Functions That Use Absolute or Elapsed Time” on page 55-41 does not apply to exporting functions from triggered subsystems.

### Requirements

- Model solver must be a fixed-step discrete solver.
- You must configure each root-level Inport block that triggers a function-call subsystem to output a function-call trigger. These Inport blocks cannot connect to an Asynchronous Task Specification block.

- Model or subsystem, must contain only the following blocks at the root level:
  - Function-call blocks (such as Function-Call Subsystem, Simulink Function, S-Functions, and Function-Call Model blocks at the root level if the solver model configuration parameter **Tasking and sample time options > Periodic sample time constraint** is set to Ensure sample time independent)
  - Inport and Outport blocks (ports)
  - Constant blocks (including blocks that resolve to constants, such as Add)
  - Blocks with a sample time of Inf
  - Merge and data store memory blocks
  - Virtual connection blocks (such as, Function-Call Split, Mux, Demux, Bus Creator, Bus Selector, Signal Specification, and virtual subsystems that contain these blocks)
  - Signal-viewer blocks, such as Scope blocks (export-function subsystems only)
- When a constant block appears at the top level of the model or subsystem, you must set the model configuration parameter **Optimization > Default parameter behavior** for the model or containing model to **Inlined**.
- Blocks inside the model or subsystem must support code generation.
- Blocks that use absolute or elapsed time must be inside a periodic function-call subsystem with a discrete sample time specified on the corresponding function-call root-level Inport block. See “Export Functions That Use Absolute or Elapsed Time” on page 55-41.
- Data signals that cross the boundary of an exported system cannot be a virtual bus and cannot be implemented as a Goto-From connection. Data signals that cross the export boundary must be scalar, muxed, or a nonvirtual bus.

In addition, for export-function models, you cannot generate code for a rate-based model that includes multiple instances of an export-function model. For example, you cannot generate code for a test harness model that you use for scheduling reusable export-function models during simulation.

For export-function subsystems, the following additional requirements apply:

- A trigger signal that crosses the boundary of an export-function subsystem must be scalar. Input and output data signals that do not act as triggers do not have to be scalar.
- When a constant signal drives an output port of an export-function subsystem, the signal must specify a storage class.

### Export Functions That Use Absolute or Elapsed Time

If you want to export function code for a modeling component with blocks that use absolute or elapsed time, those blocks must be inside a function-call subsystem that:

- You configure for periodic execution
- You configure the root-level Inport block with a discrete sample time

To configure a function-call subsystem for periodic execution:

- 1** In the function-call subsystem, right-click the Trigger block and choose **Block Parameters** from the context menu.
- 2** Set parameter **Sample time type** to **periodic**.
- 3** Set **Sample time** to the same granularity specified (directly or by inheritance) in the function-call initiator.

#### 4 Click **OK** or **Apply**.

For more information, see “Absolute and Elapsed Time Computation”.

## Limitations for Export-Function Subsystems

- Subsystem block parameters do not control the names of the files containing the generated code. The file names begin with the name of the exported subsystem.
- Subsystem block parameters do not control the names of top-level functions in the generated code. Each function name reflects the name of the signal that triggers the function or (for an unnamed signal) reflects the block from which the signal originates.
- You can export function-call systems for the C++ class code interface packaging only when its function specification is set to **Default step method**. See “Interactively Configure C++ Interface” on page 41-2. The exported function is compatible with single-threaded execution. To avoid potential data race conditions for shared signals, invoke all members for the class from the same execution thread.
- The code generator supports a SIL or PIL block in accelerator mode only if its function-call initiator is noninlined in accelerator mode. Examples of noninlined initiators include Stateflow charts.
- A Level-2 S-function initiator block, such as a Stateflow chart or the built-in Function-Call Generator block, must drive a SIL block.
- You can export an asynchronous (sample-time) function-call system, but the software does not support the SIL or PIL block for an asynchronous system.
- The use of the TLC function `LibIsFirstInit` has been removed for export-function subsystems.

## Workflow

To generate code for an exported function, iterate through the tasks listed in this table.

Task	Action	More Information
1	Review your assessment of external code characteristics and integration requirements.	“Choose an External Code Integration Workflow” on page 55-2
2	Verify that the model or subsystem that you are exporting satisfies function exporting requirements.	“Requirements” on page 55-40
3	Address data interface requirements by modifying the model or subsystem.	“Exchange Data Between External C/C++ Code and Simulink Model or Generated Code” on page 55-61
4	If necessary, configure function prototype.	“Configure Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-2 and, for fixed-step rate-based models, “Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113 or “Interactively Configure C++ Interface” on page 41-2

Task	Action	More Information
5	If necessary , update the model to place external application-specific code in generated system functions.	“Place External C/C++ Code in Generated Code” on page 55-23
6	Verify that the functions behave and perform as expected during simulation by creating and using a test harness model. The test harness model schedules execution of the functions during simulation.	“Configure Model, Generate Code, and Simulate” on page 49-2 and, if you have Simulink Test software, “Test Authoring” (Simulink Test)
7	Configure the model or subsystem for code generation.	“Model Configuration Set Customization”
8	Generate code and a code generation report.	“Code Generation”
9	Review the generated code interface and static code metrics.	“Analyze the Generated Code Interface” on page 51-13 and “Static Code Metrics” on page 51-23
10	Build an executable program that includes the exported function code.	“Build Integrated Code Outside the Simulink Environment” on page 50-52
11	Verify that executable program behaves and performs as expected.	“Verification, Testing, and Certification”

## Choose an Integration Approach

Multiple approaches are available for generating function code for export to an external development environment. The following table compares approaches. Choose the approach that aligns best with your integration requirements. For more information on how to create export-function models, see “Export-Function Models Overview”. For more information on generating code for function call subsystems, see “Generate Component Source Code for Export to External Code Base” on page 55-40.

## Generate C Function Code for Export-Function Model

This example shows how to generate function code for individual Simulink function blocks and function-call subsystems in a model without generating scheduling code.

To generate function code for export:

- 1 Create a model that contains the functions for export.
- 2 Create a test harness model that schedules execution of the functions during simulation.
- 3 Simulate the model that contains the functions by using the test harness model.

- 4 Generate code for the model that contains the functions.

### Create Model That Contains Functions for Export

The model with functions for export must satisfy architectural constraints at the model root level. At the root level, valid blocks are:

- Inport
- Outport
- Function-Call Subsystem
- Simulink Function
- Goto
- From
- Merge

The code generator produces function code for Function-Call Subsystem, Simulink Function, Initialize Function, and Reset Function blocks. For a Function-call Subsystem block, you connect the block input ports to root Inport blocks that assert function-call signals. The subsystem is executed based on the function-call signal that it receives. A Simulink Function block is executed in response to the execution of a corresponding Function Caller block or Stateflow chart. An Initialize Function block is executed on a model initialize event and a Reset Function block is executed on a user-defined reset event.

For exporting functions, model `rtwdemo_functions` contains two function-call subsystems (`f1_alg` and `f2_alg`) and a Simulink Function block (`f3`) for exporting functions. The model also contains an Initialize Function block (`Initialize Function`) and a Reset Function block (`Reset Function`). To calculate initial conditions for blocks with state in other parts of the model, State Writer blocks are used inside the Initialize Function and Reset Function blocks.

```
open_system('rtwdemo_functions')
```

### Create Model That Contains Function Caller Block

Use a Function Caller block to invoke a Simulink Function block. The Function Caller block can be in the same model or in a different model as the Simulink Function block.

Multiple Function Caller blocks can invoke a Simulink Function block. You can place the Function Caller block inside a function-call subsystem. During code generation, the code generator exports a function from the function-call subsystem.

The model `rtwdemo_caller` exports a function-call subsystem that contains a Function Caller block.

```
open_system('rtwdemo_caller')
```

### Create Test Harness Model for Simulation

When you export functions, the generated code does not include a scheduler. Create a test harness model to handle scheduling during simulation. Do not use the test harness model to generate code that you deploy.

Model `rtwdemo_export_functions` is a test harness. The model:

- Schedules the Simulink Function block with the Function Caller block in `rtwdemo_caller`.

- Provides function-call signals to other models in this example to schedule the model contents, including the model initialize and reset events.

```
open_system('rtwdemo_export_functions')
```

### Simulate the Test Harness Model

Verify that the model containing the functions that you want to export is executed as you expect by simulating the test harness model. For example, simulate `rtwdemo_export_functions`.

```
sim('rtwdemo_export_functions')
```

### Generate Function Code

Open the **Embedded Coder** app. Then, generate code for the functions that you want to export. For example, generate code for `rtwdemo_functions`.

```
slbuild('rtwdemo_functions')
```

```
Starting build procedure for: rtwdemo_functions
Successful completion of code generation for: rtwdemo_functions
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_functions	Code generated	Code generation information file does not exist.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 36.842s
```

### Review Generated Code

Review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize and execute the generated code.
- `rtwdemo_functions.c` calls the initialization function, including `Initialize Function`, and exported functions for model components `f1_alg`, `f2_alg`, and `f3`.
- `rtwdemo_functions.h` declares model data structures and a public interface to the exported entry-point functions and data structures.
- `f3.h` is a shared file that declares the call interface for the Simulink function `f3`.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

### Write Interface Code

Open and review the Code Interface Report. To write the interface code for your execution framework, use the information in that report.

- 1 Include the generated header files by adding directives `#include rtwdemo_functions.h`, `#include f3.h`, and `#include rtwtypes.h`.
- 2 Write input data to the generated code for model Inport blocks.

- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Output blocks.

Input ports:

- rtU.U1 of type `real_T` with dimension 1
- rtU.U2 of type `real_T` with dimension 1

Entry-point functions:

- Initialize entry-point function, `void rtwdemo_functions_initialize(void)`. At startup, call this function once.
- Reset entry-point function, `void rtwdemo_functions_reset(void)`. Call this function as needed.
- Exported function, `void f1(void)`. Call this function as needed.
- Exported function, `void f2(void)`. Call this function as needed.
- Simulink function, `void f3(real_T rtu_u, real_T *rtty_y)`. Call this function as needed.

Output ports:

- rtY.Accumulator1 of type `int8_T` with dimension [2]
- rtY.Accumulator2 of type `int8_T` with dimension [2]
- rtY.TicToc10 of type `int8_T` with dimension 1

### Close Example Models

```
bdclose('rtwdemo_export_functions')
bdclose('rtwdemo_functions')
bdclose('rtwdemo_caller')
```

## Generate C++ Function and Class Code for Export-Function Model

This example shows how to generate function code for an export-function model that includes a function-call subsystem. The code generator produces function and class code that does not include scheduling code.

To generate function code for export:

- 1 Create a model that contains the functions for export.
- 2 Create a test harness model that schedules execution of the functions during simulation.
- 3 Simulate the model that contains the functions by using the test harness model.

- 4 Generate code for the model that contains the functions.

### Create Model That Contains Functions and C++ Class Interface for Export

The model with functions for export with a C++ model class interface must satisfy architectural constraints at the model root level. For C++ class generation, blocks that are valid at the root level are:

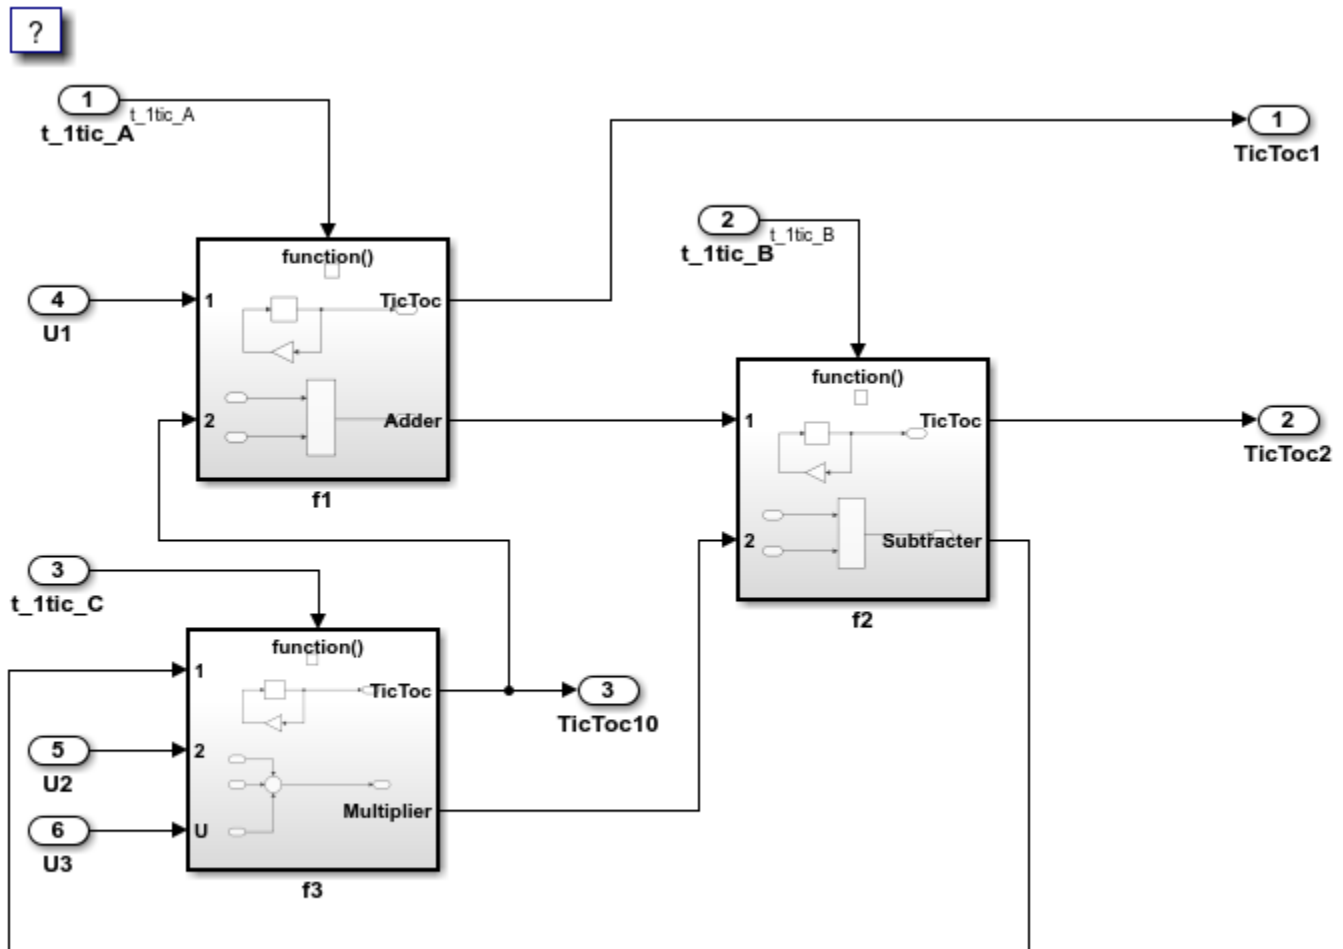

- Inport
- Outport
- Function-Call Subsystem
- Goto
- From
- Merge

**Note:** Export Function-Call Subsystem with C++ class interface does not support Simulink Function blocks.

The code generator produces function code for the Function-Call Subsystem block. For a Function-call Subsystem block, you connect the block input ports to root Inport blocks that assert function-call signals. The subsystem is executed based on the function-call signal that it receives.

Model `rtwdemo_cppclass_functions` contains function-call subsystems `f1`, `f2`, and `f3` for exporting functions.

```
open_system('rtwdemo_cppclass_functions')
```

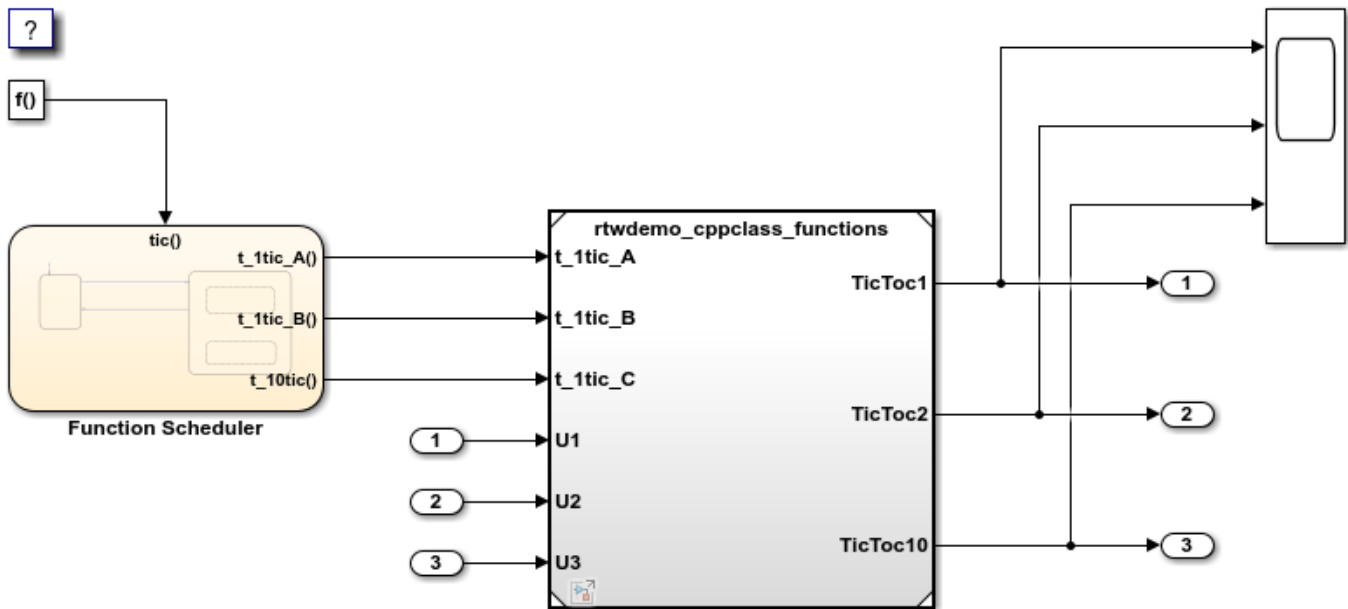

Copyright 2016-2020 The MathWorks, Inc.

### Create Test Harness Model for Simulation

When you export functions, the generated code does not include a scheduler. Create a test harness model to handle scheduling during simulation. Do not use the test harness model to generate code that you deploy.

Model `rtwdemo_cppclass_export_functions` is a test harness. The model provides function-call signals to other models in this example to schedule the model contents.

```
open_system('rtwdemo_cppclass_export_functions')
```

Copyright 2014-2020 The MathWorks, Inc.

### Simulate the Test Harness Model

Verify that the model containing the functions that you want to export is executed as you expect by simulating the test harness model. For example, simulate `rtwdemo_cppclass_export_functions`.

```
sim('rtwdemo_cppclass_export_functions')
```

### Generate Function Code and Report

Generate code and a code generation report for the functions that you want to export. For example, generate code for `rtwdemo_cppclass_functions`.

```
slbuild('rtwdemo_cppclass_functions')
```

```
Starting build procedure for: rtwdemo_cppclass_functions
Successful completion of build procedure for: rtwdemo_cppclass_functions
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_cppclass_functions	Code generated and compiled	Code generation information file does not exist

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 17.123s
```

### Review Generated Code

From the code generation report, review the generated code.

- `ert_main.cpp` is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize and execute the generated code.
- `rtwdemo_cppclass_functions.cpp` calls the initialization function, including `InitializeFunction`, and exported functions for model subsystem components `f1`, `f2`, and `f3`.
- `rtwdemo_cppclass_functions.h` declares model data structures and a public interface to the exported entry-point functions and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

### Write Interface Code

Open and review the Code Interface Report. To write the interface code for your execution framework, use the information in that report.

- 1 Include the generated header files by adding directives `#include rtwdemo_cppclass_functions.h` and `#include rtwtypes.h`.
- 2 Write input data to the generated code for model Inport blocks.
- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.U1` of type `real_T` with dimension 1
- `rtU.U2` of type `real_T` with dimension 1
- `rtU.U3` of type `real_T` with dimension 1

Entry-point functions:

- Initialize entry-point function, `void initialize(void)`. At startup, call this function once.
- Exported function, `void t_1tic_A(void)`. Call this function as needed.
- Exported function, `void t_1tic_B(void)`. Call this function as needed.
- Exported function, `void t_1tic_C(void)`. Call this function as needed.

Output ports:

- `rtY.TicToc1` of type `int8_T` with dimension [2]
- `rtY.TicToc2` of type `int8_T` with dimension [2]
- `rtY.TicToc10` of type `int8_T` with dimension 1

### More About

```

## Generate Code for Export-Function Subsystems

- “Specify a Custom Initialize Function Name” on page 55-52
- “Specify a Custom Description” on page 55-53
- “Optimize Code Generated for Export-Function Subsystems” on page 55-53

To generate code for an export-function subsystem:

- 1 Verify that the subsystem for which you are generating code satisfies exporting requirements on page 55-40.
- 2 In the Configuration Parameters dialog box:
  - a Set the parameter **System target file** to an ERT-based system target file, such as `ert.tlc`.
  - b If you want a SIL block with the generated code, for verification purposes, set model configuration parameter **Create block** to SIL.
  - c Click **OK** or **Apply**.
- 3 Right-click the subsystem block and select **C/C++ Code > Export Functions** from the context menu.

The operation creates and builds a new model, `subsystem.slx`, that contains the content of the original subsystem and creates a `ScratchModel` that contains a `Model` block. This block references the newly created `subsystem.slx` model.

The code generator produces code and places it in the working folder.

If you set **Create block** to SIL in step 2b, Simulink opens a new window that contains an S-function block that represents the generated code. This block has the same size, shape, and connectors as the original subsystem.

Code generation and optional block creation are now complete. You can test and use the code and optional block as you do for generated ERT code and S-function block. For optional workflow tasks, see “Specify a Custom Initialize Function Name” on page 55-52 and “Specify a Custom Description” on page 55-53.

### Specify a Custom Initialize Function Name

You can specify a custom name for the initialize function of your exported function as an argument to the `slbuild` command. The command takes the following form:

```
blockHandle = slbuild('subsystem', 'Mode', 'ExportFunctionCalls',...
 'ExportFunctionInitializeFunctionName', 'fcnname')
```

`fcnname` specifies the function name. For example, if you specify the name `'myinitfcn'`, the build process emits code similar to:

```
/* Model initialize function */
void myinitfcn(void){
...
}
```

## Specify a Custom Description

You can enter a custom description for an exported function by using the Block Properties dialog box of an Inport block.

- 1 Right-click the Inport block that drives the control port of the subsystem for which you are exporting code.
- 2 Select **Properties**.
- 3 In the **General** tab, in the **Description** field, enter your descriptive text.

During function export, the text you enter is emitted to the generated code in the header for the Inport block. For example, if you open the example program `rtwdemo_exporting_functions` and enter a description in the Block Properties dialog box for port `t_ltic_A`, the code generator produces code that is similar to:

```
/*
 * Output and update for exported function: t_ltic_A
 *
 * My custom description of the exported function
 */
void t_ltic_A(void)
{
 ...
}
```

## Optimize Code Generated for Export-Function Subsystems

To optimize the code generated for an export-function subsystem, specify a separate storage class for each input signal and output signal that crosses the boundary of the subsystem.

For each function-call subsystem that you are exporting:

- 1 Right-click the subsystem.
- 2 From the context menu, choose **Block Parameters (Subsystem)**.
- 3 Select the **Code Generation** tab.
- 4 Set **Function packaging** to Auto.
- 5 Click **OK** or **Apply**.

## Generate Shared Library for Export to External Code Base

### In this section...

“About Generated Shared Libraries” on page 55-54

“Workflow” on page 55-54

“Generate Shared Libraries” on page 55-55

“Create Application Code That Uses Generated Shared Libraries” on page 55-55

“Limitations” on page 55-58

### About Generated Shared Libraries

If you have Embedded Coder software, you can generate a shared library—Windows dynamic link library (.dll), UNIX shared object (.so), or Macintosh OS X dynamic library (.dylib)— from a model component. You or others can integrate the shared library into an application that runs on a Windows, UNIX, or Macintosh OS X development computer. Uses of shared libraries include:

- Adding a software component to an application for system simulation
- Reusing software modules among applications on a development computer
- Hiding intellectual property associated with software that you share with vendors

When producing a shared library, the code generator exports:

- Variables and signals of type `ExportedGlobal` as data
- Real-time model structure (`model_M`) as data
- Functions essential to executing the model code

### Workflow

To generate a shared library from a model component and use the library, complete the tasks listed in this table.

Task	Action	More Information
1	Review your assessment of external code characteristics and integration requirements.	<ul style="list-style-type: none"> <li>• “Choose an External Code Integration Workflow” on page 55-2</li> <li>• “Shared Library Limitations” on page 66-6</li> </ul>
2	Configure the model for code generation.	“Model Configuration Set Customization”
3	Configure the model for the code generator to produce a shared library and initiate code generation.	“Generate Shared Libraries” on page 55-55

Task	Action	More Information
4	<p>Verify that the generated shared library meets requirements. For example, review the code generation report and view the list of symbols in the library.</p> <ul style="list-style-type: none"> <li>• On Windows, use the Dependency Walker utility, downloadable from <a href="http://www.dependencywalker.com">www.dependencywalker.com</a></li> <li>• On UNIX, use <code>nm -D model.so</code></li> <li>• On Macintosh OS X, use <code>nm -g model.dylib</code></li> </ul>	
5	Use the shared library in application code.	“Create Application Code That Uses Generated Shared Libraries” on page 55-55
6	Compile and link application code that loads and uses the generated shared library.	“Build Integrated Code Within the Simulink Environment” on page 55-33
7	Verify that executable program behaves and performs as expected.	“Verification, Testing, and Certification”

## Generate Shared Libraries

- 1 When configuring the model for code generation, select the system target file `ert_shrlib.tlc`.
- 2 Build the model. The code generator produces source code for the model and a shared library version of the code. The code generator places the source code in the code generation folder and the shared library (`.dll`, `.so`, or `.dylib` file) in your current working folder. The code generator also produces and retains a `.lib` file to support implicit linking.

## Create Application Code That Uses Generated Shared Libraries

This example application code is generated for the example “Interface to a Development Computer Simulator By Using a Shared Library” on page 55-59.

- 1 Create an application header file that contains type declarations for model external input and output. For example:

```
#ifndef _APP_MAIN_HEADER_
#define _APP_MAIN_HEADER_

typedef struct {
 int32_T Input;
} ExternalInputs_rtwdemo_shrlib;

typedef struct {
 int32_T Output;
} ExternalOutputs_rtwdemo_shrlib;

#endif /* _APP_MAIN_HEADER_ */
```

- 2 In the application C source code, dynamically load the shared library. Use preprocessing conditional statements to invoke platform-specific commands. For example:

```

#if defined(_WIN32)||defined(_WIN64) /* WINDOWS */
#include <windows.h>
#define GETSYMBOLADDR GetProcAddress
#define LOADLIB LoadLibrary
#define CLOSELIB FreeLibrary

#else /* UNIX */
#include <dlfcn.h>
#define GETSYMBOLADDR dlsym
#define LOADLIB dlopen
#define CLOSELIB dlclose

#endif

int main()
{
 void* handleLib;
 ...
#if defined(_WIN64)
 handleLib = LOADLIB("./rtwdemo_shrlib_win64.dll");
#else #if defined(_WIN32)
 handleLib = LOADLIB("./rtwdemo_shrlib_win32.dll");
#else /* UNIX */
 handleLib = LOADLIB("./rtwdemo_shrlib.so", RTLD_LAZY);
#endif
#endif
 ...
 return(CLOSELIB(handleLib));
}

```

- 3 From the application C source code, access exported data and functions generated from the model. The code uses hooks to add user-defined initialization, step, and termination code.

```

int32_T i;
...
void (*mdl_initialize)(boolean_T);
void (*mdl_step)(void);
void (*mdl_terminate)(void);

ExternalInputs_rtwdemo_shrlib (*mdl_Uptr);
ExternalOutputs_rtwdemo_shrlib (*mdl_Yptr);

uint8_T (*sum_outptr);
...
#if defined(LCCDLL)||defined(BORLANDCDLL)
/* Exported symbols contain leading underscores
when DLL is linked with LCC or BORLANDC */
mdl_initialize =
 (void (*)(boolean_T))GETSYMBOLADDR(handleLib ,
 "_rtwdemo_shrlib_initialize");
mdl_step =
 (void (*)(void))GETSYMBOLADDR(handleLib ,
 "_rtwdemo_shrlib_step");
mdl_terminate =
 (void (*)(void))GETSYMBOLADDR(handleLib ,
 "_rtwdemo_shrlib_terminate");
mdl_Uptr =
 (ExternalInputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,

```

```

 "_rtwdemo_shrplib_U");
mdl_Yptr =
 (ExternalOutputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
 "_rtwdemo_shrplib_Y");
sum_outptr =
 (uint8_T*)GETSYMBOLADDR(handleLib , "_sum_out");
#else
mdl_initialize =
 (void*)(boolean_T)GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_initialize");
mdl_step =
 (void*)(void)GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_step");
mdl_terminate =
 (void*)(void)GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_terminate");
mdl_Uptr =
 (ExternalInputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_U");
mdl_Yptr =
 (ExternalOutputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_Y");
sum_outptr =
 (uint8_T*)GETSYMBOLADDR(handleLib , "sum_out");
#endif

if ((mdl_initialize &&
 mdl_step &&
 mdl_terminate &&
 mdl_Uptr &&
 mdl_Yptr &&
 sum_outptr)) {
 /* user application
 initialization function */
 mdl_initialize(1);
 /* insert other user defined
 application initialization code here */

 /* user application
 step function */
 for(i=0;i<=12;i++){
 mdl_Uptr->Input = i;
 mdl_step();
 printf("Counter out(sum_out):
 %d\tAmplifier in(Input):
 %d\tout(Output):
 %d\n", *sum_outptr, i,
 mdl_Yptr->Output);
 /* insert other user defined
 application step function
 code here */
 }

 /* user application
 terminate function */
 mdl_terminate();
 /* insert other user defined
 application termination

```

```
 code here */
 }
 else {
 printf("Cannot locate the specified
 reference(s) in the shared library.\n");
 return(-1);
 }
}
```

## Limitations

- Code generation for the `ert_shrlib.tlc` system target file exports the following as data:
  - Variables and signals of type `ExportedGlobal`
  - Real-time model structure (`model_M`)
- Code generation for the `ert_shrlib.tlc` system target file supports the C language only (not C++). When you select `ert_shrlib.tlc`, language selection is unavailable on the **Code Generation** pane in the Configuration Parameters dialog box.
- To reconstruct a model simulation by using a generated shared library, the application author must maintain the timing between system and shared library function calls in the original application. The timing must be consistent so that you can compare the simulation and integration results. Additional simulation considerations apply if generating a shared library from a model that enables model configuration parameters **Support: continuous time** and **Single output/update function**. For more information, see [Single output/update function \(Simulink Coder\) dependencies](#).

## Interface to a Development Computer Simulator By Using a Shared Library

This example generates a shared library for interfacing to a simulator that runs on your development computer. Generate the shared library by using the system target file `ert_shrplib.tlc`.

To build a shared library from the model and use the library in an application:

1. Develop your model. For this example, open the model `rtwdemo_shrplib`. Save a copy of the model to a writable location.

```
open_system('rtwdemo_shrplib');
```

Copyright 2006-2020 The MathWorks, Inc.

The model is a single-rate, discrete-time model. An 8-bit counter feeds the triggered subsystem named `Amplifier`. Parameters `INC`, `LIMIT`, and `RESET` are set to constant values 1, 4, and 0, respectively. When signal `equal_to_count` is true, the subsystem amplifies its input signal by a gain factor  $K=3$  and the output signal is updated.

2. Open the **Embedded Coder** app.
3. Set model configuration parameter **System target file** to `ert_shrplib.tlc`.

4. Build the shared library file. The file that the code generator produces depends on your development platform. For example, on a Windows system, the code generator produces the library file `rtwdemo_shrlib_win64.dll`.

5. Create application code that uses the shared library. This example uses application code that is available in these files:

```
matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\rtwdemo_shrlib_app.h matlabroot
\toolbox\rtw\rtwdemos\shrlib_demo\rtwdemo_shrlib_app.c
```

To view the source code in these files, in the model, click the white buttons for the `.h` and `.c` files.

6. Compile and link the file application and shared library files to produce an executable program. The following script compiles, builds, and runs the program.

```
matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\run_rtwdemo_shrlib_app.m
```

To view the script code, in the model, click the white button for the `.m` file.

To build the model and run the application that uses the generated shared library, in the model, double-click the blue button.

For more information about using a shared library, see “Package Generated Code as Shared Libraries” on page 66-2.

### More About

- “Generate Shared Library for Export to External Code Base” on page 55-54

## Exchange Data Between External C/C++ Code and Simulink Model or Generated Code

Whether you import your external code into a Simulink model (for example, by using the Legacy Code Tool) or export the generated code to an external environment, the model or the generated code typically exchange data (signals, states, and parameters) with your code.

Functions in C or C++ code, including your external functions, can exchange data with a caller or a called function through:

- Arguments (formal parameters) of functions. When a function exchanges data through arguments, an application can call the function multiple times. Each instance of the called function can manipulate its own independent set of data so that the instances do not interfere with each other.
- Direct access to global variables. Global variables can:
  - Enable different algorithms (functions) and instances of the same algorithm to share data such as calibration parameters and error status.
  - Enable the different rates (functions) of a multitasking system to exchange data.
  - Enable different algorithms to exchange data asynchronously.

In Simulink, you can organize and configure data so that a model uses these exchange mechanisms to provide, extract, and share data with your code.

Before you attempt to match data interfaces, to choose an overall integration approach, see “Choose an External Code Integration Workflow” on page 55-2.

### Import External Code into Model

To exchange data between your model and your external function, choose an exchange mechanism based on the technique that you chose to integrate the function.

- To exchange data through the arguments of your external function, construct and configure your model to create and package the data according to the data types of the arguments. Then, you connect and configure the block that calls or represents your function to accept, produce, or refer to the data from the model.

For example, if you use the Legacy Code Tool to generate an S-Function block that calls your function, the ports and parameters of the block correspond to the arguments of the function. You connect the output signals of upstream blocks to the input ports and set parameter values in the block mask. Then, you can create signal lines from the output ports of the block and connect those signals to downstream blocks.

- To exchange data through global variables that your external code already defines, a best practice is to use a Stateflow chart to call your function and to access the variables. You write algorithmic C code in the chart so that during simulation or execution of the generated code, the model reads and writes to the variables.

To use such a global variable as an item of parameter data (not signal or state data) elsewhere in a model, you can create a numeric MATLAB variable or `Simulink.Parameter` object that represents the variable. If you change the value of the C-code variable in between simulation runs, you must manually synchronize the value of the Simulink variable or object. If your algorithmic

code (function) changes the value of the C-code variable during simulation, the corresponding Simulink variable or object does not change.

If you choose to create a Simulink representation of the C-code variable, you can configure the Simulink representation so that the generated code reads and writes to the variable but does not duplicate the variable definition. Apply a storage class to the Simulink representation.

Technique for Integrating External Function	Mechanism to Exchange Data with Model	Examples and More Information
S-Function block	Function arguments	To call your function through an S-function that you create by using the Legacy Code Tool, see “Integrate C Functions into Simulink Models with Legacy Code Tool”.
Stateflow chart	Function arguments and direct access to global variables	To call your function and access global variables in a Stateflow chart, see “Access Custom Code Variables and Functions in Stateflow Charts” (Stateflow). For information about creating data items in a chart (which you can pass to your function as arguments), see “Add Stateflow Data” (Stateflow).
coder.ceval in MATLAB Function block	Function arguments	To call your function in a MATLAB Function block by using <code>coder.ceval</code> , see “Integrate C Code by Using the MATLAB Function Block”. For information about creating data items in a MATLAB Function block (which you can pass to your function as arguments), see “Create and Define MATLAB Function Block Variables”.

## Export Generated Code to External Environment

To export the generated code into your external code, see “Exchange Data Between External Calling Code and Generated Code”.

## Simulink Representations of C Data Types and Constructs

To model and reuse your custom C data such as structures, enumerations, and typedef aliases, use the information in these tables.

**Modeling Patterns for Matching Data in External C Code**

<b>C Data Type or Construct</b>	<b>Example C Code</b>	<b>Simulink Equivalent</b>	<b>More Information</b>
Primitive type alias (typedef)	typedef float mySinglePrec_T;	<p>Create a <code>Simulink.AliasType</code> object. Use the object to:</p> <ul style="list-style-type: none"> <li>• Set the data types of signals and block parameters in a model.</li> <li>• Configure data type replacements for code generation.</li> </ul> <p>Generating code that uses an alias data type requires Embedded Coder.</p>	<p>For information about defining custom data types for your model, see <code>Simulink.AliasType</code> and “Control Data Type Names in Generated Code” on page 35-2.</p> <p>For an example that shows how to export the generated code into your external code, see “Replace and Rename Data Types to Conform to Coding Standards” on page 35-22.</p>
Array	int myArray[6];	<p>Specify signal and parameter dimensions as described in “Determine Signal Dimensions”.</p> <p>The generated code defines and accesses multidimensional data, including matrices, as column-major serialized vectors. If your external code uses a different format, consider using alternative techniques to integrate the generated code. See “Code Generation of Matrices and Arrays” on page 49-60.</p>	<p>For information about how the generated code stores nonscalar data (including limitations), see “Code Generation of Matrices and Arrays”.</p> <p>For an example that shows how to export the generated code into your external code, see “Reuse Parameter Data from External Code in the Generated Code” on page 37-2.</p> <p>To model lookup tables, see <code>Simulink.LookupTable</code>.</p>

C Data Type or Construct	Example C Code	Simulink Equivalent	More Information
Enumeration	<pre>typedef enum myColorsType {     Red = 0,     Yellow,     Blue } myColorsType;</pre>	Define a Simulink enumeration that corresponds to your enumeration definition. Use the Simulink enumeration to set data types in a model.	<p>To use enumerated data in a Simulink model, see “Use Enumerated Data in Simulink Models”.</p> <p>For an example that shows how to generate enumerated parameter data, see “Enumeration” on page 25-20.</p> <p>For an example that shows how to export the generated code into your external code by exchanging enumerated data, see “Exchange Structured and Enumerated Data Between Generated and External Code” on page 35-27.</p>

C Data Type or Construct	Example C Code	Simulink Equivalent	More Information
Structure	<pre>typedef struct myStructType {     int count;     double coeff; } myStructType;</pre>	<p>Create a <code>Simulink.Bus</code> object that corresponds to your structure type.</p> <p>To create structured signal or state data, package multiple signal lines in a model into a single nonvirtual bus signal.</p> <p>To create structured parameter data, create a parameter object (such as <code>Simulink.Parameter</code>) that stores a MATLAB structure. Use the bus object as the data type of the parameter object.</p> <p>To package lookup table data into a structure, use <code>Simulink.LookupTable</code> and, optionally, <code>Simulink.Breakpoint</code> objects.</p>	<p>For information about bus signals, see “Group Signal Lines into Virtual Buses”. For information about structures of parameters, see “Organize Related Block Parameter Definitions in Structures”.</p> <p>For an example that shows how to import your external code into a model by using the Legacy Code Tool, see “Integrate C Function Whose Arguments Are Pointers to Structures”.</p> <p>For examples that show how to export the generated code into your external code, see “Exchange Structured and Enumerated Data Between Generated and External Code” on page 35-27 and “Access Structured Data Through a Pointer That External Code Defines” on page 37-10.</p> <p>To package lookup table data into a structure, <code>Simulink.LookupTable</code>.</p> <p>For general information about creating structures in the generated code, see “Organize Data into Structures in Generated Code”.</p>

## Additional Modeling Patterns for Code Generation (Embedded Coder)

C Data Type or Construct	Example C Code	Simulink Equivalent	More Information
Macro	<pre>#define myParam 9.8</pre>	<p>Apply the storage classes <code>Define</code> and <code>ImportedDefine</code> to parameters. With macros, you can reuse a parameter value in multiple locations in an algorithm and change the parameter value between code compilations without consuming memory to store the value. Typically, macros represent engineering constants that you do not expect to change during code execution.</p> <p>This technique requires Embedded Coder.</p>	“Macro Definitions ( <code>#define</code> )” on page 25-54
Storage type qualifiers such as <code>const</code> and <code>volatile</code>	<pre>const myParam = 9.8;</pre>	Apply the storage classes <code>Const</code> , <code>Volatile</code> , and <code>ConstVolatile</code> to data items.	“Protect Global Data with Keywords <code>const</code> and <code>volatile</code> ”
Bit field	<pre>typedef struct myBitField {     unsigned short int MODE : 1;     unsigned short int FAIL : 1;     unsigned short int OK : 1; } myBitField</pre>	<ul style="list-style-type: none"> <li>Apply the storage class <code>BitField</code> to signals, states, and parameters whose data type is <code>boolean</code>.</li> <li>Use a model configuration parameter to aggregate <code>Boolean</code> data into bit fields.</li> </ul> <p>These techniques require Embedded Coder.</p>	<p>“Bitfields” on page 25-69</p> <p>“Optimize Generated Code by Packing Boolean Data into Bitfields” on page 75-11</p>

C Data Type or Construct	Example C Code	Simulink Equivalent	More Information
Call to custom external function that reads or writes to data	External code: <pre> /* Call this function to acquire the value of the signal. */ double get_inSig(void) {     return myBigGlobalStruct.inSig; } </pre> Generated algorithmic code: <pre> algorithmInput = get_inSig(); </pre>	Apply the storage class <code>GetSet</code> to signals, states, and parameters. Each data item appears in the generated code as a call to your custom functions that read and write to the target data.  This technique requires Embedded Coder.	“Access Data Through Functions with Storage Class <code>GetSet</code> ” on page 37-25

## Considerations for Other Modeling Goals

Goal	Considerations and More Information
Use Simulink to run and interact with the generated code	<p>You can use SIL, PIL, and external mode simulations to connect your model to the corresponding generated application for simulation. When you import parameter data from your external code:</p> <ul style="list-style-type: none"> <li>At the time that you begin an external mode simulation, the external executable uses the value that your code uses to initialize the parameter data. However, when you change the corresponding value in Simulink during the simulation (for example by modifying the <code>Value</code> property of the corresponding parameter object), Simulink downloads the new value to the executable.</li> <li>SIL and PIL simulations do not import the parameter value from your code. Instead, the simulations use the parameter value from Simulink. If you include your external code in the Simulink Coder build process, duplicate data definitions can prevent the generated code from compiling.</li> </ul> <p>For information about SIL and PIL, see “Choose a SIL or PIL Approach” on page 82-11. For information about external mode simulation, see “External Mode Simulations for Parameter Tuning and Signal Monitoring”.</p>
Generate code comments that describe attributes of exported data including physical units, real-world initial value, and data type	<p>Generating these comments can help you match data interfaces while handwriting integration code. See “Add Custom Comments for Variables in the Generated Code” on page 52-3.</p>

## Exchange Data Between External Calling Code and Generated Code

To export the generated code into your external code, you configure the generated code to match the data interface of your external code. For example, if your external code defines a global variable for storing output data and you need the generated code to read that data as input, you can configure a corresponding Inport block so that the generated code interacts with the existing variable.

- You can generate reentrant code from a model. The generated entry-point functions typically accept data through arguments. Your calling code passes data through these arguments. You can call the functions multiple times in a single application—the application can maintain multiple instances of the model. See “Data Exchange for Reentrant Generated Code”.
- When you generate nonreentrant code, by default, the entry-point functions exchange data between the generated code and your code through global variables. You can generate variable definitions for your code to use or you can share and reuse existing variables that your code already defines. See “Data Exchange for Nonreentrant Generated Code”.

Alternatively, you can configure the entry-point functions to exchange system inputs and outputs (root-level Inport and Outport blocks) through arguments instead of global variables. Apply function prototype control to the model, which requires Embedded Coder. For more information about function prototype control, see “Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113.

For general information about exchanging data between generated and external code, including how to match specific C code patterns, see “Exchange Data Between External C/C++ Code and Simulink Model or Generated Code”.

### Data Exchange for Reentrant Generated Code

When you generate reentrant code, the model entry-point functions exchange data through arguments. You can control some of the characteristics of the arguments. For more information, see “Control Data and Function Interface in Generated Code”.

For information about creating a separate set of data for each call site in your external code, see “Modify Static Main to Allocate and Access Model Instance Data” on page 68-10.

### Data Exchange for Nonreentrant Generated Code

To make the generated code read or write to an item of signal, state, or parameter data as a global variable, apply a storage class to the data in the model. The storage class also determines whether the generated code exports the variable definition to your external code or imports the definition from your code. For general information about controlling the data interface of a model that you configure to generate nonreentrant code, see “Control Data Interface for Nonreentrant Code”. For examples, see “Design Data Interface by Configuring Inport and Outport Blocks” and “Integrate External Application Code with Code Generated from PID Controller” on page 37-45.

When you generate code that defines (allocates memory for) global data, the generated code exports that data. When your external code defines data, the generated code imports that data. Typically, storage classes that import data have the word `Import` in the storage class name, for example, `ImportedExternPointer`.

### Control File Placement of Exported Global Data (Embedded Coder)

When you export data from the generated code by using storage classes, the code generator creates an `extern` declaration. By default, this declaration typically appears in the generated header file `model.h`. You can include (`#include`) this header file in your external code.

By default, the definition (memory allocation) of exported data typically appears in `model.c`.

You can control the file placement of the declarations and definitions to:

- Create separate object files that store only global parameter data.
- Modularize the generated code by organizing declarations into separate files.

For more information about controlling file placement of declarations and definitions, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2. For an example, see “Definition, Initialization, and Declaration of Parameter Data” on page 25-5.

### Prevent Duplicate Initialization Code for Global Variables

When your external code defines global variables, you can generate code that interacts with those variables. For example, use the storage class `ImportFromFile` (see “Choose Storage Class for Controlling Data Representation in Generated Code”).

For imported variables that represent signal or state data, the code generator can produce initialization code as described in “Initialization of Signal, State, and Parameter Data in the Generated Code”. If your code already initializes a variable, consider preventing the generation of duplicate initialization code. Create your own storage class and, for that storage class, set **Data initialization** to `None`. For information about creating and applying your own storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 31-2.

### Protect Global Data with Keywords `const` and `volatile`

When your external code and the generated code exchange data through global variables, you can generate code that uses C type qualifiers `const` and `volatile` to protect data integrity and improve the safety of your application. For example:

- Apply `const` to a calibration parameter.
- Apply `volatile` to a global variable that stores the output of a hardware device operating asynchronously.
- Apply `const` and `volatile` to signals, states, and parameters that represent data defined by your external code. Then, the generated code declares and interacts with the external data by using the corresponding storage type qualifiers.

You must have Embedded Coder. For more information, see “Protect Global Data with `const` and `volatile` Type Qualifiers” on page 42-13.

## Generate Code That Matches Appearance of External Code

A key aspect of code integration, especially for larger projects, is adherence to guidelines and standards for code appearance. If code appearance requirements apply to your project, review the requirements in this table. To learn more, see the relevant information.

Requirement	More Information
Thoroughly document code or document code in a specific way.	<ul style="list-style-type: none"> <li>• “Configure Code Comments” on page 45-22</li> <li>• “Annotate Code for Justifying Polyspace Checks” on page 52-85</li> <li>• “Add Custom Comments for Variables in the Generated Code” on page 52-3</li> <li>• “Add Global Comments in the Generated Code” on page 52-5</li> </ul>
Control the length and naming of code identifiers (symbols), including the use of reserved names.	<ul style="list-style-type: none"> <li>• “Identifier Format Control” on page 52-17</li> <li>• “Specify Identifier Length to Avoid Naming Collisions” on page 45-29</li> <li>• “Specify Reserved Names for Generated Identifiers” on page 45-30</li> <li>• “Customize Generated Identifier Naming Rules” on page 52-10</li> <li>• “Avoid Identifier Name Collisions with Referenced Models” on page 52-25</li> <li>• “Control Name Mangling in Generated Identifiers” on page 52-24</li> <li>• “Specify Boolean and Data Type Limit Identifiers” on page 35-34</li> </ul>

Requirement	More Information
Control style aspects of code: <ul style="list-style-type: none"> <li>• Level of parenthesization</li> <li>• Order of operations in expressions</li> <li>• Empty primary condition expressions in <code>if</code> statements</li> <li>• <code>if-elseif-else</code> or <code>switch-case</code> statements for decision logic</li> <li>• Use of <code>extern</code> keyword in function declarations</li> <li>• Use of <code>static</code> keyword in function declarations</li> <li>• Use of <code>default</code> cases for <code>switch-case</code> statements</li> <li>• Use multiplications by powers of two or signed bitwise shifts</li> <li>• Cast expressions</li> <li>• Indent style (Kernighan and Ritchie or Allman) and size</li> <li>• Newline style</li> </ul>	“Model Configuration Parameters: Code Style”
Placement of data definitions and declarations, including location of global identifiers and global data declarations ( <code>extern</code> )	“Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2
Appearance of code for flow charts	“Enhance Readability of Code for Flow Charts” on page 52-94
Apply code templates to control organization of code and use of banners	<ul style="list-style-type: none"> <li>• “Customize Code Organization and Format” on page 52-45</li> <li>• “Template Symbols and Rules” on page 52-80</li> <li>• “Specify Templates For Code Generation” on page 52-47</li> <li>• “Generate Custom File and Function Banners” on page 52-73</li> <li>• “Change the Organization of a Generated File” on page 52-57</li> <li>• “Generate Source and Header Files with a Custom File Processing (CFP) Template” on page 52-61</li> <li>• “Customize Generated File Names” on page 52-59</li> </ul>

## Select C or C++ Programming Language

The default programming language selection for code generation is C language. In the code generation workflow, after the steps in “Select a Solver That Supports Code Generation” and “Select a System Target File from STF Browser”, an optional step is to change the programming language selection for code generation.

To change the programming language setting:

- 1 In the Configuration Parameters dialog box, from the **Language** list, select C or C++. Alternatively, set the `TargetLang` parameter at the command line.

The code generator produces `.c` or `.cpp` files, depending on your selection, and places the generated files in your build folder.

For more information, see “Language”.

- 2 Check whether you must choose and configure a compiler. If you select C++, you must choose and configure a compiler. For details, see “Select and Configure C or C++ Compiler”.
- 3 Check whether the language standard is configured for your compiler. By default, the code generator uses the ISO/IEC 9899:1999 C (C99 (ISO)) library for the C language and the ISO/IEC 14882:2003 C++ (C++03 (ISO)) library for the C++ language.

For more information, see “Language standard”.

#### More About

- “Select and Configure C or C++ Compiler”
- “Troubleshoot Compiler Issues”

## Select and Configure C or C++ Compiler

The build process requires a supported compiler. *Compiler*, in this context, refers to a development environment containing a linker and make utility, and a high-level language compiler. For details on supported compiler versions, see:

[https://www.mathworks.com/support/compilers/current\\_release](https://www.mathworks.com/support/compilers/current_release)

When creating an executable program, the build process must be able to access a supported compiler. The build process can find a compiler to use based on your default MEX compiler.

The build process also requires the selection of a toolchain or template makefile. The toolchain or template makefile determines which compiler runs, during the make phase of the build. For more information, see “Configure Toolchain or Template Makefile Build Process” on page 56-12.

To determine which templates makefiles are available for your compiler and system target file, see “Compare System Target File Support Across Products”.

For both generated files and user-supplied files, the file extension, `.c` or `.cpp`, determines whether the build process uses a C or a C++ compiler. If the file extension is `.c`, the build process uses C compiler to compile the file, and the symbols use the C linkage convention. If the file extension is `.cpp`, the build process uses a C++ compiler to compile the file, and the symbols use the C++ linkage specification.

### Language Standards Compliance

The code generator produces code that is compliant with the following standards:

Language	Supported Standard	Other Names
C	ISO/IEC 9899:1990	C89/C90
	ISO/IEC 9899:1999	C99
C++	ISO/IEC 14882:2003	C++03
	ISO/IEC 14882:2011	C++11

Code that the code generator produces from these sources is ANSI C/C++ compliant:

- Simulink built-in block algorithmic code
- Generated system-level code (task ID [TID] checks, management, functions, and so on)
- Code from other blocksets, including the Fixed-Point Designer product and the Communications Toolbox product
- Code from other code generators, such as MATLAB functions

Also, the code generator can incorporate code from:

- Embedded system target files (for example, startup code, device driver blocks)
- Custom S-functions or TLC files

---

**Note** Coding standards for these two sources are beyond the control of the code generator. These standards can be a source for compliance problems, such as code that uses C99 features not supported in the ANSI C, C89/C90 subset.

---

## Programming Language Considerations

The code generator produces C and C++ code. Consider the following as you choose a programming language:

- Does your project require you to configure the code generator to use a specific compiler? C/C++ code generation on Windows requires this selection.
- Does your project require you to change the default language configuration setting for the model? See “Select C or C++ Programming Language” on page 56-2.
- Does your project require you to integrate legacy or custom code with generated code? For a summary of integration options, see “Choose an External Code Integration Workflow” on page 55-2.
- Does your project require you to integrate C and C++ code? If so, see “Choose an External Code Integration Workflow” on page 55-2.

---

**Note** You can mix C and C++ code when integrating generated code with custom code. However, you must be aware of the differences between C and default C++ linkage conventions, and add the `extern "C"` linkage specifier where required. For the details of the differing linkage conventions and how to apply `extern "C"`, refer to a C++ programming language reference book.

---

- Does your project require code generation support from other products? See “C++ Language Support Limitations” on page 56-4.

For C++ code generation examples with Stateflow, see the `sfcn_demo_cppcount` model or `sf_cpp` model.

## C++ Language Support Limitations

To use C++ language support, you could need to configure the code generator to use a specific compiler. For example, if a supported compiler is not installed on your Microsoft Windows computer, the default compiler is the `gcc` C compiler shipped with the MATLAB product. This compiler does not support C++. If you do not configure the code generator to use a C++ compiler before you specify C++ for code generation, the software produces an error message.

Code generator limitations on C++ support include:

- The code generator does not support C++ code generation for the following:
  - Simscape Driveline
  - Simscape Multibody First Generation (Simscape Multibody Second Generation is supported)
  - Simscape Electrical Power Systems
  - Simulink Real-Time
- For ERT and ERT-based system target files with **Code interface packaging** set to **Nonreusable function**, the following fields currently do not support the `.cpp` extension.
  - **Data definition filename**
  - **Definition file** for a data object, which is an object of the `Simulink.Signal` or `Simulink.Parameter` classes or their subclasses.

If you specify a file name with a `.c` extension or with no extension and specify C++ for the code generation language, the code generator produces a `.cpp` file.

## Code Generator Assumes Wrap on Signed Integer Overflows

The code generator reduces memory usage and enhances generated code execution by assuming signed integer C operations wrap on overflow. A signed integer overflow occurs when the result of an arithmetic operation is outside the range of values that the output data type can represent. The C programming language does not define the results of such operations. Some C compilers aggressively optimize signed operations for in-range values at the expense of overflow conditions. Other compilers preserve the full wrap-on-overflow behavior. For example, the gcc and MinGW compilers provide an option to wrap on overflow reliably for signed integer overflows. The generated program image for a model can produce results that differ from model simulation results because the handling of overflows varies, depending on your compiler.

When you generate code, if you use a supported compiler with the default options configured by the code generator, the compiler preserves the full wrap-on-overflow behavior. If you change the compiler options or compile the code in another development environment, it is possible that the compiler does not preserve the full wrap-on-overflow behavior. In this case, the executable program can produce unpredictable results.

If this issue is a concern for your application, consider one or more of the following actions:

- Verify that the compiled code produces expected results.
- If your compiler can force wrapping behavior, turn it on. For example, for the gcc compiler or a compiler based on gcc, such as MinGW, configure the build process to use the compiler option `-fwrapv`.
- Choose a compiler that wraps on integer overflow.
- If you have Embedded Coder installed, develop and apply a custom code replacement library to replace code generated for signed integers. For more information, see “Code Replacement Customization”.

## Choose and Configure Compiler

To view the installed compilers and select the default compiler, in the Command Window, type:

```
mex -setup
```

On a Windows computer, you can install supported compilers and select a default compiler.

On a UNIX platform, the default compiler is GNU gcc/g++ for GNU or Xcode for Mac.

Unless the build approach configuration selects a specific compiler, the code generator uses the default compiler for the build process.

Primarily, the specified system target file determines the compiler that the code generator requires:

- If you select a toolchain-based system target file such as `grt.tlc` (Generic Real-Time Target), `ert.tlc` (Embedded Coder), or `autosar.tlc` (Embedded Coder for AUTOSAR), the **Build process** subpane displays configuration parameters for the build process. Use the **Toolchain** configuration parameter to select a compiler and associated tools for your model build. To validate the selected toolchain, click the **Validate Toolchain**.
- If you select a template makefile (TMF) based system target file, such as `rsim.tlc`, the **Build process** subpane displays template makefile parameters for configuring the build process. The **Template makefile** parameter displays the default TMF file for the selected system target file. If

the system target file supports compiler-specific template makefiles (for example, Rapid Simulation or S-Function system target files), you can set **Template makefile** to a compiler-specific TMF, such as `rsim_lcc.tmf` or `rsim_unix.tmf`. (See “Compare System Target File Support Across Products” for valid TMF names.)

If the generated code exceeds the 2 Gb static memory limit, a compiler error occurs. To resolve this issue:

- For GRT-based system target files, set model configuration parameter **Code interface packaging** to `Reusable function`.
- For ERT-based system target files, set model configuration parameter **Code interface packaging** to `Reusable function` and select parameter **Use dynamic memory allocation for model initialization**.

## Include S-Function Source Code

When the code generator builds models with S-functions, source code for the S-functions can be either in the current folder or in the same folder as their MEX-file. The code generator adds an include path to the generated makefiles whenever it finds a file named `sfncname.h` in the same folder as the S-function MEX-file. This folder must be on the MATLAB path.

Similarly, the code generator adds a rule for the folder when it finds a file `sfncname.c` (or `.cpp`) in the same folder as the S-function MEX-file is in.

## Compiler Version Mismatch Errors

### Description

The build process produces a compiler version mismatch error.

### Action

- 1 Check the list of supported and compatible compilers available at [www.mathworks.com/support/compilers/current\\_release/](http://www.mathworks.com/support/compilers/current_release/).
- 2 Upgrade or change your compiler. For more information, see “Choose and Configure Compiler” on page 56-5.
- 3 Rebuild the model.

## Results for Model Simulation and Program Execution Differ

### Description

The program generated for the model produces different results from model simulation results. The generated source code includes an arithmetic operation that produces a signed integer overflow. It is possible that your compiler does not implement wrapping behavior for signed integer overflow conditions. Or, if you are using a compiler that supports wrapping, it is possible that you did not configure it to use the `-fwrapv` option.

For more information, see “Code Generator Relies on Undefined Behavior of C Language for Integer Overflows.”

### Action

- If your compiler can force wrapping behavior, turn it on. For example, for the gcc compiler or a compiler based on gcc, such as MinGW, specify the compiler option `-fwrapv`.
- Choose a compiler that checks for integer overflows.
- If you have Embedded Coder, develop and apply a code replacement library to replace code generated for signed integers.

## Generates Expected Code and Produces Unexpected Results

### Description

The build process generates expected source code, but the executable program produces unexpected results. The generated source code appears as expected. However, the executable program produces unexpected results.

### Action

Do one of the following:

- Lower the compiler optimization level.
  - 1 Set the **Compiler optimization level** configuration parameter to **Custom**.
  - 2 In the **Custom compiler optimization flags** field, specify a lower optimization level.
  - 3 Rebuild the model.
- Disable compiler optimizations.
  - 1 Set **Compiler optimization level** to **Optimizations off (faster builds)**.
  - 2 Rebuild the model.

For more information, see “Control Compiler Optimizations” and your compiler documentation.

## Compile-Time Issues

Issue	Action
Error is present in the compiler configuration.	Make sure that MATLAB supports the compiler and version that you want to use. For a list of currently supported and compatible compilers, see <a href="http://www.mathworks.com/support/compilers/current_release/">www.mathworks.com/support/compilers/current_release/</a> . If necessary, upgrade or change your compiler (see “Choose and Configure Compiler” on page 56-5 or “Choose and Configure Compiler” on page 56-5).
Environment variables are incorrectly set up for your make utility, compiler, or linker. For example, installation of Cygwin tools on a Windows platform affects environment variables used by other compilers.	Review the environment variable settings for your system by using the <code>set</code> command on a Windows platform or <code>setenv</code> on a Linux platform. Make sure that the settings match what is required for the tools you are using.
Error is present in custom code specified as an S-Function block or in <b>Custom Code</b> . For example, the code refers to a header file that the compiler cannot find.	To isolate the source of the problem, remove the custom code from the model, debug, and rebuild the model.
The model includes a block, such as a device driver block, which is not intended for use with the currently selected system target file.	Remove the system target file-specific block or configure the model for use with another system target file.

Issue	Action
<p>A linker error about an undefined reference to the data appears when the model build generates an executable program from the model reference hierarchy and these conditions are true:</p> <ul style="list-style-type: none"> <li>You represent signal, state, or parameter data by creating a data object such as <code>Simulink.Signal</code>. You use the object in a model reference hierarchy.</li> <li>You use a custom storage class with the data object. Custom storage classes require Embedded Coder.</li> <li>You set the owner of the object to a model that does not directly access the data.</li> <li>You use the toolchain <code>lcc-win64</code>.</li> </ul>	<p>To resolve the issue, choose one of these methods:</p> <ul style="list-style-type: none"> <li>In the data object, clear the <code>Owner</code> property. Alternatively, set the owner to a model that directly accesses the data.</li> <li>Use a different toolchain, such as <code>gcc</code>, instead of <code>lcc</code>.</li> </ul>

## LCC Compiler Does Not Support Ampersands in Source Folder Paths

### Description

If you use the LCC compiler and your model folder path contains an ampersand (&), the build process produces an error.

### Action

Remove the ampersand from the model folder path. Then, rebuild the model.

## LCC Compiler Might Not Support Line Lengths of Rapid Accelerator Code

### Description

If you are compiling Rapid Accelerator code, the LCC compiler might produce an error related to line limits. Rapid Accelerator code can have longer line lengths due to obfuscation.

### Action

Compile your Rapid Accelerator code using a compiler that supports longer code lines.

## Approaches for Building Code Generated from Simulink Models

You can use a CMake, toolchain, or template makefile approach for building (compiling and linking) code that you generate from Simulink models:

- **CMake**—A third-party, open-source tool for build process management, which uses configuration (CMakeLists.txt) files to generate standard build files for native build environments, for example, makefiles, Ninja files, or Microsoft Visual Studio projects. MATLAB ships the CMake executable file. Simulink Coder and Embedded Coder support CMake versions from 3.12.0 onwards.
- **Toolchain**—The build process generates makefiles and supports custom toolchains. You can control the build process with toolchain information objects that you define by using MATLAB scripts.
- **Template makefile**—The build process uses a template makefile with a toolchain that you specify. Optionally, you can control the build process through a toolchain information object.

This table provides a support summary for each approach.

Feature	CMake	Toolchain	Template Makefile
codebuild function	Yes	Yes	Yes
Simulink model configuration parameters	No	Yes	Yes
SIL or PIL simulations with Embedded Coder	No	Yes	Yes

For information about:

- Using the codebuild function in each approach, see “Compile Code in Another Development Environment” on page 49-96.
- Configuring the toolchain or template makefile build process by using model configuration parameters, see “Configure Toolchain or Template Makefile Build Process” on page 56-12.

## Configure Toolchain or Template Makefile Build Process

This topic shows how to specify the toolchain or template makefile approach for building code generated from a model.

If you set the “System target file” configuration parameter to:

- `ert.tlc`, `ert_shrlib.tlc`, `grt.tlc`, or any toolchain-compliant system target file, the build process uses the toolchain approach on page 56-12.
- Any non-toolchain-compliant system target file, the build process uses the template makefile approach on page 56-16.

You can switch from the toolchain approach to the template makefile approach by using this command:

```
set_param(model, 'MakeCommand', 'make_rtw TMF=1')
```

### Toolchain Approach

**Toolchain settings** appear under **Build process** when you set **System target file** to:

- `grt.tlc` – Generic Real-Time Target
- `ert.tlc` – Embedded Coder (requires the Embedded Coder product)
- `ert_shrlib.tlc` – Embedded Coder (host-based shared library target) (requires Embedded Coder)
- Any toolchain-compliant system target file (If ERT-based, requires Embedded Coder)

For more information about toolchain-compliant system target files, see “Support Toolchain Approach with Custom Target”.

The **Toolchain settings** include these configuration parameters:

- “Toolchain” -- Specifies the collection of third-party software tools that builds the generated code. A toolchain can include a compiler, linker, and archiver, and other prebuild or postbuild tools.

The default value of **Toolchain** is **Automatically locate an installed toolchain**. The **Toolchain** parameter displays name of the located toolchain just below **Automatically locate an installed toolchain**.

To check that the toolchain is present and validate that the code generator has the information required to use the toolchain, in the **Advanced Parameters** section, click **Validate Toolchain**. The resulting Validation Report gives a pass/fail value for the selected toolchain, and shows issues that require resolution.

- “Build configuration” -- Specifies the optimization settings. By default, **Build Configuration** is set to **Faster Builds**. You can also select **Faster Runs**, **Debug**, and **Specify**. If you select **Specify**, you can customize the options for the toolchain. When you click **Apply**, the custom toolchain settings apply to the current model.

**Note** The following system target files, which use the template makefile approach, have the same names but different descriptions from system target files that use the toolchain approach:

- `ert.tlc` – Create Visual C/C++ Solution File for Embedded Coder
- `grt.tlc` – Create Visual C/C++ Solution File for Simulink Coder

To avoid confusion, click **Browse** to select the system target file and look at the description of each file.

---

## Upgrade Model to Use Toolchain Approach

When you open a model created before R2013b that uses the following system target files, the software tries to upgrade the model. The upgrade changes the configuration from using template makefile settings to using the toolchain settings:

- `ert.tlc` – Embedded Coder
- `ert_shrlib.tlc` – Embedded Coder (host-based shared library target)
- `grt.tlc` – Generic Real-Time Target

---

**Note** To upgrade models using a custom system target file to use the toolchain approach, see “Support Toolchain Approach with Custom Target” on page 88-58.

---

Some model configuration parameter values prevent the software from upgrading a model to use toolchain settings. The following instructions show you ways to complete the upgrade process.

Consider upgrading your models and use the toolchain build approach. Doing so is not required. You can continue generating code from a model that has not been upgraded.

---

**Note** The software does not upgrade models that use the following system target files:

- `ert.tlc` – Create Visual C/C++ Solution File for Embedded Coder
  - `grt.tlc` – Create Visual C/C++ Solution File for Simulink Coder
- 

To see if a model has been upgraded:

- 1 If the **Toolchain** and **Build configuration** configuration parameters are specified, the model has been upgraded.

If makefile configuration parameters such as **Generate makefile**, **Make command**, and **Template makefile** are specified, the model has not been upgraded.

Start by creating a working copy of the model using **File > Save As**. This action preserves the original model and configuration parameters for reference.

Try to upgrade the model using Upgrade Advisor:

- 1 On the **Modeling** tab, in the **Evaluate & Manage** section, select **Upgrade Advisor**.
- 2 In Upgrade Advisor, select **Check and update model to use toolchain approach to build generated code** and click **Run This Check**.
- 3 Perform the suggested actions and/or click **Update Model**.

When you cannot upgrade the model using Upgrade Advisor, one or more of the following parameters is not set to its default value, shown here:

- **Compiler optimization level** — Optimizations off (faster builds)
- **Generate makefile** — Enabled
- **Template makefile** — System target file-specific template makefile

- **Make command** — `make_rtw` without arguments

Sometimes, a model cannot be upgraded. Try the following procedure:

- If **Generate makefile** is disabled, this case cannot be upgradable. However, you can try enabling it and try upgrading the model using Upgrade Advisor.
- If **Compiler optimization level** is set to `Optimizations on (faster runs)`:
  - 1 Set **Compiler optimization level** is to `Optimizations off (faster builds)`.
  - 2 Upgrade the model using Upgrade Advisor.
  - 3 Set **Build configuration** to `Faster Runs`.
- If **Compiler optimization level** is set to `Custom`:
  - 1 Copy the **Custom compiler optimization flags** to a text file.
  - 2 Set **Compiler optimization level** to `Optimizations off (faster builds)`.
  - 3 Upgrade the model using Upgrade Advisor.
  - 4 Set **Build configuration** to `Specify`.
  - 5 To perform the same optimizations, edit the compiler options.
- If **Template makefile** uses a customized template makefile, this case cannot be upgradable. However, you can try the following:
  - 1 Update **Template makefile** to use the default makefile for the system target file.

---

**Note** To get the default makefile name, change the **System target file**, click **Apply**, change it back, and click **Apply** again.

---

- 2 Upgrade the model using Upgrade Advisor.
- 3 If the template makefile contains build tool options, such as compiler optimization flags, set **Build configuration** to `Specify` and update the options.
- 4 If the template makefile uses custom build tools, create and register a custom toolchain, as described in “Custom Toolchain Registration” . Then, set the **Toolchain** parameter to use the custom toolchain.

---

**Note** After registering the custom toolchain, update **Toolchain** to use the custom toolchain.

---

- 5 If the template makefile contains custom rules and logic, these customizations cannot be applied to the upgraded model.

## Template Makefile Approach

When the **System target file** is set to a `tlc` file that uses the template makefile approach, the software displays **Compiler optimization level**, **Generate makefile**, **Make command**, and **Template makefile** parameters.

### Specify Whether to Generate a Makefile

The **Generate makefile** option specifies whether the build process is to generate a makefile for a model. By default, the build process generates a makefile. Suppress generation of a makefile, for example in support of custom build processing that is not based on makefiles, by clearing **Generate makefile**. When you clear this parameter:

- The **Make command** and **Template makefile** options are unavailable.
- Set up post code generation build processing using a user-defined command, as explained in “Customize Post-Code-Generation Build Processing”.

### Specify a Make Command

Each template makefile-based system target file has an associated **make** command. The code generator uses this internal MATLAB command to control the build process. The command appears in the **Make command** field and runs when you start a build.

Most system target files use the default command, `make_rtw`. Third-party system target files could supply another make command. See the documentation from the vendor.

In addition to the name of the **make** command, you can supply makefile options in the **Make command** field. These options could include compiler-specific options, include paths, and other

parameters. When the build process invokes the `make` utility, these options are passed on the `make` command line, which adds them to the overall flags passed to the compiler.

“Template Makefiles and Make Options” on page 56-22 lists the **Make command** options you can use with each supported compiler.

### Specify the Template Makefile

The **Template makefile** field has these functions:

- If you selected a system target file with the System Target File Browser, this field displays the name of a MATLAB language file that selects a template makefile for your development environment. For example, in “Model Configuration Parameters: Code Generation”, the **Template makefile** field displays `grt_default_tmf`, indicating that the build process invokes `grt_default_tmf.m`.

“Template Makefiles and Make Options” on page 56-22 gives a detailed description of the logic by which the build process selects a template makefile.

- Alternatively, you can explicitly enter the name of a specific template makefile (including the extension) or a MATLAB language file that returns a template makefile in this field. Use this approach if you are using a system target file that does not appear in the System Target File Browser. For example, use this approach if you have written your own template makefile for a custom system target file.

If you specify your own template makefile, be sure to include the file name extension. If you omit the extension, the build process attempts to find and execute a file with the extension `.m` (that is, a MATLAB language file). The template make file (or a MATLAB language file that returns a template make file) must be on the MATLAB path. To determine whether the file is on the MATLAB path, enter the following command in the MATLAB Command Window:

```
which tmf_filename
```

### Associate the Template Makefile with a Toolchain

Specify a toolchain for the template makefile build process. This example provides a definition for a minimal toolchain and shows how you can associate the toolchain with a template makefile that is a copy of `ert_unix.tmf` or `ert_vcx64.tmf`.

- 1 Use a copy of `ert_unix.tmf` or `ert_vcx64.tmf` as the template makefile.

```
copyfile(fullfile(matlabroot, 'toolbox', 'coder', ...
 'compile', 'tmf', 'ert_vcx64.tmf'), ...
 'ert_copy.tmf')
```

- 2 In the template makefile, i.e. `ert_copy.tmf`, edit the `TOOLCHAIN_NAME` macro.

```
TOOLCHAIN_NAME = "Minimal Toolchain for TMF Build"
```

---

**Note** The `ert_unix.tmf` and `ert_vcx64.tmf` files from the current release are simplified compared to the corresponding files from releases before R2018a. The software determines whether your template makefile uses the simplified approach by checking for the presence of the variable `TOOLCHAIN_NAME`. A template makefile that is based on `ert_unix.tmf` and `ert_vcx64.tmf` files from releases before R2018a does not specify the `TOOLCHAIN_NAME` variable.

Through the `|>MODEL_MODULES<|` token, the simplified approach specifies the `main`, `model`, and other source files that require compiling. The template makefile that is based on

ert\_unix.tmf and ert\_vcx64.tmf files from releases before R2018a explicitly adds the main and *model* source files to the list of source files that require compiling.

To update a template makefile that originates from a release before R2018a:

- a Remove references to ert\_main.c, classic\_main.c or rt\_main.c. For example, literal references like ert\_main.c or tokenized references like ert\_main.\$(TARGET\_LANG\_EXT).
- b Remove references to \$(MODEL).c or \$(MODEL).\$(TARGET\_LANG\_EXT).

### 3 Associate the toolchain with the template make file.

- a Create a toolchain definition file. For this example, use this code:

#### Toolchain Definition File

```
function tc = minimalToolchainForTMF
% Create a toolchain object
tc = coder.make.ToolchainInfo('Name', 'Minimal Toolchain for TMF Build');

% Specify that the linker requires a response file instead of
% including all object file modules on the linker command line
tc.addAttribute('RequiresCommandFile', true);

if ispc
 objExt = '.obj';
else
 objExt = '.o';
end

% Specify source file and object file extension used by the C compiler
tool = tc.getBuildTool('C Compiler');
tool.setFileExtension('Source', '.c');
tool.setFileExtension('Header', '.h');
tool.setFileExtension('Object', objExt);

% Specify source file and object file extension used by the C++ compiler
tool = tc.getBuildTool('C++ Compiler');
tool.setFileExtension('Source', '.cpp');
tool.setFileExtension('Header', '.hpp');
tool.setFileExtension('Object', objExt);
```

- b Run the toolchain definition file, which generates a ToolchainInfo object, tc.

```
tc = minimalToolchainForTMF;
```

- c Save the ToolchainInfo object to a MAT file.

```
save('tcMinimal', 'tc')
```

- d Register the toolchain in RTW.TargetRegistry.

- i Place this code in an rtwTargetInfo.m file.

```
function rtwTargetInfo(tr)
tr.registerTargetInfo(@loc_createToolchain);
end

function config = loc_createToolchain
config(1) = coder.make.ToolchainInfoRegistry;
config(1).Name = 'Minimal Toolchain for TMF Build';
config(1).FileName = fullfile(fileparts(mfilename('fullpath')), ...
 'tcMinimal.mat');
config(1).TargetHWDeviceType = {'*'};
```

```
config(1).Platform = {computer('arch')};
end
```

- ii Save the file in the current working folder or in a folder that is on the MATLAB search path.
- iii Reset the TargetRegistry.

```
RTW.TargetRegistry.getInstance('reset');
```

- 4 Associate the template makefile with your model and build the model.

```
set_param(model, 'TemplateMakefile', 'ert_copy.tmf');
slbuild(model);
```

## Specify TLC for Code Generation

Target Language Compiler (TLC) is an integral part of the code generator. It enables you to customize generated code. Through customization, you can produce platform-specific code, or you can incorporate your own algorithmic changes for execution speed, code size, or compatibility with existing methods that you prefer to maintain. For additional information, see “Target Language Compiler Overview”.

TLC options that you specify for code generation appear in the summary section of the generated HTML code generation report.

---

**Note** Specifying TLC command-line options does not add flags to the make command line.

---

You can specify Target Language Compiler (TLC) command-line options and arguments for code generation using the model parameter `TLCOptions` in a `set_param` function call. For example,

```
>> set_param(gcs, 'TLCOptions', '-p0 -aWarnNonSaturatedBlocks=0')
```

Some common uses of TLC options include the following:

- `-aVarName=1` to declare a TLC variable and/or assign a value to it
- `-IC:\Work` to specify an include path
- `-v` to obtain verbose output from TLC processing (for example, when debugging)

## Use of Checksums in Recompilation of Generated Code

When you build a model with `GenerateMakefile` set to 'on' and `GenCodeOnly` set to 'off', the software generates a makefile and runs the makefile to compile the generated code. When the compilation is complete, the software creates and saves checksums for source files and configuration data.

If checksums from a previous build are available when you build the model:

- 1 The software uses the checksums to determine whether the source files and configuration data are different from the previous build.
- 2 If the software detects a difference, the software:
  - Regenerates the makefile.

- Recompiles the generated code.

If the build process uses a template makefile, you can disable the use of checksums by adding this text to the template makefile:

```
DO_NOT_USE_CHECKSUMS=1
```

In this case, the software uses file timestamps to determine whether it should recompile the generated code.

- “Custom Toolchain Registration”
- “Register Custom Toolchain and Build Executable”
- “Template Makefiles and Make Options” on page 56-22
- “Target Language Compiler Overview”
- “Executable Program Generation” on page 56-48

## Template Makefiles and Make Options

The code generator includes a set of built-in template makefiles that build programs for specific system target files.

### Types of Template Makefiles

There are two types of template makefiles:

- *Compiler-specific* template makefiles are for a particular compiler or development system.

By convention, compiler-specific template makefiles names correspond to the system target file and compiler (or development system). For example, `grt_vcx64.tmf` is the template makefile for building a generic real-time program under the Visual C++ compiler; `ert_lcc64.tmf` is the template makefile for building an Embedded Coder program under the `lcc` compiler.

- *Default* template makefiles make your model designs more portable, by choosing the compiler-specific makefile and compiler for your installation. “Select and Configure C or C++ Compiler” on page 56-3 describes the operation of default template makefiles in detail.

Default template makefiles have names that follow the pattern `target_default_tmf`. They are MATLAB language files that, when run, select the TMF for the specified system target file configuration. For example, `grt_default_tmf` is the default template makefile for building a generic real-time program; `ert_default_tmf` is the default template makefile for building an Embedded Coder program.

For details on the structure of template makefiles, see “Customize Template Makefiles” on page 88-43. This section describes compiler-specific template makefiles and common options you can use with each.

### Specify Template Makefile Options

You can specify template makefile options through the **Make command** configuration parameter. Append the options after `make_rtw` (or other make command), as in the following example:

```
make_rtw OPTS="-DMYDEFINE=1"
```

The syntax for make command options differs slightly for different compilers.

---

**Note** To control compiler optimizations for a makefile build, use the **Compiler optimization level** configuration parameter, which provides:

- System target file-independent values `Optimizations on (faster runs)` and `Optimizations off (faster builds)`, which easily allow you to toggle compiler optimizations on and off during code development
- The value `Custom` for entering custom compiler optimization flags at Simulink GUI level (rather than at other levels of the build process)

If you specify compiler options for your makefile build using `OPT_OPTS`, `MEX_OPTS` (except `MEX_OPTS="-v"`), or `MEX_OPT_FILE`, the value of **Compiler optimization level** is ignored and a warning is issued about the ignored parameter.

---

## Template Makefiles for UNIX Platforms

The template makefiles for UNIX platforms are for the Free Software Foundation's GNU Make. These makefiles conform to the guidelines specified in the IEEE<sup>6</sup> Std 1003.2-1992 (POSIX) standard:

- `ert_unix.tmf`
- `grt_unix.tmf`

You can supply options to makefiles through the **Make command** configuration parameter. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPTS` — User-specific options, for example,
 

```
OPTS="-DMYDEFINE=1"
```
- `OPT_OPTS`— Optimization options. Default is `-O`. To enable debugging, specify the option as `OPT_OPTS=-g`. Because of optimization problems in `IBM_RS`, the default is to not optimize.
- `CPP_OPTS` — C++ compiler options.
- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths, for example,
 

```
USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"
```
- `DEBUG_BUILD` — Add debug information to generated code, for example,
 

```
DEBUG_BUILD=1
```

These options are also documented in the comments at the head of the respective template makefiles.

## Template Makefiles for the Microsoft Visual C++ Compiler

- “Visual C++ Executable Build” on page 56-23
- “Visual C++ Code Generation Only” on page 56-24

### Visual C++ Executable Build

To build an executable using the Visual C++ compiler within the build process, use one of the `target_vcx64.tmf` template makefiles:

- `ert_vcx64.tmf`
- `grt_vcx64.tmf`

You can supply options to makefiles through the **Make command** configuration parameter. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPT_OPTS` — Optimization option. Default is `-O2`. To enable debugging, specify the option as `OPT_OPTS=-Zi`.

6 IEEE is a registered trademark of The Institute of Electrical and Electronics Engineers, Inc.

- `OPTS` — User-specific options.
- `CPP_OPTS` — C++ compiler options.
- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths, for example,  
`USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"`
- `DEBUG_BUILD` — Add debug information to generated code, for example,  
`DEBUG_BUILD=1`

These options are also documented in the comments at the head of the respective template makefiles.

### Visual C++ Code Generation Only

To create a Visual C++ project makefile (*model.mak*) without building an executable, use one of the *target\_msvc.tmf* template makefiles:

- `ert_msvc.tmf`
- `grt_msvc.tmf`

These template makefiles are for `nmake`, which is bundled with the Visual C++ compiler.

You can supply options to makefiles through the **Make command** configuration parameter. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPTS` — User-specific options, for example,  
`OPTS="/D MYDEFINE=1"`
- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths, for example,  
`USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"`
- `DEBUG_BUILD` — Add debug information to generated code, for example,  
`DEBUG_BUILD=1`

These options are also documented in the comments at the head of the respective template makefiles.

### Template Makefiles for the LCC Compiler

The code generator provides template makefiles to create an executable for the Windows platform using Lcc compiler Version 2.4 and GNU Make (`gmake`).

- `ert_lcc64.tmf`
- `grt_lcc64.tmf`

You can supply options to makefiles by using the **Make command** configuration parameter. Options specified in the **Make command** field are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPTS` — User-specific options, for example,  
`OPTS="-DMYDEFINE=1"`
- `OPT_OPTS` — Optimization options. Default is to not use options. To enable debugging, specify `-g4`:  
`OPT_OPTS="-g4"`
- `CPP_OPTS` — C++ compiler options.
- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths. For example:  
`USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"`  
  
For `lcc`, use `/` as file separator before the file name instead of `\`, for example, `d:\work\proj1/myfile.c`.
- `DEBUG_BUILD` — Add debug information to generated code, for example,  
`DEBUG_BUILD=1`

These options are also documented in the comments at the head of the respective template makefiles.

## Build Process Workflow for Real-Time Systems

The building process includes generating code in C or C++ from a model and building an executable program from the generated code. This example can use a generic real-time (GRT) or an embedded real-time (ERT) system target file (STF) for code generation. The resulting standalone program runs on your development computer, independent of external timing and events.

### Working Folder

This example uses a local copy of the `slexAircraftExample` model, stored in its own folder, `aircraftexample`. Set up your *working folder* as follows:

- 1 In the MATLAB Current Folder browser, navigate to a folder to which you have write access.
- 2 To create the working folder, enter the following MATLAB command:

```
mkdir aircraftexample
```

- 3 Make `aircraftexample` your working folder:

```
cd aircraftexample
```

- 4 Open the `slexAircraftExample` model:

```
openExample('slexAircraftExample')
```

The model appears in the Simulink Editor model window.

- 5 In the model window, choose **File > Save As**. Navigate to your working folder, `aircraftexample`. Save a copy of the `slexAircraftExample` model as `myAircraftExample`.

### Build Folder and Code Generation Folders

While producing code, the code generator creates a *build folder* within your working folder. The build folder name is `model_target_rtw`, derived from the name of the source model and the chosen system target file. The build folder stores generated source code and other files created during the build process. Examine the build folder contents at the end of this example.

When a model contains Model blocks (references to other models), the model build creates special subfolders in your “Code generation folder” to organize code for the referenced models. These code generation folders exist alongside product build folders and are named `s_lprj`. For more information, see “Generate Code for Model Reference Hierarchy”.

Under the `s_lprj` folder, a subfolder named `_sharedutils` contains generated code that can be shared between models.

### Set Model Parameters for Code Generation

To generate code from your model, you must change some of the model configuration parameters. In particular, the generic real-time (GRT) system target file and most other system target files require that the model specifies a fixed-step solver.

---

**Note** For models that specify variable-step solvers, the code generator produces code only if the models also specify rapid simulation (`rsim`) or S-function system target files.

---

- 1 Open the `myAircraftExample` model if it is not already open.
- 2 In the Configuration Parameters dialog box, specify configuration parameter values for the solver:
  - **Start time:** `0.0`
  - **Stop time:** `60`
  - **Type:** `Fixed-step`
  - **Solver:** `ode5 (Dormand-Prince)`
  - **Fixed step size (fundamental sample time):** `0.1`
  - **Treat each discrete rate as a separate task:** `Off`
- 3 Click **Apply**.
- 4 Save the model.

## Configure Build Process

To configure the build process for your model, choose a system target file, a toolchain or template makefile, and a make command.

In these examples and in most applications, you do not need to specify these parameters individually. The examples use the ready-to-run generic real-time target (GRT) configuration. The GRT system target file builds a standalone executable program that runs on your desktop computer.

To select the GRT system target file:

- 1 Open the `myAircraftExample` model if it is not already open.
- 2 In the Configuration Parameters dialog box, in the **System target file** field, enter `grt.tlc`. Then click **Apply**.

You see selections for **Toolchain** (Automatically locate an installed toolchain), and **Build Configuration** (Faster Builds).

- 3 Save the model.

---

**Note** If you click **Browse**, a System Target File Browser opens and displays the system target files on the MATLAB path. Some system target files require additional products. For example, `ert.tlc` requires Embedded Coder.

---

## Set Code Generation Parameters

- 1 Open the `myAircraftExample` model if it is not already open.
- 2 In the Configuration Parameters dialog box, specify settings:
  - a Use the default settings for the **Code Generation** advanced parameters, which control build verbosity and debugging:
    - **Verbose build** (RTWVerbose)
    - **Retain .rtw file** (RetainRTWFile)
    - **Profile TLC** (ProfileTLC)
    - **Start TLC debugger when generating code** (TLCDebug)

- **Start TLC coverage when generating code** (TLCCoverage)
  - **Enable TLC assertion** (TLCAssert)
- b** Use the default **Code Generation > Comments** settings.
  - c** The **Code Generation > Identifiers** options control the look and feel of generated code. Use the default settings.
  - d** Select **Code Generation > Interface**.
    - i** From the **Shared code placement** list, select **Shared location**. The build process places generated code for utilities in a subfolder within your “Code generation folder”.
    - ii** Under the **Advanced parameters**, clear the **Classic call interface** check box.
    - iii** Under the **Advanced parameters**, select the **Single output/update function** check box.
  - e** In **Code Generation > Report**, select **Create code generation report** and **Open report automatically**. This action enables the software to create and display a code generation report for the `myAircraftExample` model.
- 3** Click **Apply** and save the model.

## Build and Run a Program

The build process generates C code from the model. It then compiles and links the generated program to create an executable image. To build and run the program:

- 1** With the `myAircraftExample` model open, perform one of these actions:
  - On the **Apps** tab, open the **Simulink Coder** app. In the **C Code** tab, click **Build**.
  - Press **Ctrl+B**.
  - Run the `slbuild` command from the MATLAB command line.

You see code generation and compilation messages in the Command Window. The initial message is:

```
Starting build procedure for model: myAircraftExample
```

The contents of many of the succeeding messages depends on your compiler and operating system. The final messages include:

```
Created executable myAircraftExample.exe
Successful completion of build procedure for model: myAircraftExample
Creating HTML report file index.html
```

The code generation folder now contains an executable, `myAircraftExample.exe` (Microsoft Windows platforms) or `myAircraftExample` (UNIX platforms). In addition, the build process has created an `slprj` folder and a `myAircraftExample_grt_rtw` folder in your “Code generation folder”.

---

**Note** After generating the code for the `myAircraftExample` model, the build process displays a code generation report. See “Report Generation” for more information about how to create and use a code generation report.

---

- 2** To see the contents of the working folder after the build, enter the `dir` or `ls` command:
 

```
>> dir
```

```

. myAircraftExample.slx slprj
.. myAircraftExample.slx.autosave
myAircraftExample.exe myAircraftExample_grt_rtw

```

- 3 To run the executable from the Command Window, type `!myAircraftExample`. The `!` character passes the command that follows it to the operating system, which runs the standalone `myAircraftExample` program.

```

>> !myAircraftExample

** starting the model **
** created myAircraftExample.mat **

```

- 4 To see the files created in the build folder, use the `dir` or `ls` command again. The exact list of files produced varies among MATLAB platforms and versions. Here is a sample list from a Windows platform:

```

>> dir myAircraftExample_grt_rtw

. rt_main.obj myAircraftExample_data.c
.. rtmodel.h myAircraftExample_data.obj
buildInfo.mat rtw_proj.tmw myAircraftExample_private.h
codeInfo.mat myAircraftExample.bat myAircraftExample_ref.rsp
myAircraftExample.c myAircraftExample_types.h html
myAircraftExample.h myAircraftExample.mk
rt_logging.obj myAircraftExample.obj

```

## Contents of the Build Folder

The build process creates a build folder and names it `model_target_rtw`, where *model* is the name of the source model and *target* is the system target file selected for the model. In this example, the build folder is named `myAircraftExample_grt_rtw`.

The build folder includes the following generated files.

File	Description
<code>myAircraftExample.c</code>	Standalone C code that implements the model
<code>myAircraftExample.h</code>	An include header file containing definitions of parameters and state variables
<code>myAircraftExample_private.h</code>	Header file containing common include definitions
<code>myAircraftExample_types.h</code>	Forward declarations of data types used in the code
<code>rtmodel.h</code>	Master header file for including generated code in the static main program (its name does not change, and it simply includes <code>myAircraftExample.h</code> )

The code generation report that you created for the `myAircraftExample` model displays a link for each of these files. You can click the link [explore the file contents](#).

The build folder contains other files used in the build process. They include:

- `myAircraftExample.mk` — Makefile for building executable using the specified Toolchain.
- Object (`.obj`) files
- `myAircraftExample.bat` — Batch control file
- `rtw_proj.tmw` — Marker file
- `buildInfo.mat` — Build information for relocating generated code to another development environment

- `myAircraftExample_ref.rsp` — Data to include as command-line arguments to `mex` (Windows systems only)

The build folder also contains a subfolder, `html`, which contains the files that make up the code generation report. For more information, see “Reports for Code Generation”.

## Customized Makefile Generation

After producing code, the code generator produces a customized makefile, `model.mk`. The generated makefile instructs the `make` system utility to compile and link source code generated from the model, any required harness program, libraries, or user-provided modules. The code generator produces the file `model.mk` regardless of the approach that you use for build process control:

- If you use the toolchain approach, the code generator creates `model.mk` based on the model **Toolchain settings**. You can modify generation of the makefile through the `rtwmakecfg.m` API.
- If you use the template makefile approach, the code generator creates `model.mk` from a system template file, `system.tmf` (where *system* stands for the selected system target file name). The system template makefile is designed for your system target file. You can modify the template makefile to specify compilers, compiler options, and additional information for the creation of the executable.

For more information, see “Configure Toolchain or Template Makefile Build Process” on page 56-12.

## Build Models from a Windows Command Prompt Window

This example shows how to build models by using a batch file, entering commands at the Command Prompt in Windows®.

### About MATLAB Command-Line (Start Up) Arguments

When you start MATLAB® from a Command Prompt in Windows (as done in a batch file), you can control MATLAB start up with a number of command-line arguments.

For a description of these command-line arguments, in the Command Prompt window, type `matlab - help`.

To start MATLAB from a Command Prompt window, use these steps:

- 1 From the Windows Start menu, open a Command Prompt window.
- 2 From the Windows Command Prompt, type: `matlab`.

**Tip:** To display the path to the MATLAB root folder, at the MATLAB command prompt type: `matlabroot`.

### Run MATLAB with a Batch File

When you run MATLAB with a batch file, you can:

- Control MATLAB start up with command-line arguments
- Run a series of operating system commands (such as source control checkout/commit)
- Run a series of MATLAB scripts

A batch approach also lets you automate your overall build process. Such a process can generate code from one or more Simulink models, then use your makefile to compile custom code and generated code.

This batch file sets the `MATLABROOT` environment variable, sets the `PATH` environment variable to include `MATLABROOT`, and starts MATLAB with an input script argument `%1` and a logfile argument.

**Note:** Customize the `MATLABROOT` value in the batch file to match your system. The batch file assumes that a `c:\temp` folder exists on your system.

### Create a batch file named `mat.bat`

```
SET MATLABROOT="C:\Program Files\MATLAB\R2019a"
PATH=%MATLABROOT%;%PATH%
START matlab.exe -batch %1 -logfile c:\temp\logfile
PAUSE
```

### Create a MATLAB script `myFilesToBuild.m`

```
my_rtdemo_counter_builder
my_rtdemo_rtwinintro_builder
exit
```

### Create a MATLAB script `my_rtdemo_counter_builder.m`

```
open_system('rtdemo_counter');
save_system('rtdemo_counter','my_rtdemo_counter')
```

```
slbuild('my_rtwdemo_counter');
close_system('my_rtwdemo_counter');
```

### Create a MATLAB script `my_rtwdemo_rtwintro_builder.m`

```
open_system('rtwdemo_rtwintro');
save_system('rtwdemo_rtwintro','my_rtwdemo_rtwintro')
slbuild('my_rtwdemo_rtwintro');
close_system('my_rtwdemo_rtwintro');
```

### Run the batch file

From the Windows Start menu, open a Command Prompt window, change folders to the folder containing the batch file, and type:

```
mat myFilesToBuild
```

When you run the batch file with the input MATLAB script, the batch file runs MATLAB and loads, builds, and closes each of the example Simulink models.

### Observe the log of MATLAB operations

After the batch file runs, view the `c:\temp\logfile` file.

Omitting the semicolon (;) from the `slbuild` line in each script provides more build information in the log file.

### Optimize Your Batch File

Use the MATLAB command-line arguments to optimize the batch file. For example:

- Suppress the MATLAB splash screen on startup with the `-nosplash` argument.
- Provide command-line input to the input script or function selected with the `-batch` argument.

You can call a function `myfile.m`, which accepts two arguments:

```
matlab -batch myfile(arg1,arg2)
```

To pass numeric values into `myfile.m`, replace `arg1` and `arg2` with numeric values.

To pass string or character values into `myfile.m`, replace `arg1` and `arg2` with the string or character values surrounded in single quotes. For example, to pass the string values `hello` and `world` into `myfile.m`, in the Command Prompt window, type:

```
matlab -batch myfile('hello','world')
```

## Rebuild a Model

If you update generated source code or makefiles manually to add customizations, you can rebuild the files with the `rtwrebuild` command. This command recompiles the modified files by invoking the generated makefile. Alternatively, you can rebuild from the Model Explorer:

- 1 Open the Model Explorer
- 2 In the **Model Hierarchy** pane, expand the node for the model.
- 3 Click the **Code for *model*** node.
- 4 In the **Code** pane, next to **Code Recompile Command**, click **rebuild generated code**.

## See Also

### More About

- `rtwrebuild`
- “Build Process Workflow for Real-Time Systems”

## Control Regeneration of Top Model Code

When you rebuild a model, by default, the build process performs checks to determine whether changes to the model or relevant settings require regeneration of the top model code. The model build regenerates top model code if any of the following conditions is true:

- The structural checksum of the model has changed.
- The top-model-only checksum has changed. The top-model-only checksum provides information about top model parameters, such as application lifespan, maximum stack size, make command, verbose and `.rtw` file debug settings, and `TLCOptions`.
- Any of the following TLC debugging configuration parameters is selected:
  - **Start TLC debugger when generating code** (`TLCDebug`)
  - **Start TLC coverage when generating code** (`TLCCoverage`)
  - **Enable TLC assertion** (`TLCAssert`)
  - **Profile TLC** (`ProfileTLC`)

Whether the top model code is regenerated, the build process calls the build process hooks and reruns the makefile. The hooks include the `STF_make_rtw_hook` functions and the post code generation command. This process recompiles and links the external dependencies.

System target file authors can perform actions related to code regeneration in the `STF_make_rtw_hook` functions that the build process calls. These actions include forcing or reacting to code regeneration. For more information, see “Control Code Regeneration Using `STF_make_rtw_hook.m`” on page 87-37.

### Regeneration of Top Model Code

If the checks determine that top model code generation is required, the build process fully regenerates and compiles the model code. An example check is whether previously generated code is not current due to a model update.

The build process omits regeneration of the top model code when the checks indicate both:

- The top model generated code is current for the model.
- Model settings do not require full regeneration.

This omission can significantly reduce model build times.

With an Embedded Coder license, if you modify a code generation template (CGT) file then rebuild your model, the code generation process does not force a top model build. In this case, see “Force Regeneration of Top Model Code” on page 56-35.

### Force Regeneration of Top Model Code

If you want to control or override the default top model build behavior, use one of the following command-line options:

- To ignore the checksum and force regeneration of the top model code:

- `slbuild(model, 'ForceTopModelBuild', true)`
- `slbuild(model, 'StandaloneCoderTarget', 'ForceTopModelBuild', true)`
- To clean the model build area enough to trigger regeneration of the top model code at the next build (slbuild only):  
    `slbuild(model, 'CleanTopModel')`

You can also force regeneration of the top model code by deleting the `slprj` folder in the “Code generation folder”. If you delete the `slprj` folder, delete the `model.slxc` file too.

`codebuild`

## More About

- “Control Code Regeneration Using `STF_make_rtw_hook.m`” on page 87-37
- “Approaches for Building Code Generated from Simulink Models” on page 56-11
- “Rebuild a Model” on page 56-34
- “Reduce Build Time for Referenced Models by Using Parallel Builds” on page 56-37

## Reduce Build Time for Referenced Models by Using Parallel Builds

For models that contain large model reference hierarchies, you can reduce code generation and compilation time by building the referenced models in parallel. With Parallel Computing Toolbox software, you can distribute the code generation and compilation for referenced models across a parallel pool of MATLAB workers. If you also have MATLAB Parallel Server™ software, you can distribute the code generation and compilation across remote workers in your MATLAB Parallel Server configuration.

### Build Referenced Models in Parallel

To build referenced models in parallel:

- 1 Open the Configuration Parameters dialog box for the top model of the model hierarchy.
- 2 Select the **Enable parallel model reference builds** check box.
- 3 For each MATLAB worker, you can set up a MATLAB environment that is consistent with the MATLAB environment of the client. From the **MATLAB worker initialization for builds** drop-down list, select one of these values:
  - **None** -- Simulink does not initialize workers.
  - **Copy base workspace** -- Simulink attempts to copy the base workspace to each MATLAB worker.
  - **Load top model** -- Simulink loads the top model onto each MATLAB worker.
- 4 Build your model from the command line or the Simulink Editor Code perspective:
  - **Command line** -- Use, for example, `slbuild`. The build process displays build log messages in the Command Window.
  - **Simulink Editor Code perspective** -- Click the **Build** button. The build process displays build log messages in the Diagnostic Viewer.

If the Parallel Computing Toolbox parallel preference **Automatically create a parallel pool** is selected, a parallel pool of MATLAB workers is automatically started. For more information, see “Specify Your Parallel Preferences” (Parallel Computing Toolbox).

If a parallel pool of MATLAB workers is not running when you build your model, MATLAB automatically opens a parallel pool of workers by using the default cluster profile. To change the default behaviour of the worker cluster, you can modify properties of the cluster profile. If you have not touched your parallel preferences, the default profile is `local`. Control parallel behavior with the parallel preferences, including scaling up to a cluster, automatic pool creation, and preferred number of workers. For more information, see “Discover Clusters and Use Cluster Profiles” (Parallel Computing Toolbox).

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

### Monitor Parallel Building of Referenced Models

Through the Build Status window, you can:

- View the overall build progress for a model hierarchy.
- View the build status of individual models in the model hierarchy.
- Cancel the parallel build process.

---

**Note** The Build Status window supports only parallel building of model hierarchies. Do not use the Build Status window for serial builds.

---

To open the Build Status window, use one of these line commands:

- `coder.buildstatus.open('model')`
- `slbuild('model', ... 'OpenBuildStatusAutomatically',true)`
- `slbuild('model','StandaloneCoderTarget', ... 'OpenBuildStatusAutomatically',true)`

This example shows how you can monitor the build process for a model hierarchy. In the hierarchy, `rtwdemo_parabuild_a_1` references `rtwdemo_parabuild_b_1`, `rtwdemo_parabuild_b_2`, and `rtwdemo_parabuild_b_3`.

- 1 Copy the model files to a local folder.

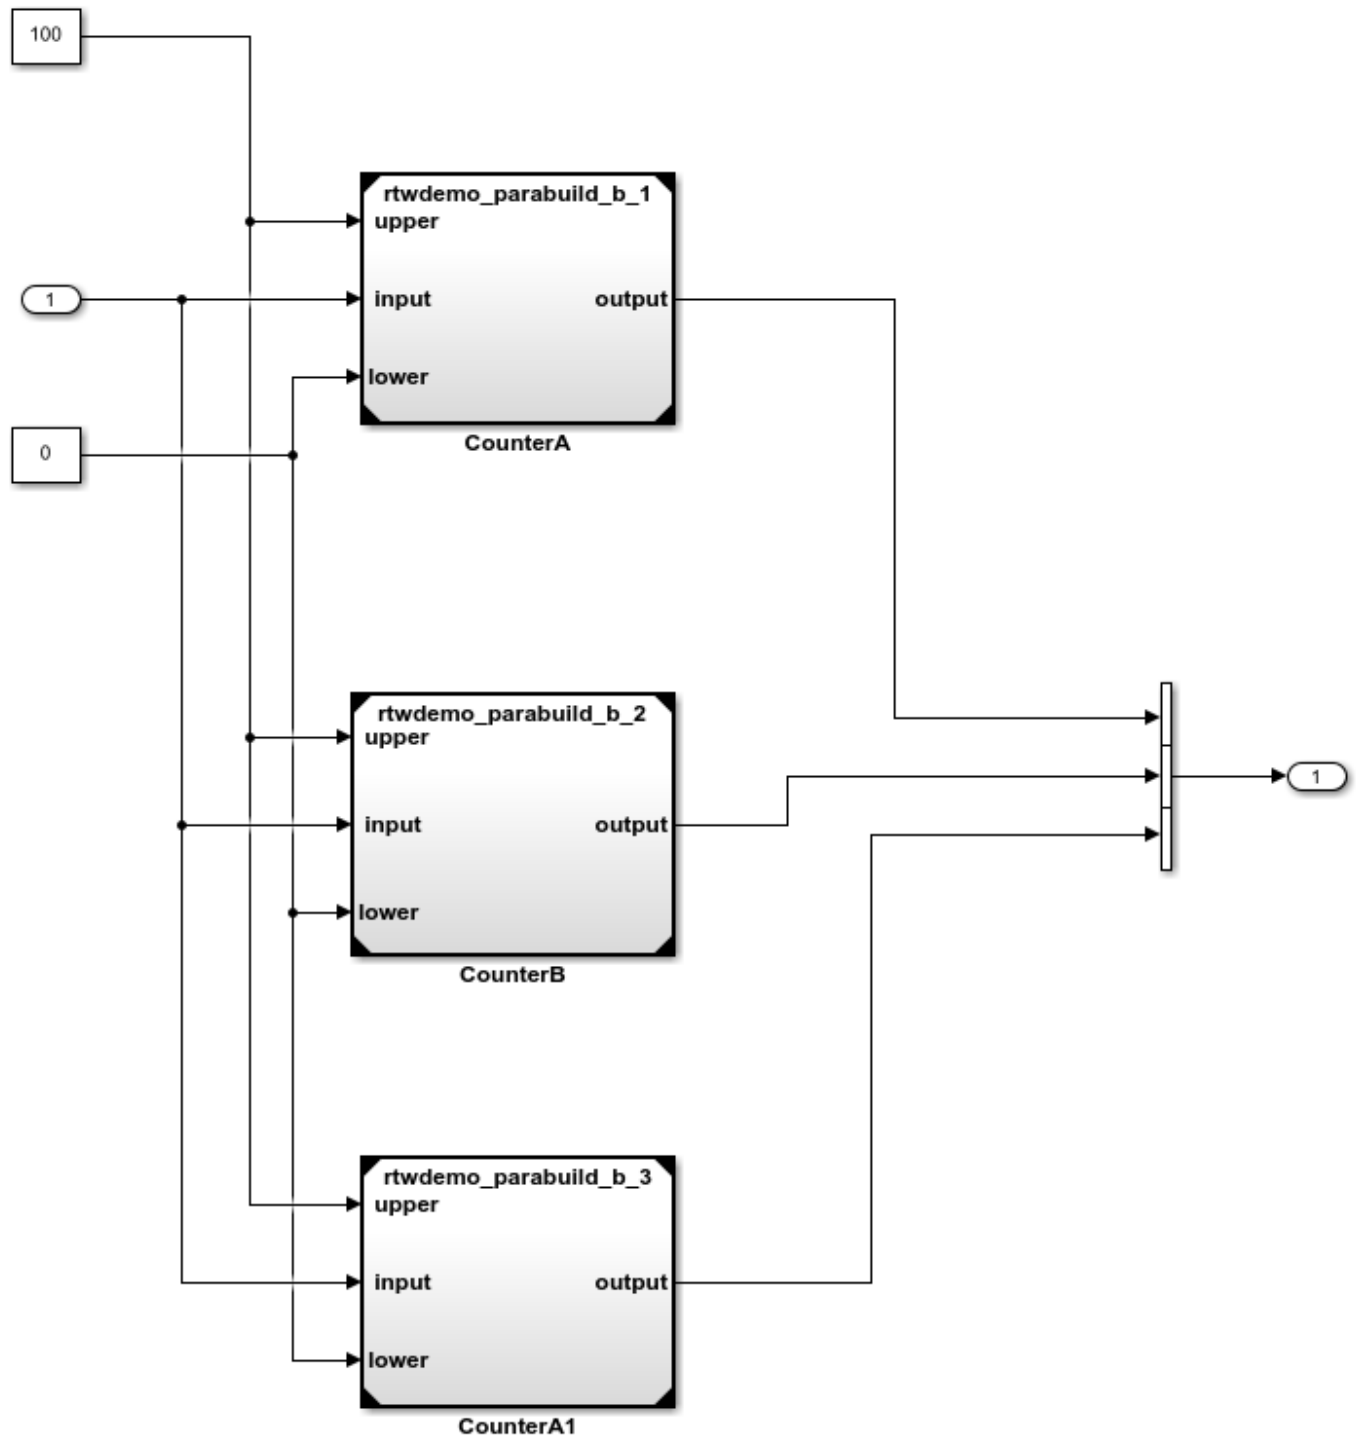

```
src_dir = ...
 fullfile(matlabroot,'toolbox','rtw','rtwdemos');
if exist(fullfile('.', 'myTempFolder'),'dir')
 rmdir('myTempFolder','s')
end
mkdir myTempFolder

copyfile(fullfile(src_dir,'rtwdemo_parabuild_a_1.slx'), ...
 'myTempFolder');
copyfile(fullfile(src_dir,'rtwdemo_parabuild_b_1.slx'), ...
 'myTempFolder');
copyfile(fullfile(src_dir,'rtwdemo_parabuild_b_2.slx'), ...
 'myTempFolder');
copyfile(fullfile(src_dir,'rtwdemo_parabuild_b_3.slx'), ...
 'myTempFolder');

cd myTempFolder
```

- 2 Open the top model.

```
open_system('rtwdemo_parabuild_a_1')
```

- 3 View the model dependencies with the Dependency Analyzer.

On the **Modeling** tab, click on the down arrow to expand the **Design** gallery. Under **Dependencies**, click **Dependency Analyzer**.

- 4 Start parallel building of the model hierarchy and open the Build Status window.

```
slbuild('rtwdemo_parabuild_a_1','OpenBuildStatusAutomatically',true)
```

The Build Status window displays the overall build progress and the build status for models as the code generator works through the model hierarchy.

Model Name	Status	Elapsed Time
rtwdemo_parabuild_a_1	Building	-
rtwdemo_parabuild_b_1	Completed	00:00:23
rtwdemo_parabuild_b_2	Completed	00:00:23
rtwdemo_parabuild_b_3	Completed	00:00:23

This table explains the **Status** column values.

Status	Description
Blocked	The code generator cannot schedule the model build because the build is blocked by dependencies. For example, a child model build is not complete.
Scheduled	In parallel building, the code generator schedules a model build when the build is not blocked by dependencies. The status of the model build is Scheduled until a parallel pool worker becomes available.
Building	The model is being built on a worker.
Completed	When a model is built without errors, the status changes to Completed.
Error	If the model build fails, the status changes to Error.

Status	Description
Up To Date	Code generation is not required for the model because the current generated code is up to date.
Canceling	When you click the <b>Cancel Build</b> button, the build process changes the status of incomplete builds to <b>Canceling</b> .
Canceled	The canceling operation is complete.

The **Elapsed Time** column shows the build times for models in the hierarchy. To reduce the total build time, analyse the build times for referenced models together with model dependency information. Then, consider, for example:

- Restructuring the referenced model hierarchy.
- Increasing the number of workers in the parallel pool.

## Relocate or Share Generated Code

To relocate or share static and generated code files, you can use the `packNGo` function. For example, use the function when you want to relocate generated code to a development environment that does not provide MATLAB and Simulink products.

### Package and Relocate Generated Code

To package generated code:

- 1 In the Configuration Parameters dialog box, select **Package code and artifacts**. This option configures the build process to run the `packNGo` function after code generation.
- 2 In the **Zip file name** field, enter the name of the ZIP file in which you want to package the generated code and artifacts. You can specify the file name with or without the `.zip` extension. If you do not specify an extension or an extension other than `.zip`, the ZIP utility adds the `.zip` extension. If you do not specify a value, the build process uses the name `model.zip`, where `model` is the name of the top model.

- 3 Apply the changes and then generate code for your model.

- 4 Verify that the packaged code is ready for relocation by using a ZIP tool to inspect the resulting ZIP file.

Relocate the ZIP file to the destination development environment and use a ZIP tool to unpack the file. To compile the unpacked code, use a build tool.

If the destination environment provides Simulink Coder or Embedded Coder, you can use `codebuild` to compile the unpacked code.

## Package and Relocate Generated Code From Command Line

To package and relocate generated code by using line commands, use this workflow:

- 1 Select a structure for the zip file. on page 56-43
- 2 Select a name for the zip file. on page 56-44
- 3 Package the model code files in the zip file. on page 56-44
- 4 Inspect the generated zip file. on page 56-45
- 5 Relocate and unpack the zip file. on page 56-45

### Select a Structure for the ZIP File

Before you generate and package the files for a model build, decide whether you want the files to be packaged in a flat or hierarchical folder structure. By default, the `packNGo` function packages the files in a single, flat folder structure.

If...	Then Use a...
You are relocating files to an IDE that does not use the generated makefile, or the code is not dependent on the relative location of required static files	Single, flat folder structure
The destination development environment must maintain the folder structure of the source environment because it uses the generated makefile, or the code depends on the relative location of files	Hierarchical structure

If you use a hierarchical structure, the `packNGo` function creates two levels of zip files, a primary zip file, which in turn contains the following secondary zip files:

- `mlrFiles.zip` — files in your *matlabroot* folder tree
- `sDirFiles.zip` — files in and under your build folder where you initiated code generation for the model
- `otherFiles.zip` — required files not in the *matlabroot* or *start* folder trees

Paths for the secondary zip files are relative to the root folder of the primary zip file, maintaining the source development folder structure.

## Select a Name for the Zip File

By default, the `packNGo` function names the primary zip file `model`. You have the option of specifying a different name. If you specify a file name and omit the file type extension, the function appends `.zip` to the name that you specify.

## Package Model Code in a Zip File

Package model code files by using the `PostCodeGenCommand` configuration parameter, `packNGo` function, and build information object for the model. You can set up the packaging operation to use:

- A system generated build information object.

In this case, before generating the model code, use `set_param` to set the configuration parameter `PostCodeGenCommand` to an explicit call to the `packNGo` function. For example:

```
set_param(bdroot, 'PostCodeGenCommand', 'packNGo(buildInfo);');
```

After generating and writing the model code to disk and before generating a makefile, this command instructs the build process to evaluate the call to `packNGo`. This command uses the system generated build information object for the currently selected model.

- A build information object that you construct programmatically.

In this case, you could use other build information functions to include paths and files selectively in the build information object that you then specify with the `packNGo` function. For example:

```
.
.
.
myModelBuildInfo = RTW.BuildInfo;
addSourceFiles(myModelBuildInfo, {'test1.c' 'test2.c' 'driver.c'});
.
.
.
packNGo(myModelBuildInfo);
```

The following examples show how you can change the default behavior of `packNGo`.

To...	Specify...
Change the structure of the file packaging to hierarchical	<code>packNGo(buildInfo, 'packType' 'hierarchical');</code>
Rename the primary zip file	<code>packNGo(buildInfo, 'fileName' 'zippedsrcs');</code>
Change the structure of the file packaging to hierarchical and rename the primary zip file	<code>packNGo(buildInfo, 'packType' 'hierarchical'... 'fileName' 'zippedsrcs');</code>
Include header files found on the include path in the zip file	<code>packNGo(buildInfo, 'minimalHeaders' false);</code>
Generate warnings for parse errors and missing files	<code>packNGo(buildInfo, 'ignoreParseError' true... 'ignoreFileMissing' true);</code>

**Note** The `packNGo` function can modify the build information in the `RTW.BuildInfo` object that is passed as the first argument of the function. The function might find additional files from source and include paths recorded in build information for the model and add that information to the `RTW.BuildInfo` object.

## Inspect Generated ZIP File

To verify that the generated ZIP file is ready for relocation, use a ZIP tool to inspect the file. Some ZIP tools allow you to view the file contents without unpacking the file. If unpacking is required and the model code files are packaged as a hierarchical structure, you have to unpack the primary and secondary ZIP files. When you unpack the secondary ZIP files, relative paths of the files are preserved.

## Relocate and Unpack ZIP File

Relocate the ZIP file to the destination development environment and use a ZIP tool to unpack the file. To compile the unpacked code, use a build tool.

If the destination environment provides Simulink Coder or Embedded Coder, you can use `codebuild` to compile the unpacked code.

## Code Packaging Example

This example shows how to package code files generated for the example model `rtwdemo_rtwinintro`:

- 1 Set your working folder to a writable folder.
- 2 Open the model `rtwdemo_rtwinintro` and save a copy to your working folder.
- 3 In the Command Window, enter:
 

```
set_param('rtwdemo_rtwinintro', 'PostCodeGenCommand',...
'packNGo(buildInfo, 'packType' 'hierarchical'));
```
- 4 Generate code for the model.
- 5 Inspect the generated ZIP file, `rtwdemo_rtwinintro.zip`. The ZIP file contains two secondary ZIP files, `mLrFiles.zip` and `sDirFiles.zip`.
- 6 Inspect `mLrFiles.zip` and `sDirFiles.zip`.
- 7 Relocate the ZIP file to your destination folder and unpack it.
- 8 To compile the unpacked code, use the `codebuild` function.

## Limitations

### packNGo Function

For information about limitations that apply to this function, see `packNGo`.

### Executable File with Nondefault Extension

If a build process uses the template makefile approach, then `packNGo` uses the executable file extension specified by the linker tool to determine binary artifacts that require packaging.

If you generate an executable file with an extension that is not a default value, check that the extension is saved in the toolchain associated with the template makefile. For more information, see “Associate the Template Makefile with a Toolchain”.

If the build process generates an executable file with an extension that is different from the extension saved in the toolchain, `packNGo` does not package the executable file.

# Compile and Debug Generated C Code with Microsoft Visual Studio

This example shows how to generate code from a model and produce a Visual Studio® Solution. For the base example, see `rtwdemo_counter`.

## About This Example

Building this example model generates a Visual Studio Solution. These model configuration parameter settings control this code generation:

- Set **System target file** to `grt.tlc`.
- Set **Template makefile** to `RTW.MSVCCBuild`.

When you build the model with this configuration, Simulink® Coder™ generates code in a Visual Studio Solution. Add this solution to a Visual Studio C/C++ project to integrate generated code with your custom Visual Studio code.

## Before You Start

- This example builds code for Microsoft® Visual Studio running on Microsoft Windows® platforms.
- This example works with Microsoft Visual Studio, but not with Visual Studio Express.
- Simulink Coder uses the GRT code format, which is intended for rapid prototyping.
- Embedded Coder® uses the ERT code format, which is intended for production deployment.

## Example Steps

- 1 Open the example model `rtwdemo_counter_msvc`. In the Command Window, type:  
`open_system('rtwdemo_counter_msvc');`
- 2 To generate debug output in the generated Visual Studio Solution, set the model configuration parameter **Make command** to `make_rtw DEBUG_BUILD=1`. (Omit this step if debug output is not required in the solution.)
- 3 To generate code and build a program executable, initiate the build process.
- 4 After the build process is complete, you can see a Visual Studio Solution was generated and placed in the `msvc` folder under folder `rtwdemo_counter_msvc_grt_rtw`.
- 5 In Microsoft Visual Studio, open the `rtwdemo_counter_msvc.sln` solution file.

Use the solution to build and debug the generated code in Visual Studio.

## Executable Program Generation

The following figure shows how the process for program building.

During the final stage of processing, the build process invokes the generated makefile, *model.mk*, which in turn compiles and links the generated code. On PC platforms, a batch file is created to invoke the generated makefile. The batch file sets up the environment for invoking the make utility and related compiler tools. To avoid recompiling C files, the make utility performs date checking on the dependencies between the object and C files; only out-of-date source files are compiled. Optionally, the makefile can download the resulting executable image to your target hardware.

This stage is optional, as illustrated by the control logic in the preceding figure. You could choose to omit this stage (for example, if you are targeting an embedded microcontroller board).

To omit this stage of processing, in the Configuration Parameters dialog box, select the **Generate code only** check box. You can then cross-compile your code and download it to your target hardware.

If you also select the **Create code generation report** check box, the code generator produces an HTML report. To view the report, on the **C Code** tab, select **Open Latest Report**. This example is a code generation report for a generic real-time (GRT) system target file.

## External Mode Simulations for Parameter Tuning and Signal Monitoring

You can use external mode simulations for rapid prototyping. An external mode simulation establishes a communication channel between Simulink on your development computer (host) and the target hardware that runs the executable file created by the code generation and build process.

Through the communication channel, you can:

- Modify or tune block parameters in real time. When you change parameters in your model, Simulink downloads the new values to the executing target application.
- Monitor and save signal data from the executing target application.

The low-level transport layer of the channel handles the transmission of messages. Simulink and the generated model code are independent of this layer. The transport layer and its interface code are isolated in separate modules that format, transmit, and receive messages and data packets.

## Communication Mechanisms for External Mode

Simulink supports two communication mechanisms for external mode simulation. To decide which mechanism to use, see the information in this table.

Communication Mechanism	Supports	Reasons for Selecting Communication Mechanism
XCP, the Universal Measurement and Calibration Protocol	<p>ERT and GRT system target files.</p> <p>Some Simulink support packages. For details, see <a href="https://www.mathworks.com/hardware-support.html?q=&amp;page=1">https://www.mathworks.com/hardware-support.html?q=&amp;page=1</a>.</p>	<p>XCP external mode:</p> <ul style="list-style-type: none"> <li>• Uses a standard communication protocol.</li> <li>• Requires only a lightweight communication software stack on the target hardware.</li> <li>• Supports signal logging and streaming for Dashboard blocks and the Simulation Data Inspector. You can stream signals from within a referenced model hierarchy.</li> <li>• Provides documented <code>ext_mode.h</code> API for external mode target connectivity.</li> <li>• Supports streaming of execution-time metrics to the Simulation Data Inspector for host-based and support package external mode simulations.</li> </ul> <p>For information about running XCP external mode simulations, see:</p> <ul style="list-style-type: none"> <li>• “External Mode Simulation by Using XCP Communication” on page 57-7</li> <li>• “Customize XCP Server Software” on page 57-42</li> </ul>
TCP/IP and serial (RS-232)	<p>ERT, GRT, and RSim system target files.</p> <p>Simulink support packages.</p>	<p>XCP external mode simulations do not support your target hardware because of known limitations.</p> <p>For information about running TCP/IP and serial external mode simulations, see:</p> <ul style="list-style-type: none"> <li>• “External Mode Simulation with TCP/IP or Serial Communication” on page 57-52</li> <li>• “Create a Transport Layer for TCP/IP or Serial External Mode Communication” on page 57-90</li> </ul>

## Simulink Feature Support for External Mode

This table summarizes feature support for both forms of external mode simulations.

Feature		XCP Support	TCP/IP and Serial Support
Parameter tuning	With Dashboard blocks	Yes	Yes
	Of tunable block parameters	Yes	Yes
Simulation Data Inspector		Yes. Includes signals within referenced models.	No
Logic Analyzer		Yes. Includes signals within referenced models.	No
Blocks that receive and display signals from target application	Dashboard library	Yes	No
	Floating Scope, Scope	Yes	Yes
	Spectrum Analyzer, Time Scope (DSP System Toolbox)	Yes	Yes
	Display	Yes	Yes
	To Workspace	Yes	Yes
	User-written S-Function.  A method, which enables user-written blocks to support external mode, is built into the S-function API.  See <i>matlabroot/simulink/include/simstruc.h</i> .	Yes	Yes
	Record, XY Graph	Yes	Yes
Signal Viewing Subsystem on page 57-71		Yes	Yes

## External Mode Simulations by Using the Run on Custom Hardware App

To run external mode simulations on your development computer or target hardware that is not supported by MathWorks support packages, use the Run on Custom Hardware app. For an external mode simulation, you:

- 1 Build the target application on your development computer.
- 2 Deploy the target application to the target hardware.
- 3 Connect Simulink to the target application that runs on the target hardware.
- 4 Start execution of generated code on the target hardware.

With the app, you can perform the steps separately or by using one-click. This table shows the workflow support that the app provides for your target hardware.

Workflow Feature or Task		Target Hardware	
		Development Computer	Custom Hardware
One-click 		Yes	Yes, if you set up connectivity on page 57-32 between Simulink and your target hardware.
Step-by-step	<b>Build for Monitoring</b> 	Yes	Yes. Software builds target application on development computer by using the toolchain that you specify.
	<b>Deploy</b> 	Yes	Yes, if you set up connectivity on page 57-32 between Simulink and your target hardware.
	<b>Connect</b> 	Yes	Yes
	<b>Start</b> 	Yes	Yes

## External Mode Control Panel

Using the External Mode Control Panel, you can perform some of the functions that the Run on Custom Hardware app provides, for example, **Connect**, **Start**, and **Disconnect**. You can also open the External Signal & Triggering dialog box, which enables you to:

- Select logged signals that you want to monitor.
- Configure a trigger for uploading target application data.

For details, see XCP panel on page 57-25 or TCP/IP and serial panel on page 57-58.

## Security for External Mode Simulations

Ensure that access to your development computer and the target hardware is secure.

Provide a secure communication channel between your development computer and the target application by applying the security measures listed in this table.

Communication Protocol	Security Measure
XCP on TCP/IP, TCP/IP	Run your development computer and target application within a trusted private network or virtual private network (VPN).
XCP on serial, serial	Use a point-to-point link between your development computer and target application, for example, a serial cable.

Before generating code for production, to reduce the risk of unintended access to the target application, disable external mode settings.

## External Mode Simulation by Using XCP Communication

In an external mode simulation, you can tune parameters in real time and monitor target application signals. Using the Run on Custom Hardware app, you can set up and run on your development computer or custom hardware external mode simulations that use an XCP communication channel.

For an external mode simulation, you:

- 1 Build the target application on your development computer.
- 2 Deploy the target application to the target hardware.
- 3 Connect Simulink to the target application that runs on the target hardware.
- 4 Start execution of generated code on the target hardware.

### Run XCP External Mode Simulation on Development Computer

Configure and run an external mode simulation that uses the XCP communication protocol. During the simulation:

- Monitor a signal by using a Scope block, a Dashboard block, and the Simulation Data Inspector.
- Tune a parameter by using a Dashboard block.

#### Configure Signal Monitoring and Parameter Tuning for XCP

- 1 Create a folder for this example.

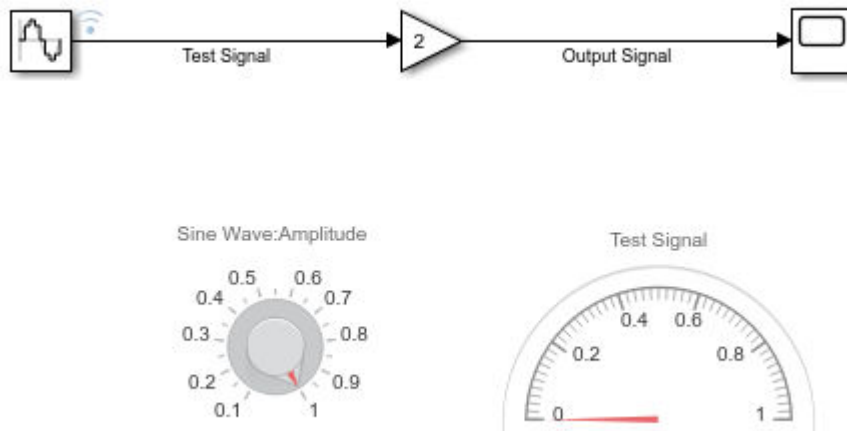

```
mkdir ext_mode_xcp_example
cd ext_mode_xcp_example
```

- 2 Open Simulink and create a simple model, `xcpExample`, which contains these blocks:
  - Sine Wave
  - Gain
  - Scope
  - Half Gauge
  - Knob
- 3 Double-click the Sine Wave block. Set **Sample time** to 0.1, and then click **OK**.
- 4 Double-click the Gain block. Set **Gain** to 2, and then click **OK**.
- 5 Connect the Sine Wave block to the Gain block and name the connection, for example, `Test Signal`.
- 6 Connect the Gain block to the Scope block and name the connection, for example, `Output Signal`.
- 7 Configure `Test Signal` for logging:
  - a Select `Test Signal`.
  - b On the **Signal** tab, in the **Monitor** section, select **Log Signals**.

If you do not enable signal logging, you cannot stream `Test Signal` to the Simulation Data Inspector.

- 8 Configure the Half Gauge block to monitor the value of `Test Signal`:

- a Double-click the Half Gauge block.
  - b In the Simulink Editor, select **Test Signal**.
  - c In the Block Parameters dialog box:
    - Connect the block to **Test Signal**.
    - In the **Maximum** field, enter a value, for example, 1.
  - d Click **OK**.
- 9 Configure the Knob block to tune the **Amplitude** parameter of the Sine Wave block:
- a Double-click the Knob block.
  - b In the Simulink Editor, select the Sine Wave block.
  - c In the Block Parameters dialog box:
    - Connect the block to the **Amplitude** parameter of the Sine Wave block.
    - In the **Minimum** and **Maximum** fields, enter values, for example, 0.1 and 1 respectively.
  - d Click **OK**.
- 10 Save the model as `xcpExample`.

### Specify Hardware and Prepare Model

- 1 From the **Apps** tab on the Simulink toolstrip, in the **Setup to Run on Hardware** section, click **Run on Custom Hardware**. On the Run on Custom Hardware pop-up dialog box, click **Finish**.
- 2 In the **Hardware** section, specify the system target file. For this example, use the default, `grt.tlc`. If you have Embedded Coder, you can specify `ert.tlc`.
- 3 In the **Prepare** gallery, under **Model Configuration**, click **Hardware Settings**. The Configuration Parameters dialog box opens, displaying **Hardware Implementation** settings that are determined by the system target file.
- 4 On the **Solver** pane:
  - a In the **Type** field, specify **Fixed-step**.
  - b Under **Solver details**, in the **Fixed-step size** field, specify a value, for example, 0.1.

- 5 On the **Code Generation > Optimization** pane, set **Default parameter behavior** to Tunable.
- 6 On the **Code Generation > Interface** pane, select the **External mode** check box.
- 7 Set **Transport layer** to XCP on TCP/IP, which specifies `ext_xcp` for **MEX-file name**.
- 8 You cannot disable the **Static memory allocation** check box. The **Static memory buffer size** value specifies the size of XCP server memory that is allocated for signal logging. For this example, use the default value.
- 9 If **System target file** is `ert.tlc`, on the **Code Generation > Templates** pane:
  - Select the **Generate an example main program** check box.
  - Set **Target operating system** to BareBoardExample.

Using the documented APIs of the external mode abstraction layer that are available in `matlabroot\toolbox\coder\xcp\src\target\ext_mode\include\ext_mode.h`, the code generator creates an example that shows how you can provide XCP external mode target connectivity for a bare board that does not run an operating system.

- 10 Click **OK**. Then save the model.

### Build and Run Target Application

In the **Run on Hardware** section:

- 1 To specify a nondefault value for the simulation stop time, in the **Stop Time** field, specify your value, for example, `inf`.

2

Click . The software:

- a Builds the target application:
  - In Windows, the build process creates:
    - `xcpExample.exe` -- The executable file.
    - `xcpExample.pdb` -- A debugging symbols file for signals and parameters.
  - In Linux, the build process places DWARF format debugging information in the created ELF executable file, `xcpExample`.
- b Runs the target application as separate process on your development computer.
- c Connects Simulink to the target application.
- d Runs the generated model code.

To perform the steps separately, click **Monitor & Tune**. Under **Step By Step Commands**, click:

- a **Build for Monitoring** 
- b **Deploy** 
- c **Connect** 
- d **Start** 

## Monitor Signal and Tune Parameter

You can monitor Test Signal through the:

- Scope block -- Double-click the block.
- Simulation Data Inspector -- Click the Simulation Data Inspector button. When the Simulation Data Inspector opens, select the **Test Signal** check box, which displays streamed data.
- Half-Gauge block.

To change the amplitude of the sine wave, rotate the pointer on the Knob block to the required value.

This table describes more ways of tuning tunable block parameters during a simulation.

Approach	Details
Model Data Editor	<p>To tune parameters through the Model Data Editor:</p> <ol style="list-style-type: none"> <li><b>1</b> On the <b>Hardware</b> tab of the Simulink Editor, in the <b>Prepare</b> section, click <b>Tune Parameters</b>, which opens the Model Data Editor.</li> <li><b>2</b> If you want to update multiple tunable parameters simultaneously, in the <b>Prepare</b> section, toggle on <b>Hold Updates</b>.</li> <li><b>3</b> On the <b>Parameters</b> tab of the Model Data Editor, in the <b>Value</b> column, specify new values for your tunable parameters.</li> <li><b>4</b> Toggle off <b>Hold Updates</b> or click <b>Update All Parameters (Ctrl+D)</b>. Simulink downloads the new values to the target application simultaneously.</li> </ol> <p>If <b>Hold Updates</b> is off, then immediately after you specify a new value, Simulink downloads the new value to the target application.</p> <p>For more information, see <b>Model Data Editor</b>.</p>

Approach	Details
Block Parameter dialog box	<p>To tune parameters through the Block Parameter dialog box:</p> <ol style="list-style-type: none"> <li><b>1</b> For each block that you want to update: <ol style="list-style-type: none"> <li><b>a</b> Double-click the block, which opens the Block Parameter dialog box.</li> <li><b>b</b> In the parameter fields, specify new parameter values.</li> <li><b>c</b> Click <b>Apply</b> or <b>OK</b>.</li> </ol> </li> <li><b>2</b> If <b>Hold Updates</b> is on, toggle off <b>Hold Updates</b> or click <b>Update All Parameters (Ctrl+D)</b>. Simulink downloads the new values to the target application simultaneously.</li> </ol> <p>If <b>Hold Updates</b> is off, then immediately after you click <b>Apply</b> or <b>OK</b>, Simulink downloads the new block values to the target application.</p>
MATLAB workspace	<p>If block parameters are MATLAB workspace variables:</p> <ol style="list-style-type: none"> <li><b>1</b> In the Command Window, assign new values to the variables.</li> <li><b>2</b> On the <b>Hardware</b> tab of the Simulink Editor, in the <b>Prepare</b> section, click <b>Update All Parameters (Ctrl+D)</b>. Simulink downloads the new values to the target application.</li> </ol> <p>For more information, see “Create and Edit Variables”.</p>

For more information about parameter tuning with generated code, see “External Mode Simulation with TCP/IP or Serial Communication” on page 57-52 and “Create Tunable Calibration Parameter in the Generated Code” on page 33-110.

If your model contains a Stateflow chart, you can view state activity. For more information, see “Animate Stateflow Charts” (Stateflow).

### Stop Target Application

To stop the execution of generated model code before `StopTime` is reached and disconnect the target application, on the Simulink Editor toolbar, click the Stop button .

If you want to disconnect the target application from Simulink without stopping code execution, click . Then, under **Step By Step Commands**, click **Disconnect**.

## Triggered Signal Monitoring for XCP External Mode Simulations

For XCP external mode simulations, you can configure a trigger that starts the uploading of target application data for signal monitoring in Simulink.

### 1 Create a simple model in a local folder.

In the Command Window, enter these commands:

```
% Create work folder
if mkdir('workFolder')
 rmdir('workFolder' s
 mkdir('workFolder')
end
cd workFolder
open_system(new_system('myModel'));

% Add, configure, and connect blocks
add_block('simulink/Sources/Sine Wave','myModel/Signal',...
 'Bias','5',...
 'Amplitude','2',...
 'SampleTime','0.01');
set_param('myModel/Signal','position',[140,80,180,120]);

add_block('simulink/Math Operations/Gain','myModel/Signal Gain',...
 'Gain','2');
set_param('myModel/Signal Gain','position',[340,80,380,120]);
add_line('myModel','Signal/1','Signal Gain/1');

% Label signal
signal=get_param('myModel/Signal','PortHandles');
set_param(signal.Outport(1),'Name','test_signal');

% And so on
add_block('simulink/Math Operations/Product','myModel/Product');
set_param('myModel/Product','position',[540,160,580,200]);
add_line('myModel','Signal Gain/1','Product/1');

add_block('simulink/Sources/Sine Wave','myModel/Carrier',...
 'Bias','5',...
 'Amplitude','10',...
 'Frequency','3',...
 'SampleTime','0.02');

set_param('myModel/Carrier','position',[140,240,180,280]);

add_block('simulink/Math Operations/Gain','myModel/Carrier Gain');
set_param('myModel/Carrier Gain','position',[340,240,380,280]);
add_line('myModel','Carrier/1','Carrier Gain/1');

signal=get_param('myModel/Carrier','PortHandles');
set_param(signal.Outport(1),'Name','test_carrier');

add_block('simulink/Signal Attributes/Rate Transition',...
 'myModel/Rate Transition');
set_param('myModel/Rate Transition','position',[440,200,480,240]);
add_line('myModel','Carrier Gain/1','Rate Transition/1');
add_line('myModel','Rate Transition/1','Product/2');

add_block('simulink/Sources/Constant','myModel/Constant',...
 'Value','0');
set_param('myModel/Constant','position',[340,320,380,360]);

add_block('simulink/Logic and Bit Operations/Relational Operator',...
 'myModel/Relational Operator','Operator','>=');
set_param('myModel/Relational Operator','position',[540,300,580,340]);
add_line('myModel','Carrier Gain/1','Relational Operator/1');
add_line('myModel','Constant/1','Relational Operator/2');

signal=get_param('myModel/Carrier Gain','PortHandles');
```

```

set_param(signal.Outport(1), 'Name', 'pos_carrier');

add_block('simulink/Sinks/Scope', 'myModel/ScopeA');
set_param('myModel/ScopeA', 'position', [740, 160, 780, 200]);
add_line('myModel', 'Product/1', 'ScopeA/1');

signal=get_param('myModel/Product', 'PortHandles');
set_param(signal.Outport(1), 'Name', 'test_output');

add_block('simulink/Sinks/Scope', 'myModel/ScopeB');
set_param('myModel/ScopeB', 'position', [740, 300, 780, 340]);
add_line('myModel', 'Relational Operator/1', 'ScopeB/1');

signal=get_param('myModel/Relational Operator', 'PortHandles');
set_param(signal.Outport(1), 'Name', 'cmp_output');

% Finally, save the model
save_system('myModel');

```

2 In the Simulink Editor, configure these signals for logging by right-clicking each signal and then selecting **Log Selected Signals**:

- test\_signal
- test\_carrier
- test\_output
- cmp\_output

- 3 From the **Apps** tab on the Simulink toolstrip, in the **Setup to Run on Hardware** section, click **Run on Custom Hardware**. On the Run on Custom Hardware pop-up dialog box, click **Finish**.
- 4 In the **Prepare** gallery, under **Model Configuration**, click **Hardware Settings**.
- 5 On the **Solver** pane, in the **Type** field, specify Fixed-step.
- 6 On the **Code Generation > Interface** pane, select the **External mode** check box.
- 7 Set **Transport layer** to XCP on TCP/IP, which specifies ext\_xcp for **MEX-file name**.
- 8 Click **OK**. Then save the model.
- 9 To open the External Signal & Triggering dialog box, from the **Prepare** gallery, under **Signal Monitoring & Tracing**, click **Control Panel**.

- 10 In the **Configuration** section, click **Signal & Triggering**, which opens the External Signal & Triggering dialog box.

Signal selection

Trigger	Selected	Signal	Source Port
	X	test_carrier	myModel/Carrier:1
	X	test_output	myModel/Product:1
	X	cmp_output	myModel/Relational Operator:1
	X	test_signal	myModel/Signal:1

Source:  Mode:  Duration:  Delay:

Arm when connecting to target  Send multiple contiguous samples in same packet

Trigger signal

Direction:  Level:  Hold-off:

OK Cancel Help Apply

Through this dialog box, you can select signals for monitoring and configure the trigger for uploading data from the target application. For this example, use the default settings. For example:

- The **Select all** check box is selected — The dialog box displays an X in each row of the **Selected** column. You can monitor all logged signals during the simulation.
- **Source** is set to **manual** -- The External Mode Control Panel provides manual control of data uploading, for example, the **Arm Trigger** button.
- The **Arm when connecting to target** check box is selected — When you connect Simulink to the target application, the trigger is armed.

- 11 Click **OK**.

- 12 From the **Hardware** tab in the Simulink Editor, in the **Run on Hardware** section:

a In the **Stop Time** field, specify your value, for example, `inf`.

b Save the model.

c

Click . The software:

- i Builds the target application:
- ii Runs the target application as separate process on your development computer.
- iii Connects Simulink to the target application.
- iv Runs the generated model code.

To view the scope displays, double-click ScopeA and ScopeB.

To monitor signals in the Simulation Data Inspector, in the **Review Results** section, click the **Data Inspector** button.

From the External Mode Control Panel, you can suspend or resume signal logging and monitoring. In the **Connection and triggering** section, click **Cancel Trigger** or **Arm Trigger** respectively.

To stop the execution of the target application and disconnect Simulink from the target environment, click **Stop Real-Time Code**.

For information about signal monitoring and trigger options, see “XCP External Mode Control Panel” on page 57-25 and “XCP External Signal & Triggering Dialog Box” on page 57-26.

## Run XCP External Mode Simulation From Command Line

You can use commands to run XCP external mode simulations. To retrieve and set the values of model parameters, use the `get_param` and `set_param` commands.

To run these commands, you must have a Simulink model open and a target application running.

- 1 Set the model simulation mode to external mode.

```
set_param(gcs, 'SimulationMode', 'external');
```

- 2 Connect Simulink to the target application.

```
set_param(gcs, 'SimulationCommand', 'connect')
```

- 3 Run generated model code.

```
set_param(gcs, 'SimulationCommand', 'start');
```

- 4 To tune a parameter, change its workspace variable value through a line command. For example, if a block parameter value is specified as a `Simulink.Parameter` object, assign the new value to the `Value` property.

```
myParamObj.Value = 5.23;
```

- 5 To download the new value to the target application, update the model.

```
set_param(gcs, 'SimulationCommand', 'update');
```

- 6 Stop the target application and disconnect Simulink from the target environment.

```
set_param(gcs, 'SimulationCommand', 'stop');
```

To disconnect Simulink from the target application without stopping execution of generated code, use this command:

```
set_param(gcs, 'SimulationCommand', 'disconnect');
```

The `set_param` commands that use the `'SimulationCommand'` argument are asynchronous. If you run the commands successively from a script, each command starts without waiting for the previous

command to complete. To check that each command is complete, in the script, use the `get_param` command with the 'SimulationStatus' argument. For example, for steps 1 to 3, specify these commands in the script:

```
set_param(gcs, 'SimulationMode', 'external');
set_param(gcs, 'SimulationCommand', 'connect');

isExternalSimulationActive = false;
while ~isExternalSimulationActive
 simStatus = get_param(gcs, 'SimulationStatus');
 isExternalSimulationActive = strcmp(simStatus, 'external');
end
set_param(gcs, 'SimulationCommand', 'start');
```

For more information, see “Run Simulations Programmatically”.

The Diagnostic Viewer displays error messages produced by the `get_param` and `set_param` commands.

This table gives parameters that you can use in `get_param` and `set_param` commands.

**XCP External Mode Command-Line Parameters**

<b>Parameter and Values</b>	<b>Dialog Box Equivalent</b>	<b>Description</b>
ExtModeArmWhenConnect off, on	External Signal & Triggering: <b>Arm when connecting to target</b> check box	Arm the trigger as soon as the Simulink Coder software connects to the target.
ExtModeBatchMode off, on	External Mode Control Panel: <b>Batch download</b> check box	Enable or disable downloading of parameters in batch mode.
ExtModeConnected off, on	External Mode Control Panel: <b>Connect/Disconnect</b> button	Indicate the state of the connection with the target application.
ExtModeEnableFloating off, on	External Mode Control Panel: <b>Enable data uploading</b> check box	Enable or disable the arming and canceling of triggers when a connection is established with floating scopes.
ExtModeLogAll off, on	External Signal & Triggering: <b>Select all</b> check box	Upload available signals from the target to the host.
ExtModeSendContiguousSamples off, on	External Signal & Triggering: <b>Send multiple contiguous samples in same packet</b> check box	Specify XCP DAQ packed mode for streaming signals to Simulink. Target application sends samples from multiple time steps in a packet. ExtModeTrigDuration determines number of samples sent in the packet.
ExtModeTrigDelay integer (0)	External Signal & Triggering: <b>Delay</b> text field	Specify the amount of time (expressed in base rate steps) that elapses between a trigger occurrence and the start of data collection.
ExtModeTrigDirection character vector - <b>rising</b> , falling, either	External Signal & Triggering: <b>Direction</b> menu	Specify the direction in which the signal must be traveling when it crosses the threshold value.

Parameter and Values	Dialog Box Equivalent	Description
ExtModeTrigDuration <i>integer (1000)</i>	External Signal & Triggering: <b>Duration</b> text field	Specify the number of base rate steps for which external mode logs data after a trigger event.  If ExtModeSendContiguousSamples is on, the number of samples sent in a packet from the target application to Simulink is equal to:  $\text{ExtModeTrigDuration}/n$ where $n = (\text{base rate})/(\text{sample rate})$  For $n=1$ , number of samples sent in a packet is exactly ExtModeTrigDuration value. For subrates in multirate models, number of samples sent in a packet is rounded down to the nearest integer. The target application discards buffer samples that are not sent to Simulink.
ExtModeTrigHoldOff <i>integer (0)</i>	External Signal & Triggering: <b>Hold-off</b> text field	Specify the base rate steps between when a trigger event terminates and the trigger is rearmed.
ExtModeTrigLevel <i>integer (0)</i>	External Signal & Triggering: <b>Level</b> text field	Specify the threshold value the trigger signal must cross to fire the trigger.
ExtModeTrigMode <i>character vector - normal, oneshot</i>	External Signal & Triggering: <b>Mode</b> menu	Specify whether the trigger is to rearm automatically after each trigger event or whether only one buffer of data is to be collected each time the trigger is armed.
ExtModeTrigSignalBlockPath <i>character vector</i>	External Signal & Triggering: In <b>Signal selection</b> view, select signal and then click <b>Trigger Signal</b> button.	Specify the path to the block that contains the output port that provides the trigger signal.
ExtModeTrigSignalOutputPortIndex <i>integer</i>	External Signal & Triggering: In <b>Signal selection</b> view, select signal and then click <b>Trigger Signal</b> button.	Specify the index of the trigger signal output port for the block specified by ExtModeTrigSignalBlockPath.

Parameter and Values	Dialog Box Equivalent	Description
ExtModeTrigType <i>character vector</i> - <b>manual</b> , signal	External Signal & Triggering: <b>Source</b> menu	Specify whether to start logging data when the trigger is armed or when a specified trigger signal satisfies trigger conditions.

## Target Application Arguments

You can run your target application with optional arguments. You can pass the optional arguments to your target application through your custom launcher implementation.

Argument	Description
-w	Specify that the target application enters and stays in a wait state until it receives a message from Simulink.  If you do not specify -w, the target application executes model code immediately. The model code runs with parameter values from the time when you built the model.
-tf <i>time</i>	Override the model parameter StopTime.  Specify <i>time</i> in: <ul style="list-style-type: none"> <li>• Seconds if PurelyIntegerCode is set to 'off'.</li> <li>• Base rate steps if PurelyIntegerCode is set to 'on'.</li> </ul> -tf inf specifies that the model runs indefinitely when model code is executed.

For host-based external mode simulations, you can specify additional `rtiostream` on page 82-44 arguments.

Argument	Description
-verbose <i>level</i>	Specify verbosity level: <ul style="list-style-type: none"> <li>• 0 -- No information</li> <li>• 1 -- Detailed information</li> </ul>
-port <i>number</i>	For XCP on TCP/IP transport layer, specify the port number of the TCP/IP server. Use an integer value between 256 and 65535. Default is 17725.  For XCP on Serial transport layer, specify the serial port ID. For example:  On Windows, 'COM1' or 1 for COM1, 'COM2' or 2 for COM2, and so on.  On Linux, '/dev/ttyS0', and so on.

Argument	Description
-baud <i>value</i>	For XCP on Serial transport layer, specify the baud value: 1200, 2400, 4800, 9600, 14400, 19200, 38400, 57600 (default), or 115200.

## XCP External Mode Limitations

This table describes limitations that apply to external mode simulations that use XCP communication.

Feature	Details
Parameter updates that change model structure	<p>You cannot change:</p> <ul style="list-style-type: none"> <li>• The number of states, inputs, or outputs of a block</li> <li>• The sample time or the number of sample times</li> <li>• The integration algorithm for continuous systems</li> <li>• The name of the model or of a block</li> </ul> <p>If you make parameter updates that change the model structure, you must rebuild the target application.</p> <p>You can change numerator and denominator polynomial parameters for the Transfer Fcn, Discrete Transfer Fcn, and Discrete Filter blocks if the number of states does not change.</p> <p>You cannot change zero entries in the State-Space, Zero-Pole, and Discrete Zero-Pole blocks in the user-specified or computed parameters, that is, the A, B, C, and D matrices obtained by a zero-pole to state-space transformation.</p> <p>In the State-Space block, if you specify the matrices in the controllable canonical realization, then changes to the A, B, C, and D matrices that preserve this realization and the dimensions of the matrices are allowed.</p> <p>If the Simulink block diagram does not match the target application, Simulink produces an error stating that the checksums do not match. The checksums take into account the top models, but not referenced models. To rebuild the target application, use the updated block diagram.</p>
Signal value display	<p>The graphical display of signal values during a simulation is not supported. For example, you cannot use the <b>Data Display in Simulation</b> menu items <b>Show Value Labels When Hovering</b>, <b>Toggle Value Labels When Clicked</b>, and <b>Show Value Label of Selected Port</b>. For more information, see “Display Signal Values in Model Diagrams”.</p>
Data archiving	<p><b>Data Archiving</b> features available on the <b>External Mode Control Panel</b> are not supported. You can use the Simulation Data Inspector to collect and export data.</p>

Feature	Details
Overriding signal logging settings	If you use the Signal Logging Selector to override signal logging settings, the controls to override the <b>Decimation</b> and <b>Limit data points</b> settings are not supported.
Subsystem signal logging	<p>For external mode simulations, signal logging occurs in response to an event on the target hardware. Currently, the only supported logging event is a new sample time tick. Some subsystems are enabled or disabled by control signals. For these subsystems, the software logs signal values even when the control signals for the subsystems are not enabled.</p> <p>For example, if signals in an Enabled Subsystem block are configured for logging, the software logs the signal values even when the control signal for the subsystem is not greater than zero. In this case, the logged values are the values the signals had when the control signal was last greater than zero.</p> <p>For more information about the subsystems for which this limitation applies, see “Simulink Subsystem Semantics”.</p>
Compiler debug symbol format	<p>Your toolchain must generate debug information in one of these formats:</p> <ul style="list-style-type: none"> <li>• DWARF</li> <li>• PDB</li> </ul>
Global variables	Signals, parameters, and states must be specified as global variables. The target memory locations where the variables are stored must lie in the range 0 - 4294967295.
Parameter structures	You cannot tune parameters that are structures.
Pure integer code	<p>Pure integer code is supported. For code generation, if <code>PurelyIntegerCode</code> is 'on', specify <code>FixedStep</code> with a resolution that is greater or equal to 1 microsecond. For example, specify 1.000001, but not 1.0000001.</p> <p>If you do not specify <code>-tf finalTime</code> in the execution command, the target application runs the generated model code indefinitely, ignoring <code>StopTime</code>.</p> <p>If you specify <code>-tf finalTime</code> in the execution command:</p> <ul style="list-style-type: none"> <li>• The <code>finalTime</code> value represents base rate steps, not seconds.</li> <li>• The maximum value for <code>finalTime</code>, in ticks, is <code>MAX_int32_T</code>.</li> </ul>
Variable-size signals	Uploading of variable-size signals is not supported.
Compiler support	<code>lcc-win64</code> is not supported.
Simulink.ImageType data type	<code>Simulink.ImageType</code> data type is not supported.
Address granularity	Target hardware that uses word addresses is not supported.

Feature	Details
Portable word sizes	When the production target hardware is word-addressable, the generation of a host-based target application by using portable word sizes is not supported. The production target hardware must support 8-bit, 16-bit, and 32-bit native data types.
Scope blocks	If your model uses Scope blocks and the amount of data logged during an external mode simulation becomes very large, Simulink might slow down. Instead of Scope blocks, you can use the Simulation Data Inspector or equivalent blocks from the Dashboard library. For more information, see “Decide How to Visualize Simulation Data”.
Scope and Floating Scope blocks, and Scope Viewer	Some signal data types are not supported. The simulation produces a warning.
Floating Scope blocks and Scope Viewer	You cannot use Floating Scope blocks and Scope Viewers to monitor signals in referenced models during external mode simulations. To monitor referenced model signals, enable signal logging and use the Simulation Data Inspector.
Scopes in referenced models	In a model hierarchy, if the top model runs in external mode, scopes in the referenced models are not displayed. To monitor signals within a referenced model, enable signal logging and use the Simulation Data Inspector.
Nonzero simulation start time	Nonzero simulation start times are not supported. Use the default value for <b>Solver &gt; Start time</b> , 0.0.
Intermediate step values	<p>Some Simulink blocks can generate multiple values in a simulation time step. For example:</p> <ul style="list-style-type: none"> <li>• A Simulink Function or Function-Call Subsystem block that is invoked multiple times in a time step.</li> <li>• Iterator subsystem blocks that execute multiple times in a time step.</li> </ul> <p>For each time step in an external mode simulation, Simulink uploads from the target application only the final values of such blocks. Simulink does not upload the intermediate values generated during the step.</p>
File-scoped data	<p>File-scoped data is not supported. For example, data items to which you apply the built-in custom storage class <code>FileScope</code>. The simulation produces a warning.</p> <p>For more information about the <code>FileScope</code> storage class, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.</p>
Row-major code generation	Code generated with the row-major format is not supported.

Feature	Details																																										
Concurrent execution	<p>On Windows and Linux computers, concurrent execution is supported.</p> <p>On Mac computers, concurrent execution using the native threads example is not supported. If the <b>External mode</b> and <b>Allow tasks to execute concurrently on target</b> check boxes are selected, you cannot build the target application unless you are using a target hardware support package that supports concurrent execution for external mode simulations.</p> <p>On a Windows computer, at run time, the base sample time in the target application is quantized to the nearest multiple of the system timer interrupt interval (usually 15.625 ms). Sampling subrates are the expected multiples of the base sample rate. Logged timestamps in the Simulation Data Inspector (SDI) correspond to simulation times rather than wall-clock times. As an example, this table shows the step times for a Simulink model that has a base sample time of 10 ms and a subrate sample time of 20 ms.</p> <table border="1" data-bbox="605 852 1464 1220"> <thead> <tr> <th colspan="3">Base Rate</th> <th colspan="3">Subrate</th> </tr> <tr> <th>Step</th> <th>Wall-Clock Time (ms)</th> <th>Logged Timestamp (ms)</th> <th>Step</th> <th>Wall-Clock Time (ms)</th> <th>Logged Timestamp (ms)</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0</td> <td>0</td> <td>0</td> <td>0</td> </tr> <tr> <td>1</td> <td>15.625</td> <td>10</td> <td></td> <td></td> <td></td> </tr> <tr> <td>2</td> <td>31.250</td> <td>20</td> <td>1</td> <td>31.250</td> <td>20</td> </tr> <tr> <td>3</td> <td>46.875</td> <td>30</td> <td></td> <td></td> <td></td> </tr> <tr> <td>4</td> <td>62.500</td> <td>40</td> <td>2</td> <td>62.500</td> <td>40</td> </tr> </tbody> </table>	Base Rate			Subrate			Step	Wall-Clock Time (ms)	Logged Timestamp (ms)	Step	Wall-Clock Time (ms)	Logged Timestamp (ms)	0	0	0	0	0	0	1	15.625	10				2	31.250	20	1	31.250	20	3	46.875	30				4	62.500	40	2	62.500	40
Base Rate			Subrate																																								
Step	Wall-Clock Time (ms)	Logged Timestamp (ms)	Step	Wall-Clock Time (ms)	Logged Timestamp (ms)																																						
0	0	0	0	0	0																																						
1	15.625	10																																									
2	31.250	20	1	31.250	20																																						
3	46.875	30																																									
4	62.500	40	2	62.500	40																																						
Saving simulation output as a single object	Saving the XCP external mode simulation output as a single object is not supported. The simulation produces a warning.

## Graphical Controls for XCP External Mode Simulations

### In this section...

“Equivalent Controls on Hardware Tab and External Mode Control Panel” on page 57-24

“XCP External Mode Control Panel” on page 57-25

“XCP External Signal & Triggering Dialog Box” on page 57-26

You can control an XCP external mode simulation through:

- The **Hardware** tab on the Simulink Editor toolbar. To display the **Hardware** tab, from the **Apps** tab on the Simulink toolstrip, click **Run on Custom Hardware**.
- The External Mode Control Panel. To open this dialog box, on the **Hardware** tab, in the **Prepare** section, click . Then, under **Signal Monitoring & Tracing**, click **Control Panel**.

### Equivalent Controls on Hardware Tab and External Mode Control Panel

This table lists external mode actions that you can perform by using controls that are available in the **Hardware** tab and the External Mode Control Panel.

External Mode Action	Hardware Tab	External Mode Control Panel
Build target application.	<b>Run on Hardware &gt; Build for Monitoring</b> 	N/A
Run application on target hardware.	<b>Run on Hardware &gt; Deploy</b> 	N/A
Connect Simulink to a waiting or running target application.	<b>Run on Hardware &gt; Connect</b> 	<b>Connect</b>
Start real-time execution of generated code in the target environment.	<b>Run on Hardware &gt; Start</b> 	<b>Start Real-Time Code</b>
Disconnect Simulink from the target environment, but do not stop real-time execution of code.	<b>Run on Hardware &gt; Disconnect</b> 	<b>Disconnect</b>
Stop target application execution and disconnect Simulink from the target environment.  If you want to reestablish the external mode connection after stopping the target application, you must perform the <b>Deploy</b> step.	In <b>Run on Hardware</b> section, <b>Stop</b> button  .	<b>Stop Real-Time Code</b>

External Mode Action	Hardware Tab	External Mode Control Panel
Tune batch of block parameters. You can modify values of tunable parameters in Simulink, and then update the parameters in the target application simultaneously. See "Monitor Signal and Tune Parameter".	In <b>Prepare</b> section, <b>Hold Updates</b>  and <b>Update All Parameters</b>  buttons.	<b>Batch download</b> and <b>Download</b>

## XCP External Mode Control Panel

The External Mode Control Panel provides these controls for XCP external mode simulations.

Section	Control	Description
<b>Connection and triggering</b>	<b>Connect</b>	Connect Simulink to a waiting or running target application.  When Simulink is connected to the target application, <b>Connect</b> changes to <b>Disconnect</b> .
	<b>Start Real-Time Code</b>	Start real-time execution of generated code in the target environment.  When the generated code starts executing, the button changes to <b>Stop Real-Time Code</b> .
	<b>Arm Trigger</b>	Arm the trigger that you specify through the External Signal & Triggering dialog box. If Simulink is not connected to the target application, the button appears dimmed.  If Simulink is connected to the target application and the trigger is armed, the button becomes <b>Cancel Trigger</b> .
	<b>Cancel Trigger</b>	Disarm the trigger. Once the trigger is disarmed, the button changes to <b>Arm Trigger</b> .
<b>Floating scope</b>	<b>Enable data uploading</b>	Selecting the check box arms the trigger for uploading target application data to Floating Scope blocks.
	<b>Duration</b>	Not supported.
<b>Parameter tuning</b>	<b>Batch download</b>	To tune a batch of block parameters: <ol style="list-style-type: none"> <li>In the External Mode Control Panel, select <b>Batch download</b>.</li> <li>In the Simulink Editor, modify the required block parameters.</li> <li>When you modify parameters, the External Mode Control Panel displays this message next to <b>Download</b>:  Parameter changes pending...  Simulink stores the modified parameters locally.</li> <li>Click <b>Download</b>. Simulink downloads the batch of modified parameters to the target application.</li> </ol>

Section	Control	Description
	<b>Download</b>	If the <b>Batch download</b> check box is not selected, the button appears dimmed.
<b>Configuration</b>	<b>Signal &amp; Triggering</b>	Open the External Signal & Triggering dialog box.
	<b>Data Archiving</b>	XCP external mode simulations do not support this button, which appears dimmed.

## XCP External Signal & Triggering Dialog Box

For an XCP external mode simulation, you can use the External Signal & Triggering dialog box to:

- Specify the logged signals that you want to monitor.
- Configure a trigger that starts the uploading of data from the target application.

The External Signal & Triggering dialog box provides these controls.

Section	Control	Description
<b>Signal selection</b>	<b>Select all</b>	The <b>Signal selection</b> view lists top-model and referenced-model signals that are configured for logging. Simulink uploads a logged signal for monitoring only if the signal is selected in the <b>Signal selection</b> view. By default, this check box is selected, which enables monitoring of all logged signals.
	<b>Clear all</b>	Deselect the signals that are selected for monitoring. If the <b>Select all</b> check box is selected, this button appears dimmed.
	<b>on, off</b>	If you select a row, clicking <b>on</b> selects the corresponding signal for monitoring. The <b>Selected</b> column displays the letter X. Clicking <b>off</b> deselects the signal. If the <b>Select all</b> check box is selected, these radio buttons appear dimmed.

Section	Control	Description
	<b>Trigger Signal</b>	<p>If you select a row, clicking this button sets the corresponding signal as the trigger for uploading target application data. The <b>Trigger</b> column displays the letter T. If the signal is already selected, clicking this button deselects the signal.</p> <p>If the configuration parameter <code>PurelyIntegerCode</code> is set to 'on', the trigger signal must be a non-complex, <code>int32</code> scalar.</p> <p>If the configuration parameter <code>PurelyIntegerCode</code> is set to 'off', the trigger signal must be a non-complex, <code>double</code> scalar.</p>
	<b>Go To Signal</b>	To locate a signal in the model, select the corresponding row in the <b>Signal selection</b> view and then click this button.
<b>Trigger options</b>	<b>Source</b>	<p>Specify how the trigger is armed:</p> <ul style="list-style-type: none"> <li>• <code>manual</code> (default) — Arm the trigger by selecting the <b>Arm when connecting to target</b> check box or by clicking the <b>Arm Trigger</b> button on the External Mode Control Panel.</li> <li>• <code>signal</code> — Use specific characteristics of the trigger signal to start uploading data.</li> </ul>

Section	Control	Description
	<b>Mode</b>	Specify trigger rearming after a trigger event is complete: <ul style="list-style-type: none"><li data-bbox="1065 386 1464 512">• <b>normal</b> (default) — The external mode simulation rearms the trigger after each trigger event.</li><li data-bbox="1065 525 1464 680">• <b>one-shot</b>— The external mode simulation collects only one buffer of data for each time that you arm the trigger.</li></ul>

Section	Control	Description
	<b>Duration</b>	<p>Specify the number of base rate steps for which the external mode simulation uploads data after a trigger event (default is 1000). For example, if <b>Duration</b> is set to 1000, and the base (fastest) rate of the model is one second:</p> <ul style="list-style-type: none"> <li>• For a signal sampled at the base rate, one second (1.0 Hz), the external mode simulation collects 1000 contiguous samples during a trigger event.</li> <li>• For a signal sampled at two seconds (0.5 Hz), the external mode simulation collects 500 samples during a trigger event.</li> </ul> <p>If <b>Send multiple contiguous samples in same packet</b> is also selected, on the target hardware, the target application:</p> <ol style="list-style-type: none"> <li>1 Stores data samples in a buffer.</li> <li>2 Sends samples from multiple time steps in a packet.</li> </ol> <p>The <b>Duration</b> value, say <code>durationFieldValue</code>, determines the number of samples sent in a packet:</p> $\text{numOfSamplesSent} = \text{durationFieldValue} / n$ <p>where <math>n = (\text{base rate}) / (\text{sample rate})</math></p> <p>When the sample rate is the base rate (<math>n=1</math>), <code>numOfSamples</code> is exactly <code>durationFieldValue</code>. For subrates (<math>n=2, 3, \dots</math>), <code>numOfSamplesSent</code> is rounded down to the nearest integer. The target application discards</p>

Section	Control	Description
		buffer samples that are not sent to Simulink.
	<b>Delay</b>	<p>Apply a delay to data collection, which is the time between a trigger event and the start of data collection expressed in base rate steps. You can specify a positive value or zero (default).</p> <p>An XCP external mode simulation does not support a negative delay (pretriggering).</p>
	<b>Arm when connecting to target</b>	<p>This check box is selected by default. Connecting Simulink to the target application arms the trigger.</p> <ul style="list-style-type: none"> <li>• If the trigger <b>Source</b> is <b>manual</b>, data uploading begins immediately.</li> <li>• If the trigger <b>Source</b> is <b>signal</b>, monitoring of the trigger signal begins immediately. Data uploading begins when the trigger signal satisfies trigger conditions (as defined in the <b>Trigger signal</b> section).</li> </ul> <p>If you clear the check box, you can arm the trigger by clicking the <b>Arm Trigger</b> button on the External Mode Control Panel.</p>
	<b>Send multiple contiguous samples in same packet</b>	<p>This check box is not selected by default.</p> <p>If you select the check box, the XCP server uses the XCP DAQ packed mode for streaming signals to Simulink, which improves the ratio of useful data to control data in streamed signals.</p> <p>The target application sends samples from multiple time steps in a packet. The <b>Duration</b> value determines the number of samples in the packet.</p>

Section	Control	Description
<b>Trigger signal</b>	<b>Direction</b>	<p>To enable the uploading of data from the target application when the trigger signal crosses the threshold value (specified by <b>Level</b>), specify the required direction of the signal:</p> <ul style="list-style-type: none"> <li>• <b>rising</b> (default) — Signal must be increasing in value.</li> <li>• <b>falling</b> — Signal must be decreasing in value.</li> <li>• <b>either</b> — Signal can be increasing or decreasing in value.</li> </ul>
	<b>Level</b>	Specify the threshold value that the signal must cross to start the uploading of target application data. Default is 0.
	<b>Hold-off</b>	Specify, in base rate steps, the time between the termination of one trigger event and the rearming of the trigger. Applies only when <b>Mode</b> value is normal. Default is 0.

## Set Up Connectivity Between Simulink and Target Hardware

For external mode simulations, you can use the `target` Package to provide connectivity between Simulink and your target hardware.

This diagram gives an overview of the components of an external mode simulation.

The target package provides classes for the implementation of components. This table lists the main classes.

Component	Class	Purpose
Target hardware	<code>target.Board</code>	Provide MATLAB with a description of target hardware.
Deployment tools	<code>target.SystemCommandExecutionTool</code> <code>target.ExecutionService</code>	You can use the classes to: <ul style="list-style-type: none"> <li>• Capture system commands for running the target</li> </ul>

Component	Class	Purpose
	<code>target.ExecutionTool</code>	<p>application from your development computer.</p> <ul style="list-style-type: none"> <li>Describe the execution service implementation for the target application.</li> <li>Provide the MATLAB service interface for the tool that manages the target application execution.</li> </ul> <p>To provide <b>Monitor &amp; Tune, Deploy, Connect, and Start</b> functionality, the Run on Custom Hardware app requires the use of <code>target.ExecutionTool</code>.</p>
Connectivity	<code>target.ExternalMode</code>	Provide communication protocol for data transfer between Simulink and target hardware.
	<code>target.CommunicationInterface</code>	Provide target hardware with details of the communication channel and the <code>rtiostream</code> API on page 84-16 implementation.

## Customise Connectivity for XCP External Mode Simulations

For code that is generated by using ERT (`ert.tlc`) and GRT (`grt.tlc`) system target files, you can run external mode simulations that use the XCP communication protocol:

- On your development computer.
- On other target hardware by using support packages.

If your system target file for custom target hardware is derived from the ERT or GRT system target files, use classes from the `target` Package to customise connectivity. For example, `target.ExternalMode` and `target.CommunicationInterface`.

This example shows how you can customise connectivity for XCP-based external mode simulations. To set up connectivity between Simulink and the target hardware:

### 1 Create board description

Create a `target.Board` object that provides MATLAB with a description of your target hardware. To support code generation, associate the object with a processor.

```
processor = target.get('Processor', 'Intel-x86-64 (Windows64)');
board = target.create('Board', ...
 'Name', 'Example Intel Board', ...
 'Processors', processor);
```

## 2 Choose deployment tool

Use one of these classes:

- `target.ExecutionTool` -- Provides the `getApplicationStatus` method, which is required by the Run on Custom Hardware app for **Monitor & Tune**, **Deploy**, **Connect**, and **Start** functionality.
- `target.SystemCommandExecutionTool` -- The `getApplicationStatus` method is not available with this class. The **Monitor & Tune**, **Deploy**, **Connect**, and **Start** functionality of the Run on Custom Hardware app is not fully supported.

In step 3 and step 4, the availability of a tool that can download the target application onto the target hardware is assumed.

## 3 Using `target.ExecutionTool`

Implement the MATLAB service interface in a class called `MyImplementationClass`. For an example pseudocode implementation, see “Execution Tool Template” on page 57-38.

```
classdef MyImplementationClass < target.ExecutionTool
 properties (Access=private)
 ...
 end

 methods
 ...
 end

 methods (Access=private)
 ...
 end
end
```

Create a `target.ExecutionService` object that contains details about executing the target application. The object describes the tool that is required to run the target application on the target hardware.

```
matlabExecution = ...
 target.create('ExecutionService', ...
 'Name', 'My Application Launcher');
matlabExecution.APIImplementation = ...
 target.create('APIImplementation', ...
 'Name', 'MyServiceImplementation');
matlabExecution.APIImplementation.BuildDependencies = ...
 target.create('MATLABDependencies');
matlabExecution.APIImplementation.BuildDependencies.Classes = ...
 {'MyImplementationClass'};
matlabExecution.APIImplementation.API = ...
 target.get('API', 'ExecutionTool');
```

Associate the `target.ExecutionService` object with the `target.Board` object.

```
board.Tools.ExecutionTools = matlabExecution;
```

## 4 Using `target.SystemCommandExecutionTool`

Create a `target.SystemCommandExecutionTool` object that captures system commands for running the target application from your development computer.

```

executionTool = target.create('SystemCommandExecutionTool', ...
 'Name', 'My Execution Tool');
executionTool.StartCommand.String = 'customDownloadTool';
executionTool.StartCommand.Arguments = {'$(EXE)'};

```

Associate the `target.SystemCommandExecutionTool` object with the `target.Board` object.

```
board.Tools.ExecutionTools = executionTool;
```

## 5 Create communication interface for target hardware

Create a `target.CommunicationInterface` object that provides the target hardware with details of the communication channel and the `rtiostream` API on page 82-44 implementation.

For the `rtiostream` API, use a `BuildDependencies` object to specify the source files that are compiled with the target application. This example uses the shipped TCP/IP `rtiostream` implementation source file, which enables you to run external mode simulations on your development computer. For your target hardware, provide your own `rtiostream` implementation.

```

buildDependencies = target.create('BuildDependencies', ...
 'SourceFiles', ...
 {fullfile('$(MATLAB_ROOT)', ...
 'toolbox', 'coder', ...
 'rtiostream', ...
 'src', ...
 'rtiostreamtcpip', ...
 'rtiostream_tcpip.c')});

apiImplementation = target.create('APIImplementation', ...
 'Name', 'TCP x86 RTIOStream Implementation', ...
 'API', target.get('API', 'rtiostream'), ...
 'BuildDependencies', buildDependencies);

tcpComms = target.create('CommunicationInterface', ...);
 'Name', 'Windows TCP Interface', ...
 'Channel', 'TCPChannel', ...
 'APIImplementations', apiImplementation);

```

To specify a TCP channel, this example uses the name-value argument `'Channel'`, `'TCPChannel'`. You can specify a serial communication channel by using the name-value argument `'Channel'`, `'RS232Channel'`.

Associate the `target.CommunicationInterface` object with the `target.Board` object.

```
board.CommunicationInterfaces = tcpComms;
```

## 6 Specify communication protocol stack

Create an object that provides the communication protocol for data transfer between Simulink and target hardware.

- a Use the `target.XCPPlatformAbstraction` class to utilize your custom implementation of the XCP platform abstraction layer. The layer provides a static memory allocator and other platform abstraction functionality.

```

xcpPlatformAbstraction = target.create('XCPPlatformAbstraction', ...
 'Name', 'XCP Platform Abstraction');

xcpPlatformAbstraction.BuildDependencies.Defines = {'XCP_CUSTOM_PLATFORM'};
customPlatformAbstractionPath = 'pathToImplementationFolder';
xcpPlatformAbstraction.BuildDependencies.SourceFiles = ...
 {fullfile(customPlatformAbstractionPath, 'myXCPPlatform.c')};
xcpPlatformAbstraction.BuildDependencies.IncludePaths = ...
 {customPlatformAbstractionPath};

```

- b** Use the `target.XCPTCPIPTransport` class to implement the XCP transport layer, which transmits and receives messages from the communication medium according to ASAM specifications. In this example, the transport protocol is TCP/IP. For serial transport, replace `target.XCPTCPIPTransport` with `target.XCPSerialTransport`.

```
xcpTransport = target.create('XCPTCPIPTransport', ...
 'Name', 'XCP Transport');
```

- c** Create a `target.XCP` object that represents the XCP protocol stack for the target hardware.

```
xcpConfiguration = target.create('XCP', ...
 'Name', 'XCP Configuration', ...
 'XCPTransport', xcpTransport, ...
 'XCPPlatformAbstraction', xcpPlatformAbstraction);
```

- d** Create an object that represents the XCP external mode connectivity options that are available in the XCP protocol stack.

```
extModeConnectivity = ...
 target.create('XCPEXternalModeConnectivity', ...
 'Name', 'External Mode Connectivity', ...
 'XCP', xcpConfiguration);
```

- e** Create an external mode protocol stack object.

```
externalMode = target.create('ExternalMode', ...
 'Name', 'External Mode', ...
 'Connectivities', extModeConnectivity);
```

---

**Note** You can create the object in a single call to `target.create`.

```
externalMode = target.create('ExternalMode', ...
 'Name', 'External Mode', ...
 'XCPTransportLayer', 'TCP', ...
 'Defines', {'XCP_CUSTOM_PLATFORM'}, ...
 'SourceFiles', {fullfile('pathToImplementationFolder', 'myXCPPlatform.c')}, ...
 'IncludePaths', {'pathToImplementationFolder'});
```

---

- f** Add the object to the list of communication protocols that the target hardware supports.

```
board.CommunicationProtocolStacks = externalMode;
```

## 7 Make board object persist across MATLAB sessions

Add the board object to an internal database and make the object persist over MATLAB sessions.

```
target.add(board, 'UserInstall', true);
```

## 8 Select board for model

In the Configuration Parameters dialog box, set **Hardware board** to Example Intel Board.

## 9 Specify connection between Simulink and target hardware

In the Configuration Parameters dialog box:

- From the **Transport layer** list, select XCP on TCP/IP. The transport protocol is in the list because of the connectivity customization.
- In the **Mex-file arguments** field, enter 'localhost' 1 0. For more information, see “MEX-file arguments”.

## Customize Connectivity for TCP/IP or Serial External Mode Simulations

For TCP/IP or serial external mode simulations, you can customize connectivity through a workflow that:

- Implements transport and communication protocols.
- Specifies the execution tool for the target application by using the `target Package` package.

To set up connectivity between Simulink and the target hardware, use the workflow described in “Customise Connectivity for XCP External Mode Simulations” with these differences:

- After step 1, using the information in “Choose Communication Protocol for Client and Server” on page 57-75 and “Create a Transport Layer for TCP/IP or Serial External Mode Communication” on page 57-90, implement the client and server sides of external mode communication for TCP/IP or serial protocols.
- Do not perform step 5 and step 6.

## Execution Tool Template

This section provides a pseudocode example for a `target.ExecutionTool` service interface. The tool starts and tracks an application on the target hardware.

```
classdef MyExecutionTool < target.ExecutionTool
 methods
 function errFlag = startApplication(this)
 % Call "customDownloadTool" to download the application.
 [status, result] = ...
 system(sprintf('customDownloadTool %s', this.Application));
 if status == 0
 errFlag = false;
 else
 disp(result);
 errFlag = true;
 end
 end

 function errFlag = stopApplication(~)
 % Add code here to stop the application, if possible.
 errFlag = false;
 end

 function [status, errFlag] = getApplicationStatus(~)
 % Add code here to return the application status, if known.
 status = target.ApplicationStatus.Unknown;
 errFlag = false;
 end
 end
end
```

- <https://www.asam.net/standards/detail/mcd-1-xcp/wiki/>

## Register Custom Launcher

---

**Note** The use of a custom launcher to set up connectivity between Simulink and your target hardware is not recommended. Use the `target` package instead. For more information, see “Set Up Connectivity Between Simulink and Target Hardware” on page 57-32

---

To support the one-click workflow or **Deploy** step for custom hardware, register your custom launcher for the target application.

- 1 Create an `rtw.connectivity.Config` subclass, which requires `myCustomLauncher`, a launcher that you provide. `myCustomLauncher` is a subclass of `rtw.connectivity.Launcher`. In `myCustomLauncher`, to support one-click functionality, provide an implementation of the `getApplicationStatus` method. For the communicator and builder subclasses, you can use dummy classes.

```
classdef myTargetConnectivityConfig < rtw.connectivity.Config
 methods
 % Constructor
 function this = myTargetConnectivityConfig(componentArgs)

 % Launcher with port 0 argument to start TCP/IP server on free port
 modelName = componentArgs.getModelName();
 bDirInfo = RTW.getBuildDir(modelName);
 exeName = fullfile(bDirInfo.CodeGenFolder, modelName);
 if ispc
 exeName = [exeName, '.exe'];
 end
 launcher = myCustomLauncher(componentArgs);
 launcher.setExe(exeName);

 % Create dummy communicator and builder
 communicator = rtw.connectivity.RtIOStreamHostCommunicator.empty();
 builder = rtw.connectivity.MakefileBuilder.empty();

 % Call super class constructor to register components
 this@rtw.connectivity.Config(componentArgs, builder, launcher, communicator);
 end
 end
end
```

- 2 To register the implementation in Simulink, create an `sl_customization.m` file.

```
function sl_customization(cm)
 cm.registerTargetInfo(@loc_createConfig);
end
% local function
function config = loc_createConfig
 config = rtw.connectivity.ConfigRegistry;
 config.ConfigClass = 'myTargetConnectivityConfig';

 % Specify compatible model configuration. For example,
 % through SystemTargetFile and TargetHWDeviceType properties.
 config.SystemTargetFile = {'ert.tlc'};
 config.TargetHWDeviceType = {'ARM Compatible->ARM Cortex'};
end
```

See “Create `sl_customization.m` File”.

- 3 Add the folder containing `sl_customization.m` to the search path and refresh your customizations.

```
addpath(sl_customization_path);
sl_refresh_customizations;
```

- “Customize XCP Server Software” on page 57-42

## Customize XCP Server Software

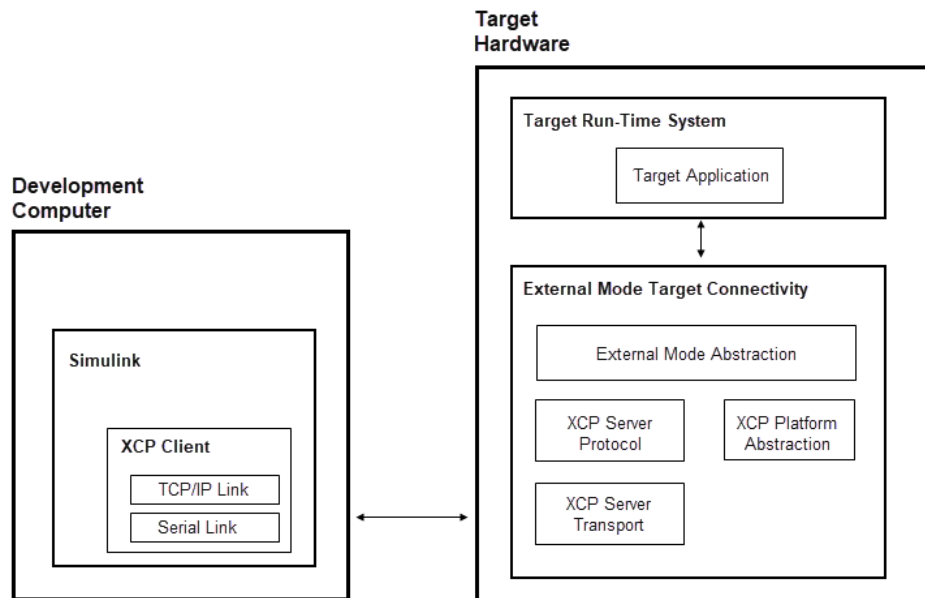

The XCP communication protocol for Simulink external mode simulations is a client-server communication protocol. By default, the software supports XCP external mode simulations:

- On your development computer for code that is generated by using ERT (`ert.tlc`) and GRT (`grt.tlc`) system target files.
- For some support packages on page 57-2.

If your system target file for custom target hardware is derived from the ERT or GRT system target files, you can use supplied APIs to provide XCP target connectivity. XCP external mode limitations on page 57-20 apply.

The external mode target connectivity software comprises:

- External mode abstraction layer
- XCP server protocol layer
- XCP server transport layer
- XCP platform abstraction layer

## External Mode Abstraction Layer

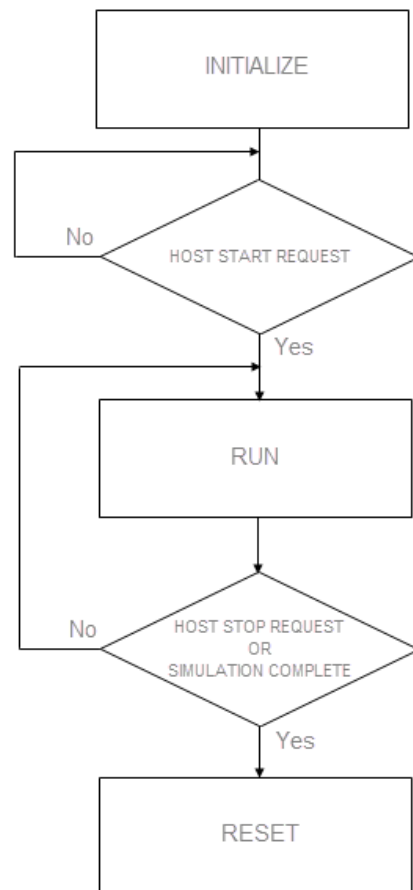

To communicate with Simulink during an external mode simulation, your target application must invoke functions from the external mode abstraction layer.

The parent folder for source code files is:

```
matlabroot\toolbox\coder\xcp\src\target\ext_mode
```

The layer APIs are declared in `include\ext_mode.h` and implemented in `src\xcp_ext_mode.c`.

To communicate with Simulink, the target application uses services exposed by the external mode abstraction layer. This flow chart shows the required target application steps to establish communication with Simulink.

This table lists the functions that your target application must invoke at each stage.

Stage	Function	Purpose
INITIALIZE	<code>extmodeParseArgs</code>	Extract external mode command-line arguments.
	<code>modelName_initialize</code>	Initialize generated Simulink model code.
	<code>extmodeInit</code>	Initialize external mode target connectivity.
HOST START REQUEST	<code>extmodeWaitForHostRequest</code>	Wait for a start request from development computer, which is created when you click Run button.
RUN	<code>modelName_step</code>	Run single step of generated Simulink model code.
	<code>extmodeEvent</code>	For sample time ID of the model, sample signals generated by model step function and pass packet content to transport layer of communication protocol for transmission to development computer.
	<code>extmodeBackgroundRun</code>	Transmit and receive packet from physical communication interface and process packet content in accordance with selected communication protocol.
HOST STOP REQUEST OR SIMULATION COMPLETE	<code>extmodeStopRequested</code>	Check whether a request to stop external mode simulation is received from the model on the development computer. The request is created when you click the Stop button.
	<code>extmodeSimulationComplete</code>	Check whether execution of generated model code is complete.
RESET	<code>modelName_terminate</code>	Terminate generated Simulink model code.
	<code>extmodeReset</code>	Reset the external mode target connectivity to initial state.

This pseudo-code example shows how you can implement the various flowchart stages in your target application. During the RUN stage, the external mode run-time environment requires at least two threads:

- A periodic thread that is responsible for the execution of the generated model code.
- A background thread that is responsible for running the external mode communication stack and transmitting and receiving packets.

The pseudo-code simulates multithreading by running `periodicThread` and `extmodeBackgroundRun` sequentially within the same `while()` loop.

```

/*----- Pseudo-Code Example -----*/
/* Define periodic thread */
void periodicThread(void)
{
 /* Run model step function */

```

```

 modelName_step();
 /* Notify external mode abstraction layer about periodic event */
 extmodeEvent(PERIODIC_EVENT_ID, currentSimulationTime);
}

/* Main function for target application */
main(int argc, char *argv[])
{
 /*----- INITIALIZE -----*/
 /* Parse external mode command line arguments */
 extmodeParseArgs(argc, argv);

 /* Initialize model */
 modelName_initialize();

 /* Initialize external mode target connectivity */
 extmodeInit(extModeInfo, finalSimulationTime);

 /*----- HOST START REQUEST -----*/
 /* Wait until a start request is received from development computer */
 extmodeWaitForHostRequest(EXTMODE_WAIT_FOREVER);

 /*----- HOST STOP REQUEST OR SIMULATION COMPLETE -----*/
 /* While simulation is not complete and stop request is not received */
 while (!extmodeSimulationComplete() && !extmodeStopRequested()) {

 /*----- RUN -----*/
 periodicThread();
 extmodeBackgroundRun();
 }

 /*----- RESET -----*/
 /* Terminate model */
 modelName_terminate();

 /* Reset external mode target connectivity */
 extmodeReset();
 return 0;
}

```

To see code that invokes the functions, complete the example in “External Mode Simulation by Using XCP Communication” on page 57-7 with **System target file** set to `ert.tlc`. Then, from the code generation folder, open `ert_main.c`.

---

**Note** If your system target file is `grt.tlc` or GRT-based, the code generator creates `rt_main.c`, and, by default, uses API defined by the internal file `ext_work.h`. To enable the use of `ext_mode.h` API, before building the target application, run:

```
set_param(model, 'TLCOptions', '-aExtModeXCPClassicInterface=0');
```

If your system target file is `ert.tlc` or ERT-based and `GenerateSampleERTMain` is set to 'on', the code generator creates `ert_main.c` and, by default, uses API defined by `ext_mode.h`. To enable the use of `ext_work.h` API, before building the target application, run:

```
set_param(model, 'TLCOptions', '-aExtModeXCPClassicInterface=1');
```

---

## XCP Server Protocol Layer

The XCP server protocol layer interprets XCP commands and data according to the Association for Standardisation of Automation and Measuring Systems (ASAM) standard, ASAM MCD-1 XCP.

The source code folder is:

```
matlabroot\toolbox\coder\xcp\src\target\slave\protocol\src
```

In an external mode simulation, the build process automatically adds the required files to the build information object.

## XCP Server Transport Layer

The XCP server transport layer transmits and receives messages from the communication medium according to ASAM specifications.

The source folder is:

```
matlabroot\toolbox\coder\xcp\src\target\slave\transport\src
```

In an external mode simulation, the build process automatically adds the required files to the build information object.

## XCP Platform Abstraction Layer

The XCP platform abstraction layer provides:

- An XCP driver on page 57-46 for sending and receiving raw data through the physical communication interface.
- The implementation of a static memory allocator on page 57-46.
- Other target hardware-specific functionality.

For a customization example, see “Create Custom Abstraction Layer” on page 57-50.

## XCP Driver

The XCP driver sends and receives XCP messages through the communication channel. In an external mode simulation, the build process automatically adds the driver files to the build information object.

The XCP driver is based on the `rtiostream` API. For example, host-based external mode simulations use these `rtiostream` files:

- *matlabroot*\toolbox\coder\rtiostream\src\rtiostreamtcpip\rtiostream\_tcpip.c
- *matlabroot*\toolbox\coder\rtiostream\src\rtiostreamserial\rtiostream\_serial.c

For details on implementing and testing an `rtiostream` communications channel, see:

- “Communications `rtiostream` API” on page 82-44
- `rtiostreamtest`

For a custom platform abstraction layer, you must add your `rtiostream` files to the build information object. For an example, see “Create Custom Abstraction Layer” on page 57-50.

## Memory Allocator

The XCP server software requires the dynamic allocation of variable-size, contiguous memory blocks to hold internal data structures.

In an external mode simulation, the build process automatically adds memory allocator files to the build information object.

The `xcpMemBlockSizes` and `xcpMemBlockCounts` preprocessor macros define memory allocation.

The default memory allocator can allocate and deallocate up to 16 different sets of memory blocks. For each set, you can override the default allocations during compilation. You can specify:

- The block size through the `XCP_MEM_BLOCK_N_SIZE` preprocessor macro.
- The number of blocks in each set through the `XCP_MEM_BLOCK_N_NUMBER` preprocessor macro.

For example, these preprocessor macros create four blocks of 64 bytes and eight blocks of 256 bytes.

```
#define XCP_MEM_BLOCK_1_SIZE 64
#define XCP_MEM_BLOCK_1_NUMBER 4
#define XCP_MEM_BLOCK_2_SIZE 256
#define XCP_MEM_BLOCK_2_NUMBER 8
```

Configure the block sizes of the different sets in ascending order:

```
XCP_MEM_BLOCK_N_SIZE < XCP_MEM_BLOCK_N+1_SIZE
```

The smallest block size, `XCP_MEM_BLOCK_1_SIZE`, must be large enough to hold a pointer.

Configure alignment for the memory allocator through the `XCP_MEM_ALIGNMENT` preprocessor macro. For example:

```
#define XCP_MEM_ALIGNMENT 8
```

### Other Platform Abstraction Layer Functionality

This file defines the platform abstraction layer interface:

```
matlabroot\toolbox\coder\xcp\src\target\slave\platform\include\xcp_platform.h
```

To implement custom platform abstraction layer functionality, add the `XCP_CUSTOM_PLATFORM` preprocessor macro to the build information object. Provide the implementation of the custom functionality in a file named `xcp_platform_custom.h`. If you do not define `XCP_CUSTOM_PLATFORM`, the build process uses default files that support Linux and Windows systems.

This table describes the functionality that you must provide for the XCP server software that you deploy on your target hardware.

Functionality	Details
Mutual exclusion	<p>To access system data structures with <i>mutual exclusion</i> support, the XCP driver depends on basic APIs for definition, initialization, lock, and unlock.</p> <p>To support mutual exclusion for your target hardware, provide a custom implementation.</p> <p>The default implementation for Linux and Windows supports mutual exclusion.</p> <pre data-bbox="589 590 1266 919"> #if defined(_WIN32)    defined(__WIN32__)    defined(WIN32) ... #define XCP_MUTEX_DEFINE(lock) HANDLE lock #define XCP_MUTEX_INIT(lock) lock = CreateMutex(0, FALSE, 0) #define XCP_MUTEX_LOCK(lock) WaitForSingleObject((lock), INFINITE) #define XCP_MUTEX_UNLOCK(lock) ReleaseMutex(lock) #else ... #include &lt;pthread.h&gt; #define XCP_MUTEX_DEFINE(lock) pthread_mutex_t lock #define XCP_MUTEX_INIT(lock) pthread_mutex_init(&amp;(lock), NULL) #define XCP_MUTEX_LOCK(lock) pthread_mutex_lock(&amp;(lock)) #define XCP_MUTEX_UNLOCK(lock) pthread_mutex_unlock(&amp;(lock)) ... #endif </pre>
Sleep	<p>Provide a sleep API that makes the calling thread sleep until a specified time has elapsed. The default implementation for Linux and Windows systems is:</p> <pre data-bbox="589 1041 1450 1392"> #if defined(_WIN32)    defined(__WIN32__)    defined(WIN32) ... #define XCP_SLEEP(seconds,microseconds) Sleep((seconds) * 1000 \ + ((microseconds) + 1000 - 1) / 1000) #else ... #if _POSIX_C_SOURCE &gt;= 199309L #define XCP_SLEEP(seconds,microseconds) do {struct timespec t;\ t.tv_sec = seconds; t.tv_nsec = microseconds * 1000; nanosleep(&amp;t, NULL);} while(0) #else /* nanosleep is not available. Use select instead. */ #define XCP_SLEEP(seconds,microseconds) do {struct timeval t; t.tv_sec = seconds;\ t.tv_usec = microseconds; select(0, NULL, NULL, NULL, &amp;t);} while(0) #endif /* _POSIX_C_SOURCE &gt;= 199309L */ ... #endif </pre>
Logging	<p>To generate diagnostic messages, the XCP server software requires a custom print API that supports logging services provided by the target hardware. If you do not define the <code>XCP_PRINTF</code> preprocessor macro, the default implementation is empty.</p>

Functionality	Details
Address conversion	<p>The XCP standard expresses the address of a variable in memory as a 32-bit address with an 8-bit extension.</p> <p>The XCP client extracts the addresses of signals and parameters of the model by parsing the debug information that the build process creates. The debug information is in DWARF or PDB format.</p> <p>The XCP client requests access to parameters and signals by sending an XCP command that contains the arguments <code>addressExtension</code> and <code>address</code>.</p> <p>When <code>addressExtension</code> and <code>address</code> information is received by the target hardware, the XCP server must convert the address to the location of the variable in the target hardware memory. The variable location is assigned by the loader and is target-specific.</p> <p>Use the <code>XCP_ADDRESS_GET()</code> macro to specify the conversion logic. The default implementation for Linux and Windows systems is:</p> <pre data-bbox="589 863 1122 1003">#if defined(__MINGW32__)    defined(__MINGW64__) #define XCP_ADDRESS_GET(addressExtension, address) \ (uint8_T*) ((uintptr_t) address) #else #define XCP_ADDRESS_GET(addressExtension, address) \ (uint8_T*) ((address) + (uint8_T*)&amp;_ImageBase) #endif</pre> <p>Currently, only 32-bit hardware architectures are supported, so <code>addressExtension</code> is 0.</p>
Set and copy memory	<p>You can specify an optimized version of copy memory and set memory operations.</p> <p>If you do not define the <code>XCP_MEMCPY</code> and <code>XCP_MEMSET</code> preprocessor macros, the default implementation specifies the standard C functions, <code>memcpy</code> and <code>memset</code>.</p> <pre data-bbox="589 1304 846 1444">#ifndef XCP_MEMCPY #define XCP_MEMCPY memcpy #endif  #ifndef XCP_MEMSET #define XCP_MEMSET memset #endif</pre>
Parsing command-line arguments	<p>If your target hardware does not support the parsing of command-line arguments, define the preprocessor macro <code>EXTMODE_DISABLE_ARGS_PROCESSING</code>.</p> <p>To replace the <code>-w</code> option, you can use this command to specify that the target application enters and stays in a wait state until it receives a Connect message from Simulink:</p> <pre data-bbox="589 1696 1321 1728">set_param(modelName, 'OnTargetWaitForStart', 'on');</pre> <p>The build process provides the required option (<code>-DON_TARGET_WAIT_FOR_START=1</code>) to the compiler.</p>

Functionality	Details
Structure packing and alignment	<p>The XCP software stack implementation requires the packing and alignment of some internal C structures. In the platform abstraction layer, provide packing and alignment information by using preprocessor directives that are compiler-specific.</p> <p>To pack and align C structures, provide these preprocessor directives:</p> <pre>#define XCP_PRAGMA_PACK_BEGIN(n) #define XCP_PRAGMA_PACK_END() #define XCP_ATTRIBUTE_ALIGNED(n) #define XCP_ATTRIBUTE_PACKED</pre> <p>For example:</p> <pre>XCP_PRAGMA_PACK_BEGIN(1) typedef struct XCP_ATTRIBUTE_PACKED XcpSetDaqListModeCmdPacketFrame {     uint8_T    PID;          /* Packet identifier, always XCP_PID_SET_DAQ_LIST_MODE */     uint8_T    mode;        /* DAQ list mode (XCP DAQ Mode bit masks) */     uint16_T   daqListId;   /* DAQ list Id */     uint16_T   eventId;     /* Event Channel Id */     uint8_T    prescaler;   /* Transmission rate prescaler */     uint8_T    priority;    /* DAQ list priority (0xFF -&gt; highest) */ } XcpSetDaqListModeCmdPacketFrame; XCP_PRAGMA_PACK_END()</pre> <pre>XCP_PRAGMA_PACK_BEGIN(XCP_MEM_ALIGNMENT) struct XCP_ATTRIBUTE_ALIGNED(XCP_MEM_ALIGNMENT) xcpFifoEntry {     struct xcpFifoEntry *next;     size_t msgFrameSize;    /* in AG units */ }; XCP_PRAGMA_PACK_END()</pre> <p>For a GCC compiler, use these directives:</p> <pre>#define XCP_PRAGMA_PACK_BEGIN(n) #define XCP_PRAGMA_PACK_END() #define XCP_ATTRIBUTE_ALIGNED(n)    __attribute__((aligned(n))) #define XCP_ATTRIBUTE_PACKED       __attribute__((packed))</pre> <p>For a Microsoft Visual C++ compiler, use these directives:</p> <pre>#define PRAGMA(n)    _Pragma(#n) #define XCP_PRAGMA_PACK_BEGIN(n)    PRAGMA(pack(push, n)) #define XCP_PRAGMA_PACK_END()       PRAGMA(pack(pop)) #define XCP_ATTRIBUTE_ALIGNED(n) #define XCP_ATTRIBUTE_PACKED</pre>

### Create Custom Abstraction Layer

For the build process, you can define a post-code generation command that creates a custom platform abstraction layer.

- 1 Specify the header file `xcp_platform_custom.h`. This Linux example defines the required functions.

```
#ifndef XCP_PLATFORM_CUSTOM_H
#define XCP_PLATFORM_CUSTOM_H

/* XCP_ADDRESS_GET */
#include <stdint.h>
#define XCP_ADDRESS_GET(addressExtension, address) (uint8_T*) ((uintptr_t) address)

/* XCP_MUTEX */
#include <pthread.h>
```

```

#define XCP_MUTEX_DEFINE(lock) pthread_mutex_t lock
#define XCP_MUTEX_INIT(lock) pthread_mutex_init(&(lock), NULL)
#define XCP_MUTEX_LOCK(lock) pthread_mutex_lock(&(lock))
#define XCP_MUTEX_UNLOCK(lock) pthread_mutex_unlock(&(lock))

/* XCP_SLEEP */
#include <sys/time.h> /* gettimeofday */
#if _POSIX_C_SOURCE >= 199309L
#include <time.h> /* for nanosleep */
#else
#include <stddef.h>
#include <sys/select.h> /* for select */
#endif

/* _POSIX_C_SOURCE >= 199309L */
#if _POSIX_C_SOURCE >= 199309L
#define XCP_SLEEP(seconds,microseconds) do {struct timespec t;\
 t.tv_sec = seconds; t.tv_nsec = microseconds * 1000; nanosleep(&t, NULL);} while(0)
#else
/* nanosleep is not available. Use select instead. */
#define XCP_SLEEP(seconds,microseconds) do {struct timeval t; t.tv_sec = seconds;\
 t.tv_usec = microseconds; select(0, NULL, NULL, NULL, &t);} while(0)
#endif /* _POSIX_C_SOURCE >= 199309L */
#endif

```

## 2 Define the post-code generation command.

```

function myXCPTargetPostCodeGenCommand(buildInfo)

 buildInfo.addDefines('-DXCP_CUSTOM_PLATFORM', 'OPTS');

 % Configure the default memory allocator
 buildInfo.addDefines('-DXCP_MEM_BLOCK_1_SIZE=64', 'OPTS');
 buildInfo.addDefines('-DXCP_MEM_BLOCK_1_NUMBER=46', 'OPTS');
 buildInfo.addDefines('-DXCP_MEM_BLOCK_2_SIZE=256', 'OPTS');
 buildInfo.addDefines('-DXCP_MEM_BLOCK_2_NUMBER=10', 'OPTS');

 % Add my rtiostream
 buildInfo.addSourceFiles(customRtIOStreamFileName, ...
 customRtIOStreamSrcPath);

 % If the target hardware does not support parsing of command
 % line arguments
 buildInfo.addDefines('-DEXTMODE_DISABLE_ARGS_PROCESSING', 'OPTS');

end

```

## More About

- “External Mode Simulations for Parameter Tuning and Signal Monitoring” on page 57-2
- “External Mode Simulation by Using XCP Communication” on page 57-7

## External Websites

- <https://www.asam.net/standards/detail/mcd-1-xcp/wiki/>

## External Mode Simulation with TCP/IP or Serial Communication

Set up and run an external mode simulation that uses a TCP/IP or serial (RS-232) communication channel.

- 1 Create and configure a simple model.
- 2 Build the target executable file.
- 3 Run the target application.
- 4 Tune parameters.

The example, which uses the GRT target, does not require external hardware. The generated executable file runs:

- On the development computer that hosts Simulink and Simulink Coder.
- As a separate process from MATLAB and Simulink.

### Create and Configure Model

In this part of the example, you create a simple model, `ex_extModeExample`. You also create a folder called `ext_mode_example` to store the model and the generated executable.

To create the folder and the model:

- 1 From the MATLAB command line, type:

```
mkdir ext_mode_example
```

- 2 Make `ext_mode_example` your working folder:

```
cd ext_mode_example
```

- 3 Create a model in Simulink with a Sine Wave block for the input signal, two Gain blocks in parallel, and two Scope blocks. Be sure to label the Gain and Scope blocks as shown.

- 4 Define and assign two MATLAB workspace variables, A and B:

```
A = 2;
B = 3;
```

- 5 Open Gain block A and set its **Gain** parameter to the variable A.

- 6 Open Gain block B and set its **Gain** parameter to the variable B.

When the target application is built and connected to Simulink in external mode, you can download new gain values to the executing target application. To do this, you can assign new values to workspace variables A and B, or edit the values in the block parameters dialog box. For more information, see “Tune Parameters” on page 57-55.

- 7 Verify operation of the model. Open the Scope blocks and run the model. When  $A = 2$  and  $B = 3$ , the output appears as shown.

- 8 Save the model as ex\_extModeExample.

## Build Target Executable

Set up the model and code generation parameters required for an external mode target application. Then, generate code and build the target application.

- 1 From the **Apps** tab on the Simulink toolstrip, in the **Setup to Run on Hardware** section, click **Run on Custom Hardware**.
- 2 In the **Hardware** section, from the **System Target File Description** list, select **Generic Real-Time Target (grt.tlc)**.
- 3 In the **Prepare** section, click **Hardware Settings**. The Configuration Parameters dialog box opens, displaying **Hardware Implementation** settings that are determined by the system target file.
- 4 On the **Solver** pane:
  - a In the **Type** field, select **Fixed-step**.
  - b In the **Solver** field, select **discrete (no continuous states)**.
  - c Click **Solver details**. In the **Fixed-step size** field, specify **0.1**. (Otherwise, when you generate code, the Simulink Coder build process produces a warning and supplies a value.)
  - d Click **Apply**.
- 5 On the **Data Import/Export** pane, clear the **Time** and **Output** check boxes. In this example, data is not logged to the workspace or to a MAT-file. Click **Apply**.
- 6 On the **Code Generation > Optimization** pane, check that **Default parameter behavior** is set to **Tunable**. If you make a change, click **Apply**.
- 7 On the **Code Generation > Interface** pane, in the **Data exchange interface** section, select **External mode**.
- 8 In the **External mode configuration** section, make sure that the default value **tcip** is selected for the **Transport layer** parameter.

External mode

External mode configuration

Transport layer:  MEX-file name:

MEX-file arguments:

Static memory allocation

External mode supports communication via TCP/IP, serial, and custom transport protocols. The **MEX-file name** specifies the name of a MEX-file that implements host-target communication. The default for TCP/IP is `ext_comm`, a MEX-file provided with the Simulink Coder software. You can override this default by supplying other files. If you need to support other transport layers, see “Create a Transport Layer for TCP/IP or Serial External Mode Communication”.

The **MEX-file arguments** field lets you specify arguments, such as a TCP/IP server port number, to be passed to the external interface program. These arguments are specific to the external interface that you are using. For information on setting these arguments, see “MEX-File Optional Arguments for TCP/IP Transport” and “MEX-File Optional Arguments for Serial Transport”.

This example uses the default arguments. Leave the **MEX-file arguments** field blank.

The **Static memory allocation** check box controls how memory is allocated for external mode communication buffers in the target. For this example, do not select the check box. For more information, see “Control Memory Allocation for Communication Buffers in Target” on page 57-58.

- 9 Click **Apply** to save the external mode settings.
- 10 Save the model.
- 11 Select the **Code Generation** pane. Make sure that **Generate code only** is cleared.
- 12 To generate code and create the target application, in the model window, press **Ctrl+B**. Or, on the **Hardware** tab, in the **Run on Hardware** section, click **Monitor & Tune**. Then, under **Step By Step Commands**, click **Build for Monitoring**.

The software creates the `ex_extModeExample` executable file in your working folder.

## Run Target Application

You now run the `ex_extModeExample` target executable and use Simulink as an interactive front end to the running target application. The executable file is in your working folder. Run the target application and establish communication between Simulink and the target.

---

**Note** An external mode program like `ex_extModeExample` is a host-based executable. Its execution is not tied to a real-time operating system (RTOS) or a periodic timer interrupt, and it does not run in real time. The program just runs as fast as possible, and the time units it counts off are simulated time units that do not correspond to time in the world outside the program.

---

To run the target application:

- 1 On the **Hardware** tab, in the **Run on Hardware** section:
  - a In the **Stop Time** field, specify `inf`, which makes the model run until the target application receives a stop message from Simulink
  - b Click **Monitor & Tune**. Then, under **Step By Step Commands**, click **Deploy**.

The target application begins execution, and enters a wait state.

- 2 Open the Scope blocks in the model. Signals are not visible on the scopes until you begin model execution.
- 3 On the **Hardware** tab, in the **Run on Hardware** section, click **Monitor & Tune**. Then, under **Step By Step Commands**, click **Connect**. This action initiates a handshake between Simulink and the target application. When Simulink and the target are connected, the **Connect** button changes to **Disconnect**.
- 4 In the **Run on Hardware** section, click , which starts execution of the generated model code. The two scopes in your model display the outputs of Gain blocks A and B.

You have established communication between Simulink and the running target application. You can now tune block parameters in Simulink and observe the effects of parameter changes.

## Tune Parameters

This table describes how you can tune tunable block parameters during a simulation.

Approach	Details
Model Data Editor	<p>To tune parameters through the Model Data Editor:</p> <ol style="list-style-type: none"> <li><b>1</b> On the <b>Hardware</b> tab of the Simulink Editor, in the <b>Prepare</b> section, click <b>Tune Parameters</b>, which opens the Model Data Editor.</li> <li><b>2</b> If you want to update multiple tunable parameters simultaneously, in the <b>Prepare</b> section, toggle on <b>Hold Updates</b>.</li> <li><b>3</b> On the <b>Parameters</b> tab of the Model Data Editor, in the <b>Value</b> column, specify new values for your tunable parameters.</li> <li><b>4</b> Toggle off <b>Hold Updates</b> or click <b>Update All Parameters (Ctrl+D)</b>. Simulink downloads the new values to the target application simultaneously.</li> </ol> <p>If <b>Hold Updates</b> is off, then immediately after you specify a new value, Simulink downloads the new value to the target application.</p> <p>For more information, see <b>Model Data Editor</b>.</p>
Block Parameter dialog box	<p>To tune parameters through the Block Parameter dialog box:</p> <ol style="list-style-type: none"> <li><b>1</b> For each block that you want to update: <ol style="list-style-type: none"> <li><b>a</b> Double-click the block, which opens the Block Parameter dialog box.</li> <li><b>b</b> In the parameter fields, specify new parameter values.</li> <li><b>c</b> Click <b>Apply</b> or <b>OK</b>.</li> </ol> </li> <li><b>2</b> If <b>Hold Updates</b> is on, toggle off <b>Hold Updates</b> or click <b>Update All Parameters (Ctrl+D)</b>. Simulink downloads the new values to the target application simultaneously.</li> </ol> <p>If <b>Hold Updates</b> is off, then immediately after you click <b>Apply</b> or <b>OK</b>, Simulink downloads the new block values to the target application.</p>

Approach	Details
MATLAB workspace	<p>If block parameters are MATLAB workspace variables:</p> <ol style="list-style-type: none"> <li><b>1</b> In the Command Window, assign new values to the variables.</li> <li><b>2</b> On the <b>Hardware</b> tab of the Simulink Editor, in the <b>Prepare</b> section, click <b>Update All Parameters (Ctrl+D)</b>. Simulink downloads the new values to the target application.</li> </ol> <p>For more information, see “Create and Edit Variables”.</p>

You cannot change the sample time of the Sine Wave block during simulation. Block sample times are part of the structural definition of the model and are part of the generated code. Therefore, if you want to change a block sample time, you must stop the external mode simulation, reset the sample time of the block, and rebuild the executable.

Block parameter tunability during external mode simulation depends on the way that the generated code represents block parameters.

For example, in the Gain A block dialog box, you cannot change the expression A in the **Gain** parameter during simulation. Instead, you must change the value of the variable A in the base workspace. You cannot change the expression because the generated code does not allocate storage in memory for the **Gain** parameter. Instead, the code creates a field A in a structure:

```

/* Parameters (auto storage) */
struct P_ex_extModeExample_T_ {
 real_T A; /* Variable: A
 */
 real_T B; /* Variable: B
 */
 real_T SineWave_Amp; /* Expression: 1
 */
 real_T SineWave_Bias; /* Expression: 0
 */
 real_T SineWave_Freq; /* Expression: 1
 */
 real_T SineWave_Phase; /* Expression: 0
 */
};

```

The generated code algorithm uses that field in the code that represents the block Gain A. In this case, the global structure variable `ex_extModeExample_P` uses the type `P_ex_extModeExample_T_`:

```
ex_extModeExample_B.GainA = ex_extModeExample_P.A * rtb_SineWave;
```

When you change the value of A in the base workspace, the simulation downloads the new value to the field A in the target application.

You can change the expressions in the Sine Wave block parameters during simulation because the generated code creates a field in the global structure `ex_extModeExample_P` to represent each

parameter in the block. When you change an expression in the block dialog box, the simulation first evaluates the new expression. The simulation then downloads the resulting numeric value to the corresponding structure field in the target application.

See “Create Tunable Calibration Parameter in the Generated Code” on page 33-110.

## Stop Target Application

To simultaneously disconnect Simulink from the host/target communication and end execution of the target application, on the **Hardware** tab, in the **Run on Hardware** section, click **Stop**.

## Control Memory Allocation for Communication Buffers in Target

If you select the **Code Generation > Interface > Static memory allocation** check box (for GRT and ERT targets), the code generator produces code for external mode that uses only static memory allocation (“malloc-free” code). Selecting **Static memory allocation** enables the **Static memory buffer size** parameter. Use this parameter to specify the size of the external mode static memory buffer. The default value is 1,000,000 bytes. If you enter too small a value for your program, the external mode simulation issues an out-of-memory error when it tries to allocate more memory than specified. In such cases, increase the value in the **Static memory buffer size** field and regenerate the code.

To determine how much memory to allocate, enable verbose mode on the target (by including `OPTS=" -DVERBOSE"` on the make command line). As it executes, external mode displays the amount of memory it tries to allocate and the amount of memory available to it each time it attempts an allocation. If an allocation fails, you can use this console log to determine the required value for the **Static memory buffer size** field.

## TCP/IP or Serial External Mode Control Panel

The External Mode Control Panel provides controls for TCP/IP or serial external mode operations, including:

- “Connect, Start, and Stop” on page 57-59
- “Upload Target Application Signal Data to Host” on page 57-59
- “Download Parameters to Target Application” on page 57-60
- “Configure Host Monitoring of Target Application Signal Data” on page 57-61
- “Configure Host Archiving of Target Application Signal Data” on page 57-67

To open the External Mode Control Panel dialog box, on the **Hardware** tab, in the **Prepare** section, click **Control Panel**.

### Connect, Start, and Stop

The External Mode Control Panel performs the same connect/disconnect and start/stop functions found on the **Hardware** tab on the Simulink toolstrip (see “Summary of Graphical Controls for TCP/IP or Serial External Mode Simulation” on page 57-69).

Clicking the **Connect** button connects your model to a waiting or running target application. While you are connected, the button changes to a **Disconnect** button. **Disconnect** disconnects your model from the target environment, but does not halt real-time code running in the target environment.

Clicking the **Start Real-Time Code** button commands the target to start running real-time code. While real-time code is running in the target environment, the button changes to a **Stop Real-Time Code** button. **Stop Real-Time Code** stops target application execution and disconnects your model from the target environment.

### Upload Target Application Signal Data to Host

The External Mode Control Panel allows you to trigger and cancel data uploads to the host. The destination for the uploaded data can be a scope block, Display block, To Workspace block, or another block or subsystem listed in “Blocks and Subsystems Compatible with External Mode” on page 57-70.

The **Arm Trigger** and **Cancel Trigger** buttons provide manual control of data uploading to compatible blocks or subsystems, except floating scopes. (For floating scopes, use the **Floating scope** section of the External Mode Control Panel.)

- To trigger data uploading to compatible blocks or subsystems, click the **Arm Trigger** button. The button changes to **Cancel Trigger**.

- To cancel data uploading, click the **Cancel Trigger** button. The button reverts to **Arm Trigger**.

You can trigger data uploads manually or automatically. To configure signals and triggers for data uploads, see “Configure Host Monitoring of Target Application Signal Data” on page 57-61.

A subset of external mode compatible blocks, including Scope, Time Scope, and To Workspace, allow you to log uploaded data to disk. To configure data archiving, see “Configure Host Archiving of Target Application Signal Data” on page 57-67.

The **Floating scope** section of the External Mode Control Panel controls when and for how long data is uploaded to Floating Scope blocks. When used in external mode, floating scopes:

- Do not appear in the External Signal & Triggering dialog box.
- Do not log data to external mode archiving.
- Support manual triggering only.

The **Floating scope** section contains the following parameters:

- **Enable data uploading** option, which functions as an **Arm Trigger** button for floating scopes. When the target is disconnected, the option controls whether to arm the trigger when connecting the floating scopes. When the target is connected, the option acts as a toggle button to arm or cancel the trigger.
  - To trigger data uploading to floating scopes, select **Enable data uploading**.
  - To cancel data uploading to floating scopes, clear **Enable data uploading**.
- **Duration** edit field, which specifies the number of base-rate steps for which external mode logs floating scopes data after a trigger event. By default, it is set to `auto`, which causes the duration value set in the External Signal & Triggering dialog box to be used. The default duration value is 1000 base rate steps.

### Download Parameters to Target Application

The **Batch download** option on the External Mode Control Panel enables or disables batch parameter changes.

By default, batch download is disabled. If batch download is disabled, when you click **OK** or **Apply**, changes made directly to block parameters by editing block parameter dialog boxes are sent to the target. When you perform an **Update Diagram**, changes to MATLAB workspace variables are sent.

If you select **Batch download**, the **Download** button is enabled. Until you click **Download**, changes made to block parameters are stored locally. When you click **Download**, the changes are sent in a single transmission.

When parameter changes are awaiting batch download, the External Mode Control Panel displays the message `Parameter changes pending...` to the right of the **Download** button. This message remains visible until the Simulink engine receives notification that the new parameters have been installed in the parameter vector of the target system.

The next figure shows the External Mode Control Panel with the **Batch download** option activated and parameter changes pending.

## Configure Host Monitoring of Target Application Signal Data

- “Role of Trigger in Signal Data Uploading” on page 57-61
- “Configure Signal Data Uploading” on page 57-62
- “Default Trigger Options” on page 57-63
- “Select Signals to Upload” on page 57-63
- “Configure Trigger Options” on page 57-63
- “Select Trigger Signal” on page 57-65
- “Set Trigger Conditions” on page 57-65
- “Modify Signal and Triggering Options While Connected” on page 57-66

### Role of Trigger in Signal Data Uploading

In external mode, uploading target application signal data to the host depends on a *trigger*. The trigger is a set of conditions that must be met for data uploading to begin. The trigger can be armed or not armed.

- When the trigger is armed, the software checks for the trigger conditions that allow data uploading to begin.
- If the trigger is not armed, the software does not check for the trigger conditions and data uploading cannot begin.
- The trigger can be armed automatically, when the host connects to the target, or manually, by clicking the **Arm Trigger** button on the External Mode Control Panel.

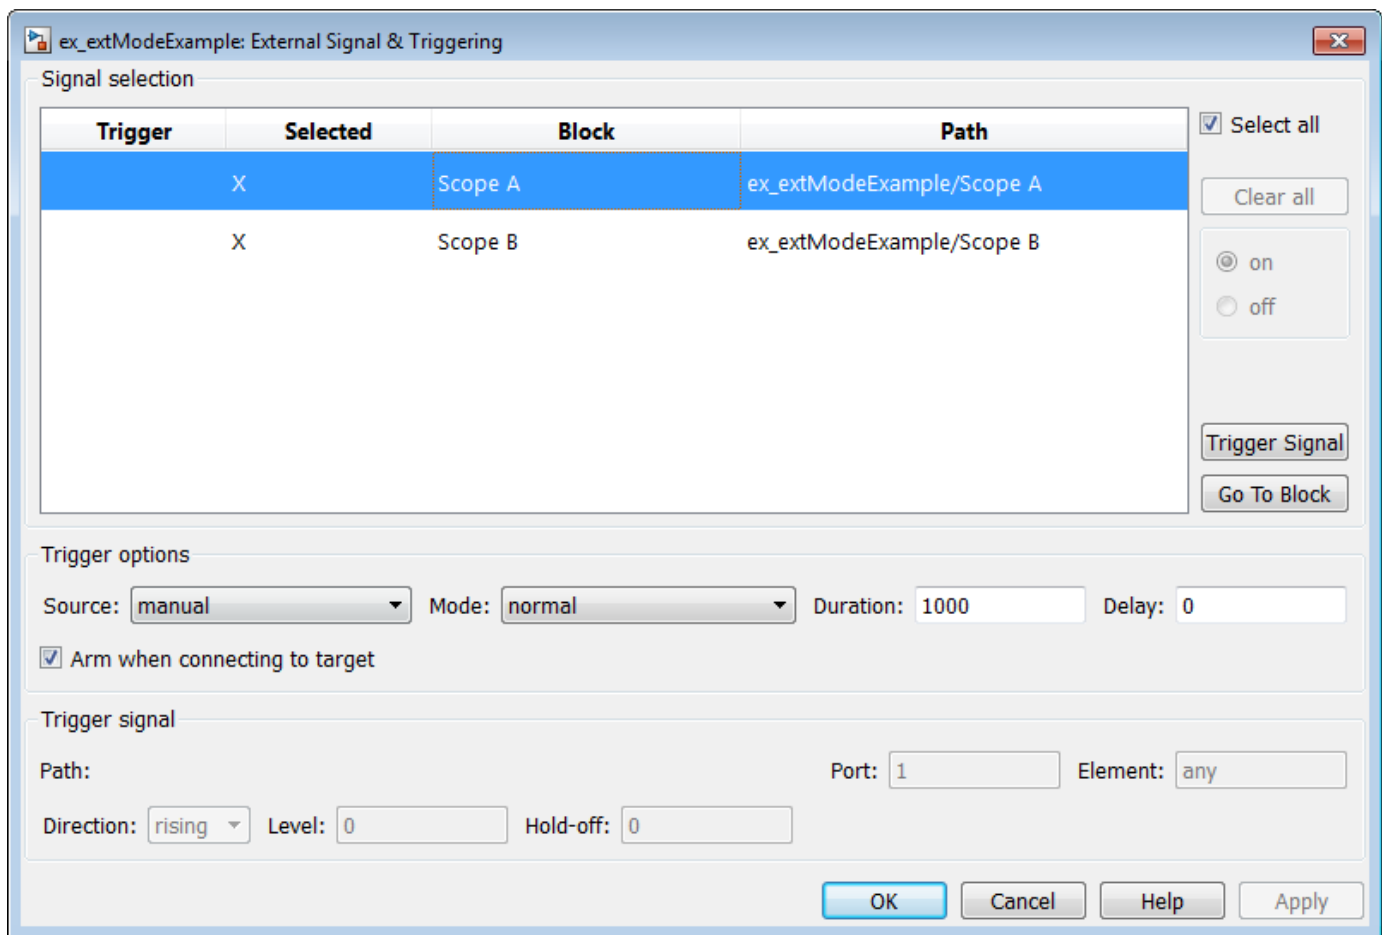

When the trigger is armed and the trigger conditions are met, the trigger fires and data uploading begins.

When data has been collected for a defined duration, the trigger event completes and data uploading stops. The trigger can then rearm, or remain unarmed until you click the **Arm Trigger** button.

To select the target application signals to upload and configure how uploads are triggered, see “Configure Signal Data Uploading” on page 57-62.

### Configure Signal Data Uploading

Clicking the **Signal & Triggering** button of the External Mode Control Panel opens the External Signal & Triggering dialog box.

The External Signal & Triggering dialog box displays a list of blocks and subsystems in your model that support external mode signal uploading. For information on which types of blocks are external mode compatible, see “Blocks and Subsystems Compatible with External Mode” on page 57-70.

In the External Signal & Triggering dialog box, you can select the signals that are collected from the target system and viewed in external mode. You can also select a trigger signal, which triggers uploading of data based on meeting certain signal conditions, and define the triggering conditions.

## Default Trigger Options

The preceding figure shows the default settings of the External Signal & Triggering dialog box. The default operation of the External Signal & Triggering dialog box simplifies monitoring the target application. If you use the default settings, you do not need to preconfigure signals and triggers. You start the target application and connect the Simulink engine to it. External mode compatible blocks are selected and the trigger is armed. Signal uploading begins immediately upon connection to the target application.

The default configuration of trigger options is:

- **Select all:** on
- **Source:** manual
- **Mode:** normal
- **Duration:** 1000
- **Delay:** 0
- **Arm when connecting to target:** on

## Select Signals to Upload

External mode compatible blocks in your model appear in the **Signal selection** list of the External Signal & Triggering dialog box. You use this list to select signals that you want to view. In the **Selected** column, an X appears for each selected block.

The **Select all** check box selects all signals. By default, **Select all** is selected.

If **Select all** is cleared, you can select or clear individual signals using the **on** and **off** options. To select a signal, click its list entry and select the **on** option. To clear a signal, click its list entry and select the **off** option.

The **Clear all** button clears all signals.

## Configure Trigger Options

As described in “Role of Trigger in Signal Data Uploading” on page 57-61, signal data uploading depends on a trigger. The trigger defines conditions that must be met for uploading to begin. Also, the trigger must be armed for data uploading to begin. When the trigger is armed and trigger conditions are met, the trigger fires and uploading begins. When data has been collected for a defined duration, the trigger event completes and data uploading stops.

To control when and how signal data is collected (uploaded) from the target system, configure the following **Trigger options** in the External Signal & Triggering dialog box.

- **Source:** manual or signal. Controls whether a button or a signal triggers data uploading.

Selecting **manual** directs external mode to use the **Arm Trigger** button on the External Mode Control Panel as the trigger to start uploading data. When you click **Arm Trigger**, data uploading begins.

Selecting **signal** directs external mode to use a trigger signal as the trigger to start uploading data. When the trigger signal satisfies trigger conditions (that is, the signal crosses the trigger level in the specified direction), a *trigger event* occurs. (Specify trigger conditions in the **Trigger signal** section.) If the trigger is *armed*, external mode monitors for the occurrence of a trigger event. When a trigger event occurs, data uploading begins.

- **Mode:** normal or one-shot. Controls whether the trigger rearms after a trigger event completes.

In normal mode, external mode automatically rearms the trigger after each trigger event. The next data upload begins when the trigger fires.

In one-shot mode, external mode collects only one buffer of data each time you arm the trigger.

For more information on the **Mode** setting, see “Configure Host Archiving of Target Application Signal Data” on page 57-67.

- **Duration:** Specifies the number of base rate steps for which external mode uploads data after a trigger event (default is 1000). For example, if **Duration** is set to 1000, and the base (fastest) rate of the model is one second:
  - For a signal sampled at the base rate, one second (1.0 Hz), external mode collects 1000 contiguous samples during a trigger event.
  - For a signal sampled at two seconds (0.5 Hz), external mode collects 500 samples during a trigger event.
- **Delay:** Specifies a delay to be applied to data collection. The delay represents the amount of time that elapses between a trigger event and the start of data collection. The delay is expressed in base rate steps. It can be positive or negative (default is 0). A negative delay corresponds to pretriggering. When the delay is negative, data from the time preceding the trigger event is collected and uploaded.
- **Arm when connecting to target:** Selected or cleared. Whether a button or a signal triggers data uploading (as defined by **Source**), the trigger must be armed to allow data uploading to begin.

If you select this option, connecting to the target arms the trigger.

- If the trigger **Source** is manual, data uploading begins immediately.
- If the trigger **Source** is signal, monitoring of the trigger signal begins immediately. Data uploading begins when the trigger signal satisfies trigger conditions (as defined in the **Trigger signal** section).

If you clear **Arm when connecting to target**, manually arm the trigger by clicking the **Arm Trigger** button on the External Mode Control Panel.

When simulating in external mode, each rate in the model creates a buffer on the target. Each entry in the buffer is big enough to hold all of the data required of every signal in that rate for one time step (time plus data plus external mode indices identifying the signal). The number of entries in the circular buffer is determined by the external mode trigger **Duration** parameter (ExtModeTrigDuration). The memory allocated on the target for buffering signals is proportional to the **Duration** and the number of signals uploading. The **Duration** also provides an indication of the number of base rate steps with log data after a trigger event in external mode.

The **Duration** value specifies the number of contiguous points of data to be collected in each buffer of data. You should enter a **Duration** value equal to the number of continuous sample points that you need to collect rather than relying on a series of buffers to be continuous. If you enter a value less than the total number of sample points, you may lose sample points during the time spent transferring values from the data buffer to the MATLAB workspace. The Simulink software maintains point continuity only within one buffer. Between buffers, because of transfer time, some samples may be omitted.

The **Duration** value can affect the **Limit data points to last** value of Scope and To Workspace blocks. The number of sample points that the blocks save to the MATLAB workspace is the smaller of the two values. To set the number of sample points that the blocks save, clear **Limit data points to last**. Then, use **Duration** to specify the number of sample points saved.

### Select Trigger Signal

You can designate one signal as a trigger signal. To select a trigger signal, from the **Source** menu in the **Trigger options** section, select **signal**. This action enables the parameters in the **Trigger signal** section. Then, select a signal in the **Signal selection** list, and click the **Trigger Signal** button.

When you select a signal to be a trigger, a T appears in the **Trigger** column of the **Signal selection** list. In the next figure, the **Scope A** signal is the trigger. **Scope B** is also selected for viewing, as indicated by the X in the **Selected** column.

After selecting the trigger signal, you can use the **Trigger signal** section to define the trigger conditions and set the trigger signal **Port** and **Element** parameters.

### Set Trigger Conditions

Use the **Trigger signal** section of the External Signal & Triggering dialog box to set trigger conditions and attributes. **Trigger signal** parameters are enabled only when the trigger parameter **Source** is set to **signal** in the **Trigger options** section.

By default, any element of the first input port of a specified trigger block can cause the trigger to fire (that is, Port 1, any element). You can modify this behavior by adjusting the **Port** and **Element** values in the **Trigger signal** section. The **Port** field accepts a number or the keyword `last`. The **Element** field accepts a number or the keywords `any` or `last`.

In the **Trigger signal** section, you also define the conditions under which a trigger event occurs.

- **Direction:** `rising`, `falling`, or `either`. The direction in which the signal must be traveling when it crosses the threshold value. The default is `rising`.
- **Level:** A value indicating the threshold the signal must cross in a designated direction to fire the trigger. By default, the level is 0.
- **Hold-off:** Applies only to `normal` mode. Expressed in base rate steps, **Hold-off** is the time between the termination of one trigger event and the rearming of the trigger.

### Modify Signal and Triggering Options While Connected

After you configure signal data uploading, and connect Simulink to a running target executable, you can modify signal and triggering options without disconnecting from the target.

If the trigger is armed (for example, if the trigger option **Arm when connecting to the target** is selected, which is the default), the External Signal & Triggering dialog box cannot be modified. To modify signal and triggering options:

- 1 Open the External Mode Control Panel.
- 2 Click **Cancel Trigger**. Triggering and display of uploaded data stops.
- 3 Open the External Signal & Triggering dialog box and modify signal and trigger options as required. For example, in the **Signal selection** section, you can enable or disable a scope, and in the **Trigger options** section, change the trigger **Mode**, for example, from `normal` to `one-shot`.
- 4 Click **Arm Trigger**. Triggering and display of uploaded data resumes, with your modifications.

## Configure Host Archiving of Target Application Signal Data

In external mode, you can use the Simulink Scope and To Workspace blocks to archive data to disk.

To understand how the archiving features work, consider the handling of data when archiving is not enabled. There are two cases, one-shot mode and normal mode.

- In one-shot mode, after a trigger event occurs, each selected block writes its data to the workspace, as it would at the end of a simulation. If another one-shot is triggered, the existing workspace data is overwritten.
- In normal mode, external mode automatically rearms the trigger after each trigger event. Consequently, you can think of normal mode as a series of one-shots. Each one-shot in this series, except for the last, is referred to as an *intermediate result*. Because the trigger can fire at any time, writing intermediate results to the workspace can result in unpredictable overwriting of the workspace variables. For this reason, the default behavior is to write only the results from the final one-shot to the workspace. The intermediate results are discarded. If you know that enough time exists between triggers for inspection of the intermediate results, you can override the default behavior by selecting the **Write intermediate results to workspace** option. This option does not protect the workspace data from being overwritten by subsequent triggers.

If you use a Simulink Scope block to archive data to disk, open the Scope parameters dialog box and select the option **Log data to workspace**. The option is required for these reasons:

- The data is first transferred from the scope data buffer to the MATLAB workspace, before being written to a MAT-file.

- The **Variable name** entered in the Scope parameters dialog box is the same as the one in the MATLAB workspace and the MAT-file. Enabling the data to be saved enables a variable named with the **Variable name** parameter to be saved to a MAT-file.

---

**Note** If you do not select the Scope block option **Log data to workspace**, the MAT-files for data logging are created, but they are empty.

---

The Enable Data Archiving dialog box supports:

- Folder notes
- File notes
- Automated data archiving

On the External Mode Control Panel, click the **Data Archiving** button to open the Enable Data Archiving dialog box. If your model is connected to the target environment, disconnect it while you configure data archiving. To enable the other controls in the dialog box, select **Enable archiving**.

These operations are supported by the Enable Data Archiving dialog box.

### Folder Notes

To add annotations for a collection of related data files in a folder, in the Enable Data Archiving dialog box, click **Edit Directory Note**. The MATLAB editor opens. Place comments that you want saved to a file in the specified folder in this window. By default, the comments are saved to the folder last written to by data archiving.

### File Notes

To add annotations for an individual data file, in the Enable Data Archiving dialog box, click **Edit File Note**. A file finder window opens, which by default is set to the last file to which you have written.

Selecting a MAT-file opens an edit window. In this window, add or edit comments that you want saved with your individual MAT-file.

### Automated Data Archiving

To configure automatic writing of logging results to disk, optionally including intermediate results, use the **Enable archiving** option and the controls it enables. The dialog box provides the following related controls:

- **Directory:** Specifies the folder in which data is saved. If you select **Increment directory when trigger armed**, external mode appends a suffix.
- **File:** Specifies the name of the file in which data is saved. If you select **Increment file after one-shot**, external mode appends a suffix.
- **Increment directory when trigger armed:** Each time that you click the **Arm Trigger** button, external mode uses a different folder for writing log files. The folders are named incrementally, for example, `dirname1`, `dirname2`, and so on.
- **Increment file after one-shot:** New data buffers are saved in incremental files: `filename1`, `filename2`, and so on. File incrementing happens automatically in normal mode.
- **Append file suffix to variable names:** Whenever external mode increments file names, each file contains variables with identical names. Selecting **Append file suffix to variable name** results in each file containing unique variable names. For example, external mode saves a variable named `xdata` in incremental files (`file_1`, `file_2`, and so on) as `xdata_1`, `xdata_2`, and so on. This approach supports loading the MAT-files into the workspace and comparing variables at the MATLAB command prompt. Without the unique names, each instance of `xdata` would overwrite the previous one in the MATLAB workspace.
- **Write intermediate results to workspace:** If you want the Simulink Coder software to write intermediate results to the workspace, select this option.

## Summary of Graphical Controls for TCP/IP or Serial External Mode Simulation

You can control a TCP/IP or serial external mode simulation through:

- The **Hardware** tab on the Simulink toolstrip. To display the **Hardware** tab, from the **Apps** tab on the Simulink toolstrip, click **Run on Custom Hardware**.
- The External Mode Control Panel. To open this dialog box, in Simulink Editor, on the **Hardware** tab, in the **Prepare** section, click . Then under **Signal Monitoring & Tracing**, click **Control Panel**.

This table lists external mode actions that you can perform by using controls that are available in the **Hardware** tab and the External Mode Control Panel.

External Mode Action	Hardware Tab	External Mode Control Panel
Build target application.	<b>Run on Hardware &gt; Build for</b> <b>Monitoring</b> 	N/A

External Mode Action	Hardware Tab	External Mode Control Panel
Run application on target hardware.	<b>Run on Hardware &gt; Deploy</b> 	N/A
Connect Simulink to a waiting or running target application.	<b>Run on Hardware &gt; Connect</b>  When Simulink is connected to the target application, <b>Connect</b> appears dimmed and <b>Disconnect</b>  is active.	<b>Connect</b> When Simulink is connected to the target application, <b>Connect</b> changes to <b>Disconnect</b> .
Start real-time execution of generated code in the target environment.	<b>Run on Hardware &gt; Start</b> 	<b>Start Real-Time Code</b> When the generated code starts executing, the button changes to <b>Stop Real-Time Code</b> .
Disconnect Simulink from the target environment, but do not stop real-time execution of code.	<b>Run on Hardware &gt;</b> <b>Disconnect</b>  When Simulink is disconnected from the target application, <b>Disconnect</b> appears dimmed and <b>Connect</b>  is active.	<b>Disconnect</b>
Stop target application execution and disconnect Simulink from the target environment.	In <b>Run on Hardware</b> section, <b>Stop</b> button  .	<b>Stop Real-Time Code</b>
Tune batch of block parameters.	In <b>Prepare</b> section, <b>Hold Updates</b>  and <b>Update All Parameters</b>  buttons.	<b>Batch download</b> and <b>Download</b>

## Blocks and Subsystems Compatible with External Mode

- “Compatible Blocks” on page 57-70
- “Signal Viewing Subsystems” on page 57-71
- “Supported Blocks for Data Archiving” on page 57-72

### Compatible Blocks

In external mode, you can use the following types of blocks to receive and view signals uploaded from the target application:

- Floating Scope and Scope blocks

- Spectrum Analyzer and Time Scope blocks from the DSP System Toolbox product
- Display blocks
- To Workspace blocks
- User-written S-Function blocks

An external mode method is built into the S-function API. This method allows user-written blocks to support external mode. See `matlabroot/simulink/include/simstruc.h`.

- Record, XY Graph blocks

You can designate certain subsystems as Signal Viewing Subsystems and use them to receive and view signals uploaded from the target application. See “Signal Viewing Subsystems” on page 57-71 for more information.

You select external mode compatible blocks and subsystems, and arm the trigger, by using the External Signal & Triggering dialog box. By default, such blocks in a model are selected, and a manual trigger is set to be armed when connected to the target application.

### Signal Viewing Subsystems

A Signal Viewing Subsystem is an atomic subsystem that encapsulates processing and viewing of signals received from the target system. A Signal Viewing Subsystem runs only on the host, and does not generate code in the target system. Signal Viewing Subsystems run in normal, accelerator, rapid accelerator, and external simulation modes.

---

**Note** Signal Viewing Subsystems are inactive if placed inside a SIL or PIL component, such as a top model in SIL or PIL mode, a Model block in SIL or PIL mode, or a SIL or PIL block. However, a SIL or PIL component can feed a Signal Viewing Subsystem running in a supported mode.

---

Signal Viewing Subsystems are useful in situations where you want to process or condition signals before viewing or logging them, but you do not want to perform these tasks on the target system. By using a Signal Viewing Subsystem, you can generate smaller and more efficient code on the target system.

Like other external mode compatible blocks, Signal Viewing Subsystems are displayed in the External Signal & Triggering dialog box.

To declare a subsystem to be a Signal Viewing Subsystem:

- 1 In the Block Parameters dialog box, select the **Treat as atomic unit** option.

For more information on atomic subsystems, see “Subcomponents and Utilities”.

- 2 To turn the `SimViewingDevice` property on, use the `set_param` command:

```
set_param('blockname', 'SimViewingDevice', 'on')
```

'blockname' is the name of the subsystem.

- 3 Make sure the subsystem meets the following requirements:

- It must be a pure Sink block. That is, it must not contain Outport blocks or Data Store blocks. It can contain Goto blocks only if the corresponding From blocks are contained within the subsystem boundaries.

- It must not have continuous states.

The following model, `sink_examp`, contains an atomic subsystem, `theSink`.

The subsystem `theSink` applies a gain and an offset to its input signal and displays it on a Scope block.

If `theSink` is declared as a Signal Viewing Subsystem, the generated target application includes only the code for the Sine Wave block. If `theSink` is selected and armed in the External Signal & Triggering dialog box, the target application uploads the sine wave signal to `theSink` during simulation. You can then modify the parameters of the blocks within `theSink` and observe the uploaded signal.

If `theSink` were not declared as a Signal Viewing Subsystem, its Gain, Constant, and Sum blocks would run as subsystem code on the target system. The Sine Wave signal would be uploaded to the Simulink engine after being processed by these blocks, and viewed on `sink_examp/theSink/Scope2`. Processing demands on the target system would be increased by the additional signal processing, and by the downloading of changes in block parameters from the host.

### Supported Blocks for Data Archiving

In external mode, you can use the following types of blocks to archive data to disk:

- Scope blocks
- To Workspace blocks

You configure data archiving by using the Enable Data Archiving dialog box, as described in “Configure Host Archiving of Target Application Signal Data” on page 57-67.

### External Mode Mechanism for Downloading Tunable Parameters

- “Download Mechanism” on page 57-73
- “Inlined and Tunable Parameters” on page 57-74

Depending on the setting of the **Default parameter behavior** option when the target application is generated, there are differences in the way parameter updates are handled. “Download Mechanism” on page 57-73 describes the operation of external mode communication with **Default parameter**

**behavior** set to Tunable. “Inlined and Tunable Parameters” on page 57-74 describes the operation of external mode with **Default parameter behavior** set to Inlined.

### Download Mechanism

In external mode, the Simulink engine does not simulate the system represented by the block diagram. By default, when external mode is enabled, the Simulink engine downloads parameters to the target system. After the initial download, the engine remains in a waiting mode until you change parameters in the block diagram or until the engine receives data from the target.

When you change a parameter in the block diagram, the Simulink engine calls the external interface MEX-file, passing new parameter values (along with other information) as arguments. The external interface MEX-file contains code that implements one side of the interprocess communication (IPC) channel. This channel connects the Simulink process (where the MEX-file executes) to the process that is executing the external program. The MEX-file transfers the new parameter values by using this channel to the external program.

The other side of the communication channel is implemented within the external program. This side writes the new parameter values into the target's parameter structure (*model\_P*).

The Simulink side initiates the parameter download operation by sending a message containing parameter information to the external program. In the terminology of client/server computing, the Simulink side is the client and the external program is the server. The two processes can be remote, or they can be local. Where the client and server are remote, a protocol such as TCP/IP is used to transfer data. Where the client and server are local, a serial connection or shared memory can be used to transfer data.

The next figure shows this relationship. The Simulink engine calls the external interface MEX-file whenever you change parameters in the block diagram. The MEX-file then downloads the parameters to the external program by using the communication channel.

## External Mode Architecture

### Inlined and Tunable Parameters

By default, parameters (except those listed in “TCP/IP and Serial External Mode Limitations” on page 57-87) in an external mode program are tunable; that is, you can change them by using the download mechanism described in this section.

If you set **Default parameter behavior** to **Inlined** (on the **Optimization** pane of the Configuration Parameters dialog box), the Simulink Coder code generator embeds the numerical values of model parameters (constants), instead of symbolic parameter names, in the generated code. Inlining parameters generates smaller and more efficient code. However, inlined parameters, because they effectively become constants, are not tunable.

The Simulink Coder software lets you improve overall efficiency by inlining most parameters, while at the same time retaining the flexibility of run-time tuning for selected parameters that are important to your application. When you inline parameters, you can use `Simulink.Parameter` objects to remove individual parameters from inlining and declare them to be tunable. In addition, you can use these objects to control how parameters are represented in the generated code.

For more information on tunable parameters, see “Create Tunable Calibration Parameter in the Generated Code” on page 33-110.

### Automatic Parameter Uploading on Host/Target Connection

Each time the Simulink engine connects to a target application that was generated with **Default parameter behavior** set to **Inlined**, the target application uploads the current value of its tunable parameters to the host. These values are assigned to the corresponding MATLAB workspace variables. This procedure synchronizes the host and target with respect to parameter values. If the tunable parameters are stored in the model workspace or a data dictionary, the values are not uploaded and Simulink produces a warning.

Workspace variables required by the model must be initialized at the time of host/target connection. Otherwise the uploading cannot proceed and an error results. Once the connection is made, these variables are updated to reflect the current parameter values on the target system.

Automatic parameter uploading takes place only if the target application was generated with **Default parameter behavior** set to **Inlined**. “Download Mechanism” on page 57-73 describes the operation of external mode communication with **Default parameter behavior** set to **Tunable**.

### Choose Communication Protocol for Client and Server

- “Introduction” on page 57-75
- “Using the TCP/IP Implementation” on page 57-75
- “Using the Serial Implementation” on page 57-78
- “Run the External Program” on page 57-79
- “Implement an External Mode Protocol Layer” on page 57-81

#### Introduction

The Simulink Coder product provides code to implement both the client and server side of external mode communication using either TCP/IP or serial protocols. You can use the socket-based external mode implementation provided by the Simulink Coder product with the generated code, provided that your target system supports TCP/IP. If not, use or customize the serial transport layer option provided.

A low-level *transport layer* handles physical transmission of messages. Both the Simulink engine and the model code are independent of this layer. Both the transport layer and code directly interfacing to the transport layer are isolated in separate modules that format, transmit, and receive messages and data packets.

#### Using the TCP/IP Implementation

You can use TCP/IP-based client/server implementation of external mode with real-time programs on The Open Group UNIX or PC systems. For help in customizing external mode transport layers, see “Create a Transport Layer for TCP/IP or Serial External Mode Communication”.

To use Simulink external mode over TCP/IP:

- Make sure that the external interface MEX-file for your target's TCP/IP transport is specified.

Targets provided by MathWorks specify the name of the external interface MEX-file in `matlabroot/toolbox/simulink/simulink/extmode_transports.m`. The name of the interface appears as uneditable text in the **External mode configuration** section of the **Interface** pane of the Configuration Parameters dialog box. The TCP/IP default is `ext_comm`.

To specify a TCP/IP transport for a custom target, you must add an entry of the following form to an `sl_customization.m` file on the MATLAB path:

```
function sl_customization(cm)
 cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
%end function
```

- `stf.tlc` is the name of the system target file for which you are registering the transport (for example, 'mytarget.tlc')
- `transport` is the transport name to display in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box (for example, 'tcpip')
- `mexfile` is the name of the transport's associated external interface MEX-file (for example, 'ext\_comm')

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```
function sl_customization(cm)
 cm.ExtModeTransports.add('mytarget.tlc', 'tcpip', 'ext_comm', 'Level1');
 cm.ExtModeTransports.add('mytarget.tlc', 'serial', ...
 'ext_serial_win32_comm', 'Level1');
%end function
```

- Be sure that the template makefile is configured to link the source files for the TCP/IP server code and that it defines the compiler flags when building the generated code.
- Build the external program.
- Run the external program.
- Set the Simulink model to external mode and connect to the target.

The next figure shows the structure of the TCP/IP-based implementation.

## TCP/IP-Based Client/Server Implementation for External Mode

### MEX-File Optional Arguments for TCP/IP Transport

In the External Target Interface dialog box, you can specify optional arguments that are passed to the external mode interface MEX-file for communicating with executing targets.

- **Target network name:** the network name of the computer running the external program. By default, this is the computer on which the Simulink product is running, for example, 'myComputer'. You can also use the IP address, for example, '148.27.151.12'.
- **Verbosity level:** controls the level of detail of the information displayed during the data transfer. The value is either 0 or 1 and has the following meaning:
  - 0 — No information
  - 1 — Detailed information
- **TCP/IP server port number:** The default value is 17725. You can change the port number to a value between 256 and 65535 to avoid a port conflict.

The arguments are positional and must be specified in the following order:

<TargetNetworkName> <VerbosityLevel> <ServerPortNumber>

For example, if you want to specify the verbosity level (the second argument), then you must also specify the target network name (the first argument). Arguments can be delimited by white space or commas. For example:

```
'148.27.151.12' 1 30000
```

You can specify command-line options to the external program when you launch it. See “Run the External Program” on page 57-79.

### Using the Serial Implementation

Controlling host/target communication on a serial channel is similar to controlling host/target communication on a TCP/IP channel.

To use Simulink external mode over a serial channel, you must:

- Make sure that the external interface MEX-file for your target's serial transport is specified.

Targets provided by MathWorks specify the name of the external interface MEX-file in *matlabroot/toolbox/simulink/simulink/extmode\_transports.m*. The name of the interface appears as uneditable text in the **External mode configuration** section of the **Interface** pane of the Configuration Parameters dialog box. The serial default is `serial`.

To specify a serial transport for a custom target, you must add an entry of the following form to an *sl\_customization.m* file on the MATLAB path:

```
function sl_customization(cm)
 cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
%end function
```

- *stf.tlc* is the name of the system target file for which you are registering the transport (for example, 'mytarget.tlc')
- *transport* is the transport name to display in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box (for example, 'serial')
- *mexfile* is the name of the transport's associated external interface MEX-file (for example, 'ext\_serial\_win32\_comm')

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```
function sl_customization(cm)
 cm.ExtModeTransports.add('mytarget.tlc', 'tcpip', 'ext_comm', 'Level1');
 cm.ExtModeTransports.add('mytarget.tlc', 'serial', ...
 'ext_serial_win32_comm', 'Level1');
%end function
```

- Be sure that the template makefile is configured to link the source files for the serial server code and that it defines the compiler flags when building the generated code.
- Build the external program.
- Run the external program.
- Set the Simulink model to external mode and connect to the target.

### MEX-File Optional Arguments for Serial Transport

In the **MEX-file arguments** field of the **Interface** pane of the Configuration Parameters dialog box, you can specify arguments that are passed to the external mode interface MEX-file for communicating with the executing targets. For serial transport, the optional arguments to `ext_serial_win32_comm` are as follows:

- **Verbosity level:** This argument controls the level of detail of the information displayed during data transfer. The value of this argument is:

- 0 (no information), or
- 1 (detailed information)
- Serial port ID: The port ID of the host, specified as an integer or character vector. For example, specify the port ID of a USB to serial converter as `'/dev/ttyusb0'`. Simulink Coder prefixes integer port IDs with `\\.COM` on Windows and by `/dev/ttyS` on Unix.

When you start the target application using a serial connection, you must specify the port ID to use to connect it to the host. Do this by including the `-port` command-line option. For example:

```
mytarget.exe -port 2 -w
```

- Baud rate: Specify an integer value. The default value is 57600.

The MEX-file options arguments are positional and must be specified in the following order:

```
<VerbosityLevel> <SerialPortID> <BaudRate>
```

For example, if you want to specify the serial port ID (the second argument), then you must also specify the verbosity level (the first argument). Arguments can be delimited by white space or commas. For example:

```
1 '/dev/ttyusb0' 57600
```

When you launch the external program, you can specify command-line options.

### Run the External Program

Before you can use the Simulink product in external mode, the external program must be running.

If the target application is executing on the same machine as the host and communication is through a loopback serial cable, the target's port ID must differ from that of the host (as specified in the **MEX-file arguments** edit field).

To run the external program, you type a command of the form:

```
model -opt1 ... -optN
```

`model` is the name of the external program and `-opt1 ... -optN` are options. (See “Command-Line Options for the External Program” on page 57-80.) In the examples in this section, the name of the external program is `ext_example`.

### Running the External Program in the Windows Environment

In the Windows environment, you can run the external programs in either of the following ways:

- Open a Command Prompt window. At the command prompt, type the name of the target executable, followed by possible options, such as:

```
ext_example -tf inf -w
```

- Alternatively, you can launch the target executable from the MATLAB Command Window. The command must be preceded by an exclamation point (!) and followed by an ampersand (&), as in the following example:

```
!ext_example -tf inf -w &
```

The ampersand (&) causes the operating system to spawn another process to run the target executable. If you do not include the ampersand, the program still runs, but you cannot enter commands at the MATLAB command prompt or manually terminate the executable.

### Running the External Program in the UNIX Environment

In the UNIX environment, you can run the external programs in either of the following ways:

- Open an Xterm window. At the command prompt, type the name of the target executable, followed by possible options, such as:

```
./ext_example -tf inf -w
```

- Alternatively, you can launch the target executable from the MATLAB Command Window. You must run it in the background so that you can still access the Simulink environment. The command must be preceded by an exclamation point (!), dot slash (./ indicating the current directory), and followed by an ampersand (&), as in the following example:

```
!./ext_example -tf inf -w &
```

The ampersand (&) causes the operating system to spawn another process to run the target executable.

### Command-Line Options for the External Program

External mode target executables generated by the Simulink Coder code generator support the following command-line options:

- `-tf n`

The `-tf` option overrides the stop time set in the Simulink model. The argument `n` specifies the number of seconds the program will run. The value `inf` directs the model to run indefinitely. In this case, the model code runs until the target application receives a stop message from the Simulink engine.

The following example sets the stop time to 10 seconds.

```
ext_example -tf 10
```

When integer-only ERT targets are built and executed in external mode, the stop time parameter (`-tf`) is interpreted by the target as the number of base rate steps rather than the number of seconds to execute.

- `-w`

Instructs the target application to enter a wait state until it receives a message from the host. At this point, the target is running, but not executing the model code. The start message is sent when you select **Start Real-Time Code** from the **Simulation** menu or click the **Start Real-Time Code** button in the External Mode Control Panel.

Use the `-w` option if you want to view target application execution data from time step 0, or if you want to modify parameters before the target application begins execution of model code.

- `-port n`

Specifies the TCP/IP port number or the serial port ID, `n`, for the target application. The port number of the target application must match that of the host for TCP/IP transport. The port number depends on the type of transport.

- For TCP/IP transport: Port number is an integer between 256 and 65535, with the default value being 17725. The selected port must not be used by another TCP/IP service that runs on the target hardware.
- For serial transport: Port ID is an integer or a character vector. For example, specify the port ID of a USB to serial converter as  `'/dev/ttyusb0'`
- `-baud r`

Specified as an integer, this option is only available for serial transport.

### Implement an External Mode Protocol Layer

If you want to implement your own transport layer for external mode communication, you must modify certain code modules provided by the Simulink Coder product and create a new external interface MEX-file. See “Create a Transport Layer for TCP/IP or Serial External Mode Communication”.

### Use External Mode Programmatically

You can run external mode simulations from the MATLAB command line or programmatically in scripts. Use the `get_param` and `set_param` commands to retrieve and set the values of model simulation command-line parameters, such as `SimulationMode` and `SimulationCommand`, and external mode command-line parameters, such as `ExtModeCommand` and `ExtModeTrigType`.

The following model simulation commands assume that a Simulink model is open and that you have loaded a target application to which the model will connect using external mode.

- 1 Change the Simulink model to external mode:

```
set_param(gcs, 'SimulationMode', 'external')
```

- 2 Connect the open model to the loaded target application:

```
set_param(gcs, 'SimulationCommand', 'connect')
```

- 3 Start running the target application:

```
set_param(gcs, 'SimulationCommand', 'start')
```

- 4 Stop running the target application:

```
set_param(gcs, 'SimulationCommand', 'stop')
```

- 5 Disconnect the target application from the model:

```
set_param(gcs, 'SimulationCommand', 'disconnect')
```

The `set_param` commands that use the `'SimulationCommand'` argument are asynchronous. If you run the commands successively from a script, each command starts without waiting for the previous command to complete. To check that each command is complete, in the script, use the `get_param` command with the `'SimulationStatus'` argument. For example, for steps 1 to 3, specify these commands in the script:

```
set_param(gcs, 'SimulationMode', 'external');
set_param(gcs, 'SimulationCommand', 'connect');
```

```
isExternalSimulationActive = false;
while ~isExternalSimulationActive
```

```
 simStatus = get_param(gcs, 'SimulationStatus');
 isExternalSimulationActive = strcmp(simStatus, 'external');
end
set_param(gcs, 'SimulationCommand', 'start');
```

For more information, see “Run Simulations Programmatically”.

The Diagnostic Viewer displays error messages produced by the `get_param` and `set_param` commands.

To tune a workspace parameter, change its value at the command prompt. If the workspace parameter is a `Simulink.Parameter` object, assign the new value to the `Value` property.

```
myVariable = 5.23;
myParamObj.Value = 5.23;
```

To download the workspace parameter in external mode, you update the model diagram. The following model simulation command initiates a model update:

```
set_param(gcs, 'SimulationCommand', 'update')
```

To trigger or cancel data uploading to scopes, use the `ExtModeCommand` values `armFloating` and `cancelFloating`, or `armWired` and `cancelWired`. For example, to trigger and then cancel data uploading to wired (nonfloating) scopes:

```
set_param(gcs, 'ExtModeCommand', 'armWired')
set_param(gcs, 'ExtModeCommand', 'cancelWired')
```

The next table lists external mode command-line parameters that you can use in `get_param` and `set_param` commands. The table provides brief descriptions, valid values (bold type highlights defaults), and a mapping to External Mode dialog box equivalents. For external mode parameters that are equivalent to **Interface** pane options in the Configuration Parameters dialog box, see “Model Configuration Parameters: Code Generation Interface”.

## External Mode Command-Line Parameters

Parameter and Values	Dialog Box Equivalent	Description
ExtModeAddSuffixToVar <b>off</b> , on	Enable Data Archiving: <b>Append file suffix to variable names</b> check box	Increment variable names for each incremented filename.
ExtModeArchiveDirName <i>character vector</i>	Enable Data Archiving: <b>Directory</b> text field	Save data in specified folder.
ExtModeArchiveFileName <i>character vector</i>	Enable Data Archiving: <b>File</b> text field	Save data in specified file.
ExtModeArchiveMode <i>character vector</i> - <b>off</b> , auto, manual	Enable Data Archiving: <b>Enable archiving</b> check box	Activate automated data archiving features.  To specify manual, run <code>set_param(gcs, 'ExtModeArchiveMode', 'manual')</code> .  Note that if you specify <b>auto</b> , <code>ExtModeAutoIncOneShot</code> is set to <b>on</b> .
ExtModeArmWhenConnect <b>off</b> , <b>on</b>	External Signal & Triggering: <b>Arm when connecting to target</b> check box	Arm the trigger as soon as the Simulink Coder software connects to the target.
ExtModeAutoIncOneShot <b>off</b> , on	Enable Data Archiving: <b>Increment file after one-shot</b> check box	Save new data buffers in incremental files.
ExtModeAutoUpdateStatusClock (Windows platforms only) <b>off</b> , <b>on</b>	Not available	Continuously upload and display target time on the model window status bar.
ExtModeBatchMode <b>off</b> , on	External Mode Control Panel: <b>Batch download</b> check box	Enable or disable downloading of parameters in batch mode.
ExtModeChangesPending <b>off</b> , on	Not available	When <code>ExtModeBatchMode</code> is enabled, indicates whether parameters remain in the queue of parameters to be downloaded to the target.

Parameter and Values	Dialog Box Equivalent	Description
ExtModeCommand <i>character vector</i> - armFloating, armWired, cancelFloating, cancelWired	<ul style="list-style-type: none"> <li>armFloating and cancelFloating are equivalent to selecting and clearing External Mode Control Panel check box <b>Floating scope &gt; Enable data uploading</b></li> <li>armWired and cancelWired are equivalent to External Mode Control Panel buttons <b>Arm Trigger</b> and <b>Cancel Trigger</b></li> </ul>	Issue an external mode command to the target application.
ExtModeConnected <b>off</b> , on	External Mode Control Panel: <b>Connect/Disconnect</b> button	Indicate the state of the connection with the target application.
ExtModeEnableFloating off, <b>on</b>	External Mode Control Panel: <b>Enable data uploading</b> check box	Enable or disable the arming and canceling of triggers when a connection is established with floating scopes.
ExtModeIncDirWhenArm <b>off</b> , on	Enable Data Archiving: <b>Increment directory when trigger armed</b> check box	Write log files to incremental folders each time the trigger is armed.
ExtModeLogAll off, <b>on</b>	External Signal & Triggering: <b>Select all</b> check box	Upload available signals from the target to the host.
ExtModeParamChangesPending <b>off</b> , on	Not available	When the Simulink Coder software is connected to the target and ExtModeBatchMode is enabled, indicates whether parameters remain in the queue of parameters to be downloaded to the target. More efficient than ExtModeChangesPending, because it checks for a connection to the target.
ExtModeSkipDownloadWhenConnect <b>off</b> , on	Not available	Connect to the target application without downloading parameters.
ExtModeTrigDelay <i>integer (0)</i>	External Signal & Triggering: <b>Delay</b> text field	Specify the amount of time (expressed in base rate steps) that elapses between a trigger occurrence and the start of data collection.
ExtModeTrigDirection <i>character vector</i> - <b>rising</b> , falling, either	External Signal & Triggering: <b>Direction</b> menu	Specify the direction in which the signal must be traveling when it crosses the threshold value.

Parameter and Values	Dialog Box Equivalent	Description
ExtModeTrigDuration <i>integer (1000)</i>	External Signal & Triggering: <b>Duration</b> text field	Specify the number of base rate steps for which external mode is to log data after a trigger event.
ExtModeTrigDurationFloating <i>character vector - integer (auto)</i>	External Mode Control Panel: <b>Duration</b> text field	Specify the duration for floating scopes. If <b>auto</b> is specified, the value of ExtModeTrigDuration is used.
ExtModeTrigElement <i>character vector - integer, any, last</i>	External Signal & Triggering: <b>Element</b> text field	Specify the elements of the input port of the specified trigger block that can cause the trigger to fire.
ExtModeTrigHoldOff <i>integer (0)</i>	External Signal & Triggering: <b>Hold-off</b> text field	Specify the base rate steps between when a trigger event terminates and the trigger is rearmed.
ExtModeTrigLevel <i>integer (0)</i>	External Signal & Triggering: <b>Level</b> text field	Specify the threshold value the trigger signal must cross to fire the trigger.
ExtModeTrigMode <i>character vector - normal, oneshot</i>	External Signal & Triggering: <b>Mode</b> menu	Specify whether the trigger is to rearm automatically after each trigger event or whether only one buffer of data is to be collected each time the trigger is armed.
ExtModeTrigPort <i>character vector - integer (1), last</i>	External Signal & Triggering: <b>Port</b> text field	Specify the input port of the specified trigger block for which elements can cause the trigger to fire.
ExtModeTrigType <i>character vector - manual, signal</i>	External Signal & Triggering: <b>Source</b> menu	Specify whether to start logging data when the trigger is armed or when a specified trigger signal satisfies trigger conditions.
ExtModeUploadStatus <i>character vector - inactive, armed, uploading</i>	Not available	Return the status of the external mode upload mechanism — inactive, armed, or uploading.
ExtModeWriteAllDataToWs <b>off, on</b>	Enable Data Archiving: <b>Write intermediate results to workspace</b> check box	Write intermediate results to the workspace.

## Animate Stateflow Charts in External Mode

If you have Stateflow, you can animate a chart in external mode. In external mode, you can animate states in a chart, and view test point signals in a floating scope or signal viewer.

- “Animate States During Simulation in External Mode” on page 57-86
- “View Test Point Data in Floating Scopes and Signal Viewers” on page 57-86

### Animate States During Simulation in External Mode

To animate states in a chart in external mode:

- 1 Load the chart you want to animate to the target machine.
- 2 In the Configuration Parameters dialog box, select the **External mode** check box.
- 3 Open the External Mode Control Panel dialog box.
- 4 Click **Signal & Triggering**.
- 5 In the External Signal & Triggering dialog box, set these parameters.

In:	Select:
<b>Signal selection</b> pane	Chart you want to animate
<b>Trigger options</b> pane	<b>Arm when connecting to target</b> check box
<b>Trigger options</b> pane	normal from drop-down menu in <b>Mode</b> field

- 6 Build the model to generate an executable file.
- 7 Deploy the target application.
- 8 Connect Simulink to the target application.
- 9 Start execution of the generated model code. The chart highlights states as they execute.

### View Test Point Data in Floating Scopes and Signal Viewers

When you simulate a chart in external mode, you can designate chart data of local scope to be test points and view the test point data in floating scopes and signal viewers.

To view test point data during simulation in external mode:

- 1 Open the Model Explorer and for each data you want to view, follow these steps:
  - a In the middle **Contents** pane, select the state or local data of interest.
  - b In the right **Dialog** pane, select the **Logging** tab and select **Test point** check box.
- 2 From a floating scope or signal viewer, click the signal selection button:

The Signal Selector dialog box opens.

- 3 In the Signal Selector **Model hierarchy** pane, select the chart.
- 4 In the Signal Selector **List contents** menu, select **Testpointed/Logged signals only** and then select the signals you want to view.
- 5 Simulate the model in external mode as described in “Animate States During Simulation in External Mode” on page 57-86.

The scope or viewer displays the values of the test point signals as the simulation runs.

For more information, see “Behavior of Scopes and Viewers with Rapid Accelerator Mode”.

## TCP/IP and Serial External Mode Limitations

Feature	Details
Changing parameters	<p>In general, you cannot change a parameter if doing so results in a change in the structure of the model. For example, you cannot change</p> <ul style="list-style-type: none"> <li>• The number of states, inputs, or outputs of a block</li> <li>• The sample time or the number of sample times</li> <li>• The integration algorithm for continuous systems</li> <li>• The name of the model or of a block</li> </ul> <p>If you make these changes to the block diagram, then you must rebuild the program with newly generated code.</p> <p>You can change parameters in transfer function and state space representation blocks in specific ways:</p> <ul style="list-style-type: none"> <li>• The parameters (numerator and denominator polynomials) for the Transfer Fcn (continuous and discrete) and Discrete Filter blocks can be changed (as long as the number of states does not change).</li> <li>• Zero entries in the State-Space and Zero Pole (both continuous and discrete) blocks in the user-specified or computed parameters (that is, the A, B, C, and D matrices obtained by a zero-pole to state-space transformation) cannot be changed once external simulation is started.</li> <li>• In the State-Space block, if you specify the matrices in the controllable canonical realization, then all changes to the A, B, C, D matrices that preserve this realization and the dimensions of the matrices are allowed.</li> </ul> <p>If the Simulink block diagram does not match the external program, Simulink produces an error stating that the checksums do not match. The checksums take into account the top models, but not referenced models. Use the updated block diagram to rebuild the target application.</p>
Uploading data	For parameters with fixed-point values, uploading of parameter values from the target application is not supported.
Uploading variable-size signals	<p>Uploading of variable-size signals is not supported for these targets:</p> <ul style="list-style-type: none"> <li>• Simulink Real-Time</li> <li>• Texas Instruments C2000™</li> </ul>
Signal value display in simulation	Graphical display of signal values in models (described in “Display Signal Values in Model Diagrams”) is not supported. For example, you cannot use the <b>Data Display in Simulation</b> menu selections <b>Show Value Labels When Hovering</b> , <b>Toggle Value Labels When Clicked</b> , and <b>Show Value Label of Selected Port</b> .
Tunable structure parameters	Uploading or downloading of tunable structure parameters is not supported.

Feature	Details
Pure integer code	<p>Pure integer code is supported.</p> <p>If you do not specify <code>-tf finalTime</code> in the execution command, the target application runs the generated model code indefinitely, ignoring <code>StopTime</code>.</p> <p>If you specify <code>-tf finalTime</code> in the execution command:</p> <ul style="list-style-type: none"> <li>• The <i>finalTime</i> value represents base rate steps, not seconds.</li> <li>• The maximum value for <i>finalTime</i>, in ticks, is <code>MAX_int32_T</code>.</li> <li>• When the 16-bit or 32-bit tick counter overflows, the simulation time in Scope blocks returns to zero.</li> </ul>
Half precision	Half-precision data types are not supported.
<code>Simulink.ImageType</code>	<code>Simulink.ImageType</code> data type is not supported.
Archiving data	For archiving data to disk, Scope and To Workspace blocks are supported. However, other scopes are not supported for data archiving. For example, you cannot use Floating Scope blocks or Viewers and Generators Manager viewer objects to archive data.
Scopes in referenced models	<p>In a model hierarchy, if the top model simulates in external mode and a referenced model simulates in normal or accelerator mode, scopes in the referenced model are not displayed.</p> <p>However, if the top model is changed to simulate in normal mode, the behavior of scopes in the referenced models differs between normal and accelerator mode. Scopes in a referenced model simulating in normal mode are displayed, while scopes in a referenced model simulating in accelerator mode are not displayed.</p>
Simulation start time	Nonzero simulation start times are not supported. In the Configuration Parameters dialog box, <b>Solver</b> pane, leave <b>Start time</b> set to the default value of <code>0.0</code> .
Intermediate step values	<p>Some Simulink blocks can generate multiple values in a simulation time step. For example:</p> <ul style="list-style-type: none"> <li>• A Simulink Function or Function-Call Subsystem block that is invoked multiple times in a time step.</li> <li>• Iterator subsystem blocks that execute multiple times in a time step.</li> </ul> <p>For each time step in an external mode simulation, Simulink uploads from the target application only the final values of such blocks. Simulink does not upload the intermediate values generated during the step.</p>
File-scoped data	File-scoped data are not supported, for example, data items to which you apply the built-in custom storage class, <code>FileScope</code> . File-scoped data are not externally accessible.
Signals with custom storage classes	Uploading of signals with custom storage classes (CSC) is not supported.

Feature	Details
Use of <code>printf</code> Statements	To show target application error and information messages on the target hardware display, you can use <code>printf</code> calls. For some target hardware, the use of <code>printf</code> statements can increase the external mode binary file size. To disable <code>printf</code> calls, specify the preprocessor macro definition <code>EXTMODE_DISABLEPRINTF</code> for your target application compiler.
Command-line arguments	<p>You can use command-line arguments for running target applications. These limitations apply:</p> <ul style="list-style-type: none"> <li>• Parsing of the command-line arguments requires the <code>sscanf</code> function, which increases the program size for some target hardware.</li> <li>• Some target applications do not accept command-line arguments.</li> </ul> <p>If your target hardware does not support the parsing of command-line arguments, specify the preprocessor macro definition <code>EXTMODE_DISABLE_ARGS_PROCESSING=1</code> for your target application compiler.</p> <p>To replace the <code>-w</code> option, you can use this command to specify that the target application enters and stays in a wait state until it receives a Connect message from Simulink:</p> <pre>set_param(modelName, 'OnTargetWaitForStart', 'on');</pre> <p>The build process provides the required option (<code>-DON_TARGET_WAIT_FOR_START=1</code>) to the compiler.</p>
Row-major code generation	Code generated with the row-major format is not supported.

## Create a Transport Layer for TCP/IP or Serial External Mode Communication

### In this section...

“Design of External Mode” on page 57-90

“External Mode Communications Overview” on page 57-92

“External Mode Source Files” on page 57-93

“Implement a Custom Transport Layer” on page 57-96

This section helps you to connect your custom target by using external mode using your own low-level communications layer. The topics include:

- An overview of the design and operation of external mode
- A description of external mode source files
- Guidelines for modifying the external mode source files and building an executable to handle the tasks of the default `ext_comm` MEX-file

This section assumes that you are familiar with the execution of Simulink Coder programs, and with the basic operation of external mode.

### Design of External Mode

External mode communication between the Simulink engine and a target system is based on a client/server architecture. The client (the Simulink engine) transmits messages requesting the server (target) to accept parameter changes or to upload signal data. The server responds by executing the request.

A low-level *transport layer* handles physical transmission of messages. Both the Simulink engine and the model code are independent of this layer. Both the transport layer and code directly interfacing to the transport layer are isolated in separate modules that format, transmit, and receive messages and data packets.

This design makes it possible for different targets to use different transport layers. The GRT, ERT, and RSim targets support host/target communication by using TCP/IP and RS-232 (serial) communication. The Simulink Desktop Real-Time target supports shared memory communication. The Wind River Systems Tornado® target supports TCP/IP only.

The Simulink Coder product provides full source code for both the client and server-side external mode modules, as used by the GRT, ERT, Rapid Simulation, and Tornado targets, and the Simulink Desktop Real-Time and Simulink Real-Time products. The main client-side module is `ext_comm.c`. The main server-side module is `ext_svr.c`.

These two modules call the specified transport layer through the following source files.

**Built-In Transport Layer Implementations**

Protocol	Client or Server?	Source Files
TCP/IP	Client (host)	<ul style="list-style-type: none"> <li><i>matlabroot/toolbox/coder/simulinkcoder_core/ext_mode/host/common/rtiostream_interface.c</i></li> <li><i>matlabroot/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c</i></li> </ul>
	Server (target)	<ul style="list-style-type: none"> <li><i>matlabroot/rtw/c/src/ext_mode/common/rtiostream_interface.c</i></li> <li><i>matlabroot/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c</i></li> </ul>
Serial	Client (host)	<ul style="list-style-type: none"> <li><i>matlabroot/toolbox/coder/simulinkcoder_core/ext_mode/host/serial/ext_serial_transport.c</i></li> <li><i>matlabroot/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream_serial.c</i></li> </ul>
	Server (target)	<ul style="list-style-type: none"> <li><i>matlabroot/rtw/c/src/ext_mode/serial/ext_svr_serial_transport.c</i></li> <li><i>matlabroot/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream_serial.c</i></li> </ul>

For serial communication, the modules *ext\_serial\_transport.c* and *rtiostream\_serial.c* implement the client-side transport functions and the modules *ext\_svr\_serial\_transport.c* and *rtiostream\_serial.c* implement the corresponding server-side functions. For TCP/IP communication, the modules *rtiostream\_interface.c* and *rtiostream\_tcpip.c* implement both client-side and server-side functions. You can edit copies of these files (but do not modify the originals). You can support external mode using your own low-level communications layer by creating similar files using the following templates:

- Client (host) side: *matlabroot/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream\_tcpip.c* (TCP/IP) or *matlabroot/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream\_serial.c* (serial)
- Server (target) side: *matlabroot/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream\_tcpip.c* (TCP/IP) or *matlabroot/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream\_serial.c* (serial)

The *rtiostream\_interface.c* file is an interface between the external mode protocol and an *rtiostream* communications channel. For more details on implementing and testing an *rtiostream* communications channel, see:

- “Communications *rtiostream* API” on page 82-44
- *rtiostreamtest*

Implement your *rtiostream* communications channel by using the documented interface to avoid having to make changes to the file *rtiostream\_interface.c* or other external mode related files.

---

**Note** Do not modify working source files. Use the templates provided in the */custom* or */rtiostream* folder as starting points, guided by the comments within them.

---

You need only provide code that implements low-level communications. You need not be concerned with issues such as data conversions between host and target, or with the formatting of messages. The Simulink Coder software handles these functions.

On the client (Simulink engine) side, communications are handled by `ext_comm` (for TCP/IP) and `ext_serial_win32_comm` (for serial) MEX-files.

On the server (target) side, external mode modules are linked into the target executable. This takes place automatically at code generation time if you select **External mode** and is based on the **Transport layer** option that you specify. The modules, called from the main program and the model execution engine, are independent of the generated model code.

The general procedure for implementing your own client-side low-level transport protocol is as follows:

- 1 Edit the template `rtiostream_tcpip.c` to replace low-level communication calls with your own communication calls.
- 2 Generate a MEX-file executable for your custom transport.
- 3 Register your new transport layer with the Simulink software, so that the transport can be selected for a model using the **Interface** pane of the Configuration Parameters dialog box.

For more details, see “Create a Custom Client (Host) Transport Protocol” on page 57-96.

The general procedure for implementing your own server-side low-level transport protocol is as follows:

- 1 Edit the template `rtiostream_tcpip.c` to replace low-level communication calls with your own communication calls. Typically this involves writing or integrating device drivers for your target hardware.
- 2 Modify template makefiles to support the new transport.

For more details, see “Create a Custom Server (Target) Transport Protocol” on page 57-99.

## External Mode Communications Overview

This section gives a high-level overview of how a Simulink Coder generated program communicates with Simulink external mode. This description is based on the TCP/IP version of external mode that ships with the Simulink Coder product.

For communication to take place, both the server (target) program and the Simulink software must be executing. This does not mean that the model code in the server system must be executing. The server can be waiting for the Simulink engine to issue a command to start model execution.

The client and server communicate by using bidirectional sockets carrying packets. Packets consist either of *messages* (commands, parameter downloads, and responses) or *data* (signal uploads).

If the target application was invoked with the `-w` command-line option, the program enters a wait state until it receives a message from the host. Otherwise, the program begins execution of the model. While the target application is in a wait state, the Simulink engine can download parameters to the target and configure data uploading.

When the user chooses the **Connect to Target** option from the **Simulation** menu, the host initiates a handshake by sending an `EXT_CONNECT` message. The server responds with information about itself. This information includes

- Checksums. The host uses model checksums to determine that the target code is an exact representation of the current Simulink model.
- Data format information. The host uses this information when formatting data to be downloaded, or interpreting data that has been uploaded.

At this point, host and server are connected. The server is either executing the model or in the wait state. (In the latter case, the user can begin model execution by selecting **Start Real-Time Code** from the **Simulation** menu.)

During model execution, the message server runs as a background task. This task receives and processes messages such as parameter downloads.

Data uploading comprises both foreground execution and background servicing of the signal packets. As the target computes model outputs, it also copies signal values into data upload buffers. This occurs as part of the task associated with each task identifier (`tid`). Therefore, data collection occurs in the foreground. Transmission of the collected data, however, occurs as a background task. The background task sends the data in the collection buffers to the Simulink engine by using data packets.

The host initiates most exchanges as messages. The target usually sends a response confirming that it has received and processed the message. Examples of messages and commands are:

- Connection message / connection response
- Start target simulation / start response
- Parameter download / parameter download response
- Arm trigger for data uploading / arm trigger response
- Terminate target simulation / target shutdown response

Model execution terminates when the model reaches its final time, when the host sends a terminate command, or when a Stop Simulation block terminates execution. On termination, the server informs the host that model execution has stopped, and shuts down its socket. The host also shuts down its socket, and exits external mode.

## External Mode Source Files

- “Client (Host) MEX-file Interface Source Files” on page 57-93
- “Server (Target) Source Files” on page 57-95
- “Other Files in the Server Folder” on page 57-96

### Client (Host) MEX-file Interface Source Files

The source files for the MEX-file interface component are located in the folder `matlabroot/toolbox/coder/simulinkcoder_core/ext_mode/host` (open), except as noted:

- `common/ext_comm.c`

This file is the core of external mode communication. It acts as a relay station between the target and the Simulink engine. `ext_comm.c` communicates to the Simulink engine by using a shared data structure, `ExternalSim`. It communicates to the target by using calls to the transport layer.

Tasks carried out by `ext_comm.c` include establishment of a connection with the target, downloading of parameters, and termination of the connection with the target.

- `common/rtiostream_interface.c`

This file is an interface between the external mode protocol and an `rtiostream` communications channel. For more details on implementing an `rtiostream` communications channel, see “Communications `rtiostream` API” on page 82-44. Implement your `rtiostream` communications channel using the documented interface to avoid having to change the file `rtiostream_interface.c` or other external mode related files.

- `matlabroot/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c`

This file implements required TCP/IP transport layer functions. The version of `rtiostream_tcpip.c` shipped with the Simulink Coder software uses TCP/IP functions including `recv()`, `send()`, and `socket()`.

- `matlabroot/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream_serial.c`

This file implements required serial transport layer functions. The version of `rtiostream_serial.c` shipped with the Simulink Coder software uses serial functions including `ReadFile()`, `WriteFile()`, and `CreateFile()`.

- `serial/ext_serial_transport.c`

This file implements required serial transport layer functions. `ext_serial_transport.c` includes `ext_serial_utils.c`, which is located in `matlabroot/rtw/c/src/ext_mode/serial` (open) and contains functions common to client and server sides.

- `common/ext_main.c`

This file is a MEX-file wrapper for external mode. `ext_main.c` interfaces to the Simulink engine by using the standard `mexFunction` call. (See the `mexFunction` reference page and “Integrate MATLAB with External Programming Languages and Systems” for more information.) `ext_main.c` contains a function dispatcher, `esGetAction`, that sends requests from the Simulink engine to `ext_comm.c`.

- `common/ext_convert.c` and `ext_convert.h`

This file contains functions used for converting data from host to target formats (and vice versa). Functions include byte-swapping (big to little- endian), conversion from non-IEEE floats to IEEE doubles, and other conversions. These functions are called both by `ext_comm.c` and directly by the Simulink engine (by using function pointers).

---

**Note** You do not need to customize `ext_convert` to implement a custom transport layer. However, you might want to customize `ext_convert` for the intended target. For example, if the target represents the `float` data type in Texas Instruments format, `ext_convert` must be modified to perform a Texas Instruments to IEEE conversion.

---

- `common/extsim.h`

This file defines the `ExternalSim` data structure and access macros. This structure is used for communication between the Simulink engine and `ext_comm.c`.

- `common/extutil.h`

This file contains only conditionals for compilation of the `assert` macro.

- `common/ext_transport.h`

This file defines functions that must be implemented by the transport layer.

### Server (Target) Source Files

These files are linked into the `model.exe` executable. They are located within `matlabroot/rtw/c/src/ext_mode` (open) except as noted.

- `common/ext_svr.c`

`ext_svr.c` is analogous to `ext_comm.c` on the host, but generally is responsible for more tasks. It acts as a relay station between the host and the generated code. Like `ext_comm.c`, `ext_svr.c` carries out tasks such as establishing and terminating connection with the host. `ext_svr.c` also contains the background task functions that either write downloaded parameters to the target model, or extract data from the target data buffers and send it back to the host.

- `common/rtiostream_interface.c`

This file is an interface between the external mode protocol and an `rtiostream` communications channel. For more details on implementing an `rtiostream` communications channel, see “Communications `rtiostream` API” on page 82-44. Implement your `rtiostream` communications channel by using the documented interface to avoid having to change the file `rtiostream_interface.c` or other external mode related files.

- `matlabroot/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c`

This file implements required TCP/IP transport layer functions. The version of `rtiostream_tcpip.c` shipped with the Simulink Coder software uses TCP/IP functions including `recv()`, `send()`, and `socket()`.

- `matlabroot/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream_serial.c`

This file implements required serial transport layer functions. The version of `rtiostream_serial.c` shipped with the software uses serial functions including `ReadFile()`, `WriteFile()`, and `CreateFile()`.

- `matlabroot/toolbox/coder/rtiostream/src/rtiostream.h`

This file defines the `rtIOStream*` functions implemented in `rtiostream_tcpip.c`.

- `serial/ext_svr_serial_transport.c`

This file implements required serial transport layer functions. `ext_svr_serial_transport.c` includes `serial/ext_serial_utils.c`, which contains functions common to client and server sides.

- `common/updown.c`

`updown.c` handles the details of interacting with the target model. During parameter downloads, `updown.c` does the work of installing the new parameters into the model's parameter vector. For data uploading, `updown.c` contains the functions that extract data from the model's `blockio` vector and write the data to the upload buffers. `updown.c` provides services both to `ext_svr.c` and to the model code (for example, `grt_main.c`). It contains code that is called by using the

background tasks of `ext_svr.c` as well as code that is called as part of the higher priority model execution.

- `matlabroot/rtw/c/src/dt_info.h` (included by generated model build file `model.h`)

These files contain data type transition information that allows access to multi-data type structures across different computer architectures. This information is used in data conversions between host and target formats.

- `common/updown_util.h`

This file contains only conditionals for compilation of the `assert` macro.

- `common/ext_svr_transport.h`

This file defines the `Ext*` functions that must be implemented by the server (target) transport layer.

### Other Files in the Server Folder

- `common/ext_share.h`

Contains message code definitions and other definitions required by both the host and target modules.

- `serial/ext_serial_utils.c`

Contains functions and data structures for communication, MEX link, and generated code required by both the host and target modules of the transport layer for serial protocols.

- The serial transport implementation includes the additional files
  - `serial/ext_serial_pkt.c` and `ext_serial_pkt.h`
  - `serial/ext_serial_port.h`

## Implement a Custom Transport Layer

- “Requirements for Custom Transport Layers” on page 57-96
- “Create a Custom Client (Host) Transport Protocol” on page 57-96
- “MATLAB Commands to Rebuild `ext_comm` and `ext_serial_win32` MEX-Files” on page 57-97
- “Register a Custom Client (Host) Transport Protocol” on page 57-98
- “Create a Custom Server (Target) Transport Protocol” on page 57-99
- “Serial Receive Buffer Smaller than 64 Bytes” on page 57-100

### Requirements for Custom Transport Layers

- By default, `ext_svr.c` and `updown.c` use `malloc` to allocate buffers in target memory for messages, data collection, and other purposes, although there is also an option to preallocate static memory. If your target uses another memory allocation scheme, you must modify these modules.
- The target is assumed to support both `int32_T` and `uint32_T` data types.

### Create a Custom Client (Host) Transport Protocol

To implement the client (host) side of your low-level transport protocol,

- 1 Edit the template file `matlabroot/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c` to replace low-level communication calls with your own communication calls.
  - a Copy and rename the file to `rtiostream_name.c` (replacing *name* with a name meaningful to you).
  - b Replace the functions `rtIOStreamOpen`, `rtIOStreamClose`, `rtIOStreamSend`, and `rtIOStreamRecv` with functions (of the same name) that call your low-level communication primitives. These functions are called from other external mode modules via `rtiostream_interface.c`. For more information, see “Communications rtiostream API” on page 82-44.
  - c Build your `rtiostream` implementation into a shared library that exports the `rtIOStreamOpen`, `rtIOStreamClose`, `rtIOStreamRecv` and `rtIOStreamSend` functions.
- 2 Build the customized MEX-file executable using the MATLAB `mex` function. See “MATLAB Commands to Rebuild `ext_comm` and `ext_serial_win32` MEX-Files” on page 57-97 for examples of `mex` invocations.

Do not replace the existing `ext_comm` MEX-file if you want to preserve its functionality. Instead, use the `-output` option to name the new executable file, for example, `my_ext_comm`. For more information, see `mex`.

- 3 Register your new client transport layer with the Simulink software, so that the transport can be selected for a model using the **Interface** pane of the Configuration Parameters dialog box. For details, see “Register a Custom Client (Host) Transport Protocol” on page 57-98.

Sample commands for rebuilding external mode MEX-files are listed in “MATLAB Commands to Rebuild `ext_comm` and `ext_serial_win32` MEX-Files” on page 57-97.

### MATLAB Commands to Rebuild `ext_comm` and `ext_serial_win32` MEX-Files

The following table lists the commands for building the standard `ext_comm` and `ext_serial_win32` modules on PC and UNIX platforms.

Platform	Commands
Windows, TCP/IP	<pre>cd (matlabroot) mex toolbox/coder/simulinkcoder_core/ext_mode/host/common/ext_comm.c ...     toolbox/coder/simulinkcoder_core/ext_mode/host/common/ext_convert.c ...     toolbox/coder/simulinkcoder_core/ext_mode/host/common/rtiostream_interface.c ...     toolbox/coder/simulinkcoder_core/ext_mode/host/common/ext_util.c ... -R2018a ... -Itoolbox/coder/rtiostream/src ... -Itoolbox/coder/rtiostream/src/utils_host ... -Itoolbox/coder/simulinkcoder_core/ext_mode/host/common/include ... -Irtw/c/src/ext_mode/common ... -lmwrtiostreamutils -lmwsl_services ... -DEXTMODE_TCPIP_TRANSPORT ... -DSL_EXT_DLL -output my_ext_comm</pre> <p><b>Note</b> The <code>rtiostream_interface.c</code> function defines <code>RTIOSTREAM_SHARED_LIB</code> as <code>libmwrtiostreamtcpip</code> and dynamically loads the MathWorks TCP/IP <code>rtiostream</code> shared library. Modify this file if you need to load a different <code>rtiostream</code> shared library.</p>

Platform	Commands

**Note** `mex` requires a compiler supported by the MATLAB API. See the `mex` reference page and “Integrate MATLAB with External Programming Languages and Systems” for more information about the `mex` function.

### Register a Custom Client (Host) Transport Protocol

To register a custom client transport protocol with the Simulink software, you must add an entry of the following form to an `sl_customization.m` file on the MATLAB path:

```
function sl_customization(cm)
 cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
% -- end of sl_customization
```

where

- *stf.tlc* is the name of the system target file for which the transport will be registered (for example, 'grt.tlc')
- *transport* is the transport name to display in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box (for example, 'mytcpip')
- *mexfile* is the name of the transport's associated external interface MEX-file (for example, 'ext\_mytcpip\_comm')

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```
function sl_customization(cm)
 cm.ExtModeTransports.add('grt.tlc', 'mytcpip', 'ext_mytcpip_comm', 'Level1');
 cm.ExtModeTransports.add('ert.tlc', 'mytcpip', 'ext_mytcpip_comm', 'Level1');
% -- end of sl_customization
```

If you place the `sl_customization.m` file containing the transport registration information on the MATLAB path, your custom client transport protocol will be registered with each subsequent Simulink session. The name of the transport will appear in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box. When you select the transport for your model, the name of the associated external interface MEX-file will appear in the noneditable **MEX-file name** field, as shown in the following figure.

External mode

External mode configuration

Transport layer:  MEX-file name: ext\_mytcpip\_comm

MEX-file arguments:

Static memory allocation

### Create a Custom Server (Target) Transport Protocol

The `rtIOStream*` function prototypes in `matlabroot/toolbox/coder/rtiostream/src/rtiostream.h` define the calling interface for both the server (target) and client (host) side transport layer functions.

- The TCP/IP implementations are in `matlabroot/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c`.
- The serial implementations are in `matlabroot/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream_serial.c`.

---

**Note** The `Ext*` function prototypes in `matlabroot/rtw/c/src/ext_mode/common/ext_svr_transport.h` are implemented in `matlabroot/rtw/c/src/ext_mode/common/rtiostream_interface.c` or `matlabroot/rtw/c/src/ext_mode/serial/rtiostream_serial_interface.c`. In most cases you will not need to modify `rtiostream_interface.c` or `rtiostream_serial_interface.c` for your custom TCP/IP or serial transport layer.

---

To implement the server (target) side of your low-level TCP/IP or serial transport protocol:

- 1 Edit the template `matlabroot/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c` or `matlabroot/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream_serial.c` to replace low-level communication calls with your own communication calls.
  - a Copy and rename the file to `rtiostream_name.c` (replacing *name* with a name meaningful to you).
  - b Replace the functions `rtIOStreamOpen`, `rtIOStreamClose`, `rtIOStreamSend`, and `rtIOStreamRecv` with functions (of the same name) that call your low-level communication drivers.

You must implement the functions defined in `rtiostream.h`, and your implementations must conform to the prototypes defined in that file. Refer to the original `rtiostream_tcpip.c` or `rtiostream_serial.c` for guidance.

- 2 Incorporate the external mode source files for your transport layer into the model build process. Use a build process mechanism such as a post code generation command or a `before_make` hook function to make the transport files available to the build process. For more information on the build process mechanisms, see “Customize Post-Code-Generation Build Processing”, “Customize Build Process with `STF_make_rtw_hook` File”, and “Customize Build Process with `sl_customization.m`”.

For example:

- Add the file created in the previous step to the build information:

```
path/rtiostream_name.c
```

- For TCP/IP, add the following file to the build information:

```
matlabroot/rtw/c/src/ext_mode/common/rtiostream_interface.c
```

- For serial, add the following files to the build information:

```
matlabroot/rtw/c/src/ext_mode/serial/ext_serial_pkt.c
matlabroot/rtw/c/src/ext_mode/serial/rtiostream_serial_interface.c
matlabroot/rtw/c/src/ext_mode/serial/ext_svr_serial_transport.c
```

---

**Note** For external mode, check that `rtIOStreamRecv` is not a blocking implementation. Otherwise, it might cause the external mode server to block until the host sends data through the `comm` layer.

---

### Serial Receive Buffer Smaller than 64 Bytes

For serial communication, if the serial receive buffer of your target is smaller than 64 bytes:

- 1 Update the following macro with the actual target buffer size:

```
#define TARGET_SERIAL_RECEIVE_BUFFER_SIZE 64
```

Implement the change in the following files:

```
matlabroot/rtw/c/src/ext_mode/serial/ext_serial_utils.c
matlabroot/toolbox/coder/simulinkcoder_core/ext_mode/host/serial/ext_serial_utils.c
```

- 2 Run the command to rebuild the `ext_serial_win32` MEX-file. See “MATLAB Commands to Rebuild `ext_comm` and `ext_serial_win32` MEX-Files” on page 57-97.

## Logging in Simulink Coder

---

## Log Program Execution Results

Multiple techniques are available by which a program generated by the Simulink Coder software can save data to a MAT-file for analysis. A generated executable can save system states, outputs, and simulation time at each model execution time step. The data is written to a MAT-file, named (by default) *model.mat*, where *model* is the name of your model. See “Log Data for Analysis” on page 58-2 for a data logging tutorial.

---

**Note** Data logging is available only for system target files that have access to a file system. In addition, only the RSim target executables are capable of accessing MATLAB workspace data.

For MAT-file logging limitations, see the configuration parameter “MAT-file logging”.

---

### Log Data for Analysis

- “Set Up and Configure Model” on page 58-2
- “Data Logging During Simulation” on page 58-3
- “Data Logging from Generated Code” on page 58-5

### Set Up and Configure Model

This example shows how data generated by a copy of the model `slexAircraftExample` is logged to the file `myAircraftExample.mat`. Refer to “Build Process Workflow for Real-Time Systems” on page 56-26 for instructions on setting up a copy of `slexAircraftExample` as `myAircraftExample` in a working folder if you have not done so already.

---

**Note** When you configure the code generator to produce code that includes support for data logging during execution, the code generator can include text for block names in the block paths included in the log file. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter `ア` with the escape sequence `&#x30A2`; . For more information, see “Internationalization and Code Generation”.

---

To configure data logging, open the Configuration Parameters dialog box and select the **Data Import/Export** pane. The process is the same as configuring a Simulink model to save output to the MATLAB workspace. For each workspace return variable you define and enable, the Simulink Coder software defines a parallel MAT-file variable. For example, if you save simulation time to the variable `tout`, your generated program logs the same data to a variable named `rt_tout`. You can change the prefix `rt_` to a suffix (`_rt`), or eliminate it entirely. You do this by setting model configuration parameter **MAT-file variable name modifier**.

To log signals in generated code, use the **Data Import/Export** model configuration parameters described below or include To File or To Workspace blocks in your model.

---

**Note** MAT-file logging for code generation does not support signal logging. If you enable MAT-file and signal logging by using **Data Import/Export** model configuration parameters and select signals for logging in the Simulink Editor, when you build the model, the code generator displays this warning:

Warning: MAT-file logging does not support signal logging.  
When your model code executes, the signal logging variable 'rt\_logout' will not be saved to the MAT-file.

To avoid this warning, clear the model configuration parameter **Signal logging**.

---

In this example, you modify the `myAircraftExample` model so that the generated program saves the simulation time and system outputs to the file `myAircraftExample.mat`. Then you load the data into the base workspace and plot simulation time against one of the outputs. The `myAircraftExample` model should be configured as described in “Build Process Workflow for Real-Time Systems” on page 56-26.

### Data Logging During Simulation

To use the data logging feature:

- 1 Open the `myAircraftExample` model if it is not already open.
- 2 Open the Configuration Parameters dialog box.
- 3 Select the **Data Import/Export** pane. The **Data Import/Export** pane lets you specify which output data is to be saved to the workspace and what variable names to use for it.
- 4 Set parameter **Format** to **Structure with time**. When you select this format, Simulink saves the model states and outputs in structures that have their names specified in the **Save to workspace or file** area. By default, the structures are `xout` for states and `yout` for output. The structure used to save output has two top-level fields: `time` and `signals`. The `time` field contains a vector of simulation times and `signals` contains an array of substructures, each of which corresponds to a model output port.
- 5 Select **Output**. This tells Simulink to save output signal data during simulation as a variable named `yout`. Selecting **Output** enables the code generator to create code that logs the root Output block (`alpha`, `rad`) to a MAT-file.
- 6 Set **Decimation** to 1.
- 7 If other parameters are selected, clear them.
- 8 Click **Apply** and **OK** to register your changes and close the dialog box.
- 9 Save the model.
- 10 In the model window, double-click the scope symbol next to the Aircraft Dynamics Model block, then simulate the model. The resulting scope display is shown below.

- 11** Verify that the simulation time and outputs have been saved to the base workspace in MAT-files. At the MATLAB prompt, type:

```
whos yout
```

Simulink displays:

Name	Size	Bytes	Class	Attributes
yout	1x1	10756	struct	

- 12** Verify that `alpha, rad` was logged by plotting simulation time versus that variable. In the Command Window, type:

```
plot(yout.time,yout.signals.values)
```

## Data Logging from Generated Code

In the second part of this example, you build and run an executable program built by the code generator for model `myAircraftExample`. The program outputs a MAT-file containing the simulation time and output you previously examined. Even though you have already generated code for the `myAircraftExample` model, you must now regenerate that code because you have changed the model by enabling data logging. The steps below explain this procedure.

To avoid overwriting workspace data with data from simulation runs, the code generator modifies identifiers for variables logged by Simulink. You can control these modifications.

- 1 Set model configuration parameter **MAT-file variable name modifier** to `_rt`. This adds the suffix `_rt` to each variable that you selected to be logged in the first part of this example.
- 2 Click **Apply** and **OK** to register your changes and close the dialog box.
- 3 Save the model.
- 4 Build an executable.
- 5 When the build concludes, run the executable program with the command:

```
!myAircraftExample
```

- 6 The program now produces two message lines, indicating that the MAT-file has been written.

```
** starting the model **
** created myAircraftExample.mat **
```

- 7 Load the MAT-file data created by the executable and look at the workspace variables from simulation and the generated program by typing:

```
load myAircraftExample.mat
whos yout*
```

Simulink displays:

Name	Size	Bytes	Class	Attributes
yout	1x1	10756	struct	
yout_rt	1x1	10756	struct	

Note the size and bytes of the structures resulting from the simulation run and generated code are the same.

- 8 Plot the generated code output by entering the following command in the Command Window:

```
plot(yout_rt.time,yout_rt.signals.values)
```

The plot should be identical to the plot that you produced in the previous part of this example.

---

**Tip** For UNIX platforms, run the executable program in the Command Window with the syntax `!./executable_name`. If preferred, run the executable program from an OS shell with the syntax `./executable_name`. For more information, see “Run External Commands, Scripts, and Programs”.

---

## Configure State, Time, and Output Logging

The **Data Import/Export** pane enables a generated program to save system states, outputs, and simulation time at each model execution time step. The data is written to a MAT-file, named (by default) `model.mat`.

Before using this data logging feature, you should learn how to configure a Simulink model to return output to the MATLAB workspace. This is discussed in “Export Simulation Data”.

For each workspace return variable that you define and enable, the code generator defines a MAT-file variable. For example, if your model saves simulation time to the workspace variable `tout`, your generated program logs the same data to a variable named (by default) `rt_tout`.

The code generated by the code generator logs the following data:

- Root Output blocks

The default MAT-file variable name for system outputs is `rt_yout`.

The sort order of the `rt_yout` array is based on the port number of the Output block, starting with 1.

- Continuous and discrete states in the model

The default MAT-file variable name for system states is `rt_xout`.

- Simulation time

The default MAT-file variable name for simulation time is `rt_tout`.

- “Override Default MAT-File Variable Names” on page 58-7
- “Override Default MAT-File Name or Buffer Size” on page 58-7

### Override Default MAT-File Variable Names

By default, the code generator prefixes the text `rt_` to the variable names for system outputs, states, and simulation time to form MAT-file variable names. To change this prefix for a model, set model configuration parameter **MAT-file variable name modifier** to `(rt_)`, a suffix `(_rt)`, or no modifier (none). Other system target files might not support this parameter.

### Override Default MAT-File Name or Buffer Size

You can specify compiler options to override the following MAT-file attributes in generated code:

MAT-File Attribute	Default	Compiler Option
Name	<code>model.mat</code>	<code>-DSAVEFILE=<i>filename</i></code>
Size of data logging buffer	1024 bytes	<code>-DDEFAULT_BUFFER_SIZE=<i>n</i></code>

**Note** Valid option syntax can vary among compilers. For example, Microsoft Visual C++ compilers typically accept `/DSAVEFILE=filename` as well as `-DSAVEFILE=filename`.

For a template makefile (TMF) based target, set model configuration parameter **Make command** to the compiler option. For example:

```
Make command: make_rtw OPTS="-DSAVEFILE=myCodeLog.mat"
```

For a toolchain-based system target file such as GRT or ERT, add the compiler option to model configuration. Set parameter **Build configuration** to `Specify`, and add the compiler option to the **C Compiler** row of the **Tool/Options** table. For example:

Tool	Options
C Compiler	<code>\$(cflags) \$(CVARSFLAG) \$(CFLAGS_ADDITIONAL) -DSAVEFILE=myCodeLog.mat /Od /Oy-</code>

To add the compiler option to a custom toolchain, you can modify and reregister the custom toolchain using the procedures shown in the example “Add Custom Toolchains to MATLAB® Coder™ Build Process”. For example, to add the compiler option to the MATLAB source file for the custom toolchain, you could define `myCompilerOpts` as follows:

```
optimsOff0pts = {'/c /Od'};
optimsOn0pts = {'/c /O2'};
cCompilerOpts = '$(cflags) $(CVARSFLAG) $(CFLAGS_ADDITIONAL)';
cppCompilerOpts = '$(cflags) $(CVARSFLAG) $(CPPFLAGS_ADDITIONAL)';
myCompilerOpts = {' -DSAVEFILE=myCodeLog.mat '};
...
```

Then you can add `myCompilerOpts` to the flags for each configuration and compiler to which it applies, for example:

```
cfg = tc.getBuildConfiguration('Faster Builds');
cfg.setOption('C Compiler', horzcat(cCompilerOpts, myCompilerOpts, optimsOff0pts));
```

As shown in “Add Custom Toolchains to MATLAB® Coder™ Build Process”, after modifying the custom toolchain, you save the configuration to a MAT-file and refresh the target registry.

## Log Data with Scope and To Workspace Blocks

The code generated by the code generator also logs data from these sources:

- Scope blocks that have the block parameter **Log data to workspace** enabled

You must specify the variable name and data format in each Scope block's dialog box.

- To Workspace blocks in the model

You must specify the variable name and data format in each To Workspace block's dialog box.

The variables are written to `model.mat`, along with variables logged from the **Workspace I/O** pane.

## Log Data with To File Blocks

You can also log data to a To File block. The generated program creates a separate MAT-file (distinct from `model.mat`) for each To File block in the model. The file contains the block time and input data. You must specify the file name, variable name, decimation, and sample time in the To File block dialog box.

---

**Note** Models referenced by Model blocks do not perform data logging in that context except for states, which you can include in the state logged for top models. Code generated by the Simulink Coder software for referenced models does not perform data logging to MAT-files.

---

## Data Logging Differences Between Single- and Multitasking

When logging data in single-tasking and multitasking systems, you will notice differences in the logging of

- Noncontinuous root Output blocks
- Discrete states

In multitasking mode, the logging of states and outputs is done after the first task execution (and not at the end of the first time step). In single-tasking mode, the code generated by the build procedure logs states and outputs after the first time step.

See *Data Logging in Single-Tasking and Multitasking Model Execution* for more details on the differences between single-tasking and multitasking data logging.

---

**Note** The rapid simulation target (RSim) provides enhanced logging options. See “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File” for more information.

- “Use C API to Access Model Parameters” on page 59-23

## Exchange Data Between Generated and External Code Using C API

Some Simulink Coder applications must interact with signals, states, root-level inputs/outputs, or parameters in the generated code for a model. For example, calibration applications monitor and modify parameters. Signal monitoring or data logging applications interface with signal, state, and root-level input/output data. Using the Simulink Coder C API, you can build target applications that log signals, states, and root-level inputs/outputs, monitor signals, states, and root-level inputs/outputs, and tune parameters, while the generated code executes.

The C API minimizes its memory footprint by sharing information common to signals, states, root-level inputs/outputs, and parameters in smaller structures. Signal, state, root-level input/output, and parameter structures include an index into the structure map, allowing multiple signals, states, root-level inputs/outputs, or parameters to share data.

To get started with an example, see “Use C API to Access Model Signals and States” on page 59-18 or “Use C API to Access Model Parameters” on page 59-23.

### In this section...

“Generated C API Files” on page 59-2

“Generate C API Files” on page 59-3

“Description of C API Files” on page 59-4

“Generate C API Data Definition File for Exchanging Data with a Target System” on page 59-15

“C API Limitations” on page 59-16

### Generated C API Files

When you configure a model to use the C API, the Simulink Coder code generator generates two additional files, *model\_capi.c* (or *.cpp*) and *model\_capi.h*, where *model* is the name of the model. The code generator places the two C API files in the build folder, based on settings in the Configuration Parameters dialog box. The C API source code file contains information about global block output signals, states, root-level inputs/outputs, and global parameters defined in the generated code model source code. The C API header file is an interface header file between the model source code and the generated C API. You can use the information in these C API files to create your application. Among the files generated are those shown in the next figure.

### Generated Files with C API Selected

**Note** When you configure the code generator to produce code that includes support for the C API interface and data logging, the code generator can include text for block names in the block paths

logged to C API files *model\_capi.c* (or *.cpp*) and *model\_capi.h*. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter  $\text{ア}$  with the escape sequence `&#x30A2;`. For more information, see “Internationalization and Code Generation”.

## Generate C API Files

To generate C API files for your model:

- 1 Select the C API interface for your model. There are two ways to select the C API interface for your model, as described in the following sections.
  - “Select C API with Configuration Parameters Dialog” on page 59-3
  - “Select C API from the Command Line” on page 59-3
- 2 Generate code for your model.

After generating code, you can examine the files *model\_capi.c* (or *.cpp*) and *model\_capi.h* in the model build folder.

### Select C API with Configuration Parameters Dialog

- 1 Open your model, and open the Configuration Parameters dialog box.
- 2 In the **Code Generation** > **Interface** pane, in the **Data exchange interface** subgroup, select one or more C API options. Based on the options you select, support for accessing signals, parameters, states, and root-level I/O will appear in the C API generated code.
  - If you want to generate C API code for global block output signals, select **Generate C API for: signals**.
  - If you want to generate C API code for global block parameters, select **Generate C API for: parameters**.
  - If you want to generate C API code for discrete and continuous states, select **Generate C API for: states**.
  - If you want to generate C API code for root-level inputs and outputs, select **Generate C API for: root-level I/O**.

### Select C API from the Command Line

From the MATLAB command line, you can use the `set_param` function to select or clear C API model configuration parameters. At the MATLAB command line, enter one or more of the following commands, where `modelName` is the name of your model.

To select **Generate C API for: signals**, enter:

```
set_param('modelName', 'RTWCAPISignals', 'on')
```

To clear **Generate C API for: signals**, enter:

```
set_param('modelName', 'RTWCAPISignals', 'off')
```

To select **Generate C API for: parameters**, enter:

```
set_param('modelName', 'RTWCAPIParams', 'on')
```

To clear **Generate C API for: parameters**, enter:

```
set_param('modelName', 'RTWCAPIParams', 'off')
```

To select **Generate C API for: states**, enter:

```
set_param('modelName', 'RTWCAPISStates', 'on')
```

To clear **Generate C API for: states**, enter:

```
set_param('modelName', 'RTWCAPISStates', 'off')
```

To select **Generate C API for: root-level I/O**, enter:

```
set_param('modelName', 'RTWCAPIRootIO', 'on')
```

To clear **Generate C API for: root-level I/O**, enter:

```
set_param('modelName', 'RTWCAPIRootIO', 'off')
```

## Description of C API Files

- “About C API Files” on page 59-4
- “Structure Arrays Generated in C API Files” on page 59-6
- “Generate Example C API Files” on page 59-8
- “C API Signals” on page 59-8
- “C API States” on page 59-11
- “C API Root-Level Inputs and Outputs” on page 59-11
- “C API Parameters” on page 59-13
- “Map C API Data Structures to rtModel” on page 59-14

### About C API Files

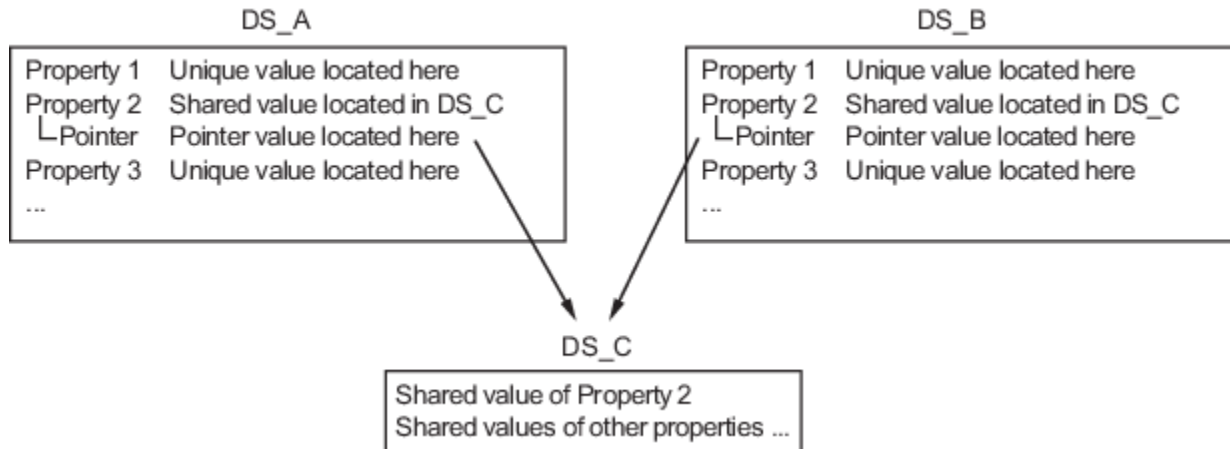

The `model_capi.c` (or `.cpp`) file provides external applications with a consistent interface to model data. Depending on your configuration settings, the data could be a signal, state, root-level input or output, or parameter. In this document, the term data item refers to either a signal, a state, a root-level input or output, or a parameter. The C API uses structures that provide an interface to the data item properties. The interface packages the properties of each data item in a data structure. If the model contains multiple data items, the interface generates an array of data structures. The members of a data structure map to data properties.

To interface with data items, an application requires the following properties for each data item:

- Name
- Block path
- Port number (for signals and root-level inputs/outputs only)
- Address
- Data type information: native data type, data size, complexity, and other attributes
- Dimensions information: number of rows, number of columns, and data orientation (scalar, vector, matrix, or  $n$ -dimensional)

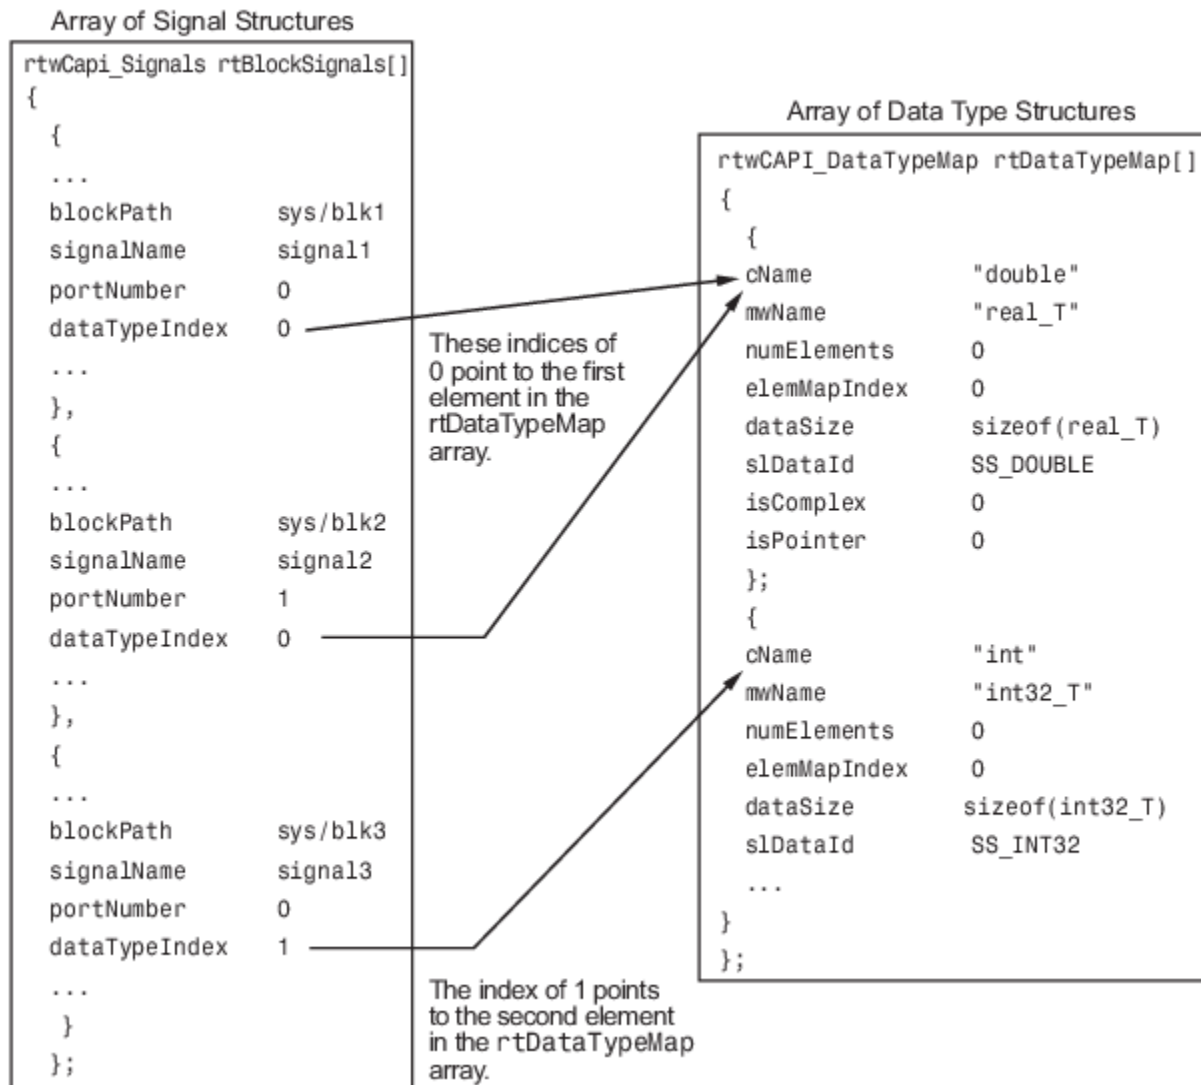

- Fixed-point information: slope, bias, scale type, word length, exponent, and other attributes
- Sample-time information (for signals, states, and root-level inputs/outputs only): sample time, task identifier, frames

As illustrated in the next figure, the properties of data item A, for example, are located in data structure DS\_A. The properties of data item B are located in data structure DS\_B.

Some property *values* can be unique to each data item, and there are some property values that several data items can share in common. Name, for example, has a unique value for each data item. The interface places the unique property values directly in the structure for the data item. The name value of data item A is in DS\_A, and the name value of data item B is in DS\_B.

But data type could be a property whose value several data items have in common. The ability of some data items to share a property allows the C API to have a reuse feature. In this case, the interface places only an index value in DS\_A and an index value in DS\_B. These indices point to a different data structure, DS\_C, that contains the actual data type value. The next figure shows this scheme with more detail.

The figure shows three signals. `signal1` and `signal2` share the same data type, `double`. Instead of specifying this data type value in each signal data structure, the interface provides only an index value, 0, in the structure. "double" is described by entry 0 in the `rtDataTypeMap` array, which is referenced by both signals. Additionally, property values can be shared between signals, states, root-level inputs/outputs, and parameters, so states, root-level inputs/outputs, and parameters also might reference the `double` entry in the `rtDataTypeMap` array. This reuse of information reduces the memory size of the generated interface.

### Structure Arrays Generated in C API Files

As with data type, the interface maps other common properties (such as address, dimension, fixed-point scaling, and sample time) into separate structures and provides an index in the structure for the data item. For a complete list of structure definitions, refer to the file `matlabroot/rtw/c/src/rtw_capi.h`. This file also describes each member in a structure. The structure arrays generated in the `model_capi.c` (or `.cpp`) file are of structure types defined in the `rtw_capi.h` file. Here is a brief description of the structure arrays generated in `model_capi.c` (or `.cpp`):

- **rtBlockSignals** is an array of structures that contains information about global block output signals in the model. Each element in the array is of type `struct rtwCAPI_Signals`. The members of this structure provide the signal name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.
- **rtBlockParameters** is an array of structures that contains information about the tunable block parameters in the model by block name and parameter name. Each element in the array is of type `struct rtwCAPI_BlockParameters`. The members of this structure provide the parameter name, block path, address, and indices to data type, dimension, and fixed-point structure arrays.
- **rtBlockStates** is an array of structures that contains information about discrete and continuous states in the model. Each element in the array is of type `struct rtwCAPI_States`. The members of this structure provide the state name, block path, type (continuous or discrete), and indices to the address, data type, dimension, fixed-point, and sample-time structure arrays.
- **rtRootInputs** is an array of structures that contains information about root-level inputs in the model. Each element in the array is of type `struct rtwCAPI_Signals`. The members of this structure provide the root-level input name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.
- **rtRootOutputs** is an array of structures that contains information about root-level outputs in the model. Each element in the array is of type `struct rtwCAPI_Signals`. The members of this structure provide the root-level output name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.
- **rtModelParameters** is an array of structures that contains information about workplace variables that one or more blocks or Stateflow charts in the model reference as block parameters. Each element in the array is of data type `rtwCAPI_ModelParameters`. The members of this structure provide the variable name, address, and indices to data type, dimension, and fixed-point structure arrays.
- **rtDataAddrMap** is an array of base addresses of signals, states, root-level inputs/outputs, and parameters that appear in the `rtBlockSignals`, `rtBlockParameters`, `rtBlockStates`, and `rtModelParameters` arrays. Each element of the `rtDataAddrMap` array is a pointer to `void` (`void*`).
- **rtDataTypeMap** is an array of structures that contains information about the various data types in the model. Each element of this array is of type `struct rtwCAPI_DataTypeMap`. The members of this structure provide the data type name, size of the data type, and information on whether or not the data is complex.
- **rtDimensionMap** is an array of structures that contains information about the various data dimensions in the model. Each element of this array is of type `struct rtwCAPI_DimensionMap`. The members of this structure provide information on the number of dimensions in the data, the orientation of the data (whether it is scalar, vector, or a matrix), and the actual dimensions of the data.
- **rtFixPtMap** is an array of structures that contains fixed-point information about the signals, states, root-level inputs/outputs, and parameters. Each element of this array is of type `struct rtwCAPI_FixPtMap`. The members of this structure provide information about the data scaling, bias, exponent, and whether or not the fixed-point data is signed. If the model does not have fixed-point data (signal, state, root-level input/output, or parameter), the Simulink Coder software assigns NULL or zero values to the elements of the `rtFixPtMap` array.
- **rtSampleTimeMap** is an array of structures that contains sampling information about the global signals, states, and root-level inputs/outputs in the model. (This array does not contain information about parameters.) Each element of this array is of type `struct rtwCAPI_SampleTimeMap`. The members of this structure provide information about the sample period, offset, and whether or not the data is frame-based or sample-based.

## Generate Example C API Files

Subtopics “C API Signals” on page 59-8, “C API States” on page 59-11, “C API Root-Level Inputs and Outputs” on page 59-11, and “C API Parameters” on page 59-13 discuss generated C API structures using the example model `rtwdemo_capi`. To generate code from the example model, do the following:

- 1 Open the model by clicking the `rtwdemo_capi` link above or by typing `rtwdemo_capi` on the MATLAB command line.
- 2 If you want to generate C API structures for root-level inputs/outputs in `rtwdemo_capi`, select model configuration parameter **Generate C API for: root-level I/O**.

The setting this parameter must match between the top model and the referenced model. If you modify the parameter setting, save the top model and the referenced model to the same writable work folder.

- 3 Generate code for the model.

The C API code examples in the next subtopics are generated with C as the target language.

This model has three global block output signals that will appear in C API generated code:

- `top_sig1`, which is a test point at the output of the Gain1 block in the top model
- `sig2_eg`, which appears in the top model and is defined in the base workspace as a `Simulink.Signal` object having storage class `ExportedGlobal`
- `bot_sig1`, which appears in the referenced model `rtwdemo_capi_bot` and is defined as a `Simulink.Signal` object having storage class `Model default`

The model also has two discrete states that will appear in the C API generated code:

- `top_state`, which is defined for the Delay1 block in the top model
- `bot_state`, which is defined for the Discrete Filter block in the referenced model

The model has root-level inputs/outputs that will appear in the C API generated code if you select model configuration parameter **Generate C API for: root-level I/O**:

- Four root-level inputs, `In1` through `In4`
- Six root-level outputs, `Out1` through `Out6`

Additionally, the model has five global block parameters that will appear in C API generated code:

- `Kp` (top model Gain1 block and referenced model Gain2 block share)
- `Ki` (referenced model Gain3 block)
- `p1` (lookup table `lu1d`)
- `p2` (lookup table `lu2d`)
- `p3` (lookup table `lu3d`)

## C API Signals

The `rtwC_API_Signals` structure captures signal information including the signal name, address, block path, output port number, data type information, dimensions information, fixed-point information, and sample-time information.

Here is the section of code in `rtwdemo_capi_capi.c` that provides information on C API signals for the top model in `rtwdemo_capi`:

```
/* Block output signal information */
static const rtwC_API_Signals rtBlockSignals[] = {
 /* addrMapIndex, sysNum, blockPath,
 * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
 */
 { 0, 0, "rtwdemo_capi/Gain1",
 "top_sig1", 0, 0, 0, 0, 0 },

 { 1, 0, "rtwdemo_capi/lu2d",
 "sig2_eg", 0, 0, 1, 0, 0 },

 {
 0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
 }
};
```

**Note** To better understand the code, read the comments in the file. For example, notice the comment that begins on the third line in the preceding code. This comment lists the members of the `rtwC_API_Signals` structure, in order. This tells you the order in which the assigned values for each member appear for a signal. In this example, the comment tells you that `signalName` is the fourth member of the structure. The following lines describe the first signal:

```
{ 0, 0, "rtwdemo_capi/Gain1",
 "top_sig1", 0, 0, 0, 0, 0 },
```

From these lines you infer that the name of the first signal is `top_sig1`.

Each array element, except the last, describes one output port for a block signal. The final array element is a sentinel, with all elements set to null values. For example, examine the second signal, described by the following code:

```
{ 1, 0, "rtwdemo_capi/lu2d",
 "sig2_eg", 0, 0, 1, 0, 0 },
```

This signal, named `sig2_eg`, is the output signal of the first port of the block `rtwdemo_capi/lu2d`. (This port is the first port because the zero-based index for `portNumber` displayed on the second line is assigned the value 0.)

The address of this signal is given by `addrMapIndex`, which, in this example, is displayed on the first line as 1. This provides an index into the `rtDataAddrMap` array, found later in `rtwdemo_capi_capi.c`:

```
/* Declare Data Addresses statically */
static void* rtDataAddrMap[] = {
 &rtwdemo_capi_B.top_sig1, /* 0: Signal */
 &sig2_eg[0], /* 1: Signal */
 &rtwdemo_capi_DWork.top_state, /* 2: Discrete State */
 &rtP_Ki, /* 3: Model Parameter */
 &rtP_Kp, /* 4: Model Parameter */
 &rtP_p1[0], /* 5: Model Parameter */
 &rtP_p2[0], /* 6: Model Parameter */
 &rtP_p3[0], /* 7: Model Parameter */
};
```

The index of 1 points to the second element in the `rtDataAddrMap` array. From the `rtDataAddrMap` array, you can infer that the address of this signal is `&sig2_eg[0]`.

This level of indirection supports multiple code instances of the same model. For multiple instances, the signal information remains constant, except for the address. In this case, the model is a single instance. Therefore, the `rtDataAddrMap` is declared statically. If you choose to generate reusable code, an initialize function is generated that initializes the addresses dynamically per instance. For details on generating reusable code, see “Configure Generated C Function Interface for Model Entry-Point Functions” and see “Configure Code Reuse Support” on page 47-10.

The `dataTypeIndex` provides an index into the `rtDataTypeMap` array, found later in `rtwdemo_capi_capi.c`, indicating the data type of the signal:

```
/* Data Type Map - use dataTypeMapIndex to access this structure */
static const rtwCAPI_DataTypeMap rtDataTypeMap[] = {
 /* cName, mwName, numElements, elemMapIndex, dataSize, slDataId, *
 * isComplex, isPointer */
 { "double", "real_T", 0, 0, sizeof(real_T), SS_DOUBLE, 0, 0 }
};
```

Because the index is 0 for `sig2_eg`, the index points to the first structure element in the array. You can infer that the data type of the signal is `double`. The value of `isComplex` is 0, indicating that the signal is not complex. Rather than providing the data type information directly in the `rtwCAPI_Signals` structure, a level of indirection is introduced. The indirection allows multiple signals that share the same data type to point to one map structure, saving memory for each signal.

The `dimIndex` (dimensions index) provides an index into the `rtDimensionMap` array, found later in `rtwdemo_capi_capi.c`, indicating the dimensions of the signal. Because this index is 1 for `sig2_eg`, the index points to the second element in the `rtDimensionMap` array:

```
/* Dimension Map - use dimensionMapIndex to access elements of ths structure*/
static const rtwCAPI_DimensionMap rtDimensionMap[] = {
 /* dataOrientation, dimArrayIndex, numDims, vardimsIndex */
 { rtwCAPI_SCALAR, 0, 2, 0 },

 { rtwCAPI_VECTOR, 2, 2, 0 },
 ...
};
```

From this structure, you can infer that this is a nonscalar signal having a dimension of 2. The `dimArrayIndex` value, 2, provides an index into `rtDimensionArray`, found later in `rtwdemo_capi_capi.c`:

```
/* Dimension Array- use dimArrayIndex to access elements of this array */
static const uint_T rtDimensionArray[] = {
 1, /* 0 */
 1, /* 1 */
 2, /* 2 */
 ...
};
```

The `fxpIndex` (fixed-point index) provides an index into the `rtFixPtMap` array, found later in `rtwdemo_capi_capi.c`, indicating fixed-point information about the signal. Your code can use the scaling information to compute the real-world value of the signal, using the equation  $V = SQ + B$ , where  $V$  is “real-world” (that is, base-10) value,  $S$  is user-specified slope,  $Q$  is “quantized fixed-point value” or “stored integer,” and  $B$  is user-specified bias. For details, see “Scaling” (Fixed-Point Designer).

Because this index is 0 for `sig2_eg`, the signal does not have fixed-point information. A fixed-point map index of zero means that the signal does not have fixed-point information.

The `sTimeIndex` (sample-time index) provides the index to the `rtSampleTimeMap` array, found later in `rtwdemo_capi_capi.c`, indicating task information about the signal. If you log multirate signals or conditionally executed signals, the sampling information can be useful.

---

**Note** `model_capi.c` (or `.cpp`) includes `rtw_capi.h`. A source file that references the `rtBlockSignals` array also must include `rtw_capi.h`.

---

## C API States

The `rtwCAPI_States` structure captures state information including the state name, address, block path, type (continuous or discrete), data type information, dimensions information, fixed-point information, and sample-time information.

Here is the section of code in `rtwdemo_capi_capi.c` that provides information on C API states for the top model in `rtwdemo_capi`:

```
/* Block states information */
static const rtwCAPI_States rtBlockStates[] = {
 /* addrMapIndex, contStateStartIndex, blockPath,
 * stateName, pathAlias, dWorkIndex, dataTypeIndex, dimIndex,
 * fixPtIdx, sTimeIndex, isContinuous
 */
 { 2, -1, "rtwdemo_capi/Delay1",
 "top_state", "", 0, 0, 0, 0, 0, 0 },

 {
 0, -1, (NULL), (NULL), (NULL), 0, 0, 0, 0, 0, 0
 }
};
```

Each array element, except the last, describes a state in the model. The final array element is a sentinel, with all elements set to null values. In this example, the C API code for the top model displays one state:

```
{ 2, -1, "rtwdemo_capi/Delay1",
 "top_state", "", 0, 0, 0, 0, 0, 0 },
```

This state, named `top_state`, is defined for the block `rtwdemo_capi/Delay1`. The value of `isContinuous` is zero, indicating that the state is discrete rather than continuous. The other fields correspond to the like-named signal equivalents described in “C API Signals” on page 59-8, as follows:

- The address of the signal is given by `addrMapIndex`, which, in this example, is 2. This is an index into the `rtDataAddrMap` array, found later in `rtwdemo_capi_capi.c`. Because the index is zero based, 2 corresponds to the third element in `rtDataAddrMap`, which is `&rtwdemo_capi_DWork.top_state`.
- The `dataTypeIndex` provides an index into the `rtDataTypeMap` array, found later in `rtwdemo_capi_capi.c`, indicating the data type of the parameter. The value 0 corresponds to a double, noncomplex parameter.
- The `dimIndex` (dimensions index) provides an index into the `rtDimensionMap` array, found later in `rtwdemo_capi_capi.c`. The value 0 corresponds to the first entry, which is `{ rtwCAPI_SCALAR, 0, 2, 0 }`.
- The `fixPtIndex` (fixed-point index) provides an index into the `rtFixPtMap` array, found later in `rtwdemo_capi_capi.c`, indicating fixed-point information about the parameter. As with the corresponding signal attribute, a fixed-point map index of zero means that the parameter does not have fixed-point information.

## C API Root-Level Inputs and Outputs

The `rtwCAPI_Signals` structure captures root-level input/output information including the input/output name, address, block path, port number, data type information, dimensions information, fixed-

point information, and sample-time information. (This structure also is used for block output signals, as previously described in “C API Signals” on page 59-8.)

Here is the section of code in `rtwdemo_capi_capi.c` that provides information on C API root-level inputs/outputs for the top model in `rtwdemo_capi`:

```

/* Root Inputs information */
static const rtwCAPI_Signals rtRootInputs[] = {
 /* addrMapIndex, sysNum, blockPath,
 * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
 */
 { 3, 0, "rtwdemo_capi/In1",
 "", 1, 0, 0, 0, 0 },

 { 4, 0, "rtwdemo_capi/In2",
 "", 2, 0, 0, 0, 0 },

 { 5, 0, "rtwdemo_capi/In3",
 "", 3, 0, 0, 0, 0 },

 { 6, 0, "rtwdemo_capi/In4",
 "", 4, 0, 0, 0, 0 },

 {
 0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
 }
};

/* Root Outputs information */
static const rtwCAPI_Signals rtRootOutputs[] = {
 /* addrMapIndex, sysNum, blockPath,
 * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
 */
 { 7, 0, "rtwdemo_capi/Out1",
 "", 1, 0, 0, 0, 0 },

 { 8, 0, "rtwdemo_capi/Out2",
 "", 2, 0, 0, 0, 0 },

 { 9, 0, "rtwdemo_capi/Out3",
 "", 3, 0, 0, 0, 0 },

 { 10, 0, "rtwdemo_capi/Out4",
 "", 4, 0, 0, 0, 0 },

 { 11, 0, "rtwdemo_capi/Out5",
 "sig2_eg", 5, 0, 1, 0, 0 },

 { 12, 0, "rtwdemo_capi/Out6",
 "", 6, 0, 1, 0, 0 },

 {
 0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
 }
};

```

---

**Note** When you generate C++ code, the code generator does not provide information on C API root-level inputs/outputs.

---

For information about interpreting the values in the `rtwCAPI_Signals` structure, see the previous section “C API Signals” on page 59-8.

## C API Parameters

The `rtwCAPI_BlockParameters` and `rtwCAPI_ModelParameters` structures capture parameter information including the parameter name, block path (for block parameters), address, data type information, dimensions information, and fixed-point information.

The `rtModelParameters` array contains entries for workspace variables that are referenced as tunable Simulink block parameters or Stateflow data of machine scope. For example, tunable parameters include `Simulink.Parameter` objects that use a storage class other than `Auto`. The Simulink Coder software assigns its elements only `NULL` or zero values in the absence of such data.

The setting that you select for the model configuration parameter **Default parameter behavior** determines how information is generated into the `rtBlockParameters` array in `model_capi.c` (or `.cpp`).

- If you set **Default parameter behavior** to `Tunable`, the `rtBlockParameters` array contains an entry for every modifiable parameter of every block in the model. However, if you use a MATLAB variable or a tunable parameter to specify a block parameter, the block parameter does not appear in `rtBlockParameters`. Instead, the variable or tunable parameter appears in `rtModelParameters`.
- If you set **Default parameter behavior** to `Inlined`, the `rtBlockParameters` array is empty. The Simulink Coder software assigns its elements only `NULL` or zero values.

The last member of each array is a sentinel, with all elements set to null values.

Here is the `rtBlockParameters` array that is generated by default in `rtwdemo_capi_capi.c`:

```
/* Individual block tuning is not valid when inline parameters is *
 * selected. An empty map is produced to provide a consistent *
 * interface independent of inlining parameters. *
 */
static const rtwCAPI_BlockParameters rtBlockParameters[] = {
 /* addrMapIndex, blockPath,
 * paramName, dataTypeIndex, dimIndex, fixPtIdx
 */
 {
 0, (NULL), (NULL), 0, 0, 0
 }
};
```

In this example, only the final, sentinel array element is generated, with all members of the structure `rtwCAPI_BlockParameters` set to `NULL` and zero values. This is because **Default parameter behavior** is set to `Inlined` by default for the `rtwdemo_capi` example model. If you set **Default parameter behavior** to `Tunable`, the block parameters are generated in the `rtwCAPI_BlockParameters` structure. However, MATLAB variables and tunable parameters appear in the `rtwCAPI_ModelParameters` structure.

Here is the `rtModelParameters` array that is generated by default in `rtwdemo_capi_capi.c`:

```
/* Tunable variable parameters */
static const rtwCAPI_ModelParameters rtModelParameters[] = {
 /* addrMapIndex, varName, dataTypeIndex, dimIndex, fixPtIndex */
 { 2, TARGET_STRING("Ki"), 0, 0, 0 },
 { 3, TARGET_STRING("Kp"), 0, 0, 0 },
 { 4, TARGET_STRING("p1"), 0, 2, 0 },
 { 5, TARGET_STRING("p2"), 0, 3, 0 },
 { 6, TARGET_STRING("p3"), 0, 4, 0 },
};
```

```
{ 0, (NULL), 0, 0, 0 }
};
```

In this example, the `rtModelParameters` array contains entries for each variable that is referenced as a tunable Simulink block parameter.

For example, the `varName` (variable name) of the fourth parameter is `p2`. The other fields correspond to the like-named signal equivalents described in “C API Signals” on page 59-8, as follows:

- The address of the fourth parameter is given by `addrMapIndex`, which, in this example, is 5. This is an index into the `rtDataAddrMap` array, found later in `rtwdemo_capi_capi.c`. Because the index is zero based, 5 corresponds to the sixth element in `rtDataAddrMap`, which is `rtP_p2`.
- The `dataTypeIndex` provides an index into the `rtDataTypeMap` array, found later in `rtwdemo_capi_capi.c`, indicating the data type of the parameter. The value 0 corresponds to a double, noncomplex parameter.
- The `dimIndex` (dimensions index) provides an index into the `rtDimensionMap` array, found later in `rtwdemo_capi_capi.c`. The value 3 corresponds to the fourth entry, which is `{ rtwCAPI_MATRIX_COL_MAJOR, 6, 2, 0 }`.
- The `fixPtIndex` (fixed-point index) provides an index into the `rtFixPtMap` array, found later in `rtwdemo_capi_capi.c`, indicating fixed-point information about the parameter. As with the corresponding signal attribute, a fixed-point map index of zero means that the parameter does not have fixed-point information.

For more information about tunable parameter storage in the generated code, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49.

### Map C API Data Structures to `rtModel`

The real-time model data structure encapsulates model data and associated information that describes the model fully. When you select the C API feature and generate code, the Simulink Coder code generator adds another member to the real-time model data structure generated in `model.h`:

```
/*
 * DataMapInfo:
 * The following substructure contains information regarding
 * structures generated in the model's C API.
 */
struct {
 rtwCAPI_ModelMappingInfo mmi;
} DataMapInfo;
```

This member defines `mmi` (for model mapping information) of type `struct rtwCAPI_ModelMappingInfo`. The structure is located in `matlabroot/rtw/c/src/rtw_modelmap.h`. The `mmi` substructure defines the interface between the model and the C API files. More specifically, members of `mmi` map the real-time model data structure to the structures in `model_capi.c` (or `.cpp`).

Initializing values of `mmi` members to the arrays accomplishes the mapping, as shown in “Map Model to C API Arrays of Structures” on page 59-15. Each member points to one of the arrays of structures in the generated C API file. For example, the address of the `rtBlockSignals` array of structures is allocated to the first member of the `mmi` substructure in `model.c` (or `.cpp`), using the following code in the `rtw_modelmap.h` file:

```
/* signals */
struct {
```

```

rtwCAPI_Signals const *signals; /* Signals Array */
uint_T numSignals; /* Num Signals */
rtwCAPI_Signals const *rootInputs; /* Root Inputs array */
uint_T numRootInputs; /* Num Root Inputs */
rtwCAPI_Signals const *rootOutputs; /* Root Outputs array */
uint_T numRootOutputs; /* Num Root Outputs */
} Signals;

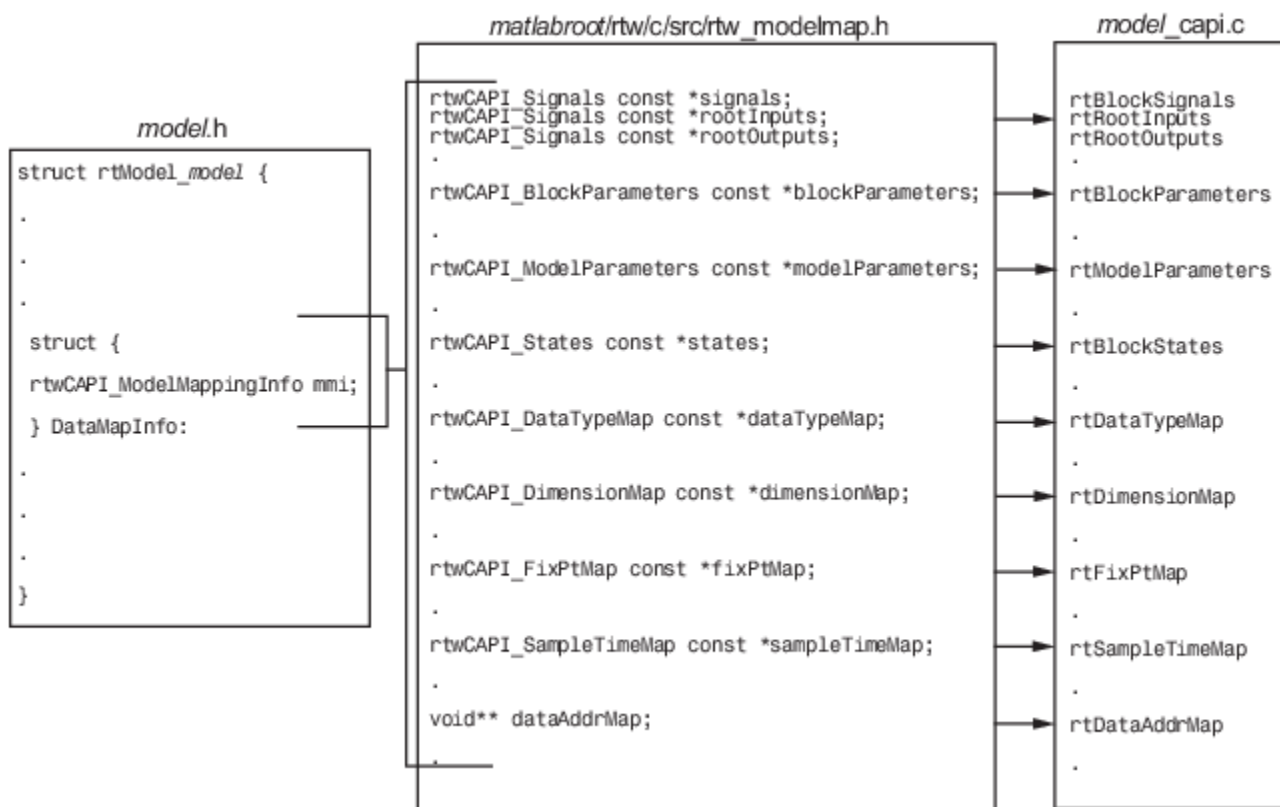

```

The model initialize function in *model.c* (or *.cpp*) performs the initializing by calling the C API initialize function. For example, the following code is generated in the model initialize function for example model *rtwdemo\_capi*:

```

/* Initialize DataMapInfo substructure containing ModelMap for C API */
rtwdemo_capi_InitializeDataMapInfo(rtwdemo_capi_M);

```

## Map Model to C API Arrays of Structures

**Note** This figure lists the arrays in the order that their structures appear in `rtw_modelmap.h`, which differs slightly from their generated order in `model_capi.c`.

## Generate C API Data Definition File for Exchanging Data with a Target System

This example shows how to use the target-based C API to interface with generated code that represents signals, states, parameters, and root-level I/O.

## Open Example Model

Open the example model `rtwdemo_capi`.

```
open_system('rtwdemo_capi');
```

The C API is useful for interacting with application data in generated code, without stopping program execution or recompiling the generated code. To use the C API interface, for a top model and its referenced models:

1. Set up a client/server protocol (such as TCP/IP or a dual-port memory connection) between your development computer and the target computer.
2. Select at least one of the C API model configuration parameters: **signals**, **parameters**, **states**, and **root-level I/O**.
3. Configure the data elements that you want to access with the C API with addressable storage classes.

C API configuration settings for the top model and referenced models must match.

The code generator places the C API interface in the file `model_capi.c`. Depending on your configuration settings, the data can represent signals, states, parameters, and root-level I/O configured with addressable storage classes. The file includes structures that provide an interface to data properties.

## C API Limitations

The C API feature has the following limitations.

- The C API does not support the following values for the CodeFormat TLC variable:
  - `S-Function`
  - `Accelerator_S-Function` (for accelerated simulation)
- For ERT-based targets, the C API requires that support for floating-point code be enabled.
- Local block output signals are not supported.
- Local Stateflow parameters are not supported.
- The following custom storage class objects are not supported:
  - Objects without the package `csc_registration` file
  - Grouped custom storage classes
  - Objects defined by using macros
  - `BitField` objects
  - `FileScope` objects
- Customized data placement is disabled when you are using the C API. The interface looks for global data declaration in `model.h` and `model_private.h`. Declarations placed in any other file by customized data placement result in code that does not compile.

---

**Note** Custom Storage Class objects work in code generation, only if you use the ERT system target file and clear the model configuration parameter **Ignore custom storage classes**.

---

## Use C API to Access Model Signals and States

This example helps you get started writing application code to interact with model signals and states. To get started writing application code to interact with model parameters, see “Use C API to Access Model Parameters” on page 59-23.

The C API provides you with the flexibility of writing your own application code to interact with model signals, states, root-level inputs/outputs, and parameters. Your target-based application code is compiled with the Simulink Coder generated code into an executable. The target-based application code accesses the C API structure arrays in *model\_capi.c* (or *.cpp*). You might have host-based code that interacts with your target-based application code. Or, you might have other target-based code that interacts with your target-based application code. The files *rtw\_modelmap.h* and *rtw\_capi.h*, located in *matlabroot/rtw/c/src* (open), provide macros for accessing the structures in these arrays and their members.

Here is an example application that logs global signals and states in a model to a text file. This code is intended as a starting point for accessing signal and state addresses. You can extend the code to perform signal logging and monitoring, state logging and monitoring, or both.

This example uses the following macro and function interfaces:

- `rtmGetDataMapInfo` macro

Accesses the model mapping information (MMI) substructure of the real-time model structure. In the following macro call, `rtM` is the pointer to the real-time model structure in *model.c* (or *.cpp*):

```
rtwCAPI_ModelMappingInfo* mmi = &(rtmGetDataMapInfo(rtM).mmi);
```

- `rtmGetTPtr` macro

Accesses the absolute time information for the base rate from the timing substructure of the real-time model structure. In the following macro call, `rtM` is the pointer to the real-time model structure in *model.c* (or *.cpp*):

```
rtmGetTPtr(rtM)
```

- Custom functions `capi_StartLogging`, `capi_UpdateLogging`, and `capi_TerminateLogging`, provided via the files *rtwdemo\_capi\_data\_log.h* and *rtwdemo\_capi\_data\_log.c*. These files are located in *matlabroot/toolbox/rtw/rtwdemos* (open).
  - `capi_StartLogging` initializes signal and state logging.
  - `capi_UpdateLogging` logs a signal and state value at each time step.
  - `capi_TerminateLogging` terminates signal and state logging and writes the logged values to a text file.

You can integrate these custom functions into generated code for a model by using these methods:

- **Custom Code** of the Model Configuration Parameters dialog box.
- Custom Code library blocks
- TLC custom code functions

This tutorial uses the **Custom Code** pane of the Model Configuration Parameters dialog box and the System Outputs block from the Custom Code library to insert calls to the custom functions into *model.c* (or *.cpp*), as follows:

- `capi_StartLogging` is called in the `model_initialize` function.
- `capi_UpdateLogging` is called in the `model_step` function.
- `capi_TerminateLogging` is called in the `model_terminate` function.

The following excerpts of generated code from `model.c` (rearranged to reflect their order of execution) show how the function interfaces are used.

```
void rtwdemo_capi_initialize(void)
{
...
/* user code (Initialize function Body) */

/* C API Custom Logging Function: Start Signal and State logging via C API.
 * capi_StartLogging: Function prototype in rtwdemo_capi_dataolog.h
 */
{
 rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
 printf("*** Started state/signal logging via C API **\n");
 capi_StartLogging(MMI, MAX_DATA_POINTS);
}
...
}
...
/* Model step function */
void rtwdemo_capi_step(void)
{
...
/* user code (Output function Trailer) */

/* System '<Root>' */

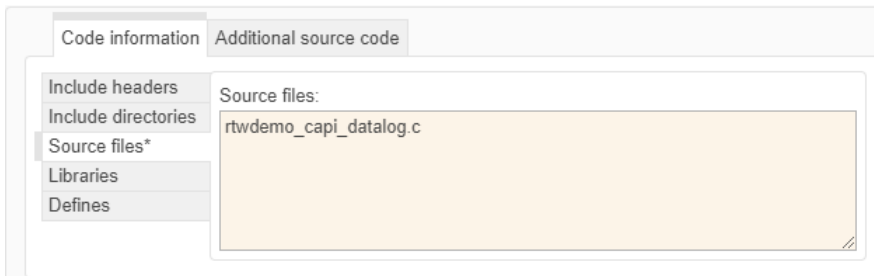

/* C API Custom Logging Function: Update Signal and State logging buffers.
 * capi_UpdateLogging: Function prototype in rtwdemo_capi_dataolog.h
 */
{
 rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
 capi_UpdateLogging(MMI, rtmGetTPtr(rtwdemo_capi_M));
}
...
}
...
/* Model terminate function */
void rtwdemo_capi_terminate(void)
{
 /* user code (Terminate function Body) */

 /* C API Custom Logging Function: Dump Signal and State buffers into a text file.
 * capi_TerminateLogging: Function prototype in rtwdemo_capi_dataolog.h
 */
 {
 capi_TerminateLogging("rtwdemo_capi_ModelLog.txt");
 printf("*** Finished state/signal logging. Created rtwdemo_capi_ModelLog.txt **\n");
 }
}
}
```

The following procedure illustrates how you can use the C API macro and function interfaces to log global signals and states in a model to a text file.

- 1 At the MATLAB command line, enter `rtwdemo_capi` to open the example model.
- 2 Save the top model `rtwdemo_capi` and the referenced model `rtwdemo_capi_bot` to the same writable work folder.
- 3 Open the Configuration Parameters dialog box.
- 4 If you are licensed for Embedded Coder software and you want to use the `ert.tlc` system target file instead of the default `grt.tlc`, change the setting of model configuration parameter **System target file**. Make sure that you also select `ert.tlc` for the referenced model `rtwdemo_capi_bot`.
- 5 For the top model, confirm these model configuration parameter settings:

- a Select parameters **Generate C API for signals**, **Generate C API for states**, and **Generate C API for parameters**.
  - b If you are using the `ert.tlc` system target file, select **Support complex numbers**
  - c Select **MAT-file logging**.
  - d Click **Apply**.
  - e Update configuration parameter settings in the referenced model, `rtwdemo_capi_bot`, to match changes you made in the top model.
- 6 Use the **Custom Code** pane to embed your custom application code in the generated code. Select the **Custom Code** pane. On the **Code information** tab, click **Include directories**. The **Include directories** input field is displayed.
  - 7 In the **Include directories** field, type `matlabroot/toolbox/rtw/rtwdemos`, where `matlabroot` represents the root of your MATLAB installation folder. (If you are specifying a Windows path that contains a space, place the text inside double quotes.)
  - 8 On the same tab, click **Source files**, and type `rtwdemo_capi_data_log.c`.

- 9 On the **Additional source code** tab, click **Additional code**, and type or copy and paste the following include statement:
 

```
#include "rtwdemo_capi_data_log.h"
```
- 10 On the same tab, in the **Initialize code** field, type or copy and paste the following application code:

```
/* C API Custom Logging Function: Start Signal and State logging via C API.
 * capi_StartLogging: Function prototype in rtwdemo_capi_data_log.h
 */
{
 rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
 printf("*** Started state/signal logging via C API **\n");
 capi_StartLogging(MMI, MAX_DATA_POINTS);
}
```

---

**Note** If you renamed the top model `rtwdemo_capi`, update the name `rtwdemo_capi_M` in the application code to reflect the new model name.

---

- 11 On the same tab, in the **Terminate code** field, type or copy and paste the following application code:

```
/* C API Custom Logging Function: Dump Signal and State buffers into a text file.
 * capi_TerminateLogging: Function prototype in rtwdemo_capi_data_log.h
 */
{
 capi_TerminateLogging("rtwdemo_capi_ModelLog.txt");
 printf("*** Finished state/signal logging. Created rtwdemo_capi_ModelLog.txt **\n");
}
```

Click **Apply**.

- 12** In the MATLAB Command Window, enter `custcode` to open the Simulink Coder Custom Code library. At the top level of the `rtwdemo_capi` model, add a System Outputs block.
- 13** Double-click the System Outputs block to open the System Outputs Function Custom Code dialog box. In the **System Outputs Function Exit Code** field, type or copy and paste the following application code:

```
/* C API Custom Logging Function: Update Signal and State logging buffers.
 * capi_UpdateLogging: Function prototype in rtwdemo_capi_dataLog.h
 */
{
 rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
 capi_UpdateLogging(MMI, rtmGetTPtr(rtwdemo_capi_M));
}
```

If you renamed the top model `rtwdemo_capi`, update two instances of the name `rtwdemo_capi_M` in the application code to reflect the new model name.

Click **OK**.

- 14** Clear model configuration parameter **Generate code only**.

Build the model and generate an executable program. For example, on a Windows system, the build generates the executable file `rtwdemo_capi.exe` in your current working folder.

- 15** In the MATLAB Command Window, enter the command `!rtwdemo_capi` to run the executable file. During execution, signals and states are logged using the C API and then written to the text file `rtwdemo_capi_ModelLog.txt` in your current working folder.

```
>> !rtwdemo_capi

** starting the model **
** Started state/signal logging via C API **
** Logging 2 signal(s) and 1 state(s). In this demo, only scalar named
 signals/states are logged **
** Finished state/signal logging. Created rtwdemo_capi_ModelLog.txt **
```

- 16** Examine the text file in the MATLAB editor or other text editor. Here is an excerpt of the signal and state logging output.

```
***** Signal Log File *****

## Use C API to Access Model Parameters

This example helps you get started writing application code to interact with model parameters. To get started writing application code to interact with model signals and states, see “Use C API to Access Model Signals and States” on page 59-18.

The C API provides you with the flexibility of writing your own application code to interact with model signals, states, root-level inputs/outputs, and parameters. Your target-based application code is compiled with generated code into an executable program. The target-based application code accesses the C API structure arrays in *model\_capi.c* (or *.cpp*). You might have host-based code that interacts with your target-based application code. Or, you might have other target-based code that interacts with your target-based application code. The files *rtw\_modelmap.h* and *rtw\_capi.h*, located in *matlabroot/rtw/c/src* (open), provide macros for accessing the structures in these arrays and their members.

Here is an example application that prints the parameter values of tunable parameters in a model to the standard output. This code is intended as a starting point for accessing parameter addresses. You can extend the code to perform parameter tuning. The application:

- Uses the `rtmGetDataMapInfo` macro to access the mapping information in the `mmi` substructure of the real-time model structure

```
rtwCAPI_ModelMappingInfo* mmi = &(rtmGetDataMapInfo(rtM).mmi);
```

where `rtM` is the pointer to the real-time model structure in *model.c* (or *.cpp*).

- Uses `rtwCAPI_GetNumModelParameters` to get the number of model parameters in mapped C API:

```
uint_T nModelParams = rtwCAPI_GetNumModelParameters(mmi);
```

- Uses `rtwCAPI_GetModelParameters` to access the array of model parameter structures mapped in C API:

```
rtwCAPI_ModelParameters* capiModelParams = \
 rtwCAPI_GetModelParameters(mmi);
```

- Loops over the `capiModelParams` array to access individual parameter structures. A call to the function `capi_PrintModelParameter` displays the value of the parameter.

The example application code is provided below:

```
{
/* Get CAPI Mapping structure from Real-Time Model structure */
rtwCAPI_ModelMappingInfo* capiMap = \
&(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);

/* Get number of Model Parameters from capiMap */
uint_T nModelParams = rtwCAPI_GetNumModelParameters(capiMap);
printf("Number of Model Parameters: %d\n", nModelParams);

/* If the model has Model Parameters, print them using the
application capi_PrintModelParameter */
if (nModelParams == 0) {
 printf("No Tunable Model Parameters in the model \n");
}
else {
```

```

unsigned int idx;

for (idx=0; idx < nModelParams; idx++) {
 /* call print utility function */
 capi_PrintModelParameter(capiMap, idx);
}
}
}

```

The print utility function is located in `matlabroot/rtw/c/src/rtw_capi_examples.c`. This file contains utility functions for accessing the C API structures.

To become familiar with the example code, try building a model that displays the tunable block parameters and MATLAB variables. You can use `rtwdemo_capi`, the C API example model. The following steps apply to both `grt.tlc` and `ert.tlc` system target files, unless otherwise indicated.

- 1 At the MATLAB command line, enter `rtwdemo_capi` to open the example model.
- 2 Save the top model `rtwdemo_capi` and the referenced model `rtwdemo_capi_bot` to the same writable work folder.
- 3 If you are licensed for Embedded Coder software and you want to use the `ert.tlc` system target file instead of the default `grt.tlc`, use model configuration parameter **System target file** to select an `ert.tlc` system target file. Make sure that you also select `ert.tlc` for the referenced model `rtwdemo_capi_bot`.
- 4 Confirm these model configuration parameter settings:
  - a Select **Generate C API for parameters**.
  - b If you are using the `ert.tlc` system target file, select **Support complex numbers**.
  - c Select **MAT-file logging**.
  - d Click **Apply**.
  - e Update configuration parameter settings in the referenced model, `rtwdemo_capi_bot`, to match changes you made in the top model.
- 5 Use the **Custom Code** pane to embed your custom application code in the generated code. Select the **Custom Code** pane. On the **Additional source code** tab, click **Initialize code**. The **Initialize code** input field is displayed.
- 6 In the **Initialize code** input field, type or copy and paste the example application code shown above step 1. This embeds the application code in the `model_initialize` function.

---

**Note** If you renamed the top model `rtwdemo_capi`, update the name `rtwdemo_capi_M` in the application code to reflect the new model name.

---

- 7 On the **Code information** tab, click **Include directories**, and type `matlabroot/rtw/c/src`, where `matlabroot` represents the root of your MATLAB installation folder. (If you are specifying a Windows path that contains a space, place the text inside double quotes.)
- 8 On the same tab, click **Source files**, and type `rtw_capi_examples.c`.

Click **Apply**.

**9** Clear model configuration parameter **Generate code only**.

Build the model and generate an executable program. For example, on a Windows system, the build generates the executable file `rtwdemo_capi.exe` in your current working folder.

**10** In the MATLAB Command Window, enter `!rtwdemo_capi` to run the executable file. Running the program displays parameter information in the Command Window.

```
>> !rtwdemo_capi

** starting the model **
Number of Model Parameters: 5
Ki =
 7
Kp =
 4
p1 =
 0.15

# ASAP2 Data Measurement and Calibration in Simulink Coder

---

- “Export ASAP2 File for Data Measurement and Calibration” on page 60-2
- “Calibrate Generated Code and Monitor Signals” on page 60-9

## Export ASAP2 File for Data Measurement and Calibration

The ASAM MCD-2 MC standard, also known as ASAP2, is a data definition standard proposed by the Association for Standardization of Automation and Measuring Systems (ASAM). ASAP2 is a non-object-oriented description of the data used for measurement, calibration, and diagnostic systems. For more information on ASAM and the ASAM MCD-2 MC (ASAP2) standard, see the ASAM website at [www.asam.net](http://www.asam.net).

The code generator enables you to export an ASAP2 file containing information about your model during the code generation process.

Simulink Coder support for ASAP2 file generation is version-neutral. By default, the software generates ASAP2 version 1.31 format, but the generated model information is generally compatible with other ASAP2 versions. ASAP2 file generation is also neutral with respect to the specific needs of ASAP2 measurement and calibration tools. The software provides customization APIs that you can use to customize ASAP2 file generation to generate an ASAP2 version and to meet the specific needs of your ASAP2 tools.

### In this section...

- “What You Should Know” on page 60-2
- “System Target Files Supporting ASAP2” on page 60-2
- “Define ASAP2 Information” on page 60-2
- “Generate an ASAP2 File” on page 60-6
- “Structure of ASAP2 File” on page 60-8

### What You Should Know

To make use of ASAP2 file generation, you should become familiar with:

- ASAM and the ASAP2 standard and terminology. See the ASAM Web site at [www.asam.net](http://www.asam.net).
- Configuring model data elements for code generation. See **Code Mappings Editor - C**.
- Storage and representation of signals and parameters in generated code. See “Data Access for Prototyping and Debugging”.
- If you have Embedded Coder, see “Data Representation”.

### System Target Files Supporting ASAP2

You can use ASAP2 file generation with varying system target file configurations. For example, GRT- and ERT- based configurations enables you to generate an ASAP2 file as part of the code generation and build process.

For procedures for generating ASAP2 files by using the system target file configurations, see “Generate an ASAP2 File” on page 60-6.

### Define ASAP2 Information

- “Define ASAP2 Information for Parameters and Signals” on page 60-3
- “Memory Address Attribute” on page 60-3

- “Automatic ECU Address Replacement for ASAP2 Files (Embedded Coder)” on page 60-4
- “Define ASAP2 Information for Lookup Tables” on page 60-5

### Define ASAP2 Information for Parameters and Signals

The ASAP2 file generation process requires information about parameters and signals in your model. Some of this information is contained in the model itself. Use Simulink data objects in a workspace or data dictionary to complete the ASAP2 file generation process. In some cases, the use of workspace objects is optional.

Use the Model Data Editor and built-in Simulink data objects to provide information, such as using `Simulink.Signal` objects to provide MEASUREMENT information and `Simulink.Parameter` objects to provide CHARACTERISTIC information. You can use data objects from data classes that are derived from `Simulink.Signal` and `Simulink.Parameter` to provide the information. See “Data Objects” and **Model Data Editor**.

This table contains the minimum set of data attributes required for ASAP2 file generation. Some data attributes are defined in the model. Others attributes are supplied in the properties of objects. For attributes that are defined in `Simulink.Signal` or `Simulink.Parameter` objects, the table lists the associated property name.

Data Attribute	Defined In	Property Name
Name (symbol)	Model and data object	Inherited from the handle of the data object to which parameter or signal name resolves
Description	Data object	Description
Data type	Model or data object	DataType
Scaling (if fixed-point data type)	Model or data object	DataType
Minimum allowable value	Model or data object	Min
Maximum allowable value	Model or data object	Max
Unit	Model or data object	Unit
Memory address (optional)	Model or data object	MemoryAddress_ASAP2 (optional; see “Memory Address Attribute” on page 60-3.)

### Memory Address Attribute

If the memory address attribute is unknown before code generation, the code generator inserts ECU Address placeholder text in the generated ASAP2 file. You can substitute an actual address for the placeholder by postprocessing the generated file. For an example, see the file `matlabroot/toolbox/rtw/targets/asap2/asap2/asap2post.m`. `asap2post.m` parses through the linker map file that you provide and replaces the ECU Address placeholders in the ASAP2 file with the actual memory addresses. Because linker map files vary from compiler to compiler, you might need to modify the regular expression code in `asap2post.m` to match the format of the linker map that you use.

If you have Embedded Coder installed on your system, and if you are generating Executable and Linkable Format (ELF) or Program Database (PDB) files for your embedded target, you can use the

`rtw.asap2SetAddress` function to automate ECU address replacement. For more information, see “Automatic ECU Address Replacement for ASAP2 Files (Embedded Coder)” on page 60-4.

If the memory address attribute is known before code generation, it can be defined in the data item or data object. By default, the `MemoryAddress_ASAP2` property does not exist in the `Simulink.Signal` or `Simulink.Parameter` data object classes. If you want to add the attribute, add a property called `MemoryAddress_ASAP2` to a custom class that is a subclass of the `Simulink` or `ASAP2` class. For information on subclassing Simulink data classes, see “Define Data Classes”.

This table indicates the Simulink object properties that have replaced the ASAP2 object properties of the previous release.

### Differences Between ASAP2 and Simulink Parameter and Signal Object Properties

ASAP2 Object Properties (Previous)	Simulink Object Properties (Current)
LONGID_ASAP2	Description
PhysicalMin_ASAP2	Min
PhysicalMax_ASAP2	Max
Units_ASAP2	Unit

### Automatic ECU Address Replacement for ASAP2 Files (Embedded Coder)

If you have Embedded Coder installed on your system, and if you are generating Executable and Linkable Format (ELF) or Program Database (PDB) files for your embedded target, you can use the `rtw.asap2SetAddress` function to automate the replacement of ECU Address placeholder memory address values with actual addresses in the generated ASAP2 file.

If the memory address attribute is unknown before code generation, the code generator inserts ECU Address placeholder text in the generated ASAP2 file, as shown

```
/begin CHARACTERISTIC
/* Name */ Ki
/* Long Identifier */ ""
/* Type */ VALUE
/* ECU Address */ 0x0000 /* @ECU_Address@Ki@ */
```

To substitute actual addresses for the ECU Address placeholders, process the generated ASAP2 file by using the `rtw.asap2SetAddress` function. The syntax is:

```
rtw.asap2SetAddress(ASAP2File,InfoFile)
```

The arguments are character vectors specifying the name of the generated ASAP2 file and the name of the generated executable ELF file, PDB file from Microsoft toolchain, or DWARF debug information files for the model. When called, `rtw.asap2SetAddress` extracts the actual ECU address from the specified ELF, PDB, or DWARF file and replaces the placeholder in the ASAP2 file with the actual address, for example:

```
/begin CHARACTERISTIC
/* Name */ Ki
/* Long Identifier */ ""
/* Type */ VALUE
/* ECU Address */ 0x40009E60
```

## Define ASAP2 Information for Lookup Tables

Simulink Coder software generates ASAP2 descriptions for lookup table data and its breakpoints. The software represents 1-D table data as **CURVE** information, 2-D table data as **MAP** information, and breakpoints as **AXIS\_DESCR** and **AXIS\_PTS** information. You can model lookup tables by using one of the following Simulink Lookup Table blocks:

- Direct Lookup Table (n-D) — 1 and 2 dimensions
- Interpolation Using Prelookup — 1 and 2 dimensions
- 1-D Lookup Table
- 2-D Lookup Table
- n-D Lookup Table — 1 and 2 dimensions

The software supports these types of lookup table breakpoints (axis points).

Breakpoint Type	Information Generated
Tunable and shared among multiple table axes (common axis)	COM_AXIS
Fixed and nontunable (fixed axis)	One of these variants of FIX_AXIS: <ul style="list-style-type: none"> <li>• FIX_AXIS_PAR if breakpoints are integers with equidistant spacing and the equidistant spacing is a power of two</li> <li>• FIX_AXIS_PAR_DIST if breakpoints are integers with equidistant spacing</li> <li>• FIX_AXIS_PAR_LIST if breakpoints are integers with non-equidistant spacing</li> </ul>
Tunable but not shared among multiple tables (standard axis)	STD_AXIS

When you configure the blocks for ASAP2 code generation:

- For table data, use a `Simulink.Parameter` data object with a non-Auto storage class.
- For tunable breakpoint data that is shared among multiple table axes (COM\_AXIS), use a `Simulink.Parameter` data object that has a non-Auto storage class.
- For fixed, nontunable breakpoint data (FIX\_AXIS), use workspace variables or arrays specified in the block parameters dialog box. The breakpoints must be stored as integers in the code. The data type must be a built-in integer type (`int8`, `int16`, `int32`, `uint8`, `uint16`, or `uint32`), a fixed-point data type, or an equivalent alias type.
- For tunable breakpoint data that is not shared among multiple tables (STD\_AXIS):
  - 1 Create a `Simulink.Bus` object to define the `struct` packaging (names and order of the fields). The fields of the parameter structure must correspond to the lookup table data and each axis of the lookup table block. For example, in an n-D Lookup Table block that has 2 dimensions, the structure must contain only three fields. This bus object describes the record layout for the lookup characteristic.
  - 2 Create a `Simulink.Parameter` object to represent a tunable parameter.
  - 3 Create table and axis values.

- 4 Optionally, specify the **Units**, **Minimum**, and **Maximum** properties for the parameter object.

Here is an example of an n-D Lookup Table record generated into an ASAP2 file in Standard Axis format:

```
/begin CHARACTERISTIC
/* Name */ STDAxisParam
...
/* Record Layout */ Lookup1D_X_WORD_Y_FLOAT32_IEEE
...
begin AXIS_DESCR
/* Description of X-Axis Points */
/* Axis Type */ STD_AXIS
...
/end AXIS_DESCR
/end CHARACTERISTIC

/begin RECORD_LAYOUT Lookup1D_X_WORD_Y_FLOAT32_IEEE
 AXIS_PTS_X 1 WORD INDEX_INCR DIRECT
 FNC_VALUES 2 FLOAT32_IEEE COLUMN_DIR DIRECT
/end RECORD_LAYOUT
```

## Generate an ASAP2 File

- “Generating ASAP2 Files” on page 60-6
- “Use GRT- or ERT- Based System Target File” on page 60-6
- “Generate ASAP2 Files for Referenced Models” on page 60-7
- “Merge ASAP2 Files for Top and Referenced Models” on page 60-7

### Generating ASAP2 Files

Use the Generic Real-Time system target file or a Embedded Coder system target file to generate an ASAP2 file as part of the code generation and build process.

Generate ASAP2 file by using the system target files that have built-in ASAP2 support.

### Use GRT- or ERT- Based System Target File

To generate the ASAP2 data definition for a model by using a Generic Real-Time(GRT) system target file or Embedded Coder system target file:

- 1 Use the **Code Mappings Editor - C** to apply storage classes to signals, block states, and model parameters, as described in “C Code Generation Configuration for Model Interface Elements” on page 32-2.

Parameters are not represented in the ASAP2 file if one or more of the following conditions exist:

- You apply storage class `Auto`, `FileScope`, `Struct`, or `Default` (through `Model default`).
  - You apply storage class through `Embedded Coder Dictionary`.
  - You apply a storage class that causes the code generator to generate a macro or non-addressable variable.
- 2 Use the Property Inspector to configure the remaining storage class properties for each data element.

- 3 Set the model configuration parameter **System target file** to a GRT- or ERT- based system target file.
- 4 Enable the configuration parameter **ASAP2 interface** with the command
 

```
set_param('model_Name','GenerateASAP2',true);
```

---

**Note** You can no longer enable generation of ASAP2 files from the Model Configuration Parameter dialog box. As “Generate ASAP2 and CDF Calibration Files” on page 61-2 describes, use the Generate Calibration Files tool, or use the command line model configuration parameter `GenerateASAP2`.

---

- 5 Select parameter **Generate code only**.
- 6 Click **Apply**.
- 7 Generate code.

The code generator writes the ASAP2 file to the build folder. By default, the file is named `model.a2l`, where `model` is the name of the model. The ASAP2 setup file controls the ASAP2 file name. For details, see “Customize Generated ASAP2 File” on page 86-2.

### Generate ASAP2 Files for Referenced Models

The build process can generate an ASAP2 file for each referenced model in a model reference hierarchy. In the generated ASAP2 file, MEASUREMENT records represent signals and states inside the referenced model.

To generate ASAP2 files for referenced models, select ASAP2 file generation for the top model and for each referenced model in the reference hierarchy. If you are using the Generic Real-Time Target or an Embedded Coder target, follow the procedure described in “Use GRT- or ERT- Based System Target File” on page 60-6 for the top model and each referenced model.

### Merge ASAP2 Files for Top and Referenced Models

Use function `rtw.asap2MergeMdlRefs` to merge the ASAP2 files generated for top and referenced models. The function has this syntax:

```
[status,info] = rtw.asap2MergeMdlRefs(topModelName,asap2FileName)
```

- `topModelName` is the name of the model containing one or more referenced models.
- `asap2FileName` is the name that you specify for the merged ASAP2 file.
- *Optional:* `status` returns false (logical 0) if the merge completed and returns true (logical 1) otherwise.
- *Optional:* `info` returns additional information about merge failure if `status` is true. Otherwise, it returns an empty character vector.

Consider the following example.

```
[status,info] = rtw.asap2MergeMdlRefs('myTopMdl','merged.a2l')
```

This command merges the ASAP2 files generated for the top model `myTopMdl` and its referenced models in the file `merged.a2l`.

## Structure of ASAP2 File

This table outlines the basic structure of the ASAP2 file and describes the Target Language Compiler (TLC) functions and files used to create each part of the file:

- Static parts of the ASAP2 file are shown in **bold**.
- Function calls are indicated by %<FunctionName(>).

File Section	Contents of asap2main.tlc	TLC File Containing Function Definition
File header	%<ASAP2UserFcnWriteFileHead(>	asap2userlib.tlc
<b>/begin PROJECT ""</b>	<b>/begin PROJECT "%&lt;ASAP2ProjectName&gt;"</b>	asap2setup.tlc

## Calibrate Generated Code and Monitor Signals

When you create an external mode target application that uses an ASAM MCD-1 XCP communication channel, you can also generate an ASAP2 file that provides a description of the Simulink Coder Universal Measurement and Calibration Protocol (XCP) server configuration. The description enables third-party calibration tools, such as ETAS® INCA and Vector CANape®, to connect to the external mode target application. You can use the third-party tools to calibrate generated code and monitor signals in environments supported by the third-party tools, for example, a vehicle, a test bench, or a virtual environment on a PC.

Configure your model to generate an ASAP2 file that provides a description of the XCP server configuration:

- 1 On the **Apps** tab, click **Run on Custom Hardware**, which displays the **Hardware** tab.
- 2 In the **Hardware** section, in the **System Target File Description** field, select **Embedded Coder (ert.tlc)**.
- 3 In the **Prepare** section, click **Hardware Settings**, which opens the Configuration Parameters dialog box.
- 4 Clear **Generate code only**.
- 5 Specify **Toolchain settings** for your development computer.
- 6 Select **External mode**.
- 7 Set **Transport layer** to **XCP on TCP/IP** or **XCP on Serial**.
- 8 For **Mex-file arguments**, specify the required arguments. For example:
  - For **XCP on TCP/IP**, specify the IP address of the target processor and the port number of the TCP/IP server.
  - For **XCP on Serial**, specify the serial port ID and the baud value.
- 9 Click **OK**.

To generate the target application and the ASAP2 file:

- 1 On the **Hardware** tab, in the **Run on Hardware** section, click **Monitor & Tune**.
- 2 Under **Step By Step Commands**, click **Build for Monitoring**.
- 3 Use **Generate Calibration Files** tool to generate the ASAP2 file. Or generate the file by using this command:

```
coder.asap2.export('modelName', 'MapFile', 'symbolFileName');
```

- 4 In the code generation folder, the build process generates the XCP external mode target application *modelName.exe* and the **Generate Calibration Files** tool generates ASAP2 file *modelName.a2l*. The ASAP2 file contains an IF\_DATA XCP block that describes the Simulink Coder XCP server configuration.

```
...
/begin IF_DATA XCP
 /begin PROTOCOL_LAYER
 ...
 /end PROTOCOL_LAYER
 ...
 /begin XCP_ON_TCP_IP
 ...
```

```
 /end XCP_ON_TCP_IP
 /end IF_DATA
 ...
```

Import the ASAP2 file into your third-party tool and manually run the external mode application on your target hardware. Through XCP, connect the third-party tool to the target application. Then, using that tool, perform data acquisition and calibration of the generated code.

# Generate ASAP2 and CDF Calibration Files

---

## Generate ASAP2 and CDF Calibration Files

Generate and customize an ASAP2 file and a CDF (Calibration Data Format) file for a model by using the **Generate Calibration Files** tool. By default, the tool generates the latest supported version of the A2L file according to ASAM MCD-2 MC standards but you can choose to generate a different version. You can customize the options for calibration files such as the version for the A2L file and the schema type for the CDF file. For more information on the ASAM MCD-2 MC (ASAP2) standard and the ASAM CDF Standards, go to the ASAM website at [www.asam.net](http://www.asam.net).

### In this section...

“Open Generate Calibration Files Tool” on page 61-2

“ASAP2 File Generation” on page 61-2

“CDF File Generation” on page 61-3

“Create a Host-Based ASAM-ASAP2 Data Definition File for Data Measurement and Calibration” on page 61-3

### Open Generate Calibration Files Tool

- 1 Enter into code perspective of the model.
- 2 Build the model.
- 3 On the **C CODE** tab, select **Share > Generate Calibration Files**.

**Note** For AUTOSAR models, select **AUTOSAR > Share > Generate Calibration Files**.

Using the tool, you can generate A2L and cdfx files at the same time for a model. You can use the tool for models configured with ERT-based, GRT-based, or Adaptive AUTOSAR system target file.

### ASAP2 File Generation

ASAP2 defines the description format of the internal ECU variables used in measurement and calibration. To generate an ASAP2 file:

- 1 By default the **Generate ASAP2** option is enabled. If it is not enabled, slide the **Generate ASAP2** to the on position to enable A2L generation.
- 2 To change the name of A2L file, specify the new name in the **File name** field.
- 3 By default, the code generator uses the build folder for the folder path of the selected model. If you want to specify a different folder path for the A2L file, you can do that in the **Folder path** field.
- 4 To replace ECU addresses in the A2L file, provide a symbol file associated with the application executable in the **Symbol file** field. Otherwise, clear the **Address replacement** field.
- 5 Set **Version** to the required version of the A2L file to be generated. The default version is 1.71.
- 6 To exclude comments in the A2L file, clear **Include comments**.
- 7 Click **Generate**.

You can also use the `coder.asap2.export` function to generate the A2L file.

## CDF File Generation

ASAM CDF defines the data description format for storing the ECU parameter values and the associated meta data. The ASAM CDF files uses XML, which can be easily validated, edited, imported, and exported by calibration tools and XML editors. To generate CDF file by using the tool:

- 1 Slide the **Generate CDF** to the on position.
- 2 To change the name of the CDF file, specify it in the **File name** field.
- 3 By default, the code generator selects the build folder for the folder path of the selected model. If you want to specify a different folder path for the CDF file, you can do that in the **Folder path** field.
- 4 Use the **Schema type** field to set to **XSD** (XML Schema Definition) or **DTD** (Document Type Definition). The **DTD** schema type is the default.

You can also use `coder.cdf.export` function to generate the CDF file.

## Create a Host-Based ASAM-ASAP2 Data Definition File for Data Measurement and Calibration

This model shows ASAP2 data export. ASAP2 is a data definition standard proposed by the Association for Standardization of Automation and Measuring Systems (ASAM).

### Open Example Model

Open the example model `rtwdemo_asap2`.

```
open_system('rtwdemo_asap2');
```

Copyright 1994-2021 The MathWorks, Inc.

See the “ASAP2 File Generation” to customize and generate the ASAP2 file.

### **See Also**

`coder.cdf.export` | `coder.asap2.export`

### **More About**

## Customize Generated ASAP2 File

---

## Customize Generated ASAP2 File

### In this section...

“Customize ASAP2 Fields by Using Base Class” on page 62-2  
 “Customize ASAP2 Sections by Deriving from Base Class” on page 62-2  
 “Customize Computation Method Names” on page 62-3  
 “Export Characteristics and Measurement Objects in Groups” on page 62-4  
 “Generate Record Layouts” on page 62-5  
 “Exclude Structures and 64-Bit Integers” on page 62-6  
 “Generate ASAP2 Containing Default Event List” on page 62-6  
 “Specify ECU Address Extension” on page 62-7

You can customize the fields of an ASAP2 file by using the code generator in any of these ways:

### Customize ASAP2 Fields by Using Base Class

- 1 Create an object from the base class.

```
obj = coder.asap2.UserCustomizeBase;
```

- 2 Modify the object fields.

```
obj.HeaderComment = 'Header comment';
obj.ModParComment = 'Mod Par comment';
obj.ModCommonComment = 'Mod Common comment';
obj.ASAP2FileName = 'File name';
obj.ByteOrder = 'BYTEORDER MSB_LAST';
```

- 3 Pass the object to the function that generates the ASAP2 file.

```
coder.asap2.export(modelName, CustomizationObject=obj);
```

### Customize ASAP2 Sections by Deriving from Base Class

- 1 Derive from the base class `coder.asap2.UserCustomizeBase`. You can place the derived file anywhere on the MATLAB path.
- 2 To edit the Header section, use the `writeHeader` function.
- 3 Use the `writeHardwareInterface` function to edit the hardware interface section consisting of the `MOD_PAR` and `MOD_COMMON` fields of the ASAP2 file.
- 4 To add text at the beginning of the ASAP2 file, use the `writeFileHead` function.
- 5 To add text at the end of the ASAP2 file, use the `writeFileTail` function.

For example, the code for generating a derived class `TestASAP2Customization` might look like this code:

```
classdef TestASAP2Customization < coder.asap2.UserCustomizeBase
 % Customization class for asap2 file
 methods
 function header = writeHeader(obj)
 header = sprintf([' /begin HEADER ' 'test Header text' '\n',...
 'header test comments from user\n',...
 ' /end HEADER']);
```

```

end

function hardwareInterface = writeHardwareInterface(obj)
 hardwareInterface = sprintf([' /begin MOD_PAR "' 'UserDefined' '"\n',...
 ' test comments from user\n',...
 ' /end MOD_PAR\n\n',...
 ' /begin MOD_COMMON "' 'UserDefined MOD_COMMON' '"\n',...
 ' user defined values for MOD_COMMON\n',...
 ' obj.ByteOrder '\n',...
 ' /end MOD_COMMON']);
end

function fileTail = writeFileTail(obj)
 fileTail = sprintf(['/* This File can be used for ' ,...
 ' calibration .*/\n'...
 '/* EOF ',obj.ASAP2FileName, '*/']);
end

function fileHeader = writeFileHead(obj)
 fileHeader = sprintf(['/******\n
 ' This is a a2l file which can be used for calibration with INCA or CANAPE\n',...
 ' *****\n
 ']);
end
end
end

```

- 6 Create an object from the derived class. For example, this command creates an object from TestASAP2Customization.

```
obj = TestASAP2Customization;
```

- 7 Pass the object to the function that generates the ASAP2 file.

```
coder.asap2.export(modelName,CustomizationObject=obj);
```

## Customize Computation Method Names

In generated ASAP2 files, computation methods translate the electronic control unit (ECU) internal representation of measurement and calibration quantities into a physical model-oriented representation. Using Simulink Coder software, you can customize the names of computation methods. You can provide names that are more intuitive, enhancing ASAP2 file readability, or names that meet organizational requirements.

To customize computation method names, use the MATLAB function `getCompuMethodName`, which is defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m`.

The `getCompuMethodName` function constructs a computation method name. The function prototype is:

```
cmName = getCompuMethodName(dataTypeName, cmUnits)
```

where

- *dataTypeName* is the name of the data type associated with the computation method.
- *cmUnits* are the units as specified in the Unit property of a Simulink.Parameter or Simulink.Signal object (for example, rpm or m/s).
- *cmName* returns the constructed computation method name.

The default constructed name returned by the function has the format:

```
<localPrefix><datatype>_<cmUnits>
```

where

- `<local_Prefix>` is a local prefix, `CM_`, defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m`.
- `<datatype>` and `<cmUnits>` are the arguments that you specified to the `getCompuMethodName` function.

Special characters in `cmUnits` are not supported in the computation method name in ASAP2 file. The special characters are converted as shown in this table.

Special Character	Conversion
%	_percent_
-	_dash_
/	_per_
*	_into_
°	_deg_

For example, if you call the `getCompuMethodName` function by using the `dataTypeName` argument 'int16' and the `cmUnits` argument 'm/s', and then generate an ASAP2 file for a model named `myModel`, the computation method name appears in the generated file:

```
/begin COMPU_METHOD
 /* Name of CompuMethod */ myModel_CM_int16_m_per_s
 /* Units */ "m/s"
 ...
/end COMPU_METHOD
```

## Export Characteristics and Measurement Objects in Groups

Starting in R2021b, you can group the characteristic and measurement objects in the ASAP2 file based on their properties. By default, the generated ASAP2 file contains `GROUPS` and `SUB_GROUPS` based on the subsystems present in the model.

- 1 Open the `sldemo_fuelsys` model.
- 2 Build the model.
- 3 Generate the ASAP2 file by using the `Generate Calibration Files` tool or by using this command:

```
coder.asap2.export("sldemo_fuelsys")
```

The data elements are grouped based on the model architecture. The top model is referred to as `GROUP` and subsystems in the model are referred to as `SUB_GROUPS`. The generated file contains these lines:

```
/begin GROUP
 /* Name */ sldemo_fuelsys
 /* Long identifier */ "sldemo_fuelsys"
 /* Root */ ROOT
 /begin SUB_GROUP
 rtB.es_o
```

```

 sldemo_fuelsys_Dashboard
 sldemo_fuelsys_Engine_Gas_Dynamics
 sldemo_fuelsys_Throttle_Command
 sldemo_fuelsys_To_Controller
 sldemo_fuelsys_To_Plant
 sldemo_fuelsys_fuel_rate_control
 /end SUB_GROUP
/end GROUP

```

- 4 To group the scalar objects into a group named GROUP\_TYPE\_SCALAR in the ASAP2 file, use this command:

```

coder.asap2.export("sldemo_fuelsys",CustomizeGroupsBy={'SCALAR'})

```

You can also group the objects of type array, and lookup tables into MAP, CURVE, CUBOID, CUBE\_4, and CUBE\_5 based on dimensions of the table.

## Generate Record Layouts

- 1 Open the sldemo\_fuelsys model.

```

open_system("sldemo_fuelsys")

```

- 2 Build the model.
- 3 Generate the ASAP2 file by using this command:

```

coder.asap2.export("sldemo_fuelsys",IncludeAllRecordLayouts=true)

```

- 4 The RecordLayouts.a2l file is generated according to the version of the ASAP2 file. In the ASAP2 file, verify this line:

```

/include "RecordLayouts.a2l"

```

- 5 The generated RecordLayouts.a2l file contains the record layouts of the data types present in the model.

---

**Note** The RecordLayouts.a2l file is required to be in the same folder as the ASAP2 file.

---

- 6 coder.asap2.export("sldemo\_fuelsys",IncludeAllRecordLayouts=false) does not generate separate record layouts file, but includes the record layouts of the data types of exported data objects in the ASAP2 file.

```

/begin RECORD_LAYOUT Scalar_FLOAT32_IEEE
 FNC_VALUES 1 FLOAT32_IEEE COLUMN_DIR DIRECT
/end RECORD_LAYOUT

/begin RECORD_LAYOUT Scalar_FLOAT64_IEEE
 FNC_VALUES 1 FLOAT64_IEEE COLUMN_DIR DIRECT
/end RECORD_LAYOUT
...

```

---

**Tip** In the ASA2P file, to preserve the shape of a lookup table that is used as a model argument, make sure that the LookUp Table block is in the referenced model. Pass the LookUp table object from the top model as an instance parameter value.

---

## Exclude Structures and 64-Bit Integers

Starting in R2022a, you can exclude the structure elements and 64-bit integers in the generated A2L file. By default, structures and 64-bit integers are included in the A2L file.

- 1 Open the `sldemo_fuelsys` model.

```
open_system("sldemo_fuelsys")
```

- 2 Build the model.

- 3 Generate the ASAP2 file by using this command:

```
coder.asap2.export("sldemo_fuelsys", SupportStructureElements=false, ...
Support64bitIntegers=false)
```

The generated ASAP2 file does not have 64-bit integers and structure elements in it.

---

**Note** Starting in R2022a, the pointer variables will not be generated in the ASAP2 file.

---

## Generate ASAP2 Containing Default Event List

Starting in R2022a, for a multirate model, the ASAP2 file contains the IF\_DATA section that has the DEFAULT\_EVENT\_LIST, enabling you to view the respective raster values for the data elements in the calibration tools.

- 1 Open the `sldemo_fuelsys` model.

```
open_system("sldemo_fuelsys")
```

- 2 Build the model.

- 3 Generate the ASAP2 file by using Generate Calibration Files tool or by using this command:

```
coder.asap2.export("sldemo_fuelsys")
```

- 4 The model has a single rate of 0.01. The generated file defines measurements as:

```
/begin MEASUREMENT
/* Name */ rtB.es_o.throttle
/* Long identifier */ ""
/* Data type */ FLOAT32_IEEE
/* Conversion method */ sldemo_fuelsys_CM_single
/* Resolution (Not used) */ 0
/* Accuracy (Not used) */ 0
/* Lower limit */ -3.4E+38
/* Upper limit */ 3.4E+38
ECU_ADDRESS 0x0000 /* @ECU_Address@rtB.es_o.throttle@ */
/end MEASUREMENT
```

- 5 Convert the model into multirate model by using this command:

```
blockName = ['sldemo_fuelsys' '/EG0 Fault Switch'];
set_param(blockName, 'SampleTime', '0.02');
```

- 6 Build the model.

- 7 Generate the ASAP2 file by using this command:

```
coder.asap2.export("sldemo_fuelsys")
```

- 8 The generated file now defines the measurements as:

```

/begin MEASUREMENT
/* Name */ rtB.es_o.throttle
/* Long identifier */ ""
/* Data type */ FLOAT32_IEEE
/* Conversion method */ sldemo_fuelsys_CM_single
/* Resolution (Not used) */ 0
/* Accuracy (Not used) */ 0
/* Lower limit */ -3.4E+38
/* Upper limit */ 3.4E+38
ECU_ADDRESS 0x0000 /* @ECU_Address@rtB.es_o.throttle@ */
/begin IF_DATA XCP
 /begin DAQ_EVENT VARIABLE
 /begin DEFAULT_EVENT_LIST
 EVENT 0x0001
 /end DEFAULT_EVENT_LIST
 /end DAQ_EVENT
/end IF_DATA
/end MEASUREMENT

```

## Specify ECU Address Extension

Starting in R2022a, you can specify additional address information in the ASAP2 file by specifying an integer value for the `EcuAddressExtension` property. By default, no additional address information is provided.

- 1 Open the `sldemo_fuelsys` model.
- 2 Build the model.
- 3 Generate the ASAP2 file by using this command:

```
coder.asap2.export("sldemo_fuelsys",EcuAddressExtension=4)
```

The `ECU_ADDRESS_EXTENSION` key word for the characteristics, measurements, and axis points are in the ASAP2 file, enabling you to specify additional address information.

```

/begin MEASUREMENT
/* Name */ rtB.MinMax
/* Long identifier */ ""
/* Data type */ FLOAT64_IEEE
/* Conversion method */ sldemo_fuelsys_CM_double
/* Resolution (Not used) */ 0
/* Accuracy (Not used) */ 0
/* Lower limit */ -1.7E+308
/* Upper limit */ 1.7E+308
ECU_ADDRESS 0x0000 /* @ECU_Address@rtB.MinMax@ */
ECU_ADDRESS_EXTENSION 4
/end MEASUREMENT

```

# Configure Model Data Elements for ASAP2 File Generation

---

## Configure Model Data Elements for ASAP2 File Generation

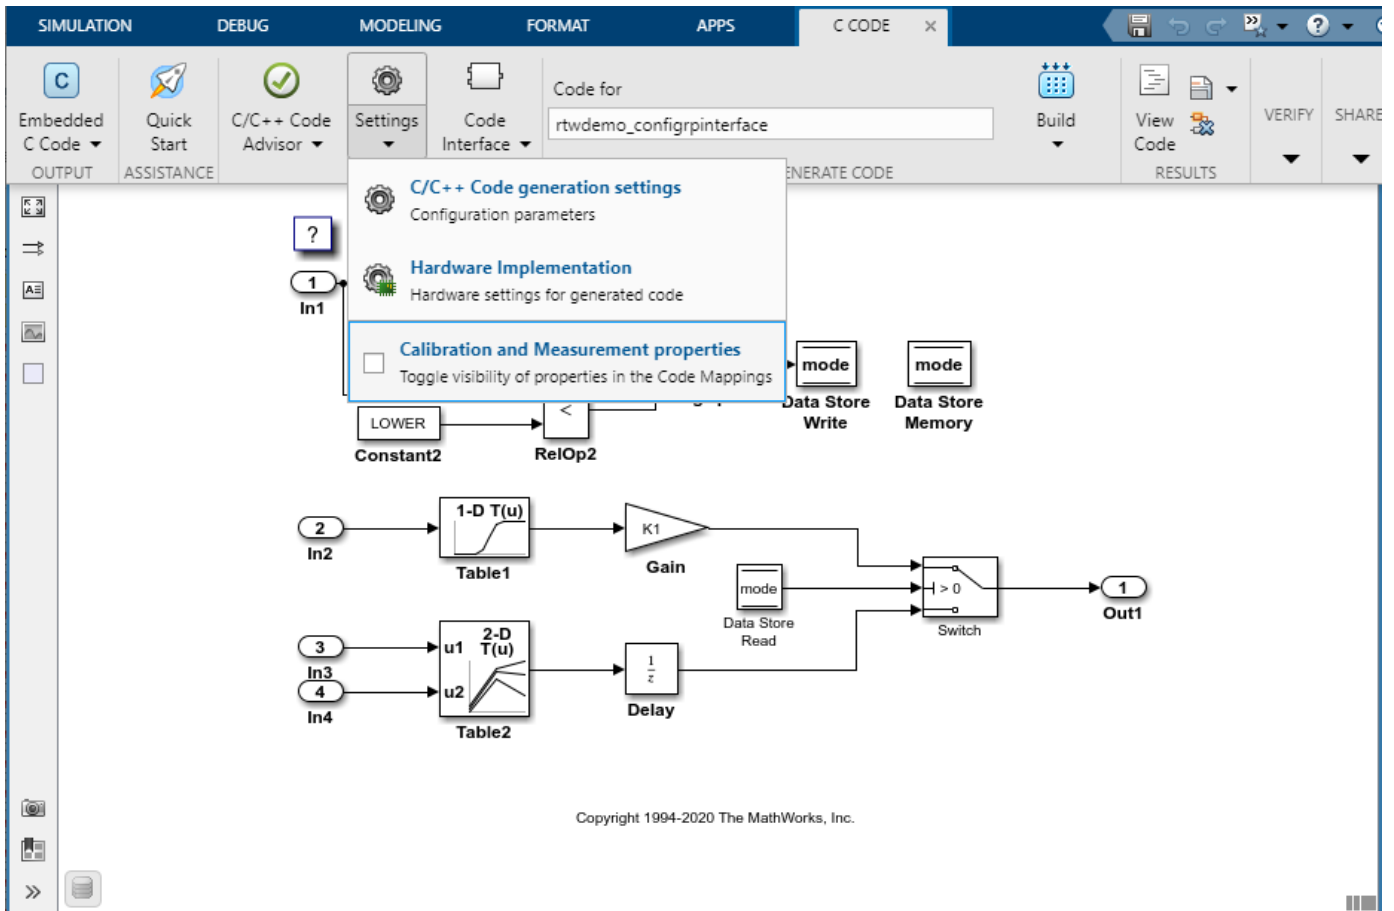

When you generate an ASAP2 file from a model, the ASAP2 file includes information about the data elements in your model such as characteristics and measurement variables. Each data element is described by information such as the memory address, storage structure, data types and conversion rules. In Simulink you can now customize how the data elements are described in an ASAP2 file. You can choose only those characteristics and measurements that you are interested in exporting into ASAP2 file.

To configure data elements for ASAP2 file generation in the **Code Mappings Editor - C** display, use the tabs:

- Inports
- Outports
- Parameters
- Data Stores
- Signals/States

### View Calibration Attributes

- 1 Open a model with multiple data elements.  
`open_system('rtwdemo_configrpinterface')`
- 2 Open the Embedded Coder app. On the **C Code** tab, select **Code Interface + Individual Element Code Mappings**.
- 3 On the **C Code** tab, select **Settings + Calibration and Measurement properties**.

## Configure Inport for ASAP2 File Generation

- 1 On the **Inports** tab, select an inport and click the  icon.
- 2 Specify the measurement property fields for the inport.

Source	Storage Class
In1	ImportedExtern
In2	Model default: ImportedExternPointer
In3	Model default: ImportedExternPointer

3 Alternatively, at the command line, you can enter these commands:

```
setInport(cm, 'In1', 'CalibrationAccess', 'Calibration');
setInport(cm, 'In1', 'CompuMethod', 'CM_Inport');
setInport(cm, 'In1', 'DisplayIdentifier', 'inport_display_name');
setInport(cm, 'In1', 'Format', '%4.2');
```

4 Build the model.

5 Generate the ASAP2 file by using this command:

```
coder.asap2.export('rtwdemo_configrinterface');
```

- 6 Verify the exported inport in the ASAP2 file and verify the fields that you specified are present.

```

/begin MEASUREMENT
/* Name */ input1
/* Long identifier */ ""
/* Data type */ FLOAT64_IEEE
/* Conversion method */ CM_Inport
/* Resolution (Not used) */ 0
/* Accuracy (Not used) */ 0
/* Lower limit */ -20
/* Upper limit */ 20
ECU_ADDRESS 0x0000 /* @ECU_Address@input1@ */
DISPLAY_IDENTIFIER inport_display_name
FORMAT "%4.2"
READ_WRITE
/end MEASUREMENT

```

You can configure an outport in the same way. By default, all the inports and outports are exported to A2L file. To avoid exporting an inport or an outport to A2L file, set the `Export` property to false using the command:

```
setInport(cm, 'In1', 'Export', false);
```

## Configure Parameter for ASAP2 File Generation

- 1 On the **Parameters** tab, select a parameter and click the  icon.
- 2 Specify the calibration property fields for the parameter.

Copyright 1994-2020 The MathWorks, Inc.

Code Mappings - C

Source	Storage Class
External Parameter Objects...	
Model Parameter Arguments (2)	
LOWER	Auto

3 Alternatively, at the command line, you can enter these commands:

```
setModelParameter(cm, 'LOWER', 'CalibrationAccess', 'NoCalibration');
setModelParameter(cm, 'LOWER', 'CompuMethod', 'CM_param');
setModelParameter(cm, 'LOWER', 'DisplayIdentifier', 'param_lower');
setModelParameter(cm, 'LOWER', 'Format', '%4.2');
```

4 Build the model.

5 Generate the ASAP2 file by using this command:

```
coder.asap2.export('rtwdemo_configrinterface');
```

- 6 Verify the exported parameter in the ASAP2 file and verify the fields that you specified are present.

```

/begin CHARACTERISTIC
/* Name */ rtwdemo_configrpinterface_InstP.LOWER
/* Long Identifier */ ""
/* Type */ VALUE
/* ECU Address */ 0x0000 /* @ECU_Address@rtwdemo_configrpinterface_InstP.LOWER@ */
/* Record Layout */ Scalar_FLOAT64_IEEE
/* Maximum Difference */ 0
/* Conversion Method */ CM_param
/* Lower Limit */ -20.000000
/* Upper Limit */ 0.000000
CALIBRATION_ACCESS NO_CALIBRATION
DISPLAY_IDENTIFIER param_lower
FORMAT "%4.2"
/end CHARACTERISTIC

```

You can configure data stores, states in the same way. By default, signals, states, and data stores are exported to A2L file. To avoid exporting a data element to A2L file, set the Export property to false using the command:

```
setModelParameter(cm, 'LOWER', 'Export', false);
```

---

**Note** To export signals, states, data stores, and parameters to the A2L file, configure the data element to a non-auto storage class.

---

# Direct Memory Access to Generated Code for Simulink Coder

---

## Access Memory in Generated Code Using Global Data Map

Simulink Coder provides a Target Language Compiler (TLC) function library that lets you create a global data map record. The global data map record, when generated, is added to the `CompiledModel` structure in the `model.rtw` file. The global data map record is a database containing information required for accessing memory in the generated code, including

- Signals (Block I/O)
- Parameters
- Data type work vectors (DWork)
- External inputs
- External outputs

Use of the global data map requires knowledge of the Target Language Compiler and of the structure of the `model.rtw` file. See “Target Language Compiler Overview” for information on these topics.

The TLC functions that are required to generate and access the global data map record are contained in `matlabroot/rtw/c/tlc/mw/globalmaplib.tlc`. The comments in the source code fully document the global data map structures and the library functions.

The global data map structures and functions might be modified or enhanced in future releases.

- “Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target” on page 65-40

## Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File

After you create a model, you can use the rapid simulation (RSim) system target file to characterize model behavior. The executable program that results from the build process is for non-real-time execution on your development computer. The executable program is highly optimized for simulating models of hybrid dynamic systems, including models that use variable-step solvers and zero-crossing detection. The speed of the generated code makes the RSim system target file ideal for building programs for batch or Monte Carlo simulations.

### About Rapid Simulation

Use the RSim target to generate an executable that runs fast, standalone simulations. You can repeat simulations with varying data sets, interactively or programmatically with scripts, without rebuilding the model. This can accelerate the characterization and tuning of model behavior and code generation testing.

Using command-line options:

- Define parameter values and input signals in one or more MAT-files that you can load and reload at the start of simulations without rebuilding your model.
- Redirect logging data to one or more MAT-files that you can then analyze and compare.
- Control simulation time.
- Specify external mode options.

---

**Note** To run an RSim executable, configure your computer to run MATLAB and have the MATLAB and Simulink installation folders accessible. To deploy a standalone host executable ( i.e., without MATLAB and Simulink installed), consider using the Host-Based Shared Library target (ert\_shrplib)."

---

### Rapid Simulation Advantage

The advantage that you gain from rapid simulation varies. Larger simulations achieve speed improvements of up to 10 times faster than standard Simulink simulations. Some models might not show noticeable improvement in simulation speed. To determine the speed difference for your model, time your standard Simulink simulation and compare the results with a rapid simulation. In addition, test the model simulation in Rapid Accelerator simulation mode.

### General Rapid Simulation Workflow

Like other stages of Model-Based Design, characterization and tuning of model behavior is an iterative process, as shown in the general workflow diagram in the figure. Tasks in the workflow are:

- 1 Identify your rapid simulation requirements. on page 65-3
- 2 Configure Inport blocks on page 65-4 that provide input source data for rapid simulations.
- 3 Configure the model on page 65-4 for rapid simulation.
- 4 Set up simulation input data. on page 65-6
- 5 Run the rapid simulations. on page 65-13

## Identify Rapid Simulation Requirements

The first step to setting up a rapid simulation is to identify your simulation requirements.

Question...	For More Information, See...
How long do you want simulations to run?	"Configure and Build Model for Rapid Simulation" on page 65-4
Are there solver requirements? Do you expect to use the same solver for which the model is configured for your rapid simulations?	"Configure and Build Model for Rapid Simulation" on page 65-4
Do your rapid simulations need to accommodate flexible custom code interfacing? Or, do your simulations need to retain storage class settings?	"Configure and Build Model for Rapid Simulation" on page 65-4
Will you be running simulations with multiple data sets?	"Set Up Rapid Simulation Input Data" on page 65-6
Will the input data consist of global parameters, signals, or both?	"Set Up Rapid Simulation Input Data" on page 65-6
What type of source blocks provide input data to the model — From File, Inport, From Workspace?	"Set Up Rapid Simulation Input Data" on page 65-6
Will the model's parameter vector ( <i>model_P</i> ) be used as input data?	"Create a MAT-File That Includes a Model Parameter Structure" on page 65-6

Question...	For More Information, See...
What is the data type of the input parameters and signals?	“Set Up Rapid Simulation Input Data” on page 65-6
Will the source data consist of one variable or multiple variables?	“Set Up Rapid Simulation Input Data” on page 65-6
Does the input data include tunable parameters?	“Create a MAT-File That Includes a Model Parameter Structure” on page 65-6
Do you need to gain access to tunable parameter information — model checksum and parameter data types, identifiers, and complexity?	“Create a MAT-File That Includes a Model Parameter Structure” on page 65-6
Will you have a need to vary the simulation stop time for simulation runs?	“Configure and Build Model for Rapid Simulation” on page 65-4 and “Override a Model Simulation Stop Time” on page 65-15
Do you want to set a time limit for the simulation? Consider setting a time limit if your model experiences frequent zero crossings and has a small minor step size.	“Set a Clock Time Limit for a Rapid Simulation” on page 65-15
Do you need to preserve the output of each simulation run?	“Specify a New Output File Name for a Simulation” on page 65-21 and “Specify New Output File Names for To File Blocks” on page 65-21
Do you expect to run the simulations interactively or in batch mode?	“Scripts for Batch and Monte Carlo Simulations” on page 65-13

## Configure Inports to Provide Simulation Source Data

You can use Inport blocks as a source of input data for rapid simulations. To do so, configure the blocks so that they can import data from external MAT-files. By default, the Inport block inherits parameter settings from downstream blocks. In most cases, to import data from an external MAT-file, you must explicitly set these block parameters to match the source data in the MAT-file.

- **Main > Interpolate data**
- **Signal Attributes > Port dimensions**
- **Signal Attributes > Data type**
- **Signal Attributes > Signal type**

If you do not have control over the model content, you might need to modify the data in the MAT-file to conform to what the model expects for input. Input data characteristics and specifications of the Inport block that receives the data must match.

For details on adjusting these parameters and on creating a MAT-file for use with an Inport block, see “Create a MAT-File for an Inport Block” on page 65-10. For descriptions of the preceding block parameters, see the block description of Inport.

## Configure and Build Model for Rapid Simulation

After you identify your rapid simulation requirements, configure the model for rapid simulation.

- 1 Set model configuration parameter **System target file** to `rsim.tlc` (Rapid Simulation Target).
- 2 Click **RSim Target** to view the **RSim Target** pane.

The screenshot shows the RSim Target configuration pane with the following settings:

- Parameter loading:**  Enable RSim executable to load parameters from a MAT-file
- Solver:** Solver selection: auto
- Storage classes:**  Force storage classes to AUTO

- 3 Set the RSim target configuration parameters for your rapid simulation requirements.

If You Want to...	Then...
Generate code that allows the RSim executable to load parameters from a MAT-file	Select <b>Enable RSim executable to load parameters from a MAT-file</b> (default).
Let the target choose a solver based on the solver already configured for the model	Set <b>Solver selection</b> to <code>auto</code> (default). The code generator uses a built-in solver if a fixed-step solver is specified on the <b>Solver</b> pane or calls the Simulink solver module (a shared library) if a variable-step solver is specified.
Explicitly instruct the target to use a fixed-step solver	Set <b>Solver selection</b> to <code>Use fixed-step solvers</code> . In the Configuration Parameters dialog box, on the <b>Solver</b> pane, specify a fixed-step solver.
Explicitly instruct the target to use a variable-step solver	Set <b>Solver selection</b> to <code>Use Simulink solver module</code> . In the Configuration Parameters dialog box, on the <b>Solver</b> pane, specify a variable-step solver.
Force storage classes to <code>Auto</code> for flexible custom code interfacing	Select <b>Force storage classes to AUTO</b> (default).
Retain storage class settings, such as <code>ExportedGlobal</code> or <code>ImportedExtern</code> , due to application requirements	Clear <b>Force storage classes to AUTO</b> .

- 4 Set up data import and export options. On the **Data Import/Export** pane, in the **Save to Workspace** section, select the **Time**, **States**, **Outputs**, and **Final States** parameters, as they apply. By default, the code generator saves simulation logging results to a file named `model.mat`. For more information, see “Export Simulation Data”.
- 5 If you are using external mode communication, set up the interface, using the **Code Generation > Interface** pane. See “External Mode Simulations for Parameter Tuning and Signal Monitoring” for details.
- 6 Press **Ctrl+B**. The code generator builds a highly optimized executable program that you can run on your development computer with varying data, without rebuilding.

For more information on compilers that are compatible with the Simulink Coder product, see “Select and Configure C or C++ Compiler” on page 56-3 and “Template Makefiles and Make Options” on page 56-22 .

## Set Up Rapid Simulation Input Data

- “About Rapid Simulation Data Setup” on page 65-6
- “Create a MAT-File That Includes a Model Parameter Structure” on page 65-6
- “Create a MAT-File for a From File Block” on page 65-9
- “Create a MAT-File for an Inport Block” on page 65-10

### About Rapid Simulation Data Setup

The format and setup of input data for a rapid simulation depends on your requirements.

If the Input Data Source Is...	Then...
The model's global parameter vector ( <i>model_P</i> )	Use the <code>rsimgetrtp</code> function to get the vector content and then save it to a MAT-file.
The model's global parameter vector and you want a mapping between the vector and tunable parameters	Call the <code>rsimgetrtp</code> function to get the global parameter structure and then save it to a MAT-file.
Provided by a From File block	Create a MAT-file that a From File block can read.
Provided by an Inport block	Create a MAT-file that adheres to one of the three data file formats that the Inport block can read.
Provided by a From Workspace block	Create structure variables in the MATLAB workspace.

The RSim target requires that MAT-files used as input for From File and Inport blocks contain data. The `grt` target inserts MAT-file data directly into the generated code, which is then compiled and linked as an executable. In contrast, RSim allows you to replace data sets for each successive simulation. A MAT-file containing From File or Inport block data must be present if a From File block or Inport block exists in your model.

### Create a MAT-File That Includes a Model Parameter Structure

To create a MAT-file that includes a model global parameter structure (*model\_P*),

- 1 Get the structure by calling the function `rsimgetrtp`.
- 2 Save the parameter structure to a MAT-file.

If you want to run simulations over varying data sets, consider converting the parameter structure to a cell array and saving the parameter variations to a single MAT-file.

#### Get the Parameter Structure for a Model

Get the global parameter structure (*model\_P*) for a model by calling the function `rsimgetrtp`.

```
param_struct = rsimgetrtp('model')
```

Argument	Description
<i>model</i>	The model for which you are running the rapid simulations.

The `rsimgetrtp` function forces an update diagram action for the specified model and returns a structure that contains the following fields.

Field	Description
modelChecksum	A four-element vector that encodes the structure of the model. The code generator uses the checksum to check whether the structure of the model has changed since the RSim executable was generated. If you delete or add a block, and then generate a new <i>model_P</i> vector, the new checksum does not match the original checksum anymore. The RSim executable detects this incompatibility in parameter vectors and exits to avoid returning incorrect simulation results. If the model structure changes, you must regenerate the code for the model.
parameters	A structure that contains the model's global parameters.

The parameter structure contains the following information.

Field	Description
dataTypeName	The name of the parameter data type, for example, <code>double</code>
dataTypeID	Internal data type identifier used by the code generator
complex	The value 0 if real; 1 if complex
dtTransIdx	Internal data index used by the code generator
values	A vector of the parameter values associated with this structure
map	This field contains the mapping information that correlates the 'values' to the tunable parameters of the model. This mapping information, in conjunction with <code>rsimsetrtpparam</code> , is useful for creating subsequent <code>rtP</code> structures without compiling the block diagram.

The code generator reports a tunable fixed-point parameter according to its stored value. For example, an `sfix(16)` parameter value of 1.4 with a scaling of  $2^{-8}$  has a value of 358 as an `int16`.

In the following example, `rsimgetrtP` returns the parameter structure for the example model `rtwdemo_rsimtf` to `param_struct`.

```
param_struct = rsimgetrtP('rtwdemo_rsimtf')

param_struct =

 modelChecksum: [1.7165e+009 3.0726e+009 2.6061e+009 2.3064e+009]
 parameters: [1x1 struct]
```

### Save the Parameter Structure to a MAT-File

After you issue a call to `rsimgetrtP`, save the return value of the function call to a MAT-file. Using a command-line option, you can then specify that MAT-file as input for rapid simulations.

The following example saves the parameter structure returned for `rtwdemo_rsimtf` to the MAT-file `myrsimdemo.mat`.

```
save myrsimdemo.mat param_struct;
```

For information on using command-line options to specify required files, see “Run Rapid Simulations” on page 65-13.

### Convert the Parameter Structure for Running Simulations on Varying Data Sets

To use rapid simulations to test changes to specific parameters, you can convert the model parameter structure to a cell array. You can then access a specific parameter set by using the @ operator to specify the index for a specific parameter set in the file.

To convert the structure to a cell array:

- 1 Use the function `rsimgetrtp` to get a structure containing parameter information for the example model `rtwdemo_rsimtf`. Store the structure in a variable `param_struct`.

```
param_struct = rsimgetrtp('rtwdemo_rsimtf');
```

The `parameters` field of the structure is a substructure that contains parameter information. The `values` field of the `parameters` substructure contains the numeric values of the parameters that you can tune during execution of the simulation code.

- 2 Use the function `rsimsetrtpparam` to expand the structure so that it contains more parameter sets. In this case, create two more parameter sets (for a total of three sets).

```
param_struct = rsimsetrtpparam(param_struct,3);
```

The function converts the `parameters` field to a cell array with three elements. Each element contains information for a single parameter set. By default, the function creates the second and third elements of the cell array by copying the first element. Therefore, all of the parameter sets use the same parameter values.

- 3 Specify new values for the parameters in the second and third parameter sets.

```
param_struct.parameters{2}.values = [-150 -5000 0 4950];
param_struct.parameters{3}.values = [-170 -5500 0 5100];
```

- 4 Save the structure containing the parameter set information to a MAT-file.

```
save rtwdemo_rsimtf.mat param_struct;
```

Alternatively, you can modify the block parameters in the model, and use `rsimgetrtp` to create multiple parameter sets:

- 1 Use the function `rsimgetrtp` to get a structure containing parameter information for the example model `rtwdemo_rsimtf`. Store the structure in a variable `param_struct`.

```
param_struct = rsimgetrtp('rtwdemo_rsimtf');
```

- 2 Use the function `rsimsetrtpparam` to expand the structure so that it contains more parameter sets. In this case, create two more parameter sets (for a total of three sets).

```
param_struct = rsimsetrtpparam(param_struct,3);
```

The function converts the `parameters` field to a cell array with three elements. Each element contains information for a single parameter set. By default, the function creates the second and third elements of the cell array by copying the first element. Therefore, all of the parameter sets use the same parameter values.

- 3 Change the values of block parameters or workspace variables. For example, change the value of the variable `w` from 70 to 72.

```
w = 72;
```

- 4 Use `rimsgetrtp` to get another structure containing parameter information. Store the structure in a temporary variable `rtp_temp`.

```
rtp_temp = rsimgetrtp('rtwdemo_rsimtf');
```

- 5 Assign the value of the `parameters` field of `rtp_temp` to the structure `param_struct` as a second parameter set.

```
param_struct.parameters{2} = rtp_temp.parameters;
```

- 6 Change the value of the variable `w` from 72 to 75.

```
w = 75;
```

- 7 Use `rimsgetrtp` to get another structure containing parameter information. Then, assign the value of the `parameters` field to `param_struct` as a third parameter set.

```
rtp_temp = rsimgetrtp('rtwdemo_rsimtf');
param_struct.parameters{3} = rtp_temp.parameters;
```

- 8 Save the structure containing the parameter set information to a MAT-file.

```
save 'rtwdemo_rsimtf.mat' param_struct;
```

For more information on how to specify each parameter set when you run the simulations, see “Change Block Parameters for an RSim Simulation” on page 65-20.

### Create a MAT-File for a From File Block

You can use a MAT-file as the input data source for a From File block. The format of the data in the MAT-file must match the data format expected by that block. For example, if you are using a matrix as an input for the MAT file, this cannot be different from the matrix size for the executable.

To create a MAT-file for a From File block:

- 1 For array format data, in the workspace create a matrix that consists of two or more rows. The first row must contain monotonically increasing time points. Other rows contain data points that correspond to the time point in that column. The time and data points must be data of type `double`.

For example:

```
t=[0:0.1:2*pi]';
Ina1=[2*sin(t) 2*cos(t)];
Ina2=sin(2*t);
Ina3=[0.5*sin(3*t) 0.5*cos(3*t)];
var_matrix=[t Ina1 Ina2 Ina3]';
```

For other supported data types, such as `int16` or fixed-point, the time data points must be of type `double`, just as for array format data. However, the sample data can be of any dimension.

For more information on setting up the input data, see the block description of From File.

- 2 Save the matrix to a MAT-file.

The following example saves the matrix `var_matrix` to the MAT-file `myrsimdemo.mat` in Version 7.3 format.

```
save '-v7.3' myrsimdemo.mat var_matrix;
```

Using a command-line option, you can then specify that MAT-file as input for rapid simulations.

### Create a MAT-File for an Inport Block

You can use a MAT-file as the input data source for an Inport block.

The format of the data in the MAT-file must adhere to one of the three column-based formats listed in the following table. The table lists the formats in order from least flexible to most flexible.

Format	Description
Single time/data matrix	<ul style="list-style-type: none"> <li>Least flexible.</li> <li>One variable.</li> <li>Two or more <i>columns</i>. Number of columns must equal the sum of the dimensions of all root Inport blocks plus 1. First column must contain monotonically increasing time points. Other columns contain data points that correspond to the time point in a given row.</li> <li>Data of type <code>double</code>.</li> </ul> <p>For an example, see <b>Single time/data matrix</b> in the following procedure, step 4. For more information, see “Loading Data Arrays to Root-Level Inputs”.</p>
Signal-and-time structure	<ul style="list-style-type: none"> <li>More flexible than the single time/data matrix format.</li> <li>One variable.</li> <li>Must contain two top-level fields: <code>time</code> and <code>signals</code>. The <code>time</code> field contains a <i>column</i> vector of the simulation times. The <code>signals</code> field contains an array of substructures, each of which corresponds to an Inport block. The substructure index corresponds to the Inport block number. Each <code>signals</code> substructure must contain a field named <code>values</code>. The <code>values</code> field must contain an array of inputs for the corresponding Inport block, where each input corresponds to a time point specified by the <code>time</code> field.</li> <li>If the <code>time</code> field is set to an empty value, clear the check box for the Inport block <b>Interpolate data</b> parameter.</li> <li>Data type must match Inport block settings.</li> </ul> <p>For an example, see <b>Signal-and-time structure</b> in the following procedure, step 4. For more information on this format, see “Loading Data Structures to Root-Level Inputs”.</p>

Format	Description
Per-port structure	<ul style="list-style-type: none"> <li>• Most flexible</li> <li>• Multiple variables. Number of variables must equal the number of Inport blocks.</li> <li>• Consists of a separate structure-with-time or structure-without-time for each Inport block. Each Inport block data structure has only one <code>signals</code> field. To use this format, in the <b>Input</b> text field, enter the names of the structures as a comma-separated list, <code>in1, in2, ..., inN</code>, where <code>in1</code> is the data for your model's first port, <code>in2</code> for the second port, and so on.</li> <li>• Each variable can have a different time vector.</li> <li>• If the <code>time</code> field is set to an empty value, clear the check box for the Inport block <b>Interpolate data</b> parameter.</li> <li>• Data type must match Inport block settings.</li> <li>• To save multiple variables to the same data file, you must save them in the order expected by the model, using the <code>-append</code> option.</li> </ul> <p>For an example, see <b>Per-port structure</b> in the following procedure, step 4. For more information, see “Loading Data Structures to Root-Level Inputs”.</p>

The supported formats and the following procedure are illustrated in `rtwdemo_rsim_i`.

To create a MAT-file for an Inport block:

- 1 Choose one of the preceding data file formats.
- 2 Update Inport block parameter settings and specifications to match specifications of the data to be supplied by the MAT-file.

By default, the Inport block inherits parameter settings from downstream blocks. To import data from an external MAT-file, explicitly set the following parameters to match the source data in the MAT-file.

- **Main > Interpolate data**
- **Signal Attributes > Port dimensions**
- **Signal Attributes > Data type**
- **Signal Attributes > Signal type**

If you choose to use a structure format for workspace variables and the `time` field is empty, clear block parameter **Interpolate data** or modify the parameter so that it is set to a nonempty value. Interpolation requires time data.

For descriptions of the preceding block parameters, see the block description of Inport.

- 3 Build an RSim executable program for the model. The build process creates and calculates a structural checksum for the model and embeds it in the generated executable. The RSim target uses the checksum to verify that data being passed into the model is consistent with what the model executable expects.
- 4 Create the MAT-file that provides the source data for the rapid simulations. You can create the MAT-file from a workspace variable. Using the specifications in the preceding format comparison table, create the workspace variables for your simulations.

An example of each format follows:

**Single time/data matrix**

```
t=[0:0.1:2*pi]';
Ina1=[2*sin(t) 2*cos(t)];
Ina2=sin(2*t);
Ina3=[0.5*sin(3*t) 0.5*cos(3*t)];
var_matrix=[t Ina1 Ina2 Ina3];
```

**Signal-and-time structure**

```
t=[0:0.1:2*pi]';
var_single_struct.time=t;
var_single_struct.signals(1).values(:,1)=2*sin(t);
var_single_struct.signals(1).values(:,2)=2*cos(t);
var_single_struct.signals(2).values=sin(2*t);
var_single_struct.signals(3).values(:,1)=0.5*sin(3*t);
var_single_struct.signals(3).values(:,2)=0.5*cos(3*t);
v=[var_single_struct.signals(1).values...
var_single_struct.signals(2).values...
var_single_struct.signals(3).values];
```

**Per-port structure**

```
t=[0:0.1:2*pi]';
Inb1.time=t;
Inb1.signals.values(:,1)=2*sin(t);
Inb1.signals.values(:,2)=2*cos(t);
t=[0:0.2:2*pi]';
Inb2.time=t;
Inb2.signals.values(:,1)=sin(2*t);
t=[0:0.1:2*pi]';
Inb3.time=t;
Inb3.signals.values(:,1)=0.5*sin(3*t);
Inb3.signals.values(:,2)=0.5*cos(3*t);
```

- 5 Save the workspace variables to a MAT-file.

**Single time/data matrix**

The following example saves the workspace variable `var_matrix` to the MAT-file `rsim_i_matrix.mat`.

```
save rsim_i_matrix.mat var_matrix;
```

**Signal-and-time structure**

The following example saves the workspace structure variable `var_single_struct` to the MAT-file `rsim_i_single_struct.mat`.

```
save rsim_i_single_struct.mat var_single_struct;
```

**Per-port structure**

To order data when saving per-port structure variables to a single MAT-file, use the `save` command's `-append` option. Be sure to append the data in the order that the model expects it.

The following example saves the workspace variables `Inb1`, `Inb2`, and `Inb3` to MAT-file `rsim_i_multi_struct.mat`.

```
save rsim_i_multi_struct.mat Inb1;
save rsim_i_multi_struct.mat Inb2 -append;
save rsim_i_multi_struct.mat Inb3 -append;
```

The `save` command does not preserve the order in which you specify your workspace variables in the command line when saving data to a MAT-file. For example, if you specify the variables `v1`, `v2`, and `v3`, in that order, the order of the variables in the MAT-file could be `v2 v1 v3`.

Using a command-line option, you can then specify the MAT-files as input for rapid simulations.

## Scripts for Batch and Monte Carlo Simulations

The RSim target is for batch simulations in which parameters and input signals vary for multiple simulations. New output file names allow you to run new simulations without overwriting prior simulation results. You can set up a series of simulations to run by creating a `.bat` file for use on a Microsoft Windows platform.

Create a file for the Windows platform with a text editor and execute it by typing the file name, for example, `mybatch`, where the name of the text file is `mybatch.bat`.

```
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run1.mat -o results1.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run2.mat -o results2.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run3.mat -o results3.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run4.mat -o results4.mat -tf 10.0
```

In this case, batch simulations run using four sets of input data in files `run1.mat`, `run2.mat`, and so on. The RSim executable saves the data to the files specified with the `-o` option.

The variable names containing simulation results in each of the files are identical. Therefore, loading consecutive sets of data without renaming the data once it is in the MATLAB workspace results in overwriting the prior workspace variable with new data. To avoid overwriting, you can copy the result to a new MATLAB variable before loading the next set of data.

You can also write MATLAB scripts to create new signals and new parameter structures, as well as to save data and perform batch runs using the bang command (`!`).

For details on running simulations and available command-line options, see “Run Rapid Simulations” on page 65-13. For an example of a rapid simulation batch script, see the example “Run Batch Simulations Without Recompiling Generated Code”.

## Run Rapid Simulations

- “Rapid Simulations” on page 65-14
- “Requirements for Running Rapid Simulations” on page 65-15
- “Set a Clock Time Limit for a Rapid Simulation” on page 65-15
- “Override a Model Simulation Stop Time” on page 65-15
- “Read the Parameter Vector into a Rapid Simulation” on page 65-16
- “Specify New Signal Data File for a From File Block” on page 65-16
- “Specify Signal Data File for an Inport Block” on page 65-18
- “Change Block Parameters for an RSim Simulation” on page 65-20
- “Specify a New Output File Name for a Simulation” on page 65-21

- “Specify New Output File Names for To File Blocks” on page 65-21

### Rapid Simulations

Using the RSim target, you can build a model once and run multiple simulations to study effects of varying parameter settings and input signals. You can run a simulation directly from your operating system command line, redirect the command from the MATLAB command line by using the bang (!) character, or execute commands from a script.

From the operating system command line, use

```
rtwdemo_rsimgtf
```

From the MATLAB command line, use

```
!rtwdemo_rsimgtf
```

The following table lists ways you can use RSim target command-line options to control a simulation.

To...	Use...
Read input data for a From File block from a MAT-file other than the MAT-file used for the previous simulation	<code>model -f oldfilename.mat=newfilename.mat</code>
Print a summary of the options for RSim executable targets	<code>executable filename -h</code>
Read input data for an Inport block from a MAT-file	<code>model -i filename.mat</code>
Time out after $n$ clock time seconds, where $n$ is a positive integer value	<code>model -L n</code>
Write MAT-file logging data to file <i>filename.mat</i>	<code>model -o filename.mat</code>
Read a parameter vector from file <i>filename.mat</i>	<code>model -p filename.mat</code>
Override the default TCP port (17725) for external mode	<code>model -port TCPport</code>
Write MAT-file logging data to a MAT-file other than the MAT-file used for the previous simulation	<code>model -t oldfilename.mat=newfilename.mat</code>
Run the simulation until the time value <i>stoptime</i> is reached	<code>model -tf stoptime</code>
Run in verbose mode	<code>model -v</code>
Wait for the Simulink engine to start the model in external mode	<code>model -w</code>

The following sections use the `rtwdemo_rsimgtf` example model in examples to illustrate some of these command-line options. In each case, the example assumes you have already done the following:

- Created or changed to a working folder.
- Opened the example model.
- Copied the data file `matlabroot/toolbox/rtw/rtwdemos/rsimgdemos/rsimg_tfddata.mat` to your working folder. You can perform this operation using the command:

```
copyfile(fullfile(matlabroot,'toolbox','rtw','rtwdemos',...
'rsimgdemos','rsimg_tfddata.mat'),pwd);
```

## Requirements for Running Rapid Simulations

The following requirements apply to both fixed and variable step executables.

- You must run the RSim executable on a computer configured to run MATLAB. Also, the RSim.exe file must be able to access the MATLAB and Simulink installation folders on this machine. To obtain that access, your PATH environment variable must include /bin and /bin/(\$ARCH), where (\$ARCH) represents your operating system architecture. For example, for a personal computer running on a Windows platform, (\$ARCH) is "win64", whereas for a Linux machine, (\$ARCH) is "glnxa64".
- On GNU Linux platforms, to run an RSim executable, define the LD\_LIBRARY\_PATH environment variable to provide the path to the MATLAB installation folder, as follows:
 

```
% setenv LD_LIBRARY_PATH /matlab/sys/os/glnx64:$LD_LIBRARY_PATH
```
- On the Apple Macintosh OS X platform, to run RSim target executables, you must define the environment variable DYLD\_LIBRARY\_PATH to include the folders bin/mac and sys/os/mac under the MATLAB installation folder. For example, if your MATLAB installation is under /MATLAB, add /MATLAB/bin/mac and /MATLAB/sys/os/mac to the definition for DYLD\_LIBRARY\_PATH.

## Set a Clock Time Limit for a Rapid Simulation

If a model experiences frequent zero crossings and the model's minor step size is small, consider setting a time limit for a rapid simulation. To set a time limit, specify the -L option with a positive integer value. The simulation aborts after running for the specified amount of clock time (not simulation time). For example,

```
!rtwdemo_rsimgtf -L 20
```

Based on your clock, after the executable runs for 20 seconds, the program terminates. You see a message similar to one of the following:

- On a Microsoft Windows platform,
 

```
Exiting program, time limit exceeded
Logging available data ...
```
- On The Open Group UNIX platform,
 

```
** Received SIGALRM (Alarm) signal @ Fri Jul 25 15:43:23 2003
** Exiting model 'vdp' @ Fri Jul 25 15:43:23 2003
```

You do not need to do anything to your model or to its configuration to use this option.

## Override a Model Simulation Stop Time

By default, a rapid simulation runs until the simulation time reaches the time specified the Configuration Parameters dialog box, on the **Solver** pane. You can override the model simulation stop time by using the -tf option. For example, the following simulation runs until the time reaches 6.0 seconds.

```
!rtwdemo_rsimgtf -tf 6.0
```

The RSim target stops and logs output data using MAT-file data logging rules.

If the model includes a From File block, the end of the simulation is regulated by the stop time setting specified in the Configuration Parameters dialog box, on the **Solver** pane, or with the RSim target

option `-tf`. The values in the block time vector are ignored. However, if the simulation time exceeds the endpoints of the time and signal matrix (if the final time is greater than the final time value of the data matrix), the signal data is extrapolated to the final time value.

### Read the Parameter Vector into a Rapid Simulation

To read the model parameter vector into a rapid simulation, you must first create a MAT-file that includes the parameter structure as described in “Create a MAT-File That Includes a Model Parameter Structure” on page 65-6. You can then specify the MAT-file in the command line with the `-p` option.

For example:

- 1 Build an RSim executable for the example model `rtwdemo_rsimtf`.
- 2 Modify parameters in your model and save the parameter structure.

```
param_struct = rsimgetrtp('rtwdemo_rsimtf');
save myrsimdata.mat param_struct
```

- 3 Run the executable with the new parameter set.

```
!rtwdemo_rsimtf -p myrsimdata.mat
```

```
** Starting model 'rtwdemo_rsimtf' @ Tue Dec 27 12:30:16 2005
** created rtwdemo_rsimtf.mat **
```

- 4 Load workspace variables and plot the simulation results by entering the following commands:

```
load myrsimdata.mat
plot(rt_yout)
```

### Specify New Signal Data File for a From File Block

If your model's input data source is a From File block, you can feed the block with input data during simulation from a single MAT-file or you can change the MAT-file from one simulation to the next. Each MAT-file must adhere to the format described in “Create a MAT-File for a From File Block” on page 65-9.

To change the MAT-file after an initial simulation, you specify the executable with the `-f` option and an `oldfile.mat=newfile.mat` parameter, as shown in the following example.

- 1 Set some parameters in the MATLAB workspace. For example:

```
w = 100;
theta = 0.5;
```

- 2 Build an RSim executable for the example model `rtwdemo_rsimtf`.
- 3 Run the executable.

```
!rtwdemo_rsimtf
```

The RSim executable runs a set of simulations and creates output MAT-files containing the specific simulation result.

- 4 Load the workspace variables and plot the simulation results by entering the following commands:

```
load rtwdemo_rsimtf.mat
plot(rt_yout)
```

The resulting plot shows simulation results based on default input data.

- 5 Create a new data file, `newfrom.mat`, that includes the following data:

```
t=[0:.001:1];
u=sin(100*t.*t);
tu=[t;u];
save newfrom.mat tu;
```

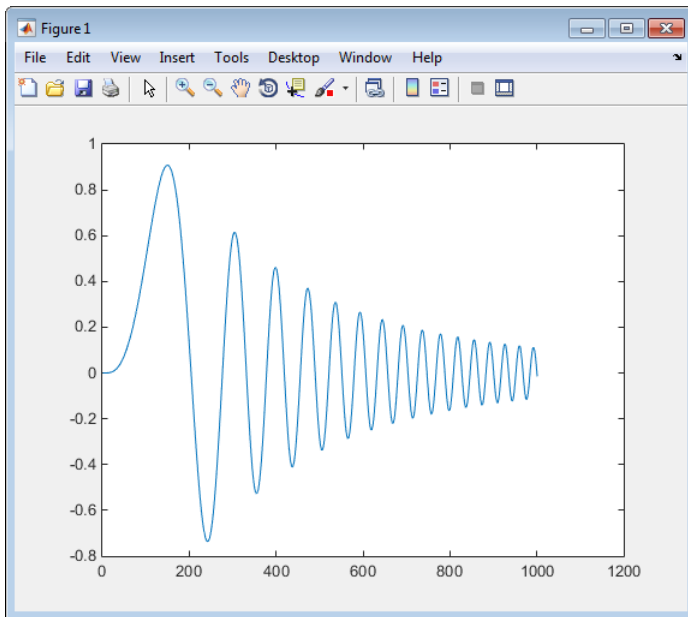

- 6 Run a rapid simulation with the new data by using the `-f` option to replace the original file, `rsim_tfdata.mat`, with `newfrom.mat`.

```
!rtwdemo_rsimtf -f rsim_tfdata.mat=newfrom.mat
```

- 7 Load the data and plot the new results by entering the following commands:

```
load rtwdemo_rsimtf.mat
plot(rt_yout)
```

The next figure shows the resulting plot.

From File blocks require input data of type `double`. If you need to import signal data of a data type other than `double`, use an Inport block (see “Create a MAT-File for an Inport Block” on page 65-10) or a From Workspace block with the data specified as a structure.

Workspace data must be in the format:

```
variable.time
variable.signals.values
```

If you have more than one signal, use the following format:

```
variable.time
variable.signals(1).values
variable.signals(2).values
```

### Specify Signal Data File for an Inport Block

If your model's input data source is an Inport block, you can feed the block with input data during simulation from a single MAT-file or you can change the MAT-file from one simulation to the next. Each MAT-file must adhere to one of the three formats described in “Create a MAT-File for an Inport Block” on page 65-10.

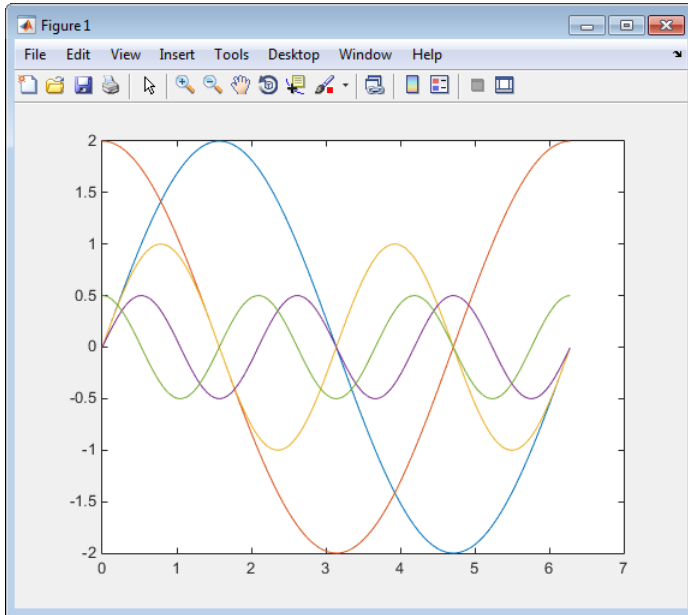

To specify the MAT-file after a simulation, you specify the executable with the `-i` option and the name of the MAT-file that contains the input data. For example:

- 1 Open the model `rtwdemo_rsim_i`.
- 2 Check the Inport block parameter settings. The following Inport block data parameter settings and specifications that you specify for the workspace variables must match settings in the MAT-file, as indicated in “Configure Inports to Provide Simulation Source Data” on page 65-4:
  - **Main > Interpolate data**
  - **Signal Attributes > Port dimensions**
  - **Signal Attributes > Data type**

- **Signal Attributes > Signal type**

- 3 Build the model.
- 4 Set up the input signals. For example:

```
t=[0:0.01:2*pi]';
s1=[2*sin(t) 2*cos(t)];
s2=sin(2*t);
s3=[0.5*sin(3*t) 0.5*cos(3*t)];
plot(t, [s1 s2 s3])
```

- 5 Prepare the MAT-file by using one of the three available file formats described in “Create a MAT-File for an Inport Block” on page 65-10. The following example defines a signal-and-time structure in the workspace and names it `var_single_struct`.

```
t=[0:0.1:2*pi]';
var_single_struct.time=t;
var_single_struct.signals(1).values(:,1)=2*sin(t);
var_single_struct.signals(1).values(:,2)=2*cos(t);
var_single_struct.signals(2).values=sin(2*t);
var_single_struct.signals(3).values(:,1)=0.5*sin(3*t);
var_single_struct.signals(3).values(:,2)=0.5*cos(3*t);
v=[var_single_struct.signals(1).values...
var_single_struct.signals(2).values...
var_single_struct.signals(3).values];
```

- 6 Save the workspace variable `var_single_struct` to MAT-file `rsim_i_single_struct`.
- 7 Run a rapid simulation with the input data by using the `-i` option. Load and plot the results.

```
!rtwdemo_rsim_i -i rsim_i_single_struct.mat

** Starting model 'rtwdemo_rsim_i' @ Tue Aug 19 10:26:53 2014
*** rsim_i_single_struct.mat is successfully loaded! ***
** created rtwdemo_rsim_i.mat **

** Execution time = 0.02024185130718954s
```

- 8 Load and plot the results.

```
load rtwdemo_rsim_i.mat
plot(rt_tout, rt_yout);
```

### Change Block Parameters for an RSim Simulation

As described in “Create a MAT-File That Includes a Model Parameter Structure” on page 65-6, after you alter one or more parameters in a Simulink block diagram, you can extract the parameter vector, *model\_P*, for the entire model. You can then save the parameter vector, along with a model checksum, to a MAT-file. This MAT-file can be read directly by the standalone RSim executable, allowing you to replace the entire parameter vector or individual parameter values, for running studies of variations of parameter values representing coefficients, new data for input signals, and so on.

RSim can read the MAT-file and replace the entire *model\_P* structure whenever you change one or more parameters, without recompiling the entire model.

For example, assume that you changed one or more parameters in your model, generated the new *model\_P* vector, and saved *model\_P* to a new MAT-file called *mylogfile.mat*. To run the same *rtwdemo\_rsimtf* model and use these new parameter values, use the *-p* option, as shown in the following example:

```
!rtwdemo_rsimtf -p mylogfile.mat
load rtwdemo_rsimtf
plot(rt_yout)
```

If you have converted the parameter structure to a cell array for running simulations on varying data sets, as described in “Convert the Parameter Structure for Running Simulations on Varying Data Sets” on page 65-8, you must add an *@n* suffix to the MAT-file specification. *n* is the element of the cell array that contains the specific input that you want to use for the simulation.

The following example converts `param_struct` to a cell array, changes parameter values, saves the changes to MAT-file `mymatfile.mat`, and then runs the executable using the parameter values in the second element of the cell array as input.

```
param_struct = rsimgetrtpp('rtwdemo_rsimtf');
param_struct = rsimsetrtpparam(param_struct,2);
param_struct.parameters{1}

ans =

 dataTypeName: 'double'
 dataTypeId: 0
 complex: 0
 dtTransIdx: 0
 values: [-140 -4900 0 4900]
 map: []
 structParamInfo: []

param_struct.parameters{2}.values=[-150 -5000 0 4950];
save mymatfile.mat param_struct;
!rtwdemo_rsimtf -p mymatfile.mat@2 -o rsim2.mat
```

### Specify a New Output File Name for a Simulation

If you have specified one or more of the **Save to Workspace** parameters — **Time**, **States**, **Outputs**, or **Final States** — in the Configuration Parameters dialog box, on the **Data Import/Export** pane, the default is to save simulation logging results to the file `model.mat`. For example, the example model `rtwdemo_rsimtf` normally saves data to `rtwdemo_rsimtf.mat`, as follows:

```
!rtwdemo_rsimtf
created rtwdemo_rsimtf.mat
```

You can specify a new output file name for data logging by using the `-o` option when you run an executable.

```
!rtwdemo_rsimtf -o rsim1.mat
```

In this case, the set of parameters provided at the time of code generation, including From File block data parameters, is run.

### Specify New Output File Names for To File Blocks

In much the same way as you can specify a new system output file name, you can also provide new output file names for data saved from one or more To File blocks. To do this, specify the original file name at the time of code generation with a new name, as shown in the following example:

```
!rtwdemo_rsimtf -t rtwdemo_rsimtf_data.mat=mynewsimdata.mat
```

In this case, assume that the original model wrote data to the output file `rtwdemo_rsimtf_data.mat`. Specifying a new file name forces RSim to write to the file `mynewsimdata.mat`. With this technique, you can avoid overwriting an existing simulation run.

## Tune Parameters Interactively During Rapid Simulation

The RSim system target file was designed to let you run batch simulations at the fastest possible speed. Using variable-step or fixed-step solvers with that system target file and a tunable parameter

data structure, whether you set **Default parameter behavior** to Tunable or to Inlined, you can create multiple parameter sets. You can run the data sets with the generated executable program (.exe on Windows). Each invocation of the executable program allows specification of the file name to use for results.

For this example, **Default parameter behavior** is set to Inlined. The model declares workspace variables as tunable parameters. To use the RSim system target file with **Default parameter behavior** set to Tunable, and without explicitly declaring tunable parameters, see “Run Batch Simulations Without Recompiling Generated Code”.

### Open Example Model

Open the example model `rtwdemo_rsim_param_tuning`.

```
open_system('rtwdemo_rsim_param_tuning');
```

This model uses the RSim target and the `rsimget` rtp function to allow a non real time executable to be passed new data without the need to recompile the Simulink model. This feature allows you to get a map of the tunable parameters declared in a model and save it in a MAT-file. You can then create your own MATLAB GUI or a standalone GUI (independent of MATLAB) to read and write the MAT-file and rerun the executable to produce new output files.

In the model, double-click the buttons sequentially to run the example.

To review the code used to create the MATLAB graphical interface and the standalone graphical interface, double-click the **View MATLAB programs** button.

For more information, see “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File”.

## Rapid Simulation Target Limitations

The RSim target has the following limitations:

- Does not support algebraic loops.
- Does not support Interpreted MATLAB Function blocks.
- Does not support noninlined MATLAB language or Fortran S-functions.
- If an RSim build includes referenced models (by using Model blocks), set up these models to use fixed-step solvers to generate code for them. The top model, however, can use a variable-step solver as long as the blocks in the referenced models are discrete.
- In certain cases, changing block parameters can result in structural changes to your model that change the model checksum. An example of such a change is changing the number of delays in a DSP simulation. In such cases, you must regenerate the code for the model.

## Run Rapid Simulations Over a Range of Parameter Values

This example shows how to use the RSim system target file to run simulations over a range of parameter values. The example uses the Van der Pol oscillator and performs a parameter sweep over a range of initial state values to obtain the phase diagram of a nonlinear system.

You can customize this example for your own application by modifying the MATLAB® script used to build this example. Click the link in the top left corner of this page to edit the MATLAB® script. Click the link in the top right corner to run this example from MATLAB®. Run the example from writable location. The example creates files that you may want to investigate later.

For this example, set model configuration parameter **Default parameter behavior** to Inlined. In the example, you create Simulink.Parameter objects as tunable parameters. To use RSim with **Default parameter behavior** set to Tunable, and without explicitly declaring tunable parameters, see “Run Batch Simulations Without Recompiling Generated Code”.

To run multiple simulations in the Simulink environment, consider using rapid accelerator instead of RSim. For information about rapid accelerator, see “What Is Acceleration?”. To sweep parameter values, see “Optimize, Estimate, and Sweep Block Parameter Values”.

### Preparation Model

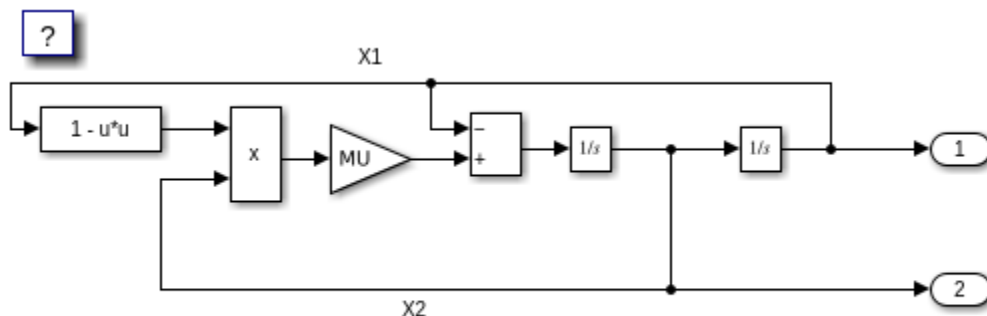

Make sure the current folder is writable. The example creates files.

```
[stat, fa] = fileattrib(pwd);
if ~fa.UserWrite
 disp('This script must be run in a writable directory');
 return
end
```

Open the model. Then, open the **Simulink Coder** app. Set model configuration parameter **System target file** to `rsim.tlc`.

For more information on doing this graphically and setting up other RSim target related options, see “Configure a System Target File”.

```
mdlName = 'rtwdemo_rsim_vdp';
open_system(mdlName);
cs = getActiveConfigSet(mdlName);
cs.switchTarget('rsim.tlc', []);
```

Copyright 2005-2020 The MathWorks, Inc.

Specify variables INIT\_X1 (the initial condition for state x1), INIT\_X2 (the initial condition for state x2), and MU (the gain value) as tunable. To create tunable parameters, convert the variables to Simulink.Parameter objects, and configure the objects to use a storage class other than Auto. In this example you investigate how the state trajectories evolve from different initial values for states x1 and x2 in the model.

```
INIT_X1 = Simulink.Parameter(INIT_X1);
INIT_X1.StorageClass = 'Model default';
```

```
INIT_X2 = Simulink.Parameter(INIT_X2);
INIT_X2.StorageClass = 'Model default';
```

```
MU = Simulink.Parameter(MU);
MU.StorageClass = 'Model default';
```

Define the names of files that will be created.

```
prmFileName = [mdlName, '_prm_sets.mat'];
logFileName = [mdlName, '_run_scr.log'];
batFileName = [mdlName, '_run_scr'];
exeFileName = mdlName;
if ispc
 exeFileName = [exeFileName, '.exe'];
 batFileName = [batFileName, '.bat'];
end
aggDataFile = [mdlName, '_results'];
startTime = cputime;
```

### Build Model

Build the RSim executable program for the model. During the build process, a structural checksum is calculated for the model and embedded into the generated executable program. This checksum is used to check that a parameter set passed to the executable program is compatible with the program.

```
slbuild(mdlName);
```

```
Starting build procedure for: rtwdemo_rsim_vdp
Generated code for 'rtwdemo_rsim_vdp' is up to date because no structural, parameter or code
Successful completion of build procedure for: rtwdemo_rsim_vdp
```

Build Summary

```
0 of 1 models built (1 models already up to date)
Build duration: 0h 0m 7.3243s
```

### Get Default Parameter Set for Model

Get the default rtP structure (parameter set) for the model. The modelChecksum field in the rtP structure is the structural checksum of the model. This must match the checksum embedded in the RSim executable program. If the two checksums do not match, the executable program produces an error. rsimgetrtp generates an rtP structure with entries for the named tunable variables INIT\_X1, INIT\_X2, and MU.

```
rtp = rsimgetrtp(mdlName)
```

```
rtp =
```

```

struct with fields:
 modelChecksum: [3.5788e+09 3.0526e+09 3.2467e+09 ...]
 parameters: [1x1 struct]
 globalParameterInfo: [1x1 struct]
 collapsedBaseWorkspaceVariables: []
 nonTunableVariables: [1x0 struct]

```

### Create Parameter Sets

Using the `rtp` structure, build a structure array with different values for the tunable variables in the model. As mentioned earlier, in this example you want see how the state trajectories evolve for different initial values for states `x1` and `x2` in the model. To do this, generate different parameter sets with different values for `INIT_X1` and `INIT_X2` and leave tunable variable `MU` set to the default value.

```

INIT_X1_vals = -5:1:5;
INIT_X2_vals = -5:1:5;
MU_vals = 1;
nPrmSets = length(INIT_X1_vals)*length(INIT_X2_vals)*length(MU_vals)

```

```

nPrmSets =
 121

```

This example has `nPrmSets` parameter sets. You need to run that many simulations. Initialize `aggData`, which is a structure array that holds the parameter set and corresponding results.

```

aggData = struct('tout', [], 'yout', [], ...
 'prms', struct('INIT_X1', [], 'INIT_X2', [], 'MU', []))
aggData = repmat(aggData, nPrmSets, 1);

```

```

aggData =
 struct with fields:
 tout: []
 yout: []
 prms: [1x1 struct]

```

The utility function `rsimsetrtpparam` builds the `rtp` structure by adding parameter sets one at a time with different parameters values.

```

idx = 1;
for iX1 = INIT_X1_vals
 for iX2 = INIT_X2_vals
 for iMU = MU_vals
 rtp = rsimsetrtpparam(rtp,idx,'INIT_X1',iX1,'INIT_X2',iX2,'MU',iMU);
 aggData(idx).prms.INIT_X1 = iX1;
 aggData(idx).prms.INIT_X2 = iX2;
 aggData(idx).prms.MU = iMU;
 idx = idx + 1;
 end
 end
end

```

```

 end
end

```

Save the `rtP` structure array with the parameter sets to a MAT-file.

```
save(prmFileName, 'rtp');
```

### Create Batch File

Create a batch script file to run the RSim executable program over the parameter sets. Each run reads the specified parameter set from the parameter MAT-file and writes the results to the specified output MAT-file. Use the time out option so that if a run hangs (for example, because the model has a singularity for that parameter set), abort the run after the specified time limit and proceed to the next run.

For example, this command (on Windows®) specifies using the third parameter set from the `rtP` structure in `prm.mat`, writes the results to `run3.mat`, and aborts execution if a run takes longer than 3600 seconds of CPU time. While running, the script pipes messages from `model.exe` to `run.log`, which you can use to debug issues.

```

 model.exe -p prm.mat@3 -o run3.mat -L 3600 2>&1>> run.log

fid = fopen(batFileName, 'w');
idx = 1;
for iX1 = INIT_X1_vals
 for iX2 = INIT_X2_vals
 for iMU = MU_vals
 outMatFile = [mdlName, '_run', num2str(idx), '.mat'];
 cmd = [exeFileName, ...
 ' -p ', prmFileName, '@', int2str(idx), ...
 ' -o ', outMatFile, ...
 ' -L 3600'];
 if ispc
 cmd = [cmd, ' 2>&1>> ', logFileName];
 else % (unix)
 cmd = ['./ filesep cmd, ' 1> ', logFileName, ' 2>&1'];
 end
 fprintf(fid, ['echo "', cmd, '"\n']);
 fprintf(fid, [cmd, '\n']);
 idx = idx + 1;
 end
 end
end
if isunix,
 system(['touch ', logFileName]);
 system(['chmod +x ', batFileName]);
end
fclose(fid);

```

Creating a batch/script file to run simulations enables you to call the system command once to run the simulations (or even run the batch script outside MATLAB®) instead of calling the system command in a loop for each simulation. This improves performance because the system command has significant overhead.

### Execute Batch File to Run Simulations

Run the batch/script file, which runs the RSim executable program once for each parameter set and saves the results to a different MAT-file each time. You can run the batch file from outside MATLAB®.

```
[stat, res] = system(['.' filesep batFileName]);
if stat ~= 0
 error(['Error running batch file ''', batFileName, '' :', res]);
end
```

This example logs simulation run results in one batch file as it runs the batch file to sequentially run  $n$  simulations over  $n$  parameter sets. You can modify the script to generate multiple batch files and run them in parallel by distributing them across multiple computers. Also, you can run the batch files without launching MATLAB®.

### Load Output MAT-Files and Collate Results

Collect the simulation results from the output MAT-files into the structure `aggData`. If the output MAT-file corresponding to a particular run is not found, set the results corresponding to that run to NaN (not a number). This situation occurs if a simulation run with a particular set of parameters encounters singularities in the model.

```
idx = 1;
for iX1 = INIT_X1_vals
 for iX2 = INIT_X2_vals
 for iMU = MU_vals
 outMatFile = [mdlName, '_run', num2str(idx), '.mat'];
 if exist(outMatFile, 'file')
 load(outMatFile);
 aggData(idx).tout = rt_tout;
 aggData(idx).yout = rt_yout;
 else
 aggData(idx).tout = nan;
 aggData(idx).yout = nan;
 end
 idx = idx + 1;
 end
 end
end
```

Save the `aggData` structure to the results MAT-file. At this point, you can delete the other MAT-files, as the `aggData` data structure contains the aggregation of input (parameters sets) and output data (simulation results).

```
save(aggDataFile, 'aggData');
disp(['Took ', num2str(cputime-startTime), ...
 ' seconds to generate results from ', ...
 num2str(nPrmSets), ' simulation runs (Steps 2 to 7).']);
```

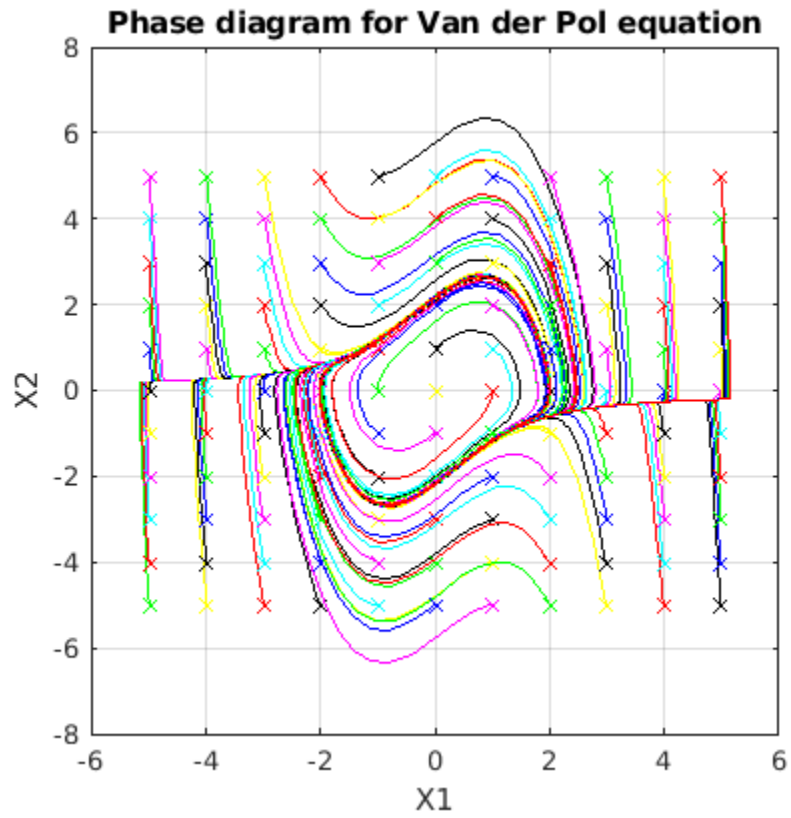

Took 945.89 seconds to generate results from 121 simulation runs (Steps 2 to 7).

### Analyze Simulation Results

Plot the phase diagram (X2 versus X1) with different initial values for X1 and X2. The diagram shows that, irrespective of the initial condition, the Van der Pol oscillator converges to its natural oscillator mode.

```
colors = {'b', 'g', 'r', 'c', 'm', 'y', 'k'}; nColors = length(colors);
for idx = 1:nPrmSets
 col = colors{idx - nColors*floor(idx/nColors) + 1};
 plot(aggData(idx).prms.INIT_X1, aggData(idx).prms.INIT_X2, [col, 'x'], ...
 aggData(idx).yout(:,1), aggData(idx).yout(:,2), col);
 hold on
```

```
end
grid on
xlabel('X1');
ylabel('X2');
axis('square');
title('Phase diagram for Van der Pol equation');
```

## Run Batch Simulations Without Recompiling Generated Code

This example shows how to run batch simulations without recompiling the generated code. The example modifies input signal data and model parameters by reading data from a MAT-file. In the first part (steps 1-5), ten parameter sets are created from the Simulink® model by changing the transfer function damping factor. The ten parameter sets are saved to a MAT-file, and the RSim executable reads the specified parameter set from the file. In the second part (step 6-7) of this example, five sets of signal data chirps are created with increasingly high frequencies. In both parts, the RSim executable runs the set of simulations and creates output MAT-files containing the specific simulation result. Finally, a composite of runs appears in a MATLAB® figure.

To quickly run multiple simulations in the Simulink environment, consider using rapid accelerator instead of RSim. See “What Is Acceleration?”.

### Step 1. Preparation

Make sure the current directory is writable because this example will be creating files.

```
[stat, fa] = fileattrib(pwd);
if ~fa.UserWrite
 disp('This script must be run in a writable directory');
 return;
end
```

Open the model and configure it to use the RSim target. For more information on doing this graphically and setting up other RSim target related options, see “Configure a System Target File” on page 47-2.

```
mdlName = 'rtwdemo_rsimgtf';
open_system(mdlName);
cs = getActiveConfigSet(mdlName);
cs.switchTarget('rsim.tlc', []);
```

Copyright 2005-2020 The MathWorks, Inc.

The MAT-file rsim\_tfdata.mat is required in the local directory.

```
if ~isempty(dir('rsim_tfdata.mat')),
 delete('rsim_tfdata.mat');
end
str1 = fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'rsimgdemos', 'rsim_tfdata.mat');
str2 = ['copyfile('', str1, '', 'rsim_tfdata.mat', 'writable')'];
eval(str2);
```

## Step 2. Build the Model

Build the RSim executable for the model. During the build process, a structural checksum is calculated for the model and embedded into the generated executable. This checksum is used to check that a parameter set passed to the executable is compatible with it.

```
evalin('base','w = 70;')
evalin('base','theta = 1.0;')
disp('Building compiled RSim simulation.')
slbuild mdlName);

Building compiled RSim simulation.
Starting build procedure for: rtwdemo_rsimtf
Successful completion of build procedure for: rtwdemo_rsimtf
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_rsimtf	Code generated and compiled	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 16.567s

## Step 3. Get the Default Parameter Set and Create 10 Parameters Sets

```
disp('Creating rtP data files')
for i=1:10
 % Extract current rtP structure using new damping factor.
 [rtpstruct]=evalin('base','rsimgetrtP(''rtwdemo_rsimtf'')');
 savestr = strcat('save params',num2str(i),'.mat rtpstruct');
 eval(savestr);
 evalin('base','theta = theta - .1;');
end
disp('Finished creating parameter data files.')

Creating rtP data files
Finished creating parameter data files.
```

## Step 4. Run 10 RSim Simulations Using New Parameter Sets and Plot the Results

```
figure
for i=1:10
 % Bang out and run a simulation using new parameter data
 runstr = ['./', filesep, 'rtwdemo_rsimtf -p params',num2str(i),'.mat', ' -v'];
 [status, result] = system(runstr);
 if status ~= 0, error(result); end
 % Load simulation data into MATLAB for plotting.
 load rtwdemo_rsimtf.mat;
 axis([0 1 0 2]);
 plot(rt_tout, rt_yout)
 hold on
end
```

The plot shows 10 simulations, each using a different damping factor.

### Step 5. Set Up a Time Vector and an Initial Frequency Vector

The time vector has 4096 points in the event we want to do windowing and spectral analysis on simulation results.

```
dt = .001;
nn = [0:1:4095];
t = dt*nn; [m,n] = size(t);
wlo = 1; whi = 4;
omega = [wlo:((whi-wlo)/n):whi - (whi-wlo)/n];
```

### Step 6. Create 5 Sets of Signal Data in MAT Files

Creating .mat files with chirp data.

```
disp('This part of the example illustrates a sequence of 5 plots. Each')
disp('plot shows an input chirp signal of certain frequency range.')
for i = 1:5
 wlo = whi; whi = 3*whi; % keep increasing frequencies
 omega = [wlo:((whi-wlo)/n):whi - (whi-wlo)/n];
 % In a real application we recommend shaping the chirp using
 % a windowing function (hamming or hanning window, etc.)
 % This example does not use a windowing function.
 u = sin(omega.*t);
 tudata = [t;u];
 % At each pass, save one more set of tudata to the next
```

```

% .mat file.
savestr = strcat('save sweep',num2str(i),'.mat tudata');
eval(savestr);
% Display each chirp. Note that this is only input data.
% Simulations have not been run yet.
plotstr = strcat('subplot(5,1,',num2str(i),')');
eval(plotstr);
plot(t,u)
pause(0.3)
end

```

This part of the example illustrates a sequence of 5 plots. Each plot shows an input chirp signal of certain frequency range.

### Step 7. Run the RSim Compiled Simulation Using New Signal Data

Replace the original signal data (rsim\_tfdata.mat) with the files sweep1.mat, sweep2.mat, and so on.

```

disp('Starting batch simulations.')
for i = 1:5
% Bang out and run the next set of data with RSim
runstr = ['. ', filesep, 'rtwdemo_rsimtf -f rsim_tfdata.mat=sweep', ...
num2str(i), '.mat -v -tf 4.096'];
[status, result] = system(runstr);
if status ~= 0, error(result); end
% Load the data to MATLAB and plot the results.
load rtwdemo_rsimtf.mat
plotstr = strcat('subplot(5,1,',num2str(i),')');

```

```
eval(plotstr);
plot(rt_tout, rt_yout); axis([0 4.1 -3 3]);
end
zoom on
% cleanup
evalin('base','clear w theta')
disp('This part of the example illustrates a sequence of 5 plots. Each plot')
disp('shows the simulation results for the next frequency range. Using the')
disp('mouse, zoom in on each signal to observe signal amplitudes.')
close_system mdlName, 0);
```

Starting batch simulations.

This part of the example illustrates a sequence of 5 plots. Each plot shows the simulation results for the next frequency range. Using the mouse, zoom in on each signal to observe signal amplitudes.

## Use MAT-Files to Feed Data to Inport Blocks for Rapid Simulations

This example shows how the code generator RSim -i option lets you use a MAT-file as the input data source for Inport blocks for rapid simulations. The data in such a MAT-file can be presented in the following formats:

- One variable that defines a time/input data matrix of double values.
- One variable that defines a structure that uses a combination of Simulink® data types.
- Multiple variables, each defining a structure that uses a combination of Simulink® data types.

This flexibility lends itself well to applications for which you must run simulations over a range of input data stored in different data files. This example explains how to use this feature.

To quickly run multiple simulations in the Simulink environment, consider using rapid accelerator instead of RSim. See “What Is Acceleration?”.

### Prepare Model

Open the model and save a copy to a writable location. Then, open the **Simulink Coder** app. Set model configuration parameter \*System target file to `rsim.tlc`.

For more information on doing this graphically and setting up other model configuration parameters relate to the RSim system target file, see “Configure a System Target File” on page 47-2.

```
mdlName = 'rtwdemo_rsim_i';
open_system(mdlName);
cs = getActiveConfigSet(mdlName);
cs.switchTarget('rsim.tlc',[]);
```

### Configure Inport Blocks

To use the RSim -i option, you must configure each Inport block properly. You can double-click an Inport block to view its properties. By default, Inport blocks inherit their properties from downstream blocks. Before you can import data from external MAT-files, you must set the parameters of each Inport block to match the data in the MAT file. In most cases, these parameters of an Inport block must be set:

- **Interpolate Data**
- **Port Dimensions**
- **Data Type**
- **Signal Type**

For more information on these parameters, click the Help button. This example model includes three Inport blocks. A requirement for the example is for Inport 1 and Inport 2 to interpolate between data, and for Inport 3 to not interpolate. The dimension of the Inport blocks are 2, 1, and 2, respectively. Signals are real. The settings are as follows:

```
for i =1:3
 portName =['/In', num2str(i)];
 Interp = get_param(strcat(mdlName,portName), 'Interpolate');
 PortDimension = get_param(strcat(mdlName,portName), 'PortDimensions');
 DataType = get_param(strcat(mdlName,portName), 'OutDataTypeStr');
```

```

 SignalType = get_param(strcat mdlName, portName), 'SignalType');
end

```

- For inports In1 and In2, interpolation is selected. For inport In3, interpolation is cleared.
- For inports In1 and In3, port dimension is set to 2. For inport In2, port dimension is set to 1.
- For inports In1, In2, and In3, data type is `double` and signal type is `real`.

### Build Model

Build an executable for the model. During the build process, a structural checksum is calculated and embedded into the generated executable program. This checksum is used to check that a parameter set passed to the executable program is compatible with the program.

```
evalc('slbuild mdlName');
```

### Identify Signals for Data File

After you configure the Inport block, prepare the data file based on the Inport blocks. This figure shows the input signals to be used.

```

t=[0:0.01:2*pi]';
s1 = [2*sin(t) 2*cos(t)];
s2 = sin(2*t);
s3 = [0.5*sin(3*t) 0.5*cos(3*t)];
figure;
plot(t, [s1 s2 s3]);

```

This figure displays the input signals.

### Prepare MAT-File

Generally, you can create the MAT-file from a workspace variable. The RSim -i option supports three data file formats:

#### One variable in TU matrix format of doubles

For this format, the first column is the time vector and the remaining columns are input vectors. The number of columns in the TU matrix equals the sum of the dimensions of the root Inport blocks plus 1. This MATLAB® code generates a MAT-file containing one variable `var_matrix` in TU matrix format. You can use this format only if the input ports in the model have the same data type.

```
t=[0:0.1:2*pi]';
Ina1 = [2*sin(t) 2*cos(t)];
Ina2 = sin(2*t);
Ina3 = [0.5*sin(3*t) 0.5*cos(3*t)];
var_matrix = [t Ina1 Ina2 Ina3];
save rsim_i_matrix.mat var_matrix;
```

MAT-file `rsim_i_matrix.mat` contains one variable `var_matrix` in TU matrix format.

#### One variable in structure format

For this format, the variable must contain two fields: time and signals. If you set the block parameter **Interpolate data** for one of the Inport blocks, the time field of the variable must not be an empty vector and the width of the signals must equal the total width of the Inport blocks. This code generates a MAT-file that contains one variable `var_matrix` in signal variable structure format. This format is more flexible than the TU matrix format because it can support input ports with different data types.

```
t= [0:0.1:2*pi]';
var_single_struct.time = t;
var_single_struct.signals(1).values(:,1) = 2*sin(t);
var_single_struct.signals(1).values(:,2) = 2*cos(t);
var_single_struct.signals(2).values = sin(2*t);
var_single_struct.signals(3).values(:,1) = 0.5*sin(3*t) ;
var_single_struct.signals(3).values(:,2) = 0.5*cos(3*t) ;
v=[var_single_struct.signals(1).values var_single_struct.signals(2).values ...
 var_single_struct.signals(3).values];
save rsim_i_single_struct.mat var_single_struct;
```

MAT-file `rsim_i_single_struct.mat` contains one variable `var_single_struct` in struct format.

#### Multiple variables in structure format

For this format, the number of variables equals the number of Inport blocks. Different variables can have different time vectors. This code generates a MAT-file that contains multiple variables, each in structure format. This is the most flexible format because it allows each Inport block to have its own time vector.

```
t= [0:0.1:2*pi]';
Inb1.time = t;
Inb1.signals.values(:,1) = 2*sin(t);
Inb1.signals.values(:,2) = 2*cos(t);
```

```

t= [0:0.2:2*pi]';
Inb2.time = t;
Inb2.signals.values(:,1) = sin(2*t);
t= [0:0.1:2*pi]';
Inb3.time = t;
Inb3.signals.values(:,1) = 0.5*sin(3*t);
Inb3.signals.values(:,2) = 0.5*cos(3*t);
save rsim_i_multi_struct.mat Inb1;
save rsim_i_multi_struct.mat Inb2 -append;
save rsim_i_multi_struct.mat Inb3 -append;

```

MAT-file `rsim_i_multi_struct.mat` contains three variables `Inb1`, `Inb2`, and `Inb3` in struct format. Use the `save` command with the `-append` option to preserve the order of variables in the generated MAT-file.

### Run RSim Simulations and Plot Results

You can use RSim `-i` options for batch mode simulation. Prepare different MAT-files and run the RSim program executable with them.

This part of the example shows three plots. Each plot shows simulation results for a MAT-file with a different variable format. The model is compiled once.

```

figure
fileName = ({'rsim_i_matrix', 'rsim_i_single_struct', 'rsim_i_multi_struct'});
for i=1:3
 % bang out and run a simulation using new parameter data
 name = fileName(i);
 runstr = ['./', filesep, 'rtwdemo_rsim_i -i ',char(name),'.mat', ' -v'];
 evalc('system(runstr)');
 pause(0.5);
 % load simulation data into MATLAB(R) for plotting.
 load rtwdemo_rsim_i.mat;
 subplot(3,1,i);
 axis([0,6, -5, 5]);
 plot(rt_tout, rt_yout);
 hold on
end

```

```
close_system mdlName, 0;
```

## Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target

S-functions are an important class of system target file for which the code generator can produce code. The ability to encapsulate a subsystem into an S-function allows you to increase its execution efficiency and facilitate code reuse.

The following sections describe the properties of S-function targets and illustrate how to generate them. For more details on the structure of S-functions, see “C/C++ S-Function Basics”.

### In this section...

- “About the S-Function Target” on page 65-40
- “Create S-Function Blocks from a Subsystem” on page 65-42
- “Tunable Parameters in Generated S-Functions” on page 65-45
- “System Target File” on page 65-46
- “Checksums and the S-Function Target” on page 65-46
- “Generated S-Function Compatibility” on page 65-47
- “S-Function Target Limitations” on page 65-47

### About the S-Function Target

Using the S-function target, you can build an S-function component and use it as an S-Function block in another model. The following sections describe deployment considerations for the S-function target.

- “Required Files for S-Function Deployment” on page 65-41
- “Sample Time Propagation in Generated S-Functions” on page 65-41
- “Choose a Solver Type” on page 65-42

The 'S-Function' value for CodeFormat TLC variable used by the S-function target generates code that conforms to the Simulink C MEX S-function application programming interface (API). Applications of this format include

- Conversion of a model to a component. You can generate an S-Function block for a model, m1. Then, you can place the generated S-Function block in another model, m2. Regenerating code for m2 does not require regenerating code for m1.
- Conversion of a subsystem to a component. By extracting a subsystem to a separate model and generating an S-Function block from that model, you can create a reusable component from the subsystem. See “Create S-Function Blocks from a Subsystem” on page 65-42 for an example of this procedure.
- Speeding up simulation. Often, an S-function generated from a model performs more efficiently than the original model.
- Code reuse. You can incorporate multiple instances of one model inside another without replicating the code for each instance. Each instance continues to maintain its own unique data.

You can place a generated S-function block into another model from which you can generate another S-function. This approach allows levels of nested S-functions. For limitations related to nesting, see “Nesting S-Functions” on page 65-51.

**Note** If you are generating code for a modeled software component, use a reference model instead of generating an S-function block from a subsystem.

---

**Note** While you can use the S-function target to deploy an application component for reuse while shielding its internal logic from inspection and modification, the preferred solutions for protecting intellectual property in distributed components are:

- The protected model, a referenced model that hides block and line information. For more information, see “Reference Protected Models from Third Parties”.
  - The shared library system target file, used to generate a shared library for a model or subsystem for use in a system simulation external to Simulink. For more information, see “Package Generated Code as Shared Libraries” on page 66-2.
- 

### Required Files for S-Function Deployment

There are different files required to deploy a generated S-Function block for simulation versus code generation.

To deploy your generated S-Function block for inclusion in other models *for simulation*, you need only provide the binary MEX-file object that was generated in the current working folder when the S-Function block was created. The required file is:

- `subsys_sf.mexext`

where *subsys* is the subsystem name and *mexext* is a platform-dependent MEX-file extension (see *mexext*). For example, `SourceSubsys_sf.mexw64`.

To deploy your generated S-Function block for inclusion in other models *for code generation*, provide the files that were generated in the current working folder when the S-Function block was created. The required files are:

- `subsys_sf.c` or `.cpp`, where *subsys* is the subsystem name (for example, `SourceSubsys_sf.c`)
- `subsys_sf.h`
- `subsys_sf.mexext`, where *mexext* is a platform-dependent MEX-file extension (see *mexext*)
- Subfolder `subsys_sfcn_rtw` and its contents

The generated S-function code uses **Configuration Parameters > Hardware Implementation** parameter values that match the host system on which the function was built. When you use the S-function in a model for code generation, make sure that these parameter values for the model match the parameter values of the S-function.

### Sample Time Propagation in Generated S-Functions

A generated S-Function block can inherit its sample time from the model in which it is placed if certain criteria are met. Conditions that govern sample time propagation for both Model blocks and generated S-Function blocks are described in “Referenced Model Sample Times” and “S-Functions That Specify Sample Time Inheritance Rules” on page 12-81.

To generate an S-Function block that meets the criteria for inheriting sample time, you must constrain the solver for the model from which the S-Function block is generated. Set model

configuration parameter **Type** to **Fixed-step** and **Periodic sample time constraint** to **Ensure sample time independent**. If the model is unable to inherit sample times, this setting causes the Simulink software to display an error message when building the model. For more information about this option, see “Periodic sample time constraint”.

### Choose a Solver Type

The table shows the possible combinations of top-level model solver types as these types relate to whether the model has discrete or continuous sample times and solver types for generated S-functions.

#### Top-Level Model Solver Options and Sample Times

	Model Configuration Parameters: Top-level model configuration	
Sample Times	Solver Options, Type: Variable-step	Solver Options, Type: Fixed-step
Discrete	Generated S-function requires a variable-step solver	Generated S-function can have a variable-step solver or a fixed-step solver
Continuous	Generated S-function requires a variable-step solver	Generated S-function requires a fixed-step solver

S-functions generated from a subsystem have parameters that are hardcoded into the block. Simulink calculates parameters such as sample time when it generates the block, not during simulation run time. It is important to verify whether the generated S-Function block works as expected in the destination model.

### Create S-Function Blocks from a Subsystem

This section shows how to extract a subsystem from a model and generate a reusable S-function component from it.

The next figure shows `SourceModel`, a simple model that inputs signals to a subsystem. The subsequent figure shows the subsystem, `SourceSubsys`. The signals, which have different widths and sample times, are:

- A Step block with sample time 1
- A Sine Wave block with sample time 0.5
- A Constant block whose value is the vector [-2 3]

### SourceModel

### SourceSubsys

The objective is to extract `SourceSubsys` from the model and build an S-Function block from it, using the S-function target. The S-Function block must perform identically to the subsystem from which it was generated.

In this model, `SourceSubsys` inherits sample times and signal widths from its input signals. However, S-Function blocks created from a model using the S-function system target file has signal attributes (such as signal widths or sample times) hard-wired. (The sole exception to this rule concerns sample times, as described in “Sample Time Propagation in Generated S-Functions” on page 65-41.)

In this example, you want the S-Function block to retain the properties of `SourceSubsys` as it exists in `SourceModel`. Therefore, before you build the subsystem as a separate S-function component, you must set the inport sample times and widths explicitly. In addition, the solver parameters of the S-function component must be the same as those parameters of the original model. The generated S-function component operates identically to the original subsystem (see “Choose a Solver Type” on page 65-42 for more information).

To build `SourceSubsys` as an S-function component,

- 1 Create a new model and copy/paste the `SourceSubsys` block into the empty window.
- 2 Set the signal widths and sample times of inports inside `SourceSubsys` such that they match those of the signals in the original model. Inport 1, `Filter`, has a width of 1 and a sample time of 1. Inport 2, `XferFcn`, has a width of 1 and a sample time of 0.5. Inport 3, `offsets`, has a width of 2 and a sample time of 0.5.

- 3 The generated S-Function block should have three inports and one output. Connect inports and an output to SourceSubsys, as shown in the next figure.

The signal widths and sample times are propagated to these ports.

- 4 Set the solver type, mode, and other solver parameters such that they are identical to those of the source model. This is easiest to do if you use Model Explorer.
- 5 Set model configuration parameter **System target file** to `rtwsfcn.tlc`.
- 6 Select the **S-Function Target** pane. Make sure that **Create new model** is selected, as shown in the next figure:

When this option is selected, the build process creates a new model after it builds the S-function component. The new model contains an S-Function block, linked to the S-function component.

Click **Apply**.

- 7 Save the new model containing your subsystem, for example as `SourceSubsys`.
- 8 Build the model.
- 9 The build process produces the S-function component in the working folder. After the build, a new model window is displayed.

Optionally you can save the generated model, for example as `SourceSubsys_Sfunction`.

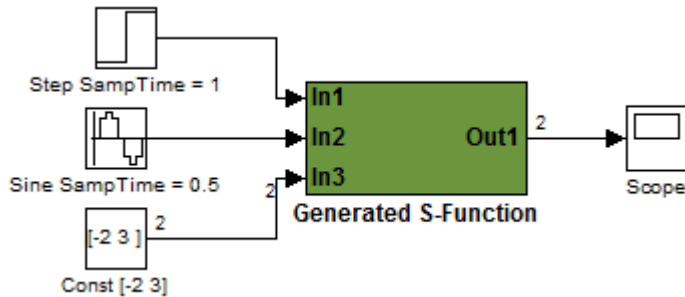

- 10 You can now copy the S-Function block generated from the new model and use it in other models or in a library.

---

**Note** For a list of files required to deploy your S-Function block for simulation or code generation, see "Required Files for S-Function Deployment" on page 65-41.

---

The next figure shows the S-Function block plugged into the original model. Given identical input signals, the S-Function block performs identically to the original subsystem.

### Generated S-Function Configured Like SourceModel

The speed at which the S-Function block executes is typically faster than the original model. This difference in speed is more pronounced for larger and more complicated models. By using generated S-functions, you can increase the efficiency of your modeling process.

## Tunable Parameters in Generated S-Functions

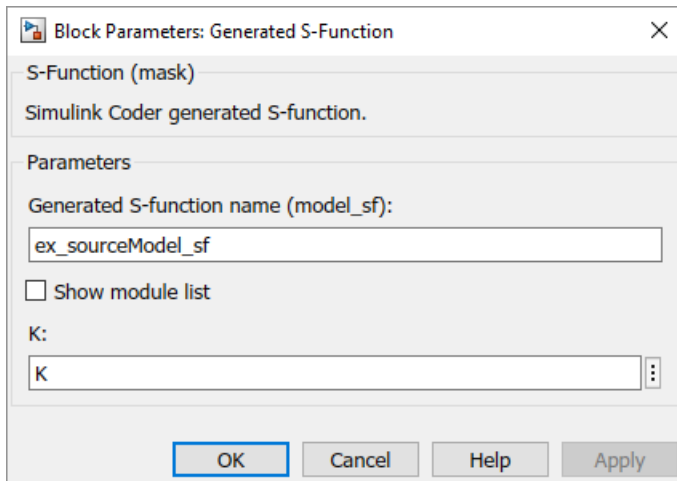

You can use tunable parameters in generated S-functions in two ways:

- Use the **Generate S-function** feature (see “Generate S-Function from Subsystem” on page 12-64).
- or
- Use the Model Parameter Configuration dialog box (see “Declare Workspace Variables as Tunable Parameters Using the Model Parameter Configuration Dialog Box”) to declare desired block parameters tunable.

Block parameters that you declare as tunable with the `auto` storage class in the source model become tunable parameters of the generated S-function. These parameters do not become part of a generated `model_P` (formerly `rtP`) parameter data structure, as they would in code generated from other system target files. Instead, the generated code accesses these parameters by using MEX API calls such as `mxGetPr` or `mxGetData`. Your code should access these parameters in the same way.

For more information on MEX API calls, see “About C MEX S-Functions” and “Integrate MATLAB with External Programming Languages and Systems”.

S-Function blocks created by using the S-function target are automatically masked. The mask displays each tunable parameter in an edit field. By default, the edit field displays the parameter by variable name, as in the following example.

You can choose to display the value of the parameter rather than its variable name by selecting model configuration parameter **Use value for tunable parameters**.

When select this parameter, the value of the variable (at code generation time) is displayed in the edit field.

## System Target File

The `rtwsfcn.tlc` system target file is provided for use with the S-function target.

## Checksums and the S-Function Target

The code generator creates a checksum for a model and uses the checksum during the build process for code reuse, model reference, and external mode features.

The code generator calculates a model checksum by

- 1 Calculating a checksum for each subsystem in the model. A subsystem's checksum is the combination of properties (data type, complexity, sample time, port dimensions, and so forth) of the subsystem blocks.
- 2 Combining the subsystem checksums and other model-level information.

An S-function can add additional information, not captured during the block property analysis, to a checksum by calling the function `ssSetChecksumVal`. For the S-Function target, the value that gets added to the checksum is the checksum of the model or subsystem from which the S-function is generated.

The code generator applies the subsystem and model checksums as follows:

- Code reuse — If two subsystems in a model have the same checksum, the code generator produces code for one function only.
- Model reference — If the current model checksum matches the checksum when the model was built, the build process does not rebuild referenced models.
- External mode — If the current model checksum does not match the checksum of the code that is running on the target hardware, the build process generates an error.

## Generated S-Function Compatibility

When you build a MEX S-function from your model, the code generator builds a level 2 noninlined S-function. Cross-release usage limitations on the generated code and binary MEX file (for example, \*.mexw64) include:

- S-function target generated code from previous MATLAB release software is not compatible with newer releases. Do not recompile the generated code from a previous release with newer MATLAB release software. Use the same MATLAB release software to generate code for the S-function target and compile the code into a MEX file.
- You can use binary S-function MEX files generated from previous MATLAB release software with the same or newer releases with the same compatibility considerations as handwritten S-functions. For more information, see “S-Function Compatibility”.
- The code generator can generate code and build an executable from a model that contains generated S-functions. This support requires that the S-functions are built with the same MATLAB release software that builds the model. It is not possible to incorporate a generated S-function MEX file from previous MATLAB release software into a model and build the model with newer releases.

## S-Function Target Limitations

- “Run-Time Parameters and S-Function Compatibility Diagnostics” on page 65-48
- “Goto and From Block” on page 65-49
- “Building and Updating S-Functions” on page 65-50

- “Unsupported Blocks” on page 65-50
- “Model Operating Point not Supported for Code Generation” on page 65-51
- “Nesting S-Functions” on page 65-51
- “User-Defined Data Types” on page 65-51
- “Right-Click Generation of an S-Function Target” on page 65-51
- “Bus I/O Signals” on page 65-51
- “Subsystems with Function-Call I/O Signals” on page 65-52
- “Function-Call Subsystem Modeling Pattern” on page 65-52
- “Data Store Access” on page 65-53
- “Cannot Specify Inport or Outport Block Parameters Through Subsystem Mask” on page 65-53

### Configuring Inport and Outport Blocks with Continuous Sample Time

The right-click build method for generating an S-function does not preserve continuous sample time for Inport and Outport blocks. Because the sample time is not preserved, simulation of the generated S-Function block can be affected.

### Using Tunable Variables in Expressions

Certain limitations apply to the use of tunable variables in expressions. When the code generator encounters an unsupported expression while producing code, a warning appears and the equivalent numeric value is generated in the code. For a list of the limitations, see “Tunable Expression Limitations” on page 33-120.

### Parameter Tuning

The S-Function block does not support tuning of tunable parameters with:

- Complex values.
- Values or data types that are transformed to a constant (by setting the model configuration parameter **Optimization > Default parameter behavior** to **Inlined**).
- Data types that are not built-in.
- Floating-point data types that are not equivalent to a built-in type.

If you select these tunable parameters (through the Generate S-Function for Subsystem dialog box):

- The software produces warnings during the build process.
- The generated S-Function block mask does not display these parameters.

---

**Note** During S-Function generation from a subsystem, the software ignores variables that you select to be tunable if the model is connected to a Simulink data dictionary.

---

### Run-Time Parameters and S-Function Compatibility Diagnostics

If you set model configuration parameter **S-function upgrades needed** to warning or error, the code generator instructs you to upgrade S-functions that you create with the **Generate S-function** feature. This is because the S-function system target file does not register run-time parameters. Run-time parameters are only supported for inlined S-Functions and the generated S-Function supports

features that prevent it from being inlined (for example, it can call or contain other noninlined S-functions).

You can work around this limitation by setting parameter **S-function upgrades needed** to none.

### Goto and From Block

When using the S-function system target file, the code generator restricts I/O to correspond to the root model Inport and Outport blocks (or the Inport and Outport blocks of the Subsystem block from which the S-function target was generated). The code generator does not produce code for Goto or From blocks.

To work around this restriction, create your model and subsystem with the required Inport and Outport blocks, instead of using Goto and From blocks to pass data between the root model and subsystem. In the model that incorporates the generated S-function, you would then add Goto and From blocks.

### Example Before Work Around

- Root model that includes a From block and subsystem, Subsystem1

- Subsystem1 that includes a Goto block that has global visibility and passes its input to the From block in the root model

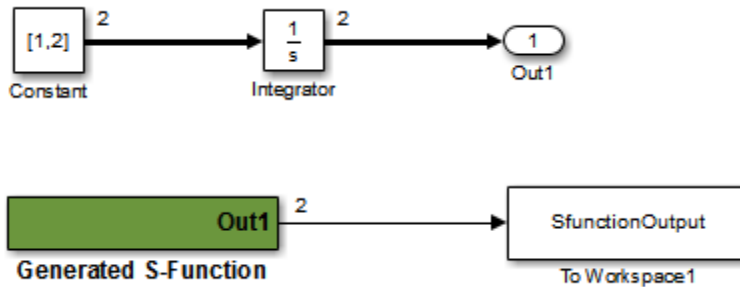

- Subsystem1 replaced with an S-function generated with the S-Function system target file — a warning results when you run the model because the generated S-function does not implement the Goto block

### Example After Work Around

An Outport block replaces the GoTo block in Subsystem1. When you plug the generated S-function into the root model, its output connects directly to the To Workspace block.

## Building and Updating S-Functions

The following limitations apply to building and updating S-functions using the S-function system target file:

- You cannot build models that contain Model blocks using the S-function system target file. This also means that you cannot build a subsystem by using the right-click context menu if the subsystem contains Model blocks. This restriction applies only to S-functions generated using the S-function target, not to ERT S-functions.
- You can build a model with:
  - A toolchain only if the toolchain supports MEX-file generation.
  - A template makefile only if the template makefile is associated with a toolchain on page 56-18 that supports MEX-file generation.
- If you modify the model that generated an S-Function block, the build process does not automatically rebuild models containing the generated S-Function block. This is in contrast to the practice of automatically rebuilding models referenced by Model blocks when they are modified (depending on the Model Reference **Rebuild** configuration setting).
- Handwritten S-functions without corresponding TLC files must contain exception-free code. For more information on exception-free code, see “Exception Free Code”.

## Unsupported Blocks

The S-function format does not support the following built-in blocks:

- Interpreted MATLAB Function block
- S-Function blocks containing any of the following:
  - MATLAB language S-functions (unless you supply a TLC file for C code generation)
  - Fortran S-functions (unless you supply a TLC file for C code generation)
  - C/C++ MEX S-functions that call into the MATLAB environment
- Simulink Function block
- Function Caller block
- Scope block
- To Workspace block

The S-function format does not support blocks from the `embeddedtargetslib` block library.

## Model Operating Point not Supported for Code Generation

You can write C-MEX and Level-2 MATLAB S-functions that leverage the model operating point, which is used to save and restore the simulation state, as described in “S-Function Compliance with the ModelOperatingPoint”. The model operating point is not supported for code generation, including with the S-function system target file.

When you generate code for an S-Function that specifies default operating point compliance or no operating point support, the generated code does not include the model operating point functionality. You cannot generate code for an S-Function that implements custom operating point functionality.

## Nesting S-Functions

The following limitations apply to nesting a generated S-Function block in a model or subsystem from which you generate another S-function:

- The software does not support nonvirtual bus input and output signals for a nested S-function.
- Avoid nesting an S-function in a model or subsystem having the same name as the S-function (possibly several levels apart). In such situations, the S-function can be called recursively. The software currently does not detect such loops in S-function dependency, which can result in aborting or hanging your MATLAB session. To prevent this from happening, name the subsystem or model to be generated as an S-function target uniquely to avoid duplicating existing MEX filenames on the MATLAB path.

## User-Defined Data Types

The S-function system target file does not support the `HeaderFile` property that can be specified on user-defined data types, including those based on `Simulink.AliasType`, `Simulink.Bus`, and `Simulink.NumericType` objects. If a user-defined data type in your model uses the `HeaderFile` property to specify an associated header file, code generation with the S-function system target file disregards the value and does not generate a corresponding include statement.

## Right-Click Generation of an S-Function Target

If you generate an S-function target by right-clicking a Function-Call Subsystem block, the original subsystem and the generated S-function might not be consistent. An inconsistency occurs when the **States when enabling** parameter of the Trigger Port block inside the Function-Call Subsystem block is set to **inherit**. You must set the **States when enabling** parameter to **reset** or **held**, otherwise Simulink reports an error.

## Bus I/O Signals

If an S-function generated using the S-function target has bus input or output signals, the generated bus data structures might include padding to align fields of the bus elements with the Simulink representation used during simulation. However, if you insert the S-function in a model and generate code using a model target such as `grt.tlc`, the bus structure alignment generated for the model build might be incompatible with the padding generated for the S-function and might impact the numerical results of code execution. To make the structure alignment consistent between model simulation and execution of the model code, for each `Simulink.Bus` object, you can modify the `HeaderFile` property to remove the unpadding bus structure header file. This will cause the bus typedefs generated for the S-function to be reused in the model code.

### Subsystems with Function-Call I/O Signals

The S-function target does not support creating an S-Function block from a subsystem that has a function-call trigger input or a function-call output.

### Function-Call Subsystem Modeling Pattern

If a model includes this function-call subsystem modeling pattern, you must insert a Signal Conversion block.

The function-call subsystem connects directly to an Output block and the signal line that connects the subsystem to the Output block branches to a block that has an Update function (block that updates at each major time step, such as Unit Delay and Memory). The branch can be inside or outside of the subsystem. In the model that includes the function-call subsystem, you must insert a Signal Conversion block in one of these locations:

- 1 Between the subsystem block and the branch
- 2 Between the branch and the root Output block
- 3 Between the branch and the block that has the Update function

Before generating the S-Function block for the subsystem, set these Signal Conversion block parameters:

- Set **Output** to Signal copy
- Select **Exclude this block from 'Block reduction' optimization**

If you do not apply the workaround, when you add the generated S-Function block to a model and then simulate that model, MATLAB might crash.

## Data Store Access

When an S-Function in your model accesses a data store during simulation, Simulink disables data store diagnostics.

- If you created the S-Function from a model, the diagnostic is disabled for global data stores as well.
- If you created the S-Function from a subsystem, the diagnostic is disabled for the following data stores:
  - Global data stores
  - Data stores placed outside the subsystem, but accessed by Data Store Read or Data Store Write blocks.

## Cannot Specify Inport or Outport Block Parameters Through Subsystem Mask

You cannot specify Inport or Outport block parameters by using subsystem mask variables if you want to generate an S-Function block from the subsystem. The software produces an error when you try to run a simulation that uses the S-Function block, for example:

```
Invalid setting in 'testSystem/Subsystem/__OutputSSForSFun__/Out2'
for parameter 'PortDimensions'
...
```

## Package Generated Code as Shared Libraries

If you have an Embedded Coder license, you can package generated source code from a model component for easy distribution and shared use by building the code as a shared library—Windows dynamic link library (.dll), UNIX shared object (.so), or Macintosh OS X dynamic library (.dylib). You or others can integrate the shared library into an application that runs on a Windows, UNIX, or Macintosh OS X development computer. The generated .dll, .so, or .dylib file is shareable among different applications and upgradeable without having to recompile the applications that use it.

### About Generated Shared Libraries

You build a shared library by configuring the code generator to use the system target file `ert_shrlib.tlc`. Code generation for that system target file exports:

- Variables and signals of type `ExportedGlobal` as data
- Real-time model structure (`model_M`) as data
- Functions essential to executing your model code

To view a list of symbols contained in a generated shared library:

- On Windows, use the Dependency Walker utility, downloadable from <https://www.dependencywalker.com>
- On UNIX, use `nm -D model.so`
- On Macintosh OS X, use `nm -g model.dylib`

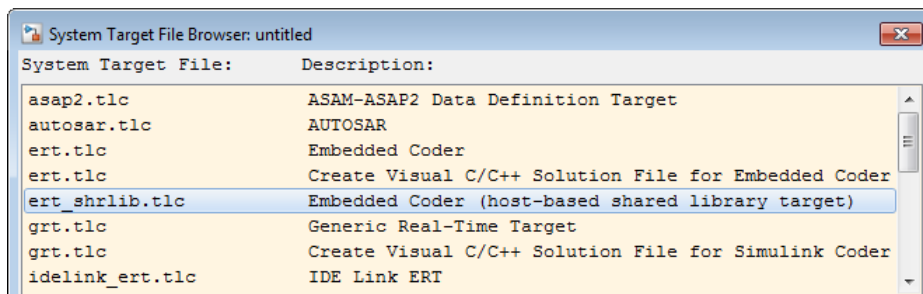

To generate and use a shared library:

- 1 Generate a shared library version of your model code
- 2 Create application code to load and use your shared library file

### Generate Shared Library Version of Model Code

To generate a shared library version of your model code:

- 1 Open your model and configure it to use the `ert_shrlib.tlc` system target file.

Selecting the `ert_shrlib.tlc` system target file causes the build process to generate a shared library version of your model code into your current working folder. The selection does not change the code that the code generator produces for your model.

- 2 Build the model.

- 3 After the build completes, examine the generated code in the model subfolder and examine the `.dll`, `.so`, or `.dylib` file in your current folder.

## Create Application Code to Use Shared Library

To illustrate how application code can load a shared library file and access its functions and data, MathWorks provides the model `rtwdemo_shrlib`.

---

**Note** Navigate to a writable working folder before running the `rtwdemo_shrlib` script.

---

In the model, click the blue button to run a script. The script:

- 1 Builds a shared library file from the model (for example, `rtwdemo_shrlib_win64.dll` on 64-bit Windows).
- 2 Compiles and links an example application, `rtwdemo_shrlib_app`, that loads and uses the shared library file.
- 3 Executes the example application.

---

**Tip** Explicit linking is preferred for portability. However, on Windows systems, the `ert_shrlib` system target file generates and retains the `.lib` file to support implicit linking.

---

To use implicit linking, the generated header file needs a small modification for you to use it with the generated C file. For example, if you are using Visual C++, declare `__declspec(dllimport)` in front of data to be imported implicitly from the shared library file.

---

The model uses the following example application files, which are located in the folder `matlabroot/toolbox/rtw/rtwdemos/shrlib_demo` (open).

File	Description
<code>rtwdemo_shrlib_app.h</code>	Example application header file
<code>rtwdemo_shrlib_app.c</code>	Example application that loads and uses the shared library file generated for the model
<code>run_rtwdemo_shrlib_app.m</code>	Script to compile, link, and execute the example application

You can view each of these files by clicking white buttons in the model window. Additionally, running the script places the relevant source and generated code files in your current folder. The files can be used as templates for writing application code for your own ERT shared library files.

The following sections present key excerpts of the example application files.

### Example Application Header File

The example application header file `rtwdemo_shrlib_app.h` contains type declarations for the model's external input and output.

```
#ifndef _APP_MAIN_HEADER_
#define _APP_MAIN_HEADER_
```

```

typedef struct {
 int32_T Input;
} ExternalInputs_rtwdemo_shrplib;

typedef struct {
 int32_T Output;
} ExternalOutputs_rtwdemo_shrplib;

#endif /* _APP_MAIN_HEADER_ */

```

### Example Application C Code

The example application `rtwdemo_shrplib_app.c` includes the following code for dynamically loading the shared library file. Notice that, depending on platform, the code invokes Windows or UNIX library commands.

```

#if defined(_WIN32)||defined(_WIN64) /* WINDOWS */
#include <windows.h>
#define GETSYMBOLADDR GetProcAddress
#define LOADLIB LoadLibrary
#define CLOSELIB FreeLibrary

#else /* UNIX */
#include <dlfcn.h>
#define GETSYMBOLADDR dlsym
#define LOADLIB dlopen
#define CLOSELIB dlclose

#endif

int main()
{
 void* handleLib;
 ...
 #if defined(_WIN64)
 handleLib = LOADLIB("./rtwdemo_shrplib_win64.dll");
 #else
 #if defined(_WIN32)
 handleLib = LOADLIB("./rtwdemo_shrplib_win32.dll");
 #else /* UNIX */
 handleLib = LOADLIB("./rtwdemo_shrplib.so", RTLD_LAZY);
 #endif
 #endif
 ...
 return(CLOSELIB(handleLib));
}

```

The following code excerpt shows how the C application accesses the model's exported data and functions. Notice the hooks for adding user-defined initialization, step, and termination code.

```

int32_T i;
...
void (*mdl_initialize)(boolean_T);
void (*mdl_step)(void);
void (*mdl_terminate)(void);

ExternalInputs_rtwdemo_shrplib (*mdl_Uptr);
ExternalOutputs_rtwdemo_shrplib (*mdl_Yptr);

uint8_T (*sum_outptr);
...
#if defined(LCCDLL)||defined(BORLANDCDLL)
/* Exported symbols contain leading underscores when DLL is linked with
LCC or BORLANDC */
mdl_initialize =(void*)(boolean_T)GETSYMBOLADDR(handleLib ,
 "_rtwdemo_shrplib_initialize");
mdl_step =(void*)(void)GETSYMBOLADDR(handleLib ,
 "_rtwdemo_shrplib_step");
mdl_terminate =(void*)(void)GETSYMBOLADDR(handleLib ,
 "_rtwdemo_shrplib_terminate");

```

```

mdl_Uptr =(ExternalInputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
 "_rtwdemo_shrplib_U");
mdl_Yptr =(ExternalOutputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
 "_rtwdemo_shrplib_Y");
sum_outptr =(uint8_T*)GETSYMBOLADDR(handleLib , "_sum_out");
#else
mdl_initialize=(void(*) (boolean_T))GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_initialize");
mdl_step =(void(*) (void))GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_step");
mdl_terminate=(void(*) (void))GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_terminate");
mdl_Uptr =(ExternalInputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_U");
mdl_Yptr =(ExternalOutputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_Y");
sum_outptr =(uint8_T*)GETSYMBOLADDR(handleLib , "sum_out");
#endif

if ((mdl_initialize && mdl_step && mdl_terminate && mdl_Uptr && mdl_Yptr &&
 sum_outptr)) {
 /* === user application initialization function === */
 mdl_initialize(1);
 /* insert other user defined application initialization code here */

 /* === user application step function === */
 for(i=0;i<=12;i++){
 mdl_Uptr->Input = i;
 mdl_step();
 printf("Counter out(sum_out): %d\tAmplifier in(Input): %d\tout(Output): %d\n",
 *sum_outptr, i, mdl_Yptr->Output);
 /* insert other user defined application step function code here */
 }

 /* === user application terminate function === */
 mdl_terminate();
 /* insert other user defined application termination code here */
}
else {
 printf("Cannot locate the specified reference(s) in the shared library.\n");
 return(-1);
}

```

### Example Application Script

The application script `run_rtwdemo_shrplib_app` loads and rebuilds the model, and then compiles, links, and executes the model's shared library target file. You can view the script source file by opening `rtwdemo_shrplib` and clicking a white button to view source code. The script constructs platform-dependent command character vectors for compilation, linking, and execution that may apply to your development environment. To run the script, click the blue button.

---

**Note** To run the `run_rtwdemo_shrplib_app` script without first opening the `rtwdemo_shrplib` model, navigate to a writable working folder and issue the following MATLAB command:

```
addpath(fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'shrplib_demo'))
```

---

**Note** It is invalid to invoke the terminate function twice in a row. The terminate function clears pointers and sets them to NULL. Invoking the function a second time dereferences null pointers and results in a program failure.

---

## Shared Library Limitations

The following limitations apply to building shared libraries:

- Code generation for the `ert_shrlib.tlc` system target file exports the following as data:
  - Variables and signals of type `ExportedGlobal`
  - Real-time model structure (`model_M`)
- For a model that contains a function-call subsystem, code generation for the `ert_shrlib.tlc` system target file exports to the shared library only symbols associated with the initialize and terminate entry-point functions.
- Code generation for the `ert_shrlib.tlc` system target file supports the C language only (not C++). When you select `ert_shrlib.tlc`, model configuration parameter **Language** is greyed out.
- To reconstruct a model simulation using a generated shared library, the application author must maintain the timing between system and shared library function calls in the original application. The timing needs to be consistent so that you can compare the simulation and integration results. Additional simulation considerations apply if generating a shared library from a model that enables model configuration parameters **Support: continuous time** and **Single output/update function**. For more information, see “Single output/update function” dependencies.

## Deploy Algorithm Model for Real-Time Rapid Prototyping

Use the code generator to deploy algorithm models for real-time rapid prototyping.

### About Real-Time Rapid Prototyping

Real-time rapid prototyping requires the use of a real-time simulator, potentially connected to system hardware (for example, physical plant or vehicle) being controlled. You generate, deploy, and tune code as it runs on the real-time simulator or embedded microprocessor. This design step is crucial for verifying whether a component can adequately control the system, and allows you to assess, interact with, and optimize code.

The following figure shows a typical approach for real-time rapid prototyping.

### Goals of Real-Time Rapid Prototyping

Assuming that you have documented functional requirements, refined concept models, system hardware for the physical plant or vehicle being controlled, and access to target products you intend to use (for example, for example, the Simulink Real-Time or Simulink Desktop Real-Time product), you can use real-time prototyping to:

- Refine component and environment model designs by rapidly iterating between algorithm design and prototyping
- Validate whether a component can adequately control the physical system in real time
- Evaluate system performance before laying out hardware, coding production software, or committing to a fixed design
- Test hardware

### Refine Code With Real-Time Rapid Prototyping

To perform real-time rapid prototyping:

- 1 Create or acquire a real-time system that runs in real time on rapid prototyping hardware. The Simulink Real-Time product facilitates real-time rapid prototyping. This product provides a real-

time operating system that makes PCs run in real time. It also provides device driver blocks for numerous hardware I/O cards. You can then create a rapid prototyping system using inexpensive commercial-off-the-shelf (COTS) hardware. In addition, third-party vendors offer products based on the Simulink Real-Time product or other code generation technology that you can integrate into a development environment.

- 2 Use provided system target files to generate code that you can deploy onto a real-time simulator. See the following information.

Engineering Tasks	Related Product Information	Examples
Generate code for real-time rapid prototyping	“Compare System Target File Support Across Products” “Event-Based Scheduling” Embedded Coder “Support for Standards and Guidelines” on page 22-2	rtwdemo_counter rtwdemo_counter_msvc
Generate code for rapid prototyping in hard real time, using PCs	Simulink Real-Time “Simulink Real-Time Options Pane” (Simulink Real-Time)	slrt_ex_osc (and others)
Generate code for rapid prototyping in soft real time, using PCs	Simulink Desktop Real-Time “Simulink Desktop Real-Time Pane” (Simulink Desktop Real-Time)	sldrtex_vdp (and others)

- 3 Monitor signals, tune parameters, and log data.

## Deploy Environment Model for Real-Time Hardware-In-the-Loop (HIL) Simulation

### In this section...

“About Hardware-In-the-Loop Simulation” on page 67-4

“Set Up and Run HIL Simulations” on page 67-4

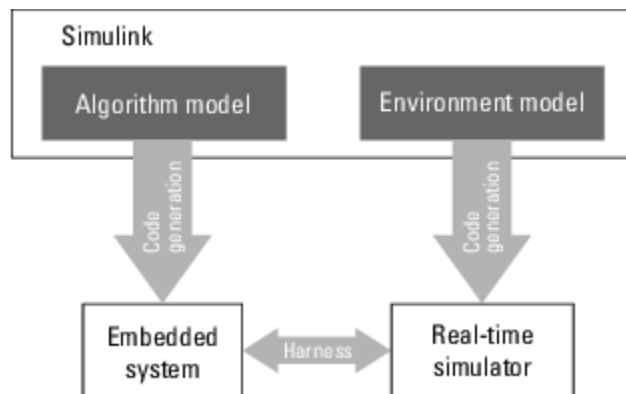

### About Hardware-In-the-Loop Simulation

Hardware-in-the-loop (HIL) simulation tests and verifies an embedded system or control unit in the context of a software test platform. Examples of test platforms include real-time target systems and instruction set simulators (IISs). You use Simulink software to develop and verify a model that represents the test environment. Using the code generator, you produce, build, and download an executable program for the model to the HIL simulation platform. After you set up the environment, you can run the executable to validate the embedded system or control unit in real time.

During HIL simulation, you gradually replace parts of a system environment with hardware components as you refine and fabricate the components. HIL simulation offers an efficient design process that eliminates costly iterations of part fabrication.

The code that you build for the system simulator provides real-time system capabilities. For example, the code can include VxWorks from Wind River or another real-time operating system (RTOS).

The following figure shows a typical HIL setup.

The HIL platform available from MathWorks is the Simulink Real-Time product. Several third-party products are also available for use as HIL platforms. The Simulink Real-Time product offers hard real-time performance for PCs with Intel or AMD® 32-bit processors functioning as your real-time target. The Simulink Real-Time product enables you to add I/O interface blocks to your models and automatically generate code with code generation technology. The Simulink Real-Time product can download the code to a second PC running the Simulink Real-Time real-time kernel. System integrator solutions that are based on Simulink Real-Time are also available.

### Set Up and Run HIL Simulations

To set up and run HIL simulations iterate through the following steps:

- 1** Develop a model that represents the environment or system under development.  
For more information, see “Compare System Target File Support Across Products”.
- 2** Generate an executable for the environment model.
- 3** Download the executable for the environment model to the HIL simulation platform.
- 4** Replace software representing a system component with corresponding hardware.
- 5** Test the hardware in the context of the HIL system.
- 6** Repeat steps 4 and 5 until you can simulate the system after including components that require testing.

- “Real-Time Simulation and Testing” (Simulink Real-Time)

## Untrusted Custom Code, Custom Targets, and Callbacks

You can use custom code in:

- Simulations on your development computer.
- Applications that you deploy on external hardware.

Untrusted custom code, custom targets, or callbacks have risks. For example, unintended modification of your design, unauthorized acquisition of sensitive code and data by third parties, and unapproved destruction of data.

Best practices for exchanging sensitive code and data with a supplier or customer are:

- For code packaging, use a secure container that supports encryption such as an Open Packaging Conventions (OPC) container.
- For file transfer, use a secure transfer protocol such as HTTPS or SFTP.

- “Generate Main Program for Deployment to Bare-Metal Target Hardware” on page 68-24
- “Deploy Generated Component Software to Application Target Platforms” on page 68-26

## Deploy Generated Standalone Executable Programs To Target Hardware

By default, the Embedded Coder software generates *standalone* executable programs that do not require an external real-time executive or operating system. A standalone program requires minimal modification to be adapted to the target hardware. The standalone program architecture supports execution of models with either single or multiple sample rates.

### In this section...

“Generate a Standalone Program” on page 68-2

“Standalone Program Components” on page 68-2

“Main Program” on page 68-3

“rt\_OneStep and Scheduling Considerations” on page 68-4

“Static Main Program Module” on page 68-8

“Rate Grouping Compliance and Compatibility Issues” on page 68-12

“Generate Code That Dereferences Data from a Literal Memory Address” on page 68-15

### Generate a Standalone Program

To generate a standalone program:

- 1 Select the model configuration parameter **Generate an example main program**. This enables the **Target operating system** menu.
- 2 From the **Target operating system** menu, select `BareBoardExample`.
- 3 Generate code.

Different code is generated for multirate models depending on these factors:

- Whether the model executes in single-tasking or multitasking mode.
- Whether or not reusable code is being generated.

These factors can impact the scheduling algorithms used in generated code, and in some cases impact the API for the model entry-point functions. The following sections discuss these variants.

### Standalone Program Components

The core of a standalone program is the main loop. On each iteration, the main loop executes a background or null task and checks for a termination condition.

The main loop is periodically interrupted by a timer. The function `rt_OneStep` is either installed as a timer interrupt service routine (ISR), or called from a timer ISR at each clock step.

The execution driver, `rt_OneStep`, sequences calls to the `model_step` functions. The operation of `rt_OneStep` differs depending on whether the generating model is single-rate or multirate. In a single-rate model, `rt_OneStep` simply calls the `model_step` function. In a multirate model, `rt_OneStep` prioritizes and schedules execution of blocks according to the rates at which they run.

## Main Program

- “Overview of Operation” on page 68-3
- “Guidelines for Modifying the Main Program” on page 68-3

### Overview of Operation

The following pseudocode shows the execution of a main program.

```
main()
{
 Initialization (including installation of rt_OneStep as an
 interrupt service routine for a real-time clock)
 Initialize and start timer hardware
 Enable interrupts
 While(not Error) and (time < final time)
 Background task
 EndWhile
 Disable interrupts (Disable rt_OneStep from executing)
 Complete any background tasks
 Shutdown
}
```

The pseudocode is a design for a harness program to drive your model. The main program only partially implements this design. You must modify it according to your specifications.

### Guidelines for Modifying the Main Program

This section describes the minimal modifications you should make in your production version of the main program module to implement your harness program.

- 1 Call *model\_initialize*.
- 2 Initialize target-specific data structures and hardware, such as ADCs or DACs.
- 3 Install *rt\_OneStep* as a timer ISR.
- 4 Initialize timer hardware.
- 5 Enable timer interrupts and start the timer.

---

**Note** *rtModel* is not in a valid state until *model\_initialize* has been called. Servicing of timer interrupts should not begin until *model\_initialize* has been called.

---

- 6 Optionally, insert background task calls in the main loop.
- 7 On termination of the main loop (if applicable):
  - Disable timer interrupts.
  - Perform target-specific cleanup such as zeroing DACs.
  - Detect and handle errors. Note that even if your program is designed to run indefinitely, you may need to handle severe error conditions, such as timer interrupt overruns.

You can use the macros *rtmGetErrorStatus* and *rtmSetErrorStatus* to detect and signal errors.

## rt\_OneStep and Scheduling Considerations

- “Overview of Operation” on page 68-4
- “Single-Rate Single-Tasking Operation” on page 68-4
- “Multirate Multitasking Operation” on page 68-5
- “Multirate Single-Tasking Operation” on page 68-7
- “Guidelines for Modifying rt\_OneStep” on page 68-7

### Overview of Operation

The operation of `rt_OneStep` depends upon

- Whether your model is single-rate or multirate. In a single-rate model, the sample times of all blocks in the model, and the model's fixed step size, are the same. A model in which the sample times and step size do not meet these conditions is termed multirate.
- Your model's solver mode (`SingleTasking` versus `MultiTasking`)

Permitted Solver Modes for Embedded Real-Time System Target Files summarizes the permitted solver modes for single-rate and multirate models. Note that for a single-rate model, only `SingleTasking` solver mode is allowed.

### Permitted Solver Modes for Embedded Real-Time System Target Files

Mode	Single-Rate	Multirate
<code>SingleTasking</code>	Allowed	Allowed
<code>MultiTasking</code>	Disallowed	Allowed
<code>Auto</code>	Allowed (defaults to <code>SingleTasking</code> )	Allowed (defaults to <code>MultiTasking</code> )

The generated code for `rt_OneStep` (and associated timing data structures and support functions) is tailored to the number of rates in the model and to the solver mode. The following sections discuss each possible case.

### Single-Rate Single-Tasking Operation

The only valid solver mode for a single-rate model is `SingleTasking`. Such models run in “single-rate” operation.

The following pseudocode shows the design of `rt_OneStep` in a single-rate program.

```
rt_OneStep()
{
 Check for interrupt overflow or other error
 Enable "rt_OneStep" (timer) interrupt
 Model_Step() -- Time step combines output, logging, update
}
```

For the single-rate case, the generated `model_step` function is

```
void model_step(void)
```

Single-rate `rt_OneStep` is designed to execute `model_step` within a single clock period. To enforce this timing constraint, `rt_OneStep` maintains and checks a timer overrun flag. On entry, timer interrupts are disabled until the overrun flag and other error conditions have been checked. If the overrun flag is clear, `rt_OneStep` sets the flag, and proceeds with timer interrupts enabled.

The overrun flag is cleared only upon successful return from `model_step`. Therefore, if `rt_OneStep` is reinterrupted before completing `model_step`, the reinterruption is detected through the overrun flag.

Reinterruption of `rt_OneStep` by the timer is an error condition. If this condition is detected `rt_OneStep` signals an error and returns immediately. (Note that you can change this behavior if you want to handle the condition differently.)

Note that the design of `rt_OneStep` assumes that interrupts are disabled before `rt_OneStep` is called. `rt_OneStep` should be noninterruptible until the interrupt overflow flag has been checked.

### Multirate Multitasking Operation

In a multirate multitasking system, code generation uses a prioritized, preemptive multitasking scheme to execute the different sample rates in your model.

The following pseudocode shows the design of `rt_OneStep` in a multirate multitasking program.

```
rt_OneStep()
{
 Check for base-rate interrupt overrun
 Enable "rt_OneStep" interrupt
 Determine which rates need to run this time step

 Model_Step0() -- run base-rate time step code

 For N=1:NumTasks-1 -- iterate over sub-rate tasks
 If (sub-rate task N is scheduled)
 Check for sub-rate interrupt overrun
 Model_StepN() -- run sub-rate time step code
 EndIf
 EndFor
}
```

### Task Identifiers

The execution of blocks having different sample rates is broken into tasks. Each block that executes at a given sample rate is assigned a *task identifier* (`tid`), which associates it with a task that executes at that rate. Where there are `NumTasks` tasks in the system, the range of task identifiers is `0..NumTasks-1`.

### Prioritization of Base-Rate and Subrate Tasks

Tasks are prioritized, in descending order, by rate. The *base-rate* task is the task that runs at the fastest rate in the system (the hardware clock rate). The base-rate task has highest priority (`tid 0`). The next fastest task (`tid 1`) has the next highest priority, and so on down to the slowest, lowest priority task (`tid NumTasks-1`).

The slower tasks, running at multiples of the base rate, are called *subrate* tasks.

### Rate Grouping and Rate-Specific `model_step` Functions

In a single-rate model, the block output computations are performed within a single function, `model_step`. For multirate, multitasking models, the code generator tries to use a different strategy. This strategy is called *rate grouping*. Rate grouping generates separate `model_step` functions for the base rate task and each subrate task in the model. The function naming convention for these functions is

```
model_stepN
```

where  $N$  is a task identifier. For example, for a model named `my_model` that has three rates, the following functions are generated:

```
void my_model_step0 (void);
void my_model_step1 (void);
void my_model_step2 (void);
```

Each `model_stepN` function executes the blocks sharing `tid N`; in other words, the block code that executes within task  $N$  is grouped into the associated `model_stepN` function.

### Scheduling `model_stepN` Execution

On each clock tick, `rt_OneStep` maintains scheduling counters and *event flags* for each subrate task. The counters are implemented as `taskCounter` arrays indexed on `tid`. The event flags are implemented as arrays indexed on `tid`.

The scheduling counters and task flags for sub-rates are maintained by `rt_OneStep`. The scheduling counters are basically clock rate dividers that count up the sample period associated with each sub-rate task. A pair of tasks that exchanges data maintains an interaction flag at the faster rate. Task interaction flags indicate that both fast and slow tasks are scheduled to run.

The event flags indicate whether or not a given task is scheduled for execution. `rt_OneStep` maintains the event flags based on a task counter that is maintained by code in the main program module for the model. When a counter indicates that a task's sample period has elapsed, the main code sets the event flag for that task.

On each invocation, `rt_OneStep` updates its scheduling data structures and steps the base-rate task (`rt_OneStep` calls `model_step0` because the base-rate task must execute on every clock step). Then, `rt_OneStep` iterates over the scheduling flags in `tid` order, unconditionally calling `model_stepN` for any task whose flag is set. The tasks are executed in order of priority.

### Preemption

Note that the design of `rt_OneStep` assumes that interrupts are disabled before `rt_OneStep` is called. `rt_OneStep` should be noninterruptible until the base-rate interrupt overflow flag has been checked (see pseudocode above).

The event flag array and loop variables used by `rt_OneStep` are stored as local (stack) variables. Therefore, `rt_OneStep` is reentrant. If `rt_OneStep` is reinterrupted, higher priority tasks preempt lower priority tasks. Upon return from interrupt, lower priority tasks resume in the previously scheduled order.

### Overrun Detection

Multirate `rt_OneStep` also maintains an array of timer overrun flags. `rt_OneStep` detects timer overrun, per task, by the same logic as single-rate `rt_OneStep`.

---

**Note** If you have developed multirate S-functions, or if you use a customized static main program module, see “Rate Grouping Compliance and Compatibility Issues” on page 68-12 for information about how to adapt your code for rate grouping compatibility. This adaptation lets your multirate, multitasking models generate more efficient code.

---

### Multirate Single-Tasking Operation

In a multirate single-tasking program, by definition, sample times in the model must be an integer multiple of the model's fixed-step size.

In a multirate single-tasking program, blocks execute at different rates, but under the same task identifier. The operation of `rt_OneStep`, in this case, is a simplified version of multirate multitasking operation. Rate grouping is not used. The only task is the base-rate task. Therefore, only one `model_step` function is generated:

```
void model_step(void)
```

On each clock tick, `rt_OneStep` checks the overrun flag and calls `model_step`. The scheduling function for a multirate single-tasking program is `rate_scheduler` (rather than `rate_monotonic_scheduler`). The scheduler maintains scheduling counters on each clock tick. There is one counter for each sample rate in the model. The counters are implemented in an array (indexed on `tid`) within the `Timing` structure within `rtModel`.

The counters are clock rate dividers that count up the sample period associated with each subrate task. When a counter indicates that a sample period for a given rate has elapsed, `rate_scheduler` clears the counter. This condition indicates that blocks running at that rate should execute on the next call to `model_step`, which is responsible for checking the counters.

### Guidelines for Modifying `rt_OneStep`

`rt_OneStep` does not require extensive modification. The only required modification is to reenables interrupts after the overrun flags and error conditions have been checked. If applicable, you should also

- Save and restore your FPU context on entry and exit to `rt_OneStep`.
- Set model inputs associated with the base rate before calling `model_step0`.
- Get model outputs associated with the base rate after calling `model_step0`.

---

**Note** If you modify `rt_OneStep` to read a value from a continuous output port after each base-rate model step, see the relevant cautionary guideline below.

---

- In a multirate, multitasking model, set model inputs associated with subrates before calling `model_stepN` in the subrate loop.
- In a multirate, multitasking model, get model outputs associated with subrates after calling `model_stepN` in the subrate loop.

Comments in `rt_OneStep` indicate the place to add your code.

In multirate `rt_OneStep`, you can improve performance by unrolling `for` and `while` loops.

In addition, you may choose to modify the overrun behavior to continue execution after error recovery is complete.

Also observe these cautionary guidelines:

- You should not modify the way in which the counters, event flags, or other timing data structures are set in `rt_OneStep`, or in functions called from `rt_OneStep`. The `rt_OneStep` timing data structures (including `rtModel`) and logic are critical to the operation of the generated program.
- If you have customized the main program module to read model outputs after each base-rate model step, be aware that selecting model configuration parameters **Support: continuous time** and **Single output/update function** together can cause output values read from `main` for a continuous output port to differ slightly from the corresponding output values in the model's logged data. This is because, while logged data is a snapshot of output at major time steps, output read from `main` after the base-rate model step potentially reflects intervening minor time steps. To eliminate the discrepancy, either separate the generated output and update functions (clear the **Single output/update function** parameter) or place a Zero-Order Hold block before the continuous output port.
- It is possible to observe a mismatch between results from simulation and logged MAT file results from generated code if you do not set model inputs before each time you call the model step function. In the generated example main program, the following comments show the locations for setting the inputs and stepping the model with your code:

```
/* Set model inputs here */
/* Step the model */
```

If your model applies signal reuse and you are using `MatFileLogging` for comparing results from simulation against generated code, modify `rt_OneStep` to write model inputs in every time step as directed by these comments. Alternatively, you could “Choose a SIL or PIL Approach” on page 82-11 for verification.

## Static Main Program Module

- “Overview” on page 68-8
- “Rate Grouping and Static Main Program” on page 68-9
- “Modify the Static Main Program” on page 68-9
- “Modify Static Main to Allocate and Access Model Instance Data” on page 68-10

### Overview

A strategy for deploying generated code is to use model configuration parameter **Generate an example main program option** to generate an example main program module (`ert_main.c` or `.cpp`). For more information, see “Generate a Standalone Program” on page 68-2.

Alternatively, you can clear the **Generate an example main program** parameter and use a generated static main program module as an example or template for developing your embedded application. Static main program modules provided by MathWorks include:

- `matlabroot/rtw/c/src/common/rt_main.c` — Supports the Nonreusable function setting for model configuration parameter **Code interface packaging**.
- `matlabroot/rtw/c/src/common/rt_malloc_main.c` — Supports the Reusable function setting for parameter **Code interface packaging**. You must select model configuration parameter **Use dynamic memory allocation for model initialization** and set parameter **Pass root-level I/O as** to Part of model data structure.
- `matlabroot/rtw/c/src/common/rt_cppclass_main.cpp` — Supports the C++ class setting for parameter **Code interface packaging**.

Static main programs are not part of the generated code. The programs are provided as a basis for developing custom modifications and for use in simulation.

A static main program contains:

- `rt_OneStep`—A timer interrupt service routine (ISR) that calls the entry-point function `model_step` to execute processing for one clock period of the model.
- Skeletal `main` function—As provided, `main` is useful for simulation only. You must modify `main` for real-time interrupt-driven execution.

For single-rate models, operation of `rt_OneStep` and the `main` function in the static main program are the same as they are in the automatically generated version described in “Deploy Generated Standalone Executable Programs To Target Hardware” on page 68-2. For multirate, multitasking models, the static main program and generated code differ as described in the next section.

To develop an application by using a static main program:

- 1 Copy the program module to your working folder.
- 2 Rename the file. For example, rename `rt_main.c` to `model_rt_main.c`.
- 3 Customize the program module content.
- 4 Modify the template makefile or toolchain settings such that the build process creates a corresponding object file, such as `model_rt_main.obj` (on UNIX, `model_rt_main.o`), in the build folder.

If your existing application depends upon a static `ert_main.c` developed in releases before R2012b, `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp`, you might need to continue using that static main program.

### Rate Grouping and Static Main Program

ERT-based system target files can use a static main program module and disallow use of the model configuration parameter **Generate an example main program**. A custom system target file does not disallow use of that model configuration parameter when target-specific changes have been made to the static main program and those modifications must be preserved. A generated example main program does not preserve the changes to the static main program.

For models configured for multitasking (**Treat each discrete rate as a separate task** is selected) or concurrency (**Allow task to execute concurrently on target is** selected), the code generator uses a rate grouping scheme, producing a step entry-point function for each rate (`model_stepN`, where  $N$  identifies the rate). The Code Interface Report lists the individual entry-point functions that a main program can call.

To specify that only the rate-based step functions are generated without the wrapper function, use the TLC variable `RateBasedStepFcn`. If your target calls the rate grouping compatible function directly, set `RateBasedStepFcn` to 1. In this case, the wrapper function is not generated.

In your system target file, prior to the `%include "codegenentry.tlc"` statement, set the TLC variable `RateBasedStepFcn` to 1. Alternatively, set `RateBasedStepFcn` to 1 in your `target_settings.tlc` file.

### Modify the Static Main Program

Make few modifications to the main loop and the `rt_OneStep` function. See “Guidelines for Modifying the Main Program” on page 68-3 and “Guidelines for Modifying `rt_OneStep`” on page 68-7.

Replace the `rt_OneStep` call in the main loop with a background task call or null statement.

Other modifications you might need to make are:

- If applicable, follow comments in the code regarding where to add code for reading and writing model I/O and saving and restoring FPU context.
- If you modify `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp` to read a value from a continuous output port after each base-rate model step, see the relevant cautionary guideline in “Guidelines for Modifying `rt_OneStep`” on page 68-7.
- When you clear the model configuration parameter **Generate an example main program**, the code generator produces `rtmodel.h` to provide an interface between the main program module and generated model code. If you create your own static main program module, include `rtmodel.h`.

Alternatively, you can suppress generation of `rtmodel.h` and include `model.h` directly in your main program module. To suppress generation of `rtmodel.h`, use the following statement in your system target file:

```
%assign AutoBuildProcedure = 0
```

- If you have cleared the model configuration parameter **Terminate function required**, remove or comment out the following items in your production version of `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp`:
  - The `#if TERMFCN...` compile-time error check
  - The call to `MODEL_TERMINATE`
- For only `rt_main.c`: If you do *not* want to combine output and update functions, clear the model configuration parameter **Single output/update function** and make the following changes in your production version of `rt_main.c`:
  - Replace calls to `MODEL_STEP` with calls to `MODEL_OUTPUT` and `MODEL_UPDATE`.
  - Remove the `#if ONESTEPFCN...` error check.
- The static program module `rt_main.c` does not support `Reusable` function code interface packaging. If you use `Reusable` function code interface packaging illegally, this error check raises a compile-time error.

```
#if MULTI_INSTANCE_CODE==1
```

### Modify Static Main to Allocate and Access Model Instance Data

If you are using a static main program module and your model is configured for `Reusable` function code interface packaging, but the model configuration parameter **Use dynamic memory allocation for model initialization** is cleared, you must allocate model instance data statically or dynamically by the calling main code. Pointers to the individual model data structures such as `BlockIO`, `DWork`, and `Parameters` must be set up in the top-level real-time model data structure.

To support main modifications, the build process generates a subset of these real-time model (RTM) macros, based on the data requirements of your model, into `model.h`.

RTM Macro Syntax	Description
<code>rtmGetBlockIO(rtm)</code>	Get the block I/O data structure
<code>rtmSetBlockIO(rtm, val)</code>	Set the block I/O data structure

RTM Macro Syntax	Description
<code>rtmGetContStates(rtm)</code>	Get the continuous states data structure
<code>rtmSetContStates(rtm, val)</code>	Set the continuous states data structure
<code>rtmGetDefaultParam(rtm)</code>	Get the default parameters data structure
<code>rtmSetDefaultParam(rtm, val)</code>	Set the default parameters data structure
<code>rtmGetPrevZCSigState(rtm)</code>	Get the previous zero-crossing signal state data structure
<code>rtmSetPrevZCSigState(rtm, val)</code>	Set the previous zero-crossing signal state data structure
<code>rtmGetRootDWork(rtm)</code>	Get the DWork data structure
<code>rtmSetRootDWork(rtm, val)</code>	Set the DWork data structure
<code>rtmGetU(rtm)</code>	Get the root inputs data structure (when root inputs are passed as part of the model data structure)
<code>rtmSetU(rtm, val)</code>	Set the root inputs data structure (when root inputs are passed as part of the model data structure)
<code>rtmGetY(rtm)</code>	Get the root outputs data structure (when root outputs are passed as part of the model data structure)
<code>rtmSetY(rtm, val)</code>	Set the root outputs data structure (when root outputs are passed as part of the model data structure)

To access individual model data structures within the RTM data structure, use these macros in your static main program. For example, suppose that the example model `rtwdemo_reusable` is configured with `Reusable` function code interface packaging, **Use dynamic memory allocation for model initialization** cleared, **Pass root-level I/O as set to Individual** arguments, and **Optimization** pane option **Remove root level I/O zero initialization** is cleared. Building the model generates these model data structures and model entry-points into `rtwdemo_reusable.h`:

```
/* Block states (auto storage) for system '<Root>' */
typedef struct {
 real_T Delay_DSTATE; /* '<Root>/Delay' */
} D_Work;

/* Parameters (auto storage) */
struct Parameters_ {
 real_T k1; /* Variable: k1
 * Referenced by: '<Root>/Gain'
 */
};

/* Model entry point functions */
extern void rtwdemo_reusable_initialize(RT_MODEL *const rtM, real_T *rtU_In1,
 real_T *rtU_In2, real_T *rtY_Out1);
extern void rtwdemo_reusable_step(RT_MODEL *const rtM, real_T rtU_In1, real_T
 rtU_In2, real_T *rtY_Out1);
```

If you do not select the model configuration parameter **Generate an example main program** for the model, `rtwdemo_reusable.h` contains definitions for the RTM macros `rtmGetDefaultParam`, `rtmsetDefaultParam`, `rtmGetRootDWork`, and `rtmSetRootDWork`.

For reference, the generated `rtmodel.h` file contains an example parameter definition that has initial values (nonexecuting code):

```
#if 0

/* Example parameter data definition with initial values */
static Parameters rtP = {
 2.0 /* Variable: k1
```

```

 * Referenced by: '<Root>/Gain'
 */
};
 /* Modifiable parameters */
#endif

```

In the definitions section of your static main file, you can use the following code to statically allocate the real-time model data structures and arguments for the `rtwdemo_reusable` model:

```

static RT_MODEL rtM;
static RT_MODEL *const rtM = &rtM; /* Real-time model */
static Parameters rtP = {
 2.0
 /* Variable: k1
 * Referenced by: '<Root>/Gain'
 */
};
 /* Modifiable parameters */

static D_Work rtDWork; /* Observable states */

/* '<Root>/In1' */
static real_T rtU_In1;

/* '<Root>/In2' */
static real_T rtU_In2;

/* '<Root>/Out1' */
static real_T rtY_Out1;

```

In the body of your main function, you can use the following RTM macro calls to set up the model parameters and DWork data in the real-time model data structure:

```

int_T main(int_T argc, const char *argv[])
{
 ...
 /* Pack model data into RTM */

 rtmSetDefaultParam(rtM, &rtP);
 rtmSetRootDWork(rtM, &rtDWork);

 /* Initialize model */
 rtwdemo_reusable_initialize(rtM, &rtU_In1, &rtU_In2, &rtY_Out1);
 ...
}

```

Follow a similar approach to set up multiple instances of model data, where the real-time model data structure for each instance has its own data. In particular, the parameter structure (`rtP`) must be initialized for each instance, to the values that you want, statically as part of the `rtP` data definition or at run time.

## Rate Grouping Compliance and Compatibility Issues

- “Main Program Compatibility” on page 68-12
- “Make Your S-Functions Rate Grouping Compliant” on page 68-12

### Main Program Compatibility

When you clear model configuration parameter **Generate an example main program**, the code generator produces slightly different rate grouping code, for compatibility with the older static `ert_main.c` module. See “Rate Grouping and Static Main Program” on page 68-9 for details.

### Make Your S-Functions Rate Grouping Compliant

Built-in Simulink blocks, as well as DSP System Toolbox blocks, are compliant with the requirements for generating rate grouping code. However, user-written multirate inlined S-functions might not be

rate grouping compliant. Noncompliant blocks generate less efficient code, but are otherwise compatible with rate grouping. To take full advantage of the efficiency of rate grouping, upgrade multirate inlined S-functions to be fully rate grouping compliant. You should upgrade your TLC S-function implementations, as described in this section.

Use of noncompliant multirate blocks to generate rate-grouping code generates dead code. This can cause two problems:

- Reduced code efficiency.
- Warning messages issued at compile time. Such warnings are caused when dead code references temporary variables before initialization. Since the dead code does not run, this problem does not affect the run-time behavior of the generated code.

To make your S-functions rate grouping compliant, you can use the following TLC functions to generate `ModelOutputs` and `ModelUpdate` code, respectively:

```
OutputsForTID(block, system, tid)
UpdateForTID(block, system, tid)
```

The code listings below illustrate generation of output computations without rate grouping (Listing 1) and with rate grouping (Listing 2). Note the following:

- The `tid` argument is a task identifier ( $0 \dots \text{NumTasks} - 1$ ).
- Only code guarded by the `tid` passed in to `OutputsForTID` is generated. The `if (%<LibIsSFcnSampleHit(portName)>)` test is not used in `OutputsForTID`.
- When generating rate grouping code, `OutputsForTID` and/or `UpdateForTID` is called during code generation. When generating non-rate-grouping code, `Outputs` and/or `Update` is called.
- In rate grouping compliant code, the top-level `Outputs` and/or `Update` functions call `OutputsForTID` and/or `UpdateForTID` functions for each rate (`tid`) involved in the block. The code returned by `OutputsForTID` and/or `UpdateForTID` must be guarded by the corresponding `tid` guard:

```
if (%<LibIsSFcnSampleHit(portName)>)
```

as in Listing 2.

### Listing 1: Outputs Code Generation Without Rate Grouping

## Generate Code That Dereferences Data from a Literal Memory Address

This example shows how to generate code that reads the value of a signal by dereferencing a memory address that you specify. With this technique, you can generate a control algorithm that interacts with memory that your hardware populates (for example, memory that stores the output of an analog-to-digital converter in a microcontroller).

In this example, you generate an algorithm that acquires input data from a 16-bit block of memory at address 0x8675309. Assume that a hardware device asynchronously populates only the lower 10 bits of the address. The algorithm must treat the address as read-only (`const`), volatile (`volatile`) data, and ignore the upper 6 bits of the address.

The generated code can access the data by defining a macro that dereferences 0x8675309 and masks the unnecessary bits:

```
#define A2D_INPUT (*(volatile const uint16_T *)0x8675309)&0x03FF)
```

To configure a model to generate code that defines and uses this macro:

- 1 Create the example model.
- 2 Create package to contain definitions of data class and storage class.
- 3 Use Custom Storage Class Designer to create a storage class.
- 4 Define a class to store property settings for the storage class.
- 5 Write Target Language Compiler (TLC) code that emits the correct C code for the storage class.
- 6 Define a class for the inport data.
- 7 Load the package into the Embedded Coder Dictionary.
- 8 Configure the model root-level inport to use the storage class.

## 9 Generate and inspect the code.

For an example that shows how to use the Custom Storage Class Designer without writing TLC code, see “Create and Apply a Storage Class” on page 37-14.

As an alternative to writing TLC code, you can use memory sections to generate code that includes pragmas. Depending on your build toolchain, you can use pragmas to specify a literal memory address for storing a global variable. For more information about memory sections, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

### Derivation of Macro Syntax

In this example, you configure the generated code to define and use the dereferencing macro. To determine the correct syntax for the macro, start by recording the target address.

```
0x8675309
```

Cast the address as a pointer to a 16-bit integer. Use the Simulink Coder data type name `uint16_T`.

```
(uint16_T *)0x8675309
```

Add the storage type qualifier `const` because the generated code must not write to the address. Add `volatile` because the hardware can populate the address at an arbitrary time.

```
(volatile const uint16_T *)0x8675309
```

Dereference the address.

```
*(volatile const uint16_T *)0x8675309
```

After the dereference operation, apply a mask to retain only the 10 bits that the hardware populates. Use explicit parentheses to control the order of operations.

```
(* (volatile const uint16_T *)0x8675309)&0x03FF
```

As a safe coding practice, wrap the entire construct in another layer of parentheses.

```
((*(volatile const uint16_T *)0x8675309)&0x03FF)
```

### Create Example Model

Create the example model `ex_memmap_simple`.

For the Inport block, set the output data type to `uint16`. Name the signal as `A2D_INPUT`. The Inport block and the signal line represent the data that the hardware populates.

For the Gain block, set the output data type to `double`.

### Create Package to Contain Definitions of Data Class and Storage Class

In your current folder, create a folder named `+MemoryMap`. The folder defines a package named `MemoryMap`.

To make the package available for use outside of your current folder, you can add the folder containing the +MemoryMap folder to the MATLAB path.

### Create Storage Class

To generate code that defines and reads A2D\_INPUT as a macro, you must create a storage class that you can apply to the model root-level inport. Later, you write TLC code that complements the storage class.

Open the Custom Storage Class designer in advanced mode. To design a storage class that operates through custom TLC code, you must use the advanced mode.

```
cscdesigner('MemoryMap', '-advanced');
```

In the Custom Storage Class Designer, click **New**. A new custom storage class, NewCSC\_1, appears in the list of storage class definitions.

Rename the storage class to MemoryMappedAddress.

For MemoryMappedAddress, on the **General** tab, set:

- **Type** to **Other**. The storage class can operate through custom TLC code that you write later.
- **Data scope** to **Exported**. For data items that use this custom storage class, Simulink Coder generates the definition (for example, the #define statement that defines a macro).
- **Data initialization** to **None**. Simulink Coder does not generate code that initializes the data item. Use this setting because this custom storage class represents read-only data. You do not select **Macro** because the Custom Storage Class Designer does not allow you to use **Macro** for signal data.
- **Definition file** to **Specify** (leave the text box empty). For data items that consume memory in the generated code, **Definition file** specifies the .c source file that allocates the memory. This storage class yields a macro, which does not require memory. Typically, header files (.h), not .c files, define macros. Setting **Definition file** to **Specify** instead of **Instance specific** prevents users of the storage class from unnecessarily specifying a definition file.
- **Header file** to **Instance specific**. To control the file placement of the macro definition, the user of the storage class must specify a header file for each data item that uses this storage class.
- **Owner** to **Specify** (leave the text box empty). **Owner** applies only to data items that consume memory.

After you finish selecting the settings, click **Apply** and **Save**.

Now, when you apply the storage class to a data item, such as inport In1, you can specify a header file to contain the generated macro definition. You cannot yet specify a memory address for the data item. To enable specification of a memory address, create a custom attributes class that you can associate with the MemoryMappedAddress storage class.

### Define Class to Store Property Settings for Storage Class

Define a MATLAB class to store additional information for data items that use the storage class. In this case, the additional information is the memory address.

In the MemoryMap package (the +MemoryMap folder), create a folder named @MemoryMapAttribs.

In the @MemoryMapAttribs folder, create a file named MemoryMapAttribs. The file defines a class that derives from the built-in class Simulink.CustomStorageClassAttributes.

```

classdef MemoryMapAttribs < Simulink.CustomStorageClassAttributes
 properties(PropertyType = 'char')
 MemoryAddress = '';
 end
end
end

```

Later, you associate this MATLAB class with the `MemoryMappedAddress` storage class. Then, when you apply the storage class to a data item, you can specify a memory address.

### Write TLC Code That Emits Correct C Code

Write TLC code that uses the attributes of the storage class, such as `HeaderFile` and `MemoryAddress`, to generate correct C code for each data item.

In the `+MemoryMap` folder, create a folder named `tlc`.

Navigate to the new folder.

Inspect the built-in template TLC file, `TEMPLATE_v1.tlc`.

```

edit(fullfile(matlabroot,...
 'toolbox','rtw','targets','ecoder','csc_templates','TEMPLATE_v1.tlc'))

```

Save a copy of `TEMPLATE_v1.tlc` in the `tlc` folder. Rename the copy `memory_map_csc.tlc`.

In `memory_map_csc.tlc`, find the portion that controls the generation of C-code data declarations.

```

%case "declare"

 %% LibDefaultCustomStorageDeclare is the default declare function to
 %% declares a global variable whose identifier is the name of the data.
 %return "extern %<LibDefaultCustomStorageDeclare(record)>"
 %%break

 %% =====

```

The `declare` case (`%case`) constructs a return value (`%return`), which the code generator emits into the header file that you specify for each data item. To control the C code that declares each data item, adjust the return value in the `declare` case.

Replace the existing `%case` content with this new code, which specifies a different return value:

```

%case "declare"

 %% In TLC code, a 'record' is a data item (for example, a signal line).
 %% 'LibGetRecordIdentifier' returns the name of the data item.
 %assign id = LibGetRecordIdentifier(record)

 %assign dt = LibGetRecordCompositeDataTypeName(record)

 %% The 'CoderInfo' property of a data item stores a
 %% 'Simulink.CoderInfo' object, which stores code generation settings
 %% such as the storage class or custom storage class that you specify
 %% for the item.

```

```

%assign ci = record.Object.ObjectProperties.CoderInfo
%% The 'ci' variable now stores the 'Simulink.CoderInfo' object.

%% By default, the 'CustomAttributes' property of a 'Simulink.CoderInfo'
%% object stores a 'Simulink.CustomStorageClassAttributes' object.
%% This nested object stores specialized code generation settings
%% such as the header file and definition file that you specify for
%% the data item.
%%
%% The 'MemoryMap' package derives a new class,
%% 'MemoryMapAttribs', from 'Simulink.CustomStorageClassAttributes'.
%% The new class adds a property named 'MemoryAddress'.
%% This TLC code determines the memory address of the data item by
%% acquiring the value of the 'MemoryAddress' property.
%assign ca = ci.Object.ObjectProperties.CustomAttributes
%assign address = ca.Object.ObjectProperties.MemoryAddress

%assign width = LibGetDataWidth(record)

%% This TLC code constructs the full macro, with correct C syntax,
%% based on the values of TLC variables such as 'address' and 'dt'.
%% This TLC code also asserts that the data item must be a scalar.
%if width == 1
 %assign macro = ...
 "#define %<id> ((*volatile const %<dt>*)%<address>) & 0x03FF)"
%else
 %error("Non scalars are not supported yet.")
%endif

%return "%<macro>"
%%break

%% =====

```

The new TLC code uses built-in, documented TLC functions, such as `LibGetRecordIdentifier`, and other TLC commands and operations to access information about the data item. Temporary variables such as `dt` and `address` store that information. The TLC code constructs the full macro, with the correct C syntax, by expanding the variables, and stores the macro in the variable `macro`.

In the same file, find the portion that controls the generation of data definitions.

```

%case "define"

 %% LibDefaultCustomStorageDefine is the default define function to define
 %% a global variable whose identifier is the name of the data. If the
 %% data is a parameter, the definition is also statically initialized to
 %% its nominal value (as set in MATLAB).
 %return "%<LibDefaultCustomStorageDefine(record)>"
 %%break

%% =====

```

The `define` case derives a return value that the code generator emits into a `.c` file, which defines data items that consume memory.

Replace the existing `%case` content with this new content:

```
%case "define"
 %return ""
 %%break
```

```
%% =====
```

`MemoryMappedAddress` yields a macro in the generated code, so you use the `declare` case instead of the `define` case to construct and emit the macro. To prevent the `define` case from emitting a duplicate macro definition, the new TLC code returns an empty string.

Find the portion that controls the generation of code that initializes data.

```
%case "initialize"
```

```
 %% LibDefaultCustomStorageInitialize is the default initialization
 %% function that initializes a scalar element of a global variable to 0.
 %return LibDefaultCustomStorageInitialize(record, idx, reim)
 %%break
```

```
%% =====
```

The `initialize` case generates code that initializes data items (for example, in the `model_initialize` function).

Replace the existing `%case` content with this new content:

```
%case "initialize"
 %return ""
 %%break
```

```
%% =====
```

`MemoryMappedAddress` yields a macro, so the generated code must not attempt to initialize the value of the macro. The new TLC code returns an empty string.

### Complete the Definition of the Storage Class

Your new MATLAB class, `MemoryMapAttribs`, can enable users of your storage class, `MemoryMappedAddress`, to specify a memory address for each data item. To allow this specification, associate `MemoryMapAttribs` with `MemoryMappedAddress`. To generate correct C code based on the information that you specify for each data item, associate the customized TLC file, `memory_map_csc.tlc`, with `MemoryMappedAddress`.

Navigate to the folder that contains the `+MemoryMap` folder.

Open the Custom Storage Class Designer again.

```
cscdesigner('MemoryMap', '-advanced');
```

For `MemoryMappedAddress`, on the **Other Attributes** tab, set:

- **TLC file name** to `memory_map_csc.tlc`.
- **CSC attributes class** to `MemoryMap.MemoryMapAttribs`.

Click **Apply** and **Save**.

### Define Signal Data Class

To apply the storage class to a data element in a model, in the `MemoryMap` package, you must create a MATLAB class that derives from `Simulink.Signal`. When you configure the signal in the model, you select this new data class instead of the default class, `Simulink.Signal`.

In the `MemoryMap` package, create a folder named `@Signal`.

In the `@Signal` folder, create a file named `Signal.m`.

```
classdef Signal < Simulink.Signal
 methods
 function setupCoderInfo(this)
 useLocalCustomStorageClasses(this, 'MemoryMap');
 return;
 end
 end
end
```

The file defines a class named `MemoryMap.Signal`. The class definition overrides the `setupCoderInfo` method, which the `Simulink.Signal` class already implements. The new implementation specifies that objects of the `MemoryMap.Signal` class use custom storage classes from the `MemoryMap` package (instead of storage classes from the `Simulink` package). When you configure a signal in a model by selecting the `MemoryMap.Signal` class, you can select the new custom storage class, `MemoryMappedAddress`.

### Load Package into Embedded Coder Dictionary

Navigate to the folder that contains the example model and open the model.

Open the **Embedded Coder** app.

Open the Embedded Coder Dictionary. On the **C Code** tab, select **Code Interface > Embedded Coder Dictionary**.

In the Embedded Coder Dictionary, click **Manage Packages**.

In the Manage Package dialog box, click **Refresh**. When the refresh is complete, select the package `MemoryMap`. Click **Load**.

Close the Embedded Coder Dictionary.

### Configure Root-Level Inport to Use Storage Class

In the **Embedded Coder** app, use the Code Mappings editor and Property Inspector to configure Inport In1 to use the storage class that you defined.

Open the Code Mappings editor. On the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.

In the Code Mappings Editor, on the **Inports** tab, select inport In1. Set the storage class for In1 to `MemoryMappedAddress`.

In the Property Inspector, under **Code**, set the **HeaderFile** property to `memory_mapped_addresses.h` and the **MemoryAddress** property to `0x8675309`.

Save the model.

### Generate and Inspect Code

Generate code from the model.

```
Starting build procedure for: ex_memmap_simple
```

```
tf =
```

```
 logical
```

```
 0
```

```
Successful completion of build procedure for: ex_memmap_simple
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
ex_memmap_simple	Code generated and compiled	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 26.573s

Inspect the generated header file `memory_mapped_addresses.h`. The file defines the macro `A2D_INPUT`, which corresponds to the signal line in the model.

```
/* Declaration of data with custom storage class MemoryMappedAddress */
#define A2D_INPUT ((*(volatile const uint16_T*)0x8675309) & 0x03FF)
```

Inspect the generated file `ex_memmap_simple.c`. The generated algorithmic code (which corresponds to the Gain block) calculates the model output, `rtY.Out1`, by operating on `A2D_INPUT`.

```
/* Model step function */
void step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 * Inport: '<Root>/In1'
 */
 rtY.Out1 = 42.0 * (real_T)A2D_INPUT;
}
```

## Generate Main Program for Deployment to Bare-Metal Target Hardware

This example shows how to configure a model such that the code generator produces an example main program that you can customize for deployment on bare-metal target hardware (does not have an operating system). When you select the model configuration parameter **Generate an example main program**, the code generator produces the example `ert_main.c` or `ert_main.cpp` file. The file includes:

- `main()` function for the generated program
- Task scheduling code that determines how and when block computations execute on each time step of the model

Operation of the main program and the scheduling algorithm depend primarily on:

- Whether the model is a single-rate or multirate model
- Whether the model solver mode is set to single-tasking or multitasking

For more information, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 68-2.

Alternatively, you can configure a model to generate an example main program for deployment on target hardware that is running threaded code that runs on your host operating system. The example file `ert_main.c` that the code generator produces, shows how to deploy the generated example code.

You can customize a generated main program by using a custom file processing (CFP) template. Consider using a template file to:

- Assemble generated code in buffers
- Call an API to obtain buffered code into specific sections of generated source and header files

For more information, see “File customization template”.

### Open Example Model

Open the example model `rtwdemo_exemplemain`.

```
open_system('rtwdemo_exemplemain');
```

### Configure Model

1. Open the **Embedded Coder** app.
2. Select model configuration parameter **Generate an example main program**. When you select this parameter, you enable parameter **Target operating system**.
3. Set parameter **Target operating system** to `BareBoardExample` or `NativeThreadsExample`. For more information, see “Target operating system”.
4. Consider whether you want to specify a custom file processing template. To configure a template, specify the file name and extension for your template TLC file as a string for model configuration parameter **File customization template**.

**Generate Code**

Generate and inspect the code.

**Add Hand-Coded Customizations**

Augment the generated code with hand code as needed.

## Deploy Generated Component Software to Application Target Platforms

The code generator supports integration of generated code with operating systems and processors. For details, see “Embedded Coder Supported Hardware”.

### Interface to an Example Real-Time Multitasking System

This example shows how to simulate and generate code for asynchronous events on a real-time multitasking system.

The operating system integration techniques that the example demonstrates use one or more blocks in the `vxlib1` library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

#### Example Model

Open the `rtwdemo_vxworks` model.

```
model = 'rtwdemo_vxworks';
open_system(model);
%
```

#### Model Description

The example model contains two asynchronously executed subsystems, `Count` and `Algorithm`. `Count` executes at interrupt level. `Algorithm` executes in an asynchronous task. The generated code for these blocks is tailored for the VxWorks® operating system. However, you can modify the `Async Interrupt` and `Task Sync` blocks to generate code for your run-time environment whether you are using an operating system or not.

#### Data Transfer Assumptions

This example assumes the following about the target platform environment:

- Data transitions occur between a single task that reads data and a single task that writes data.
- A read or write of a byte-sized variable is atomic.
- When two tasks interact during a data transfer, only one of the tasks can preempt the other task.
- For periodic tasks, the task that executes at the faster rate has a higher priority than the tasks that executes at the slower rate. The task executing at the faster rate preempts the tasks executing at the slower rate.
- Tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash and restart during a data transfers.

## What Is Code Replacement Customization?

Customize how and when the code generator replaces C/C++ code that it generates by default for functions and operators by developing a custom code replacement library. You can develop libraries interactively with the **Code Replacement Tool** or programmatically.

- Develop libraries tailored to specific application requirements
- Add identifiers to the list of reserved keywords the code generator considers during code replacement
- Customize the code generator’s match and replacement process for functions

To get started, “Quick Start Code Replacement Library Development - Simulink” on page 69-21.

### Code Replacement Match and Replacement Process

When the code generator encounters a call site for a function or operator, it:

- 1 Creates and partially populates a code replacement entry object with the function or operator name or key and conceptual arguments.
- 2 Uses the entry object to query the configured code replacement library for a conceptual representation match. The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. When searching for a match, the code generator takes into account:
  - Conceptual name or key
  - Arguments, including quantity, type, type qualifiers, and complexity
  - Algorithm (computation method)
  - Fixed-point saturation and rounding modes
  - Priority
- 3 When a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority. If the code generator finds multiple matches within a table, the entry priority determines the match. The priority can range from 0 to 100. The highest priority is 0. The code generator uses a higher-priority entry over a similar entry with a lower priority.
- 4 Uses the C or C++ replacement function prototype in the code replacement object to generate code.

### Code Replacement Customization Limitations

- Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code. See “Verify Code Replacement Library” on page 69-55.
- Code replacement for matrices — Code replacement libraries do not support the replacement of functions that have variable-size inputs.
- Tokens in file paths—You can include tokens in file paths when specifying build information for a code replacement entry by using the programming interface only. The ability to include tokens is not available from the Code Replacement Tool. See Specify build information in “Define Code Replacement Library Optimizations” on page 69-36.

- Addition and subtraction operation replacements—See “Replace Addition and Subtraction Operator Code” on page 69-151 for relevant limitations.
- Data alignment—
  - Not supported for
    - Arguments associated with a built-in storage class with `DataScope` set to `Exported` or the imported built-in storage class `GetSet`
    - Software-in-the-loop (SIL)
    - Processor-in-the-loop (PIL)
    - Model reference parameters
    - Exported functions in Stateflow charts
    - Replaced functions that are generated with C function prototype control or C++ class I/O arguments step method and that use root-level I/O variables
    - Replaced functions that are generated with the AUTOSAR system target file and that use root-level I/O or AUTOSAR inter-runnable access functions
  - If the following conditions exist, the code generator includes data alignment directives for root-level I/O variables in the `ert_main.c` or `ert_main.cpp` file it produces:
    - Compiler supports global variable alignment
    - Generate an example main program (select **Configuration Parameters > Generate an example main program**)
    - Generate a reusable function interface for the model (set **Configuration Parameters > Code Generation > Interface > Code interface packaging** to `Reusable function`)
    - Function uses root-level I/O variables that are passed in as individual arguments (set **Configuration Parameters > Code Generation > Interface > Pass root-level I/O as to Individual arguments**)
    - Replaced function uses a root-level I/O variable
    - Replaced function imposes alignment requirements
  - If you discard the generated example main program, align used root-level I/O variables correctly.
  - If you choose not to generate an example main program in this case, the code generator does not replace the function.
  - If a replacement imposes alignment requirements on the shared utility interface arguments, the code generator does not honor data alignment. Under these conditions, replacement does not occur. Replacement is allowed if the registered data alignment type specification supports alignment of local variables, and the replacement involves only local variables.
  - For `Simulink.Bus`:
    - If user registered alignment specifications do not support structure field alignment, aligning `Simulink.Bus` objects is not supported unless the `Simulink.Bus` is imported.
    - When aligning a `Simulink.Bus` data object, the elements in the bus object are aligned on the same boundary. The boundary is the lowest common multiple of the alignment requirements for each individual bus element.
  - When you specify alignment for functions that occur in a model reference hierarchy, and multiple models in the hierarchy operate on the same function data, the bottommost model dictates alignment for the rest of the hierarchy. If the alignment requirement for a function in a

model higher in the hierarchy cannot be honored due to the alignment set by a model lower in the hierarchy, the replacement in the higher model does not occur. In some cases, an error message is generated. To work around this issue, if the shared data is represented by a bus or signal object, manually set the alignment property on the shared data by setting the alignment property of the `Simulink.Bus` or `Simulink.Signal` object.

- It is your responsibility to honor the `Alignment` property setting for storage classes that you create.

See “Data Alignment for Code Replacement” on page 69-105.

- `coder.replace` function — See `coder.replace` for relevant limitations.

## Code You Can Replace From Simulink Models

Code that the code generator replaces depends on the code replacement library (CRL) that you use. By default, the code generator does not apply a code replacement library. Your choice of libraries is dependent on product licensing and whether you have access to custom libraries.

For information on how to explore functions and operators that a code replacement library supports, see “Choose a Code Replacement Library” on page 54-6.

### Math Functions - Simulink Support

When generating C/C++ code from a Simulink model, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following math functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
abs <sup>1</sup>	Integer Floating point Fixed point	Scalar Vector Matrix	Real
acos	Floating point	Scalar	Real Complex input/complex output Real input/complex output

tanh	Floating point	Scalar Vector Matrix	Real Complex input/complex output Real input/complex output
<sup>1</sup> Wrap on integer overflow only. Clear block parameter <b>Saturate on integer overflow</b> . <sup>2</sup> Only when used with the MATLAB Function block. <sup>3</sup> Supports the CORDIC approximation method and the Lookup approximation method. <sup>4</sup> Stateflow support only.			

## Math Functions - Stateflow Support

When generating C/C++ code from Stateflow charts, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following math functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
abs <sup>1</sup>	Integer Floating point	Scalar	Real
acos <sup>2</sup>	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
acosd <sup>3</sup>	Floating point	Scalar Vector Matrix	Real Complex
acot <sup>3</sup>	Floating point	Scalar Vector Matrix	Real Complex
acotd <sup>3</sup>	Floating point	Scalar Vector Matrix	Real Complex
acoth <sup>3,5</sup>	Floating point	Scalar Vector Matrix	Real Complex
acsc <sup>3</sup>	Floating point	Scalar Vector Matrix	Real Complex
acscd <sup>3</sup>	Floating point	Scalar Vector Matrix	Real Complex
acsch <sup>3</sup>	Floating point	Scalar Vector Matrix	Real Complex
asec <sup>3</sup>	Floating point	Scalar Vector Matrix	Real Complex
asecd <sup>3</sup>	Floating point	Scalar Vector Matrix	Real Complex
asech <sup>3</sup>	Floating point	Scalar Vector Matrix	Real Complex

<b>Function</b>	<b>Data Type Support</b>	<b>Scalar, Vector, Matrix Support</b>	<b>Real, Complex Support</b>
asin <sup>2</sup>	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
asind <sup>3</sup>	Floating point	Scalar Vector Matrix	Real Complex

<p><sup>1</sup> Wrap on integer overflow only.</p> <p><sup>2</sup> For models involving vectors or matrices, the code generator replaces only functions coded in the MATLAB action language.</p> <p><sup>3</sup> The code generator replaces only functions coded in the MATLAB action language.</p> <p><sup>4</sup> Embedded Coder does not support the use of code replacement libraries for machine-parented data.</p>			

## Memory Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following memory functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
memcmp	Void pointer (void*)	Scalar Vector Matrix	Real Complex
memcpy	Void pointer (void*)	Scalar Vector Matrix	Real Complex
memset	Void pointer (void*)	Scalar Vector Matrix	Real Complex
memset2zero	Void pointer (void*)	Scalar Vector Matrix	Real Complex

Some target processors provide optimized functions to set memory to zero. Use the code replacement library programming interface to replace the `memset2zero` function with more efficient target-specific functions.

## Nonfinite Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following nonfinite functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
getInf	Floating point	Scalar	Real
getMinusInf	Floating point	Scalar	Real
getNaN	Floating point	Scalar	Real
rtIsInf	Floating point	Scalar	Real Complex
rtIsNaN	Floating point	Scalar	Real Complex

## Mutex and Semaphore Functions

Mutex and semaphore functions control access to resources shared by multiple processes in multicore target environments. MathWorks provides code replacement libraries that support mutex and semaphore replacement for Rate Transition and Task Transition blocks on Windows, Linux, Mac, and VxWorks platforms.

Generated mutex and semaphore code typically consists of:

- In model initialization code, an initialization function call to create a mutex or semaphore to control entry to a critical section of code.
- In model step code:

- Before code for a data transfer between tasks enters the critical section, mutex lock or semaphore wait function calls to reserve a critical section of code.
- After code for a data transfer between tasks finishes executing the critical section, mutex unlock or semaphore post function calls to release the critical section of code.
- In model termination code, an optional destroy function call to explicitly delete the mutex or semaphore.

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following mutex and semaphore functions with application-specific implementations.

Function	Key
Mutex Destroy	RTW_MUTEX_DESTROY
Mutex Init	RTW_MUTEX_INIT
Mutex Lock	RTW_MUTEX_LOCK
Mutex Unlock	RTW_MUTEX_UNLOCK
Semaphore Destroy	RTW_SEM_DESTROY
Semaphore Init	RTW_SEM_INIT
Semaphore Post	RTW_SEM_POST
Semaphore Wait	RTW_SEM_WAIT

## Operators

When generating C/C++ code from a Simulink model, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following operators with application-specific implementations.

Mixed data type support indicates that you can specify different data types for different inputs.

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Addition (+) <sup>1</sup>	RTW_OP_ADD	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Subtraction (-) <sup>1</sup>	RTW_OP_MINUS	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Multiplication (*) <sup>2</sup>	RTW_OP_MUL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex

<b>Operator</b>	<b>Key</b>	<b>Data Type Support</b>	<b>Scalar, Vector, Matrix Support</b>	<b>Real, Complex Support</b>
Division (/)	RTW_OP_DIV	Integer Floating point Fixed-point Mixed	Scalar	Real Complex
Data type conversion (cast)	RTW_OP_CAST	Integer Floating point <sup>3</sup> Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Shift left (<<)	RTW_OP_SL	Integer Fixed-point Mixed	Scalar Vector Matrix <sup>4</sup>	Real
Shift right arithmetic (>>) <sup>5</sup>	RTW_OP_SRA	Integer Fixed-point Mixed	Scalar Vector Matrix <sup>4</sup>	Real
Shift right logical (>>)	RTW_OP_SRL	Integer Fixed-point Mixed	Scalar Vector Matrix <sup>4</sup>	Real
Element-wise matrix multiplication (.*) <sup>6</sup>	RTW_OP_ELEM_MUL	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Matrix right division (/)	RTW_OP_RDIV	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Matrix left division (\)	RTW_OP_LDIV	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex

## Develop a Code Replacement Library

Iterate through the following steps, as necessary, to develop a code replacement library:

- 1 “Identify Code Replacement Library Requirements” on page 69-35
- 2 “Define Code Replacement Library Optimizations” on page 69-36
- 3 “Register Code Replacement Library” on page 69-51
- 4 “Verify Code Replacement Library” on page 69-55
- 5 “Deploy Code Replacement Library” on page 69-57

To experiment with the process and tools, see “Quick Start Code Replacement Library Development - Simulink” on page 69-21.

# Quick Start Code Replacement Library Development - Simulink

This example shows how to develop a code replacement library that includes an entry for generating replacement code for the math function `sin`. You use the Code Replacement Tool.

## Prerequisites

To complete this example, install the following software:

- MATLAB®
- MATLAB Coder™
- Simulink®
- Simulink Coder™
- Embedded Coder®
- Compiler

For instructions on installing MathWorks® products, see the MATLAB installation documentation. If you have installed MATLAB and want to see what other MathWorks products are installed, in the Command Window, enter `ver`.

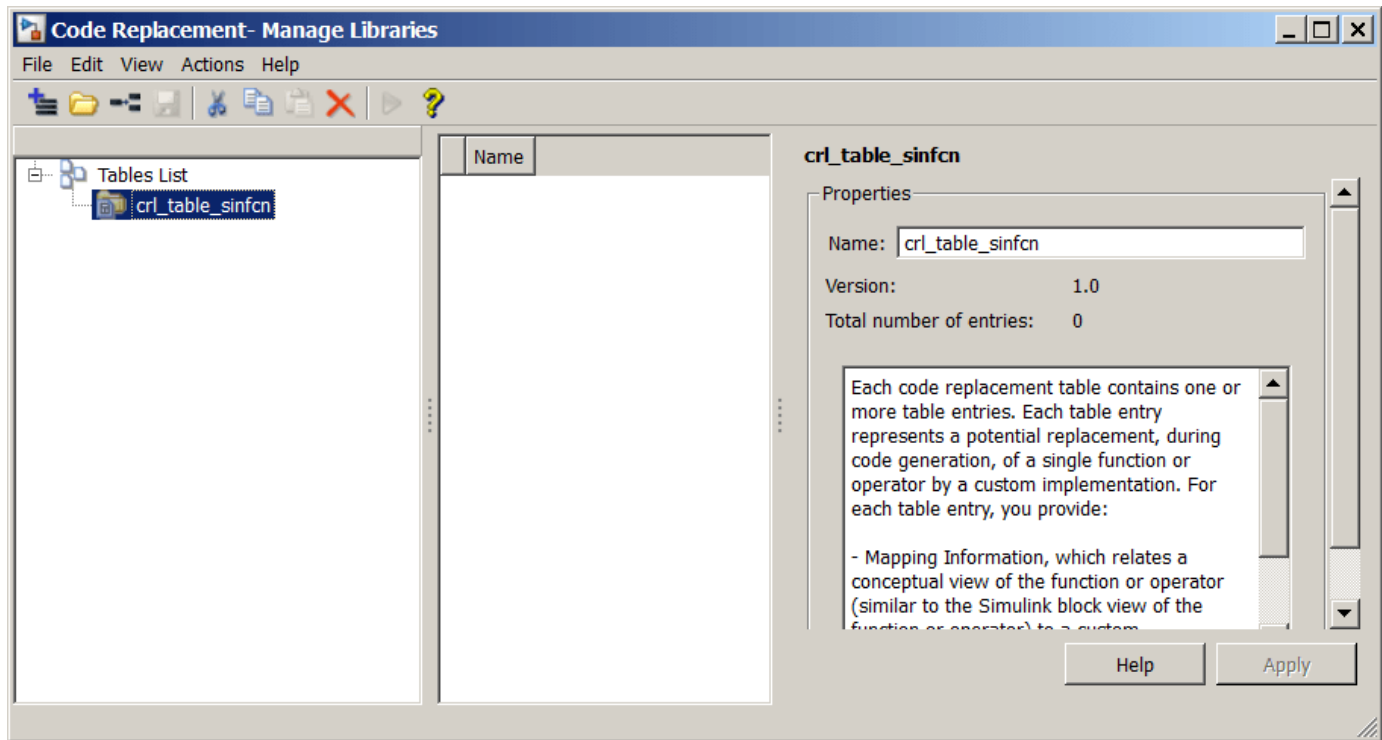

For a list of supported compilers, see [https://www.mathworks.com/support/compilers/current\\_release/](https://www.mathworks.com/support/compilers/current_release/).

## Open the Code Replacement Tool

1. Start a MATLAB session.
2. Create or navigate (`cd`) to an empty folder.
3. At the command prompt, enter the `crtool` command. The Code Replacement Tool window opens.

## Create Code Replacement Table

1. In the Code Replacement Tool window, select **File > New table**
2. In the right pane, name the table `crl_table_sinfcn` and click **Apply**. When you save the table, the tool saves it with the file name `crl_table_sinfcn.m`.

### Create Table Entry

Create a table entry that maps a `sin` function with double input and double output to a custom implementation function.

1. In the left pane, select table `crl_table_sinfcn`. Then, select **File > New entry > Function**. The entry appears in the middle pane, initially without a name.
2. In the middle pane, select the new entry.
3. In the right pane, on the **Mapping Information** tab, from the **Function** menu, select `sin`.
4. Leave **Algorithm** set to `Unspecified`, and leave parameters in the **Conceptual function** group set to default values.
5. In the **Replacement function** group, name the replacement function `sin_dbl`.
6. Leave the remaining parameters in the **Replacement function** group set to default values.
7. Click **Apply**. The tool updates the **Function signature preview** to reflect the specified replacement function name.
8. Scroll to the bottom of the **Mapping Information** tab and click **Validate entry**. The tool validates your entry.

The following figure shows the completed mapping information.

Mapping Information

Build Information

Function: sin

Entry information

Algorithm: Unspecified

Conceptual function

*Used by code generation process for matching purposes*

Conceptual arguments

y1  
u1

Argument properties

Data type: double

Complex

Argument type: Scalar

Make conceptual and implementation argument types the same

Replacement function

Function prototype

Name: sin\_dbl C++ namespace:

Function returns void

Function arguments

y1(return arg)  
u1

Argument properties

Data type: double I/O type: OUTPUT

Const  Pointer  Complex

✕ +

Function signature preview

`double sin_dbl( double u1 );`

Implementation attributes

Integer saturation mode: Unspecified Saturation

Rounding mode: Unspecified Rounding  
Floor  
Ceil  
Zero

Allow expressions as inputs

Function modifies internal or global state

[Click here to add Build Information](#)

Validation

Validate entry Status: Validated

### Specify Build Information for Replacement Code

1. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_dbl.h`.
2. Leave the remaining parameters set to default values.
3. Click **Apply**.

4. Optionally, you can revalidate the entry. Return to the **Mapping Information** tab and click **Validate entry**.

### Create Another Table Entry

Create an entry that maps a `sin` function with `single` input and `double` output to a custom implementation function named `sin_sgl`. Create the entry by copying and pasting the `sin_dbl` entry.

1. In the middle pane, select the `sin_dbl` entry.
2. Select **Edit > Copy**.
3. Select **Edit > Paste**.
4. On the **Mapping Information** tab, in the **Conceptual function** section, set the data type of input argument `u1` to `single`.
5. In the **Replacement function** section, name the function `sin_sgl`. Set the data type of input argument `u1` to `single`.
6. Click **Apply**. Note the changes that appear for the **Function signature preview**.
7. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_sgl.h`. Leave the remaining parameters set to default values and click **Apply**.

### Validate the Code Replacement Table

1. Select **Actions > Validate table**.
2. If the tool reports errors, fix them, and rerun the validation. Repeat fixing and validating errors until the tool does not report errors. The following figure shows a validation report.

Name	Implementation	NumIn	In1Type	In2Type	Out1Type	Out2Type	Priority
✓ sin	sin_dbl	1	double		double		100
✓ sin	sin_sgl	1	single		double		100

## Save the Code Replacement Table

Save the code replacement table to a MATLAB file in your working folder. Select **File > Save table**. By default, the tool uses the table name to name the file. For this example, the tool saves the table in the file `crl_table_sinfcn.m`.

## Review the Code Replacement Table Definition

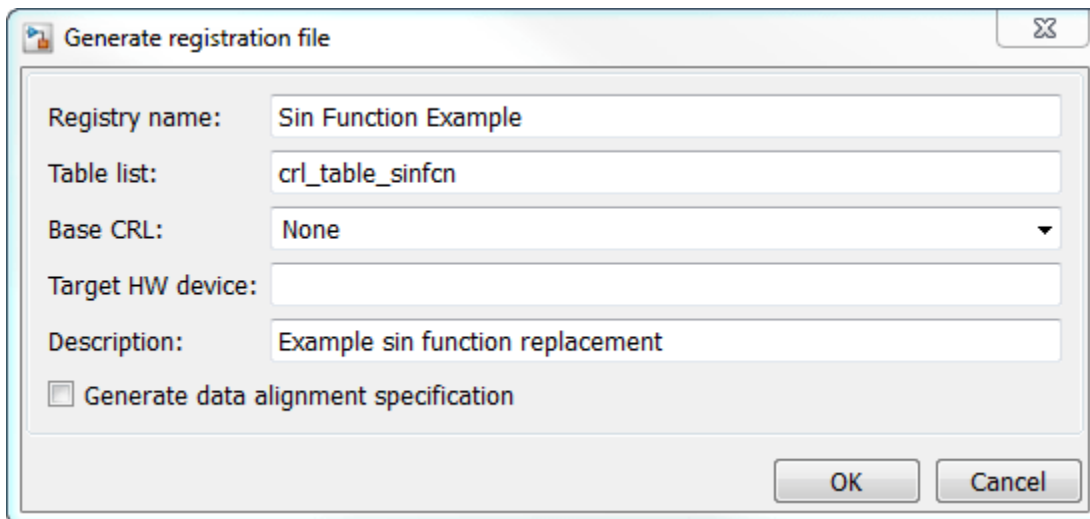

Consider reviewing the MATLAB code for your code replacement table definition. After using the tool to create an initial version of a table definition file, you can update, enhance, or copy the file in a text editor.

To review it, in MATLAB or another text editor, open the file `crl_table_sinfcn.m`.

## Generate a Registration File

Before you can use your code replacement table, you must register it as part of a code replacement library. Use the Code Replacement Tool to generate a registration file.

1. In the Code Replacement Tool, select **File > Generate registration file**.
2. In the **Generate registration file** dialog box, edit the dialog box fields to match the following figure, and click **OK**.

3. In the **Select location to save the registration file** dialog box, specify a location for the registration file. The location must be on the MATLAB path or in the current working folder. Save the file. The tool saves the file as `rtwTargetInfo.m`.

## Register the Code Replacement Table

At the command prompt, enter:

```
RTW.TargetRegistry.getInstance('reset');
```

## Review and Test Code Replacements

Apply your code replacement library. Verify that the code generator makes code replacements that you expect.

1. Check for errors. At the command line, invoke the table definition file. For example:

```
tbl = crl_table_sincfn
```

```
tbl =
```

```
TflTable with properties:
```

```

 Version: '1.0'
 ReservedSymbols: []
StringResolutionMap: []
 AllEntries: [2x1 RTW.TflCFunctionEntry]
 EnableTrace: 1|

```

If an error exists in the definition file, the invocation triggers a message. Fix the error and try again.

2. Use the Code Replacement Viewer to check your code replacement entries. For example:

```
crviewer('Sin Function Example')
```

In the viewer, select entries in your table and verify that the content is what you expect. The viewer can help you detect issues such as:

- Incorrect argument order.
- Conceptual argument names that do not match what the code generator expects.
- Incorrect priority settings.

3. Identify existing model or create a model that includes a Trigonometric block that is set to the `sin` function. For example:

4. Open the model and configure it for code generation with an Embedded Coder (ERT-based) target.

5. See whether your library is listed as an available option for the **Code Generation > Interface > Code replacement library** model configuration parameter. If it is, select it.

If it is not listed, open the registration file, `rtwTargetInfo.m`. See whether you entered the correct code replacement table name when you created the file. If you hover the cursor over the selected library, a tool tip appears. This tip contains information derived from your code replacement library registration file, such as the library description and the list of tables it contains.

6. To find parameters quickly, in the Configuration Parameters dialog box **Search** field, type the parameter name. Configure the code generation report for code replacement analysis by selecting the following parameters:

- **Create code generation report**
- **Open report automatically**
- **Code-to-model**
- **Model-to-code**
- **Summarize which blocks triggered code replacements**
- **Include comments**
- **Simulink block comments**
- **Simulink block descriptions**

7. Configure the model to generate code only. Before you build an executable program, confirm that the code generator is replacing code as expected.

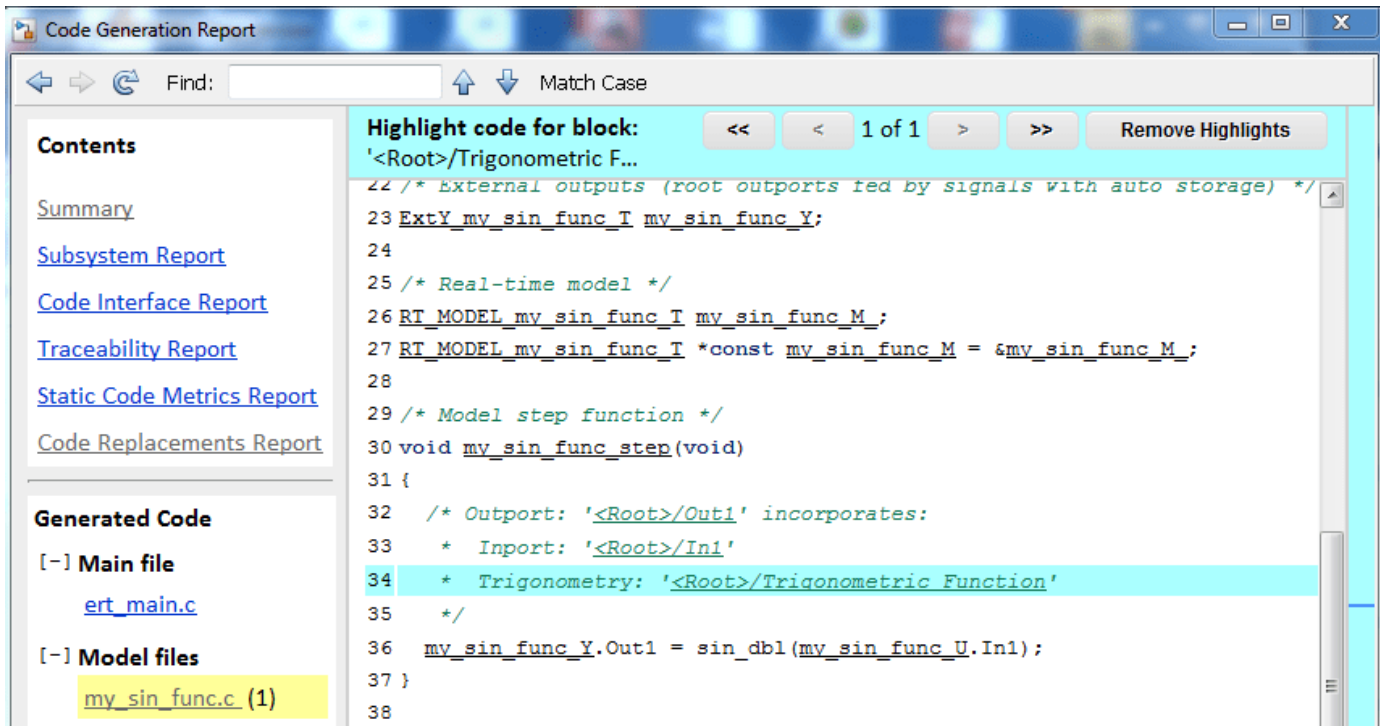

8. Generate code for the model.

9. Review code replacement results in the Code Replacement Report section of the code generation report.

The report indicates that the code generator found a match and applied the replacement code for the function `sin_dbl`.

10. Review the code replacements. In the model window, right-click the Trigonometric Function block. Select **C/C++ Code > Navigate to C/C++ Code**. The code generation report opens and highlights the code replacement in `my_sin_func.c`. In this case, the code generator replaced `sin` with `sin_dbl`.

## Semaphore and Mutex Function Replacement

You can create a code replacement table for a custom target that supports concurrent execution. Create table entries that specify custom implementations of semaphore or mutex operations. The table must have four semaphore entries, four mutex entries, or both, and include the table in a custom code replacement library. (The semaphore or mutex entries are mutually dependent. Provide them in complete sets of four.)

---

**Note** A custom target that supports concurrent multitasking must set the target configuration parameter `ConcurrentExecutionCompliant`. For more information, see “Support Concurrent Execution of Multiple Tasks”.

---

If the build process generates semaphore or mutex function calls for data transfer between tasks during code generation for a multicore target environment, use a custom library. The library can specify code replacements for custom semaphore or mutex implementations that are optimal for your target environment. Using the Code Replacement Tool (`crtool`) or equivalent code replacement functions, you can:

- Configure code replacement table entries for custom semaphore or mutex functions. During system startup, execution of the code for data transfer between tasks, and system shutdown the generated code calls these functions.
- Configure DWork arguments that represent global data, which the semaphore or mutex functions access. A DWork pointer is passed to the model entry functions.

Generated mutex and semaphore code typically consists of these elements:

Code	Generated Code
Model initialization	Initialization function call that creates a mutex or semaphore function to control entry to a critical section of code.
Model step	<ul style="list-style-type: none"> <li>• Before code for a data transfer between tasks enters the critical section, mutex lock or semaphore wait function calls reserve the critical section of code.</li> <li>• After code for a data transfer between tasks finishes executing the critical section, mutex unlock or semaphore post function calls release the critical section of code.</li> </ul>
Model termination	Optional destroy function call to delete the mutex or semaphore explicitly.

This example shows how to create code replacement table entries for a mutex replacement scenario. You configure a multicore target model for concurrent execution and for data transfer between tasks of differing rates, which Rate Transition blocks handle. In the generated code for the model, each Rate Transition block has a separate, unique mutex. Mutex lock and unlock operations within the Rate Transition block generated code share access to the same global data. They achieve this by using the unique mutex created for that Rate Transition block.

- 1 Open the **Code Replacement Tool**.
- 2 Create and open a new table.
- 3 Name the table `crl_table_rt_mutex`.

- 4 Create an entry for a mutex initialization function replacement.
  - a Select **File > New entry > Semaphore entry** to open a new table entry for configuring a semaphore or mutex replacement.
  - b In the **Mapping Information** tab, use the **Function** parameter to select `Mutex Init`. Initial default values for the table entry appear. In the **Conceptual function** section, typically you can leave the argument settings at their defaults.
  - c In the **DWork attributes** section, the **Allocate DWork** option is selected. The dialog box provides a unique entry tag for the DWork argument `d1`.

The screenshot shows a dialog box titled "DWork attributes". At the top, there is a checked checkbox labeled "Allocate DWork". Below this, there is a section for "DWork argument" containing a text field "Entry tag (unique):" with the value "entry\_25576". Underneath, there is a list box titled "DWork arguments" containing the entry "d1". To the right of the list box is a section titled "Argument properties" which includes a "Data type:" field set to "void" and a checked checkbox labeled "Pointer".

On the **DWork attributes** pane, configure a DWork argument to the replacement function. The DWork argument supports sharing of a semaphore or mutex between:

- Code that creates the semaphore or mutex
- Code that requests and relinquishes access
- Code that deletes the semaphore or mutex

In this example, the DWork argument for the `Mutex Init` function defines a unique entry tag, `entry_25576`. That function also defines DWork arguments for `Mutex Lock`, `Mutex Unlock`, and `Mutex Destroy`, which reference the entry tag to share the DWork data.

The only data type supported for the DWork **Data type** parameter is `void*`.

- d In the **Replacement function** section, enter a function name in the **Name** field. This example uses `myMutexCreate`. In the list of **Function arguments**, leave the DWork argument `d1` data type as `void**`.

The C function signature preview is:

```
void myMutexCreate (void** d1);
```

- e In the **Replacement function** section, select **Function modifies internal or global state**. This option instructs the code generator not to optimize away the implementation function described by this entry because it accesses global memory values. Click **Apply**. Optionally, you can click **Validate entry** to validate the information entered in the **Mapping Information** tab.
 

To create a sample table entry, configure the replacement function signature without the replacement function and its build information. If header and source files for these functions are available, select the **Build Information** table to specify them.
- f The `Mutex Init` table entry is complete. Optionally, you can save the table to a file, and inspect the MATLAB code created for the table definition so far.
- 5 Repeat the following sequence to create the table entries for the mutex lock, unlock, and destroy function replacements. Each table entry references the `DWork` unique tag entry, `entry_25576`, defined in the `Mutex Init` table entry.
  - a Select **File > New entry > Semaphore entry**.
  - b In the **Mapping Information** tab, use the **Function** parameter to select `Mutex Lock`, `Mutex Unlock`, or `Mutex Destroy`. Initial default values for the table entry appear. In the **Conceptual function** section, typically you can leave the argument settings at their defaults.
  - c For a Rate Transition block mutex, the wait, post, and destroy functions operate on the `DWork` allocated at system startup by the mutex initialization function. In the **DWork attributes** section, verify that the **Allocate DWork** option is cleared. From the **DWork Allocator entry** drop-down list, select the entry tag matching the value in the `Mutex Init` table entry. In this example, the entry tag is `entry_25576`.

DWork attributes

Allocate DWork

DWork Allocator entry:

- d** In the **Replacement function** section, **Name** field, enter a function name. This example uses `myMutexLock`, `myMutexUnlock`, and `myMutexDelete`. In the list of **Function arguments**, leave the DWork argument `d1` data type as `void*`.

Replacement function

Function prototype

Name:  C++ namespace:

Function returns void

Function arguments

y1(return arg)	
d1	

Argument properties

Data type:  I/O type:

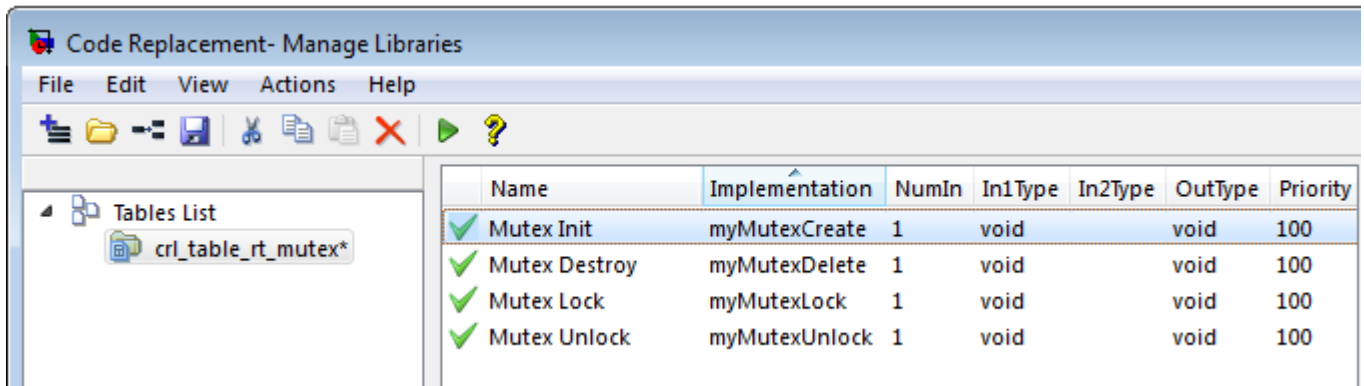

Const  Pointer  Pointer-Pointer

Alignment value:

Function signature preview

```
void myMutexLock (void* d1);
```

- e** In the **Implementation attributes** section, select the option **Function modifies internal or global state**. This option instructs the code generator not to optimize away the implementation function described by this entry because it accesses global memory values.
- f** Optionally, supply build information for the replacement function on the **Build Information** tab.
- g** Click **Apply**. In the middle pane, right-click the table entry and select **Validate entry(s)**.
- 6** When you have added the table entries for `Mutex Lock`, `Mutex Unlock`, and `Mutex Destroy` to the entry for `Mutex Init`, the rate transition mutex replacement table is complete. In the left-most pane, right-click the table name and select **Validate table**. Address errors and repeat the table validation.

- 7 Save the table to a MATLAB file in your working folder, for example, using **File > Save table**. The name of the saved file is the table name, `crl_table_rt_mutex`, with an `.m` extension. Optionally, you can open the saved file and examine the MATLAB code for the code replacement table definition.

To test this example:

- 1 Register the code replacement mapping.
- 2 Create a model that contains a rate transition for which the build process generates mutex function calls. For example:

- 3 Configure the model for a multicore target environment and the following settings:
  - On the **Solver** pane, select a fixed-step solver.
  - On the **Code Generation** pane, select an ERT-based system target file.
  - On the **Code Generation > Interface** pane, select the code replacement library that contains your mutex entry.

# Identify Code Replacement Library Requirements

## What Is a Code Replacement Library?

A code replacement library defines optimizations for generated C or C++ code from Simulink models or MATLAB code for specific targets. You can configure the code generator to use your code replacement library to replace specified functions in your model or MATLAB code with optimized implementations.

## What Functions Can Be Optimized with a Code Replacement Library?

You can use a code replacement library to optimize the performance of functions defined either by Simulink models or MATLAB code. To look up functions that are available to optimize, see “Code You Can Replace From Simulink Models” on page 69-6 and “Code You Can Replace from MATLAB Code” on page 70-5.

## How to Develop a Code Replacement Library

You can develop a code replacement library either interactively, using the **Code Replacement Tool** (crtool), or programmatically, using the MATLAB programming interface. The Code Replacement Tool is quick, easy, and ideal for first time library development, while the MATLAB Programming interface provides more customization and control options. To determine which approach to use, identify your use case below:

### Interactive Approach:

- Developing a code replacement library for the first time
- Rapid prototyping

### Programmatic Approach:

- Specifying code replacement attributes not available with the Code Replacement Tool
- Creating or modifying code replacement library entries by copying, pasting, and editing
- Modifying a registration file by copying and pasting content

## Identify Basic Requirements

- What model or MATLAB code do you want to optimize by using a code replacement library?
- What functions and operations within your model or MATLAB code do you want to replace? What is the signature for each function or operation that you want to replace?
- What build files (source, header, object) do you need to provide to the code generator?

## Define Code Replacement Library Optimizations

A code replacement library contains one or more code replacement tables. Each table contains one or more code replacement entries. Each entry contains a mapping and entry parameters. The entry maps the conceptual representation of an automatically generated MATLAB or Simulink function to an implementation representation of an optimized C or C++ function. The entry parameters describe additional properties for the code generator to honor during code replacement.

To define a code replacement library, first define code replacement tables in a customization file. Then, during the registration step, create a code replacement library by selecting tables to include in your library. You can define your code replacement tables both interactively or programmatically using the same work flow.

The interactive and programmatic approaches both follow these 8 steps:

- 1 Open the environment.
- 2 Create a table.
- 3 Create an entry.
- 4 Create entry parameters.
- 5 Create the conceptual representation.
- 6 Create the implementation representation.
- 7 Specify build information.
- 8 Validate and save.

### Interactively Develop a Code Replacement Library

- 1 Open the environment.

To interactively create a code replacement library, open the **Code Replacement Tool** (crtool) from the MATLAB command line with the command:

```
>> crtool
```

## 2 Create a table.

A code replacement table organizes code replacement entries into groupings that are easier to manage.

To create a code replacement table:

- a From the crtool menu, select **File > New table**.
- b In the right pane, name the table and click **Apply**.

## 3 Create an entry.

A code replacement table entry contains entry parameters and a mapping of a conceptual representation that describes a generated function to an implementation representation that describes an optimized implementation of that function.

To create a code replacement entry, use one of these methods:

- From the crtool toolbar, click the **entry-type** icon then select the **entry-type**.
- From the crtool menu, select **File > New entry > entry-type**.
- Right-click on a table and select **New entry > entry-type**.

The new entry appears without a name in the middle pane.

## 4 Create entry parameters.

Entry parameters specify optimization and build requirements for the code generator to honor during code replacement. These parameters vary and automatically appear in various sections of the crtool interface depending on the type of function replacement.

To create entry parameters:

- In the **Function** or **Operation** drop-down list, select the name of the function you want to replace.

This selection determines the entry parameters that appear in the crtool.

## 5 Create the conceptual representation.

The conceptual representation describes the signature of the function you want to replace. The conceptual representation consists of the function name, return arguments, and parameters. The return arguments are referred to as output arguments, and the parameters are referred to as input arguments. Specify each conceptual argument with a name, I/O type, and, depending on the type of replacement, other properties that appear in the crtool.

To define your conceptual representation:

- In the **Conceptual Function** or **Conceptual Operation** subsection of the crtool, specify the input and output arguments of the function you want the code generator to replace.

## 6 Create the implementation representation.

The implementation representation describes the signature of the replacement function defined in the code replacement library. The implementation representation consists of a function name, return arguments, and parameters. Specify each implementation argument with a type, type qualifier, and complexity.

To define your implementation representation:

- In the **Implementation Function** or **Operation Function** subsection of the crtool, specify the input and output arguments for the optimized function defined in the code replacement library.

## 7 Specify build information.

Build information provides the code generator with the files to perform function replacement.

To specify build information:

- In the crtool, click the **Build Information** tab to open the build requirements pane. Specify necessary build information in these fields:

Parameter	Description
Implementation header file	Name of header file needed for code replacement.
Implementation source file	Name of source file needed for code replacement.
Additional header files/include paths	Name and path of additional header files needed for code replacement.
Additional source files/paths	Name and path of additional source files needed for code replacement.
Additional object files/paths	Name and path of additional object files needed for code replacement.
Additional link flags	Flags the linker needs to generate an executable file for the replacement code.
Additional compile flags	Flags the compiler needs to generate object code for the replacement code.
Copy files to build directory	Flags whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. If you specify files with <b>Additional header files/include paths</b> or <b>Additional source files/ paths</b> and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files.

## 8 Validate and save.

Save your code replacement library with the same name as your code replacement table on your MATLAB path. Saving your library automatically validates unvalidated content.

To validate and save your library:

- From the crtool menu, select **File > Save Table > Save**.

## Programmatically Develop a Code Replacement Library

- 1 Open the environment.

To programmatically create a code replacement library, open a MATLAB function file. From the MATLAB menu select **New > Function**.

- 2 Create a table.

A code replacement table organizes code replacement entries into groupings that are easier to manage.

To create a code replacement table:

- a Create a function you can use to call your code replacement library table. The function should not have arguments and return a table object.
- b Create a table object with a call to `RTW.TflTable`.

```
function hTable = code_replacement_library_table()
% Create a function to call code replacement library table

%% Create a code replacement library table object
hTable = RTW.TflTable;

end
```

- 3 Create an entry.

A code replacement table entry contains entry parameters and a mapping of a conceptual representation of a generated function to the implementation representation of an optimized implementation of that function.

To create a code replacement table:

- a Identify the type of function you want to replace.
- b Call the corresponding Entry Function to create an entry in your table.

Type of Function You Want to Replace	Entry Function
Math Operation	RTW.TflCOperationEntry
Function	RTW.TflCFunctionEntry
BLAS operation	RTW.TflBlasEntryGenerator
CBLAS operation	RTW.TflCBlasEntryGenerator
Fixed-point addition and subtraction operations	RTW.TflCOperationEntryGenerator
Net slope fixed-point operation	RTW.TflCOperationEntryGenerator_NetSlope
Semaphore or mutex	RTW.TflCSemaphoreEntry
Custom function	RTW.TflCFunctionEntryML
Custom operation	RTW.TflCOperationEntryML

```
function hTable = code_replacement_library_table()
% Create a function to call code replacement library table
```

```

%% Create a code replacement library table object
hTable = RTW.TflTable;

%% Create a code replacement library entry
% Pick one from list below
hEntry = RTW.TfLCOperationEntry;
hEntry = RTW.TflCFunctionEntry;
hEntry = RTW.TflBlasEntryGenerator;
hEntry = RTW.TflCBlasEntryGenerator;
hEntry = RTW.TfLCOperationEntryGenerator;
hEntry = RTW.TfLCOperationEntryGenerator_NetSlope;
hEntry = RTW.TflCSemaphoreEntry;
hEntry = RTW.TflCFunctionEntryML;
hEntry = RTW.TfLCOperationEntryML;

end

```

#### 4 Create entry parameters.

Entry parameters specify optimization and build requirements for the code generator to honor during code replacement. These parameters vary depending on the type of function replacement.

To create your entry parameters:

- Call the Set Parameters function that corresponds with the type of function you want to replace identified in the previous step (step 3).

Type of Function You Want to Replace	Set Parameters function
Math operation, BLAS operation, CBLAS operation, Fixed-Point, Net Slope Fixed-Point, Custom operation	setTfLCOperationEntryParameters
Function, Custom function	setTflCFunctionEntryParameters
Semaphore or Mutex	setTflCSemaphoreEntryParameters

Each Set Parameter function is shown with all available properties set to their default values. The exact properties and values you need to specify depends on the function you replace. See examples for specific replacement details.

```

function hTable = code_replacement_library_table()
% Create a function to call code replacement library table

%% Create a code replacement library table object
hTable = RTW.TflTable;

%% Create a code replacement library entry
% Pick one from list below
hEntry = RTW.TfLCOperationEntry;
hEntry = RTW.TflCFunctionEntry;
hEntry = RTW.TflBlasEntryGenerator;
hEntry = RTW.TflCBlasEntryGenerator;
hEntry = RTW.TfLCOperationEntryGenerator;
hEntry = RTW.TfLCOperationEntryGenerator_NetSlope;
hEntry = RTW.TflCSemaphoreEntry;
hEntry = RTW.TflCFunctionEntryML;
hEntry = RTW.TfLCOperationEntryML;

```

```

%% Create entry parameters
% Pick one from list below
hEntry.setTflCOperationEntryParameters(...
 'Key', ...,
 'Priority', 100, ...
 'AcceptExprInput', true, ...
 'AdditionalHeaderFiles', {}, ...

 'RoundingModes', 'RTW_ROUND_UNSPECIFIED', ...
 'SaturationMode', 'RTW_SATURATE_UNSPECIFIED', ...
 'SideEffects', false, ...
 'StoreFcnReturnInLocalVar', false);

end

```

##### 5 Create the conceptual representation.

The conceptual representation describes the signature of the function you want to replace. It consists of the function name, return arguments, and parameters. The return arguments are referred to as output arguments, and the parameters are referred to as input arguments. Specify each conceptual argument with the required properties, and, depending on the type of replacement, other optional properties.

Required properties:

- **Name**- Defined as y1..yn for output arguments and u1..un for input arguments
- **I/O type**- Defined as RTW\_IO\_OUTPUT or RTW\_IO\_INPUT

To define your conceptual representation, use one of these approaches:

Approach	Function	Goal
1	createAndAddConceptualArg	Customization and control. If you want to explicitly specify arguments as scalar or matrix and other properties.
2	getTfLArgFromString	Rapid prototyping. If you want to quickly specify arguments with built-in data types.

Programming approaches are shown with all available properties set to default values. The exact properties and values you need to specify depends on the function you replace. See examples for specific replacement details.

```

function hTable = code_replacement_library_table()
% Create a function to call code replacement library table

%% Create a code replacement library table object
hTable = RTW.TflTable;

%% Create a code replacement library entry
% Pick one from list below
hEntry = RTW.TflCOperationEntry;
hEntry = RTW.TflCFunctionEntry;
hEntry = RTW.TflBlasEntryGenerator;
hEntry = RTW.TflCBlasEntryGenerator;
hEntry = RTW.TflCOperationEntryGenerator;
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;
hEntry = RTW.TflCSemaphoreEntry;
hEntry = RTW.TflCFunctionEntryML;
hEntry = RTW.TflCOperationEntryML;

%% Create entry parameters
% Pick one from list below
% To view properties, see step 4
hEntry.setTflCOperationEntryParameters();
hEntry.setTflCFunctionEntryParameters();
hEntry.setTflCSemaphoreEntryParameters();

%% Create the conceptual representation

% Approach 1: createAndAddConceptualArg
% arg = createAndAddConceptualArg(hEntry, argType, varargin)
% argType - 'RTW.TflArgNumeric' | 'RTW.TflArgMatrix'
% varargin - 'name', 'value' pairs shown below set to default values,
% includes name and I/O type

% Define Output Arguments
hEntry.createAndAddConceptualArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', true, ...
 'WordLength', 32, ...
 'CheckSlope', true, ...
 'CheckBias', true, ...
 'DataTypeMode', 'Fixed-point:binary point scaling', ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'Slope', 1, ...
 'SlopeAdjustmentFactor', 1.0, ...
 'FixedExponent', -15, ...
 'Bias', 0.0, ...
 'FractionLength', 15, ...
 'BaseType', 'double', ...
 'DimRange', [2,2]);

% Define Input Arguments
hEntry.createAndAddConceptualArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...

```

```

 'IsSigned', true, ...
 'WordLength', 32, ...
 'CheckSlope', true, ...
 'CheckBias', true, ...
 'DataTypeMode', 'Fixed-point:binary point scaling', ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'Slope', 1, ...
 'SlopeAdjustmentFactor', 1.0, ...
 'FixedExponent', -15, ...
 'Bias', 0.0, ...
 'FractionLength', 15, ...
 'BaseType', 'double', ...
 'DimRange', [2,2]);

% Approach 2: getTflArgFromString
% arg = getTflArgFromString(hEntry, name, I/O type)
% name- y1..yn | u1..un
% I/O type- RTW_IO_OUTPUT | RTW_IO_INPUT

% Define Output Arguments
arg = getTflArgFromString('y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.addConceptualArg(arg);

% Define Input Arguments
arg = getTflArgFromString('u1', 'double');
arg.IOType = 'RTW_IO_INPUT';
hEntry.addConceptualArg(arg);

end

```

## 6 Create the implementation representation.

The implementation representation describes the signature of the replacement function defined by the code replacement library. It consists of the function name, return arguments, and parameters. Specify the implementation arguments with a type, type qualifier, and complexity. After you define your implementation representation, add your completed entry to the code replacement table with a call to the function `addEntry`.

To define your implementation representation, use one of these approaches:

Approach	Function	Goal
1	<code>copyConceptualArgsToImplementation</code>	Identical arguments.  Specify implementation arguments and conceptual arguments have the same properties.
2	<code>createAndAddImplementationArg</code> <code>createAndSetCImplementationReturn</code>	Same order, different properties.  Specify implementation arguments have the same order as conceptual arguments but have different properties.

Approach	Function	Goal
3	getTflArgFromString	Add constant value.  Specify implementation arguments with a constant value.
4	getTflDWorkFromString	Mutex/Semaphore replacement.  Specify implementation arguments for mutex or semaphore functions.
5	createCRLEntry	Create entry with one function.  Declare and define a code replacement table entry (conceptual and implementation arguments) in one function.

Programming approaches are shown with all available properties set to their default values. The exact properties and values you need to specify depends on the function you replace. See examples for specific replacement details.

```
function hTable = code_replacement_library_table()
% Create a function to call code replacement library table

%% Create a code replacement library table object
hTable = RTW.TflTable;

%% Create a code replacement library entry
% Pick one from list below
hEntry = RTW.TflCOperationEntry;
hEntry = RTW.TflCFunctionEntry;
hEntry = RTW.TflBlasEntryGenerator;
hEntry = RTW.TflCBlasEntryGenerator;
hEntry = RTW.TflCOperationEntryGenerator;
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;
hEntry = RTW.TflCSemaphoreEntry;
hEntry = RTW.TflCFunctionEntryML;
hEntry = RTW.TflCOperationEntryML;

%% Create entry parameters
% Pick one from list below
% To view properties, see step 4
hEntry.setTflCOperationEntryParameters();
hEntry.setTflCFunctionEntryParameters();
hEntry.setTflCSemaphoreEntryParameters();

%% Create the conceptual representation

% Approach 1: createAndAddConceptualArg
% arg = createAndAddConceptualArg(hEntry, argType, varargin)
% argType - 'RTW.TflArgNumeric' | 'RTW.TflArgMatrix'
% varargin - 'name', 'value' pairs shown below set to default values,
% includes name and I/O type, to view properties, see step 5

% Define Output Arguments
hEntry.createAndAddConceptualArg();
```

```

% Define Input Arguments
hEntry.createAndAddConceptualArg();

% Approach 2: getTflArgFromString
% arg = getTflArgFromString(hEntry, name, I/O type)
% name- y1..yn | u1..un
% I/O type- RTW_IO_OUTPUT | RTW_IO_INPUT

% Define Output Arguments
arg = getTflArgFromString('y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.addConceptualArg(arg);

% Define Input Arguments
arg = getTflArgFromString('u1', 'double');
arg.IOType = 'RTW_IO_INPUT';
hEntry.addConceptualArg(arg);

%% Create the implementation representation

% Approach 1: copyConceptualArgsToImplementation
copyConceptualArgsToImplementation(hEntry);

% Approach 2: createAndSetCImplementation, createAndSetCImplementationArg
% arg = createAndAddImplementation(hEntry, argType,varargin),
% arg = createAndSetCImplementationReturn(hEntry, argType,varargin)
% argType - 'RTW.TflArgNumeric' | 'RTW.TflArgMatrix'
% varargin - 'name', 'value' pairs shown below set to default values,
% includes name and I/O type

% Define Output Arguments
hEntry.createAndSetCImplementationReturn(...
 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'DataTypeMode', 'Fixed-point:binary point scaling', ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'Slope', 1.0, ...
 'SlopeAdjustmentFactor', 1.0, ...
 'FixedExponent', -15, ...
 'Bias', 0.0, ...
 'FractionLength', 15, ...
 'Value', 0);

% Define Input Arguments
hEntry.createAndAddImplementationArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...

```

```

 'IsSigned', true, ...
 'WordLength', 16, ...
 'DataTypeMode', 'Fixed-point:binary point scaling', ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'Slope', 1.0, ...
 'SlopeAdjustmentFactor', 1.0, ...
 'FixedExponent', -15, ...
 'Bias', 0.0, ...
 'FractionLength', 15, ...
 'Value', 0);

% Approach 3: getTflArgFromString
% arg = getTflArgFromString(hEntry, name, datatype)
% name- y1..yn | u1..un, datatype - built-in data type

% Define Output arguments
arg = getTflArgFromString(hEntry, 'y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.Implementation.setReturn(arg);

% Define Input arguments
arg = getTflArgFromString(hEntry, 'u1', 'double', 0);
hEntry.Implementation.addArgument(arg);

% Approach 4: getTflDWorkFromString
% arg = getTflDWorkFromString(hEntry, name, datatype)

% Define arguments
arg = getTflDWorkFromString('d1', 'void*');
hEntry.addDWorkArg(arg);

% Approach 5: createCRLEntry
% tableEntry = createCRLEntry(crTable,conceptualSpecification,implementationSpecification)

% Define code replacement conceptual and implementation arguments
hEntry = createCRLEntry(...
 hTable, ...
 'conceptualSpecification', ...
 'implementationSpecification');

%% Add code replacement library entry to table
hTable.addEntry(hEntry);

end

```

## 7 Specify build information.

Specify build information for your code replacement library. Build information provides the code generator with the files necessary to perform function replacement.

To specify build information:

- Specify your build parameters in the Entry Parameters function you defined in step 4 or with the specified functions. Specify build information with the following properties:

Parameter	Description
Implementation header file Set properties <code>ImplementationHeaderFile</code> and <code>ImplementationHeaderPath</code> .	Name of header file needed for code replacement.
Implementation source file Set properties <code>ImplementationSourceFile</code> and <code>ImplementationSourcePath</code> .	Name of source file needed for code replacement.
Additional header files/include paths For each file, specify the file name and path in calls to the functions <code>addAdditionalHeaderFile</code> and <code>addAdditionalIncludePath</code> .	Name and path of additional header files needed for code replacement.
Additional source files/paths For each file, specify the file name and path in calls to the functions <code>addAdditionalSourceFile</code> and <code>addAdditionalSourcePath</code> .	Name and path of additional source files needed for code replacement.
Additional object files/paths For each file, specify the file name and path in calls to the functions <code>addAdditionalLinkObj</code> and <code>addAdditionalLinkObjPath</code> .	Name and path of additional object files needed for code replacement.
Additional link flags Set the entry property <code>AdditionalLinkFlags</code> to a cell array of character vectors or string array representing the required compile flags.	Flags the linker needs to generate an executable file for the replacement code.
Additional compile flags Set the entry property <code>AdditionalCompileFlags</code> to a cell array of character vectors or string array representing the required link flags.	Flags the compiler needs to generate object code for the replacement code.

Parameter	Description
<p>Copy files to build directory.</p> <p>Set property <code>GenCallback</code> to <code>'RTW.copyFileToBuildDir'</code>.</p> <p>If a match occurs for a table entry, a call to the function <code>RTW.copyFileToBuildDir</code> copies required files to the build folder.</p> <p>If you specify additional header files/include paths or additional source files/paths and you copy files, the compiler and utilities such as <code>packNGo</code> might find duplicate instances of files.</p>	<p>Flags whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. If you specify files with <b>Additional header files/include paths</b> or <b>Additional source files/ paths</b> and you copy files, the compiler and utilities such as <code>packNGo</code> might find duplicate instances of files.</p>

- If an entry uses header, source, or object files, consider whether to make the files accessible to the code generator. You can copy files to the build folder or you can specify individual file names and paths explicitly.
- If you specify *additional* header files/include paths or source files/paths and you copy files, the compiler and utilities such as `packNGo` might find duplicate instances of files (an instance in the build folder and an instance in the original folder).
- If you choose to copy files to the build folder and you are using the `packNGo` function to relocate static and generated code files to another development environment:
  - In the call to `packNGo`, specify the property-value pair `'minimalHeaders' true` (the default). That setting instructs the function to include the minimal header files required to build the code in the zip file.
  - Do not collocate files that you copy with files that you do not copy. If the `packNGo` function finds multiple instances of the same file, the function returns an error.
- If you use the programming interface, paths that you specify can include tokens. A token is a variable defined as a character vector, cell array of character vectors, or string array in the MATLAB workspace that you enclose with dollar signs (`$variable$`). The code generator evaluates and replaces a token with the defined value. For example, consider the path `$myfolder$\folder1`, where `myfolder` is a character vector or string scalar variable defined in the MATLAB workspace as `'d:\work\source\module1'`. The code generator generates the custom path as `d:\work\source\module1\folder1`.

## 8 Validate and save.

Save your code replacement library customization file with the same name as your code replacement library table on your MATLAB path.

To save and validate your library:

- Save your file. From the MATLAB menu, select **File > Save**.
- Validate your library by calling it from the MATLAB command line. For example:

```
>> hTable = code_replacement_library_table()
```

## Register Code Replacement Library

Create a code replacement library by defining in a registration file the library name, code replacement tables, and other information. After you define and register your library it becomes available to the code generator for code replacement.

### Interactively Develop and Load a Registration file

- 1 In the crtool, select **File > Generate registration file**.

- 2 In the **Generate registration file** dialog box, specify registration information. Then click **OK**.

Parameter	Description
Registry name (Required)	Code replacement library name.
Table list (Required)	Comma-separated list of one or more code replacement tables that you want in the library. Specify tables by using either their names (if located on the MATLAB search path), absolute paths, or relative paths.
Base CRL	Enables you to specify library hierarchies. Provide the name of a registered library to serve as a base for the library that you are currently registering. For example, a TI device library can be a base for a TI C28x library.
Target HW device	Comma-separated list of one or more hardware devices that this library supports. Indicate support of all devices with an asterisk (*).
Description	Description of the purpose and content of the library.
Generate data alignment specification	Flag that enables data alignment.

- To use your registered code replacement library, refresh your current MATLAB session with the command:

```
>> sl_refresh_customizations
```

## Programmatically Develop and Load a Registration File

- Open a MATLAB function file. From the MATLAB menu, select **New > Function**.
- Save the function file with the name `rtwTargetInfo.m`.
- Copy and paste the following code into your file to use as a template.

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry; %instantiates a registration entry
this(1).Name = 'Example Code Replacement Library';
this(1).TableList = {'example_code_replacement_table.m'};
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'This registers an example library';

end
```

- In the template, specify the following registration information:

Parameter	Description
Registry name (Required)	Code replacement library name.
Table list (Required)	Comma-separated list of one or more code replacement tables that you want in the library. Specify tables by using either their names (if located on the MATLAB search path), absolute paths, or relative paths.
Base CRL	Enables you to specify library hierarchies. Provide the name of a registered library to serve as a base for the library that you are currently registering. For example, a TI device library can be a base for a TI C28x library.
Target HW device	Comma-separated list of one or more hardware devices that this library supports. Indicate support of all devices with an asterisk (*).
Description	Description of the purpose and content of the library.
Generate data alignment specification	Flag that enables data alignment.

- Save the file on your MATLAB path.
- To use your registered code replacement library, refresh your current MATLAB session with the command:

```
>> sl_refresh_customizations
```

## Examples

### Register one code replacement library

```
function rtwTargetInfo(cm)
cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry; %instantiates a registration entry
this(1).Name = 'Example Code Replacement Library';
this(1).TableList = {'example_code_replacement_table.m'};
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'This registers an example library';

end
```

### Register multiple code replacement libraries

```
function rtwTargetInfo(cm)
cm.registerTargetInfo(@loc_register_crl);
end

function thisCRL = loc_register_crl
% Register a code replacement library for use with model: rtwdemo_crladdsub
thisCrl(1) = RTW.TflRegistry;
thisCrl(1).Name = 'Addition & Subtraction Examples';
thisCrl(1).Description = 'Example of addition/subtraction op replacement';
thisCrl(1).TableList = {'crl_table_addsub'};
thisCrl(1).TargetHWDeviceType = {'*'};

% Register a code replacement library for use with model: rtwdemo_crlmuldiv
thisCrl(2) = RTW.TflRegistry;
thisCrl(2).Name = 'Multiplication & Division Examples';

## Verify Code Replacement Library

Verify your code replacement library by examining its structure, replacement, and performance. Use the Code Replacement Viewer (crviewer) to verify the structure of your library. Use the code replacement report to verify the replacements made with your library in generated code. Use crviewer again to verify the performance of your library during code generation by examining the replacement hit and miss logs.

### Verify Library Structure

Use the Code Replacement Viewer (crviewer) to open and view the structure of your code replacement library by examining its tables and table entries.

- 1 From the MATLAB command prompt, open your code replacement library using the crviewer with the command:
 

```
>> crviewer('library')
```
- 2 The viewer opens your code replacement library and shows its code replacement tables in the left pane. Verify that your library lists all required tables in the correct relative order.
- 3 Open and view the entries for each code replacement table. In the crtool, click each table listed in the left pane to view its entries in the middle pane.

If you are not using the crviewer, you can open each table directly from the MATLAB command prompt with the command:

```
crviewer(table)
```

- 4 For each table in your library, verify that it lists all required entries in the correct relative order. Verify that the conceptual representation and implementation representation are correct for each entry in the table.

### Verify Library Replacement

Use the Code Replacements Report to verify that when the code generator uses your code replacement library it creates replacements as expected in the generated code. For each instance of replacement, the Code Replacements Report provides a mapping between the Simulink block that triggered the replacement and its implementation in the generated code. Use this mapping to verify correct code replacement by tracing between the report and the code in either direction (from report to code or code to report).

To generate the Code Replacements Report:

- 1 Configure your model to use your code replacement library.
- 2 Configure your model to open the Code Generation Report. The Code Replacements Report is a tab within this report. In the Model Configuration Parameters dialog box, in the **Code Generation > Report** pane, select:
  - **Create code generation report**
  - **Open report automatically**
  - **Model-to-code**
  - **Summarize which block triggered code replacements**

- 3 Configure the generated code to include comments. In the Model Configuration Parameters dialog box, in the **Code Generation > Comments** pane, select:
  - **Include comments**
  - Either or both of **Simulink block comments** and **Simulink block descriptions**
- 4 Build your model to generate code only. The Code Generation Report opens automatically. On the left pane, click to open the Code Replacements Report.
- 5 Verify that code replacements occur as expected.
  - **Navigate from report to model:** In the Code Replacements Report, click each block link to see the source that triggered replacement.
  - **Navigate from model to report:** In the Simulink model window, use model-to-code highlighting to trace code replacements. Right-click blocks where you expected code replacement to occur and select **C/C++ Code > Navigate to C/C++ Code**. The report appears with the corresponding replacement code highlighted.

## Verify Library Performance

Verify the performance of your code replacement library by examining the hits and misses that occurred during code generation using your library. During code generation, when the code generator finds a match for code replacement from your code replacement library, it logs the hit in a hit cache. When it does not find a code replacement match, it logs the failed attempt in the miss cache. Each time that you generate code, the code generator overwrites its previous hit and miss cache logs.

To review trace information from the hit and miss cache data, use the Code Replacement Viewer (crviewer). From the hit cache, you can identify when code replacement successfully occurred, and from the miss cache, you can troubleshoot when code replacement did not take place. The miss cache trace information provides you information about the reason for the miss, a link to the relevant source location for the miss, and the call site object of the miss. For more information, see “Troubleshoot Code Replacement Misses” on page 69-59.

## Deploy Code Replacement Library

Package and deploy your code replacement library.

- 1** Move your code replacement library customization and registration files to a location on the MATLAB® search path that is accessible to other users. If another registration file already exists in that location, copy and paste the information for your code replacement library into the existing registration file.
- 2** Refresh your session and verify that the library is available as a configuration option for the code generator.
- 3** Verify that code replacement occurs as expected in generated code.
- 4** Inform users that the code replacement library is available.

## Troubleshoot Code Replacement Library Registration

If a code replacement library is not listed as a configuration option or does not appear in the Code Replacement Viewer:

- Refresh the library registration information within the current MATLAB session (RTW.TargetRegistry.getInstance('reset'); or for the Simulink environment,sl\_refresh\_customizations).
- See whether the registration file, rtwTargetInfo.m, contains an error.

- “Register Code Replacement Library” on page 69-51

## Troubleshoot Code Replacement Misses

Use miss reason messages that appear in the **Code Replacement Viewer** to analyze and correct code replacement misses.

### Miss Reason Messages

The Code Replacement Viewer displays miss reason messages in trace information for code replacement misses. A legend listing each message that appears in the miss report precedes the report details. A message consists of:

- Numeric identifier, which identifies the message in the report details.
- Message text, which in some cases includes placeholders for names of arguments, call site object values, table entry values, and property names.

For example:

1. Mismatched data types (argument name, CS0 value, table entry value)

The parenthetical information represents placeholders for actual values that appear in the report details.

In the **Miss Source Locations** table that lists the miss details, the **Reason** column includes:

- The message identifier, as listed in the legend.
- The placeholder values for that instance of the miss reason message.

The following **Reason** details indicate a data type mismatch because the call site object specifies data type `int8` for arguments `y1`, `u1`, and `u2`, while the code replacement table entry specifies `uint32`.

1. `y1, int8, uint32`  
`u1, int8, uint32`  
`u2, int8, uint32`

Depending on your situation and the reported miss reason, troubleshoot reported misses by looking for instances of the following:

- A typo in the code replacement table entry definition or a source parameter setting.
- Information missing from the code replacement table entry or a source parameter setting.
- Invalid or incorrect information in the code replacement table entry definition or a source parameter setting.
- Arguments incorrectly ordered in the code replacement table entry definition or the source being replaced with replacement code.
- Failed algorithm classification for an addition or subtraction operation due to:
  - An ideal accumulator not being calculated because the type of an input argument is not fixed-point or the slope adjustment factors of the input arguments are not equal.
  - Input or output casts with a floating-point cast type.
  - Input or output casts with cast types that have different slope adjustment factors or biases.
  - Output casts not being convertible to a single output cast.

- Input casts resulting in loss of bits.

## Analyze and Correct Code Replacement Misses

The following example shows how to use Code Replacement Viewer trace information to troubleshoot code replacement misses. You must have already reviewed and tested code replacements for your model.

- 1 Review the code generated for a model element, looking for expected code replacements. For this example, examine the code generated for block Sub32 in model `rtwdemo_crladdsub`. Right-click the block and select **C/C++ Code > Navigate to C/C++ Code**.

The Code Generation Report opens to the location of the generated code for that block.

```

63 /* Output: '<Root>/Out5' incorporates:
64 * Inport: '<Root>/In10'
65 * Inport: '<Root>/In9'
66 * Sum: '<Root>/Sub32'
67 */
68 rtY.Out5 = s32_sub_s32_s32(rtU.In9, rtU.In10);

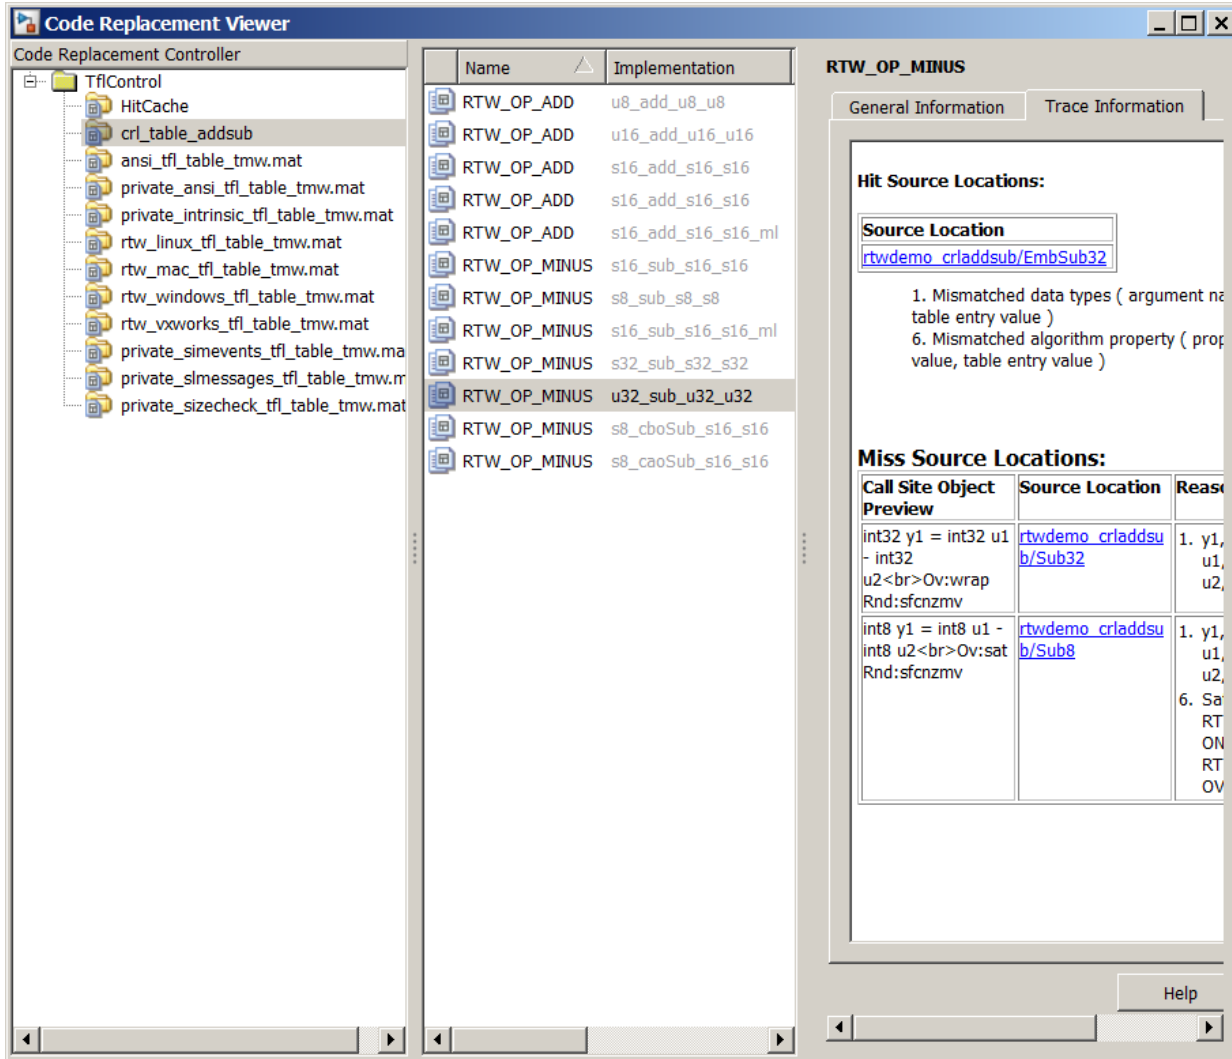

```

The code generator replaced code, but the replacement was for the signed version of the 32-bit subtraction operation. You expected an unsigned operation.

- 2 Regenerate or reopen the Code Replacements Report for your model. If you already generated the code generation report that includes the Code Replacements Report for model `rtwdemo_crladdsub`, open the file `rtwdemo_crladdsub_ert_rtw/html/index.html`. For information on how to regenerate the report, see “Verify Code Replacement Library” on page 69-55.
- 3 Click the link to open the Code Replacement Viewer.
- 4 In the viewer left pane, select your code replacement table. The following display shows entries for code replacement table `crl_table_addsub`.

- 5 In the middle pane, select table entry RTW\_OP\_MINUS with implementation function u32\_sub\_u32\_u32.
- 6 In the right pane, select the **Trace Information** tab.

The **Trace Information** is a table that lists the following information for each miss:

- Call site object preview. The call site object is the conceptual representation of a subtraction operator. The code generator uses this object to query the code replacement library for a match.
- A link to the source location in the model for which the code generator considered replacing code.
- The reasons that the miss occurred. For the list of reasons that misses occur, see “Miss Reason Messages” on page 69-59.

For this example, the report shows misses for two blocks: Sub32 and Sub8.

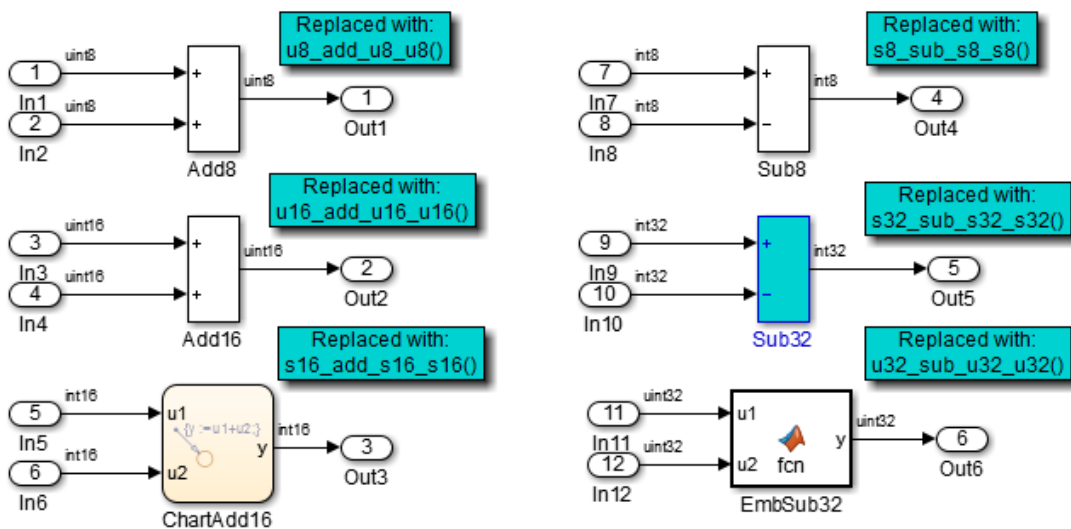

- 7 Find that source in the trace information. Depending on your situation and the reported miss reason, consider looking for a condition such as a typo in the code replacement table entry

definition or in a source parameter setting. “Miss Reason Messages” on page 69-59 lists conditions to consider.

For this example, determine why code for the Sub32 block was not replaced with code for an unsigned 32-bit subtraction operation. The miss reason for the Sub32 block indicates a data type mismatch. The data type in the call site object for the three arguments is a signed 32-bit integer. The code replacement entry specifies an unsigned 32-bit integer.

- 8 Correct the model or code replacement table entry. If the issue is in the model, use the source location link in the trace information to find the model element to correct. For this example, you expected an unsigned subtraction operation for the Sub32 block. Click the link in the trace report for the Sub32 block.

The model opens with the Sub32 block highlighted.

Change the data type setting for the two input signals and the output signal for the Sub32 block to `uint32`.

- 9 Regenerate code. Use the Code Replacement Viewer trace information to verify that your model or code replacement table entry corrects the code replacement issue. In the following display, the trace information shows a hit for block Sub32.

## Math Function Code Replacement

This example shows how to develop a code replacement library to optimize the performance of math functions by providing information on how to define code replacement for a `sin` function. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

### Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:  

```
>>crtool
```
- 2 Create a table.
  - a From the crtool context menu, select **File > New Table**.
  - b In the right pane, name the table `crl_table_sin`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Function**.
- 4 Create entry parameters. In the **Function** drop-down list, select `sin`. Algorithm information appears in the crtool. For this example, leave the parameter unspecified.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1`, with the **Data Type** of `double` and the **Argument Type** of `Scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. Click the **Mapping Information** tab and verify the fields are filled in as shown. Click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
  - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_sin
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCFunctionEntry`.

```
function hTable = crl_table_sin
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = rtw.TflCFunctionEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_table_sin()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'sin', ...
 'Priority', 30, ...
 'ImplementationName', 'mySin', ...
 'ImplementationHeaderFile', 'basicMath.h', ...
 'ImplementationSourceFile', 'basicMath.c');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `createAndAddConceptualArg`.

```
function hTable = crl_table_sin()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'sin', ...
 'Priority', 30, ...
 'ImplementationName', 'mySin', ...
 'ImplementationHeaderFile', 'basicMath.h', ...
 'ImplementationSourceFile', 'basicMath.c');
```

```
%% Create the conceptual representation
hEntry.createAndAddConceptualArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'y1',...
 'IOType', 'RTW_IO_OUTPUT',...
 'DataTypeMode', 'double');
```

```
hEntry.createAndAddConceptualArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT',...
 'DataTypeMode', 'double');
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `copyConceptualArgsToImplementation`. Add the complete entry to the table by calling the function `addEntry`.

```

function hTable = crl_table_sin()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'sin', ...
 'Priority', 30, ...
 'ImplementationName', 'mySin', ...
 'ImplementationHeaderFile', 'basicMath.h', ...
 'ImplementationSourceFile', 'basicMath.c');

%% Create the conceptual representation
hEntry.createAndAddConceptualArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'DataTypeMode', 'double');

hEntry.createAndAddConceptualArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'DataTypeMode', 'double');

%% Create the Implementation Representation
copyConceptualArgsToImplementation(hEntry);

%% Add the entry to the table
hTable.addEntry(hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_sin
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) with these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for sin function replacement';
this(1).TableList = {'crl_table_sin.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

```

```
end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Generate Code by Using Math Code Replacement Library

In this section, you generate code using the code replacement library that you created in the first two sections of this example. A math function `sin` is replaced with a call to a custom function in the generated code. This example does not provide an implementation function. Write your own implementation.

### Example Model

Open the model `crl_mathfunction` for configuring the code replacement library.

```
open_system('crl_mathfunction');
```

```
copyfile mathFnRtwTargetInfo.txt rtwTargetInfo.m
```

Run the MATLAB® customization file to create a code replacement table and register the file. The customization file has already been executed. Run the `sl_refresh_customizations` function to register the library.

```
sl_refresh_customizations;
```

### Enable Code Replacement Library

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Interface** pane, set **Code Replacement Library** by clicking **Select** and adding CRL for `sin` function replacement to the **Selected code replacement libraries - prioritized** list pane. Alternatively, use the command-line API to enable the code replacement:

```
set_param('crl_mathfunction', 'CodeReplacementLibrary', 'CRL for sin function replacement');
```

Generate code from the model:

```
evalc('slbuild(''crl_mathfunction'')');
```

View the generated code. Here is a portion of `crl_mathfunction.c`.

```
cfile = fullfile('crl_mathfunction_ert_rtw','crl_mathfunction.c');
rtwdemodbtype(cfile,'/* Model step function ','/* Model initialize function',1, 1);
```

```
/* Model step function */
void crl_mathfunction_step(void)
{
 /* Output: '<Root>/Y1' incorporates:
 * Inport: '<Root>/U1'
 * Trigonometry: '<Root>/Trigonometric Function'
 */
 crl_mathfunction_Y.Y1 = mySin(crl_mathfunction_U.U1);
}
```

The `sin` function is replaced with a custom `mysin` function.

Close the model and code generation report.

```
delete ./rtwTargetInfo.m
bdclose('crl_mathfunction');
rtwdemoclean;
```

## Buffer Index Calculation Code Replacement

This example shows how to develop a code replacement library to optimize the performance of the buffer index calculation for a Delay block. Optimize the buffer index calculation by defining a code replacement for the circular index calculation function. To develop a code replacement library, use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

### Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool). At the MATLAB command line, enter:  

```
>>crtool
```
- 2 Create a table.
  - a From the crtool context menu, select **File > New Table**.
  - b In the right pane, name the table `crl_table_circularIndex`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Function**.
- 4 Create entry parameters. In the **Function** drop-down list, select `circularIndex`.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input arguments, `u1`, `u2`, and `u3`, that use the **Data Type** of `int32` and the **Argument Type** of `Scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.
- 7 Specify the name of the replacement function. In the **Replacement Function** section, set **Name** to `myCircularIndexFunc`.
- 8 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 9 Validate and save the table. Click the **Mapping Information** tab and verify that the fields are filled in as shown. Click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

**10** Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

- **Registry name** — CRL for circular buffer index replacement
- **Table list** — crl\_table\_circularIndex
- **Description** — Example code replacement library

To use your code replacement library, refresh your current MATLAB session. At the command line, enter:

```
>>sl_refresh_customizations
```

**11** Verify the code replacement library. At the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
  - b Create a table object by calling `RTW.TfTable`.

```

function hTable = crl_table_circularIndex()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

```

- 3** Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCFunctionEntry`.

```

function hTable = crl_table_circularIndex()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

```

```

%% Create an entry
hEntry = rtw.TflCFunctionEntry;

```

- 4** Create entry parameters. Because this example replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```

function hTable = crl_table_circularIndex()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

```

```

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

```

```

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'circularIndex', ...
 'Priority', 30, ...
 'ImplementationName', 'myCircularIndexFunc');

```

- 5** Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `createAndAddConceptualArg`.

```

function hTable = crl_table_circularIndex()
% Create a code replacement library table

```

```

%% Create a table object
hTable = RTW.TflTable;

```

```

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

```

```

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'circularIndex', ...
 'Priority', 30, ...
 'ImplementationName', 'myCircularIndexFunc');

```

```

%% Create the conceptual representation
hEntry.createAndAddConceptualArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...

```

```

 'DataTypeMode', 'int32');

hEntry.createAndAddConceptualArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT',...
 'DataTypeMode', 'int32');

hEntry.createAndAddConceptualArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT',...
 'DataTypeMode', 'int32');

hEntry.createAndAddConceptualArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'u3', ...
 'IOType', 'RTW_IO_INPUT',...
 'DataTypeMode', 'int32');

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `copyConceptualArgsToImplementation`. Add the complete entry to the table by calling the function `addEntry`.

```

function hTable = crl_table_circularIndex()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflFunctionEntry;

%% Create entry parameters
hEntry.setTflFunctionEntryParameters(...
 'Key', 'circularIndex', ...
 'Priority', 30, ...
 'ImplementationName', 'myCircularIndexFunc');

%% Create the conceptual representation
hEntry.createAndAddConceptualArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'y1',...
 'IOType', 'RTW_IO_OUTPUT',...
 'DataTypeMode', 'int32');

hEntry.createAndAddConceptualArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT',...
 'DataTypeMode', 'int32');

hEntry.createAndAddConceptualArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT',...

```

```

 'DataTypeMode', 'int32');

hEntry.createAndAddConceptualArg(...
 'RTW.TflArgNumeric', ...
 'Name', 'u3', ...
 'IOType', 'RTW_IO_INPUT',...
 'DataTypeMode', 'int32');

%% Create the Implementation Representation
copyConceptualArgsToImplementation(hEntry);

%% Add the entry to the table
hTable.addEntry(hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator requires for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. At the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_circularIndex
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) by using these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for circular index calculation replacement';
this(1).TableList = {'crl_table_circularIndex.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session. At the command line, enter:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. At the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Generate Code by Using Circular Index Code Replacement Library

Generate code by using the code replacement library that you previously created in this example. The code that calculates the circular index for a delay buffer is replaced with a call to a custom function in the generated code. This example does not provide an implementation function. Write your own implementation or use the target specific implementation.

### Example Model

The example model contains a Delay block with these properties:

- **Delay length** — Input port
- **Input processing** — Columns as channels (frame-based)
- **Use circular buffer for state** — On

The Delay block receives a 32 by 2 data input signal and a scalar delay length input signal. To replace the buffer index calculation, for the Delay block, you must enable **Use circular buffer for state** enabled and use frame-based input processing. Frame-based input processing requires DSP System Toolbox. For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

### Enable Code Replacement Library

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Interface** pane, set **Code Replacement Library** by clicking **Select**. Add CRL for circular index calculation replacement to the **Selected code replacement libraries - prioritized** list pane. Alternatively, use the command-line API to enable the code replacement.

```
set_param('delayModel', 'CodeReplacementLibrary', 'CRL for circular index calculation');
```

- 3 Generate code from the model.

View the generated code. The portion of `delayModel.c` that calculates the buffer index uses the replacement function `myCircularIndexFunc`.

```
/* Update for Delay: '<Root>/Delay' incorporates:
 * Inport: '<Root>/Input'
 */
currIdx = rtDW->CircBufIdx;
for (frameIdx = 0; frameIdx < 32; frameIdx++) {
 rtDW->Delay_DSTATE[currIdx] = rtInput[frameIdx];
 rtDW->Delay_DSTATE[currIdx + 200] = rtInput[frameIdx + 32];
 currIdx = myCircularIndexFunc(currIdx, 1, 200);
}

if (rtDW->CircBufIdx < 168) {
 rtDW->CircBufIdx += 32;
} else {
 rtDW->CircBufIdx -= 168;
}

/* End of Update for Delay: '<Root>/Delay' */
```

## Memory Function Code Replacement

This example shows how to develop a code replacement library to optimize the performance of memory functions by providing information on how to define code replacement for a memcpy function. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

### Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```

- 2 Create a table.

- a From the crtool context menu, select **File > New Table**.

- b In the right pane, name the table `cr1_table_memcpy`. Click **Apply**.

- 3 Create an entry. From the crtool context menu, select **File > New entry > Function**.

- 4 Create entry parameters. In the **Function** drop-down list, select `memcpy`.

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, with the **Data Type** of `void` and the **Argument Type** of `Pointer`, the input arguments, `u1` and `u2` with the **Data Type** of `void` and the **Argument Type** of `Pointer` and `u3` with the **Data Type** of `unsigned integral` and the **Argument Type** of `Scalar`.

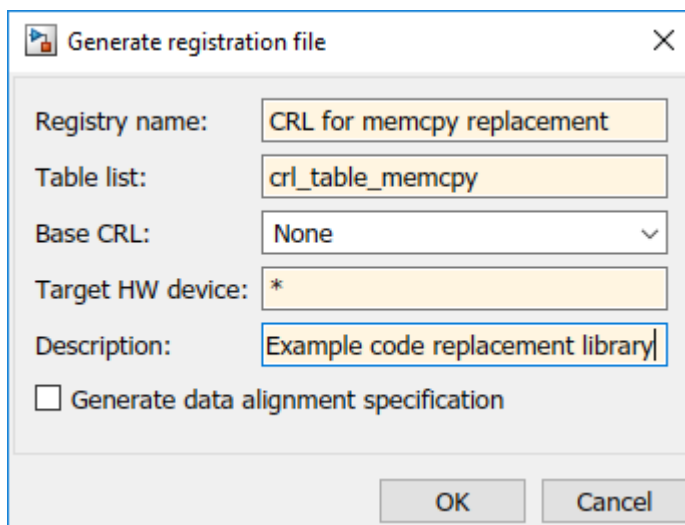

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.

Specify a **Name** for the replacement function under **Function prototype**.

- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:  
`>>sl_refresh_customizations`

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function to call your code replacement library table. The function should not have arguments and return a table object.
  - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_memcpy()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCFunctionEntry`.

```
function hTable = crl_table_memcpy()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = rtw.TflCFunctionEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_table_memcpy()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
% Set SideEffects to 'true' for function returning void to prevent it from
% being optimized away.
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'memcpy', ...
 'Priority', 90, ...
 'ImplementationName', 'memcpy_int', ...
 'ImplementationHeaderFile', 'memcpy_int.h',...
 'SideEffects', true);
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString`.

```

function hTable = crl_table_memcpy()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflFunctionEntry;

%% Create entry parameters
% Set SideEffects to 'true' for function returning void to prevent it from
% being optimized away.
hEntry.setTflFunctionEntryParameters(...
 'Key', 'memcpy', ...
 'Priority', 90, ...
 'ImplementationName', 'memcpy_int', ...
 'ImplementationHeaderFile', 'memcpy_int.h', ...
 'SideEffects', true);

%% Create conceptual arguments
arg = getTflArgFromString(hTable, 'y1', 'void*');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u1', 'void*');
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u2', 'void*');
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u3', 'size_t');
addConceptualArg(hEntry, arg);

```

- 6** Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `copyConceptualArgsToImplementation`. Add the complete entry to the table by calling the function `addEntry`.

```

function hTable = crl_table_memcpy()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflFunctionEntry;

%% Create entry parameters
setTflFunctionEntryParameters(hEntry, ...
 'Key', 'memcpy', ...
 'Priority', 90, ...
 'ImplementationName', 'memcpy_int', ...
 'ImplementationHeaderFile', 'memcpy_int.h', ...
 'SideEffects', true);

%% Create conceptual arguments
arg = getTflArgFromString(hTable, 'y1', 'void*');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u1', 'void*');
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u2', 'void*');
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u3', 'size_t');
addConceptualArg(hEntry, arg);

```

```

%% Create the Implementation Representation
copyConceptualArgsToImplementation(hEntry);

```

```

%% Add the entry to the table
hTable.addEntry(hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_memcpy
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file with these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for memory function replacement';
this(1).TableList = {'crl_table_memcpy.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Nonfinite Function Code Replacement

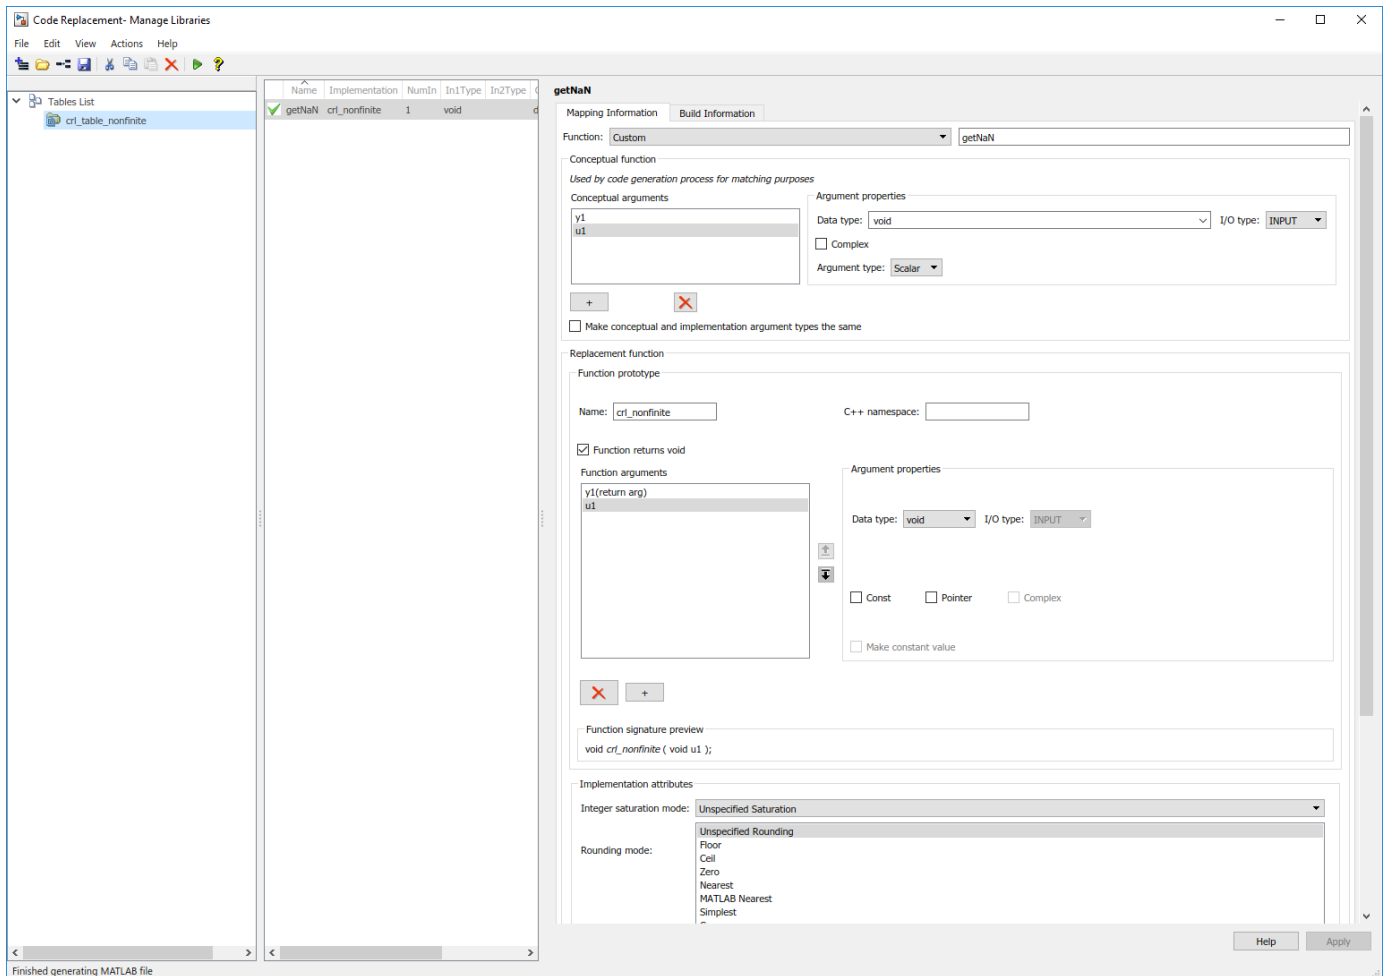

This example shows how to develop a code replacement library to optimize the performance of nonfinite functions by providing information on how to define code replacement for a `sqrt` function. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

### Interactively Develop a Code Replacement Library

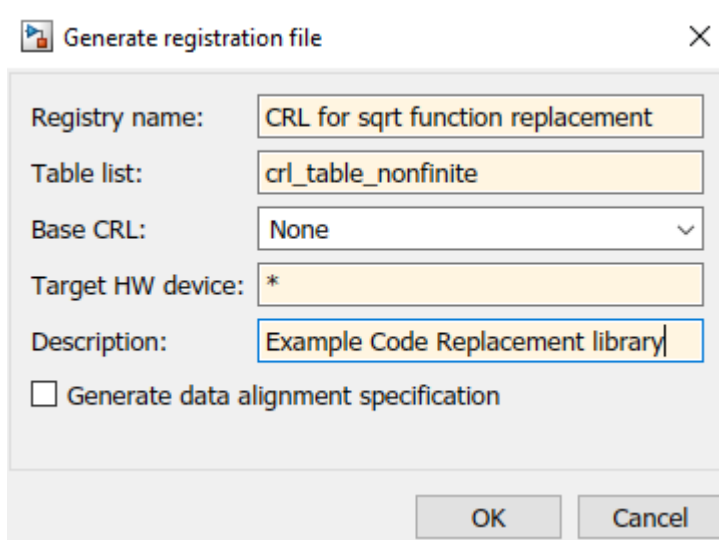

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:
 

```
>>crtool
```
- 2 Create a table.
  - a From the crtool context menu, select **File > New Table**.
  - b In the right pane, name the table `cr1_table_nonfinite`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Function**.
- 4 Create entry parameters. In the **Function** drop-down list, select `custom`. Function information appears in the crtool. For this example, specify the parameter as `getNaN`.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, with the **Data Type** of `double` and the **Argument Type** of `scalar` and the input argument, `u1`, with the **Data Type** of `void` and the **Argument Type** of `scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.
 

Specify a **Name** for the replacement function under **Function prototype**.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, set the **Implementation header file** to `nonfin.h`.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function to call your code replacement library table. The function should not have arguments and return a table object.
  - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_nonfinite()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCFunctionEntry`.

```
function hTable = crl_table_nonfinite()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = rtw.TflCFunctionEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_table_nonfinite()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'getNaN', ...
 'Priority', 30, ...
 'ImplementationName', 'mygetNaN', ...
 'ImplementationHeaderFile', 'getInf.h', ...
 'ImplementationSourceFile', 'getInf.c');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString`.

```
function hTable = crl_table_nonfinite()
% Create a code replacement library table
```

```

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'getNaN', ...
 'Priority', 30, ...
 'ImplementationName', 'mygetNaN', ...
 'ImplementationHeaderFile', 'getInf.h', ...
 'ImplementationSourceFile', 'getInf.c');

%% Create the conceptual representation
arg = getTflArgFromString(hTable, 'y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u1', 'void');
addConceptualArg(hEntry, arg);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `copyConceptualArgsToImplementation`. Add the complete entry to the table by calling the function `addEntry`.

```

function hTable = crl_table_nonfinite()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'getNaN', ...
 'Priority', 30, ...
 'ImplementationName', 'mygetNaN', ...
 'ImplementationHeaderFile', 'getInf.h', ...
 'ImplementationSourceFile', 'getInf.c');

%% Create the conceptual representation
arg = getTflArgFromString(hTable, 'y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u1', 'void');
addConceptualArg(hEntry, arg);

%% Create the Implementation Representation
copyConceptualArgsToImplementation(hEntry);

%% Add the entry to the table
addEntry(hTable, hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_nonfinite
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file with these specifications:

```

function rtwTargetInfo(cm)
cm.registerTargetInfo(@loc_register_crl);

```

```
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for nonfinite function replacement';
this(1).TableList = {'crl_table_nonfinite.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10** Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

- “Develop a Code Replacement Library” on page 69-20
- “Optimize Generated Code by Developing and Using Code Replacement Libraries - Simulink” on page 74-30

## Algorithm-Based Code Replacement

You can develop a code replacement library to optimize the performance of certain math functions based on the computation or approximation algorithm configured for a block.

For example, you can configure:

- The Reciprocal Sqrt block to use the Newton-Raphson or Exact computation method.
- The Trigonometric Function block, with **Function** set to `sin`, `cos`, `sincos`, or `atan2`, to use the approximation method CORDIC, Lookup, or None.

To develop a code replacement library, use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

### Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```

- 2 Create a table.
  - a From the crtool context menu, select **File > New Table**.
  - b In the right pane, name the table `cr1_rsqr`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Function**.
- 4 Create entry parameters. In the **Function** drop-down list, select `rSqr`. Algorithm information appears in the crtool. For this example, set the parameter to **Newton Raphson**.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1`, by using the **Data Type** of double and the **Argument Type** of Scalar.

Specify a **Name** for the replacement function under **Function prototype**.

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function to call your code replacement library table. The function cannot have arguments or return a table object.
  - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_rsqr()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCFunctionEntry`.

```
function hTable = crl_rsqr()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

To use the algorithm for a function in an entry definition, set the `EntryInfoAlgorithm` property in a call to the function `setTflCFunctionEntryParameters` as `RTW_Newton_Raphson`.

```
function hTable = crl_rsqr()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'rSqr', ...
 'Priority', 80, ...
 'ImplementationName', 'rsqr_newton', ...
 'ImplementationHeaderFile', 'rsqr.h', ...
 'EntryInfoAlgorithm', 'RTW_NEWTON_RAPHSON');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `createAndAddConceptualArg`.

```
function hTable = crl_rsqr()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'rSqr', ...
 'Priority', 80, ...
 'ImplementationName', 'rsqr_newton', ...
 'ImplementationHeaderFile', 'rsqr.h', ...
 'EntryInfoAlgorithm', 'RTW_NEWTON_RAPHSON');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'DataTypeMode', 'double');

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'DataTypeMode', 'double');
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `copyConceptualArgsToImplementation`. Add the complete entry to the table by calling the function `addEntry`.

```
function hTable = crl_rsqr()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'rSqr', ...
 'Priority', 80, ...
 'ImplementationName', 'rsqr_newton', ...
 'ImplementationHeaderFile', 'rsqr.h', ...
 'EntryInfoAlgorithm', 'RTW_NEWTON_RAPHSON');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
```

```

 'DataTypeMode', 'double');

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'DataTypeMode', 'double');

%% Create the Implementation Representation
copyConceptualArgsToImplementation(hEntry);

%% Add the entry to the table
hTable.addEntry(hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_rsqr
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file by using these specifications:

```

function rtwTargetInfo(cm)
cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl
this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for algorithm function replacement';
this(1).TableList = {'crl_rsqr.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';
end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Lookup Table Function Code Replacement

You can configure the algorithm for table lookup operations and index searches and generate code. If the code generated for available algorithm options does not meet requirements for your application, create custom code replacement table entries to replace the generated algorithm code. You can develop a code replacement library to optimize the performance of algorithms in a lookup table block. For more information, see “Develop a Code Replacement Library” on page 69-20. For more information about using lookup table blocks, see “Nonlinearity”.

### Lookup Table Function Signatures

To create code replacement table entries for a function corresponding to a lookup table algorithm, you must have:

- Information about the conceptual function signature.
- Relevant algorithm parameters.

This table provides the conceptual function signature information.

Conceptual Function Signature	Argument Summary
<code>y1 = interp1D(u1, u2, u3, u4)</code>	y1 - output u1 - index u2 - fraction u3 - table data u4 - table dimension length
<code>y1 = interp2D(u1, u2, u3, u4, u5, u6, u7)</code>	y1 - output u1, u3 - index u2, u4 - fraction u5 - table data u6, u7 - table dimension lengths
<code>y1 = interp3D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10)</code>	y1 - output u1, u3, u5 - index u2, u4, u6 - fraction u7 - table data u8, u9, u10 - table dimension lengths
<code>y1 = interp4D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13)</code>	y1 - output u1, u3, u5, u7 - index u2, u4, u6, u8 - fraction u9 - table data u10, u11, u12, u13 - table dimension lengths
<code>y1 = interp5D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16)</code>	y1 - output u1, u3, u5, u7, u9 - index u2, u4, u6, u8, u10 - fraction u11 - table data u12, u13, u14, u15, u16 - table dimension lengths

Conceptual Function Signature	Argument Summary
$y1 = \text{interpND}(\{u_i, u_f, \dots, u_t, u_n, \dots\})$	y1 - output u <sub>i</sub> , u <sub>f</sub> is an index and fraction pair per dimension u <sub>t</sub> - table data u <sub>n</sub> - table dimension lengths
Explicit values $y1 = \text{lookup1D}(u1, u2, u3, u4)$	y1 - output u1 - input u2 - breakpoint data u3 - table data u4 - table dimension length
Even spacing $y1 = \text{lookup1D}(u1, u2, u3, u4, u5)$	y1 - output u1 - input u2 - first point of breakpoint data u3 - spacing of breakpoints u4 - table data u5 - table dimension length
Explicit values $y1 = \text{lookup2D}(u1, u2, u3, u4, u5, u6, u7)$	y1 - output u1, u2 - input u3, u4 - breakpoint data u5 - table data u6, u7 - table dimension lengths
Even spacing $y1 = \text{lookup2D}(u1, u2, u3, u4, u5, u6, u7, u8, u9)$	y1 - output u1, u2 - input u3, u5 - first point of breakpoint data u4, u6 - spacing of breakpoints u7 - table data u8, u9 - table dimension lengths
Explicit spacing $y1 = \text{lookup3D}(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10)$	y1 - output u1, u2, u3 - input u4, u5, u6 - breakpoint data u7 - table data u8, u9, u10 - table dimension lengths
Even spacing $y1 = \text{lookup3D}(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13)$	y1 - output u1, u2, u3 - input u4, u6, u8 - first point of breakpoint data u5, u7, u9 - spacing of breakpoints u10 - table data u11, u12, u13 - table dimension lengths
Explicit values $y1 = \text{lookup4D}(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13)$	y1 - output u1, u2, u3, u4 - input u5, u6, u7, u8 - breakpoint data u9 - table data u10, u11, u12, u13 - table dimension lengths

Conceptual Function Signature	Argument Summary
<p>Even spacing  <code>y1 = lookup4D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16, u17)</code></p>	<p>y1 - output  u1, u2, u3, u4 - input  u5, u7, u9, u11 - first point of breakpoint data  u6, u8, u10, u12 - spacing of breakpoints  u13 - table data  u14, u15, u16, u17 - table dimension lengths</p>
<p>Explicit values  <code>y1 = lookup5D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16)</code></p>	<p>y1 - output  u1, u2, u3, u4, u5 - input  u6, u7, u8, u9, u10 - breakpoint data  u11 - table data  u12, u13, u14, u15, u16 - table dimension lengths</p>
<p>Even spacing  <code>y1 = lookup5D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16, u17, u18, u19, u20, u21)</code></p>	<p>y1 - output  u1, u2, u3, u4, u5 - input  u6, u8, u10, u12, u14 - first point of breakpoint data  u7, u9, u11, u13, u15 - spacing of breakpoints  u16 - table data  u17, u18, u19, u20, u21 - table dimension lengths</p>
<p>Explicit values  <code>y1 = lookupND(un,..., ub,..., ut, un...)</code></p>	<p>y1 - output  un, input per dimension  ub, breakpoint per dimension  ut - table data  un - table dimension lengths</p>
<p>Even spacing  <code>y1 = lookupND(un,..., {ufn, usn,...} ut, un...)</code></p>	<p>y1 - output  un - input per dimension  ufn - first point of breakpoint data per dimension  usn - spacing of breakpoint per dimension  ut - table data  un - table dimension lengths</p>
<p><code>y1 = lookupND_Direct(u1, u2,...ui, ui+1)</code></p>	<p>y1 - output  u1...ui - input  ui+1 - table data</p>
<p>Explicit values  <code>y1, y2 = prelookup(u1, u2, u3)</code></p>	<p>y1 - index  y2 - fraction  u1 - input  u2 - breakpoint data  u3 - number of breakpoints</p>

Conceptual Function Signature	Argument Summary
Evenly spaced y1, y2 = prelookup(u1, u2, u3, u4)	y1 - index y2 - fraction u1 - input u2 - first point of breakpoint data u3 - spacing of breakpoints u4 - number of breakpoints

When defining a table entry programmatically, you might also need to change the values of required (primary) and optional algorithm parameters.

- Set values for required parameters to achieve code replacement.
- If you do not set a value for an optional parameter, the algorithm parameter software applies don't care. The code replacement software ignores the parameter while searching for matches.

## Interactively Develop a Code Replacement Library

This example shows how to specify a code replacement table entry for a lookup table algorithm `interp1D` by using the Code Replacement Tool.

- 1 Open the **Code Replacement Tool** (`crtool`), from the MATLAB command line with the following command:
 

```
>>crtool
```
- 2 Create a table.
  - a From the `crtool` context menu, select **File > New Table**.
  - b In the right pane, name the table `cr_l_LUT`. Click **Apply**.
- 3 Create an entry. From the `crtool` context menu, select **File > New entry > Function**.
- 4 Create entry parameters. In the **Function** drop-down list, select `custom`. Function information appears in the `crtool`. For this example, specify the parameter as `lookup1D`. Set these algorithm parameters as shown in the `crtool` snapshot below:
  - **Extrapolation method** — Linear
  - **Interpolation method** — Linear point-slope
  - **Integer rounding mode** — Round
  - **Saturate on overflow** — off
  - **Index search method** — Linear search
  - **Remove out-of-range input protection** — off
  - **Support tunable table size** — off
  - **Use last table value for inputs at or above last breakpoint** — off
  - **Begin index search using previous index result** — off
  - **Use algorithms optimized for row-major array layout** — off
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the `crtool`, specify the return argument, `y1`, and the input argument `u1` with the **Data Type** of `double` and `u4`, with the **Data Type** of `uint32` and the **Argument Type** of `Scalar`.

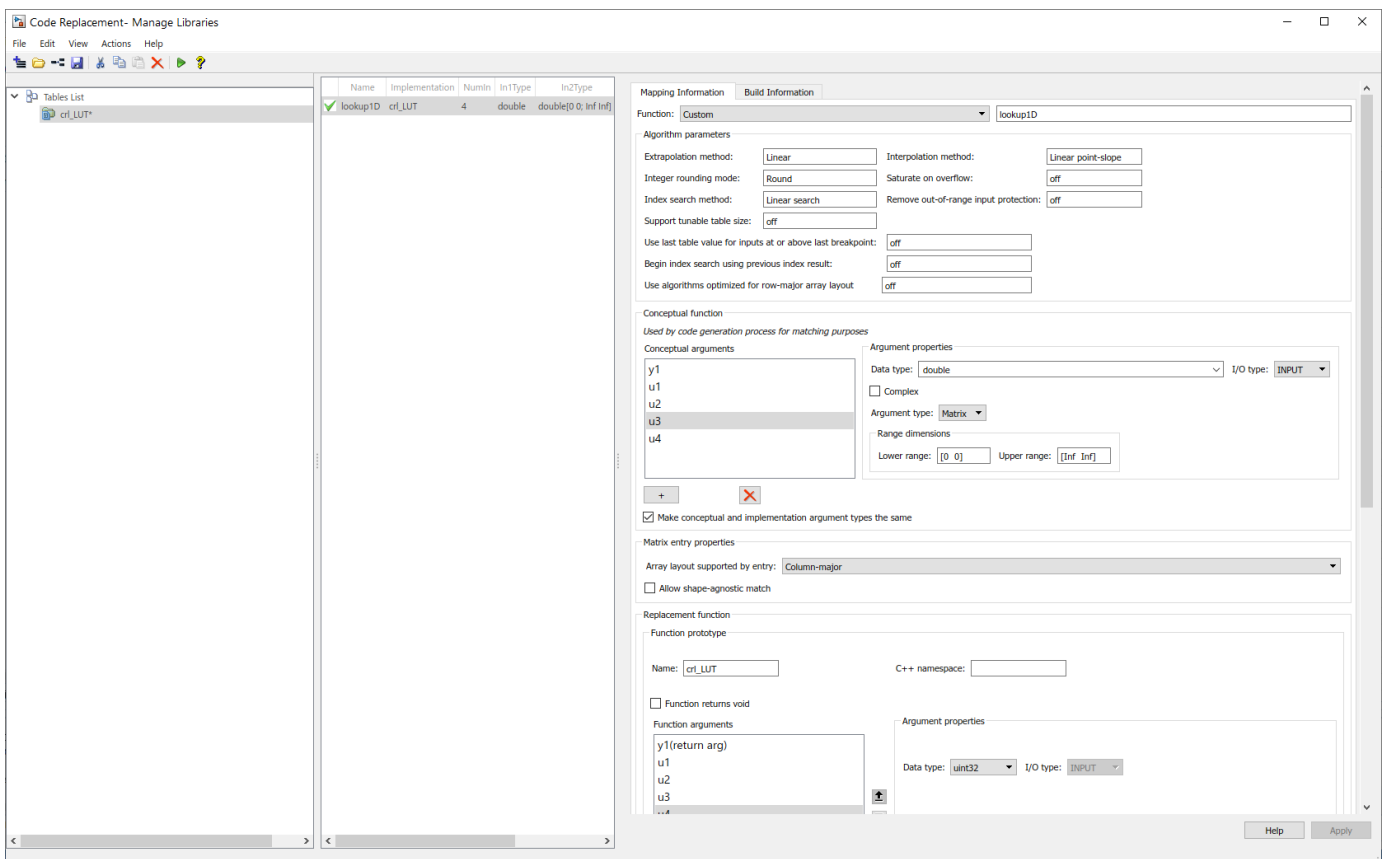

Specify the **Argument Type** of input arguments u2 and u3 as **Matrix** and **Data Type** as **double**. Set the **Algorithm parameters** as shown in the figure below.

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.

Add the return argument y1 and the arguments u1, u2, u3 and u4.

Specify a **Name** for the replacement function under **Function prototype**.

- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. Click the **Mapping Information** tab and verify the fields are filled in as shown. Click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically develop a code replacement library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
  - b Create a table object by calling `RTW.TflTable`.

```
function hTable = my_lookup_replacement_table
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCFunctionEntry`.

```
function hTable = my_lookup_replacement_table
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = my_lookup_replacement_table()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
setTflCFunctionEntryParameters(hEntry, ...
 'Key', 'lookup1D', ...
 'Priority', 100, ...
 'ImplementationName', 'my_Lookup1D_Repl', ...
 'ImplementationHeaderFile', 'myLookup1D.h', ...
 'ImplementationSourceFile', 'myLookup1D.c', ...
 'GenCallback', 'RTW.copyFileToBuildDir');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString`.

```
function hTable = my_lookup_replacement_table()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
setTflCFunctionEntryParameters(hEntry, ...
 'Key', 'lookup1D', ...
 'Priority', 100, ...
 'ImplementationName', 'my_Lookup1D_Repl', ...
 'ImplementationHeaderFile', 'myLookup1D.h', ...
 'ImplementationSourceFile', 'myLookup1D.c', ...
 'GenCallback', 'RTW.copyFileToBuildDir');

%% Create the conceptual representation
arg = hEntry.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = hEntry.getTflArgFromString('u1','double');
addConceptualArg(hEntry, arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT', 'double');
arg.DimRange = [0 0; Inf Inf];
addConceptualArg(hEntry, arg);

arg = RTW.TflArgMatrix('u3', 'RTW_IO_INPUT', 'double');
arg.DimRange = [0 0; Inf Inf];
addConceptualArg(hEntry, arg);
```

```
arg = hEntry.getTflArgFromString('u4','uint32');
addConceptualArg(hEntry, arg);
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `getTflArgFromString`.

```
function hTable = my_lookup_replacement_table()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
setTflCFunctionEntryParameters(hEntry, ...
 'Key', 'lookupID', ...
 'Priority', 100, ...
 'ImplementationName', 'my_LookupID_Repl', ...
 'ImplementationHeaderFile', 'myLookupID.h', ...
 'ImplementationSourceFile', 'myLookupID.c', ...
 'GenCallback', 'RTW.copyFileToBuildDir');

%% Create the conceptual representation
arg = hEntry.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = hEntry.getTflArgFromString('u1','double');
addConceptualArg(hEntry, arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT', 'double');
arg.DimRange = [0 0; Inf Inf];
addConceptualArg(hEntry, arg);

arg = RTW.TflArgMatrix('u3', 'RTW_IO_INPUT', 'double');
arg.DimRange = [0 0; Inf Inf];
addConceptualArg(hEntry, arg);

arg = hEntry.getTflArgFromString('u4','uint32');
addConceptualArg(hEntry, arg);

algParams = getAlgorithmParameters(hEntry);
algParams.InterpMethod = 'Linear';
algParams.ExtrapMethod = 'Clip';
algParams.UseRowMajorAlgorithm = 'off';
algParams.RndMeth = 'Round';
algParams.IndexSearchMethod = 'Linear search';
algParams.UseLastTableValue = 'off';
algParams.RemoveProtectionInput = 'off';
algParams.SaturateOnIntegerOverflow = 'off';
algParams.SupportTunableTableSize = 'off';
algParams.BPPower2Spacing = 'off';
algParams.BeginIndexSearchUsingPreviousIndexResult = 'off';
setAlgorithmParameters(hEntry, algParams);

%% Create the Implementation Representation
arg = hEntry.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.Implementation.setReturn(arg);

arg = hEntry.getTflArgFromString('u1','double');
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTflArgFromString('u2','double*');
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTflArgFromString('u3','double*');
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTflArgFromString('u4','uint32');
hEntry.Implementation.addArgument(arg);
```

```

%% Add the entry to the table
hTable.addEntry(hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = my_lookup_replacement_table
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) with these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for LUT 1D function replacement';
this(1).TableList = {'my_lookup_replacement_table.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Generate Code by Using Lookup Table Code Replacement Library

In this section, you generate code using the code replacement library that you created in the first two sections of this example. A Lookup table function is replaced with a call to a custom function in the generated code. This example does not provide an implementation function. Write your own implementation.

### Example Model

Open the model `crl_LUTfunction` for configuring the code replacement library.

```
open_system('crl_LUTfunction');
```

```
copyfile LutFnRtwTargetInfo.txt rtwTargetInfo.m
```

Run the MATLAB customization file to create a code replacement table and register the file. The customization file has already been executed. Run the `sl_refresh_customizations` function to load the library.

```
sl_refresh_customizations;
```

### Enable Code Replacement Library

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Interface** pane, set **Code Replacement Library** by clicking **Select** and adding CRL for LUT function replacement to the **Selected code replacement libraries - prioritized** list pane.

```
%
% Alternatively, use the command-line API to enable the code replacement:
set_param('crl_LUTfunction', 'CodeReplacementLibrary', 'CRL for LUT function replacement');
```

Generate code from the model:

```
evalc('slbuild(bdroot)');
```

View the generated code. Here is a portion of `crl_LUTfunction.c`.

```
cfile = fullfile('crl_LUTfunction_ert_rtw','crl_LUTfunction.c');
rtwdemodbtpe(cfile,'/* Model step function ','/* Model initialize function',1, 1);

/* Model step function */
void crl_LUTfunction_step(void)
{
 int32_T iU;

 /* Lookup_n-D: '<Root>/1-D Lookup Table2' incorporates:
 * Constant: '<Root>/Constant2'
 */
 for (iU = 0; iU < 9; iU++) {
 crl_LUTfunction_Y.Y1[iU] = my_Lookup1D_Repl
 (crl_LUTfunction_ConstP.Constant2_Value[iU],
 &crl_LUTfunction_ConstP.uDLookupTable2_bp01Data[0],
 &crl_LUTfunction_ConstP.uDLookupTable2_tableData[0], 10U);
 }

 /* End of Lookup_n-D: '<Root>/1-D Lookup Table2' */
}
```

The Lookup Table function is replaced with a custom `my_Lookup1D_Repl` function.

Close the model and code generation report.

```
delete ./rtwTargetInfo.m
bdclose('crl_LUTfunction');
rtwdemoclean;
```

## Data Alignment for Code Replacement

Code replacement libraries can align data objects passed into a replacement function to a specified boundary.

### Code Replacement Data Alignment

You can take advantage of function implementations that require aligned data to optimize application performance. To configure data alignment for a function implementation:

- 1 Specify the data alignment requirements in a code replacement entry. Specify alignment separately for each implementation function argument or collectively for all function arguments. See “Specify Data Alignment Requirements for Function Arguments” on page 69-105.
- 2 Specify the data alignment capabilities and syntax for one or more compilers. Include the alignment specifications in a library registration entry in the `rtwTargetInfo.m` file. See “Provide Data Alignment Specifications for Compilers” on page 69-106.
- 3 Register the library containing the table entry and alignment specification object.
- 4 Configure the code generator to use the code replacement library and generate code. Observe the results.

For examples, see “Basic Example of Code Replacement Data Alignment” on page 69-109 and the “Data Alignment for Function Implementations” section of the “Optimize Generated Code by Developing and Using Code Replacement Libraries - Simulink” on page 74-30 example page.

### Specify Data Alignment Requirements for Function Arguments

To specify the data alignment requirement for an argument in a code replacement entry:

- If you are defining a replacement function in a code replacement table registration file, create an argument descriptor object (`RTW.ArgumentDescriptor`). Use its `AlignmentBoundary` property to specify the required alignment boundary and assign the object to the `ArgumentDescriptor` property.
- If you are defining a replacement function using the **Code Replacement Tool**, on the **Mapping Information** tab, in the **Argument properties** section for the replacement function, enter a value for the **Alignment value** parameter.

The screenshot shows the 'Replacement function' configuration window. It is divided into several sections:

- Function prototype:**
  - Name: `sin_dbl`
  - C++ namespace: (empty)
  - Function returns void
- Function arguments:**
  - A list box containing `y1(return arg)` and `u1`. `y1(return arg)` is selected.
  - Up and down arrow buttons are next to the list box.
- Argument properties:**
  - Data type: `double` (dropdown)
  - I/O type: `INPUT` (dropdown)
  - Const
  - Pointer
  - Complex
  - Alignment value: `-1` (text input)

The `AlignmentBoundary` property (or **Alignment value** parameter) specifies the alignment boundary for data passed to a function argument, in number of bytes. The `AlignmentBoundary` property is valid only for addressable objects, including matrix and pointer arguments. It is not applicable for value arguments. Valid values are:

- -1 (default) — If the data is a `Simulink.Bus`, `Simulink.Signal`, or `Simulink.Parameter` object, specifies that the code generator determines an optimal alignment based on usage. Otherwise, specifies that there is not an alignment requirement for this argument.
- Positive integer that is a power of 2, not exceeding 128 — Specifies number of bytes in the boundary. The starting memory address for the data allocated for the function argument is a multiple of the specified value. If you specify an alignment boundary that is less than the natural alignment of the argument data type, the alignment directive is emitted in the generated code. However, the target compiler ignores the directive.

The following code specifies the `AlignmentBoundary` for an argument as 16 bytes.

```
hLib = RTW.TflTable;
entry = RTW.TflCOperationEntry;
arg = getTflArgFromString(hLib, 'u1', 'single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);
```

The equivalent alignment boundary specification in the Code Replacement Tool dialog box is in this figure.

The screenshot shows a dialog box titled "Argument properties". It contains the following controls:

- Data type:** A dropdown menu with "single" selected.
- I/O type:** A dropdown menu with "INPUT" selected.
- Const:** An unchecked checkbox.
- Pointer:** A checked checkbox.
- Complex:** An unchecked checkbox.
- Alignment value:** A text input field containing the number "16".

---

**Note** If your model imports `Simulink.Bus`, `Simulink.Parameter`, or `Simulink.Signal` objects, specify an alignment boundary in the object properties, using the **Alignment** property. For more information, see `Simulink.Bus`, `Simulink.Parameter`, and `Simulink.Signal`.

---

## Provide Data Alignment Specifications for Compilers

To support data alignment in generated code, describe the data alignment capabilities and syntax for your compilers in the code replacement library registration. Provide one or more alignment specifications for each compiler in a library registry entry.

To describe the data alignment capabilities and syntax for a compiler:

- If you are defining a code replacement library registration entry in a `rtwTargetInfo.m` customization file, add one or more `AlignmentSpecification` objects to an `RTW.DataAlignment` object. Attach the `RTW.DataAlignment` object to the `TargetCharacteristics` object of the registry entry.

The `RTW.DataAlignment` object also has the property `DefaultMallocAlignment`, which specifies the default alignment boundary, in bytes, that the compiler uses for dynamically allocated memory. If the code generator uses dynamic memory allocation for a data object involved in a code replacement, this value determines if the memory satisfies the alignment requirement of the replacement. If not, the code generator does not use the replacement. The default value for `DefaultMallocAlignment` is `-1`, indicating that the default alignment boundary used for dynamically allocated memory is unknown. In this case, the code generator uses the natural alignment of the data type to determine whether to allow a replacement.

Additionally, you can specify the alignment boundary for complex types by using the `addComplexTypeAlignment` function.

- If you are generating a customization file function using the Code Replacement Tool, fill out the following fields for each compiler.

Generate data alignment specification

Alignment Specification 1

Alignment type: DATA\_ALIGNMENT\_LOCAL\_VAR  
DATA\_ALIGNMENT\_STRUCT\_FIELD  
DATA\_ALIGNMENT\_WHOLE\_STRUCT  
DATA\_ALIGNMENT\_GLOBAL\_VAR

Alignment position: DATA\_ALIGNMENT\_PREDIRECTIVE

Alignment syntax:

Supported languages:

+ -

Click the plus (+) symbol to add additional compiler specifications.

For each data alignment specification, provide the following information.

Alignment-Specification Property	Dialog Box Parameter	Description
AlignmentType	<b>Alignment type</b>	<p>Cell array of predefined enumerated strings, specifying which types of alignment this specification supports.</p> <ul style="list-style-type: none"> <li>• DATA_ALIGNMENT_LOCAL_VAR — Local variables.</li> <li>• DATA_ALIGNMENT_GLOBAL_VAR — Global variables.</li> <li>• DATA_ALIGNMENT_STRUCT_FIELD — Individual structure fields.</li> <li>• DATA_ALIGNMENT_WHOLE_STRUCT — Whole structure, with padding (individual structure field alignment, if specified, is favored and takes precedence over whole structure alignment).</li> </ul> <p>Each alignment specification must specify at least DATA_ALIGNMENT_GLOBAL_VAR and DATA_ALIGNMENT_STRUCT_FIELD.</p>
AlignmentPosition	<b>Alignment position</b>	<p>Predefined enumerated string specifying the position in which you must place the compiler alignment directive for alignment type DATA_ALIGNMENT_WHOLE_STRUCT:</p> <ul style="list-style-type: none"> <li>• DATA_ALIGNMENT_PREDIRECTIVE — The alignment directive is emitted before <code>struct st_tag{...}</code>, as part of the type definition statement (for example, MSVC).</li> <li>• DATA_ALIGNMENT_POSTDIRECTIVE — The alignment directive is emitted after <code>struct st_tag{...}</code>, as part of the type definition statement (for example, gcc).</li> <li>• DATA_ALIGNMENT_PRECEDING_STATEMENT — The alignment directive is emitted as a standalone statement immediately preceding the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax.</li> <li>• DATA_ALIGNMENT_FOLLOWING_STATEMENT — The alignment directive is emitted as a standalone statement immediately following the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax.</li> </ul> <p>For alignment types other than DATA_ALIGNMENT_WHOLE_STRUCT, code generation uses alignment position DATA_ALIGNMENT_PREDIRECTIVE.</p>

Alignment-Specification Property	Dialog Box Parameter	Description
AlignmentSyntax-Template	<b>Alignment syntax</b>	Specifies the alignment directive string that the compiler supports. The string is registered as a syntax template that has placeholders in it. These placeholders are supported: <ul style="list-style-type: none"> <li>• %n — Replaced by the alignment boundary for the replacement function argument.</li> <li>• %s — Replaced by the aligned symbol, usually the identifier of a variable.</li> </ul> For example, for the gcc compiler, you can specify <code>__attribute__((aligned(%n)))</code> , or for the MSVC compiler, <code>__declspec(align(%n))</code> .
SupportedLanguages	<b>Supported languages</b>	Cell array specifying the languages to which this alignment specification applies, among c and c++. Sometimes alignment syntax and position differ between languages for a compiler.

Here is a data alignment specification for the GCC compiler:

```
da = RTW.DataAlignment;

as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
 'DATA_ALIGNMENT_STRUCT_FIELD', ...
 'DATA_ALIGNMENT_GLOBAL_VAR'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.AlignmentPosition = 'DATA_ALIGNMENT_PREDIRECTIVE';
as.SupportedLanguages = {'c', 'c++'};
da.addAlignmentSpecification(as);

tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;
```

Here is the corresponding specification in the **Generate customization** dialog box of the Code Replacement Tool.

Generate data alignment specification

Alignment Specification 1

Alignment type: DATA\_ALIGNMENT\_LOCAL\_VAR  
DATA\_ALIGNMENT\_STRUCT\_FIELD  
DATA\_ALIGNMENT\_WHOLE\_STRUCT  
DATA\_ALIGNMENT\_GLOBAL\_VAR

Alignment position: DATA\_ALIGNMENT\_PREDIRECTIVE

Alignment syntax: \_\_attribute\_\_((aligned(%n)))

Supported languages: c, c++

## Basic Example of Code Replacement Data Alignment

A simple example of the complete workflow for data alignment specified for code replacement is:

- 1 Create and save the following code replacement table definition file, `crl_table_mmul_4x4_single_align.m`. This table defines a replacement entry for the \* (multiplication) operator, the single data type, and input dimensions [4,4]. The entry also specifies a data alignment boundary of 16 bytes for each replacement function argument. The entry expresses the requirement that the starting memory address for the data allocated for the function arguments during code generation is a multiple of 16.

```
function hLib = crl_table_mmul_4x4_single_align
%CRL_TABLE_MMUL_4x4_SINGLE_ALIGN - Describe matrix operator entry with data alignment

hLib = RTW.TflTable;
entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(entry, ...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 90, ...
 'ImplementationName', 'matrix_mul_4x4_s');

% conceptual arguments
createAndAddConceptualArg(entry, 'RTW.TflArgMatrix',...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'single', ...
 'DimRange', [4 4]);

createAndAddConceptualArg(entry, 'RTW.TflArgMatrix',...
 'Name', 'u1', ...
 'BaseType', 'single', ...
 'DimRange', [4 4]);

createAndAddConceptualArg(entry, 'RTW.TflArgMatrix',...
 'Name', 'u2', ...
 'BaseType', 'single', ...
 'DimRange', [4 4]);

% implementation arguments
arg = getTflArgFromString(hLib, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hLib, 'y1', 'single*');
arg.IOType = 'RTW_IO_OUTPUT';
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hLib, 'u1', 'single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hLib, 'u2', 'single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

hLib.addEntry(entry);
```

- 2 Create and save the following registration file, `rtwTargetInfo.m`. If you want to compile the code generated in this example, first modify the `AlignmentSyntaxTemplate` property for the compiler that you use. For example, for the MSVC compiler, replace the gcc template specification `__attribute__((aligned(%n)))` with `__declspec(align(%n))`.

```
function rtwTargetInfo(cm)
% rtwTargetInfo function to register a code replacement library (CRL)
% for use with code generation
```

```

% Register the CRL defined in local function locCrlRegFcn
cm.registerTargetInfo(@locCrlRegFcn);

end % End of RTWTARGETINFO

% Local function to define a CRL containing crl_table_mmul_4x4_single_align
function thisCrl = locCrlRegFcn

% create an alignment specification object, assume gcc
as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
 'DATA_ALIGNMENT_GLOBAL_VAR', ...
 'DATA_ALIGNMENT_STRUCT_FIELD'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.SupportedLanguages={'c', 'c++'};

% add the alignment specification object
da = RTW.DataAlignment;
da.addAlignmentSpecification(as);

% add the data alignment object to target characteristics
tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;

% Instantiate a CRL registry entry
thisCrl = RTW.TflRegistry;

% Define the CRL properties
thisCrl.Name = 'Data Alignment Example';
thisCrl.Description = 'Example of replacement with data alignment';
thisCrl.TableList = {'crl_table_mmul_4x4_single_align'};
thisCrl.TargetCharacteristics = tc;

end % End of LOCCRLREGFCN

```

- 3 To register your library with code generator without having to restart MATLAB, enter this command:

```
RTW.TargetRegistry.getInstance('reset');
```
- 4 Configure the code generator to use your code replacement library.
- 5 Generate code and a code generation report.
- 6 Review the code replacements. For example, check whether a multiplication operation is replaced with a `matrix_mul_4x4_s` function call. In `mmalign.h`, check whether the gcc alignment directive `__attribute__((aligned(16)))` is generated to align the function variables.

## Replace MATLAB Functions with Custom Code by Using the `coder.replace` Function

You can develop a code replacement library to optimize the performance of MATLAB functions specified within a MATLAB function block containing a `coder.replace` function. To develop a code replacement library, use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

### Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```

- 2 Create a table.
  - a From the crtool context menu, select **File > New Table**.
  - b In the right pane, name the table `cr1_matlab_fcn_coder_replace`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Function**.
- 4 Create entry parameters. In the **Function** drop-down list, select `custom`. Function information appears in the crtool. For this example, specify the parameter as `calculate`.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1`, with the **Data Type** of `double` and the **Argument Type** of `Scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.

Add the return argument `y1` and the arguments `u1`.

Specify a **Name** for the replacement function under **Function prototype**.

- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. Click the **Mapping Information** tab and verify the fields are filled in as shown. Click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
  - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_matlab_fcn_coder_replace
% Create a function to call the code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCFunctionEntry`.

```
function hTable = crl_matlab_fcn_coder_replace
% Create a function to call the code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCFunctionEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_matlab_fcn_coder_replace
% Create a function to call the code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCFunctionEntry;
```

```
%% Create entry parameters
setTflCFunctionEntryParameters(hEntry, ...
 'Key', 'calculate', ...
 'Priority', 100, ...
 'ArrayLayout', 'COLUMN_MAJOR', ...
 'ImplementationName', ...
```

```

'replacement_calculate_impl', ...
'ImplementationHeaderFile', ...
'replacement_calculate_impl.h', ...
'ImplementationSourceFile', ...
'replacement_calculate_impl.c');

```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString`.

```

function hTable = cml_matlab_fcn_coder_replace
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
setTflCFunctionEntryParameters(hEntry, ...
 'Key', 'calculate', ...
 'Priority', 100, ...
 'ArrayLayout', 'COLUMN_MAJOR', ...
 'ImplementationName', ...
 'replacement_calculate_impl', ...
 'ImplementationHeaderFile', ...
 'replacement_calculate_impl.h', ...
 'ImplementationSourceFile', ...
 'replacement_calculate_impl.c');

%% Create the conceptual representation
arg = getTflArgFromString(hEntry, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hEntry, 'u1','double');
addConceptualArg(hEntry, arg);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `getTflArgFromString`.

```

function hTable = cml_matlab_fcn_coder_replace
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
setTflCFunctionEntryParameters(hEntry, ...
 'Key', 'calculate', ...
 'Priority', 100, ...
 'ArrayLayout', 'COLUMN_MAJOR', ...
 'ImplementationName', ...

```

```

'replacement_calculate_impl', ...
'ImplementationHeaderFile', ...
'replacement_calculate_impl.h', ...
'ImplementationSourceFile', ...
'replacement_calculate_impl.c');

%% Create the conceptual representation
arg = getTflArgFromString(hEntry, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hEntry, 'u1','double');
addConceptualArg(hEntry, arg);

%% Create the Conceptual Representation
arg = getTflArgFromString(hEntry, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.Implementation.setReturn(arg);

arg = getTflArgFromString(hEntry, 'u1','double');
hEntry.Implementation.addArgument(arg);

%% Add the entry to the table
hTable.addEntry(hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_matlab_fcn_coder_replace
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file by using these specifications:

```

function rtwTargetInfo(cm)
cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for matlab function with custom code using coder.replace';
this(1).TableList = {'crl_matlab_fcn_coder_replace.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Replace `coder.ceval` Calls to External Functions

The `coder.ceval` function calls external C/C++ functions from code generated from MATLAB code. The code replacement software supports replacement of the function that you specify in a call to `coder.ceval`. An application of this code replacement scenario is to write generic MATLAB code that you can customize for different platforms with code replacements. A code replacement library can define hardware-specific code replacements for the function call. Use `coder.ceval` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

### Example Files

For the examples in “Interactively Develop a Code Replacement Library” on page 70-86 and “Programmatically Develop a Code Replacement Library” on page 69-121 you must have set up the following:

- Custom C function `my_add.c`.

```
/* my_add.c */

#include "my_add.h"

double my_add(double in1, double in2)
{
 return in1 + in2;
}
```

- Custom C header file `my_add.h`.

```
/* my_add.h */

double my_add(double in1, double in2);
```

- MATLAB function `call_my_add.m`, which uses `coder.ceval` to invoke `my_add.c`.

```
function y = call_my_add(in1, in2) %#codegen

y=0.0;

if ~coder.target('Rtw')
% Executing in MATLAB, call MATLAB equivalent of C function my_add
 y= in1+in2;
else
% Executing in generated code, call C function my_add
 y = coder.ceval('my_add', in1, in2);
end
```

- MATLAB test function `call_my_add_test.m`, which calls `call_my_add.m`.

```
in1=10;
in2=20;
```

```

y = call_my_add(in1, in2);

disp('Output')
disp('y =')
disp(y);

```

- Replacement C function `my_add_replacement.c`.

```

/* my_add_replacement.c */

#include "my_add_replacement.h"

double my_add_replacement(double in1, double in2)
{
 return in1 + in2;
}

```

- Replacement C header file `my_add_replacement.h`.

```

/* my_add_replacement.h */

double my_add_replacement(double in1, double in2);

```

## Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (`crtool`), from the MATLAB command line with the following command:

```
>>crtool
```

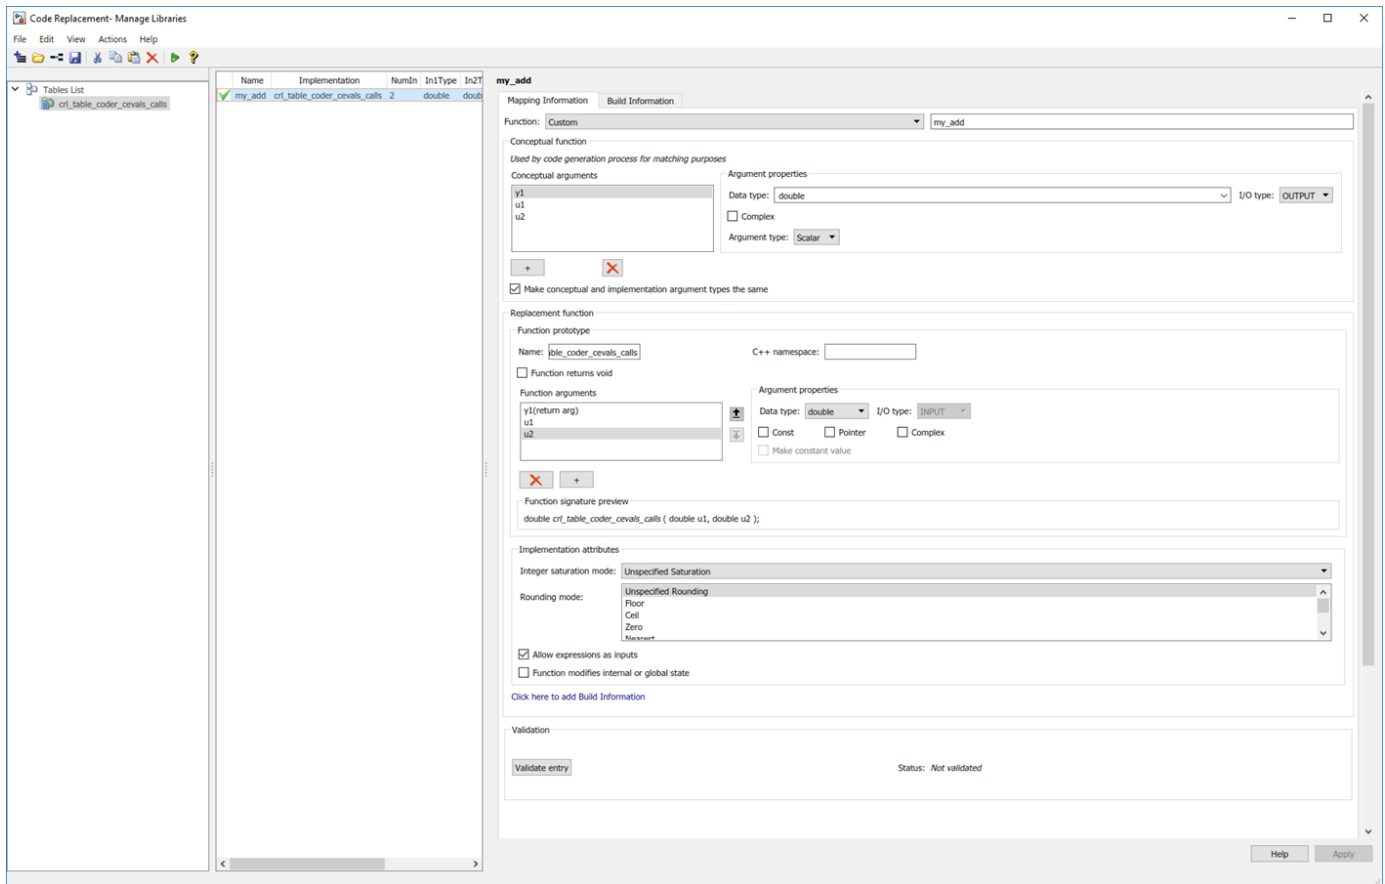

- 2 Create a table.
  - a From the `crtool` menu, select **File > New Table**.
  - b In the right pane, name the table `crl_table_coder_cevals_calls`. Click **Apply**.

- 3 Create an entry. From the `crtool` menu, select **File > New entry > Function**.

- 4 Create entry parameters. In the **Function** drop-down list, select `custom`. Function information appears in the `crtool`. For this example, specify the parameter as `my_add`.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the `crtool`, specify the return argument, `y1`, and the input arguments, `u1` and `u2` with the **Data Type** of `double` and the **Argument Type** of `Scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.

Specify a **Name** for the replacement function under **Function prototype**.

- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, set the **Implementation header file** to `my_add_replacement.h`.
- 8 Validate and save the table. Click the **Mapping Information** tab and verify the fields are filled in as shown. Click **Validate entry**. In the `crtool` menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
  - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_coder_cevals_calls()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCFunctionEntry`.

```
function hTable = crl_table_coder_cevals_calls()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_table_coder_cevals_calls()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'my_add', ...
 'Priority', 100, ...
 'ImplementationName', 'my_add_replacement', ...
 'ImplementationHeaderFile', 'my_add_replacement.h', ...
 'ImplementationSourceFile', 'my_add_replacement.c');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString`.

```
function hTable = crl_table_coder_cevals_calls()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'my_add', ...
 'Priority', 100, ...
 'ImplementationName', 'my_add_replacement', ...
 'ImplementationHeaderFile', 'my_add_replacement.h', ...
 'ImplementationSourceFile', 'my_add_replacement.c');

%% Create the conceptual representation
arg = hEntry.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.addConceptualArg(arg);

arg = hEntry.getTflArgFromString('u1','double');
hEntry.addConceptualArg(arg);

arg = hEntry.getTflArgFromString('u2','double');
hEntry.addConceptualArg(arg);
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `getTflArgFromString`.

```
function hTable = crl_table_coder_cevals_calls()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'my_add', ...
 'Priority', 100, ...
 'ImplementationName', 'my_add_replacement', ...
 'ImplementationHeaderFile', 'my_add_replacement.h', ...
 'ImplementationSourceFile', 'my_add_replacement.c');

%% Create the conceptual representation
arg = hEntry.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.addConceptualArg(arg);
```

```
arg = hEntry.getTflArgFromString('u1','double');
hEntry.addConceptualArg(arg);
```

```
arg = hEntry.getTflArgFromString('u2','double');
hEntry.addConceptualArg(arg);
```

```
%% Create the implementation representation
arg = hEntry.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.Implementation.setReturn(arg);
```

```
arg = hEntry.getTflArgFromString('u1','double');
hEntry.Implementation.addArgument(arg);
```

```
arg = hEntry.getTflArgFromString('u2','double');
hEntry.Implementation.addArgument(arg);
```

```
%% Add the entry to the table
hTable.addEntry(hEntry);
```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_coder_cevals_calls
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file by using these specifications:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for coder.ceval calls to external functions code replacement';
this(1).TableList = {'crl_table_coder_cevals_calls.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## **See Also**

### **More About**

- “Code You Can Replace From Simulink Models” on page 69-6

- “Optimize Generated Code by Developing and Using Code Replacement Libraries - Simulink” on page 74-30

## Custom Function Code Replacement

This example shows how to replace a custom function from your model with a different function in the generated code. Use this replacement when your model uses a MATLAB Function block to call a function for simulation and you want the generated code to use a different version of the function that is optimized for your code generation target. You can replace a function in these scenarios:

- The MATLAB function uses the `coder.ceval` function to call a custom C function.
- The MATLAB function uses the `coder.replace` function to indicate that you want to replace a call to a custom MATLAB function.

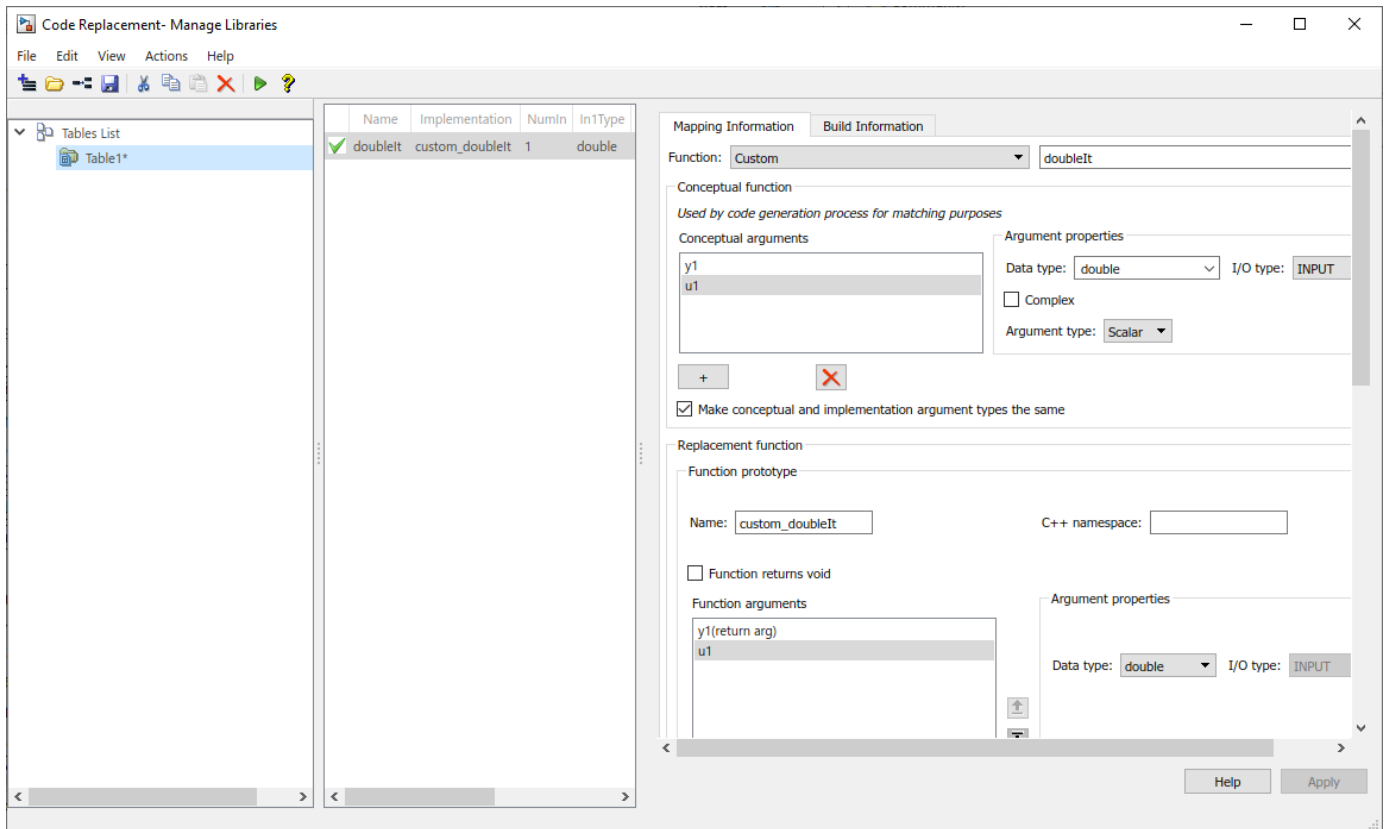

To replace a custom function, define a custom entry in a code replacement library.

### Interactively Develop a Code Replacement Library

Specify a code replacement entry for a custom C function by using the Code Replacement Tool.

- 1 At the MATLAB command prompt, open the Code Replacement Tool by using the `crtool` command.
 

```
crtool
```
- 2 Create a table. From the `crtool` context menu, select **File > New Table**.
- 3 Create an entry. From the `crtool` context menu, select **File > New entry > Function**.
- 4 Create entry parameters. In the **Function** drop-down list, select **Custom**. Next to the drop-down list, specify the name of the function that you want to replace. For this example, set the function name to `doubleIt`.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection, add the return argument `y1` and the input argument `u1`. For both arguments, specify the **Data Type** of **double** and the **Argument Type** of **scalar**. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.
- 6 Create the implementation representation. In the **Replacement function > Function prototype** section, specify the name of the replacement function. For this example, set the name to `custom_doubleIt`. In the **Function arguments** section, add the return argument `y1` and the input argument `u1`.
- 7 Optionally, specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, specify the source file `custom_doubleIt.c` and the header file `custom_doubleIt.h`.
- 8 Validate and save the table. Click the **Mapping Information** tab and verify that the fields are filled in as shown. Click **Validate entry**. In the `crtool` context menu, select **File > Save table > Save** and name the table `customCRL.m`.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, specify the registry name Custom Function CRL and the table list customCRL. To use your code replacement library, refresh your current MATLAB session by using the command `sl_refresh_customizations`.

```
sl_refresh_customizations
```

- 10 Verify the code replacement library. At the MATLAB command prompt, open the library by using the Code Replacement Viewer and verify that the table and entry are correctly specified.

## Programmatically Develop a Code Replacement Library

Programmatically specify a code replacement entry for a custom C function.

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function that has the name of your code replacement library table, which does not have arguments and returns a table object. Use this function to call your code replacement library table.
  - b Create a table object by calling `RTW.TfTable`.

```
function hTable = crl_table_custom()
% Create a function to call the code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCFunctionEntry`.

```
function hTable = crl_table_custom()
% Create a code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCFunctionEntry;
```

- 4 Create entry parameters. Because this example replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_table_custom()
% Create a code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCFunctionEntry;
```

```
%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'doubleIt', ...
 'ImplementationName', 'custom_doubleIt', ...
 'ImplementationHeaderFile', 'custom_doubleIt.h', ...
 'ImplementationSourceFile', 'custom_doubleIt.c');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString`.

```
function hTable = crl_table_custom()
% Create a code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCFunctionEntry;
```

```
%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'doubleIt', ...
 'ImplementationName', 'custom_doubleIt', ...
 'ImplementationHeaderFile', 'custom_doubleIt.h', ...
 'ImplementationSourceFile', 'custom_doubleIt.c');
```

```
%% Create the conceptual representation
arg = getTflArgFromString(hTable, 'y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);
```

```
arg = getTflArgFromString(hTable, 'u1', 'double');
```

```
arg.IOType = 'RTW_IO_INPUT';
addConceptualArg(hEntry, arg);
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `copyConceptualArgsToImplementation`. Add the entry to the table by calling the function `addEntry`.

```
function hTable = crl_table_custom()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
 'Key', 'doubleIt', ...
 'ImplementationName', 'custom_doubleIt', ...
 'ImplementationHeaderFile', 'custom_doubleIt.h', ...
 'ImplementationSourceFile', 'custom_doubleIt.c');

%% Create the conceptual representation
arg = getTflArgFromString(hTable, 'y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u1', 'double');
arg.IOType = 'RTW_IO_INPUT';
addConceptualArg(hEntry, arg);

%% Create the implementation representation
copyConceptualArgsToImplementation(hEntry);

%% Add the entry to the table
hTable.addEntry(hEntry);
end
```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator requires for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. At the command prompt, validate the code replacement library table by calling it:

```
>> hTable = crl_table_custom
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file by using these specifications:

```
function rtwTargetInfo(cm)
cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl
```

```

this(1) = RTW.TflRegistry;
this(1).Name = 'Custom Function CRL';
this(1).TableList = {'crl_table_custom.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. At the command prompt, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Generate Code by Using Custom Function Code Replacement

Generate code using the code replacement library that you previously created. A custom C function that is called in a MATLAB Function block is replaced with a call to a different custom function in the generated code.

### Example Model

Open the model `myDoubleModel` for configuring the code replacement library.

```
open_system('myDoubleModel')
```

The MATLAB Function block in the model uses the `coder.ceval` function to call the custom C function `doubleIt`.

```
function y = fcn(u)

y = 0.0;

y = coder.ceval('doubleIt',u);
```

The code replacement library replaces this function with a call to the custom function `custom_doubleIt`. For this example, the code replacement table is saved in the file `customCRL.m` and the library is registered in the registration file `rtwTargetInfo.m`.

To use the code replacement library, refresh the current MATLAB session.

```
copyfile targetInfoFile/rtwTargetInfo.m
sl_refresh_customizations
```

### Enable Code Replacement Library

Configure the model to use the code replacement library and generate code.

- 1 Open the Configuration Parameters dialog box. On the **Modeling** tab, click **Settings**.
- 2 On the **Code Generation > Interface** pane, for the **Code replacement libraries** parameter, click **Select**. Select the code replacement library `Custom Function CRL` and click **OK**.

*% Alternatively, use the command-line API to enable the code replacement:*  

```
set_param('myDoubleModel', 'CodeReplacementLibrary', 'Custom Function CRL');
```

Generate code for the model. Press **Ctrl+B** or open the Embedded Coder app and click **Generate Code**.

```
evalc('slbuild(bdroot)');
```

In the Code view, confirm that the step function calls the custom C function `custom_doubleIt`.

```
cfile = fullfile('myDoubleModel_ert_rtw','myDoubleModel.c');
rtwdemodbtype(cfile,'/* Model step function ','/* Model initialize function',1, 1);

/* Model step function */
void myDoubleModel_step(void)
{
 /* Output: '<Root>/y' incorporates:
 * Inport: '<Root>/u'
 * MATLAB Function: '<Root>/MATLAB Function'
 */
 myDoubleModel_Y.y = custom_doubleIt(myDoubleModel_U.u);
}
```

The function `doubleIt` is replaced with the custom function `custom_doubleIt`.

## Reserved Identifiers and Code Replacement

The code generator and C programming language use, internally, reserved keywords for code generation. Do not use reserved keywords as identifiers or function names. Reserved keywords for code generation include many code replacement library identifiers, the majority of which are function names, such as `acos`.

To view a list of reserved identifiers for the code replacement library that you use to generate code, specify the name of the library in a call to the function

`RTW.TargetRegistry.getInstance.getTflReservedIdentifiers`. For example:

```
crL_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU99 (GNU)')
```

In a code replacement table, the code generator registers each function implementation name defined by a table entry as a reserved identifier. You can register additional reserved identifiers for the table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier-related compile and link issues.

To register additional code replacement reserved identifiers, use the `setReservedIdentifiers` function. This function registers specified reserved identifiers to be associated with a code replacement table.

You can register up to four reserved identifier structures in a code replacement table. You can associate one set of reserved identifiers with a code replacement library, while the other three (if present) must be associated with ANSI C. The following example shows a reserved identifier structure that specifies two identifiers and the associated header file.

```
d{1}.LibraryName = 'ANSI_C';
d{1}.HeaderInfos{1}.HeaderName = 'math.h';
d{1}.HeaderInfos{1}.ReservedIds = {'y0', 'y1'};
```

The code generator adds the identifiers to the list of reserved identifiers and honors them during the build procedure.

## Customize Match and Replacement Process

During the build process, the code generator uses:

- Preset match criteria to identify functions and operators for which application-specific implementations replace default implementations.
- Preset replacement function signatures.

It is possible that preset match criteria and preset replacement function signatures do not completely meet your function and operator replacement needs. For example:

- You want to replace an operator with a particular fixed-point implementation function only when fraction lengths are within a particular range.
- When a match occurs, you want to modify your replacement function signature based on compile-time information, such as passing fraction-length values into the function.

To add extra logic into the code replacement match and replacement process, create custom code replacement table entries. With custom entries, you can specify additional match criteria and modify the replacement function signature to meet application needs.

To create a custom code replacement entry:

- 1 Create a custom code replacement entry class, derived from `RTW.TfLCFunctionEntryML` (for function replacement) or `RTW.TfLCOperationEntryML` (for operator replacement).
- 2 In your derived class, implement a `do_match` method with a fixed preset signature as a MATLAB function. In your `do_match` method, provide either or both of the following customizations that instantiate the class:
  - Add match criteria that the base class does not provide. The base class provides a match based on:
    - Argument number
    - Argument name
    - Signedness
    - Word size
    - Slope (if not specified with wildcards)
    - Bias (if not specified with wildcards)
    - Math modes, such as saturation and rounding
    - Operator or function key
  - Modify the implementation signature by adding additional arguments or setting constant input argument values. You can inject a constant value, such as an input scaling value, as an additional argument to the replacement function.
- 3 Create code replacement entries that instantiate the custom entry class.
- 4 Register a library containing the code replacement table that includes your entries.

During code generation, the code replacement match process tries to match function or operator call sites with the base class of your derived entry class. If the process finds a match, the software calls your `do_match` method to execute your additional match logic (if any) and your replacement function customizations (if any).

## Customize Code Match and Replacement for Functions

This example shows how to use custom code replacement table entries to refine the match and replacement logic for functions. The example shows how to:

- Modify a sine function replacement only if the integer size on the current target platform is 32 bits.
  - Change the replacement such that the implementation function passes in a degrees-versus-radians flag as an input argument.
- 1 To exercise the table entries that you create in this example, create an ERT-based model with a sine function block. For example:

In the Inport block parameters, set the signal **Data type** to `double`. If the value selected for **Configuration Parameters > Hardware Implementation > Device type** supports an integer size other than 32, do one of the following:

- Select a temporary target platform with a 32-bit integer size.
  - Modify the code to match the integer size of your target platform.
- 2 Create a class, for example `TflCustomFunctionEntry`, that is derived from the base class `RTW.TflCFunctionEntryML`. The derived class defines a `do_match` method with the signature:

```

function ent = do_match(hThis, ...
 hCS0, ...
 targetBitPerChar, ...
 targetBitPerShort, ...
 targetBitPerInt, ...
 targetBitPerLong, ...
 targetBitPerLongLong)

```

In the `do_match` signature:

- `ent` is the return handle, which is returned either as empty (indicating that the match failed) or as a `TflCFunctionEntry` handle.
- `hThis` is a handle to the class instance.
- `hCS0` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method:

- Adds required additional match criteria that the base class does not provide.
- Makes required modifications to the implementation signature.

In this case, the `do_match` method must match only `targetBitPerInt`, representing the number of bits in the C `int` data type for the current target, to the value 32. If the code generator finds a match, the method sets the return handle and creates and adds an input argument. The input argument represents whether units are expressed as degrees or radians, to the replacement function signature.

Alternatively, create and add the additional implementation function argument for passing a units flag in each code replacement table definition file that instantiates this class. In that case, this class definition code does not create the argument. That code sets only the argument value. For an example of creating and adding additional implementation function arguments in a table definition file, see “Customize Code Match and Replacement for Scalar Operations” on page 69-138.

```
classdef TflCustomFunctionEntry < RTW.TflCFunctionEntryML
 methods
 function ent = do_match(hThis, ...
 hCS0, ... %#ok
 targetBitPerChar, ... %#ok
 targetBitPerShort, ... %#ok
 targetBitPerInt, ... %#ok
 targetBitPerLong, ... %#ok
 targetBitPerLongLong) %#ok
 % DO_MATCH - Create a custom match function. The base class
 % checks the types of the arguments prior to calling this
 % method. This will check additional data and perhaps modify
 % the implementation function.

 ent = []; % default the return to empty, indicating the match failed.

 % Match sine function only if the target int size is 32 bits
 if targetBitPerInt == 32
 % Need to modify the default implementation, starting from a copy
 % of the standard TflCFunctionEntry.
 ent = RTW.TflCFunctionEntry(hThis);

 % If the target int size is 32 bits, the implementation function
 % takes an additional input flag argument indicating degrees vs.
 % radians. The additional argument can be created and added either
 % in the CRL table definition file that instantiates this class, or
 % here in the class definition, as follows:
 createAndAddImplementationArg(ent, 'RTW.TflArgNumericConstant', ...
 'Name', 'u2', ...
 'IsSigned', true, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 1);
 end
 end
 end
end
```

Exit the class folder and return to the previous working folder.

- 3 Create and save the following code replacement table definition file, `crl_table_custom_sinfcn_double.m`. This file defines a code replacement table that contains a function table entry for sine with `double` input and output. This entry instantiates the derived class from the previous step, `TflCustomFunctionEntry`.

```
function hTable = crl_table_custom_sinfcn_double

hTable = RTW.TflTable;

%% Add TflCustomFunctionEntry
fcn_entry = TflCustomFunctionEntry;
setTflCFunctionEntryParameters(fcn_entry, ...
 'Key', 'sin', ...
 'Priority', 30, ...
 'ImplementationName', 'mySin', ...
 'ImplementationHeaderFile', 'mySin.h', ...
 'ImplementationSourceFile', 'mySin.c');

createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'DataTypeMode', 'double');
```

```

createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'DataTypeMode', 'double');

% TflCustomFunctionEntry class do_match method will create and add
% an implementation function argument during code generation if
% the supported integer size on the current target is 32 bits.
copyConceptualArgsToImplementation(fcn_entry);

addEntry(hTable, fcn_entry);

```

#### 4 Check the validity of the code replacement table entry.

- At the command prompt, invoke the table definition file.
 

```
tbl = crl_table_custom_sinfcn_double
```
- In the Code Replacement Viewer, view the table definition file.
 

```
crviewer(crl_table_custom_sinfcn_double)
```

## Customize Code Match and Replacement for Nonscalar Operations

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a nonscalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

This example restricts the match criteria for an element-wise multiplication replacement to entries with a specific dimension range. When a match occurs, the custom `do_match` method modifies the replacement signature to pass the number of elements into the function.

Files for developing and testing this code replacement library example are available in `matlab/help/toolbox/ecoder/examples/code_replacement/custom_lemmult`:

- `do_match` method — `@MyElemMultEntry/MyElemMultEntry.m`
- Replacement function source and header files — `src/myMulImplLib.c` and `src/myMulImplLib.h`
- Model — `myElemMul.slx`
- Code replacement table definition — `myElemMultCrlTable.m`
- Registration file — `rtwTargetInfo.m`

To create custom code replacement entries that add logic to the code replacement match and replacement process:

- 1 Create a class, for example `MyElemMultEntry`, which is derived from the base class `RTW.TflCOperationEntryML`. The derived class defines a `do_match` method with the following signature:

```

function ent = do_match(hThis, ...
 hCS0, ...
 targetBitPerChar, ...
 targetBitPerShort, ...
 targetBitPerInt, ...
 targetBitPerLong, ...
 targetBitPerLongLong)

```

In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `TfLCOperationEntry` handle.
- `hThis` is the handle to the derived instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method:

- Adds match criteria that the base class does not provide.
- Makes changes to the implementation signature.

The `do_match` method relies on the base class for checking data types and dimension ranges. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Uses the conceptual arguments to compute the number of elements in the array. In the replacement entry returned, sets the value of the constant implementation argument as the number of elements of the array.
- Updates the code replacement entry such that it matches CSOs that have the same argument dimensions.

```
classdef MyElemMultEntry < RTW.TfLCOperationEntryML
 methods
 function obj = MyElemMultEntry(varargin)
 mlock;
 obj@RTW.TfLCOperationEntryML(varargin{:});
 end

 function ent = do_match(hThis, ...
 hCSO, ... %#ok
 targetBitPerChar, ... %#ok
 targetBitPerShort, ... %#ok
 targetBitPerInt, ... %#ok
 targetBitPerLong, ... %#ok
 targetBitPerLongLong) %#ok

 % Fourth implementation arg represents number of elements for producing matches.
 assert(strcmp(hThis.Implementation.Arguments(4).Name, 'numElements'));

 ent = RTW.TfLCOperationEntry(hThis);

 % Calculate number of elements and set value of injected constant.
 ent.Implementation.Arguments(4).Value = prod(hCSO.ConceptualArgs(1).DimRange(1,:));

 % Since implementation has been modified for specific DimRange, update
 % returned entry to match similar CSOs only.
 for idx =1:3
 ent.ConceptualArgs(idx).DimRange = hCSO.ConceptualArgs(idx).DimRange;
 end
 end
 end
end
```

- 2 Create and save the following code replacement table definition file, `myElemMultCrlTable.m`. This file defines a code replacement table that contains an operator entry generator for element-wise multiplication. The table entry:

- Instantiates the derived class `myElemMultEntry` from the previous step.
- Sets operator entry parameters with the call to the `setTfLCOperationEntryParameters` function.

- Creates conceptual arguments `y1`, `u1`, and `u2`. The argument class `RTW.TflArgMatrix` specifies matrix arguments to match. The three arguments are set up to match 2-dimensional matrices with at least two elements in each dimension.
- Calls the `getTflArgFromString` function to create a return value and four implementation arguments. Arguments `u1` and `u2` are the operands, `y1` is the product, and the fourth argument is the number of elements.

Alternatively, the `do_match` method of the derived class `myElemMultEntry` can create and add the implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.

- Calls `addEntry` to add the entry to a code replacement table.

```
function hLib = myElemMultCrLTable

libPath = fullfile(fileparts(which(mfilename)), 'src');

hLib = RTW.TflTable;
%----- entry: RTW_OP_ELEM_MUL -----
hEnt = MyElemMultEntry;
hEnt.setTflCoperationEntryParameters(...
 'Key', 'RTW_OP_ELEM_MUL', ...
 'Priority', 100, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'ImplementationName', 'myElemMul_s32', ...
 'ImplementationSourceFile', 'myMulImplLib.c', ...
 'ImplementationSourcePath', libPath, ...
 'ImplementationHeaderFile', 'myMulImplLib.h', ...
 'ImplementationHeaderPath', libPath, ...
 'SideEffects', true, ...
 'GenCallback', 'RTW.copyFileToBuildDir');

% Conceptual Args

arg = RTW.TflArgMatrix('y1', 'RTW_IO_OUTPUT', 'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u1', 'RTW_IO_INPUT', 'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT', 'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

% Implementation Args

arg = hEnt.getTflArgFromString('unused', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1', 'int32*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2', 'int32*');
```

```

hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('y1','int32*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('numElements','uint32',0);
hEnt.Implementation.addArgument(arg);

hLib.addEntry(hEnt);

```

**3** Check the validity of the code replacement table entry.

- At the command prompt, invoke the table definition file.

```
tbl = myElemMultCrlTable
```

- In the Code Replacement Viewer, view the table definition file.

```
crviewer(myElemMultCrlTable)
```

## Customize Code Match and Replacement for Scalar Operations

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a scalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

For example:

- When fraction lengths are within a specific range, replace an operator with a fixed-point implementation function.
- When a match occurs, modify the replacement function signature based on compile-time information, such as passing fraction-length values into the function.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.

To create custom code replacement entries that add logic to the code replacement match and replacement process:

- 1** Create a class, for example `TflCustomOperationEntry`, that is derived from the base class `RTW.TflCOperationEntryML`. The derived class defines a `do_match` method with the following signature:

```

function ent = do_match(hThis, ...
 hCS0, ...
 targetBitPerChar, ...
 targetBitPerShort, ...
 targetBitPerInt, ...
 targetBitPerLong, ...
 targetBitPerLongLong)

```

In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `TflCOperationEntry` handle.

- hThis is the handle to the class instance.
- hCS0 is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method adds match criteria that the base class does not provide. The method makes modifications to the implementation signature. In this case, the `do_match` method relies on the base class for checking word size and signedness. `do_match` must match only the number of conceptual arguments to the value 3 (two inputs and one output) and the bias for each argument to value 0. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Removes slope and bias wild cards from the conceptual arguments (the match is for specific slope and bias values).
- Writes fraction-length values for the inputs and output into replacement function arguments 3, 4, and 5.

You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them to a code replacement table definition file, and sets them to specific values in the class definition code.

```
classdef TflCustomOperationEntry < RTW.TflCOperationEntryML
 methods
 function ent = do_match(hThis, ...
 hCS0, ... %#ok
 targetBitPerChar, ... %#ok
 targetBitPerShort, ... %#ok
 targetBitPerInt, ... %#ok
 targetBitPerLong, ... %#ok
 targetBitPerLongLong) %#ok

 % DO_MATCH - Create a custom match function. The base class
 % checks the types of the arguments prior to calling this
 % method. This class will check additional data and can
 % modify the implementation function.

 % The base class checks word size and signedness. Slopes and biases
 % have been wildcarded, so the only additional checking to do is
 % to check that the biases are zero and that there are only three
 % conceptual arguments (one output, two inputs)

 ent = []; % default the return to empty, indicating the match failed

 if length(hCS0.ConceptualArgs) == 3 && ...
 hCS0.ConceptualArgs(1).Type.Bias == 0 && ...
 hCS0.ConceptualArgs(2).Type.Bias == 0 && ...
 hCS0.ConceptualArgs(3).Type.Bias == 0

 % Modify the default implementation. Since this is a
 % generator entry, a concrete entry is created using this entry
 % as a template. The type of entry being created is a standard
 % TflCOperationEntry. Using the standard operation entry
 % provides required information, and you do not need
 % a custom match function.
 ent = RTW.TflCOperationEntry(hThis);

 % Since this entry is modifying the implementation for specific
 % fraction-length values (arguments 3, 4, and 5), the conceptual argument
 % wild cards must be removed (the wildcards were inherited from the
 % generator when it was used as a template for the concrete entry).
 % This concrete entry is now for a specific slope and bias.
 % hCS0 holds the slope and bias values (created by the code generator).
```

```

 for idx=1:3
 ent.ConceptualArgs(idx).CheckSlope = true;
 ent.ConceptualArgs(idx).CheckBias = true;

 % Set the specific Slope and Biases
 ent.ConceptualArgs(idx).Type.Slope = hCS0.ConceptualArgs(idx).Type.Slope;
 ent.ConceptualArgs(idx).Type.Bias = 0;
 end

 % Set the fraction-length values in the implementation function.
 ent.Implementation.Arguments(3).Value = ...
 -1.0*hCS0.ConceptualArgs(2).Type.FixedExponent;
 ent.Implementation.Arguments(4).Value = ...
 -1.0*hCS0.ConceptualArgs(3).Type.FixedExponent;
 ent.Implementation.Arguments(5).Value = ...
 -1.0*hCS0.ConceptualArgs(1).Type.FixedExponent;
end
end
end
end

```

Exit the class folder and return to the previous working folder.

- 2 Create and save the following code replacement table definition file, `crl_table_custom_add_ufix32.m`. This file defines a code replacement table that contains a single operator entry, an entry generator for unsigned 32-bit fixed-point addition operations, with arbitrary fraction-length values on the inputs and the output. The table entry:

- Instantiates the derived class `TflCustomOperationEntry` from the previous step. If you want to replace word sizes and signedness attributes, you can use the same derived class, but not the same entry, because you cannot use a wild card with the `WordLength` and `IsSigned` arguments. For example, to support `uint8`, `int8`, `uint16`, `int16`, and `int32`, add five other distinct entries. To use different implementation functions for saturation and rounding modes other than overflow and round to floor, add entries for those match permutations.
- Sets operator entry parameters with the call to the `setTflCOperationEntryParameters` function.
- Calls the `createAndAddConceptualArg` function to create conceptual arguments `y1`, `u1`, and `u2`.
- Calls `createAndSetCImplementationReturn` and `createAndAddImplementationArg` to define the signature for the replacement function. Three of the calls to `createAndAddImplementationArg` create implementation arguments to hold the fraction-length values for the inputs and output. Alternatively, the entry can omit those argument definitions. Instead, the `do_match` method of the derived class `TflCustomOperationEntry` can create and add the three implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.
- Calls `addEntry` to add the entry to a code replacement table.

```

function hTable = crl_table_custom_add_ufix32

hTable = RTW.TflTable;

% Add TflCustomOperationEntry
op_entry = TflCustomOperationEntry;

setTflCOperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...

```

```

'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
'ImplementationName', 'myFixptAdd', ...
'ImplementationHeaderFile', 'myFixptAdd.h', ...
'ImplementationSourceFile', 'myFixptAdd.c');

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);

% Specify replacement function signature
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

% Add 3 fraction-length args. Actual values are set during code generation.

```

```
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
 'Name', 'fl_in1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
 'Name', 'fl_in2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
 'Name', 'fl_out', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

addEntry(hTable, op_entry);
```

### 3 Check the validity of the operator entry.

- At the command prompt, invoke the table definition file.  

```
tbl = crl_table_custom_add_ufix32
```
- In the Code Replacement Viewer, view the table definition file.  

```
crviewer(crl_table_custom_add_ufix32)
```

# Scalar Operator Code Replacement

This example shows how to develop a code replacement library to optimize the performance of scalar operators by providing information on how to define code replacement for a `multiply` operation. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

## Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```

- 2 Create a table.
  - a From the crtool context menu, select **File > New Table**.
  - b In the right pane, name the table `cr1_table_scalar`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Math Operation**.
- 4 Create entry parameters. In the **Operation** drop-down list, select `Multiply`.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input arguments, `u1` and `u2` with the **Data Type** of `uint8` and the **Argument Type** of `Scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.

Specify a **Name** for the replacement function under **Function prototype**.

- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function to call your code replacement library table. The function should not have arguments and return a table object.
  - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_scalar()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function .

```
function hTable = crl_table_scalar()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCOperationEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_table_scalar()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'ImplementationName', 'u8_mul_u8_u8', ...
 'ImplementationHeaderFile', 'u8_mul_u8_u8.h', ...
 'ImplementationSourceFile', 'u8_mul_u8_u8.c');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString`.

```

function hTable = crl_table_scalar()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'ImplementationName', 'u8_mul_u8_u8', ...
 'ImplementationHeaderFile', 'u8_mul_u8_u8.h', ...
 'ImplementationSourceFile', 'u8_mul_u8_u8.c');

%% Create the conceptual representation
arg = getTflArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(hEntry, arg);

```

- 6** Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `copyConceptualArgsToImplementation`. Add the complete entry to the table by calling the function `addEntry`.

```

function hTable = crl_table_scalar()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'ImplementationName', 'u8_mul_u8_u8', ...
 'ImplementationHeaderFile', 'u8_mul_u8_u8.h', ...
 'ImplementationSourceFile', 'u8_mul_u8_u8.c');

%% Create the conceptual representation
arg = getTflArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(hEntry, arg);

%% Create the Implementation Representation
copyConceptualArgsToImplementation(hEntry);

```

```
%% Add the entry to the table
hTable.addEntry(hEntry);
```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_scalar
```

- 9 Create a registration file for the code replacement library with these specifications:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for scalar operator replacement';
this(1).TableList = {'crl_table_scalar.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Addition and Subtraction Algorithm Types for Code Replacement

When you replace an addition or subtraction operator, your library function algorithm must match the algorithm type of the operator that you want to replace. Addition and subtraction operations are either cast-before-operation or cast-after-operation algorithms. First, determine which type of algorithm your library function implements. Then, to replace an operator in the generated code, determine how the code generator classifies the operator algorithm. Match your library function algorithm to the classification. For an example, see “Replace Addition and Subtraction Operator Code” on page 69-151.

### Algorithm Options

When creating a code replacement table entry for an addition or subtraction operator, first determine the type of algorithm that your library function implements.

- Cast-before-operation (CBO), default — Prior to performing the addition or subtraction operation, the algorithm type casts input values to the output type. If the output data type cannot exactly represent the input values, losses can occur as a result of the cast to the output type. Additional loss can occur when the result of the operation is cast to the final output type.

- Cast-after-operation (CAO) — The algorithm computes the ideal result of the addition or subtraction operation of the two inputs. The algorithm then type casts the result to the output data type. Loss occurs during the type cast. This algorithm behaves similarly to the C language except when the signedness of the operands does not match. For example, when you add a signed long operand to an unsigned long operand, standard C language rules convert the signed long operand to an unsigned long operand. The result is a value that is not ideal.

### Algorithm Classification

During code generation, the code generator examines addition and subtraction operations, including adjacent type cast operations, to determine the type of algorithm to compute the expression result. Based on the data types in the expression and the type of the accumulator (type used to hold the result of the addition or subtraction operation), the code generator uses these rules.

- Floating-point types only

Input 1 Data Type	Input 2 Data Type	Accumulator Data Type	Output Data Type	Classification
double	double	double	double	CBO, CAO
double	double	double	single	—
double	double	single	double	—

Input 1 Data Type	Input 2 Data Type	Accumulator Data Type	Output Data Type	Classification
double	double	single	single	CBO
double	single	double	double	CBO, CAO
double	single	double	single	—
double	single	single	double	—
double	single	single	single	CBO
single	single	single	single	CBO, CAO
single	single	single	double	—
single	single	double	single	—
single	single	double	double	CBO, CAO

- Floating-point and fixed-point types on the immediate addition or subtraction operation

Algorithm	Conditions
CBO	One of the following is true: <ul style="list-style-type: none"> <li>• Operation type is double.</li> <li>• Operation type is single and input types are single or fixed-point.</li> </ul>
CAO	Operation type is a superset of input types—that is, output type can represent values of input types without loss of data.

- Fixed-point types only

Algorithm	Conditions
CBO	At least one of the following is true: <ul style="list-style-type: none"> <li>• Accumulator type equals output type (<math>T_{acc} == T_{out}</math>).</li> <li>• Output type is a superset of input types (<math>T_{acc} \geq \{T_{in1}, T_{in2}\}</math>) and accumulator type is a superset of output type (<math>T_{acc} \geq T_{out}</math>).</li> <li>• Operation does not incur range or precision loss.</li> </ul>
CAO	Net bias is zero and the data types in the expression have equal slope adjustment factors. For more information on net bias, see “Addition” or “Subtraction” in “Fixed-Point Operator Code Replacement” on page 70-134 (for MATLAB code) or “Fixed-Point Operator Code Replacement” on page 69-186 (for Simulink models).

In many cases, the numerical result of a CBO operation is equal to that of a CAO operation. For example, if the input and output types are such that the operation produces the ideal result, as in the case of  $int8 + int8 \rightarrow int16$ . To maximize the probability of code replacement occurring in such cases, set the algorithm to cast-after-operation.

## Limitations

- When classifying an operation as a CAO operation, the code generator includes the adjacent casts in the expression when the expression involves only fixed-point types. Otherwise, the code generator classifies and replaces only the immediate addition or subtraction operation. Casts that the code generator excludes from the classification appear in the generated code.

- To enable the code generator to include multiple cast operations, which follow an addition or subtraction of fixed-point data, in the classification of an expression, the rounding mode must be `simplest` or `floor`. Consider the expression `y=(cast A)(cast B)(u1+u2)`. If the rounding mode of `(cast A)`, `(cast B)`, and the addition operator `(+)` are set to `simplest` or `floor`, the code generator takes into account `(cast A)` and `(cast B)` when classifying the expression and performing the replacement only.

## Replace Addition and Subtraction Operator Code

This example shows how to develop a code replacement library to optimize the performance of addition and subtraction operators by providing information on how to define code replacement for a addition operator. To develop a code replacement library use either the interactive or programmatic approach. When you replace an addition or subtraction operator, your library function algorithm must match the algorithm type of the operator that you want to replace. For more information, see “Addition and Subtraction Algorithm Types for Code Replacement” on page 69-148.

### Interactively Develop a Code Replacement Library

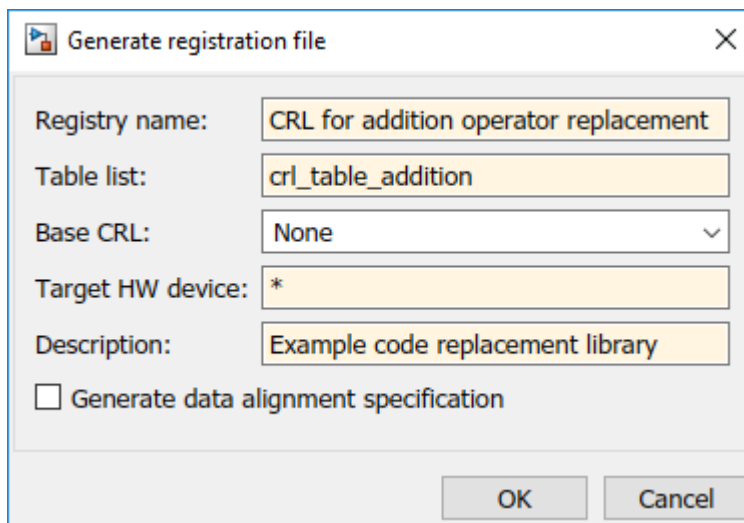

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:
 

```
>>crtool
```
- 2 Create a table.
  - a From the crtool context menu, select **File > New Table**.
  - b In the right pane, name the table `cr1_table_addition`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Math Operation**.
- 4 Create entry parameters. In the **Function** drop-down list, select **Addition**. Algorithm information appears in the crtool. For this example, select the parameter to `Cast` before operation.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, with the **Data Type** of `uint8` and the **Argument Type** of `Scalar`, the input arguments, `u1` and `u2` with the **Data Type** of `uint16` and the **Argument Type** of `Scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.
 

Specify a **Name** for the replacement function under **Function prototype**.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
  - b Create a table object by calling `RTW.TflTable`.

```
function hTflTable = make_cbo_add_crl_table
% Create a function to call the code replacement library table

%% Create a table object
hTflTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCOperationEntry`.

```
function hTflTable = make_cbo_add_crl_table
% Create a function to call the code replacement library table

%% Create a table object
hTflTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCOperationEntryParameters`.

```
function hTflTable = make_cbo_add_crl_table
% Create a function to call the code replacement library table

%% Create a table object
hTflTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
 'Key', 'RTW_OP_ADD', ...
 'EntryInfoAlgorithm', 'RTW_CAST_BEFORE_OP', ...
 'ImplementationName', 'u8_add_cao_u16_u16');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString`.

```
function hTflTable = make_cbo_add_crl_table
% Create a function to call the code replacement library table
```

```

%% Create a table object
hTflTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
 'Key', 'RTW_OP_ADD', ...
 'EntryInfoAlgorithm', 'RTW_CAST_BEFORE_OP', ...
 'ImplementationName', 'u8_add_cao_u16_u16');

%% Create the conceptual representation
arg = getTflArgFromString(hTflTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTflTable, 'u1', 'uint16');
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTflTable, 'u2', 'uint16');
addConceptualArg(hEntry, arg);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `copyConceptualArgsToImplementation`. Add the complete entry to the table by calling the function `addEntry`.

```

function hTflTable = make_cbo_add_crl_table()
% Create a function to call the code replacement library table

%% Create a table object
hTflTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
 'Key', 'RTW_OP_ADD', ...
 'EntryInfoAlgorithm', 'RTW_CAST_BEFORE_OP', ...
 'ImplementationName', 'u8_add_cao_u16_u16');

%% Create the conceptual representation
arg = getTflArgFromString(hTflTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTflTable, 'u1', 'uint16');
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTflTable, 'u2', 'uint16');
addConceptualArg(hEntry, arg);

%% Create the Implementation Representation
copyConceptualArgsToImplementation(hEntry);

%% Add the entry to the table
addEntry(hTflTable, hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = make_cbo_add_crl_table
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) with these specifications:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for addition subtraction operator replacement';
this(1).TableList = {'make_cbo_add_crl_table.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Generate Code using Addition and Subtraction Operator Code Replacement Library

In this section, you generate code using the code replacement library that you created in the first two sections of this example. The generated code contains the implementation function signature that modifies an addition operator. For this example, the addition operator contains the `Cast` before operation parameter. This example does not provide an implementation function. You should write the implementation function that contains the optimization that you want to see in the generated code.

### Example Model

Open the model `crl_AddSubfunction` for configuring the code replacement library.

```
crl_AddSubfunction
```

```
copyfile AddSubFnRtwTargetInfo.txt rtwTargetInfo.m
```

The input ports are of data type `uint16` and the output port is of data type `uint8`. For the Add block, the **Accumulator data type** is set to `uint8`. Based on these data types, the addition is a cast-before-operation algorithm.

To create a code replacement table and register the file, run the MATLAB customization file. For this example, the customization file has already been executed. To register the library, run the `sl_refresh_customizations` function.

```
sl_refresh_customizations;
```

### Enable Code Replacement Library

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Interface** pane, set **Code Replacement Library**. Click **Select** and add CRL for Addition and Subtraction operator replacement to the **Selected code replacement libraries - prioritized** list pane. Alternatively, use the command-line API to enable the code replacement:

```
set_param('crl_AddSubfunction', 'CodeReplacementLibrary', 'CRL for Addition and Subtraction operator');
```

Generate code from the model:

```
evalc('slbuild(''crl_AddSubfunction'')');
```

View the generated code. Here is a portion of `crl_AddSubfunction.c`.

```
cfile = fullfile('crl_AddSubfunction_ert_rtw','crl_AddSubfunction.c');
rtwdemodbtype(cfile,'/* Model step function ','/* Model initialize function',1, 1);

/* Model step function */
void crl_AddSubfunction_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 * Sum: '<Root>/Add8'
 */
 crl_AddSubfunction_Y.Out1 = u8_add_cbo_u16_u16(crl_AddSubfunction_U.In1,
 crl_AddSubfunction_U.In2);
}
```

The + operator can be replaced with your custom implementation.

Close the model.

```
delete ./rtwTargetInfo.m
bdclose('crl_AddSubfunction');
rtwdemoclean;
```

## Matrix Multiplication Operation to MathWorks BLAS Code Replacement

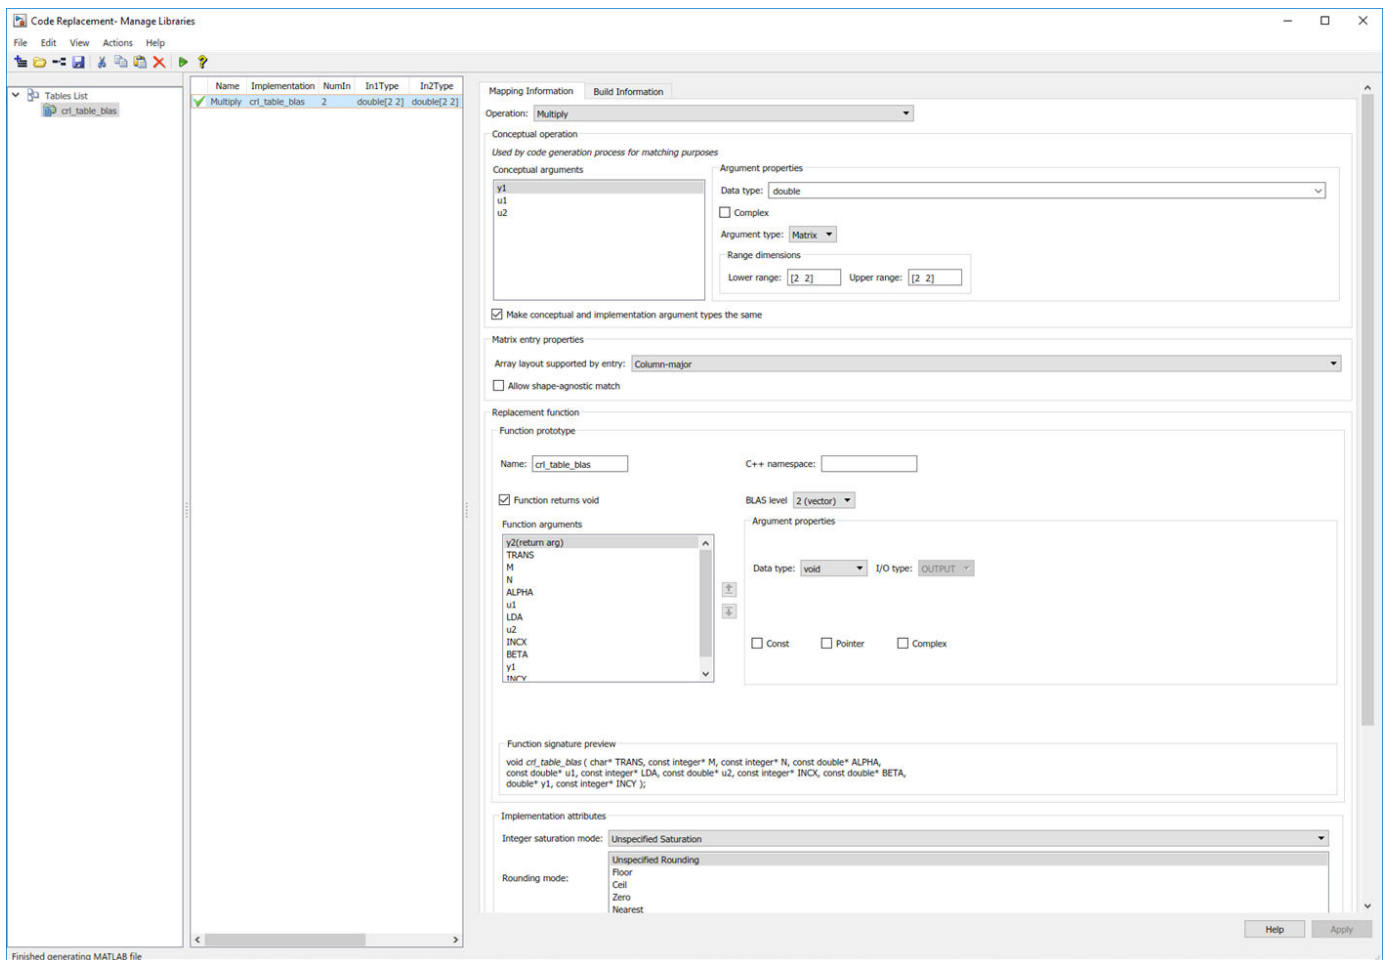

You can develop a code replacement library for floating-point matrix/matrix and matrix/vector multiplication operations with the multiplication functions `dgemm` and `dgemv` defined in the MathWorks BLAS library. If you use a third-party BLAS library for replacement, you must change the build requirements in this example to point to your library. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

### Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:
 

```
>>crtool
```
- 2 Create a table.
  - a From the crtool context menu, select **File > New Table**.
  - b In the right pane, name the table `cr1_table_blas`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Blas Operation (Fortran)**.
- 4 Create entry parameters. In the **Function** drop-down list, select **Multiply**.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1` and `u2` with the **Data Type** of **double** and the **Argument Type** of **Matrix**.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box. Set the **BLAS level** to **2(Vector)**.
 

Specify a **Name** for the replacement function under **Function prototype**.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function to call your code replacement library table. The function should not have arguments and return a table object.
  - b Create a table object by calling `RTW.TfTable`.

```
function hTable = crl_table_blas
% Create a function to call the code replacement library table
```

```
%% Create a table object
hTable = RTW.TfTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TfBlasEntryGenerator`.

```
function hTable = crl_table_blas
% Create a code replacement library table
```

```
%% Create a table object
hTable = RTW.TfTable;
```

```
%% Create an entry
```

```

%% Define library path for Windows or UNIX block%%
arch = computer('arch');
if ~ispc
 LibPath = fullfile('${MATLAB_ROOT}', 'bin', arch);
else
 % Use Stateflow to get the compiler info
 compilerInfo = sf('Private','compilerman','get_compiler_info');
 compilerName = compilerInfo.compilerName;
 if strcmp(compilerName, 'msvc90') || ...
 strcmp(compilerName, 'msvc80') || ...
 strcmp(compilerName, 'msvc71') || ...
 strcmp(compilerName, 'msvc60'), ...
 compilerName = 'microsoft';
 end
 LibPath = fullfile('${MATLAB_ROOT}', 'extern', 'lib', arch, compilerName);
end

if ispc
 libExt = 'lib';
elseif ismac
 libExt = 'dylib';
else
 libExt = 'so';
end

```

```

%% Beginning of entries for the first dgemm block%%

```

```

% Create table entry for dgemm32
hEntry = RTW.TflBlasEntryGenerator;

```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```

function hTable = crl_table_blas
% Create a code replacement library table

% Create a table object
hTable = RTW.TflTable;

% Create an entry
%% Define library path for Windows or UNIX block%%
arch = computer('arch');
if ~ispc
 LibPath = fullfile('${MATLAB_ROOT}', 'bin', arch);
else
 % Use Stateflow to get the compiler info
 compilerInfo = sf('Private','compilerman','get_compiler_info');
 compilerName = compilerInfo.compilerName;
 if strcmp(compilerName, 'msvc90') || ...
 strcmp(compilerName, 'msvc80') || ...
 strcmp(compilerName, 'msvc71') || ...
 strcmp(compilerName, 'msvc60'), ...
 compilerName = 'microsoft';
 end
 LibPath = fullfile('${MATLAB_ROOT}', 'extern', 'lib', arch, compilerName);
end

if ispc
 libExt = 'lib';
elseif ismac
 libExt = 'dylib';
else
 libExt = 'so';
end

```

```

%% Beginning of entries for the first dgemm block%%

```

```

% Create table entry for dgemm32
hEntry = RTW.TflBlasEntryGenerator;

% Create entry parameters
setTflCOperationEntryParameters(hEntry, ...
 'Key', 'RTW_OP_MUL', ...

```

```

'Priority', 100, ...
'ImplementationName', 'dgemm32', ...
'ImplementationHeaderFile', 'blascompat32_crl.h', ...
'ImplementationHeaderPath', fullfile('${MATLAB_ROOT}','extern','include'), ...
'AdditionalLinkObjs', {'libmwbblascompat32.' libExt}}, ...
'AdditionalLinkObjsPaths', {LibPath}, ...
'SideEffects', true);

```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `createAndAddConceptualArg`. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions `[2 2; inf inf]`, while the conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions `[2 1; inf 1]`.

```

function hTable = crl_table_blas
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
%%

arch = computer('arch');
if ~ispc
 LibPath = fullfile('${MATLAB_ROOT}', 'bin', arch);
else
 % Use Stateflow to get the compiler info
 compilerInfo = sf('Private','compilerman','get_compiler_info');
 compilerName = compilerInfo.compilerName;
 if strcmp(compilerName, 'msvc90') || ...
 strcmp(compilerName, 'msvc80') || ...
 strcmp(compilerName, 'msvc71') || ...
 strcmp(compilerName, 'msvc60'), ...
 compilerName = 'microsoft';
 end
 LibPath = fullfile('${MATLAB_ROOT}', 'extern', 'lib', arch, compilerName);
end

if ispc
 libExt = 'lib';
elseif ismac
 libExt = 'dylib';
else
 libExt = 'so';
end

%%

% Create table entry for dgemm32
hEntry = RTW.TflBlasEntryGenerator;

%% Create entry parameters
setTflCoperationEntryParameters(hEntry, ...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 100, ...
 'ImplementationName', 'dgemm32', ...
 'ImplementationHeaderFile', 'blascompat32_crl.h', ...
 'ImplementationHeaderPath', fullfile('${MATLAB_ROOT}','extern','include'), ...
 'AdditionalLinkObjs', {'libmwbblascompat32.' libExt}}, ...
 'AdditionalLinkObjsPaths', {LibPath}, ...
 'SideEffects', true);

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'double', ...

```

```

 'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(hEntry, 'RTW.TfLArgMatrix', ...
 'Name', 'u1', ...
 'BaseType', 'double', ...
 'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(hEntry, 'RTW.TfLArgMatrix', ...
 'Name', 'u2', ...
 'BaseType', 'double', ...
 'DimRange', [1 1; inf inf]);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `getTfLArgFromString`. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments. Add the complete entry to the table by calling the function `addEntry`.

```

function hTable = crl_table_blas
% Create a code replacement library table

%% Create a table object
hTable = RTW.TfLTable;

%% Create an entry
%%
arch = computer('arch');
if ~ispc
 LibPath = fullfile('${MATLAB_ROOT}', 'bin', arch);
else
 % Use Stateflow to get the compiler info
 compilerInfo = sf('Private','compilerman','get_compiler_info');
 compilerName = compilerInfo.compilerName;
 if strcmp(compilerName, 'msvc90') || ...
 strcmp(compilerName, 'msvc80') || ...
 strcmp(compilerName, 'msvc71') || ...
 strcmp(compilerName, 'msvc60'), ...
 compilerName = 'microsoft';
 end
 LibPath = fullfile('${MATLAB_ROOT}', 'extern', 'lib', arch, compilerName);
end

if ispc
 libExt = 'lib';
elseif ismac
 libExt = 'dylib';
else
 libExt = 'so';
end

%%

% Create table entry for dgemm32
hEntry = RTW.TfLBlasEntryGenerator;

%% Create entry parameters
setTfLCOperationEntryParameters(hEntry, ...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 100, ...
 'ImplementationName', 'dgemm32', ...
 'ImplementationHeaderFile', 'blascompat32_crl.h', ...
 'ImplementationHeaderPath', fullfile('${MATLAB_ROOT}','extern','include'), ...
 'AdditionalLinkObjs', {'libmwblascompat32.' libExt}, ...
 'AdditionalLinkObjsPaths', {LibPath}, ...
 'SideEffects', true);

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TfLArgMatrix', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'double', ...
 'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(hEntry, 'RTW.TfLArgMatrix', ...

```

```

 'Name', 'u1', ...
 'BaseType', 'double', ...
 'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix', ...
 'Name', 'u2', ...
 'BaseType', 'double', ...
 'DimRange', [1 1; inf inf]);

%% Create the Implementation Representation
% Using RTW.TflBlasEntryGenerator for xgemv requires the following
% implementation signature:
%
% void f(char* TRANSA, char* TRANSB, int* M, int* N, int* K,
% type* ALPHA, type* u1, int* LDA, type* u2, int* LDB,
% type* BETA, type* y, int* LDC)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and inserts them into the
% generated code. TRANSA and TRANSB are set to 'N'.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.Implementation.setReturn(arg);

arg = RTW.TflArgCharConstant('TRANSA');
% Possible values for PassByType property are
% RTW_PASSBY_AUTO, RTW_PASSBY_POINTER,
% RTW_PASSBY_VOID_POINTER, RTW_PASSBY_BASE_POINTER
arg.PassByType = 'RTW_PASSBY_POINTER';
hEntry.Implementation.addArgument(arg);

arg = RTW.TflArgCharConstant('TRANSB');
arg.PassByType = 'RTW_PASSBY_POINTER';
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

```

```

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
arg.PassByType = 'RTW_PASSBY_POINTER';
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

```

```

%% Add the entry to the table
addEntry(hTable, hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_blas
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file with these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for matrix multiplication for Mathworks Blas code';
this(1).TableList = {'crl_table_blas.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Convert a Matrix Multiplication Operation to MathWorks BLAS Through Code Replacement

In this section, you generate code using the code replacement library that you created in the first two sections of this example. A floating-point matrix/matrix multiplication operation is replaced with a custom multiplication function `dgemm` in the generated code. This example does not provide an implementation function. Write your own implementation.

### Example Model

Open the model `crl_blas` for configuring the code replacement library.

```
open_system('crl_blas');
copyfile BlasTargetInfo.txt rtwTargetInfo.m
```

Run the MATLAB customization file to create a code replacement table and register the file. The customization file has already been executed. Run the `sl_refresh_customizations` function to register the library.

```
sl_refresh_customizations;
```

### Enable Code Replacement Library

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Interface** pane, set **Code Replacement Library** by clicking **Select** and adding CRL for matrix multiplication for Mathworks Blas code to the **Selected code replacement libraries - prioritized** list pane. Alternatively, use the command-line API to enable the code replacement:

```
set_param('crl_blas', 'CodeReplacementLibrary', 'CRL for matrix multiplication for Mathworks Blas');
```

Generate code from the model:

```
evalc('slbuild(''crl_blas'')');
```

View the generated code. Here is a portion of `crl_blas.c`.

```
cfile = fullfile('crl_blas_ert_rtw','crl_blas.c');
rtwdemodbtype(cfile,'/* Model step function ','/* Model initialize function',1, 1);

/* Model step function */
void crl_blas_step(void)
{
 real_T ALPHA;
 real_T BETA;
 int32_T K;
 int32_T LDA;
 int32_T LDB;
 int32_T LDC;
 int32_T M;
 int32_T N;
 char_T TRANSA;
```

```

char_T TRANSB;

/* Product: '<Root>/DGEMM32' */
TRANSA = 'N';
TRANSB = 'N';
M = 10;
N = 10;
K = 20;
ALPHA = 1.0;
LDA = 10;
LDB = 20;
BETA = 0.0;
LDC = 10;

/* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 * Product: '<Root>/DGEMM32'
 */
dgemm32(&TRANSA, &TRANSB, &M, &N, &K, &ALPHA, &rtU.In1[0], &LDA, &rtU.In2[0],
 &LDB, &BETA, &rtY.Out1[0], &LDC);

/* MATLAB Function: '<Root>/DGEMM32_2' */
/* MATLAB Function 'DGEMM32_2': '<S1>:1' */
/* '<S1>:1:5' */
TRANSA = 'N';
TRANSB = 'N';

/* Outport: '<Root>/Out7' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 * MATLAB Function: '<Root>/DGEMM32_2'
 */
dgemm32(&TRANSA, &TRANSB, &M, &N, &K, &ALPHA, &rtU.In1[0], &LDA, &rtU.In2[0],
 &LDB, &BETA, &rtY.Out7[0], &LDC);
}

```

The matrix/matrix multiplication operation is repalced with the custom `dgemm32` function.

Close the model and code generation report.

```

delete ./rtwTargetInfo.m
bdclose('crl_blas');
rtwdemoclean;

```

## Matrix Multiplication Operation to ANSI/ISO C BLAS Code Replacement

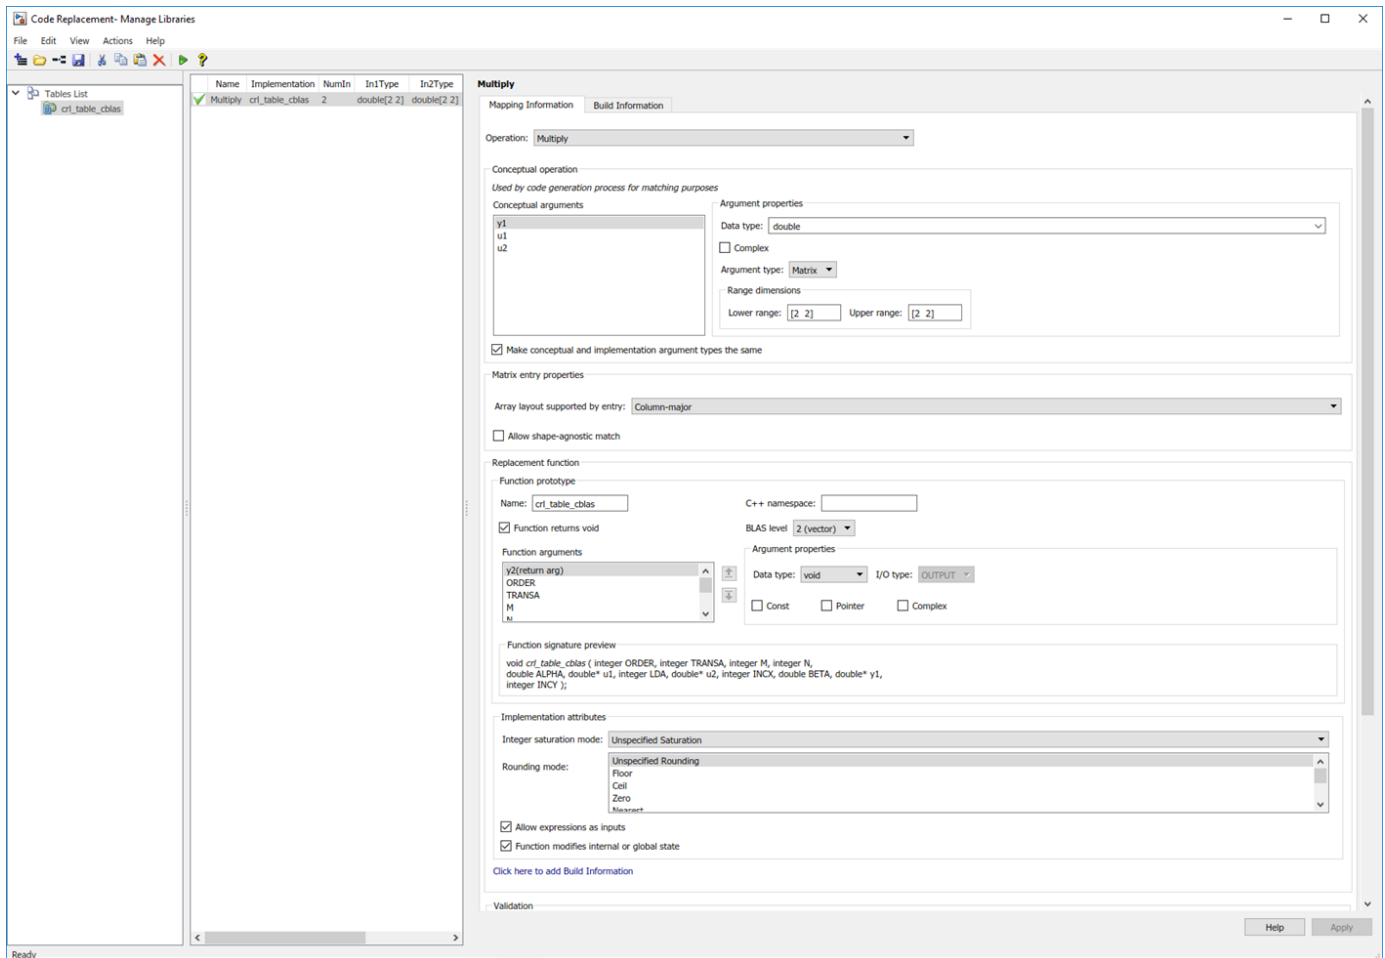

You can develop a code replacement library for floating-point matrix/matrix and matrix/vector multiplication operations with the multiplication functions `sgemm` defined in the MathWorks C BLAS library. Use a third-party C BLAS library for replacement and change the build requirements in this example to point to your library. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

### Interactively Develop a Code Replacement Library

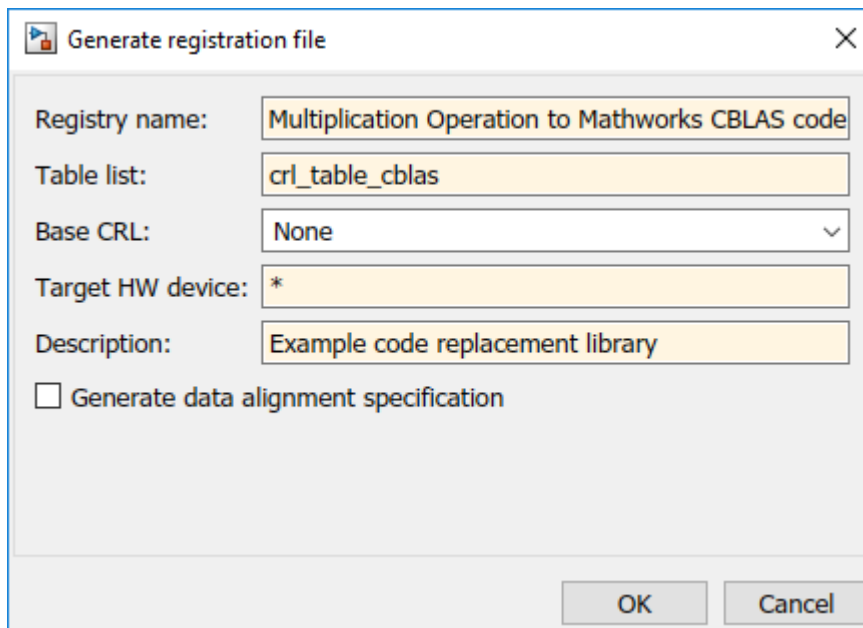

- 1 Open the **Code Replacement Tool** (`crtool`), from the MATLAB command line with the following command:  

```
>>crtool
```
- 2 Create a table.
  - a From the `crtool` context menu, select **File > New Table**.
  - b In the right pane, name the table `cr1_table_cblas`. Click **Apply**.
- 3 Create an entry. From the `crtool` context menu, select **File > New entry > CBlas Operation (Atlas)**.
- 4 Create entry parameters. In the **Function** drop-down list, select **Multiply**.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the `crtool`, specify the return argument, `y1`, and the input argument, `u1` and `u2` with the **Data Type** of `single` and the **Argument Type** of `Matrix`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box. Set the **BLAS level** to `3(Vector)`.  
  
Specify a **Name** for the replacement function under **Function prototype**.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the `crtool` context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function to call your code replacement library table. The function should not have arguments and return a table object.
  - b Create a table object by calling `RTW.TfTable`.

```
function hTable = crl_table_cblas
% Create a function to call the code replacement library table
```

```
%% Create a table object
hTable = RTW.TfTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TfCblasEntryGenerator`.

```
function hTable = crl_table_cblas
% Create a code replacement library table
```

```
%% Create a table object
hTable = RTW.TfTable;
```

```
%% Create an entry
```

```

%%% Define library path Cblas library file%%%
LibPath = fullfile('<Specify the path of your cblas library>');

if ispc
 libExt = 'lib';
elseif ismac
 libExt = 'dylib';
else
 libExt = 'so';
end

```

```

% Create table entry for dgemm32
hEntry = RTW.TfLCLblasEntryGenerator;

```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTfLCLFunctionEntryParameters`.

```

function hTable = crl_table_cblas
% Create a code replacement library table

%% Create a table object
hTable = RTW.TfLTable;

%% Create an entry
%%% Define library path Cblas library file%%%
LibPath = fullfile('<Specify the path of your cblas library>');

if ispc
 libExt = 'lib';
elseif ismac
 libExt = 'dylib';
else
 libExt = 'so';
end

% Create table entry for dgemm32
hEntry = RTW.TfLCLblasEntryGenerator;

%% Create entry parameters
hEntry.setTfLCLOperationEntryParameters(...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 100, ...
 'ImplementationName', 'cblas_sgemm', ...
 'ImplementationSourceFile', 'ccblas.c', ...
 'ImplementationHeaderFile', 'ccblas.h', ...
 'AdditionalIncludePaths', {LibPath}, ...
 'AdditionalLinkObjs', {'libcblas' libExt}, ...
 'AdditionalLinkFlags', {'-lgfortran'}, ...
 'SideEffects', true);

```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `createAndAddConceptualArg`. To specify a matrix argument in the function call, use the argument class `RTW.TfLArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger.

```

function hTable = crl_table_cblas
% Create a code replacement library table

%% Create a table object
hTable = RTW.TfLTable;

%% Create an entry
%%% Define library path Cblas library file%%%
LibPath = fullfile('<Specify the path of your cblas library>');

if ispc
 libExt = 'lib';
elseif ismac
 libExt = 'dylib';
else
 libExt = 'so';
end

```

```

 libExt = 'so';
end

% Create table entry for dgemm32
hEntry = RTW.TfLCBlasEntryGenerator;

%% Create entry parameters
hEntry.setTfLCOperationEntryParameters(...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 100, ...
 'ImplementationName', 'cblas_sgemm', ...
 'ImplementationSourceFile', 'ccblas.c', ...
 'ImplementationHeaderFile', 'ccblas.h', ...
 'AdditionalIncludePaths', {LibPath}, ...
 'AdditionalLinkObjs', {['libcblas' libExt]}, ...
 'AdditionalLinkFlags', { '-lgfortran'}, ...
 'SideEffects', true);

%% Create the conceptual representation
arg = RTW.TfLArgMatrix('y1', 'RTW_IO_OUTPUT', 'single');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TfLArgMatrix('u1', 'RTW_IO_INPUT', 'single');
arg.DimRange = [2 1; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TfLArgMatrix('u2', 'RTW_IO_INPUT', 'single');
arg.DimRange = [1 2; Inf Inf];
hEnt.addConceptualArg(arg);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `getTfLArgFromString`. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments. Add the complete entry to the table by calling the function `addEntry`.

```

function hTable = crl_table_cblas
% Create a code replacement library table

%% Create a table object
hTable = RTW.TfLTable;

%% Create an entry
%%%
LibPath = fullfile('<Specify the path of your cblas library>');

if ispc
 libExt = 'lib';
elseif ismac
 libExt = 'dylib';
else
 libExt = 'so';
end

% Create table entry for dgemm32
hEntry = RTW.TfLCBlasEntryGenerator;

%% Create entry parameters
hEntry.setTfLCOperationEntryParameters(...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 100, ...
 'ImplementationName', 'cblas_sgemm', ...
 'ImplementationSourceFile', 'ccblas.c', ...
 'ImplementationHeaderFile', 'ccblas.h', ...
 'AdditionalIncludePaths', {LibPath}, ...
 'AdditionalLinkObjs', {['libcblas' libExt]}, ...
 'AdditionalLinkFlags', { '-lgfortran'}, ...
 'SideEffects', true);

%% Create the conceptual representation

```

```

arg = RTW.TfLArgMatrix('y1', 'RTW_IO_OUTPUT', 'single');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TfLArgMatrix('u1', 'RTW_IO_INPUT', 'single');
arg.DimRange = [2 1; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TfLArgMatrix('u2', 'RTW_IO_INPUT', 'single');
arg.DimRange = [1 2; Inf Inf];
hEnt.addConceptualArg(arg);

%% Create the Implementation Representation
% Using RTW.TfLCBlasEntryGenerator for sgemm requires the following
% implementation signature:
%
% void no_name(const integer ORDER, const integer TRANSA, const integer TRANSB,
% const integer M, const integer N, const integer K, const double ALPHA,
% const double* u1, const integer LDA, const double* u2, const integer LDB,
% const double BETA, double* y1, const integer LDC);
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and inserts them into the
% generated code. TRANSA and TRANSB are set to 'N'.

% Specify replacement function signature
arg = hEntry.getTfLArgFromString('y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.Implementation.setReturn(arg);

arg = hEntry.getTfLArgFromString('ORDER', 'integer', 102.00000000000000);
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTfLArgFromString('TRANSA', 'integer', 111.00000000000000);
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTfLArgFromString('TRANSB', 'integer', 111.00000000000000);
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTfLArgFromString('M', 'integer', 0.00000000000000);
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTfLArgFromString('N', 'integer', 0.00000000000000);
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTfLArgFromString('K', 'integer', 0.00000000000000);
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTfLArgFromString('ALPHA', 'double', 1.00000000000000);
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTfLArgFromString('u1', 'single*');
arg.Type.BaseType.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTfLArgFromString('LDA', 'integer', 0.00000000000000);
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTfLArgFromString('u2', 'single*');
arg.Type.BaseType.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTfLArgFromString('LDB', 'integer', 0.00000000000000);
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTfLArgFromString('BETA', 'double', 0.00000000000000);
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTfLArgFromString('y1', 'single*');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.Implementation.addArgument(arg);

```

```
arg = hEntry.getTflArgFromString('LDC','integer',0.0000000000000000);
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);
```

```
%% Add the entry to the table
addEntry(hTable, hEntry);
```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_cblas
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file with these specifications:

```
function rtwTargetInfo(cm)
cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for matrix multiplication for Mathworks CBlas code';
this(1).TableList = {'crl_table_cblas.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Small Matrix Operation to Processor Code Replacement

This example shows how to develop a code replacement library to optimize the performance of non-scalar small matrix operations with processor-specific intrinsic functions by providing information on how to define code replacement for a **addition** operator. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

### Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:
 

```
>>crtool
```
- 2 Create a table.
  - a From the crtool context menu, select **File > New Table**.
  - b In the right pane, name the table `cr1_table_small_matrix`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Math Operation**.
- 4 Create entry parameters. In the **Function** drop-down list, select **Addition**. Algorithm information appears in the crtool. For this example, select the parameter to **Cast before operation**.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, with the **Data Type** of `double` and the **Argument Type** of **Matrix**, the input argument, `u1` with the **Data Type** of `double` and the **Argument Type** of **Matrix** and the input argument, `u2` with the **Data Type** of `double` and the **Argument Type** of **Matrix**.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box. Specify the return argument `y1`, `u1` and `u2`, with the **Data Type** of `double` and select the **Pointer** dialog box.
 

Specify a **Name** for the replacement function under **Function prototype**.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
  - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_small_matrix_operator()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
LibPath= fullfile(matlabroot, 'examples', 'coder');
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCOperationEntry`.

```
function hTable = crl_table_small_matrix_operator()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
LibPath= fullfile(matlabroot, 'examples', 'coder');
```

```
%% Create an entry
hEntry = RTW.TflCOperationEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCOperationEntryParameters`.

```
function hTable = crl_table_small_matrix_operator()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
LibPath= fullfile(matlabroot, 'examples', 'coder');
```

```
%% Create an entry
hEntry = RTW.TflCOperationEntry;
```

```
%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
 'Key', 'RTW_OP_ADD', ...
```

```

 'Priority', 30, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'ImplementationName', 'matrix_sum_2x2_double', ...
 'ImplementationHeaderFile', 'MatrixMath.h', ...
 'ImplementationSourceFile', 'MatrixMath.c', ...
 'ImplementationHeaderPath', LibPath, ...
 'ImplementationSourcePath', LibPath, ...
 'AdditionalIncludePaths', {LibPath}, ...
 'GenCallback', 'RTW.copyFileToBuildDir', ...
 'SideEffects', true);

```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `createAndAddConceptualArg`.

```

function hTable = cml_table_small_matrix_operator()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
LibPath= fullfile(matlabroot, 'examples', 'coder');

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
 'Key', 'RTW.OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'ImplementationName', 'matrix_sum_2x2_double', ...
 'ImplementationHeaderFile', 'MatrixMath.h', ...
 'ImplementationSourceFile', 'MatrixMath.c', ...
 'ImplementationHeaderPath', LibPath, ...
 'ImplementationSourcePath', LibPath, ...
 'AdditionalIncludePaths', {LibPath}, ...
 'GenCallback', 'RTW.copyFileToBuildDir', ...
 'SideEffects', true);

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'double', ...
 'DimRange', [2 2]);
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix', ...
 'Name', 'u1', ...
 'BaseType', 'double', ...
 'DimRange', [2 2]);
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix', ...
 'Name', 'u2', ...
 'BaseType', 'double', ...
 'DimRange', [2 2]);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `getTflArgFromString`.

```

function hTable = crl_table_small_matrix_operator()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
LibPath= fullfile(matlabroot,'examples','coder');

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'ImplementationName', 'matrix_sum_2x2_double', ...
 'ImplementationHeaderFile', 'MatrixMath.h', ...
 'ImplementationSourceFile', 'MatrixMath.c', ...
 'ImplementationHeaderPath', LibPath, ...
 'ImplementationSourcePath', LibPath, ...
 'AdditionalIncludePaths', {LibPath}, ...
 'GenCallback', 'RTW.copyFileToBuildDir', ...
 'SideEffects', true);

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'double', ...
 'DimRange', [2 2]);
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix',...
 'Name', 'u1', ...
 'BaseType', 'double', ...
 'DimRange', [2 2]);
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix',...
 'Name', 'u2', ...
 'BaseType', 'double', ...
 'DimRange', [2 2]);

%% Create the Implementation Representation
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);

arg.IOType = 'RTW_IO_OUTPUT';
hEntry.Implementation.addArgument(arg);

```

```
%% Add the entry to the table
hTable.addEntry(hEntry);
```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_small_matrix
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) with these specifications:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for small matrix operator to processor';
this(1).TableList = {'crl_table_small_matrix.m'};
% table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Generate Code to Optimize Performance of a Small Matrix Operation for Processor-Specific Intrinsic Function

In this section, you generate code using the code replacement library that you created in the first two sections of this example. A nonscalar small matrix multiplication operation is replaced with a call to a custom function in the generated code. This example does not provide an implementation of the custom function. Write your own implementation.

### Example Model

Open the model `crl_SmallMatrixOperation` for configuring the code replacement library.

```
open_system('crl_SmallMatrixOperation');
copyfile SmallMatrixOperatorTargetInfo.txt rtwTargetInfo.m
```

Copyright 2007-2020 The MathWorks, Inc.

Run the MATLAB® customization file to create a code replacement table and register the file. The customization file has already been executed. Run the `sl_refresh_customizations` function to register the library.

```
sl_refresh_customizations;
```

### Enable Code Replacement Library

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Interface** pane, set **Code Replacement Library** by clicking **Select** and adding CRL for small matrix operator to the **Selected code replacement libraries - prioritized** list pane. Alternatively, use the command-line API to enable the code replacement:

```
set_param('crl_SmallMatrixOperation', 'CodeReplacementLibrary', 'CRL for small matrix operator')
```

Generate code from the model:

```
evalc('slbuild(''crl_SmallMatrixOperation'')');
```

View the generated code. Here is a portion of `crl_SmallMatrixOperation.c`.

```
cfile = fullfile('crl_SmallMatrixOperation_ert_rtw','crl_SmallMatrixOperation.c');
rtwdemodbtype(cfile,'/* Model step function ', '/* Model initialize function',1, 1);

/* Model step function */
void crl_SmallMatrixOperation_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 * Sum: '<Root>/Add'
 */
 matrix_sum_2x2_double(&crl_SmallMatrixOperation_U.In1[0],
 &crl_SmallMatrixOperation_U.In2[0],
 &crl_SmallMatrixOperation_Y.Out1[0]);
}
```

The matrix multiplication operation on 2X2 matrices are replaced with the `matrix_sum_2x2_double` function.

Close the model and code generation report.

```
delete ./rtwTargetInfo.m
bdclose('crl_SmallMatrixOperation');
rtwdemoclean;
```

## Remap Operator Output to Function Input

If your generated code must meet a specific coding pattern or you want more flexibility, for example, to further improve performance, you can remap operator outputs to input positions in an implementation function argument list.

---

**Note** Remapping outputs to implementation function inputs is supported only for operator replacement.

---

For example, for a sum operation, the code generator produces code similar to:

```
add8_Y.Out1 = u8_add_u8_u8(add8_U.In1, add8_U.In2);
```

If you remap the output to the first input, the code generator produces code similar to:

```
u8_add_u8_u8(&add8_Y.Out1;, add8_U.In1, add8_U.In2);
```

The following table definition file for a sum operation remaps operator output y1 as the first function input argument.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = csl_table_add_uint8
```

- 2 Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

- 3 Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

```
% Create operation entry
op_entry = RTW.TflCOperationEntry;
```

- 4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. In the function call, set the property `SideEffects` to `true`.

```
setTflCOperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 90, ...
 'ImplementationName', 'u8_add_u8_u8', ...
 'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
 'ImplementationSourceFile', 'u8_add_u8_u8.c', ...
 'SideEffects', true);
```

- 5 Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTflArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
```

```
arg = getTflArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(op_entry, arg);
```

```
arg = getTflArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(op_entry, arg);
```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the

arguments. When defining the implementation function return argument, create a new `void` output argument, for example, `y2`. When defining the implementation function argument for the conceptual output argument (`y1`), set the operator output argument as an additional input argument. Mark its `IOType` as output. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Create new void output y2
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

% Set y1 as first input arg, mark IOType as output, and use pointer type
arg=getTflArgFromString(hTable, 'y1', 'uint8*');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg=getTflArgFromString(hTable, 'u1', 'uint8');
op_entry.Implementation.addArgument(arg);

arg=getTflArgFromString(hTable, 'u2', 'uint8');
op_entry.Implementation.addArgument(arg);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

- 1 Register the code replacement mapping.
- 2 Create a model that includes an Add block.

- 3 Configure the model with the following settings:
  - On the **Solver** pane, select a fixed-step solver.
  - On the **Code Generation** pane, select an ERT-based system target file.
  - On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.
  - Set the **Optimize global data access** parameter to Use global to hold temporary results to reduce data copies in the generated code.
- 4 Generate code and a code generation report.
- 5 Review the code replacements.

## Fixed-Point Operator Code Replacement

If you have a Fixed-Point Designer license, you can define fixed-point operator code replacement entries to match:

- A binary-point-only scaling combination on the operator inputs and output.
- A slope bias scaling combination on the operator inputs and output.
- Relative scaling or net slope between multiplication or division operator inputs and output. Use one of these methods to map a range of slope and bias values to a replacement function for multiplication or division.
- Equal slope and zero net bias across addition or subtraction operator inputs and output. Use this method to disregard specific slope and bias values and map relative slope and bias values to a replacement function for addition or subtraction.

### Common Ways to Match Fixed-Point Operator Entries

The following table maps common ways to match fixed-point operator code replacement entries with the associated fixed-point parameters that you specify in a code replacement table definition file.

Match	Create entry	Minimally specify parameters
A specific binary-point-only scaling combination on the operator inputs and output.	RTW.Tf1COperationEntry	createAndAddConceptualArg function: <ul style="list-style-type: none"> <li>• CheckSlope: Specify the value true.</li> <li>• CheckBias: Specify the value true.</li> <li>• DataTypeMode (or DataType/Scaling equivalent): Specify fixed-point binary-point-only scaling.</li> <li>• FractionLength: Specify a fraction length (for example, 3).</li> </ul>
A specific slope bias scaling combination on the operator inputs and output. ## Fixed-Point Numbers and Arithmetic

Fixed-point numbers use integers and integer arithmetic to represent real numbers and arithmetic with the following encoding scheme:

$$V = \tilde{V} = SQ + B$$

- $V$  is an arbitrarily precise real-world value.
- $\tilde{V}$  is the approximate real-world value that results from fixed-point representation.
- $Q$  is an integer that encodes  $\tilde{V}$ , referred to as the quantized integer.
- $S$  is a coefficient of  $Q$ , referred to as the slope.
- $B$  is an additive correction, referred to as the bias.

The general equation for an operation between fixed-point operands is:

$$(S_0Q_0 + B_0) = (S_1Q_1 + B_1) < op > (S_2Q_2 + B_2)$$

The objective of fixed-point operator replacement is to replace an operator that accepts and returns fixed-point or integer inputs and output with a function that accepts and returns built-in C numeric data types. The following sections provide additional programming information for each supported operator.

## Addition

The operation  $V_0 = V_1 + V_2$  implies that

$$Q_0 = \left(\frac{S_1}{S_0}\right)Q_1 + \left(\frac{S_2}{S_0}\right)Q_2 + \left(\frac{B_1 + B_2 - B_0}{S_0}\right)$$

If an addition replacement function is defined such that the scaling on the operands and sum are equal and the net bias

$$\left(\frac{B_1 + B_2 - B_0}{S_0}\right)$$

is zero (for example, a function `s8_add_s8_s8` that adds two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. To match for replacement, the slopes must be the same for all addition conceptual arguments. (For parameter descriptions, see the reference page for the function `setTfLCOperationEntryParameters`.)

## Subtraction

The operation  $V_0 = V_1 - V_2$  implies that

$$Q_0 = \left(\frac{S_1}{S_0}\right)Q_1 - \left(\frac{S_2}{S_0}\right)Q_2 + \left(\frac{B_1 - B_2 - B_0}{S_0}\right)$$

If a subtraction replacement function is defined such that the scaling on the operands and difference are equal and the net bias

$$\left(\frac{B_1 - B_2 - B_0}{S_0}\right)$$

is zero (for example, a function `s8_sub_s8_s8` that subtracts two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters

`SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. To match for replacement, the slopes must be the same for all subtraction conceptual arguments. (For parameter descriptions, see the reference page for the function `setTfLCOperationEntryParameters`.)

## Multiplication

There are different ways to specify multiplication replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few known slope and bias combinations. Use the `TfLCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry.

The operation  $V_0 = V_1 * V_2$  implies, for binary-point-only scaling, that

$$S_0 Q_0 = (S_1 Q_1)(S_2 Q_2)$$

$$Q_0 = \left( \frac{S_1 S_2}{S_0} \right) Q_1 Q_2$$

$$Q_0 = S_n Q_1 Q_2$$

where  $S_n$  is the net slope.

It is common to replace all multiplication operations that have a net slope of 1.0 with a function that performs C-style multiplication. For example, to replace all signed 8-bit multiplications that have a net scaling of 1.0 with the `s8_mul_s8_u8` replacement function, the operator entry must define a net slope factor,  $F2^E$ . You specify the values for  $F$  and  $E$  using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. For the `s8_mul_s8_u8` function, set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0. Also, set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all multiplication conceptual arguments. (For parameter descriptions, see the reference page for the function `setTfLCOperationEntryParameters`.)

---

**Note** When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

---

## Division

There are different ways to specify division replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few known slope and bias combinations. Use the `TfLCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry (see “Customize Match and Replacement Process” on page 69-132).

The operation  $V_0 = (V_1 / V_2)$  implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left( \frac{S_1 Q_1}{S_2 Q_2} \right)$$

$$Q_0 = S_n \left( \frac{Q_1}{Q_2} \right)$$

where  $S_n$  is the net slope.

It is common to replace all division operations that have a net slope of 1.0 with a function that performs C-style division. For example, to replace all signed 8-bit divisions that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor,  $F2^E$ . You specify the values for  $F$  and  $E$  using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. For the `s16_netslope0p5_div_s16_s16` function, you would set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0. Also, set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all division conceptual arguments. (For parameter descriptions, see the reference page for the function `setTfLCOperationEntryParameters`.)

---

**Note** When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

---

## Data Type Conversion (Cast)

The data type conversion operation  $V_0 = V_1$  implies, for binary-point-only scaling, that

$$Q_0 = \left( \frac{S_1}{S_0} \right) Q_1$$

$$Q_0 = S_n Q_1$$

where  $S_n$  is the net slope. Set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all cast conceptual arguments. (For parameter descriptions, see the reference page for the function `setTfLCOperationEntryParameters`.)

## Shift

The shift left or shift right operation  $V_0 = (V_1 / 2^n)$  implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left( \frac{S_1 Q_1}{2^n} \right)$$

$$Q_0 = \left( \frac{S_1}{S_0} \right) \left( \frac{Q_1}{2^n} \right)$$

$$Q_0 = S_n \left( \frac{Q_1}{2^n} \right)$$

where  $S_n$  is the net slope. Set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all shift conceptual arguments. (For parameter descriptions, see the reference page for the function `setTfLCOperationEntryParameters`.)

## Binary-Point-Only Scaling Code Replacement

You can define code replacement entries for operations on fixed-point data types such that they match a binary-point-only scaling combination of operator inputs and output. This example shows how to develop a code replacement library to optimize the performance of fixed point data type operations by providing information that maps a binary point scale entry to a addition operator. To develop a code replacement library use only the programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.

To create custom code replacement entries that add logic to the code replacement match and replacement process see “Customize Code Match and Replacement for Scalar Operations” on page 69-138. You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them to a code replacement table definition file, and sets them to specific values in the class definition code.

```
classdef TflCustomOperationEntryBinaryPoint < RTW.TflCOperationEntryML
 methods
 function ent = do_match(hThis, ...
 hCS0, ... %#ok
 targetBitPerChar, ... %#ok
 targetBitPerShort, ... %#ok
 targetBitPerInt, ... %#ok
 targetBitPerLong, ... %#ok
 targetBitPerLongLong) %#ok

 % DO_MATCH - Create a custom match function. The base class
 % checks the types of the arguments prior to calling this
 % method. This class will check additional data and can
 % modify the implementation function.

 % The base class checks word size and signedness. Slopes and biases
 % have been wildcarded, so the only additional checking to do is
 % to check that the biases are zero and that there are only three
 % conceptual arguments (one output, two inputs)

 ent = []; % default the return to empty, indicating the match failed

 if length(hCS0.ConceptualArgs) == 3 && ...
 hCS0.ConceptualArgs(1).Type.Bias == 0 && ...
 hCS0.ConceptualArgs(2).Type.Bias == 0 && ...
 hCS0.ConceptualArgs(3).Type.Bias == 0

 % Modify the default implementation. Since this is a
 % generator entry, a concrete entry is created using this entry
 % as a template. The type of entry being created is a standard
 % TflCOperationEntry. Using the standard operation entry
 % provides required information, and you do not need
 % a custom match function.
 ent = RTW.TflCOperationEntry(hThis);

 % Since this entry is modifying the implementation for specific
 % fraction-length values (arguments 3, 4, and 5), the conceptual argument
 % wild cards must be removed (the wildcards were inherited from the
 % generator when it was used as a template for the concrete entry).
 % This concrete entry is now for a specific slope and bias.
 % hCS0 holds the slope and bias values (created by the code generator).
 for idx=1:3
 ent.ConceptualArgs(idx).CheckSlope = true;
 ent.ConceptualArgs(idx).CheckBias = true;

 % Set the specific Slope and Biases
 ent.ConceptualArgs(idx).Type.Slope = hCS0.ConceptualArgs(idx).Type.Slope;
 ent.ConceptualArgs(idx).Type.Bias = 0;
 end

 % Set the fraction-length values in the implementation function.
 ent.Implementation.Arguments(3).Value = ...
 end
 end
 end
end
```

```

-1.0*hCS0.ConceptualArgs(2).Type.FixedExponent;
ent.Implementation.Arguments(4).Value = ...
-1.0*hCS0.ConceptualArgs(3).Type.FixedExponent;
ent.Implementation.Arguments(5).Value = ...
-1.0*hCS0.ConceptualArgs(1).Type.FixedExponent;
end
end
end
end

```

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
  - b Create a table object by calling `RTW.TflTable`.

```

function hTable = crl_table_fixed_binptscale()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the custom entry function .

```

function hTable = crl_table_fixed_binptscale()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntryBinaryPoint;

```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCOperationEntryParameters`.

```

function hTable = crl_table_fixed_binptscale()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntryBinaryPoint;

%% Create entry parameters
setTflCOperationEntryParameters(hEntry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'ImplementationName', 'myFixptAdd_binarypoint', ...
 'ImplementationHeaderFile', 'myFixptAdd.h', ...
 'ImplementationSourceFile', 'myFixptAdd.c');

```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `createAndAddConceptualArg`.

```
function hTable = crl_table_fixed_binptscale()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntryBinaryPoint;

%% Create entry parameters
setTflCoperationEntryParameters(hEntry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'ImplementationName', 'myFixptAdd_binarypoint', ...
 'ImplementationHeaderFile', 'myFixptAdd.h', ...
 'ImplementationSourceFile', 'myFixptAdd.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `createAndSetCImplementationReturn` and `createAndAddImplementationArg`. Add the complete entry to the table by calling the function `addEntry`.

```
function hTable = crl_table_fixed_binptscale()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntryBinaryPoint;

%% Create entry parameters
setTflCoperationEntryParameters(hEntry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'ImplementationName', 'myFixptAdd_binarypoint', ...
```

```

 'ImplementationHeaderFile', 'myFixptAdd.h', ...
 'ImplementationSourceFile', 'myFixptAdd.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);

%% Create the implementation Representation
% Specify replacement function signature
createAndSetImplementationReturn(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

% Add 3 fraction-length args. Actual values are set during code generation.
createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
 'Name', 'fl_in1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
 'Name', 'fl_in2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
 'Name', 'fl_out', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

```

```

 %% Add the entry to the table
 hTable.addEntry(op_entry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_fixed_binptscale
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) with these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for binary point scaling CRL';
this(1).TableList = {'crl_table_fixed_binptscale.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Slope Bias Scaling Code Replacement

You can define code replacement for operations on fixed-point data types as matching a slope bias scaling combination on the operator inputs and output. This example shows how to develop a code replacement library to optimize the performance of fixed point data type operations by providing information on how to define code replacement for a division operator. To develop a code replacement library use only the programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.

To create custom code replacement entries that add logic to the code replacement match and replacement process, see “Customize Code Match and Replacement for Scalar Operations” on page 69-138. You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them to a code replacement table definition file, and sets them to specific values in the class definition code.

```
classdef TflCustomOperationEntrySlopeBias < RTW.TflCOperationEntryML
 methods
 function ent = do_match(hThis, ...
 hCS0, ... %#ok
 targetBitPerChar, ... %#ok
 targetBitPerShort, ... %#ok
 targetBitPerInt, ... %#ok
 targetBitPerLong, ... %#ok
 targetBitPerLongLong) %#ok

 % DO_MATCH - Create a custom match function. The base class
 % checks the types of the arguments prior to calling this
 % method. This class will check additional data and can
 % modify the implementation function.

 % The base class checks word size and signedness. Slopes and biases
 % have been wildcarded, so the only additional checking to do is
 % to check that the biases are zero and that there are only three
 % conceptual arguments (one output, two inputs)

 ent = []; % default the return to empty, indicating the match failed

 if length(hCS0.ConceptualArgs) == 3

 % Modify the default implementation. Since this is a
 % generator entry, a concrete entry is created using this entry
 % as a template. The type of entry being created is a standard
 % TflCOperationEntry. Using the standard operation entry
 % provides required information, and you do not need
 % a custom match function.
 ent = RTW.TflCOperationEntry(hThis);

 % Since this entry is modifying the implementation for specific
 % fraction-length values (arguments 3, 4, and 5), the conceptual argument
 % wild cards must be removed (the wildcards were inherited from the
 % generator when it was used as a template for the concrete entry).
 % This concrete entry is now for a specific slope and bias.
 % hCS0 holds the slope and bias values (created by the code generator).
 for idx=1:3
 ent.ConceptualArgs(idx).CheckSlope = true;
 ent.ConceptualArgs(idx).CheckBias = true;

 % Set the specific Slope and Biases
 ent.ConceptualArgs(idx).Type.Slope = hCS0.ConceptualArgs(idx).Type.Slope;
 ent.ConceptualArgs(idx).Type.Bias = hCS0.ConceptualArgs(idx).Type.Bias;
 end

 % Set the Slope and Bias values in the implementation function.
 ent.Implementation.Arguments(3).Value = hCS0.ConceptualArgs(2).Type.Slope;
 ent.Implementation.Arguments(4).Value = hCS0.ConceptualArgs(2).Type.Bias;
 ent.Implementation.Arguments(5).Value = hCS0.ConceptualArgs(3).Type.Slope;
 ent.Implementation.Arguments(6).Value = hCS0.ConceptualArgs(3).Type.Bias;
 end
 end
 end
end
```

```

ent.Implementation.Arguments(7).Value = hCS0.ConceptualArgs(1).Type.Slope;
ent.Implementation.Arguments(8).Value = hCS0.ConceptualArgs(1).Type.Bias;
end
end
end
end

```

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
  - b Create a table object by calling `RTW.TflTable`.

```

function hTable = crl_table_custom_add_ufix32_slopebias
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the custom entry function .

```

function hTable = crl_table_custom_add_ufix32_slopebias
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntrySlopeBias;;

```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```

function hTable = crl_table_custom_add_ufix32_slopebias
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntrySlopeBias;;

%% Create entry parameters
setTflCFunctionEntryParameters(hEntry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'ImplementationName', 'myFixptAdd_slopebias', ...
 'ImplementationHeaderFile', 'myFixptAdd.h', ...
 'ImplementationSourceFile', 'myFixptAdd.c');

```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `createAndAddConceptualArg`.

```
function hTable = crl_table_custom_add_ufix32_slopebias
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntrySlopeBias;;

%% Create entry parameters
setTflCoperationEntryParameters(hEntry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'ImplementationName', 'myFixptAdd_slopebias', ...
 'ImplementationHeaderFile', 'myFixptAdd.h', ...
 'ImplementationSourceFile', 'myFixptAdd.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'SlopeBias', ...
 'IsSigned', false, ...
 'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'SlopeBias', ...
 'IsSigned', false, ...
 'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'SlopeBias', ...
 'IsSigned', false, ...
 'WordLength', 32);
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function

`createAndSetCImplementationReturn` and `createAndAddImplementationArg`. Add the complete entry to the table by calling the function `addEntry`.

```
function hTable = crl_table_custom_add_ufix32_slopebias
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntrySlopeBias;;

%% Create entry parameters
setTflCOperationEntryParameters(hEntry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'ImplementationName', 'myFixptAdd_slopebias', ...
 'ImplementationHeaderFile', 'myFixptAdd.h', ...
 'ImplementationSourceFile', 'myFixptAdd.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'SlopeBias', ...
 'IsSigned', false, ...
 'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'SlopeBias', ...
 'IsSigned', false, ...
 'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'SlopeBias', ...
 'IsSigned', false, ...
 'WordLength', 32);

%% Create the implementation Representation
% Specify replacement function signature
createAndSetCImplementationReturn(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

% Add 3 fraction-length args. Actual values are set during code generation.
createAndSetCImplementationReturn(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
```

```

 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

% Add 6 args for slopes and biases.
% Actual values are set during code generation.
createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
 'Name', 'slope_in1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
 'Name', 'bias_in1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
 'Name', 'slope_in2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
 'Name', 'bias_in2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
 'Name', 'slope_out1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
 'Name', 'bias_out1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

addEntry(hTable, hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_custom_add_ufix32_slopebias
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) with these specifications:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for slope bias scaling function replacement';
this(1).TableList = {'crl_table_custom_add_ufix32_slopebias.m'};
% table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Net Slope Scaling Code Replacement

You can define code replacement entries for multiplication and division operations on fixed-point data types such that they match the net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example shows how to develop a code replacement library to optimize the performance of fixed point net slope operations by providing information on how to define code replacement for a `divide` operation. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

### Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```

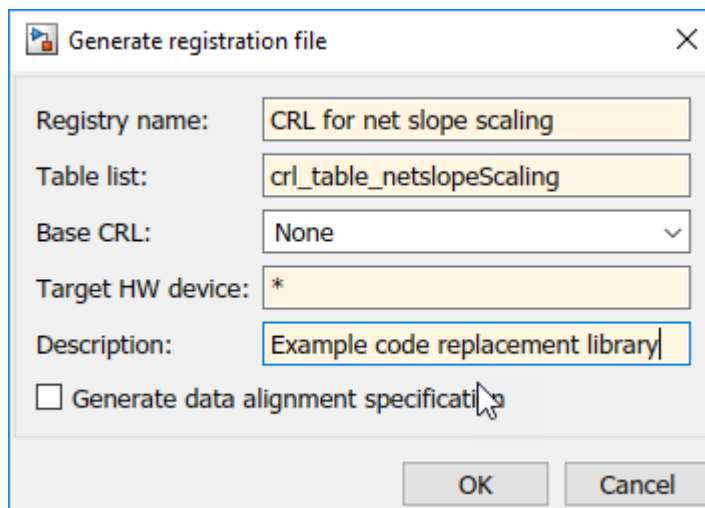

- 2 Create a table.
  - a From the crtool context menu, select **File > New Table**.
  - b In the right pane, name the table `crl_table_netslopeScaling`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Fixed Point Net Slope Operation**.
- 4 Create entry parameters. In the **Operation** drop-down list, select `Divide`.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1` and `u2` with the **Data Type** of `fixdt(true,16,*,*)` and the **Argument Type** of `Scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. In the **Function arguments** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1` and `u2` with the **Data Type** of `int16`. Also set the **Net slope Adjustment Factor** as 1 and **Net Fixed Exponent** as 0.

Specify a **Name** for the replacement function under **Function prototype**.

- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For

more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
  - b Create a table object by calling `RTW.TfTable`.

```
function hTable = crl_table_netslopeScaling
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TfTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TfCOperationEntryGenerator_NetSlope`.

```
function hTable = crl_table_netslopeScaling
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TfTable;
```

```
%% Create an entry
hEntry = RTW.TfCOperationEntryGenerator_NetSlope;
```

- 4 Set operator entry parameters with a call to the `setTfCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as wrap on overflow, rounding modes as unspecified, and the name of the replacement function as `user_div_*`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the F and E parts of the net slope  $F2^E$ .

```
function hTable = crl_table_netslopeScaling
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TfTable;
```

```
%% Create an entry
hEntry = RTW.TfCOperationEntryGenerator_NetSlope;
```

```
%% Create entry parameters
hEntry.setTfCOperationEntryParameters(...
 'Key', 'RTW_OP_DIV', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_CEILING'}, ...
 'NetSlopeAdjustmentFactor', 1.0, ...
 'NetFixedExponent', 0.0, ...
 'ImplementationName', 's16_div_s16_s16', ...
```

- ```

    'ImplementationHeaderFile', 's16_div_s16_s16.h', ...
    'ImplementationSourceFile', 's16_div_s16_s16.c');

```
- 5 Create conceptual arguments y1, u1, and u2. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point, 16 bits, and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```

function hTable = crl_table_netslopeScaling
% Create a function to call the code replacement library table

```

```

%% Create a table object
hTable = RTW.TflTable;

```

```

%% Create an entry
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;

```

```

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
    'Key', 'RTW_OP_DIV', ...
    'Priority', 90, ...
    'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_CEILING'}, ...
    'NetSlopeAdjustmentFactor', 1.0, ...
    'NetFixedExponent', 0.0, ...
    'ImplementationName', 's16_div_s16_s16', ...
    'ImplementationHeaderFile', 's16_div_s16_s16.h', ...
    'ImplementationSourceFile', 's16_div_s16_s16.c');

```

```

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'IsSigned', true, ...
    'WordLength', 16);

```

```

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'IsSigned', true, ...
    'WordLength', 16);

```

```

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'IsSigned', true, ...
    'WordLength', 16);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```
function hTable = crl_table_netslopeScaling
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
    'Key', 'RTW_OP_DIV', ...
    'Priority', 90, ...
    'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_CEILING'}, ...
    'NetSlopeAdjustmentFactor', 1.0, ...
    'NetFixedExponent', 0.0, ...
    'ImplementationName', 's16_div_s16_s16', ...
    'ImplementationHeaderFile', 's16_div_s16_s16.h', ...
    'ImplementationSourceFile', 's16_div_s16_s16.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'IsSigned', true, ...
    'WordLength', 16);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'IsSigned', true, ...
    'WordLength', 16);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'IsSigned', true, ...
    'WordLength', 16);

%% Create the Implementation Representation
```

```

createAndSetCImplementationReturn(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'IsSigned', true, ...
    'WordLength', 16, ...
    'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', true, ...
    'WordLength', 16, ...
    'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', true, ...
    'WordLength', 16, ...
    'FractionLength', 0);

```

```

%% Add the entry to the table
addEntry(hTable, hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = cml_table_netslopeScaling
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file by using these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_cml);
end

function this = loc_register_cml

this(1) = RTW.TflRegistry;
this(1).Name = 'CML for net slope scaling';
this(1).TableList = {'cml_table_netslopeScaling.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Equal Slope and Zero Net Bias Code Replacement

You can define code replacement entries for addition or subtraction of fixed-point data types such that they match the relative slope and bias values (equal slope and zero net bias) across operator inputs and output. These entries allow you to disregard slope and bias values when mapping relative slope and bias values to a replacement function for addition or subtraction.

This example shows how to develop a code replacement library to optimize the performance of fixed point net slope operations by providing information on how to define code replacement for an addition operation. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```

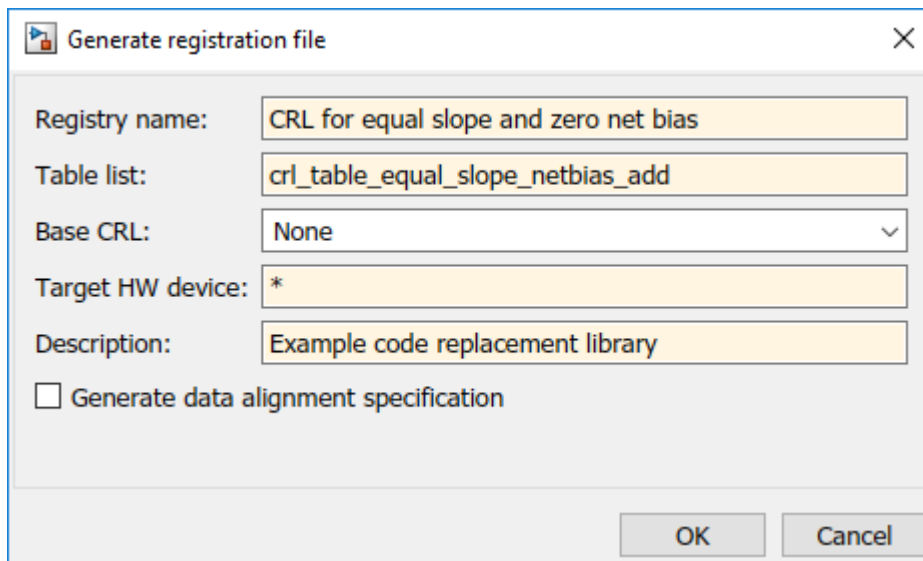

- 2 Create a table.
 - a From the crtool context menu, select **File > New Table**.
 - b In the right pane, name the table `crl_table_equal_slope_netbias_add`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Fixed Point Net Slope Operation**.
- 4 Create entry parameters. In the **Operation** drop-down list, select **Addition**.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1` and `u2` with the **Data Type** of `fixdt(true,16,*,*)` and the **Argument Type** of **Scalar**.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. In the **Function arguments** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1` and `u2` with the **Data Type** of `int16`.

Specify a **Name** for the replacement function under **Function prototype**.

- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function to call your code replacement library table. The function should not have arguments and return a table object.
 - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_equal_slope_netbias_add
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCOperationEntryGenerator_NetSlope`.

```
function hTable = crl_table_equal_slope_netbias_add
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCOperationEntryParameters`.

```
function hTable = crl_table_equal_slope_netbias_add
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 90, ...
    'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
    'SlopesMustBeTheSame', true, ...
    'MustHaveZeroNetBias', true, ...
    'ImplementationName', 'u16_add_SameSlopeZeroBias', ...
    'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h', ...
    'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');
```

- 5 Create conceptual arguments y_1 , u_1 , and u_2 . This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point, 16 bits, and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
function hTable = crl_table_equal_slope_netbias_add
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TfLTable;

%% Create an entry
hEntry = RTW.TfLCOperationEntryGenerator_NetSlope;

%% Create entry parameters
hEntry.setTfLCOperationEntryParameters(...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 90, ...
    'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
    'SlopesMustBeTheSame', true, ...
    'MustHaveZeroNetBias', true, ...
    'ImplementationName', 'u16_add_SameSlopeZeroBias', ...
    'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h', ...
    'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TfLArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'IsSigned', false, ...
    'WordLength', 16);

createAndAddConceptualArg(hEntry, 'RTW.TfLArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'IsSigned', false, ...
    'WordLength', 16);

createAndAddConceptualArg(hEntry, 'RTW.TfLArgNumeric', ...
    'Name', 'u2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'IsSigned', false, ...
    'WordLength', 16);
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. This example uses calls to the `createAndSetCImplementationReturn` function to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```
function hTable = crl_table_equal_slope_netbias_add
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TfLTable;

%% Create an entry
hEntry = RTW.TfLCOperationEntryGenerator_NetSlope;

%% Create entry parameters
hEntry.setTfLCOperationEntryParameters(...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 90, ...
    'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
    'SlopesMustBeTheSame', true, ...
    'MustHaveZeroNetBias', true, ...
```

```

    'ImplementationName',      'u16_add_SameSlopeZeroBias', ...
    'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h', ...
    'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name',      'y1', ...
    'IOType',    'RTW_IO_OUTPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'IsSigned',  false, ...
    'WordLength', 16);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name',      'u1', ...
    'IOType',    'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'IsSigned',  false, ...
    'WordLength', 16);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name',      'u2', ...
    'IOType',    'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'IsSigned',  false, ...
    'WordLength', 16);

%% Create the Implementation Representation
createAndSetCImplementationReturn(hEntry, 'RTW.TflArgNumeric', ...
    'Name',      'y1', ...
    'IOType',    'RTW_IO_OUTPUT', ...
    'IsSigned',  false, ...
    'WordLength', 16, ...
    'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name',      'u1', ...
    'IOType',    'RTW_IO_INPUT', ...
    'IsSigned',  false, ...
    'WordLength', 16, ...
    'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name',      'u2', ...
    'IOType',    'RTW_IO_INPUT', ...
    'IsSigned',  false, ...
    'WordLength', 16, ...
    'FractionLength', 0);

%% Add the entry to the table
addEntry(hTable, hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_equal_slope_netbias_add
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file with these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for equal slope and zero net bias code replacement';

```

```
this(1).TableList = {'crl_table_equal_slope_netbias_add.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10** Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Data Type Conversions (Casts) and Operator Code Replacement

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

Interactively Develop a Code Replacement Library

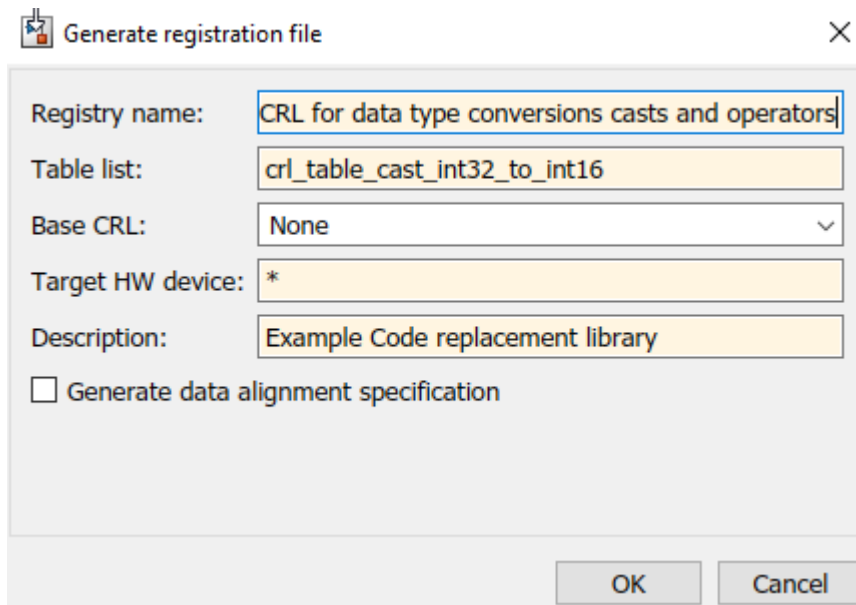

- 1 Open the **Code Replacement Tool** (crtool), at the MATLAB command line, enter:

```
>>crtool
```
- 2 Create a table.
 - a From the crtool context menu, select **File > New Table**.
 - b In the right pane, name the table `cr1_table_cast_int32_to_int16`. Click **Apply**.
- 3 Create entry parameters. In the **Operation** drop-down list, select **Cast**.
- 4 Create an entry. From the crtool context menu, select **File > New entry > Fixed Point Net Slope Operation**.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1` with the **Data Type** of `int16`, and the input argument, `u1` with the **Data Type** of `int32` and the **Argument Type** of **Scalar**.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box. In the **Function arguments** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1` with the **Data Type** of `int16` and `int32`.

Specify a **Name** for the replacement function under **Function prototype**.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function to call your code replacement library table. The function should not have arguments and return a table object.
 - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_cast_int32_to_int16()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCOperationEntry`.

```
function hTable = crl_table_cast_int32_to_int16()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TfLCOperationEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTfLCOperationEntryParameters`. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_sat_cast`.

```
function hTable = crl_table_cast_int32_to_int16()
% Create a code replacement library table
```

```
%% Create a table object
hTable = RTW.TfLTable;
```

```
%% Create an entry
hEntry = RTW.TfLCOperationEntry;
```

```
%% Create entry parameters
hEntry.setTfLCOperationEntryParameters(...
    'Key', 'RTW_OP_CAST', ...
    'Priority', 50, ...
    'ImplementationName', 'my_sat_cast', ...
    'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
    'ImplementationHeaderFile', 'some_hdr.h', ...
    'ImplementationSourceFile', 'some_hdr.c');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTfLArgFromString`.

```
function hTable = crl_table_cast_int32_to_int16()
% Create a code replacement library table
```

```
%% Create a table object
hTable = RTW.TfLTable;
```

```
%% Create an entry
hEntry = RTW.TfLCOperationEntry;
```

```
%% Create entry parameters
hEntry.setTfLCOperationEntryParameters(...
    'Key', 'RTW_OP_CAST', ...
    'Priority', 50, ...
    'ImplementationName', 'my_sat_cast', ...
    'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
    'ImplementationHeaderFile', 'some_hdr.h', ...
    'ImplementationSourceFile', 'some_hdr.c');
```

```
%% Create the conceptual representation
```

```
arg = getTfLArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);
hEntry.Implementation.setReturn(arg);
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the

same order and properties as the conceptual arguments, call the function `getTflArgFromString`. Add the complete entry to the table by calling the function `addEntry`.

```
function hTable = crl_table_cast_int32_to_int16()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
    'Key', 'RTW_OP_CAST', ...
    'Priority', 50, ...
    'ImplementationName', 'my_sat_cast', ...
    'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
    'ImplementationHeaderFile', 'some_hdr.h', ...
    'ImplementationSourceFile', 'some_hdr.c');

%% Create the conceptual and implementation representation

arg = getTflArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);
hEntry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', 'int32');
addConceptualArg(hEntry, arg);
hEntry.Implementation.addArgument(arg);

%% Add the entry to the table
addEntry(hTable,hEntry);
```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_cast_int32_to_int16
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file with these specifications:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for data type conversions(casts) abd operator code replacement';
this(1).TableList = {'crl_table_cast_int32_to_int16.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10** Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Shift Left Operations and Code Replacement

This example shows how to develop a code replacement library to optimize the performance of shift left (<<) operation by providing information on how to define code replacement for a `shift left` function. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 69-20.

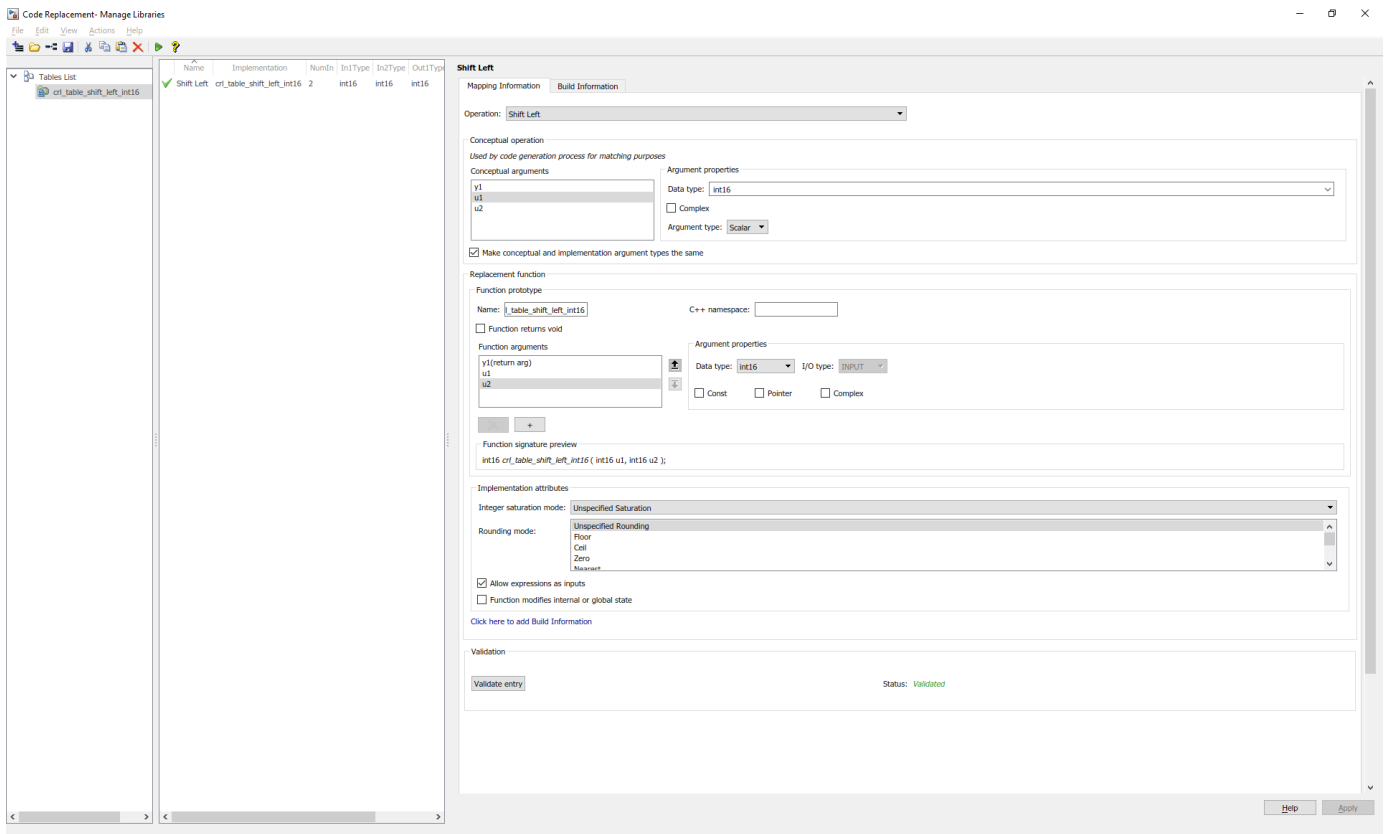

Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```

- 2 Create a table.
 - a From the crtool context menu, select **File > New Table**.
 - b In the right pane, name the table `crl_table_shift_left_int16`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Math Operation**.
- 4 Create entry parameters. In the **Operator** drop-down list, select `Shift Left`.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input arguments, `u1`, and `u2`, with **Data Type** of `int16` and the **Argument Type** of `scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.

Under **Function prototypes** specify a **Name** for the replacement function.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. Click the **Mapping Information** tab and verify the fields are filled in as shown. Click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:
`>>sl_refresh_customizations`

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Programatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
 - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_shift_left_int16
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCOperationEntry`.

```
function hTable = crl_table_shift_left_int16()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;
```

- 4 Create entry parameters. Because this example replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_table_shift_left_int16()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
setTflCFunctionEntryParameters(hEntry, ...
    'Key', 'RTW_OP_SL', ...
    'Priority', 50, ...
    'ImplementationName', 'my_shift_left', ...
    'ImplementationHeaderFile', 'some_hdr.h', ...
    'ImplementationSourceFile', 'some_hdr.c');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString` and `addConceptualArg`.

```

function hTable = crl_table_shift_left_int16()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
setTflCOperationEntryParameters(hEntry, ...
    'Key', 'RTW_OP_SL', ...
    'Priority', 50, ...
    'ImplementationName', 'my_shift_left', ...
    'ImplementationHeaderFile', 'some_hdr.h', ...
    'ImplementationSourceFile', 'some_hdr.c');

%% Create the conceptual representation
arg = getTflArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);
hEntry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', 'int16');
addConceptualArg(hEntry, arg);
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', 'int16');
arg.CheckType = false;
addConceptualArg(hEntry, arg);
hEntry.Implementation.addArgument(arg);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To explicitly specify argument properties, call the function `getTflArgFromString`.

```

function hTable = crl_table_shift_left_int16()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
setTflCOperationEntryParameters(hEntry, ...
    'Key', 'RTW_OP_SL', ...
    'Priority', 50, ...
    'ImplementationName', 'my_shift_left', ...
    'ImplementationHeaderFile', 'some_hdr.h', ...
    'ImplementationSourceFile', 'some_hdr.c');

%% Create the conceptual and implementation representation
arg = getTflArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);
hEntry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', 'int16');
addConceptualArg(hEntry, arg);
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', 'int16');
arg.CheckType = false;
addConceptualArg(hEntry, arg);
hEntry.Implementation.addArgument(arg);

```

```

%% Add the entry to the table
hTable.addEntry(hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_shift_left_int16
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) by using these specifications.

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for shift left operation';
this(1).TableList = {'crl_table_shift_left_int16.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

- “Optimize Generated Code by Developing and Using Code Replacement Libraries - Simulink” on page 74-30
- “Replace Addition and Subtraction Operator Code” on page 69-151

Optimize Generated Code by Using Multiple Code Replacement Libraries

You can generate code that has code replacements enabled by multiple code replacement libraries. You can select multiple Code Replacement libraries in a unified workflow so that the generated code contains optimizations from varied code replacement libraries such as AUTOSAR 4.0 and GNU C99 extensions. You can also select your own custom code replacement libraries along with libraries included with Embedded Coder® to further optimize the generated code. You can select and use a combination of libraries and achieve the requisite functionalities, and need not author separate libraries. In instances where there are multiple custom code replacement libraries and you need functionalities from all of them, individually select the libraries.

Example Model

This example shows how to replace the generated code for a model containing an Add block and an Abs block by using multiple code replacement libraries. You replace the Abs block using a code replacement customization that replaces the regular `fabs` function with the custom implementation `CRL_abs_d` from the `ScalarFcn` library. You replace the Add block with the custom implementation `CRL_d_add_d_d_cao` from the `ScalarOp` library.

Open the model `mMultiLibrary_abs` that has an Add block and an Abs block.

```
model = 'mMultiLibrary_abs';
open_system(model);
```

```
copyfile multipleFnRtwTargetInfo.txt rtwTargetInfo.m
```

Copyright 2021 The MathWorks, Inc.

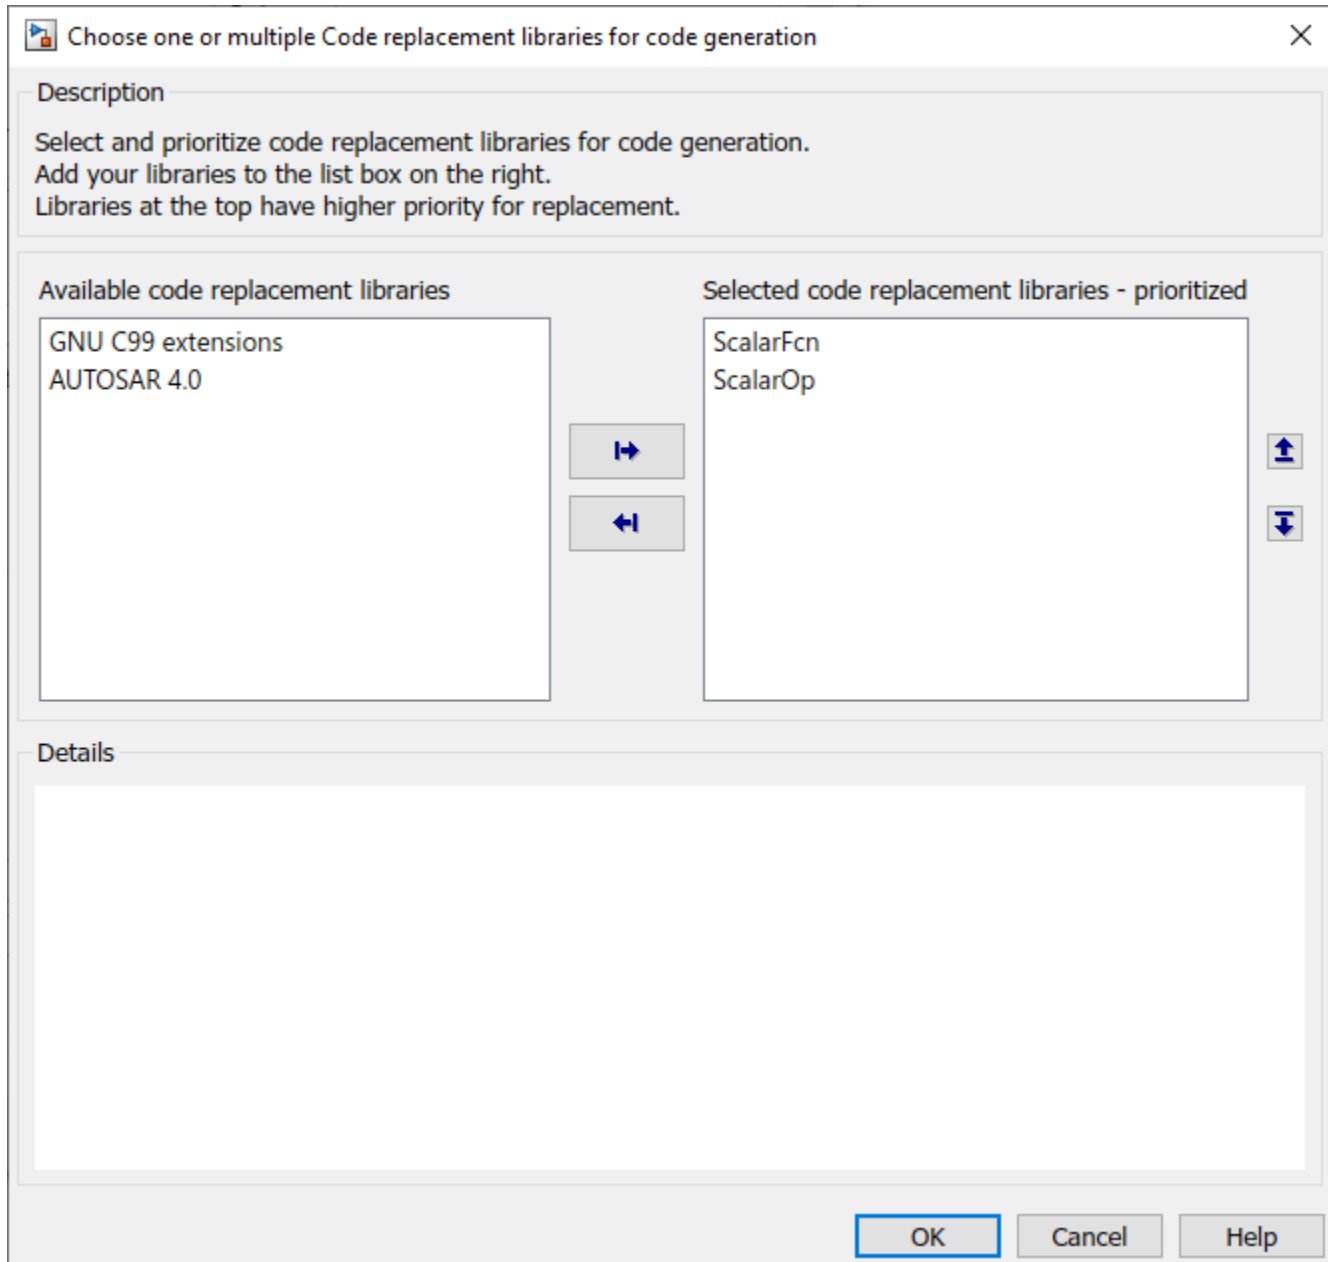

The MATLAB® customization files `hcrl_make_abs` and `hcrl_sum_float` have already been executed. Run the `sl_refresh_customizations` function to register the libraries `ScalarFcn` and `ScalarOp`.

```
sl_refresh_customizations;
```

Select Code Replacement Libraries

- 1 Open the Configuration Parameters dialog box.
- 2 In the Configuration Parameters dialog box, set the correct **Device Vendor** and **Device Type** depending on the hardware target. In this example Intel is the **Device Vendor** and `x86-64 (Windows64)` is the **Device Type**.
- 3 On the **Interface** pane, set **Code Replacement Library** parameter by clicking **Select** and adding the code replacement libraries to the **Selected code replacement libraries - prioritized** list pane. For this example, choose `ScalarFcn` and `ScalarOp`. The libraries work on the Windows® platforms. Linux® users must supply a different library.

- Order the code replacement libraries according to the priority in which you want to see them replaced in the generated code. Code replacement libraries at the top of order have a higher priority during code replacement.

Alternatively, use the command-line API to enable the code replacement:

```
set_param('mMultiLibrary_abs', 'CodeReplacementLibrary', 'ScalarFcn,ScalarOp')
```

Generate code for the model.

```
evalc('slbuild(model)');
```

NOTE: When registering a code replacement library, you cannot use a comma in the code replacement library name.

View the generated code with the replacements. Here is a portion of `mMultiLibrary_abs.c`.

```
cfile = fullfile('mMultiLibrary_abs_ert_rtw','mMultiLibrary_abs.c');
rtwdemodbtype(cfile,'/* Model step function ','/* Model initialize function',1, 1);

/* Model step function */
void mMultiLibrary_abs_step(void)
{
    int32_T i;

    /* Output: '<Root>/Out1' incorporates:
     * Abs: '<Root>/Abs1'
     * Inport: '<Root>/In1'
     */
    mMultiLibrary_abs_Y.Out1 = CRL_abs_d(mMultiLibrary_abs_U.In1);

    /* Output: '<Root>/Output' incorporates:
     * Inport: '<Root>/In2'
     * Inport: '<Root>/In3'
     * Sum: '<Root>/Add'
     */
    for (i = 0; i < 2500; i++) {
        mMultiLibrary_abs_Y.Output[i] = CRL_d_add_d_d_cao(mMultiLibrary_abs_U.In2[i],
            mMultiLibrary_abs_U.In3[i]);
    }

    /* End of Output: '<Root>/Output' */
}
```

The generated code contains the `CRL_abs_d` function enabled by the custom code replacement library `ScalarFcn`. Note that this library only works for Windows. The code also contains the function `CRL_d_add_d_d_cao` enabled by the `ScalarOp` code replacement library. Selecting multiple code replacement libraries enables multiple optimizations in the generated code.

Close the model and code generation report.

```
delete ./rtwTargetInfo.m
bdclose(model)
rtwdemoclean;
```

Limitations:

- When you use different argument types such as matrix and scalar, the priority ordering is ignored. A matrix code replacement library has a higher priority than a scalar code replacement library, regardless of the order specified by the code replacement library.

- When the code replacement library parameter specifies a Standard Math Library, for instance through its BaseTfl, and it does not match the **Standard Math Library** parameter, the library specified by the **Standard Math Library** parameter is used.

What Is Code Replacement Customization?

Customize how and when the code generator replaces C/C++ code that it generates by default for functions and operators by developing a custom code replacement library. You can develop libraries interactively with the **Code Replacement Tool** or programmatically.

- Develop libraries tailored to specific application requirements
- Add identifiers to the list of reserved keywords the code generator considers during code replacement
- Customize the code generator’s match and replacement process for functions

To get started, “Quick Start Code Replacement Library Development - Simulink” on page 69-21.

Code Replacement Match and Replacement Process

When the code generator encounters a call site for a function or operator, it:

- 1 Creates and partially populates a code replacement entry object with the function or operator name or key and conceptual arguments.
- 2 Uses the entry object to query the configured code replacement library for a conceptual representation match. The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. When searching for a match, the code generator takes into account:
 - Conceptual name or key
 - Arguments, including quantity, type, type qualifiers, and complexity
 - Algorithm (computation method)
 - Fixed-point saturation and rounding modes
 - Priority
- 3 When a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority. If the code generator finds multiple matches within a table, the entry priority determines the match. The priority can range from 0 to 100. The highest priority is 0. The code generator uses a higher-priority entry over a similar entry with a lower priority.
- 4 Uses the C or C++ replacement function prototype in the code replacement object to generate code.

Code Replacement Customization Limitations

- Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code. See “Verify Code Replacement Library” on page 70-43.
- Tokens in file paths—You can include tokens in file paths when specifying build information for a code replacement entry by using the programming interface only. The ability to include tokens is not available from the Code Replacement Tool. See Specify build information in “Define Code Replacement Library Optimizations” on page 70-23.
- Addition and subtraction operation replacements—See “Addition and Subtraction Operator Code Replacement” on page 70-104 for relevant limitations.

- `coder.replace` function — See `coder.replace` for relevant limitations.
- `coder.dataAlignment` function — See `coder.dataAlignment` for relevant limitations.

Code You Can Replace from MATLAB Code

Code that the code generator replaces depends on the code replacement library (CRL) that you use. By default, the code generator does not apply a code replacement library. Your choice of libraries is dependent on product licensing and whether you have access to custom libraries.

In this section...

Memory Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following memory functions with application-specific implementations.

| Function | Data Type Support | Scalar, Vector, Matrix Support | Real, Complex Support |
|-------------|----------------------|--------------------------------|-----------------------|
| memcmp | Void pointer (void*) | Scalar
Vector
Matrix | Real
Complex |
| memcpy | Void pointer (void*) | Scalar
Vector
Matrix | Real
Complex |
| memset | Void pointer (void*) | Scalar
Vector
Matrix | Real
Complex |
| memset2zero | Void pointer (void*) | Scalar
Vector
Matrix | Real
Complex |

Some target processors provide optimized functions to set memory to zero. Use the code replacement library programming interface to replace the `memset2zero` function with more efficient target-specific functions.

Operators

When generating C/C++ code from MATLAB code, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following operators with application-specific implementations.

Mixed data type support indicates you can specify different data types of different inputs.

| Operator | Key | Data Type Support | Scalar, Vector, Matrix Support | Real, Complex Support |
|---------------------------------|--------------|---|--------------------------------|-----------------------|
| Addition (+) ¹ | RTW_OP_ADD | Integer
Floating point
Fixed-point
Mixed | Scalar
Vector
Matrix | Real
Complex |
| Subtraction (-) ¹ | RTW_OP_MINUS | Integer

Develop a Code Replacement Library

Iterate through the following steps, as necessary, to develop a code replacement library:

- 1 “Identify Code Replacement Library Requirements” on page 70-21
- 2 “Define Code Replacement Library Optimizations” on page 70-23
- 3 “Register Code Replacement Library” on page 70-38
- 4 “Verify Code Replacement Library” on page 70-43
- 5 “Deploy Code Replacement Library” on page 70-50

To get started, see “Identify Code Replacement Library Requirements” on page 70-21.

To experiment with the process and tools, see “Quick Start Library Development” on page 70-14.

See Also

More About

- “Identify Code Replacement Library Requirements” on page 70-21
- “Code You Can Replace from MATLAB Code” on page 70-5
- “Quick Start Library Development” on page 70-14
- “What Is Code Replacement Customization?” on page 70-3

Quick Start Library Development

This example shows how to develop a code replacement library that includes an entry for generating replacement code for the math function `sin`. You use the **Code Replacement Tool**.

Prerequisites

To complete this example, install the following software:

- MATLAB
- MATLAB Coder
- Embedded Coder
- C compiler

For instructions on installing MathWorks products, see “Installation and Licensing”. If you have installed MATLAB and want to see what other MathWorks products are installed, in the Command Window, enter `ver`.

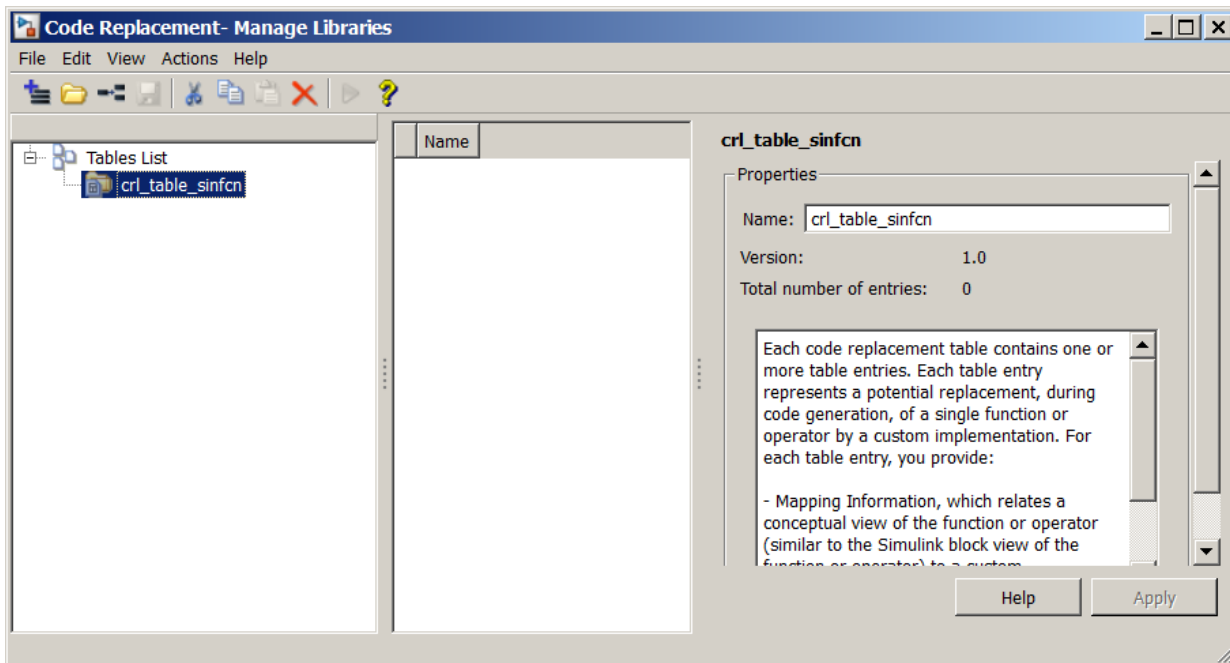

For a list of supported compilers, see https://www.mathworks.com/support/compilers/current_release/.

Open the Code Replacement Tool

- 1 Start a new MATLAB session.
- 2 Create or navigate (`cd`) to an empty folder.
- 3 At the command prompt, enter the `crtool` command. The **Code Replacement Tool** window opens.

Create Code Replacement Table

- 1 In the **Code Replacement Tool** window, select **File > New table**.
- 2 In the right pane, name the table `crl_table_sinfcn` and click **Apply**. Later, when you save the table, the tool saves it with the file name `crl_table_sinfcn.m`.

Create Table Entry

Create a table entry that maps a `sin` function with double input and double output to a custom implementation function.

- 1 In the left pane, select table `crl_table_sinfcn`. Then, select **File > New entry > Function**. The new entry appears in the middle pane, initially without a name.
- 2 In the middle pane, select the new entry.
- 3 In the right pane, on the **Mapping Information** tab, from the **Function** menu, select `sin`.
- 4 Leave **Algorithm** set to **Unspecified**, and leave parameters in the **Conceptual function** group set to default values.
- 5 In the **Replacement function** group, name the replacement function `sin_dbl`.
- 6 Leave the remaining parameters in the **Replacement function** group set to default values.
- 7 Click **Apply**. The tool updates the **Function signature preview** to reflect the specified replacement function name.
- 8 Scroll to the bottom of the **Mapping Information** tab and click **Validate entry**. The tool validates your entry.

The following figure shows the completed mapping information.

The screenshot shows the 'Build Information' tab for the 'sin' function. The 'Function' dropdown is set to 'sin'. Under 'Entry information', the 'Algorithm' is 'Unspecified'. The 'Conceptual function' section includes 'Conceptual arguments' (y1, u1) and 'Argument properties' (Data type: double, Complex: unchecked, Argument type: Scalar). A checkbox 'Make conceptual and implementation argument types the same' is checked. The 'Replacement function' section shows 'Function prototype' with Name: 'sin_dbl' and C++ namespace: empty. 'Function returns void' is unchecked. 'Function arguments' are 'y1(return arg)' and 'u1'. 'Argument properties' show Data type: 'double', I/O type: 'OUTPUT', and Const, Pointer, and Complex are unchecked. The 'Function signature preview' shows 'double sin_dbl(double u1);'. The 'Implementation attributes' section has 'Integer saturation mode: Unspecified Saturation' and 'Rounding mode: Unspecified Rounding'. 'Allow expressions as inputs' is checked, and 'Function modifies internal or global state' is unchecked. A link 'Click here to add Build Information' is present. The 'Validation' section has a 'Validate entry' button and 'Status: Validated'. At the bottom are 'Help' and 'Apply' buttons.

Specify Build Information for Replacement Code

- 1 On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_dbl.h`.
- 2 Leave the remaining parameters set to default values.
- 3 Click **Apply**.

This screenshot shows the 'Build Information' tab with the 'Implementation header File' field set to 'sin_dbl.h'. The 'Implementation source File' field is empty. The 'Additional header files/ include paths' field is also empty. The 'Mapping Information' tab is visible in the background.

- Optionally, you can revalidate the entry. Return to the **Mapping Information** tab and click **Validate entry**.

Create Another Table Entry

Create an entry that maps a `sin` function with `single` input and `double` output to a custom implementation function named `sin_sgl`. Create the entry by copying and pasting the `sin_dbl` entry.

- In the middle pane, select the `sin_dbl` entry.
- Select **Edit > Copy**
- Select **Edit > Paste**
- On the **Mapping Information** tab, in the **Conceptual function** section, set the data type of input argument `u1` to `single`.
- In the **Replacement function** section, name the function `sin_sgl`. Set the data type of input argument `u1` to `single`.
- Click **Apply**. Note the changes that appear for the **Function signature preview**.
- On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_sgl.h`. Leave the remaining parameters set to default values and click **Apply**.

Validate the Code Replacement Table

- Select **Actions > Validate table**.
- If the tool reports errors, fix them, and rerun the validation. Repeat fixing and validating errors until the tool does not report errors. The following figure shows a validation report.

| Name | Implementation | NumIn | In1Type | In2Type | Out1Type | Out2Type | Priority |
|-------|----------------|-------|---------|---------|----------|----------|----------|
| ✓ sin | sin_dbl | 1 | double | | double | | 100 |
| ✓ sin | sin_sgl | 1 | single | | double | | 100 |

Save the Code Replacement Table

Save the code replacement table to a MATLAB file in your working folder. Select **File > Save table**. By default, the tool uses the table name to name the file. For this example, the tool saves the table in the file `crl_table_sinfcn.m`.

Review the Code Replacement Table Definition

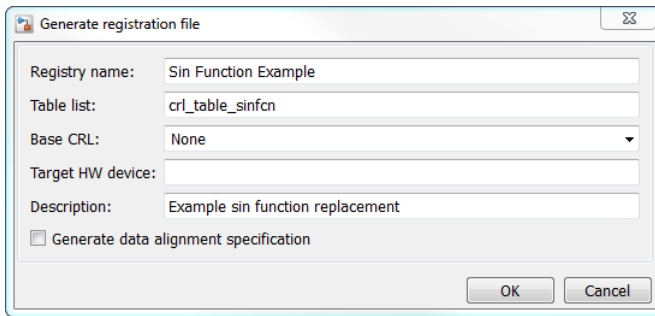

Consider reviewing the MATLAB code for your code replacement table definition. After using the tool to create an initial version of a table definition file, you can update, enhance, or copy the file in a text editor.

To review it, in MATLAB or another text editor, open the file `crl_table_sinfcn.m`.

Generate a Registration File

Before you can use your code replacement table, you must register it as part of a code replacement library. Use the Code Replacement Tool to generate a registration file.

- In the Code Replacement Tool, select **File > Generate registration file**.
- In the **Generate registration file** dialog box, edit the dialog box fields to match the following figure, and then click **OK**.

- 3 In the **Select location to save the registration file** dialog box, specify a location for the registration file. The location must be on the MATLAB path or in the current working folder. Save the file. The tool saves the file as `rtwTargetInfo.m`.

Register the Code Replacement Table

At the command prompt, enter:

```
RTW.TargetRegistry.getInstance('reset');
```

Review and Test Code Replacements

Apply your code replacement library. Verify that the code generator makes code replacements that you expect.

- 1 Check for errors. At the command line, invoke the table definition file. For example:

If an error exists in the definition file, the invocation triggers a message to appear. Fix the error and try again.

```
tbl = crl_table_sinfcn
```

```
tbl =
```

```
TfLTable with properties:
    Version: '1.0'
    ReservedSymbols: []
    StringResolutionMap: []
    AllEntries: [2x1 RTW.TfLFunctionEntry]
    EnableTrace: 1|
```

- 2 Use the Code Replacement Viewer to check your code replacement entries. For example:

```
crviewer('Sin Function Example')
```

In the viewer, select entries in your table and verify that the content is what you expect. The viewer can help you detect issues such as:

- Incorrect argument order.
- Conceptual argument names that do not match what is expected by the code generator.
- Incorrect priority settings.

- 3 Identify existing or create new MATLAB code that calls the `sin` function. For example:

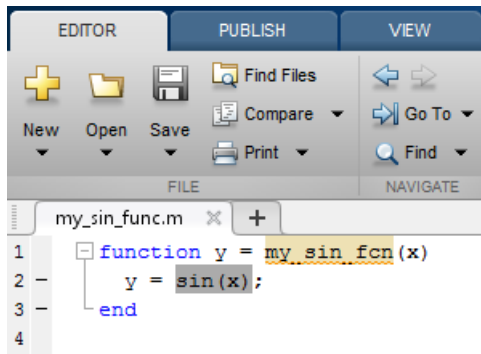

```
function y = my_sin_fnc(x)
    y = sin(x);
end
```

Note If you are replacing a custom function, use the `coder.replace` function.

- 4 Open the MATLAB Coder app.
- 5 Add the function that includes a call to the `sin` function as an entry-point file. For example, add `my_sin_func.m`. The app creates a project named `my_sin_func.prj`.
- 6 Click **Next** to go to the **Define Input Type** step. Define the types for the entry-point function inputs.
- 7 Click **Next** to go to the **Check for Run-Time Issues** step. This step is optional. However, it is a best practice to perform this step. Provide a test file that calls your entry-point function. The app generates a MEX function from your entry-point function. Then, the app runs the test file, replacing calls to the MATLAB function with calls to the generated MEX function.
- 8 Click **Next** to go to the **Generate Code** step. To open the **Generate** dialog box, click the **Generate** arrow .
- 9 Set **Build type** to generate a library or executable.
- 10 Click **More Settings**.
- 11 Configure the code generator to use your code replacement library. On the **Custom Code** tab, set the **Code replacement library** parameter to the name of your library. For example, `Sin Function Example`.
- 12 Configure the code generation report. On the **Debug** tab, set the **Always create a report**, **Code replacements**, and **Automatically launch a report if one is generated** parameters.
- 13 Configure the code generator to generate code only. For **Build type**, select **Source code**. You want to review your code replacements in the generated code before building an executable.
- 14 Click **Generate** to generate C code and a report.
- 15 Review code replacement results in the Code Replacements Report section of the code generation report.

The report indicates that the code generator found a match and applied the replacement code for the function `sin_dbl`.

- 16 Review the code replacements. In the report, click the MATLAB function that triggered the replacement, `my_sin_func.m`. The MATLAB Editor opens and highlights the function call that triggers the code replacement.

Identify Code Replacement Library Requirements

What Is a Code Replacement Library?

A code replacement library defines optimizations for generated C or C++ code from Simulink models or MATLAB code for specific targets. You can configure the code generator to use your code replacement library to replace specified functions in your model or MATLAB code with optimized implementations.

What Functions Can Be Optimized with a Code Replacement Library?

You can use a code replacement library to optimize the performance of functions defined either by Simulink models or MATLAB code. To look up functions that are available to optimize, see “Code You Can Replace From Simulink Models” on page 69-6 and “Code You Can Replace from MATLAB Code” on page 70-5.

How to Develop a Code Replacement Library

You can develop a code replacement library either interactively, using the **Code Replacement Tool** (crtool), or programmatically, using the MATLAB programming interface. The Code Replacement Tool is quick, easy, and ideal for first time library development, while the MATLAB Programming interface provides more customization and control options. To determine which approach to use, identify your use case below:

Interactive Approach:

- Developing a code replacement library for the first time
- Rapid prototyping

Programmatic Approach:

- Specifying code replacement attributes not available with the Code Replacement Tool
- Creating or modifying code replacement library entries by copying, pasting, and editing
- Modifying a registration file by copying and pasting content

Identify Basic Requirements

- What model or MATLAB code do you want to optimize by using a code replacement library?
- What functions and operations within your model or MATLAB code do you want to replace? What is the signature for each function or operation that you want to replace?
- What build files (source, header, object) do you need to provide to the code generator?

Define Code Replacement Library Optimizations

A code replacement library contains one or more code replacement tables. Each table contains one or more code replacement entries. Each entry contains a mapping and entry parameters. The entry maps the conceptual representation of an automatically generated MATLAB or Simulink function to an implementation representation of an optimized C or C++ function. The entry parameters describe additional properties for the code generator to honor during code replacement.

To define a code replacement library, first define code replacement tables in a customization file. Then, during the registration step, create a code replacement library by selecting tables to include in your library. You can define your code replacement tables both interactively or programmatically using the same work flow.

The interactive and programmatic approaches both follow these 8 steps:

- 1 Open the environment.
- 2 Create a table.
- 3 Create an entry.
- 4 Create entry parameters.
- 5 Create the conceptual representation.
- 6 Create the implementation representation.
- 7 Specify build information.
- 8 Validate and save.

Interactively Develop a Code Replacement Library

- 1 Open the environment.

To interactively create a code replacement library, open the **Code Replacement Tool** (crtool) from the MATLAB command line with the command:

```
>> crtool
```

2 Create a table.

A code replacement table organizes code replacement entries into groupings that are easier to manage.

To create a code replacement table:

- a From the crtool menu, select **File > New table**.
- b In the right pane, name the table and click **Apply**.

3 Create an entry.

A code replacement table entry contains entry parameters and a mapping of a conceptual representation that describes a generated function to an implementation representation that describes an optimized implementation of that function.

To create a code replacement entry, use one of these methods:

- From the crtool toolbar, click the **entry-type** icon then select the **entry-type**.
- From the crtool menu, select **File > New entry > entry-type**.
- Right-click on a table and select **New entry > entry-type**.

The new entry appears without a name in the middle pane.

4 Create entry parameters.

Entry parameters specify optimization and build requirements for the code generator to honor during code replacement. These parameters vary and automatically appear in various sections of the crtool interface depending on the type of function replacement.

To create entry parameters:

- In the **Function** or **Operation** drop-down list, select the name of the function you want to replace.

This selection determines the entry parameters that appear in the crtool.

5 Create the conceptual representation.

The conceptual representation describes the signature of the function you want to replace. The conceptual representation consists of the function name, return arguments, and parameters. The return arguments are referred to as output arguments, and the parameters are referred to as input arguments. Specify each conceptual argument with a name, I/O type, and, depending on the type of replacement, other properties that appear in the crtool.

To define your conceptual representation:

- In the **Conceptual Function** or **Conceptual Operation** subsection of the crtool, specify the input and output arguments of the function you want the code generator to replace.

6 Create the implementation representation.

The implementation representation describes the signature of the replacement function defined in the code replacement library. The implementation representation consists of a function name, return arguments, and parameters. Specify each implementation argument with a type, type qualifier, and complexity.

To define your implementation representation:

- In the **Implementation Function** or **Operation Function** subsection of the crtool, specify the input and output arguments for the optimized function defined in the code replacement library.

7 Specify build information.

Build information provides the code generator with the files to perform function replacement.

To specify build information:

- In the crtool, click the **Build Information** tab to open the build requirements pane. Specify necessary build information in these fields:

| Parameter | Description |
|---------------------------------------|---|
| Implementation header file | Name of header file needed for code replacement. |
| Implementation source file | Name of source file needed for code replacement. |
| Additional header files/include paths | Name and path of additional header files needed for code replacement. |
| Additional source files/paths | Name and path of additional source files needed for code replacement. |
| Additional object files/paths | Name and path of additional object files needed for code replacement. |
| Additional link flags | Flags the linker needs to generate an executable file for the replacement code. |
| Additional compile flags | Flags the compiler needs to generate object code for the replacement code. |
| Copy files to build directory | Flags whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. If you specify files with Additional header files/include paths or Additional source files/ paths and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files. |

8 Validate and save.

Save your code replacement library with the same name as your code replacement table on your MATLAB path. Saving your library automatically validates unvalidated content.

To validate and save your library:

- From the crtool menu, select **File > Save Table > Save**.

Programmatically Develop a Code Replacement Library

- 1 Open the environment.

To programmatically create a code replacement library, open a MATLAB function file. From the MATLAB menu select **New > Function**.

- 2 Create a table.

A code replacement table organizes code replacement entries into groupings that are easier to manage.

To create a code replacement table:

- a Create a function you can use to call your code replacement library table. The function should not have arguments and return a table object.
- b Create a table object with a call to `RTW.TflTable`.

```
function hTable = code_replacement_library_table()
% Create a function to call code replacement library table

%% Create a code replacement library table object
hTable = RTW.TflTable;

end
```

- 3 Create an entry.

A code replacement table entry contains entry parameters and a mapping of a conceptual representation of a generated function to the implementation representation of an optimized implementation of that function.

To create a code replacement table:

- a Identify the type of function you want to replace.
- b Call the corresponding Entry Function to create an entry in your table.

| Type of Function You Want to Replace | Entry Function |
|---|--|
| Math Operation | RTW.TflCOperationEntry |
| Function | RTW.TflCFunctionEntry |
| BLAS operation | RTW.TflBlasEntryGenerator |
| CBLAS operation | RTW.TflCBlasEntryGenerator |
| Fixed-point addition and subtraction operations | RTW.TflCOperationEntryGenerator |
| Net slope fixed-point operation | RTW.TflCOperationEntryGenerator_NetSlope |
| Semaphore or mutex | RTW.TflCSemaphoreEntry |
| Custom function | RTW.TflCFunctionEntryML |
| Custom operation | RTW.TflCOperationEntryML |

```
function hTable = code_replacement_library_table()
% Create a function to call code replacement library table
```

```
%% Create a code replacement library table object
hTable = RTW.TflTable;
```

```
%% Create a code replacement library entry
% Pick one from list below
hEntry = RTW.TfLCOperationEntry;
hEntry = RTW.TfLCFunctionEntry;
hEntry = RTW.TflBlasEntryGenerator;
hEntry = RTW.TflCBlasEntryGenerator;
hEntry = RTW.TfLCOperationEntryGenerator;
hEntry = RTW.TfLCOperationEntryGenerator_NetSlope;
hEntry = RTW.TfLCSemaphoreEntry;
hEntry = RTW.TfLCFunctionEntryML;
hEntry = RTW.TfLCOperationEntryML;
```

```
end
```

4 Create entry parameters.

Entry parameters specify optimization and build requirements for the code generator to honor during code replacement. These parameters vary depending on the type of function replacement.

To create your entry parameters:

- Call the Set Parameters function that corresponds with the type of function you want to replace identified in the previous step (step 3).

| Type of Function You Want to Replace | Set Parameters function |
|---|---------------------------------|
| Math operation, BLAS operation, CBLAS operation, Fixed-Point, Net Slope Fixed-Point, Custom operation | setTfLCOperationEntryParameters |
| Function, Custom function | setTfLCFunctionEntryParameters |
| Semaphore or Mutex | setTfLCSemaphoreEntryParameters |

Each Set Parameter function is shown with all available properties set to their default values. The exact properties and values you need to specify depends on the function you replace. See examples for specific replacement details.

```
function hTable = code_replacement_library_table()
% Create a function to call code replacement library table
```

```
%% Create a code replacement library table object
hTable = RTW.TflTable;
```

```
%% Create a code replacement library entry
% Pick one from list below
hEntry = RTW.TfLCOperationEntry;
hEntry = RTW.TfLCFunctionEntry;
hEntry = RTW.TflBlasEntryGenerator;
hEntry = RTW.TflCBlasEntryGenerator;
hEntry = RTW.TfLCOperationEntryGenerator;
hEntry = RTW.TfLCOperationEntryGenerator_NetSlope;
hEntry = RTW.TfLCSemaphoreEntry;
hEntry = RTW.TfLCFunctionEntryML;
hEntry = RTW.TfLCOperationEntryML;
```

```

%% Create entry parameters
% Pick one from list below
hEntry.setTfLCOperationEntryParameters(...
    'Key', ' ', ...

    'RoundingModes',                   'RTW_ROUND_UNSPECIFIED', ...
    'SaturationMode',                  'RTW_SATURATE_UNSPECIFIED', ...
    'SideEffects',                     false, ...
    'StoreFcnReturnInLocalVar',        false);

end

```

5 Create the conceptual representation.

The conceptual representation describes the signature of the function you want to replace. It consists of the function name, return arguments, and parameters. The return arguments are referred to as output arguments, and the parameters are referred to as input arguments. Specify each conceptual argument with the required properties, and, depending on the type of replacement, other optional properties.

Required properties:

- **Name**- Defined as y1..yn for output arguments and u1..un for input arguments
- **I/O type**- Defined as RTW_IO_OUTPUT or RTW_IO_INPUT

To define your conceptual representation, use one of these approaches:

| Approach | Function | Goal |
|----------|---------------------------|---|
| 1 | createAndAddConceptualArg | Customization and control.
If you want to explicitly specify arguments as scalar or matrix and other properties. |
| 2 | getTfLArgFromString | Rapid prototyping.
If you want to quickly specify arguments with built-in data types. |

Programming approaches are shown with all available properties set to default values. The exact properties and values you need to specify depends on the function you replace. See examples for specific replacement details.

```

function hTable = code_replacement_library_table()
% Create a function to call code replacement library table

%% Create a code replacement library table object
hTable = RTW.TflTable;

%% Create a code replacement library entry
% Pick one from list below
hEntry = RTW.TflCOperationEntry;
hEntry = RTW.TflCFunctionEntry;
hEntry = RTW.TflBlasEntryGenerator;
hEntry = RTW.TflCBlasEntryGenerator;
hEntry = RTW.TflCOperationEntryGenerator;
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;
hEntry = RTW.TflCSemaphoreEntry;
hEntry = RTW.TflCFunctionEntryML;
hEntry = RTW.TflCOperationEntryML;

%% Create entry parameters
% Pick one from list below
% To view properties, see step 4
hEntry.setTflCOperationEntryParameters( );
hEntry.setTflCFunctionEntryParameters( );
hEntry.setTflCSemaphoreEntryParameters( );

%% Create the conceptual representation

% Approach 1: createAndAddConceptualArg
% arg = createAndAddConceptualArg(hEntry, argType, varargin)
% argType - 'RTW.TflArgNumeric' | 'RTW.TflArgMatrix'
% varargin - 'name', 'value' pairs shown below set to default values,
% includes name and I/O type

% Define Output Arguments
hEntry.createAndAddConceptualArg(...
    'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'IsSigned', true, ...
    'WordLength', 32, ...
    'CheckSlope', true, ...
    'CheckBias', true, ...
    'DataTypeMode', 'Fixed-point:binary point scaling', ...
    'DataType', 'Fixed', ...
    'Scaling', 'BinaryPoint', ...
    'Slope', 1, ...
    'SlopeAdjustmentFactor', 1.0, ...
    'FixedExponent', -15, ...
    'Bias', 0.0, ...
    'FractionLength', 15, ...
    'BaseType', 'double', ...
    'DimRange', [2,2]);

% Define Input Arguments
hEntry.createAndAddConceptualArg(...
    'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...

```

```

        'IsSigned',           true, ...
        'WordLength',       32, ...
        'CheckSlope',       true, ...
        'CheckBias',        true, ...
        'DataTypeMode',     'Fixed-point:binary point scaling', ...
        'DataType',         'Fixed', ...
        'Scaling',          'BinaryPoint', ...
        'Slope',            1, ...
        'SlopeAdjustmentFactor', 1.0, ...
        'FixedExponent',    -15, ...
        'Bias',             0.0, ...
        'FractionLength',   15, ...
        'BaseType',         'double', ...
        'DimRange',         [2,2]);

% Approach 2: getTflArgFromString
% arg = getTflArgFromString(hEntry, name, I/O type)
% name- y1..yn | u1..un
% I/O type- RTW_IO_OUTPUT | RTW_IO_INPUT

% Define Output Arguments
arg = getTflArgFromString('y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.addConceptualArg(arg);

% Define Input Arguments
arg = getTflArgFromString('u1', 'double');
arg.IOType = 'RTW_IO_INPUT';
hEntry.addConceptualArg(arg);

end

```

6 Create the implementation representation.

The implementation representation describes the signature of the replacement function defined by the code replacement library. It consists of the function name, return arguments, and parameters. Specify the implementation arguments with a type, type qualifier, and complexity. After you define your implementation representation, add your completed entry to the code replacement table with a call to the function `addEntry`.

To define your implementation representation, use one of these approaches:

| Approach | Function | Goal |
|----------|--|--|
| 1 | <code>copyConceptualArgsToImplementation</code> | Identical arguments.

Specify implementation arguments and conceptual arguments have the same properties. |
| 2 | <code>createAndAddImplementationArg</code>
<code>createAndSetCImplementationReturn</code> | Same order, different properties.

Specify implementation arguments have the same order as conceptual arguments but have different properties. |

| Approach | Function | Goal |
|----------|-----------------------|---|
| 3 | getTflArgFromString | Add constant value.

Specify implementation arguments with a constant value. |
| 4 | getTflDWorkFromString | Mutex/Semaphore replacement.

Specify implementation arguments for mutex or semaphore functions. |
| 5 | createCRLEntry | Create entry with one function.

Declare and define a code replacement table entry (conceptual and implementation arguments) in one function. |

Programming approaches are shown with all available properties set to their default values. The exact properties and values you need to specify depends on the function you replace. See examples for specific replacement details.

```
function hTable = code_replacement_library_table()
% Create a function to call code replacement library table

%% Create a code replacement library table object
hTable = RTW.TflTable;

%% Create a code replacement library entry
% Pick one from list below
hEntry = RTW.TflCOperationEntry;
hEntry = RTW.TflCFunctionEntry;
hEntry = RTW.TflBlasEntryGenerator;
hEntry = RTW.TflCBlasEntryGenerator;
hEntry = RTW.TflCOperationEntryGenerator;
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;
hEntry = RTW.TflCSemaphoreEntry;
hEntry = RTW.TflCFunctionEntryML;
hEntry = RTW.TflCOperationEntryML;

%% Create entry parameters
% Pick one from list below
% To view properties, see step 4
hEntry.setTflCOperationEntryParameters( );
hEntry.setTflCFunctionEntryParameters( );
hEntry.setTflCSemaphoreEntryParameters( );

%% Create the conceptual representation

% Approach 1: createAndAddConceptualArg
% arg = createAndAddConceptualArg(hEntry, argType, varargin)
% argType - 'RTW.TflArgNumeric' | 'RTW.TflArgMatrix'
% varargin - 'name', 'value' pairs shown below set to default values,
% includes name and I/O type, to view properties, see step 5

% Define Output Arguments
hEntry.createAndAddConceptualArg( );
```

```

% Define Input Arguments
hEntry.createAndAddConceptualArg( );

% Approach 2: getTflArgFromString
% arg = getTflArgFromString(hEntry, name, I/O type)
% name- y1..yn | u1..un
% I/O type- RTW_IO_OUTPUT | RTW_IO_INPUT

% Define Output Arguments
arg = getTflArgFromString('y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.addConceptualArg(arg);

% Define Input Arguments
arg = getTflArgFromString('u1', 'double');
arg.IOType = 'RTW_IO_INPUT';
hEntry.addConceptualArg(arg);

%% Create the implementation representation

% Approach 1: copyConceptualArgsToImplementation
copyConceptualArgsToImplementation(hEntry);

% Approach 2: createAndSetCImplementation, createAndSetCImplementationArg
% arg = createAndAddImplementation(hEntry, argType,varargin),
% arg = createAndSetCImplementationReturn(hEntry, argType,varargin)
% argType - 'RTW.TflArgNumeric' | 'RTW.TflArgMatrix'
% varargin - 'name', 'value' pairs shown below set to default values,
% includes name and I/O type

% Define Output Arguments
hEntry.createAndSetCImplementationReturn(...
    'RTW.TflArgNumeric',      ...
    'Name',                  'y1', ...
    'IOType',                'RTW_IO_OUTPUT', ...
    'IsSigned',              true, ...
    'WordLength',            16, ...
    'DataTypeMode',          'Fixed-point:binary point scaling', ...
    'DataType',              'Fixed', ...
    'Scaling',               'BinaryPoint', ...
    'Slope',                 1.0, ...
    'SlopeAdjustmentFactor', 1.0, ...
    'FixedExponent',         -15, ...
    'Bias',                  0.0, ...
    'FractionLength',        15, ...
    'Value',                 0);

% Define Input Arguments
hEntry.createAndAddImplementationArg(...
    'RTW.TflArgNumeric',      ...
    'Name',                  'u1', ...
    'IOType',                'RTW_IO_INPUT', ...

```

```

        'IsSigned',           true, ...
        'WordLength',       16, ...
        'DataTypeMode',     'Fixed-point:binary point scaling', ...
        'DataType',         'Fixed', ...
        'Scaling',          'BinaryPoint', ...
        'Slope',            1.0, ...
        'SlopeAdjustmentFactor', 1.0, ...
        'FixedExponent',    -15, ...
        'Bias',             0.0, ...
        'FractionLength',   15, ...
        'Value',            0);

% Approach 3: getTflArgFromString
% arg = getTflArgFromString(hEntry, name, datatype)
% name- y1..yn | u1..un, datatype - built-in data type

% Define Output arguments
arg = getTflArgFromString(hEntry, 'y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.Implementation.setReturn(arg);

% Define Input arguments
arg = getTflArgFromString(hEntry, 'u1', 'double', 0);
hEntry.Implementation.addArgument(arg);

% Approach 4: getTflDWorkFromString
% arg = getTflDWorkFromString(hEntry, name, datatype)

% Define arguments
arg = getTflDWorkFromString('d1', 'void*');
hEntry.addDWorkArg(arg);

% Approach 5: createCRLEntry
% tableEntry = createCRLEntry(crTable,conceptualSpecification,implementationSpecification)

% Define code replacement conceptual and implementation arguments
hEntry = createCRLEntry(...
    hTable, ...
    'conceptualSpecification', ...
    'implementationSpecification');

%% Add code replacement library entry to table
hTable.addEntry(hEntry);

end

```

7 Specify build information.

Specify build information for your code replacement library. Build information provides the code generator with the files necessary to perform function replacement.

To specify build information:

- Specify your build parameters in the Entry Parameters function you defined in step 4 or with the specified functions. Specify build information with the following properties:

| Parameter | Description |
|---|---|
| Implementation header file
Set properties
<code>ImplementationHeaderFile</code> and
<code>ImplementationHeaderPath</code> . | Name of header file needed for code replacement. |
| Implementation source file
Set properties
<code>ImplementationSourceFile</code> and
<code>ImplementationSourcePath</code> . | Name of source file needed for code replacement. |
| Additional header files/include paths
For each file, specify the file name and path in calls to the functions
<code>addAdditionalHeaderFile</code> and
<code>addAdditionalIncludePath</code> . | Name and path of additional header files needed for code replacement. |
| Additional source files/paths
For each file, specify the file name and path in calls to the functions
<code>addAdditionalSourceFile</code> and
<code>addAdditionalSourcePath</code> . | Name and path of additional source files needed for code replacement. |
| Additional object files/paths
For each file, specify the file name and path in calls to the functions
<code>addAdditionalLinkObj</code> and
<code>addAdditionalLinkObjPath</code> . | Name and path of additional object files needed for code replacement. |
| Additional link flags
Set the entry property
<code>AdditionalLinkFlags</code> to a cell array of character vectors or string array representing the required compile flags. | Flags the linker needs to generate an executable file for the replacement code. |
| Additional compile flags
Set the entry property
<code>AdditionalCompileFlags</code> to a cell array of character vectors or string array representing the required link flags. | Flags the compiler needs to generate object code for the replacement code. |

| Parameter | Description |
|---|---|
| Copy files to build directory.
Set property GenCallback to 'RTW.copyFileToBuildDir'.
If a match occurs for a table entry, a call to the function RTW.copyFileToBuildDir copies required files to the build folder.
If you specify additional header files/include paths or additional source files/paths and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files. | Flags whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. If you specify files with Additional header files/include paths or Additional source files/ paths and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files. |

- If an entry uses header, source, or object files, consider whether to make the files accessible to the code generator. You can copy files to the build folder or you can specify individual file names and paths explicitly.
 - If you specify *additional* header files/include paths or source files/paths and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files (an instance in the build folder and an instance in the original folder).
 - If you choose to copy files to the build folder and you are using the packNGo function to relocate static and generated code files to another development environment:
 - In the call to packNGo, specify the property-value pair 'minimalHeaders' true (the default). That setting instructs the function to include the minimal header files required to build the code in the zip file.
 - Do not collocate files that you copy with files that you do not copy. If the packNGo function finds multiple instances of the same file, the function returns an error.
 - If you use the programming interface, paths that you specify can include tokens. A token is a variable defined as a character vector, cell array of character vectors, or string array in the MATLAB workspace that you enclose with dollar signs (*\$variable\$*). The code generator evaluates and replaces a token with the defined value. For example, consider the path *\$myfolder\$folder1*, where *myfolder* is a character vector or string scalar variable defined in the MATLAB workspace as 'd:\work\source\module1'. The code generator generates the custom path as d:\work\source\module1\folder1.
- 8** Validate and save.

Save your code replacement library customization file with the same name as your code replacement library table on your MATLAB path.

To save and validate your library:

- a** Save your file. From the MATLAB menu, select **File > Save**.
- b** Validate your library by calling it from the MATLAB command line. For example:

```
>> hTable = code_replacement_library_table()
```

Register Code Replacement Library

Create a code replacement library by defining in a registration file the library name, code replacement tables, and other information. After you define and register your library it becomes available to the code generator for code replacement.

Interactively Develop and Load a Registration file

- 1 In the crtool, select **File > Generate registration file**.

- 2 In the **Generate registration file** dialog box, specify registration information. Then click **OK**.

| Parameter | Description |
|---------------------------------------|---|
| Registry name (Required) | Code replacement library name. |
| Table list (Required) | Comma-separated list of one or more code replacement tables that you want in the library. Specify tables by using either their names (if located on the MATLAB search path), absolute paths, or relative paths. |
| Base CRL | Enables you to specify library hierarchies. Provide the name of a registered library to serve as a base for the library that you are currently registering. For example, a TI device library can be a base for a TI C28x library. |
| Target HW device | Comma-separated list of one or more hardware devices that this library supports. Indicate support of all devices with an asterisk (*). |
| Description | Description of the purpose and content of the library. |
| Generate data alignment specification | Flag that enables data alignment. |

- 3 To use your registered code replacement library, refresh your current MATLAB session with the command:

```
>> sl_refresh_customizations
```

Programmatically Develop and Load a Registration File

- 1 Open a MATLAB function file. From the MATLAB menu, select **New > Function**.
- 2 Save the function file with the name `rtwTargetInfo.m`.
- 3 Copy and paste the following code into your file to use as a template.

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry; %instantiates a registration entry
this(1).Name = 'Example Code Replacement Library';
this(1).TableList = {'example_code_replacement_table.m'};
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'This registers an example library';

end
```

- 4 In the template, specify the following registration information:

| Parameter | Description |
|---------------------------------------|---|
| Registry name (Required) | Code replacement library name. |
| Table list (Required) | Comma-separated list of one or more code replacement tables that you want in the library. Specify tables by using either their names (if located on the MATLAB search path), absolute paths, or relative paths. |
| Base CRL | Enables you to specify library hierarchies. Provide the name of a registered library to serve as a base for the library that you are currently registering. For example, a TI device library can be a base for a TI C28x library. |
| Target HW device | Comma-separated list of one or more hardware devices that this library supports. Indicate support of all devices with an asterisk (*). |
| Description | Description of the purpose and content of the library. |
| Generate data alignment specification | Flag that enables data alignment. |

- 5 Save the file on your MATLAB path.
- 6 To use your registered code replacement library, refresh your current MATLAB session with the command:

```
>> sl_refresh_customizations
```

Examples

Register one code replacement library

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry; %instantiates a registration entry
this(1).Name = 'Example Code Replacement Library';
this(1).TableList = {'example_code_replacement_table.m'};
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'This registers an example library';

end
```

Register multiple code replacement libraries

```
function rtwTargetInfo(cm)
cm.registerTargetInfo(@loc_register_crl);
end

function thisCRL = loc_register_crl
% Register a code replacement library for use with model: rtwdemo_crladdsub
thisCrl(1) = RTW.TflRegistry;
thisCrl(1).Name = 'Addition & Subtraction Examples';
thisCrl(1).Description = 'Example of addition/subtraction op replacement';
thisCrl(1).TableList = {'crl_table_addsub'};
thisCrl(1).TargetHWDeviceType = {'*'};

% Register a code replacement library for use with model: rtwdemo_crlmuldiv
thisCrl(2) = RTW.TflRegistry;
thisCrl(2).Name = 'Multiplication & Division Examples';
thisCrl(2).Description = 'Example of mult/div op repl for built-in integers';
thisCrl(2).TableList = {'c:/work_crl/crl_table_muldiv'};
thisCrl(2).TargetHWDeviceType = {'*'};

% Register a code replacement library for use with model: rtwdemo_crlfixpt
thisCrl(3) = RTW.TflRegistry;
thisCrl(3).Name = 'Fixed-Point Examples';
thisCrl(3).Description = 'Example of fixed-point operator replacement';
thisCrl(3).TableList = {fullfile('${MATLAB_ROOT}', ...
    'toolbox', 'rtw', 'rtwdemos', 'crl_demo', 'crl_table_fixpt')};
thisCrl(3).TargetHWDeviceType = {'*'};

end
```

Register a code replacement hierarchy

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end
```

```

function thisCRL = loc_register_crl
    % Register a code replacement library that includes common entries
    thisCrl(1) = RTW.TflRegistry;
    thisCrl(1).Name = 'Common Replacements';
    thisCrl(1).Description = 'Common code replacement entries shared by other libraries';
    thisCrl(1).TableList = {'crl_table_general'};
    thisCrl(1).TargetHWDeviceType = {'*'};

    % Register a code replacement library for TI devices
    thisCrl(2) = RTW.TflRegistry;
    thisCrl(2).Name = 'TI Device Replacements';
    thisCrl(2).Description = 'Code replacement entries shared across TI devices';
    thisCrl(2).TableList = {'crl_table_TI_devices'};
    thisCrl(2).TargetHWDeviceType = {'TI C28x', 'TI C55x', 'TI C62x', 'TI C64x', 'TI 67x'};
    thisCrl(2).BaseTfl = 'Common Replacements'

    % Register a code replacement library for TI c6xx devices
    thisCrl(3) = RTW.TflRegistry;
    thisCrl(3).Name = 'TI c6xx Device Replacements';
    thisCrl(3).Description = 'Code replacement entries shared across TI C6xx devices';
    thisCrl(3).TableList = {'crl_table_TIC6xx_devices'};
    thisCrl(3).TargetHWDeviceType = {'TI C62x', 'TI C64x', 'TI 67x'};

    % Register a code replacement library for the TI c67x device
    thisCrl(4) = RTW.TflRegistry;
    thisCrl(4).Name = 'TI c67x Device Replacements';
    thisCrl(4).Description = 'Code replacement entries for the TI C67x device';
    thisCrl(4).TableList = {'crl_table_TIC67x_device'};
    thisCrl(4).TargetHWDeviceType = {'TI 67x'};

end

```

- “Code You Can Replace from MATLAB Code” on page 70-5

Troubleshoot Code Replacement Library Registration

If a code replacement library is not listed as a configuration option or does not appear in the Code Replacement Viewer:

- Refresh the library registration information within the current MATLAB session (RTW.TargetRegistry.getInstance('reset'); or for the Simulink environment,sl_refresh_customizations).
- See whether the registration file, rtwTargetInfo.m, contains an error.

See Also

More About

- “Register Code Replacement Library” on page 70-38

Verify Code Replacement Library

Verify your code replacement library by examining its structure, replacement, and performance. Use the Code Replacement Viewer (crviewer) to verify the structure of your library. Use the code replacement report to verify the replacements made with your library in generated code. Use crviewer again to verify the performance of your library during code generation by examining the replacement hit and miss logs.

Verify Library Structure

Use the Code Replacement Viewer (crviewer) to open and view the structure of your code replacement library by examining its tables and table entries.

- 1 From the MATLAB command prompt, open your code replacement library using the crviewer with the command:

```
>> crviewer('library')
```
- 2 The viewer opens your code replacement library and shows its code replacement tables in the left pane. Verify that your library lists all required tables in the correct relative order.
- 3 Open and view the entries for each code replacement table. In the crtool, click each table listed in the left pane to view its entries in the middle pane.

If you are not using the crviewer, you can open each table directly from the MATLAB command prompt with the command:

```
crviewer(table)
```

- 4 For each table in your library, verify that it lists all required entries in the correct relative order. Verify that the conceptual representation and implementation representation are correct for each entry in the table.

Verify Library Replacement

Use the Code Replacements Report to verify that when the code generator uses your code replacement library it creates replacements as expected in the generated code. For each instance of replacement, the Code Replacements Report provides a mapping between the Simulink block that triggered the replacement and its implementation in the generated code. Use this mapping to verify correct code replacement by tracing between the report and the code in either direction (from report to code or code to report).

To generate the Code Replacements Report:

- 1 Configure your model to use your code replacement library.
- 2 Configure your model to open the Code Generation Report. The Code Replacements Report is a tab within this report. In the Model Configuration Parameters dialog box, in the **Code Generation > Report** pane, select:
 - **Create code generation report**
 - **Open report automatically**
 - **Model-to-code**
 - **Summarize which block triggered code replacements**

- 3 Configure the generated code to include comments. In the Model Configuration Parameters dialog box, in the **Code Generation > Comments** pane, select:
 - **Include comments**
 - Either or both of **Simulink block comments** and **Simulink block descriptions**
- 4 Build your model to generate code only. The Code Generation Report opens automatically. On the left pane, click to open the Code Replacements Report.
- 5 Verify that code replacements occur as expected.
 - **Navigate from report to model:** In the Code Replacements Report, click each block link to see the source that triggered replacement.
 - **Navigate from model to report:** In the Simulink model window, use model-to-code highlighting to trace code replacements. Right-click blocks where you expected code replacement to occur and select **C/C++ Code > Navigate to C/C++ Code**. The report appears with the corresponding replacement code highlighted.

Verify Library Performance

Verify the performance of your code replacement library by examining the hits and misses that occurred during code generation using your library. During code generation, when the code generator finds a match for code replacement from your code replacement library, it logs the hit in a hit cache. When it does not find a code replacement match, it logs the failed attempt in the miss cache. Each time that you generate code, the code generator overwrites its previous hit and miss cache logs.

To review trace information from the hit and miss cache data, use the Code Replacement Viewer (crviewer). From the hit cache, you can identify when code replacement successfully occurred, and from the miss cache, you can troubleshoot when code replacement did not take place. The miss cache trace information provides you information about the reason for the miss, a link to the relevant source location for the miss, and the call site object of the miss. For more information, see “Troubleshoot Code Replacement Misses” on page 69-59.

Review Code Replacements

After you review the content of your code replacement library and tables, generate code and a code generation report. Verify that the code generator replaces code as you expect.

The Code Replacements Report details the code replacement library functions that the code generator uses for code replacements. The report provides a mapping between each replacement instance and the line of MATLAB code that triggered the replacement. The Code Replacements report is not available for generated MEX functions.

The following example illustrates two complementary approaches for reviewing code replacements:

- Check the Code Replacements Report section of the code generation report for expected replacements.
 - Trace code replacements.
- 1 Identify the MATLAB function where you anticipate that a function or operator replacement occurs. This example uses the function `matlabroot/toolbox/rtw/rtwdemos/crl_demo/addsub_two_int16.m`.

```
function [y1, y2] = addsub_two_int16(u1, u2)
```

```
y1 = int16(u1 + u2);
y2 = int16(u1 - u2);
```

- 2 Identify or create code or a script to exercise the function. For example, consider test file `addsub_to_int16_test.m`, which includes the following code:

```
disp('Input')
u1 = int16(10)
u2 = int16(10)
```

```
[y1, y2] = addsub_two_int16(u1, u2);
```

```
disp('Output')
disp('y1 =')
disp(y1);
disp('y2 =')
disp(y2);
```

- 3 Open the MATLAB Coder app.
- 4 On the **Select Source Files** page, add your function to the project. For this example, add function `addsub_two_int16`. Click **Next**.
- 5 On the **Define Input Types** page, use the test file `addsub_to_int16_test` to automatically define the input types. Click **Next**.
- 6 On the **Check for Run-Time Issues** page, specify the test file `addsub_to_int16_test`. The app runs the test file, replacing calls to `addsub_to_int16_test` with calls to a MEX version of `addsub_to_int16_test`. Click **Next**.
- 7 To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
- 8 Set **Build type** to generate source code. Before you build an executable, you want to review your code replacements in the generated code.
- 9 In the Generate dialog box, click **More Settings**.
- 10 Configure the code generator to use your code replacement library. On the **Custom Code** tab, set the **Code replacement library** parameter to the name of your library. For this example, set the library to `Addition & Subtraction Examples`.
- 11 Configure the code generation report to include the Code Replacements Report. On the **Debugging** tab, select:
 - **Always create a code generation report**
 - **Code replacements**
 - **Automatically launch a report if one is generated**
- 12 To generate code and a report, set **Build type** to `Source Code`. Then, click **Generate**.
- 13 Open the **Code Replacements Report** section of the code generation report.

That report lists the replacement functions that the code generator used. The report provides a mapping between each replacement instance and the MATLAB code that triggered the replacement.

Review the report:

- Check whether expected function and operator code replacements occurred.

- In the replacements sections, click each code link to see the source that triggered the reported code replacement.

If a function or operator is not replaced as expected, the code generator used a higher-priority (lower-priority value) match or did not find a match.

To analyze and troubleshoot code replacement misses, use the trace information that the **Code Replacement Viewer** provides.

- “What Is Code Replacement Customization?” on page 70-3

Troubleshoot Code Replacement Misses

Use miss reason messages that appear in the **Code Replacement Viewer** to analyze and correct code replacement misses.

Miss Reason Messages

The Code Replacement Viewer displays miss reason messages in trace information for code replacement misses. A legend listing each message that appears in the miss report precedes the report details. A message consists of:

- Numeric identifier, which identifies the message in the report details.
- Message text, which in some cases includes placeholders for names of arguments, call site object values, table entry values, and property names.

For example:

1. Mismatched data types (argument name, CS0 value, table entry value)

The parenthetical information represents placeholders for actual values that appear in the report details.

In the **Miss Source Locations** table that lists the miss details, the **Reason** column includes:

- The message identifier, as listed in the legend.
- The placeholder values for that instance of the miss reason message.

The following **Reason** details indicate a data type mismatch because the call site object specifies data type `int8` for arguments `y1`, `u1`, and `u2`, while the code replacement table entry specifies `uint32`.

1. `y1, int8, uint32`
`u1, int8, uint32`
`u2, int8, uint32`

Depending on your situation and the reported miss reason, troubleshoot reported misses by looking for instances of the following:

- A typo in the code replacement table entry definition or a source parameter setting.
- Information missing from the code replacement table entry or a source parameter setting.
- Invalid or incorrect information in the code replacement table entry definition or a source parameter setting.
- Arguments incorrectly ordered in the code replacement table entry definition or the source being replaced with replacement code.
- Failed algorithm classification for an addition or subtraction operation due to:
 - An ideal accumulator not being calculated because the type of an input argument is not fixed-point or the slope adjustment factors of the input arguments are not equal.
 - Input or output casts with a floating-point cast type.
 - Input or output casts with cast types that have different slope adjustment factors or biases.
 - Output casts not being convertible to a single output cast.

- Input casts resulting in loss of bits.

Analyze and Correct Code Replacement Misses

The following example shows how to use Code Replacement Viewer trace information to troubleshoot code replacement misses. You must have already reviewed and tested code replacements for your MATLAB code.

- 1 Review the code generated for a specific code element, looking for expected code replacement. Regenerate or reopen the code generation report for your MATLAB code. If you already generated the code generation report that includes the Code Replacements Report for *matlabroot/toolbox/rtw/rtwdemos/crl_demo/addsub_two_int16.m*, open the file *codegen/lib/addsub_two_int16/html/mldatx.html*. For information on how to regenerate the report, see “Verify Code Replacement Library” on page 70-43.

To examine the code generated for the function, from the code generation report, open the generated file *addsub_two_int16.h*.

```
extern void addsub_two_int16(double u1, double u2, short *b_y1, short *y2);
```

The code generator replaced code, but the replacement is for the signed version of the 16-bit addition and subtraction operations. You expected code replacements for operations on unsigned data.

- 2 Open the Code Replacements Report for the MATLAB code.
- 3 Click the link to open the Code Replacement Viewer.
- 4 In the viewer left pane, select your code replacement table. For this example, select code replacement table *crl_table_addsub*.
- 5 In the middle pane, select table entry *RTW_OP_ADD* with implementation function *u16_add_u16_u16*.
- 6 In the right pane, select the **Trace Information** tab.

The **Trace Information** is a table that lists the following information for each miss:

- Call site object preview. The call site object is the conceptual representation of addition operator. The code generator uses this object to query the code replacement library for a match.
- A link to the source location in the MATLAB function where the code generator considered replacing code.
- The reasons that the miss occurred. See “Miss Reason Messages” on page 70-47.

For this example, the report shows misses for function *addsub_two_int16.m*.

- 7 Find the source in the trace information. Depending on your situation and the reported miss reason, consider looking for a condition such as a typo in the code replacement table entry definition or a source parameter setting. For a list of conditions to consider, see “Miss Reason Messages” on page 70-47.

For this example, determine why code for function *addsub_two_int16* is not replaced with code for an unsigned 16-bit addition operation. The miss reasons for the function indicate data type and algorithm mismatches:

- The data type in the call site object is a signed 16-bit integer. The code replacement entry specifies an unsigned 16-bit integer.

- The algorithm property in the call site object is `RTW_CAST_AFTER_OP` while the code replacement entry specifies `RTW_CAST_BEFORE_OP`.
- 8** Fix the specified MATLAB code and relevant specifications or code replacement table entry. If the issue concerns the MATLAB code, use the source location in the trace information to find the code to fix. For this example, you expected an unsigned addition operation to occur for the `addsub_two_int16` function.

To fix the mismatches, in the test file `addsub_to_int16_test`, change the data types definitions for `u1` and `u2` as follows:

```
u1 = uint16(10)
u2 = uint16(10)
```

In the MATLAB Coder app:

- Open the project that contains the `addsub_to_int16` function.
 - Use the updated test file `addsub_to_int16_test` to automatically redefine the input types.
 - Change the addition and subtraction algorithm setting. Open the code replacement library `crl_table_addsub`. Change the entry **Algorithm** parameter setting from `Cast before operation (RTW_CAST_BEFORE_OP)` to `Cast after operation (RTW_CAST_AFTER_OP)`.
 - Regenerate code and a report.
- 9** From the Code Replacements Report, open the Code Replacement Viewer. Use the Code Replacement Viewer trace information to verify that your MATLAB code or code replacement table entry corrects the code replacement issue. The trace information shows a hit for function `addsub_two_int16`.

- “Verify Code Replacement Library” on page 70-43

Deploy Code Replacement Library

Package and deploy your code replacement library.

- 1** Move your code replacement library customization and registration files to a location on the MATLAB® search path that is accessible to other users. If another registration file already exists in that location, copy and paste the information for your code replacement library into the existing registration file.
- 2** Refresh your session and verify that the library is available as a configuration option for the code generator.
- 3** Verify that code replacement occurs as expected in generated code.
- 4** Inform users that the code replacement library is available.

Math Function Code Replacement

This example shows how to develop a code replacement library to optimize the performance of math functions by providing information on how to define code replacement for a `sin` function. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

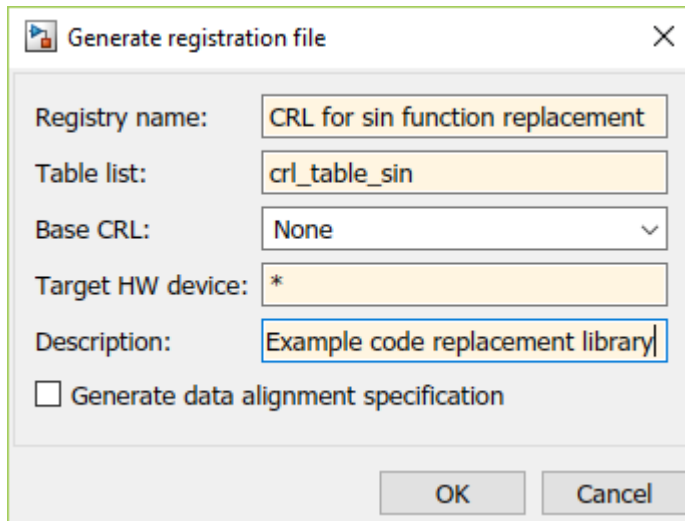

Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```
- 2 Create a table.
 - a From the crtool context menu, select **File > New Table**.
 - b In the right pane, name the table `crl_table_sin`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Function**.
- 4 Create entry parameters. In the **Function** drop-down list, select `sin`. Algorithm information appears in the crtool. For this example, leave the parameter unspecified.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1`, with the **Data Type** of `double` and the **Argument Type** of `Scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. Click the **Mapping Information** tab and verify the fields are filled in as shown. Click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
 - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_sin
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCFunctionEntry`.

```
function hTable = crl_table_sin
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = rtw.TflCFunctionEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_table_sin()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
    'Key', 'sin', ...
    'Priority', 30, ...
    'ImplementationName', 'mySin', ...
    'ImplementationHeaderFile', 'basicMath.h', ...
    'ImplementationSourceFile', 'basicMath.c');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `createAndAddConceptualArg`.

```
function hTable = crl_table_sin()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
    'Key', 'sin', ...
    'Priority', 30, ...
    'ImplementationName', 'mySin', ...
    'ImplementationHeaderFile', 'basicMath.h', ...
    'ImplementationSourceFile', 'basicMath.c');
```

```
%% Create the conceptual representation
hEntry.createAndAddConceptualArg(...
    'RTW.TflArgNumeric', ...
    'Name', 'y1',...
    'IOType', 'RTW_IO_OUTPUT',...
    'DataTypeMode', 'double');
```

```
hEntry.createAndAddConceptualArg(...
    'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT',...
    'DataTypeMode', 'double');
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `copyConceptualArgsToImplementation`. Add the complete entry to the table by calling the function `addEntry`.

```

function hTable = crl_table_sin()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
    'Key', 'sin', ...
    'Priority', 30, ...
    'ImplementationName', 'mySin', ...
    'ImplementationHeaderFile', 'basicMath.h', ...
    'ImplementationSourceFile', 'basicMath.c');

%% Create the conceptual representation
hEntry.createAndAddConceptualArg(...
    'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'DataTypeMode', 'double');

hEntry.createAndAddConceptualArg(...
    'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'DataTypeMode', 'double');

%% Create the Implementation Representation
copyConceptualArgsToImplementation(hEntry);

%% Add the entry to the table
hTable.addEntry(hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_sin
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) with these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for sin function replacement';
this(1).TableList = {'crl_table_sin.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

```

end

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10** Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Memory Function Code Replacement

This example shows how to develop a code replacement library to optimize the performance of memory functions by providing information on how to define code replacement for a memcpy function. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```

- 2 Create a table.

- a From the crtool context menu, select **File > New Table**.

- b In the right pane, name the table `cr1_table_memcpy`. Click **Apply**.

- 3 Create an entry. From the crtool context menu, select **File > New entry > Function**.

- 4 Create entry parameters. In the **Function** drop-down list, select memcpy.

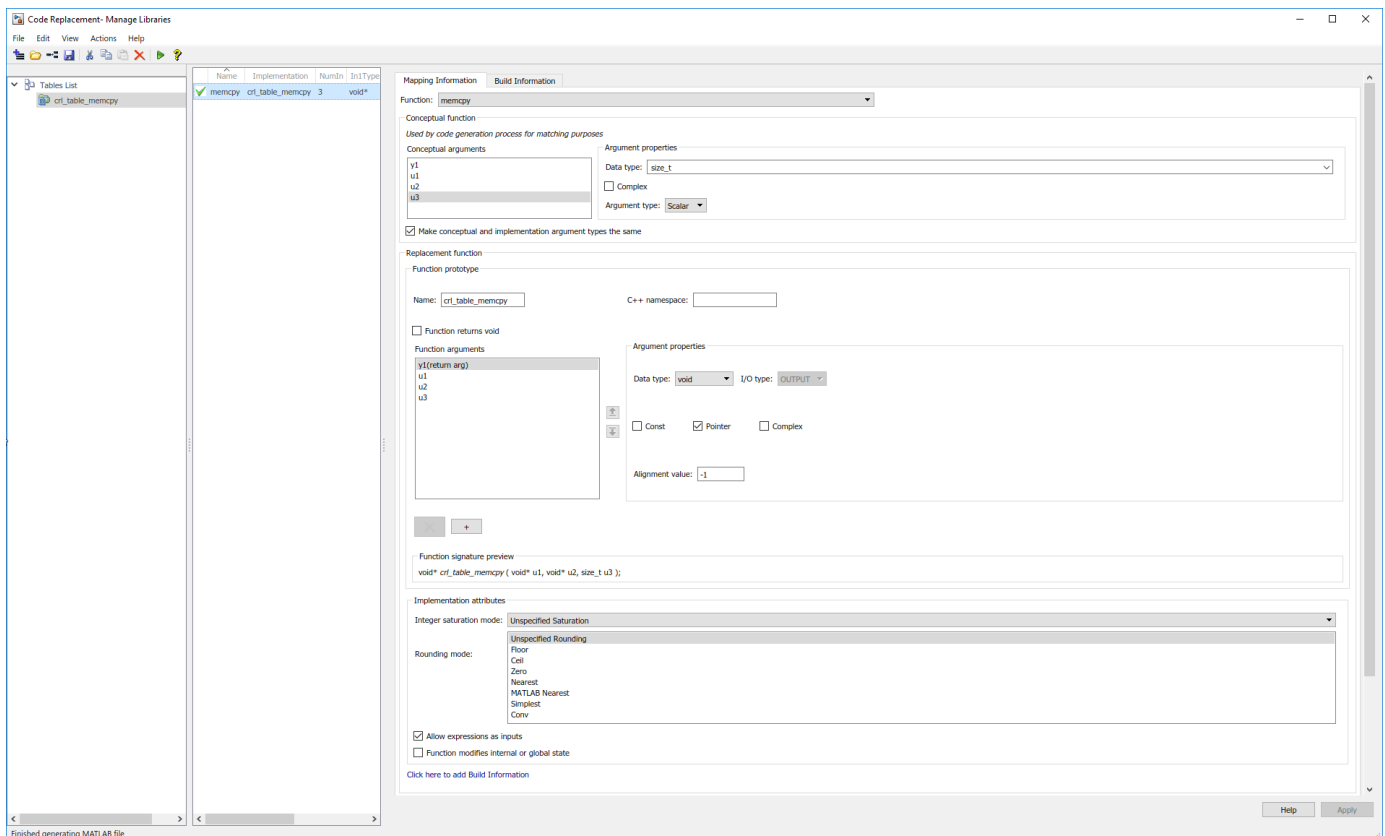

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, y1, with the **Data Type** of void and the **Argument Type** of Pointer, the input arguments, u1 and u2 with the **Data Type** of void and the **Argument Type** of Pointer and u3 with the **Data Type** of unsigned integral and the **Argument Type** of Scalar.

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.

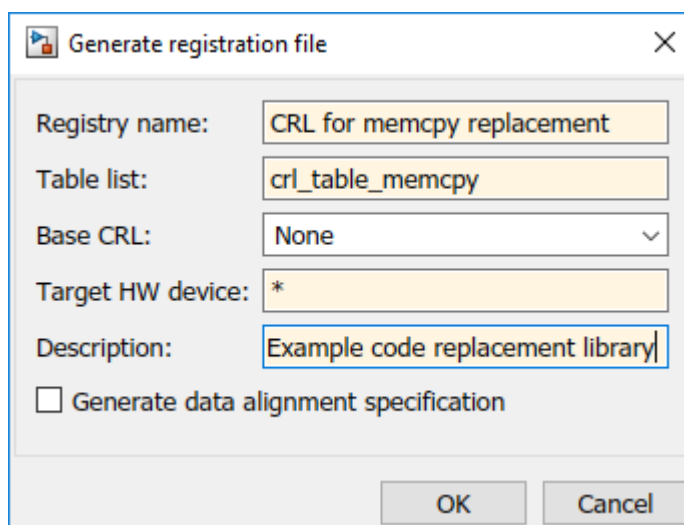

Specify a **Name** for the replacement function under **Function prototype**.

- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.

- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:
`>>sl_refresh_customizations`

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function to call your code replacement library table. The function should not have arguments and return a table object.
 - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_memcpy()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCFunctionEntry`.

```
function hTable = crl_table_memcpy()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = rtw.TflCFunctionEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_table_memcpy()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
% Set SideEffects to 'true' for function returning void to prevent it from
% being optimized away.
hEntry.setTflCFunctionEntryParameters(...
    'Key', 'memcpy', ...
    'Priority', 90, ...
    'ImplementationName', 'memcpy_int', ...
    'ImplementationHeaderFile', 'memcpy_int.h',...
    'SideEffects', true);
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString`.

```

function hTable = crl_table_memcpy()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflFunctionEntry;

%% Create entry parameters
% Set SideEffects to 'true' for function returning void to prevent it from
% being optimized away.
hEntry.setTflFunctionEntryParameters(...
    'Key', 'memcpy', ...
    'Priority', 90, ...
    'ImplementationName', 'memcpy_int', ...
    'ImplementationHeaderFile', 'memcpy_int.h', ...
    'SideEffects', true);

%% Create conceptual arguments
arg = getTflArgFromString(hTable, 'y1', 'void*');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u1', 'void*');
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u2', 'void*');
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u3', 'size_t');
addConceptualArg(hEntry, arg);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `copyConceptualArgsToImplementation`. Add the complete entry to the table by calling the function `addEntry`.

```

function hTable = crl_table_memcpy()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflFunctionEntry;

%% Create entry parameters
setTflFunctionEntryParameters(hEntry, ...
    'Key', 'memcpy', ...
    'Priority', 90, ...
    'ImplementationName', 'memcpy_int', ...
    'ImplementationHeaderFile', 'memcpy_int.h', ...
    'SideEffects', true);

%% Create conceptual arguments
arg = getTflArgFromString(hTable, 'y1', 'void*');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u1', 'void*');
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u2', 'void*');
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u3', 'size_t');
addConceptualArg(hEntry, arg);

```

```

%% Create the Implementation Representation
copyConceptualArgsToImplementation(hEntry);

```

```

%% Add the entry to the table
hTable.addEntry(hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_memcpy
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file with these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for memory function replacement';
this(1).TableList = {'crl_table_memcpy.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

- “Math Function Code Replacement” on page 70-51

Specify In-Place Code Replacement

In-place code replacement is an optimization technique that uses a single buffer, that is, the same memory, to store function input and output data, as in $x = \text{foo}(x)$.

You can develop a code replacement library to optimize in-place function argument replacement. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

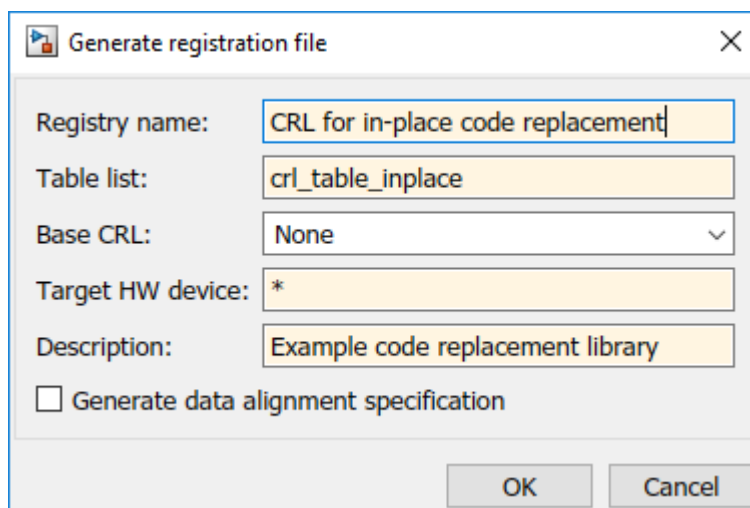

Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```
- 2 Create a table.
 - a From the crtool context menu, select **File > New Table**.
 - b In the right pane, name the table `crl_table_inplace`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Function**.
- 4 Create entry parameters. In the **Function** drop-down list, select **custom**. Function information appears in the crtool. For this example, specify the parameter as `customFunction`.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1`, with the **Data Type** of **double** and the **Argument Type** of **Pointer**.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. Add the implementation parameter `y1` and `u1`. For each input argument that you want to specify as in-place with a corresponding output argument, in the **Argument** properties box, select the **Pointer** check box. For the implementation parameter `y1` in the **Argument properties** section of the dialog box, set the **In-place argument** to `u1`.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For

more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
 - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_inplace()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCFunctionEntry`.

```
function hTable = crl_table_inplace
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = rtw.TflCFunctionEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_table_inplace()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
    'Key', 'customFunction', ...
    'Priority', 100, ...
    'ImplementationName', 'custom_function_inplace_impl', ...
    'SideEffects', true);
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString` and `addConceptualArg`.

```
function hTable = crl_table_inplace()
% Create a code replacement library table
```

```

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
    'Key', 'customFunction', ...
    'Priority', 100, ...
    'ImplementationName', 'custom_function_inplace_impl', ...
    'SideEffects', true);

%% Create the conceptual representation
arg = getTflArgFromString(hEntry, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hEntry, 'u1','double');
addConceptualArg(hEntry, arg);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. This example uses calls to the `getTflArgFromString` function to create implementation arguments that map to arguments in the replacement function prototype: output argument `y1` and input argument `u1`. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

```

function hTable = crl_table_inplace()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters(...
    'Key', 'customFunction', ...
    'Priority', 100, ...
    'ImplementationName', 'custom_function_inplace_impl', ...
    'SideEffects', true);

%% Create the conceptual representation
arg = getTflArgFromString(hEntry, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hEntry, 'u1','double');
addConceptualArg(hEntry, arg);

%% Create the Implementation Representation

arg = getTflArgFromString(hEntry, 'y2','void');
arg.IOType = 'RTW_IO_OUTPUT';

```

```

hEntry.Implementation.setReturn(arg);

arg = getTflArgFromString(hEntry, 'u1', 'double*');
arg.ArgumentForInPlaceUse = 'y1';
hEntry.Implementation.addArgument(arg);

```

```
%% Add the entry to the table
```

```
hTable.addEntry(hEntry);
```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_inplace
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) with these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for inplace function replacement';
this(1).TableList = {'crl_table_inplace.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Data Alignment for Code Replacement

Code replacement libraries can align data objects passed into a replacement function to a specified boundary.

Code Replacement Data Alignment

You can take advantage of function implementations that require aligned data to optimize application performance when using MATLAB Coder. To configure data alignment for a function implementation:

- 1 Specify the data alignment requirements in a code replacement entry. Specify alignment separately for each implementation function argument or collectively for all function arguments. See “Specify Data Alignment Requirements for Function Arguments” on page 69-105.
- 2 Specify the data alignment capabilities and syntax for one or more compilers. Include the alignment specifications in a library registration entry in the `rtwTargetInfo.m` file. See “Provide Data Alignment Specifications for Compilers” on page 69-106.
- 3 Register the library containing the table entry and alignment specification object.
- 4 Configure the code generator to use the code replacement library and generate code. Observe the results.

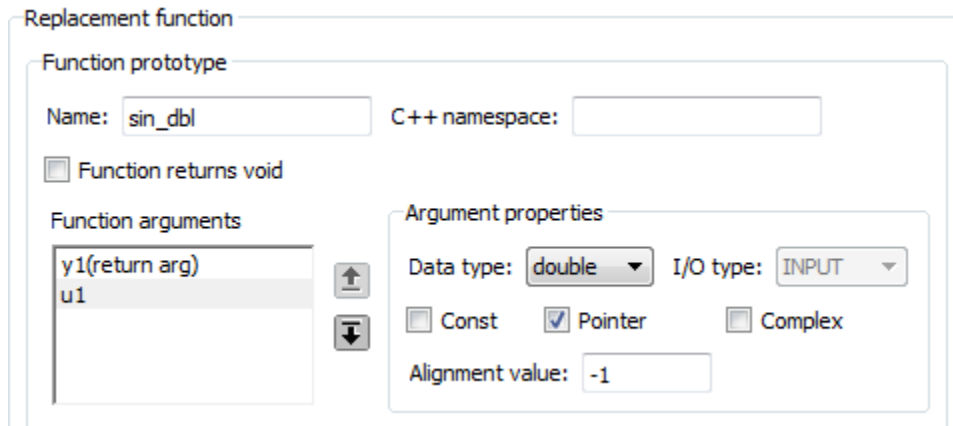

For examples, see “Basic Example of Code Replacement Data Alignment” on page 69-109 and the “Data Alignment for Function Implementations” section of the “Optimize Generated Code by Developing and Using Code Replacement Libraries - Simulink” on page 74-30 example page.

Note If replacement that requires alignment uses imported data (for example, I/O of an entry-point function or exported function), specify the data alignment with `coder.dataAlignment` statements in the MATLAB code. Specify alignment separately for each instance of imported data. See “Specify Data Alignment in MATLAB Code for Imported Data” on page 70-72.

Specify Data Alignment Requirements for Function Arguments

To specify the data alignment requirement for an argument in a code replacement entry:

- If you are defining a replacement function in a code replacement table registration file, create an argument descriptor object (`RTW.ArgumentDescriptor`). Use its `AlignmentBoundary` property to specify the required alignment boundary and assign the object to the `ArgumentDescriptor` property.
- If you are defining a replacement function using the **Code Replacement Tool**, on the **Mapping Information** tab, in the **Argument properties** section for the replacement function, enter a value for the **Alignment value** parameter.

The `AlignmentBoundary` property (or **Alignment value** parameter) specifies the alignment boundary for data passed to a function argument, in number of bytes. The `AlignmentBoundary` property is valid only for addressable objects, including matrix and pointer arguments. It is not applicable for value arguments. Valid values are:

- -1 (default) — If the data is a `Simulink.Bus`, `Simulink.Signal`, or `Simulink.Parameter` object, specifies that the code generator determines an optimal alignment based on usage. Otherwise, specifies that there is not an alignment requirement for this argument.
- Positive integer that is a power of 2, not exceeding 128 — Specifies number of bytes in the boundary. The starting memory address for the data allocated for the function argument is a multiple of the specified value. If you specify an alignment boundary that is less than the natural alignment of the argument data type, the alignment directive is emitted in the generated code. However, the target compiler ignores the directive.

The following code specifies the `AlignmentBoundary` for an argument as 16 bytes.

```
hLib = RTW.TflTable;
entry = RTW.TflOperationEntry;
arg = getTflArgFromString(hLib, 'u1', 'single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);
```

The equivalent alignment boundary specification in the Code Replacement Tool dialog box is in this figure.

Note If your model imports `Simulink.Bus`, `Simulink.Parameter`, or `Simulink.Signal` objects, specify an alignment boundary in the object properties, using the **Alignment** property. For more information, see `Simulink.Bus`, `Simulink.Parameter`, and `Simulink.Signal`.

Provide Data Alignment Specifications for Compilers

To support data alignment in generated code, describe the data alignment capabilities and syntax for your compilers in the code replacement library registration. Provide one or more alignment specifications for each compiler in a library registry entry.

To describe the data alignment capabilities and syntax for a compiler:

- If you are defining a code replacement library registration entry in a `rtwTargetInfo.m` customization file, add one or more `AlignmentSpecification` objects to an `RTW.DataAlignment` object. Attach the `RTW.DataAlignment` object to the `TargetCharacteristics` object of the registry entry.

The `RTW.DataAlignment` object also has the property `DefaultMallocAlignment`, which specifies the default alignment boundary, in bytes, that the compiler uses for dynamically allocated memory. If the code generator uses dynamic memory allocation for a data object involved in a code replacement, this value determines if the memory satisfies the alignment requirement of the replacement. If not, the code generator does not use the replacement. The default value for `DefaultMallocAlignment` is -1, indicating that the default alignment boundary used for dynamically allocated memory is unknown. In this case, the code generator uses the natural alignment of the data type to determine whether to allow a replacement.

Additionally, you can specify the alignment boundary for complex types by using the `addComplexTypeAlignment` function.

- If you are generating a customization file function using the Code Replacement Tool, fill out the following fields for each compiler.

Generate data alignment specification

Alignment Specification 1

Alignment type: DATA_ALIGNMENT_LOCAL_VAR
DATA_ALIGNMENT_STRUCT_FIELD
DATA_ALIGNMENT_WHOLE_STRUCT
DATA_ALIGNMENT_GLOBAL_VAR

Alignment position: DATA_ALIGNMENT_PREDIRECTIVE

Alignment syntax:

Supported languages:

Click the plus (+) symbol to add additional compiler specifications.

For each data alignment specification, provide the following information.

| Alignment-Specification Property | Dialog Box Parameter | Description |
|----------------------------------|---------------------------|--|
| AlignmentType | Alignment type | <p>Cell array of predefined enumerated strings, specifying which types of alignment this specification supports.</p> <ul style="list-style-type: none"> • DATA_ALIGNMENT_LOCAL_VAR — Local variables. • DATA_ALIGNMENT_GLOBAL_VAR — Global variables. • DATA_ALIGNMENT_STRUCT_FIELD — Individual structure fields. • DATA_ALIGNMENT_WHOLE_STRUCT — Whole structure, with padding (individual structure field alignment, if specified, is favored and takes precedence over whole structure alignment). <p>Each alignment specification must specify at least DATA_ALIGNMENT_GLOBAL_VAR and DATA_ALIGNMENT_STRUCT_FIELD.</p> |
| AlignmentPosition | Alignment position | <p>Predefined enumerated string specifying the position in which you must place the compiler alignment directive for alignment type DATA_ALIGNMENT_WHOLE_STRUCT:</p> <ul style="list-style-type: none"> • DATA_ALIGNMENT_PREDIRECTIVE — The alignment directive is emitted before <code>struct st_tag{...}</code>, as part of the type definition statement (for example, MSVC). • DATA_ALIGNMENT_POSTDIRECTIVE — The alignment directive is emitted after <code>struct st_tag{...}</code>, as part of the type definition statement (for example, gcc). • DATA_ALIGNMENT_PRECEDING_STATEMENT — The alignment directive is emitted as a standalone statement immediately preceding the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax. • DATA_ALIGNMENT_FOLLOWING_STATEMENT — The alignment directive is emitted as a standalone statement immediately following the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax. <p>For alignment types other than DATA_ALIGNMENT_WHOLE_STRUCT, code generation uses alignment position DATA_ALIGNMENT_PREDIRECTIVE.</p> |

| Alignment-Specification Property | Dialog Box Parameter | Description |
|----------------------------------|----------------------------|--|
| AlignmentSyntax-Template | Alignment syntax | Specifies the alignment directive string that the compiler supports. The string is registered as a syntax template that has placeholders in it. These placeholders are supported: <ul style="list-style-type: none"> • %n — Replaced by the alignment boundary for the replacement function argument. • %s — Replaced by the aligned symbol, usually the identifier of a variable. For example, for the gcc compiler, you can specify <code>__attribute__((aligned(%n)))</code> , or for the MSVC compiler, <code>__declspec(align(%n))</code> . |
| SupportedLanguages | Supported languages | Cell array specifying the languages to which this alignment specification applies, among c and c++. Sometimes alignment syntax and position differ between languages for a compiler. |

Here is a data alignment specification for the GCC compiler:

```
da = RTW.DataAlignment;

as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
                  'DATA_ALIGNMENT_STRUCT_FIELD', ...
                  'DATA_ALIGNMENT_GLOBAL_VAR'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.AlignmentPosition = 'DATA_ALIGNMENT_PREDIRECTIVE';
as.SupportedLanguages = {'c', 'c++'};
da.addAlignmentSpecification(as);

tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;
```

Here is the corresponding specification in the **Generate customization** dialog box of the Code Replacement Tool.

Generate data alignment specification

Alignment Specification 1

Alignment type: DATA_ALIGNMENT_LOCAL_VAR
DATA_ALIGNMENT_STRUCT_FIELD
DATA_ALIGNMENT_WHOLE_STRUCT
DATA_ALIGNMENT_GLOBAL_VAR

Alignment position: DATA_ALIGNMENT_PREDIRECTIVE

Alignment syntax: __attribute__((aligned(%n)))

Supported languages: c, c++

Specify Data Alignment in MATLAB Code for Imported Data

If MATLAB Coder code replacements that require data alignment use imported data, such as an entry-point or exported function I/O, specify data alignment to external code with `coder.dataAlignment` statements in the MATLAB code.

If MATLAB Coder code replacements occur that require data alignment (uses imported data), such as an entry-point or exported function with I/O, specify code replacement data alignment with `coder.DataAlignment` statements in the MATLAB code.

To specify the data alignment requirements for imported data in a MATLAB code:

- For each instance of imported data that requires data alignment, specify the alignment in the function with a `coder.dataAlignment` statement of the form:

```
coder.dataAlignment('varName', align_value)
```

- The *varName* is a character array of the variable name that requires alignment information specification. The *align_value* is an integer number which should be a power of 2, from 2 through 128. This number specifies the power-of-2 byte alignment boundary.
- An example function that specifies data alignment is:

```
function y = testFunction(x1,x2)

coder.dataAlignment('x1',16);    % Specifies information
coder.dataAlignment('x2',16);    % Specifies information
coder.dataAlignment('y',16);     % Specifies information

y = x1 + x2;

end
```

If `testFunction` is an entry-point or exported function, imported data `x1`, `x2`, and `y` are not aligned automatically by the code generator. The `coder.DataAlignment` statements for these variables are only meant as information for the code generator. The call sites allocating memory for the data need to ensure that the data is aligned as specified.

You also can specify code replacement data alignment for exported data, such as a `global` variable or an `ExportedGlobal` storage class. For more information, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.

Array Layout and Code Replacement

To improve execution speed of algorithms or simplify integration with external code or data, you can define code replacement mappings that apply a specific layout for storing array elements in memory. By default, the code generator stores array elements in a column-major layout. To change the layout to row-major, change the value of the entry parameter `ArrayLayout` to `ROW_MAJOR`.

The following table definition file for a sum operation uses the row-major array layout.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_rowmajor_matrix
```

- 2 Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

- 3 Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

```
% Create operation entry
hEnt = RTW.TflCOperationEntry;
```

- 4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. In the function call, set the parameter `ArrayLayout` to `ROW_MAJOR`

```
setTflCOperationEntryParameters(hEnt, ...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 100, ...
    'ArrayLayout', 'ROW_MAJOR', ...
    'ImplementationName', 'MyMul_ROW', ...
    'ImplementationHeaderFile', 'MyMul_ROW.h', ...
    'ImplementationSourceFile', 'MyMul_ROW.c');
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = RTW.TflArgMatrix('y1', 'RTW_IO_OUTPUT', 'double');
arg.DimRange = [2 2; 50 50];
hEnt.addConceptualArg(arg);
```

```
arg = RTW.TflArgMatrix('u1', 'RTW_IO_INPUT', 'double');
arg.DimRange = [2 3; 2 3];
hEnt.addConceptualArg(arg);
```

```
arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT', 'double');
arg.DimRange = [3 4; 3 4];
hEnt.addConceptualArg(arg);
```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. When defining the implementation function return argument, create a `void` output argument. When defining the implementation function argument for the conceptual output argument (`y1`), set the operator output argument as an additional input argument. Mark its `IOType` as `output`. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Implementation Args
arg = hEnt.getTflArgFromString('unused','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('y1','double*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u3','uint32',2);
arg.Type.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u4','uint32',3);
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u5','uint32',3);
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u6','uint32',4);
hEnt.Implementation.addArgument(arg);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, hEnt);
```

- 8 Save the table definition file. To name the file, use the name of the table definition function . Then, generate code and a code generation report and review the code replacements.

Allow Shape Agnostic Match

Code replacement shape-agnostic match allows matrix inputs for certain operations to be matched based on the number of elements as opposed to matrix shape. For example, a 6×1 matrix matches a 2×3 matrix in shape-agnostic match because both have a total of 6 elements. Such matches can only be made if the output and inputs are contiguously allocated in memory and if the replacement function can be performed element-wise. Shape-agnostic matrix match increases replacement rate so it is advantageous for replacement that does not require matrix shape to be considered.

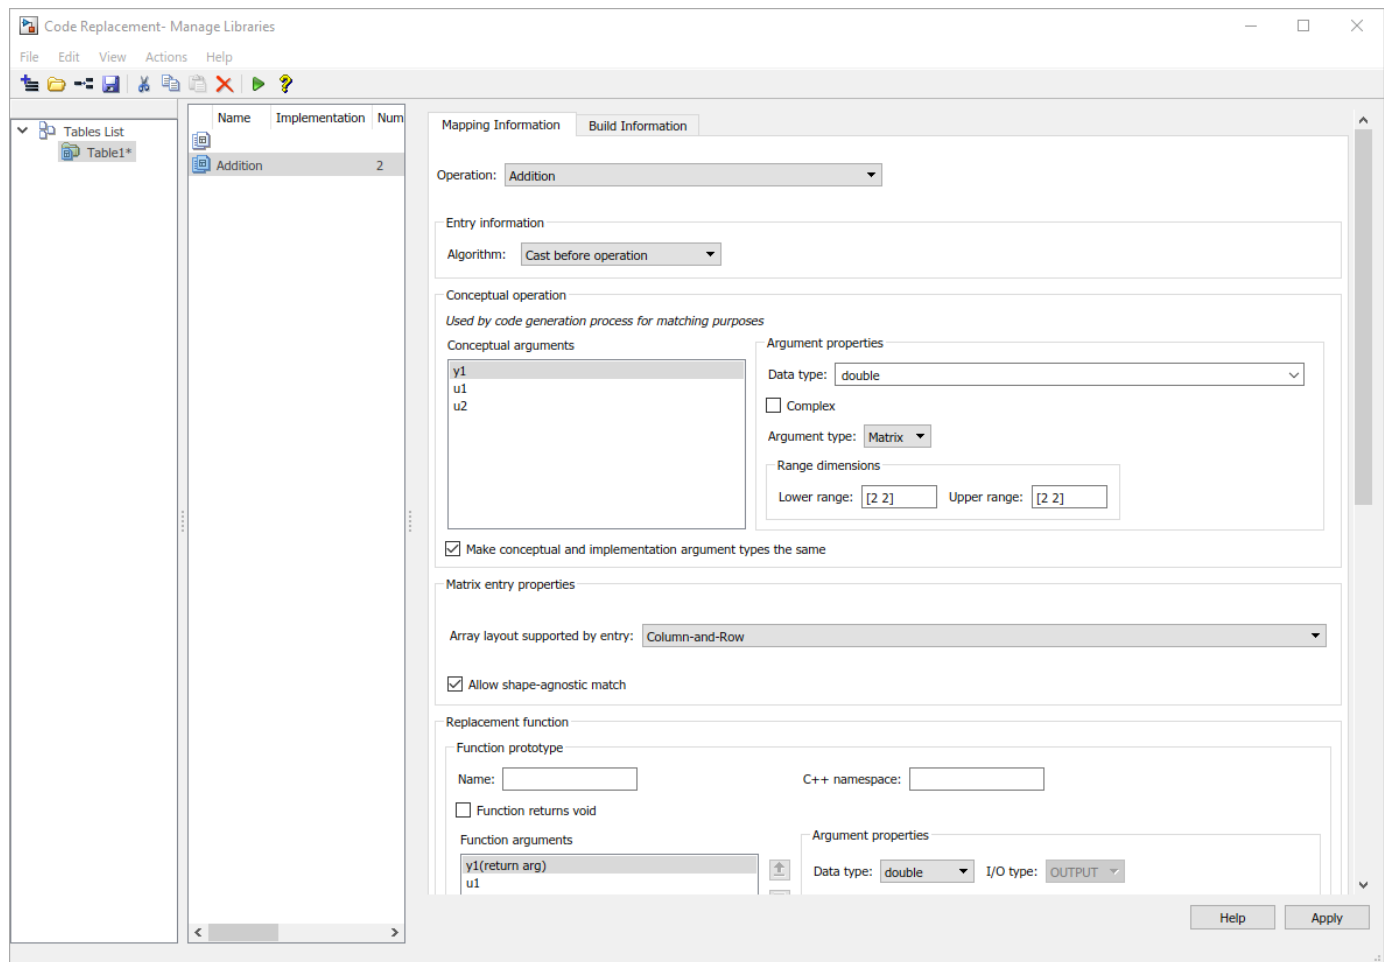

Shape-agnostic code replacement entries can be created either with the user interface of the **Code Replacement Tool** or programmatically.

User Interface Method- Code Replacement Tool

This example shows how to set up shape-agnostic matrix replacement for an addition code replacement table entry.

- 1 Open the Code Replacement Tool. From the MATLAB command line, enter `crtool`.
- 2 Create a code replacement table. Go to **File > New Table**.
- 3 Create a table entry. Shape-agnostic matrix replacement only supports **Math Operation** table entries. Either right-click on your table or go to **File > New Entry** and select **Math Operation**. Mapping information appears. From the Operation drop down menu, select **addition**.
- 4 Create conceptual arguments. The **Conceptual operation** section defines each of your conceptual arguments. To enable shape-agnostic replacement set the **Argument type:** to **matrix** to open the **Matrix entry properties** menu.
- 5 Set entry parameters. In the **Matrix entry properties** menu, select the **Allow shape-agnostic match** checkbox to enable shape-agnostic replacement.
- 6 Validate your table entry. Either click the **validate entry** button or right-click the entry and select **Validate entries**.
- 7 Click **save**.

This display shows the **Code Replacement Tool** settings for this example.

Programmatic Method

This example shows how to set up a shape-agnostic matrix replacement for an addition code replacement table entry.

- 1 Create the code replacement table. Create a function definition with the table name 'ShapeAgnosticTable'. Call `RTW.TflTable` to create the table.

```
function hLib = ShapeAgnosticTable
hLib = RTW.TflTable;
```

- 2 Create a table entry for code replacement. Shape-agnostic replacement only supports operation entries, as specified with a call to `RTW.TflCOperationEntry`.

```
hEnt = RTW.TflCOperationEntry;
```

- 3 Set entry parameters to customize input processing. You can enable shape-agnostic matrix replacement by setting the entry parameter 'AllowShapeAgnosticMatch' to true.

```
hEnt.setTflCOperationEntryParameters( ...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 100, ...
    'AllowShapeAgnosticMatch', true, ...
```

```
'ImplementationName', 'MyAdd_Matrix', ...
'SideEffects', true);
```

- 4 Create conceptual arguments. For this example, create conceptual arguments y1, u1, and u2 with calls to the create function, `RTW.TflArgMatrix`, and add function, `addConceptualArg`.

```
arg = RTW.TflArgMatrix('y1', 'RTW_IO_OUTPUT', 'double');
arg.DimRange = [2 2; 50 50];
hEnt.addConceptualArg(arg);
```

```
arg = RTW.TflArgMatrix('u1', 'RTW_IO_INPUT', 'double');
arg.DimRange = [2 3; 2 3];
hEnt.addConceptualArg(arg);
```

```
arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT', 'double');
arg.DimRange = [2 3; 2 3];
hEnt.addConceptualArg(arg);
```

- 5 Create implementation arguments. For this example, call the function `getTflArgFromString` to create the arguments. Define the implementation return argument as a void output argument. Define the conceptual output argument, y1, as a pointer with the IOType as output.

```
arg = hEnt.getTflArgFromString('unused','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);
```

```
arg = hEnt.getTflArgFromString('u1','double*');
hEnt.Implementation.addArgument(arg);
```

```
arg = hEnt.getTflArgFromString('u2','double*');
hEnt.Implementation.addArgument(arg);
```

```
arg = hEnt.getTflArgFromString('y1','double*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);
```

```
arg = hEnt.getTflArgFromString('numElements','uint32',6);
hEnt.Implementation.addArgument(arg);
```

- 6 Add this entry to a code replacement table with the function `addEntry`.

```
hLib.addEntry( hEnt );
```

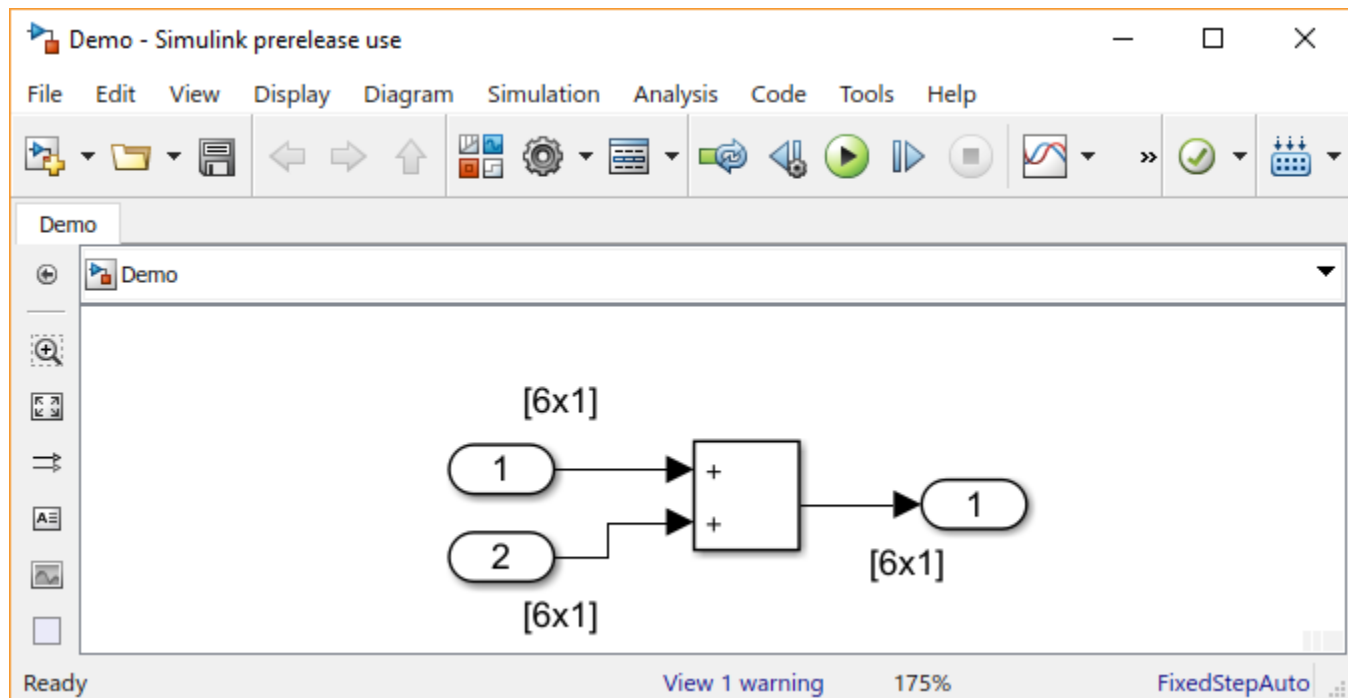

- 7 Save the table as its function name. For this example, `ShapeAgnosticTable`.

- 8 Validate your entry at the MATLAB command line. Invoke the table definition file with the following command.

```
hTbl = ShapeAgnosticTable
```

Example Model

An example of this code replacement table entry is demonstrated through the following model. Even though the matrix shape in this model does not match the entry, the operation can be performed element-wise and the entry enables shape-agnostic match, so code replacement is observed in the generated code.

```

/* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 * Sum: '<Root>/Add'
 */
MyAdd_Matrix(Demo_U.In1, Demo_U.In2, Demo_Y.Out1, 6U);

```

Limitations

- If you enable shape-agnostic match for an operation that is inherently not computed element-wise, a regular match is performed.
- When shape-agnostic match is enabled, code replacement does not honor the setting for 'DimRange'. Instead, it computes the number of elements and uses that value to match.
- If you are working with customized code replacement entries, adjust the 'do_match' function to accept the total number of elements as opposed to matrix dimensions. For more information, see "Customize Match and Replacement Process" on page 69-132.

Replace MATLAB Functions with Custom Code by Using the `coder.replace` Function

You can develop a code replacement library to optimize the performance of MATLAB functions containing a `coder.replace` function. To develop a code replacement library, use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (`crtool`), from the MATLAB command line with the following command:

```
>>crtool
```

- 2 Create a table.
 - a From the `crtool` context menu, select **File > New Table**.
 - b In the right pane, name the table `cr1_matlab_fcn_coder_replace`. Click **Apply**.
- 3 Create an entry. From the `crtool` context menu, select **File > New entry > Function**.
- 4 Create entry parameters. In the **Function** drop-down list, select `custom`. Function information appears in the `crtool`. For this example, specify the parameter as `calculate`.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the `crtool`, specify the return argument, `y1`, and the input argument, `u1`, with the **Data Type** of `double` and the **Argument Type** of `Scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.

Add the return argument `y1` and the arguments `u1`.

Specify a **Name** for the replacement function under **Function prototype**.

- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. Click the **Mapping Information** tab and verify the fields are filled in as shown. Click **Validate entry**. In the `crtool` context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
 - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_matlab_fcn_coder_replace
% Create a function to call the code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCFunctionEntry`.

```
function hTable = crl_matlab_fcn_coder_replace
% Create a function to call the code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCFunctionEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_matlab_fcn_coder_replace
% Create a function to call the code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCFunctionEntry;
```

```
%% Create entry parameters
setTflCFunctionEntryParameters(hEntry, ...
    'Key', 'calculate', ...
    'Priority', 100, ...
    'ArrayLayout', 'COLUMN_MAJOR', ...
    'ImplementationName', ...
```

```

'replacement_calculate_impl', ...
'ImplementationHeaderFile', ...
'replacement_calculate_impl.h', ...
'ImplementationSourceFile', ...
'replacement_calculate_impl.c');

```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString`.

```

function hTable = crl_matlab_fcn_coder_replace
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
setTflCFunctionEntryParameters(hEntry, ...
    'Key', 'calculate', ...
    'Priority', 100, ...
    'ArrayLayout', 'COLUMN_MAJOR', ...
    'ImplementationName', ...
    'replacement_calculate_impl', ...
    'ImplementationHeaderFile', ...
    'replacement_calculate_impl.h', ...
    'ImplementationSourceFile', ...
    'replacement_calculate_impl.c');

%% Create the conceptual representation
arg = getTflArgFromString(hEntry, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hEntry, 'u1','double');
addConceptualArg(hEntry, arg);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `getTflArgFromString`.

```

function hTable = crl_matlab_fcn_coder_replace
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
setTflCFunctionEntryParameters(hEntry, ...
    'Key', 'calculate', ...
    'Priority', 100, ...
    'ArrayLayout', 'COLUMN_MAJOR', ...
    'ImplementationName', ...

```

```

'replacement_calculate_impl', ...
'ImplementationHeaderFile', ...
'replacement_calculate_impl.h', ...
'ImplementationSourceFile', ...
'replacement_calculate_impl.c');

%% Create the conceptual representation
arg = getTflArgFromString(hEntry, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hEntry, 'u1','double');
addConceptualArg(hEntry, arg);

%% Create the Conceptual Representation
arg = getTflArgFromString(hEntry, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.Implementation.setReturn(arg);

arg = getTflArgFromString(hEntry, 'u1','double');
hEntry.Implementation.addArgument(arg);

%% Add the entry to the table
hTable.addEntry(hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_matlab_fcn_coder_replace
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file by using these specifications:

```

function rtwTargetInfo(cm)
cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for matlab function with custom code using coder.replace';
this(1).TableList = {'crl_matlab_fcn_coder_replace.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

- “Define Code Replacement Library Optimizations” on page 70-23
- “Develop a Code Replacement Library” on page 70-13
- “Replace coder.ceval Calls to External Functions” on page 70-85

Replace coder.ceval Calls to External Functions

The `coder.ceval` function calls external C/C++ functions from code generated from MATLAB code. The code replacement software supports replacement of the function that you specify in a call to `coder.ceval`. An application of this code replacement scenario is to write generic MATLAB code that you can customize for different platforms with code replacements. A code replacement library can define hardware-specific code replacements for the function call. Use `coder.ceval` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

Example Files

For the examples in “Interactively Develop a Code Replacement Library” on page 70-86 and “Programmatically Develop a Code Replacement Library” on page 69-121 you must have set up the following:

- Custom C function `my_add.c`.

```
/* my_add.c */

#include "my_add.h"

double my_add(double in1, double in2)
{
    return in1 + in2;
}
```

- Custom C header file `my_add.h`.

```
/* my_add.h */

double my_add(double in1, double in2);
```

- MATLAB function `call_my_add.m`, which uses `coder.ceval` to invoke `my_add.c`.

```
function y = call_my_add(in1, in2) %#codegen

y=0.0;

if ~coder.target('Rtw')
% Executing in MATLAB, call MATLAB equivalent of C function my_add
    y= in1+in2;
else
% Executing in generated code, call C function my_add
    y = coder.ceval('my_add', in1, in2);
end
```

- MATLAB test function `call_my_add_test.m`, which calls `call_my_add.m`.

```
in1=10;
in2=20;
```

```

y = call_my_add(in1, in2);

disp('Output')
disp('y =')
disp(y);

```

- Replacement C function `my_add_replacement.c`.

```

/* my_add_replacement.c */

#include "my_add_replacement.h"

double my_add_replacement(double in1, double in2)
{
    return in1 + in2;
}

```

- Replacement C header file `my_add_replacement.h`.

```

/* my_add_replacement.h */

double my_add_replacement(double in1, double in2);

```

Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (`crtool`), from the MATLAB command line with the following command:

```
>>crtool
```

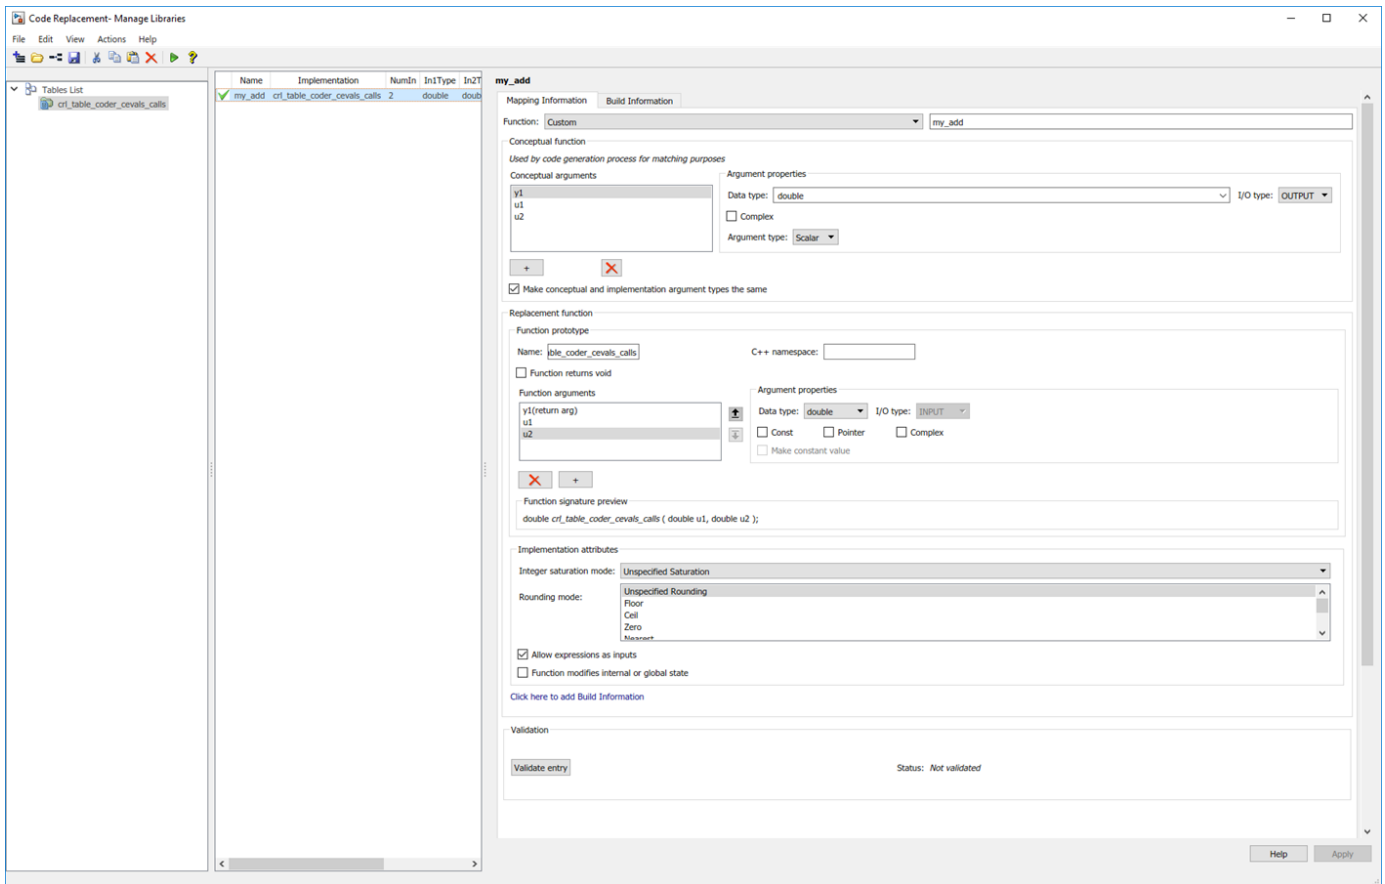

- 2 Create a table.
 - a From the `crtool` menu, select **File > New Table**.
 - b In the right pane, name the table `crl_table_coder_cevals_calls`. Click **Apply**.

- 3 Create an entry. From the `crtool` menu, select **File > New entry > Function**.

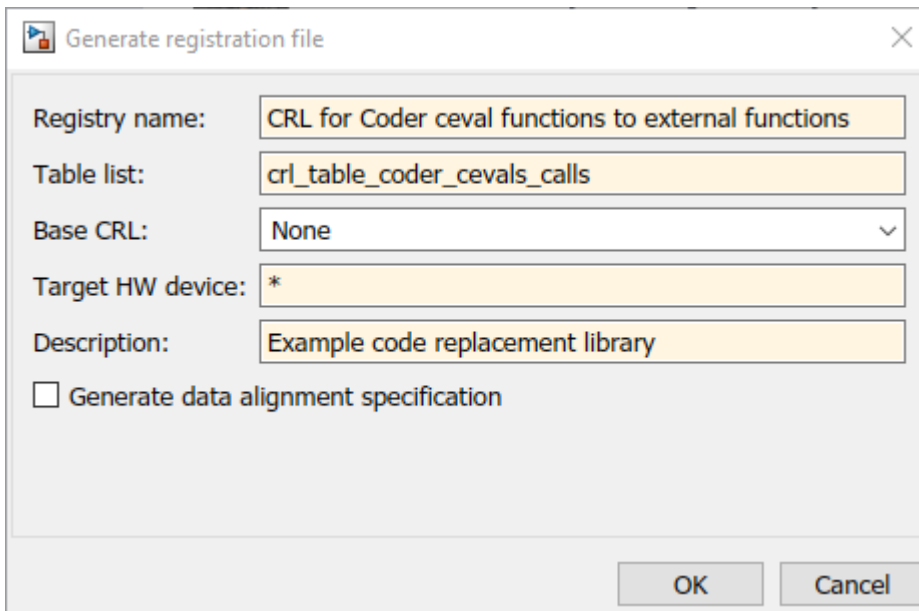

- 4 Create entry parameters. In the **Function** drop-down list, select `custom`. Function information appears in the `crtool`. For this example, specify the parameter as `my_add`.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the `crtool`, specify the return argument, `y1`, and the input arguments, `u1` and `u2` with the **Data Type** of `double` and the **Argument Type** of `Scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.

Specify a **Name** for the replacement function under **Function prototype**.

- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, set the **Implementation header file** to `my_add_replacement.h`.
- 8 Validate and save the table. Click the **Mapping Information** tab and verify the fields are filled in as shown. Click **Validate entry**. In the `crtool` menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
 - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_coder_cevals_calls()
% Create a function to call the code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCFunctionEntry`.

```
function hTable = crl_table_coder_cevals_calls()
% Create a code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCFunctionEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_table_coder_cevals_calls()
% Create a code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCFunctionEntry;
```

```
%% Create entry parameters
hEntry.setTflCFunctionEntryParameters( ...
    'Key', 'my_add', ...
    'Priority', 100, ...
    'ImplementationName', 'my_add_replacement', ...
    'ImplementationHeaderFile', 'my_add_replacement.h', ...
    'ImplementationSourceFile', 'my_add_replacement.c');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString`.

```
function hTable = crl_table_coder_cevals_calls()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters( ...
    'Key', 'my_add', ...
    'Priority', 100, ...
    'ImplementationName', 'my_add_replacement', ...
    'ImplementationHeaderFile', 'my_add_replacement.h', ...
    'ImplementationSourceFile', 'my_add_replacement.c');

%% Create the conceptual representation
arg = hEntry.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.addConceptualArg(arg);

arg = hEntry.getTflArgFromString('u1','double');
hEntry.addConceptualArg(arg);

arg = hEntry.getTflArgFromString('u2','double');
hEntry.addConceptualArg(arg);
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `getTflArgFromString`.

```
function hTable = crl_table_coder_cevals_calls()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCFunctionEntry;

%% Create entry parameters
hEntry.setTflCFunctionEntryParameters( ...
    'Key', 'my_add', ...
    'Priority', 100, ...
    'ImplementationName', 'my_add_replacement', ...
    'ImplementationHeaderFile', 'my_add_replacement.h', ...
    'ImplementationSourceFile', 'my_add_replacement.c');

%% Create the conceptual representation
arg = hEntry.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.addConceptualArg(arg);
```

```

arg = hEntry.getTflArgFromString('u1','double');
hEntry.addConceptualArg(arg);

arg = hEntry.getTflArgFromString('u2','double');
hEntry.addConceptualArg(arg);

%% Create the implementation representation
arg = hEntry.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.Implementation.setReturn(arg);

arg = hEntry.getTflArgFromString('u1','double');
hEntry.Implementation.addArgument(arg);

arg = hEntry.getTflArgFromString('u2','double');
hEntry.Implementation.addArgument(arg);

```

```

%% Add the entry to the table
hTable.addEntry(hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_coder_cevals_calls
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file by using these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for coder.ceval calls to external functions code replacement';
this(1).TableList = {'crl_table_coder_cevals_calls.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Reserved Identifiers and Code Replacement

The code generator and C programming language use, internally, reserved keywords for code generation. Do not use reserved keywords as identifiers or function names. Reserved keywords for code generation include many code replacement library identifiers, the majority of which are function names, such as `acos`.

To view a list of reserved identifiers for the code replacement library that you use to generate code, specify the name of the library in a call to the function

`RTW.TargetRegistry.getInstance.getTflReservedIdentifiers`. For example:

```
crl_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU99 (GNU)')
```

In a code replacement table, the code generator registers each function implementation name defined by a table entry as a reserved identifier. You can register additional reserved identifiers for the table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier-related compile and link issues.

To register additional code replacement reserved identifiers, use the `setReservedIdentifiers` function. This function registers specified reserved identifiers to be associated with a code replacement table.

You can register up to four reserved identifier structures in a code replacement table. You can associate one set of reserved identifiers with a code replacement library, while the other three (if present) must be associated with ANSI C. The following example shows a reserved identifier structure that specifies two identifiers and the associated header file.

```
d{1}.LibraryName = 'ANSI_C';  
d{1}.HeaderInfos{1}.HeaderName = 'math.h';  
d{1}.HeaderInfos{1}.ReservedIds = {'y0', 'y1'};
```

The code generator adds the identifiers to the list of reserved identifiers and honors them during the build procedure.

More About

- “Code You Can Replace from MATLAB Code” on page 70-5
- “Customize Match and Replacement Process” on page 70-93
- “Define Code Replacement Library Optimizations” on page 70-23
- “Develop a Code Replacement Library” on page 70-13

Customize Match and Replacement Process

During the build process, the code generator uses:

- Preset match criteria to identify functions and operators for which application-specific implementations replace default implementations.
- Preset replacement function signatures.

It is possible that preset match criteria and preset replacement function signatures do not completely meet your function and operator replacement needs. For example:

- You want to replace an operator with a particular fixed-point implementation function only when fraction lengths are within a particular range.
- When a match occurs, you want to modify your replacement function signature based on compile-time information, such as passing fraction-length values into the function.

To add extra logic into the code replacement match and replacement process, create custom code replacement table entries. With custom entries, you can specify additional match criteria and modify the replacement function signature to meet application needs.

To create a custom code replacement entry:

- 1 Create a custom code replacement entry class, derived from `RTW.TfLCFunctionEntryML` (for function replacement) or `RTW.TfLCOperationEntryML` (for operator replacement).
- 2 In your derived class, implement a `do_match` method with a fixed preset signature as a MATLAB function. In your `do_match` method, provide either or both of the following customizations that instantiate the class:
 - Add match criteria that the base class does not provide. The base class provides a match based on:
 - Argument number
 - Argument name
 - Signedness
 - Word size
 - Slope (if not specified with wildcards)
 - Bias (if not specified with wildcards)
 - Math modes, such as saturation and rounding
 - Operator or function key
 - Modify the implementation signature by adding additional arguments or setting constant input argument values. You can inject a constant value, such as an input scaling value, as an additional argument to the replacement function.
- 3 Create code replacement entries that instantiate the custom entry class.
- 4 Register a library containing the code replacement table that includes your entries.

During code generation, the code replacement match process tries to match function or operator call sites with the base class of your derived entry class. If the process finds a match, the software calls your `do_match` method to execute your additional match logic (if any) and your replacement function customizations (if any).

Customize Match and Replacement Process for Operators

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a scalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

For example:

- When fraction lengths are within a specific range, replace an operator with a fixed-point implementation function.
- When a match occurs, modify the replacement function signature based on compile-time information, such as passing fraction-length values into the function.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.

To create custom code replacement entries that add logic to the code replacement match and replacement process:

- 1 Create a class, for example `TflCustomOperationEntry`, that is derived from the base class `RTW.TflCOperationEntryML`. The derived class defines a `do_match` method with the following signature:

```
function ent = do_match(hThis, ...
    hCS0, ...
    targetBitPerChar, ...
    targetBitPerShort, ...
    targetBitPerInt, ...
    targetBitPerLong, ...
    targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `TflCOperationEntry` handle.
- `hThis` is the handle to the class instance.
- `hCS0` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method adds match criteria that the base class does not provide. The method makes modifications to the implementation signature. In this case, the `do_match` method relies on the base class for checking word size and signedness. `do_match` must match only the number of conceptual arguments to the value 3 (two inputs and one output) and the bias for each argument to value 0. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Removes slope and bias wild cards from the conceptual arguments (the match is for specific slope and bias values).
- Writes fraction-length values for the inputs and output into replacement function arguments 3, 4, and 5.

You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this

class. This example creates the arguments, adds them to a code replacement table definition file, and sets them to specific values in the class definition code.

```
classdef TflCustomOperationEntry < RTW.TflCOperationEntryML
    methods
        function ent = do_match(hThis, ...
            hCS0, ... %#ok
            targetBitPerChar, ... %#ok
            targetBitPerShort, ... %#ok
            targetBitPerInt, ... %#ok
            targetBitPerLong, ... %#ok
            targetBitPerLongLong) %#ok

            % DO_MATCH - Create a custom match function. The base class
            % checks the types of the arguments prior to calling this
            % method. This class will check additional data and can
            % modify the implementation function.

            % The base class checks word size and signedness. Slopes and biases
            % have been wildcarded, so the only additional checking to do is
            % to check that the biases are zero and that there are only three
            % conceptual arguments (one output, two inputs)

            ent = []; % default the return to empty, indicating the match failed

            if length(hCS0.ConceptualArgs) == 3 && ...
                hCS0.ConceptualArgs(1).Type.Bias == 0 && ...
                hCS0.ConceptualArgs(2).Type.Bias == 0 && ...
                hCS0.ConceptualArgs(3).Type.Bias == 0

                % Modify the default implementation. Since this is a
                % generator entry, a concrete entry is created using this entry
                % as a template. The type of entry being created is a standard
                % TflCOperationEntry. Using the standard operation entry
                % provides required information, and you do not need
                % a custom match function.
                ent = RTW.TflCOperationEntry(hThis);

                % Since this entry is modifying the implementation for specific
                % fraction-length values (arguments 3, 4, and 5), the conceptual argument
                % wild cards must be removed (the wildcards were inherited from the
                % generator when it was used as a template for the concrete entry).
                % This concrete entry is now for a specific slope and bias.
                % hCS0 holds the slope and bias values (created by the code generator).
                for idx=1:3
                    ent.ConceptualArgs(idx).CheckSlope = true;
                    ent.ConceptualArgs(idx).CheckBias = true;

                    % Set the specific Slope and Biases
                    ent.ConceptualArgs(idx).Type.Slope = hCS0.ConceptualArgs(idx).Type.Slope;
                    ent.ConceptualArgs(idx).Type.Bias = 0;
                end

                % Set the fraction-length values in the implementation function.
                ent.Implementation.Arguments(3).Value = ...
                    -1.0*hCS0.ConceptualArgs(2).Type.FixedExponent;
                ent.Implementation.Arguments(4).Value = ...
                    -1.0*hCS0.ConceptualArgs(3).Type.FixedExponent;
                ent.Implementation.Arguments(5).Value = ...
                    -1.0*hCS0.ConceptualArgs(1).Type.FixedExponent;
            end
        end
    end
end
```

Exit the class folder and return to the previous working folder.

- 2 Create and save the following code replacement table definition file, `crl_table_custom_add_ufix32.m`. This file defines a code replacement table that contains a

single operator entry, an entry generator for unsigned 32-bit fixed-point addition operations, with arbitrary fraction-length values on the inputs and the output. The table entry:

- Instantiates the derived class `TflCustomOperationEntry` from the previous step. If you want to replace word sizes and signedness attributes, you can use the same derived class, but not the same entry, because you cannot use a wild card with the `WordLength` and `IsSigned` arguments. For example, to support `uint8`, `int8`, `uint16`, `int16`, and `int32`, add five other distinct entries. To use different implementation functions for saturation and rounding modes other than overflow and round to floor, add entries for those match permutations.
- Sets operator entry parameters with the call to the `setTflCOperationEntryParameters` function.
- Calls the `createAndAddConceptualArg` function to create conceptual arguments `y1`, `u1`, and `u2`.
- Calls `createAndSetCImplementationReturn` and `createAndAddImplementationArg` to define the signature for the replacement function. Three of the calls to `createAndAddImplementationArg` create implementation arguments to hold the fraction-length values for the inputs and output. Alternatively, the entry can omit those argument definitions. Instead, the `do_match` method of the derived class `TflCustomOperationEntry` can create and add the three implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.
- Calls `addEntry` to add the entry to a code replacement table.

```
function hTable = crl_table_custom_add_ufix32

hTable = RTW.TflTable;

% Add TflCustomOperationEntry
op_entry = TflCustomOperationEntry;

setTflCOperationEntryParameters(op_entry, ...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 30, ...
    'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
    'ImplementationName', 'myFixptAdd', ...
    'ImplementationHeaderFile', 'myFixptAdd.h', ...
    'ImplementationSourceFile', 'myFixptAdd.c');

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'Scaling', 'BinaryPoint', ...
    'IsSigned', false, ...
    'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
```

```

        'Scaling',    'BinaryPoint', ...
        'IsSigned',  false, ...
        'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',        'u2', ...
    'IOType',      'RTW_IO_INPUT', ...
    'CheckSlope',  false, ...
    'CheckBias',   false, ...
    'DataType',    'Fixed', ...
    'Scaling',     'BinaryPoint', ...
    'IsSigned',    false, ...
    'WordLength', 32);

% Specify replacement function signature
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',        'y1', ...
    'IOType',      'RTW_IO_OUTPUT', ...
    'IsSigned',    false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',        'u1', ...
    'IOType',      'RTW_IO_INPUT', ...
    'IsSigned',    false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',        'u2', ...
    'IOType',      'RTW_IO_INPUT', ...
    'IsSigned',    false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

% Add 3 fraction-length args. Actual values are set during code generation.
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
    'Name',        'fl_in1', ...
    'IOType',      'RTW_IO_INPUT', ...
    'IsSigned',    false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value',       0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
    'Name',        'fl_in2', ...
    'IOType',      'RTW_IO_INPUT', ...
    'IsSigned',    false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value',       0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
    'Name',        'fl_out', ...
    'IOType',      'RTW_IO_INPUT', ...
    'IsSigned',    false, ...
    'WordLength', 32, ...

```

```
'FractionLength', 0, ...  
'Value',          0);
```

```
addEntry(hTable, op_entry);
```

3 Check the validity of the operator entry.

- At the command prompt, invoke the table definition file.

```
tbl = crl_table_custom_add_ufix32
```

- In the Code Replacement Viewer, view the table definition file.

```
crviewer(crl_table_custom_add_ufix32)
```

Scalar Operator Code Replacement

This example shows how to develop a code replacement library to optimize the performance of scalar operators by providing information on how to define code replacement for a `multiply` operation. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

Interactively Develop a Code Replacement Library

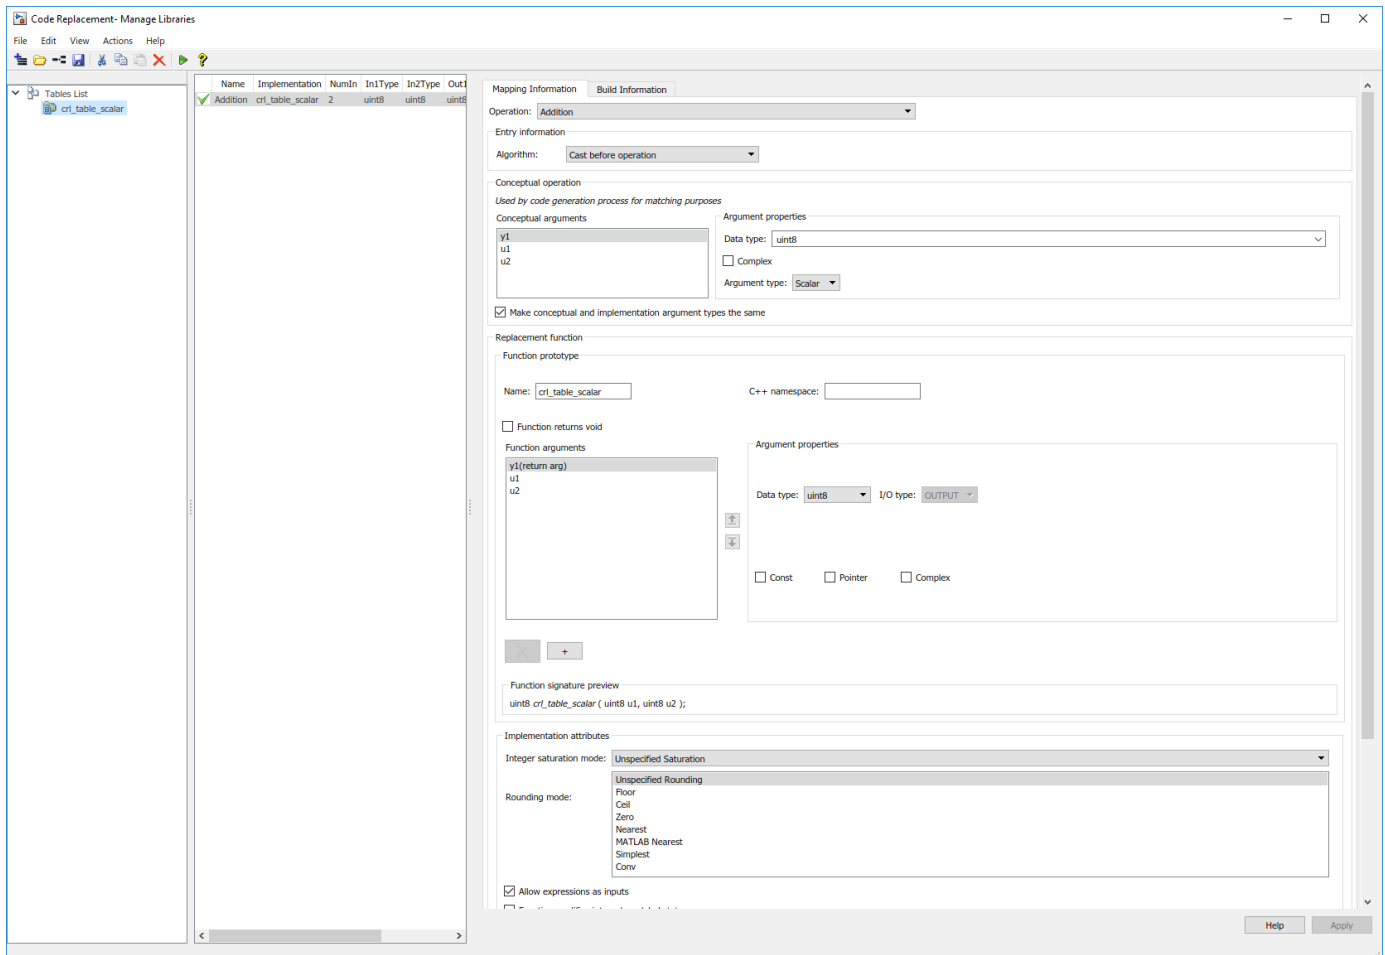

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```

- 2 Create a table.
 - a From the crtool context menu, select **File > New Table**.
 - b In the right pane, name the table `cr1_table_scalar`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Math Operation**.
- 4 Create entry parameters. In the **Operation** drop-down list, select `Multiply`.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input arguments, `u1` and `u2` with the **Data Type** of `uint8` and the **Argument Type** of `Scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.

Specify a **Name** for the replacement function under **Function prototype**.

- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function to call your code replacement library table. The function should not have arguments and return a table object.
 - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_scalar()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function .

```
function hTable = crl_table_scalar()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCOperationEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_table_scalar()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
    'Key', 'RTW_OP_MUL', ...
    'Priority', 90, ...
    'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
    'ImplementationName', 'u8_mul_u8_u8', ...
    'ImplementationHeaderFile', 'u8_mul_u8_u8.h', ...
    'ImplementationSourceFile', 'u8_mul_u8_u8.c' );
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString`.

```

function hTable = crl_table_scalar()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
    'Key', 'RTW_OP_MUL', ...
    'Priority', 90, ...
    'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
    'ImplementationName', 'u8_mul_u8_u8', ...
    'ImplementationHeaderFile', 'u8_mul_u8_u8.h', ...
    'ImplementationSourceFile', 'u8_mul_u8_u8.c' );

%% Create the conceptual representation
arg = getTflArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(hEntry, arg );

arg = getTflArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(hEntry, arg );

```

- 6** Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `copyConceptualArgsToImplementation`. Add the complete entry to the table by calling the function `addEntry`.

```

function hTable = crl_table_scalar()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
    'Key', 'RTW_OP_MUL', ...
    'Priority', 90, ...
    'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
    'ImplementationName', 'u8_mul_u8_u8', ...
    'ImplementationHeaderFile', 'u8_mul_u8_u8.h', ...
    'ImplementationSourceFile', 'u8_mul_u8_u8.c' );

%% Create the conceptual representation
arg = getTflArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(hEntry, arg );

arg = getTflArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(hEntry, arg );

%% Create the Implementation Representation
copyConceptualArgsToImplementation(hEntry);

```

```

%% Add the entry to the table
hTable.addEntry(hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_scalar
```

- 9 Create a registration file for the code replacement library with these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for scalar operator replacement';
this(1).TableList = {'crl_table_scalar.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Addition and Subtraction Operator Code Replacement

This example shows how to develop a code replacement library to optimize the performance of addition and subtraction operators by providing information on how to define code replacement for an addition operator. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

Algorithm Options

When creating a code replacement table entry for an addition or subtraction operator, first determine the type of algorithm that your library function implements.

- Cast-before-operation (CBO), default — Prior to performing the addition or subtraction operation, the algorithm type casts input values to the output type. If the output data type cannot exactly represent the input values, losses can occur as a result of the cast to the output type. Additional loss can occur when the result of the operation is cast to the final output type.

- Cast-after-operation (CAO) — The algorithm computes the ideal result of the addition or subtraction operation of the two inputs. The algorithm then type casts the result to the output data type. Loss occurs during the type cast. This algorithm behaves similarly to the C language except when the signedness of the operands does not match. For example, when you add a signed long operand to an unsigned long operand, standard C language rules convert the signed long operand to an unsigned long operand. The result is a value that is not ideal.

Algorithm Classification

During code generation, the code generator examines addition and subtraction operations, including adjacent type cast operations, to determine the type of algorithm to compute the expression result. Based on the data types in the expression and the type of the accumulator (type used to hold the result of the addition or subtraction operation), the code generator uses these rules.

- Floating-point types only

| Input 1 Data Type | Input 2 Data Type | Accumulator Data Type | Output Data Type | Classification |
|-------------------|-------------------|-----------------------|------------------|----------------|
| double | double | double | double | CBO, CAO |
| double | double | double | single | — |
| double | double | single | double | — |
| double | double | single | single | CBO |
| double | single | double | double | CBO, CAO |
| double | single | double | single | — |

| Input 1 Data Type | Input 2 Data Type | Accumulator Data Type | Output Data Type | Classification |
|-------------------|-------------------|-----------------------|------------------|----------------|
| double | single | single | double | — |
| double | single | single | single | CBO |
| single | single | single | single | CBO, CAO |
| single | single | single | double | — |
| single | single | double | single | — |
| single | single | double | double | CBO, CAO |

- Floating-point and fixed-point types on the immediate addition or subtraction operation

| Algorithm | Conditions |
|-----------|--|
| CBO | One of the following is true: <ul style="list-style-type: none"> • Operation type is double. • Operation type is single and input types are single or fixed-point. |
| CAO | Operation type is a superset of input types—that is, output type can represent values of input types without loss of data. |

- Fixed-point types only

| Algorithm | Conditions |
|-----------|--|
| CBO | At least one of the following is true: <ul style="list-style-type: none"> • Accumulator type equals output type ($T_{acc} == T_{out}$). • Output type is a superset of input types ($T_{acc} \geq \{T_{in1}, T_{in2}\}$) and accumulator type is a superset of output type ($T_{acc} \geq T_{out}$). • Operation does not incur range or precision loss. |
| CAO | Net bias is zero and the data types in the expression have equal slope adjustment factors. For more information on net bias, see “Addition” or “Subtraction” in “Fixed-Point Operator Code Replacement” on page 70-134 (for MATLAB code) or “Fixed-Point Operator Code Replacement” on page 69-186 (for Simulink models). |

In many cases, the numerical result of a CBO operation is equal to that of a CAO operation. For example, if the input and output types are such that the operation produces the ideal result, as in the case of $int8 + int8 \rightarrow int16$. To maximize the probability of code replacement occurring in such cases, set the algorithm to cast-after-operation.

Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```

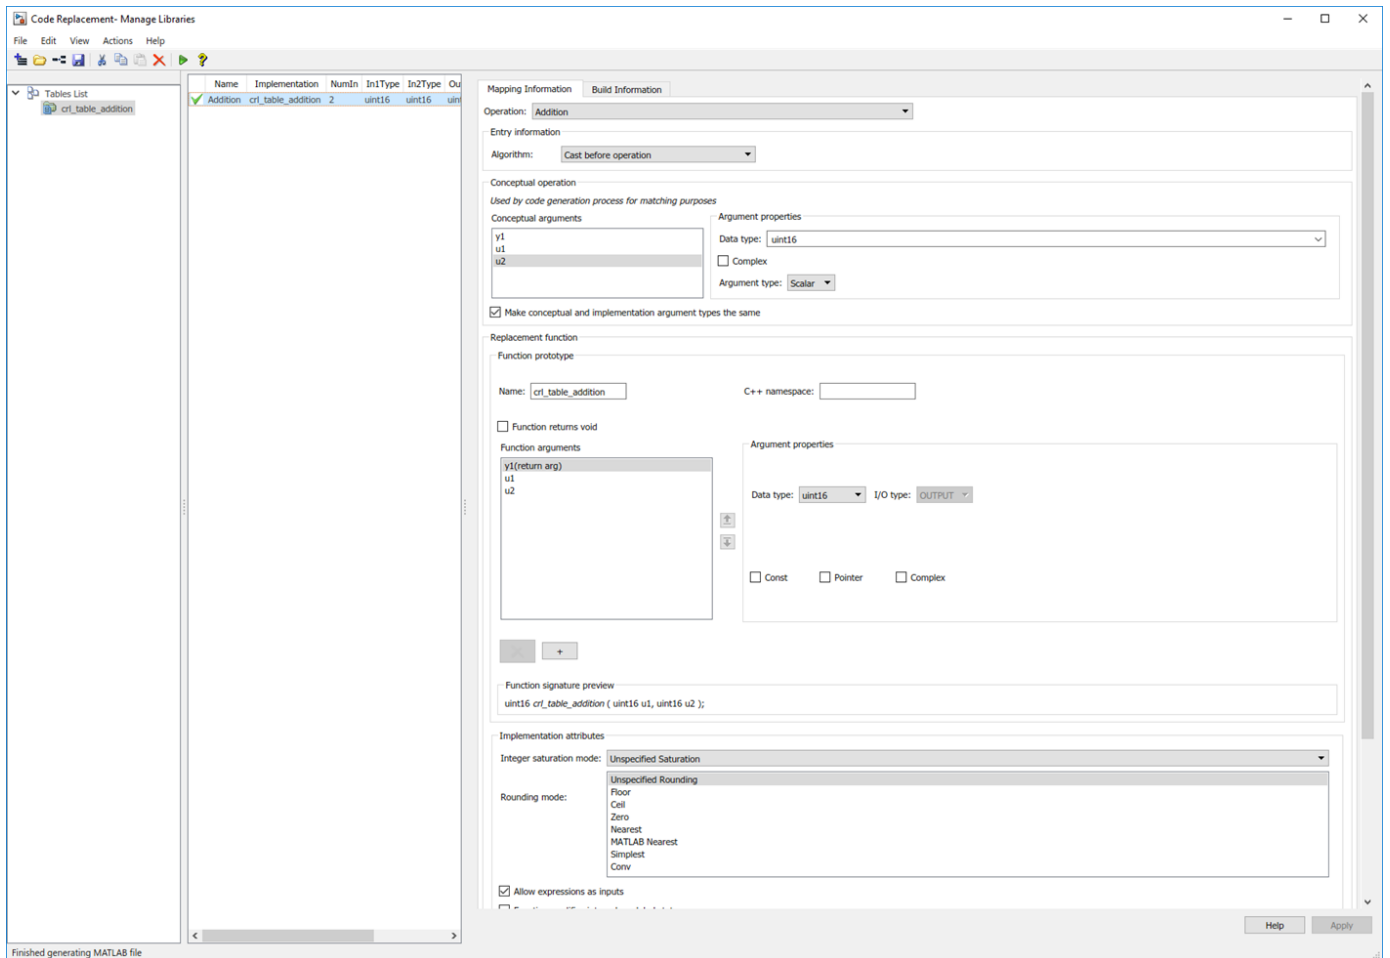

- 2 Create a table.

- a From the crtool context menu, select **File > New Table**.

- b** In the right pane, name the table `cr1_table_addition`. Click **Apply**.
- 3** Create an entry. From the crtool context menu, select **File > New entry > Math Operation**.
- 4** Create entry parameters. In the **Function** drop-down list, select **Addition**. Algorithm information appears in the crtool. For this example, select the parameter to **Cast before operation**.
- 5** Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, with the **Data Type** of `uint8` and the **Argument Type** of **Scalar**, the input arguments, `u1` and `u2` with the **Data Type** of `uint16` and the **Argument Type** of **Scalar**.
- 6** Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.

Specify a **Name** for the replacement function under **Function prototype**.

- 7** Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8** Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
 - b Create a table object by calling `RTW.TflTable`.

```
function hTflTable = make_cbo_add_crl_table
% Create a function to call the code replacement library table

%% Create a table object
hTflTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCOperationEntry`.

```
function hTflTable = make_cbo_add_crl_table
% Create a function to call the code replacement library table

%% Create a table object
hTflTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCOperationEntryParameters`.

```
function hTflTable = make_cbo_add_crl_table
% Create a function to call the code replacement library table

%% Create a table object
hTflTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
    'Key', 'RTW_OP_ADD', ...
    'EntryInfoAlgorithm', 'RTW_CAST_BEFORE_OP', ...
    'ImplementationName', 'u8_add_cao_u16_u16');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString`.

```
function hTflTable = make_cbo_add_crl_table
% Create a function to call the code replacement library table
```

```

%% Create a table object
hTflTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
    'Key', 'RTW_OP_ADD', ...
    'EntryInfoAlgorithm', 'RTW_CAST_BEFORE_OP', ...
    'ImplementationName', 'u8_add_cao_u16_u16');

%% Create the conceptual representation
arg = getTflArgFromString(hTflTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTflTable, 'u1', 'uint16');
addConceptualArg(hEntry, arg );

arg = getTflArgFromString(hTflTable, 'u2', 'uint16');
addConceptualArg(hEntry, arg );

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `copyConceptualArgsToImplementation`. Add the complete entry to the table by calling the function `addEntry`.

```

function hTflTable = make_cbo_add_crl_table()
% Create a function to call the code replacement library table

%% Create a table object
hTflTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
    'Key', 'RTW_OP_ADD', ...
    'EntryInfoAlgorithm', 'RTW_CAST_BEFORE_OP', ...
    'ImplementationName', 'u8_add_cao_u16_u16');

%% Create the conceptual representation
arg = getTflArgFromString(hTflTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);

arg = getTflArgFromString(hTflTable, 'u1', 'uint16');
addConceptualArg(hEntry, arg );

arg = getTflArgFromString(hTflTable, 'u2', 'uint16');
addConceptualArg(hEntry, arg );

%% Create the Implementation Representation
copyConceptualArgsToImplementation(hEntry);

%% Add the entry to the table
addEntry(hTflTable, hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = make_cbo_add_crl_table
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) with these specifications:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for addition subtraction operator replacement';
this(1).TableList = {'make_cbo_add_crl_table.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Limitations

- When classifying an operation as a CAO operation, the code generator includes the adjacent casts in the expression when the expression involves only fixed-point types. Otherwise, the code generator classifies and replaces only the immediate addition or subtraction operation. Casts that the code generator excludes from the classification appear in the generated code.
- To enable the code generator to include multiple cast operations, which follow an addition or subtraction of fixed-point data, in the classification of an expression, the rounding mode must be `simplest` or `floor`. Consider the expression `y=(cast A)(cast B)(u1+u2)`. If the rounding mode of `(cast A)`, `(cast B)`, and the addition operator `(+)` are set to `simplest` or `floor`, the code generator takes into account `(cast A)` and `(cast B)` when classifying the expression and performing the replacement only.

Small Matrix Operation to Processor Code Replacement

This example shows how to develop a code replacement library to optimize the performance of non-scalar small matrix operations with processor-specific intrinsic functions by providing information on how to define code replacement for a **addition** operator. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

Interactively Develop a Code Replacement Library

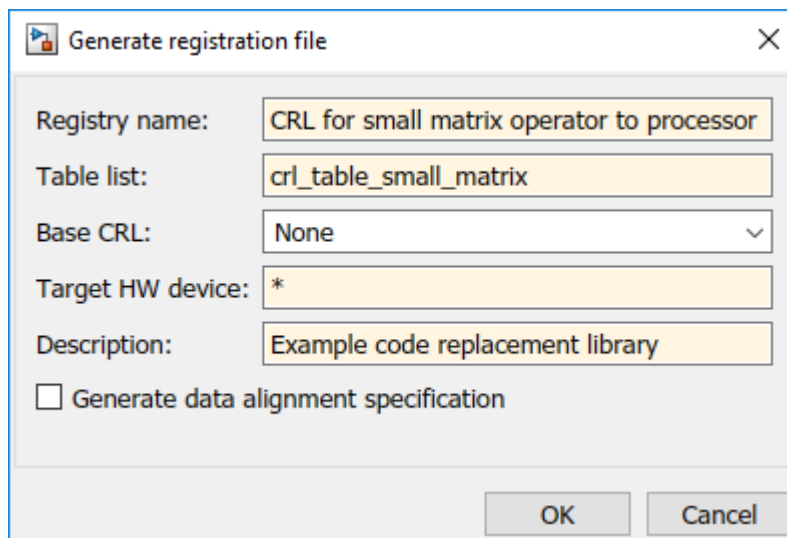

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```
- 2 Create a table.
 - a From the crtool context menu, select **File > New Table**.
 - b In the right pane, name the table `cr1_table_small_matrix`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Math Operation**.
- 4 Create entry parameters. In the **Function** drop-down list, select **Addition**. Algorithm information appears in the crtool. For this example, select the parameter to **Cast before operation**.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, with the **Data Type** of `double` and the **Argument Type** of `Matrix`, the input argument, `u1` with the **Data Type** of `double` and the **Argument Type** of `Matrix` and the input argument, `u2` with the **Data Type** of `double` and the **Argument Type** of `Matrix`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box. Specify the return argument `y1`, `u1` and `u2`, with the **Data Type** of `double` and select the **Pointer** dialog box.

Specify a **Name** for the replacement function under **Function prototype**.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
 - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_small_matrix_operator()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
LibPath= fullfile(matlabroot, 'examples', 'coder');
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCOperationEntry`.

```
function hTable = crl_table_small_matrix_operator()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
LibPath= fullfile(matlabroot, 'examples', 'coder');
```

```
%% Create an entry
hEntry = RTW.TflCOperationEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCOperationEntryParameters`.

```
function hTable = crl_table_small_matrix_operator()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
LibPath= fullfile(matlabroot, 'examples', 'coder');
```

```
%% Create an entry
hEntry = RTW.TflCOperationEntry;
```

```
%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
    'Key', 'RTW_OP_ADD', ...
```

```

    'Priority',          30, ...
    'SaturationMode',  'RTW_WRAP_ON_OVERFLOW', ...
    'ImplementationName', 'matrix_sum_2x2_double', ...
    'ImplementationHeaderFile', 'MatrixMath.h', ...
    'ImplementationSourceFile', 'MatrixMath.c', ...
    'ImplementationHeaderPath', LibPath, ...
    'ImplementationSourcePath', LibPath, ...
    'AdditionalIncludePaths', {LibPath}, ...
    'GenCallback',      'RTW.copyFileToBuildDir', ...
    'SideEffects',      true);

```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `createAndAddConceptualArg`.

```

function hTable = crl_table_small_matrix_operator()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
LibPath= fullfile(matlabroot, 'examples', 'coder');

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
    'Key',          'RTW.OP_ADD', ...
    'Priority',     30, ...
    'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
    'ImplementationName', 'matrix_sum_2x2_double', ...
    'ImplementationHeaderFile', 'MatrixMath.h', ...
    'ImplementationSourceFile', 'MatrixMath.c', ...
    'ImplementationHeaderPath', LibPath, ...
    'ImplementationSourcePath', LibPath, ...
    'AdditionalIncludePaths', {LibPath}, ...
    'GenCallback',  'RTW.copyFileToBuildDir', ...
    'SideEffects',  true);

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix', ...
    'Name',          'y1', ...
    'IOType',        'RTW_IO_OUTPUT', ...
    'BaseType',      'double', ...
    'DimRange',      [2 2]);
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix', ...
    'Name',          'u1', ...
    'BaseType',      'double', ...
    'DimRange',      [2 2]);
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix', ...
    'Name',          'u2', ...
    'BaseType',      'double', ...
    'DimRange',      [2 2]);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `getTflArgFromString`.

```

function hTable = crl_table_small_matrix_operator()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
LibPath= fullfile(matlabroot,'examples','coder');

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 30, ...
    'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
    'ImplementationName', 'matrix_sum_2x2_double', ...
    'ImplementationHeaderFile', 'MatrixMath.h', ...
    'ImplementationSourceFile', 'MatrixMath.c', ...
    'ImplementationHeaderPath', LibPath, ...
    'ImplementationSourcePath', LibPath, ...
    'AdditionalIncludePaths', {LibPath}, ...
    'GenCallback', 'RTW.copyFileToBuildDir', ...
    'SideEffects', true);

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'BaseType', 'double', ...
    'DimRange', [2 2]);
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix',...
    'Name', 'u1', ...
    'BaseType', 'double', ...
    'DimRange', [2 2]);
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix',...
    'Name', 'u2', ...
    'BaseType', 'double', ...
    'DimRange', [2 2]);

%% Create the Implementation Representation
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
hEntry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);

arg.IOType = 'RTW_IO_OUTPUT';
hEntry.Implementation.addArgument(arg);

```

```
%% Add the entry to the table
hTable.addEntry(hEntry);
```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_small_matrix
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) with these specifications:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for small matrix operator to processor';
this(1).TableList = {'crl_table_small_matrix.m'};
% table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Matrix Multiplication Operation to MathWorks BLAS Code Replacement

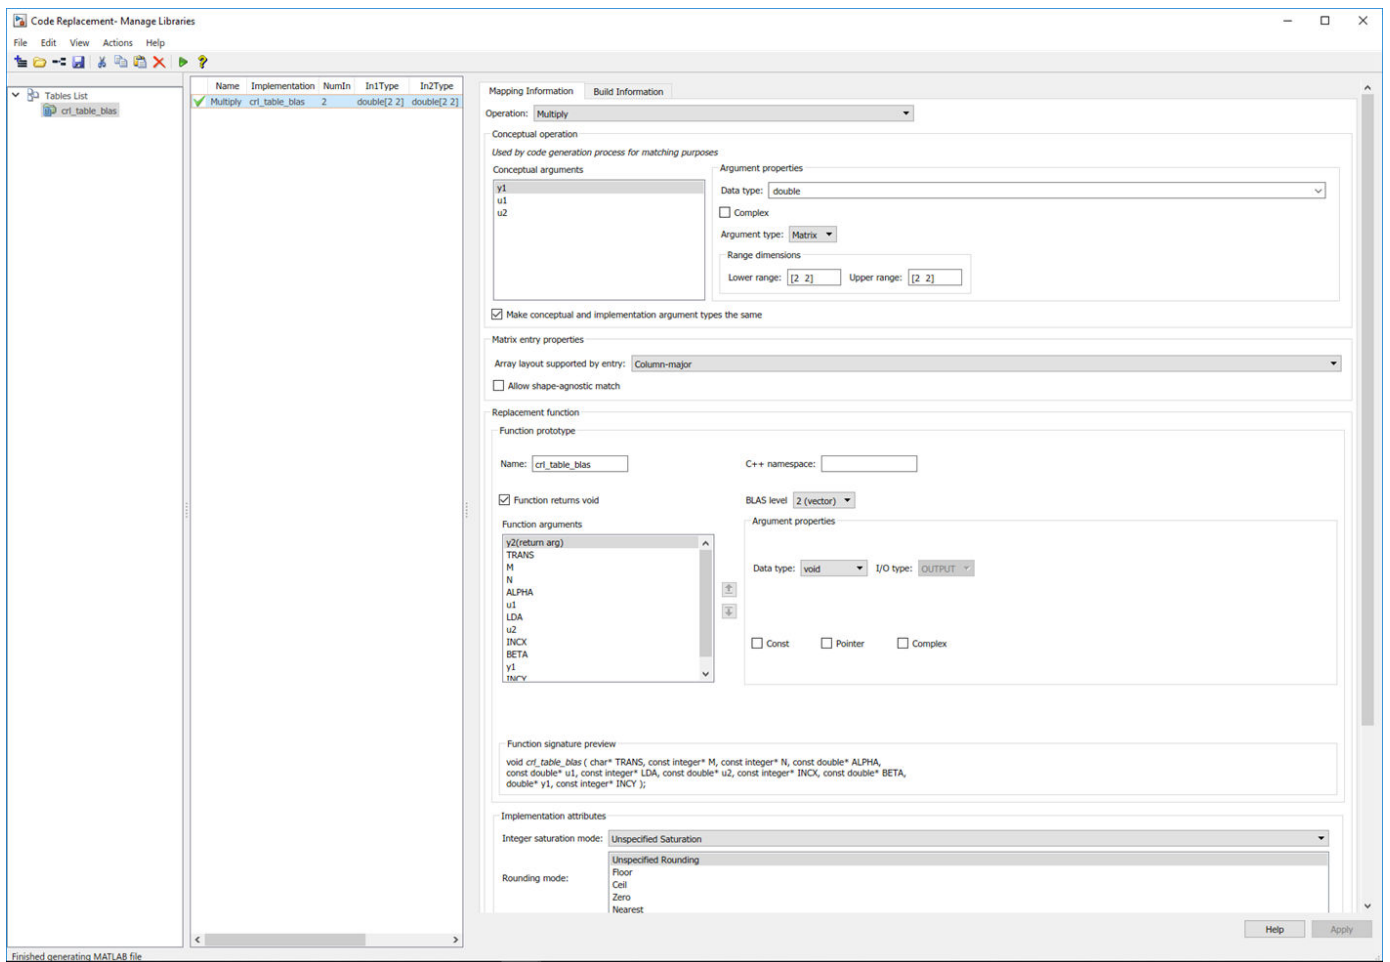

You can develop a code replacement library for floating-point matrix/matrix and matrix/vector multiplication operations with the multiplication functions `dgemm` and `dgemv` defined in the MathWorks BLAS library. If you use a third-party BLAS library for replacement, you must change the build requirements in this example to point to your library. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```
- 2 Create a table.
 - a From the crtool context menu, select **File > New Table**.
 - b In the right pane, name the table `cr1_table_blas`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Blas Operation (Fortran)**.
- 4 Create entry parameters. In the **Function** drop-down list, select **Multiply**.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1` and `u2` with the **Data Type** of **double** and the **Argument Type** of **Matrix**.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box. Set the **BLAS level** to **2(Vector)**.

Specify a **Name** for the replacement function under **Function prototype**.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function to call your code replacement library table. The function should not have arguments and return a table object.
 - b Create a table object by calling `RTW.TfTable`.

```
function hTable = crl_table_blas
% Create a function to call the code replacement library table
```

```
%% Create a table object
hTable = RTW.TfTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TfBlasEntryGenerator`.

```
function hTable = crl_table_blas
% Create a code replacement library table
```

```
%% Create a table object
hTable = RTW.TfTable;
```

```
%% Create an entry
```

```

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%% Define library path for Windows or UNIX block%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
arch = computer('arch');
if ~ispc
    LibPath = fullfile('$MATLAB_ROOT', 'bin', arch);
else
    % Use Stateflow to get the compiler info
    compilerInfo = sf('Private','compilerman','get_compiler_info');
    compilerName = compilerInfo.compilerName;
    if strcmp(compilerName, 'msvc90') || ...

```

% Create table entry for dgemm32
hEntry = RTW.TfLBlasEntryGenerator;

```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTfLCFunctionEntryParameters`.

```

function hTable = crl_table_blas
% Create a code replacement library table

% Create a table object
hTable = RTW.TfLTable;

% Create an entry
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%% Define library path for Windows or UNIX block%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
arch = computer('arch');
if ~ispc
    LibPath = fullfile('$MATLAB_ROOT', 'bin', arch);
else
    % Use Stateflow to get the compiler info
    compilerInfo = sf('Private','compilerman','get_compiler_info');
    compilerName = compilerInfo.compilerName;
    if strcmp(compilerName, 'msvc90') || ...
        strcmp(compilerName, 'msvc80') || ...
        strcmp(compilerName, 'msvc71') || ...
        strcmp(compilerName, 'msvc60'), ...
        compilerName = 'microsoft';
    end
    LibPath = fullfile('$MATLAB_ROOT', 'extern', 'lib', arch, compilerName);
end

if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
end

```

```

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%Beginning of entries for the first dgemm block%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

```

```

% Create table entry for dgemm32
hEntry = RTW.TfLBlasEntryGenerator;

```

```

% Create entry parameters
setTfLCOperationEntryParameters(hEntry, ...
    'Key', 'RTW_OP_MUL', ...

```

```

'Priority',          100, ...
'ImplementationName', 'dgemm32', ...
'ImplementationHeaderFile', 'blascompat32_crl.h', ...
'ImplementationHeaderPath', fullfile('${MATLAB_ROOT}','extern','include'), ...
'AdditionalLinkObjs', {'libmwblascompat32.' libExt}}, ...
'AdditionalLinkObjsPaths', {LibPath}, ...
'SideEffects',      true);

```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `createAndAddConceptualArg`. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions `[2 2; inf inf]`, while the conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions `[2 1; inf 1]`.

```

function hTable = crl_table_blas
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

arch = computer('arch');
if ~ispc
    LibPath = fullfile('${MATLAB_ROOT}', 'bin', arch);
else
    % Use Stateflow to get the compiler info
    compilerInfo = sf('Private','compilerman','get_compiler_info');
    compilerName = compilerInfo.compilerName;
    if strcmp(compilerName, 'msvc90') || ...
        strcmp(compilerName, 'msvc80') || ...
        strcmp(compilerName, 'msvc71') || ...
        strcmp(compilerName, 'msvc60'), ...
        compilerName = 'microsoft';
    end
    LibPath = fullfile('${MATLAB_ROOT}', 'extern', 'lib', arch, compilerName);
end

if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
end

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

% Create table entry for dgemm32
hEntry = RTW.TflBlasEntryGenerator;

%% Create entry parameters
setTflCoperationEntryParameters(hEntry, ...
    'Key',          'RTW_OP_MUL', ...
    'Priority',     100, ...
    'ImplementationName', 'dgemm32', ...
    'ImplementationHeaderFile', 'blascompat32_crl.h', ...
    'ImplementationHeaderPath', fullfile('${MATLAB_ROOT}','extern','include'), ...
    'AdditionalLinkObjs', {'libmwblascompat32.' libExt}}, ...
    'AdditionalLinkObjsPaths', {LibPath}, ...
    'SideEffects', true);

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix', ...
    'Name',          'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'BaseType',     'double', ...

    'BaseType',        'double', ...
    'DimRange',        [2 2; inf inf]);
createAndAddConceptualArg(hEntry, 'RTW.TflArgMatrix', ...
    'Name',            'u2', ...
    'BaseType',        'double', ...
    'DimRange',        [1 1; inf inf]);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `getTflArgFromString`. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments. Add the complete entry to the table by calling the function `addEntry`.

```

function hTable = crl_table_blas
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
arch = computer('arch');

arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

```

```

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
arg.PassByType = 'RTW_PASSBY_POINTER';
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);

%% Add the entry to the table
addEntry(hTable, hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_blas
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file with these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for matrix multiplication for Mathworks Blas code';
this(1).TableList = {'crl_table_blas.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Matrix Multiplication Operation to ANSI/ISO C BLAS Code Replacement

You can develop a code replacement library for floating-point matrix/matrix and matrix/vector multiplication operations with the multiplication functions `sgemm` defined in the MathWorks C BLAS library. Use a third-party C BLAS library for replacement and change the build requirements in this example to point to your library. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (`crtool`), from the MATLAB command line with the following command:

```
>>crtool
```
- 2 Create a table.
 - a From the `crtool` context menu, select **File > New Table**.
 - b In the right pane, name the table `cr1_table_cblas`. Click **Apply**.
- 3 Create an entry. From the `crtool` context menu, select **File > New entry > CBlas Operation (Atlas)**.
- 4 Create entry parameters. In the **Function** drop-down list, select **Multiply**.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the `crtool`, specify the return argument, `y1`, and the input argument, `u1` and `u2` with the **Data Type** of `single` and the **Argument Type** of `Matrix`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box. Set the **BLAS level** to `3(Vector)`.

Specify a **Name** for the replacement function under **Function prototype**.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the `crtool` context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function to call your code replacement library table. The function should not have arguments and return a table object.
 - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_cblas
% Create a function to call the code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCblasEntryGenerator`.

```
function hTable = crl_table_cblas
% Create a code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
```

```

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%% Define library path Cblas library file%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
LibPath = fullfile('<Specify the path of your cblas library>');

if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
end

```

```

% Create table entry for dgemm32
hEntry = RTW.TfLcBblasEntryGenerator;

```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTfLcFunctionEntryParameters`.

```

function hTable = crl_table_cblas
% Create a code replacement library table

%% Create a table object
hTable = RTW.TfLTable;

%% Create an entry
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%% Define library path Cblas library file%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
LibPath = fullfile('<Specify the path of your cblas library>');

if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
end

% Create table entry for dgemm32
hEntry = RTW.TfLcBblasEntryGenerator;

%% Create entry parameters
hEntry.setTfLcOperationEntryParameters( ...
    'Key', 'RTW_OP_MUL', ...
    'Priority', 100, ...
    'ImplementationName', 'cblas_sgemm', ...
    'ImplementationSourceFile', 'ccblas.c', ...
    'ImplementationHeaderFile', 'ccblas.h', ...
    'AdditionalIncludePaths', {LibPath}, ...
    'AdditionalLinkObjs', {'libcblas' libExt}, ...
    'AdditionalLinkFlags', {'-lgfortran'}, ...
    'SideEffects', true);

```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `createAndAddConceptualArg`. To specify a matrix argument in the function call, use the argument class `RTW.TfLArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger.

```

function hTable = crl_table_cblas
% Create a code replacement library table

%% Create a table object
hTable = RTW.TfLTable;

%% Create an entry
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%% Define library path Cblas library file%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
LibPath = fullfile('<Specify the path of your cblas library>');

if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
end

```

```

    libExt = 'so';
end

% Create table entry for dgemm32
hEntry = RTW.TfLCBlasEntryGenerator;

%% Create entry parameters
hEntry.setTfLCOperationEntryParameters( ...
    'Key', 'RTW_OP_MUL', ...
    'Priority', 100, ...
    'ImplementationName', 'cblas_sgemm', ...
    'ImplementationSourceFile', 'ccblas.c', ...
    'ImplementationHeaderFile', 'ccblas.h', ...
    'AdditionalIncludePaths', {LibPath}, ...
    'AdditionalLinkObjs', {[ 'libcblas' libExt]}, ...
    'AdditionalLinkFlags', { '-lgfortran'}, ...
    'SideEffects', true);

%% Create the conceptual representation
arg = RTW.TfLArgMatrix('y1', 'RTW_IO_OUTPUT', 'single');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TfLArgMatrix('u1', 'RTW_IO_INPUT', 'single');
arg.DimRange = [2 1; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TfLArgMatrix('u2', 'RTW_IO_INPUT', 'single');
arg.DimRange = [1 2; Inf Inf];
hEnt.addConceptualArg(arg);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `getTfLArgFromString`. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments. Add the complete entry to the table by calling the function `addEntry`.

```

function hTable = crl_table_cblas
% Create a code replacement library table

%% Create a table object
hTable = RTW.TfLTable;

%% Create an entry
%%%%%%%%%% Define library path Cblas library file%%%%%%%%%%

LibPath = fullfile('<Specify the path of your cblas library>');

if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
end

% Create table entry for dgemm32
hEntry = RTW.TfLCBlasEntryGenerator;

%% Create entry parameters
hEntry.setTfLCOperationEntryParameters( ...
    'Key', 'RTW_OP_MUL', ...
    'Priority', 100, ...
    'ImplementationName', 'cblas_sgemm', ...
    'ImplementationSourceFile', 'ccblas.c', ...
    'ImplementationHeaderFile', 'ccblas.h', ...
    'AdditionalIncludePaths', {LibPath}, ...
    'AdditionalLinkObjs', {[ 'libcblas' libExt]}, ...
    'AdditionalLinkFlags', { '-lgfortran'}, ...
    'SideEffects', true);

%% Create the conceptual representation

```

```

arg = RTW.TflArgMatrix('y1', 'RTW_IO_OUTPUT', 'single');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u1', 'RTW_IO_INPUT', 'single');
arg.DimRange = [2 1; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT', 'single');
arg.DimRange = [1 2; Inf Inf];
hEnt.addConceptualArg(arg);

%% Create the Implementation Representation
% Using RTW.TflCBlasEntryGenerator for sgemm requires the following
% implementation signature:
%
% void no_name( const integer ORDER, const integer TRANSA, const integer TRANSB,
% const integer M, const integer N, const integer K, const double ALPHA,
% const double* u1, const integer LDA, const double* u2, const integer LDB,
% const double BETA, double* y1, const integer LDC );
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and inserts them into the
% generated code. TRANSA and TRANSB are set to 'N'.

```
arg = hEntry.getTflArgFromString('LDC','integer',0.0000000000000000);
arg.Type.ReadOnly = true;
hEntry.Implementation.addArgument(arg);
```

```
%% Add the entry to the table
addEntry(hTable, hEntry);
```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_cblas
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file with these specifications:

```
function rtwTargetInfo(cm)
cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for matrix multiplication for Mathworks CBlas code';
this(1).TableList = {'crl_table_cblas.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Remap Operator Output to Function Input

If your generated code must meet a specific coding pattern or you want more flexibility, for example, to further improve performance, you can remap operator outputs to input positions in an implementation function argument list.

Note Remapping outputs to implementation function inputs is supported only for operator replacement.

For example, for a sum operation, the code generator produces code similar to:

```
add8_Y.Out1 = u8_add_u8_u8(add8_U.In1, add8_U.In2);
```

If you remap the output to the first input, the code generator produces code similar to:

```
u8_add_u8_u8(&add8_Y.Out1;, add8_U.In1, add8_U.In2);
```

The following table definition file for a sum operation remaps operator output `y1` as the first function input argument.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_add_uint8
```

- 2 Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

- 3 Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

```
% Create operation entry
op_entry = RTW.TflCOperationEntry;
```

- 4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. In the function call, set the property `SideEffects` to `true`.

```
setTflCOperationEntryParameters(op_entry, ...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 90, ...
    'ImplementationName', 'u8_add_u8_u8', ...
    'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
    'ImplementationSourceFile', 'u8_add_u8_u8.c', ...
    'SideEffects', true );
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTflArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
```

```
arg = getTflArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(op_entry, arg );
```

```
arg = getTflArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(op_entry, arg );
```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the

arguments. When defining the implementation function return argument, create a new `void` output argument, for example, `y2`. When defining the implementation function argument for the conceptual output argument (`y1`), set the operator output argument as an additional input argument. Mark its `IOType` as output. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Create new void output y2
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

% Set y1 as first input arg, mark IOType as output, and use pointer type
arg=getTflArgFromString(hTable, 'y1', 'uint8*');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg=getTflArgFromString(hTable, 'u1', 'uint8');
op_entry.Implementation.addArgument(arg);

arg=getTflArgFromString(hTable, 'u2', 'uint8');
op_entry.Implementation.addArgument(arg);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

Fixed-Point Operator Code Replacement

If you have a Fixed-Point Designer license, you can define fixed-point operator code replacement entries to match:

- A binary-point-only scaling combination on the operator inputs and output.
- A slope bias scaling combination on the operator inputs and output.
- Relative scaling or net slope between multiplication or division operator inputs and output. Use one of these methods to map a range of slope and bias values to a replacement function for multiplication or division.
- Equal slope and zero net bias across addition or subtraction operator inputs and output. Use this method to disregard specific slope and bias values and map relative slope and bias values to a replacement function for addition or subtraction.

Common Ways to Match Fixed-Point Operator Entries

The following table maps common ways to match fixed-point operator code replacement entries with the associated fixed-point parameters that you specify in a code replacement table definition file.

| Match | Create entry | Minimally specify parameters |
|---|------------------------|---|
| A specific binary-point-only scaling combination on the operator inputs and output. | RTW.Tf1COperationEntry | createAndAddConceptualArg function: <ul style="list-style-type: none"> • CheckSlope: Specify the value true. • CheckBias: Specify the value true. • DataTypeMode (or DataType/Scaling equivalent): Specify fixed-point binary-point-only scaling. • FractionLength: Specify a fraction length (for example, 3). |
| A specific slope bias scaling combination on the operator inputs and output. | RTW.Tf1COperationEntry | createAndAddConceptualArg function: <ul style="list-style-type: none"> • CheckSlope: Specify the value true. • CheckBias: Specify the value true. • DataTypeMode (or DataType/Scaling equivalent): Specify fixed-point [slope bias] scaling. • Slope (or SlopeAdjustmentFactor/ - FixedExponent equivalent): Specify a slope value (for example, 15). • Bias: Specify a bias value (for example, 2). |

| Match | Create entry | Minimally specify parameters |
|---|---|--|
| Net slope between operator inputs and output (multiplication and division). | RTW.TfLCOperationEntry-Generator_NetSlope | setTfLCOperationEntryParameters function: <ul style="list-style-type: none"> • NetSlopeAdjustmentFactor: Specify the slope adjustment factor (F) part of the net slope, $F2^E$ (for example, 1.0). • NetFixedExponent: Specify the fixed exponent (E) part of the net slope, $F2^E$ (for example, -3.0). createAndAddConceptualArg function: <ul style="list-style-type: none"> • CheckSlope: Specify the value false. • CheckBias: Specify the value false. • DataType: Specify the value 'Fixed'. |
| Relative scaling between operator inputs and output (multiplication and division). | RTW.TfLCOperationEntry-Generator | setTfLCOperationEntryParameters function: <ul style="list-style-type: none"> • RelativeScalingFactorF: Specify the slope adjustment factor (F) part of the relative scaling factor, $F2^E$ (for example, 1.0). • RelativeScalingFactorE: Specify the fixed exponent (E) part of the relative scaling factor, $F2^E$ (for example, -3.0). createAndAddConceptualArg function: <ul style="list-style-type: none"> • CheckSlope: Specify the value false. • CheckBias: Specify the value false. • DataType: Specify the value 'Fixed'. |
| Equal slope and zero net bias across operator inputs and output (addition and subtraction). | RTW.TfLCOperationEntry-Generator | setTfLCOperationEntryParameters function: <ul style="list-style-type: none"> • SlopesMustBeTheSame: Specify the value true. • MustHaveZeroNetBias: Specify the value true. createAndAddConceptualArg function: <ul style="list-style-type: none"> • CheckSlope: Specify the value false. • CheckBias: Specify the value false. |

Fixed-Point Numbers and Arithmetic

Fixed-point numbers use integers and integer arithmetic to represent real numbers and arithmetic with the following encoding scheme:

$$V = \tilde{V} = SQ + B$$

- V is an arbitrarily precise real-world value.
- \tilde{V} is the approximate real-world value that results from fixed-point representation.
- Q is an integer that encodes \tilde{V} , referred to as the quantized integer.
- S is a coefficient of Q , referred to as the slope.
- B is an additive correction, referred to as the bias.

The general equation for an operation between fixed-point operands is:

$$(S_0Q_0 + B_0) = (S_1Q_1 + B_1) < op > (S_2Q_2 + B_2)$$

The objective of fixed-point operator replacement is to replace an operator that accepts and returns fixed-point or integer inputs and output with a function that accepts and returns built-in C numeric data types. The following sections provide additional programming information for each supported operator.

Addition

The operation $V_0 = V_1 + V_2$ implies that

$$Q_0 = \left(\frac{S_1}{S_0}\right)Q_1 + \left(\frac{S_2}{S_0}\right)Q_2 + \left(\frac{B_1 + B_2 - B_0}{S_0}\right)$$

If an addition replacement function is defined such that the scaling on the operands and sum are equal and the net bias

$$\left(\frac{B_1 + B_2 - B_0}{S_0}\right)$$

is zero (for example, a function `s8_add_s8_s8` that adds two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. To match for replacement, the slopes must be the same for all addition conceptual arguments. (For parameter descriptions, see the reference page for the function `setTfLCOperationEntryParameters`.)

Subtraction

The operation $V_0 = V_1 - V_2$ implies that

$$Q_0 = \left(\frac{S_1}{S_0}\right)Q_1 - \left(\frac{S_2}{S_0}\right)Q_2 + \left(\frac{B_1 - B_2 - B_0}{S_0}\right)$$

If a subtraction replacement function is defined such that the scaling on the operands and difference are equal and the net bias

$$\left(\frac{B_1 - B_2 - B_0}{S_0}\right)$$

is zero (for example, a function `s8_sub_s8_s8` that subtracts two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters

`SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. To match for replacement, the slopes must be the same for all subtraction conceptual arguments. (For parameter descriptions, see the reference page for the function `setTfLCOperationEntryParameters`.)

Multiplication

There are different ways to specify multiplication replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few known slope and bias combinations. Use the `TfLCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry.

The operation $V_0 = V_1 * V_2$ implies, for binary-point-only scaling, that

$$S_0 Q_0 = (S_1 Q_1)(S_2 Q_2)$$

$$Q_0 = \left(\frac{S_1 S_2}{S_0} \right) Q_1 Q_2$$

$$Q_0 = S_n Q_1 Q_2$$

where S_n is the net slope.

It is common to replace all multiplication operations that have a net slope of 1.0 with a function that performs C-style multiplication. For example, to replace all signed 8-bit multiplications that have a net scaling of 1.0 with the `s8_mul_s8_u8` replacement function, the operator entry must define a net slope factor, $F2^E$. You specify the values for F and E using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. For the `s8_mul_s8_u8` function, set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0. Also, set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all multiplication conceptual arguments. (For parameter descriptions, see the reference page for the function `setTfLCOperationEntryParameters`.)

Note When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

Division

There are different ways to specify division replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few known slope and bias combinations. Use the `TfLCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry (see “Customize Match and Replacement Process” on page 69-132).

The operation $V_0 = (V_1 / V_2)$ implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left(\frac{S_1 Q_1}{S_2 Q_2} \right)$$

$$Q_0 = S_n \left(\frac{Q_1}{Q_2} \right)$$

where S_n is the net slope.

It is common to replace all division operations that have a net slope of 1.0 with a function that performs C-style division. For example, to replace all signed 8-bit divisions that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor, $F2^E$. You specify the values for F and E using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. For the `s16_netslope0p5_div_s16_s16` function, you would set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0. Also, set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all division conceptual arguments. (For parameter descriptions, see the reference page for the function `setTfLCOperationEntryParameters`.)

Note When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

Data Type Conversion (Cast)

The data type conversion operation $V_0 = V_1$ implies, for binary-point-only scaling, that

$$Q_0 = \left(\frac{S_1}{S_0} \right) Q_1$$

$$Q_0 = S_n Q_1$$

where S_n is the net slope. Set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all cast conceptual arguments. (For parameter descriptions, see the reference page for the function `setTfLCOperationEntryParameters`.)

Shift

The shift left or shift right operation $V_0 = (V_1 / 2^n)$ implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left(\frac{S_1 Q_1}{2^n} \right)$$

$$Q_0 = \left(\frac{S_1}{S_0} \right) \left(\frac{Q_1}{2^n} \right)$$

$$Q_0 = S_n \left(\frac{Q_1}{2^n} \right)$$

where S_n is the net slope. Set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all shift conceptual arguments. (For parameter descriptions, see the reference page for the function `setTfLCOperationEntryParameters`.)

Binary-Point-Only Scaling Code Replacement

You can define code replacement entries for operations on fixed-point data types such that they match a binary-point-only scaling combination of operator inputs and output. This example shows how to develop a code replacement library to optimize the performance of fixed point data type operations by providing information that maps a binary point scale entry to a addition operator. To develop a code replacement library use only the programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.

To create custom code replacement entries that add logic to the code replacement match and replacement process see “Customize Code Match and Replacement for Scalar Operations” on page 69-138. You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them to a code replacement table definition file, and sets them to specific values in the class definition code.

```
classdef TflCustomOperationEntryBinaryPoint < RTW.TflCOperationEntryML
    methods
        function ent = do_match(hThis, ...
            hCS0, ... %#ok
            targetBitPerChar, ... %#ok
            targetBitPerShort, ... %#ok
            targetBitPerInt, ... %#ok
            targetBitPerLong, ... %#ok
            targetBitPerLongLong) %#ok

            % DO_MATCH - Create a custom match function. The base class
            % checks the types of the arguments prior to calling this
            % method. This class will check additional data and can
            % modify the implementation function.

            % The base class checks word size and signedness. Slopes and biases
            % have been wildcarded, so the only additional checking to do is
            % to check that the biases are zero and that there are only three
            % conceptual arguments (one output, two inputs)

            ent = []; % default the return to empty, indicating the match failed

            if length(hCS0.ConceptualArgs) == 3 && ...
                hCS0.ConceptualArgs(1).Type.Bias == 0 && ...
                hCS0.ConceptualArgs(2).Type.Bias == 0 && ...
                hCS0.ConceptualArgs(3).Type.Bias == 0

                % Modify the default implementation. Since this is a
                % generator entry, a concrete entry is created using this entry
                % as a template. The type of entry being created is a standard
                % TflCOperationEntry. Using the standard operation entry
                % provides required information, and you do not need
                % a custom match function.
                ent = RTW.TflCOperationEntry(hThis);

                % Since this entry is modifying the implementation for specific
                % fraction-length values (arguments 3, 4, and 5), the conceptual argument
                % wild cards must be removed (the wildcards were inherited from the
                % generator when it was used as a template for the concrete entry).
                % This concrete entry is now for a specific slope and bias.
                % hCS0 holds the slope and bias values (created by the code generator).
                for idx=1:3
                    ent.ConceptualArgs(idx).CheckSlope = true;
                    ent.ConceptualArgs(idx).CheckBias = true;

                    % Set the specific Slope and Biases
                    ent.ConceptualArgs(idx).Type.Slope = hCS0.ConceptualArgs(idx).Type.Slope;
                    ent.ConceptualArgs(idx).Type.Bias = 0;
                end

                % Set the fraction-length values in the implementation function.
                ent.Implementation.Arguments(3).Value = ...

```

```

-1.0*hCS0.ConceptualArgs(2).Type.FixedExponent;
ent.Implementation.Arguments(4).Value = ...
-1.0*hCS0.ConceptualArgs(3).Type.FixedExponent;
ent.Implementation.Arguments(5).Value = ...
-1.0*hCS0.ConceptualArgs(1).Type.FixedExponent;
end
end
end
end

```

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
 - b Create a table object by calling `RTW.TflTable`.

```

function hTable = crl_table_fixed_binptscale()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the custom entry function .

```

function hTable = crl_table_fixed_binptscale()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCOperationEntryParameters`.

```

function hTable = crl_table_fixed_binptscale()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntryBinaryPoint;

%% Create entry parameters
setTflCOperationEntryParameters(hEntry, ...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 30, ...
    'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
    'ImplementationName', 'myFixptAdd_binarypoint', ...
    'ImplementationHeaderFile', 'myFixptAdd.h', ...
    'ImplementationSourceFile', 'myFixptAdd.c');

```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `createAndAddConceptualArg`.

```
function hTable = crl_table_fixed_binptscale()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntryBinaryPoint;

%% Create entry parameters
setTflCoperationEntryParameters(hEntry, ...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 30, ...
    'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
    'ImplementationName', 'myFixptAdd_binarypoint', ...
    'ImplementationHeaderFile', 'myFixptAdd.h', ...
    'ImplementationSourceFile', 'myFixptAdd.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'Scaling', 'BinaryPoint', ...
    'IsSigned', false, ...
    'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'Scaling', 'BinaryPoint', ...
    'IsSigned', false, ...
    'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'Scaling', 'BinaryPoint', ...
    'IsSigned', false, ...
    'WordLength', 32);
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function `createAndSetCImplementationReturn` and `createAndAddImplementationArg`. Add the complete entry to the table by calling the function `addEntry`.

```
function hTable = crl_table_fixed_binptscale()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntryBinaryPoint;

%% Create entry parameters
setTflCoperationEntryParameters(hEntry, ...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 30, ...
    'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
    'ImplementationName', 'myFixptAdd_binarypoint', ...
```

```

    'ImplementationHeaderFile', 'myFixptAdd.h', ...
    'ImplementationSourceFile', 'myFixptAdd.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'Scaling', 'BinaryPoint', ...
    'IsSigned', false, ...
    'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'Scaling', 'BinaryPoint', ...
    'IsSigned', false, ...
    'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'Scaling', 'BinaryPoint', ...
    'IsSigned', false, ...
    'WordLength', 32);

%% Create the implementation Representation
% Specify replacement function signature
createAndSetImplementationReturn(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

% Add 3 fraction-length args. Actual values are set during code generation.
createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
    'Name', 'fl_in1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
    'Name', 'fl_in2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
    'Name', 'fl_out', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value', 0);

```

```

    % Add the entry to the table
    hTable.addEntry(op_entry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_fixed_binptscale
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) with these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for binary point scaling CRL';
this(1).TableList = {'crl_table_fixed_binptscale.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Slope Bias Scaling Code Replacement

You can define code replacement for operations on fixed-point data types as matching a slope bias scaling combination on the operator inputs and output. This example shows how to develop a code replacement library to optimize the performance of fixed point data type operations by providing information on how to define code replacement for a division operator. To develop a code replacement library use only the programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.

To create custom code replacement entries that add logic to the code replacement match and replacement process, see “Customize Code Match and Replacement for Scalar Operations” on page 69-138. You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them to a code replacement table definition file, and sets them to specific values in the class definition code.

```
classdef TflCustomOperationEntrySlopeBias < RTW.TflCOperationEntryML
    methods
        function ent = do_match(hThis, ...
            hCS0, ... %#ok
            targetBitPerChar, ... %#ok
            targetBitPerShort, ... %#ok
            targetBitPerInt, ... %#ok
            targetBitPerLong, ... %#ok
            targetBitPerLongLong) %#ok

            % DO_MATCH - Create a custom match function. The base class
            % checks the types of the arguments prior to calling this
            % method. This class will check additional data and can
            % modify the implementation function.

            % The base class checks word size and signedness. Slopes and biases
            % have been wildcarded, so the only additional checking to do is
            % to check that the biases are zero and that there are only three
            % conceptual arguments (one output, two inputs)

            ent = []; % default the return to empty, indicating the match failed

            if length(hCS0.ConceptualArgs) == 3

                % Modify the default implementation. Since this is a
                % generator entry, a concrete entry is created using this entry
                % as a template. The type of entry being created is a standard
                % TflCOperationEntry. Using the standard operation entry
                % provides required information, and you do not need
                % a custom match function.
                ent = RTW.TflCOperationEntry(hThis);

                % Since this entry is modifying the implementation for specific
                % fraction-length values (arguments 3, 4, and 5), the conceptual argument
                % wild cards must be removed (the wildcards were inherited from the
                % generator when it was used as a template for the concrete entry).
                % This concrete entry is now for a specific slope and bias.
                % hCS0 holds the slope and bias values (created by the code generator).
                for idx=1:3
                    ent.ConceptualArgs(idx).CheckSlope = true;
                    ent.ConceptualArgs(idx).CheckBias = true;

                    % Set the specific Slope and Biases
                    ent.ConceptualArgs(idx).Type.Slope = hCS0.ConceptualArgs(idx).Type.Slope;
                    ent.ConceptualArgs(idx).Type.Bias = hCS0.ConceptualArgs(idx).Type.Bias;
                end

                % Set the Slope and Bias values in the implementation function.
                ent.Implementation.Arguments(3).Value = hCS0.ConceptualArgs(2).Type.Slope;
                ent.Implementation.Arguments(4).Value = hCS0.ConceptualArgs(2).Type.Bias;
                ent.Implementation.Arguments(5).Value = hCS0.ConceptualArgs(3).Type.Slope;
                ent.Implementation.Arguments(6).Value = hCS0.ConceptualArgs(3).Type.Bias;
            end
        end
    end
end
```

```

ent.Implementation.Arguments(7).Value = hCS0.ConceptualArgs(1).Type.Slope;
ent.Implementation.Arguments(8).Value = hCS0.ConceptualArgs(1).Type.Bias;
end
end
end
end

```

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
 - b Create a table object by calling `RTW.TflTable`.

```

function hTable = crl_table_custom_add_ufix32_slopebias
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the custom entry function .

```

function hTable = crl_table_custom_add_ufix32_slopebias
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntrySlopeBias;;

```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```

function hTable = crl_table_custom_add_ufix32_slopebias
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntrySlopeBias;;

%% Create entry parameters
setTflCFunctionEntryParameters(hEntry, ...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 30, ...
    'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
    'ImplementationName', 'myFixptAdd_slopebias', ...
    'ImplementationHeaderFile', 'myFixptAdd.h', ...
    'ImplementationSourceFile', 'myFixptAdd.c');

```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `createAndAddConceptualArg`.

```
function hTable = crl_table_custom_add_ufix32_slopebias
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntrySlopeBias;;

%% Create entry parameters
setTflCoperationEntryParameters(hEntry, ...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 30, ...
    'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
    'ImplementationName', 'myFixptAdd_slopebias', ...
    'ImplementationHeaderFile', 'myFixptAdd.h', ...
    'ImplementationSourceFile', 'myFixptAdd.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'Scaling', 'SlopeBias', ...
    'IsSigned', false, ...
    'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'Scaling', 'SlopeBias', ...
    'IsSigned', false, ...
    'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'Scaling', 'SlopeBias', ...
    'IsSigned', false, ...
    'WordLength', 32);
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the same order and properties as the conceptual arguments, call the function

`createAndSetCImplementationReturn` and `createAndAddImplementationArg`. Add the complete entry to the table by calling the function `addEntry`.

```
function hTable = crl_table_custom_add_ufix32_slopebias
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = TflCustomOperationEntrySlopeBias;;

%% Create entry parameters
setTflCOperationEntryParameters(hEntry, ...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 30, ...
    'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
    'ImplementationName', 'myFixptAdd_slopebias', ...
    'ImplementationHeaderFile', 'myFixptAdd.h', ...
    'ImplementationSourceFile', 'myFixptAdd.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'Scaling', 'SlopeBias', ...
    'IsSigned', false, ...
    'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'Scaling', 'SlopeBias', ...
    'IsSigned', false, ...
    'WordLength', 32);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataType', 'Fixed', ...
    'Scaling', 'SlopeBias', ...
    'IsSigned', false, ...
    'WordLength', 32);

%% Create the implementation Representation
% Specify replacement function signature
createAndSetCImplementationReturn(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

% Add 3 fraction-length args. Actual values are set during code generation.
createAndSetCImplementationReturn(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
```

```

    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
    'Name', 'u2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

% Add 6 args for slopes and biases.
% Actual values are set during code generation.
createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
    'Name', 'slope_in1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
    'Name', 'bias_in1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', true, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
    'Name', 'slope_in2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
    'Name', 'bias_in2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', true, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
    'Name', 'slope_out1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumericConstant', ...
    'Name', 'bias_out1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', true, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value', 0);

addEntry(hTable, hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_custom_add_ufix32_slopebias
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) with these specifications:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for slope bias scaling function replacement';
this(1).TableList = {'crl_table_custom_add_ufix32_slopebias.m'};
% table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Net Slope Scaling Code Replacement

You can define code replacement entries for multiplication and division operations on fixed-point data types such that they match the net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example shows how to develop a code replacement library to optimize the performance of fixed point net slope operations by providing information on how to define code replacement for a `divide` operation. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```

- 2 Create a table.
 - a From the crtool context menu, select **File > New Table**.
 - b In the right pane, name the table `crl_table_netslopeScaling`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Fixed Point Net Slope Operation**.
- 4 Create entry parameters. In the **Operation** drop-down list, select `Divide`.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1` and `u2` with the **Data Type** of `fixdt(true,16,*,*)` and the **Argument Type** of `Scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. In the **Function arguments** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1` and `u2` with the **Data Type** of `int16`. Also set the **Net slope Adjustment Factor** as 1 and **Net Fixed Exponent** as 0.

Specify a **Name** for the replacement function under **Function prototype**.

- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For

more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
 - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
 - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_netslopeScaling
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCOperationEntryGenerator_NetSlope`.

```
function hTable = crl_table_netslopeScaling
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;
```

- 4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as wrap on overflow, rounding modes as unspecified, and the name of the replacement function as `user_div_*`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the F and E parts of the net slope $F2^E$.

```
function hTable = crl_table_netslopeScaling
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;
```

```
%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
    'Key', 'RTW_OP_DIV', ...
    'Priority', 90, ...
    'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_CEILING'}, ...
    'NetSlopeAdjustmentFactor', 1.0, ...
    'NetFixedExponent', 0.0, ...
    'ImplementationName', 's16_div_s16_s16', ...
```

- ```

 'ImplementationHeaderFile', 's16_div_s16_s16.h', ...
 'ImplementationSourceFile', 's16_div_s16_s16.c');

```
- 5 Create conceptual arguments y1, u1, and u2. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point, 16 bits, and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```

function hTable = crl_table_netslopeScaling
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCoperationEntryGenerator_NetSlope;

%% Create entry parameters
hEntry.setTflCoperationEntryParameters(...
 'Key', 'RTW_OP_DIV', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_CEILING'}, ...
 'NetSlopeAdjustmentFactor', 1.0, ...
 'NetFixedExponent', 0.0, ...
 'ImplementationName', 's16_div_s16_s16', ...
 'ImplementationHeaderFile', 's16_div_s16_s16.h', ...
 'ImplementationSourceFile', 's16_div_s16_s16.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'IsSigned', true, ...
 'WordLength', 16);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'IsSigned', true, ...
 'WordLength', 16);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'IsSigned', true, ...
 'WordLength', 16);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```
function hTable = crl_table_netslopeScaling
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
 'Key', 'RTW_OP_DIV', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_CEILING'}, ...
 'NetSlopeAdjustmentFactor', 1.0, ...
 'NetFixedExponent', 0.0, ...
 'ImplementationName', 's16_div_s16_s16', ...
 'ImplementationHeaderFile', 's16_div_s16_s16.h', ...
 'ImplementationSourceFile', 's16_div_s16_s16.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'IsSigned', true, ...
 'WordLength', 16);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'IsSigned', true, ...
 'WordLength', 16);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'IsSigned', true, ...
 'WordLength', 16);

%% Create the Implementation Representation
```

```

createAndSetCImplementationReturn(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);

```

```

%% Add the entry to the table
addEntry(hTable, hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_netslopeScaling
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file by using these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for net slope scaling';
this(1).TableList = {'crl_table_netslopeScaling.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

- “Develop a Code Replacement Library” on page 70-13
- “Equal Slope and Zero Net Bias Code Replacement” on page 70-158

## Equal Slope and Zero Net Bias Code Replacement

You can define code replacement entries for addition or subtraction of fixed-point data types such that they match the relative slope and bias values (equal slope and zero net bias) across operator inputs and output. These entries allow you to disregard slope and bias values when mapping relative slope and bias values to a replacement function for addition or subtraction.

This example shows how to develop a code replacement library to optimize the performance of fixed point net slope operations by providing information on how to define code replacement for an addition operation. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

### Interactively Develop a Code Replacement Library

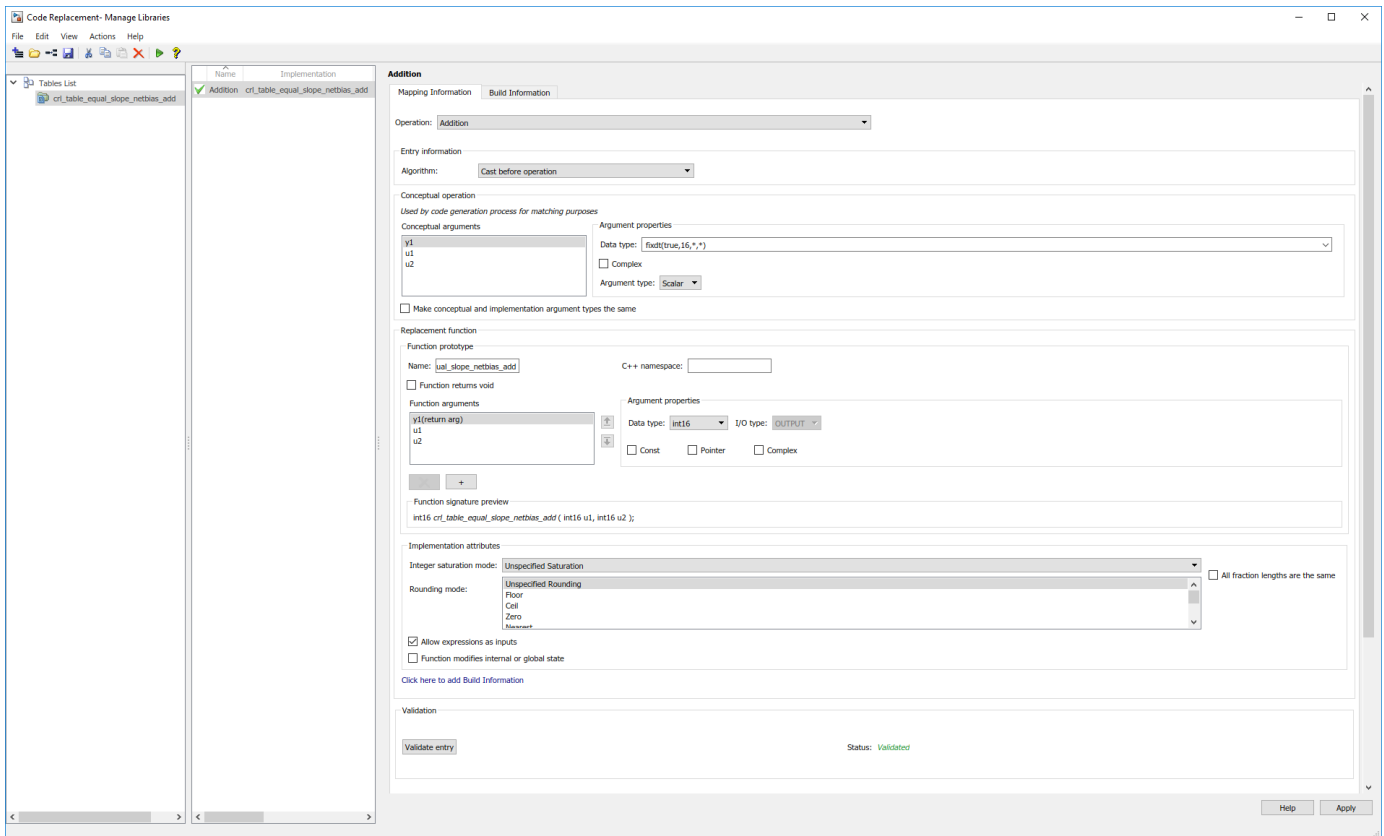

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:

```
>>crtool
```

- 2 Create a table.
  - a From the crtool context menu, select **File > New Table**.
  - b In the right pane, name the table `crl_table_equal_slope_netbias_add`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Fixed Point Net Slope Operation**.
- 4 Create entry parameters. In the **Operation** drop-down list, select **Addition**.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1` and `u2` with the **Data Type** of `fixdt(true,16,*,*)` and the **Argument Type** of **Scalar**.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. In the **Function arguments** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1` and `u2` with the **Data Type** of `int16`.

Specify a **Name** for the replacement function under **Function prototype**.

- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function to call your code replacement library table. The function should not have arguments and return a table object.
  - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_equal_slope_netbias_add
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCOperationEntryGenerator_NetSlope`.

```
function hTable = crl_table_equal_slope_netbias_add
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTflCOperationEntryParameters`.

```
function hTable = crl_table_equal_slope_netbias_add
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'SlopesMustBeTheSame', true, ...
 'MustHaveZeroNetBias', true, ...
 'ImplementationName', 'u16_add_SameSlopeZeroBias', ...
 'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h', ...
 'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point, 16 bits, and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
function hTable = crl_table_equal_slope_netbias_add
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'SlopesMustBeTheSame', true, ...
 'MustHaveZeroNetBias', true, ...
 'ImplementationName', 'u16_add_SameSlopeZeroBias', ...
 'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h', ...
 'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'IsSigned', false, ...
 'WordLength', 16);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'IsSigned', false, ...
 'WordLength', 16);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'IsSigned', false, ...
 'WordLength', 16);
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. This example uses calls to the `createAndSetCImplementationReturn` function to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```
function hTable = crl_table_equal_slope_netbias_add
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntryGenerator_NetSlope;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'SlopesMustBeTheSame', true, ...
 'MustHaveZeroNetBias', true, ...
```

```

 'ImplementationName', 'u16_add_SameSlopeZeroBias', ...
 'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h', ...
 'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');

%% Create the conceptual representation
createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'IsSigned', false, ...
 'WordLength', 16);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'IsSigned', false, ...
 'WordLength', 16);

createAndAddConceptualArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'IsSigned', false, ...
 'WordLength', 16);

%% Create the Implementation Representation
createAndSetCImplementationReturn(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', false, ...
 'WordLength', 16, ...
 'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 16, ...
 'FractionLength', 0);

createAndAddImplementationArg(hEntry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 16, ...
 'FractionLength', 0);

%% Add the entry to the table
addEntry(hTable, hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_equal_slope_netbias_add
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file with these specifications:

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for equal slope and zero net bias code replacement';

```

```
this(1).TableList = {'crl_table_equal_slope_netbias_add.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10** Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Data Type Conversions (Casts) and Operator Code Replacement

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

### Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), at the MATLAB command line, enter:  

```
>>crtool
```
- 2 Create a table.
  - a From the crtool context menu, select **File > New Table**.
  - b In the right pane, name the table `cr1_table_cast_int32_to_int16`. Click **Apply**.
- 3 Create entry parameters. In the **Operation** drop-down list, select **Cast**.
- 4 Create an entry. From the crtool context menu, select **File > New entry > Fixed Point Net Slope Operation**.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1` with the **Data Type** of `int16`, and the input argument, `u1` with the **Data Type** of `int32` and the **Argument Type** of **Scalar**.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box. In the **Function arguments** subsection of the crtool, specify the return argument, `y1`, and the input argument, `u1` with the **Data Type** of `int16` and `int32`.  
  
Specify a **Name** for the replacement function under **Function prototype**.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. In the **Mapping Information** tab, click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programmatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function to call your code replacement library table. The function should not have arguments and return a table object.
  - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_cast_int32_to_int16()
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCOperationEntry`.

```
function hTable = crl_table_cast_int32_to_int16()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TfLCOperationEntry;
```

- 4 Create entry parameters. Because this examples replaces a function, create entry parameters by calling the function `setTfLCOperationEntryParameters`. The parameters specify the type of operation as `cast`, the saturation mode as `saturate on integer overflow`, rounding modes as `toward negative infinity`, and the name of the replacement function as `my_sat_cast`.

```
function hTable = crl_table_cast_int32_to_int16()
% Create a code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TfLCOperationEntry;
```

```
%% Create entry parameters
hEntry.setTfLCOperationEntryParameters(...
 'Key', 'RTW_OP_CAST', ...
 'Priority', 50, ...
 'ImplementationName', 'my_sat_cast', ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'ImplementationHeaderFile', 'some_hdr.h', ...
 'ImplementationSourceFile', 'some_hdr.c');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString`.

```
function hTable = crl_table_cast_int32_to_int16()
% Create a code replacement library table
```

```
%% Create a table object
hTable = RTW.TflTable;
```

```
%% Create an entry
hEntry = RTW.TfLCOperationEntry;
```

```
%% Create entry parameters
hEntry.setTfLCOperationEntryParameters(...
 'Key', 'RTW_OP_CAST', ...
 'Priority', 50, ...
 'ImplementationName', 'my_sat_cast', ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'ImplementationHeaderFile', 'some_hdr.h', ...
 'ImplementationSourceFile', 'some_hdr.c');
```

```
%% Create the conceptual representation
```

```
arg = getTflArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);
hEntry.Implementation.setReturn(arg);
```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To specify that the implementation arguments have the

same order and properties as the conceptual arguments, call the function `getTflArgFromString`. Add the complete entry to the table by calling the function `addEntry`.

```
function hTable = crl_table_cast_int32_to_int16()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
hEntry.setTflCOperationEntryParameters(...
 'Key', 'RTW_OP_CAST', ...
 'Priority', 50, ...
 'ImplementationName', 'my_sat_cast', ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'ImplementationHeaderFile', 'some_hdr.h', ...
 'ImplementationSourceFile', 'some_hdr.c');

%% Create the conceptual and implementation representation

arg = getTflArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);
hEntry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', 'int32');
addConceptualArg(hEntry, arg);
hEntry.Implementation.addArgument(arg);

%% Add the entry to the table
addEntry(hTable,hEntry);
```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_cast_int32_to_int16
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file with these specifications:

```
function rtwTargetInfo(cm)
cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for data type conversions(casts) abd operator code replacement';
this(1).TableList = {'crl_table_cast_int32_to_int16.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end
```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10** Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Shift Left Operations and Code Replacement

This example shows how to develop a code replacement library to optimize the performance of shift left (<<) operation by providing information on how to define code replacement for a `shift left` function. To develop a code replacement library use either the interactive or programmatic approach. For more information, see “Develop a Code Replacement Library” on page 70-13.

### Interactively Develop a Code Replacement Library

- 1 Open the **Code Replacement Tool** (crtool), from the MATLAB command line with the following command:  

```
>>crtool
```
- 2 Create a table.
  - a From the crtool context menu, select **File > New Table**.
  - b In the right pane, name the table `crl_table_shift_left_int16`. Click **Apply**.
- 3 Create an entry. From the crtool context menu, select **File > New entry > Math Operation**.
- 4 Create entry parameters. In the **Operator** drop-down list, select `Shift Left`.
- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. In the **Conceptual function** subsection of the crtool, specify the return argument, `y1`, and the input arguments, `u1`, and `u2`, with **Data Type** of `int16` and the **Argument Type** of `scalar`.
- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. For this example, to specify that the implementation arguments have the same order and properties as the conceptual arguments, select the **Make conceptual and implementation argument types the same** check box.  
  
Under **Function prototypes** specify a **Name** for the replacement function.
- 7 Specify build information. Click the **Build Information** tab to open the build requirements pane. Specify the files (source, header, object) that the code generator requires for code replacement. For this example, you do not need to specify build information.
- 8 Validate and save the table. Click the **Mapping Information** tab and verify the fields are filled in as shown. Click **Validate entry**. In the crtool context menu, select **File > Save table > Save**.

- 9 Register a code replacement library. Registration creates a library composed of the tables that you specify. Select **File > Generate registration file**. In the Generate registration file dialog box, fill out these fields:

To use your code replacement library, refresh your current MATLAB session with the command:  
`>>sl_refresh_customizations`

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

## Programatically Develop a Code Replacement Library

- 1 Open the programmatic interface from the **MATLAB** menu by selecting **New > Function**.
- 2 Create a table.
  - a Create a function with the name of your code replacement library table that does not have arguments and returns a table object. You can use this function to call your code replacement library table.
  - b Create a table object by calling `RTW.TflTable`.

```
function hTable = crl_table_shift_left_int16
% Create a function to call the code replacement library table

%% Create a table object
hTable = RTW.TflTable;
```

- 3 Create an entry. Because this example replaces a function, create a code replacement entry in your table by calling the entry function `RTW.TflCOperationEntry`.

```
function hTable = crl_table_shift_left_int16()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;
```

- 4 Create entry parameters. Because this example replaces a function, create entry parameters by calling the function `setTflCFunctionEntryParameters`.

```
function hTable = crl_table_shift_left_int16()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
setTflCFunctionEntryParameters(hEntry, ...
 'Key', 'RTW_OP_SL', ...
 'Priority', 50, ...
 'ImplementationName', 'my_shift_left', ...
 'ImplementationHeaderFile', 'some_hdr.h', ...
 'ImplementationSourceFile', 'some_hdr.c');
```

- 5 Create the conceptual representation. The conceptual representation describes the signature of the function that you want to replace. To explicitly specify argument properties, call the function `getTflArgFromString` and `addConceptualArg`.

```

function hTable = crl_table_shift_left_int16()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
setTflCOperationEntryParameters(hEntry, ...
 'Key', 'RTW_OP_SL', ...
 'Priority', 50, ...
 'ImplementationName', 'my_shift_left', ...
 'ImplementationHeaderFile', 'some_hdr.h', ...
 'ImplementationSourceFile', 'some_hdr.c');

%% Create the conceptual representation
arg = getTflArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);
hEntry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', 'int16');
addConceptualArg(hEntry, arg);
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', 'int16');
arg.CheckType = false;
addConceptualArg(hEntry, arg);
hEntry.Implementation.addArgument(arg);

```

- 6 Create the implementation representation. The implementation representation describes the signature of the optimization function. To explicitly specify argument properties, call the function `getTflArgFromString`.

```

function hTable = crl_table_shift_left_int16()
% Create a code replacement library table

%% Create a table object
hTable = RTW.TflTable;

%% Create an entry
hEntry = RTW.TflCOperationEntry;

%% Create entry parameters
setTflCOperationEntryParameters(hEntry, ...
 'Key', 'RTW_OP_SL', ...
 'Priority', 50, ...
 'ImplementationName', 'my_shift_left', ...
 'ImplementationHeaderFile', 'some_hdr.h', ...
 'ImplementationSourceFile', 'some_hdr.c');

%% Create the conceptual and implementation representation
arg = getTflArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEntry, arg);
hEntry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', 'int16');
addConceptualArg(hEntry, arg);
hEntry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', 'int16');
arg.CheckType = false;
addConceptualArg(hEntry, arg);
hEntry.Implementation.addArgument(arg);

```

```

%% Add the entry to the table
hTable.addEntry(hEntry);

```

- 7 Specify build information. In the entry parameters, specify files (header, source, object) that the code generator needs for code replacement. For this example, build information is not required.
- 8 Validate and save the customization file. From the **MATLAB** menu, save this customization file by selecting **File > Save**. From the command line, validate the code replacement library table by calling it:

```
>> hTable = crl_table_shift_left_int16
```

- 9 Register the code replacement library. Registration creates a code replacement library by defining the library name, code replacement tables, and other information. Create a registration file (a new function file) by using these specifications.

```

function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);
end

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'CRL for shift left operation';
this(1).TableList = {'crl_table_shift_left_int16.m'}; % table created in this example
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example code replacement library';

end

```

To use your code replacement library, refresh your current MATLAB session with the command:

```
>>sl_refresh_customizations
```

- 10 Verify the code replacement library. From the MATLAB command line, open the library by using the **Code Replacement Viewer** and verify that the table and entry are correctly specified. For more information, see “Verify Code Replacement Library” on page 69-55. Configure your model to use the code replacement library, generate code, and verify that replacement occurs as expected. If unexpected behavior occurs, examine the hit and miss logs to troubleshoot the issues.

# Optimize Generated Code by Developing and Using Code Replacement Libraries - MATLAB

Develop and use code replacement libraries to replace function and operators in generated code. Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware
- Integration with existing application code
- Compliance with a standard, such as AUTOSAR
- Modification of code behavior, such as enabling or disabling nonfinite or inline support
- Application- or project-specific code requirements, such as use of BLAS or elimination of `math.h`, system header files, or calls to `memcpy` or `memset`.

You can configure the code generator to use a code replacement library that MathWorks® provides. If you have an Embedded Coder® license, you can develop your own code replacement library interactively with the Code Replacement Tool or programmatically.

This example provides MATLAB® code that shows a variety of ways you can define code replacement mappings. With each example MATLAB function, the example provides MATLAB files that illustrate how to develop function and operator code replacements programmatically.

## Additional Requirements:

- MATLAB Coder™
- Embedded Coder
- Fixed-Point Designer™

For more information, see “What Is Code Replacement Customization?” on page 70-3 and “Develop a Code Replacement Library” on page 70-13.

## Create a New Folder and Copy Relevant Files

The following code creates a sub folder in your current working folder (`pwd`). The new folder contains files that are relevant for this example.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
coderdemo_setup('coderdemo_crl');
```

## Steps for Developing a Code Replacement Library

- 1 Identify your code replacement requirements with respect to function or operating mappings, build information, and registration information.
- 2 Prepare for code replacement library development (for example, identify or develop models to test your library).
- 3 Define code replacement mappings.
- 4 Specify build information for replacement code.

- 5 Register code replacement mappings.
- 6 Verify code replacements.
- 7 Deploy the library.

For more information, see “Develop a Code Replacement Library” on page 70-13.

### Math Function Replacement

This example defines and registers code replacement mappings for math functions. You can define code replacement mappings for a variety of functions. For details, see “Code You Can Replace from MATLAB Code” on page 70-5.

1. Open and explore the MATLAB file for this example.

```
edit(fullfile(matlabroot, 'toolbox', 'coder', 'codegendemos', 'coderdemo_crl', 'replace_math_fcns.m'))
```

2. Configure the code generator to use the code replacement library **Function Replacement Examples**.

```
RTW.TargetRegistry.getInstance('reset');
cfg = coder.config('lib', 'ecoder', true);
cfg.CodeReplacementLibrary = 'Function Replacement Examples';
cfg.GenerateReport = false;
cfg.LaunchReport = false;
```

3. Set up the configuration parameters to build and define the function input type.

```
t = single(2);
```

4. Explore the code replacement table definition file.

```
edit(fullfile(matlabroot, 'toolbox', 'coder', 'codegendemos', 'coderdemo_crl', 'crl_table_functions.m'))
```

5. Compile the MATLAB program into a C source file by using the configuration parameters that point to the code replacement library and the example input class defined in step 3 as input parameters to the codegen command.

```
codegen('replace_math_fcns', '-config', cfg, '-args', {t, t});
```

```
Warning: Unrecognized function or variable 'simmechanics.sli.internal.register_datatypes'.
```

```
Warning: Unrecognized function or variable 'customizationXpcCrlRegistration'.
```

```
Code generation successful.
```

6. Open the file `replace_math_fcns.c` and explore the generated source code.

```
open(fullfile('codegen', 'lib', 'replace_math_fcns', 'replace_math_fcns.c'))
```

7. Close `replace_math_fcns.m`.

For more information on math function replacement, see “Math Function Code Replacement” on page 70-51.

## Addition and Subtraction Operator Replacement

This example shows how to define and register code replacement mappings for addition (+) and subtraction (-) operations. When defining entries for addition and subtraction operations, you can specify which of the following algorithms (`EntryInfoAlgorithm`) your library functions implement:

- Cast-before-operation (CBO) (`RTW_CAST_BEFORE_OP`), the default
- Cast-after-operation (CAO) (`RTW_CAST_AFTER_OP`)

1. Open and explore the MATLAB file for this example.

```
edit(fullfile(matlabroot, 'toolbox', 'coder', 'codegendemos', 'coderdemo_crl', 'addsub_two_int16.m'))
%
% CBO, the default algorithm, is assumed.
```

2. Configure the code generator to use a code replacement library **Addition & Subtraction Examples**.

```
RTW.TargetRegistry.getInstance('reset');
cfg = coder.config('lib', 'ecoder', true);
cfg.CodeReplacementLibrary = 'Addition & Subtraction Examples';
cfg.GenerateReport = false;
cfg.LaunchReport = false;
```

3. Set up the configuration parameters to build and define the operation input type.

```
t = int16(2);
```

4. Explore the code replacement table definition file.

```
edit(fullfile(matlabroot, 'toolbox', 'coder', 'codegendemos', 'coderdemo_crl', 'crl_table_addsub.m'))
```

5. Compile the MATLAB program into a C source file by using the configuration parameters that point to the desired code replacement library and the example input class defined in step 3 as input parameters to the `codegen` command.

```
codegen('addsub_two_int16', '-config', cfg, '-args', {t, t});
Warning: Unrecognized function or variable 'simmechanics.sli.internal.register_datatypes'.
Warning: Unrecognized function or variable 'customizationXpcCrlRegistration'.
Code generation successful.
```

6. Open the file `addsub_two_int16.c` and explore the generated source code.

```
open(fullfile('codegen', 'lib', 'addsub_two_int16', 'addsub_two_int16.c'))
```

7. Close `addsub_two_int16.m`.

For more information on addition and subtraction operator replacement, see “Scalar Operator Code Replacement” on page 70-99 and “Addition and Subtraction Operator Code Replacement” on page 70-104.

## Matrix Operator Replacement

This example defines and registers code replacement mappings for matrix operations: addition, subtraction, multiplication, transposition, conjugate, and Hermitian.

Supported types include:

- single, double
- int8, uint8
- int16, uint16
- int32, uint32
- csingle, cdouble
- cint8, cuint8
- cint16, cuint16
- cint32, cuint32
- fixed-point integers
- mixed types (different type on each input)

1. Open and explore the MATLAB file for this example:

```
edit(fullfile(matlabroot, 'toolbox', 'coder', 'codegendemos', 'coderdemo_crl', 'replace_matrix_ops.m'))
```

2. Configure the code generator to use a code replacement library **Matrix Op Replacement Examples**.

```
RTW.TargetRegistry.getInstance('reset');
cfg = coder.config('lib', 'ecoder', true);
cfg.CodeReplacementLibrary = 'Matrix Op Replacement Examples';
cfg.GenerateReport = false;
cfg.LaunchReport = false;
```

3. Set up the configuration parameters to build and define the operation input type.

```
t = [1.0 2.0; 3.0, 4.0];
```

4. Explore the code replacement table definition file.

```
edit(fullfile(matlabroot, 'toolbox', 'coder', 'codegendemos', 'coderdemo_crl', 'crl_table_matops.m'))
```

5. Compile the MATLAB program using the configuration parameters that point to the desired code replacement library and the example input class defined in step 3 as input parameters to the `codegen` command.

```
codegen('replace_matrix_ops', '-config', cfg, '-args', {t, t});
```

```
Warning: Unrecognized function or variable 'simmechanics.sli.internal.register_datatypes'.
```

```
Warning: Unrecognized function or variable 'customizationXpcCrlRegistration'.
```

```
Code generation successful.
```

6. Open the file `replace_matrix_ops.c` and explore the generated source code.

```
open(fullfile('codegen', 'lib', 'replace_matrix_ops', 'replace_matrix_ops.c'))
```

7. Close `replace_matrix_ops.m`.

For more information on matrix operator replacement, see “Small Matrix Operation to Processor Code Replacement” on page 70-111.

## Matrix Multiplication Replacement for BLAS

This example defines and registers code replacement mappings for Basic Linear Algebra Subroutines (BLAS) subroutines xGEMM and xGEMV. You can map the following operations to a BLAS subroutine:

- Matrix multiplication
- Matrix multiplication with transpose on single or both inputs
- Matrix multiplication with Hermitian operation on single or both inputs

1. Open and explore the MATLAB file for this example.

```
edit(fullfile(matlabroot, 'toolbox', 'coder', 'codegendemos', 'coderdemo_crl', 'replace_matrix_ops_bla
```

2. Configure the code generator to use a code replacement library **BLAS Replacement Examples**.

```
RTW.TargetRegistry.getInstance('reset');
cfg = coder.config('lib', 'ecoder', true);
cfg.CodeReplacementLibrary = 'BLAS Replacement Examples';
cfg.GenerateReport = false;
cfg.LaunchReport = false;
```

3. Set up the configuration parameters to build and define the function input type.

```
t = [1.0 2.0 3.0; 4.0 5.0 6.0; 7.0 8.0 9.0];
```

4. Explore the code replacement table definition file.

```
edit(fullfile(matlabroot, 'toolbox', 'coder', 'codegendemos', 'coderdemo_crl', 'crl_table_blas.m'))
```

5. Compile the MATLAB program using the configuration parameters that point to the desired code replacement library and the example input class defined in step 3 as input parameters to the codegen command.

```
codegen('replace_matrix_ops_blas', '-config', cfg, '-args', {t, t});
```

```
Warning: Unrecognized function or variable 'simmechanics.sli.internal.register_datatypes'.
```

```
Warning: Unrecognized function or variable 'customizationXpcCrlRegistration'.
```

```
Code generation successful.
```

6. Open the file `replace_matrix_ops_blas.c` and explore the generated source code.

```
open(fullfile('codegen', 'lib', 'replace_matrix_ops_blas', 'replace_matrix_ops_blas.c'))
```

7. Close `replace_matrix_ops_blas.m`.

For more information on matrix multiplication replacement for BLAS, see “Matrix Multiplication Operation to MathWorks BLAS Code Replacement” on page 70-117.

## MATLAB Function Replacement Using `Coder.Replace`

Code replacement libraries support the replacement of MATLAB functions with scalar and matrix inputs and outputs for built-in, complex, and fixed-point data types.

1. Open and explore the MATLAB file for this example.

```
edit(fullfile(matlabroot, 'toolbox', 'coder', 'codegendemos', 'coderdemo_crl', 'coder_replace_fcn.m'))
```

2. Configure the code generator to use a code replacement library **Coder Replace Examples**.

```
RTW.TargetRegistry.getInstance('reset');
cfg = coder.config('lib','ecoder',true);
cfg.CodeReplacementLibrary = 'Coder Replace Examples';
cfg.GenerateReport = false;
cfg.LaunchReport = false;
```

3. Set up the configuration parameters to build and define the function input type.

```
t = [1 2; 3 4];
```

4. Explore the code replacement table definition file.

```
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','crl_table_coder_replac
```

5. Compile the MATLAB program using the configuration parameters that point to the desired code replacement library and the example input class defined in step 3 as input parameters to the `codegen` command.

```
codegen('coder_replace_fcn', '-config', cfg, '-args', {t, t});
Warning: Unrecognized function or variable 'simmechanics.sli.internal.register_datatypes'.
Warning: Unrecognized function or variable 'customizationXpcCrlRegistration'.
Code generation successful.
```

6. Open the file `coder_replace_fcn.c` and explore the generated source code.

```
open(fullfile('codegen','lib','coder_replace_fcn','coder_replace_fcn.c'))
```

7. Close `coder_replace_fcn.m`.

For more information, see “Replace MATLAB Functions with Custom Code by Using the `coder.replace` Function” on page 70-79.

### Build Information

For each entry in a code replacement table, you can specify build information such as the following, for replacement functions:

- Header file dependencies
- Source file dependencies
- Additional include paths
- Additional source paths
- Additional link flags

Additionally, you can specify `RTW.copyFileToBuildDir` to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. You can specify `RTW.copyFileToBuildDir` by setting it as the value of:

- Property `GenCallback` in a call to `setTfLCFunctionEntryParameters`, `setTfLCOperationEntryParameters`, or `setTfLCSemaphoreEntryParameters`.
- Argument `genCallback` in a call to `registerCFunctionEntry`, `registerCOperationEntry`, or `registerCSemaphoreEntry`.

**Note:** Models in this example are configured for code generation only because the implementations for the replacement functions are not provided.

For more information on specifying build information for replacement code, see “Develop a Code Replacement Library” on page 70-13.

### **Cleanup**

Remove files and return to original folder

```
RTW.TargetRegistry.getInstance('reset');
rtwdemoclean;
clear coderdemo_crl
cd ../
```

## Increase Code Generation Speed

### In this section...

“Build a Model in Increments” on page 71-3

“Build Large Model Reference Hierarchies in Parallel” on page 71-3

“Minimize Memory Requirements During Code Generation” on page 71-4

“Generate Only Code” on page 71-4

“Suppress Creation of a Code Generation Report” on page 71-4

The amount of time it takes to generate code for a model depends on the size and configuration settings of the model. For instance, if you are working with a large model, it can take awhile to generate code. To decrease the amount of time for code generation of a model, try one or more of the following methods:

- Build a model in increments
- Build large model reference hierarchies in parallel
- Minimize memory requirements during code generation
- Generate only code
- Disable the creation of a code generation report

### Build a Model in Increments

You can use the `slbuild` command to build a model and generate code. By default, when rebuilding a model, `slbuild` provides an incremental model build, which only rebuilds a model or submodels that have changed since the most recent model build. Incremental model build saves code generation time. Use the **Rebuild** parameter on the **Model Referencing** pane to change the method that Simulink uses to determine when to rebuild code for referenced models. For more information on the **Rebuild** parameter, see “Rebuild”.

### Build Large Model Reference Hierarchies in Parallel

In a parallel computing environment, whenever conditions allow, you can increase the speed of code generation and compilation by building models containing large model reference hierarchies in parallel. For example, if you have Parallel Computing Toolbox software, you can distribute code generation and compilation for each referenced model across the cores of a multicore host computer. If you have MATLAB Parallel Server software, you can distribute code generation and compilation for each referenced model across remote workers in your MATLAB Parallel Server configuration.

The execution speed improvement realized by using parallel builds for referenced models depends on several factors, including:

- How many models can be built in parallel for a given model referencing hierarchy
- The size of the referenced models
- Parallel computing resources such as the number of local and remote workers available
- The hardware attributes of the local and remote machines (amount of RAM, number of cores, and so on)

For more information, see “Reduce Build Time for Referenced Models by Using Parallel Builds”.

## Minimize Memory Requirements During Code Generation

Models that have large amounts of parameter and constant data (such as lookup tables) can tax memory resources and slow code generation. The code generator copies this data to the `model.rtw` file. The `model.rtw` file is a partial representation of the model that the Target Language Compiler parses to transform block computations, parameters, signals, and constant data into a high-level language (for example, C). The Target Language Compiler (TLC) is an integral part of the code generator. The code generator copies parameters and data into `model.rtw`, whether they originate in the model or come from variables or objects in a workspace.

You can improve code generation speed by specifying the maximum number of elements that data vectors can have for the code generator to copy this data to `model.rtw`. When a data vector exceeds the specified size, the code generator places a reference key in `model.rtw`. The TLC uses this key to access the data from Simulink and format it into the generated code. Reference keys result in maintaining only one copy of large data vectors in memory.

The default value above which the code generator uses reference keys in place of actual data values is 10 elements. You can verify this value. In the Command Window, type the following command:

```
get_param(0, 'RTWDataReferencesMinSize')
```

To set the threshold to a different value, in the Command Window, type the following `set_param` function:

```
set_param(0, 'RTWDataReferencesMinSize', <size>)
```

Provide an integer value for `size` that specifies the number of data elements above which the code generator uses reference keys in place of actual data values.

## Generate Only Code

You can increase code generation speed by specifying that the build process generate code and a makefile, but not invoke the make command. When the code generator invokes the make command, the build process takes longer because the code generator generates code, compiles code, and creates an executable file.

On the **Code Generation** pane in the Model Configuration Parameters dialog box, you can specify that the build process generate only code by selecting the **Generate code only** parameter. You can specify that the code generation process build a makefile by selecting the **Configuration Parameters > Code Generation > Build process > Makefile configuration > Generate makefile** parameter.

## Suppress Creation of a Code Generation Report

You can speed up code generation by not generating a code generation report as a part of the build process. To disable the creation of a code generation report, on the **Code Generation > Report** pane, clear the **Create code generation report** parameter. To generate a code generation report after the build process, see “Generate Code Generation Report” on page 51-5.

## See Also

### Related Examples

- “MATLAB worker initialization for builds”
- “Reduce Build Time for Referenced Models by Using Parallel Builds” on page 56-37

## Control Compiler Optimizations

To control compiler optimizations for a makefile build at the GUI level, use the **Compiler optimization level** parameter. The **Compiler optimization level** parameter provides

- Target-independent values `Optimizations on (faster runs)` and `Optimizations off (faster builds)`, which allow you to easily toggle compiler optimizations on and off during code development
- The value `Custom` for entering custom compiler optimization flags at the Simulink GUI level, rather than editing compiler flags into template makefiles (TMFs) or supplying compiler flags to build process make commands

The default setting is `Optimizations off (faster builds)`. Selecting the value `Custom` enables the **Custom compiler optimization flags** field, in which you can enter custom compiler optimization flags (for example, `-O2`).

If you specify compiler options for your makefile build using `OPT_OPTS`, `MEX_OPTS` (except `MEX_OPTS="-v"`), or `MEX_OPT_FILE`, the value of **Compiler optimization level** is ignored and a warning is issued about the ignored parameter.

For a rapid simulation that uses the MinGW compiler:

- If `RTWCompilerOptimization` is set to `'on'`, the build process customizes compiler optimization to minimize run time. The build process ignores the `BuildConfiguration` and `CustomToolchainOptions` settings.
- If `RTWCompilerOptimization` is set to `'custom'` or `'off'`, the build process uses `BuildConfiguration` and `CustomToolchainOptions` settings. The build process ignores the `RTWCompilerOptimization` setting.

# Optimize Generated Code with Code Efficiency Tools and Techniques

## Use the Model Advisor to Optimize a Model for Code Generation

You can use the Model Advisor to analyze a model for code generation and identify aspects of your model that impede production deployment or limit code efficiency. You can select from a set of checks to run on a model's current configuration. The Model Advisor analyzes the model and generates check results providing suggestions for improvements in each area. Most Model Advisor diagnostics do not require the model to be in a compiled state; those that do are noted.

Before running the Model Advisor, select the target you plan to use for code generation. The Model Advisor works most effectively with ERT and ERT-based system target files.

Use the following examples to investigate optimizing models for code generation using the Model Advisor:

- `rtwdemo_advisor1`
- `rtwdemo_advisor2`
- `rtwdemo_advisor3`

---

**Note** Example models `rtwdemo_advisor2` and `rtwdemo_advisor3` require Stateflow and Fixed-Point Designer software.

---

For more information on using the Model Advisor, see “Run Model Advisor Checks”. For more information about the checks, see “Simulink Coder Checks”.

## Design Tips for Optimizing Generated Code for Stateflow Objects

### Do Not Access Machine-Parented Data In a Graphical Function

This restriction prevents long parameter lists from appearing in the code generated for a graphical function. You can access local data that resides in the same chart as the graphical function. For more information, see “Reuse Logic Patterns by Defining Graphical Functions” (Stateflow).

### Be Explicit About the Inline Option of a Graphical Function

When you use a graphical function in a Stateflow chart, select `Inline` or `Function` for the property **Function Inline Option**. Otherwise, the code generated for a graphical function may not appear as you want. For more information, see “Specify Properties of Graphical Functions” (Stateflow).

### Avoid Using Multiple Edge-Triggered Events in Stateflow Charts

If you use more than one trigger, you generate multiple code statements to handle rising or falling edge detections. If multiple triggers are required, use function-call events instead. For more information, see “Activate a Stateflow Chart by Sending Input Events” (Stateflow).

## Combine Input Signals of a Chart Into a Single Bus Object

When you use a bus object, you reduce the number of parameters in the parameter list of a generated function. This guideline also applies to output signals of a chart. For more information, see “Define Stateflow Structures” (Stateflow).

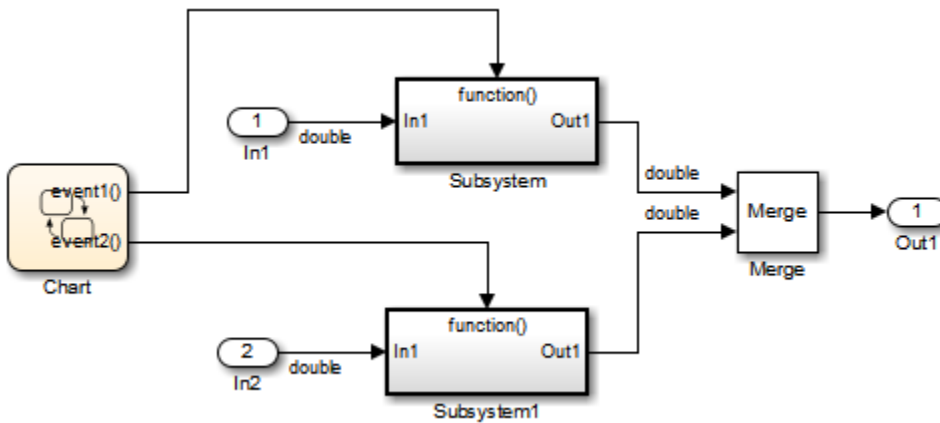

## Use Charts with Discrete Sample Times

The code generated for discrete charts that are not inside a triggered or enabled subsystem uses integer counters to track time instead of Simulink provided time. This allows for more efficient code generation in terms of overhead and memory, as well as enabling this code for use in software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations.

## Additional Optimization Techniques

You can apply the following techniques to optimize a model for code generation:

- For Embedded Coder users, if your application uses only integer arithmetic, clear the **Support floating-point numbers** parameter in the **Software environment** section of the **Interface** pane so that the generated code does not contain floating-point data or operations. When this parameter is cleared, an error is raised if noninteger data or expressions are encountered during code generation. The error message reports the offending blocks and parameters.
- Disable the **Configuration Parameters > Code Generation > Interface > Advanced parameters > MAT-file logging** parameter. Deselecting this parameter eliminates extra code and memory usage for initializing, updating, and cleaning-up logging variables. In addition, the code generated to support MAT-file logging invokes `malloc`, which can be undesirable for your application.
- Use the Upgrade Advisor to upgrade older models (saved by prior versions or the current version) to use current features. For details, see “Model Upgrades”.
- Before building, set optimization flags for the compiler (for example, `-O2` for `gcc`, `-Ot` for the Microsoft Visual C++ compiler).
- Directly inline C/C++ S-functions into the generated code by writing a TLC file for the S-function. For more information, see “Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target” and see “Inline C MEX S-Functions”.
- Use a Simulink data type other than `double` when possible. The available data types are `Boolean`, signed and unsigned 8-, 16-, and 32-bit integers, and 32- and 64-bit floats (a `double` is a 64-bit float). For more information, see “About Data Types in Simulink”. For a block-by-block summary, click `showblockdatatypetable` or type the command in the Command Window.
- For tunable block parameters that you configure to store in memory in the generated code, you can match parameter data types with signal data types to eliminate unnecessary typecasts and C shifts. Where possible, store parameter values in small integer data types. See “Parameter Data Types in the Generated Code” on page 33-129.
- Remove repeated values in lookup table data.
- Use the Merge block to merge the output of signals wherever possible. This block is particularly helpful when you need to control the execution of function-call subsystems with a Stateflow chart. The following model shows an example of how to use the Merge block.

When more than one signal connected to a Merge block has a non-Auto storage class, all non-Auto signals connected to that block must *be identically labeled* and *have the same storage class*. When Merge blocks connect directly to one another, these rules apply to the signals connected to any of the Merge blocks in the group.

## Control Memory Allocation for Time Counters

The **Application lifespan (days)** parameter lets you control the allocation of memory for absolute and elapsed time counters. Such counters exist in the code for blocks that use absolute or elapsed time. For a list of such blocks, see “Absolute Time Limitations”.

The size of the time counters in generated code is 8, 16, 32, or 64 bits. The size is set automatically to the minimum that can accommodate the duration value specified by **Application lifespan (days)** given the step size specified in the Configuration Parameters **Solver** pane. To minimize the amount of RAM used by time counters, specify the smallest lifespan possible and the largest step size possible.

An application runs to its specified lifespan. It may be able to run longer. For example, running a model with a step size of one millisecond (0.001 seconds) for one day requires a 32-bit timer, which could continue running without overflow for 49 days more.

To maximize application lifespan, specify **Application lifespan (days)** as `inf`. This value allocates 64 bits (two `uint32` words) for each timer. Using 64 bits to store timing data would allow a model with a step size of 0.001 microsecond (10E-09 seconds) to run for more than 500 years, which would rarely be required. 64-bit counters do not violate the usual code generator length limitation of 32 bits because the value of a time counter does not provide the value of a signal, state, or parameter.

## Execution Profiling for Generated Code

Use code execution profiling to:

- Determine whether the generated code meets execution time requirements for real-time deployment on your target hardware.
- Identify code sections that require execution speed improvements.

The following tasks represent a general workflow that uses code execution profiling:

- 1 With the Simulink model, design and optimize your algorithm.
- 2 Configure the model for code execution profiling, and generate code.
- 3 Execute generated code on target. For example, you can:
  - Run a software-in-the-loop (SIL) simulation on your development computer.
  - Run a processor-in-the-loop (PIL) simulation using a target support package or custom PIL target.
  - Perform real-time execution with Simulink Real-Time or a target support package.
- 4 Analyze execution speed through code execution profiling plots and reports. For example, check that the algorithm code satisfies execution time requirements for real-time deployment:
  - If the algorithm code easily meets the requirements, consider enhancing your algorithm to exploit available processing power.
  - If the code cannot be executed in real time, look for ways to reduce execution time.

Identify the tasks that require the most time. For these tasks, investigate whether trade-offs between functionality and speed are possible.

If your target is a multicore processor, distribute the execution of algorithm code across available cores.

- 5 If required, refine the model and return to step 2.

To find information about code execution profiling with Simulink products, use the following table.

Target	Execution Feature	Type of Profiling	Relevant Products	See
Development computer	Model configured for concurrent execution	Execution time	Simulink Coder	<ul style="list-style-type: none"> <li>• “Optimize and Deploy on a Multicore Target”</li> </ul>

## Optimize Generated Code by Combining Multiple for Constructs

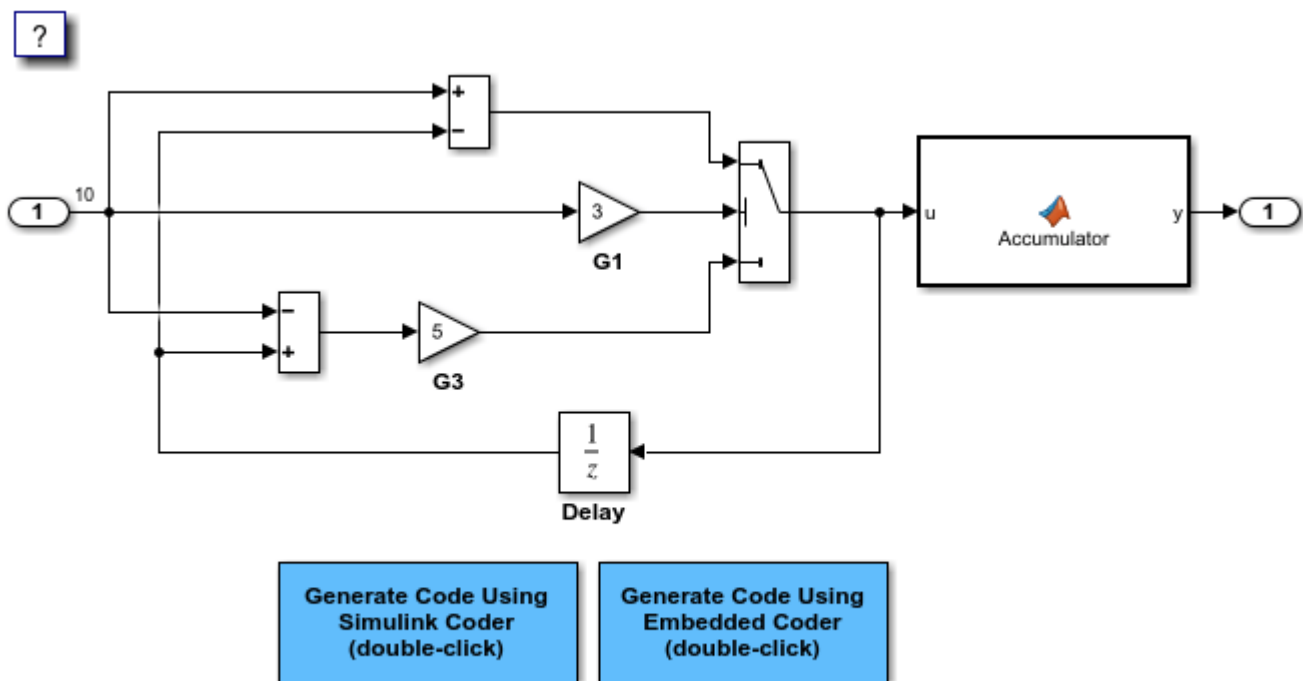

This example shows how the code generator combines for loops. The generated code uses for constructs to represent a variety of modeling patterns, such as a matrix signal or Iterator blocks. Using data dependency analysis, the code generator combines for constructs to reduce static code size and runtime branching.

The benefits of optimizing for loops are:

- Reducing ROM and RAM consumption.
- Increasing execution speed.

### for Loop Modeling Patterns

In the model, `rtwdemo_forloop`, the Switch block and MATLAB Function block represent for constructs. In the In1 Block Parameters dialog box, the **Port dimensions** parameter is set to 10 .

Copyright 1994-2020 The MathWorks, Inc.

### Generate Code

The model does not contain data dependencies across the for loop iterations. Therefore, the code generator combines for loops into one loop. Open the **Simulink Coder** or **Embedded Coder** app. Then, generate and view the code.

```
Starting build procedure for: rtwdemo_forloop
Successful completion of build procedure for: rtwdemo_forloop
```

## Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_forloop	Code generated and compiled	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 38.417s

The generated file, `rtwdemo_forloop.c`, contains the code for the single for loop.

```

/* Model step function */
void rtwdemo_forloop_step(void)
{
 int32_T k;

 /* MATLAB Function: '<Root>/Accum' */
 /* MATLAB Function 'Accum': '<S1>:1' */
 /* '<S1>:1:3' */
 /* '<S1>:1:4' */
 rtwdemo_forloop_Y.Out1 = 0.0;

 /* '<S1>:1:5' */
 for (k = 0; k < 10; k++) {
 /* Switch: '<Root>/Switch' incorporates:
 * Gain: '<Root>/G1'
 * Gain: '<Root>/G3'
 * Inport: '<Root>/In1'
 * Sum: '<Root>/Sum1'
 * Sum: '<Root>/Sum2'
 * UnitDelay: '<Root>/Delay'
 */
 if (3.0 * rtwdemo_forloop_U.In1[k] >= 0.0) {
 rtwdemo_forloop_DW.Delay_DSTATE[k] = rtwdemo_forloop_U.In1[k] -
 rtwdemo_forloop_DW.Delay_DSTATE[k];
 } else {
 rtwdemo_forloop_DW.Delay_DSTATE[k] = (rtwdemo_forloop_DW.Delay_DSTATE[k] -
 rtwdemo_forloop_U.In1[k]) * 5.0;
 }

 /* End of Switch: '<Root>/Switch' */

 /* MATLAB Function: '<Root>/Accum' */
 /* '<S1>:1:5' */
 /* '<S1>:1:6' */
 rtwdemo_forloop_Y.Out1 += ((real_T)k + 1.0) +
 rtwdemo_forloop_DW.Delay_DSTATE[k];
 }
}

```

Close the model.

## Subnormal Number Execution Speed

Subnormal numbers, formerly known as denormal numbers in floating-point literature, fill the underflow gap around zero in floating-point arithmetic. Subnormal values are a special category of floating-point values that are too close to  $0.0$  to be represented as a normalized value. The leading significand (mantissa) of a subnormal number is zero. When adding and subtracting floating-point numbers, subnormal numbers prevent underflow.

Using subnormal numbers provides precision beyond the normal representation by using leading zeros in the significand to represent smaller values after the representation reaches the minimum exponent. As the value approaches  $0.0$ , you trade off precision for extended range. Subnormal numbers are useful if your application requires extra range.

However, in a real-time system, using subnormal numbers can dramatically increase execution latency, resulting in excessive design margins and real-time overruns. If the simulation or generated code performs calculations that produce or consume subnormal numbers, the execution of these calculations can be up to 50 times slower than similar calculations on normal numbers. The actual simulation or code execution time for subnormal number calculations depends on your computer operating environment. Typically, for desktop processors, the execution time for subnormal number calculations is five times slower than similar calculations on normal numbers.

To minimize the possibility of execution slowdowns or overruns due to subnormal number calculation latency, do one of the following:

- In your model, manually flush to zero any incoming or computed subnormal values at inputs and key operations, such as washouts and filters. For an example, see “Flush Subnormal Numbers to Zero” on page 71-17.

To detect a subnormal value for a single precision, 32-bit floating-point number:

- 1 Find the smallest normalized number on a MATLAB host. In the Command Window, type:

```
>> SmallestNormalSingle = realmin('single')
```

In the C language, `FLT_MIN`, defined in `float.h`, is equivalent to `realmin('single')`.

- 2 Look for values in range:

$$0 < \text{fabsf}(x) < \text{SmallestNormalSingle}$$

To detect a subnormal value for a double precision, 64-bit floating-point number:

- 1 Find the smallest normalized number on a MATLAB host. In the Command Window, type:

```
>> SmallestNormalDouble = realmin('double')
```

In the C language, `DBL_MIN`, defined in `float.h`, is equivalent to `realmin('double')`.

- 2 To detect a subnormal value, look for values in this range:

$$0 < \text{fabs}(x) < \text{SmallestNormalDouble}$$

- Set the **Simulation behavior for denormal numbers** parameter to **Flush to zero (FTZ)** to emulate flush-to-zero behavior for all denormal results from arithmetic operations. For more information, see “Simulation behavior for denormal numbers”.
- On your processor, set flush-to-zero mode or, with your compiler, specify an option to disable subnormal numbers. Flush-to-zero modes treat a subnormal number as 0 when it is an input to a floating-point operation. Underflow exceptions do not occur in flush-to-zero mode.

For example, in Intel® processors, the flush-to-zero (FTZ) and denormals-are-zero (DAZ) flags in the MXCSR register control floating-point calculations. For the gcc compiler on Linux, `-ffast-math` sets abrupt underflow (FTZ), flush-to-zero, while `-O3 -ffast-math` reverts to gradual underflow, using subnormal numbers.

For more information, see the IEEE Standard 754, *IEEE Standard for Floating-Point Arithmetic*.

## Simulation Time With and Without Subnormal Numbers

This model shows how using subnormal numbers increases simulation time by ~5 times.

Open the model `ex_subnormal`. The Gain is set to subnormal value `realmin('double')/2`.

To run a simulation, in the Command Window, type for `k=1:5`, `tic; sim('ex_subnormal');` `toc,end`. Observe the elapsed times for simulation using subnormals, similar to the following:

```
>> for k=1:5, tic; sim('ex_subnormal'); toc,end
Elapsed time is 9.909326 seconds.
Elapsed time is 9.617966 seconds.
Elapsed time is 9.797183 seconds.
Elapsed time is 9.702397 seconds.
Elapsed time is 9.893946 seconds.
```

Set the Gain to a number, 2, that is not a subnormal value:

```
>> set_param('ex_subnormal/Gain', 'Gain', '2');
```

To run a simulation, in the Command Window, type for `k=1:5`, `tic; sim('ex_subnormal');` `toc,end`. Observe elapsed times for simulations that do not use subnormal values, similar to the following:

```
>> for k=1:5, tic; sim('ex_subnormal'); toc,end
Elapsed time is 2.045123 seconds.
Elapsed time is 1.796598 seconds.
Elapsed time is 1.758458 seconds.
Elapsed time is 1.721721 seconds.
Elapsed time is 1.780569 seconds.
```

## Flush Subnormal Numbers to Zero

This example shows how to flush single precision subnormal numbers to zero.

- 1 Open the model `ex_flush_to_zero`:

- Repeating Sequence Stair generates a sequence of numbers from two raised to the power of 0 through two raised to the power of -165. The sequence approaches zero.
- ConditionRealScalar flushes subnormal single precision values that are less than `realmin('single')` to zero.

- MATLAB function block `log2` generates the base 2 logarithm of the Repeating Sequence Stair output. Specifically, `log2` generates the numbers 0 through -165.
- 2 On the **Simulation > Step Back > Configure simulation stepping** pane:
    - Select **Enable stepping back**.
    - Select **Pause simulation when time reaches** and enter 121.
  - 3 In the model window, run the simulation. The simulation pauses at  $T=121$ . The displayed values:
    - ConditionRealScalar output approaches zero.
    - Repeating Sequence Stair output approaches zero.
  - 4 Step the simulation forward to  $T=127$ . ConditionRealScalar flushes the subnormal value output from Repeating Sequence Stair to zero.

- Continue stepping the simulation forward. `ConditionRealScalar` flushes the subnormal single precision values output from `Repeating Sequence Stair` to zero. When  $T=150$ , the output of `Repeating Sequence Stair` is itself zero.

## Remove Code for Out-of-Range Floating Point to Integer Conversions

This example shows how to generate optimized code by removing code for out-of-range floating point to integer conversions. Standard C does not define the behavior of out-of-range floating point to integer conversions, while these conversions are well-defined during simulation. When you select the configuration parameter **Remove code from floating-point to integer conversions that wraps out-of-range values**, the code generator removes the wrapping code that handles out-of-range floating point to integer conversion and improves code efficiency. Without this code, there might be a mismatch between simulation and code generation results for out-of range values.

If the input values in your application are in the range of the output type, remove code for out-of-range floating-point to integer conversions. Removing this code reduces the size and increases the speed of the generated code.

### Example Model

Open the example model `rtwdemo_float_mul_for_net_slope_correction`.

```
model = 'rtwdemo_float_mul_for_net_slope_correction';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

The model contains a Data Type Conversion block. To configure the model to convert the input signal from a `single` to a `uint8`, open the Data Type Conversion dialog box. For the **Output data type** parameter, select `uint8`. Alternatively, use this command-line API to set the **Output data type**:

```
set_param('rtwdemo_float_mul_for_net_slope_correction/Data Type Conversion', 'OutDataTypeStr', 'u8');
```

A `uint8` can support values from 0 to 255. If the input signal has a value outside of this range, an out-of-range conversion occurs.

### Generate Code Without Optimization

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

2. Open the Configuration Parameters dialog box. On the Optimization pane, clear the **Remove code from floating-point to integer conversions that wraps out-of-range values** parameter check box. Alternatively, use the command-line API to disable the optimization:

```
set_param(model, 'EfficientFloat2IntCast', 'off');
```

3. Build the model by using the `slbuild` function or by pressing **Ctrl+B**.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_float_mul_for_net_slope_correction
Successful completion of build procedure for: rtwdemo_float_mul_for_net_slope_correction
```

```
Build Summary
```

```
Top model targets built:
```

Model	Action	Rebuild Reason
rtwdemo_float_mul_for_net_slope_correction	Code generated and compiled	Code generation information

```
1 of 1 models built (0 models already up to date)
```

```
Build duration: 0h 0m 20.276s
```

4. Inspect the generated `rtwdemo_float_mul_for_net_slope_correction_step` step function in the `rtwdemo_float_mul_for_net_slope_correction.c`.

```
file = fullfile('rtwdemo_float_mul_for_net_slope_correction_ert_rtw','rtwdemo_float_mul_for_net_slope_correction_step');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function',1,1);
```

```
/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
 real32_T tmp;

 /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
 * Inport: '<Root>/Input'
 */
 tmp = (real32_T)fmod((real_T)(real32_T)floor((real_T)rtU.Input), 256.0);

 /* Outport: '<Root>/Output' incorporates:
 * DataTypeConversion: '<Root>/Data Type Conversion'
 */
 rtY.Output = (uint8_T)(tmp < 0.0F ? (int32_T)(uint8_T)(int32_T)-(int32_T)
 (int8_T)(uint8_T)-tmp : (int32_T)(uint8_T)tmp);
}
```

The code generator applies the `fmod` function to handle out-of-range-results. In this case, the generated code is larger but the results of the generated code match the simulation results.

### Generate Code With Optimization

1. Open the Configuration Parameters dialog box. On the Optimization pane, select the **Remove code from floating-point to integer conversions that wraps out-of-range values** parameter. Alternatively, use the command-line API to enable the optimization:

```
set_param(model, 'EfficientFloat2IntCast', 'on')
```

2. Build the model. Inspect the generated `rtwdemo_float_mul_for_net_slope_correction_step` step function with optimization in the `rtwdemo_float_mul_for_net_slope_correction.c`

```
slbuild(model);
file = fullfile('rtwdemo_float_mul_for_net_slope_correction_ert_rtw','rtwdemo_float_mul_for_net_slope_correction_step');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function',1,1);
```

```
Starting build procedure for: rtwdemo_float_mul_for_net_slope_correction
Successful completion of build procedure for: rtwdemo_float_mul_for_net_slope_correction
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_float_mul_for_net_slope_correction	Code generated and compiled	Generated code was out of

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 16.958s
```

```
/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
 /* Output: '<Root>/Output' incorporates:
 * DataTypeConversion: '<Root>/Data Type Conversion'
 * Inport: '<Root>/Input'
 */
 rtY.Output = (uint8_T)rtU.Input;
}
```

The generated code is more efficient without the protective code, but it is possible that the execution of the generated code does not produce the same results as simulation for values not in the range of 0 to 255.

### Clean Up Example Folders and Files

Close the model and remove temporary folders and files.

```
bdclose(model);
cd(currentDir);
rtwdemoclean;
```

### See Also

“Remove code from floating-point to integer conversions that wraps out-of-range values”

### Related Examples

- “hisl\_0053: Configuration Parameters > Code Generation > Optimization > Remove code from floating-point to integer conversions that wraps out-of-range values”
- “Optimize Generated Code with Code Efficiency Tools and Techniques” on page 71-7
- “Remove Code That Maps NaN to Integer Zero” on page 71-23

## Remove Code That Maps NaN to Integer Zero

This example shows how to remove code that maps NaN to integer zero. For floating point to integer conversions involving saturation, Simulink converts NaN to integer zero during simulation. If your model contains an input value of NaN, you can specify that the code generator produce code that maps NaN to zero. Without this code, there is a mismatch between simulation and code generation results because in Standard C, every condition involving NaN evaluates to false.

If input values of NaN do not exist in your application, you can remove code that maps NaN to integer zero. Removing this code reduces the size and increases the speed of the generated code.

### Example Model

Open the example model `rtwdemo_float_mul_for_net_slope_correction` by entering the model name in the Command Window.

Copyright 2014-2020 The MathWorks, Inc.

The model contains a Data Type Conversion block. Configure the model to convert the input signal from a `single` to a `uint8`.

1. Open the Data Type Conversion dialog box. For the **Output data type** parameter, select `uint8`.
2. Select the **Saturate on integer overflow** parameter check box. Selecting this parameter specifies that an out-of-range signal value equals either the minimum or maximum value that the data type can represent.
3. Open the Configuration Parameters dialog box. Select the **Support: non-finite numbers** parameter check box. Selecting this parameter enables generating nonfinite data and operations on nonfinite data.

### Generate Code Without Optimization

1. Create a temporary folder for the build and inspection process.
2. Open the Configuration Parameters dialog box. On the Optimization pane, clear the **Remove code from floating-point to integer conversions with saturation that maps NaN to zero** parameter check box.
3. Build the model.

```
Starting build procedure for: rtwdemo_float_mul_for_net_slope_correction
Successful completion of build procedure for: rtwdemo_float_mul_for_net_slope_correction
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_float_mul_for_net_slope_correction	Code generated and compiled	Code generation informa

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 19.99s

4. Inspect the generated `rtwdemo_float_mul_for_net_slope_correction_step` step function in the `rtwdemo_float_mul_for_net_slope_correction.c`.

```
/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
 /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
 * Inport: '<Root>/Input'
 */
 if (rtU.Input < 256.0F) {
 if (rtU.Input >= 0.0F) {
 /* Output: '<Root>/Output' */
 rtY.Output = (uint8_T)rtU.Input;
 } else {
 /* Output: '<Root>/Output' */
 rtY.Output = 0U;
 }
 } else if (rtU.Input >= 256.0F) {
 /* Output: '<Root>/Output' */
 rtY.Output = MAX_uint8_T;
 } else {
 /* Output: '<Root>/Output' */
 rtY.Output = 0U;
 }

 /* End of DataTypeConversion: '<Root>/Data Type Conversion' */
}
```

The code generator applies condition to map NaN to interger zero. In this case, the generated code is larger but the results of the generated code match with simulation results.

### Generate Code With Optimization

1. Open the Configuration Parameters dialog box.
2. On the Optimization pane, select the **Remove code from floating-point to integer conversions with saturation that maps NaN to zero** parameter.
3. Build the model.

```
Starting build procedure for: rtwdemo_float_mul_for_net_slope_correction
Successful completion of build procedure for: rtwdemo_float_mul_for_net_slope_correction

Build Summary

Top model targets built:
```

Model	Action	Rebuild Reason
rtwdemo_float_mul_for_net_slope_correction	Code generated and compiled	Generated code was out of date

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 18.741s

4. Inspect the generated `rtwdemo_float_mul_for_net_slope_correction_step` step function with optimization in the `rtwdemo_float_mul_for_net_slope_correction.c`.

```
/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
 /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
 * Inport: '<Root>/Input'
 */
 if (rtU.Input < 256.0F) {
 if (rtU.Input >= 0.0F) {
 /* Output: '<Root>/Output' */
 rtY.Output = (uint8_T)rtU.Input;
 } else {
 /* Output: '<Root>/Output' */
 rtY.Output = 0U;
 }
 } else {
 /* Output: '<Root>/Output' */
 rtY.Output = MAX_uint8_T;
 }

 /* End of DataTypeConversion: '<Root>/Data Type Conversion' */
}
```

The generated code maps NaN to 255 and not integer zero. The generated code is more efficient without the extra code that maps NaN to integer zero. But it is possible that the execution of generated code does not produce the same results as the simulation for NaN values.

## Disable Nonfinite Checks or Inlining for Math Functions

When the code generator produces code for math functions:

- If the model option **Support non-finite numbers** is selected, nonfinite number checking is generated uniformly for math functions, without the ability to specify that nonfinite number checking should be generated for some functions, but not for others.
- By default, inlining is applied uniformly for math functions, without the ability to specify that inlining should be generated for some functions, while invocations should be generated for others.

You can use code replacement library (CRL) customization entries to:

- Selectively disable nonfinite checks for math functions. This can improve the execution speed of the generated code.
- Selectively disable inlining of math functions. This can increase code readability and decrease code size.

The functions for which these customizations are supported include the following:

- Floating-point only: `atan2`, `copysign`, `fix`, `hypot`, `log`, `log10`, `round`, `sincos`, and `sqrt`
- Floating-point and integer: `abs`, `max`, `min`, `mod`, `rem`, `saturate`, and `sign`

The general workflow for disabling nonfinite number checking and/or inlining is as follows:

- 1 If you can disable nonfinite number checking for a particular math function, or if you want to disable inlining for a particular math function and instead generate a function invocation, you can copy the following MATLAB function code into a MATLAB file with an `.m` file name extension, for example, `crl_table_customization.m`.

```
function hTable = crl_table_customization

% Create an instance of the Code Replacement Library table for controlling
% function intrinsic inlining and nonfinite support

hTable = RTW.TflTable;

% Inline - true (if function needs to be inline)
% false (if function should not be inlined)
% SNF (support nonfinite) - ENABLE (if non-finite checking should be performed)
% DISABLE (if non-finite checking should NOT be performed)
% UNSPECIFIED (Default behavior)

% registerCustomizationEntry(hTable, ...
% Priority, numInputs, key, inType, outType, Inline, SNF);

registerCustomizationEntry(hTable, ...
 100, 1, 'copy sign', 'single', 'single', true, 'UNSPECIFIED');

```

- 2 To reduce the size of the file, you can delete the `registerCustomizationEntry` lines for functions for which the default nonfinite number checking and inlining behavior is acceptable.
- 3 For each remaining entry,
  - Set the `Inline` argument to `true` if the function should be inlined or `false` if it should not be inlined.
  - Set the `SNF` argument to `ENABLE` if nonfinite checking should be generated, `DISABLE` if nonfinite checking should not be generated, or `UNSPECIFIED` to accept the default behavior based on the model option settings.

Save the file.

- 4 Optionally, perform a quick check of the syntactic validity of the customization table entries by invoking the table definition file at the MATLAB command line (`>> tbl = crl_table_customization`). Fix syntax errors that are flagged.
- 5 Optionally, view the customization table entries in the **Code Replacement Viewer** (`>> crviewer(crl_table_customization)`). For more information about viewing code replacement tables, see “Choose a Code Replacement Library”.
- 6 To register these changes and make them appear in the **Code replacement library** drop-down list located on the **Code Generation > Interface** pane of the Configuration Parameters dialog box, first copy the following MATLAB function code into an instance of the file `rtwTargetInfo.m`.

---

**Note** For the example below, specify the argument 'RTW' if a GRT target is selected for your model, otherwise omit the argument.

---

```

function rtwTargetInfo(cm)
% rtwTargetInfo function to register a code replacement library (CRL)

 % Register the CRL defined in local function locCrlRegFcn
 cm.registerTargetInfo(@locCrlRegFcn);

end % End of RTWTARGETINFO

% Local function to define a CRL containing crl_table_customization
function thisCrl = locCrlRegFcn

 % Instantiate a CRL registry entry - specify 'RTW' for GRT
 thisCrl = RTW.TflRegistry('RTW');

 % Define the CRL properties
 thisCrl.Name = 'CRL Customization Example';
 thisCrl.Description = 'Example of CRL Customization';
 thisCrl.TableList = {'crl_table_customization'};
 thisCrl.TargetHWDeviceType = {'*'};

```

```
end % End of LOCCRLREGFCN
```

You can edit the **Name** field to specify the library name that appears in the **Code replacement library** drop-down list. Also, the file name in the **TableList** field must match the name of the file you created in step 1.

To register your changes, with both of the MATLAB files you created present in the MATLAB path, enter the following command at the MATLAB command line:

```
sl_refresh_customizations
```

- 7** Create or open a model that generates function code corresponding to one of the math functions for which you specified a change in nonfinite number checking or inlining behavior.
- 8** Open the Configuration Parameters dialog box, go to the **Code Generation > Interface** pane, and use the **Code replacement library** drop-down list to select the code replacement entry you registered in step 6, for example, **CRL Customization Example**.
- 9** Generate code for the model and examine the generated code to verify that the math functions are generated as expected.

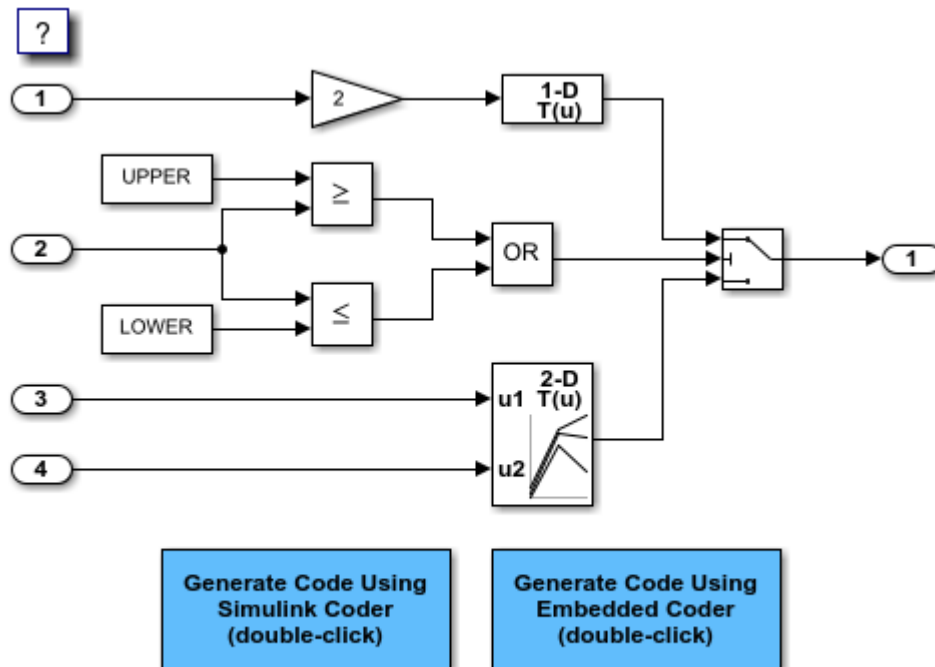

## Fold Expressions

Expression folding optimizes code to minimize the computation of intermediate results at block outputs and the storage of such results in temporary buffers or variables. When expression folding is on, the code generator collapses (folds) block computations into a single expression, instead of generating separate code statements and storage declarations for each block in a model. Most Simulink blocks support expression folding.

Expression folding improves the efficiency of generated code, frequently achieving results that compare favorably to hand-optimized code. In many cases, entire groups of model computations fold into a single, highly optimized line of code.

### Example Model

```
model = 'rtwdemo_slexprfold';
open_system(model);
```

Copyright 1994-2020 The MathWorks, Inc.

### Generate Code

Expression folding is available only when the **Signal storage reuse** parameter is set to on because expression folding operates only on expressions involving local variables. The **Signal storage reuse** and **Eliminate superfluous local variables (expression folding)** parameters are on by default. Clear the **Eliminate superfluous local variables (expression folding)** parameter or enter the following command in the MATLAB Command Window to turn the parameter off:

```
set_param(model, 'ExpressionFolding', 'off');
```

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_slexprfold
Successful completion of build procedure for: rtwdemo_slexprfold
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_slexprfold	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 28.924s

With expression folding off, in the `rtwdemo_slexprfold.c` file, there are separate code statements before and in the Switch block operation.

```
cfile = fullfile(cgDir,'rtwdemo_slexprfold_grt_rtw','rtwdemo_slexprfold.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_slexprfold_step(void)
{
 real_T rtb_Gain;
 boolean_T rtb_LogicalOperator;
 boolean_T rtb_RelationalOperator;

 /* RelationalOperator: '<Root>/Relational Operator1' incorporates:
 * Constant: '<Root>/Constant'
 * Inport: '<Root>/In2'
 */
 rtb_LogicalOperator = (rtwdemo_slexprfold_P.UPPER >= rtwdemo_slexprfold_U.In2);

 /* RelationalOperator: '<Root>/Relational Operator' incorporates:
 * Constant: '<Root>/Constant1'
 * Inport: '<Root>/In2'
 */
 rtb_RelationalOperator = (rtwdemo_slexprfold_U.In2 <=
 rtwdemo_slexprfold_P.LOWER);

 /* Logic: '<Root>/Logical Operator' */
 rtb_LogicalOperator = (rtb_LogicalOperator || rtb_RelationalOperator);

 /* Switch: '<Root>/Switch' */
 if (rtb_LogicalOperator) {
 /* Gain: '<Root>/Gain' incorporates:
 * Inport: '<Root>/In1'
 */
 rtb_Gain = 2.0 * rtwdemo_slexprfold_U.In1;
 }
}
```

```

 /* Lookup_n-D: '<Root>/Look-Up Table' incorporates:
 * Gain: '<Root>/Gain'
 */
 rtwdemo_slexprfold_Y.Out1 = look1_binlx(rtb_Gain,
 rtwdemo_slexprfold_P.T1Break, rtwdemo_slexprfold_P.T1Data, 10U);
} else {
 /* Lookup_n-D: '<Root>/Look-Up Table' incorporates:
 * Inport: '<Root>/In3'

 * Lookup_n-D: '<Root>/Look-Up Table (2-D)'
 */
 rtwdemo_slexprfold_Y.Out1 = look2_binlx(rtwdemo_slexprfold_U.In3,
 rtwdemo_slexprfold_U.In4, rtwdemo_slexprfold_P.T2Break,
 rtwdemo_slexprfold_P.T2Break, rtwdemo_slexprfold_P.T2Data,
 rtCP_LookUpTable2D_maxIndex, 3U);
}

/* End of Switch: '<Root>/Switch' */
}

```

### Generate Code with Optimization

Enter the following command to turn expression folding on:

```
set_param(model, 'ExpressionFolding', 'on');
```

Build the model.

```
slbuild(model);
```

```
Starting build procedure for: rtwdemo_slexprfold
Successful completion of build procedure for: rtwdemo_slexprfold
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_slexprfold	Code generated and compiled	Generated code was out of date.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 25.953s
```

The following is a portion of rtwdemo\_slexprfold.c. In the optimized code, the code generator folds all computations into the Switch block operation.

```
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);
```

```

/* Model step function */
void rtwdemo_slexprfold_step(void)
{
 /* Switch: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant'
 * Constant: '<Root>/Constant1'
 * Inport: '<Root>/In2'
 * Logic: '<Root>/Logical Operator'
 * RelationalOperator: '<Root>/Relational Operator'

```

```
* RelationalOperator: '<Root>/Relational Operator1'
*/
if ((rtwdemo_slexprfold_P.UPPER >= rtwdemo_slexprfold_U.In2) ||
 (rtwdemo_slexprfold_U.In2 <= rtwdemo_slexprfold_P.LOWER)) {
/* Output: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 * Inport: '<Root>/In1'
 * Lookup_n-D: '<Root>/Look-Up Table'
 */
rtwdemo_slexprfold_Y.Out1 = look1_binlx(2.0 * rtwdemo_slexprfold_U.In1,
 rtwdemo_slexprfold_P.T1Break, rtwdemo_slexprfold_P.T1Data, 10U);
} else {
/* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In3'
 * Inport: '<Root>/In4'
 * Lookup_n-D: '<Root>/Look-Up Table (2-D)'
 */
rtwdemo_slexprfold_Y.Out1 = look2_binlx(rtwdemo_slexprfold_U.In3,
 rtwdemo_slexprfold_U.In4, rtwdemo_slexprfold_P.T2Break,
 rtwdemo_slexprfold_P.T2Break, rtwdemo_slexprfold_P.T2Data,
 rtCP_LookUpTable2D_maxIndex, 3U);
}

/* End of Switch: '<Root>/Switch' */
}
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Minimize Computations and Storage for Intermediate Results at Block Outputs

### Expression Folding

*Expression folding* optimizes code to minimize the computation of intermediate results at block outputs and the storage of such results in temporary buffers or variables. When expression folding is on, the code generator collapses (folds) block computations into a single expression, instead of generating separate code statements and storage declarations for each block in the model. Most Simulink blocks support expression folding.

Expression folding improves the efficiency of generated code, frequently achieving results that compare favorably to hand-optimized code. In many cases, entire groups of model computations fold into a single, highly optimized line of code.

You can use expression folding in your own inlined S-function blocks. For more information, see “S-Functions That Support Expression Folding”.

### Example Model

### Generate Code

With expression folding off, in the `explfld.c` file, the code generator generates this code.

```

/* Model step function */
void exprfld_step(void)
{
 /* Gain: '<Root>/Gain' incorporates:
 * Inport: '<Root>/In1'
 */
 exprfld_B.S1 = exprfld_P.Gain_Gain * exprfld_U.i1;

```

```

/* Gain: '<Root>/Gain1' incorporates:
 * Inport: '<Root>/In2'
 */
exprfld_B.S2 = exprfld_P.Gain1_Gain * exprfld_U.i2;

/* Output: '<Root>/Out1' incorporates:
 * Product: '<Root>/Product'
 */
exprfld_Y.Out1 = exprfld_B.S1 * exprfld_B.S2;
}

```

There are separate code statements for both Gain blocks. Before final output, these code statements compute temporary results for the Gain blocks.

## Enable Optimization

Expression folding is on by default. To see if expression folding is on for an existing model:

- 1 Expression folding is available only when the **Configuration Parameters > Signal storage reuse** parameter is selected because expression folding operates only on expressions involving local variables. Enable the **Signal storage reuse** parameter.
- 2 When you select **Signal storage reuse**, the **Enable local block outputs**, **Reuse local block outputs**, and **Eliminate superfluous local variables (expression folding)** parameters are all on by default.

## Generate Code with Optimization

With expression folding, the code generator generates a single-line output computation, as shown in the `expfld.c` file. The generated comments document the block parameters that appear in the expression.

```

/* Model step function */
void exprfld_step(void)
{
/* Output: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 * Gain: '<Root>/Gain1'
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 * Product: '<Root>/Product'
 */
exprfld_Y.Out1 =
 exprfld_P.Gain_Gain *
 exprfld_U.i1 *
 (exprfld_P.Gain1_Gain * exprfld_U.i2);
}

```

For an example of expression folding in the context of a more complex model, click `rtwdemo_slexprfold`, or at the command prompt, type:

```
rtwdemo_slexprfold
```

For more information, see “Enable and Reuse Local Block Outputs in Generated Code”

- “C Code Generation Configuration for Model Interface Elements” on page 32-2

## Inline Invariant Signals

You can optimize the generated code by selecting **Inline invariant signals** on the **Optimization** pane. The generated code uses the numerical values of the invariant signals instead of their symbolic names.

An invariant signal is a block output signal that does not change during Simulink simulation. For example, the signal S3 is an invariant signal. An *invariant signal* is not the same as an *invariant constant*. The two constants (1 and 2) and the gain value of 3 are invariant constants. To inline invariant constants, set **Default parameter behavior** to **Inlined**.

## Optimize Generated Code Using Inline Invariant Signals

This example shows how to use inline invariant signals to optimize the generated code. This optimization transforms symbolic names of invariant signals into constant values.

The `InlineInvariantSignals` optimization:

- Reduces ROM and RAM consumption.
- Improves execution speed.

### Example Model

Consider the model `rtwdemo_inline_invariant_signals`.

```
model = 'rtwdemo_inline_invariant_signals';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

### Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model using Simulink Coder.

```
slbuild(model)

Starting build procedure for: rtwdemo_inline_invariant_signals
Successful completion of build procedure for: rtwdemo_inline_invariant_signals
```

Build Summary

{
 /* Product: '<S1>/Product' */
 localB->Product = rtu_In1 * localC->Sum_p;
}
```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, select **Inline Invariant Signals**.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model, 'InlineInvariantSignals', 'on');
```

### Generate Code with Optimization

The generated code uses the numerical values of the folded constants instead of creating an additional structure (`rtwdemo_inline_invariant_ConstB`).

Build the model using Simulink Coder.

```
slbuild(model)

Starting build procedure for: rtwdemo_inline_invariant_signals
Successful completion of build procedure for: rtwdemo_inline_invariant_signals
```

### Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_inline_invariant_signals	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 26.628s

View the generated code with the optimization. These lines of code are in `rtwdemo_minmax.c`.

```
rtwdemodbtype(cfile,...
 /* Output and update for atomic system', /* Model output', 1, 0);

/* Output and update for atomic system: '<Root>/InlinedConstFcn' */
void rtwdemo_inline__InlinedConstFcn(int32_T rtu_In1,
 B_InlinedConstFcn_rtwdemo_inl_T *localB)
{
 /* Product: '<S1>/Product' */
 localB->Product = rtu_In1 << 5;
}
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Inline Numeric Values of Block Parameters

This example shows how to optimize the generated code by inlining the numeric values of block parameters. *Block parameters* include the **Gain** parameter of a Gain block and the table data and breakpoint sets of an n-D Lookup Table block.

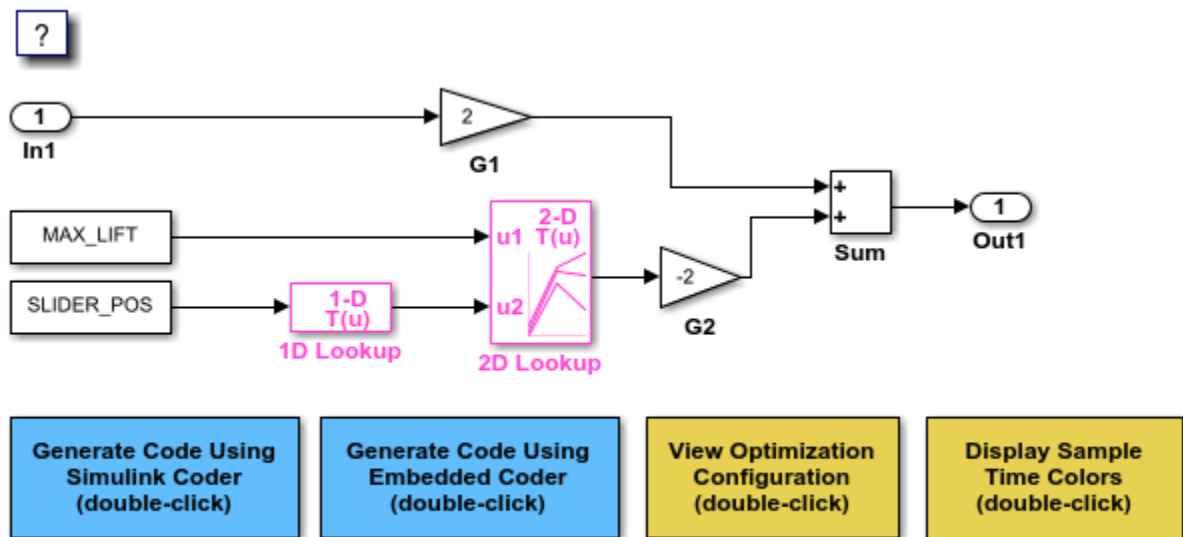

This optimization determines whether numeric block parameters occupy global memory in the generated code. The optimization can:

- Improve execution speed.
- Reduce RAM and ROM consumption.

### Explore Example Model

Open the example model `rtwdemo_paraminline` and configure it to show the generated names of blocks.

```
load_system('rtwdemo_paraminline')
set_param('rtwdemo_paraminline','HideAutomaticNames','off')
open_system('rtwdemo_paraminline')
```

Copyright 1994-2020 The MathWorks, Inc.

The model contains blocks that have these numeric parameters:

- The **Gain** parameters of the Gain blocks
- The **Constant value** parameters of the Constant blocks
- The table data and breakpoint sets of the n-D Lookup Table blocks

The output of the block G2, and the outputs of blocks upstream of G2, change only if you tune the values of the block parameters during simulation or during code execution. When you update the model diagram, these blocks and signal lines appear magenta in color.

Several blocks use `Simulink.Parameter` objects in the base workspace to set the values of their parameters. The parameter objects all use the storage class `Auto`, which means that you can configure the generated code to inline the parameter values.

### Generate Code Without Optimization

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Disable the optimization by setting **Configuration Parameters > Default parameter behavior** to `Tunable`.

```
set_param('rtwdemo_paraminline','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```
slbuild('rtwdemo_paraminline')
```

```
Starting build procedure for: rtwdemo_paraminline
Successful completion of build procedure for: rtwdemo_paraminline
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_paraminline	Code generated and compiled	Code generation information file does not exist

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 21.88s
```

In the code generation report, view the source file `rtwdemo_paraminline_data.c`. The code defines a global structure that contains the block parameter values. Each block parameter in the model, such as a lookup table array, breakpoint set, or gain, appears as a field of the structure.

```
cfile = fullfile(...
 cgDir,'rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline_data.c');
rtwdemodbtype(cfile,'/* Block parameters (default storage) */', '}', 1, 1);
```

```
/* Block parameters (default storage) */
P_rtwdemo_paraminline_T rtwdemo_paraminline_P = {
 /* Variable: MAX_LIFT
 * Referenced by: '<Root>/Constant'
 */
 10.0,

 /* Variable: SLIDER_POS
 * Referenced by: '<Root>/Constant1'
 */
 0.0,

 /* Variable: T1Break
 * Referenced by: '<Root>/1D Lookup'
 */
```

```

{ -5.0, -4.0, -3.0, -2.0, -1.0, 0.0, 1.0, 2.0, 3.0, 4.0, 5.0 },

/* Variable: T1Data
 * Referenced by: '<Root>/1D Lookup'
 */
{ -1.0, -0.99, -0.98, -0.96, -0.76, 0.0, 0.76, 0.96, 0.98, 0.99, 1.0 },

/* Variable: T2Break
 * Referenced by: '<Root>/2D Lookup'
 */
{ 1.0, 2.0, 3.0 },

/* Variable: T2Data
 * Referenced by: '<Root>/2D Lookup'
 */
{ 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 },

/* Expression: 2
 * Referenced by: '<Root>/G1'
 */
2.0,

/* Expression: -2
 * Referenced by: '<Root>/G2'
 */
-2.0,

/* Computed Parameter: uDLookup_maxIndex
 * Referenced by: '<Root>/2D Lookup'
 */
{ 2U, 2U }
};

```

You can tune the structure fields during code execution because they occupy global memory. However, at each step of the generated algorithm, the code must calculate the output of each block, including the outputs of the block G2 and the upstream blocks. View the algorithm in the model step function in the file `rtwdemo_paraminline.c`.

```

cfile = fullfile(cgDir, 'rtwdemo_paraminline_grt_rtw', 'rtwdemo_paraminline.c');
rtwdemodbtype(...
 cfile, /* Model step function */, /* Model initialize function */, 1, 0);

/* Model step function */
void rtwdemo_paraminline_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant'
 * Constant: '<Root>/Constant1'
 * Gain: '<Root>/G1'
 * Gain: '<Root>/G2'
 * Inport: '<Root>/In1'
 * Lookup_n-D: '<Root>/1D Lookup'
 * Lookup_n-D: '<Root>/2D Lookup'
 * Sum: '<Root>/Sum'
 */
 rtwdemo_paraminline_Y.Out1 = rtwdemo_paraminline_P.G1_Gain *
 rtwdemo_paraminline_U.In1 + rtwdemo_paraminline_P.G2_Gain * look2_binlx

```

```

 (rtwdemo_paraminline_P.MAX_LIFT, look1_binlx
 (rtwdemo_paraminline_P.SLIDER_POS, rtwdemo_paraminline_P.T1Break,
 rtwdemo_paraminline_P.T1Data, 10U), rtwdemo_paraminline_P.T2Break,
 rtwdemo_paraminline_P.T2Break, rtwdemo_paraminline_P.T2Data,
 rtwdemo_paraminline_P.udLookup_maxIndex, 3U);
}

```

### Generate Code with Optimization

Set **Default parameter behavior** to Inlined.

```
set_param('rtwdemo_paraminline','DefaultParameterBehavior','Inlined')
```

Generate code from the model.

```
slbuild('rtwdemo_paraminline')
```

```
Starting build procedure for: rtwdemo_paraminline
Successful completion of build procedure for: rtwdemo_paraminline
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_paraminline	Code generated and compiled	Global variable MAX_LIFT has changed.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 17.579s

In the code generation report, view the algorithm in the file `rtwdemo_paraminline.c`.

```

rtwdemodbtype(...
 cfile, /* Model step function */, /* Model initialize function */, 1, 0);

/* Model step function */
void rtwdemo_paraminline_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Gain: '<Root>/G1'
 * Inport: '<Root>/In1'
 * Sum: '<Root>/Sum'
 */
 rtwdemo_paraminline_Y.Out1 = 2.0 * rtwdemo_paraminline_U.In1 + 150.0;
}

```

The code does not allocate memory for block parameters or for parameter objects that use the storage class `Auto`. Instead, the code generator uses the parameter values from the model, and from the parameter objects, to calculate and inline the constant output of the block `G2`, `150.0`. The generator also inlines the value of the **Gain** parameter of the Gain block `G1`, `2.0`.

With the optimization, the generated code leaves out computationally expensive algorithmic code for blocks such as the lookup tables. The optimized code calculates the output of a block only if the output can change during execution. For this model, only the outputs of the Inport block `In1`, the Gain block `G1`, and the Sum block can change.

Close the model and the code generation report.

```
bdclose('rtwdemo_paraminline')
rtwdemoclean;
cd(currentDir)
```

### Preserve Block Parameter Tunability

When you set **Default parameter behavior** to `Inlined`, you can preserve block parameter tunability by creating `Simulink.Parameter` objects for individual parameters. You can configure each object to appear in the code as a tunable field of the global parameter structure or as an individual global variable. You can change parameter values during code execution and interface the generated code with your own handwritten code. For more information, see “Create Tunable Calibration Parameter in the Generated Code”.

### Inline Invariant Signals

You can select the **Inline invariant signals** code generation option (which also places constant values in the generated code) only when you set **Default parameter behavior** to `Inlined`. See “Inline Invariant Signals”.

### See Also

“Default parameter behavior”

- “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49

## Configure Loop Unrolling Threshold

The **Loop unrolling threshold** parameter on the **Optimization** pane determines when a wide signal or parameter should be wrapped into a `for` loop and when it should be generated as a separate statement for each element of the signal. The default threshold value is 5.

For example, consider the model below:

The gain parameter of the Gain block is the vector `myGainVec`.

Assume that the loop unrolling threshold value is set to the default, 5.

If `myGainVec` is declared as

```
myGainVec = [1:10];
```

an array of 10 elements, `myGainVec_P.Gain_Gain[]`, is declared within the `Parameters_model` data structure. The size of the gain array exceeds the loop unrolling threshold. Therefore, the code generated for the Gain block iterates over the array in a `for` loop, as shown in the following code:

```
{
 int32_T i1;

 /* Gain: '<Root>/Gain' */
 for(i1=0; i1<10; i1++) {
 myGainVec_B.Gain_f[i1] = rtb_foo *
 myGainVec_P.Gain_Gain[i1];
 }
}
```

If `myGainVec` is declared as

```
myGainVec = [1:3];
```

an array of three elements, `myGainVec_P.Gain_Gain[]`, is declared within the `Parameters` data structure. The size of the gain array is below the loop unrolling threshold. The generated code consists of inline references to each element of the array, as in the code below.

```
/* Gain: '<Root>/Gain' */
myGainVec_B.Gain_f[0] = rtb_foo * myGainVec_P.Gain_Gain[0];
myGainVec_B.Gain_f[1] = rtb_foo * myGainVec_P.Gain_Gain[1];
myGainVec_B.Gain_f[2] = rtb_foo * myGainVec_P.Gain_Gain[2];
```

See “Explore Variable Names and Loop Rolling” for more information on loop rolling.

---

**Note** When a model includes Stateflow charts or MATLAB Function blocks, you can apply a set of Stateflow optimizations on the **Optimization** pane. The settings you select for the Stateflow options also apply to MATLAB Function blocks in the model. This is because the MATLAB Function blocks and Stateflow charts are built on top of the same technology and share a code base. You do not need a Stateflow license to use MATLAB Function blocks.

---

**Note** If your MATLAB Function block contains code with two nested `for`-loops:

- If the number of iterations of the inner loop is less than the threshold, the code generator first unrolls the inner loop. Subsequently, if the product of the number of iterations of the two loops is also less than the threshold, the code generator unrolls the outer loop. Otherwise the code generator produces the outer `for`-loop.
  - If the number of iterations of the inner loop is equal to or greater than the threshold, the code generator produces both `for`-loops
  - For an N-Dimensional array the code generator unrolls each contiguous loop until the product of loop iterations is less than the threshold value.
-

## Use memcpy Function to Optimize Generated Code for Vector Assignments

### In this section...

“Example Model” on page 71-48

“Generate Code” on page 71-49

“Generate Code with Optimization” on page 71-50

You can use the **Use memcpy for vector assignment** parameter to optimize generated code for vector assignments by replacing `for` loops with `memcpy` function calls. The `memcpy` function is more efficient than `for`-loop controlled element assignment for large data sets. This optimization improves execution speed.

Selecting the **Use memcpy for vector assignment** parameter enables the associated parameter **Memcpy threshold (bytes)**, which allows you to specify the minimum array size in bytes for which `memcpy` function calls should replace `for` loops in the generated code. For more information, see “Use memcpy for vector assignment” and “Memcpy threshold (bytes)”. In considering whether to use this optimization,

- Verify that your target supports the `memcpy` function.
- Determine whether your model uses signal vector assignments (such as `Y=expression`) to move large amounts of data, for example, using the Selector block.

To apply this optimization,

- 1 Consider first generating code without this optimization and measuring its execution speed, to establish a baseline for evaluating the optimized assignment.
- 2 Select **Use memcpy for vector assignment** and examine the setting of **Memcpy threshold (bytes)**, which by default specifies 64 bytes as the minimum array size for which `memcpy` function calls replace `for` loops. Based on the array sizes used in your application's signal vector assignments, and target environment considerations that might bear on the threshold selection, accept the default or specify another array size.
- 3 Generate code, and measure its execution speed against your baseline or previous iterations. Iterate on steps 2 and 3 until you achieve an optimal result.

---

**Note** The `memcpy` optimization may not occur under certain conditions, including when other optimizations have a higher precedence than the `memcpy` optimization, or when the generated code is originating from Target Language Compiler (TLC) code, such as a TLC file associated with an S-function block.

---

---

**Note** If you are licensed for Embedded Coder software, you can use a code replacement library (CRL) to provide your own custom implementation of the `memcpy` function to be used in generated model code. For more information, see “Memory Function Code Replacement” on page 69-78.

---

### Example Model

To examine the result of using the **Use memcpy for vector assignment** parameter on the generated vector assignment code, create a model that generates signal vector assignments. For example,

- 1 Use In, Out, and Selector blocks to create the following model.

- 2 Open Model Explorer and configure the **Signal Attributes** for the In1 and In2 source blocks. For each, set **Port dimensions** to [1, 100], and set **Data type** to int32. Apply the changes and save the model. In this example, the model has the name vectorassign.
- 3 For each Selector block, set the **Index** parameter to 1:50. Set the **Input port size** parameter to 100.

## Generate Code

- 1 The **Use memcpy for vector assignment** parameter is on by default. To turn off the parameter, go to the **Optimization** pane and clear the **Use memcpy for vector assignment** parameter.
- 2 Go to the **Code Generation > Report** pane of the Configuration Parameters dialog box and select the **Create code generation report** parameter and the **Open report automatically** parameter. Then go to the **Code Generation** pane, select the **Generate code only** option, and generate code for the model. When code generation completes, the HTML code generation report is displayed.
- 3 In the HTML code generation report, click the `vectorassign.c` section and inspect the model step function. Notice that the vector assignments are implemented using for loops.

```

/* Model step function */
void vectorassign_step(void)
{
 int32_T i;
 for (i = 0; i < 50; i++) {
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 */
 vectorassign_Y.Out1[i] = vectorassign_U.In1[i];

 /* Output: '<Root>/Out2' incorporates:
 * Inport: '<Root>/In2'
 */
 vectorassign_Y.Out2[i] = vectorassign_U.In2[i];
 }
}

```

## Generate Code with Optimization

- 1 Go to the **Optimization** pane of the Configuration Parameters dialog box and select the **Use memcpy for vector assignment** option. Leave the **Memcpy threshold (bytes)** option at its default setting of 64. Apply the changes and regenerate code for the model. When code generation completes, the HTML code generation report again is displayed.
- 2 In the HTML code generation report, click the `vectorassign.c` section and inspect the model output function. Notice that the vector assignments now are implemented using `memcpy` function calls.

```
/* Model step function */
void vectorassign_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 */
 memcpy(&vectorassign_Y.Out1[0], &vectorassign_U.In1[0], 50U * sizeof(real_T));

 /* Output: '<Root>/Out2' incorporates:
 * Inport: '<Root>/In2'
 */
 memcpy(&vectorassign_Y.Out2[0], &vectorassign_U.In2[0], 50U * sizeof(real_T));
}
```

## See Also

“Use memcpy for vector assignment”

## Generate Target Optimizations Within Algorithm Code

Some application components are hardware-specific and cannot simulate on a host system. For example, consider a component that includes pragmas and assembly code for enabling hardware instructions for saturate on add operations or a Fast Fourier Transform (FFT) function.

The following table lists integration options to customize generated algorithm code with target-specific optimizations.

---

**Note** Solutions marked with *EC only* require an Embedded Coder license.

---

If...	Then...	For More Information, See
You want to optimize the execution speed and memory of the model code by replacing default math functions and operators with target-specific code	<i>EC only</i> —Implement function and operator replacements by using the <b>Code Replacement Tool</b> , code replacement library (CRL) API, and <b>Code Replacement Viewer</b> to create, examine, validate, and register hardware-specific replacement tables	“Optimize Generated Code by Developing and Using Code Replacement Libraries - Simulink” on page 74-30
You want to control how code generation technology declares, stores, and represents signals, tunable parameters, block states, and data objects in generated code	<i>EC only</i> —Design (create) and apply custom storage classes	<ul style="list-style-type: none"> <li>• rtwdemo_cscpredef</li> <li>• rtwdemo_importstruct</li> <li>• rtwdemo_configinterface</li> <li>• “Organize Parameter Data into a Structure by Using Struct Storage Class” on page 32-67</li> </ul>

---

**Note** To simulate an algorithm that includes target-specific elements in a host environment, you must create code that is equivalent to the target code and can run in the host environment.

---

## Remove Code for Blocks That Have No Effect on Computational Results

This example shows how the code generator optimizes generated code by removing code that has no effect on computational results. This optimization:

- Increases execution speed.
- Reduces ROM consumption.

### Example

In the model `rtwdemo_blockreduction`, a Gain block of value `1.0` is in between Inport and Outport blocks.

```
model = 'rtwdemo_blockreduction';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

### Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir=pwd;
[~,cgDir]=rtwdemodir();
```

Build the model.

```
set_param(model, 'BlockReduction', 'off');
slbuild(model)
```

```
Starting build procedure for: rtwdemo_blockreduction
Successful completion of build procedure for: rtwdemo_blockreduction
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_blockreduction	Code generated and compiled	Code generation information file does not exist

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 35.906s
```

This code is the code from `rtwdemo_blockreduction.c`.

```

cfile = fullfile(cgDir,'rtwdemo_blockreduction_ert_rtw','rtwdemo_blockreduction.c');
rtwdemodbtype(cfile, '/* Model step function */',...
 '/* Model initialize function */', 1, 0);

/* Model step function */
void rtwdemo_blockreduction_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 * Inport: '<Root>/In1'
 */
 rtwdemo_blockreduction_Y.Out1 = 1.0 * rtwdemo_blockreduction_U.In1;
}

```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 If the **Block reduction** check box is not selected, select it.

Alternatively, use the command-line API to enable the optimization.

```
set_param(model, 'BlockReduction', 'on');
```

### Generate Code with Optimization

```
slbuild(model)
```

```

Starting build procedure for: rtwdemo_blockreduction
Successful completion of build procedure for: rtwdemo_blockreduction

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_blockreduction	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 48.758s

Here is the optimized code from `rtwdemo_blockreduction.c`.

```

cfile = fullfile(cgDir,'rtwdemo_blockreduction_ert_rtw','rtwdemo_blockreduction.c');
rtwdemodbtype(cfile, '/* Model step function */',...
 '/* Model initialize function */', 1, 0);

/* Model step function */
void rtwdemo_blockreduction_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 */
 rtwdemo_blockreduction_Y.Out1 = rtwdemo_blockreduction_U.In1;
}

```

Because multiplying the input signal by a value of 1.0 does not impact computational results, the code generator excludes the Gain block from the generated code. Close the model and clean up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

### Limitations

The code generator cannot remove blocks under these circumstances:

- The block output is configured as a test point or has a storage class and the block input and output have different data types, complexities, or widths.
- The block has a nonconstant sample time, has an output connected to a root output, and has a source that has a constant sample time.
- The block has multiple sources, some of which have constant sample times and some of which have nonconstant sample times.
- The block output has a storage class and has a source that is muxed, is a virtual bus, is connected to a root output, is configured as a test point, or has a storage class.
- The block has an output that is connected to the block input.
- The block is inside an Initialize Function subsystem, Reset Function subsystem, or Terminate Function subsystem whose output is connected to an output of the subsystem.
- The block has an output that is connected to a Subsystem Output block that has an initial condition.
- The block has an output that is connected to an output of an Initialize Function subsystem, Reset Function subsystem, or Terminate Function subsystem.
- The block has an output that is connected to an output for which the parameter **Ensure output is virtual** is selected.
- The block has an output that is connected to an output that has an initial condition parameter.
- The block has an output that is connected to a Merge, a Vector Concatenate, or a Matrix Concatenate block.
- The block has tunable run-time parameters.
- The block is inside a reusable subsystem whose output is connected to a block outside the reusable subsystem.
- The block has a continuous state.
- The block has a discrete state and the states are logged or have a nonauto storage class.
- The block is an S-Function, unless you use `ssSetBlockReduction` to enable block reduction.
- The block output is configured as a test point or has a storage class and its source is a block inside a different conditional subsystem.

## Eliminate Dead Code Paths in Generated Code

This example shows how the code generator eliminates dead (that is, unused) code paths from generated code. This optimization increases execution speed and conserves ROM and RAM consumption.

### Example

In the model `rtwdemo_deadpathElim`, the signal leaving the Sum block divides into two separate code paths. The top path is not a dead code path. If the user disables the Assertion block, the bottom path becomes a dead code path.

```
model = 'rtwdemo_deadpathElim';
open_system(model);
```

Copyright 2019-2020 The MathWorks, Inc.

### Generate Code with an Enabled Assertion Block

- 1 For the Assertion block, open the block parameters dialog box.
- 2 Select the **Enable assertion** box. Alternatively, use the command-line API to enable the Assertion block.

```
set_param(['/Assert1'], 'Enabled', 'on');
```

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_deadpathElim
Successful completion of build procedure for: rtwdemo_deadpathElim
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
=====		

```
rtwdemo_deadpathElim Code generated and compiled Code generation information file does not exist
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 25.879s
```

Because the Assertion block is enabled, these lines of `rtwdemo_deadpathElim.c` include code for the Gain and Assertion blocks.

```
cfile = fullfile(cgDir, 'rtwdemo_deadpathElim_grt_rtw', 'rtwdemo_deadpathElim.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize function */', 0, 1);

void rtwdemo_deadpathElim_step(void)
{
 /* Sum: '<Root>/Sum1' incorporates:
 * Constant: '<Root>/Constant1'
 * Inport: '<Root>/In1'
 */
 rtwdemo_deadpathElim_Y.Out1 = rtwdemo_deadpathElim_U.In1 + 1.0;

 /* Assertion: '<Root>/Assert1' incorporates:
 * Gain: '<Root>/G1'
 */
 utAssert(2.0 * rtwdemo_deadpathElim_Y.Out1 != 0.0);
}
```

### Generate Code with a Disabled Assertion Block

Disable the Assertion block to generate a dead code path. The code generator detects the dead code path and eliminates it from the generated code.

- 1 For the Assertion block, open the Block Parameters dialog box.
- 2 Deselect the **Enable assertion** box.

Alternatively, use the command-line API to disable the Assertion block.

```
set_param([model '/Assert1'], 'Enabled', 'off');
```

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_deadpathElim
Successful completion of build procedure for: rtwdemo_deadpathElim
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_deadpathElim	Code generated and compiled	Generated code was out of date.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 19.523s
```

Because the Assertion block is disabled, these lines of `rtwdemo_deadpathElim.c` do not include code for the Gain and Assertion blocks.

```
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize function */', 0, 1);

void rtwdemo_deadpathElim_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant1'
 * Inport: '<Root>/In1'
 * Sum: '<Root>/Sum1'
 */
 rtwdemo_deadpathElim_Y.Out1 = rtwdemo_deadpathElim_U.In1 + 1.0;
}
```

**Close the model and clean-up.**

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

For another example of how the code generator eliminates dead code paths in the generated code, see `rtwdemo_deadpath`.

## Floating-Point Multiplication to Handle a Net Slope Correction

This example shows how to use floating-point multiplication to handle a net slope correction. When converting floating-point data types to fixed-point data types in the generated code, a net slope correction is one method of scaling fixed-point data types. Scaling the fixed-point data types avoids overflow conditions and minimizes quantization errors.

For processors that support efficient multiplication, using floating-point multiplication to handle a net slope correction improves code efficiency. If the net slope correction has a value that is not a power of two, using division improves precision.

**Note:** This example requires a Fixed-Point Designer™ license.

### Example

In the model `rtwdemo_float_mul_for_net_slope_correction`, a Convert block converts an input signal from a floating-point data type to a fixed-point data type. The net slope correction has a value of 3.

```
model = 'rtwdemo_float_mul_for_net_slope_correction';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

### Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_float_mul_for_net_slope_correction
Successful completion of build procedure for: rtwdemo_float_mul_for_net_slope_correction
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_float_mul_for_net_slope_correction	Code generated and compiled	Code generation informat

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 38.822s
```

In these lines of `rtwdemo_float_mul_for_net_slope_correction.c` code, the code generator divides the input signal by  $3.0F$ .

```
cfile = fullfile(cgDir, 'rtwdemo_float_mul_for_net_slope_correction_ert_rtw', ...
 'rtwdemo_float_mul_for_net_slope_correction.c');
rtwdemobtype(cfile, /* Model step', /* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
 /* Output: '<Root>/Output' incorporates:
 * DataTypeConversion: '<Root>/Data Type Conversion'
 * Inport: '<Root>/Input'
 */
 rtY.Output = (int16_T)(real32_T)floor((real_T)(rtU.Input / 3.0F));
}
```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Math and Data Types** pane, select **Use floating-point multiplication to handle net slope corrections**. This optimization is on by default.

Alternatively, you can use the command-line API to enable the optimization.

```
set_param(model, 'UseFloatMulNetSlope', 'on');
```

### Generate Code with Optimization

```
slbuild(model)

Starting build procedure for: rtwdemo_float_mul_for_net_slope_correction
Successful completion of build procedure for: rtwdemo_float_mul_for_net_slope_correction

Build Summary

## Use Conditional Input Branch Execution

This example shows how to optimize the generated code for a model that contains Switch and Multiport Switch blocks. When you select the model configuration parameter **Conditional input branch execution**, Simulink® executes only blocks that compute the control input and data input that the control input selects. This optimization improves execution speed.

### Example Model

In this example, switch paths are conditionally executed. If Switch1 control input is true, Switch1 executes blocks grouped in the Switch1:Path1 branch. If Switch1 control input is false, Switch1 executes blocks grouped in the Switch1:Path2 branch. If Switch1 executes blocks in the Switch1:Path2 branch and Switch2 control input is true, Switch2 executes blocks in the Switch2:Path1 branch. If Switch2 control input is false, Switch2 executes blocks in the Switch2:Path2 branch. The pseudo code shows this logic.

```
model='rtwdemo_condinput';
open_system(model);
```

Copyright 1994-2020 The MathWorks, Inc.

## Generate Code

The **Conditional input branch execution** parameter is on by default. Enter the following command-line API to turn off the parameter.

```
set_param(model, 'ConditionallyExecuteInputs', 'off');
```

Create a temporary folder for the build and inspection process.

```
currentDir=pwd;
[~,cgDir]=rtwdemodir();
```

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_condinput
Successful completion of build procedure for: rtwdemo_condinput
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_condinput	Code generated and compiled	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 22.072s

View the generated code without the optimization. These lines of code are in the `rtwdemo_condinput.c` file.

```
cfile = fullfile(cgDir,'rtwdemo_condinput_grt_rtw','rtwdemo_condinput.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_condinput_step(void)
{
 /* Switch: '<Root>/ Switch2' incorporates:
 * Constant: '<Root>/C_5'
 * Inport: '<Root>/input'
 * RelationalOperator: '<Root>/Relational Operator'
 */
 if (rtwdemo_condinput_U.input >= -5.0) {
 /* Switch: '<Root>/Switch1' incorporates:
 * Gain: '<Root>/ G3'
 */
 rtwdemo_condinput_Y.output = 3.0 * rtwdemo_condinput_U.input;
 } else {
 /* Switch: '<Root>/Switch1' incorporates:
 * Constant: '<Root>/ C_10'
 * Sum: '<Root>/ Sum'
 */
 rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + -10.0;
 }

 /* End of Switch: '<Root>/ Switch2' */
}
```

```

/* Switch: '<Root>/Switch1' incorporates:
 * Constant: '<Root>/C5'
 * Inport: '<Root>/input'
 * RelationalOperator: '<Root>/Relational Operator1'
 */
if (rtwdemo_condinput_U.input >= 5.0) {
/* Switch: '<Root>/Switch1' incorporates:
 * Constant: '<Root>/ C10'
 * Outport: '<Root>/output'
 * Sum: '<Root>/ Sum1'
 */
rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + 10.0;
}

/* End of Switch: '<Root>/Switch1' */
}

```

The generated code contains an `if-else` statement for the `Switch2` block and an `if` statement for the `Switch1` block. Therefore, the generated code for `Switch1:Path2` executes even if the `if` statement for `Switch1:Path1` evaluates to true.

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 Select the **Conditional input branch execution** parameter. Alternatively, you can use the command-line API to enable the optimization.

```
set_param(model, 'ConditionallyExecuteInputs','on');
```

### Generate Code with Optimization

```
slbuild(model)
cfile = fullfile(cgDir,'rtwdemo_condinput_grt_rtw','rtwdemo_condinput.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
Starting build procedure for: rtwdemo_condinput
Successful completion of build procedure for: rtwdemo_condinput
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_condinput	Code generated and compiled	Generated code was out of date.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 22.829s
```

```

/* Model step function */
void rtwdemo_condinput_step(void)
{
/* Switch: '<Root>/Switch1' incorporates:
 * Constant: '<Root>/C5'
 * Constant: '<Root>/C_5'
 * Inport: '<Root>/input'
 * RelationalOperator: '<Root>/Relational Operator'

```

```

* RelationalOperator: '<Root>/Relational Operator1'
* Switch: '<Root>/ Switch2'
*/
if (rtwdemo_condinput_U.input >= 5.0) {
/* Outport: '<Root>/output' incorporates:
* Constant: '<Root>/ C10'
* Sum: '<Root>/ Sum1'
*/
rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + 10.0;
} else if (rtwdemo_condinput_U.input >= -5.0) {
/* Switch: '<Root>/ Switch2' incorporates:
* Gain: '<Root>/ G3'
* Outport: '<Root>/output'
*/
rtwdemo_condinput_Y.output = 3.0 * rtwdemo_condinput_U.input;
} else {
/* Outport: '<Root>/output' incorporates:
* Constant: '<Root>/ C_10'
* Sum: '<Root>/ Sum'
* Switch: '<Root>/ Switch2'
*/
rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + -10.0;
}

/* End of Switch: '<Root>/Switch1' */
}

```

The generated code contains one `if` statement. The generated code for `Switch1:Path2` only executes if the `if` statement evaluates to false.

### Close Model and Code Generation Report

## Optimize Generated Code for Complex Signals

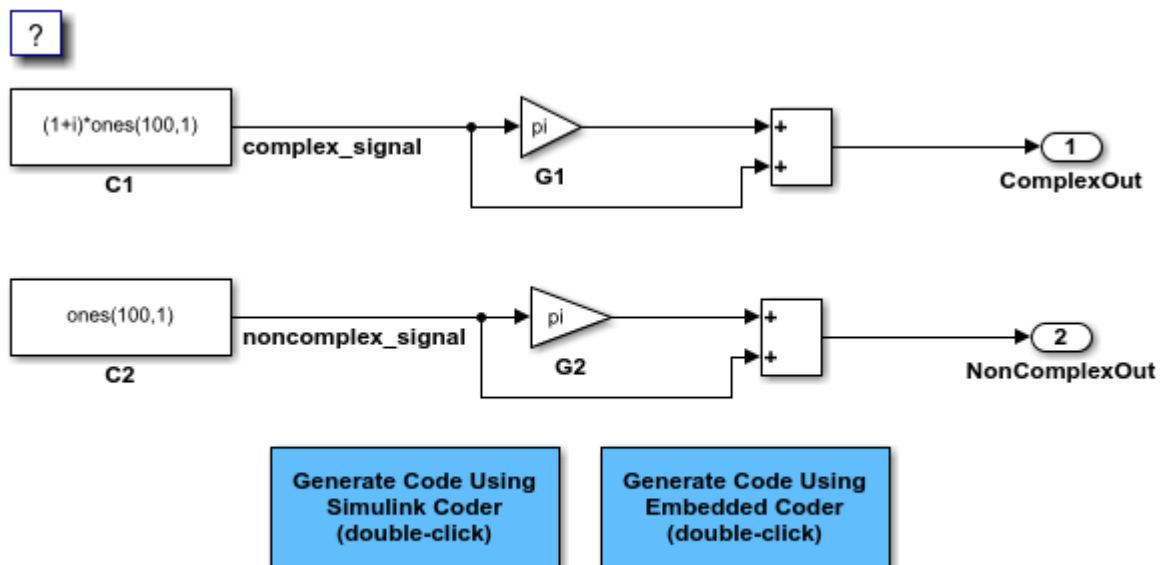

This example shows how Simulink Coder handles complex signals efficiently. To view the data types of the signals, update the model. On the **Debug** menu, select **Update Model**. Complex signals are represented as structures in generated code. Simulink Coder performs various optimizations on these structures. For example:

- Expression Folding: Gain and Sum operations on the complex signal are folded into a single expression.
- For-loop fusion: Two separate for-loops, one for the complex signal and one for noncomplex signal, are combined into a single for-loop.
- Inlined block parameters: The value of Gain block "pi" is inlined in the expression of the complex Gain-Sum.

Because of optimizations such as these, the code generated for complex and noncomplex signals is equally efficient.

### Example Model

```
model='rtwdemo_complex';
open_system(model);
```

## Speed Up Linear Algebra in Code Generated from a MATLAB Function Block

To improve the execution speed of code generated for certain linear algebra functions in a MATLAB Function block, specify that the code generator produce LAPACK calls. LAPACK is a software library for numerical linear algebra. The code generator uses the LAPACKE C interface to LAPACK. If you specify that you want to generate LAPACK calls, and the input arrays for the linear algebra functions meet certain criteria, the code generator produces the LAPACK calls. Otherwise, the code generator produces code for the linear algebra functions.

The code generator uses the LAPACK library that you specify. Specify a LAPACK library that is optimized for your execution environment. See [www.netlib.org/lapack/faq.html#\\_what\\_and\\_where\\_are\\_the\\_lapack\\_vendors\\_implementations](http://www.netlib.org/lapack/faq.html#_what_and_where_are_the_lapack_vendors_implementations).

### Specify LAPACK Library

To generate LAPACK calls, you must have access to a LAPACK callback class. A LAPACK callback class specifies the LAPACK library and LAPACKE header file for the LAPACK calls. To indicate that you want to generate LAPACK calls and that you want to use a specific LAPACK library, specify the name of the LAPACK callback class. In the Configuration Parameters dialog box, set **Custom LAPACK library callback** to the name of the callback class, for example, useMyLAPACK.

### Write LAPACK Callback Class

To specify the locations of a particular LAPACK library and LAPACKE header file, write a LAPACK callback class. Share the callback class with others who want to use this LAPACK library for LAPACK calls in generated code.

The callback class must derive from the abstract class `coder.LAPACKCallback`. Use this example callback class as a template.

```
classdef useMyLAPACK < coder.LAPACKCallback
 methods (Static)
 function hn = getHeaderFilename()
 hn = 'mylapacke_custom.h';
 end
 function updateBuildInfo(buildInfo, buildctx)
 buildInfo.addIncludePaths(fullfile(pwd,'include'));
 libName = 'mylapack';
 libPath = fullfile(pwd,'lib');
 [~,linkLibExt] = buildctx.getStdLibInfo();
 buildInfo.addLinkObjects([libName linkLibExt], libPath, ...
 '', true, true);
 buildInfo.addDefines('HAVE_LAPACK_CONFIG_H');
 buildInfo.addDefines('LAPACK_COMPLEX_STRUCTURE');
 buildInfo.addDefines('LAPACK_ILP64');
 end
 end
end
```

You must provide the `getHeaderFilename` and `updateBuildInfo` methods. The `getHeaderFilename` method returns the LAPACKE header file name. In the example callback class, replace `mylapacke_custom.h` with the name of your LAPACKE header file. The `updateBuildInfo`

method provides the information required for the build process to link to the LAPACK library. Use code like the code in the template to specify the location of header files and the full path name of the LAPACK library. In the example callback class, replace `mylapack` with the name of your LAPACK library.

If your compiler supports only complex data types that are represented as structures, include these lines in the `updateBuildInfo` method.

```
buildInfo.addDefines('HAVE_LAPACK_CONFIG_H');
buildInfo.addDefines('LAPACK_COMPLEX_STRUCTURE');
```

You must specify the integer type that your LAPACK library uses. Not specifying this integer type can result in incorrect behaviors or crashes. Do one of the following:

- Include these lines in the `updateBuildInfo` method.

```
buildInfo.addDefines('HAVE_LAPACK_CONFIG_H');
buildInfo.addDefines('LAPACK_ILP64');
```

- Alternatively, you can directly specify the integer type that your LAPACK library uses. For example, if the integer type is `long long`, include this line in the `updateBuildInfo` method.

```
buildInfo.addDefines('lapack_int=long long');
```

## Generate LAPACK Calls by Specifying a LAPACK Callback Class

This example shows how to generate code that calls LAPACK functions in a specific LAPACK library. For this example, assume that the LAPACK callback class `useMyLAPACK` specifies the LAPACK library that you want.

- 1 Create a Simulink model.
- 2 Add a MATLAB Function block to the model.
- 3 In the MATLAB Function block, add code that calls a linear algebra function. For example, add the function `mysvd` that calls the MATLAB function `svd`.

```
function s = mysvd(A)
 %#codegen
 s = svd(A);
end
```

- 4 Add a Constant block to the left of the MATLAB Function block. Set the value to `zeros(500)`.
- 5 Add an Outport block to the right of the MATLAB Function block.
- 6 Connect the blocks.

- 7 Set the **Configuration Parameters > Code Generation > Advanced parameters > Custom LAPACK library callback** parameter to `useMyLAPACK`.

The callback class must be on the MATLAB path.

- 8 Build the model.

If the input to `mysvd` is large enough, the code generator produces a LAPACK call for `svd`. An example of a call to the LAPACK library function for `svd` is:

```
info_t = LAPACKE_dgesvd(...
 LAPACK_COL_MAJOR, 'N', 'N', (lapack_int)500, ...
 (lapack_int)500, &A[0], (lapack_int)500, &S[0], ...
 NULL, (lapack_int)1, NULL, (lapack_int)1, &superb[0]);
```

## Locate LAPACK Library in Execution Environment

The LAPACK library must be available in your execution environment. If your LAPACK library is shared, use environment variables or linker options to specify the location of the LAPACK library.

- On a Windows platform, modify the `PATH` environment variable.
- On a Linux platform, modify the `LD_LIBRARY_PATH` environment variable or use the `rpath` linker option.
- On a macOS platform, modify the `DYLD_LIBRARY_PATH` environment variable or use the `rpath` linker option.

To specify the `rpath` linker option, you can use the build information `addLinkFlags` method in the `updateBuildInfo` method of your `coder.LAPACKCallback` class. For example, for a GCC compiler:

```
buildInfo.addLinkFlags(sprintf('-Wl,-rpath,"%s"', libPath));
```

## Speed Up Matrix Operations in Code Generated from a MATLAB Function Block

To improve the execution speed of code generated for certain low-level vector and matrix operations (such as matrix multiplication) in a MATLAB Function block, specify that you want the code generator to produce BLAS calls. BLAS is a software library for low-level vector and matrix computations that has several highly optimized machine-specific implementations. The code generator uses the CBLAS C interface to BLAS. If you specify that you want to generate BLAS calls, and the input arrays for the matrix functions meet certain criteria, the code generator produces the BLAS calls. Otherwise, the code generator produces code for the matrix functions.

The code generator uses the BLAS library that you specify. Specify a BLAS library that is optimized for your execution environment.

### Specify BLAS Library

To produce BLAS calls in generated code, you must have access to a BLAS callback class. A BLAS callback class specifies the BLAS library, the CBLAS header file, certain C data types the particular CBLAS interface uses and the compiler and linker options for the build process.

To indicate that you want to generate BLAS calls and use a specific BLAS library, specify the name of the BLAS callback class. In the Configuration Parameters dialog box, set **Custom BLAS library callback** to the name of the callback class.

### Write BLAS Callback Class

To generate calls to a specific BLAS library in the generated code, write a BLAS callback class. Share the callback class with others who want to use this BLAS library for BLAS calls in standalone code.

The callback class must derive from the abstract class `coder.BLASCallback`. This example is an implementation of the callback class `mklcallback` for integration with the Intel MKL BLAS library on a Windows platform.

```
classdef mklcallback < coder.BLASCallback
 methods (Static)
 function updateBuildInfo(buildInfo, ~)
 libPath = fullfile(pwd, 'mkl', 'WIN', 'lib', 'intel64');
 libPriority = '';
 libPreCompiled = true;
 libLinkOnly = true;
 libs = {'mkl_intel_ilp64.lib' 'mkl_intel_thread.lib' 'mkl_core.lib'};
 buildInfo.addLinkObjects(libs, libPath, libPriority, libPreCompiled, ...
 libLinkOnly);
 buildInfo.addLinkObjects('libiomp5md.lib', fullfile(matlabroot, 'bin', ...
 'win64'), libPriority, libPreCompiled, libLinkOnly);
 buildInfo.addIncludePaths(fullfile(pwd, 'mkl', 'WIN', 'include'));
 buildInfo.addDefines('-DMKL_ILP64');
 end
 function headerName = getHeaderFilename()
 headerName = 'mkl_cblas.h';
 end
 function intTypeName = getBLASIntTypeName()
 intTypeName = 'MKL_INT';
 end
 end
end
```

```

 end
 end
end

```

You must provide the `getHeaderFilename`, `getBLASIntTypeName`, and `updateBuildInfo` methods. The `getHeaderFilename` method returns the CBLAS header file name. If you are using a different BLAS library, replace `mkL_cblas.h` with the name of your CBLAS header file. The `getBLASIntTypeName` method returns the name of the integer data type that your CBLAS interface uses. If you are using a different BLAS library, replace `MKL_INT` with the name of the integer data type specific to your CBLAS interface. The `updateBuildInfo` method provides the information required for the build process to link to the BLAS library. Use code that is like the code in the example callback class to specify the location of header file, the full path name of the BLAS library, and the compiler and linker options. If you use the Intel MKL BLAS library, use the link line advisor to see which libraries and compiler options are recommended for your use case.

There are three other methods that are already implemented in `coder.BLASCallback`. These methods are `getBLASDoubleComplexTypeName`, `getBLASSingleComplexTypeName`, and `useEnumNameRatherThanTypedef`. By default, your callback class inherits these implementations from `coder.BLASCallback`. In certain situations, you must override these methods with your own definitions when you define your callback class.

The `getBLASDoubleComplexTypeName` method returns the type used for double-precision complex variables in the generated code. If your BLAS library takes a type other than `double*` and `void*` for double-precision complex array arguments, include this method in your callback class definition.

```

function doubleComplexTypeName = getBLASDoubleComplexTypeName()
doubleComplexTypeName = 'my_double_complex_type';
end

```

Replace `my_double_complex_type` with the type that your BLAS library takes for double-precision complex array arguments.

The `getBLASSingleComplexTypeName` method returns the type used for single-precision complex variables in the generated code. If your BLAS library takes a type other than `float*` and `void*` for single-precision complex array arguments, include this method in your callback class definition.

```

function singleComplexTypeName = getBLASSingleComplexTypeName()
doubleComplexTypeName = 'my_single_complex_type';
end

```

Replace `my_single_complex_type` with the type that your BLAS library takes for single-precision complex array arguments.

The `useEnumNameRatherThanTypedef` method returns `false` by default. If types for enumerations in your BLAS library include the `enum` keyword, redefine this method to return `true` in your callback class definition.

```

function p = useEnumNameRatherThanTypedef()
p = true;
end

```

An excerpt from generated C source code that includes the `enum` keyword is:

```

enum CBLAS_SIDE t;
enum CBLAS_UPLO b_t;
double temp;

```

```
enum CBLAS_TRANSPOSE c_t;
enum CBLAS_DIAG d_t;
```

## Generate BLAS Calls by Specifying a BLAS Callback Class

This example shows how to generate code that calls BLAS functions in a specific BLAS library. The BLAS callback class `useMyBLAS` specifies the BLAS library that you want to use in this example.

- 1 Create a Simulink model.
- 2 Add a MATLAB Function block to the model.
- 3 In the MATLAB Function block, add code that calls a function for a basic matrix operation. For example, add the function `myMultiply` that multiplies two matrices A and B.

```
function C = myMultiply(A,B) %#codegen
C = A*B;
end
```

- 4 Add two Constant blocks to the left of the MATLAB Function block. Set their values to `zeros(1000)`.
- 5 Add an Output block to the right of the MATLAB Function block.
- 6 Connect the blocks.

- 7 In the Configuration Parameters dialog box, set **Custom BLAS library callback** to the name of the callback class `useMyBLAS`.

The callback class must be on the MATLAB path.

- 8 Build the model.

If A and B are large enough, the code generator produces a BLAS call for the matrix multiplication function.

## Locate BLAS Library in Execution Environment

The BLAS library must be available in your execution environment. If your BLAS library is shared, use environment variables or linker options to specify the location of the BLAS library.

- On a Windows platform, modify the `PATH` environment variable.
- On a Linux platform, modify the `LD_LIBRARY_PATH` environment variable or use the `rpath` linker option.
- On a macOS platform, modify the `DYLD_LIBRARY_PATH` environment variable or use the `rpath` linker option.

To specify the `rpath` linker option, use the build information `addLinkFlags` method in the `updateBuildInfo` method of your BLAS callback class. For example, for a GCC compiler:

```
buildInfo.addLinkFlags(sprintf('-Wl,-rpath,"%s"', libPath));
```

## Usage Notes and Limitations for OpenBLAS Library

If you generate code that includes calls to the OpenBLAS library functions, follow these guidelines and restrictions:

- If you generate C++ code that includes calls to OpenBLAS library functions, compiling it with the `-pedantic` option produces warnings. To disable the `-pedantic` compiler option, include these lines in the `updateBuildInfo` method:

```
if ctx.getTargetLang() == 'C++'
 buildInfo.addCompileFlags('-Wno-pedantic');
end
```

- OpenBLAS does not support the C89/C90 standard.

## Speed Up Fast Fourier Transforms in Code Generated from a MATLAB Function Block

This example shows how to generate calls to a specific installed FFTW library. For more information about FFTW, see [www.fftw.org](http://www.fftw.org).

When you simulate a model that includes a MATLAB Function block that calls MATLAB fast Fourier transform (FFT) functions, the simulation software uses the library that MATLAB uses for FFT algorithms. If you generate C/C++ code for this model, by default, the code generator produces code for the FFT algorithms instead of producing FFT library calls. To increase the speed of fast Fourier transforms in generated code, specify that the code generator produce calls to a specific installed FFTW library.

The code generator produces FFTW library calls when all of these conditions are true:

- A MATLAB Function block calls one of these MATLAB functions: `fft`, `fft2`, `fftn`, `ifft`, `ifft2`, or `ifftn`.
- You generate C/C++ code from a model that includes the MATLAB Function block.
- You have access to an FFTW library installation, version 3.2 or later.
- You specify the FFTW library installation in an FFT library callback class that derives from `coder.fftw.StandaloneFFTW3Interface`.
- You set the **Custom FFT library callback** configuration parameter to the name of the callback class.

### Install an FFTW Library

If you do not have access to an installed FFTW library, version 3.2 or later, then you must install one.

For a Linux platform or a Mac platform, consider using a package manager to install the FFTW library.

For a Windows platform, in addition to `.dll` files, you must have `.lib` import libraries, as described in the Windows installation notes on the FFTW website.

See the installation instructions for your platform on the FFTW website.

### Write FFT Callback Class

To specify your installation of the FFTW library, write an FFT callback class. Share the callback class with others who want to use this FFTW library for FFTW calls.

The callback class must derive from the abstract class `coder.fftw.StandaloneFFTW3Interface`. Use this example callback class as a template.

```
% copyright 2017 The MathWorks, Inc.
classdef useMyFFTW < coder.fftw.StandaloneFFTW3Interface
 methods (Static)
 function th = getNumThreads
 coder.inline('always');
 th = int32(coder.const(1));
 end
 end
end
```

```

function updateBuildInfo(buildInfo, ctx)
 fftwLocation = '/usr/lib/fftw';
 includePath = fullfile(fftwLocation, 'include');
 buildInfo.addIncludePaths(includePath);
 libPath = fullfile(fftwLocation, 'lib');

 %Double
 libName1 = 'libfftw3-3';
 [~, libExt] = ctx.getStdLibInfo();
 libName1 = [libName1 libExt];
 addLinkObjects(buildInfo, libName1, libPath, 1000, true, true);

 %Single
 libName2 = 'libfftw3f-3';
 [~, libExt] = ctx.getStdLibInfo();
 libName2 = [libName2 libExt];
 addLinkObjects(buildInfo, libName2, libPath, 1000, true, true);
end
end

```

Implement the `updateBuildInfo` and `getNumThreads` methods. In the `updateBuildInfo` method, set `fftwLocation` to the full path for your installation of the library. Set `includePath` to the full path of the folder that contains `fftw3.h`. Set `libPath` to the full path of the folder that contains the library files. If your FFTW installation uses multiple threads, modify the `getNumThreads` method to return the number of threads that you want to use.

Optionally, you can implement these methods:

- `getPlanMethod` to specify the FFTW planning method. See `coder.fftw.StandaloneFFTW3Interface`.
- `lock` and `unlock` to synchronize multithreaded access to the FFTW planning process. See “Synchronize Multithreaded FFTW Planning in Code Generated from a MATLAB Function Block”.

## Generate FFTW Calls by Specifying an FFT Callback Class

- 1 Create a Simulink model.
- 2 Add a MATLAB Function block to the model.
- 3 In the MATLAB Function block, add code that calls a MATLAB FFT function. For example, add the function `myfft` that calls the MATLAB function `fft`.

```

function y = myfft()
 t = 0:1/50:10-1/50;
 x = sin(2*pi*15*t) + sin(2*pi*20*t);
 y = fft(x);
end

```

- 4 Connect the blocks.

- 5 Indicate that the code generator produce calls to the FFTW library specified in the FFT library callback class `useMyFFTW`. In the Configuration Parameters dialog box, set **Custom FFT library callback** to `useMyFFTW`.

The callback class must be on the MATLAB path.

## 6 Build the model.

### Locate FFTW Library in Execution Environment

The FFTW library must be available in your execution environment. If the FFTW library is shared, use environment variables or linker options to specify the location of the library.

- On a Windows platform, modify the PATH environment variable.
- On a Linux platform, modify the LD\_LIBRARY\_PATH environment variable or use the rpath linker option.
- On a macOS platform, modify the DYLD\_LIBRARY\_PATH environment variable or use the rpath linker option.

To specify the rpath linker option, you can use the build information `addLinkFlags` method in the `updateBuildInfo` method of your `coder.fftw.StandaloneFFTW3Interface` class. For example, for a GCC compiler:

```
buildInfo.addLinkFlags(sprintf('-Wl,-rpath,"%s"',libPath));
```

## Synchronize Multithreaded FFTW Planning in Code Generated from a MATLAB Function Block

This example shows how to generate code that synchronizes multithreaded access to the FFTW planning process for FFTW library calls in code generated from a MATLAB Function block.

The code generator produces FFTW library calls when all of these conditions are true:

- A MATLAB Function block calls one of these functions: `fft`, `fft2`, `fftn`, `ifft`, `ifft2`, or `ifftn`.
- You generate C/C++ code for a model that includes the MATLAB Function block.
- You have access to an FFTW library installation, version 3.2 or later.
- You specify the FFTW library installation in an FFT library callback class that derives from `coder.fftw.StandaloneFFTW3Interface`.
- You set the **Custom FFT library callback** configuration parameter to the name of the callback class.

If you integrate the code that contains the FFTW calls with external code that runs on multiple threads, then you must prevent concurrent access to the FFTW planning process. In your FFT library callback class, implement the `lock` and `unlock` methods. You must also provide C code that manages a lock or mutex. Many libraries, such as OpenMP, pthreads, and the C++ standard library (C++ 11 and later), provide locks. This example shows how to implement the `lock` and `unlock` methods and provide supporting C code. To manage a lock, this example uses the OpenMP library.

### Prerequisites

Before you start, for the basic workflow for generating FFTW library calls for fast Fourier transforms in a MATLAB Function block, see “Speed Up Fast Fourier Transforms in Code Generated from a MATLAB Function Block”.

You must have:

- Access to an installed FFTW library.
- A compiler that supports the OpenMP library. To use a different library, such as pthreads, modify the supporting C code accordingly.

### Create a Model with a MATLAB Function Block That Calls an FFT Function

- 1 Create a Simulink model and add a MATLAB Function block to it.
- 2 Add this code to the MATLAB Function block.

```
function y = mycustomfft()

t = 0:1/50:10-1/50;
x = sin(2*pi*15*t) + sin(2*pi*20*t);
y = fft(x);
for k = 1:100
 y = y + ifft(x+k);
end
```

- 3 Add an `outport` block and connect it to the MATLAB Function block.

## Write Supporting C Code

Write C functions that initialize, set, and unset a lock. This example uses the OpenMP library to manage the lock. For a different library, modify the code accordingly.

- Create a file `mylock.c` that contains this C code:

```
#include "mylock.h"
#include "omp.h"

static omp_nest_lock_t lockVar;

void mylock_initialize(void)
{
 omp_init_nest_lock(&lockVar);
}

void mylock(void)
{
 omp_set_nest_lock(&lockVar);
}

void myunlock(void)
{
 omp_unset_nest_lock(&lockVar);
}
```

- Create a header file `mylock.h` that contains:

```
#ifndef MYLOCK_H
#define MYLOCK_H

void mylock_initialize(void);
void mylock(void);
void myunlock(void);

#endif
```

## Create an FFT Library Callback Class

Write an FFT callback class `myfftc` that:

- Specifies the FFTW library.
- Implements `lock` and `unlock` methods that call the supporting C code to control access to the FFTW planning.

Use this class as a template. Replace `fftwLocation` with the location of your FFTW library installation.

```
classdef myfftwcb < coder.fftw.StandaloneFFTW3Interface

 methods (Static)
 function th = getNumThreads
 coder.inline('always');
 th = int32(coder.const(1));
 end

 function lock()
 coder.cinclude('mylock.h', 'InAllSourceFiles', true);
 coder.inline('always');
 coder.ceval('mylock');
 end

 function unlock()
 coder.cinclude('mylock.h', 'InAllSourceFiles', true);
 coder.inline('always');
 coder.ceval('myunlock');
 end

 function updateBuildInfo(buildInfo, ctx)
 fftwLocation = '\usr\lib\fftw';
 includePath = fullfile(fftwLocation, 'include');
 buildInfo.addIncludePaths(includePath);
 libPath = fullfile(fftwLocation, 'lib');

 %Double
 libName1 = 'libfftw3-3';
 [~, libExt] = ctx.getStdLibInfo();
 libName1 = [libName1 libExt];
 addLinkObjects(buildInfo, libName1, libPath, 1000, true, true);

 %Single
 libName2 = 'libfftw3f-3';
 [~, libExt] = ctx.getStdLibInfo();
 libName2 = [libName2 libExt];
 addLinkObjects(buildInfo, libName2, libPath, 1000, true, true);
 end
 end
end
```

## Configure Code Generation Parameters and Build the Model

- 1 Configure code generation to use the FFTW callback class and the C code called by the `lock` and `unlock` methods. Configure code generation to generate a call to `mylock_initialize` in the initialization code.

In the Configuration Parameters dialog box:

- Set **Custom FFT library callback** to `myfftwcb`.
- In **Code Generation > Custom Code**, under **Additional build information**, set **Source files** to `mylock.c`.

- In **Code Generation > Custom Code**, under **Insert custom C code in generated**, set **Initialize function** to `mylock_initialize();`.

2 Build the model.

## Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block

Dynamic memory allocation allocates memory on the heap as needed at run time, instead of allocating memory statically on the stack. You can use dynamic memory allocation for arrays inside a MATLAB Function block.

You cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.
- Discrete state properties of System objects associated with a MATLAB System block.

Dynamic memory allocation is beneficial when:

- You do not know the upper bound of an array.
- You do not want to allocate memory on the stack for large arrays.

Dynamic memory allocation and the freeing of this memory can result in slower execution of the generated code. To control the use of dynamic memory allocation for variable-size arrays in a MATLAB Function block, you can:

- Provide upper bounds for variable-size arrays on page 71-82.
- Disable dynamic memory allocation for MATLAB Function blocks on page 71-82.
- Modify the dynamic memory allocation threshold on page 71-82.

### Provide Upper Bounds for Variable-Size Arrays

For an unbounded variable-size array, the code generator allocates memory dynamically on the heap. For a bounded variable-size array, if the size, in bytes, is less than the dynamic memory allocation threshold, the code generator allocates memory statically on the stack. To avoid dynamic memory allocation, provide upper bounds for the array dimensions so that the size of the array, in bytes, is less than the dynamic memory allocation threshold. See “Specify Upper Bounds for Variable-Size Arrays”.

### Disable Dynamic Memory Allocation for MATLAB Function Blocks

By default, dynamic memory allocation for MATLAB Function blocks is enabled for GRT-based targets and disabled for ERT-based targets. To change the setting, in the Configuration Parameters dialog box, clear or select **Dynamic memory allocation in MATLAB functions**.

If you disable dynamic memory allocation, you must provide upper bounds for variable-size arrays.

### Modify the Dynamic Memory Allocation Threshold

Instead of disabling dynamic memory allocation for all variable-size arrays, you can use the dynamic memory allocation threshold to specify when the code generator uses dynamic memory allocation.

Use the dynamic memory allocation threshold to:

- Disable dynamic memory allocation for smaller arrays. For smaller arrays, static memory allocation can speed up generated code. However, static memory allocation can lead to unused storage space. You can decide that the unused storage space is not a significant consideration for smaller arrays.
- Enable dynamic memory allocation for larger arrays. For larger arrays, when you use dynamic memory allocation, you can significantly reduce storage requirements.

The default value of the dynamic memory allocation threshold is 64 kilobytes. To change the threshold, in the Configuration Parameters dialog box, set the **Dynamic memory allocation threshold in MATLAB functions** parameter.

To use dynamic memory allocation for all variable-size arrays, set the threshold to 0.

## Optimize Memory Usage for Time Counters

This example shows how to optimize the amount of memory that the code generator allocates for time counters. The example optimizes the memory that stores elapsed time, the interval of time between two events.

The code generator represents time counters as unsigned integers. The word size of time counters is based on the setting of the model configuration parameter **Application lifespan (days)**, which specifies the expected maximum duration of time the application runs. You can use this parameter to prevent time counter overflows. The default size is 64 bits.

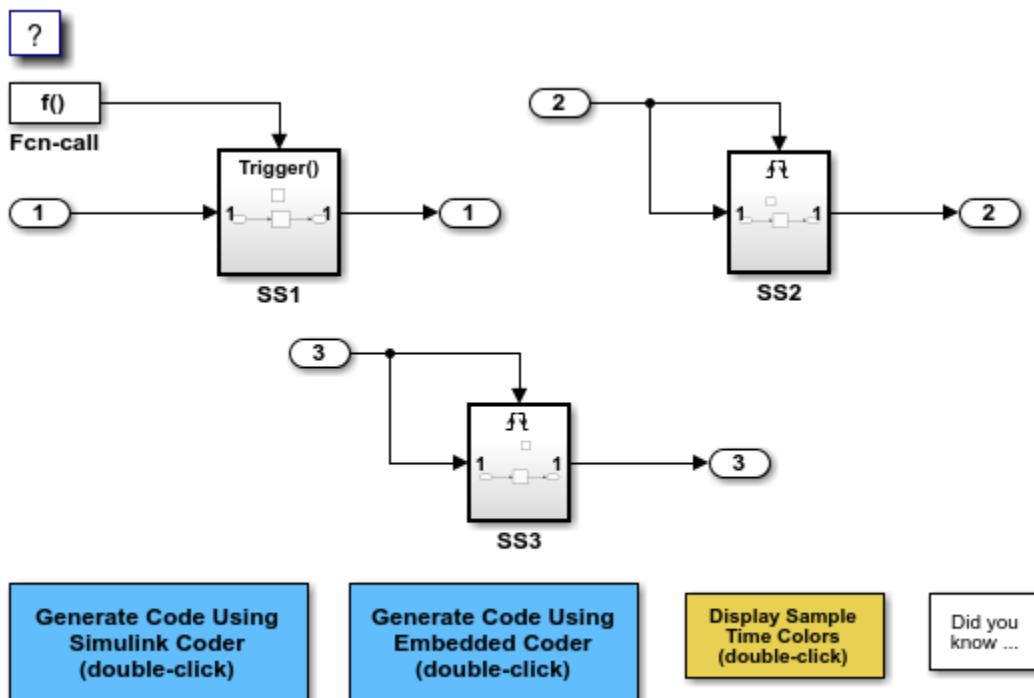

The number of bits that a time counter uses depends on the setting of the **Application lifespan (days)** parameter. For example, if a time counter increments at a rate of 1 kHz, to avoid an overflow, the counter has the following number of bits:

- Lifespan < 0.25 sec: 8 bits
- Lifespan < 1 min: 16 bits
- Lifespan < 49 days: 32 bits
- Lifespan > 50 days: 64 bits

A 64-bit time counter does not overflow for 590 million years.

### Open Example Model

Open the example model `rtwdemo_abstime`.

Copyright 1994-2020 The MathWorks, Inc.

The model consists of three subsystems SS1, SS2, and SS3. Open the Model Configuration Parameters dialog box. On the **Math and Data Types** pane, the **Application lifespan (days)** parameter is set to the default, which is `inf`.

The three subsystems contain a discrete-time integrator that requires elapsed time as input to compute its output value. The subsystems vary as follows:

- SS1 - Clocked at 1 kHz. Does not require a time counter. **Sample time type** parameter for trigger port is set to `periodic`. Elapsed time is inlined as 0.001.
- SS2 - Clocked at 100 Hz. Requires a time counter. Based on a lifespan of 1 day, a 32-bit counter stores the elapsed time.
- SS3 - Clocked at 0.5 Hz. Requires a time counter. Based on a lifespan of 1 day, a 16-bit counter stores the elapsed time.

### Simulate the Model

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for the three subsystems appear red, green, and blue. Triggered subsystems are blue-green.

### Generate Code and Report

1. Create a temporary folder for the build and inspection process.
2. Configure the model for the code generator to use the GRT system target file and a lifespan of `inf` days.
3. Build the model.

```
Starting build procedure for: rtwdemo_abstime
Successful completion of build procedure for: rtwdemo_abstime
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_abstime	Code generated and compiled	Code generation information file does not exist.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 22.027s
```

### Review Generated Code

Open the generated source file `rtwdemo_abstime.h`.

```
struct tag_RTM_rtwdemo_abstime_T {
 const char_T *errorStatus;

 /*
 * Timing:
 * The following substructure contains information regarding
 * the timing information for the model.
 */
};
```

```

struct {
 uint32_T clockTick1;
 uint32_T clockTickH1;
 uint32_T clockTick2;
 uint32_T clockTickH2;
 struct {
 uint16_T TID[3];
 uint16_T cLimit[3];
 } TaskCounters;
} Timing;
};

/* Block states (default storage) */
extern DW_rtdemo_abstime_T rtdemo_abstime_DW;

/* Zero-crossing (trigger) state */
extern PrevZCX_rtdemo_abstime_T rtdemo_abstime_PrevZCX;

/* External inputs (root inport signals with default storage) */
extern ExtU_rtdemo_abstime_T rtdemo_abstime_U;

/* External outputs (root outputs fed by signals with default storage) */
extern ExtY_rtdemo_abstime_T rtdemo_abstime_Y;

/* Model entry point functions */
extern void rtdemo_abstime_initialize(void);
extern void rtdemo_abstime_step0(void);
extern void rtdemo_abstime_step1(void);
extern void rtdemo_abstime_step2(void);
extern void rtdemo_abstime_terminate(void);

/* Real-time Model object */
extern RT_MODEL_rtdemo_abstime_T *const rtdemo_abstime_M;

/*-
 * The generated code includes comments that allow you to trace directly
 * back to the appropriate location in the model. The basic format
 * is <system>/block_name, where system is the system number (uniquely
 * assigned by Simulink) and block_name is the name of the block.
 *
 * Use the MATLAB hilite_system command to trace the generated code back
 * to the model. For example,
 *
 * hilite_system('<S3>') - opens system 3
 * hilite_system('<S3>/Kp') - opens and selects block Kp which resides in S3
 *
 * Here is the system hierarchy for this model
 *
 * '<Root>' : 'rtdemo_abstime'
 * '<S1>' : 'rtdemo_abstime/SS1'
 * '<S2>' : 'rtdemo_abstime/SS2'
 * '<S3>' : 'rtdemo_abstime/SS3'
 */
#endif
/* RTW_HEADER_rtdemo_abstime_h_ */

```

Four 32-bit unsigned integers, `clockTick1`, `clockTickH1`, `clockTick2`, and `clockTickH2` are counters for storing the elapsed time of subsystems SS2 and SS3.

## Enable Optimization and Regenerate Code

1. Reconfigure the model to set the lifespan to 1 day.
2. Build the model.

```
Starting build procedure for: rtwdemo_abstime
Successful completion of build procedure for: rtwdemo_abstime
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_abstime	Code generated and compiled	Incremental checksum has changed.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 19.938s
```

## Review the Regenerated Code

```
struct tag_RTM_rtwdemo_abstime_T {
 const char_T *errorStatus;

 /*
 * Timing:
 * The following substructure contains information regarding
 * the timing information for the model.
 */
 struct {
 uint32_T clockTick1;
 uint16_T clockTick2;
 struct {
 uint16_T TID[3];
 uint16_T cLimit[3];
 } TaskCounters;
 } Timing;
};

/* Block states (default storage) */
extern DW_rtwdemo_abstime_T rtwdemo_abstime_DW;

/* Zero-crossing (trigger) state */
extern PrevZCX_rtwdemo_abstime_T rtwdemo_abstime_PrevZCX;

/* External inputs (root inport signals with default storage) */
extern ExtU_rtwdemo_abstime_T rtwdemo_abstime_U;

/* External outputs (root outports fed by signals with default storage) */
extern ExtY_rtwdemo_abstime_T rtwdemo_abstime_Y;

/* Model entry point functions */
extern void rtwdemo_abstime_initialize(void);
extern void rtwdemo_abstime_step0(void);
extern void rtwdemo_abstime_step1(void);
extern void rtwdemo_abstime_step2(void);
```

```

extern void rtwdemo_abstime_terminate(void);

/* Real-time Model object */
extern RT_MODEL_rtwdemo_abstime_T *const rtwdemo_abstime_M;

/*-
 * The generated code includes comments that allow you to trace directly
 * back to the appropriate location in the model. The basic format
 * is <system>/block_name, where system is the system number (uniquely
 * assigned by Simulink) and block_name is the name of the block.
 *
 * Use the MATLAB hilite_system command to trace the generated code back
 * to the model. For example,
 *
 * hilite_system('<S3>') - opens system 3
 * hilite_system('<S3>/Kp') - opens and selects block Kp which resides in S3
 *
 * Here is the system hierarchy for this model
 *
 * '<Root>' : 'rtwdemo_abstime'
 * '<S1>' : 'rtwdemo_abstime/SS1'
 * '<S2>' : 'rtwdemo_abstime/SS2'
 * '<S3>' : 'rtwdemo_abstime/SS3'
 */
#endif /* RTW_HEADER_rtwdemo_abstime_h_ */

```

The new setting for the **Application lifespan (days)** parameter instructs the code generator to set aside less memory for the time counters. The regenerated code includes:

- 32-bit unsigned integer, `clockTick1`, for storing the elapsed time of the task for SS2
- 16-bit unsigned integer, `clockTick2`, for storing the elapsed time of the task for SS3

## Optimize Generated Code Using Boolean Data for Logical Signals

Optimize generated code by storing logical signals as Boolean data. When you select the model configuration parameter **Implement logic signals as Boolean data (vs. double)**, blocks that generate logic signals output Boolean signals.

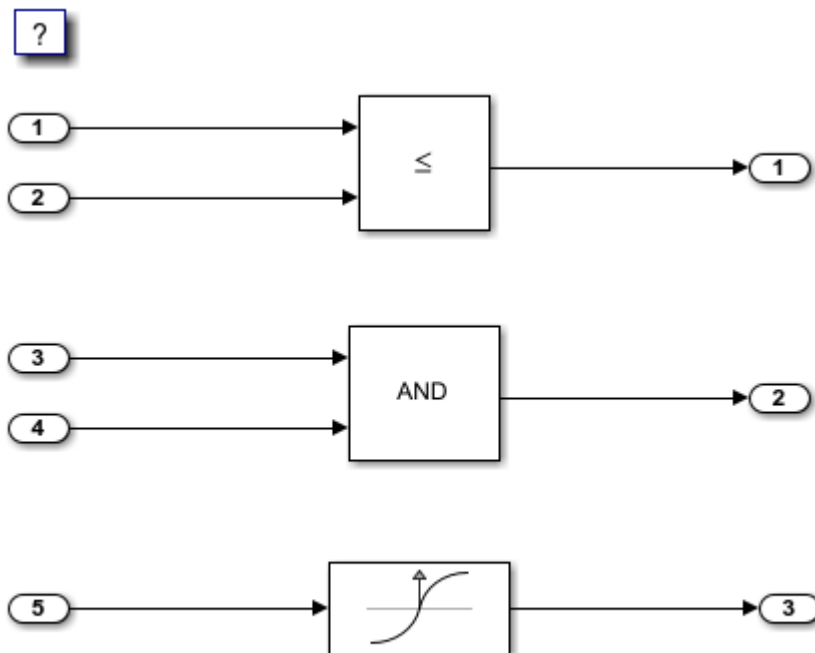

The optimization:

- Reduces the ROM and RAM consumption.
- Improves execution speed.

### Example Model

Consider the model `rtwdemo_logicalAsBoolean`. The outputs of the Relational Operator, Logical Operator and HitCrossing blocks are double, even though they represent logical data.

```
model = 'rtwdemo_logicalAsBoolean';
open_system(model);
```

Copyright 1994-2020 The MathWorks, Inc.

### Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_logicalAsBoolean
Successful completion of build procedure for: rtwdemo_logicalAsBoolean
```

```
Build Summary
```

```
Top model targets built:
```

Model	Action	Rebuild Reason
rtwdemo_logicalAsBoolean	Code generated and compiled	Code generation information file does not

```
1 of 1 models built (0 models already up to date)
```

```
Build duration: 0h 0m 36.834s
```

View the generated code without the optimization. These lines of code are in `rtwdemo_logicalAsBoolean.h`.

```
hfile = fullfile(cgDir,'rtwdemo_logicalAsBoolean_ert_rtw',...
 'rtwdemo_logicalAsBoolean.h');
rtwdemodbtype(hfile,'/* External outputs','/* Parameters (default storage) */',1,0);
```

```
/* External outputs (root outputs fed by signals with default storage) */
typedef struct {
 real_T Out1; /* '<Root>/Out1' */
 real_T Out2; /* '<Root>/Out2' */
 real_T Out3; /* '<Root>/Out3' */
} ExtY_rtwdemo_logicalAsBoolean_T;
```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 Select the **Implement logic signals as Boolean data (vs. double)** parameter.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model,'BooleanDataType','on');
```

### Generate Code with Optimization

The generated code stores the logical signal output as Boolean data.

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_logicalAsBoolean
Successful completion of build procedure for: rtwdemo_logicalAsBoolean
```

```
Build Summary
```

```
Top model targets built:
```

Model	Action	Rebuild Reason
rtwdemo_logicalAsBoolean	Code generated and compiled	Generated code was out of date.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 21.659s
```

View the generated code with the optimization. These lines of code are in `rtwdemo_logicalAsBoolean.h`.

```
rtwdemodbtype(hfile, '/* External outputs', '/* Parameters (default storage) */', 1, 0);
```

```
/* External outputs (root outputs fed by signals with default storage) */
typedef struct {
 boolean_T Out1; /* '<Root>/Out1' */
 boolean_T Out2; /* '<Root>/Out2' */
 boolean_T Out3; /* '<Root>/Out3' */
} ExtY_rtwdemo_logicalAsBoolean_T;
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Reduce Memory Usage for Boolean and State Configuration Variables

- 1 Open the Model Configuration Parameters dialog box.
- 2 In the Model Configuration Parameters dialog box, select the **Optimization** pane.
- 3 Choose from these options:
  - **Use bitsets for storing state configuration** — Reduces the amount of memory that stores state configuration variables. However, it can increase the amount of memory that stores target code if the target processor does not include instructions for manipulating bitsets.
  - **Use bitsets for storing Boolean data** — Reduces the amount of memory that stores Boolean variables. However, it can increase the amount of memory that stores target code if the target processor does not include instructions for manipulating bitsets.

---

**Note** You cannot use bitsets when you generate code for these cases:

- An external mode simulation
  - A target that specifies an explicit structure alignment
-

## Customize Stack Space Allocation

Your application might be constrained by limited memory. Controlling the maximum allowable size for the stack is one way to modify whether data is defined as local or global in the generated code. You can limit the use of stack space by specifying a positive integer value for the “Maximum stack size (bytes)” parameter, on the **Optimization** pane of the Configuration parameter dialog box. Specifying the maximum allowable stack size provides control over the number of local and global variables in the generated code. Specifically, lowering the maximum stack size might generate more variables into global structures. The number of local and global variables help determine the required amount of stack space for execution of the generated code.

If your model contains a variable that is larger than 4096 bytes, the code generator implements it in global memory by default. You can increase the size of variables that the code generator places in local memory by changing the value of the TLC variable `MaxStackSize`. You can change this value by typing the following command in MATLAB Command Window:

```
set_param(modelName, 'TLCOptions', '-aMaxStackSize=N')
```

The default setting for “Maximum stack size (bytes)” is `Inherit from target`. In this case, the value of the maximum stack size is the smaller value of the following: the default value set by the code generator (200,000 bytes) or the value of the TLC variable `MaxStackSize` found in the system target file (`ert.tlc`).

To specify a smaller stack size for your application, select the `Specify a value` option of the **Maximum stack size (bytes)** parameter and enter a positive integer value. To specify a smaller stack size at the command line, use:

```
set_param(model_name, 'MaxStackSize', 65000);
```

---

**Note** For overall executable stack usage metrics, you might want to do a target-specific measurement, such as using runtime (empirical) analysis or static (code path) analysis with object code.

---

It is recommended that you use the **Maximum stack size (bytes)** parameter to control stack space allocation instead of modifying the TLC variable, `MaxStackSize`, in the system target file. However, a target author might want to set the TLC variable, `MaxStackSize`, for a target. To set `MaxStackSize`, use `assign` statements in the system target file (`ert.tlc`), as in the following example.

```
%assign MaxStackSize = 4096
```

Write your `%assign` statements in the `Configure RTW code generation settings` section of the system target file. The `%assign` statement is described in “Target Language Compiler”.

## Optimize Generated Code Using memset Function

This example shows how to optimize the generated code by using the `memset` function to clear the internal storage. When you select the model configuration parameter **Use memset to initialize floats and doubles to 0.0**, the `memset` function clears internal storage, to the integer bit pattern 0 (that is, all bits are off).

If your compiler and target CPU both represent floating-point zero with the integer bit pattern 0, consider setting this parameter to gain execution and ROM efficiency.

**NOTE:** The command-line values are the reverse of the settings values. 'on' in the command line corresponds to clearing the setting. 'off' in the command line corresponds to selecting the setting.

This optimization:

- Reduces ROM consumption.
- Improves execution speed.

### Example Model

Consider the model `matlab:rtwdemo_memset`.

```
model = 'rtwdemo_memset';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

### Generate Code

The code generator uses a loop to initialize the Constant block values.

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwmoddir();
```

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_memset
Successful completion of build procedure for: rtwdemo_memset
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
-------	--------	----------------

```
=====
rtwdemo_memset Code generated and compiled Code generation information file does not exist.

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 35.138s
```

View the generated code without the optimization. These lines of code are in `rtwdemo_memset.c`.

```
cfile = fullfile(cgDir,'rtwdemo_memset_grt_rtw','rtwdemo_memset.c');
rtwdemodbtype(cfile,'/* Model initialize function */',...
 '/* Model terminate function */',1,0);
```

```
/* Model initialize function */
void rtwdemo_memset_initialize(void)
{
 /* Registration code */

 /* initialize error status */
 rtmSetErrorStatus(rtwdemo_memset_M, (NULL));

 /* external outputs */
 {
 int32_T i;
 for (i = 0; i < 50; i++) {
 rtwdemo_memset_Y.Out1[i] = 0.0;
 }
 }

 {
 int32_T i;

 /* ConstCode for Outport: '<Root>/Out1' */
 for (i = 0; i < 50; i++) {
 rtwdemo_memset_Y.Out1[i] = 56.0;
 }

 /* End of ConstCode for Outport: '<Root>/Out1' */
 }
}
```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 In the Configuration Parameter dialog box select the **Use memset to initialize floats and doubles to 0.0** parameter. Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model, 'InitFltsAndDblsToZero', 'off');
```

```
% # Open the Configuration Parameters dialog box.
```

### Generate Code with Optimization

The code generator uses the `memset` function to initialize the Constant block values.

Build the model.

```
slbuild(model)

Starting build procedure for: rtwdemo_memset
Successful completion of build procedure for: rtwdemo_memset
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_memset	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 24.033s

View the generated code with the optimization. These lines of code are in `rtwdemo_memset.c`.

```
rtwdemodbtype(cfile, /* Model initialize function */, ...
 /* Model terminate function */, 1, 0);

/* Model initialize function */
void rtwdemo_memset_initialize(void)
{
 /* Registration code */

 /* initialize error status */
 rtmSetErrorStatus(rtwdemo_memset_M, (NULL));

 /* external outputs */
 (void)memset(&rtwdemo_memset_Y, 0, sizeof(ExtY_rtwdemo_memset_T));

 {
 int32_T i;

 /* ConstCode for Output: '<Root>/Out1' */
 for (i = 0; i < 50; i++) {
 rtwdemo_memset_Y.Out1[i] = 56.0;
 }

 /* End of ConstCode for Output: '<Root>/Out1' */
 }
}
```

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Vector Operation Optimization

This example shows how Simulink® Coder™ optimizes generated code by setting block output that generates vectors to scalars, for blocks such as the Mux, Sum, Gain, and Bus. This optimization reduces stack memory by replacing temporary local arrays with local variables.

### Example Model

In the model, `rtwdemo_VectorOptimization`, the output of Gain blocks G1 and G2 are the vector signals `tmp1` and `tmp2`. These vectors have a width of 10.

```
model = 'rtwdemo_VectorOptimization';
open_system(model);
set_param(model, 'SimulationCommand', 'update')
```

Copyright 2014-2020 The MathWorks, Inc.

### Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwmoddir();
```

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_VectorOptimization
Successful completion of build procedure for: rtwdemo_VectorOptimization
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_VectorOptimization	Code generated and compiled	Code generation information file does not exist

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 24.341s
```

The optimized code is in `rtwdemo_VectorOptimization.c`. The signals `tmp1` and `tmp2` are the local variables `rtb_tmp1` and `rtb_tmp2`.

```

cfile = fullfile(cgDir, 'rtwdemo_VectorOptimization_grt_rtw', ...
 'rtwdemo_VectorOptimization.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_VectorOptimization_step(void)
{
 real_T rtb_Sum3;
 real_T rtb_tmp1;
 real_T rtb_tmp2;
 int32_T i;
 for (i = 0; i < 10; i++) {
 /* Gain: '<Root>/G2' incorporates:
 * UnitDelay: '<Root>/X2'
 */
 rtb_tmp2 = 0.3 * rtwdemo_VectorOptimization_DW.X2_DSTATE[i];

 /* Gain: '<Root>/G1' incorporates:
 * UnitDelay: '<Root>/X1'
 */
 rtb_tmp1 = 0.2 * rtwdemo_VectorOptimization_DW.X1_DSTATE[i];

 /* Sum: '<Root>/Sum3' incorporates:
 * Gain: '<Root>/G3'
 * Inport: '<Root>/In2'
 * Sum: '<Root>/Sum1'
 * Sum: '<Root>/Sum2'
 * UnitDelay: '<Root>/X3'
 */
 rtb_Sum3 = ((rtwdemo_VectorOptimization_U.In2[i] - 0.4 *
 rtwdemo_VectorOptimization_DW.X3_DSTATE[i]) - rtb_tmp2) -
 rtb_tmp1;

 /* Outport: '<Root>/Out2' */
 rtwdemo_VectorOptimization_Y.Out2[i] = rtb_Sum3;

 /* Update for UnitDelay: '<Root>/X3' */
 rtwdemo_VectorOptimization_DW.X3_DSTATE[i] = rtb_tmp2;

 /* Update for UnitDelay: '<Root>/X2' */
 rtwdemo_VectorOptimization_DW.X2_DSTATE[i] = rtb_tmp1;

 /* Update for UnitDelay: '<Root>/X1' */
 rtwdemo_VectorOptimization_DW.X1_DSTATE[i] = rtb_Sum3;
 }
}

```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Enable and Reuse Local Block Outputs in Generated Code

### In this section...

“Example Model” on page 71-102

“Generate Code Without Optimization” on page 71-102

“Enable Local Block Outputs and Generate Code” on page 71-103

“Reuse Local Block Outputs and Generate Code” on page 71-104

This example shows how to specify block output as local variables. The code generator can potentially reuse these local variables in the generated code. Declaring block output as local variables conserves ROM consumption. Reusing local variables conserves RAM consumption, reduces data copies, and increases execution speed.

### Example Model

- 1 Use Inport, Outport, Gain, and Switch blocks to create the following model. In this example, the model is named `local_variable_ex`.

- 2 For G2, open the Gain Block Parameters dialog box. Enter a value of 2.
- 3 For G1, enter a value of 3.
- 4 For the Switch block, open the Block Parameters dialog box. For the **Criteria for passing first input** parameter, select `u2 >= Threshold`.

### Generate Code Without Optimization

- 1 Open the Model Configuration Parameters dialog box. Select the **Solver** pane. For the **Type** parameter, select `Fixed-step`.
- 2 Clear the **Configuration Parameters > Signal storage reuse** parameter.
- 3 Select the **Code Generation > Report** pane and select **Create code generation report**.
- 4 Select the **Code Generation** pane. Select **Generate code only**, and then, in the model window, press **Ctrl+B**. When code generation is complete, an HTML code generation report appears.
- 5 In the code generation report, select the `local_variable_ex.c` section and view the model step function. The Gain block outputs are the global variables `local_variable_ex_B.G2` and `local_variable_ex_B.G1`.

```

/* Model step function */
void local_variable_ex_step(void)
{
 /* Switch: '<Root>/Switch' incorporates:
 * Inport: '<Root>/In1'
 */
 if (local_variable_ex_U.In1 >= 0.0) {
 /* Gain: '<Root>/G2' */
 local_variable_ex_B.G2 = 2.0 * local_variable_ex_U.In1;

 /* Output: '<Root>/Out1' */
 local_variable_ex_Y.Out1 = local_variable_ex_B.G2;
 } else {
 /* Gain: '<Root>/G1' */
 local_variable_ex_B.G1 = 3.0 * local_variable_ex_U.In1;

 /* Output: '<Root>/Out1' */
 local_variable_ex_Y.Out1 = local_variable_ex_B.G1;
 }

 /* End of Switch: '<Root>/Switch' */
}

```

## Enable Local Block Outputs and Generate Code

- 1 Select the **Configuration Parameters > Signal Storage Reuse** parameter. The **Signal Storage Reuse** enables the following optimization parameters:
  - **Enable local block outputs**
  - **Reuse local block outputs**
  - **Eliminate superfluous local variables (expression folding)**
- 2 Clear **Reuse local block outputs** and **Eliminate superfluous local variables (expression folding)**.
- 3 Generate code and view the model step function. There are three local variables in the model step function because you selected the optimization parameter **Enable Local Block Outputs**. The local variables `rtb_G2` and `rtb_G1` hold the outputs of the Gain blocks. The local variable `rtb_Switch` holds the output of the Switch block.

```

/* Model step function */
void local_variable_ex_step(void)
{
 real_T rtb_Switch;
 real_T rtb_G2;
 real_T rtb_G1;

 /* Switch: '<Root>/Switch' incorporates:
 * Inport: '<Root>/In1'
 */
 if (local_variable_ex_U.In1 >= 0.0) {
 /* Gain: '<Root>/G2' */
 rtb_G2 = 2.0 * local_variable_ex_U.In1;
 rtb_Switch = rtb_G2;
 } else {
 /* Gain: '<Root>/G1' */
 rtb_G1 = 3.0 * local_variable_ex_U.In1;
 rtb_Switch = rtb_G1;
 }
}

```

```
}

/* End of Switch: '<Root>/Switch' */

/* Output: '<Root>/Out1' */
local_variable_ex_Y.Out1 = rtb_Switch;
```

## Reuse Local Block Outputs and Generate Code

- 1 Select the **Configuration Parameters > Reuse local block outputs** parameter.
- 2 Generate code. In the `local_variable_ex.c` section, view the model step function. There is one local variable, `rtb_G2`, that the code generator uses three times.

```
/* Model step function */
void local_variable_ex_step(void)
{
 real_T rtb_G2;

 /* Switch: '<Root>/Switch' incorporates:
 * Inport: '<Root>/In1'
 */
 if (local_variable_ex_U.In1 >= 0.0) {
 /* Gain: '<Root>/G2' */
 rtb_G2 = 2.0 * local_variable_ex_U.In1;
 } else {
 /* Gain: '<Root>/G1' */
 rtb_G2 = 3.0 * local_variable_ex_U.In1;
 }

 /* End of Switch: '<Root>/Switch' */

 /* Output: '<Root>/Out1' */
 local_variable_ex_Y.Out1 = rtb_G2;
```

The extra temporary variable `rtb_Switch` and the associated data copy is not in the generated code.

## Generate SIMD Code from Simulink Blocks

You can generate single instruction, multiple data (SIMD) code from certain Simulink blocks by using Intel SSE and, if you have Embedded Coder, Intel AVX technology. SIMD is a computing paradigm in which a single instruction processes multiple data. Many modern processors have SIMD instructions that, for example, perform several additions or multiplications at once. For computationally intensive operations on supported blocks, SIMD intrinsics can significantly improve the performance of the generated code on Intel platforms.

### Blocks That Support SIMD Code Generation

When certain conditions are met, you can generate SIMD code by using Intel SSE or Intel AVX technology. This table lists blocks that support SIMD code generation. The table also details the conditions under which the support is available.

Block	Conditions
Add	<ul style="list-style-type: none"> <li>For AVX, SSE, and FMA, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For AVX2, SSE4.1, and SSE2, the input signal has a data type of <code>single</code>, <code>double</code>, <code>int8</code>, <code>int16</code>, <code>int32</code>, or <code>int64</code>.</li> <li>For AVX512F, the input signal has a data type of <code>single</code> or <code>double</code>.</li> </ul>
Subtract	<ul style="list-style-type: none"> <li>For AVX, SSE, and FMA, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For AVX2, SSE4.1, and SSE2, the input signal has a data type of <code>single</code>, <code>double</code>, <code>int8</code>, <code>int16</code>, <code>int32</code>, or <code>int64</code>.</li> <li>For AVX512F, the input signal has a data type of <code>single</code> or <code>double</code>.</li> </ul>
Sum of Elements	<ul style="list-style-type: none"> <li>For AVX, SSE, and FMA, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For AVX2, SSE4.1, and SSE2, the input signal has a data type of <code>single</code>, <code>double</code>, <code>int8</code>, <code>int16</code>, <code>int32</code>, or <code>int64</code>.</li> <li>For AVX512F, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>The <b>Optimize reductions</b> configuration parameter is set to <code>on</code>.</li> </ul>

Block	Conditions
Product	<ul style="list-style-type: none"> <li>• For AVX, SSE, and FMA, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>• For AVX2, SSE4.1, and SSE2, the input signal has a data type of <code>single</code>, <code>double</code>, <code>int16</code> or <code>int32</code>.</li> <li>• For AVX512F, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>• Set <b>Multiplication</b> parameter to <code>Element-wise(.*)</code></li> </ul>
Product of Elements	<ul style="list-style-type: none"> <li>• For AVX, SSE, and FMA, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>• For AVX2, SSE4.1, and SSE2, the input signal has a data type of <code>single</code>, <code>double</code>, <code>int16</code> or <code>int32</code>.</li> <li>• For AVX512F, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>• Set <b>Multiplication</b> parameter to <code>Element-wise(.*)</code></li> <li>• Set the <b>Optimize reductions</b> configuration parameter to <code>on</code>.</li> </ul>
Gain	<ul style="list-style-type: none"> <li>• For AVX, and SSE, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>• For AVX2, SSE4.1, and SSE2, the input signal has a data type of <code>single</code>, <code>double</code>, <code>int16</code>, or <code>int32</code>.</li> <li>• For Intel AVX512F, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>• Set <b>Multiplication</b> parameter to <code>Element-wise(.*)</code></li> </ul>
Divide	The input signal has a data type of <code>single</code> or <code>double</code> .
Sqrt	The input signal has a data type of <code>single</code> or <code>double</code> .
Ceil	<ul style="list-style-type: none"> <li>• For AVX2, AVX, SSE4.1, SSE2, and SSE, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>• AVX512F is not supported.</li> </ul>
Floor	<ul style="list-style-type: none"> <li>• For AVX2, AVX, SSE4.1, SSE2, and SSE, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>• AVX512F is not supported.</li> </ul>

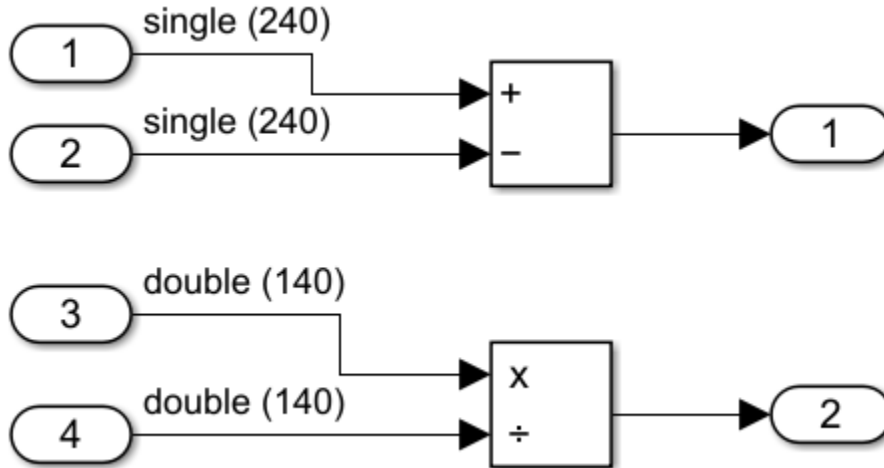

Block	Conditions
MinMax	<ul style="list-style-type: none"> <li>The input signal has a data type of single or double.</li> <li>The value of the <b>Support: non-finite numbers</b> configuration parameter is set to off.</li> </ul>
MinMax of Elements	<ul style="list-style-type: none"> <li>The input signal has a data type of single or double.</li> <li>The value of the <b>Support: non-finite numbers</b> configuration parameter is set to off.</li> <li>The <b>Optimize reductions</b> configuration parameter is set to on.</li> </ul>
MATLAB Function	MATLAB code meets the conditions specified in this topic: “Generate SIMD Code for MATLAB Functions” on page 91-27.
For Each Subsystem	<ul style="list-style-type: none"> <li>The For Each Subsystem block contains a block listed in this table that meets the specified conditions.</li> <li>The value of the <b>Partition Dimension</b> block parameter must be above the value of the <b>Loop unrolling threshold</b> configuration parameter.</li> </ul>
Bitwise Operator	<ul style="list-style-type: none"> <li>The value of the <b>Operator</b> block parameter must be AND, OR, or XOR.</li> <li>For SSE2, the input signal has a data type of int8, int16, int32, or int64.</li> <li>For AVX2, and AVX512F, the input signal has a data type of int8, int16, int32, or int64.</li> </ul>
Shift Arithmetic	<ul style="list-style-type: none"> <li>The input signal has a data type of int32.</li> </ul>

If you have DSP System Toolbox, you can also generate SIMD code from certain DSP System Toolbox blocks. For more information, see “Simulink Blocks in DSP System Toolbox that Support SIMD Code Generation” (DSP System Toolbox).

## Generate SIMD Code Compared to Plain C Code

For this example, create a simple model `simdDemo` that has a Subtract block and a Divide block. The Subtract block has an input signal that has a dimension of 240 and an input data type of `single`. The Divide block has an input signal that has a dimension of 140 and an input data type of `double`.

The plain generated C code for this model is:

```
void simdDemo_step(void)
{
 int32_T i;
 for (i = 0; i < 240; i++) {
 simdDemo_Y.Out1[i] = simdDemo_U.In1[i] - simdDemo_U.In2[i];
 }

 for (i = 0; i < 140; i++) {
 simdDemo_Y.Out2[i] = simdDemo_U.In3[i] / simdDemo_U.In4[i];
 }
}
```

In the plain (non-SIMD) C code, each loop iteration produces one result.

To generate SIMD code:

- 1 Open the Simulink Coder app or the Embedded Coder app.
- 2 Click **Settings > Hardware Implementation**.
- 3 Set the **Device vendor** parameter to Intel or AMD.
- 4 Set the **Device type** parameter to x86-64(Windows 64) or x86-64(Linux 64).
- 5 On the **Optimization** pane, for the **Leverage target hardware instruction set extensions** parameter, select the instruction set extension that your processor supports. For example, select SSE2. If you use Embedded Coder, you can also select from the instruction sets SSE, SSE4.1, AVX, AVX2, FMA, and AVX512F. For more information, see <https://www.intel.com/content/www/us/en/support/articles/000005779/processors.html>.
- 6 Optionally, select the **Optimize reductions** parameter to generate SIMD code for reduction operations.
- 7 Generate code from the model.

```
void simdDemo_step(void)
{
 int32_T i;
 for (i = 0; i <= 236; i += 4) {
 _mm_storeu_ps(&simdDemo_Y.Out1[i], _mm_sub_ps(_mm_loadu_ps(&simdDemo_U.In1[i]),
 _mm_loadu_ps(&simdDemo_U.In2[i])));
 }
}
```

```

}
for (i = 0; i <= 138; i += 2) {
 _mm_storeu_pd(&simdDemo_Y.Out2[i], _mm_div_pd(_mm_loadu_pd(&simdDemo_U.In3[i]),
 _mm_loadu_pd(&simdDemo_U.In4[i])));
}
}

```

This code is for the SSE2 instruction set extension. The SIMD instructions are the intrinsic functions that start with the identifier `_mm`. These functions process multiple data in a single iteration of the loop because the loop increments by four for single data types and by two for double data types. For models that process more data and are computationally more intensive than this one, the presence of SIMD instructions can significantly speed up the code execution time.

For a list of a Intel intrinsic functions for supported Simulink blocks, see <https://www.intel.com/content/www/us/en/docs/intrinsics-guide/index.html>.

## Limitations

The generated code is not optimized through SIMD if:

- The code in a MATLAB Function block contains scalar data types outside the body of loops. For instance, if `a`, `b`, and `c` are scalars, the generated code does not optimize an operation such as `c=a+b`.
- The code in a MATLAB Function block contains indirectly indexed arrays or matrices. For instance if `A`, `B`, `C`, and `D` are vectors, the generated code is not vectorized for an operation such as `D(A)=C(A)+B(A)`.
- The blocks within a reusable subsystem might not be optimized.
- If the code in a MATLAB Function block contains parallel for-Loops (`parfor`), the `parfor` loop is not optimized with SIMD code, but loops within the body of the `parfor` loop can be optimized with SIMD code.
- Polyspace does not support analysis of generated code that includes SIMD instructions. Disable SIMD code generation by setting the **Leverage target hardware instruction set extensions** parameter to `None`.
- Reduction operations that operate on floating-point values when support for nonfinite numbers is enabled. To generate SIMD code for reduction operations that operate on floating-point values, set the configuration parameter **Support: non-finite numbers** to `Off`.

- “Generate SIMD Code for MATLAB Functions” on page 91-27

## Optimize Code for Reduction Operations by Using SIMD

This example shows how to generate optimized single instruction, multiple data (SIMD) code that performs reduction operations. A reduction is an operation that reduces a set of elements, such as an array, to a single value using an associative binary operator. For example, calculating the sum of the elements in an array is a reduction operation that uses the addition operator. For processors that support SIMD instructions, you can optimize reduction operations by generating parallel code that uses the SIMD instructions for the operation.

### Example Model

Open the example model `ex_rowmajor_algorithm`. The model calculates the sum of the elements in a 4 by 3 by 2 array.

```
model = 'ex_rowmajor_algorithm';
open_system(model)
```

Copyright 2021 The MathWorks, Inc.

### Generate SIMD Code Without Reduction Optimization

Open the configuration parameters for the model. On the **Modeling** tab, click **Settings**. On the **Code Generation** pane, set **System target file** to `grt.tlc`. On the **Optimization** pane, set the **Leverage target hardware instruction set extensions** to SSE2. Alternatively, use the command-line.

```
set_param(model, 'SystemTargetFile', 'grt.tlc');
set_param(model, 'SaveOutput', 'off');
set_param(model, 'RTWVerbose', 'off');
set_param(model, 'InstructionSetExtensions', 'SSE2');
```

De-select the parameter **Optimize reductions**.

```
set_param(model, 'OptimizeReductions', 'off');
```

Build the model.

```
slbuild(model);
```

```
Starting build procedure for: ex_rowmajor_algorithm
Successful completion of build procedure for: ex_rowmajor_algorithm
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
ex_rowmajor_algorithm	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 14.621s

Inspect the generated `rtwdemo_simd_reductions_step` function.

```
file = fullfile('ex_rowmajor_algorithm_grt_rtw','ex_rowmajor_algorithm.c');
rtwdemodbtype(file,'/* Model step function */','/* End of Sum',1,1);

/* Model step function */
void ex_rowmajor_algorithm_step(void)
{
 int32_T i;

 /* Sum: '<Root>/Sum of Elements Dim1' incorporates:
 * Constant: '<Root>/Constant1'
 */
 ex_rowmajor_algorithm_Y.Out2 = -0.0F;
 for (i = 0; i < 24; i++) {
 ex_rowmajor_algorithm_Y.Out2 +=
 ex_rowmajor_algorithm_ConstP.Constant1_Value[i];
 }
}
```

The generated code contains a non-vectorized loop that adds each array element individually.

### Generate SIMD Code With Reduction Optimization

Open the configuration parameters for the model. On the **Modeling** tab, click **Settings**. On the **Optimization** pane, set the **Leverage target hardware instruction set extensions** to SSE2. Alternatively, use the command-line.

```
set_param(model, 'InstructionSetExtensions', 'SSE2');
```

Select the parameter **Optimize reductions**. If you want to optimize reduction operations that operate on floating-point values, set **Support: Non-finite numbers** to Off. Reduction optimization does not support operations on floating-point values when non-finite numbers are supported.

```
set_param(model, 'OptimizeReductions', 'on');
```

Build the model.

```
slbuild(model);
```

```
Starting build procedure for: ex_rowmajor_algorithm
Successful completion of build procedure for: ex_rowmajor_algorithm
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
ex_rowmajor_algorithm	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 13.355s

Inspect the generated `rtwdemo_simd_reductions_step` function.

```
file = fullfile('ex_rowmajor_algorithm_grt_rtw','ex_rowmajor_algorithm.c');
rtwdemodbtype(file,'/* Model step function */','/* Matfile',1,1);

/* Model step function */
void ex_rowmajor_algorithm_step(void)
{
 int32_T i;

 /* Sum: '<Root>/Sum of Elements Dim1' incorporates:
 * Constant: '<Root>/Constant1'
 */
 ex_rowmajor_algorithm_Y.Out2 = -0.0F;
 for (i = 0; i < 24; i++) {
 ex_rowmajor_algorithm_Y.Out2 +=
 ex_rowmajor_algorithm_ConstP.Constant1_Value[i];
 }

 /* End of Sum: '<Root>/Sum of Elements Dim1' */
}
```

The vectorized loop uses the SSE2 function `mm_add_ps`, which adds four elements of the array to the sum in one step. This optimization improves the execution speed of the generated code.

Open the code generation report. On the **C Code** tab, click **Open Report**.

## Additional Information

Code Generation Advisor	Not run
Optimize reductions	Reductions are optimized using SSE2 Instruction Set Extensions

On the report summary, in the **Additional Information** section, the report indicates that reduction operations are optimized using the SSE2 instruction set.

# Configuration in Embedded Coder

---

## Set Hardware Implementation Parameters

Specification of target hardware device characteristics (such as word sizes for `char`, `short`, `int`, and `long` data types, or desired rounding behaviors in integer operations) for generated code can be critical in embedded systems development. The **Hardware Implementation** category of parameters in a configuration set provides a way to control such characteristics in simulation and code generation.

By configuring the **Hardware Implementation** parameters of the active configuration set for a model to match the behaviors of your compiler and hardware, you can generate more efficient code. For example, if you specify the **Byte ordering** parameter, you can avoid generation of extra code that tests the byte ordering of the target CPU.

Before generating and deploying code, get familiar with the **Hardware Implementation** pane of the Configuration Parameters dialog box. By default, target hardware microprocessor device details are hidden. To view the details, click the **Device details** arrow. See “Hardware Implementation Pane” and “Configure Run-Time Environment Options” for more information.

## Optimize Global Variable Usage

### In this section...

“Use Global to Hold Temporary Results” on page 73-2

“Minimize Global Data Access” on page 73-6

To tune your application and choose tradeoffs for execution speed and memory usage, you can choose a global variable reference optimization for the generated code.

On the Configuration Parameters dialog box, in the **Optimize global data access** drop-down list, three parameter options control global variable usage optimizations.

- **None.** Use default optimizations. This choice works well for most models. The code generator balances the use of local and global variables. It generates code which balances RAM and ROM consumption and execution speed.
- **Use global to hold temporary results.** Reusing global variables improves code efficiency and readability. This optimization reuses global variables, which results in the code generator defining fewer variables. It reduces RAM and ROM consumption and data copies.
- **Minimize global data access.** Using local variables to cache global data reduces ROM consumption by reducing code size. This optimization improves execution speed because the code uses fewer instructions for local variable references than for global variable references.

Minimizing the use of global variables by using local variables interacts with stack usage control. For example, stack size can determine the number of local and global variables that the code generator can allocate in the generated code. For more information, see “Customize Stack Space Allocation”.

### Use Global to Hold Temporary Results

The code generator uses global and local variables when you select **None** versus when you select **Use global to hold temporary results**.

#### Example Model

In the model `matlab:rtwdemo_optimize_global_ebf`, an Assignment block assigns values coming from the Inport and Constant blocks to an output signal. The output signal feeds into a Gain block.

```

model = 'rtwdemo_optimize_global_ebf';
load_system('rtwdemo_optimize_global_ebf')

```

## Generate Code Without Optimization

- 1 In the Configuration Parameters dialog box, verify that the **Signal storage reuse** parameter is selected.
- 2 In the Configuration Parameters dialog box, for the **Optimize global data access** parameter, select **None** or enter the following command in the MATLAB® Command Window:

```
set_param('rtwdemo_optimize_global_ebf','GlobalVariableUsage','None');
```

In your system's temporary folder, create a folder for the build and inspection process:

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
slbuild(model);

Starting build procedure for: rtwdemo_optimize_global_ebf
Successful completion of build procedure for: rtwdemo_optimize_global_ebf
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_optimize_global_ebf	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 48.602s

View the generated code without the optimization. Here is a portion of `rtwdemo_optimize_global_ebf.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ebf_ert_rtw',...
 'rtwdemo_optimize_global_ebf.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);

/* Model step function */
void rtwdemo_optimize_global_ebf_step(void)
{
 real_T rtb_Assignment[5];
 int32_T i;

 /* SignalConversion generated from: '<Root>/Assignment' incorporates:
 * Constant: '<Root>/Constant'
 */
 for (i = 0; i < 5; i++) {
 rtb_Assignment[i] = rtCP_Constant_Value[i];
 }

 /* End of SignalConversion generated from: '<Root>/Assignment' */

 /* Assignment: '<Root>/Assignment' incorporates:
 * Inport: '<Root>/In1'
 */
 rtb_Assignment[1] = rtU.In1;
```

```

/* Outport: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 */
for (i = 0; i < 5; i++) {
 rtY.Out1[i] = 2.0 * rtb_Assignment[i];
}

/* End of Outport: '<Root>/Out1' */
}

```

The code assigns values to the local vector `rtb_Assignment`. The last statement copies the values in the local vector `rtb_Assignment` to the global vector `rtY.Out1`. Fewer global variable references result in improved execution speed. The code uses more instructions for global variable references than for local variable references.

In the Static Code Metrics Report, examine the Global Variables section.

- 1 In the Code Generation Report window, select **Static Code Metrics Report**.
- 2 Scroll down to the **Global Variables** section.
- 3 Select the **[+]** sign before each variable to expand it.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
<a href="#">[-] rtY</a>	40	1	1
Out1	40	1	1
<a href="#">[-] rtU</a>	8	1	1
In1	8	1	1
<a href="#">[-] rtM_</a>	4	0*	0*
errorStatus	4	0	0
<b>Total</b>	<b>52</b>	<b>2</b>	

\* The global variable is not directly used in any function.

The total number of reads and writes for global variables is 2.

### Generate Code with Optimization

In the Configuration Parameters dialog box, for the **Optimize global data access** parameter, select **Use global to hold temporary results**, or enter the following command in the MATLAB Command Window:

```
set_param('rtwdemo_optimize_global_ebf',...
 'GlobalVariableUsage','Use global to hold temporary results');
```

Build the model.

```
slbuild(model);
```

```
Starting build procedure for: rtwdemo_optimize_global_ebf
Successful completion of build procedure for: rtwdemo_optimize_global_ebf
```

## Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_optimize_global_ebf	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 31.575s

View the generated code with the optimization. Here is a portion of `rtwdemo_optimize_global_ebf.c`.

```
cfile = fullfile(cgDir, 'rtwdemo_optimize_global_ebf_ert_rtw', ...
 'rtwdemo_optimize_global_ebf.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_optimize_global_ebf_step(void)
{
 int32_T i;

 /* SignalConversion generated from: '<Root>/Assignment' incorporates:
 * Assignment: '<Root>/Assignment'
 * Constant: '<Root>/Constant'
 */
 for (i = 0; i < 5; i++) {
 rtY.Out1[i] = rtCP_Constant_Value[i];
 }

 /* End of SignalConversion generated from: '<Root>/Assignment' */

 /* Assignment: '<Root>/Assignment' incorporates:
 * Inport: '<Root>/In1'
 */
 rtY.Out1[1] = rtU.In1;

 /* Outputport: '<Root>/Out1' incorporates:
 * Assignment: '<Root>/Assignment'
 * Gain: '<Root>/Gain'
 */
 for (i = 0; i < 5; i++) {
 rtY.Out1[i] *= 2.0;
 }

 /* End of Outputport: '<Root>/Out1' */
}
```

The code assigns values to the global vector `rtY.Out1` without using a local variable. This assignment improves ROM and RAM consumption and reduces data copies. The code places the value in the destination variable for each assignment instead of copying the value at the end. In the Static Code Metrics Report, examine the Global Variables section.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[ - ] <a href="#">rtY</a>	40	4	4
Out1	40	4	4
[ - ] <a href="#">rtU</a>	8	1	1
In1	8	1	1
[ - ] <a href="#">rtM_</a>	4	0*	0*
errorStatus	4	0	0
<b>Total</b>	<b>52</b>	<b>5</b>	

\* The global variable is not directly used in any function.

As a result of using global variables to hold local results, the total number of reads and writes for global variables has increased from 2 to 5. This optimization reduces data copies by reusing global variables.

Close the code generation report.

```
rtwdemoclean;
cd(currentDir)
```

## Minimize Global Data Access

Generate optimized code that reads from and writes to global variables less frequently.

### Example Model

In the model matlab:rtwdemo\_optimize\_global, five signals feed into a Multiport Switch block.

```
model = 'rtwdemo_optimize_global';
load_system('rtwdemo_optimize_global')
```

### Generate Code Without Optimization

- 1 In the Configuration Parameters dialog box, verify that the **Signal storage reuse** parameter is selected.
- 2 In the Configuration Parameters dialog box, for the **Optimize global data access** parameter, select **None** or enter the following command in the MATLAB® Command Window:

```
set_param('rtwdemo_optimize_global','GlobalVariableUsage','None');
```

In your system's temporary folder, create a folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
slbuild(model);
```

```
Starting build procedure for: rtwdemo_optimize_global
Successful completion of build procedure for: rtwdemo_optimize_global
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_optimize_global	Code generated and compiled	Code generation information file does not e

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 45.428s
```

View the generated code without the optimization. Here is a portion of `rtwdemo_optimize_global.c`.

```

cfile = fullfile(cgDir,'rtwdemo_optimize_global_ert_rtw',...
 'rtwdemo_optimize_global.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);

/* Model step function */
void rtwdemo_optimize_global_step(void)
{
 /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
 * Inport: '<Root>/In1'
 */
 switch ((int32_T)rtU.In1) {
 case 1:
 /* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant'
 */
 rtY.Out1 = 1.0;
 break;

 case 2:
 /* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant1'
 */
 rtY.Out1 = 2.0;
 break;

 case 3:
 /* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant2'
 */
 rtY.Out1 = 3.0;
 break;

 default:
 /* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant3'
 */
 rtY.Out1 = 4.0;
 break;
 }

 /* End of MultiPortSwitch: '<Root>/Multiport Switch' */
}

```

In the Static Code Metrics Report, examine the `Global Variables` section.

- 1 In the Code Generation Report window, select **Static Code Metrics Report**.
- 2 Scroll down to the `Global Variables` section.
- 3 Select the **[+]** sign before each variable to expand it.

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[ - ] <a href="#">rtU</a>	8	1	1
In1	8	1	1
[ - ] <a href="#">rtY</a>	8	4	4
Out1	8	4	4
[ - ] <a href="#">rtM</a>	4	0*	0*
errorStatus	4	0	0
<b>Total</b>	<b>20</b>	<b>5</b>	

\* The global variable is not directly used in any function.

The total number of reads and writes for global variables is 5.

### Enable Optimization and Generate Code

In the Configuration Parameters dialog box, for the **Optimize global data access** parameter, select **Minimize global data access** or enter the following command in the MATLAB Command Window:

```
set_param('rtwdemo_optimize_global',...
 'GlobalVariableUsage','Minimize global data access');
```

Build the model.

```
slbuild(model);
```

```
Starting build procedure for: rtwdemo_optimize_global
Successful completion of build procedure for: rtwdemo_optimize_global
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_optimize_global	Code generated and compiled	Generated code was out of date.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 29.323s
```

View the generated code with the optimization. Here is a portion of `rtwdemo_optimize_global.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ert_rtw',...
 'rtwdemo_optimize_global.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);

/* Model step function */
void rtwdemo_optimize_global_step(void)
{
 real_T tmp_Out1;

 /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
```

```
* Inport: '<Root>/In1'
*/
switch ((int32_T)rtU.In1) {
case 1:
/* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant'
 */
tmp_Out1 = 1.0;
break;

case 2:
/* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant1'
 */
tmp_Out1 = 2.0;
break;

case 3:
/* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant2'
 */
tmp_Out1 = 3.0;
break;

default:
/* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant3'
 */
tmp_Out1 = 4.0;
break;
}

/* End of MultiPortSwitch: '<Root>/Multiport Switch' */

/* Outport: '<Root>/Out1' */
rtY.Out1 = tmp_Out1;
}
```

In `rtwdemo_optimize_global.c`, the code assigns a constant value to the local variable `tmp_Out1` in each case statement. The last statement in the code copies the value of `tmp_Out1` to the global variable `rtY.Out1`. Fewer global variable references result in fewer instructions and improved execution speed.

In the **Static Code Metrics Report**, examine the **Global Variables** section. As a result of minimizing global data accesses, the total number of reads and writes for global variables has decreased from 5 to 2.

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[ - ] <a href="#">rtU</a>	8	1	1
In1	8	1	1
[ - ] <a href="#">rtY</a>	8	1	1
Out1	8	1	1
[ - ] <a href="#">rtM</a>	4	0*	0*
errorStatus	4	0	0
<b>Total</b>	<b>20</b>	<b>2</b>	

\* The global variable is not directly used in any function.

Close the code generation report.

```
rtwdemoclean;
cd(currentDir)
```

- “Reuse Global Block Outputs in the Generated Code” on page 73-12

## Reuse Global Block Outputs in the Generated Code

Reduce ROM and RAM consumption and data copies and increase execution speed of generated code. Configure the code generator to reuse global variables by selecting the model configuration parameter **Reuse global block outputs**.

### Example

In the Command Window, type `rtwdemo_reuse_global`.

### Generate Code Without Optimization

- 1 On the Configuration Parameters dialog box, verify that **Signal storage reuse** is selected.
- 2 Clear **Reuse global block outputs** and click **Apply**.
- 3 On the **Code Generation > Report** pane, select **Generate static code metrics**.
- 4 In your system's temporary folder, create a folder for the build and inspection process.

Press **Ctrl+B** to generate code.

```
Starting build procedure for: rtwdemo_reuse_global
Successful completion of build procedure for: rtwdemo_reuse_global
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_reuse_global	Code generated and compiled	Code generation information file does not exist

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 17.484s
```

View the generated code without the optimization. Here is a portion of `rtwdemo_reuse_global.c`.

```
/* Model step function */
```

```

void rtwdemo_reuse_global_step(void)
{
 /* Sum: '<Root>/Sum' incorporates:
 * Delay: '<Root>/Delay'
 * Inport: '<Root>/In1'
 */
 rtDW.Delay_DSTATE += rtU.In1;

 /* Output: '<Root>/Out1' incorporates:
 * Delay: '<Root>/Delay'
 */
 rtY.Out1 = rtDW.Delay_DSTATE;
}

```

The generated code contains a data copy to the global variable `rtDW.Delay_DSTATE`. Open the Static Code Metrics Report. The total number of reads and writes for global variables is 8. The total size is 32 bytes.

### Enable Optimization and Generate Code

- 1 On the Configuration Parameters dialog box, select **Reuse global block outputs** and click **Apply**.
- 2 Generate code.
- 3 View the generated code with the optimization. Here is a portion of `rtwdemo_reuse_global.c`.

```

Starting build procedure for: rtwdemo_reuse_global
Successful completion of build procedure for: rtwdemo_reuse_global

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_reuse_global	Code generated and compiled	Generated code was out of date.

```

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 15.176s

```

```

/* Model step function */
void rtwdemo_reuse_global_step(void)
{
 /* Sum: '<Root>/Sum' incorporates:
 * Delay: '<Root>/Delay'
 * Inport: '<Root>/In1'
 */
 rtY.Out1 += rtU.In1;
}

```

The code generator eliminates a data copy, reduces two statements to one statement and three global variables to two global variables.

Open the Static Code Metrics Report. For global variables, this optimization reduces the total number of reads and writes for global variables from 8 to 5 and the total size from 32 bytes to 24 bytes.

- “Optimize Global Variable Usage” on page 73-2

## Virtualized Output Ports Optimization

The *virtualized output ports* optimization lets you store the signal entering the root output port as a global variable. Clearing the **MAT-file logging** option and setting the TLC variable `FullRootOutputVector` to 0, both defaults for Embedded Coder, eliminate code and data storage associated with root output ports.

Consider the model in the following block diagram. The signal `exportedSig` has `exportedGlobal` storage class.

In the default case, the output of the Gain block is written to the signal storage location, `exportedSig`. The code generator does not generate code or data for the `Out1` block, which has become a virtual block.

```
/* Gain Block: <Root>/Gain */
exportedSig = rtb_PulseGen * VirtOutPortLogOFF_P.Gain_Gain;
```

In cases where you enable **MAT-file logging** or set `FullRootOutputVector = 1`, the generated code represents root output ports as members of an external outputs vector.

The following code fragment was generated with **MAT-file logging** enabled. The output port is represented as a member of the external outputs vector `VirtOutPortLogON_Y`. The Gain block output value is copied to `exportedSig` and to the external outputs vector.

```
/* Gain Block: <Root>/Gain */
exportedSig = rtb_PulseGen * VirtOutPortLogON_P.Gain_Gain;

/* Output Block: <Root>/Out1 */
VirtOutPortLogON_Y.Out1 = exportedSig;
```

Data maintenance in the external outputs vector can be significant for smaller models that perform benchmarks.

You can force root output ports to be stored in the external outputs vector (regardless of the setting of **MAT-file logging**) by setting the TLC variable `FullRootOutputVector` to 1. Add the statement

```
%assign FullRootOutputVector = 1
```

to the Embedded Coder system target file. Alternatively, you can enter the assignment from the MATLAB command line using the `set_param` command, the model parameter `TLCOptions`, and the TLC option `-a`. For more information, see “Specify TLC for Code Generation” and “Configure TLC”.

For more information on how to control signal storage in generated code, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 33-49 and “C Code Generation Configuration for Model Interface Elements” on page 32-2.

### **Related Examples**

- “Optimize Generated Code with Code Efficiency Tools and Techniques” on page 71-7
- “Specify Buffer Reuse for Signals in a Path” on page 73-17
- “Optimize Global Variable Usage” on page 73-2

## Specify Buffer Reuse for Signals in a Path

If your model has the optimal parameter settings for removing data copies, you might be able to remove additional data copies by using the `Reusable` storage class on the signals through the Code Mappings editor or `Simulink.Signal` data objects. This optimization decreases data copies and memory consumption and increases code execution speed. After studying the generated code and the Static Code Metrics Report and identifying areas where you think buffer reuse is possible, you specify the `Reusable` storage class on signal lines.

You can specify buffer reuse on signals that include a pair of root inport and outport signals. You can also specify buffer reuse on just a pair of root inport and outport signals. This optimization reduces ROM and RAM consumption because there are less global variables and data copies in the generated code. Code execution speed also increases.

### Example Model

The model `ex_reusable_csc` contains the nonreusable subsystem `DeltaSubsystem` and the MATLAB Function block `Downsample`. `DeltaSubsystem` contains the MATLAB Function blocks `DeltaX` and `DeltaY`.

```
model = 'ex_reusable_csc';
open_system(model);
```

Testing - Copyright 2021 The MathWorks, Inc.

### Specify Reusable Storage Class in Code Mappings Editor

- 1 Open the **Embedded Coder** app.
- 2 To open the Code Mappings editor, click **Code Interface > Individual Element Code Mappings**.
- 3 In the model, select the `RCSC_REAL` signal line. To view this signal or any signal in the Code Mappings editor, on the **Signals/States** tab, click the **Add selected signals to code mappings** button.
- 4 For the row that represents the signal line, set the **Storage Class** column to `Reusable`.
- 5 Similarly, add these signals to the Code Mappings editor and set **Storage Class** to `Reusable`:
  - `RCSC_IMAG`
  - `RCSC_REAL2`
  - `RCSC_IMAG2`

And these signals inside the subsystem:

- `RCSC_REAL`
- `RCSC_IMAG`

- RCSC\_REAL2
- RCSC\_IMAG2

Alternatively, use these commands in the MATLAB® Command Window:

```
cmo = coder.mapping.utils.create(model);
cm = coder.mapping.api.get(model);

portHandles = get_param(...
 'ex_reusable_csc/Complex to Real-Imag', 'portHandles');
addSignal(cm, [portHandles.Output(1), portHandles.Output(2)], ...
 'StorageClass', 'Reusable');

portHandles = get_param(...
 'ex_reusable_csc/Downsample', 'portHandles');
addSignal(cm, [portHandles.Output(1), portHandles.Output(2)], ...
 'StorageClass', 'Reusable');

portHandles = get_param(...
 'ex_reusable_csc/DeltaSubsystem/DeltaX', 'portHandles');
addSignal(cm, [portHandles.Output(1), portHandles.Output(2)], ...
 'StorageClass', 'Reusable');

portHandles = get_param(...
 'ex_reusable_csc/DeltaSubsystem/DeltaY', 'portHandles');
addSignal(cm, [portHandles.Output(1), portHandles.Output(2)], ...
 'StorageClass', 'Reusable');
```

Build the model.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
slbuild(model);

Starting build procedure for: ex_reusable_csc
Successful completion of build procedure for: ex_reusable_csc
```

Build Summary

 * MATLAB Function: '<S1>/DeltaY'
 * SignalConversion generated from: '<S1>/DeltaY'
 * */
 DeltaY(&RCSC_REAL[0], &RCSC_IMAG[0], &RCSC_REAL2[0], &RCSC_IMAG2[0]);
}

/* Model step function */
void ex_reusable_csc_step(void)
{
 int32_T i;

 /* ComplexToRealImag: '<Root>/Complex to Real-Imag' incorporates:
 * Inport: '<Root>/ComplexData'
 */
 for (i = 0; i < 1048576; i++) {
 RCSC_REAL[i] = rtU.ComplexData[i].re;
 RCSC_IMAG[i] = rtU.ComplexData[i].im;
 }

 /* End of ComplexToRealImag: '<Root>/Complex to Real-Imag' */

 /* MATLAB Function: '<Root>/Downsample' */
 Downsample(&RCSC_REAL[0], &RCSC_IMAG[0], &RCSC_REAL2[0], &RCSC_IMAG2[0]);

 /* Outputs for Atomic SubSystem: '<Root>/DeltaSubsystem' */
 DeltaSubsystem();

 /* End of Outputs for SubSystem: '<Root>/DeltaSubsystem' */

 /* Outport: '<Root>/Out1' incorporates:
 * RealImagToComplex: '<Root>/Real-Imag to Complex'

```

```

 * SignalConversion generated from: '<S1>/DeltaY'
 * */
 for (i = 0; i < 261121; i++) {
 rtY.Out1[i].re = RCSC_REAL2[i];
 rtY.Out1[i].im = RCSC_IMAG2[i];
 }

 /* End of Output: '<Root>/Out1' */
}

```

The variables `RCSC_REAL` and `RCSC_IMAG` hold the outputs of the Complex to Real-Image block and `DeltaX`. These variables hold the inputs to the `DeltaY` block. The variables `RCSC_REAL2` and `RCSC_IMAG2` hold the outputs of `Downsample` and `DeltaY`. These variables hold the inputs to the `DeltaX` block. By interleaving buffers in this way, you eliminate redundant data copies in the generated code.

To remove the signals from the Code Mappings editor, on the **Signals/States** tab, select the signals and click the **Remove selected signals to code mappings** button.

Alternatively, use these commands in the MATLAB Command Window:

```

portHandles = get_param(...
 'ex_reusable_csc/Complex to Real-Imag', 'portHandles');
removeSignal(cm, [portHandles.Outputport(1), portHandles.Outputport(2)]);

portHandles = get_param(...
 'ex_reusable_csc/Downsample', 'portHandles');
removeSignal(cm, [portHandles.Outputport(1), portHandles.Outputport(2)]);

portHandles = get_param(...
 'ex_reusable_csc/DeltaSubsystem/DeltaX', 'portHandles');
removeSignal(cm, [portHandles.Outputport(1), portHandles.Outputport(2)]);

portHandles = get_param(...
 'ex_reusable_csc/DeltaSubsystem/DeltaY', 'portHandles');
removeSignal(cm, [portHandles.Outputport(1), portHandles.Outputport(2)]);

```

When you generate code for the model, the `ex_reusable_csc.h` contains two extra global variables:

```

slbuild(model);
cfile = fullfile(cgDir, ...
 'ex_reusable_csc_ert_rtw', 'ex_reusable_csc.h');
rtwdemodbtype(cfile, ...
 '/* Block signals and states', ...
 '} D_Work;', 1, 0);

Starting build procedure for: ex_reusable_csc
Successful completion of build procedure for: ex_reusable_csc

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
ex_reusable_csc	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 24.354s

```
/* Block signals and states (default storage) for system '<Root>' */
typedef struct {
 real_T z2[262144]; /* '<S1>/DeltaY' */
 real_T z1[262144]; /* '<S1>/DeltaY' */
 real_T z1_m[261632]; /* '<S1>/DeltaX' */
 real_T z2_c[261632]; /* '<S1>/DeltaX' */
 real_T RCSC_REAL[1048576]; /* '<Root>/Complex to Real-Imag' */
 real_T RCSC_IMAG[1048576]; /* '<Root>/Complex to Real-Imag' */
}
```

The `ex_reusable_csc.c` file now contains this code.

```
cfile = fullfile(cgDir,...
 'ex_reusable_csc_ert_rtw','ex_reusable_csc.c');
rtwdemodbtype(cfile,...
 '/* Output and update for atomic system: '<Root>/DeltaSubsystem' */',...
 '/* Output and update for atomic system: '<Root>/Downsample' */',1,0);
rtwdemodbtype(cfile,...
 '/* Model step function */','/* Model initialize function */',1,0);

/* Output and update for atomic system: '<Root>/DeltaSubsystem' */
static void DeltaSubsystem(void)
{
 /* MATLAB Function: '<S1>/DeltaX' */
 DeltaX(rtDWork.z2, rtDWork.z1, rtDWork.z1_m, rtDWork.z2_c);

 /* MATLAB Function: '<S1>/DeltaY' */
 DeltaY(rtDWork.z1_m, rtDWork.z2_c, &rtDWork.z1[0], &rtDWork.z2[0]);
}

/* Model step function */
void ex_reusable_csc_step(void)
{
 int32_T i;

 /* ComplexToRealImag: '<Root>/Complex to Real-Imag' incorporates:
 * Inport: '<Root>/ComplexData'
 */
 for (i = 0; i < 1048576; i++) {
 rtDWork.RCSC_REAL[i] = rtU.ComplexData[i].re;
 rtDWork.RCSC_IMAG[i] = rtU.ComplexData[i].im;
 }

 /* End of ComplexToRealImag: '<Root>/Complex to Real-Imag' */

 /* MATLAB Function: '<Root>/Downsample' */
 Downsample(rtDWork.RCSC_REAL, rtDWork.RCSC_IMAG, rtDWork.z2, rtDWork.z1);

 /* Outputs for Atomic SubSystem: '<Root>/DeltaSubsystem' */
 DeltaSubsystem();

 /* End of Outputs for SubSystem: '<Root>/DeltaSubsystem' */

 /* Outport: '<Root>/Out1' incorporates:
 * RealImagToComplex: '<Root>/Real-Imag to Complex'
 */
}
```

```

*/
for (i = 0; i < 261121; i++) {
 rtY.Out1[i].re = rtDWork.z1[i];
 rtY.Out1[i].im = rtDWork.z2[i];
}

/* End of Outport: '<Root>/Out1' */
}

```

The generated code contains two additional global variables for holding block inputs and outputs.

### Limitations for the Model That Use Reusable Storage Class in Code Mappings Editor

For reused data elements, you can specify the same value for the **Identifier** property. If you do not specify a value for the **Identifier**, the code generator uses the same signal label to name the reusable signal in the generated code. The code generator does not reuse signals if:

- The signals have the same labels but different identifiers.
- The signals have the same identifier but different values for these properties: **DataScope**, **HeaderFile**, **DefinitionFile**, and **Owner**. If there is a mismatch in any of the properties, the code generator stops and produces an error if the model configuration parameter **Detect non-reused custom storage classes** is set to error.

### Specify a Simulink Signal Object for Reuse

1. Open the model `rtwdemo_reusable`.

```

model = 'rtwdemo_reusable_csc';
open_system(model);

```

Copyright 2017-2020 The MathWorks, Inc.

2. The signals in the model resolve to the corresponding `Simulink.Signal` data objects in the Base Workspace. Right-click on the `RCSC_REAL` signal line. From the context menu, select **Properties**. In the Signal Properties dialog box, inspect that the signal name is `RCSC_REAL` and the parameter **Signal name must resolve to Simulink signal object** is selected. This setting indicates that there is a `Simulink.Signal` data object in the Base Workspace with the same name as `RCSC_REAL`.

3. In the model, navigate into the `DeltaSubsystem` subsystem. Select the `RCSC_REAL` signal line in this subsystem. This signal also resolves to the signal object in the Base Workspace.

4. In the Base Workspace, double click the data object `RCSC_REAL`. The `Simulink.Signal` dialog box opens.

5. On the **Code Generation** tab, inspect that the **Storage class** parameter is set to `Reusable`. This setting instructs the code generator to generate code for the signal as a global variable named

RCSC\_REAL. With the Reusable storage class, the generated code can store the output of the Complex to Real-Imag block (at the root-level of the model) and the output of the MATLAB Function block DeltaX (in the subsystem) in the RCSC\_REAL global variable.

6. In the **Apps** gallery, under **Code Generation**, click **Embedded Coder**. The **C Code** tab opens.

7. Click the **Build** button.

The generated code achieves the same results as the preceding workflow where you add signals to the Code Mappings editor and set **Storage Class** to Reusable.

Note: You can specify buffer reuse on signals that the code generator cannot implement. For those cases, use two diagnostics to specify the message type that the model displays. In the Configuration Parameters dialog box, these diagnostics are **Detect non-reused custom storage classes** and **Detect ambiguous custom storage class final values**.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

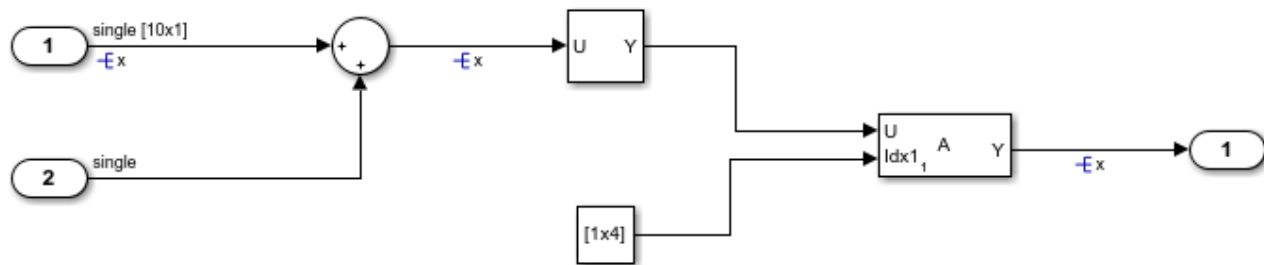

### Buffer Reuse for Unit Delay and Delay Blocks

To reuse the signal of a Unit Delay or Delay block, use the same reusable storage class specification for a pair of input and state arguments or a pair of output and state arguments of a Unit Delay or a Delay block. For Delay blocks, you must set the **Delay length** parameter to 1 and **Initial condition > Source** to Dialog. To access these parameters, in the model, open the Property Inspector and click the block in the model.

### Limitations for Root Inport and Outport Signals

These limitations apply to a model in which you specify buffer reuse for a pair of root inport and outport signals:

- The output ports cannot be conditional.
- If the code generator cannot reuse the same buffer in a top model, the generated code contains additional buffers. If the top model is a referenced model, the code generator reports an error. To resolve the error, remove the Simulink.Signal specification from the signal that connects to the outport port.
- When you run the executable that the code generator produces, and you reuse a pair of root inport and outport signals, when the root input value is zero, the root output value must also be zero. If the output value is nonzero and you reuse the signals, then the results from the simulation can differ from the results that the executable produces.
- There might be a simulation versus code generation mismatch when you assign the same Reusable storage class to pair of root inport and root outport signals. This mismatch occurs when an Assignment block drives the Root Outport block, and the Assignment block does not assign a value to every element of the output signal because the Y port of the Assignment block is not active. This image shows a model in which the mismatch occurs:

During simulation, the unwritten Assignment block output values are zero. During code generation, the unwritten output values are the same as the input.

### Limitations for the Model That Use Simulink Signal Object

These limitations apply to a model in which you specify buffer reuse for signals by using a `Simulink.Signal` data object:

- Signals that you specify for reuse must have the same data types and sampling rates.
- For user-specified buffer reuse, blocks that modify a signal specified for reuse must execute before blocks that use the original signal value. Sometimes the code generator has to change the block operation order so that buffer reuse can occur. For models in which the code generator is unable to reorder block operations, buffer reuse does not occur.
- For models in which the code generator reorders block operations so that `Simulink.Signal` reuse can occur, you can observe the difference in the sorted order. On the **Debug** tab, in the **Diagnostics** section select the **Information Overlays** drop-down arrow. In the **Blocks** section of the dialog, select **Execution Order**. To display the sorted execution order during simulation, on the **Modeling** tab, select **Update Model**. To display the execution order in the generated code, on the **C Code** tab, select **Build Model**.
- You can specify buffer reuse for a chain of reusable subsystems as long as these subsystems do not get reused anywhere in the model.

## Specify Buffer Reuse for MATLAB Function Blocks in a Path

### In this section...

“Example Model” on page 73-25

“Generate Code with Optimization” on page 73-25

You can specify buffer reuse across MATLAB Function blocks by using the same variable name for the input and output arguments. The code generator tries to reuse the output of one MATLAB Function block as the input to the next MATLAB Function block. This optimization conserves RAM and ROM consumption and reduces data copies.

### Example Model

- 1 Use Inport, Outport, and MATLAB Function blocks to create the model `mf_inplace`.

- 2 Open each MATLAB Function block and copy the following code:

```
function y = fcn(y)
%#codegen
```

```
y=y+4;
```

- 3 Open the Configuration Parameters dialog box. On the **Code Generation** tab, change the **System target file** to `ert.tlc`.
- 4 On the **Solver** tab, change the **Type** parameter to Fixed-step.

### Generate Code with Optimization

Generate code for the model. The `mf_inplace.c` file contains this code:

```
void mf_inplace_MATLABFunction(real_T *rty_y)
{
 *rty_y += 4.0;
}

void mf_inplace_step(void)
{
 real_T rtb_y_p5;
 rtb_y_p5 = mf_inplace_U.In1;
 mf_inplace_MATLABFunction(&rtb_y_p5);
 mf_inplace_MATLABFunction(&rtb_y_p5);
 mf_inplace_MATLABFunction(&rtb_y_p5);
 mf_inplace_Y.Out1 = rtb_y_p5;
 mf_inplace_MATLABFunction(&mf_inplace_Y.Out1);
}
```

The code generator reuses the variable `rtb_y_p5` for the input and output arguments of each MATLAB Function block.

---

**Note** On the **Code Generation** tab in the Subsystem Block Parameters dialog box, if the **Function packaging** parameter is set to **Nonreusable function** and the **Function interface** parameter is set to **Allow arguments (Optimized)**, the code generator cannot reuse the input and output arguments.

## Remove Data Copies by Reordering Block Operations in the Generated Code

This example shows how to remove data copies by changing the **Optimize block order in the generated code** parameter from off to Improved Execution Speed. Changing this setting indicates to the code generator to reorder block operations where possible to remove data copies. This parameter is in the Configuration Parameters dialog box. This optimization conserves RAM and ROM consumption.

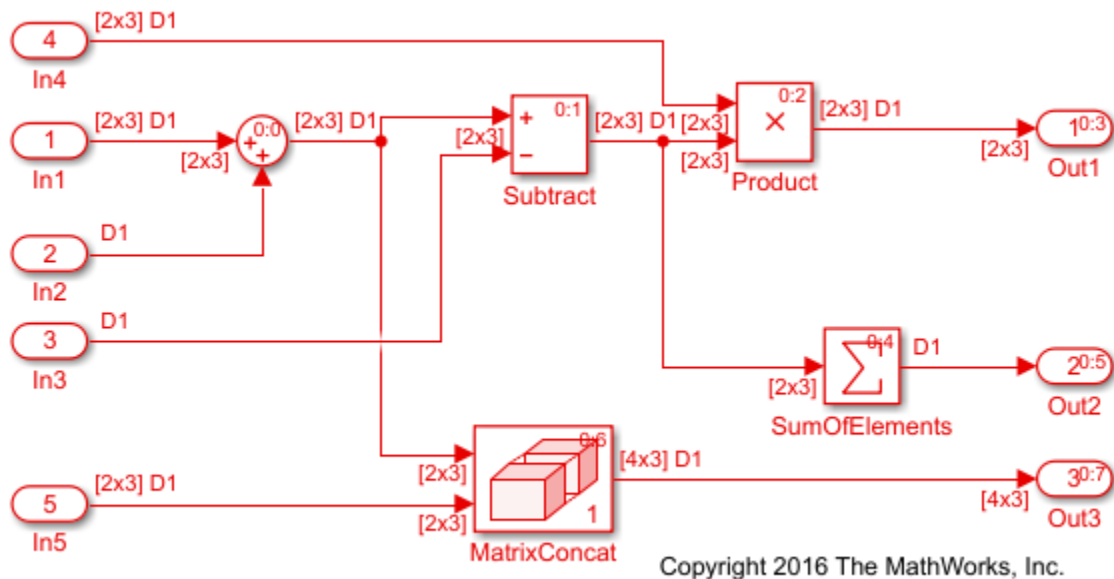

### Example Model

In the model `ex_optimizeblockorder`, the signal that leaves the Sum block enters a Subtract block and a Concatenate block. The signal that leaves the Subtract block enters a Product block and a Sum of Elements block.

### Generate Code without Optimization

The image shows the model `ex_optimizeblockorder` after a model build. The red numbers indicate the default block order in the generated code. The Subtract block executes before the Concatenate block. The Product block executes before the Sum of Elements block.

View the generated code without the optimization. Here is the `ex_optimizeblockorder_step` function.

```

/* Model step function */
void ex_optimizeblockorder_step(void)
{
 real_T rtb_Sum2x3[6];
 int32_T i;
 real_T rtb_Sum2x3_d;
 real_T rtb_Subtract;

 /* Sum: '<Root>/SumOfElements' */
 rtY.Out2 = -0.0;
 for (i = 0; i < 6; i++) {
 /* Sum: '<Root>/Sum2x3' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 */
 rtb_Sum2x3_d = rtU.In1[i] + rtU.In2;

 /* Sum: '<Root>/Subtract' incorporates:
 * Inport: '<Root>/In3'
 */
 rtb_Subtract = rtb_Sum2x3_d - rtU.In3;

 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In4'
 * Product: '<Root>/Product'
 */
 rtY.Out1[i] = rtU.In4[i] * rtb_Subtract;

 /* Sum: '<Root>/Sum2x3' */
 rtb_Sum2x3[i] = rtb_Sum2x3_d;
 }
}

```

```

/* Sum: '<Root>/SumOfElements' */
rtY.Out2 += rtb_Subtract;
}

/* Concatenate: '<Root>/MatrixConcat ' */
for (i = 0; i < 3; i++) {
/* Outport: '<Root>/Out3' incorporates:
 * Inport: '<Root>/In5'
 */
rtY.Out3[i << 2] = rtb_Sum2x3[i << 1];
rtY.Out3[2 + (i << 2)] = rtU.In5[i << 1];
rtY.Out3[1 + (i << 2)] = rtb_Sum2x3[(i << 1) + 1];
rtY.Out3[3 + (i << 2)] = rtU.In5[(i << 1) + 1];
}

/* End of Concatenate: '<Root>/MatrixConcat ' */
}

```

With the default order, the generated code contains three buffers, `rtb_Sum2x3[6]`, `rtb_Sum2x3_d`, and `rtb_Subtract`. The generated code contains these temporary variables and associated data copies because the Matrix Concatenate block must use the output from the Sum block and the Sum of Elements block must use the output from the Subtract block.

## Generate Code with Optimization

The image shows the `ex_optimizeblockorder` model after setting the **Optimize block operation order in the generated code** parameter to Improved Execution Speed and building the model. The Subtract block executes after the Concatenate block. The Product block executes after the Sum of Elements block.

In the optimized code, the three buffers `rtb_Sum2x3[6]`, `rtb_Sum2x3_d`, and `rtb_Subtract` and their associated data copies are gone. The generated code does not require these temporary variables to hold the outputs of the Sum and Subtract blocks because the Subtract block executes after the Concatenate block and the Product block executes after the Sum of Elements block.

```

/* Model step function */
void ex_optimizeblockorder_step(void)
{
 int32_T i;

 /* Sum: '<Root>/Sum2x3' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 */
 for (i = 0; i < 6; i++) {
 rtY.Out1[i] = rtU.In1[i] + rtU.In2;
 }

 /* End of Sum: '<Root>/Sum2x3' */

 /* Concatenate: '<Root>/MatrixConcat ' */
 for (i = 0; i < 3; i++) {
 /* Outport: '<Root>/Out3' incorporates:
 * Inport: '<Root>/In5'
 */
 rtY.Out3[i << 2] = rtY.Out1[i << 1];
 rtY.Out3[2 + (i << 2)] = rtU.In5[i << 1];
 rtY.Out3[1 + (i << 2)] = rtY.Out1[(i << 1) + 1];
 rtY.Out3[3 + (i << 2)] = rtU.In5[(i << 1) + 1];
 }

 /* End of Concatenate: '<Root>/MatrixConcat ' */

 /* Sum: '<Root>/SumOfElements' */
 rtY.Out2 = -0.0;
 for (i = 0; i < 6; i++) {
 /* Sum: '<Root>/Subtract' incorporates:
 * Inport: '<Root>/In3'
 */
 rtY.Out1[i] -= rtU.In3;

 /* Sum: '<Root>/SumOfElements' */
 rtY.Out2 += rtY.Out1[i];

 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In4'
 * Product: '<Root>/Product'
 */
 rtY.Out1[i] *= rtU.In4[i];
 }
}

```

To implement buffer reuse, the code generator does not violate user-specified block priorities.

## Data Copy Reduction for Data Store Read and Data Store Write Blocks

This example shows how the code generator removes temporary buffers for Data Store Read and Data Store Write blocks. This optimization improves execution speed and reduces RAM consumption.

### Example Model

The model `rtwdemo_optimizedatastorebuffers` contains the Function caller `UpdateFunc`, which calls the Simulink Function `DefineUpdateFunc`. The Data Store Read block `DSR` reads from `mem`. The Data Store Write block `DSW` writes to `mem`.

```
model='rtwdemo_optimizedatastorebuffers';
open_system(model);
```

Copyright 2016-2020 The MathWorks, Inc.

### Generate Code Without Optimization

In the Configuration Parameters dialog box, deselect the **Reuse buffers for Data Store Read and Data Store Write blocks parameter** or at the MATLAB® command prompt, enter this command:

```
set_param(model, 'OptimizeDataStoreBuffers', 'off');
```

Build the model.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
slbuild(model)
```

```
Starting build procedure for: rtwdemo_optimizedatastorebuffers
Successful completion of build procedure for: rtwdemo_optimizedatastorebuffers
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_optimizedatastorebuffers	Code generated and compiled	Code generation information file

1 of 1 models built (0 models already up to date)  
Build duration: 0h 1m 0.845s

View the generated code without the optimization. This code is in `rtwdemo_optimizedatastorebuffers.c`.

```
cfile = fullfile(cgDir, 'rtwdemo_optimizedatastorebuffers_ert_rtw', ...
 'rtwdemo_optimizedatastorebuffers.c');
rtwdemodbtype(cfile, /* Model step', /* Model initialize', 1, 0);

/* Model step function */
void step(void)
{
 real_T rtb_DSR_last;
 real_T rtb_SimFuncCall_o1;
 real_T rtb_Sum_p;

 /* DataStoreRead: '<Root>/DSR' */
 rtb_DSR_last = mem.last;

 /* Switch: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant'
 * DataStoreRead: '<Root>/DSR'
 * Inport: '<Root>/Clear'
 */
 if (rtU.Clear) {
 rtb_SimFuncCall_o1 = 0.0;
 } else {
 rtb_SimFuncCall_o1 = mem.max;
 }

 /* End of Switch: '<Root>/Switch' */

 /* FunctionCaller: '<Root>/SimFuncCall' incorporates:
 * Inport: '<Root>/DataNew'
 */
 UpdateFunc(rtb_SimFuncCall_o1, rtU.DataNew, &rtb_SimFuncCall_o1, &rtb_Sum_p);

 /* DataStoreWrite: '<Root>/DSW' */
 mem.last = rtb_SimFuncCall_o1;
 mem.max = rtb_Sum_p;

 /* Outport: '<Root>/Delta' incorporates:
 * DataStoreRead: '<Root>/DSR'
 * Inport: '<Root>/DataNew'
 * Sum: '<Root>/Sum'
 */
 rtY.Delta = rtU.DataNew - rtb_DSR_last;
}
```

The generated code contains data copies for the Data Store Read and Data Store Write blocks, respectively.

### Generate Code with Optimization

In the Configuration Parameters dialog box, clear the **Reuse buffers for Data Store Read and Data Store Write blocks** parameter or at the MATLAB command prompt, enter this command:

```
set_param(model, 'OptimizeDataStoreBuffers', 'on');
```

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_optimizedatastorebuffers
Successful completion of build procedure for: rtwdemo_optimizedatastorebuffers
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_optimizedatastorebuffers	Code generated and compiled	Generated code was out of date.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 35.046s
```

View the generated code with the optimization. This code is in `rtwdemo_optimizedatastorebuffers.c`.

```
cfile = fullfile(cgDir, 'rtwdemo_optimizedatastorebuffers_ert_rtw', ...
 'rtwdemo_optimizedatastorebuffers.c');
rtwdemodbtype(cfile, /* Model step', /* Model initialize', 1, 0);
```

```
/* Model step function */
void step(void)
{
 real_T rtb_DSR_last;
 real_T tmp;

 /* DataStoreRead: '<Root>/DSR' */
 rtb_DSR_last = mem.last;

 /* Switch: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant'
 * DataStoreRead: '<Root>/DSR'
 * Inport: '<Root>/Clear'
 */
 if (rtU.Clear) {
 tmp = 0.0;
 } else {
 tmp = mem.max;
 }

 /* End of Switch: '<Root>/Switch' */
```

```

/* FunctionCaller: '<Root>/SimFuncCall' incorporates:
 * DataStoreWrite: '<Root>/DSW'
 * Inport: '<Root>/DataNew'
 */
UpdateFunc(tmp, rtU.DataNew, &mem.last, &mem.max);

/* Outport: '<Root>/Delta' incorporates:
 * DataStoreRead: '<Root>/DSR'
 * Inport: '<Root>/DataNew'
 * Sum: '<Root>/Sum'
 */
rtY.Delta = rtU.DataNew - rtb_DSR_last;
}

```

The data copy for the Data Store Write block is not in the generated code. The code contains the data copy for the Data Store Read block because the Sum block executes after the Data Store Write block. The generated code contains the variable `rtb_DSR_last` to hold the output of the Sum block. Therefore, the Sum block gets the values that `SimFuncCall` calculates at the start of the time step rather than those values at the next time step. If the priority of the Sum block is lower than `SimFuncCall`, the code generator can remove the data copy for the Data Store Read block. Some other cases in which the code generator might not eliminate data copies are:

- A Simulink Function internally writes to the Data Store Memory block.
- The Data Store Read or Data Store Write blocks select elements of an array from the Data Store Memory block.
- The Data Store Memory block has a custom storage class.
- The Data Store Read and Data Store Write blocks occur on the same block unless that block is a Bus Assignment block or an Assignment block.

Close the model and clean up.

```

bdclose(model)
rtwdemoclean;
cd(currentDir)

```

## Reduce Data Copies for Bus Assignment Blocks in Generated Code

For models containing a Bus Assignment block, if possible, the code generator uses the same variable for the block input and output. Reusing these variables reduces data copies, conserves RAM consumption and increases code execution speed.

### Example Model

For example, in `bus_assignoptim`, a bus signal containing six elements feeds into a Bus Assignment block and a Bus Selector block. The Bus Assignment block assigns new values to the bus element `a1_real_array`. This bus signal feeds into `Out1`.

### Generate Code Without Optimization

Generate code without the optimization by setting the **Perform in-place updates for Assignment and Bus Assignment blocks** parameter to off. Without the optimization the `bus_assignoptim_step` function contains this code:

```
void bus_assignoptim_step(void)
{
 real_T rtb_Assignment[36];
 int32_T i;

 /* Assignment: '<Root>/Assignment' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 * Product: '<Root>/Product'
 * Selector: '<Root>/Selector'
 * Sum: '<Root>/Sum1'
 */
 for (i = 0; i < 36; i++) {
 rtb_Assignment[i] = bus_assignoptim_U.In1.a1_real_array[i];
 }

 for (i = 0; i < 2; i++) {
 rtb_Assignment[(int32_T)(i + 22)] = (bus_assignoptim_U.In1.a1_real_array
 [(int32_T)(i + 22)] + bus_assignoptim_U.In1.a1_num) *
 bus_assignoptim_U.In2;
 }

 /* End of Assignment: '<Root>/Assignment' */

 /* Output: '<Root>/Out' incorporates:
```

```

 * BusAssignment: '<Root>/Bus Assignment'
 * Inport: '<Root>/In1'
 */
bus_assignoptim_Y.Out = bus_assignoptim_U.In1;

/* BusAssignment: '<Root>/Bus Assignment' incorporates:
 * Output: '<Root>/Out'
 */
for (i = 0; i < 36; i++) {
 bus_assignoptim_Y.Out.a1_real_array[i] = rtb_Assignment[i];
}
}

```

The generated code contains the temporary array `rtb_Assignment` for holding data before this data is assigned to `bus_assignoptim_Y.Out.a1_real_array`.

## Generate Code with Optimization

Generate code with the optimization by setting the **Perform in-place updates for Assignment and Bus Assignment blocks** parameter to on. With the optimization, the `bus_assignoptim_step` function contains this code:

```

/* Model step function */
void bus_assignoptim_step(void)
{
 int32_T i;

 /* Output: '<Root>/Out' incorporates:
 * Inport: '<Root>/In1'
 * SignalConversion: '<Root>/TmpBusAssignmentBufferAtBus AssignmentInport1'
 */
 bus_assignoptim_Y.Out = bus_assignoptim_U.In1;

 /* Assignment: '<Root>/Assignment' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 * Output: '<Root>/Out'
 * Product: '<Root>/Product'
 * Selector: '<Root>/Selector'
 * Sum: '<Root>/Sum1'
 */
 for (i = 0; i < 36; i++) {
 bus_assignoptim_Y.Out.a1_real_array[i] =
 bus_assignoptim_U.In1.a1_real_array[i];
 }

 for (i = 0; i < 2; i++) {
 bus_assignoptim_Y.Out.a1_real_array[(int32_T)(i + 22)] =
 (bus_assignoptim_U.In1.a1_real_array[(int32_T)(i + 22)] +
 bus_assignoptim_U.In1.a1_num) * bus_assignoptim_U.In2;
 }

 /* End of Assignment: '<Root>/Assignment' */
}

```

The generated code does not contain the temporary array `rtb_Assignment1` for holding data. The generated code directly assigns this data to `bus_assignoptim_Y.Out.a1_real_array`.

- “Data Copy Reduction”

## Optimize Generated Code by Using Signal Labels to Guide Buffer Reuse

If your model has the optimal parameter settings for removing data copies, you might be able to remove additional data copies by using signal labels. After studying the generated code and the Static Code Metrics Report and identifying areas where you think buffer reuse is possible, you can add labels to signal lines. If possible, the code generator reorders block operations to implement the reuse specification.

Specifying buffer reuse improves execution speed and may reduce RAM consumption.

### Example Model

The model `rtwdemo_label_guided_reuse` demonstrates how you can use signal labels to request buffer reuse for block input and output signals. For this model, the code generator can use the same variable for the Atomic Subsystem and either the Gain or Saturation block outputs. The generated code uses the same variable for the Saturation and Atomic Subsystem block outputs because those signals contain the same label and the **Use Signal Labels to Guide Buffer Reuse** parameter is selected.

### Generate Code Without Optimization

- 1 Open the model.
 

```
model='rtwdemo_label_guided_reuse';
open_system(model);
```
- 2 In the Configuration Parameters dialog box, clear the **Use Signal Labels to Guide Buffer Reuse** parameter.
- 3 Build the model. The `rtwdemo_label_guided_reuse_step` function contains this code:

```
void rtwdemo_label_guided_reuse_step(void)
{
 real_T rtb_Saturation[4];
 real_T rtb_Bias[4];
 int32_T i;
 AtomicSubsystem(rtU.In1, rtb_Bias);
 for (i = 0; i < 4; i++) {
```

```

 if (rtb_Bias[i] > 10.0) {
 rtb_Saturation[i] = 10.0;
 } else if (rtb_Bias[i] < -10.0) {
 rtb_Saturation[i] = -10.0;
 } else {
 rtb_Saturation[i] = rtb_Bias[i];
 }

 rtb_Bias[i] *= 3.0;
}

AtomicSubsystem1(rtb_Saturation, rtb_Bias, rtY.Out1);
}

```

By default, within the `for` loop, the Gain block executes after the Saturation block. The generated code uses the same variable for the output of the Atomic Subsystem and the Gain blocks. As a result, the generated code contains two local variables `rtb_Saturation` and `rtb_Bias` for holding intermediate results.

## Generate Code with Optimization

In the Configuration Parameters dialog box, select the **Use Signal Labels to Guide Buffer Reuse** parameter and build the model. The `rtwdemo_label_guided_reuse_step` function contains this code:

```

void rtwdemo_label_guided_reuse_step(void)
{
 real_T rtb_Gain1[4];
 int32_T i;
 AtomicSubsystem(rtU.In1, rtY.Out1);
 for (i = 0; i < 4; i++) {
 rtb_Gain1[i] = 3.0 * rtY.Out1[i];
 if (rtY.Out1[i] > 10.0) {
 rtY.Out1[i] = 10.0;
 } else {
 if (rtY.Out1[i] < -10.0) {
 rtY.Out1[i] = -10.0;
 }
 }
 }
}

AtomicSubsystem1(rtY.Out1, rtb_Gain1, rtY.Out1);
}

```

The code generator changed the block execution order so that within the `for` loop, the Saturation block executes after the Gain block. The generated code contains one local variable `rtb_Gain1` for holding intermediate results.

In addition to requesting which buffers to reuse, another possible use case is to request buffer reuse for block input and output signals that are complex.

## Using Label-Based Reuse Versus Reusable Storage Classes

You can also use the same `Reusable` storage class specification on different signal lines to specify which buffers to reuse. As compared to using `Reusable` storage classes, using signal labels to specify reuse has these benefits:

- Signal labels are not observation points in the generated code, so using them does not block other optimizations such as dead code elimination and expression folding.
- The code generator does not force a signal with a label to be a global variable in the generated code. The signal can be a local or global variable.
- Signals with labels can reuse buffers with signals that do not have labels, so reuse among local and global variables is possible.

Using signal labels is a more conservative method of specifying reuse than using `Reusable` storage classes. The code generator does not implement label-based reuse when it can implement reuse by using `Reusable` storage classes in these cases:

- Reuse that can potentially prevent other optimizations from occurring in the generated code.
- Reuse on root inport and outport ports.
- Reuse across model reference or subsystem boundaries.
- Within a subsystem, buffer reuse on an intermediary signal and an input or output port.

## Reduce Memory Usage for Signals

The configuration parameter **Signal storage reuse** reduces the memory requirements of your real-time program by enabling parameters that reuse the memory allocated for signals with an `auto` storage class. These parameters are the following:

- **Enable local block outputs**
- **Reuse local block outputs**
- **Reuse global block outputs**
- **Optimize global data access**

When the **Enable local block outputs** parameter is on, where possible the code generator declares block outputs as local variables instead of global variables. Replacing global variables with local variables improves execution speed and reduces RAM/ROM consumption. Creating more local variables can increase stack usage. Some of the global variables that the code generator can localize include:

- Global signals that cross subsystem boundaries
- Global signals across Simulink and Stateflow domains
- Unused global state variables
- Redundant local Data Store Memory block signals

When the **Reuse local block outputs** parameter is on, wherever possible the code generator reuses local (function) variables for block outputs. When you select **Reuse global block outputs**, the code generator reuses global (function) variables wherever possible.

The **Optimize global data access** parameter has these settings:

- None
- Use global to hold temporary results
- Minimize global data access

When you select `None`, the code generator uses the default optimizations. The setting `Use global to hold temporary results` maximizes the use of global variables. The setting `Minimize global data access` minimizes the use of global variables by using local variables to hold intermediate values.

Clearing **Signal storage reuse** makes all block outputs global and unique, which often significantly increases RAM and ROM usage.

The code generator does not localize global variables for MATLAB system objects or AUTOSAR.

## Remove Zero Initialization Code

The “Remove root level I/O zero initialization” and “Remove internal data zero initialization” parameters control whether the generated code contains initialization code for internal data (block states and block outputs) and external data (root inports and outports) whose value is zero. Eliminating zero initialization code accelerates model initialization, reduces ROM consumption, and increases the execution speed of the generated code.

During startup, standards-compliant C and C++ compilers initialize global data to zero eliminating the need to include zero initialization code for this data in the generated code. Standards-compliant compilers do not necessarily initialize dynamically allocated data and local variables to zero. Before leaving the **Remove root level I/O zero initialization** and **Remove internal data zero initialization** parameters selected, confirm the following:

- If your compiler is not standards compliant, confirm that it initializes global data to zero.
- If you set the “Code interface packaging” to `Reusable function` or `C++ class`, confirm that data is either statically allocated or that dynamically allocated data is initialized to zero.

If you set the **Code interface packaging** parameter to `Reusable function` and select the “Use dynamic memory allocation for model initialization” parameter, the **Remove root level I/O zero initialization** and **Remove internal data zero initialization** check boxes are cleared and at the command line, `ZeroExternalMemoryAtStartup` and `ZeroInternalMemoryAtStartup` parameters are set to 'on'.

For a model in which the **Code interface packaging** parameter is set to `C++ class` and the “Use dynamic memory allocation for model block instantiation” parameter is selected, the **Remove internal data zero initialization** check box is cleared and `ZeroInternalMemoryAtStartup` is set to 'on' and is read-only.

### Remove Zero Initialization Code for Internal Data

This example shows how to eliminate code that initializes internal data to zero.

#### Example Model

Open the model `rtwdemo_internal_init`. The model contains an enabled subsystem whose initial output is zero. The subsystem contains a Unit Delay block whose initial condition is 0.

```
model = 'rtwdemo_internal_init';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

### Generate Code Without Optimization

Build the model by using Embedded Coder®.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
evalc('slbuild(model)');
```

This code is in the `rtwdemo_internal_init.c` file.

```
cfile = fullfile(cgDir,'rtwdemo_internal_init_ert_rtw','rtwdemo_internal_init.c');
rtwdemodbtype(cfile,'/* Model initialize', '* File trailer', 1, 0);
```

```
/* Model initialize function */
void rtwdemo_internal_init_initialize(void)
{
 /* Registration code */

 /* initialize error status */
 rtmSetErrorStatus(rtM, (NULL));

 /* states (dwork) */
 (void) memset((void *)&rtDWork, 0,
 sizeof(D_Work));

 /* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem' */
 /* InitializeConditions for UnitDelay: '<S1>/Unit Delay' */
 rtDWork.UnitDelay_DSTATE = 0.0;

 /* End of SystemInitialize for SubSystem: '<Root>/Enabled Subsystem' */
}

/*
```

### Enable Optimization

Open the Configuration Parameters dialog box. On the **Optimization** pane, select **Remove internal data zero initialization**.

Alternatively, you can use the command prompt to enable the optimization. Set the model parameter `ZeroInternalMemoryAtStartup` to 'off'.

```
set_param(model, 'ZeroInternalMemoryAtStartup', 'off');
set_param(model, 'ZeroInternalMemoryAtStartup', 'off');
```

### Generate Code with Optimization

Build the model by using Embedded Coder.

```
evalc('slbuild(model)');
```

This code is in the `rtwdemo_internal_init.c` file. The generated code does not initialize internal data by assignment to zero.

```
rtwdemodbtype(cfile,'/* Model initialize', '* File trailer', 1, 0);
```

```
/* Model initialize function */
```

```

void rtwdemo_internal_init_initialize(void)
{
 /* (no initialization code required) */
}

/*

bdclose(model)
rtwdemoclean;
cd(currentDir)

```

## Remove Initialization Code from Root-Level Inports and Outports Set to Zero

This example shows how to remove initialization code from root-level inports and outports set to zero.

### Example Model

In the model `rtwdemo_rootlevel_zero_initialization`, all of the input and output signals have a numeric value of zero. Because signals `sig1` and `sig2` have data types `int16` and `Boolean`, respectively, and all of the output signals have data type `double`, these signals also have initial values of bitwise zero. The signals have an integer bit pattern of 0, meaning that all bits are off. Signals `sig1_b` and `sig2_b` have a fixed-point data type with bias, so their initial value is not bitwise zero.

```

model = 'rtwdemo_rootlevel_zero_initialization';
open_system(model);

```

?

Copyright 2014-2020 The MathWorks, Inc

### Generate Code

In your system temporary folder, create a temporary folder for the build and inspection process.

```

currentDir = pwd;
[~,cgDir] = rtwdemodir();

```

Build the model by using Embedded Coder.

```

set_param(model, 'ZeroExternalMemoryAtStartup', 'on');
evalc('slbuild(model)');

```

These lines of `rtwdemo_rootlevel_zero_initialization.c` code show the initialization of root-level inports and outports without the optimization. The four input signals are individually initialized

as global variables. The four output signals are members of a global structure that the `memset` function initializes to bitwise zero.

```
cfile = fullfile(cgDir, 'rtwdemo_rootlevel_zero_initialization_ert_rtw', ...
 'rtwdemo_rootlevel_zero_initialization.c');
rtwdemodbtype(cfile, 'rtwdemo_rootlevel_zero_initialization_initialize', ...
 'trailer for generated code', 1, 0);
```

```
void rtwdemo_rootlevel_zero_initialization_initialize(void)
{
 /* Registration code */

 /* external inputs */
 sig1 = 0;
 sig1_b = -3;
 sig2 = false;
 sig2_b = -3;

 /* external outputs */
 (void)memset(&rtY, 0, sizeof(ExternalOutputs));
}

/*
```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, select **Remove root level I/O zero initialization**.

Alternatively, use the command-line API to enable the optimization:

```
set_param(model, 'ZeroExternalMemoryAtStartup', 'off');
```

### Generate Code with Optimization

The optimized code does not contain initialization code for the input signals `sig1`, `sig2`, and the four output signals because their initial values are bitwise zero.

Build the model.

```
evalc('slbuild(model)');
```

Here is the `rtwdemo_rootlevel_zero_initialization.c` optimized code in the initialization function.

```
cfile = fullfile(cgDir, 'rtwdemo_rootlevel_zero_initialization_ert_rtw', ...
 'rtwdemo_rootlevel_zero_initialization.c');
rtwdemodbtype(cfile, 'rtwdemo_rootlevel_zero_initialization_initialize', ...
 'trailer for generated code', 1, 0);
```

```
void rtwdemo_rootlevel_zero_initialization_initialize(void)
{
 /* Registration code */

 /* external inputs */
 sig1_b = -3;
```

```
 sig2_b = -3;
}

/*
```

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Additional Information

- You can use the **Use memset to initialize floats and doubles** parameter to control the representation of zero during initialization. See “Use memset to initialize floats and doubles to 0.0”.
- The code still initializes data structures whose value is not zero when you select the **Remove internal data zero initialization** and **Remove root level I/O zero initialization** parameters.
- The data of `ImportedExtern` or `ImportedExternPointer` storage classes are not initialized, regardless of the settings of the **Remove internal data zero initialization** and **Remove root level I/O zero initialization** parameters.

## Simplify Multiply Operations in Array Indexing

### In this section...

“Example Model” on page 74-8

“Generate Code” on page 74-8

“Generate Code with Optimization” on page 74-9

The generated code might have multiply operations when indexing an element of an array. You can select the optimization parameter “Simplify array indexing” to replace multiply operations in the array index with a temporary variable. This optimization can improve execution speed by reducing the number of times the multiply operation executes.

### Example Model

If you have the following model:

The Constant blocks have the following **Constant value**:

- Const1: `reshape(1:30,[1 5 3 2])`
- Const2: `reshape(1:20,[1 5 2 2])`
- Const3: `reshape(1:90,[1 5 9 2])`

The Concatenate block parameter **Mode** is set to `Multidimensional array`. The Constant blocks **Sample time** parameter is set to `-1`.

### Generate Code

Building the model with the **Simplify array indexing** parameter turned off generates the following code:

```
int32_T i;
int32_T i_0;
int32_T i_1;

for (i = 0; i < 2; i++) {
 for (i_1 = 0; i_1 < 3; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[(i_0 + 5 * i_1) + 70 * i] =
```

```

 ex_arrayindex_P.Constant1_Value[(5 * i_1 + i_0) + 15 * i];
 }
}
}
for (i = 0; i < 2; i++) {
 for (i_1 = 0; i_1 < 2; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[(i_0 + 5 * (i_1 + 3)) + 70 * i] =
 ex_arrayindex_P.Constant2_Value[(5 * i_1 + i_0) + 10 * i];
 }
 }
}
for (i = 0; i < 2; i++) {
 for (i_1 = 0; i_1 < 9; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[(i_0 + 5 * (i_1 + 5)) + 70 * i] =
 ex_arrayindex_P.Constant3_Value[(5 * i_1 + i_0) + 45 * i];
 }
 }
}
}
}

```

## Generate Code with Optimization

Open the Configuration Parameters dialog box and select the **Simplify array indexing** parameter. Build the model again. In the generated code,  $[(i\_0 + tmp\_1) + tmp]$  replaces a multiply operation in the array index,  $[(i\_0 + 5 * i\_1) + 70 * i]$ . The generated code is now:

```

int32_T i;
int32_T i_0;
int32_T i_1;
int32_T tmp;
int32_T tmp_0;
int32_T tmp_1;

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
 tmp_1 = 0;
 for (i_1 = 0; i_1 < 3; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[(i_0 + tmp_1) + tmp] =
 ex_arrayindex_P.Constant1_Value[(i_0 + tmp_1) + tmp_0];
 }

 tmp_1 += 5;
 }

 tmp += 70;
 tmp_0 += 15;
}

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
 tmp_1 = 0;

```

```
for (i_1 = 0; i_1 < 2; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[((i_0 + tmp_1) + tmp) + 15] =
 ex_arrayindex_P.Constant2_Value[(i_0 + tmp_1) + tmp_0];
 }

 tmp_1 += 5;
}

tmp += 70;
tmp_0 += 10;
}

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
 tmp_1 = 0;
 for (i_1 = 0; i_1 < 9; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[((i_0 + tmp_1) + tmp) + 25] =
 ex_arrayindex_P.Constant3_Value[(i_0 + tmp_1) + tmp_0];
 }

 tmp_1 += 5;
 }

 tmp += 70;
 tmp_0 += 45;
}
```

## Replace boolean with Specific Integer Data Type

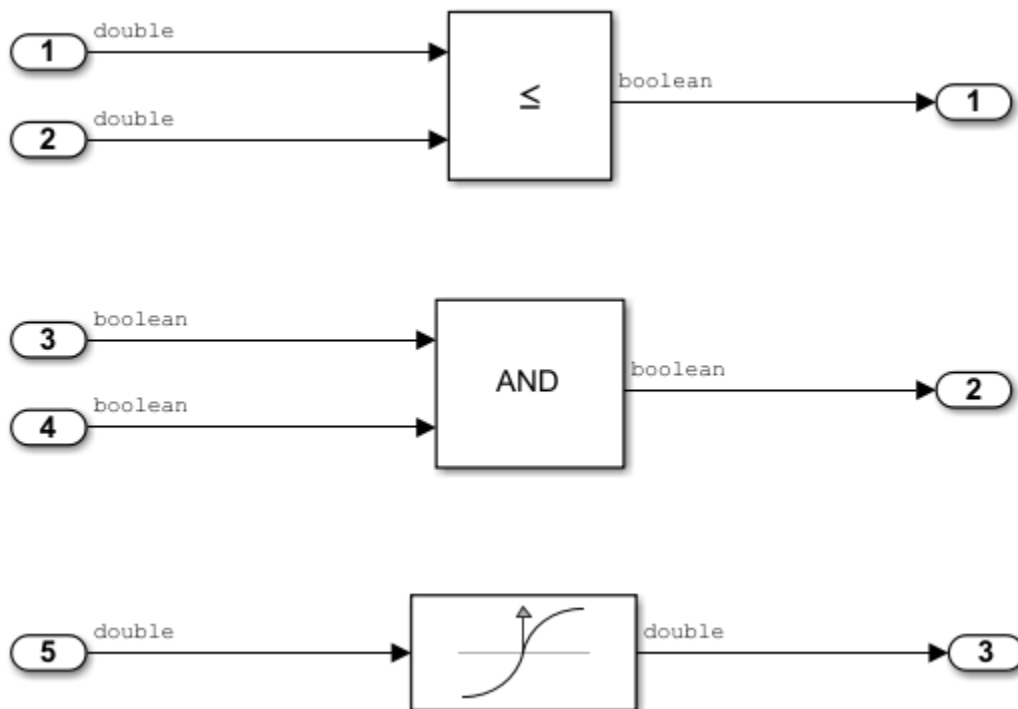

Depending on the architecture of the processor that your production hardware uses, you can improve the execution speed of the generated code. Select a specific integer data type for the built-in type `boolean`. Using data type replacement, in the generated code you can replace the `boolean` built-in data type with one of these integer types:

- `int8`
- `uint8`
- `intn`

To match the integer word size for the production hardware, replace  $n$  with 8, 16, or 32 .

### Example Model

The model `ex_bool` contains two blocks that output `boolean` values and two blocks that take `boolean` values as inputs. This example shows how to replace the data type `boolean` with the integer data type `int32` in the code generated for a 32-bit hardware target.

### Generate Code That Contains the Default boolean Data Type

View the generated file `rtwtypes.h`. The `typedef` statements contain the generic type definition of `boolean_T`, which is the code generation name for `boolean`.

```
/*=====
 * Generic type definitions: boolean_T, char_T, byte_T, int_T, uint_T,
 *
```

```

* real_T, time_T, ulong_T. *
=====/
typedef double real_T;
typedef double time_T;
typedef unsigned char boolean_T;
typedef int int_T;
typedef unsigned int uint_T;
typedef unsigned long ulong_T;
typedef char char_T;
typedef unsigned char uchar_T;
typedef char_T byte_T;

```

View the generated file `ex_bool.c`. The code declares `boolean` variables by using the type `boolean_T`.

```

/* External inputs (root inport signals with auto storage) */
typedef struct {
 real_T In1; /* '<Root>/In1' */
 real_T In2; /* '<Root>/In2' */
 boolean_T In3; /* '<Root>/In3' */
 boolean_T In4; /* '<Root>/In4' */
 real_T In5; /* '<Root>/In5' */
} ExtU_ex_bool_T;

/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
 boolean_T Out1; /* '<Root>/Out1' */
 boolean_T Out2; /* '<Root>/Out2' */
 real_T Out3; /* '<Root>/Out3' */
} ExtY_ex_bool_T;

```

## Generate Code That Contains the Target boolean Data Type

- 1 Define a `Simulink.AliasType` object with a base type of `int32`. Name the object using the replacement name that you want to appear in the generated code.

```

mybool = Simulink.AliasType;
mybool.BaseType = 'int32';

```

- 2 In the Configuration Parameters dialog box, specify the **Replacement Name** field for the data type `boolean` as `mybool`.

Data type names		
Simulink Name	Code Generation Name	Replacement Name
double	real_T	<input type="text"/>
single	real32_T	<input type="text"/>
int32	int32_T	<input type="text"/>
int16	int16_T	<input type="text"/>
int8	int8_T	<input type="text"/>
uint32	uint32_T	<input type="text"/>
uint16	uint16_T	<input type="text"/>
uint8	uint8_T	<input type="text"/>
boolean	boolean_T	mybool
int	int_T	<input type="text"/>
uint	uint_T	<input type="text"/>
char	char_T	<input type="text"/>

View the generated file `rtwtypes.h`. The code maps the identifier `mybool` to the native integer type of the target hardware by creating `typedef` statements.

```
/* Generic type definitions ... */
...
typedef int boolean_T;
...
/* Define Simulink Coder replacement data types. */
typedef boolean_T mybool; /* User defined replacement datatype for boolean_T */
```

View the generated file `ex_bool.c`. The code declares `boolean` variables that use the type `mybool`.

```
/* External inputs (root inport signals with auto storage) */
typedef struct {
 real_T In1; /* '<Root>/In1' */
 real_T In2; /* '<Root>/In2' */
 mybool In3; /* '<Root>/In3' */
 mybool In4; /* '<Root>/In4' */
 real_T In5; /* '<Root>/In5' */
} ExtU_ex_bool_T;

/* External outputs (root outputs fed by signals with auto storage) */
typedef struct {
 mybool Out1; /* '<Root>/Out1' */
 mybool Out2; /* '<Root>/Out2' */
 real_T Out3; /* '<Root>/Out3' */
} ExtY_ex_bool_T;
```

## Remove Code from Tunable Parameter Expressions That Saturate Against Integer Overflow

Optimize generated code by removing code that protects parameter expressions from integer overflow for integers and fixed-point data. If you are sure that you will not tune the terms of tunable parameter expressions to cause them to evaluate to a value that is below or above the representable value of a data type, enable this optimization. This optimization increases execution speed and results in smaller code that reduces ROM consumption.

### Risks

When you select the `EfficientTunableParamExpr` parameter, and you tune the terms of the expression so that it encounters an integer overflow, the result will wrap around in the generated code. This behavior can cause the application to behave unexpectedly at run-time.

**NOTE:** If you enable this optimization, it is possible that simulation results and results from generated code are not in bit-for-bit agreement. This example requires Embedded Coder®.

### Example Model

In the model `matlab:mEfficientParamExpr`, an input signal of type `int8` feeds into a Gain block.

```
model = 'mEfficientParamExpr';
open_system(model);
```

Copyright 2021 The MathWorks, Inc.

### Generate Code

In your system temporary folder, create another temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
set_param(model, 'EfficientTunableParamExpr', 'off');
evalc('slbuild(model)');
```

View the generated code without the optimization. Here is a portion of `mEfficientParamExpr.c`.

```
cfile = fullfile(cgDir,'mEfficientParamExpr_ert_rtw','mEfficientParamExpr.c');
rtwdemodbtype(cfile,'/* Model step function ','/* Model initialize function',1, 1);

/* Model step function */
void mEfficientParamExpr_step(void)
{
 int32_T tmp;
```

```

/* Gain: '<Root>/Gain' */
tmp = P + Q;
if (tmp > 127) {
 tmp = 127;
} else if (tmp < -128) {
 tmp = -128;
}

/* Output: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 * Inport: '<Root>/In1'
 */
rtY.Out1 = (int8_T)(tmp * rtU.In1);
}

```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, select **Remove code from tunable parameter expressions that saturates out-of-range values**.

Alternatively, use the command-line API to enable the optimization:

```
set_param(model, 'EfficientTunableParamExpr', 'on');
```

### Generate Code with Optimization

The optimized code does not contain code that checks the bounds of the representable value of a data type.

Build the model.

```
evalc('slbuild(model)');
```

The following is a portion of `mEfficientParamExpr.c`. The code that protects against expression overflow is not in the generated code.

```

rtwdemodbtype(cfile, '/* Model step function ', '/* Model initialize function', 1, 1);

/* Model step function */
void mEfficientParamExpr_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 * Inport: '<Root>/In1'
 */
 rtY.Out1 = (int8_T)((int8_T)(P + Q) * rtU.In1);
}

```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Remove Code That Guards Against Division Exceptions for Integers and Fixed-Point Data

Optimize generated code by removing code that protects against division by zero and overflows in division  $\text{INT\_MIN} / -1$  operations for integers and fixed-point data. If you are sure that these arithmetic exceptions do not occur during program execution, enable this optimization but it may lead to a quotient that cannot be represented.

This optimization:

- Increases execution speed.
- Results in smaller code thereby reducing ROM consumption.

### Risks

When you select the `NoFixptDivByZeroProtection` parameter, the code generator removes code that protects against the following errors:

- When you divide by zero it is undefined and results in a runtime error in the generated code.
- When you divide the minimum representable value of a signed integer by negative one, the ideal result is equal to the maximum representable value plus one ( $\text{INT\_MAX} + 1$ ), which is not representable. This exception may cause the application to unexpectedly halt or crash at run-time.

**NOTE:** If you enable this optimization, it is possible that simulation results and results from generated code are not in bit-for-bit agreement. This example requires an Embedded Coder® license.

### Example Model

In the model `rtwdemo_nzcheck`, two signals of type `int8` feed into a divide block.

```
model = 'rtwdemo_nzcheck';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

### Generate Code

In your system's temporary folder, create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
set_param(model, 'NoFixptDivByZeroProtection', 'off');
slbuild(model);

Starting build procedure for: rtwdemo_nzcheck
Successful completion of code generation for: rtwdemo_nzcheck
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_nzcheck	Code generated	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 41.159s

View the generated code without the optimization. Here is a portion of rtwdemo\_nzcheck.c.

```
cfile = fullfile(cgDir, 'rtwdemo_nzcheck_ert_rtw', 'rtwdemo_nzcheck.c');
rtwdemodbtype(cfile, '/* Real-time model', '/* Model initialize function', 1, 1);

/* Real-time model */
static RT_MODEL_rtwdemo_nzcheck rtwdemo_nzcheck_M_;
RT_MODEL_rtwdemo_nzcheck *const rtwdemo_nzcheck_M = &rtwdemo_nzcheck_M_;

 * Inport: '<Root>/In2'
 */
 Y = U1 / U2;
}
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

**Additional Information**

There are several other factors that can affect the appearance of the generated code for division operations. The generated code for blocks containing MATLAB® code with integer or fixed-point division operations differs from the built-in Divide block in Simulink®. To balance the efficiency and semantics of fixed-point and integer divisions in these blocks, use `fi` objects and set the `fimath` properties to fit your needs and requires a Fixed-Point Designer™ license. Rounding and overflow modes also affect the size and efficiency of the generated code.

## Optimize Generated Code by Consolidating Redundant If-Else Statements

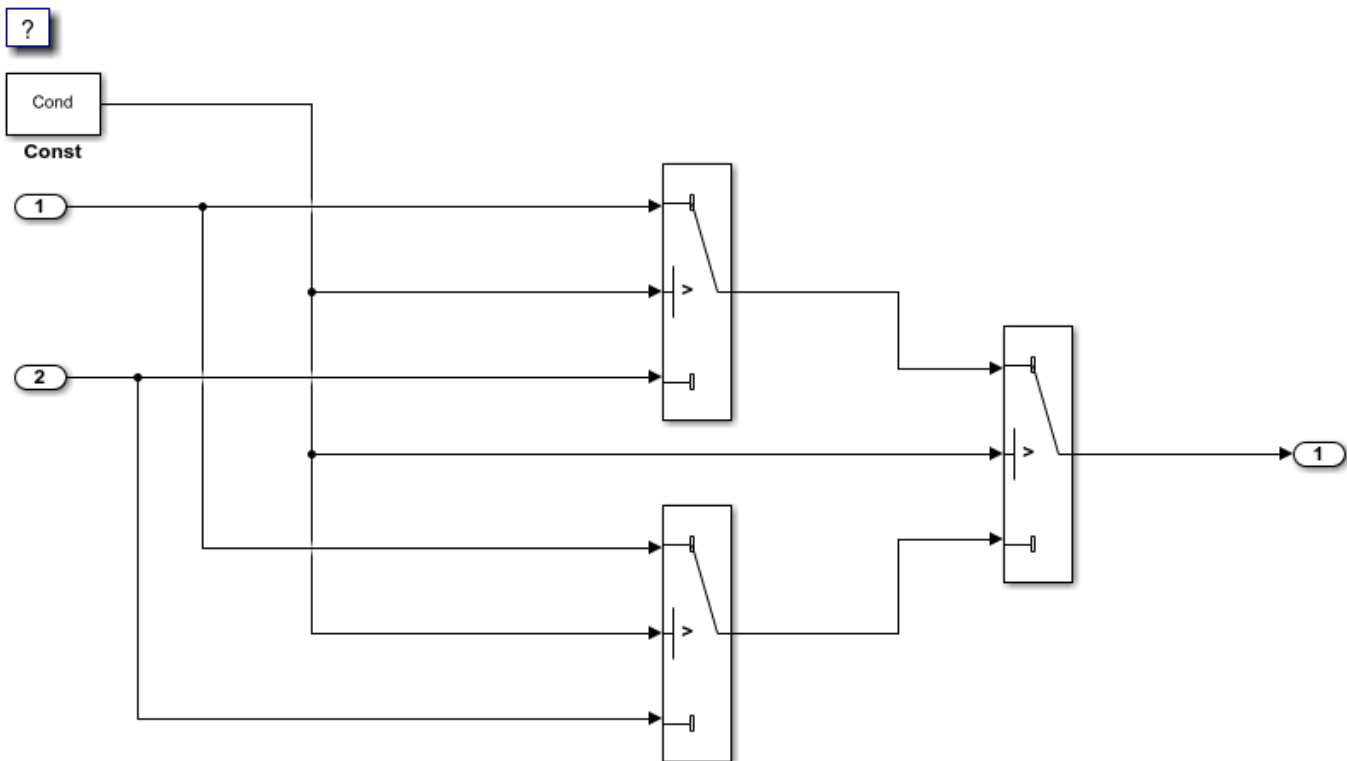

This example shows how to optimize generated code by combining `if-else` statements that share the same condition. This optimization:

- Improves control flow.
- Reduces code size.
- Reduces RAM consumption.
- Increases execution speed.

### Example

The model `rtwdemo_controlflow_opt` contains three Switch blocks. The Constant block provides the control input to the Switch blocks. The variable named `Cond` determines the value of the Constant block.

```
model = 'rtwdemo_controlflow_opt';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

### Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_controlflow_opt
Successful completion of build procedure for: rtwdemo_controlflow_opt
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_controlflow_opt	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 1m 0.609s

These lines of `rtwdemo_controlflow_opt.c` code show that in the generated code, two `if-else` statements and one `else-if` statement represent the three Switch blocks.

```
cfile = fullfile(cgDir,'rtwdemo_controlflow_opt_ert_rtw',...
 'rtwdemo_controlflow_opt.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_controlflow_opt_step(void)
{
 /* Switch: '<Root>/Switch3' incorporates:
 * Constant: '<Root>/Const'
 * Switch: '<Root>/Switch2'
 */
 if (Cond) {
 /* Switch: '<Root>/Switch1' */
 if (Cond) {
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 */
 rtY.Out1 = rtU.In1;
 } else {
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In2'
 */
 rtY.Out1 = rtU.In2;
 }

 /* End of Switch: '<Root>/Switch1' */
 } else if (Cond) {
 /* Switch: '<Root>/Switch2' incorporates:
 * Inport: '<Root>/In1'
 * Outport: '<Root>/Out1'
 */
 rtY.Out1 = rtU.In1;
 } else {
```

```

 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In2'
 */
 rtY.Out1 = rtU.In2;
}

/* End of Switch: '<Root>/Switch3' */
}

```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Code generation-> Code Style** pane, clear **Preserve condition expression in if statement**. This parameter is on by default.

Alternatively, use the command-line API to turn off the parameter:

```
set_param(model, 'PreserveIfCondition', 'off');
```

### Generate Code with Optimization

In the optimized code, the code generator consolidates the two `if-else` statements and one `else-if` statement into one `if-else` statement. The code generator consolidates these statements because they all share the same condition. There is no intervening code that affects the outcomes of these statements.

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_controlflow_opt
Successful completion of build procedure for: rtwdemo_controlflow_opt
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_controlflow_opt	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 41.04s

Here is the `rtwdemo_controlflow_opt.c` optimized code.

```
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);
```

```

/* Model step function */
void rtwdemo_controlflow_opt_step(void)
{
 /* Switch: '<Root>/Switch1' incorporates:
 * Constant: '<Root>/Const'
 * Switch: '<Root>/Switch3'
 */
 if (Cond) {
 /* Outport: '<Root>/Out1' incorporates:

```

```
 * Inport: '<Root>/In1'
 */
 rtY.Out1 = rtU.In1;
} else {
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In2'
 */
 rtY.Out1 = rtU.In2;
}

/* End of Switch: '<Root>/Switch1' */
}
```

Close the model and clean up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Optimize Generated Code for Fixed-Point Data Operations

This example shows how the code generator optimizes fixed-point operations by replacing expensive division operations with highly efficient product operations. This optimization improves execution speed.

### Example Model

In the model `rtwdemo_fixptdiv`, two fixed point signals connect to a Divide block. The **Number of inputs** parameter has the value `/*`.

```
model='rtwdemo_fixptdiv';
load_system(model)
set_param(model,'HideAutomaticNames','off','SimulationCommand','Update')
open_system(model);
```

Copyright 1994-2020 The MathWorks, Inc.

### Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwmodedir();
```

Build the model.

```
set_param(model,'GenCodeOnly','on');
slbuild(model);
```

```
Starting build procedure for: rtwdemo_fixptdiv
Successful completion of code generation for: rtwdemo_fixptdiv
```

Build Summary

Top model targets built:

```
Model Action Rebuild Reason
=====
rtwdemo_fixptdiv Code generated Code generation information file does not exist.

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 20.69s
```

View the generated code. Here is a portion of `rtwdemo_fixptdiv.c`.

```
cfile = fullfile(cgDir,'rtwdemo_fixptdiv_ert_rtw','rtwdemo_fixptdiv.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_fixptdiv_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 * Product: '<Root>/Divide'
 */
 rtY.Out1 = (int16_T)(rtU.In1 >> 3);
}
```

The generated code contains a highly efficient right shift operation instead of an expensive division operation. The generated code also contains the precomputed value for the constant input to the Product block.

Note that the resulting operation also includes the adjustment in signal scaling from  $2^{-3}$  to  $2^{-5}$ .

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Unroll Parallel for-Loop That Has Small Number of Iterations

This example shows how to use the model configuration parameter “Loop unrolling threshold” to generate optimized code by unrolling parallel for-loops (parfor-loops). For a small number of loop iterations that perform some simple calculation, parallelization is inefficient as it introduces overhead, which includes time taken for thread creation, data synchronization between threads, and thread deletion. By unrolling small parallel for-loops, you can achieve improved execution speed. Unrolling loops that have a large number of iterations can significantly increase code generation time and generate inefficient code.

### Example Model

Open the example model `rtwdemo_unroll_parfor`. The model is configured to generate multithreaded code by selecting the **Generate parallel for loops** parameter.

```
model = 'rtwdemo_unroll_parfor';
open_system(model)
```

The MATLAB Function block contains this code:

```
type('myloop.m')

function y = myloop(u)
 y = ones(1,100);
 parfor (i = 1:5)
 y(i) = i+u;
 end
end
```

The code contains a parfor-loop that has five iterations.

### Generate Code by Using the Default Threshold Value

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

2. Build the model.

```
slbuild(model);

Starting build procedure for: rtwdemo_unroll_parfor
Successful completion of build procedure for: rtwdemo_unroll_parfor
```

## Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_unroll_parfor	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 28.13s

Inspect the generated `rtwdemo_unroll_parfor_step` step function in the `rtwdemo_unroll_parfor.c`.

```
file = fullfile('rtwdemo_unroll_parfor_ert_rtw','rtwdemo_unroll_parfor.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function',1,1);
```

```
/* Model step function */
void rtwdemo_unroll_parfor_step(void)
{
 int32_T i;
 int32_T i_0;

 /* MATLAB Function: '<Root>/MATLAB Function' */
 for (i_0 = 0; i_0 < 100; i_0++) {
 rtwdemo_unroll_parfor_Y.Outport[i_0] = 1.0;
 }

 #pragma omp parallel for num_threads(omp_get_max_threads())

 for (i = 0; i < 5; i++) {
 rtwdemo_unroll_parfor_Y.Outport[i] = ((real_T)i + 1.0) + 2.0;
 }

 /* End of MATLAB Function: '<Root>/MATLAB Function' */
}
```

The code generator generates a parallel `for`-loop for the MATLAB Function block because it has 5 iterations which is equal to the default threshold value.

### Generate Code by Raising the Threshold Value

1. Open the Configuration Parameters dialog box. On the **Optimization** pane, set the **Loop unrolling threshold** to 6. Alternatively, use the command-line API:

```
set_param(model, 'RollThreshold', '6')
```

Build the model. Inspect the generated `rtwdemo_unroll_parfor_step` step function in the `rtwdemo_unroll_parfor.c`.

```
slbuild(model);
file = fullfile('rtwdemo_unroll_parfor_ert_rtw','rtwdemo_unroll_parfor.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function',1,1);

Starting build procedure for: rtwdemo_unroll_parfor
Successful completion of build procedure for: rtwdemo_unroll_parfor
```

## Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_unroll_parfor	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 18.163s

```

/* Model step function */
void rtwdemo_unroll_parfor_step(void)
{
 int32_T i;

 /* MATLAB Function: '<Root>/MATLAB Function' */
 for (i = 0; i < 100; i++) {
 rtwdemo_unroll_parfor_Y.Outputport[i] = 1.0;
 }

 rtwdemo_unroll_parfor_Y.Outputport[0] = 3.0;
 rtwdemo_unroll_parfor_Y.Outputport[1] = 4.0;
 rtwdemo_unroll_parfor_Y.Outputport[2] = 5.0;
 rtwdemo_unroll_parfor_Y.Outputport[3] = 6.0;
 rtwdemo_unroll_parfor_Y.Outputport[4] = 7.0;

 /* End of MATLAB Function: '<Root>/MATLAB Function' */
}

```

The code generator unrolls the parallel for-loop and produces a copy of the loop body for each iteration because it has fewer iterations compared to the threshold value.

## Clean Up Example Folders and Files

Close the model and remove temporary folders and files.

```

bdclose(model);
cd(currentDir);
rtwdemoclean;

```

## Optimize Generated Code by Developing and Using Code Replacement Libraries - Simulink

Develop and use code replacement libraries to replace function and operators in generated code. Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware
- Integration with existing application code
- Compliance with a standard, such as AUTOSAR
- Modification of code behavior, such as enabling or disabling nonfinite or inline support
- Application- or project-specific code requirements, such as use of BLAS or elimination of `math.h`, system header files, or calls to `memcpy` or `memset`.

You can configure a model such that the code generator uses a code replacement library that MathWorks® provides. If you have an Embedded Coder® license, you can develop your own code replacement library interactively with the Code Replacement Tool or programmatically.

This example uses models to show a variety of ways you can define code replacement mappings programmatically. Each model includes buttons that you can use to

- View the code replacement library table definitions from the Code Replacement Viewer
- Open the library table definition file in the editor
- Open the library registration file in the editor
- View the model configuration
- Generate code

For more information, see “Define Code Replacement Library Optimizations” on page 69-36 and “Register Code Replacement Library” on page 69-51.

### Steps for Developing a Code Replacement Library

- 1 Identify your code replacement requirements with respect to function or operating mappings, build information, and registration information.
- 2 Prepare for code replacement library development (for example, identify or develop models to test your library).
- 3 Define code replacement mappings.
- 4 Specify build information for replacement code.
- 5 Register code replacement mappings.
- 6 Verify code replacements.
- 7 Deploy the library.

For more information, see “Quick Start Code Replacement Library Development - Simulink” on page 69-21.

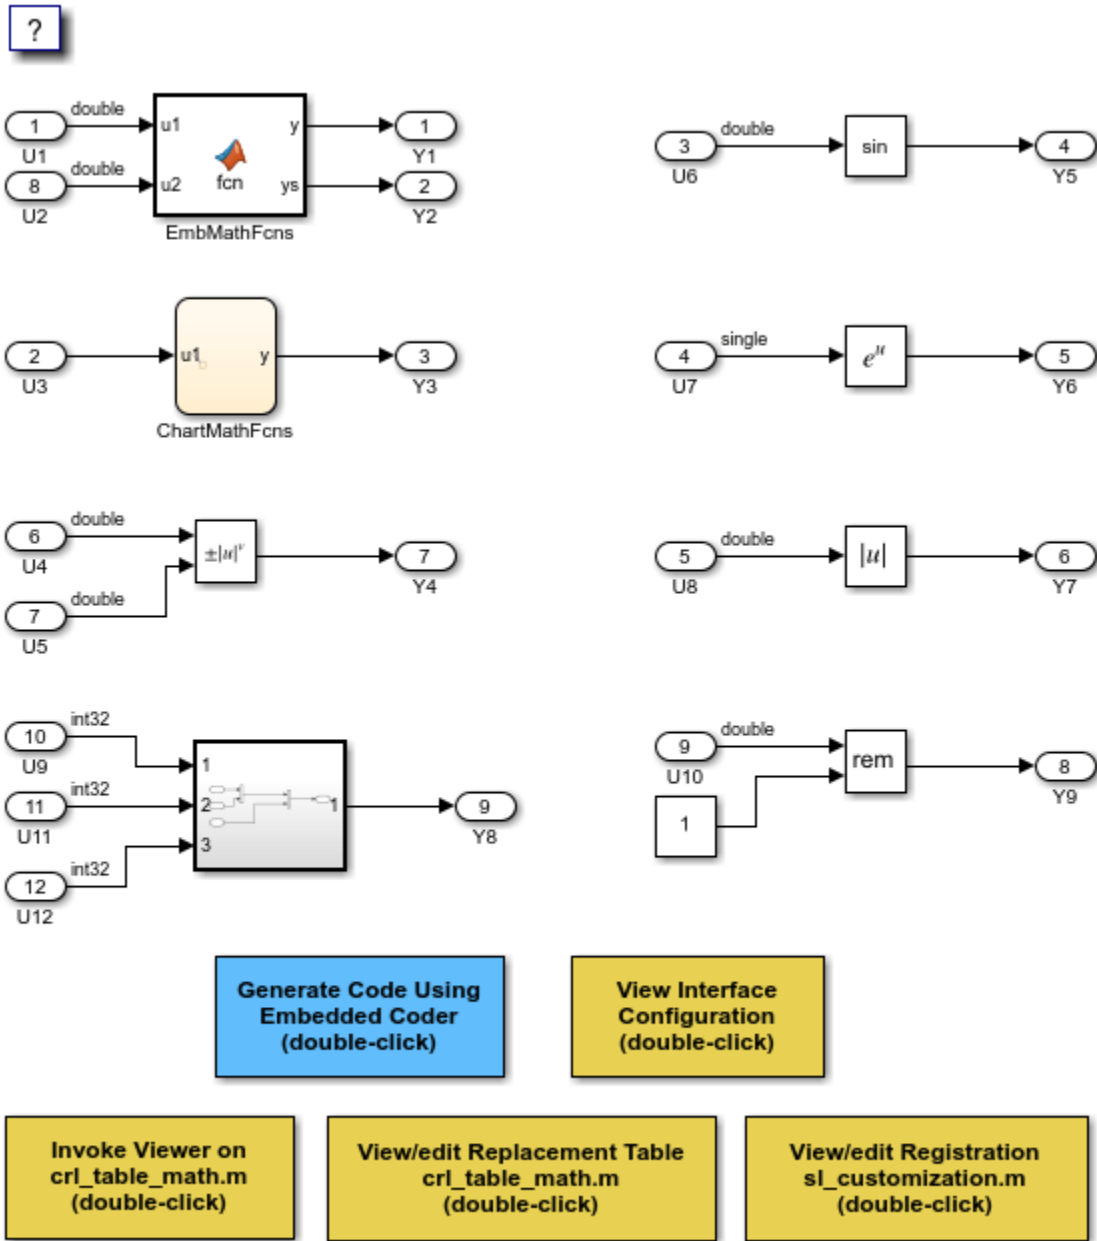

## Math Function Replacement

This example defines and registers code replacement mappings for math functions. You can define code replacement mappings for a variety of functions (see “Code You Can Replace From Simulink Models” on page 69-6).

Open the model `rtwdemo_crlmath` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information, see “Math Function Code Replacement” on page 69-64.

```
open_system('rtwdemo_crlmath')
```

Copyright 2007-2020 The MathWorks, Inc.

### Addition and Subtraction Operator Replacement

This example shows how to define and register code replacement mappings for addition (+) and subtraction (-) operations. When defining entries for addition and subtraction operations, you can specify which of the following algorithms (`EntryInfoAlgorithm`) your library functions implement:

- Cast-before-operation (CBO) (`RTW_CAST_BEFORE_OP`), the default
- Cast-after-operation (CAO) (`RTW_CAST_AFTER_OP`)

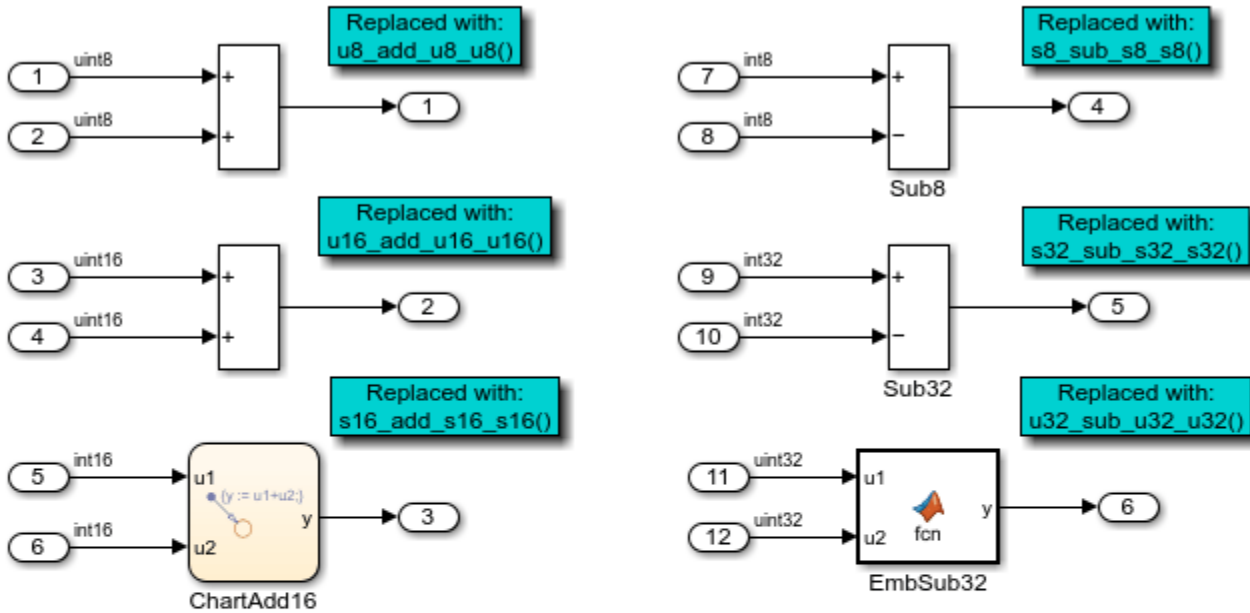

1. Open the model `rtwdemo_crladdsub`. The model shows how to define and register code replacement mappings for scalar addition subtraction (-) operations on two operands with the following pairings of built-in integer data types:

- `int8, uint8`
- `int16, uint16`
- `int32, uint32`

CBO, the default algorithm, is assumed.

```
open_system('rtwdemo_crladdsub')
```

?

**Generate Code Using Embedded Coder (double-click)**

**View Interface Configuration (double-click)**

**Invoke Viewer on `crl_table_addsub.m` (double-click)**

**View/edit Replacement Table `crl_table_addsub.m` (double-click)**

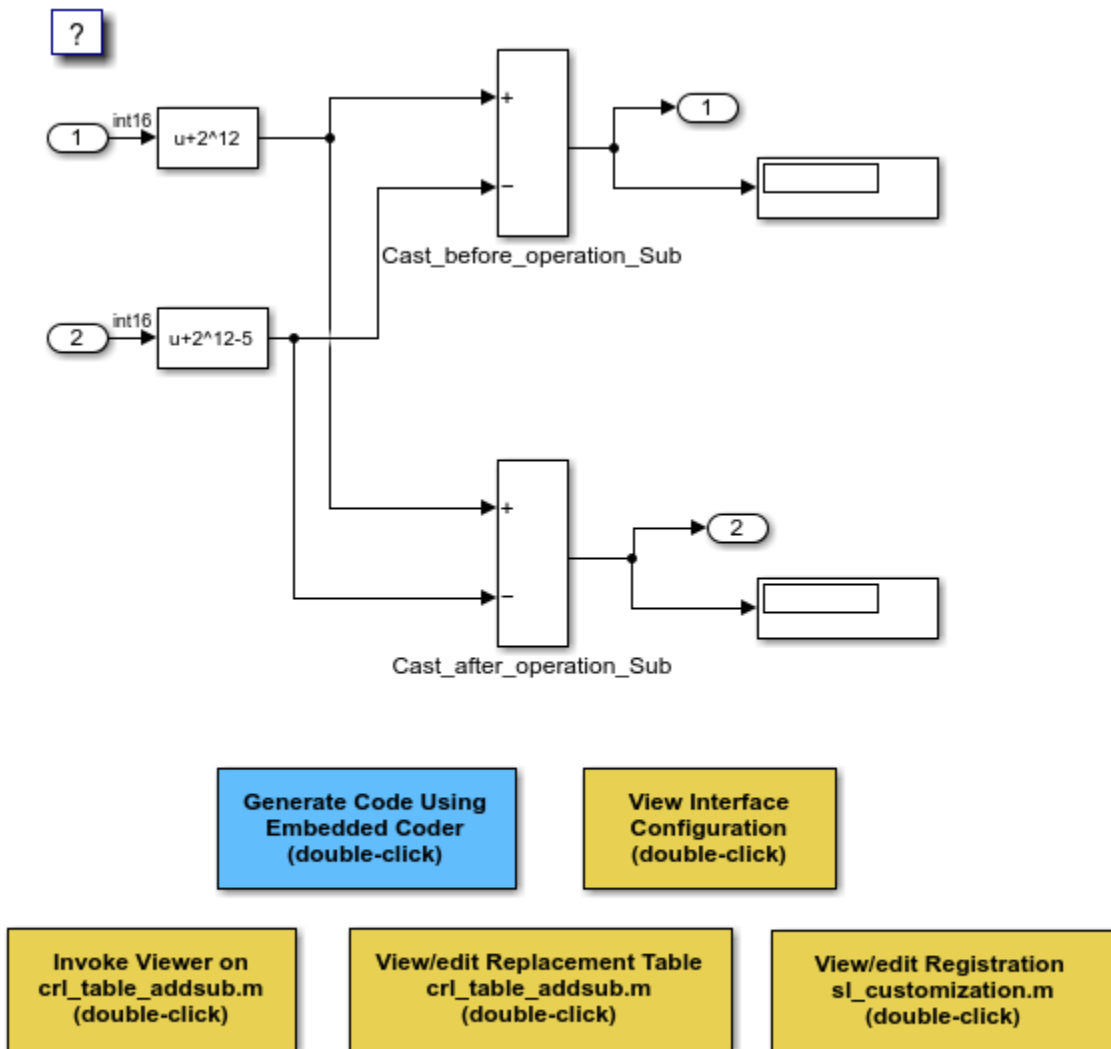

**View/edit Registration `sl_customization.m` (double-click)**

2. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

3. Explore the differences between the CBO and CAO algorithms by opening the model `rtwdemo_crl_cbo_cao`. The model shows two SUM blocks, each demonstrating one of the algorithm settings to match a corresponding code replacement entry.

- For the `Cast_before_operation_Sub` block, the code generator calculates the subtraction operation in the accumulator data type (`int8`), which is smaller than the input data type (`int16`). This is equivalent to a CBO because the code generator converts the input to the output data type before calculating the result.
- For the `Cast_after_operation_Sub` block, the code generator calculates the subtraction operation in the accumulator data type (`int32`), which is larger than the input data type (`int16`). This is equivalent to a CAO because the code generator produces the same result by calculating the result without loss of range or precision before converting to the output data type.

```
open_system('rtwdemo_crl_cbo_cao')
```

4. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on addition and subtraction operator replacement, see “Replace Addition and Subtraction Operator Code” on page 69-151. For more information on the addition and subtraction algorithm (EntryInfoAlgorithm) options, see setTfLCOperationEntryParameters.

### Multiplication and Division Operator Replacement for Built-In Integers

This example defines and registers code replacement mappings for scalar multiplication (\*) and division (/) operations. The operations take two operands with the following pairings of built-in integer data types:

- int8, uint8

- int16, uint16
- int32, uint32

Open the model `rtwdemo_crlmuldiv` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

`open_system('rtwdemo_crlmuldiv')`

Copyright 2007-2020 The MathWorks, Inc.

### Scalar Operator Replacement

This example defines and registers code replacement mappings for scalar operations: addition, subtraction, multiplication, complex conjugate, cast, arithmetic shift right, and arithmetic shift left.

Supported types include:

- single, double
- int8, uint8
- int16, uint16
- int32, uint32
- csingle, cdouble
- cint8, cuint8
- cint16, cuint16
- cint32, cuint32
- fixed-point integers
- mixed types (different type on each input)

Open the model `rtwdemo_cr_scalarops` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on scalar operator replacement, “Scalar Operator Code Replacement” on page 69-143.

CBO, the default algorithm for addition and subtraction operations, is assumed.

```
open_system('rtwdemo_cr_scalarops')
```

Copyright 2007-2020 The MathWorks, Inc.

### Matrix Operator Replacement

This example defines and registers code replacement mappings for matrix operations: addition, subtraction, multiplication, transposition, conjugate, and Hermitian.

Supported types include:

- `single`, `double`
- `int8`, `uint8`

- `int16, uint16`
- `int32, uint32`
- `csingle, cdouble`
- `cint8, cuint8`
- `cint16, cuint16`
- `cint32, cuint32`
- fixed-point integers
- mixed types (different type on each input)

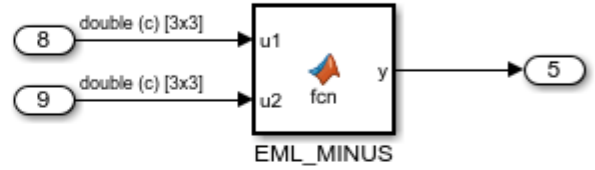

Open the model `rtwdemo_crlmatops`, which shows some of these replacements. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on matrix operator replacement, see “Small Matrix Operation to Processor Code Replacement” on page 69-175.

CBO, the default algorithm for addition and subtraction operations, is assumed.

```
open_system('rtwdemo_crlmatops')
```

?

**Generate Code Using Embedded Coder (double-click)**

**View Interface Configuration (double-click)**

**Invoke Viewer on crl\_table\_matrixops.m (double-click)**

**View/edit Replacement Table crl\_table\_matrixop.m (double-click)**

**View/edit Registration sl\_customization.m (double-click)**

## Matrix Multiplication Replacement for BLAS

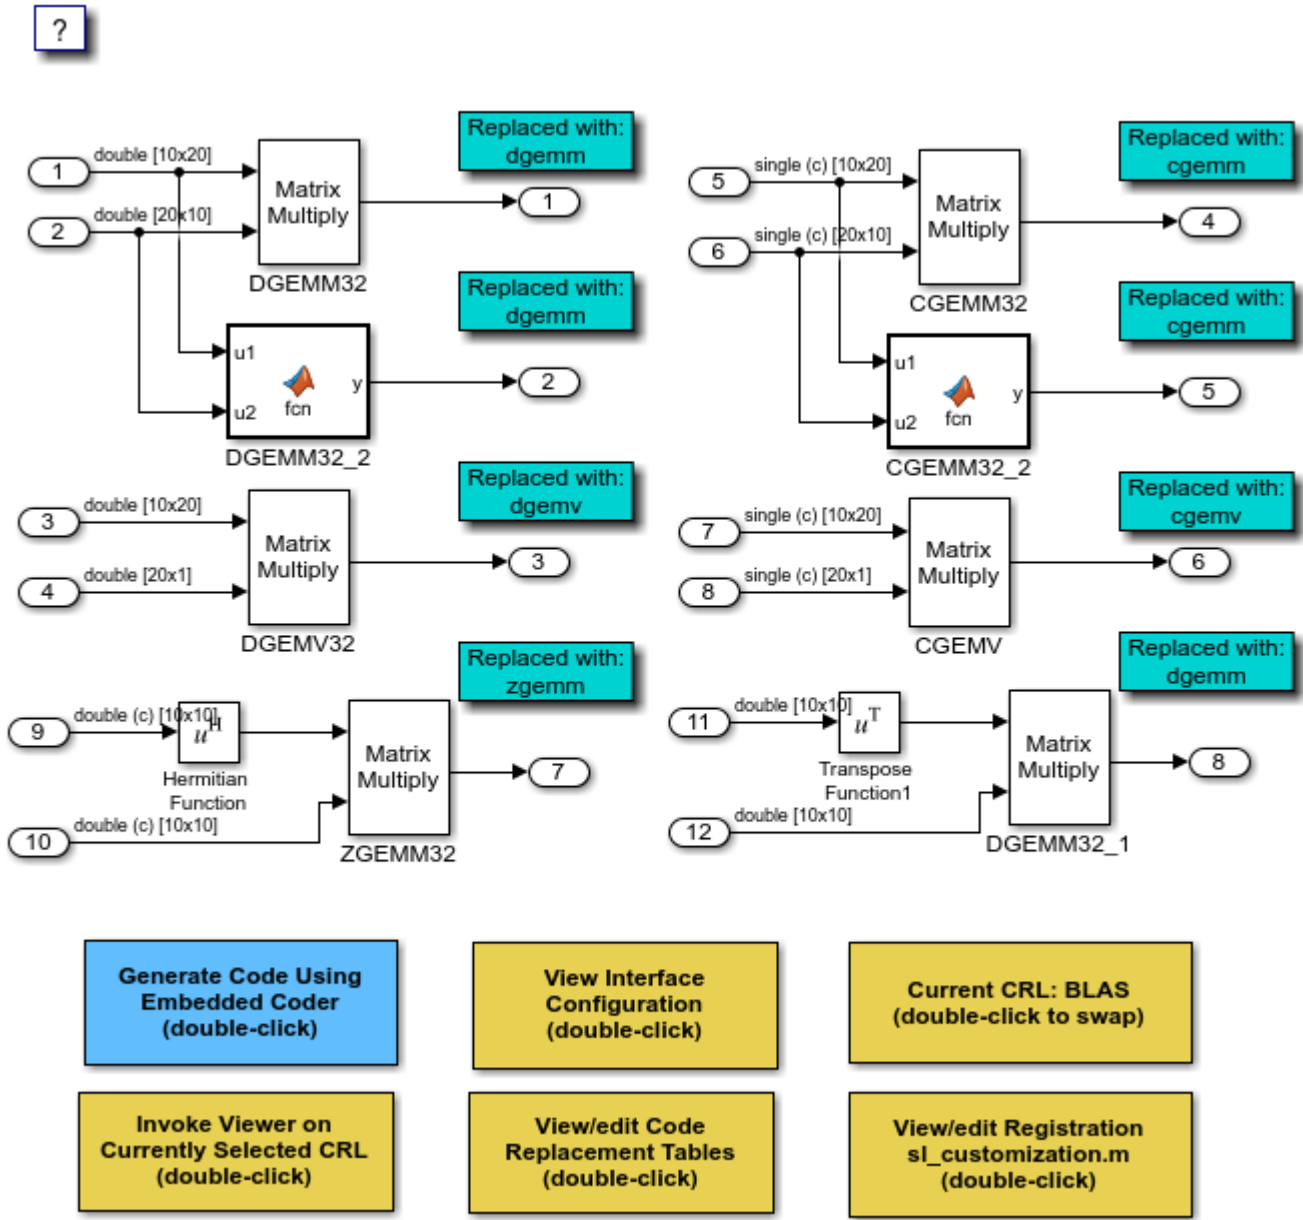

This example defines and registers code replacement mappings for Basic Linear Algebra Subroutines (BLAS) subroutines xGEMM and xGEMV. You can map the following operations to a BLAS subroutine:

- Matrix multiplication
- Matrix multiplication with transpose on single or both inputs
- Matrix multiplication with Hermitian operation on single or both inputs

Open the model `rtwdemo_cr\blas` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on matrix multiplication replacement for BLAS, see “Matrix Multiplication Operation to MathWorks BLAS Code Replacement” on page 69-158.

```
open_system('rtwdemo_cr\blas')
```

Copyright 2007-2020 The MathWorks, Inc.

**Fixed-Point Operator Replacement for Basic Operators**

This example defines and registers code replacement mappings for scalar addition (+), subtraction (-), multiplication (\*), and division (/) operations. The operations take two operands with fixed-point data types.

You can define code replacements as matching:

- Slope/bias scaling combination on the inputs and output
- Binary-point scaling combination on the inputs and output

- Relative scaling between the inputs and output
- Same slope value and a zero net bias across the inputs and output

Open the model `rtwdemo_crlfixpt` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

- By default, for addition and subtraction operator code replacements, the code generator assumes that replacement code implements a cast-before-operation (CBO) algorithm.
- Using fixed-point data types in a model requires a Fixed-Point Designer™ license.

For more information about fixed-point operator code replacement, see “Fixed-Point Operator Code Replacement” on page 69-186.

```
open_system('rtwdemo_crlfixpt')
```

### Match and Replacement Process Customization for Functions

This example defines and registers code replacement mappings for custom entries. You can create your own entry by subclassing from `RTW.TflCFunctionEntryML` or `RTW.TflCOperationEntryML`. Your entry class must implement a `do_match` method that customizes your matching logic or modifies the matched entry. The `do_match` method must have a fixed preset signature.

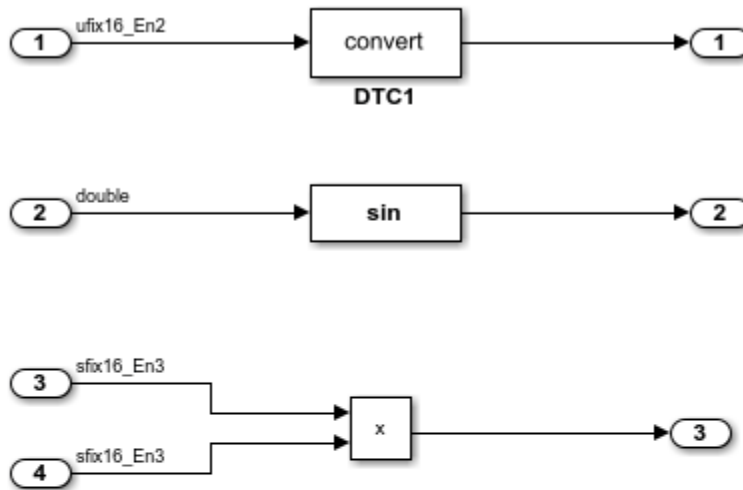

Open the model `rtwdemo_crlcustomentry`. The model shows how to modify the matched entry by injecting constants as additional implementation function arguments. `DTC1`, `Trigonometric Function`, and `Product` show custom entry code replacement for:

- Cast operation that demonstrates how to extract the fraction lengths from types and pass them into the implementation function - `Out1 = custom_cast(In1, 2, 4)`.
- Sine that demonstrates how to pass a constant value to the implementation function - `Out2=custom_sin(In2, 1)`.
- Multiplication operation that demonstrates how to compute the net slope of an operation and pass that into the implementation function - `Out3=custom_multiply_shift_right(In3,In4,3)`.

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings.

For more information on custom entries, see “Customize Match and Replacement Process” on page 69-132.

`open_system('rtwdemo_crlcustomentry')`

## MATLAB Function Replacement

This example defines and registers code replacement mappings for MATLAB® functions specified in the MATLAB Function block. The function can be opted for replacement by specifying `coder.replace` within it. This feature supports replacement of MATLAB functions with the following:

- Single or multiple inputs
- Single or multiple outputs
- Scalar and matrix inputs and outputs

Open the model `rtwdemo_crlcoderreplace`. The model shows some of these requirements. Supported types include:

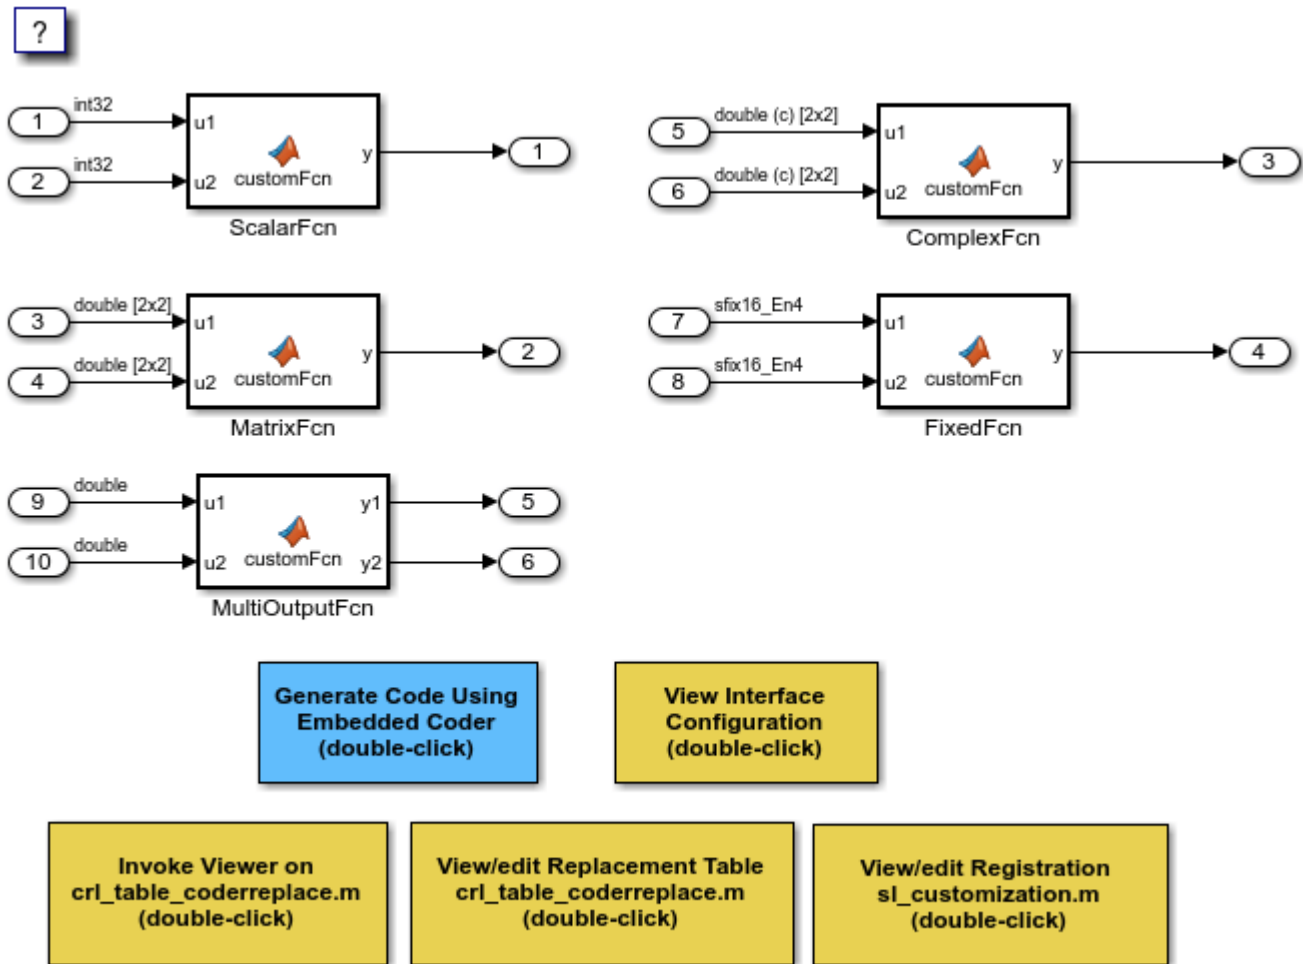

- `single`, `double`
- `int8`, `uint8`
- `int16`, `uint16`
- `int32`, `uint32`
- `csingle`, `cdouble`
- `cint8`, `cuint8`
- `cint16`, `cuint16`
- `cint32`, `cuint32`
- Fixed-point integers
- Mixed types (different type on each input)

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings.

For more information on MATLAB function replacement, see `coder.replace`.

```
open_system('rtwdemo_crlcoderreplace')
```

### Data Alignment for Function Implementations

This example shows how to specify the alignment of matrix operands passed into a replacement function. Some target-specific function implementations require data to be aligned to optimize application performance. To configure data alignment for a function implementation:

- Specify the data alignment requirements in a table entry. You can specify alignment for implementation function arguments individually or collectively.
- Specify the data alignment capabilities and syntax for your compiler. Attach an AlignmentSpecification object to the TargetCharacteristics object of the registry entry specified in your rtwTargetInfo.m file.

Open the model rtwdemo\_crlalign. The model shows three data alignment code replacement scenarios:

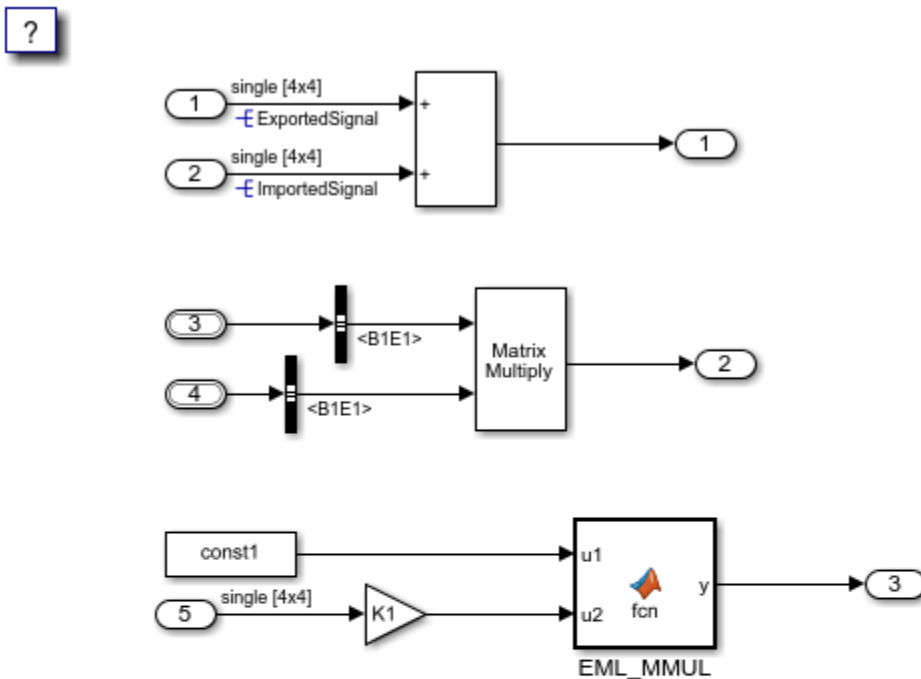

- Add - Alignment of exported and imported signals. You can specify an exact value for the alignment in the Signal Properties dialog box or allow the code generator to determine the best alignment based on usage by leaving the alignment value set to -1.

- **Product** - Alignment of virtual and nonvirtual bus types. You can specify an exact value for the alignment for the **Alignment** property of the Simulink.Bus object or allow the code generator to determine the best alignment based on usage by leaving the **Alignment** property set to -1.
- **EML\_MMUL** - Alignment of local variables, global variables, and block parameters.

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings. Note that the model is configured to use a GCC, Clang, MSVC, or MinGW compiler.

For more information on specifying data alignment for code replacement, see “Data Alignment for Code Replacement” on page 69-105.

```
open_system('rtwdemo_crlalign')
```

<b>Generate Code Using Embedded Coder</b> (double-click)	<b>View Interface Configuration</b> (double-click)	<b>View Workspace Variables</b> (double-click)
<b>Invoke Viewer on crl_table_align.m</b> (double-click)	<b>View/edit Replacement Table crl_table_align.m</b> (double-click)	<b>View/edit Registration sl_customization.m</b> (double-click)

### Code Replacement Library Exploration and Verification

This example shows Code Replacement Viewer. You can use the Code Replacement Viewer to:

- Explore which code replacement library to use
- Verify the list of tables in a library and the entries in each table
- Review table entry specifications
- Troubleshoot code replacement misses

The following commands open the Code Replacement Viewer for code replacement table `crl_tablemuldiv`:

```
crl = crl_table_muldiv;
crviewer(crl);
```

For more information on the Code Replacement Viewer, see “Verify Code Replacement Library” on page 69-55.

### Build Information

For each entry in a code replacement table, you can specify build information such as the following, for replacement functions:

- Header file dependencies
- Source file dependencies
- Additional include paths
- Additional source paths
- Additional link flags

Additionally, you can specify `RTW.copyFileToBuildDir` to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. You can specify `RTW.copyFileToBuildDir` by setting it as the value of:

- Property `GenCallback` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`.
- Argument `genCallback` in a call to `registerCFunctionEntry`, `registerCOperationEntry`, or `registerCSemaphoreEntry`.

**Note:** Models in this example are configured for code generation only because the implementations for the replacement functions are not provided.

For more information on specifying build information, see Specify build information in “Define Code Replacement Library Optimizations” on page 69-36.

### Reserved Identifiers

Each function implementation name defined by a code replacement table entry is reserved as a unique identifier. You can specify other identifiers with a table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier related compile and link issues.

For more information on specifying reserved identifiers, see “Reserved Identifiers and Code Replacement” on page 69-131.

### Remove Example Code Replacement Libraries

When you finish using the example models, remove the example code replacement libraries and close the example models with these commands:

```
rmpath(fullfile(matlabroot,'toolbox','rtw','rtwdemos','crl_demo'));
sl_refresh_customizations;

close_system('rtwdemo_crladdsub', 0)
close_system('rtwdemo_crl_cbo_cao', 0)

```

## Improve Execution Efficiency by Reordering Block Operations in the Generated Code

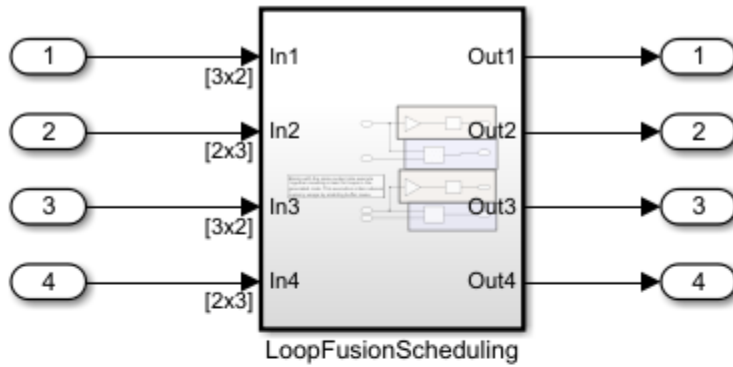

To improve execution efficiency, the code generator can change the block execution order. In the Configuration Parameters dialog box, when you set the **Optimize Block Order** parameter to **Improved Execution Speed**, the code generator can change the block operation order to implement these optimizations:

- Eliminate data copies for blocks that perform inplace operations (that is, use the same input and output variable) and contain algorithm code with unnecessary data copies.
- Combine more `for` loops by executing blocks together that have the same size.
- Reuse the same variable for the input, output, and state of a Unit Delay block by executing the Unit Delay block before upstream blocks.

These optimizations improve execution speed and conserve RAM and ROM consumption.

### Example Model

Open the model `matlab:rtwdemo_optimizeblockorder`. This model contains three subsystems for demonstrating how reordering block operations improves execution efficiency.

Copyright 2017 The MathWorks, Inc.

### for Loop Fusion

The subsystem LoopFusionScheduling shows how the code generator reorders block operations so that blocks that have the same output size execute together. This reordering enables for loop fusion. Set the **Optimize block order in the generated code** parameter to Off.

In your system's temporary folder, create a folder for the build and inspection process and build the model.

```
Starting build procedure for: rtwdemo_optimizeblockorder
Successful completion of build procedure for: rtwdemo_optimizeblockorder
```

Build Summary

Top model targets built:

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 23.689s

View the generated code without the optimization. Code for the LoopFusionScheduling subsystem:

```

/* Output and update for atomic system: '<Root>/LoopFusionScheduling' */
static void LoopFusionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
 const real_T rtu_In3[6], const real_T rtu_In4[6], real_T rty_Out1[6], real_T
 rty_Out2[9], real_T rty_Out3[6], real_T rty_Out4[9])
{
 int32_T i;
 int32_T i_0;
 int32_T tmp;
 int32_T tmp_0;

 /* Bias: '<S2>/Bias' incorporates:
 * Gain: '<S2>/Gain'
 */
 for (i = 0; i < 6; i++) {
 rty_Out1[i] = -0.3 * rtu_In1[i] + 0.5;
 }

 /* End of Bias: '<S2>/Bias' */

 /* Product: '<S2>/Product' */
 for (i = 0; i < 3; i++) {
 for (i_0 = 0; i_0 < 3; i_0++) {
 tmp = 3 * i + i_0;
 rty_Out2[tmp] = 0.0;
 tmp_0 = i << 1;
 rty_Out2[tmp] += rtu_In2[tmp_0] * rtu_In1[i_0];
 rty_Out2[tmp] += rtu_In2[tmp_0 + 1] * rtu_In1[i_0 + 3];
 }
 }

 /* End of Product: '<S2>/Product' */

 /* Bias: '<S2>/Bias1' incorporates:
 * Gain: '<S2>/Gain1'
 */
 for (i = 0; i < 6; i++) {
 rty_Out3[i] = -0.3 * rtu_In3[i] + 0.5;
 }

 /* End of Bias: '<S2>/Bias1' */

 /* Product: '<S2>/Product1' */
 for (i = 0; i < 3; i++) {
 for (i_0 = 0; i_0 < 3; i_0++) {
 tmp = 3 * i + i_0;
 rty_Out4[tmp] = 0.0;
 tmp_0 = i << 1;
 rty_Out4[tmp] += rtu_In4[tmp_0] * rtu_In3[i_0];
 rty_Out4[tmp] += rtu_In4[tmp_0 + 1] * rtu_In3[i_0 + 3];
 }
 }
}

```

```

 }
}

/* End of Product: '<S2>/Product1' */
}

```

With the default execution order, the blocks execute from left to right and from top to bottom. As a result, there are separate **for** loops for the two combinations of Gain and Bias blocks and the Product blocks.

Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to **Improved Execution Speed** and build the model.

```

Starting build procedure for: rtwdemo_optimizeblockorder
Successful completion of build procedure for: rtwdemo_optimizeblockorder

```

Build Summary

```

/* Output and update for atomic system: '<Root>/LoopFusionScheduling' */
static void LoopFusionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
 const real_T rtu_In3[6], const real_T rtu_In4[6], real_T rty_Out1[6], real_T
 rty_Out2[9], real_T rty_Out3[6], real_T rty_Out4[9])
{
 int32_T i;
 int32_T i_0;
 int32_T tmp;
 int32_T tmp_0;
 for (i = 0; i < 3; i++) {
 for (i_0 = 0; i_0 < 3; i_0++) {
 /* Product: '<S2>/Product' incorporates:
 * Product: '<S2>/Product1'
 */
 tmp = 3 * i + i_0;
 rty_Out2[tmp] = 0.0;

 /* Product: '<S2>/Product1' */
 rty_Out4[tmp] = 0.0;

 /* Product: '<S2>/Product' incorporates:
 * Product: '<S2>/Product1'
 */
 tmp_0 = i << 1;
 rty_Out2[tmp] += rtu_In2[tmp_0] * rtu_In1[i_0];

 /* Product: '<S2>/Product1' */
 rty_Out4[tmp] += rtu_In4[tmp_0] * rtu_In3[i_0];
 }
 }
}

```

```

 /* Product: '<S2>/Product' */
 rty_Out2[tmp] += rtu_In2[tmp_0 + 1] * rtu_In1[i_0 + 3];

 /* Product: '<S2>/Product1' incorporates:
 * Product: '<S2>/Product'
 */
 rty_Out4[tmp] += rtu_In4[tmp_0 + 1] * rtu_In3[i_0 + 3];
}
}

for (i = 0; i < 6; i++) {
 /* Bias: '<S2>/Bias' incorporates:
 * Gain: '<S2>/Gain'
 */
 rty_Out1[i] = -0.3 * rtu_In1[i] + 0.5;

 /* Bias: '<S2>/Bias1' incorporates:
 * Gain: '<S2>/Gain1'
 */
 rty_Out3[i] = -0.3 * rtu_In3[i] + 0.5;
}
}

```

In the optimized code, blocks with the same output size execute together. The two sets of Gain and Bias blocks have an output dimension size of 6, so they execute together. The Product blocks have an output dimension size of 9, so they execute together. The fusion of for loops enables the code generator to set the value of the expression  $3 * i + i\_0$  equal to the temporary variable tmp\_0. This optimization also improves execution efficiency.

### Buffer Reuse for the Input, Output, and State of Unit Delay Blocks

The subsystem RegionScheduling shows how the code generator reorders block operations to enable buffer reuse for the input, output, and state of Unit Delay blocks. When computation is part of separate regions that connect only through Delay blocks, the code generator can change the block execution order so that the downstream regions execute before the upstream regions. This execution order enables maximum reuse of Delay block states and input and output variables. Set the **Optimize block order in the generated code** parameter to Off and build the model.

```

Starting build procedure for: rtwdemo_optimizeblockorder
Successful completion of build procedure for: rtwdemo_optimizeblockorder

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_optimizeblockorder	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
 Build duration: 0h 0m 20.177s

View the generated code without the optimization. Code for the RegionScheduling subsystem:

```

/* Output and update for atomic system: '<Root>/RegionScheduling' */

```

```

static void RegionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
 real_T rty_Out1[6], rtDW_RegionScheduling *localDW)
{
 real_T rtb_Sum;
 int32_T i;
 for (i = 0; i < 6; i++) {
 /* Sum: '<S3>/Sum' incorporates:
 * UnitDelay: '<S3>/Delay'
 * UnitDelay: '<S3>/UnitDelay'
 */
 rtb_Sum = localDW->Delay_DSTATE[i] + localDW->UnitDelay_DSTATE[i];

 /* UnitDelay: '<S3>/UnitDelay2' */
 rty_Out1[i] = localDW->UnitDelay2_DSTATE[i];

 /* Update for UnitDelay: '<S3>/Delay' incorporates:
 * Bias: '<S3>/Bias'
 */
 localDW->Delay_DSTATE[i] = rtu_In1[i] + 3.0;

 /* Update for UnitDelay: '<S3>/UnitDelay' incorporates:
 * Gain: '<S3>/Gain'
 */
 localDW->UnitDelay_DSTATE[i] = 2.0 * rtu_In2[i];

 /* Update for UnitDelay: '<S3>/UnitDelay2' */
 localDW->UnitDelay2_DSTATE[i] = rtb_Sum;
 }
}

```

With the default execution order, the generated code contains the extra, temporary variable `rtb_Sum` and a data copy.

Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to **Improved Execution Speed** and build the model.

```

Starting build procedure for: rtwdemo_optimizeblockorder
Successful completion of build procedure for: rtwdemo_optimizeblockorder

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_optimizeblockorder	Code generated and compiled	Generated code was out of date.

```

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 18.969s

```

View the generated code with the optimization.

```

/* Output and update for atomic system: '<Root>/RegionScheduling' */
static void RegionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
 real_T rty_Out1[6], rtDW_RegionScheduling *localDW)
{
 int32_T i;

```

```

for (i = 0; i < 6; i++) {
 /* UnitDelay: '<S3>/UnitDelay2' */
 rty_Out1[i] = localDW->UnitDelay2_DSTATE[i];

 /* Sum: '<S3>/Sum' incorporates:
 * UnitDelay: '<S3>/Delay'
 * UnitDelay: '<S3>/UnitDelay'
 * UnitDelay: '<S3>/UnitDelay2'
 */
 localDW->UnitDelay2_DSTATE[i] = localDW->Delay_DSTATE[i] +
 localDW->UnitDelay_DSTATE[i];

 /* Bias: '<S3>/Bias' incorporates:
 * UnitDelay: '<S3>/Delay'
 */
 localDW->Delay_DSTATE[i] = rty_In1[i] + 3.0;

 /* Gain: '<S3>/Gain' incorporates:
 * UnitDelay: '<S3>/UnitDelay'
 */
 localDW->UnitDelay_DSTATE[i] = 2.0 * rty_In2[i];
}
}

```

In the optimized code, the blocks in Regions 3, 2, and 1 execute in that order. With that execution order, the generated code does not contain the temporary variable `rtb_Sum` and the corresponding data copy.

### Eliminate Data Copies for Blocks That Perform Inplace Operations

The subsystem `InplaceScheduling` shows how the code generator reorders block operations to eliminate data copies for blocks that perform inplace operations. In the Configuration Parameters dialog box, set the **Optimize block order in the generated code** parameter to `Off` and build the model.

```

Starting build procedure for: rtwdemo_optimizeblockorder
Successful completion of build procedure for: rtwdemo_optimizeblockorder

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_optimizeblockorder	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
 Build duration: 0h 0m 20.173s

View the generated code without the optimization. Code for the `InplaceScheduling` subsystem:

```

/* Output and update for atomic system: '<Root>/InplaceScheduling' */
static void InplaceScheduling(void)
{
 real_T rtb_Max[6];
 real_T acc;
 int32_T idx1;

```

```

int32_T idx2;
int32_T k;
for (idx1 = 0; idx1 < 6; idx1++) {
 /* Sum: '<S1>/Sum2x3' incorporates:
 * Inport: '<Root>/In7'
 * UnitDelay: '<S1>/Unit Delay'
 */
 rtDWork.UnitDelay_DSTATE[idx1] += rtU.In7[idx1];

 /* MinMax: '<S1>/Max' */
 acc = rtDWork.UnitDelay_DSTATE[idx1];
 if (acc <= 2.0) {
 rtb_Max[idx1] = 2.0;
 } else {
 rtb_Max[idx1] = acc;
 }

 /* End of MinMax: '<S1>/Max' */
}

/* S-Function (sdsp2norm2): '<S1>/Normalization' incorporates:
 * Outport: '<Root>/Out7'
 */
idx1 = 0;
idx2 = 0;
acc = 0.0;
for (k = 0; k < 6; k++) {
 acc += rtb_Max[idx1] * rtb_Max[idx1];
 idx1++;
}

acc = 1.0 / (sqrt(acc) + 1.0E-10);
for (k = 0; k < 6; k++) {
 rtY.Out7[idx2] = rtb_Max[idx2] * acc;
 idx2++;

 /* Outport: '<Root>/Out6' incorporates:
 * Bias: '<S1>/Bias'
 * Inport: '<Root>/In8'
 * Outport: '<Root>/Out7'
 * Product: '<S1>/Product'
 */
 rtY.Out6[k] = (rtU.In8 + 1.0) * rtDWork.UnitDelay_DSTATE[k];

 /* Switch: '<S1>/Switch' incorporates:
 * Inport: '<Root>/In9'
 */
 if (rtU.In9[k] > 0.0) {
 /* Update for UnitDelay: '<S1>/Unit Delay' incorporates:
 * Sum: '<S1>/Sum2x3'
 */
 rtDWork.UnitDelay_DSTATE[k] = 0.0;
 } else {
 /* Update for UnitDelay: '<S1>/Unit Delay' incorporates:
 * Sum: '<S1>/Sum2x3'
 */
 rtDWork.UnitDelay_DSTATE[k] = rtb_Max[k];
 }
}

```

```

 /* End of Switch: '<S1>/Switch' */
}

/* End of S-Function (sdsp2norm2): '<S1>/Normalization' */
}

```

With the default execution order, the Max block executes before the Product block. To hold the Sum block output, the generated code contains two variables, UnitDelay\_DSTATE and rtb\_Max.

Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to **Improved Execution Speed** and build the model.

```

Starting build procedure for: rtwdemo_optimizeblockorder
Successful completion of build procedure for: rtwdemo_optimizeblockorder

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason

1 of 1 models built (0 models already up to date)  
 Build duration: 0h 0m 20.153s

View the generated code with the optimization.

```

/* Output and update for atomic system: '<Root>/InplaceScheduling' */
static void InplaceScheduling(void)
{
 real_T acc;
 int32_T idx1;
 int32_T idx2;
 int32_T k;
 for (idx1 = 0; idx1 < 6; idx1++) {
 /* Sum: '<S1>/Sum2x3' incorporates:
 * Inport: '<Root>/In7'
 * MinMax: '<S1>/Max'
 * UnitDelay: '<S1>/Unit Delay'
 */
 rtDWork.UnitDelay_DSTATE[idx1] += rtU.In7[idx1];

 /* Outport: '<Root>/Out6' incorporates:
 * Bias: '<S1>/Bias'
 * Inport: '<Root>/In8'
 * Product: '<S1>/Product'
 */
 rtY.Out6[idx1] = (rtU.In8 + 1.0) * rtDWork.UnitDelay_DSTATE[idx1];

 /* MinMax: '<S1>/Max' */
 acc = rtDWork.UnitDelay_DSTATE[idx1];
 if (acc <= 2.0) {
 rtDWork.UnitDelay_DSTATE[idx1] = 2.0;
 } else {
 rtDWork.UnitDelay_DSTATE[idx1] = acc;
 }
 }
}

```

```

 }

 /* End of MinMax: '<S1>/Max' */
}

/* S-Function (sdsp2norm2): '<S1>/Normalization' incorporates:
 * Output: '<Root>/Out7'
 */
idx1 = 0;
idx2 = 0;
acc = 0.0;
for (k = 0; k < 6; k++) {
 acc += rtDWork.UnitDelay_DSTATE[idx1] * rtDWork.UnitDelay_DSTATE[idx1];
 idx1++;
}

acc = 1.0 / (sqrt(acc) + 1.0E-10);
for (k = 0; k < 6; k++) {
 rtY.Out7[idx2] = rtDWork.UnitDelay_DSTATE[idx2] * acc;
 idx2++;
}

/* End of S-Function (sdsp2norm2): '<S1>/Normalization' */

/* Update for UnitDelay: '<S1>/Unit Delay' */
for (idx1 = 0; idx1 < 6; idx1++) {
 /* Switch: '<S1>/Switch' incorporates:
 * Inport: '<Root>/In9'
 * MinMax: '<S1>/Max'
 */
 if (rtU.In9[idx1] > 0.0) {
 rtDWork.UnitDelay_DSTATE[idx1] = 0.0;
 }

 /* End of Switch: '<S1>/Switch' */
}

/* End of Update for UnitDelay: '<S1>/Unit Delay' */
}

```

The optimized code does not contain the variable `rtb_Max` or the data copy. The generated code contains one variable, `UnitDelay_DSTATE`, for holding the Sum block output. The Product block reads from `UnitDelay_DSTATE` and the Max block reads from and writes to `UnitDelay_DSTATE`.

To implement buffer reuse, the code generator does not violate user-specified block priorities.

## Optimize SIMD Code by Performing Fused Multiply Add Operations

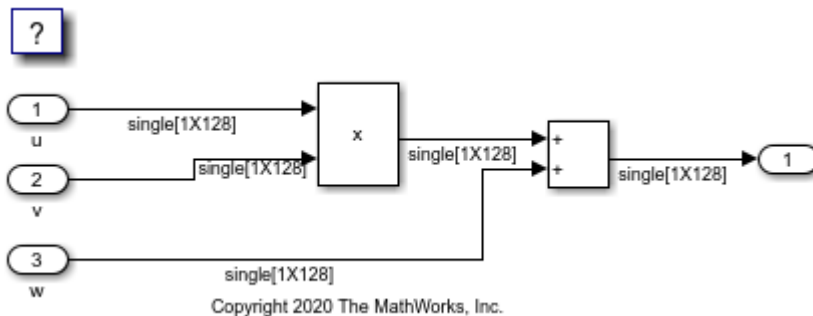

This example shows how to generate optimized single instruction, multiple data (SIMD) code that performs fused multiply-add operations. A fused multiply-add operation is performed in one step with a single rounding rather than performing a multiplication operation followed by an addition, with multiple roundings.

For processors that support fused multiply-add (FMA) instructions, when you set the **Leverage target hardware instruction set** to FMA, the code generator generates code with FMA intrinsics to perform fused multiply-add operations. Using this optimization improves the execution speed of the generated SIMD code. Because of the single rounding behavior of fused multiply-add operations, this optimization might introduce a mismatch between simulation and code generation results.

### Example Model

Open the example model `rtwdemo_simd_with_fma`. The model contains a multiplication operation followed by an addition.

```
model = 'rtwdemo_simd_with_fma';
open_system(model)
```

### Generate SIMD Code Without FMA Optimization

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

2. On the **Optimization** pane, set the **Leverage target hardware instruction set extensions** to SSE2. Alternatively, you can use the command-line API:

```
set_param(model, 'InstructionSetExtensions', 'SSE2');
```

3. Build the model.

```
slbuild(model);
```

```
Starting build procedure for: rtwdemo_simd_with_fma
Successful completion of build procedure for: rtwdemo_simd_with_fma
```

```
Build Summary
```

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_simd_with_fma	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 21.415s

4. Inspect the generated `rtwdemo_simd_with_fma_step` step function in the `rtwdemo_simd_with_fma.c`.

```
file = fullfile('rtwdemo_simd_with_fma_ert_rtw','rtwdemo_simd_with_fma.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function',1,1);
```

```
/* Model step function */
void rtwdemo_simd_with_fma_step(void)
{
 int32_T i;
 for (i = 0; i <= 124; i += 4) {
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/u'
 * Inport: '<Root>/v'
 * Inport: '<Root>/w'
 */
 _mm_storeu_ps(&rtwdemo_simd_with_fma_Y.Out1[i], _mm_add_ps(_mm_mul_ps
 (_mm_loadu_ps(&rtwdemo_simd_with_fma_U.single1X128[i]), _mm_loadu_ps
 (&rtwdemo_simd_with_fma_U.single1X128_f[i])), _mm_loadu_ps
 (&rtwdemo_simd_with_fma_U.single1X128_k[i])));
 }
}
```

The generated code contains a vectorized loop that performs the multiplication and addition operations sequentially, with two roundings.

### Generate SIMD Code with FMA Optimization

1. To enable FMA optimization, on the **Optimization** pane, set the **Leverage target hardware instruction set extensions** to FMA Alternatively, you can use the command-line API:

```
set_param(model, 'InstructionSetExtensions', 'FMA');
```

2. Build the model again.

```
[status, message, messageid] = rmdir('slprj', 's')
currentDir = pwd;
[~,cgDir] = rtwdemodir();
slbuild(model);
```

```
status =
 logical
 1
```

```

message =
 0x0 empty char array

messageid =
 0x0 empty char array

Starting build procedure for: rtwdemo_simd_with_fma
Successful completion of build procedure for: rtwdemo_simd_with_fma

Build Summary

Top model targets built:

Model Action Rebuild Reason
=====
rtwdemo_simd_with_fma Code generated and compiled Code generation information file does not ex

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 20.144s

```

3. Inspect the generated `rtwdemo_simd_with_fma_step` step function in the `rtwdemo_simd_with_fma.c`.

```

file = fullfile('rtwdemo_simd_with_fma_ert_rtw','rtwdemo_simd_with_fma.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function',1,1);

/* Model step function */
void rtwdemo_simd_with_fma_step(void)
{
 int32_T i;
 for (i = 0; i <= 120; i += 8) {
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/u'
 * Inport: '<Root>/v'
 * Inport: '<Root>/w'
 */
 _mm256_storeu_ps(&rtwdemo_simd_with_fma_Y.Out1[i], _mm256_fmadd_ps
 (_mm256_loadu_ps(&rtwdemo_simd_with_fma_U.single1X128[i]),
 _mm256_loadu_ps(&rtwdemo_simd_with_fma_U.single1X128_f[i]),
 _mm256_loadu_ps(&rtwdemo_simd_with_fma_U.single1X128_k[i])));
 }
}

```

The vectorized loop contains the intrinsic function `mm256_fmadd_ps` that performs multiplication-addition in one step, with a single rounding. This optimization improves the execution speed of the generated code. It is possible that the execution of the generated code does not produce the same result as the simulation.

The presence of FMA optimization is reported in the code generation report as follows.

**Code Information**

System Target File	ert.tlc
Hardware Device Type	Intel->x86-64 (Windows64)
Simulink Coder Version	9.6 (R2021b) 14-May-2021
Timestamp of Generated Source Code	Mon Jun 28 16:20:46 2021
Location of Generated Source Code	C:\Users\sferdous\Documents\Examples\ecoder-ex02442880\rtwdemo_simd_with_fma_ert_rtw
Type of Build	Model
Objectives Specified	Unspecified

**Additional Information**

Code Generation Advisor	Not run
FMA Instruction Set Extensions	FMA optimization is triggered

It is reported that the code generator used FMA instruction set extensions and the FMA optimization is triggered for the `rtwdemo_simd_with_fma` model code. If you are working with a model hierarchy and FMA optimization is triggered only for referenced models, the code generator does not report the presence of FMA optimization in the code generation report created for the top model.

**Clean Up Example Folders and Files**

Close the model and remove temporary folders and files.

```
bdclose(model);
cd(currentDir);
rtwdemoclean;
```

## Speed Up for-Loop Implementation in Code Generated by Using parfor

When you generate C/C++ code for a model by using a MATLAB Function, a MATLAB System, and For Each subsystem block, by default, the code generator produces code that implements for-loops in a single thread. This for-loop can be optimized for MATLAB Function and MATLAB System blocks. The iterations of the parfor-loop can run in parallel on multiple cores on the target hardware.

Running the iterations in parallel might significantly improve execution speed of generated code. For more information, see “How parfor-Loops Improve Execution Speed” on page 74-65.

The code generator implements the for-loops in parallel by using OpenMP.

Embedded Coder software uses the Open Multiprocessing (OpenMP) application interface to support shared-memory, multicore code generation. By default, Embedded Coder uses as many threads as it finds available. If you specify the number of threads to use, Embedded Coder uses at most that number of threads, even if additional threads are available. For more information, see parfor.

### How parfor-Loops Improve Execution Speed

A parfor-loop might provide better execution speed than its analogous for-loop because several threads can compute concurrently on the same loop.

Each execution of the body of a parfor-loop is called an iteration. The threads evaluate iterations in an arbitrary order and independently of each other. Because each iteration is independent, the threads do not have to be synchronized. If the number of threads is equal to the number of loop iterations, each thread performs one iteration of the loop. If the number of iterations is greater than the number of threads, some threads perform more than one loop iteration.

For example, when a loop of 100 iterations runs on 20 threads, each thread simultaneously executes five iterations of the loop. If your loop takes a long time to run because of the large number of iterations or lengthy individual iterations, you can reduce the run time significantly by using multiple threads. In this example, you might not get 20 times improvement in speed because of parallelization overheads, such as thread creation and deletion.

### When to Use parfor-Loops

Use parfor when you have:

- Many iterations of a simple calculation. parfor divides the loop iterations into groups so that each thread executes one group of iterations.
- A loop iteration that takes a long time to execute. parfor executes the iterations simultaneously on different threads. Although this simultaneous execution does not reduce the time spent on an individual iteration, it might significantly reduce overall time spent on the loop.

### When Not to Use parfor-Loops

Do not use parfor when:

- An iteration of your loop depends on other iterations. Running the iterations in parallel can lead to erroneous results.

To help you avoid using `parfor` when an iteration of your loop depends on other iterations, Embedded Coder specifies a rigid classification of variables. For more information, see “Classification of Variables in `parfor`-Loops”. If Embedded Coder detects loops that do not conform to the `parfor` specifications, it does not generate code and produces an error.

Reductions are an exception to the rule that loop iterations must be independent. A reduction variable accumulates a value that depends on all the iterations together, but is independent of the iteration order. For more information, see “Reduction Variables” (Parallel Computing Toolbox).

- There are only a few iterations that perform some simple calculations.

---

**Note** For small number of loop iterations, you might not accelerate execution due to parallelization overheads. Such overheads include time taken for thread creation, data synchronization between threads, and thread deletion.

---

- For Each Subsystem contains an S-Function block. The generated code will not contain `parfor`.

## Write Code by Using `parfor`-Loops

To run for-loops in parallel in the generated code, write the code within a MATLAB Function, or a MATLAB System, block using `parfor`.

- 1 Create a Simulink model.
- 2 Add the MATLAB Function or the MATLAB System block to the model.
- 3 Add the code to the MATLAB Function or the MATLAB System block.

```
function y = access3a(u) %#codegen
% Copyright 2010 The MathWorks, Inc.

persistent pA;
if isempty(pA)
 pA = 0;
end
A = ones(20,50);
t = 0;

parfor (i = 1:10,4)
 A(i,1) = A(i,1) + 1;
end
```

```
y = A(1,4) + u + t + pA;
```

- 4 In the **Optimization** pane select the Maximize execution speed option from the “Priority” drop-down list. The parameter “Generate parallel for-loops” is automatically selected. The parameter enables the compiler to compute loops in parallel.
- 5 Connect the blocks.

- 6 Build the model and generate code.

In the generated code, the pragma instructs the compiler to execute the looping in OpenMP parallel for-loops through multithreading :

```
#pragma omp parallel for num_threads(4 >
 omp_get_max_threads() ? omp_get_max_threads() : 4)
```

The number 4 indicates the number of processing threads.

Because the loop body can execute in parallel on multiple threads, it must conform to certain restrictions. If the Embedded Coder software detects loops that do not conform to `parfor` specifications, it produces an error. For more information, see “`parfor` Restrictions”.

## Optimize Generated Code Using Minimum and Maximum Values

To optimize the generated code for your model, you can choose an option to use input range information, also known as design minimum and maximum, that you specify on signals and parameters. These minimum and maximum values usually represent environmental limits, such as temperature, or mechanical and electrical limits, such as output ranges of sensors.

In the Configuration Parameters dialog box, on the **Optimization** pane, when you select the **Optimize using specified minimum and maximum values** check box, the software uses the minimum and maximum values to derive range information for downstream signals in the model. It then uses this derived range information to determine if it is possible to streamline the generated code by:

- Reducing expressions to constants
- Removing dead branches of conditional statements
- Eliminating unnecessary mathematical operations

This optimization results in:

- Reduced ROM and RAM consumption
- Improved execution speed

### Configure Your Model

To make optimization more likely:

- Provide as much design minimum and maximum information as possible. Specify minimum and maximum values for signals and parameters in the model for:
  - Inport and Outport blocks
  - Block outputs
  - Block inputs, for example, for the MATLAB Function and Stateflow Chart blocks
  - `Simulink.Signal` objects
- Before generating code, test the minimum and maximum values for signals and parameters. Otherwise, optimization might result in numerical mismatch with simulation. You can simulate your model with simulation range checking enabled. If errors or warnings occur, fix these issues before generating code.

#### Enable Simulation Range Checking

- 1 In the Configuration Parameters dialog box, select **Diagnostics > Data Validity**.
  - 2 On the **Data Validity** pane, under **Signals**, set **Simulation range checking** to warning or error.
- Provide design minimum and maximum information upstream of blocks as close to the inputs of the blocks as possible. If you specify minimum and maximum values for a block output, these values are most likely to affect the outputs of the blocks immediately downstream.

## Optimize Generated Code Using Specified Minimum and Maximum Values

This example shows how the minimum and maximum values specified on signals and parameters in a model are used to optimize the generated code.

### Overview

The specified minimum and maximum values usually represent environmental limits, such as temperature, or mechanical and electrical limits, such as output ranges of sensors.

This optimization uses these values to streamline the generated code. For example, it reduces expressions to constants or removes dead branches of conditional statements.

**NOTE:** Make sure the minimum and maximum values that you specify are valid limits. Otherwise, this optimization might result in numerical mismatch with simulation.

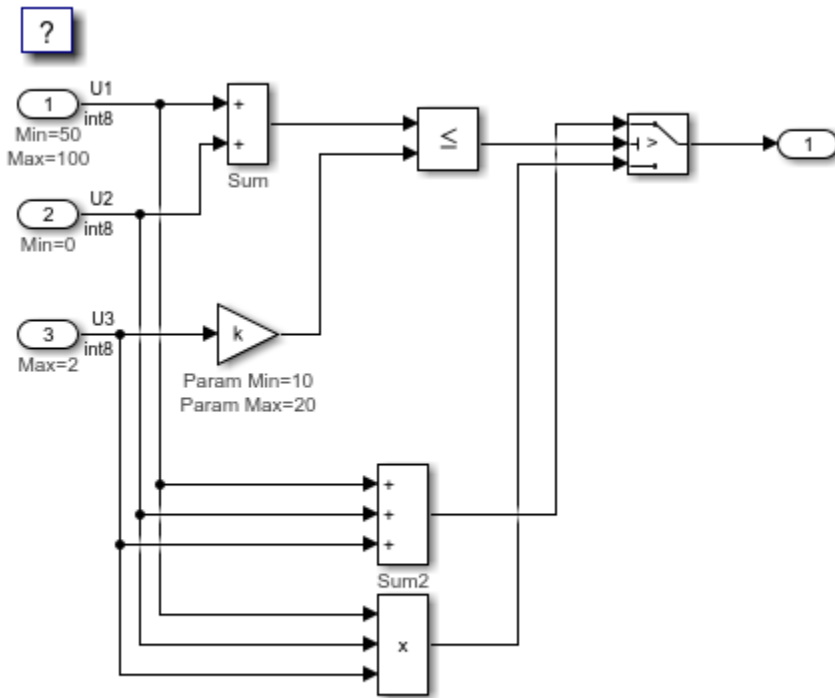

The benefits of optimizing the generated code are:

- Reducing the ROM and RAM consumption.
- Improving the execution speed.

### Review Minimum and Maximum Information

Consider the model `rtwdemo_minmax`. In this model, there are minimum and maximum values specified on Inports and on the gain parameter of the Gain block.

```
model = 'rtwdemo_minmax';
open_system(model);
```

Copyright 2010-2020 The MathWorks, Inc.

### Generate Code Without This Optimization

First, generate code for this model without considering the min and max values.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
rtwconfiguredemo(model, 'ERT')
slbuild(model)
```

```
Starting build procedure for: rtwdemo_minmax
Successful completion of build procedure for: rtwdemo_minmax
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_minmax	Code generated and compiled	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 24.22s

A portion of `rtwdemo_minmax.c` is listed below.

```
cfile = fullfile(cgDir, 'rtwdemo_minmax_ert_rtw', 'rtwdemo_minmax.c');
rtwdemodbtype(cfile, /* Model step', /* Model initialize', 1, 0);
```

```
/* Model step function */
```

```

void rtwdemo_minmax_step(void)
{
 int32_T tmp;

 /* Sum: '<Root>/Sum' incorporates:
 * Inport: '<Root>/U1'
 * Inport: '<Root>/U2'
 * Sum: '<Root>/Sum2'
 * Switch: '<Root>/Switch'
 */
 tmp = U1 + U2;

 /* Switch: '<Root>/Switch' incorporates:
 * Gain: '<Root>/Gain'
 * Inport: '<Root>/U3'
 * RelationalOperator: '<Root>/Relational Operator'
 * Sum: '<Root>/Sum'
 */
 if (tmp <= k * U3) {
 /* Outport: '<Root>/Out1' incorporates:
 * Sum: '<Root>/Sum2'
 */
 rtY.Out1 = tmp + U3;
 } else {
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/U1'
 * Inport: '<Root>/U2'
 * Product: '<Root>/Product'
 */
 rtY.Out1 = U1 * U2 * U3;
 }
}

```

### Enable This Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, select **Optimize using the specified minimum and maximum values**.

Alternatively, you can enable this optimization by setting the command-line parameter.

```
set_param(model, 'UseSpecifiedMinMax', 'on');
```

### Generate Code with This Optimization

In the model, with the specified minimum and maximum values for U1 and U2, the sum of U1 and U2 has a minimum value of 50. Considering the range of U3 and the specified minimum and maximum values for the Gain block parameter, the maximum value of the Gain block's output is 40.

The output of the Relational Operator block remains false, and the output of the Switch block remains the product of the three inputs.

Configure and build the model using Embedded Coder®.

```

rtwconfiguredemo(model, 'ERT')
slbuild(model)

Starting build procedure for: rtwdemo_minmax
Successful completion of build procedure for: rtwdemo_minmax

```

### Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_minmax	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 18.935s

View the optimized code from `rtwdemo_minmax.c`.

```
cfile = fullfile(cgDir, 'rtwdemo_minmax_ert_rtw', 'rtwdemo_minmax.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_minmax_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/U1'
 * Inport: '<Root>/U2'
 * Inport: '<Root>/U3'
 * Product: '<Root>/Product'
 * Switch: '<Root>/Switch'
 */
 rtY.Out1 = U1 * U2 * U3;
}
```

Close the model and cleanup.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Limitations

- This optimization does not take into account minimum and maximum values for:
  - Merge block inputs. To work around this issue, use a `Simulink.Signal` object on the Merge block output and specify the range on this object.
  - Bus elements.
  - Conditionally-executed subsystem (such as a triggered subsystem) block outputs that are directly connected to an Output block.

Output blocks in conditionally-executed subsystems can have an initial value specified for use only when the system is not triggered. In this case, the optimization cannot use the range of the block output because the range might not cover the initial value of the block.

- If you use Polyspace software to verify code generated using this optimization, it might mark code that was previously green as orange. For example, if your model contains a division where the range of the denominator does not include zero, the generated code does not include protection against division by zero. Polyspace might mark this code orange because it does not have information about the minimum and maximum values for the inputs to the division.

Polyspace Code Prover automatically captures some minimum and maximum values specified in the MATLAB workspace, for example, for `Simulink.Signal` and `Simulink.Parameter` objects. In this example, to provide range information to the Polyspace software, use a `Simulink.Signal` object on the input of the division and specify a range that does not include zero.

Polyspace Code Prover stores these values in a Data Range Specification (DRS) file. However, they do not capture all minimum and maximum values in your Simulink model. To provide additional minimum and maximum information to Polyspace, you can manually define a DRS file.

- If you are using double-precision data types and the **non-finite numbers** configuration parameter is selected, this optimization does not occur.
- If your model contains multiple instances of a reusable subsystem and each instance uses input signals with different minimum and maximum values, this optimization might result in different generated code for each subsystem so code reuse does not occur. Without this optimization, code is generated once for the subsystem and shares this code among the multiple instances of the subsystem.
- The Model Advisor check Check safety-related optimization settings generates a warning if this option is selected. For many safety-critical applications, removing dead code automatically is unacceptable because doing so might make code untraceable.

- “Specify Signal Ranges”

## Reduce Global Variables in Nonreusable Subsystem Functions

Global variables can increase memory requirements and reduce execution speed. To reduce global RAM for a nonreusable subsystem, you can generate a function interface that passes data through arguments instead of global variables. The Subsystem block parameter **Function interface** provides this option. To compare the outputs for the **Function interface** options, first generate a function for a subsystem with a `void-void` interface, and then generate a function with arguments.

### Generate void-void Function

By default, when you configure a Subsystem block as a nonreusable function, it generates a `void-void` interface.

- 1 Open the example model `rtwdemo_roll`.
- 2 Right-click the subsystem `RollAngleReference`. From the list select `Block Parameter (Subsystem)`.
- 3 In the `Block Parameters` dialog box, confirm that the **Treat as atomic unit** check box is selected.
- 4 Click the **Code Generation** tab and set the **Code interface packaging** parameter to `Nonreusable function`.
- 5 The **Function interface** parameter is already set to `void_void`.
- 6 Click **Apply** and **OK**.
- 7 Repeat steps 2-6, for the other subsystems `HeadingMode` and `BasicRollMode`.
- 8 Generate code and the static code metrics report for `rtwdemo_roll`. This model is configured to generate a code generation report and to open the report automatically. For more information, see “Generate Static Code Metrics Report for Simulink Model” on page 51-26.

In the code generation report, in `rtwdemo_roll.c`, the generated code for subsystem `RollAngleReference` contains a `void-void` function definition:

```
static void RollAngleReference(void)
{
 ...
}
```

In the static code metrics report, navigate to **Global Variables**. With the `void_void` option, the number of bytes for global variables is 47.

## 2. Global Variables [\[hide\]](#)

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[+] <a href="#">rtU</a>	26	14	6
[+] <a href="#">rtDW</a>	17	34	24
[+] <a href="#">rtY</a>	4	1	1
<b>Total</b>	<b>47</b>	<b>49</b>	

Next, generate the same function with the `Allow arguments (Optimized)` option to compare the results.

## Generate Function with Arguments

To reduce global RAM, improve ROM usage and execution speed, generate a function that allows arguments:

- 1 Open the Subsystem Block Parameter dialog box for RollAngleReference.
- 2 Click the **Code Generation** tab. Set the **Function interface** parameter to `Allow arguments (Optimized)`.
- 3 Click **Apply** and **OK**.
- 4 Repeat steps 2 and 3, for the other subsystems HeadingMode and BasicRollMode.
- 5 Generate code and the static code metrics report for `rtwdemo_roll`.

In the code generation report, in `rtwdemo_roll.c`, the generated code for subsystem RollAngleReference now has arguments:

```
static real32_T RollAngleReference(real32_T rtu_Phi,...
 boolean_T rtu_AP_Eng,...
 real32_T rtu_Turn_Knob)
{
 ...
}
```

In the static code metrics report, navigate to **Global Variables**. With the `Allow arguments` option set, the total number of bytes for global variables is now 39 bytes.

## 2. Global Variables [\[hide\]](#)

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[+] <a href="#">rtU</a>	26	11	11
[+] <a href="#">rtDW</a>	9	17	14
[+] <a href="#">rtY</a>	4	2	2
<b>Total</b>	<b>39</b>	<b>30</b>	

In some cases, when generating optimized code, the code generator might not generate a function that has arguments. To generate a predictable function interface that has arguments, set **Function interface** to `Allow arguments (Match graphical interface)`.

## See Also

“Function interface”

## Optimize Generated Code by Packing Boolean Data into Bitfields

This example shows how to optimize the generated code by packing Boolean data into bitfields. When you select the model configuration parameter **Pack Boolean data into bitfields**, Embedded Coder® packs the Boolean signals into 1-bit bitfields, reducing RAM consumption. By default, the optimization is enabled. This optimization reduces the RAM consumption. Be aware that this optimization can potentially increase code size and execution speed.

### Example Model

Consider the model `rtwdemo_pack_boolean`.

```
model = 'rtwdemo_pack_boolean';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

### Disable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, clear **Pack Boolean data into bitfields**.

Alternatively, you can use the command-line API to disable the optimization:

```
set_param(model, 'BooleansAsBitfields', 'off');
```

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

### Generate Code Without Optimization

Build the model using Embedded Coder.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_pack_boolean
Successful completion of build procedure for: rtwdemo_pack_boolean
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_pack_boolean	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 18.058s

View the generated code without the optimization. These lines of code are in `rtwdemo_pack_boolean.h`.

```
hfile = fullfile(cgDir,'rtwdemo_pack_boolean_ert_rtw','rtwdemo_pack_boolean.h');
rtwdemodbtype(hfile,'/* Block signals and states','/* External inputs',1,0);
```

```
/* Block signals and states (default storage) for system '<Root>' */
typedef struct {
 boolean_T LogicalOp1; /* '<Root>/Logical Op1' */
 boolean_T LogicalOp2; /* '<Root>/Logical Op2' */
 boolean_T LogicalOp5; /* '<Root>/Logical Op5' */
 boolean_T LogicalOp3; /* '<Root>/Logical Op3' */
 boolean_T LogicalOp4; /* '<Root>/Logical Op4' */
 boolean_T RelationalOperator; /* '<Root>/Relational Operator' */
 boolean_T UnitDelay_DSTATE; /* '<Root>/Unit Delay' */
} DW;
```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, select **Pack Boolean data into bitfields**.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model,'BooleansAsBitfields','on');
```

### Generate Code with Optimization

Build the model using Embedded Coder:

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_pack_boolean
Successful completion of build procedure for: rtwdemo_pack_boolean
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_pack_boolean	Code generated and compiled	Generated code was out of date.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 17.308s
```

View the generated code with the optimization. These lines of code are in `rtwdemo_pack_boolean.h`.

```
hfile = fullfile(cgDir,'rtwdemo_pack_boolean_ert_rtw','rtwdemo_pack_boolean.h');
rtwdemodbtype(hfile,'/* Block signals and states', '/* External inputs',1,0);
```

```
/* Block signals and states (default storage) for system '<Root>' */
typedef struct {
 struct {
 uint_T LogicalOp1:1; /* '<Root>/Logical Op1' */
 uint_T LogicalOp2:1; /* '<Root>/Logical Op2' */
 uint_T LogicalOp5:1; /* '<Root>/Logical Op5' */
 uint_T LogicalOp3:1; /* '<Root>/Logical Op3' */
 uint_T LogicalOp4:1; /* '<Root>/Logical Op4' */
 uint_T RelationalOperator:1; /* '<Root>/Relational Operator' */
 uint_T UnitDelay_DSTATE:1; /* '<Root>/Unit Delay' */
 } bitsForTID0;
} DW;
```

Selecting **Pack Boolean data into bitfields** enables model configuration parameter **Bitfield declarator type specifier**. To optimize your code further, select `uchar_t`. However, the optimization benefit of the **Bitfield declarator type specifier** setting depends on your choice of target.

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Optimize Generated Code by Passing Reusable Subsystem Outputs as Individual Arguments

This example shows how passing reusable subsystem outputs as individual arguments instead of as a pointer to a structure stored in global memory optimizes the generated code. This optimization conserves RAM consumption and increases code execution speed by reducing global memory usage and eliminating data copies from local variables back to global block I/O structures.

### Example Model

Consider the model `rtwdemo_reusable_sys_outputs`. In this model, the reusable subsystem outputs feed the root outputs of the model.

```
model = 'rtwdemo_reusable_sys_outputs';
open_system(model);
```

Copyright 2014-2020 The MathWorks, Inc.

### Generate Code Without This Optimization

Generate code for this model while passing subsystem outputs as a structure reference. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_reusable_sys_outputs
Successful completion of build procedure for: rtwdemo_reusable_sys_outputs
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
-------	--------	----------------

```

=====
rtwdemo_reusable_sys_outputs Code generated and compiled Code generation information file does
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 19.156s

```

The code snippet shows portions of `rtwdemo_reusable_sys_outputs.c`. Notice the global block I/O structure and in the model step function a data copy from this structure.

```

cfile = fullfile(cgDir,'rtwdemo_reusable_sys_outputs_ert_rtw',...
'rtwdemo_reusable_sys_outputs.c');
rtwdemodbtype(cfile,'/* Output and update for atomic system',...
'/* Model initialize', 1, 0);

/* Output and update for atomic system: '<Root>/ReusableSubsystem' */
static void ReusableSubsystem(real_T rtu_In1, real_T rtu_In2, real_T rtu_In3,
 DW_ReusableSubsystem *localDW)
{
 /* Gain: '<S1>/Gain' */
 localDW->Gain = 5.0 * rtu_In1;

 /* Gain: '<S1>/Gain1' */
 localDW->Gain1 = 6.0 * rtu_In2;

 /* Gain: '<S1>/Gain2' */
 localDW->Gain2 = 7.0 * rtu_In3;
}

/* Model step function */
void rtwdemo_reusable_sys_outputs_step(void)
{
 /* Outputs for Atomic SubSystem: '<Root>/ReusableSubsystem' */

 /* Inport: '<Root>/In1' incorporates:
 * Inport: '<Root>/In2'
 * Inport: '<Root>/In3'
 */
 ReusableSubsystem(rtU.In1, rtU.In2, rtU.In3, &rtDW.ReusableSubsystem_d);

 /* End of Outputs for SubSystem: '<Root>/ReusableSubsystem' */

 /* Output: '<Root>/Out1' */
 rtY.Out1 = rtDW.ReusableSubsystem_d.Gain;

 /* Output: '<Root>/Out2' */
 rtY.Out2 = rtDW.ReusableSubsystem_d.Gain1;

 /* Output: '<Root>/Out3' */
 rtY.Out3 = rtDW.ReusableSubsystem_d.Gain2;
}

```

### Enable This Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, set **Pass reusable subsystem outputs as** to Individual arguments.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model, 'PassReuseOutputArgsAs', 'Individual arguments');
```

### Generate Code with This Optimization

With this optimization, the ReusableSubsystem function has three output arguments, which are direct references to the external outputs. The `rtDW` global structure no longer exists, and the data copies from this structure to the `rtY` (external outputs) structure are not in the generated code.

Build the model.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_reusable_sys_outputs
Successful completion of build procedure for: rtwdemo_reusable_sys_outputs
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_reusable_sys_outputs	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 18.349s

The code snippet below is a portion of `rtwdemo_reusable_sys_outputs.c`. Observe the optimized code.

```
rtwdemodbtype(cfile, /* Output and update for atomic system',...
/* Model initialize', 1, 0);

/* Output and update for atomic system: '<Root>/ReusableSubsystem' */
static void ReusableSubsystem(real_T rtu_In1, real_T rtu_In2, real_T rtu_In3,
 real_T *rty_Out1, real_T *rty_Out2, real_T *rty_Out3)
{
 /* Gain: '<S1>/Gain' */
 *rty_Out1 = 5.0 * rtu_In1;

 /* Gain: '<S1>/Gain1' */
 *rty_Out2 = 6.0 * rtu_In2;

 /* Gain: '<S1>/Gain2' */
 *rty_Out3 = 7.0 * rtu_In3;
}

/* Model step function */
void rtwdemo_reusable_sys_outputs_step(void)
{
 /* Outputs for Atomic SubSystem: '<Root>/ReusableSubsystem' */

 /* Inport: '<Root>/In1' incorporates:
 * Inport: '<Root>/In2'
 * Inport: '<Root>/In3'
 * Outport: '<Root>/Out1'
```

```
* Output: '<Root>/Out2'
* Output: '<Root>/Out3'
*/
ReusableSubsystem(rtU.In1, rtU.In2, rtU.In3, &rtY.Out1, &rtY.Out2, &rtY.Out3);

/* End of Outputs for SubSystem: '<Root>/ReusableSubsystem' */
}
```

Close the model and cleanup.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Convert Data Copies to Pointer Assignments

The code generator optimizes generated code for vector signal assignments by trying to replace for loop controlled element assignments and memcpy function calls with pointer assignments. Pointer assignments avoid expensive data copies. Therefore, they use less stack space and offer faster execution speed than for loop controlled element assignments and memcpy function calls. If you assign large data sets to vector signals, this optimization can result in significant improvements to code efficiency.

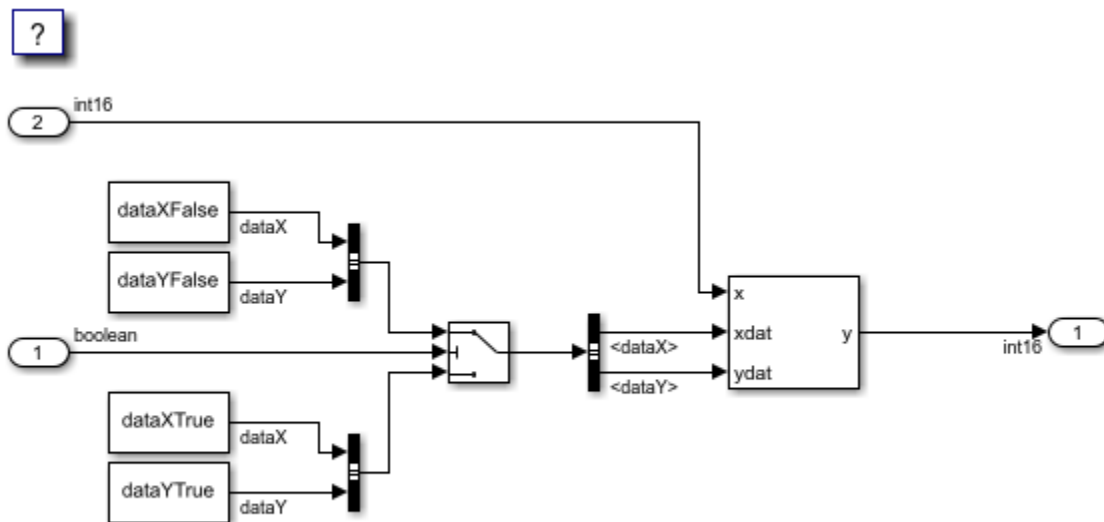

### Configure Model to Optimize Generated Code for Vector Signal Assignments

To apply this optimization:

- 1 Verify that your target supports the memcpy function.
- 2 Determine whether your model uses vector signal assignments (such as `Y=expression`) to move large amounts of data. For example, your model could use a Selector block to select input elements from a vector, matrix, or multidimension signal.
- 3 On the **Optimization** pane, the **Use memcpy for vector assignment parameter**, which is on by default, enables the associated **Memcpy threshold (bytes)** parameter.
- 4 Examine the setting of **Memcpy threshold (bytes)**. By default, it specifies 64 bytes as the minimum array size for which memcpy function calls or pointer assignments can replace for loops in the generated code. Based on the array sizes in your application's vector signal assignments, and target environment considerations on the threshold selection, accept the default value or specify another array size.

### Example Model

Consider the following model named `rtwdemo_pointer_conversion`. This model uses a Switch block to assign data to a vector signal. This signal then feeds into a Bus Selector block.

Copyright 2016-2020, The MathWorks, Inc.

## Generate Code Without Optimization

- 1 In the Configuration Parameters dialog box, clear the **Use memcopy for vector assignment** parameter.
- 2 Create a temporary folder for the build and inspection process.
- 3 Press **Ctrl+B** to generate code.

```
Starting build procedure for: rtwdemo_pointer_conversion
Successful completion of build procedure for: rtwdemo_pointer_conversion
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_pointer_conversion	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 1m 20.108s

View the generated code without the optimization. Here is a portion of `rtwdemo_pointer_conversion.c`.

```
/* Model step function */
void rtwdemo_pointer_conversion_step(void)
{
 int32_T i;
 int16_T rtb_dataX[100];
 int16_T rtb_dataY[100];

 /* Switch generated from: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant'
 * Constant: '<Root>/Constant1'
 * Constant: '<Root>/Constant2'
 * Constant: '<Root>/Constant3'
 * Inport: '<Root>/In1'
 */
 for (i = 0; i < 100; i++) {
 if (rtU.In1) {
 rtb_dataX[i] = rtCP_Constant_Value[i];
 rtb_dataY[i] = rtCP_Constant1_Value[i];
 } else {
 rtb_dataX[i] = rtCP_Constant2_Value[i];
 rtb_dataY[i] = rtCP_Constant3_Value[i];
 }
 }
}

/* End of Switch generated from: '<Root>/Switch' */

/* S-Function (sfix_look1_dyn): '<Root>/Lookup Table Dynamic' incorporates:
 * Inport: '<Root>/In2'
 * Output: '<Root>/Out1'
 */
/* Dynamic Look-Up Table Block: '<Root>/Lookup Table Dynamic'
 * Input0 Data Type: Integer S16
```

```

* Input1 Data Type: Integer S16
* Input2 Data Type: Integer S16
* Output0 Data Type: Integer S16
* Lookup Method: Linear_Endpoint
*
*/
Lookup_S16_S16(&(rtY.Out1), &rtb_dataY[0], rtU.In2, &rtb_dataX[0], 99U);
}

```

Without the optimization, the generated code contains for loop controlled element assignments.

### Enable Optimization and Generate Code

- 1 In the Configuration Parameter dialog box, select the **Use memcopy for vector assignment** parameter.
- 2 Generate code.

```

Starting build procedure for: rtwdemo_pointer_conversion
Successful completion of build procedure for: rtwdemo_pointer_conversion

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_pointer_conversion	Code generated and compiled	Generated code was out of date.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 51.178s

View the generated code without the optimization. Here is a portion of `rtwdemo_pointer_conversion.c`.

```

/* Model step function */
void rtwdemo_pointer_conversion_step(void)
{
 const int16_T *rtb_dataX_0;
 const int16_T *rtb_dataY_0;

 /* Inport: '<Root>/In1' */
 if (rtU.In1) {
 /* Switch generated from: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant'
 */
 rtb_dataX_0 = &rtCP_Constant_Value[0];

 /* Switch generated from: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant1'
 */
 rtb_dataY_0 = &rtCP_Constant1_Value[0];
 } else {
 /* Switch generated from: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant2'
 */
 rtb_dataX_0 = &rtCP_Constant2_Value[0];
 }
}

```

```

/* Switch generated from: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant3'
 */
rtb_dataY_0 = &rtCP_Constant3_Value[0];
}

/* End of Inport: '<Root>/In1' */

/* S-Function (sfix_look1_dyn): '<Root>/Lookup Table Dynamic' incorporates:
 * Inport: '<Root>/In2'
 * Output: '<Root>/Out1'
 */
/* Dynamic Look-Up Table Block: '<Root>/Lookup Table Dynamic'
 * Input0 Data Type: Integer S16
 * Input1 Data Type: Integer S16
 * Input2 Data Type: Integer S16
 * Output0 Data Type: Integer S16
 * Lookup Method: Linear_Endpoint
 *
 */
Lookup_S16_S16(&(rtY.Out1), &rtb_dataY_0[0], rtU.In2, &rtb_dataX_0[0], 99U);
}

```

Because the setting of the **Memcpy threshold (bytes)** parameter is below the array sizes in the generated code, the optimized code contains pointer assignments for the vector signal assignments.

## Reuse Buffers of Different Sizes and Dimensions

You can reuse buffers for matrices that have different sizes and shapes. In the Configuration Parameters dialog box, you enable this optimization by selecting **Reuse buffers of different sizes and dimensions**. This optimization conserves RAM and ROM usage and improves code execution speed.

### Example Model

The model `rtwdemo_differentsizereuse` contains signals of different sizes and dimensions.

```
model='rtwdemo_differentsizereuse';
open_system(model);
```

Copyright 2017-2020 The MathWorks, Inc.

### Generate Code Without Optimization

In the Configuration Parameters dialog box, set **Reuse buffers of different sizes and dimension** parameter to `off` or in the MATLAB® Command Window, enter:

```
set_param('rtwdemo_differentsizereuse','DifferentSizesBufferReuse','off');
```

Create a folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwmoddir();
```

Turn off comments and build the model.

```
set_param('rtwdemo_differentsizereuse','GenerateComments','off');
slbuild('rtwdemo_differentsizereuse');
```

```
Starting build procedure for: rtwdemo_differentsizereuse
Successful completion of build procedure for: rtwdemo_differentsizereuse
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_differentsizereuse	Code generated and compiled	Code generation information file does not exist

```

 }
 }
}

static void NoninplaceableSS2(void)
{
 DeltaX(rtDWork.z, &rtDWork.z_o[0]);
 DeltaX(&rtDWork.z_h[0], &rtDWork.z[0]);
}

static void DeltaY(const real_T rtu_u[4032], real_T rty_z[3969])
{
 int32_T tmp;
 int32_T x;

```

```

int32_T y;
for (x = 0; x < 63; x++) {
 for (y = 0; y < 63; y++) {
 tmp = 63 * y + x;
 rty_z[tmp] = fabs(rtu_u[tmp] - rtu_u[(y + 1) * 63 + x]);
 }
}

static void NoninplaceableSS3(void)
{
 DeltaY(&rtDWork.z_o[0], &rtDWork.z_h[0]);
 DeltaY(&rtDWork.z[0], &rtDWork.z_o[0]);
}

void rtwdemo_differentsizereuse_step(void)
{
 int32_T i;
 for (i = 0; i < 16384; i++) {
 rtDWork.z_h[i] = rtU.ComplexData[i].re;
 rtDWork.z_o[i] = rtU.ComplexData[i].im;
 }

 NoninplaceableSS1();
 NoninplaceableSS2();
 NoninplaceableSS3();
 for (i = 0; i < 3969; i++) {
 rtY.Outl[i].re = rtDWork.z_h[i];
 rtY.Outl[i].im = rtDWork.z_o[i];
 }
}

```

The `D_work` structure now contains three global variables instead of eight global variables for holding the inputs and outputs of `Downsample`, `DeltaX`, and `DeltaY`. The generated code uses these variables to hold the differently-sized inputs and outputs.

Close the model and code generation report.

```

bdclose(model)
rtwdemoclean;
cd(currentDir)

```

### Limitations

- If you use a `Reusable` custom storage class to specify reuse on signals that have different sizes and shapes, you must select the **Reuse buffers of different sizes and dimensions** parameter. Otherwise, the model does not build.
- The code generator does not replace a buffer with a lower priority buffer that has a smaller size.
- The code generator does not reuse buffers that have different sizes and symbolic dimensions.

## Remove Reset and Disable Functions from the Generated Code

### In this section...

“Example Model” on page 75-29

“Generate Code” on page 75-30

“Enable Optimization” on page 75-30

This example shows how the code generator removes unreachable (dead code) instances of the reset and disable functions from the generated code for ERT-based systems that include model referencing hierarchies. Optimizing the generated code to remove unreachable code is a requirement for safety-critical systems. This optimization also improves execution speed and reduces ROM consumption.

If a model contains blocks with states, the generated code contains reset and disable functions. If the model is not part of a conditionally executed system, such as an enabled subsystem, the code generator can remove the disable function because the generated code does not call it. If the model is not part of a conditionally executed system that can reset states when a control input enables it, the code generator can remove the reset function because the generated code does not call it.

### Example Model

A referenced model, `rtwdemo_optionalDisableResetFunc_bot`, is in `rtwdemo_optionalDisableResetFunc_top`. The referenced model contains two blocks with states, a Delay block and a Discrete-Time Integrator block.

Copyright 2016 The MathWorks, Inc

Copyright 2016 The MathWorks, Inc

## Generate Code

- 1 Open the models. In the Command Window, type `rtwdemo_optionalDisableResetFunc_bot` and `rtwdemo_optionalDisableResetFunc_top`.
- 2 In your system temporary folder, create a temporary folder for the build and inspection process.
- 3 Build the model.
- 4 Open the `rtwdemo_optionalDisableResetFunc_top.c` and `rtwdemo_optionalDisableResetFunc_bot.c` files.

The `rtwdemo_optionalDisableResetFunc_bot.c` file contains these reset and disable functions.

```

/* System reset for referenced model: 'rtwdemo_optionalDisableResetFunc_bot' */
void rtwdemo_optionalDisableResetFunc_bot_Reset
(DW_rtwdemo_optionalDisableResetFunc_bot_f_T *localDW)
{
 /* InitializeConditions for Delay: '<Root>/Delay' */
 localDW->Delay_DSTATE = 0.0;

 /* InitializeConditions for DiscreteIntegrator: '<Root>/Discrete-Time Integrator' */
 localDW->DiscreteTimeIntegrator_DSTATE = 3.0;
}

/* Disable for referenced model: 'rtwdemo_optionalDisableResetFunc_bot' */
void rtwdemo_optionalDisableResetFunc_bot_Disable(real_T *rty_Out1,
DW_rtwdemo_optionalDisableResetFunc_bot_f_T *localDW)
{
 /* Disable for DiscreteIntegrator: '<Root>/Discrete-Time Integrator' */
 localDW->DiscreteTimeIntegrator_DSTATE = *rty_Out1;
}

```

The `rtwdemo_optionalDisableResetFunc_top_step` function does not call the `rtwdemo_optionalDisableResetFunc_bot_Disable` function because the model is not part of a conditionally executed system. The `rtwdemo_optionalDisableResetFunc_top_step` function does not call the `rtwdemo_optionalDisableResetFunc_bot_Reset` function because the model is not part of a conditionally executed system that can reset states when a control input enables it.

## Enable Optimization

- 1 Open the Model Configuration Parameters dialog box for `rtwdemo_optionalDisableResetFunc_bot`.
- 2 Select **Remove Disable Function** and **Remove Reset Function**.

Open the `rtwdemo_optionalDisableResetFunc_bot.c` file. The code does not contain the `rtwdemo_optionalDisableResetFunc_bot_Reset` function or the `rtwdemo_optionalDisableResetFunc_bot_Disable` function.

## See Also

## Control Operator Type in Generated Code

This example shows how to optimize the generated code by controlling the operator type in the code. You can generate code with Bitwise or Logical operators or a combination of both for inputs with Boolean data type. Selecting bitwise operators in the code might improve ROM efficiency when the code contains bitwise operators.

When you select a value for the **Operator to represent Bitwise and Logical Operator blocks** parameter, the generated code maintains the operators as modelled or converts all operators into either bitwise or logical operators independent of the modeling blocks.

**NOTE:** This example requires Embedded Coder®.

### Example Model

In the model `matlab:logicalandbitwise`, a Logical AND block connects to a Bitwise AND block.

```
model = 'logicalandbitwise';
open_system(model);
```

Copyright 2021 The MathWorks, Inc.

### Generate Code as Modeled

Use your system temporary folder for building and inspection process.

```
currentDir = pwd;
```

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, set the **Operator to represent Bitwise and Logical Operator blocks** parameter to Same as modeled.

Alternatively, use the command-line API to set the parameter value:

```
set_param(model, 'BitwiseOrLogicalOp', 'Same as modeled');
evalc('slbuild(model)');
```

View the generated code with operators in the code that matches the modeled blocks. Here is a portion of `logicalandbitwise.c`.

```
cfile = fullfile(currentDir, 'logicalandbitwise_ert_rtw', 'logicalandbitwise.c');
rtwdemodbtype(cfile, '/* Model step function ', '/* Model initialize function', 1, 1);

/* Model step function */
void logicalandbitwise_step(void)
{
```

```

/* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/Input'
 * Inport: '<Root>/Input1'
 * Inport: '<Root>/Input2'
 * Logic: '<Root>/Logical AND'
 * S-Function (sfix_bitop): '<Root>/Bitwise AND'
 */
logicalandbitwise_Y.Out1 = (logicalandbitwise_U.Input1 &&
 logicalandbitwise_U.Input2) & logicalandbitwise_U.Input;
}

```

The generated code contains both a logical && operator and a bitwise & operator representing the Logical AND block and Bitwise AND block in the code.

### Generate Code with Logical Operators

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, set the **Operator to represent Bitwise and Logical Operator blocks** parameter to Logical operator.

Alternatively, use the command-line API to set the parameter value:

```

set_param(model, 'BitwiseOrLogicalOp', 'Logical operator');
evalc('slbuild(model)');

```

View the generated code with only logical operators. Here is a portion of `logicalandbitwise.c`.

```

cfile = fullfile(currentDir, 'logicalandbitwise_ert_rtw', 'logicalandbitwise.c');
rtwdemodbtype(cfile, '/* Model step function ', '/* Model initialize function', 1, 1);

```

```

/* Model step function */
void logicalandbitwise_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/Input'
 * Inport: '<Root>/Input1'
 * Inport: '<Root>/Input2'
 * Logic: '<Root>/Logical AND'
 * S-Function (sfix_bitop): '<Root>/Bitwise AND'
 */
 logicalandbitwise_Y.Out1 = (logicalandbitwise_U.Input &&
 (logicalandbitwise_U.Input1 && logicalandbitwise_U.Input2));
}

```

The generated code contains only the logical && operator. The Bitwise AND block in the model is converted into the logical && operator in the code.

### Generate Code with Bitwise Operators

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, set the **Operator to represent Bitwise and Logical Operator blocks** parameter to Bitwise operator.

Alternatively, use the command-line API to set the parameter value:

```
set_param(model, 'BitwiseOrLogicalOp', 'Bitwise operator');
evalc('slbuild(model)');
```

View the generated code with only bitwise operators. Here is a portion of `logicalandbitwise.c`.

```
cfile = fullfile(currentDir, 'logicalandbitwise_ert_rtw', 'logicalandbitwise.c');
rtwdemodtype(cfile, '/* Model step function ', '/* Model initialize function', 1, 1);
```

```
/* Model step function */
void logicalandbitwise_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/Input'
 * Inport: '<Root>/Input1'
 * Inport: '<Root>/Input2'
 * Logic: '<Root>/Logical AND'
 * S-Function (sfix_bitop): '<Root>/Bitwise AND'
 */
 logicalandbitwise_Y.Out1 = (boolean_T)(logicalandbitwise_U.Input1 &
 logicalandbitwise_U.Input2) & logicalandbitwise_U.Input;
}
```

The generated code contains only the bitwise & operator. The Logical AND block in the model is converted into the bitwise & operator in the code.

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

- “Stack Usage Profiling for Code Generated from Simulink Models” on page 76-30

## Code Execution Profiling with SIL and PIL

You can configure a software-in-the-loop (SIL) or processor-in-the-loop (PIL) on page 82-2 simulation to produce execution-time metrics for tasks and functions in your generated code. The software calculates execution times from data that is obtained through code instrumentation added to the SIL or PIL application or the generated code under test. You can use the execution-time metrics to determine whether the generated code meets the requirements for real-time deployment on your target hardware.

For example, you can perform the following analysis:

- 1 Identify tasks that require the most time. Tasks are main entry points into the generated code. For example, the step function for a sample rate or the `model_initialize` function.
- 2 In these tasks, investigate code sections that require the most time.
- 3 Identify variations in execution time over time steps.

If you are trying to reduce execution times, the analysis results help you to focus on the most critical code sections. To observe performance changes for an updated model, rerun the SIL or PIL simulation and compare the new metrics against previous metrics.

---

**Note** Execution-time measurements depend greatly on the hardware that you use. For reliable results, collect execution-time metrics using hardware on which you plan to deploy the generated code, that is, run PIL simulations that execute code on your target hardware. SIL simulations, which execute code on your host computer, might not produce representative metrics.

---

When the SIL or PIL simulation is complete, you can:

- View execution-time metrics through a display window or report.
- Use the Simulation Data Inspector to view and compare the variation of execution times over a simulation.
- Analyze the measurements within the MATLAB environment.

### Configure Code Execution Profiling

To configure code execution profiling for a SIL or PIL simulation:

- 1 In your top model, open the Configuration Parameters dialog box, and select the **Code Generation > Verification** pane.
- 2 Select the **Measure task execution time** check box.
- 3 For function execution times, from the **Measure function execution times** drop-down list, select one of these options:
  - **Coarse (referenced models and subsystems only)** -- if you want to analyse generated function code for the main model components.
  - **Detailed (all function call sites)** -- if you want to analyse generated function code for all blocks in the model.
- 4 In the **Workspace variable** field, specify a name. When you run the simulation, the software generates a variable with this name in the MATLAB base workspace. The variable contains the execution-time measurements, and is an object of type `coder.profile.ExecutionTime`.

If the **Data Import/Export > Single simulation output** check box is selected, the software creates the variable in the Simulink.SimulationOutput object that you specify.

- 5 From the “Save options” drop-down list, select one of these options:
  - **Summary data only** — Stream execution times to the Simulation Data Inspector during the simulation. Store minimal information at the end of the simulation. Use this option if you want to generate only a report and reduce memory usage, for example, in a long simulation.
  - **All data** — Stream execution times to the Simulation Data Inspector during the simulation. Store execution-time profiles in the base workspace and generate a report. After the simulation, you can use methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes to retrieve execution-time measurements for every call to each profiled section of code that occurs during the simulation.

If you select this option, the metrics display window and generated report display the Simulation Data Inspector icon . When you click the icon, the software imports simulation results into the Simulation Data Inspector. You can then plot execution times and manage and compare plots from various simulations.

- **Metrics only** -- Reduces bandwidth usage for the communication channel between Simulink and the target application. During the simulation, the software does not stream execution times to the Simulation Data Inspector. On the target hardware, the software stores maximum execution times, average execution times, and number of calls. At the end of the simulation, Simulink uploads the data from the target hardware to your development computer.
- 6 Click **OK**.

For a PIL simulation:

- You must configure a hardware-specific timer. When you set up target connectivity, create a timer object. This action is not required for a SIL simulation. For more information, see “Set Up PIL Connectivity by Using target Package” on page 82-50 or “Create PIL Target Connectivity Configuration for Simulink” on page 82-40.
- You can remove instrumentation overheads from execution times. For more information, see “Remove Instrumentation Overheads from Execution Time Measurements” on page 76-20.

## Control Profiling Granularity

You can control the granularity of execution-time profiling, that is, prevent the addition of code instrumentation to specific function-call sites. Through the control of profiling granularity, you can:

- Focus on the performance of model components that require improvement. For example, after an initial run, disable profiling for blocks that require little processing time. This action reduces the number of items displayed by the profiling report.
- Reduce the code instrumentation overhead. For example, for simple functions, the code instrumentation overhead can be greater than the execution time of the function code.

To generate execution-time metrics for tasks only, on the **Code Generation > Verification** pane of the Configuration Parameters dialog box, select the **Measure task execution time** check box and set **Measure function execution times** to **Off**.

To generate function execution data for referenced models and atomic subsystems in the top model, on the **Code Generation > Verification** pane, select the **Measure task execution time** check box

and set **Measure function execution times** to Coarse (referenced models and subsystems only).

The generation of function execution data requires the insertion of measurement probes into the generated code. The software inserts measurement probes for an atomic subsystem only if you set the **Function packaging** field (on the **Code Generation** tab of the Function Block Parameters dialog box) to either **Nonreusable function** or **Reusable function**. If the field is set to **Auto**, then the insertion of probes depends on the packaging choice that results from the **Auto** setting. If the field is set to **Inline**, the software does not insert probes.

**Note** In the generated code, the software wraps each function call with measurement probes except when:

- The call site cannot be wrapped because of expression folding (see “Minimize Computations and Storage for Intermediate Results at Block Outputs”).
- The call site is located in the shared utility code (see “Sharing Utility Code”).

To generate function execution times for model reference hierarchies:

- 1 In the top model, open the Configuration Parameters dialog box, and select the **Code Generation > Verification** pane.
- 2 Select the **Measure task execution time** check box
- 3 For each Model block that you want to profile, specify **Measure function execution times** only at the reference level for which you require function execution times.

For example, consider a top model that has Model block A, which in turn contains Model block B.

If you want to generate execution times for functions from model B, select **Measure task execution time** for the top model and specify **Measure function execution times** for model B.

These parameters of the top model override the corresponding parameters of referenced models:

- **Measure task execution time.** If you disable this parameter for the top model, you also disable function profiling for referenced models.
- **Workspace variable**
- **Save options**

To control code execution profiling for a block in a model, for example, a subsystem block, use the `CodeProfilingOverride` block parameter:

- 1 In the Simulink Editor, select the block.
- 2 In the Command Window, run:

```
set_param(gcb, 'CodeProfilingOverride', blockParameterValue)
```

Use one of these values for *blockParameterValue*:

- 'off' -- Disables profiling for the block.
- 'on' -- Enables profiling for the block if profiling is enabled for the parent model.
- 'inherit' (default) -- Applies profiling settings of parent block.

Changing the block profiling configuration does not cause the regeneration of production code.

If your top model has a PIL block, the execution profiling settings that apply to the PIL block are the settings from the original model that you used to create the PIL block. See “Simulation with Subsystem Blocks” on page 82-17. You cannot use `CodeProfilingOverride` to control profiling for a PIL block.

- “Analyze Code Execution Data” on page 76-18
- “Specify Hardware Timer” on page 82-47
- “View and Analyze Simulation Results”

## View and Compare Code Execution Times

You run a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation that produces execution-time metrics for tasks and functions in your generated code. During the simulation, you can use the Simulation Data Inspector to observe streamed execution times. At the end of the simulation, you can:

- View execution-time metrics for a profiled model component.
- Open a report of execution-time metrics for all profiled components. Through report icons, you can view, for example, the profiled code section and the execution-time distribution for each profiled function.
- Use the Simulation Data Inspector to plot and compare execution times from various simulations.

### Run SIL Simulation That Generates Execution-Time Metrics

Open the `rtwdemo_sil_topmodel` model, which has two subsystems `CounterTypeA` and `CounterTypeB`. At the command line, type `rtwdemo_sil_topmodel`.

To run a SIL simulation that generates execution-time metrics, on the **SIL/PIL** tab:

- 1 In the **Mode** section, select **SIL/PIL Simulation Only**.
- 2 In the **Prepare** section, specify these settings:
  - a **System Under Test** — Top model
  - b **SIL/PIL Mode** — Software-in-the-Loop (SIL)
- 3 To measure code execution times for the subsystems, in the **Prepare** section:
  - a Click **Settings**.
  - b Under **Profiling**:
    - Click the **Task Profiling** button on. This action selects the **Measure task execution time** configuration parameter, which provides execution-time metrics for the task generated from the top model `rtwdemo_sil_topmodel`.
    - Click the **Save Options** button until it displays ALL DATA. This action sets the **Save options** configuration parameter to All data.
    - Click the **Functions** button until it displays COARSE. This action sets the **Measure function execution times** configuration parameter to Coarse (referenced models and subsystems only), which provides execution-time metrics for the functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.
  - c Under **Coverage**, click the **Coverage Collection** button off, which disables code coverage analysis. You collect code coverage data separately from profiling data.
  - d Click the **Settings** button to open the Configuration Parameters dialog box. On the **Data Import/Export** pane, clear **Single simulation output**.
- 4 To view streamed execution times during the simulation, open the Simulation Data Inspector. In the **Results** section, click .
- 5 In the **Run** section, click **Run SIL/PIL**.

In the MATLAB base workspace, the simulation generates a variable with the default name, `executionProfile`, which stores the execution profiling data. You can specify an alternative name through the **Workspace variable** configuration parameter.

**Note** If the **Data Import/Export > Single simulation output** check box is selected, the simulation creates the variable in your specified Simulink.SimulationOutput object.

When the simulation is complete, the profiled model components are colored blue and the Code view displays the generated code. To view execution-time metrics for a profiled component, click the component. For example, subsystem `CounterTypeB`.

The Profiling window for `CounterTypeB` displays the following metrics:

Block: CounterTypeB	Maximum Execution Time in ns	Average Execution Time in ns	Maximum Self Time in ns	Average Self Time in ns	Calls
Initialize:CounterTypeB	11	11	11	11	1
step [0.1 0]:CounterTypeB	649	33	649	33	101

The code view shows the following snippet:

```

107 /* Switch: '<S2>/Switch1' incorporates:
108 * Constant: '<S2>/C1'
109 * Inport: '<Root>/reset'
110 * Inport: '<Root>/ticks_to_count'
111 * Output: '<Root>/count_b'
112 * Sum: '<S2>/Add'
113 */
114 if (rtU.reset) {
115 rty.count_b = 0U;

```

For top-model SIL or PIL simulations, the Simulink Editor background is also colored blue. When you click the background, the display window shows execution-time metrics for top-model tasks.

You can trace from a model component to the profiled code section in the Code view. In the Profiling display window, on a code section row, click the icon . For example, if you click the model background and then click the icon for the `rtwdemo_sil_topmodel_initialize` task, you see the measurement probes around the call site in the SIL application. To see the profiling metrics for the component, place your cursor on the call site.

```

62 {
63 return XIL_INTERFACE_SUCCESS;
64 }
65
66 XIL_154 void initialize(void)
67 {
68 XI Maximum Execution Time 602
69 Average Execution Time 602
70 /* Maximum Self Time 348
71 /* Average Self Time 348
72 if Number of Calls 1
73 Unit of time : seconds
602 1 74 initialize();
75 taskTimeEnd_rt_0c8405b404040924(1U);
76 } else {
77 errorCode = XIL_INTERFACE_UNKNOWN_FCNIID;
78 }

```

If you click the icon for a function, the call site is highlighted. The Code view displays the average execution time and number of function calls to the left of the code line. In this example, the maximum and average times are the same because the initialization function was called only one time.

```

136 /* Outputs for Enabled SubSystem: '<Root>/CounterTypeA' */
312 101 137 CounterTypeA();
138
139 /* End of Outputs for SubSystem: '<Root>/CounterTypeA' */

```

The Profiling display window also has links to:

- The complete profiling report, which provides execution-time metrics for all profiled code sections.
- The Simulation Data Inspector, which allows you to plot and compare execution-time measurements for the profiled code section.
- The execution-time distribution for the profiled code section.
- Pie charts that show the relative execution times of caller and called functions

If you close the model or display window, you can reopen the colored model and display window with this line command:

```
annotate(executionProfile)
```

## Code Execution Profiling Report Sections

At the end of the simulation, you can open the report through the Profiling display window or by using this line command:

```
report(executionProfile)
```

The report contains these sections:

## 1 Summary

This section gives information about the creation of the report.

### 1. Summary

Total time	19232
Unit of time	ns
Command	report(executionProfile, 'Units', 'seconds', 'ScaleFactor', '1e-09', 'NumericFormat', '%0.0f');
Timer frequency (ticks per second)	3.6e+09
Profiling data created	30-Nov-2021 19:04:25

## 2 Feasibility Checks

If the number of timer ticks per second is known, the simulation performs feasibility checks and displays results in this section. The checks are shown in this table.

Check	Comments
Overall average CPU utilization lower than threshold	The default threshold value is 70%. To change the threshold value, for example, to 85%, use this command: <code>executionProfile.CPUUtilization=0.85;</code>  For information about CPU utilization, see section 5.
Overall maximum CPU utilization lower than threshold	
All average execution times are shorter than their task period	Use the results of these checks to verify that task overrun does not occur.
All maximum execution times are shorter than their task period	

In the **Results** column, the report displays Passed or Failed.

### 2. Feasibility Checks [\[hide\]](#)

Check Description	Results
Overall average CPU utilization lower than threshold (70%)	Passed
Overall maximum CPU utilization lower than threshold (70%)	Passed
All average execution times are shorter than their task period	Passed
All maximum execution times are shorter than their task period	Passed

## 3 Profiled Sections of Code

This section contains information about profiled code sections. In the **Section** column, expand and collapse profiled sections by clicking [+] and [-] respectively. This graphic shows fully expanded sections.

### 3. Profiled Sections of Code

Section	Maximum Execution Time in ns	Average Execution Time in ns	Maximum Self Time in ns	Average Self Time in ns	Calls	
[ - ] <a href="#">initialize</a>	72	72	42	42	1	   
<a href="#">CounterTypeA</a>	19	19	19	19	1	  
<a href="#">CounterTypeB</a>	11	11	11	11	1	  
[ - ] <a href="#">step [0.1 0]</a>	973	190	309	103	101	    
<a href="#">CounterTypeA</a>	353	53	353	53	101	   
<a href="#">CounterTypeB</a>	649	33	649	33	101	   

In this example, the report contains time measurements for:

- The model initialization function `initialize`.
- A task represented by the step function `step [0.1 0]`.
- Functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.

From the report, you can trace the model component that produces a set of metrics. For example, in the **Section** column, if you click the `CounterTypeA` hyperlink, the Simulink Editor identifies the subsystem.

By default, the report displays time in nanoseconds ( $10^{-9}$  seconds). You can specify the time unit and numeric display format. For example, to display time in microseconds ( $10^{-6}$  seconds), use the following command:

```
report(executionProfile, ...
 'Units', 'Seconds', ...
 'ScaleFactor', '1e-06', ...
 'NumericFormat', '%0.3f')
```

The report displays time in seconds only if the timer is calibrated, that is, the number of timer ticks per second is known. On a Windows machine, the software determines this value for a SIL simulation. On a Linux machine, calibrate the timer manually. For example, if your processor speed is 1 GHz, specify the number of timer ticks per second:

```
executionProfile.TimerTicksPerSecond = 1e9;
```

To view execution-time metrics for a task or function in the Command Window, on the corresponding row, click .

```
>> executionProfile.Sections(5)
ExecutionTimeCodeSection with properties:

 Name: 'CounterTypeA'
 Number: 5
 ExecutionTimeInTicks: [122 102 100 86 88 88 88 86 88 88 156 122 ...]
 SelfTimeInTicks: [122 102 100 86 88 88 88 86 88 88 156 122 ...]
 TurnaroundTimeInTicks: [122 102 100 86 88 88 88 86 88 88 156 122 ...]
 TotalExecutionTimeInTicks: 19436
 TotalSelfTimeInTicks: 19436
 TotalTurnaroundTimeInTicks: 19436
 MaximumExecutionTimeInTicks: 1270
 MaximumExecutionTimeCallNum: 27
 MaximumSelfTimeInTicks: 1270
 MaximumSelfTimeCallNum: 27
 MaximumTurnaroundTimeInTicks: 1270
 MaximumTurnaroundTimeCallNum: 27
 NumCalls: 101
 ExecutionTimeInSeconds: [3.3889e-08 2.8333e-08 2.7778e-08 2.3889e-08 ...]
 Time: [101x1 double]
```

To display measured execution times in the Simulation Data Inspector, click the icon . Use the Simulation Data Inspector to manage and compare plots from various simulations.

To display the execution-time distribution, click the icon .

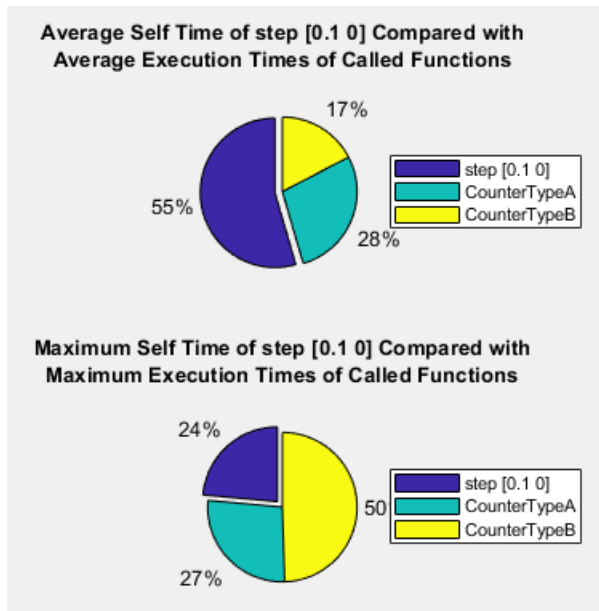

In this example, to create the histogram, the software uses these commands:

```
section=executionProfile.Sections(5);
data=section.ExecutionTimeInSeconds;
histogram(data, 30, 'Normalization', 'probability');
```

The software creates the histogram only if the number of calls is greater than one.

If the generated code for your model contains nested functions, the simulation generates pie charts that show the relative execution times of caller and called functions. To display the pie charts, click the icon  for the caller function. For example, step [0.1 0].

The pie charts, which display average and maximum execution time distributions, can help you to identify functions that are bottlenecks in code execution.

This table describes the information that **Profiled Sections of Code** provides.

Column	Description
Section	Name of task, top model, subsystem, or Model block. Click the link to go to the model.  With a task, the sample period and sample offset are listed next to the task name. For example, <i>rtwdemo_sil_topmodel_step [0.1 0]</i> indicates that the sample period is 0.1 seconds and the sample offset is 0.
Maximum Turnaround Time (Simulink Real-Time and support packages in real-time mode)	Longest time between start and end of code section. Includes preemption time.
Average Turnaround Time (Simulink Real-Time and support packages in real-time mode)	Average time between start and end of code section. Includes preemption time.
Maximum Execution Time	Longest time between start and end of code section.
Average Execution Time	Average time between start and end of code section.
Maximum Self Time	Maximum execution time, excluding time in child sections.
Average Self Time	Average execution time, excluding time in child sections.

Column	Description
Calls	Number of calls to the code section.
	Icon that you click to see the profiled code section in the Code view of the SIL/PIL app. The code section can be a task or a function.  The specified workspace variable, for example, <code>executionProfile</code> , must be present in the base workspace.
	Icon that you click to display the profiled code section in the Command Window. Equivalent to executing the command <code>executionProfile.Sections(i)</code> .  The specified workspace variable, for example, <code>executionProfile</code> , must be present in the base workspace.
	Icon that you click to display measured execution times with Simulation Data Inspector.  The specified workspace variable, for example, <code>executionProfile</code> , must be present in the base workspace.
	Icon that you click to display the execution-time distribution for the profiled code section.  The specified workspace variable, for example, <code>executionProfile</code> , must be present in the base workspace.
	Icon that you click to display pie charts that show the relative execution times of caller and called functions in the generated code.

#### 4 Execution Times in Percentages

This section provides function execution times as percentages of caller function and total execution times, which can help you to identify performance bottlenecks in generated code.

#### 4. Execution Times in Percentages [\[hide\]](#)

Section	Self Time / Caller Function	Self Time / Task	Self Time / Simulation	Function / Simulation
[ - ] <a href="#">initialize</a>	58.14%	58.14%	0.21665%	0.37264%
<a href="#">CounterTypeA</a>	27.132%	27.132%	0.1011%	0.1011%
<a href="#">CounterTypeB</a>	14.729%	14.729%	0.054885%	0.054885%
[ - ] <a href="#">step.[0.1.0]</a>	54.501%	54.501%	54.298%	99.627%
<a href="#">CounterTypeA</a>	28.177%	28.177%	28.072%	28.072%
<a href="#">CounterTypeB</a>	17.321%	17.321%	17.257%	17.257%

This table describes the information that each column provides.

Column	Comparison Performed
<b>Self Time / Caller Function</b>	Function self time compared with the total execution time of the caller function.

Column	Comparison Performed
<b>Self Time / Task</b>	Function self time compared with the total execution time of the task.
<b>Self Time / Simulation</b>	Function self time compared with the total execution time of the simulation.
<b>Function / Simulation</b>	Function execution time, which includes self time and time spent in child functions, compared with the total execution time of the simulation.

## 5 CPU Utilization

To help you to decide whether you can run the generated code on your target hardware, this section of the code execution profiling report provides CPU workload information:

- Average and maximum CPU time required by each task during a sample period.
- Total CPU usage in a sample period.

The software computes the percentage of CPU time assigned to a task by dividing task execution time by sample time.

### 5. CPU Utilization [\[hide\]](#)

Task	Average CPU Utilization	Maximum CPU Utilization
<a href="#">step [0.1 0]</a>	0.0001897%	0.0009728%
Overall CPU Utilization	0.0001897%	0.0009728%

The software generates **CPU Utilization** only if the number of timer ticks per second is known.

## 6 Definitions

This section provides descriptions of some metrics.

### 6. Definitions

**CPU Utilization:** Percentage of CPU time assigned to a task. Computed by dividing task execution time by sample time.

**CPU Utilization Threshold:** Maximum CPU utilization that allows task scheduling without deadline misses or overruns. To override the default (70%), use the `CPUUtilization` parameter.

**Execution Time:** Time between start and end of code section.

**Self Time:** Execution time, excluding time in child sections.

## View Code Execution Profiles for Multiple Model Blocks

You can configure a top-model simulation that runs multiple Model blocks in SIL or PIL mode with code execution profiling enabled. When you run the simulation, it generates separate code execution profiling reports for the referenced models.

- 1 Open the top model that contains Model blocks. For example, at the command line, type `rtwdemo_sil_modelblock`.

- 2 On the **SIL/PIL** tab, in the **Mode** section, specify **SIL/PIL Simulation Only**.
- 3 In the **Prepare** section, specify these settings:
  - **System Under Test** -- Model blocks in SIL/PIL mode
  - **Top Model Mode** -- Normal
- 4 Model block Counter A is already configured to run in SIL mode. For Model block Counter B, set the block parameter **Simulation mode** to Software-in-the-loop (SIL).
- 5 Both Model blocks reference the model `rtwdemo_sil_counter`. To generate execution times for the Model blocks:
  - a Select CounterA or CounterB.
  - b On the **Model Block** tab, in the **Actions** section, click **Open as Top Model**.
  - c On the **SIL/PIL** tab, in the **Settings** gallery, click **Functions** to COARSE, which sets the **Measure function execution times** configuration parameter for `rtwdemo_sil_counter` to Coarse (referenced models and subsystems only).
- 6 To run a top-model simulation:
  - a Select the `rtwdemo_sil_modelblock` window.
  - b On the **SIL/PIL** tab, in the **Run** section, click **Run SIL/PIL**.

Since the **Single simulation output** check box is selected, the simulation creates the variable `executionProfile` in `out`, a `Simulink.SimulationOutput` object.

- 7 When the simulation is complete, to show the number of Model blocks that are profiled, in the Command Window, enter:

```
NumOfReports=out.executionProfile.getModuleNumber()
```

```
NumOfReports =
2
```

- 8 To open the report for CounterA, the first Model block, run:

```
report(out.executionProfile.getModule(1))
```

## 1. Summary

Total time	4955
Unit of time	ns
Command	<code>report('Units', 'seconds', 'ScaleFactor', '1e-09', 'NumericFormat', '%0.0f');</code>
Timer frequency (ticks per second)	3.6e+09
Profiling data created	03-Dec-2021 12:24:45

The simulation ran multiple model blocks in SIL or PIL mode with code execution profiling enabled. To view execution-time metrics for a model block, click the corresponding report link:

<a href="#">rtwdemo_sil_modelblock/CounterA</a>	This report
<a href="#">rtwdemo_sil_modelblock/CounterB</a>	<a href="#">Open report</a>

## 2. Profiled Sections of Code

- 9 In the **Summary** section, the report provides a link to the second Model block report. To open the report for CounterB, click Open report or run:

```
report(out.executionProfile.getModule(2))
```

For more information about generating function execution times for model reference hierarchies, see “Control Profiling Granularity” on page 76-3.

## Compare Code Execution-Time Performance Against Baseline

You can create a code execution profiling report that compares the performance of the generated code against the performance of a reference version. For example, suppose you want to use the current execution-time metrics in `executionProfile` as the baseline for `rtwdemo_sil_topmodel`.

- 1 In the Workspace browser, rename `executionProfile` to `executionProfileBaseline`.
- 2 Run another SIL simulation.
- 3 To create a report that compares the latest performance against the baseline, in the Command Window, run:

```
report(executionProfile, 'baseline', executionProfileBaseline)
```

In the report, the **Comparison with Baseline Performance** and **CPU Utilization** sections provide comparisons of execution-time metrics. The differences in execution-time metrics are color-coded:

- Red — An increase in execution times or CPU usage.
- Green — A decrease in execution times or CPU usage.
- Black — No change.

### 5. Comparison with Baseline Performance [\[hide\]](#)

Section	Maximum Execution Time	Average Execution Time	Maximum Self Time	Average Self Time
<code>[-] initialize</code>	-22.75%	-22.75%	-20.86%	-20.86%
CounterTypeA	-26.47%	-26.47%	-26.47%	-26.47%
CounterTypeB	-23.53%	-23.53%	-23.53%	-23.53%
<code>[-] step [0.1 0]</code>	+53.35%	+11.26%	+52.67%	+7.55%
CounterTypeA	+125.25%	+20.19%	+125.25%	+20.19%
CounterTypeB	-69.86%	+9.09%	-69.86%	+9.09%

### 6. CPU Utilization [\[hide\]](#)

Task	Average CPU Utilization Baseline in brackets	Maximum CPU Utilization Baseline in brackets
<code>step [0.1 0]</code>	0.0001181% (0.0001062%)	0.0003689% (0.0002406%)
Overall CPU Utilization	0.0001181% (0.0001062%)	0.0003689% (0.0002406%)

## Visualize Task Scheduling

You can use the Simulation Data Inspector to visualize task scheduling and the order of function calls. At the end of the simulation, perform one of these actions:

- Run the `schedule` function. For details, see “Visualize Task Scheduling”
- From the **SIL/PIL** tab, in the **Results** gallery, click **Generate Schedule**. For more information, see “Analyze Results and Export Test Cases” on page 82-75.

## More About

- “Tips and Limitations” on page 76-27

## Analyze Code Execution Data

After a SIL or PIL simulation, you can analyze execution-time data using methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes.

- 1 Open `rtwdemo_sil_topmodel`.
- 2 On the **Configuration Parameters > Code Generation > Verification** pane, specify profiling options:
  - Select the **Measure task execution time** check box.
  - Specify a **Workspace variable**, for example, `myExecutionProfile`.
  - From the **Save options** drop-down list, select `All data`.
- 3 Run a SIL simulation.

The software generates the workspace variable `myExecutionProfile`, an `coder.profile.ExecutionTime` object.

To get the total number of code sections that have profiling data, use the `Sections` method.

```
>> no_of_Sections = myExecutionProfile.Sections
no_of_Sections =
 1x2 ExecutionTimeTaskSection array with properties:
 Name
 Number
 ExecutionTimeInTicks
 SelfTimeInTicks
 TurnaroundTimeInTicks
 TotalExecutionTimeInTicks
 TotalSelfTimeInTicks
 TotalTurnaroundTimeInTicks
 MaximumExecutionTimeInTicks
 MaximumExecutionTimeCallNum
 MaximumSelfTimeInTicks
 MaximumSelfTimeCallNum
 MaximumTurnaroundTimeInTicks
 MaximumTurnaroundTimeCallNum
 NumCalls
 ExecutionTimeInSeconds
 Time
```

To get the `coder.profile.ExecutionTimeSection` object for a profiled code section, use the method `Sections`.

```
>> FirstSectionProfile = myExecutionProfile.Sections(1)
SecondSectionProfile = myExecutionProfile.Sections(2)
FirstSectionProfile =
 ExecutionTimeTaskSection with properties:
 Name: 'rtwdemo_sil_topmodel_initialize'
 Number: 1
 ExecutionTimeInTicks: 1188
 SelfTimeInTicks: 1188
 TurnaroundTimeInTicks: 1188
 TotalExecutionTimeInTicks: 1188
 TotalSelfTimeInTicks: 1188
 TotalTurnaroundTimeInTicks: 1188
 MaximumExecutionTimeInTicks: 1188
 MaximumExecutionTimeCallNum: 1
 MaximumSelfTimeInTicks: 1188
```

```

 MaximumSelfTimeCallNum: 1
 MaximumTurnaroundTimeInTicks: 1188
 MaximumTurnaroundTimeCallNum: 1
 NumCalls: 1
 ExecutionTimeInSeconds: 5.4000e-07
 Time: 0

```

```
SecondSectionProfile =
```

```
 ExecutionTimeTaskSection with properties:
```

```

 Name: 'rtwdemo_sil_topmodel_step [0.1 0]'
 Number: 2
 ExecutionTimeInTicks: [1×101 uint64]
 SelfTimeInTicks: [1×101 uint64]
 TurnaroundTimeInTicks: [1×101 uint64]
 TotalExecutionTimeInTicks: 70316
 TotalSelfTimeInTicks: 70316
 TotalTurnaroundTimeInTicks: 70316
 MaximumExecutionTimeInTicks: 2448
 MaximumExecutionTimeCallNum: 2
 MaximumSelfTimeInTicks: 2448
 MaximumSelfTimeCallNum: 2
 MaximumTurnaroundTimeInTicks: 2448
 MaximumTurnaroundTimeCallNum: 2
 NumCalls: 101
 ExecutionTimeInSeconds: [1×101 double]
 Time: [101×1 double]

```

Use `coder.profile.ExecutionTimeSection` methods to extract profiling information for a particular code section. For example, use `Name` to obtain the name of a profiled task.

```

>> name_of_section = SecondSectionProfile.Name

name_of_section =

rtwdemo_sil_topmodel_step [0.1 0]

```

If the timer is uncalibrated and you know the timer rate, for example 2.2 GHz, you can use the `coder.profile.ExecutionTime` method `TimerTicksPerSecond` to calibrate the timer:

```

>> myExecutionProfile.TimerTicksPerSecond = 2.2e9;
>> SecondSectionProfile = myExecutionProfile.Sections(2);

```

## Remove Instrumentation Overheads from Execution Time Measurements

To improve execution-time profiling of generated code that runs on deterministic hardware, you can run processor-in-the-loop (PIL) simulations that automatically filter the overheads associated with code instrumentation. You can use the target hardware to estimate the average overhead value or you can specify the value manually.

---

**Note** By default, the software filters the execution times of AUTOSAR Runtime Environment (RTE) code and functions that run within Simulink, for example, Function Caller blocks.

---

### Approach for Estimating and Removing Instrumentation Overhead

When you set up target connectivity for PIL simulations, you can specify objects or functions for estimating and removing instrumentation overheads from execution-time measurements.

You can:

- Set up a benchmark program that Simulink runs a specified number of times at the start of a PIL simulation. The benchmark program estimates the overheads for the timer API and for timer freezing and unfreezing, task, and function instrumentation code. Simulink obtains average values for the instrumentation overheads.
- Manually specify instrumentation overhead values.

During the PIL simulation, Simulink subtracts the instrumentation overhead values from the execution-time measurements. The Simulation Data Inspector and the code execution profiling report display the corrected measurement values.

This figure shows how the uncorrected and corrected timer values correspond to invocations of code sections.

The corrected timer value excludes execution time associated with instrumentation code, RTE code, and function code that runs within Simulink.

To estimate and remove instrumentation overheads from execution-time measurements:

- If PIL connectivity is set up by using the `target` package, use overhead classes from the package.
- If PIL connectivity is set up by using the `rtw.connectivity.Config` class, use functions from the class.

## Remove Instrumentation Overheads by Using `target` Package

To provide the software with instrumentation overhead values, use one of these methods:

- Set up the benchmark program that estimates overhead values.
- Using overhead classes, manually specify overhead values.

### Set Up Benchmark Program

When you set up `target` connectivity on page 82-50, implement these steps:

- 1 Retrieve the `target.Processor` and `target.Timer` objects.

```
processor = target.get('Processor', myProcessorObjectId);
timer = target.get('Timer', myTimerObjectId);
```

- 2 Create a `target.ProfilingTaskOverhead` object.

```
taskOverhead = target.create('ProfilingTaskOverhead', ...
 'Name', 'Timer Task Overhead');
taskOverhead.Counter = timer;
taskOverhead.MinimumBenchmarkIterations = 150;
```

- 3 Associate the overhead values with the processor.

```
processor.Overheads = taskOverhead;
```

### Specify Overhead Values

When you set up `target` connectivity on page 82-50, create overhead class objects and use the `Value` property to specify your value for the corresponding instrumentation overhead.

- 1 Retrieve the `target.Processor` and `target.Timer` objects.

```
processor = target.get('Processor', myProcessorObjectId);
timer = target.get('Timer', myTimerObjectId);
```

- 2 Create a `target.ProfilingTaskOverhead` object.

```
taskOverhead = target.create('ProfilingTaskOverhead', ...
 'Name', 'Timer Task Overhead');
taskOverhead.Value = 10;
taskOverhead.Counter = timer;
```

- 3 Create a `target.ProfilingFunctionOverhead` object.

```
functionOverhead = target.create('ProfilingFunctionOverhead', ...
 'Name', 'Timer Function Overhead');
functionOverhead.Value = 20;
functionOverhead.Counter = timer;
```

- 4 Create a `target.ProfilingFreezingOverhead` object.

```
freezingOverhead = target.create('ProfilingFreezingOverhead', ...
 'Name', 'Timer Freezing Overhead');
```

```
freezingOverhead.Value = 30;
freezingOverhead.Counter = timer;
```

- 5 Associate the overhead values with the processor.

```
processor.Overheads = ...
[taskOverhead, functionOverhead, freezingOverhead];
```

## Remove Instrumentation Overheads by Using Functions from `rtw.connectivity.Config`

The `rtw.connectivity.Config` class provides these functions for the removal of instrumentation overheads.

Function	Description
<code>activateOverheadFiltering</code>	<code>obj.activateOverheadFiltering (value)</code> ; activates filtering of instrumentation overheads if value is true. Deactivates overhead filtering if value is false.
<code>isOverheadFilteringActive</code>	<code>obj.isOverheadFilteringActive</code> returns true if instrumentation overhead filtering is activated. Otherwise, returns false.
<code>runOverheadBenchmark</code>	<code>obj.runOverheadBenchmark (value)</code> ; runs a benchmark program if value is true. Does not run the benchmark program if value is false.
<code>isOverheadBenchmarkExecuted</code>	<code>obj.isOverheadBenchmarkExecuted</code> ; returns true if execution of benchmark program is complete. Otherwise, returns false.
<code>setOverheadBenchmarkSteps</code>	<code>obj.setOverheadBenchmarkSteps (steps)</code> ; specifies number of steps for benchmark program.
<code>getOverheadBenchmarkSteps</code>	<code>steps = obj.getOverheadBenchmarkSteps</code> returns the number of specified steps for the benchmark program.
<code>setOverheads</code>	<code>obj.setOverheads (taskInstrumentationOverhead, functionInstrumentationOverhead, freezingInstrumentation)</code> ; specifies the overhead values for task, function, and freezing instrumentation respectively.
<code>getOverheads</code>	<code>[taskInstrumentationOverhead, functionInstrumentationOverhead, freezingInstrumentation] = obj.getOverheads</code> ; returns overhead values for task, function, and freezing instrumentation respectively.

When you set up target connectivity on page 82-40 for PIL simulations, configure the removal of the instrumentation overheads through an `rtw.connectivity.Config` subclass. For example, this code shows how you can run the benchmark program.

```

classdef overheadConnectivityConfig < rtw.connectivity.Config
 methods
 function this = customConnectivityConfig(componentArgs)

 % Create builder
 targetApplicationFramework = ...
 mypil.TargetApplicationFramework(componentArgs);
 builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
 targetApplicationFramework, '');

 % Create launcher
 launcher = mypil.Launcher(componentArgs, builder);

 % Set up communication
 hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(...
 componentArgs, ...
 launcher, ...
 rtiostreamLibTCPIP);

 % Call super class constructor to register components
 this@rtw.connectivity.Config(componentArgs,...
 builder,...
 launcher,...
 hostCommunicator);

 % Register hardware-specific timer, which enables
 % code execution profiling. This example uses a
 % timer for the host platform.
 timer = coder.profile.crlHostTimer();
 this.setTimer(timer);

 % Specify removal of profiling instrumentation overheads
 this.activateOverheadFiltering(true);
 this.runOverheadBenchmark(true);
 this.setOverheadBenchmarkSteps(50);

 end
 end
end

```

Instead of running the benchmark program, you can use `setOverheads` to provide your values for instrumentation overheads.

```

...
% Remove instrumentation overhead using manually specified values
this.activateOverheadFiltering(true);
this.setOverheads (taskInstrumentationOverhead, ...
 functionInstrumentationOverhead, freezingInstrumentation);
...

```

## Retrieve Benchmark Results

When a PIL simulation is complete, you can retrieve benchmark results from the variable that you specify in the **Code Generation > Verification > Workspace variable** field (CodeExecutionProfileVariable), for example, myExecutionProfile.

```
benchmarkResults = myExecutionProfile.getOverheadBenchmarkData();
```

*benchmarkResults* is a structure that contains code instrumentation overhead values.

```
>> benchmarkResults
ans =
 struct with fields:
 TimestampOverhead: [1x1 struct]
 TaskOverhead: [1x1 struct]
 FunctionOverhead: [1x1 struct]
 FreezingOverhead: [1x1 struct]

>> benchmarkResults.TaskOverhead
ans =
 struct with fields:
 Data: [1x100 uint64]
 NumSamples: 100
 Average: 45.2800
```

## Capture Main Profiling Metrics on Target Hardware

For code execution profiling, to reduce the communication channel bandwidth usage during a software-in-the-loop (SIL) simulation, processor-in-the-loop simulation (PIL), or XCP external mode simulation, you can capture and store only these profiling metrics on the target hardware:

- Maximum execution time of code section
- Average execution time of code section
- Number of calls to code section

At the end of the simulation, Simulink uploads the metrics from the target hardware to your development computer.

To run a SIL simulation that generates only the main execution-time metrics:

- 1 Open the `rtwdemo_sil_topmodel` model, which has two subsystems `CounterTypeA` and `CounterTypeB`.
- 2 On the SIL/PIL tab, in the **Mode** section, select **SIL/PIL Simulation Only**.
- 3 In the **Prepare** section, specify these settings:
  - a **System Under Test** — Top model
  - b **SIL/PIL Mode** — Software-in-the-Loop (SIL)
- 4 To measure code execution times for the subsystems:
  - a Click .
  - b In the Configuration Parameters dialog box, select **Measure task execution time**, which provides execution-time metrics for the task generated from the top model `rtwdemo_sil_topmodel`.
  - c Set **Measure function execution times** to Coarse (referenced models and subsystems only), which provides execution-time metrics for the functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.
  - d Specify a **Workspace variable**, for example, `executionProfile`. If the **Data Import/Export > Single simulation output** check box is selected, the software creates the variable in the `Simulink.SimulationOutput` object that you specify.
  - e From the **Save options** drop-down list, select `Metrics only`.
  - f Click **OK**.
- 5 In the **Prepare** section, click **Settings**. Under **Coverage**, click the **Coverage Collection** button off.
- 6 In the **Run** section, click **Run SIL/PIL**.

The simulation generates the variable `executionProfile` in the MATLAB base workspace.

To open the code execution profiling report, in the Profiling window, click the displayed link. In section 2, the report displays the profiled code sections as a flattened list.

## 2. Profiled Sections of Code

Section	Maximum Execution Time in ns	Average Execution Time in ns	Calls	
<a href="#">rtwdemo_sil_topmodel_initialize</a>	299	299	1	 
<a href="#">rtwdemo_sil_topmodel_step[0,1,0]</a>	450	275	101	 
<a href="#">CounterTypeA (CounterTypeA)</a>	106	78	101	 
<a href="#">CounterTypeB (CounterTypeB)</a>	72	37	101	 
<a href="#">CounterTypeA (CounterTypeA_Init)</a>	57	57	1	 
<a href="#">CounterTypeB (CounterTypeB_Init)</a>	33	33	1	 

The software cannot extract the hierarchy of calls to code sections because this information is not stored on the target hardware.

Overhead filtering on page 76-20 is not supported when **Save options** is set to **Metrics** only.

## Tips and Limitations

### Triggered Model Block

Consider the case where a triggered Model block is configured to run in the SIL or PIL simulation mode. The software generates one execution-time measurement each time the referenced model is triggered to run. If there are multiple triggers in a single time step, the software generates multiple measurements for the triggered Model block. Conversely, if there is no trigger in a given time step, the software generates no time measurements.

### Outliers in Execution-Time Profiles

When you run a SIL simulation with execution time profiling enabled, you might see spikes in execution-time measurements.

The spikes are due to process preemption that occurs with a multitasking host operating system. If the operating system preempts the SIL process and runs another process, the measured execution time includes the time during which the SIL process is suspended. With a PIL simulation, you do not see spikes because code execution on the target is not preempted.

Counter wrapping produces execution-time measurements that are smaller than expected. For SIL, the counter wraps when an execution-time period is greater than  $2^{64}$  ticks ( $2^{32}$  ticks if the MEX compiler is LCC). For PIL, the wrapping point depends on the timer you specify and can be  $2^8$ ,  $2^{16}$ ,  $2^{32}$ , or  $2^{64}$  ticks.

Consider a PIL example where the timer frequency is 20 MHz. For a 32-bit timer, wrapping occurs when the execution-time period is greater than  $1/(20\text{e}6) * (2^{32} - 1)$ , that is, 214.7 s. However, for a 16-bit timer, the point at which wrapping occurs is 0.0033 s.

For a real-time, multi-core application, the software accommodates synchronization discrepancies when recording timer values for different cores, which effectively reduces the timer measurement range.

## Hardware-Specific Timer

If your target configuration does not already specify a timer, create a timer object that provides details of the hardware-specific timer and associated source files:

- For SIL simulation, the timer word length is 64 bits.
- For PIL simulation, specify an unsigned 8-, 16-, 32-, or 64-bit timer. For more information, see “Specify Hardware Timer” on page 82-47.

## Effect of Instrumentation Code on Instruction Cycle

Instrumentation code increases the volume of code to run and can result in the CPU requiring more cycles to fetch code blocks from memory. This is one of the effects of instrumentation code on the fetch stage and depends on how the code is aligned in memory. If the instrumented code does not fit in the same number of blocks as code that is not instrumented, the prefetch unit must transfer more blocks.

## Task Context Switching Due to Preemption

Profiling instrumentation is intrusive and affects the quantity that it is meant to measure. Therefore, the design goal is to maximize code understanding with a minimum of instrumentation. For example, with a real-time system, there can be task context switches due to preemption. These context switches are not explicitly instrumented. To record the start and end of each task, the software must infer context switches from instrumentation. As a result, the software reports behavior that is an estimate. The estimate is subject to error because of incomplete instrumentation within the kernel.

In some cases, when the software cannot accurately determine behavior, the software generates a warning:

```
Warning: Analysis unsuccessful for one or more profiling data points. ...
```

For example, the software might generate this warning when not all mutex take system calls (associated with rate transitions) are instrumented. In the case of Simulink Real-Time, this situation might arise if you generate code for a model reference hierarchy without enabling function profiling for all referenced models (`set_param(model, 'CodeProfilingInstrumentation', 'on')`). If a mutex take system call is not instrumented, a task context switch might occur that is not visible to the execution profiling analysis.

In other cases, although the software cannot accurately determine behavior, the software does *not* generate a warning.

## Subsystem Code Reuse

You cannot generate execution-time profiles for function call sites within subsystem code that is reused across a model or multiple models. For information about subsystem code reuse, see “Generate Reusable Code from Library Subsystems Shared Across Models”.

## **Cannot Load Execution-Time Measurements from Previous Release**

You cannot load execution-time measurements saved with a previous release. For example, using R2014a, you save workspace variables to a MAT-file. One of the workspace variables contains execution-time measurements. In R2015b, if you try to load the MAT-file, you see this error:

```
Format of execution profiling data is invalid. This error can occur if
you load data from a previous release. Loading data from a previous
release is not supported.
```

## Stack Usage Profiling for Code Generated from Simulink Models

To determine the size of stack memory that is required to run generated code, you can run a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation that generates a stack usage profile. The SIL or PIL simulation instruments the generated code and uses the instrumentation to calculate stack usage. When the simulation is complete, you can view a code stack profiling report that shows minimum, average, and maximum memory demand. Using the Simulation Data Inspector, you can observe streamed stack usage information during and after the simulation. The profiles that you generate enable you to observe the effect of compiler optimization and data input on stack usage.

You can generate stack usage profiles by using the top-model or Model block SIL/PIL workflows. Subsystem SIL/PIL workflows do not support stack usage profiling.

### Benefits of Dynamic Stack Usage Profiling

Static stack usage analysis has some limitations. For example, it does not consider:

- Memory optimization performed by a compiler. For example, variables that are optimized away or stored in registers.
- Additional memory that the compiler uses in a function call. Compilers store the address to which the execution returns after the function call.
- Memory alignment that the compiler applies.

The dynamic stack usage profiling provided by a SIL or PIL simulation does not have the listed limitations because the simulation calculates actual memory usage.

### Configure Stack Usage Profiling

To run a SIL or PIL simulation that generates stack usage metrics:

- 1 In the Simulink Editor, open your model.
- 2 On the **Apps** tab, click **SIL/PIL Manager**.
- 3 In the **Mode** section, select **SIL/PIL Simulation Only**.
- 4 In the **Prepare** section, specify **System Under Test** and, if required, **SIL/PIL Mode**. A PIL simulation requires a driver implementation that obtains stack usage data from the target hardware. For more information, see [Implement Driver to Obtain PIL Stack Usage Data](#).
- 5 To enable stack usage profiling, in the **Prepare** section:
  - a Click **Settings**.
  - b Under **Profiling**, click the **Task Profiling** button off, which disables the generation of execution-time metrics.
  - c Under **Coverage**, click the **Coverage Collection** button off, which disables code coverage analysis.
  - d Under **Stack Profiling**, click the **Stack Profiling** button on. This action selects the **Measure task stack usage** configuration parameter, which provides stack usage measurements for each generated task. The top model setting for the parameter overrides the corresponding setting in referenced models.

- e Click the **Settings** button to open the Configuration Parameters dialog box. On the **Data Import/Export** pane, clear the **Single simulation output** check box.
- 6 To view streamed stack usage during the simulation, open the Simulation Data Inspector. In the **Results** section, click .
- 7 In the **Run** section, click **Run SIL/PIL**.

In the MATLAB base workspace, the simulation generates a variable with the default name, `stackProfile`, which stores the stack usage data. You can specify an alternative name through the **Stack workspace variable** configuration parameter.

## Observe Stack Usage of Generated Code

Suppose you run a SIL simulation of this model:

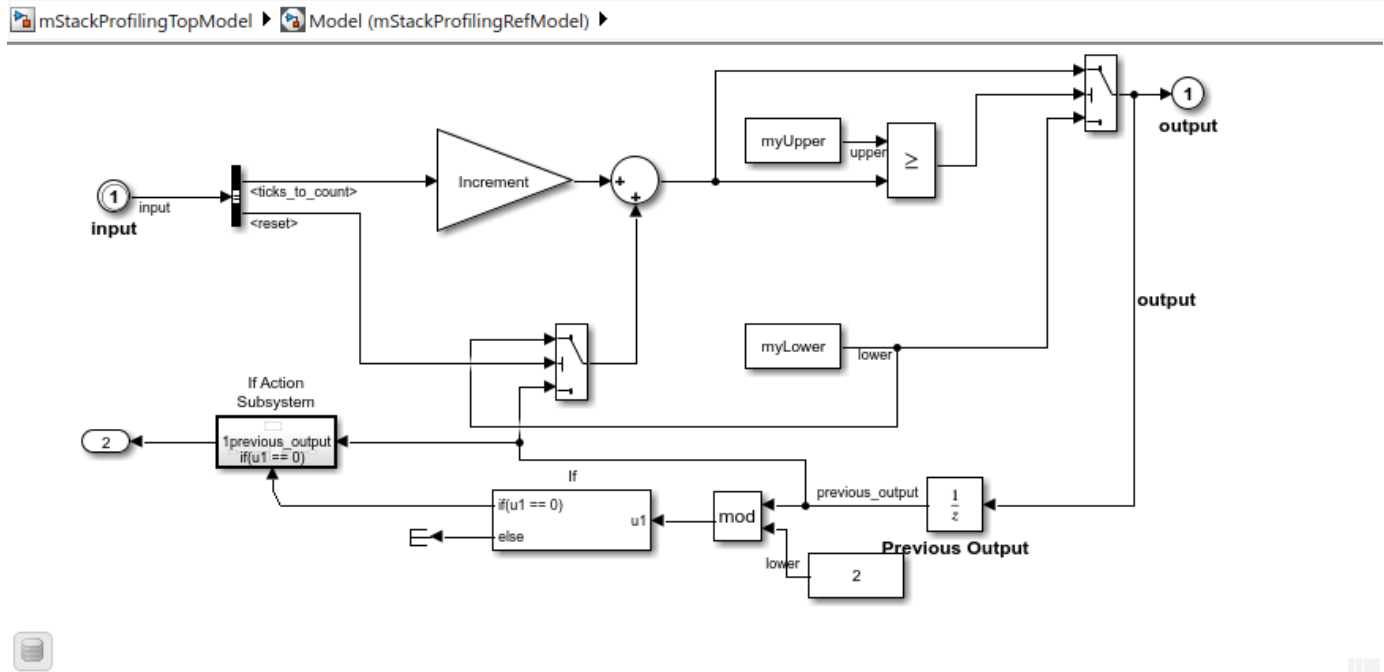

### mStackProfilingTopModel

The top model, `mStackProfilingTopModel`, is a modification of the shipped model `rtwdemo_sil_modelblock`.

 `mStackProfilingTopModel` ▶

The referenced model, `mStackProfilingRefModel`, is a modification of the shipped model `rtwdemo_sil_counter`.

The If Action Subsystem block contains this subsystem.

When the SIL simulation is complete, the code stack profiling report opens.

## Code Stack Profiling Report for mStackProfilingTopModel/Model

The code stack profiling report provides metrics based on data collected from a SIL or PIL execution. Stack usage is calculated from data recorded by instrumentation probes added to the SIL or PIL test harness and inside the code generated for each component. See [Code Execution Profiling](#) for more information.

### 1. Summary

Largest atomic integer type	Long
Word size (bits)	32
Pointer size (bits)	64
Stack driver	Target specific
Profiling data created	18-Oct-2021 17:07:16

### 2. Profiled Tasks

Task	Minimum Stack Usage in bytes	Average Stack Usage in bytes	Maximum Stack Usage in bytes	Calls	
<a href="#">mStackProfilingRefModel_initialize</a>	48	48	48	1	
<a href="#">mStackProfilingRefModel_step</a>	64	89	112	101	 

**Note** If you close the report, you can reopen the report. In the **Results** gallery, under **Stack Profiling Results**, click **Generate Report**.

In section 1, the report:

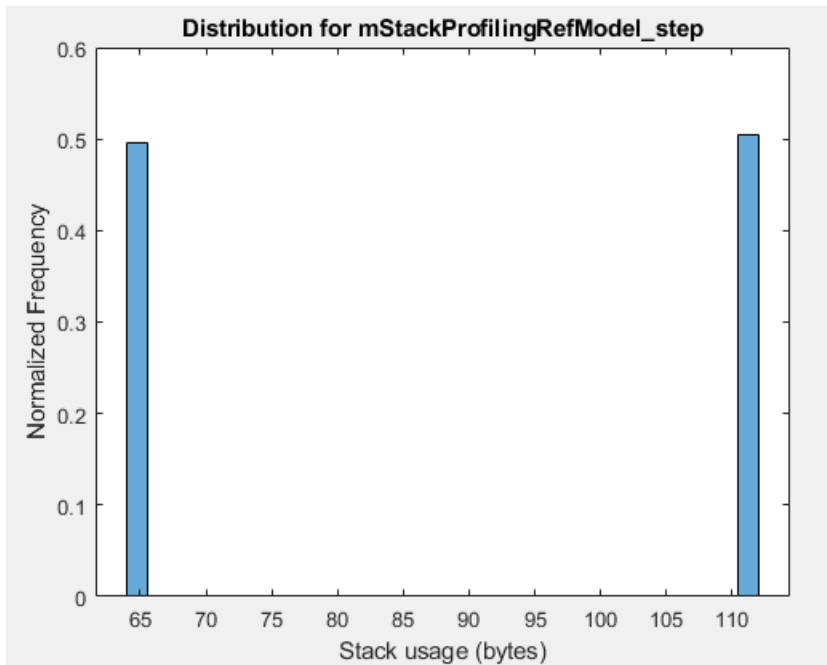

- Provides information that indicates how the target compiler views memory and aligns variables.
- States whether a target-specific or generic driver obtained stack usage data from the target hardware.
- Provides a timestamp for the report.

For each task, section 2 of the report provides this information:

- Minimum, average, and maximum stack usage in bytes.
- Number of times that the generated code is called.

The report provides more information through clickable icons. The specified workspace variable, for example, `stackProfile`, must be present in the base workspace.

If you click , you can view the stack usage distribution for the simulation.

If you click , you can view the variation of stack usage over the simulation.

Stack memory usage for `mStackProfilingRefModel_step` fluctuates between 112 and 64 bytes. The fluctuation occurs because the nested function generated from the If Action Subsystem block is called by `mStackProfilingRefModel_step` only when the signal `previous_output` has an even value.

```

...
if ((int32_T)(uint8_T)((int32_T)rtb_previous_output % 2) == 0) {
 /* Outputs for IfAction SubSystem: '<Root>/If Action Subsystem' incorporates:
 * ActionPort: '<S1>/Action Port'
 */

 /* Outputs for Atomic SubSystem: '<S1>/Subsystem' */
 Subsystem(rtb_previous_output, &rtY.Out1);

 /* End of Outputs for SubSystem: '<S1>/Subsystem' */
 /* End of Outputs for SubSystem: '<Root>/If Action Subsystem' */
}
...

```

If you specify a value for **Maximum stack size (bytes)** (`MaxStackSize`), the report provides Section 3. This section displays the maximum stack use for each task with reference to the maximum stack size permitted, which the bar chart displays as a horizontal red line. If the `MaxStackSize` value is much greater than the stack usage of the tasks, the bar chart does not display the red line. To help your visual analysis of stack usage requirements, you can use the `MaxStackUsageAllowed` property of the workspace variable to respecify the maximum stack size value. For example:

```

stackProfile.MaxStackUsageAllowed = 64;
report(stackProfile);

```

## Implement Driver to Obtain Stack Usage Data During PIL Simulation

A PIL simulation requires a driver implementation that obtains stack usage data from the target hardware. The driver must return the value of the stack register.

---

**Note** If you do not specify a driver for your target hardware, the PIL simulation tries to use a default generic driver.

---

When you set up PIL target connectivity, specify the driver through an `rtw.connectivity.Config` subclass. This code provides an example.

```
classdef overheadConnectivityConfig < rtw.connectivity.Config
 methods
 function this = customConnectivityConfig(componentArgs)

 % Create builder
 targetApplicationFramework = ...
 mypil.TargetApplicationFramework(componentArgs);
 builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
 targetApplicationFramework, '');

 % Create launcher
 launcher = mypil.Launcher(componentArgs, builder);

 % Set up communication
 hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(...
 componentArgs, ...
 launcher, ...
 rtiostreamLibTCPIP);

 % Call super class constructor to register components
 this@rtw.connectivity.Config(componentArgs,...
 builder,...
 launcher,...
 hostCommunicator);

 % Specify driver implementation that obtains stack usage
 % data from the target hardware
 stackUsageDriver = coder.profile.StackDriver();

 stackUsageDriver.ptrDataType = 'uint64';
 stackUsageDriver.headerFile = 'myHeaderFile.h';
 stackUsageDriver.SourceFile = 'mySourceFile.c';
 stackUsageDriver.IncludePaths = {'path/To/myFolder1', ...
 'path/To/myFolder2', ...
 'path/To/myFolder3'};

 stackUsageDriver.driverFunction = 'myDriverFunction';
 this.setStackDriver(stackUsageDriver);
 end
 end
end
```

For more information about setting up PIL target connectivity, see:

- “Create PIL Target Connectivity Configuration for Simulink” on page 82-40

- “Create PIL Target Connectivity Configuration for MATLAB” on page 84-12

## Execution Time Profiling for SIL and PIL

During a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, you can produce a profile of execution times for code generated from entry-point functions. The software calculates execution times from data that is obtained through instrumentation probes added to the SIL or PIL application.

Use the execution time profile to check whether your code runs within the required time on your target hardware:

- If code execution overruns, look for ways to reduce execution time.
- If your code easily meets time requirements, consider enhancing functionality to exploit the unused processing power.

At the end of the SIL or PIL execution, you can:

- View a report of code execution times.
- Use the Simulation Data Inspector to view and compare plots of function execution times.
- Access and analyze execution time profiling data.

### See Also

#### Related Examples

- “Analyze Execution Time Data” on page 77-9

## Generate Execution Time Profile

Before running a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, enable execution time profiling:

- 1 To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
- 2  To open your project, click  and then click **Open existing project**. Select the project.
- 3 On the **Generate Code** page, click **Verify Code**.
- 4 Select the **Enable entry point execution profiling for SIL/PIL** check box.
- 5 If you also want to generate execution time profiles for functions that are called within entry-point functions, select the **Enable function execution profiling** check box.

---

**Note** Function profiling does not support the OpenMP library. Before you generate code, on the **Generate Code** page, click the arrow next to **Generate**. Then, click **More Settings**. Under **Advanced**, set **Enable OpenMP library if possible** to No.

On a Mac operating system, SIL and PIL execution does not support execution-time profiling for functions that are called within entry-point functions.

---

Or, from the Command Window, specify properties of your `coder.EmbeddedCodeConfig` object. For example:

```
% Enable entry point execution profiling
config.CodeExecutionProfiling = true;

% Enable function execution profiling
config.CodeProfilingInstrumentation = true;

% Disable OpenMP
config.EnableOpenMP = false;
```

### More About

- “Execution Time Profiling for SIL and PIL” on page 77-2

## View Execution Times

### In this section...

“Code Execution Profiling Report” on page 77-4

“Visualize Task Scheduling” on page 77-8

You can run a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution that produces execution-time metrics for tasks and functions in your generated code. During execution, you can use the Simulation Data Inspector to observe streamed execution times. When execution is complete, you can:

- View execution-time metrics for a profiled entry-point function.
- Open a report of execution-time metrics for all profiled functions. Through report icons, you can view, for example, the profiled code section and the execution-time distribution for each profiled function.
- Use the Simulation Data Inspector to plot and compare execution times from various execution runs.

### Code Execution Profiling Report

When you run a SIL or PIL execution with execution time profiling enabled, the software generates a message in the **Test Output** tab. For example:

```
Current plot held
Starting SIL execution for 'euclidean'
 To terminate execution: clear euclidean_sil
 Execution profiling data is available for viewing. Go to Simulation Data Inspector.
 Execution profiling report available after termination.
```

To observe streamed execution times while the execution runs, click the [Simulation Data Inspector](#) link.

To open the code execution profiling report:

- 1 Click the `clear euclidean_sil` link.

The software terminates the execution process and displays a new link.

```
Stopping SIL execution for 'euclidean'
 Execution profiling report: report(getCoderExecutionProfile('euclidean'))
```

- 2 Click the new link.

The report contains these sections:

- 1 **Summary**

This section gives information about the creation of the report.

## 1. Summary

Total time	105583
Unit of time	ns
Command	report('Units', 'seconds', 'ScaleFactor', '1e-09', 'NumericFormat', '%0.0f');
Timer frequency (ticks per second)	3.6e+09
Profiling data created	01-Dec-2021 19:33:56

## 2 Profiled Sections of Code

This section contains information about profiled code sections. In the **Section** column, expand and collapse profiled sections by clicking [+] and [-] respectively. This graphic shows fully expanded sections.

### 2. Profiled Sections of Code

Section	Maximum Execution Time in ns	Average Execution Time in ns	Maximum Self Time in ns	Average Self Time in ns	Calls	
<a href="#">euclidean_initialize</a>	155	155	155	155	1	 
[-] <a href="#">euclidean</a>	52841	52631	27382	27242	2	   
<a href="#">fabs</a>	126	124	126	124	2	  
<a href="#">fabs</a>	27	26	27	26	2	  
<a href="#">fabs</a>	27	26	27	26	2	  
<a href="#">sqrt</a>	428	322	428	322	2	  
<a href="#">fabs</a>	183	30	183	30	430	  
<a href="#">fabs</a>	42	27	42	27	430	  
<a href="#">fabs</a>	32	27	32	27	430	  
<a href="#">sqrt</a>	67	32	67	32	430	  
<a href="#">euclidean_terminate</a>	166	166	166	166	1	 

The report contains time measurements for:

- The *entry\_point\_fn\_initialize* function, for example, `euclidean_initialize`.
- The entry-point function, for example, `euclidean`.
- The *entry\_point\_fn\_terminate* function, for example, `euclidean_terminate`.

By default, the report displays time in nanoseconds ( $10^{-9}$  seconds). You can specify the time unit and numeric display format. For example, to display time in microseconds ( $10^{-6}$  seconds), use the report command:

```
% Create workspace variable
executionProfile=getCoderExecutionProfile('kalman01');

report(executionProfile, ...
 'Units', 'Seconds', ...
```

```
'ScaleFactor', '1e-06', ...
'NumericFormat', '%0.3f')
```

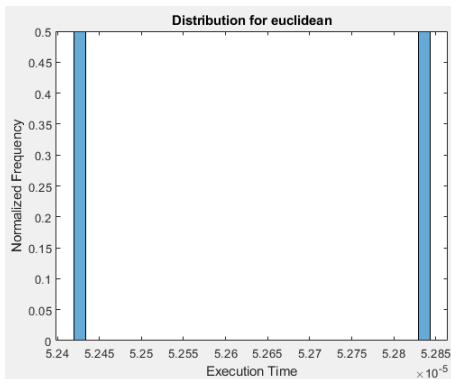

The report displays time in seconds only if the timer is calibrated, that is, the number of timer ticks per second is known. On a Windows machine, the software determines this value for a SIL simulation. On a Linux machine, you must manually calibrate the timer. For example, if your processor speed is 1 GHz, specify the number of timer ticks per second:

```
executionProfile.TimerTicksPerSecond = 1e9;
```

To view execution-time metrics for a code section in the Command Window, on the corresponding row, click the icon .

To display measured execution times, click the Simulation Data Inspector icon . You can use the Simulation Data Inspector to manage and compare plots from various executions.

To display the execution-time distribution, click the icon .

In this example, to create the histogram, the software uses these commands:

```
executionProfile=getCoderExecutionProfile('kalman01')
section=executionProfile.Sections(2);
data=section.ExecutionTimeInSeconds;
histogram(data, 30,'Normalization','probability');
```

The software creates the histogram only if the number of calls to the function is greater than one.

If the generated code contains nested functions, the execution generates pie charts that show the relative execution times of caller and called functions. To display the pie charts, click the icon  for the caller function.

The following table lists the information provided in the code section profiles.

Column	Description
Section	Name of function from which code is generated.
Maximum Execution Time	Longest time between start and end of code section.
Average Execution Time	Average time between start and end of code section.

Column	Description
Maximum Self Time	Maximum execution time, excluding time in child sections.
Average Self Time	Average execution time, excluding time in child sections.
Calls	Number of calls to the code section.
	Icon that you click to display the profiled code section.
	Icon that you click to display measured execution times with Simulation Data Inspector.
	Icon that you click to display the execution-time distribution for the profiled code section.
	Icon that you click to display pie charts that show the relative execution times of caller and called functions in the generated code.

### 3 Execution Times in Percentages

This section provides function execution times as percentages of caller function and total execution times, which can help you to identify performance bottlenecks in generated code.

#### 3. Execution Times in Percentages [\[hide\]](#)

Section	Self Time / Caller Function	Self Time / Task	Self Time / Simulation	Function / Simulation
<a href="#">euclidean_initialize</a>	100%	100%	0.1468%	0.1468%
[ - ] <a href="#">euclidean</a>	51.761%	51.761%	51.604%	99.696%
<a href="#">fabs</a>	0.23539%	0.23539%	0.23468%	0.23468%
<a href="#">fabs</a>	0.049612%	0.049612%	0.049461%	0.049461%
<a href="#">fabs</a>	0.049084%	0.049084%	0.048935%	0.048935%
<a href="#">sqrt</a>	0.61117%	0.61117%	0.60932%	0.60932%
<a href="#">fabs</a>	12.094%	12.094%	12.057%	12.057%
<a href="#">fabs</a>	11.086%	11.086%	11.052%	11.052%
<a href="#">fabs</a>	11.109%	11.109%	11.075%	11.075%
<a href="#">sqrt</a>	13.006%	13.006%	12.966%	12.966%
<a href="#">euclidean_terminate</a>	100%	100%	0.1568%	0.1568%

This table describes the information that each column provides.

Column	Comparison Performed
<b>Self Time / Caller Function</b>	Function self time compared with the total execution time of the caller function.
<b>Self Time / Task</b>	Function self time compared with the total execution time of the task.
<b>Self Time / Simulation</b>	Function self time compared with the total execution time.
<b>Function / Simulation</b>	Function execution time, which includes self time and time spent in child functions, compared with the total execution time.

## 4 Definitions

This section provides descriptions of some metrics.

### 4. Definitions

**Execution Time:** Time between start and end of code section.

**Self Time:** Execution time, excluding time in child sections.

## Visualize Task Scheduling

You can use the Simulation Data Inspector to visualize task scheduling and the order of function calls. At the end of the execution, run the `schedule` function. For more information, see “Visualize Task Scheduling”.

## See Also

### Related Examples

- “Generate Execution Time Profile” on page 77-3

- Simulation Data Inspector

## Analyze Execution Time Data

After a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, you can analyze execution-time data using methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes.

In the following example, you run a SIL execution and apply supplied methods to execution-time data.

### Extract Execution Time Data for Kalman Estimator Code

#### 1 Run SIL execution to generate execution time data

Copy MATLAB code to your working folder.

```
src_dir = ...
 fullfile(docroot, 'toolbox', 'coder', 'examples', 'kalman');

copyfile(fullfile(src_dir, 'kalman01.m'), '.')
copyfile(fullfile(src_dir, 'test01_ui.m'), '.')
copyfile(fullfile(src_dir, 'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir, 'position.mat'), '.')
```

For a description of the Kalman estimator, see “Generate C Code at the Command Line”.

Create a `coder.EmbeddedCodeConfig` object.

```
config = coder.config('lib');
config.GenerateReport = true; % HTML report
```

Configure the object for SIL and enable execution time profiling.

```
config.VerificationMode = 'SIL';
config.CodeExecutionProfiling = true;
```

If you want to generate execution time profiles for functions that are called within entry-point functions, you must also disable the OpenMP library.

```
config.CodeProfilingInstrumentation = true;
config.EnableOpenMP = false;
```

On a Mac operating system, SIL and PIL execution does not support execution-time profiling for functions that are called within entry-point functions.

Generate library code for the `kalman01` MATLAB function and the SIL interface.

```
codegen('-config', config, '-args', {zeros(2,1)}, 'kalman01');
```

Run the MATLAB test file `test01_ui` with `kalman01_sil`. `kalman01_sil` is the SIL interface for `kalman01`.

```
coder.runTest('test01_ui', ['kalman01_sil.' mexext]);
```

You see the following message.

```
Starting SIL execution for 'kalman01'
To terminate execution: clear kalman01_sil
Execution profiling data is available for viewing. Go to Simulation Data Inspector.
```

Execution profiling report available after termination.  
Current plot released

Terminate the SIL execution process. Click the link `clear kalman01_sil`.

```
Stopping SIL execution for 'kalman01'
Execution profiling report: report(getCoderExecutionProfile('kalman01'))
```

## 2 Create workspace variable that holds execution time data

Use the `getCoderExecutionProfile` function to create a workspace variable that holds execution time profiling data.

```
executionProfile=getCoderExecutionProfile('kalman01');
```

## 3 Extract code sections

Use the `Sections` method.

```
allSections = executionProfile.Sections
```

The software displays the number of code sections and a list of properties.

```
allSections =
 1x3 ExecutionTimeTaskSection array with properties:
 Name
 Number
 ExecutionTimeInTicks
 SelfTimeInTicks
 TurnaroundTimeInTicks
 TotalExecutionTimeInTicks
 TotalSelfTimeInTicks
 TotalTurnaroundTimeInTicks
 MaximumExecutionTimeInTicks
 MaximumExecutionTimeCallNum
 MaximumSelfTimeInTicks
 MaximumSelfTimeCallNum
 MaximumTurnaroundTimeInTicks
 MaximumTurnaroundTimeCallNum
 NumCalls
 ExecutionTimeInSeconds
 Time
```

## 4 Extract execution time data from specific code section

Specify the code section that you want to examine.

```
secondSectionProfile = executionProfile.Sections(2)
```

The software displays profile data for the code section.

```
secondSectionProfile =
 ExecutionTimeTaskSection with properties:
 Name: 'kalman01'
 Number: 2
 ExecutionTimeInTicks: [1x300 uint64]
 SelfTimeInTicks: [1x300 uint64]
 TurnaroundTimeInTicks: [1x300 uint64]
 TotalExecutionTimeInTicks: 6641016
 TotalSelfTimeInTicks: 6641016
 TotalTurnaroundTimeInTicks: 6641016
 MaximumExecutionTimeInTicks: 48864
 MaximumExecutionTimeCallNum: 158
 MaximumSelfTimeInTicks: 48864
 MaximumSelfTimeCallNum: 158
```

```

MaximumTurnaroundTimeInTicks: 48864
MaximumTurnaroundTimeCallNum: 158
 NumCalls: 300
ExecutionTimeInSeconds: [1x300 double]
 Time: [300x1 double]

```

You can extract specific properties, for example, the name of a profiled function.

```
nameOfSection = secondSectionProfile.Name
```

The software displays the name.

```
nameOfSection =
'kalman01'
```

The following table lists the information that you can extract from each code section.

Property	Description
Name	Name of entry-point function
Number	Code section number
ExecutionTimeInTicks	Vector of execution times, measured in timer ticks. Each element contains the difference between the timer reading at the start and at the end of the code section. The data type is the same data type as the data type of the timer used on the target, which allows you to infer the maximum range of the timer measurements.
SelfTimeInTicks	Vector of timer tick numbers. Each element contains the number of ticks recorded for the code section, excluding the time spent in calls to child functions.
TurnaroundTimeInTicks	Vector of timer tick numbers. Each element contains the number of ticks recorded between the start and the finish of the code section. Unless the code is preempted, this number is the same number as the execution time.
TotalExecutionTimeInTicks	Total number of timer ticks recorded for the code section over the entire execution.
TotalSelfTimeInTicks	Total number of timer ticks recorded for the profiled code section over the entire execution. However, this number excludes the time spent in calls to child functions.
TotalTurnaroundTimeInTicks	Total number of timer ticks recorded between the start and the finish of the profiled code section over the entire execution. Unless the code is preempted, this number is the same as the total execution time.
MaximumExecutionTimeInTicks	Maximum number of timer ticks recorded for a single invocation of the code section over the execution.
MaximumExecutionTimeCallNum	Number of call in which MaximumExecutionTimeInTicks occurs.
MaximumSelfTimeInTicks	Maximum number of timer ticks recorded for a single code section invocation, but excluding the time spent in calls to child functions.
MaximumSelfTimeCallNum	Number of call in which MaximumSelfTimeInTicks occurs.

Property	Description
MaximumTurnaroundTimeInTicks	Maximum number of timer ticks recorded between the start and the finish of a single invocation of the profiled code section over the execution. Unless the code is preempted, this time is the same as the maximum execution time.
MaximumTurnaroundTimeCallNum	Number of call in which MaximumTurnaroundTimeInTicks occurs.
NumCalls	Total number of calls to the code section over the entire execution.
ExecutionTimeInSeconds	Vector of execution times, measured in seconds. Each element contains the difference between the timer reading at the start and at the end of the code section. Produced only if TimerTicksPerSecond is set.
Time	Vector of execution time measurements for the code section.

- Simulation Data Inspector

## Stack Usage Profiling for Code Generated From MATLAB Code

To determine the size of stack memory that is required to run generated code, you can run a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution that generates a stack usage profile. The SIL or PIL execution instruments the generated code and uses the instrumentation to calculate stack usage. When the execution is complete, you can view a code stack profiling report that shows minimum, average, and maximum memory demand. Using the Simulation Data Inspector, you can observe streamed stack usage information during and after the execution. The profiles that you generate enable you to observe the effect of compiler optimization and data input on stack usage.

### Benefits of Dynamic Stack Usage Profiling

Static stack usage analysis has some limitations. For example, it does not consider:

- Memory optimization performed by a compiler. For example, variables that are optimized away or stored in registers.
- Additional memory that the compiler uses in a function call. Compilers store the address to which the execution returns after the function call.
- Memory alignment that the compiler applies.

The dynamic stack usage profiling provided by a SIL or PIL execution does not have the listed limitations because the execution calculates actual memory usage.

### Generate Stack Usage Profile

Before running a software-in-the-loop on page 84-4 or processor-in-the-loop (PIL) on page 84-23 execution, enable stack usage profiling:

- 1 To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** , under **Code Generation**, click the app icon.
- 2 To open your project, click  and then click **Open existing project**. Select the project.
- 3 On the **Generate Code** page, click the arrow next to **Generate**.
- 4 In the Generate dialog box:
  - a Click **More Settings**.
  - b Click **Debugging**.
  - c Under **SIL/PIL**, select the **Enable entry point stack profiling** check box.
  - d Click **Close**.
  - e Click **Generate**.

---

**Note** Stack usage profiling does not support the OpenMP library. Before you generate code, on the **Generate Code** page, click the arrow next to **Generate**. Then, click **More Settings**. Under **Advanced**, set **Enable OpenMP library if possible** to **No**.

---

Or, from the Command Window, specify properties of your coder.EmbeddedCodeConfig object. For example:

```
% Enable entry point stack usage profiling
config.CodeStackProfiling = true;

% Disable OpenMP
config.EnableOpenMP = false;
```

## View Stack Usage Profile From SIL Execution

For a MATLAB function, perform a software-in-the-loop execution that generates stack usage measurements and then use the data to determine stack memory requirements.

In your local working folder, create the function `foo.m`, which evaluates an integer factorial by using a recursive function.

```
function out = foo(in)
 coder.inline('never');
 out = factorial_(in);
end

function out = factorial_(in)
 coder.inline('never');
 if in == 1
 out = 1;
 else
 out = in * factorial_(in-1);
 end
end
```

Configure stack usage profiling for the SIL execution.

```
config = coder.config('lib');
config.GenerateReport = true;
config.VerificationMode = 'SIL';
config.CodeStackProfiling = true;
config.EnableOpenMP = false;
```

In the folder, create `test_example.m`, a MATLAB script that calls the compiled function multiple times.

```
for idx = 1: size(X,1)
 Y(idx,1) = foo(X(idx,1));
end
```

Create a test vector of integers.

```
X=[1 2 5 8]';
```

Generate library code for the `foo` MATLAB function and the SIL interface and start the SIL execution.

```
codegen -report -config config foo -args {1} -test test_example
```

Code generation successful: [View report](#)

```
Running test file: 'test_example' with MEX function 'foo_sil.mexw64'.
Starting SIL execution for 'foo'
 To terminate execution: clear foo_sil
 Stack profiling data is available for viewing. Open Simulation Data Inspector.
 Stack profiling report available after termination.
```

To observe streamed stack usage measurements while the execution runs, click the [Simulation Data Inspector](#) link.

To open the code stack profiling report, terminate the SIL execution process by clicking the link `clear foo_sil`.

```
Application stopped
Stopping SIL execution for 'foo'
 Stack profiling report: report(getCoderStackProfile('foo'))
```

Then, click the link `report(getCoderStackProfile('foo'))`.

You can create a workspace variable that holds the execution time data.

```
stackUsageProfile= getCoderStackProfile('foo');
```

If you close the report, you can reopen the report by running:

```
report(stackUsageProfile)
```

## Code Stack Profiling Report for foo

The code stack profiling report provides metrics based on data collected from a SIL or PIL execution. Stack usage is calculated from data recorded by instrumentation probes added to the SIL or PIL test harness and inside the code generated for each component. See [Code Stack Profiling](#) for more information.

### 1. Summary

Largest atomic integer type	Char
Word size (bits)	64
Pointer size (bits)	64
Maximum stack (bytes)	200000
Stack driver	Target specific
Profiling data created	28-Oct-2021 12:15:19

### 2. Profiled Tasks

Task	Minimum Stack Usage in bytes	Average Stack Usage in bytes	Maximum Stack Usage in bytes	Calls	
<a href="#">foo_initialize</a>	48	48	48	1	
<a href="#">foo</a>	112	304	560	4	 
<a href="#">foo_terminate</a>	48	48	48	1	

Section 1:

- Provides information that indicates how the target compiler views memory and aligns variables.
- States whether a target-specific or generic driver obtained stack usage data from the target hardware.
- Provides a timestamp for the report.

Section 2 provides, for each task, this information:

- Minimum, average, and maximum stack usage in bytes.
- Number of times the generated code is called.

The report provides more information through clickable icons. The workspace variable, for example, `stackUsageProfile`, must be present in the base workspace.

If you click , you can view the stack usage distribution for the execution.

If you click , you can view the variation of stack usage over the execution.

The integer value of the input argument for `foo` increases with successive calls to the function. As the integer value increases, the number of recursive calls to the function `factorial_()` also increases, which results in the observed increases of stack memory usage.

Section 3 displays the maximum stack use for each task with reference to the maximum stack size permitted. In the SIL or PIL execution, the MATLAB Coder configuration setting `StackUsageMax` parameter specifies the maximum stack size, which the bar chart displays as a horizontal red line. If the `StackUsageMax` value is much greater than the stack usage of the tasks, the bar chart does not display a red line. To help your visual analysis of stack usage requirements, you can use the `MaxStackUsageAllowed` property of the workspace variable to respecify the maximum stack size value. For example:

```
stackUsageProfile= getCoderStackProfile('foo');
stackUsageProfile.MaxStackUsageAllowed = 550;
report(stackUsageProfile);
```

## Implement Driver to Obtain Stack Usage Data During PIL Execution

A PIL execution requires a driver implementation that obtains stack usage data from the target hardware. The driver must return the value of the stack register.

---

**Note** If you do not specify a driver for your target hardware, the PIL execution tries to use a default generic driver.

---

When you set up PIL target connectivity, specify the driver through an `rtw.connectivity.Config` subclass. This code provides an example.

```
classdef overheadConnectivityConfig < rtw.connectivity.Config
 methods
```

```

function this = customConnectivityConfig(componentArgs)

 % Create builder
 targetApplicationFramework = ...
 mypil.TargetApplicationFramework(componentArgs);
 builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
 targetApplicationFramework, '');

 % Create launcher
 launcher = mypil.Launcher(componentArgs, builder);

 % Set up communication
 hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(...
 componentArgs, ...
 launcher, ...
 rtiostreamLibTCPIP);

 % Call super class constructor to register components
 this@rtw.connectivity.Config(componentArgs,...
 builder,...
 launcher,...
 hostCommunicator);

 % Specify driver implementation that obtains stack usage
 % data from the target hardware
 stackUsageDriver = coder.profile.StackDriver();

 stackUsageDriver.ptrDataType = 'uint64';
 stackUsageDriver.headerFile = 'myHeaderFile.h';
 stackUsageDriver.SourceFile = 'mySourceFile.c';
 stackUsageDriver.IncludePaths = {'path/To/myFolder1', ...
 'path/To/myFolder2', ...
 'path/To/myFolder3'};

 stackUsageDriver.driverFunction = 'myDriverFunction';
 this.setStackDriver(stackUsageDriver);
end
end
end

```

For more information about setting up PIL target connectivity, see:

- “Create PIL Target Connectivity Configuration for Simulink” on page 82-40
- “Create PIL Target Connectivity Configuration for MATLAB” on page 84-12

## See Also

`coder.profile.StackDriver`

## Related Examples

- “Software-in-the-Loop Execution with the MATLAB Coder App” on page 84-4

## Removal of Unused Class Properties in the Generated C/C++ Code

C/C++ code generated by Embedded Coder contains unused class properties or structure fields. Removing unused properties or fields helps improve the memory footprint and run time of the code. By default, the code generator removes properties or fields that are unused in the generated C/C++ code.

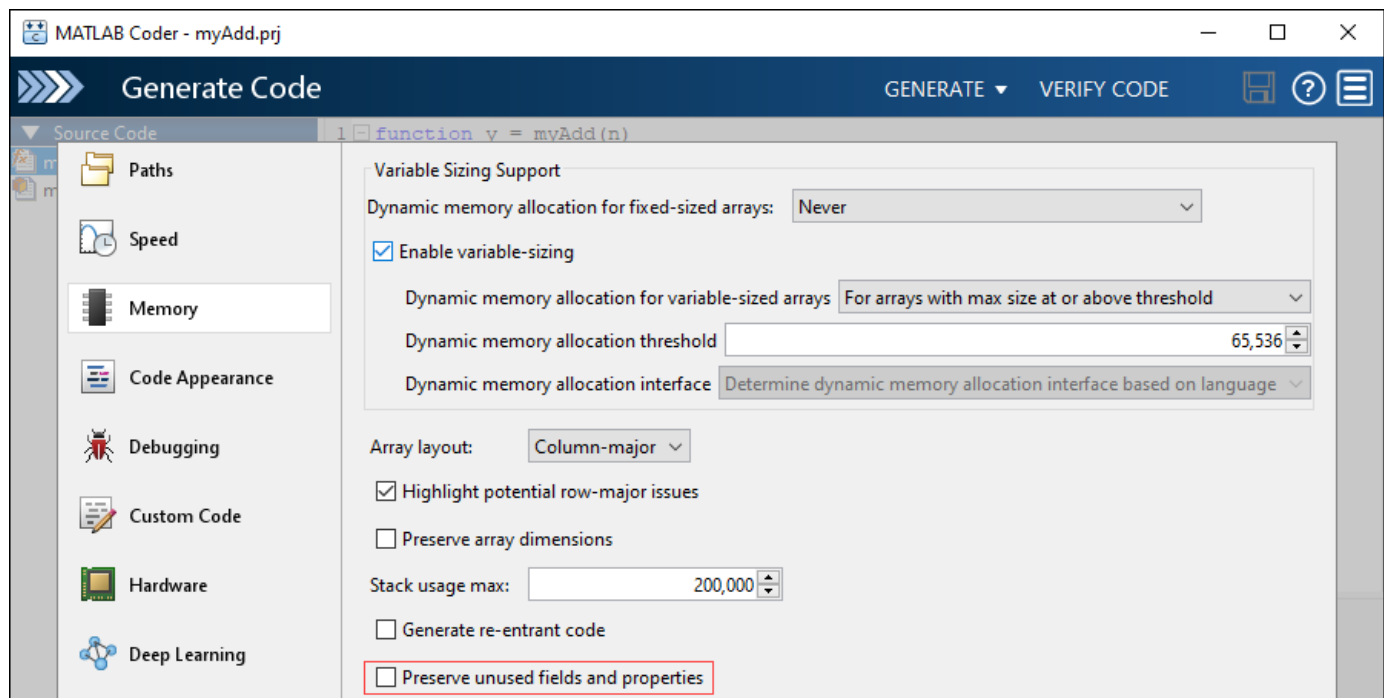

To preserve the unused properties or fields, set the configuration parameter `PreserveUnusedStructFields` to `true`.

The `PreserveUnusedStructFields` configuration option applies to standalone code generation.

### Preserve Unused Class Properties by using MATLAB Coder App

To preserve unused properties or fields:

- 1 Open the MATLAB Coder App.
- 2 On the **Generate Code** page, click **More Settings**.
- 3 On the **Memory** tab, select the **Preserve unused fields and properties** check box.

### Preserve Unused Class Properties at the Command Line

You can preserve the unused properties or fields at the command-line interface:

```
cfg = coder.config('lib');
cfg.PreserveUnusedStructFields = true;
```

For example, consider the MATLAB class `myClass` and the entry point function `myAdd`.

```
classdef myClass
 properties
 a
 b
 c
 end

 methods
 function obj = myClass(x)
 coder.inline('never')
 obj.a = x;
 obj.b = x + 1;
 obj.c = x + 2;
 end
 end
end

function y = myAdd(n)
 %#codegen
 o = myClass(n);
 y = o.a + o.b; % class property 'c' is unused
end
```

At the MATLAB command line, run this `codegen` command:

```
codegen myAdd -args {5} -config cfg -lang:C++ -report
```

Open the code generation report to see the generated code. The unused property `c` is preserved in the generated code.

```
class myClass {
 public:
 void init(double x);
 double a;
 double b;
 double c;
};
```

## Usage Notes and Limitations

- When `PreserveUnusedStructFields` is set to `false`, the code generator preserves properties or fields of the entry-point function input and output arguments and values passed to `coder.ceval`.
- When `PreserveUnusedStructFields` is set to `true`, the code generator removes properties or fields whose data types are unknown.
- The class properties or structure fields are preserved when properties or fields are assigned but not used.

# Simulation and Code Comparison in Simulink Coder

---

## Simulation and Code Comparison

### In this section...

“Configure Signal Data for Logging” on page 78-2

“Log Simulation Data” on page 78-3

“Run Executable and Load Data” on page 78-4

“Visualize and Compare Results” on page 78-5

“Compare States for Simulation and Code Generation” on page 78-7

This example shows how to verify the answers computed by code generated from the `slexAircraftExample` model. It shows how to capture and compare two sets of output data. Simulating the model produces one set of output data. Executing the generated code produces a second set of output data.

**Note** To obtain a valid comparison between model output and the generated code, use the same **Solver selection** and **Step size** for the simulation run and the build process.

### Configure Signal Data for Logging

Configure the model for logging and recording signal data.

- 1 Make sure that `slexAircraftExample` is closed. Clear the base workspace to eliminate the results of previous simulation runs. In the Command Window, type:

```
clear
```

The clear operation clears variables created during previous simulations and all workspace variables, some of which are standard variables that the `slexAircraftExample` model requires.

- 2 To open the model, in the Command Window, enter:

```
openExample('slexAircraftExample')
```

- 3 In the model window, choose **File > Save As**, navigate to the working folder, and save a copy of the `slexAircraftExample` model as `myAircraftExample`.
- 4 Set up your model to log signal data for signals: `Stick`, `alpha`, `rad`, and `q`, `rad/sec`. For each signal:
  - a Right-click the signal. From the context menu, select **Properties**.
  - b In the Signal Properties dialog box, select **Log signal data**.
  - c In the **Logging name** section, from the drop-down list, select **Custom**.
  - d In the text field, enter the logging name for the corresponding signal.

Signal Name	Logging Name
Stick	Stick_input
alpha, rad	Alpha

Signal Name	Logging Name
q, rad/sec	Pitch_rate

- e Click **Apply** and **OK**.

For more information, see “Export Signal Data Using Signal Logging”.

- 5 In the Configuration Parameters dialog box:
  - a Set **Type** to Fixed-step.
  - b Set **Format** to Structure with time.
  - c Clear the **States** check box.
  - d Select the **Signal logging** check box.
  - e Select the **Record logged workspace data in Simulation Data Inspector** check box.
- 6 Save the model.

Proceed to “Log Simulation Data” on page 78-3.

## Log Simulation Data

Run the simulation, log the signal data, and view the data in the Simulation Data Inspector.

- 1 Run the model. When the simulation is done, on the Simulink Editor toolbar, the **Simulation Data Inspector** button is highlighted to indicate that new simulation output is available in the Simulation Data Inspector.

- 2 Click the **Simulation Data Inspector** button to open the Simulation Data Inspector.
- 3 Group the signals:
  - a On the **Visualize** tab, click **Group Signals**.
  - b In the Group Signals dialog box, select Data Hierarchy from the **Then By** list.

- c Click **OK**.

- 4 Click the **Logout** expander to view the logged signals.
- 5 Click the **Format** tab.
- 6 Click the **Subplots** button and select 3x1 to show three subplots.
- 7 For each signal:
  - a Click the top subplot. A blue border indicates the plot selection.
  - b Select the check box next to the Alpha signal name. The signal data appears in the subplot.
  - c Plot the Pitch\_rate signal in the middle subplot.
  - d Plot the Stick\_input signal in the bottom subplot.

Proceed to “Run Executable and Load Data” on page 78-4.

## Run Executable and Load Data

You must rebuild and run the `myAircraftExample` executable to obtain a valid data file because you have modified the model.

- 1 In the Configuration Parameters dialog box, set the **MAT-file variable name modifier** parameter to `rt_`. `rt_` is prefixed to each variable that you selected for logging in the first part of this example.
- 2 Click **Apply** and **OK**.
- 3 Save the model.
- 4 To generate code, on the **C Code** tab, click **Build** button.
- 5 When the build is finished, run the standalone program from the Command Window.

```
!myAircraftExample
```

The executing program writes the following messages to the Command Window.

```
** starting the model **
** created myAircraftExample.mat **
```

- 6 Load the data file `myAircraftExample.mat`.

```
load myAircraftExample
```

---

**Tip** For UNIX platforms, run the executable program in the Command Window with the syntax `!./executable_name`. If preferred, run the executable program from an OS shell with the syntax `./executable_name`. For more information, see “Run External Commands, Scripts, and Programs”.

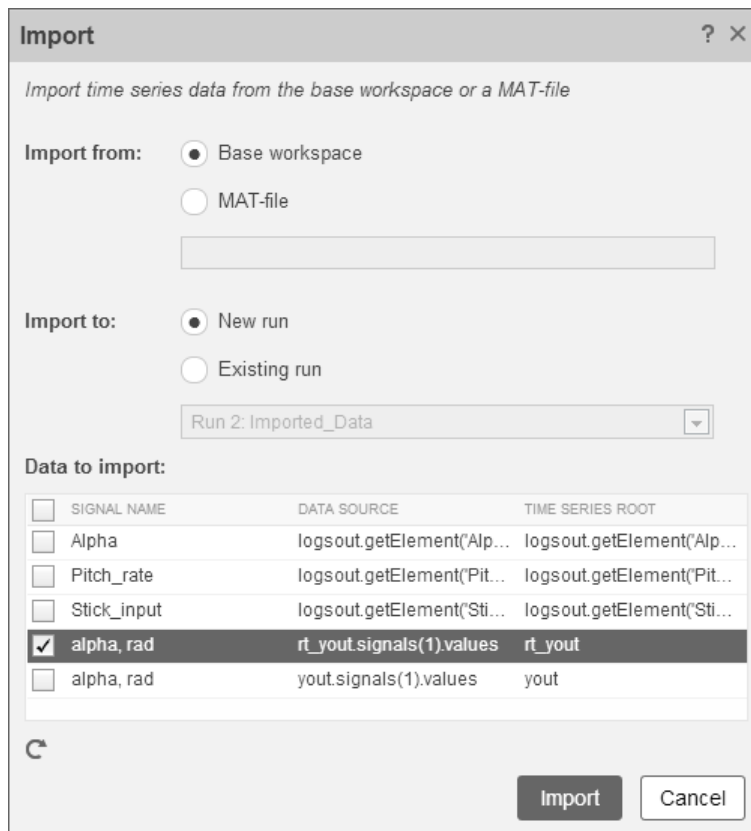

---

Proceed to “Visualize and Compare Results” on page 78-5.

## Visualize and Compare Results

When you follow the example sequence that began in “Configure Signal Data for Logging” on page 78-2, you obtain data from a Simulink run of the model and from a run of the program generated from the model.

- 1 To view the execution output for `alpha , rad`, import the data into the Simulation Data Inspector.
  - a On the Simulation Data Inspector **Visualize** tab, click the **Import** button to open the Import dialog.
  - b Specify **Import from** as **Base workspace**.
  - c Specify **Import to** as **New run**.
  - d To the left of **Signal Name**, click the check mark to clear the check boxes.
  - e Select the check box for the `alpha , rad` data where the **Time Series Root** is `rt_yout`.
  - f Click **Import**.

The selected data is now under **Run 2: Imported\_Data**.

- 2 View a plot of the executed data.
  - a Click the `rt_yout` expander.
  - b Click the top subplot and select the check box next to the `alpha, rad` signal name. The signal data appears in the top subplot.

The `alpha, rad` signal from Run 1 and Run 2 overlap in the subplot because the signals are equivalent.

It is possible to see a very small difference between simulation and code generation results. A slight difference can be caused by many factors, including:

- Different compiler optimizations
- Statement ordering
- Run-time libraries

For example, a function call such as `sin(2.0)` can return a slightly different value depending on which C library you use. Such variations can also cause differences between your results and these results.

## Compare States for Simulation and Code Generation

The order in which Simulink logs states during simulation is different than the order in which Simulink Coder logs states during code generation. If you want to compare states between simulation and code generation, sort the states by block name.

For example, by default, Simulink exports state data to the MATLAB variable, `xout`. Simulink Coder exports state data to the variable `rt_xout`. To sort the state data for these variables, enter the following commands in the MATLAB Command Window:

```
[~,idx1]=sort({xout.signals.blockName});
xout_sorted=[xout.signals(idx1).values];
[~,idx2]=sort({rt_xout.signals.blockName});
rt_xout_sorted=[rt_xout.signals(idx2).values];
```

You can confirm that the logging order is the same between code generation and simulation by entering the following command in the MATLAB Command Window:

```
isequal(xout_sorted, rt_xout_sorted)
```

# Code Tracing in Embedded Coder

---

- “Verify Generated Code by Using Code Tracing” on page 79-2
- “Trace Simulink Model Elements in Generated Code” on page 79-8
- “Trace Stateflow Elements in Generated Code” on page 79-12
- “Link Generated Code to Requirements” on page 79-24
- “Reload Existing Traceability Information” on page 79-28
- “Customize Traceability Reports” on page 79-30
- “Trace Generated Code to Blocks” on page 79-33
- “Use Traceability in MATLAB Function Blocks” on page 79-35

## Verify Generated Code by Using Code Tracing

Code tracing (traceability) uses hyperlinks to navigate between a line of generated code and its corresponding elements in a model. To find the lines of code and their corresponding elements, you can also right-click an element or elements in a model. This two-way navigation is *bidirectional* traceability.

Using code tracing, you can:

- Verify that generated code is as you expect. You can identify which model elements correspond to a line of code. You can track code from different elements that you have or have not reviewed.
- Verify that generated code meets the design requirements. You can link requirements to the model element and use code tracing to verify that the generated code for a model element meets the assigned requirements.

When you generate code from a Simulink model, traceability information is embedded in the generated code, unless explicitly unspecified. The traceability information includes links for tracing between the generated source code and the model. You can view the generated code by either the:

- “Code View” on page 79-3: View the generated code in the Code view of the Code perspective.
- “Code Generation Report” on page 79-4: View the generated code as an HTML report in the MATLAB web browser.

The generated code includes resources that support code tracing:

- Code element hyperlinks (indicated by underlining when you place your cursor over the code) to trace variables or types in the generated code to their declarations or definitions in the header files.
- Tags in code comments that identify elements in a model from which lines of code are generated.
- Line number hyperlinks that link to the model component from which the line of code was generated.

### Traceable Elements

Bidirectional traceability is supported for Simulink blocks and these Stateflow elements:

- States
- Transitions
- State transition tables
- MATLAB functions. Traceability is not supported for external code that you call from a MATLAB function.
- Truth table blocks
- Graphical functions
- Simulink functions

Traceability in one direction is supported for these Stateflow elements:

- Events (code-to-model)

Code-to-model traceability works for explicit events, but not implicit events. Clicking a hyperlink for an explicit event in the generated code highlights that item in the **Contents** pane of the Model Explorer.

- Junctions (model-to-code)

Model-to-code traceability works for junctions with at least one outgoing transition. Right-clicking such a junction in the Stateflow Editor highlights the line of code that corresponds to the first outgoing transition for that junction.

For more information, see “Trace Stateflow Elements in Generated Code” on page 79-12.

MATLAB Function blocks that you insert directly into a Simulink model are also traceable. For more information, see “Use Traceability in MATLAB Function Blocks” on page 79-35.

## Traceability in Generated Code

- “Code View” on page 79-3
- “Code Generation Report” on page 79-4

### Code View

- 1 Open the model `rtwdemo_comments`.
- 2 Open the Embedded Coder app. Build the model. On the **C Code** tab, click **Build**.

The HTML code generation report opens by default. To use the report, see “Code Generation Report” on page 79-4.

- 3 View the generated code in the Code view in the Code perspective.
- 4 Switch between the generated source files by using the drop-down list at the top of the Code view.
- 5 The source code contains traceability information such as hyperlinked comments, line numbers, variables, and operators. Place your cursor over or click a comment or line number hyperlink. The Simulink Editor highlights the corresponding block or blocks in the model.

The screenshot displays the Embedded Coder environment. On the left, the Simulink model 'rtwdemo\_comments' is shown. A 'Matrix Multiply' block is highlighted with a blue box. A blue callout box says 'Generate Code Using Embedded Coder (double-click)'. Below the model is the 'Code Mappings - C' table:

Model Element Category	Storage Class
Inports	Default
Outputs	Default
Model parameters	Default
Model parameter arguments	Default
External parameter objects	Default

On the right, the 'Code' window shows the generated C code for the 'Matrix Multiply' block. Line 64 is highlighted, showing the declaration of the 'indexed\_data' variable:

```

64 real_T indexed_data; /* '<Root>/Product'

```

- 6 To highlight the generated code for a block in the model, select the block. The generated code for the block is highlighted in the Code view.
- 7 To open the generated code for a referenced model, open the referenced model and view the generated code in the Code view.

### Code Generation Report

- 1 Open the model `rtwdemo_comments`.
- 2 Open the Embedded Coder app. On the **C Code** tab, click **Settings** to open the Configuration Parameters dialog box. Select **Create code generation report** if it is not already selected. By default, **Open report automatically**, **Code-to-model**, and **Model-to-code** are selected.
- 3 If your model contains referenced models and you want to enable traceability for the referenced model's code generation report, repeat the previous step for each referenced model.
- 4 Build the model. On the **C Code** tab, click **Build**. The build process opens the code generation report in a MATLAB web browser.
- 5 In the left navigation pane, select a source code file. The source code and line numbers in the right pane contain hyperlinks to blocks in the model.
- 6 Click a comment or line number hyperlink. The Simulink Editor displays and highlights the corresponding block or blocks in the model.

- 7 To highlight the generated code for a block in the model, right-click the block and select **C/C++ Code > Navigate to C/C++ Code**. The generated code for the block is then highlighted in the HTML code generation report. To highlight the generated code for multiple blocks that you select, hold the **SHIFT** key, select multiple blocks, and then right-click any one block to select **C/C++ Code > Navigate to C/C++ Code**. The generated code for the blocks is then highlighted in the HTML code generation report.
- 8 If you have a referenced model in your model, in the left navigation pane, under **Reference Models**, click the link to a referenced model. The code generation report for the referenced model is now displayed in the MATLAB web browser.
- 9 In the left navigation pane, you can click the **Back** button to go back to the previous code generation report.

## Traceability Tags

A traceability tag appears in a comment above the corresponding line of generated code. The format of the tag is `<system>/block_name`.

- *system* is one of the following:
  - The text Root
  - A unique system number assigned by the Simulink engine
- *block\_name* is the name of the source block.

The code generator documents the tags for a model in the comments section of the generated header file `model.h`. For example, this comment appears in the header file for a model, `foo`, that has a subsystem `Outer` and a nested subsystem `Inner`:

```

/* Here is the system hierarchy for this model.
 *
 * <Root> : foo
 * <S1> : foo/Outer
 * <S2> : foo/Outer/Inner
 */

```

This code shows a tag comment above the generated line of code. A Gain block at the root level of a source model generates this code:

```

/* Gain: '<Root>/UnDeadGain1' */
rtb_UnDeadGain1_h = dead_gain_U.In1 * dead_gain_P.UnDeadGain1_Gain;

```

This code shows a tag comment above the generated line of code. A Gain block within a subsystem one level below the root level of the source model generates this code:

```

/* Gain: '<S1>/Gain' */
dead_gain_B.temp0 *= (dead_gain_P.s1_Gain_Gain);

```

## Operator Traceability

The generated code provides traceability between operators in the generated code and Simulink blocks, Stateflow elements, or MATLAB Function blocks.

To verify the generated code by using operator traceability, in the generated code, click an operator hyperlink to highlight the source block in the model.

These operators are supported.

Operator Type	Operators
Arithmetic	+, -, *, /, % +=, -=, *=, /=, %= ++, -- (prefix and postfix)
Logical	!, &&,
Relational	==, !=, <, >, <=, >=
Bit	~,  , ^, &, >>, << &=, ^=,  =, <<=, >>=
Conditional	?:

These operators are not supported.

Operator Type	Operator Examples
Assignment operator	=
Member of and pointer operators	Array subscript: a[b] Address of and pointer dereference: &a, *a Member of: a.b, a->b
Other operators	Parenthesis in function call: foo(a, b) Comma: a, b

Operator Type	Operator Examples
	Scope resolution: <code>a : b</code>
	Cast: <code>type(a)</code>
	<code>new, new[]</code>
	<code>delete, delete[]</code>

## Traceability Limitations

These limitations apply to reports generated by Embedded Coder software:

- Under the following conditions, model-to-code traceability is disabled for a block if the block name contains:
  - A single quote (`'`).
  - An asterisk (`*`) that causes a name-mangling ambiguity relative to other names in the model. This name-mangling ambiguity occurs if in a block name or at the end of a block name, an asterisk precedes or follows a slash (`/`).
  - The character `ÿ` (`char(255)`).
- If a block name contains a newline character (`\n`), the generated code comment for the block path hyperlink replaces the newline character with a space for readability.
- You cannot trace blocks representing these types of subsystems to generated code:
  - Virtual subsystems
  - Masked subsystems
  - Nonvirtual subsystems for which code has been removed due to optimization

If you cannot trace a subsystem at subsystem level, you can trace individual blocks within the subsystem.

- If you open a model on a platform that is different from the platform used to generate code, you cannot use model-to-code and code-to-model traceability.
- Inline traceability is not available for files that are generated in `shared_utils` folder.

## See Also

### Related Examples

- “Trace Simulink Model Elements in Generated Code” on page 79-8
- “Trace Stateflow Elements in Generated Code” on page 79-12
- “Use Traceability in MATLAB Function Blocks” on page 79-35

## Trace Simulink Model Elements in Generated Code

To verify the generated code, Embedded Coder provides bidirectional traceability between the Simulink model and the generated code. You can use either method for traceability:

- Code-to-model: The generated code displays these hyperlinks in comment lines in the generated code:
  - Block/subsystems names
  - Line numbers
  - Operators

To highlight the corresponding block or subsystem in the Simulink Editor, click the hyperlinks.

- Model-to-code: You can select single or multiple blocks of a model in the Simulink Editor and navigate to the corresponding generated code.

---

**Note** The Code view in code perspective provides bidirectional traceability by default.

---

### Code-to-Model Traceability

To use hyperlinks for tracing code-to-model elements:

- 1 Open the model and configure it as an ERT target.
- 2 Build or generate code for the model. The Code view opens by default to display the generated code next to the model.
- 3 In the generated code, place your cursor over the block names in comments to highlight source blocks. For example, generate an HTML report for the model `rtwdemo_hyperlinks`. In the generated code for the model step function in `rtwdemo_hyperlinks.c`, place your cursor over the `UnitDelay: '<Root>/X'` block. In the model window, the corresponding `UnitDelay` block is highlighted.

The screenshot shows the Simulink environment with a model window on the left and a code window on the right. The model window displays a block diagram with an 'INC' block, a 'Sum' block, a '1/z' block, a 'Switch' block, a 'Constant' block, a 'Chart' block, and an 'Out1' block. The code window shows the generated C code for the 'Chart' block, with line 153 highlighted. The code includes comments for the chart's structure and state transitions.

To use line numbers for tracing code-to-model elements:

- 1 In the previous model, `rtwdemo_hyperlinks`, click the hyperlink at line number 153. The line numbers can differ from the numbers that appear in your generated code.
- 2 In the model window, the Chart subsystem is highlighted and contains the functionality on line 153.

### Traceability to Hidden Blocks

The code generator sometimes inserts hidden blocks during the code generation process for various reasons, for example, to maintain data integrity. Comments for the hidden blocks are included in the generated code. These comments, and the code generated from the hidden block, trace back to the original block in the model that triggered the insertion of the hidden block. Comments to hidden blocks follow this template:

```
/* <Hidden_Block_Type> generated from: <Hyperlinked_Original_Block_Name> */
```

For example,

```
/* SignalConversion generated from: '<Root>/Subsystem' */
Varianttground_B.VM_Conditional_Signal_Subsystem_0 = 0.0;
```

The hidden block SignalConversion is not present in the model. You can trace to the '<Root>/Subsystem' block in the model that triggered the insertion of the hidden block by clicking on the hyperlink on '<Root>/Subsystem'. For more information on this example, see “Code Generation for Variant Blocks with One Variant Choice” on page 26-17.

## Model-to-Code Traceability

To trace model elements to their corresponding generated code:

- 1 Complete steps 1 and 2 as in “Code-to-Model Traceability” on page 79-8
- 2 Build or generate code for the model. The generated code is displayed in the Code view window next to the model.
- 3 In the model window, click on a model element. To select multiple blocks, hold the **SHIFT** key and select additional blocks.
- 4 In the generated code in Code view window, you see the first instance of highlighted code that is generated for the model element. At the top of the Code view, numbers that appear to the right of generated file names indicate the total number of highlighted lines in each file. This figure shows the result of tracing the Unit Delay block in model `rtwdemo_hyperlinks`.

The screenshot shows the Embedded Coder interface. On the left, the Simulink model 'rtwdemo\_hyperlinks' is displayed. A Unit Delay block is highlighted with a blue selection box. Below the model, there are two buttons: 'Generate Code Using Embedded Coder (double-click)' and 'View Report Configuration (double-click)'. On the right, the Code view window shows the generated C code for 'rtwdemo\_hyperlinks.c'. The code is highlighted in pink, showing the Unit Delay block's implementation. The code includes comments for the Unit Delay block and the function call 'rtb.y3 = gfcn(rtdWork.X + 2.0, rtdCP\_Constant\_Value);'. The code view also shows the total number of highlighted lines in each file, which is 1/8.

At the top of the code window, use the navigation bar to move forward and backward through multiple instances of highlighted lines. Use the navigation sidebar to go directly to a line of code.

If you close and reopen a model, the Code view does not open until you open the **Embedded Coder** app. The Code view might not be available because Embedded Coder cannot find a build folder for your model in the current working folder. Reset the current working folder to the parent folder of the existing build folder.

If you are using the code generation report and want to reload existing traceability information, see “Reload Existing Traceability Information” on page 79-28.

## See Also

### Related Examples

- “Verify Generated Code by Using Code Tracing” on page 79-2
- “Trace Stateflow Elements in Generated Code” on page 79-12

## Trace Stateflow Elements in Generated Code

To verify the generated code for your Stateflow elements, you can trace Stateflow elements in your model to the generated code by using these types of navigation:

- **Code-to-model:** Trace generated code back to the model by clicking hyperlinks in the comments or the hyperlinked line numbers, which highlights the corresponding model element in the Simulink Editor.
- **Model-to-code:** Trace the model elements in the Simulink Editor to corresponding lines in generated code by right-clicking the model element and navigating to the generated code. This traceability is not supported for some Stateflow elements in Code view.

These examples illustrate how to trace different Stateflow elements.

### Inline Traceability for Stateflow Elements

Inline traceability refers to the line-level traceability available in the generated code. You can click the hyper-linked line numbers to trace single or multiple Stateflow elements at the same time.

- 1 Open the model.  

```
openExample('old_sf_car')
```
- 2 Configure the model as an ERT target.
- 3 On the **Code Generation > Report** pane, select these model configuration parameters:
  - **Create code generation report**
  - **Open report automatically**
  - **Code-to-model**
  - **Model-to-code**
- 4 Select **Code Generation > Comments > Stateflow object comments** configuration parameter. This parameter enables the traceability comments for Stateflow elements.
- 5 Go to the **Code Generation > Interface** pane. In the **Software environment** section, select **continuous time**. Click **Apply**. Before generating code, you must perform this step because this model contains a block with a continuous sample time.
- 6 On the **C Code** tab, click **Build**.

After the code generation process is complete, the code generation report appears.

- 7 In the report, on the left navigation pane, click the `old_sf_car.c` hyperlink.
- 8 To view the inline traceability hyperlinks, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.

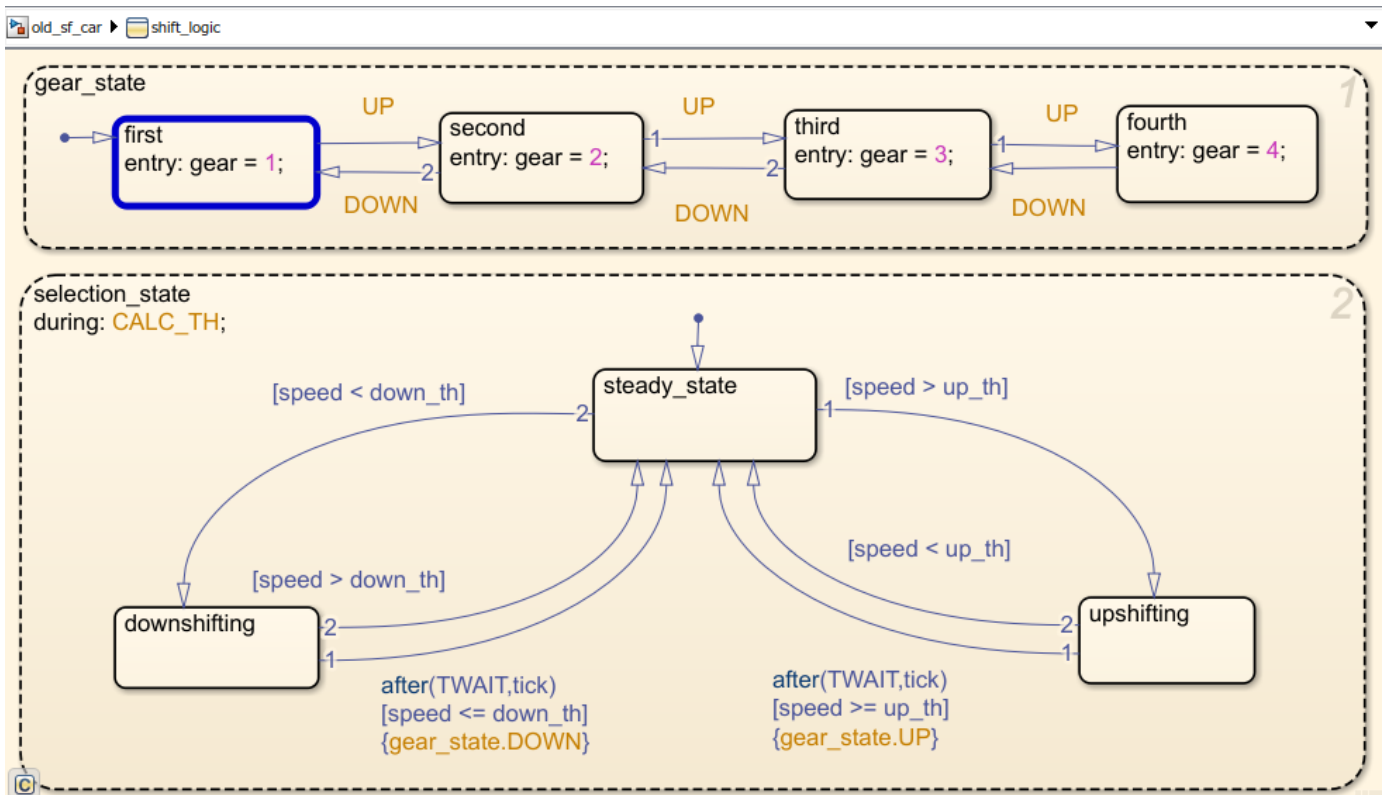

```

185 /* Function for Chart: '<Root>/shift_logic' */
186 static void old_sf_car_gear_state(const int32_T *sfEvent)
187 {
188 switch (old_sf_car_DW.is_gear_state) {
189 case old_sf_car_IN_first:
190 old_sf_car_B.gear = 1.0;
191 if (*sfEvent == old_sf_car_event_UP) {
192 old_sf_car_DW.is_gear_state = old_sf_car_IN_second;
193 old_sf_car_B.gear = 2.0;
194 }
195 break;

```

- 9 Click the hyperlink on line number 190. The corresponding element is highlighted.

## Bidirectional Traceability for States and Transitions

- 1 Open the model.  

```
openExample('old_sf_car')
```
- 2 Complete steps 2 through 5 in “Inline Traceability for Stateflow Elements” on page 79-12.
- 3 Press **Ctrl+B** to generate source code and header files for the `old_sf_car` model that contains the `shift_logic` chart. After the code generation process is complete, the code generation report appears.

- 4 In the report, click the `old_sf_car.c` hyperlink.

### View Results

- 1 To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.

```

188 /* Function for Chart: '<Root>/shift_Logic' */
189 static void old_sf_car_gear_state(const int32_T *sfEvent)
190 {
191 /* During 'gear_state': '<S5>:2' */
192 switch (old_sf_car_DW.is_gear_state) {
193 case old_sf_car_IN_first:
194 old_sf_car_B.gear = 1.0;
195
196 /* During 'first': '<S5>:6' */
197 if (*sfEvent == old_sf_car_event_UP) {
198 /* Transition: '<S5>:12' */
199 old_sf_car_DW.is_gear_state = old_sf_car_IN_second;
200
201 /* Entry 'second': '<S5>:4' */
202 old_sf_car_B.gear = 2.0;

```

- 2 Click the `<S5>:2` hyperlink in this traceability comment:

```
/* During 'gear_state': '<S5>:2' */
```

The corresponding state appears highlighted in the chart.

- 3 Click the `<S5>:12` hyperlink in this traceability comment:

```
/* Transition: '<S5>:12' */
```

The corresponding transition appears highlighted in the chart. To remove highlighting from an element in the chart, press the **Esc** key.

- 4 You can also trace elements in the model to lines of generated code. In the chart, right-click the element `gear_state` and select **C/C++ Code > Navigate to C/C++ Code**.

The code for that state appears highlighted in `old_sf_car.c`.

```

188 /* Function for Chart: '<Root>/shift_Logic' */
189 static void old_sf_car_gear_state(const int32_T *sfEvent)
190 {
191 /* During 'gear_state': '<S5>:2' */
192 switch (old_sf_car_DW.is_gear_state) {
193 case old_sf_car_IN_first:
194 old_sf_car_B.gear = 1.0;

```

- 5 In the chart, right-click the transition with the condition `[speed > up_th]` and select **C/C++ Code > Navigate to C/C++ Code**.

The code for that transition appears highlighted in `old_sf_car.c`.

```

492 case old_sf_car_IN_steady_state:
493 /* During 'steady_state': '<S5>:9' */
494 if (old_sf_car_B.mph > interp_up) {
495 /* Transition: '<S5>:18' */
496 old_sf_car_DW.is_selection_state = old_sf_car_IN_upshifting;
497 old_sf_car_DW.temporalCounter_i1 = 0U;
498 } else {
499 if (old_sf_car_B.mph < interp_down) {
500 /* Transition: '<S5>:19' */

```

---

**Note** For a list of the Stateflow elements in your model that are traceable, click the **Traceability Report** hyperlink in the code generation report.

---

## Bidirectional Traceability for State Transition Tables

This example shows how to navigate bidirectionally between elements in a state transition table and the generated C/C++ and HDL code for traceability.

- 1 Open the model. This model is already configured for traceability.  

```
openExample('sf_cdplayer_STT')
```
- 2 Press **Ctrl+B** to generate source code and header files for the `sf_cdplayer_STT` model. After the code generation process is complete, the code generation report appears.
- 3 Click the `sf_cdplayer_STT.c` hyperlink in the report.
- 4 To see the traceability comments, scroll through the code. The line numbers shown can differ from the numbers that appear in your code generation report.

```

60 /* Function for State Transition Table: '<Root>/CdPlayerModeManager' */
61 static void sf_cdplayer_S_enter_internal_ON(void)
62 {
63 /* Entry Internal 'ON': '<S2>:58' */
64 switch (sf_cdplayer_STT_DWork.bitsForTID1.was_ON) {
65 case sf_cdplayer_STT_IN_AMMode:
66 sf_cdplayer_STT_DWork.bitsForTID1.is_ON = sf_cdplayer_STT_IN_AMMode;
67 sf_cdplayer_STT_DWork.bitsForTID1.was_ON = sf_cdplayer_STT_IN_AMMode;
68
69 /* Entry 'AMMode': '<S2>:61' */
70 sf_cdplayer_STT_B.CurrentRadioMode = AM;
71 sf_cdplayer_STT_B.MechCmd = STOP;
72 break;
73

```

- 5 Click the `<S2>:58` hyperlink in this traceability comment:

```
/* Entry Internal 'ON': '<S2>:58' */
```

The corresponding state 'ON' appears highlighted in the state transition table.

STATES	TRANSITIONS		
	IF	ELSE-IF(2)	ELSE-IF(3)
ModeManager	[DiscEject]		
Standby entry: CurrentRadioMode = RadioRequestMode; MechCmd = CdRequestMode.STOP;	Eject		
ON	ON	[RadioReq == RadioRequestMode.OFF]	
Eject entry: MechCmd = CdRequestMode.EJECT;	ModeManager	Standby	

- 6 You can trace a state or transition from the state transition table to the generated code. Right-click the state Standby and select **C/C++ Code > Navigate to C/C++ Code**.

The entry code for the state Standby is highlighted in the generated code.

```

206 /* During 'ON': '<S2>:58' */
207 if (sf_cdplayer_STT_P.RR_Value == OFF) {
208 /* Transition: '<S2>:71' */
209 sf_cdplayer_ST_exit_internal_ON();
210 sf_cdplayer_STT_DWork.bitsForTID1.is_ModeManager =
211 sf_cdplayer_STT_IN_Standby;
212 sf_cdplayer_STT_DWork.bitsForTID1.was_ModeManager =
213 sf_cdplayer_STT_IN_Standby;
214
215 /* Entry 'Standby': '<S2>:57' */
216 sf_cdplayer_STT_B.MechCmd = STOP;
217 } else if (*RadioReq_prev != sf_cdplayer_STT_DWork.RadioReq_start) {
218 /* Transition: '<S2>:75' */
219 if (sf_cdplayer_STT_P.RR_Value == CD) {

```

## Bidirectional Traceability for Truth Table Blocks

- 1 Open the model.  

```
openExample('sf_climate_control')
```
- 2 Complete steps 2 through 5 in “Inline Traceability for Stateflow Elements” on page 79-12.
- 3 To build the model, press **Ctrl+B**.
- 4 In the code generation report, click the `sf_climate_control.c` hyperlink.
- 5 To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code.

```

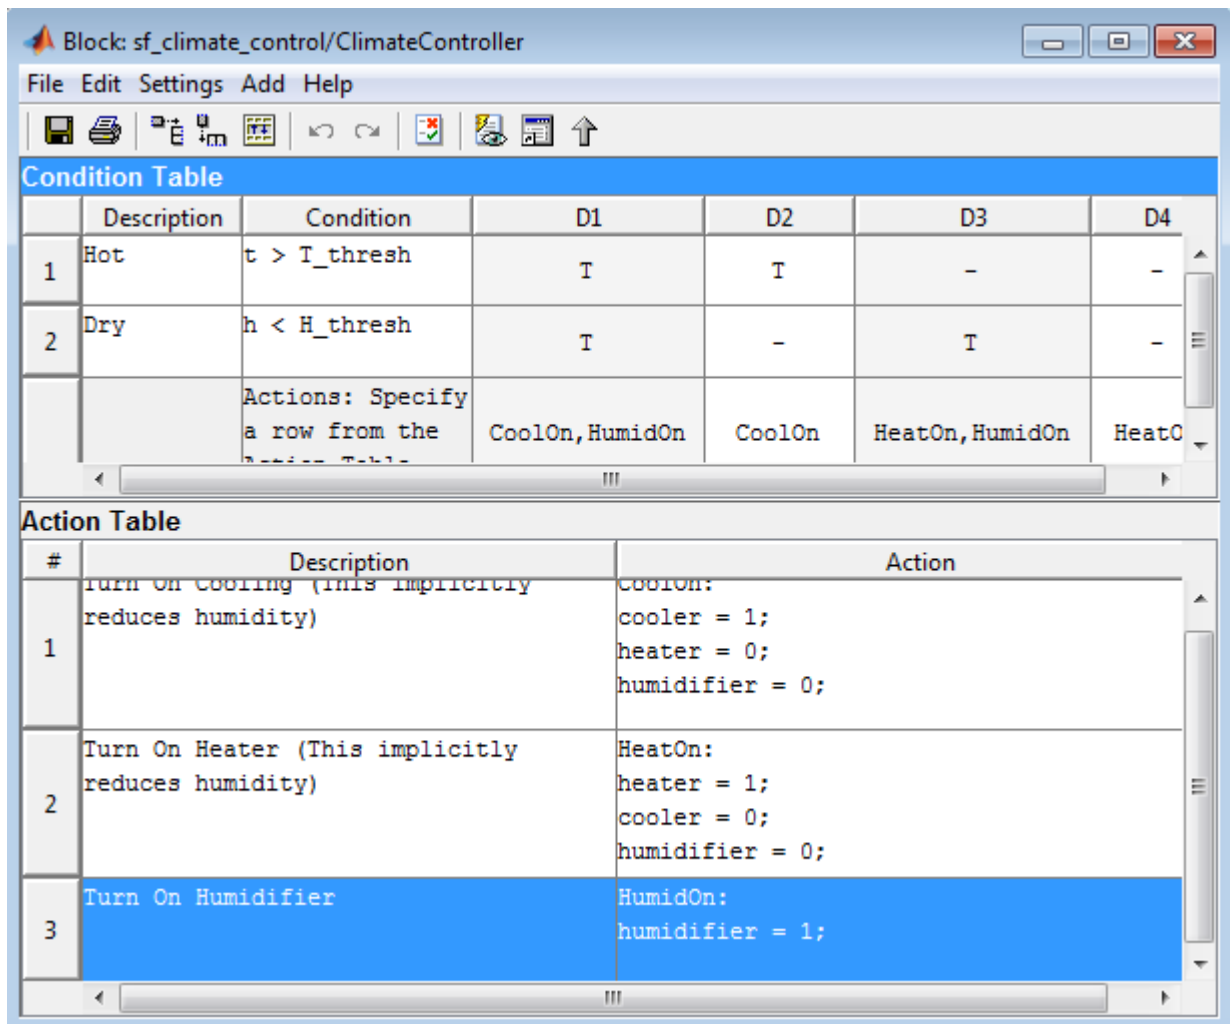

68 /* Turn On Humidifier */
69 /* Action '3': '<S1>:1:47' */
70 rtb_humidifier = 1;
71 } else if (aVarTruthTableCondition_1) {
72 /* Decision 'D2': '<S1>:1:18' */
73 /* Turn On Cooling (This implicitly reduces humidity) */
74 /* Action '1': '<S1>:1:31' */
75 rtb_cooler = 1;

```

- 6 Click the `<S1>:1:47` hyperlink in this traceability comment:

```
/* Action '3': '<S1>:1:47' */
```

In the Truth Table Editor, row 3 of the Action Table appears highlighted.

- 7 You can also trace a condition, decision, or action in the table to a line of generated code. For example, right-click a cell in the column D2 and select **C/C++ Code > Navigate to C/C++ Code**.

The code for that decision appears highlighted in `sf_climate_control.c`.

```

68 /* Turn On Humidifier */
69 /* Action '3': '<S1>:1:47' */
70 rtb_humidifier = 1;
71 } else if (aVarTruthTableCondition_1) {
72 /* Decision 'D2': '<S1>:1:18' */
73 /* Turn On Cooling (This implicitly reduces humidity) */
74 /* Action '1': '<S1>:1:31' */
75 rtb_cooler = 1;

```

**Tip** To select **C/C++ Code > Navigate to C/C++ Code** for a condition, decision, or action, right-click a cell in the row or column that corresponds to that truth table element.

## Bidirectional Traceability for Graphical Functions

- 1 Open the model.  

```
openExample("stateflow/ClutchWithEnabledSubsystemsExample")
```
- 2 Complete steps 2 through 5 in “Inline Traceability for Stateflow Elements” on page 79-12.
- 3 In the Configuration Parameters dialog box, go to the **Solver** pane. In the **Solver selection** section, select Fixed-step in the **Type** field. Click **Apply**. Before generating code, you must perform this step because the model does not work with variable-step solvers.
- 4 To build the model, press **Ctrl+B**.
- 5 In the code generation report, click the `sf_clutch_enabled_subsystems.c` hyperlink.
- 6 To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.

```

376 /* During 'Slipping': '<S1>:1' */
377 /* Graphical Function 'detectLockup': '<S1>:10' */
378 /* Transition: '<S1>:28' */
379 /* Graphical Function 'getSlipTorque': '<S1>:3' */
380 /* Transition: '<S1>:12' */

```

- 7 Click the `<S1>:3` hyperlink in this traceability comment:

```
/* Graphical Function 'getSlipTorque': '<S1>:3' */
```

In the chart, the graphical function `getSlipTorque` appears highlighted.

- 8 You can trace a graphical function in the chart to a line of generated code. For example, right-click the graphical function `detectSlip` and select **C/C++ Code > Navigate to C/C++ Code**.

The code for that graphical function appears highlighted in `sf_clutch_enabled_subsystems.c`.

```

309 /* During 'Locked': '<S1>:2' */
310 /* Graphical Function 'detectSlip': '<S1>:6' */
311 /* Transition: '<S1>:15' */
312 /* Graphical Function 'getLockedTorque': '<S1>:5' */
313 /* Transition: '<S1>:14' */
314 if (fabs((5.0 * sf_clutch_enabled_subsystems_B.Tin - (5.0 * 2.0 - 1.0 *
315 1.0) *
316 sf_clutch_enabled_subsystems_X.EngineVehicleIntegrator_CSTATE) /
317 (5.0 + 1.0)) > RatioofstatictoKinetic) {
318 /* Transition: '<S1>:17' */

```

## Code-to-Model Traceability for Events

- 1 Open the model.  

```
openExample('sf_security')
```
- 2 Complete steps 2 through 5 in “Inline Traceability for Stateflow Elements” on page 79-12.

- 3 To build the model, press **Ctrl+B**.
- 4 In the code generation report, click the `sf_security.c` hyperlink.
- 5 To see this traceability comment, scroll through the code. These numbers can differ from the numbers that appear in your code generation report.

```

236 /* Entry 'Pending': '<S3>:5' */
237 /* Event: '<S3>:56' */
238 sf_security_DW.SoundEventCounter++;
239 }
240 break;

```

- 6 Click the `<S3>:56` hyperlink in this traceability comment:

```
/* Event: '<S3>:56' */
```

In the **Contents** pane of the Model Explorer, the event `Sound` appears highlighted.

## Model-to-Code Traceability for Junctions

- 1 Open the model.

```
openExample('ex_if_else_SF')
```

- 2 Complete steps 2 through 5 in “Inline Traceability for Stateflow Elements” on page 79-12.
- 3 To build the model, press **Ctrl+B**.
- 4 In the code generation report, open the Stateflow chart named Chart.
- 5 Right-click the top-left junction and select **C/C++ Code > Navigate to C/C++ Code**.

The code for the first outgoing transition of that junction appears highlighted in `ex_if_else_SF.c`.

```
39 if (U.u1 > U.u2) {
40 /* Output: '<Root>/y1' */
41 /* Transition: '<S1>:13' */
42 /* Transition: '<S1>:12' */
43 Y.y1 = U.u1;
```

## Format of Traceability Comments for Stateflow Elements

The format of a traceability comment depends on the Stateflow element type.

### State

#### Syntax

```
/* <ActionType> '<StateName>': '<elementHyperlink>' */
```

#### Example

```
/* During 'gear_state': '<S5>:2' */
```

This comment refers to the during action of the state `gear_state`, which has the hyperlink `<S5>:2`.

### Transition

#### Syntax

```
/* Transition: '<elementHyperlink>' */
```

#### Example

```
/* Transition: '<S5>:12' */
```

This comment refers to a transition, which has the hyperlink `<S5>:12`.

### MATLAB Function

#### Syntax

```
/* MATLAB Function '<Name>': '<elementHyperlink>' */
```

Within the inlined code for a MATLAB function, comments that link to individual lines of the function have this syntax:

```
/* '<elementHyperlink>' */
```

#### Examples

```
/* MATLAB Function 'test_function': '<S50>:99' */
```

```
/* '<S50>:99:20' */
```

The first comment refers to the MATLAB function named `test_function`, which has the hyperlink `<S50>:99`.

The second comment refers to line 20 of the MATLAB function in your chart.

### Truth Table Block

#### Syntax

```
/* Truth Table Function '<Name>': '<elementHyperlink>' */
```

Within the inlined code for a Truth Table block, comments for conditions, decisions, and actions have this syntax:

```
/* Condition '#<Num>': '<elementHyperlink>' */
/* Decision 'D<Num>': '<elementHyperlink>' */
/* Action '<Num>': '<elementHyperlink>' */
```

`<Num>` is the row or column number that appears in the Truth Table Editor.

#### Examples

```
/* Truth Table Function 'truth_table_default': '<S10>:100' */
/* Condition '#1': '<S10>:100:8' */
/* Decision 'D1': '<S10>:100:16' */
/* Action '1': '<S10>:100:31' */
```

The first comment refers to a Truth Table block named `truth_table_default`, which has the hyperlink `<S10>:100`.

The other three comments refer to elements of that Truth Table block. Each condition, decision, and action in the Truth Table block has a unique hyperlink.

### Truth Table Function

For syntax and examples, see “Truth Table Block” on page 79-22.

### Graphical Function

#### Syntax

```
/* Graphical Function '<Name>': '<elementHyperlink>' */
```

#### Example

```
/* Graphical Function 'hello': '<S1>:123' */
```

This comment refers to a graphical function named `hello`, which has the hyperlink `<S1>:123`.

### Simulink Function

#### Syntax

```
/* Simulink Function '<Name>': '<elementHyperlink>' */
```

#### Example

```
/* Simulink Function 'simfcn': '<S4>:10' */
```

This comment refers to a Simulink function named `simfcn`, which has the hyperlink `<S4>:10`.

**Event****Syntax**

```
/* Event: '<elementHyperlink>' */
```

**Example**

```
/* Event: '<S3>:33' */
```

This comment refers to an event, which has the hyperlink `<S3>:33`.

- “Trace Data, Events, and Messages” (Stateflow)

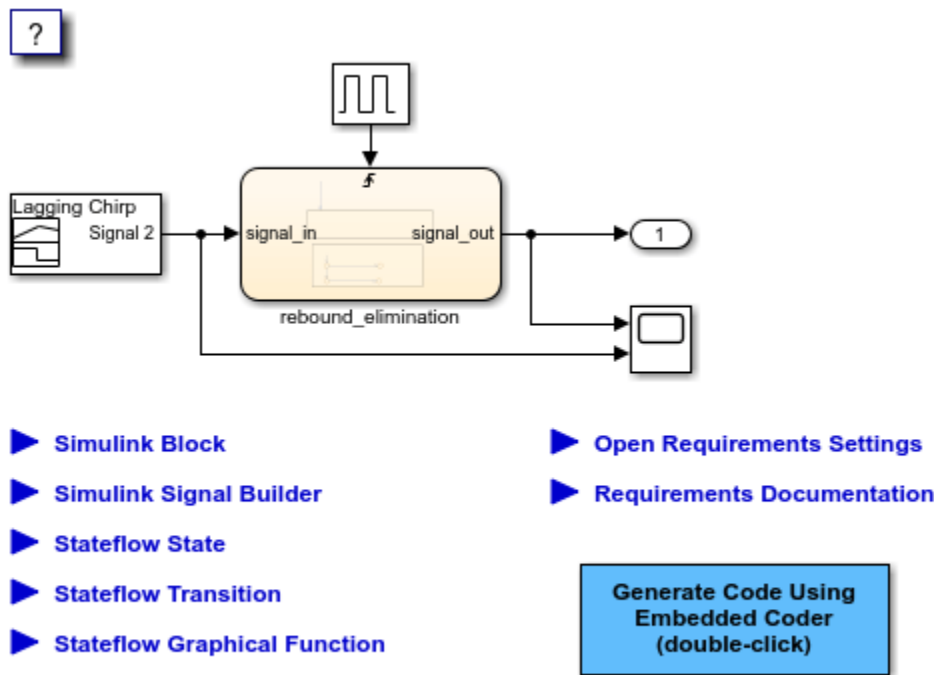

## Link Generated Code to Requirements

Link generated code to model element requirements. Using configuration parameters, you can specify whether to include requirement descriptions as comments in the generated code.

### Open Model

Open the `rtwdemo_requirements` model. The model contains Simulink® and Stateflow® elements with associated requirements.

```
model='rtwdemo_requirements';
open_system(model);
```

Copyright 1994-2020 The MathWorks, Inc.

### View Requirements

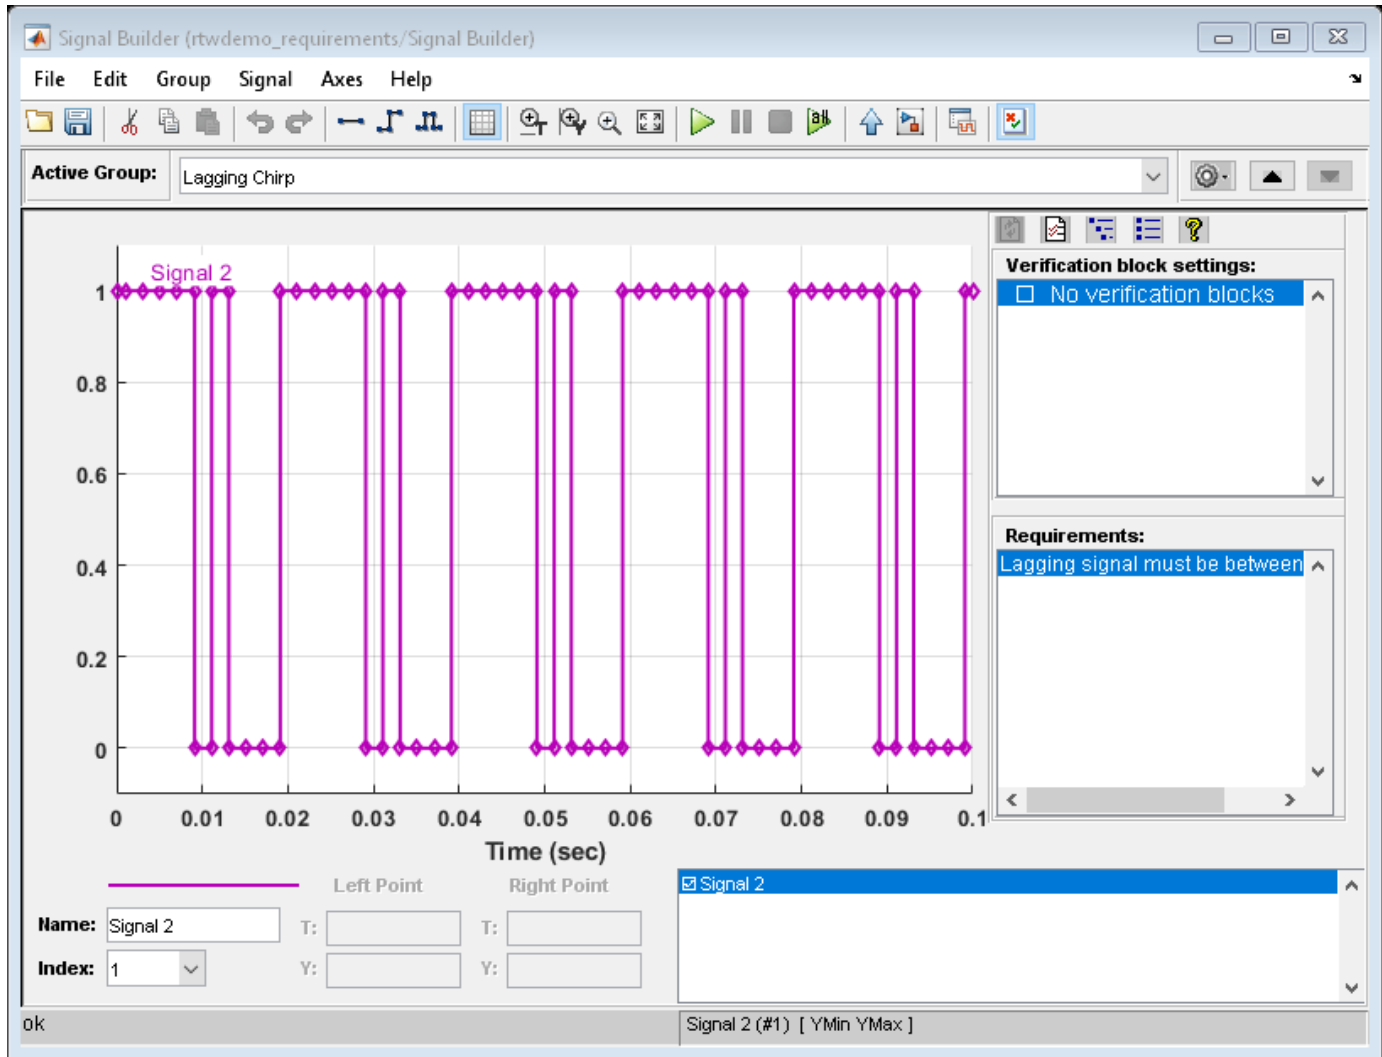

You can view requirements linked to the model by using the Requirements Editor. In the Simulink Editor, open the **Requirements Manager** app. On the **Requirements** tab, click **Requirements Editor**. You can view requirements specific to model objects by using the object context menu. Right-click an element and select **Requirements > Open Outgoing Links dialog**. To view the requirements, use these commands:

1. To view the requirements for the `DiscretePulseGenerator` block, right-click the `DiscretePulseGenerator` block and select **Requirements > Open Outgoing Links dialog** to open Outgoing Links Editor. Using Outgoing Links Editor, you can create, edit, and delete requirements traceability links.

```
clockblock='rtwdemo_requirements/clock';
clockblockh=get_param(clockblock,'handle');
rmi('edit',clockblockh);
```

2. To view the requirements, open the **Signal Builder** block by double-clicking it.

```
sigblock='rtwdemo_requirements/Signal Builder';
open_system(sigblock)
```

3. To view the requirements for the Stateflow® state, open the Outgoing Links Editor.

```
state=find(sfroot, '-isa', 'Stateflow.State', '-and', 'Tag', 'req_state');
rmi('edit',state.id);
```

4. To view the requirements for the Stateflow transition, open the Outgoing Links Editor.

```
trans=find(sfroot, '-isa', 'Stateflow.Transition', '-and', 'Tag', 'req_trans');
rmi('edit',trans.id);
```

5. To view the requirements for the Stateflow function, open the Outgoing Links Editor.

```
func=find(sfroot, '-isa', 'Stateflow.Function', '-and', 'Tag', 'req_function');
rmi('edit',func.id);
```

Close the open windows.

```
close_system(sigblock);
```

### Set Configuration Parameters

Open the Configuration Parameters dialog box **Code Generation > Comments** pane. View the configuration parameter settings.

```
model = bdroot;
configSet = getActiveConfigSet(model);
openDialog(configSet);
```

### Generate Code

Generate code for the model.

```
slbuild('rtwdemo_requirements')
```

```
Starting build procedure for: rtwdemo_requirements
Successful completion of build procedure for: rtwdemo_requirements
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_requirements	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 25.304s

In the generated code, view the comments containing the requirements. To view all the requirements, click the hyperlinked requirement comment.

```
rtwdemodbtype('rtwdemo_requirements_ert_rtw/rtwdemo_requirements.c',...
 /* Function for Chart:', 'return result;',1,0);

/* Function for Chart: '<Root>/rebound_elimination' */
static real_T rebound_fcn(real_T prev_in, real_T prev_out, real_T curr_in)
{
 real_T result;

 /* Graphical Function 'rebound_fcn': '<S2>:2':
 * 1. Result Computation
 */
 /* Transition: '<S2>:4' */
 if (prev_in == curr_in) {
 /* Transition: '<S2>:5' */
 result = curr_in;
 } else {
 /* Transition: '<S2>:6' */
 /* Transition: '<S2>:7' */
 result = prev_out;
 }
}
```

**Close Model**

```
rtwdemoclean;
close_system('rtwdemo_requirements',0);
```

## Reload Existing Traceability Information

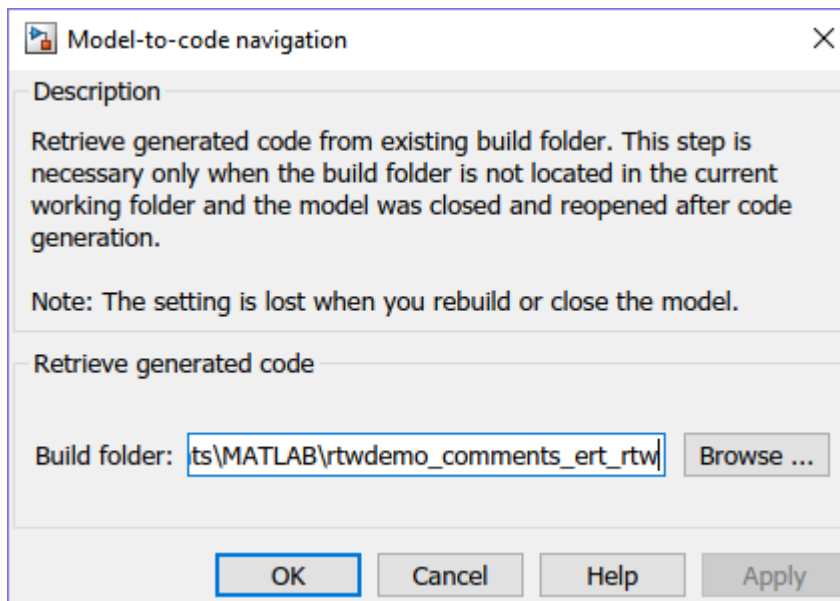

When you build a model, the traceability information is stored in the build folder. The format of the build folder for an ERT-based target is *model\_ert\_rtw*.

**Model-to-code** parameter should be selected in the original build to be able to reload the traceability information in a new Simulink session. To reload existing traceability information for a model:

- 1 Reset the current working folder to the parent folder of the existing build folder.
- 2 In the Configuration Parameters dialog box, next to **Model-to-code**, click **Configure**.
- 3 In the Model-to-code navigation dialog box, in the **Build folder** field, type or browse to the build folder that contains the existing traceability information.

If you close and reopen a model, the **Navigate to Code** context menu option might not be available because Embedded Coder cannot find a build folder for your model in the current working folder. In that case, perform these steps:

- 1 To open the Model-to-code navigation dialog box, click **Configure**.
- 2 In the Model-to-code navigation dialog box, click **Browse**.
- 3 Browse to the build folder for your model and select the folder. The build folder path is displayed in the **Build folder** field.

- 4 If you selected **Model-to-code** for the build, clicking **Apply** or **OK** loads traceability information from the earlier build into your Simulink session.
- 5 To open the context menu and trace a model element to corresponding code, right-click a model element and select **C/C++ Code > Navigate to C/C++ Code**.

### **Related Examples**

- “Generate Code Generation Report” on page 51-5

## Customize Traceability Reports

Even a relatively small model can generate hundreds of lines of C/C++ code. To help you navigate more easily between the generated code and your source model, Embedded Coder provides the traceability report section. When you enable traceability, Embedded Coder displays the generated code in Code view or code generation report. You can generate reports in the Configuration Parameters dialog box or at the command line.

In the Configuration Parameters dialog box, the **Code Generation > Report** pane lists parameters that you can select and clear to customize the content of your traceability reports.

Select or clear any combination of these parameters. These parameters are on by default.

- **Eliminated / virtual blocks** (account for blocks that are untraceable)
- **Traceable Simulink blocks**
- **Traceable Stateflow elements**
- **Traceable MATLAB functions**

If you select all parameters, you get a complete mapping between model elements and the generated code.

This figure shows the top section of the traceability report, which is generated when you select all traceability content parameters for model `rtwdemo_hyperlinks`.

## Generate a Traceability Matrix

The traceability matrix provides traceability among model elements, generated code, and model requirements in a Microsoft Excel® file format.

If you have DO Qualification Kit software or IEC Certification Kit software and are using a Windows host, you can generate a traceability matrix into Microsoft Excel format directly from the traceability report.

Go to the **Traceability Report** section of the HTML code generation report and click **Generate Traceability Matrix**.

Generate Traceability Matrix

To select an existing matrix file to update or specify a matrix file to create, use the options in the Generate Traceability Matrix dialog box. Optionally, you can select and create an order to the columns that appear in the generated matrix. After specifying the location where you want the matrix file, click the **Generate** button.

For more information, see "Generating a Traceability Matrix" in either the DO Qualification Kit documentation (DO Qualification Kit).

### Related Examples

- "Reports for Code Generation" on page 51-2

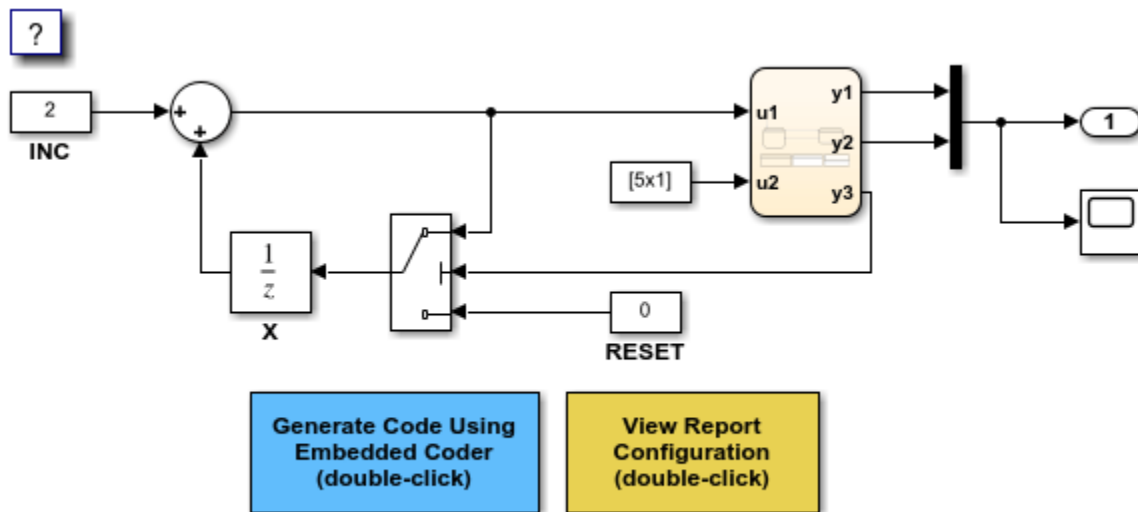

## Trace Generated Code to Blocks

Navigate and trace between generated code and its source model for verification.

### Open Example Model

Open the example model `rtwdemo_hyperlinks`.

```
model='rtwdemo_hyperlinks';
open_system(model)
```

### Code to Model Navigation

Navigate from the generated code to the model.

- 1 In the Configuration Parameters dialog box, open the **Code Generation > Report** pane.
- 2 Verify that the following parameters are selected: **Create code generation report**, **Open report automatically** and **Code-to-model**.
- 3 In the model editor window, press **Ctrl+B** to generate code. After the code generation process is complete, the code generation report appears.
- 4 In the generated report, click the `rtwdemo_hyperlinks.c` link to see the code with embedded hyperlinks.
- 5 Click links in the code to trace generated code segments to the highlighted elements in the model. For example, if you click the hyperlink `<Root>/Sum`, the Sum block in the model is highlighted.

### Model to Code Navigation

Navigate from the model to the generated code.

- 1 In the Configuration Parameters dialog box, open the **Code Generation > Report** pane.
- 2 Verify that the following parameters are selected: **Create code generation report**, **Open report automatically** and **Model-to-code**.

- 3 In the model editor window, press **Ctrl+B** to generate code. After the code generation process is complete, the code generation report appears.
- 4 In the model window, right-click any block and select **C/C++ Code > Navigate To C/C++ Code**. The software highlights the generated code for this block in the code generation report.
- 5 Inspect the highlighted lines in the code generation report. The total number of highlighted lines is displayed next to each source file name in the left pane of the report. Use the **Previous** and **Next** buttons to navigate through the highlighted lines.

Note: **Model-to-code** navigation also works for Stateflow® objects and **MATLAB** functions.

Note: The report displays a diagnostic message if there is no code to highlight for the selected block (for example, if you select a virtual block).

### Traceability Report

Generate and inspect the **Traceability Report**.

- 1 In the Configuration Parameters dialog box, open the **Code Generation > Report** pane.
- 2 Verify that the following parameters are selected: **Create code generation report, Open report automatically**
- 3 Search for the traceability report parameters using keyword `GenerateTraceReport`. Verify all the listed parameters are selected.
- 4 In the model editor window, press **Ctrl+B** to generate code. After the code generation process is complete, the code generation report appears.
- 5 To see a report of the untraceable (not in the generated code) and traceable blocks in your model, on the left pane of the generated report click **Traceability Report**.
- 6 In the **Traceability Report**, inspect the **Eliminated / Virtual Blocks** and **Traceable Blocks** lists. For example, the **Scope** block is an untraceable block. It is listed under **Eliminated / Virtual Blocks** because the code generator does not generate code for this block.

## Use Traceability in MATLAB Function Blocks

### Extent of Traceability in MATLAB Function Blocks

Like other Simulink blocks, MATLAB Function blocks support bidirectional traceability, but extend navigation to lines of source code. That is, you can navigate between a line of generated code and its corresponding line of source code. In other Simulink blocks, you can navigate between a line of generated code and its corresponding object.

In addition, you can select to include the source code as comments in the generated code. When you select **MATLAB source code as comments** parameter, the MATLAB source code appears immediately after the associated traceability tag. For more information, see “Include MATLAB Code as Comments in Generated Code” on page 45-23.

For information about how traceability works in Simulink blocks, see “Verify Generated Code by Using Code Tracing” on page 79-2.

### Traceability Requirements

To enable traceability comments in your code, you must have a license for Embedded Coder software. These comments appear only in code that you generate for an Embedded Real-Time (ERT) target.

---

**Note** Traceability is not supported for MATLAB files that you call from a MATLAB Function block.

---

### Using Traceability in a MATLAB Function Block

This example shows how to trace between source code and generated code in a MATLAB Function block in the `rtwdemo_dynamicio` model. Follow these steps:

- 1 Open model `rtwdemo_dynamicio`.
- 2 Open the **Embedded Coder** app.
- 3 Change the system target file to `ert.tlc` when prompted. Traceability comments appear hyperlinked in generated code only for embedded real-time (`ert.tlc`) targets.
- 4 In the Configuration Parameters dialog box, on the **Code Generation > Report** pane, select these parameters, if not already selected:
  - **Create code generation report**
  - **Code-to-model**
  - **Model-to-code**
- 5 In the **Code Generation > Comments** pane, select the **MATLAB source code as comments** and **Stateflow object comments** parameters. These parameters control different parts of the traceability comment.
- 6 In the model window, press **Ctrl+B**.

This action generates source code and header files for the `rtwdemo_dynamicio` model that contains the `emlHorizontalSum` and `emlVerticalSum` blocks. After the code generation process is complete, the Code view appears automatically to the right of the model and displays the `rtwdemo_dynamicio.c` file.

- 7 Scroll down through the code to see the traceability comments, which appear as links inside `/*...*/` brackets, as in this example.

```

91 /* Output: '<Root>/Out1' incorporates:
92 * Chart: '<Root>/sfVerticalSum'
93 * MATLAB Function: '<Root>/emlHorizontalSum'
94 */
95 /* MATLAB Function 'emlHorizontalSum': '<S1>:1' */
96 /* '<S1>:1:2' y = sum(u,2); */
97 rtwdemo_dynamicio_Y.Out1 = (tmp[0] * rtwdemo_dynamicio_P.K + tmp[1] *
98 rtwdemo_dynamicio_P.K) + tmp[2] * rtwdemo_dynamicio_P.K;

```

- 8 Click the `<S1>:1:2` hyperlink in this traceability comment:

```
/* '<S1>:1:2' y = sum(u,2); */
```

Line 2 of the function in the source code appears highlighted in the MATLAB Function Block Editor.

- 9 You can trace a line in a MATLAB function to lines of generated code. For example, right-click on line 2 of your function and select **Code Generation > Navigate to Code** from the context menu.

The code location for line 2 appears highlighted in `rtwdemo_dynamicio.c`.

- 10 You can trace a line of generated code to a line of source code in a MATLAB function using the line number hyperlinks in the generated code.

# Component Verification in Embedded Coder

---

## Component Verification in Target Environment

After you generate production code for a component design, you need to integrate, compile, link, and deploy the code as a complete application on the embedded system. One approach is to manually integrate the code into an existing software framework that consists of an operating system, device drivers, and support utilities. The algorithm can include externally written legacy or custom code.

An easier approach to verifying a component in a target environment is to use processor-in-the-loop (PIL) simulation. For information about PIL simulations, see “SIL and PIL Simulations” on page 82-2.

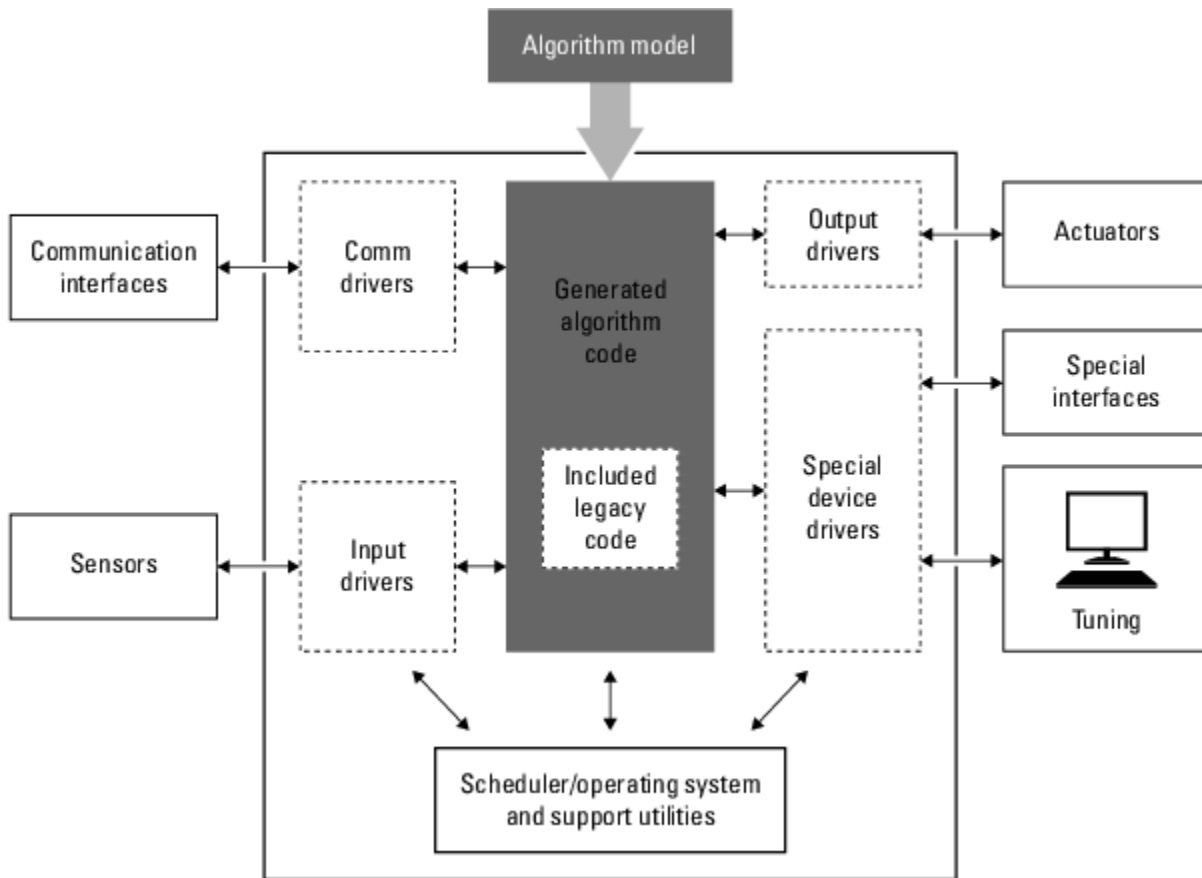

### Goals of Component Verification

Assuming that you have generated production source code and integrated required externally written code, such as drivers and a scheduler, you can verify that the integrated software operates as expected by testing it in the target environment. During testing, you can achieve either of the following goals, depending on whether you export code that is strictly ANSI C/C++ or mixes ANSI C/C++ with code optimized for a target environment.

Goal	Type of Code Export
Maximize code portability and configurability	ANSI C/C++
Simplify integration and maximize use of processor resources and code efficiency	Mixed code

Regardless of your goal, you must integrate required external drivers and scheduling software. To achieve real-time execution, you must integrate the real-time scheduling software.

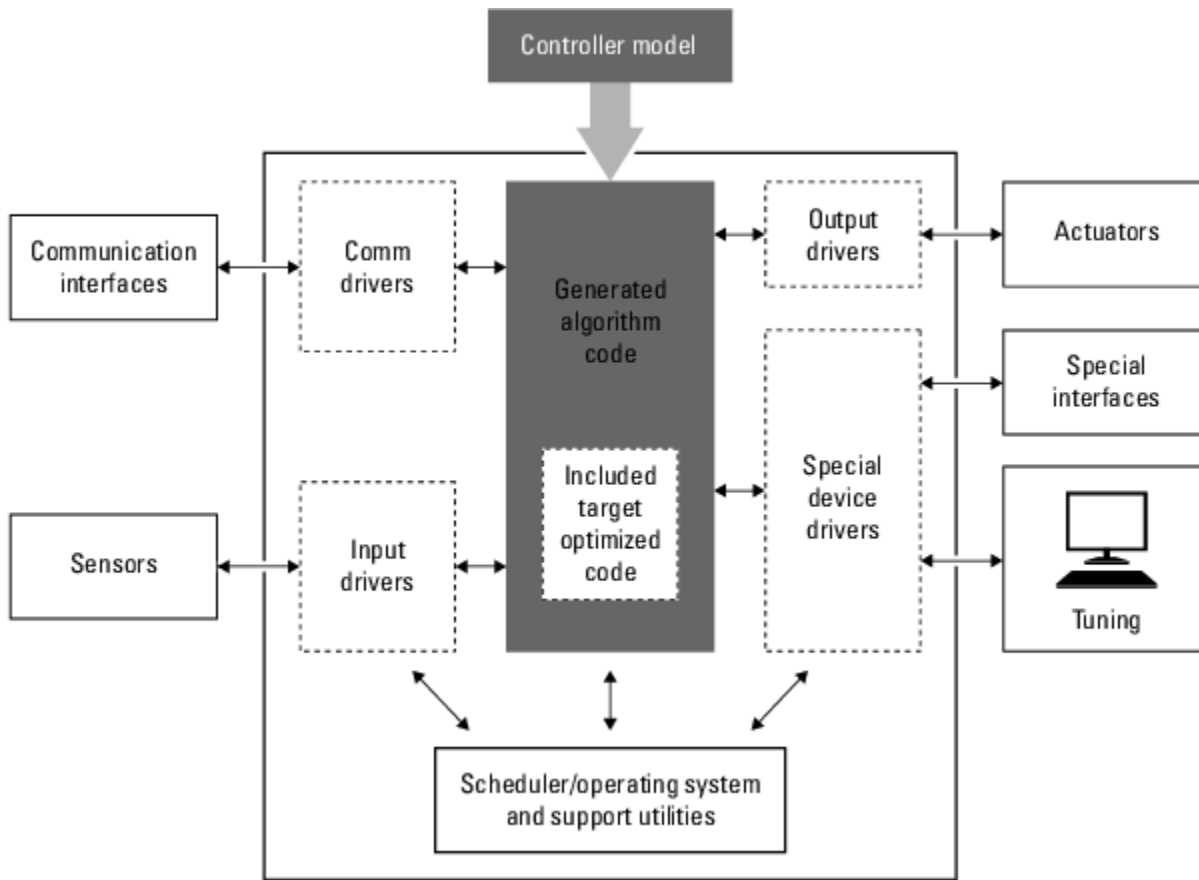

To maximize code portability and configurability, limit the application code to ANSI/ISO C or C++ code only, as the following figure shows.

To simplify code integration and maximize code efficiency for a target environment, use Embedded Coder features for:

- Controlling code interfaces
- Exporting subsystems
- Including target-specific code, including compiler optimizations

The following figure shows a mix of ANSI C/C++ code with code that is optimized for a target environment.

## Run Component Tests

The workflow for running software component tests in the target environment is:

- 1 Integrate external code, for example, for device drivers and a scheduler, with the generated C or C++ code for your component model. For more information, see “S-Functions and Code Generation”. For more specific references that depend on your verification goals, see the following table.

For	See
ANSI C/C++ code integration	“Integrate C Functions Using Legacy Code Tool”. Also, open <code>rtwdemos</code> and navigate to the <b>Custom Code</b> folder.

- 6 Create a zip file that contains generated code files, static files, and dependent data to build the generated code in an environment other than your host computer. See “Relocate or Share Generated Code”, and example `rtwdemo_buildinfo`.

# Component Verification With a Real-Time Target Environment in Embedded Coder

---

## Real-Time Software Component Verification

One approach to verifying a software component is to build the component into a complete software system that can execute in real time in the target environment. A complete software system includes:

- Algorithm for the software component
- Scheduling algorithms
- Calls to drivers for board-specific devices

This single build approach is more time consuming to set up, but makes it easier to get the complete application running in the target environment.

The following figure shows code generated for an algorithm being built into a complete system executable for the target environment.

The workflow for testing component software as part of a complete real-time target environment is:

- 1 Develop a component model and generate source code for production.

For information on building in scheduling and real-time system support, see:

- "Time-Based Scheduling and Code Generation" and "Modeling for Multitasking Execution". For an example, open `rtwdemos` and navigate to the **Multirate Support** folder.

 “Imported Data and Additional Generated Code” on page 82-6

### What Are SIL and PIL Simulations?

With Embedded Coder, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations of your model. These simulations generate source code for either the top model or part of the model. A SIL simulation compiles and runs the generated code on your development computer. A PIL simulation cross-compiles source code on your development computer, and then downloads and runs the object code on a target processor or an equivalent instruction set simulator.

With SIL and PIL simulations, you can:

- Test whether your model and generated code are numerically equivalent.
- Observe code coverage.
- Perform code execution profiling.

### Why Use SIL and PIL

Through SIL and PIL, you can early on test and fix defects. For example, you can model and test a system component in normal mode. Then, you can reuse your test suites in a SIL or PIL simulation that runs compiled generated code. To check numerical equivalence, you compare normal and SIL or PIL simulation results. You do not have to leave the Simulink environment to test generated code on a separate infrastructure.

This table describes situations where you can use SIL and PIL.

Situation	Use
Test numerical equivalence between model and generated code by reusing test vectors developed for normal mode simulation to verify numerical output of generated (or legacy) code. See “SIL/PIL Manager Verification Workflow” on page 82-72 and “Test Two Simulations for Equivalence” (Simulink Test)	SIL and PIL
Collect metrics for generated code: <ul style="list-style-type: none"> <li>• Code coverage. See “Code Coverage”.</li> <li>• Execution profiling. See “Code Execution Profiling with SIL and PIL” on page 76-2</li> </ul>	SIL and PIL

Situation	Use
<p>(Requires an IEC Certification Kit license.)</p> <p>Perform verification and validation activities on the generated C/C++ code in accordance to the requirements of the overall software safety lifecycle as defined by the ISO 26262-6, IEC 61508-3, IEC 62304, EN 50128, and EN 50657 functional safety standards. For detailed information about the SIL and PIL verification activities in the IEC Certification Kit Model-Based Design workflow, see the <i>Reference Workflow for Embedded C/C++ Applications</i> (<code>certkitiec_ecoder_workflow.docx/pdf</code>) artifact in the Artifacts Explorer (IEC Certification Kit).</p>	SIL and PIL
<p>(Requires a DO Qualification Kit license.)</p> <p>Test the output of the integration process to satisfy relevant objectives in the DO-178C and DO-333 safety standards. For additional information, see Testing of Outputs of Integration Process (DO Qualification Kit). Without target hardware, get a convenient alternative to PIL.	SIL
<p>With target hardware, for example, an evaluation board or instruction set simulator:</p> <ul style="list-style-type: none"> <li>• Verify behavior of target-specific code, for example, code replacement optimizations, and legacy code. See “What Is Code Replacement?” on page 54-2 and “What Is Code Replacement Customization?” on page 69-3.</li> <li>• Optimize the execution speed and memory footprint of your code. In this table, see the information about collecting execution profiling and stack profiling metrics.</li> <li>• Investigate effects of compiler settings and optimizations, for example, deviation from ANSI C overflow behavior.</li> </ul> <p>Normal simulation techniques do not account for restrictions and requirements that the hardware imposes, such as limited memory resources or behavior of target-specific optimized code.</p> <p>For information about running PIL simulations on specific targets, see “Sample Custom Targets” in the Simulink Coder documentation.</p>	PIL

**Note** The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?”.

## How SIL and PIL Simulations Work

In a SIL or PIL simulation, code is generated for either the top model or part of the model. With SIL, this code is compiled for and executed on your development computer. With PIL, the code is cross-compiled for the target hardware and runs on the target processor.

Through a communication channel, Simulink sends stimulus signals to the code on your computer or target processor for each sample interval of the simulation.

- For a top model, Simulink uses stimulus signals from the base or model workspace.
- If you have designated only part of the model to simulate in SIL or PIL mode, then a part of the model remains in Simulink and code is not generated for this part of the model. Typically, you configure this part of the model to provide test vectors for the software executing on the hardware. This part of the model can represent other parts of the algorithm or the environment in which the algorithm operates.

When your computer or target processor receives signals from Simulink, the processor executes the SIL or PIL algorithm for one sample step. The SIL or PIL algorithm returns output signals calculated during this step to Simulink through a communication channel. One sample cycle of the simulation is complete, and Simulink proceeds to the next sample interval. The process keeps repeating itself and the simulation progresses. SIL and PIL simulations do not run in real time. In each sample period, Simulink and the object code exchange I/O data.

## Comparison of SIL and PIL Simulations

Type of SIL or PIL Simulation	What Happens in SIL Simulation	What Happens in PIL Simulation
Specify through: <ul style="list-style-type: none"> <li>• Top-model simulation mode</li> <li>• Model block <b>Simulation mode</b> parameter</li> </ul>	<ul style="list-style-type: none"> <li>• Test behavior of generated source code on development computer. Simulation does not test code compiled for target hardware because code is compiled for the development computer (different compiler and different processor architecture than the target).</li> <li>• Generated production code compiled and executed on development computer as separate process, independent of MATLAB process.</li> <li>• Execution is host/host and nonreal time.</li> </ul>	<ul style="list-style-type: none"> <li>• Test object code that you intend to deploy in production on either real target hardware or an instruction set simulator.</li> <li>• On development computer, generated production code cross-compiled for target. Object code downloaded and executed on target processor or instruction set simulator.</li> <li>• Execution is host/target and nonreal time.</li> </ul>
Use SIL or PIL block created from subsystem.	<ul style="list-style-type: none"> <li>• Simulation runs compiled object code through S-function. S-function communicates with object code executing as standalone application on development computer. SIL block execution is independent of the MATLAB process.</li> <li>• Execution is host/host and nonreal time.</li> </ul>	<ul style="list-style-type: none"> <li>• Simulation runs cross-compiled object code through S-function on development computer. S-function communicates with object code executing as standalone application on target processor or instruction set simulator.</li> <li>• Execution is host/target and nonreal time.</li> </ul>

## Code Interfaces for SIL and PIL

You generate standalone code when you perform, for example, a top-model or right-click subsystem build for a single deployable component. You can compile and link standalone code into a standalone executable or integrate it with other code. For more information on the standalone code interface, see “Configure Generated C Function Interface for Model Entry-Point Functions”.

When you generate code for a referenced model hierarchy, the software generates standalone executable code for the top model and a library module called a *model reference target* for each referenced model. When the code executes, the standalone executable invokes the applicable model reference targets to compute the referenced model outputs. For more information, see “Build Model Reference Targets”.

To integrate generated code with legacy code, use standalone code because the standalone code interface is documented.

---

**Note** SIL and PIL simulations do not provide direct support for custom code interfaces. You can incorporate these interfaces into Simulink as an S-function, for example, using the Legacy Code Tool, S-Function Builder, or handwritten code. Then, you can verify the custom code by using SIL and PIL simulations.

---

This table provides the interfaces that SIL and PIL simulations generate.

SIL/PIL Simulation	Code Interface
Top-model	SIL/PIL simulation generates the standalone code interface. If the code exists, simulation calls the standalone code for the model . If the code does not exist, simulation generates the standalone code.
Model block	<p>If you set the <b>Code interface</b> block parameter to <code>Top model</code>, SIL/PIL simulation generates the standalone code interface. Simulation calls the standalone code for the model if it exists. Otherwise, simulation generates standalone code by using the <code>slbuild('model')</code> command.</p> <p>If you set the <b>Code interface</b> block parameter to <code>Model reference</code>, SIL/PIL simulation generates the model reference code interface. Simulation calls the model reference target for the Model block if it exists. Otherwise, simulation generates the model reference target by using the <code>slbuild('model', 'ModelReferenceCoderTarget')</code> command.</p>
SIL or PIL block	The block uses the standalone code interface.

## Scheduling Considerations

Item	Information
Algebraic loops	<p>There are algebraic loops that occur in SIL and PIL simulations but not in normal mode simulations:</p> <ul style="list-style-type: none"> <li>• <b>Single output/update function</b> in code generation optimization can introduce algebraic loops because the option introduces direct feedthrough via a combined output and update function.</li> </ul> <p><b>Single output/update function</b> is not compatible with <b>Minimize algebraic loop occurrences</b> (in the Subsystem Parameters dialog box and <b>Configuration Parameters &gt; Model Referencing</b> pane). <b>Minimize algebraic loop occurrences</b> allows code generation to remove algebraic loops by partitioning generated code between output and update functions to avoid direct feedthrough.</p> <ul style="list-style-type: none"> <li>• If you generate code for a virtual subsystem, code generation treats the subsystem as atomic and generates the code accordingly. The resulting code can change the execution behavior of your model, for example, by applying algebraic loops, and introduce inconsistencies to the simulation behavior.</li> </ul> <p>To enable consistent simulation and execution behavior for your model, declare virtual subsystems as atomic subsystems.</p> <p>For more information, see:</p> <ul style="list-style-type: none"> <li>• “Algebraic Loop Concepts”</li> <li>• “Algebraic Loops”</li> <li>• “Subcomponents and Utilities”</li> </ul>
Exported functions in feedback loops	<p>If your model has function-call subsystems and you export a subsystem that has context-dependent inputs (for example, feedback signals), the results of a SIL/PIL simulation with the generated code and the results of the normal mode simulation of your model can differ. One approach to make SIL/PIL and normal mode simulations yield identical results is to use Function-Call Feedback Latch blocks in your model. You can make context-dependent inputs become context-independent.</p> <p>If you set the <b>Context-dependent inputs</b> configuration parameter to <code>warning</code>, Embedded Coder generates a warning that identifies context-dependent inputs of exported function-call subsystems.</p> <p>For more information, see:</p> <ul style="list-style-type: none"> <li>• “Subcomponents and Utilities”</li> <li>• Function-Call Feedback Latch</li> <li>• “Context-dependent inputs”</li> </ul>

## Imported Data and Additional Generated Code

A SIL or PIL simulation does not modify the code generated from the model. If you use imported data, the SIL or PIL simulation generates additional code that is required to support compiling and linking

of the SIL or PIL target application. The additional generated code corresponds to interfaces that you specify in the model.

This section describes:

- For imported data, when the SIL or PIL simulation defines storage and when you must define storage.
- Interfaces for which a SIL or PIL simulation generates additional code

### Imported Data in SIL or PIL Simulations

In SIL and PIL simulations, you can use signals, parameters, and data stores that specify storage classes with imported data definitions. The simulations define storage for imported data associated with:

- Signals at the root level of the component (on the I/O boundary).
- Parameters in the base workspace or a data dictionary. For parameters in the model workspace:
  - Top-model SIL/PIL and SIL/PIL block simulations define storage.
  - Model block SIL/PIL simulations do not define storage. You must define storage and specify initial values that match MATLAB values.
- Global data stores.

SIL and PIL simulations do not define storage for other imported data. For example, the simulations do not define storage for imported data associated with:

- Internal signals (not on the I/O boundary). Note that, if the data for internal signals is in structures that are imported through the use of pointers, the simulations define storage.
- Local data stores.

In these cases, define the storage through custom code included by the component under test or through the PIL `rtw.pil.RtIOStreamApplicationFramework` API.

See also “Tunable Parameters and SIL/PIL” on page 82-79.

### Interfaces That Produce Additional Generated Code

This table describes scenarios where a SIL or PIL simulation generates additional code for interfaces.

Scenario	Details
GetSet custom storage class	SIL and PIL simulations support the GetSet custom storage class. The SIL/PIL test harness provides C definitions of the Get and Set functions that are used during simulations. For more information, see “Access Data Through Functions with Storage Class GetSet” on page 37-25.

Scenario	Details
Custom storage class of type <code>Other</code>	<p>To enable SIL and PIL support for the custom storage class where <b>Type</b> is set to <code>Other</code>, create a custom attributes class for the custom storage class and associate the custom attributes class with a Boolean property, <code>SupportSILPIL</code>, set to <code>true</code>.</p> <pre> classdef CSCOtherAttributes &lt; Simulink.CustomStorageClassAttributes     properties(PropertyType = 'logical scalar')         SupportSILPIL = true;     end end </pre> <p>For more information about custom attributes, see “Further Customize Generated Code by Writing TLC Code” on page 37-22 and “Finely Control Data Representation by Writing TLC Code for a Storage Class” on page 37-23.</p> <p>To build the SIL or PIL application interface, the code generator calls the <code>DataAccess</code> and <code>ClassAccess</code> functions in the associated custom TLC file to get required information. The code generator stores the extracted information in build artifacts in the build folder.</p> <p>For a custom storage class that is not grouped:</p> <ul style="list-style-type: none"> <li>• The code generator calls <code>DataAccess</code> with the request argument taking values of <code>define</code>, <code>declare</code>, <code>layout</code>, <code>contents</code>, <code>address</code>, or <code>set</code>.</li> <li>• The code generator uses the string returned by <code>DataAccess(record, "define", "", "")</code> to define the variable in the SIL or PIL application if one of these is true: <ul style="list-style-type: none"> <li>• The signal or parameter has an <code>Imported</code> data scope.</li> <li>• The model uses a model reference code interface.</li> <li>• The model uses a top model code interface, <code>EnableDataOwnership</code> is on, and the <code>Owner</code> attribute for the custom storage class is not empty and not equal to the name of the current model</li> </ul> </li> <li>• The code generator uses the string returned by <code>DataAccess(record, "declare", "", "")</code> to declare the variable in the SIL or PIL application if the following are true: <ul style="list-style-type: none"> <li>• The model uses a top model code interface.</li> <li>• The signal or parameter uses an <code>Exported</code> storage class.</li> <li>• <code>EnableDataOwnership</code> is off, or <code>EnableDataOwnership</code> is on and the <code>Owner</code> attribute for the custom storage class is empty or equal to the model name.</li> <li>• Code packaging is configured so that the variable is not declared in <code>model.h</code> or a header file that is included by <code>model.h</code></li> </ul> </li> </ul> <p>For a custom storage class that is grouped:</p> <ul style="list-style-type: none"> <li>• The code generator calls <code>DataAccess</code> with the request argument taking values of <code>layout</code>, <code>address</code>, or <code>set</code>.</li> </ul>

Scenario	Details
	<ul style="list-style-type: none"> <li>• The code generator calls <code>ClassAccess</code> with the <code>request</code> argument taking the value of <code>groupTypeDeclDefn</code>.</li> <li>• You must provide the grouped type (<code>struct</code>) definition and the <code>extern</code> declaration of the grouped variable if one of these is true: <ul style="list-style-type: none"> <li>• The signal or parameter has an <code>Imported</code> data scope.</li> <li>• The model uses a model reference code interface.</li> <li>• The model uses a top model code interface, <code>EnableDataOwnership</code> is on, and the <code>Owner</code> attribute for the custom storage class is not empty and not equal to the name of the current model</li> </ul> </li> </ul> <p>Provide the definition and declaration in a header file associated with the custom storage class by using the <code>HeaderFile</code> attribute or custom code that you include through the <code>model.h</code> file. To define the variable in the SIL or PIL application, the code generator uses the string returned by <code>ClassAccess(record, "groupTypeDeclDefn")</code>.</p> <ul style="list-style-type: none"> <li>• Static initialization can assume an order of <code>struct</code> elements that is different from the order that is generated if the data scope is <code>Exported</code>. When the code generator queries <code>ClassAccess(record, "groupTypeDeclDefn")</code>, it temporarily overrides the data initialization attribute of the custom storage class with the value <code>None</code>.</li> </ul> <p>To determine whether the SIL or PIL application can access the variable in the code by address, the code generator uses the elements returned by <code>DataAccess(record, "layout", "", "")</code>. To create the functionality in the application that transfers input or output port, tunable parameter, or global data store memory values between the development computer and target hardware, the code generator uses the output from:</p> <ul style="list-style-type: none"> <li>• <code>DataAccess(record, "address", idx, reim)</code> if the first returned element is <code>scalar</code>, <code>vector</code>, <code>row-mat</code>, or <code>col-mat</code>.</li> <li>• <code>DataAccess(record, "contents", idx, reim)</code> (or <code>DataAccess(record, "set", idx, reim)</code>) if the first returned element is <code>other</code>.</li> </ul> <p>The code generator assumes that for <code>row-mat</code> and <code>col-mat</code>, matrices are stored in row-major format respectively. The assumption is independent of the array layout for the rest of the model. The code generator assumes that if the array layout of the storage implemented by the custom storage class differs from the rest of the model, the TLC file associated with the custom storage file performs the required transformations.</p> <p>You can construct the custom TLC file associated with a custom storage class of type <code>Other</code> to perform other functions (in addition to returning the requested code fragments). For example, write directly to a custom file or call MATLAB functions that change the state of the base workspace. If you do not always want to execute these functions when <code>DataAccess</code> or <code>ClassAccess</code> are called, use the <code>LibIsAccessingCustomDataForSILPIL(record)</code> TLC function to distinguish between target code generation and requests for code fragments for the construction of the SIL or PIL application. For example:</p>

Scenario	Details
	<pre data-bbox="516 298 1349 489"> ... %case "contents"   %if !LibIsAccessingCustomDataForSILPIL(record)     %matlab functionWithSideEffects()   %endif %return LibDefaultCustomStorageContents(record, idx, reim) ... </pre> <p data-bbox="516 520 1279 548">See also Other custom storage class limitations on page 82-83.</p>
AUTOSAR Runtime Environment	<p data-bbox="516 564 1466 747">You can use top-model and Model block SIL/PIL and SIL/PIL block simulations to perform model-based testing of an AUTOSAR software component. The software links generated code for the AUTOSAR software component with a basic component-specific AUTOSAR Runtime Environment (RTE) to create a test application. This application tests AUTOSAR API calls made by the AUTOSAR software component.</p> <p data-bbox="516 783 1425 869">For a top-level AUTOSAR software component that contains referenced models, you can run top-model or Model block (<b>Code interface</b> set to Top model) SIL or PIL simulations. In the simulations, the software:</p> <ul data-bbox="516 900 1466 999" style="list-style-type: none"> <li>• Before compilation of referenced models, generates AUTOSAR RTE header files.</li> <li>• Provides the RTE include path for referenced model compilation.</li> </ul> <p data-bbox="516 1035 1466 1180">You can also run Model block (<b>Code interface</b> set to Model reference) SIL or PIL simulations for a referenced model within the top-level AUTOSAR SWC. In this case, before you run a simulation, you must build the parent component to generate the RTE header files. If you do not build the parent component, the SIL or PIL simulation fails.</p>

## Choose a SIL or PIL Approach

### In this section...

“Test Top-Model Code” on page 82-12

“Test Referenced Model Code” on page 82-12

“Test Subsystem Code” on page 82-12

“Summary” on page 82-13

Consider a top model that consists of components A, B, C, and D:

- A and B are existing components for which code has previously been generated and tested.
- C, a referenced model, and D, a subsystem, are new components.

With software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations, you can use the following approaches to numerical equivalence testing:

- Test code from all components together. See “Test Top-Model Code” on page 82-12.
- Test new components separately (before testing code from all components). See “Test Referenced Model Code” on page 82-12 and “Test Subsystem Code” on page 82-12.

For some forms of testing, you require a test harness model. The test harness model:

- Generates test vectors or stimulus inputs that feed the block under test.
- Makes it possible for you to observe or capture output from the block.

The following example shows a simple test harness model.

The block under test is a Model block. The Sine Wave block generates the input for the Model block. Through the Scope block, you can observe the output from the Model block. For information about creating and using test harnesses, see “Create Test Harnesses and Select Properties” (Simulink Test) and “Code Generation Verification Workflow with Simulink Test” (Simulink Test).

## Test Top-Model Code

To test code generated from the top-model components together (A, B, C, and D), you can use top-model SIL/PIL or Model block SIL/PIL.

- Top-model SIL/PIL:
  - 1 Create test vectors or stimulus inputs in the MATLAB workspace.
  - 2 Run the top model in normal, SIL, and PIL simulation modes. The software loads the test vectors or stimulus inputs from the MATLAB workspace.
  - 3 For each simulation mode, observe or capture outputs.
  - 4 Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.
- Model block SIL/PIL:
  - 1 Create a Model block that contains the top-model components.
  - 2 Insert the Model block in a simulation model, for example, your test harness model.
  - 3 Run simulations, switching the Model block between normal, SIL, and PIL modes. For the SIL and PIL simulation modes, set the **Code interface** Model block parameter to `Top model`.
  - 4 Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

For more information, see “Simulation with Top Model” on page 82-15 and “SIL/PIL Manager Verification Workflow” on page 82-72.

## Test Referenced Model Code

To test code generated from the component C as part of a model reference hierarchy, use the Model block SIL/PIL approach:

- Insert the Model block C in a simulation model, for example, your test harness model.
- Run simulations, switching the Model block between normal, SIL, and PIL modes. For the SIL and PIL simulation modes, set the **Code interface** Model block parameter to `Model reference`.
- Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

For more information, see “Simulation with Model Blocks” on page 82-16 and “SIL/PIL Manager Verification Workflow” on page 82-72.

## Test Subsystem Code

To test code that is generated from the subsystem D, use one of these workflows.

Workflow	Description
Simulink Test harness with SIL/PIL Manager	<p>Perform unit tests on subsystem code that is part of the code generated from the parent model.</p> <ol style="list-style-type: none"> <li><b>1</b> Generate code for the model that contains the subsystem by running <code>slbuild(model)</code> or <code>slbuild(model, 'RTWModelReferenceTargetOnly')</code>.</li> <li><b>2</b> In the model, right-click the subsystem and then create a test harness for the subsystem.</li> <li><b>3</b> Open the SIL/PIL Manager. If required, enable code coverage analysis. Then run back-to-back model and SIL or PIL simulations.</li> <li><b>4</b> If required, export an equivalence test case.</li> </ol> <p>For more information, see “Test Atomic Subsystem Generated Code” on page 82-18.</p> <p>If the subsystem is not supported by this workflow, use the SIL or PIL block workflow. For more information about unsupported subsystems and other limitations, see “Atomic Subsystem Workflow Limitations” on page 82-88.</p>
SIL or PIL block	<p>Generate and test new standalone code from the subsystem.</p> <ol style="list-style-type: none"> <li><b>1</b> Insert the subsystem in a simulation model, for example, your test harness model.</li> <li><b>2</b> Run a normal mode simulation, capturing the outputs.</li> <li><b>3</b> Create a SIL or PIL block from the subsystem.</li> <li><b>4</b> In the model, replace the subsystem with the SIL or PIL block.</li> <li><b>5</b> Run a simulation of the model, capturing the outputs.</li> <li><b>6</b> Verify numerical equivalence by comparing normal mode subsystem outputs against SIL or PIL block outputs.</li> </ol> <p>For more information, see “SIL or PIL Block Simulation” on page 82-19.</p>

## Summary

Component From Which Code Is Generated	Simulation Uses	Steps	Generated Code Interface	Test Signal Source
Top model	Top-model SIL/PIL	<p>In SIL/PIL Manager:</p> <ol style="list-style-type: none"> <li><b>1</b> Select <b>SIL/PIL Simulation Only</b> mode.</li> <li><b>2</b> In <b>System Under Test</b>, select Top model.</li> </ol>	Standalone	MATLAB workspace

Component From Which Code Is Generated	Simulation Uses	Steps	Generated Code Interface	Test Signal Source
Model referenced by Model block	Model block SIL/PIL	<ol style="list-style-type: none"> <li><b>1</b> In SIL/PIL Manager:               <ol style="list-style-type: none"> <li><b>a</b> Select <b>SIL/PIL Simulation Only</b> mode.</li> <li><b>b</b> In <b>System Under Test</b>, select Model blocks in SIL/PIL mode.</li> </ol> </li> <li><b>2</b> In Model blocks, set <b>Simulation mode</b> to <b>Software-in-the-loop (SIL)</b> or <b>Processor-in-the-loop (PIL)</b>.</li> </ol>	Determined by Model block parameter <b>Code interface</b> -- standalone or model reference.	Simulation model, for example, test harness model
Subsystem	Simulink Test harness and SIL/PIL Manager	<ol style="list-style-type: none"> <li><b>1</b> Generate code for model that contains the atomic subsystem.</li> <li><b>2</b> Create a test harness for the subsystem.</li> <li><b>3</b> From SIL/PIL Manager, run back-to-back model and SIL or PIL simulations.</li> <li><b>4</b> If required, export equivalence test case.</li> </ol>	Determined by generated parent model code -- standalone or model reference. ## Configure and Run SIL Simulation

### In this section...

“Simulation with Top Model” on page 82-15  
 “Simulation with Model Blocks” on page 82-16  
 “Simulation with Subsystem Blocks” on page 82-17  
 “Test Atomic Subsystem Generated Code” on page 82-18  
 “SIL or PIL Block Simulation” on page 82-19  
 “Configure Hardware Implementation Settings” on page 82-20  
 “Log Signals of a Component” on page 82-22  
 “Prevent Code Changes in Multiple Simulations” on page 82-23  
 “Speed Up Testing” on page 82-24  
 “Simulation with Function Calls” on page 82-24

There are three ways of running SIL and PIL simulations. You can use:

- The top model.
- Model blocks.
- SIL and PIL blocks that you create from subsystems.

### Simulation with Top Model

To configure and run a top-model SIL or PIL simulation:

- 1 In the Simulink Editor, open your model.
- 2 On the **Apps** tab, click **SIL/PIL Manager**.
- 3 In the **Mode** section, select **SIL/PIL Simulation Only**.
- 4 In the **Prepare** section, set **System Under Test** to Top model.
- 5 In the **SIL/PIL Mode** field, select either Software-in-the-Loop (SIL) or Processor-in-the-Loop (PIL). The option supports only ERT, GRT, or AUTOSAR system target files. See “Model Configuration Parameters: Code Generation” and “Configure AUTOSAR Code Generation” (AUTOSAR Blockset) for configuration information.
- 6 To monitor component signals and state data and compare values from the model and SIL or PIL simulations:
  - a For each signal that you want to log:
    - i In the Simulink Editor, select the signal.
    - ii On the **SIL/PIL** tab, click **Monitor Signals**. From the gallery, select these options:
      - **Log Selected Signals**
      - **Make Selected Signals Testpoints**
      - **Signal Logging**
  - b To log state data, from the **Monitor Signals** gallery, select **State Logging**.
  - c If the **Language** configuration parameter is C++, in the **Code Mappings** editor, set the **Data Visibility** for the signals, states, and internal data model element categories to public.

- 7 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. In the Configuration Parameters dialog box, select the **Enable portable word sizes** check box.
- 8 If required, configure:
  - Code coverage.
  - Code execution profiling on page 76-2.
  - Creation of code generation report and static code metrics on page 82-70.
- 9 In the **Run** section, in the **Stop Time** field, specify simulation time.
- 10 Click **Run SIL/PIL**.
- 11 At the end of the simulation, in the **Results** section, click **Data Inspector** to view simulation results.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

You cannot:

- Close the model while the simulation is running. To interrupt the simulation, in the Command Window, press **Ctrl+C**.
- Alter the model during the simulation. You can move blocks and lines as long as it does not alter the behavior of the model.

You can run a top-model SIL or PIL simulation with the command `sim(model)`. The software supports the `sim` command option `SrcWorkspace` for the value `'base'`.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## Simulation with Model Blocks

To configure a Model block for a SIL or PIL simulation:

- 1 In the Simulink Editor, open your model, for example, `rtwdemo_sil_modelblock`.
- 2 Right-click your Model block, for example, `Counter A`. In the context menu, select **Block Parameters (ModelReference)**, which opens the Function Block Parameters dialog box.
- 3 From the **Simulation Mode** drop-down list, select the required mode, for example, `Software-in-the-loop (SIL)`.
- 4 From the **Code interface** drop-down list, specify the code that you want to test, for example, `Model reference`.
- 5 Click **OK**. The software displays the simulation mode as a block label.

If you select `Top model`, the software displays the block label (`SIL: Top`).

- 6 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. In the Configuration Parameters dialog box, select the **Enable portable word sizes** check box.
- 7 On the **Apps** tab, click **SIL/PIL Manager**.
- 8 In the **Mode** section, select **SIL/PIL Simulation Only**.
- 9 In the **Prepare** section, set **System Under Test** to `Model` blocks in SIL/PIL mode.
- 10 In the **Top Model Mode** field, select either `Normal` or `Accelerator`.
- 11 If required, configure:
  - “Code Coverage”.
  - Code execution profiling on page 76-2 for your `Model` block, by configuring execution profiling for the top model.
  - Creation of code generation report and static code metrics on page 82-70.
- 12 In the **Run** section:
  - In the **Stop Time** field, specify simulation time.
  - If you want to avoid rebuilding code after the initial build, click **Fast Restart**. See “Prevent Code Changes in Multiple Simulations” on page 82-32.
  - Click **Run SIL/PIL**.
- 13 At the end of the simulation, in the **Results** section, click `Data Inspector` to view simulation results.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## Simulation with Subsystem Blocks

You can use one of these workflows:

- Simulink Test harness with the SIL/PIL Manager—If you have a model that contains subsystems, you can use Simulink Test and the SIL/PIL Manager to perform unit tests on code generated from

the subsystems. This workflow tests the generated subsystem code as part of the code generated from the parent model. For workflow details, see “Test Atomic Subsystem Generated Code” on page 82-29.

If this workflow does not support a subsystem, use the SIL or PIL block workflow as an alternative.

- **SIL or PIL block**—Create a SIL or PIL block from the subsystem, and then run the block in an environment or test harness model that supplies test vectors or stimulus input. This workflow generates and tests new standalone code from the subsystem. For more information, see “SIL or PIL Block Simulation” on page 82-30.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## Test Atomic Subsystem Generated Code

To perform unit tests on code generated from an atomic subsystem:

- 1 Open the model that contains the atomic subsystem. For example, in the Command Window, enter:

```
rtwdemo_sil_block
```

- 2 In a new folder, save the model as `plant_model`.
- 3 Modify configuration parameter settings that are not supported for this workflow. In the Command Window, enter:

```
set_param('plant_model', ...
 'CreateSILPILBlock', 'None', ...
 'PreserveStaticInFcnDecls', 'Off');

% For this example, use these values for block parameters.
set_param('plant_model/Controller', ...
 'RTWSystemCode', 'Nonreusable function', ...
 'RTWFileNameOpts', 'Auto');
```

For more information about limitations, see “Atomic Subsystem Workflow Limitations” on page 82-88.

- 4 Generate code for the model that contains the atomic subsystem. In the Command Window, enter:
 

```
slbuild('plant_model')
```
- 5 Create a test harness for the subsystem. Right-click the `Controller` subsystem and select **Test Harness > Create for 'Controller'**.
- 6 Set the harness properties:

- **Name** -- `controller_subsystem_harness`
- **Sources and Sinks:** Inport and Outport
- Select **Open harness after creation**.

Click **OK**.

Simulink Test creates a test harness for the `Controller` subsystem.

- 7 Specify format for saving data. In the Command Window, enter:

```
set_param('controller_subsystem_harness', ...
 'SaveFormat', 'Dataset')
```

- 8 In the Test Harness window, open the SIL/PIL Manager. On the **Apps** tab, click **SIL/PIL Manager**.
- 9 If required, configure code coverage.
- 10 Run back-to-back model and SIL simulations:
  - a In the **Mode** section, select **Automated Verification**.
  - b In the **Run Automated Verification** section, click **Run Verification**.
- 11 From the **Results** gallery, you can:
  - Use the Simulation Data Inspector to analyze results. For example, compare the controller\_model\_output signals from the model and SIL simulations.
  - Export an equivalence test case.

For more information, see “Analyze Results and Export Test Cases” on page 82-75.

## SIL or PIL Block Simulation

To create a SIL or PIL block from a subsystem and use this block to test the code generated from the subsystem:

- 1 From the **Configuration Parameters > Code Generation > Verification > Advanced Parameters > Create block** drop-down list, select either SIL or PIL.
- 2 If required, configure code execution profiling.
- 3 Click **OK**.
- 4 In your model window, right-click the subsystem that you want to simulate.
- 5 Select **C/C++ Code > Build This Subsystem**.
- 6 Click **Build**, which starts the subsystem build process that creates a SIL or PIL block for the generated subsystem code.
- 7 Add the generated block to an environment or test harness model that supplies test vectors or stimulus input.
- 8 Run simulations with the environment or test harness model.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

You cannot create a SIL or PIL block if you do one of the following:

- Disable the CreateSILPILBlock property.
- Select a code coverage tool.

**Create block** appears dimmed.

## Configure Hardware Implementation Settings

For a SIL simulation, you must configure hardware implementation settings, which enables generated code compilation for your development computer. These settings can differ from the hardware implementation settings that you use when building the model for your production hardware. Use one of these approaches.

Approach	Details
Portable word sizes	<p>Switch between SIL and PIL modes without regenerating code. You use the same generated source code files for the SIL simulation on your development computer and for production deployment on the target platform.</p> <p>To configure a model to use portable word sizes, set:</p> <ul style="list-style-type: none"> <li>• ProdEqTarget to 'on'.</li> <li>• PortableWordSizes to 'on'.</li> </ul> <p>When you generate code for a model with portable word sizes specified, the code generator conditionalizes data type definitions in <code>rtwtypes.h</code>:</p> <pre>#ifdef PORTABLE_WORDSIZES          /* PORTABLE_WORDSIZES defined */ ... #else                                /* PORTABLE_WORDSIZES not defined */ ... #endif                               /* PORTABLE_WORDSIZES */</pre> <p>The template makefile that you use to build code for your target must not contain the <code>PORTABLE_WORDSIZES</code> definition.</p> <p>For the template makefile and toolchain approaches to building code, the software specifies <code>-DPORTABLE_WORDSIZES</code> for the compiler only for host-based builds.</p> <p>For information about the template makefile and toolchain approaches to building code, see “Configure Toolchain or Template Makefile Build Process” on page 56-12.</p>

Approach	Details
	<p>Consider the case where your target uses code that your development computer cannot compile. When you switch from the PIL mode to the SIL mode and try to simulate the model, you see compilation errors. You can try to work around this problem by adding the source code files to the <code>SkipForSil</code> group in the build information object <code>RTW.BuildInfo</code>. The SIL build on the host platform does not compile source files present in the <code>SkipForSil</code> group. For information about how you add source code files to a group in the build information object, see:</p> <ul style="list-style-type: none"> <li>• <code>addSourceFiles</code> in the Simulink Coder documentation</li> <li>• “Customize Post-Code-Generation Build Processing” in the Simulink Coder documentation</li> </ul> <p>Numerical results can differ between generated code executing in a SIL simulation and generated code executing on the production hardware under one of these conditions:</p> <ul style="list-style-type: none"> <li>• Your model contains blocks implemented in TLC, for which C integral promotion in expressions can behave differently between the MATLAB host and the production hardware target. Normal and PIL simulation results match, but SIL simulation results can differ.</li> <li>• Your production hardware implements rounding to <code>Floor</code> for signed integer division, and divisions in your model use rounding mode <code>Ceiling</code>, <code>Floor</code>, <code>Simplest</code>, or <code>Zero</code>. Normal and PIL simulation results match, but SIL simulation results can differ.</li> <li>• The byte ordering for your production hardware is <code>Big Endian</code>. Normal and PIL simulation results match, but SIL simulation results can differ. For example, when generated code depends on byte order <i>and</i> generated production code is implemented with the aim that its behavior matches normal simulation behavior.</li> <li>• You use custom code with the Stateflow product. In this case, type conversion statements are not inserted into the custom code, which target overflow behavior on the host can require. Normal and PIL simulation results match, but SIL simulation results can differ.</li> </ul>
Test hardware	<p>Use this approach only when you want to work around a limitation of portable word sizes.</p> <p>Set:</p> <ul style="list-style-type: none"> <li>• <code>PortableWordSizes</code> to 'off'.</li> <li>• <code>ProdEqTarget</code> to 'off'.</li> <li>• <code>TargetHWDeviceType</code> to 'Custom Processor-&gt;MATLAB Host Processor'.</li> </ul>
Production hardware	<p>Use this approach only when the production hardware settings match your development computer architecture.</p> <p>Set:</p> <ul style="list-style-type: none"> <li>• <code>PortableWordSizes</code> to 'off'.</li> <li>• <code>ProdEqTarget</code> to 'on'.</li> <li>• <code>ProdHWDeviceType</code> to match your development computer architecture.</li> </ul>

For information about test and production targets, see “Configure Run-Time Environment Options” in the Simulink Coder documentation.

## Log Signals of a Component

SIL and PIL component outputs are available for observation and comparison with other simulation mode outputs. If you want to examine an internal signal, you can enable internal signal logging for top-model or Model block SIL or PIL. With signal logging, you can:

- Collect signal logging outputs during SIL/PIL simulations, for example, `logout`.
- Log the internal signals and the root-level outputs of a SIL/PIL component.
- Manage the SIL/PIL signal logging settings with the Simulink Signal Logging Selector.
- Use the Simulation Data Inspector to:
  - Observe streamed signals during normal, SIL, and PIL simulations.
  - Compare logged signals from normal, SIL, and PIL simulations.

To enable signal logging to the MATLAB workspace and signal streaming to the Simulation Data Inspector during SIL or PIL simulations:

- 1 For each signal that you want to monitor:
  - a In the Simulink Editor, select the signal.
  - b On the **SIL/PIL** tab, click **Monitor Signals**. From the gallery, select these options:
    - **Log Selected Signals**
    - **Make Selected Signals Testpoints**
    - **Signal Logging**
- 2 If the **Language** configuration parameter is C++, in the **Code Mappings** editor, set the **Data Visibility** for the signals, states, and internal data model element categories to `public`.

You can use other methods to examine internal signals of the SIL or PIL component:

- Manually route the signal to the top level.
- Use global data stores to access internal signals:
  - 1 Inside the component, connect a Data Store Write block to the required signal.
  - 2 Outside the component, use a Data Store Read block to access the signal value.
- Use MAT-file logging. Note that:
  - MAT-file logging does not support signal logging. If signal logging is enabled, `logout` is generated but not stored in the MAT-file.
  - For PIL, the target environment must support MAT-file logging.

For more information, see:

- “Configure Signals as Test Points”
- “Export Signal Data Using Signal Logging”
- “Local and Global Data Stores”

- “Global Data Store Example”
- “Log Program Execution Results”

## Prevent Code Changes in Multiple Simulations

Use Model block SIL/PIL or the SIL/PIL block with fast restart when you want to run multiple SIL or PIL simulations with:

- Varying test vectors (parameter sets and input data).
- Unchanged generated code, that is, none of the simulations regenerate or rebuild code after the initial build. For example, you want to avoid the incremental code generation that an initial value change can trigger.

For Model block SIL/PIL, you can also use one of these methods:

- In your test harness model, in the Configuration Parameters dialog box, set **Rebuild** to **Never**. If the Model block **Code interface** parameter is `Model reference`, the software does not rebuild the referenced model code. (If the **Code interface** parameter is `Top model`, the software ignores the **Rebuild** setting.)
- Create a protected model and generate source or binary code. Then, insert the protected model in your test harness model. With this method, you can verify top-model code (with the standalone code interface) or model reference code.

For the alternative methods of running Model block SIL/PIL, the following table summarizes code generation behavior after the initial build.

SIL and PIL Approach		Code Generation Behavior After Initial Build
Model block	<b>Rebuild</b> configuration parameter of test harness model set to <b>Never</b> .	<ol style="list-style-type: none"> <li><b>1</b> Component (algorithm) code from initial build is not regenerated.</li> <li><b>2</b> Component code makefile is not called.</li> <li><b>3</b> SIL/PIL application files from initial build are not regenerated.</li> <li><b>4</b> SIL/PIL application makefile is called.</li> </ol>
Model block (protected model)	Source code from protected model.	You observe the same behavior except for feature 2. In this case, the component code makefile is run. The component code is recompiled and linked to produce new object code.
	Binary code from protected model.	You observe features 1-4.

For more information, see:

- “Model Configuration Parameters: Model Referencing”
- “Protect Models to Conceal Contents”

## Speed Up Testing

If your model has SIL/PIL blocks or Model blocks in SIL/PIL mode, you can speed up SIL/PIL testing by:

- Running the top-model simulation in accelerator mode. This mode accelerates the simulation of model components that are not in SIL or PIL mode.
- Turning on fast restart. After the first simulation, you can tune parameters and rerun simulations without model recompilation. The SIL/PIL Manager provides a **Fast Restart** button.

---

**Note** The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?”.

---

## Simulation with Function Calls

Use the Simulink Function block and Simulink Function block when you want to:

- Generate code that makes a function-call to external code, for example, driver or legacy code.
- Provide a subsystem that behaves like the external code in normal, SIL, or PIL simulations.

The example in “Configure Calls to AUTOSAR NVRAM Manager Service” (AUTOSAR Blockset) shows how you can configure client calls to Basic Software (BSW) NVRAM Manager (NvM) service interfaces from your AUTOSAR software component. In a simulation, Simulink implements the BSW NvM calls through Simulink Function and preconfigured Function Caller blocks. For the final system, you link function-call stubs with external BSW function code that runs in the AUTOSAR Runtime Environment (RTE).

For more information, see “Simulink Function Blocks and Code Generation”.

 “Simulation with Model Blocks” on page 82-27  
 “Simulation with Subsystem Blocks” on page 82-28  
 “Test Atomic Subsystem Generated Code” on page 82-29  
 “SIL or PIL Block Simulation” on page 82-30  
 “Log Signals of a Component” on page 82-31  
 “Prevent Code Changes in Multiple Simulations” on page 82-32  
 “Speed Up Testing” on page 82-33  
 “Simulation with Function Calls” on page 82-33

There are three ways of running SIL and PIL simulations. You can use:

- The top model.
- Model blocks.
- SIL and PIL blocks that you create from subsystems.

### Simulation with Top Model

To configure and run a top-model SIL or PIL simulation:

- 1 In the Simulink Editor, open your model.
- 2 On the **Apps** tab, click **SIL/PIL Manager**.
- 3 In the **Mode** section, select **SIL/PIL Simulation Only**.
- 4 In the **Prepare** section, set **System Under Test** to Top model.
- 5 In the **SIL/PIL Mode** field, select either Software-in-the-Loop (SIL) or Processor-in-the-Loop (PIL). The option supports only ERT, GRT, or AUTOSAR system target files. See “Model Configuration Parameters: Code Generation” and “Configure AUTOSAR Code Generation” (AUTOSAR Blockset) for configuration information.
- 6 To monitor component signals and state data and compare values from the model and SIL or PIL simulations:
  - a For each signal that you want to log:
    - i In the Simulink Editor, select the signal.
    - ii On the **SIL/PIL** tab, click **Monitor Signals**. From the gallery, select these options:
      - **Log Selected Signals**
      - **Make Selected Signals Testpoints**
      - **Signal Logging**
  - b To log state data, from the **Monitor Signals** gallery, select **State Logging**.
  - c If the **Language** configuration parameter is C++, in the **Code Mappings** editor, set the **Data Visibility** for the signals, states, and internal data model element categories to public.

- 7 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. In the Configuration Parameters dialog box, select the **Enable portable word sizes** check box.
- 8 If required, configure:
  - Code coverage.
  - Code execution profiling on page 76-2.
  - Creation of code generation report and static code metrics on page 82-70.
- 9 In the **Run** section, in the **Stop Time** field, specify simulation time.
- 10 Click **Run SIL/PIL**.
- 11 At the end of the simulation, in the **Results** section, click **Data Inspector** to view simulation results.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

You cannot:

- Close the model while the simulation is running. To interrupt the simulation, in the Command Window, press **Ctrl+C**.
- Alter the model during the simulation. You can move blocks and lines as long as it does not alter the behavior of the model.

You can run a top-model SIL or PIL simulation with the command `sim(model)`. The software supports the `sim` command option `SrcWorkspace` for the value `'base'`.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## Simulation with Model Blocks

To configure a Model block for a SIL or PIL simulation:

- 1 In the Simulink Editor, open your model, for example, `rtwdemo_sil_modelblock`.
- 2 Right-click your Model block, for example, `Counter A`. In the context menu, select **Block Parameters (ModelReference)**, which opens the Function Block Parameters dialog box.
- 3 From the **Simulation Mode** drop-down list, select the required mode, for example, `Software-in-the-loop (SIL)`.
- 4 From the **Code interface** drop-down list, specify the code that you want to test, for example, `Model reference`.
- 5 Click **OK**. The software displays the simulation mode as a block label.

If you select `Top model`, the software displays the block label (`SIL: Top`).

- 6 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. In the Configuration Parameters dialog box, select the **Enable portable word sizes** check box.
- 7 On the **Apps** tab, click **SIL/PIL Manager**.
- 8 In the **Mode** section, select **SIL/PIL Simulation Only**.
- 9 In the **Prepare** section, set **System Under Test** to `Model blocks in SIL/PIL mode`.
- 10 In the **Top Model Mode** field, select either `Normal` or `Accelerator`.
- 11 If required, configure:
  - “Code Coverage”.
  - Code execution profiling on page 76-2 for your Model block, by configuring execution profiling for the top model.
  - Creation of code generation report and static code metrics on page 82-70.
- 12 In the **Run** section:
  - In the **Stop Time** field, specify simulation time.
  - If you want to avoid rebuilding code after the initial build, click **Fast Restart**. See “Prevent Code Changes in Multiple Simulations” on page 82-32.
  - Click **Run SIL/PIL**.
- 13 At the end of the simulation, in the **Results** section, click Data Inspector to view simulation results.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## Simulation with Subsystem Blocks

You can use one of these workflows:

- Simulink Test harness with the SIL/PIL Manager—If you have a model that contains subsystems, you can use Simulink Test and the SIL/PIL Manager to perform unit tests on code generated from

the subsystems. This workflow tests the generated subsystem code as part of the code generated from the parent model. For workflow details, see “Test Atomic Subsystem Generated Code” on page 82-29.

If this workflow does not support a subsystem, use the SIL or PIL block workflow as an alternative.

- **SIL or PIL block**—Create a SIL or PIL block from the subsystem, and then run the block in an environment or test harness model that supplies test vectors or stimulus input. This workflow generates and tests new standalone code from the subsystem. For more information, see “SIL or PIL Block Simulation” on page 82-30.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## Test Atomic Subsystem Generated Code

To perform unit tests on code generated from an atomic subsystem:

- 1 Open the model that contains the atomic subsystem. For example, in the Command Window, enter:

```
rtwdemo_sil_block
```

- 2 In a new folder, save the model as `plant_model`.
- 3 Modify configuration parameter settings that are not supported for this workflow. In the Command Window, enter:

```
set_param('plant_model', ...
 'CreateSILPILBlock', 'None', ...
 'PreserveStaticInFcnDecls', 'Off');

% For this example, use these values for block parameters.
set_param('plant_model/Controller', ...
 'RTWSystemCode', 'Nonreusable function', ...
 'RTWFileNameOpts', 'Auto');
```

For more information about limitations, see “Atomic Subsystem Workflow Limitations” on page 82-88.

- 4 Generate code for the model that contains the atomic subsystem. In the Command Window, enter:
 

```
slbuild('plant_model')
```
- 5 Create a test harness for the subsystem. Right-click the `Controller` subsystem and select **Test Harness > Create for 'Controller'**.
- 6 Set the harness properties:

- **Name** -- `controller_subsystem_harness`
- **Sources and Sinks:** Inport and Outport
- Select **Open harness after creation**.

Click **OK**.

Simulink Test creates a test harness for the `Controller` subsystem.

- 7 Specify format for saving data. In the Command Window, enter:
 

```
set_param('controller_subsystem_harness', ...
 'SaveFormat', 'Dataset')
```
- 8 In the Test Harness window, open the SIL/PIL Manager. On the **Apps** tab, click **SIL/PIL Manager**.
- 9 If required, configure code coverage.
- 10 Run back-to-back model and SIL simulations:
  - a In the **Mode** section, select **Automated Verification**.
  - b In the **Run Automated Verification** section, click **Run Verification**.
- 11 From the **Results** gallery, you can:
  - Use the Simulation Data Inspector to analyze results. For example, compare the controller\_model\_output signals from the model and SIL simulations.
  - Export an equivalence test case.

For more information, see “Analyze Results and Export Test Cases” on page 82-75.

## SIL or PIL Block Simulation

To create a SIL or PIL block from a subsystem and use this block to test the code generated from the subsystem:

- 1 From the **Configuration Parameters > Code Generation > Verification > Advanced Parameters > Create block** drop-down list, select either SIL or PIL.
- 2 If required, configure code execution profiling.
- 3 Click **OK**.
- 4 In your model window, right-click the subsystem that you want to simulate.
- 5 Select **C/C++ Code > Build This Subsystem**.
- 6 Click **Build**, which starts the subsystem build process that creates a SIL or PIL block for the generated subsystem code.
- 7 Add the generated block to an environment or test harness model that supplies test vectors or stimulus input.
- 8 Run simulations with the environment or test harness model.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

You cannot create a SIL or PIL block if you do one of the following:

- Disable the CreateSILPILBlock property.
- Select a code coverage tool.

**Create block** appears dimmed.

## Log Signals of a Component

SIL and PIL component outputs are available for observation and comparison with other simulation mode outputs. If you want to examine an internal signal, you can enable internal signal logging for top-model or Model block SIL or PIL. With signal logging, you can:

- Collect signal logging outputs during SIL/PIL simulations, for example, `logout`.
- Log the internal signals and the root-level outputs of a SIL/PIL component.
- Manage the SIL/PIL signal logging settings with the Simulink Signal Logging Selector.
- Use the Simulation Data Inspector to:
  - Observe streamed signals during normal, SIL, and PIL simulations.
  - Compare logged signals from normal, SIL, and PIL simulations.

To enable signal logging to the MATLAB workspace and signal streaming to the Simulation Data Inspector during SIL or PIL simulations:

- 1** For each signal that you want to monitor:
  - a** In the Simulink Editor, select the signal.
  - b** On the **SIL/PIL** tab, click **Monitor Signals**. From the gallery, select these options:
    - **Log Selected Signals**
    - **Make Selected Signals Testpoints**
    - **Signal Logging**
- 2** If the **Language** configuration parameter is C++, in the **Code Mappings** editor, set the **Data Visibility** for the signals, states, and internal data model element categories to `public`.

You can use other methods to examine internal signals of the SIL or PIL component:

- Manually route the signal to the top level.
- Use global data stores to access internal signals:
  - 1** Inside the component, connect a Data Store Write block to the required signal.
  - 2** Outside the component, use a Data Store Read block to access the signal value.
- Use MAT-file logging. Note that:
  - MAT-file logging does not support signal logging. If signal logging is enabled, `logout` is generated but not stored in the MAT-file.

- For PIL, the target environment must support MAT-file logging.

For more information, see:

- “Configure Signals as Test Points”
- “Export Signal Data Using Signal Logging”
- “Local and Global Data Stores”
- “Global Data Store Example”
- “Log Program Execution Results”

## Prevent Code Changes in Multiple Simulations

Use Model block SIL/PIL or the SIL/PIL block with fast restart when you want to run multiple SIL or PIL simulations with:

- Varying test vectors (parameter sets and input data).
- Unchanged generated code, that is, none of the simulations regenerate or rebuild code after the initial build. For example, you want to avoid the incremental code generation that an initial value change can trigger.

For Model block SIL/PIL, you can also use one of these methods:

- In your test harness model, in the Configuration Parameters dialog box, set **Rebuild** to **Never**. If the Model block **Code interface** parameter is `Model` reference, the software does not rebuild the referenced model code. (If the **Code interface** parameter is `Top model`, the software ignores the **Rebuild** setting.)
- Create a protected model and generate source or binary code. Then, insert the protected model in your test harness model. With this method, you can verify top-model code (with the standalone code interface) or model reference code.

For the alternative methods of running Model block SIL/PIL, the following table summarizes code generation behavior after the initial build.

SIL and PIL Approach		Code Generation Behavior After Initial Build
Model block	<b>Rebuild</b> configuration parameter of test harness model set to <b>Never</b> .	<ol style="list-style-type: none"> <li><b>1</b> Component (algorithm) code from initial build is not regenerated.</li> <li><b>2</b> Component code makefile is not called.</li> <li><b>3</b> SIL/PIL application files from initial build are not regenerated.</li> <li><b>4</b> SIL/PIL application makefile is called.</li> </ol>

SIL and PIL Approach		Code Generation Behavior After Initial Build
Model block (protected model)	Source code from protected model.	You observe the same behavior except for feature 2. In this case, the component code makefile is run. The component code is recompiled and linked to produce new object code.
	Binary code from protected model.	You observe features 1-4.

For more information, see:

- “Model Configuration Parameters: Model Referencing”
- “Protect Models to Conceal Contents”

## Speed Up Testing

If your model has SIL/PIL blocks or Model blocks in SIL/PIL mode, you can speed up SIL/PIL testing by:

- Running the top-model simulation in accelerator mode. This mode accelerates the simulation of model components that are not in SIL or PIL mode.
- Turning on fast restart. After the first simulation, you can tune parameters and rerun simulations without model recompilation. The SIL/PIL Manager provides a **Fast Restart** button.

---

**Note** The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?”.

---

## Simulation with Function Calls

Use the Simulink Function block and Simulink Function block when you want to:

- Generate code that makes a function-call to external code, for example, driver or legacy code.
- Provide a subsystem that behaves like the external code in normal, SIL, or PIL simulations.

The example in “Configure Calls to AUTOSAR NVRAM Manager Service” (AUTOSAR Blockset) shows how you can configure client calls to Basic Software (BSW) NVRAM Manager (NvM) service interfaces from your AUTOSAR software component. In a simulation, Simulink implements the BSW NvM calls through Simulink Function and preconfigured Function Caller blocks. For the final system, you link function-call stubs with external BSW function code that runs in the AUTOSAR Runtime Environment (RTE).

For more information, see “Simulink Function Blocks and Code Generation”.

- “SIL and PIL Limitations” on page 82-79

## Simulation Mode Override Behavior in Model Reference Hierarchy

When the top model contains a Model block, the simulation mode of the top model can override the simulation mode of the Model block. The model referenced by the Model block can be a parent model that contains Model blocks at lower levels of the model hierarchy. When you simulate the model hierarchy, the simulation mode of a parent model can override the simulation mode of Model blocks that the parent model contains.

You can specify the simulation mode of a top model to be normal, accelerator, rapid accelerator, SIL, or PIL. With a Model block, you can specify all modes *except* rapid accelerator. This table shows how the software determines the effective simulation mode of a Model block in a model hierarchy.

Simulation Mode Used by Parent Model	Simulation Mode of Model Block			
	Normal	Accelerator	SIL	PIL
<b>Normal</b>	Compatible	Compatible	Compatible	Compatible
<b>Accelerator</b>	Overridden	Compatible	Compatible if top model mode is accelerator. Error if parent block mode is accelerator.	Compatible if top model mode is accelerator. Error if parent block mode is accelerator.
<b>Rapid accelerator</b> (top model only)	Overridden	Compatible	Error	Error
<b>SIL</b>	Overridden	Overridden	Compatible	Error
<b>PIL</b>	Overridden	Overridden	Error	Compatible

The different types of behavior are:

- **Compatible** — The software simulates the Model block in the mode specified for it.
- **Error** — The simulation produces an error. For example, if a top model specifies rapid accelerator mode but contains a Model block in SIL or PIL mode, then running a simulation produces an error: the rapid accelerator mode cannot override the SIL and PIL mode of Model blocks. This behavior avoids the risk of false positives, that is, the simulation of a model in rapid accelerator mode does not lead to the conclusion that generated source or object code of Model blocks is tested or verified.
- **Overridden** — The simulation mode of the top model or parent model overrides the simulation mode of the Model block. For example, if a top model or parent model that you configured for a SIL simulation contains a Model block with normal or accelerator simulation mode, then the software simulates the referenced model in SIL mode. The override behavior:
  - Allows a Model block in the model hierarchy to have SIL or PIL mode.
  - Makes lower-level referenced models execute in SIL or PIL mode if you simulate the top model or parent model in SIL or PIL mode. You do not have to switch the simulation mode of every referenced model in the hierarchy.

Multiple Model blocks, starting at the top of a model hierarchy, can execute in SIL or PIL mode. However, if code coverage or code execution profiling is enabled, only one Model block can execute at a time in SIL or PIL mode.

---

**Note** You can view your model hierarchy in the Dependency Analyzer. In the Model Instances view, the software displays Model blocks differently to indicate their simulation modes, for example, normal, accelerator, SIL, and PIL. In this view, the software does not indicate the simulation mode of the top model.

---

## Debug Generated Code During SIL Simulation

If a software-in-the-loop (SIL) simulation fails or you notice differences between the outputs of your original functions and the generated code, you can rerun the SIL simulation with a debugger enabled. By inserting breakpoints, you can observe the behavior of code sections, which can help you to understand the cause of the issue.

For a SIL simulation failure, you can also view information from the standard output and standard error streams in the Diagnostic Viewer. For example:

- Output from `printf` statements in your code.
- Error messages sent to `stderr`.
- Some low-level system messages.

During a SIL simulation, the SIL application redirects the `stdout` and `stderr` streams. When the application terminates, the Diagnostic Viewer displays the information from the redirected streams. The SIL application also provides a basic signal handler, which captures the POSIX® signals `SIGFPE`, `SIGILL`, `SIGABRT`, and `SIGSEV`. For this signal handler, the SIL application includes the file `signal.h`.

This table gives information about debugger support.

Operating System	Supported Debuggers
Windows	Microsoft Visual Studio IDE.
	Visual Studio Code with MinGW GDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package, which you can download from MATLAB Central™ File Exchange.
macOS	LLDB.
	Visual Studio Code with LLDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package, which you can download from MATLAB Central File Exchange.
Linux	GNU Data Display Debugger (DDD).
	Visual Studio Code with GDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package, which you can download from MATLAB Central File Exchange.

**Note** You can perform SIL debugging only if the Simulink product family supports your Microsoft Visual C++, Xcode, or GNU GCC compiler. For more information, see supported compilers.

To enable your debugger for a SIL simulation, perform one of these actions:

- On the **SIL/PIL** tab, click **Settings > SIL Debugging**.

- In the Configuration Parameters dialog box, select the **Enable source-level debugging for SIL** check box.

If your top model has Model blocks, the **Enable source-level debugging for SIL** parameter for the top model overrides the corresponding parameter for referenced models.

When you run the SIL simulation, your *model.c* or *model.cpp* file opens, for example, in the Microsoft Visual Studio IDE with debugger breakpoints at the start of the *model\_initialize* and *model\_step* functions.

```

Solution Explorer
Solution 'tp2d0d6316_c327'
 rtwdemo_sil_topmodel

rtwdemo_sil_topmodel.c
(Unknown Scope)
void rtwdemo_sil_topmodel_step(void)
{
 /* Logic: '<Root>/Logical Operator2' incorporates:
 * Input: '<Root>/count_enable'
 * Input: '<Root>/counter_mode'
 * Logic: '<Root>/Logical Operator'
 */
 enableA = ((!rtU.counter_mode) && rtU.count_enable);

 /* Outputs for Enabled SubSystem: '<Root>/CounterTypeA' */
 CounterTypeA();

 /* End of Outputs for SubSystem: '<Root>/CounterTypeA' */
 /* Logic: '<Root>/Logical Operator1' incorporates:
 * Input: '<Root>/count_enable'
 * Input: '<Root>/counter_mode'
 */
 enableB = (rtU.counter_mode && rtU.count_enable);

 /* Outputs for Enabled SubSystem: '<Root>/CounterTypeB' */
 CounterTypeB();

 /* End of Outputs for SubSystem: '<Root>/CounterTypeB' */
}

/* Model initialize function */
void rtwdemo_sil_topmodel_initialize(void)
{
}
100%

```

You can now use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

- 1 Remove all breakpoints.
- 2 Click the Continue button (**F5**).

The SIL simulation runs to completion and the Microsoft Visual Studio IDE closes.

**Note** In the Microsoft Visual Studio IDE, if you select **Debug > Stop Debugging**, the SIL simulation times out with the following error message:

The timeout of 1 seconds for receiving data from the rtiostream interface has been exceeded. There are multiple possible causes for this failure.

...  
...

## Create PIL Target Connectivity Configuration for Simulink

### In this section...

“Target Connectivity Configurations for PIL” on page 82-40  
“Create a Target Connectivity API Implementation” on page 82-40  
“Register a Connectivity API Implementation” on page 82-42  
“Verify Target Connectivity Configuration” on page 82-42  
“Target Connectivity API Examples” on page 82-42

### Target Connectivity Configurations for PIL

Use target connectivity configurations and the target connectivity API to customize processor-in-the-loop (PIL) simulation for your target environments.

Through a target connectivity configuration, you specify:

- A configuration name for a target connectivity API implementation.
- Settings that define the set of compatible Simulink models. For example, the set of models that have a particular system target file, template makefile, and hardware implementation.

A PIL simulation requires a target connectivity API implementation that integrates third-party tools for:

- Cross-compiling generated code, creating the PIL application that runs on the target hardware.
- Downloading, starting, and stopping the application on the target.
- Communicating between Simulink and the target.

You can have many different target connectivity configurations for PIL simulation. Register a connectivity configuration with Simulink by creating an `sl_customization.m` file and placing it on the MATLAB search path.

When you run a PIL simulation, the software determines which of the available connectivity configurations to use. The software looks for a connectivity configuration that is compatible with the model under test. If the software finds multiple or no compatible connectivity configurations, the software generates an error message with information about resolving the problem.

### Create a Target Connectivity API Implementation

This diagram shows the components of the PIL target connectivity API.

You must provide implementations of the three API components:

- Build API — Specify the Simulink Coder toolchain or template makefile approach for building generated code.
- Launcher API — Control how Simulink starts and stops the PIL executable.
- Communications API — Customize connectivity between Simulink and the PIL target. Embedded Coder provides host-side support for TCP/IP and serial communications, which you can adapt for other protocols.

These steps outline how you create a target connectivity API implementation. The example code shown in the steps is taken from `ConnectivityConfig.m` in “Configure Processor-In-The-Loop (PIL) for a Custom Target” on page 82-109.

**1** Create a subclass of `rtw.connectivity.Config`.

```
ConnectivityConfig < rtw.connectivity.Config
```

**2** In the subclass:

- Instantiate `rtw.connectivity.MakefileBuilder`, which configures the build process.

```
builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
 targetApplicationFramework, ...
 exeExtension);
```

- Create a subclass of `rtw.connectivity.Launcher`, which downloads and executes the application using a third-party tool.

```
launcher = mypil.Launcher(componentArgs, builder);
```

**3** Configure your `rtiostream` API implementation of the host-target communications on page 82-44 channel.

- For the target side, you must provide the driver code for communications, for example, TCP/IP or serial communications. To integrate this code into the build process, create a subclass of `rtw.pil.RtIOStreamApplicationFramework`.
- For the host side, you can use a supplied library for TCP/IP or serial communications. Instantiate `rtw.connectivity.RtIOStreamHostCommunicator`, which loads and initializes the library that you specify.

```
hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(componentArgs, ...
 launcher, ...
 rtiostreamLib);
```

- 4 If you require execution-time profiling for generated code, create a timer object that provides details of the hardware-specific timer and associated source files. For more information, see “Specify Hardware Timer” on page 82-47.
- 5 If you require stack usage profiling for generated code, specify a driver implementation that obtains stack usage data from the target hardware. The driver must return the value of the stack register. If you do not specify a driver, the PIL simulation tries to use a default generic driver. For more information, see “Implement Driver to Obtain Stack Usage Data During PIL Simulation” on page 76-36.

---

**Note** Each time you modify a connectivity implementation, close and reopen the models to refresh them.

---

## Register a Connectivity API Implementation

To register a target connectivity API implementation as a target connectivity configuration in Simulink:

- 1 Create or update an `sl_customization.m` file. In this file:
  - Create a target connectivity configuration object that specifies, for example, the configuration name for a target connectivity API implementation and compatible models.
  - Invoke `registerTargetInfo`.
- 2 Add the folder containing `sl_customization.m` to the search path and refresh your customizations.

```
addpath(sl_customization_path);
sl_refresh_customizations;
```

For more information, see `rtw.connectivity.ConfigRegistry`.

## Verify Target Connectivity Configuration

To verify your target connectivity configuration early on and independently of your model development and code generation, use the supplied `piltest` function. With the function, you can run a suite of tests. In the tests, the function runs various normal, SIL, and PIL simulations. The function compares results and produces errors if it detects differences between simulation modes.

## Target Connectivity API Examples

For step-by-step examples, see:

- “Configure Processor-In-The-Loop (PIL) for a Custom Target” on page 82-109

This example shows you how to create a custom PIL implementation using the target connectivity APIs. You can examine the code that configures the build process to support PIL, a downloading and execution tool, and a communication channel between host and target. To activate a full host-based PIL configuration, follow the steps in the example.

- “Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation” on page 82-104

This example shows you how to implement a communication channel for use with the Embedded Coder product and your embedded target. This communication channel enables exchange of data between different processes. PIL simulation requires exchange of data between the Simulink software running on your development computer and deployed code executing on target hardware.

The `rtiostream` interface provides a generic communication channel that you can implement in the form of target connectivity drivers for a range of connection types. The example shows how to configure your own target-side driver for TCP/IP, to operate with the default host-side TCP/IP driver. The default TCP/IP communications allow high-bandwidth communication between host and target, which you can use for transferring data such as video.

---

**Note** If you customize the `rtiostream` TCP/IP implementation for your PIL simulations, you must turn off Nagle's algorithm for the server side of the connection. If Nagle's algorithm is not turned off, your PIL simulations can run at a significantly slower speed. The `matlabroot/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c` file shows how you can turn off Nagle's algorithm:

```
/* Disable Nagle's Algorithm*/
option = 1;
sockStatus = setsockopt(lFd, IPPROTO_TCP, TCP_NODELAY, (char*)&option, sizeof(option));
```

---

The code for your custom TCP/IP implementation can require modification.

---

The example also shows how to implement custom target connectivity drivers, for example, using serial, CAN, or USB for both host and target sides of the communication channel.

This section provides information about using the `rtiostream` API for communication between your development computer and target hardware during a processor-in-the-loop (PIL) simulation.

### Communications `rtiostream` API

The `rtiostream` API supports communications for the target connectivity API. Use the `rtiostream` API to implement a communication channel that enables data exchange between different processes.

PIL simulation requires a host-target communications channel. This communications channel comprises driver code that runs on the host and target. The `rtiostream` API defines the signature of target-side and host-side functions that this driver code must implement.

The API is independent of the physical layer that sends the data. Possible physical layers include RS232, Ethernet, or Controller Area Network (CAN).

A full `rtiostream` implementation requires both host-side and target-side drivers. Code generation software includes host-side drivers for the default TCP/IP implementation and a version for serial communications. To use:

- The TCP/IP `rtiostream` communications channel, you must provide, or obtain from a third party, target-specific TCP/IP device drivers.
- The serial communications channel, you must provide, or obtain from a third party, target-specific serial device drivers.

For other communication channels and platforms, the code generation software does not provide default implementations. You must provide both the host-side and the target-side drivers.

The `rtiostream` API comprises the following functions:

- `rtIOStreamOpen`
- `rtIOStreamSend`
- `rtIOStreamRecv`
- `rtIOStreamClose`

For information about:

- Using `rtiostream` functions in a connectivity implementation, see “Create a Target Connectivity API Implementation” on page 82-40.
- Testing the `rtiostream` shared library methods from MATLAB code, see `rtiostream_wrapper`.
- Debugging and verifying the behavior of custom `rtiostream` interface implementations, see “Test an `rtiostream` Driver” on page 82-45 and `rtiostreamtest`.

## Synchronize Host and Target

If you use the `rtiostream` API to implement the communications channel, the host and target must be synchronized, which prevents Simulink from transmitting and receiving data before the target application is fully initialized.

To synchronize the host and target for TCP/IP `rtiostream` implementations, use the `setInitCommsTimeout` method from `rtw.connectivity.RtIOStreamHostCommunicator`. This approach works well for connection-oriented TCP/IP `rtiostream` implementations because Simulink automatically waits until the target server is running.

With other `rtiostream` implementations, for example, serial, the Simulink side of the `rtiostream` connection opens without waiting for the target to be fully initialized. In this case, you must make your `Launcher` implementation wait until the target application is fully initialized. Use one of the following approaches to synchronize your host and target:

- Add a pause at the end of the `Launcher` implementation that makes the `Launcher` wait until target initialization is complete.
- In the `Launcher` implementation, use third-party downloader or debugger APIs that wait until target initialization is complete.
- Implement a handshaking mechanism in the `Launcher` / `rtiostream` implementation that confirms completion of target initialization.

## Test an rtiostream Driver

Use a test suite to debug and verify the behavior of custom `rtiostream` interface implementations.

The test suite can help you to:

- Reduce the time required for integrating custom hardware that does not have built-in `rtiostream` support.
- Reduce the time required for testing custom `rtiostream` drivers.
- Analyze the performance of custom `rtiostream` drivers.

The test suite consists of two parts. One part is an application that runs on the target hardware. The other part runs in MATLAB. For details, see `rtiostreamtest`.

## Troubleshooting Host-Target Communication

To display communication I/O information in the Diagnostic Viewer during the PIL simulation, in the Command Window, enter:

```
set_param(model, 'SILPILVerboseOutput', 'on');
```

By default, the configuration parameter `SILPILVerboseOutput` is set to `off`.

If you run a SIL simulation with `SILPILVerboseOutput` set to on, the simulation displays I/O information for communication that occurs between Simulink and the target application that runs as a separate process on your development computer.

## Word Addressable Target Hardware

In the Configuration Parameters dialog box, when you specify settings for **Device vendor** and **Device type**, you provide PIL simulations with memory addressing information about the target hardware.

For example, consider the case when **Device vendor** is set to Texas Instruments and **Device type** is set to C5000.

The settings specify that the target hardware uses 16-bit word addresses and big-endian word order. The `rtiostream` implementation operates with 16-bit words.

On the target hardware, if an `rtIOStream` function specifies a size of 1, then the target hardware must send or receive one 16-bit word (2 bytes). `sizeof(char)` and `sizeof(short)` return 1, which corresponds to one 16-bit word. The `rtIOStream` function expects the byte order within the word to be little-endian, that is, less significant bytes are transmitted before more significant bytes.

`rtiostreamtest` identifies the target hardware and handles data in terms of 16-bit words, for example, a byte value is transferred as a 16-bit word value.

## Specify Hardware Timer

For processor-in-the-loop (PIL) code execution profiling, you must create a timer object that provides details of the hardware-specific timer and associated source files. You can use the **Code Replacement Tool** or the code replacement library API to specify this hardware-specific timer.

To specify the timer with the Code Replacement Tool:

- 1** Open the Code Replacement Tool. In the Command Window, enter `crtool`.
- 2** Create a new code replacement table. Select **File > New table**.
- 3** Create a new function entry. Under **Tables List**, right-click the new table. Then, from the context-menu, select **New entry > Function**.
- 4** In the middle view, select the new unnamed function.
- 5** On the **Mapping Information** pane:
  - a** From the **Function** drop-down list, select `code_profile_read_timer`.
  - b** Specify the count direction for your timer. For example, from the **Count direction** drop-down list, select **Up**.
  - c** In the **Ticks per second** field, specify the number of ticks per second for your timer, for example, `1e+09`.

The default value is 0. In this case, the software reports time measurements in terms of ticks, not seconds.

- d** In the **Conceptual function** section, from the **Data type** list, select `uint8`, `uint16`, `uint32`, or `uint64`.
- e** In the **Function prototype** section, in the **Name** field, specify a replacement function name, for example, `MyTimer`.
- f** Click **Apply**.

- g** To validate the function entry, click **Validate entry**.
- 6** On the **Build Information** pane, specify the required build information. See Specify build information in “Define Code Replacement Library Optimizations” on page 69-36.
- 7** Save the table (**Ctrl+S**). When you save the table for the first time, use the Save As dialog box to specify the file name and location.

You must save the table in a location that is on the MATLAB search path. For example, you can save this file in the folder for your subclass of `rtw.connectivity.Config`.

The software stores your timer information as a code replacement library table.

- 8** Assuming you save the table as `MyCrlTable.m`, in your subclass of `rtw.connectivity.Config`, add the following line:

```
setTimer(this, MyCrlTable)
```

## Set Up PIL Connectivity by Using target Package

Before you can run processor-in-the-loop (PIL) simulations, you must set up connectivity between Simulink and your target hardware. The connectivity enables the PIL simulation to:

- Build the target application.
- Download, start, and stop the application on the target hardware.
- Support communication between Simulink and the target hardware.

Use one of these workflows.

Workflow	When to use
target package with rtiostream API	<p>Use this workflow if your target application has large I/O requirements that need high-bandwidth communication.</p> <p>For more information, see “Use rtiostream API for PIL Target Connectivity” on page 82-50.</p>
target package with debugger	<p>Use this workflow if:</p> <ul style="list-style-type: none"> <li>• You want a single debugger integration to provide PIL connectivity for target hardware systems that are supported by the debugger. This workflow requires little or no target-specific code.</li> <li>• The I/O requirements of the target application are small. For example, unit tests on a component. If you use this workflow for a target application that has large I/O requirements, the execution of the application is slower.</li> </ul> <p>For more information, see “Use Debugger for PIL Target Connectivity” on page 82-53.</p>

### Use rtiostream API for PIL Target Connectivity

To provide PIL connectivity between Simulink and the target hardware, you can use the `target` Package with the `rtiostream` API on page 82-44. In this example, your development computer is the target hardware.

#### 1 Create the board description

Create a `target.Board` object that provides MATLAB with a description of your target hardware.

```
hostTarget = target.create('Board', ...
 'Name', 'Example Intel Board');
```

To support code generation and data I/O in PIL simulations, associate the object with processor, connection, and communication descriptions.

## 2 Associate the board with a processor

To support code generation, associate the board with a `target.Processor` object that contains a language implementation. For this example, create a `target.Processor` object and reuse an existing `target.LanguageImplementation` object. For information about setting up a custom `target.LanguageImplementation` object, see “Register New Hardware Devices” on page 9-11.

```
processor = target.create('Processor', 'Name', 'ExampleProcessor');
processor.LanguageImplementations = target.get('LanguageImplementation', ...
 'Intel-x86-64 (Windows64)');
```

Associate the `target.Board` object with the new `target.Processor` object by using the `Processors` property

```
hostTarget.Processors = processor;
```

## 3 Specify execution information for the target hardware

Create an object that contains details about executing the target application. The object describes the tool that is required to run the target application on the target hardware. To capture system commands for starting and stopping the target application, you can use the `HostProcessExecutionTool` or `SystemCommandExecutionTool` class.

```
applicationExecution = target.create('HostProcessExecutionTool');
applicationExecution.Name = 'Windows Application';
```

Create a `Command` object for downloading and running the target application. Assign the string variable `'$(EXE)'` to the `String` property as a place holder for the target application name, which is not known until execution.

```
runCommand = target.create('Command');
runCommand.String = '$(EXE)';
applicationExecution.StartCommand = runCommand;
hostTarget.Tools.ExecutionTools = applicationExecution;
```

## 4 Create the communication interface for the target hardware

Create a `CommunicationInterface` object that provides the target hardware with details of the communication channel and the `rtiostream` API on page 82-44 implementation.

Use:

- The shipped TCP/IP `rtiostream` implementation source file.
- A `BuildDependencies` object to specify, for the `rtiostream` API, the source files that are compiled with the target application.
- A `MainFunction` object to pass arguments to the target application

```
comms = target.create('CommunicationInterface');
comms.Name = 'Windows TCP Interface';
comms.Channel = 'TCPChannel';
comms.APIImplementations = target.create('APIImplementation', ...
 'Name', 'x86 RTIOStream Implementation');
comms.APIImplementations.API = target.create('API', 'Name', 'RTIO Stream');
comms.APIImplementations.BuildDependencies = target.create('BuildDependencies');
comms.APIImplementations.BuildDependencies.SourceFiles = ...
 {fullfile('${MATLAB_ROOT}', ...
 'toolbox', ...
 'coder', ...
 'rtiostream', ...
 'src', ...
 'rtiostreamtcpip', ...
 'rtiostream_tcpip.c')};
```

```
comms.APIImplementations.MainFunction = target.create('MainFunction', ...
 'Name', 'TCP RtIOStream Main');
comms.APIImplementations.MainFunction.Arguments = {'-blocking', '1', '-port', '0'};
hostTarget.CommunicationInterfaces = comms;
```

## 5 Specify PIL protocol information

This step is optional. A PIL simulation uses a communication protocol for the transfer of data between Simulink and the target hardware. The `target.PILProtocol` class describes the parameters of the protocol. For this example, you can improve target run-time performance by increasing the I/O buffer size that the protocol uses.

Create a `target.PILProtocol` object and specify I/O buffer size.

```
pilProtocol = target.create('PILProtocol');
pilProtocol.Name = 'Windows PIL Protocol';
pilProtocol.SendBufferSize = 50000;
pilProtocol.ReceiveBufferSize = 50000;
hostTarget.CommunicationProtocolStacks = pilProtocol;
```

If you do not perform this step, default `target.PILProtocol` values are used.

## 6 Add profiling timer

You can configure a PIL simulation to produce execution-time profiles for the generated code. To support code execution profiling, you must create a timer object that describes the retrieval of current time from generated code running on the target hardware. The timer object description must include a description of the function that retrieves time and its implementation.

This example uses a C function, `timestamp_x86`, which returns the current time as a `uint64` data type.

```
timerSignature = target.create('Function');
timerSignature.Name = 'timestamp_x86';
timerSignature.ReturnType = 'uint64';
```

Capture the function in an API object.

```
timerApi = target.create('API');
timerApi.Functions = timerSignature;
timerApi.Language = target.Language.C;
timerApi.Name = 'Windows Timer API';
```

Capture the dependencies of the function, that is, the source and header files that are required to run the function.

```
timerDependencies = target.create('BuildDependencies');
timerDependencies.IncludeFiles = {'host_timer_x86.h'};
timerDependencies.IncludePaths = {'$(MATLAB_ROOT)/toolbox/coder/profile/src'};
timerDependencies.SourceFiles = {'host_timer_x86.c'};
```

Create an object that combines the API and dependencies.

```
timerImplementation = target.create('APIImplementation');
timerImplementation.API = timerApi;
timerImplementation.BuildDependencies = timerDependencies;
timerImplementation.Name = 'Windows Timer Implementation';
```

Create the timer object and associate it with the timer information.

```
timer = target.create('Timer');
timer.APIImplementation = timerImplementation;
timer.Name = 'Windows Timer';
```

Assign the timer to the processor object.

```
processor.Timers = timer;
```

## 7 Specify connection between development computer and target hardware

The previous steps created target hardware support for communications and running the target application. Now, set up a connection between your development computer and the target hardware by creating a `TargetConnection` object. Specify:

- The communication channel, which is the same channel specified in the target hardware communication interface -- see step 4.
- The connection properties.
- The target, which is the board description specified in previous steps.

```
connection = target.create('TargetConnection');
connection.Name = 'Host Process Connection';
connection.Target = hostTarget;
connection.CommunicationChannel = target.create('TCPChannel');
connection.CommunicationChannel.Name = 'External Process TCPCommunicationChannel';
connection.CommunicationChannel.IPAddress = 'localhost';
connection.CommunicationChannel.Port = '0';
```

## 8 Make board and connection objects persist across MATLAB sessions

To register the connectivity in MATLAB, add the target hardware and connection information to an internal database by using the `target.add` function. By default, the information is only available for the current MATLAB session. To make the registration persist across MATLAB sessions, specify the name-value pair `'UserInstall', true`.

```
target.add([hostTarget connection], 'UserInstall', true);
```

## 9 Specify board for model

You can now specify your development computer as the target hardware for PIL simulations. Before you run a PIL simulation, in the Configuration Parameters dialog box, set **Hardware board** to Example Intel Board.

# Use Debugger for PIL Target Connectivity

To provide PIL connectivity between Simulink and the target hardware, you can use the `target` Package with a debugger, for example, the GNU Debugger.

## 1 Implement the target.DebugIOTool debugger abstraction interface

Implement the interface in a class called `myImplementationClass`. For an example pseudocode implementation, see “`DebugIOTool` Template” on page 82-54.

```
classdef myImplementationClass < target.DebugIOTool
 properties (Access=private)
 ...
 end

 methods
 ...
 end

 methods (Access=private)
 ...
 end
end
```

## 2 Create the board description

Create `target.Board` object that provides MATLAB with a description of your target hardware.

```
hostTarget = target.create('Board', ...
 'Name', 'GDB Debug PIL IO');
```

### 3 Associate the board with a processor

To support code generation, associate the board with a `target.Processor` object that contains a language implementation. For this example, create a `target.Processor` object and reuse an existing `target.LanguageImplementation` object. For information about setting up a custom `target.LanguageImplementation` object, see “Register New Hardware Devices” on page 9-11.

```
hostTarget.Processors = target.get('Processor', ...
 'Intel-x86-64 (Linux 64)');
```

### 4 Describe the debugger execution service implementation

Create a `target.ExecutionService` object that references the debugger abstraction interface.

```
matlabExecution = target.create('ExecutionService', ...
 'Name', 'GDB Launch');
matlabExecution.APIImplementation = ...
 target.create('APIImplementation', ...
 'Name', 'myServiceImplementation');
matlabExecution.APIImplementation.BuildDependencies = ...
 target.create('MATLABDependencies');
matlabExecution.APIImplementation.BuildDependencies.Classes = ...
 {'myImplementationClass'};
matlabExecution.APIImplementation.API = ...
 target.get('API', ...
 'DebugIOTool');
```

### 5 Associate debugger execution service with the board

Associate the `target.ExecutionService` object with the `target.Board` object.

```
hostTarget.Tools.DebugTools = matlabExecution;
```

### 6 Make board object persist across MATLAB sessions

Add the board object to an internal database and make the object persist across MATLAB sessions.

```
target.add(hostTarget, 'UserInstall', true);
```

### 7 Specify board for model

Before you run a PIL simulation, in the Configuration Parameters dialog box, set **Hardware board** to GDB Debug PIL IO.

## DebugIOTool Template

This section provides a pseudocode example of `target.DebugIOTool` debugger abstraction. Use a `target.DebugIOTool` object to:

- Control the lifetime of an application running in the debugger.
- Automate common debugger actions. For example, applying breakpoints and continuing execution from a paused state.
- Read and write to memory that the application uses.

For interactions with the debugger, you can use MATLAB external language interfaces to APIs, which the debugger vendor supplies.

**Section Descriptions for target.DebugIOTool Debugger Abstraction Example**

target.DebugIOTool Object	Comments
<pre>classdef DebugIOToolTemplate &lt; target.DebugIOTool</pre>	<p>Example implementation of target.DebugIOTool debugger abstraction.</p>

The function assumes that code execution has reached the breakpoint that requires this action.</p> <p>memoryStream is a vector of uint64 values. The uint64 values act as a container for the smallest addressable integer on the target platform, which in most cases is the size of char, typically 8 bits.</p> <p>The variable represents a pointer to the smallest addressable integer type. For example, write operations on a target platform where char represents the smallest addressable integer are equivalent to the memcpy call in C code:</p> <pre>(void*)memcpy(&lt;variableName&gt;,     (unsigned char[&lt;sizeofMemoryStream&gt;])     {&lt;memoryStream(1)&gt;, &lt;memoryStream(2)&gt;},     &lt;sizeofMemoryStream&gt;);</pre> <p>If your debugger allows immediate execution of code when execution is broken, use the memcpy approach to write data to the variable.</p>

target.DebugIOTool Object	Comments
<pre>function [memoryStream, errFlag] = read(this,     variableName,     sizeToRead)      memoryStream = this.callExternalDebugger(         sprintf("read (unsigned char [%d])", ...             sizeToRead, variableName));      memoryStream = uint64(memoryStream);      errFlag = false; end</pre>	<p>Read the memory stream from target platform <code>variableName</code> memory specified by variable name.</p> <p>Add logic to read from the <code>variableName</code> variable on the target platform. The function assumes that code execution has reached the breakpoint that requires this action.</p> <p>The <code>memoryStream</code> return value is a vector of <code>uint64</code> values. The <code>uint64</code> values act as a container for the smallest addressable integer on the target platform, which in most cases is the size of <code>char</code>, typically 8 bits.</p> <p>The variable represents a pointer to the smallest addressable integer type. Read operations are equivalent to this C code:</p> <pre>(unsigned char [&lt;sizeToRead&gt;])*&lt;variableName&gt;</pre> <p>If your debugger allows immediate execution of code when execution is broken, use the C code approach to inspect the value of the buffer and return it to MATLAB.</p>
<pre>end</pre>	end statement for methods.
<pre>methods (Access=private)      function output = callExternalDebugger(~, varargin)          output = [];         fprintf("\nInstructed the debugger to '%s'\n", varargin{1});          if nargin &gt; 2             disp('Using arguments:');             disp(varargin(2:end));         end     end end</pre>	Private methods.
<pre>end</pre>	end statement for classdef.

### Pseudocode for target.DebugIOTool Debugger Abstraction Example

```
classdef DebugIOToolTemplate < target.DebugIOTool
% DEBUGIOTOOLTEMPLATE Example implementation of target.DebugIOTool
% debugger abstraction.

% Copyright 2020 The MathWorks, Inc.

 properties (Access=private)

 % Optional
 % Add any state required to interact with the debugger or
 % application being run in the debugger as a property of
 % DebugIOTool. Apply private access so that only this file
 % can access the state.
 %
 % For example, the state could be a handle to the debugger
```

```

 % application provided by the debugger external API.
 DebuggerHandle;
end

% Method implementations that perform debugger interactions.
% Each method will return a 'errFlag' logical flag. If the method
% executes without error, 'errFlag' is set to false.
% Consider also using the MATLAB error method to report custom
% error information.
methods

 % Constructor for the target.DebugIOTool. The constructor
 % creates an instance of the tool allowing its methods to be called
 % on that instance. Optional.
 function this = DebugIOToolTemplate()

 % Basic initialization can be performed here. For example
 % setting state ready for calls to open
 end

 % Open the debugger. Optional.
 function errFlag = open(this)

 % Add logic here to open the debugger. Typically, use system
 % commands or the external API provided by the debugger.
 %
 % If you cannot open the debugger without also loading the
 % application into the debugger, this method should not be
 % implemented and the logic should be performed in the
 % 'loadApplication' method.
 %
 % If you cannot open the debugger without also starting
 % execution of the application, this method should not be
 % implemented and the logic should be performed in the
 % 'startApplication' method.

 this.DebuggerHandle = this.callExternalDebugger('open');
 errFlag = false;
 end

 % Load the application into the debugger. Optional.
 function errFlag = loadApplication(this)

 % Add logic here to load the application into the debugger.
 % This could be loading a project into an IDE debugger or
 % loading the application executable into the debugger harness.
 %
 % Additionally add logic to set breakpoints in the debugger to
 % break execution.
 %
 % The path to the application to load is stored in the
 % Application property of this class which can be accessed
 % using this.Application in this method.
 %
 % Additional command line arguments to pass to the the
 % application are stored in
 % this.ApplicationCommandLineArguments.
 %
 % Breakpoints to set are stored in this.Breakpoints
 %
 % If you cannot load the application without also starting
 % execution of the application, this method should not be
 % implemented and the logic should be performed in the
 % 'startApplication' method.

 this.callExternalDebugger('load application', ...
 this.Application, ...
 this.ApplicationCommandLineArguments);

 this.callExternalDebugger('set breakpoints', this.Breakpoints);

 errFlag = false;
 end
end

```

```

end

% Start the application execution in the debugger. Required.
function errFlag = startApplication(this)

 % Add logic here to start the application execution in the
 % debugger.
 %

 % Add logic to write the memoryStream data to the variableName
 % variable in the target. This function should assume that the
 % appropriate breakpoint has been hit to perform such an
 % action.
 %
 % memoryStream is a vector of uint64 values to be written to
 % the target platform. The uint64 values act as a container for
 % the smallest addressable integer on the target platform. In
 % most cases this will be a container for the size of char on
 % the target platform, which will commonly be 8-bit.
 %
 % The specified variable will represent a pointer to the
 % smallest addressable integer type.

 % As an example write operations on a target platform where
 % char represents the smallest addressable integer should be
 % equivalent to the following memcpy call in C code:
 %
 % (void*)memcpy(<variableName>,
 % (unsigned char[<sizeofMemoryStream>])
 % {<memoryStream(1)>,<memoryStream(2)>, ...},
 % <sizeofMemoryStream>);
 %
 % A lot of debuggers allow for immediate execution of code when
 % execution is broken, if so, attempt to use the above command
 % to write data to the variable like the below example:

 sizeofMemoryVariable = uint64(numel(memoryStream));
 arrayFormat = repmat('%d,', [1 sizeofMemoryVariable]);
 arrayFormat(end) = [];

 this.callExternalDebugger(sprintf(['execute (void*)memcpy(%s,' ...
 '(unsigned char [%d]){%s}, %d)'], ...
 variableName, ...
 sizeofMemoryVariable, ...
 sprintf(arrayFormat, memoryStream), ...
 sizeofMemoryVariable));

```

```

 errFlag = false;
 end

 % read the memory stream from the target platform memory specified
 % by the given variable name.
 function [memoryStream, errFlag] = read(this, ...
 variableName, ...
 sizeToRead)

 % Add logic to read from the variableName variable on the
 % target. This function should assume that the appropriate
 % breakpoint has been hit to perform such an action.
 %
 % The memoryStream return value should be a vector of uint64
 % values. The uint64 values act as a container for the smallest
 % addressable integer on the target platform. In most cases
 % this will be a container for the size of char on the target
 % platform, which will commonly be 8-bit.
 %
 % The specified variable will represent a pointer to the
 % smallest addressable integer type.

 % Read operations should be equivalent to inspecting the result
 % of the following C code:
 % (unsigned char [<sizeToRead>])*<variableName>
 %
 % A lot of debuggers allow for immediate execution of code when
 % execution is broken, if so, attempt to use the above command
 % to inspect the value of the buffer and return it to MATLAB.

 memoryStream = this.callExternalDebugger(...
 sprintf("read (unsigned char [%d])*%s", ...
 sizeToRead, variableName));

 % The memory stream must be returned as a vector of uint64
 % values
 memoryStream = uint64(memoryStream);

 errFlag = false;
 end
end

methods (Access=private)

## Custom Toolchain Directives Required for Code Coverage and Execution Profiling

If you use a custom toolchain for building a processor-in-the-loop (PIL) target application that supports Simulink Coverage analysis or Embedded Coder code execution profiling, in the toolchain definition file, you must provide these compiler directives:

- `CompileFlag` — Specify the flag that C or C++ compiler uses to compile source files without linking. For example, if the compiler in the toolchain is GNU C or C++, set the directive to `-c`.
- `PreprocessFile` — Specify the flag that C or C++ compiler uses to preprocess the source files without running other compiler stages. For example, if the compiler in the toolchain is GNU C or C++, set the directive to `-E`.

This section from a toolchain definition file example shows how you can use the `setDirective` method to provide the directives.

```
tc = coder.make.ToolchainInfo('BuildArtifact','nmake makefile');
tc.Name = 'My Toolchain Name';
tc.Platform = 'win64';
tc.SupportedVersion = '14';
...
% -----
% C Compiler
% -----
tool = tc.getBuildTool('C Compiler');
tool.setName('My C Compiler');
...
tool.setDirective('CompileFlag','-c');
tool.setDirective('PreprocessFile','-E');
...
```

## PIL Simulation Sequence

A processor-in-the-loop (PIL) simulation cross-compiles production source code, and then downloads and runs object code on your target hardware. The connectivity configuration that you create controls the way code is compiled and executed on the target. This table describes the sequence of stages in a PIL simulation.

Stage		Description
1	Start	<p>For top-model PIL, on the Simulink Editor toolbar, you select the <b>Processor-in-the-Loop (PIL)</b> mode, and then click the Run button.</p> <p>For Model block PIL, you set the <b>Simulation mode</b> parameter of the Model block to <b>Processor-in-the-loop (PIL)</b>, and then run a simulation of the harness model that contains the Model block.</p> <p>For the PIL block, you run a simulation of the harness model that contains the PIL block.</p>
2	Validate target connectivity	The software verifies that a target connectivity configuration is registered for PIL. Otherwise, the software produces an error.
3	Generate production source code and build object code for target	<p>The generated source code is identical to the code that is produced when you run the <code>slbuild</code> command.</p> <ul style="list-style-type: none"> <li>• For top-model PIL or Model block PIL with block parameter <b>Code interface</b> set to <code>Top model</code>, the generated code is identical to the code produced when you run <code>slbuild('model')</code>.</li> <li>• For Model block PIL with block parameter <b>Code interface</b> set to <code>Model reference</code>, the generated code is identical to the code produced when you run <code>slbuild('model', 'ModelReferenceCoderTarget')</code>.</li> </ul> <p>The software builds object code for the target by using the template makefile or toolchain that you specify.</p>
4	Create instances of PIL API components	The software instantiates your <code>rtw.connectivity.Config</code> class, which creates instances of <code>rtw.connectivity.MakefileBuilder</code> , <code>rtw.connectivity.Launcher</code> , <code>rtw.pil.RtIOStreamApplicationFramework</code> , and <code>rtw.connectivity.RtIOStreamHostCommunicator</code> .
5	Generate PIL files	The generated PIL files are in the <code>pil</code> folder. At the end of the simulation, use the code generation report to view the files.

Stage		Description
6	Build target application	<p>The software:</p> <ul style="list-style-type: none"> <li>• Uses your instance of <code>rtw.connectivity.MakefileBuilder</code> to build the target application.</li> <li>• Compiles the PIL interface file, <code>xil_interface.c</code>, and other PIL files into the target executable file. On a Windows system, for example, this file is called <code>modelName.exe</code>. The object code, including the executable file, is in the <code>pil</code> folder.</li> <li>• If configured, produces the code generation report.</li> </ul>
7	Start target application	The software uses <code>rtw.connectivity.Launcher</code> to start the application on the target.
8	Simulink engine interacts with PIL S-function	<p>The Simulink engine interacts with the PIL S-function in the same way that it interacts with a C S-function.</p> <p>From the host-side, the PIL S-function communicates with the target executable code through <code>rtIOStream</code> commands. On the target side, <code>xil_interface</code> executes generated code.</p>
9	Stop target application	The software uses <code>rtw.connectivity.Launcher</code> to stop the application on the target.
10	End PIL simulation	<p>For top-model PIL, at the end of the simulation, the software destroys the <code>rtw.connectivity.Config</code> instance.</p> <p>For Model block PIL and PIL block, the block creates and owns the <code>rtw.connectivity.Config</code> instance, which is not destroyed at the end of the simulation. You can rerun the simulation, which now does not require the creation of another <code>rtw.connectivity.Config</code> instance. If you want to destroy the instance, close the parent model.</p>

## Verification of Code Generation Assumptions

At the start of a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation, the software verifies some configuration parameter settings with reference to the target hardware.

For example, in the Configuration Parameters dialog box, the **Hardware Implementations** settings specify target behavior, which result in the implementation of implicit assumptions in the generated code. Incorrect settings can lead to:

- Suboptimal code
- Code execution failure, incorrect code output, and nondeterministic code behavior

The software checks:

- The correctness of settings. For example, the integer bit length in the **Number of bits: int** field.
- Whether the settings are optimized. For example, the rounding of signed integer division in the **Signed integer division rounds to** field.

The simulation generates a Coder Assumptions page on page 55-13 for the code generation report, which provides a list of:

- Code generation assumptions that are checked
- Expected results for the assumption checks

This table shows when checks occur and outcomes when code generation assumptions are incorrect.

Stage	What is Checked	Outcome
Preprocessor	<p><b>Number of bits</b> per:</p> <ul style="list-style-type: none"> <li>• <b>char</b> (ProdBitPerChar)</li> <li>• <b>short</b> (ProdBitPerShort)</li> <li>• <b>int</b> (ProdBitPerInt)</li> <li>• <b>long</b> (ProdBitPerLong)</li> </ul> <p>If <b>Support long long</b> (ProdLongLongMode) is selected, number of bits per long long</p> <p>For each data type, the preprocessor check is not performed if the number of bits exceeds these settings for the target C preprocessor:</p> <ul style="list-style-type: none"> <li>• For signed integer math, TargetPreprocMaxBitsSint.</li> <li>• For unsigned integer math, TargetPreprocMaxBitsUint.</li> </ul>	Error if data type sizes for model and target hardware do not match.

Stage	What is Checked	Outcome
Run-time	<b>Number of bits</b> per: <ul style="list-style-type: none"> <li>• <b>char</b> (ProdBitPerChar)</li> <li>• <b>short</b> (ProdBitPerShort)</li> <li>• <b>int</b> (ProdBitPerInt)</li> <li>• <b>long</b> (ProdBitPerLong)</li> </ul>	Error if data type sizes for model and target hardware do not match.
	If <b>Support long long</b> (ProdLongLongMode) is selected, number of bits per long long	Error if: <ul style="list-style-type: none"> <li>• Target hardware does not support long long.</li> <li>• Data type sizes for model and target hardware do not match.</li> </ul>
	Size of: <ul style="list-style-type: none"> <li>• float</li> <li>• double</li> </ul> <p>You cannot configure these data type sizes through the <b>Hardware Implementation</b> pane. The check is performed only if <b>Support: floating-point numbers</b> is selected.</p>	Warning if data type sizes for model and target hardware do not match. <p>For double, warning is generated if size of target hardware data type is not 32 or 64 bits.</p>
	<b>Number of bits</b> per: <ul style="list-style-type: none"> <li>• <b>pointer</b> (ProdBitPerPointer)</li> <li>• <b>size_t</b> (ProdBitPerSizeT)</li> <li>• <b>ptrdiff_t</b> (ProdBitPerPtrDiffT)</li> </ul>	Error if data type sizes for model and target hardware do not match.
	<b>Signed integer division rounds to</b> (ProdIntDivRoundTo) setting	Warning if model parameter setting is Undefined. <p>Error if target hardware behavior is undefined and model parameter setting is not Undefined.</p> <p>Error if target hardware behavior is defined but settings for model and target hardware do not match.</p>
	<b>Byte ordering</b> (ProdEndianness) setting	Warning if setting is Unspecified. Otherwise, error if settings for model and target hardware do not match.

Stage	What is Checked	Outcome
	<b>Shift right on a signed integer as arithmetic shift</b> (ProdShiftRightIntArith) setting	Error if settings for model and target hardware do not match.
	<b>Remove root level I/O zero initialization</b> (ZeroExternalMemoryAtStartup) setting	Warning if ZeroExternalMemoryAtStartup is 'off' and initial values of global variables in the target application are not zero.
	<b>Remove internal data zero initialization</b> (ZeroInternalMemoryAtStartup) setting	Warning if ZeroInternalMemoryAtStartup is 'off' and initial values of global variables in the target application are not zero.
	<b>Use dynamic memory allocation for model initialization</b> (GenerateAllocFcn) setting	Warning if GenerateAllocFcn is 'on' and initial values of dynamically allocated memory in the target application are not zero.
	<b>Simulation behavior for denormal numbers</b> (DenormalBehavior) setting	Error if behavior for model and target hardware does not match.

## View SIL and PIL Files in Code Generation Report

With top-model and Model block SIL and PIL simulations, you can produce a code generation report and static code metrics that cover SIL and PIL files. The information helps you to:

- Understand and review the SIL and PIL testing process.
- See how your registered custom target connectivity files fit into the target application that runs during a SIL or PIL simulation.

This capability is not supported for simulations that you run with the PIL block.

To configure the creation of a code generation report and static code metrics, in the Configuration Parameters dialog box, select the **Create code generation report**, **Open report automatically**, and **Generate static code metrics** check boxes. Then click **OK**.

At the end of the simulation, in the Code Generation Report window:

- To review code metrics, in the **Contents** view, click **Static Code Metrics Report**.
- To review SIL and PIL files, in the **Generated Code** view, expand the **SIL/PIL files** node. For example:
  - To review the S-function that runs on the host, click `modelName_sbs.c` or `modelName_pbs.c`.
  - To view the SIL or PIL interface that runs on the target, click `xil_interface.c`.

The screenshot shows the 'Code Generation Report' window. On the left, there is a 'Contents' pane with links to various reports, including 'Static Code Metrics Report' which is highlighted. Below that is a 'Generated Code' section with a tree view of files. The main area displays a table of static code metrics for various functions and a '3. Function Information' section with a detailed table of function metrics.

Function Name	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
<b>Total</b>	<b>102,483</b>	<b>304</b>			
<a href="#">fid</a>	2	6	6	6	6
<a href="#">xilWriteDataAvail</a>	2	6	4	4	4
<a href="#">pwsEnabled</a>	1	4	3	3	3
<a href="#">enableA</a>	1	2	1	1	1
<a href="#">enableB</a>	1	2	1	1	1

\* The global variable is not directly used in any function.

### 3. Function Information [\[hide\]](#)

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View: Call Tree | [Table](#)

Function Name	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
[ - ] <a href="#">main</a>	1,556	12	22	32	6
[ + ] <a href="#">_xillnit</a>	1,544	0	20	33	6
[ + ] <a href="#">_xilTerminateComms</a>	532	0	9	18	1

## SIL/PIL Manager Verification Workflow

The **SIL/PIL Manager** is an app that provides a simplified workflow for verifying generated model code.

### Open the App

To open the SIL/PIL Manager in the Simulink Editor, on the **Apps** tab, click **SIL/PIL Manager**. Or, on the **C Code** tab in the Embedded Coder app, select **Verify Code > SIL/PIL Manager**.

### Select the Mode

In the **Mode** section, specify the simulations that you want the app to run. You can select:

- **Automated Verification** -- The app runs two simulations back-to-back. The first simulation is a model simulation in normal, accelerator, or rapid accelerator mode. The second simulation is a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation. After the second simulation is complete, the app uses the Simulation Data Inspector to compare the results of the simulations.

For the first simulation, if the model contains a Model block with the **Simulation mode** block parameter set to **Software-in-the-loop (SIL)** or **Processor-in-the-loop (PIL)**, at the start of the simulation, the app changes the block parameter to **Normal**. At the end of the simulation, the app reverts the block parameter to the previous value.

- **Simulation Only** -- The app runs a model simulation in normal, accelerator, or rapid accelerator mode.

If the model contains a Model block with the **Simulation mode** block parameter set to **Software-in-the-loop (SIL)** or **Processor-in-the-loop (PIL)**, at the start of the simulation, the app changes the block parameter to **Normal**. At the end of the simulation, the app reverts the block parameter to the previous value.

- **SIL/PIL Simulation Only** -- The app runs a SIL or PIL simulation.

### Prepare the Model

In the **Prepare** section:

- Specify the numeric testing approach.
- Specify the main configuration parameters.
- Enable or disable code execution profiling and code coverage analysis.

This table shows how the field settings in the **Prepare** section control simulations that the app runs.

<b>Workflow</b>	<b>Field Settings</b>	<b>Model Simulation</b>	<b>SIL or PIL Simulation</b>
Top model	<p><b>System Under Test</b> — Top model</p> <p><b>Simulation Mode</b> — Normal, Accelerator, or Rapid Accelerator</p> <p><b>SIL/PIL Mode</b> — Software-in-the-Loop (SIL) or Processor-in-the-Loop (PIL)</p>	<p>Top model simulation mode specified by <b>Simulation Mode</b> setting.</p> <p>Model blocks in SIL or PIL mode are set to normal mode.</p>	<p>Top model simulation mode specified by <b>SIL/PIL Mode</b> setting.</p> <p>Model blocks use specified simulation modes.</p>
Model block	<p><b>System Under Test</b> — Model blocks in SIL/PIL mode</p> <p><b>Top Model Mode</b> — Normal or Accelerator</p>	<p>Top model simulation mode specified by <b>Top Model Mode</b> setting.</p> <p>Model blocks in SIL or PIL mode are set to normal mode.</p>	<p>Top model simulation mode specified by <b>Top Model Mode</b> setting.</p> <p>Model blocks use specified simulation modes.</p>
<p>Test harness</p> <p>The app supports test harnesses that you create from models and Model blocks. For information about creating test harnesses, see “Create Test Harnesses and Select Properties” (Simulink Test).</p>	<p><b>System Under Test</b> — Harness owner. Not editable.</p> <p><b>Simulation Mode</b> — Normal, Accelerator, or Rapid Accelerator</p> <p><b>SIL/PIL Mode</b> — Software-in-the-Loop (SIL) or Processor-in-the-Loop (PIL)</p>	<p>Harness model in normal mode.</p> <p>Model block mode for harness owner specified by <b>Simulation Mode</b> setting.</p> <p>Internal Model blocks of harness owner in SIL or PIL mode set to normal mode.</p>	<p>Harness model in normal mode.</p> <p>Model block for harness owner specified by SIL/PIL Mode setting.</p> <p>Internal Model blocks of harness owner use specified simulation modes.</p>

If you click **Settings**, the app provides these controls:

- Under **SIL/PIL Settings**:
  - **Settings** — Display **Verification** parameters in the Configuration Parameters dialog box.
  - **Portable Word Sizes** — Select or clear **Enable portable word sizes**. For information about how you can generate code that supports compilation on your development computer, see “Configure Hardware Implementation Settings” on page 82-20.
  - **SIL Debugging** — Select or clear **Enable source-level debugging for SIL**.
- Under **Coverage**:
  - **Coverage Settings** — Display **Coverage** parameters in the Configuration Parameters dialog box.

- **Coverage Collection** — Enable or disable code coverage. If code coverage with Simulink Coverage is enabled, clicking the button toggles CovEnable between 'on' and 'off'. For more information, see “Code Coverage”.
- Under **Time Profiling**:
  - **Task Profiling** — Select or clear **Measure task execution time**.
  - **Save Options** — If **Task Profiling** is selected, clicking the button sets the **Save options** configuration parameter to **Summary data only**, **All data**, and **Metrics only** cyclically. If **Task Profiling** is not selected, the button is dimmed.
  - **Functions** — Clicking the button sets the **Measure function execution times** configuration parameter to **Off**, **Coarse (referenced models and subsystems only)**, and **Detailed (all function call sites)** cyclically.

For more information, see “Configure Code Execution Profiling” on page 76-2 and “Control Profiling Granularity” on page 76-3.

- Under **Stack Profiling**, **Stack Profiling**— Select or clear **Measure task stack usage**. For more information, see “Stack Usage Profiling for Code Generated from Simulink Models” on page 76-30.

If you click **Monitor Signals**, the app provides these controls:

- Under **Monitor Signals**:
  - **Log Selected Signals** — Enable signal logging for model simulation.
  - **Make Selected Signals Testpoints** — Required for signal observation in SIL or PIL simulations.
- Under **Logging Options**:
  - **Signal Logging** — Set the **SignalLogging** configuration parameter to 'on' or 'off', which enables or disables signal logging to the MATLAB workspace and signal streaming to the Simulation Data Inspector.
  - **State Logging** — Set the **SaveState** configuration parameter to 'on' or 'off', which enables or disables state data logging to the MATLAB workspace and state data streaming to the Simulation Data Inspector.
  - **Signal Table** — Display the **Signals** tab in the Model Data Editor.
  - **Configure Logging** — Display the **Data Import/Export** parameters in the Configuration Parameters dialog box.
  - **Normal Mode Visibility** — Open the Model Block Normal Mode Visibility dialog box.

To monitor component signals and state data and compare values from the model and SIL or PIL simulations:

- 1 For each signal that you want to log:
  - a In the Simulink Editor, select the signal.
  - b On the **SIL/PIL** tab, click **Monitor Signals**. From the gallery, select these options:
    - **Log Selected Signals**
    - **Make Selected Signals Testpoints**
    - **Signal Logging**

- 2 To log state data, from the **Monitor Signals** gallery, select **State Logging**.
- 3 If the **Language** configuration parameter is C++, in the **Code Mappings** editor, set the **Data Visibility** for the signals, states, and internal data model element categories to `public`.

For more information, see “Log Signals of a Component” on page 82-31.

## Run Automated Verification, Model Simulation, or SIL/PIL Simulation

With one click, you can run back-to-back model and SIL or PIL simulations. You can also run individual simulations.

If you select the **Automated Verification** mode, the **SIL/PIL** tab displays the **Run Automated Verification** section. To run back-to-back simulations:

- 1 In the **Stop Time** field, specify the simulation time. For the **Automated Verification** mode, you cannot specify `inf`.
- 2 Click **Run Verification**.

If you select the **Simulation Only** or **SIL/PIL Simulation Only** mode, the **SIL/PIL** tab displays the **Run** section. In this case, the toolbar provides additional controls:

- **Fast Restart** — Click to turn on fast restart. For the **Simulation Only** mode, the compiled model does not contain components in SIL or PIL mode.
- **Step Back and Step Forward** — You can configure stepping through a simulation by using the Simulation Stepping Options dialog box. To open the dialog box, click **Step Back**, and then select **Configure simulation stepping**.

Simulation stepping is not available if the mode is **SIL/PIL Simulation Only** and **System Under Test** is `Top model`.

To run an individual simulation:

- 1 In the **Stop Time** field, specify the simulation time.
- 2 Click **Run Simulation** or **Run SIL/PIL**.

## Analyze Results and Export Test Cases

In the app **Results** section, you can analyze results. If you click **Compare Runs** or **Data Inspector**, the app provides these controls in the Results gallery.

Section	Control	Description
<b>Numerical Equivalence Results</b>	<b>Compare Runs</b>	<p>Compare results from the last model and SIL/PIL simulations by using the Simulation Data Inspector. Use the comparison to decide whether the results are numerically consistent.</p> <p>If the mode is <b>Automated Verification</b>, at the end of back-to-back simulations, the Simulation Data Inspector compares logged signals from the model and SIL or PIL simulations.</p>

Section	Control	Description
	<b>Data Inspector</b>	Open the Simulation Data Inspector.
<b>Code</b>	<b>Code View</b>	By default, at the end of SIL or PIL simulations, the SIL/PIL Manager displays the Code view, which enables you to: <ul style="list-style-type: none"> <li>Analyze generated code.</li> <li>See code metrics.</li> <li>Trace between model elements and generated code.</li> </ul> If the view is closed and you want to reopen it, click <b>Code View</b> .
<b>Execution Profiling Results</b>	<b>Highlight Profiling</b>	Highlight blocks profiled in the last SIL or PIL simulation.
	<b>Generate Report</b>	Open code execution profiling report for the last SIL or PIL simulation. For more information, see “View and Compare Code Execution Times” on page 76-6.
	<b>Generate Schedule</b>	In the Simulation Data Inspector, show task scheduling for the last SIL or PIL simulation. For more information, see “Visualize Task Scheduling”.
<b>Stack Profiling Results</b>	<b>Generate Report</b>	Open stack usage profiling report for the last SIL or PIL simulation. For more information, see “Observe Stack Usage of Generated Code” on page 76-31.
<b>Coverage Analysis Results</b>  (Controls available only if you have a Simulink Coverage license)	<b>Coverage Highlighting</b>	Highlight blocks that are analyzed for coverage and provide summary results.
	<b>Coverage Details</b>	Display the code coverage report in the Simulink Editor.
	<b>Results Explorer</b>	Open Results Explorer. For more information, see “Access, Manage, and Aggregate Coverage Results” (Simulink Coverage).
	<b>Generate Report</b>	Generate the code coverage report in a web browser.

## Security for PIL Simulations

Ensure that access to your development computer and the target hardware is secure.

Provide a secure communication channel between your development computer and the target application by applying the security measures listed in this table.

<b>Communication Protocol</b>	<b>Security Measure</b>
TCP/IP	Run your development computer and target application within a trusted private network or virtual private network (VPN).
Serial	Use a point-to-point link between your development computer and target application, for example, a serial cable.

## SIL and PIL Limitations

### In this section...

"About SIL and PIL Limitations" on page 82-79  
 "General SIL and PIL Limitations" on page 82-79  
 "Top-Model SIL/PIL Limitations" on page 82-86  
 "Model Block SIL/PIL Limitations" on page 82-87  
 "Subsystem Block SIL/PIL Limitations" on page 82-88

### About SIL and PIL Limitations

With Embedded Coder, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations by using:

- The top-model.
- Model blocks.
- Blocks from subsystems.

The following sections describe modeling and code generation features that are either unsupported or partially supported by SIL and PIL simulations.

### General SIL and PIL Limitations

#### Tunable Parameters and SIL/PIL

For Model block SIL/PIL and SIL/PIL block simulations, you can tune tunable *workspace* parameters but not tunable *dialog box* parameters. For information about tuning parameters, see "Tune and Experiment with Block Parameter Values".

For a top model with tunable parameters, you can run a SIL/PIL simulation but you cannot tune the parameters during the simulation.

The software cannot define, initialize, or tune the following types of tunable workspace parameters.

Parameter description	Software response		
	Top-Model SIL/PIL	Model Block SIL/PIL	SIL/PIL Block
Parameters with storage class that applies "static" scope or "const" keyword. For example, Custom, Const, or ConstVolatile	Warning	Warning	Warning
Parameters with multiword, fixed-point data types	Warning	Error	Warning
Parameters with data types that have different sizes on host and target	Warning	Error	Warning

For C++ class code, SIL/PIL you can tune tunable workspace parameters when **Parameter visibility** is public. If **Parameter visibility** is private or protected, tuning is supported only if **Parameter access** is Method or Inlined method.

For top-model SIL/PIL and the SIL/PIL block, consider the case where all of the following conditions apply:

- **Code Generation > Interface > Code interface packaging** is Reusable function.
- **Code Generation > Interface > Use dynamic memory allocation for model initialization** is not selected.
- **Optimization > Default parameter behavior** is Tunable.
- In the Code Mapping Editor for the model, the default storage class for the **Global parameters** or **Local parameters** category is set to Default, and the model contains corresponding parameters that use the storage classes Auto or Model default.

If the SIL/PIL component cannot dynamically initialize tunable parameters in the rtP model parameter structure, you see an error message like the following:

```
Parameter Dialog:InitialOutput in 'rtwdemo_sil_topmodel/CounterTypeA/count'
is part of the imported "rtP" structure in the generated code but cannot be
initialized by SIL or PIL. To avoid this error, make sure the parameter
corresponds to a tunable workspace variable. Alternatively, set
"Configuration Parameters > Code Generation > Interface > Code interface packaging"
to 'Nonreusable function', or search for 'Use dynamic memory allocation
for model initialization' in the Configuration Parameters dialog box
and select the checkbox.
```

If you select **Code Generation > Interface > Use dynamic memory allocation for model initialization**, this limitation does not apply.

For Model block SIL/PIL, if you specify **Code interface** to be Top model, you can tune parameters while a simulation runs. If you tune parameters between successive runs of the simulation, the software generates new code for the later run. The new code uses your latest settings as initial parameter values.

For top model or Model block SIL/PIL, if you change the value of a MATLAB variable or parameter object (such as Simulink.Parameter) that you store in a workspace, Simulink Coder regenerates the C code.

Model block SIL/PIL does not support test harness data definition, dynamic initialization, or tuning of model workspace parameters.

### Global and Local Data Stores

SIL/PIL supports global data stores. For components that are not export-function models, SIL/PIL block simulations that access global data stores must be single rate. Otherwise, the software produces an error.

SIL/PIL does not support local data stores.

Model block SIL/PIL does not support local Data Store Memory blocks that have these parameter settings:

- **Share across model instances** - Selected.
- **Storage class** - Auto or Model default.

You cannot create SIL/PIL blocks from models that use local Data Store Memory blocks with the **Share across model instances** parameter selected.

### **SIL/PIL Does Not Check Simulink Coder Error Status**

SIL/PIL does not check the Simulink Coder error status of the generated code under test. This error status flags exceptional conditions during execution of the generated code.

Blocks in the model can also set the Simulink Coder error status, for example, custom blocks that you create. SIL/PIL does not check this error status and report errors.

### **Missing Code Interface Description File Errors**

SIL/PIL requires a code interface description file, which is created during code generation for the component under test. If the code interface description file is missing, the SIL/PIL simulation cannot proceed. You see an error reporting that the file does not exist. If you select the unsupported option **Classic call interface**, this error can occur. Therefore, do not select the option.

### **To Workspace Block**

If you enable MAT-file logging, top-model SIL/PIL and SIL/PIL blocks support To Workspace blocks.

Model block SIL/PIL does not support To Workspace blocks.

### **Cannot Connect SIL/PIL Outputs to Merge Block**

If you connect Model block SIL/PIL or SIL/PIL block outputs to a Merge block, you see an error because S-function memory is not reusable.

### **Unsupported Blocks**

SIL/PIL does not support the following blocks:

- Scope blocks, and all types of run-time display. For example, display of port values and signal values.
- Stop blocks. SIL/PIL ignores the Stop Simulation block and continues simulating.

### **Multiword Fixed-Point I/O**

You cannot run SIL and PIL simulations of models that have multiword, fixed-point signals across component boundaries.

### **Fixed-Point Data Types Wider Than 32 Bits**

SIL/PIL supports fixed-point data types that are wider than 32 bits. For example:

- 64-bit `long` and `long long`
- 64-bit execution profiling timer data type
- `int64` and `uint64` in MATLAB Coder SIL execution.

The following constraints apply:

- For 64-bit data type support, the data type must be representable as `long` or `long long` on the MATLAB host *and* the target. Otherwise, the software uses the multiword, fixed-point approach, which SIL/PIL does not support.

- The software does not support the 40-bit long data type of the TI's C6000™ target.

Through the **Configuration > Hardware Implementation** pane, you can enable support for the 64-bit long data type. For data types with widths between 33 and 40 bits (inclusive), the software implements the data types using the 40-bit long data type, which SIL/PIL does not support.

### Data Type Replacement

For SIL/PIL, the data type replacement name for `boolean` must resolve to `boolean`, `uint8`, or `int8`.

### Simulink.ImageType Data Type

SIL/PIL does not support Simulink Function and Data Store Memory blocks that require the transfer of `Simulink.ImageType` data between Simulink and the target application. At the interface:

- For Simulink Function blocks, the data type of function arguments must not be `Simulink.ImageType`.
- Data Store Memory blocks must not use `Simulink.ImageType` data.

If the Simulink Function and Data Store Memory blocks are not at the interface but inside the target application, the limitation does not apply.

### Continuous Sample Times

Top-model SIL/PIL and SIL/PIL block do not support continuous sample times at the SIL or PIL component boundary. However, they support continuous sample times within the component.

Model block SIL/PIL does not support continuous sample times.

### Variable-Size Signals

Model block SIL/PIL simulations support variable-size signals only if **Diagnostics > Model Referencing > Propagate sizes of variable-size signals** is `During execution`.

Top-model SIL/PIL and SIL/PIL block simulations treat variable-size signals at the I/O boundary of the SIL/PIL component as fixed-size signals, which can lead to errors during propagation of signal sizes. To avoid such errors, use only fixed-size signals at the I/O boundary of the SIL/PIL component.

There can be cases where no error occurs during propagation of signal sizes. In these cases, the software treats variable-size input signals as zero-size signals.

### Internal Signal Logging

SIL/PIL blocks do not support signal logging. For a workaround, see “Log Signals of a Component” on page 82-22.

The following internal signal logging limitations apply to top-model and Model block SIL/PIL simulations.

Limitation	Applies To	
	Top-Model SIL/PIL	Model Block SIL/PIL
Signals feeding merge blocks are not supported for logging in normal simulation but are logged in SIL/PIL mode. The logged values during SIL/PIL are the same as the logged values for the output of the merge block.	Yes	No
Top-model normal simulation logs data at a periodic rate but top-model SIL/PIL simulation logs data at a constant rate under these circumstances: <ul style="list-style-type: none"> <li>• <b>Default parameter behavior</b> is Tunable.</li> <li>• A constant sample time signal from a Model block is logged in the top model.</li> <li>• The logged signal is not directly connected to a root-level output port.</li> </ul> To avoid this behavior and log at the constant rate in all simulation modes, set <b>Default parameter behavior</b> to Inlined.	Yes	No
Features not supported: <ul style="list-style-type: none"> <li>• Signal logging in models referenced by the SIL/PIL component.</li> <li>• Signal logging in Simulink Function block.</li> <li>• Virtual signals.</li> <li>• Virtual buses.</li> <li>• Frame-based signals, which are logged as sample-based signals.</li> <li>• Continuous, asynchronous, and triggered sample times. At the top-level of export-function models, you can log signals with triggered sample times.</li> <li>• Logging of Stateflow states and local data.</li> </ul>	Yes	Yes
Variable-size, function-call, and Action signals are not supported. A normal simulation produces an error. A SIL/PIL simulation produces a warning.	Yes	No
State port signals are not supported. A normal simulation produces an error. A SIL/PIL simulation does not produce a warning.	Yes	No

### Custom Storage Class of Type Other

SIL/PIL simulations support the custom storage class where **Type** is set to **Other** on page 82-7. These limitations apply:

- If the code fragments returned by the TLC file associated with the custom storage class are incomplete, the SIL/PIL application might fail to compile, or produce incorrect results.
- Custom storage classes with **Imported** scope and **Pointer** access are supported, but you must provide code to initialize the pointer. For example, you can modify the response to `DataAccess(record, "define", "", "")` to provide a definition of the storage implementation, and initialize the pointer to the address of the implementation variable.

- To determine whether a variable is `const` and therefore not tunable, the build process for the SIL/PIL application uses the memory section definition in the custom storage class. If the custom storage class defines a variable as `const` and is not associated with a `const` memory section, the target application might fail to compile, or produce an error during the simulation. In this case, associate the custom storage class with a memory section for which `Is const` is specified, for example, `MemConst`. Alternatively, if `SupportSILPIL` is an instance-specific parameter in the custom attributes class, for the associated signal or parameter, set `CoderInfo.CustomAttributes.SupportSILPIL` to `false`.

### Unsupported Implementation Errors

If you use a data store, signal, or parameter implementation that SIL/PIL does not support, you can see errors like the following:

The following *data interfaces* have implementations that are not supported by SIL or PIL.

*data interfaces* can be global data stores, inports, outports, or parameters.

The model output port has been optimized through virtual output port optimization. See “Virtualized Output Ports Optimization” on page 73-15. The error occurs because the properties (for example, data type, dimensions) of the signal or signals entering the virtual root output port have been modified by routing the signals in one of the following ways:

- Through a Mux block.
- Through a block that changes the signal data type. To check the consistency of data types in the model, display **Port Data Types**.
- Through a block that changes the signal dimensions. To check the consistency of data types in the model, display **Signal Dimensions**.

### Hardware Implementation

PIL does not support multiword data types where the word order differs from the target byte order. The PIL simulation fails, displaying undefined behavior.

PIL requires that you configure the correct **Hardware Implementation** settings for the target environment, including byte ordering for targets. If you do not specify the correct byte ordering, the PIL simulation fails, displaying undefined behavior.

### Bus Elements Mapped to Imported Bit-Field Definitions

If you map Simulink bus elements to bit fields through an imported header file, a SIL or PIL simulation produces a build error. For example, if your model has an Inport block connected to a bus that is a `Simulink.Bus` object with these properties:

- **Name** — `myBus`
- **Bus elements** — An array of `Simulink.BusElement` objects with these properties.

Name	Data Type	Complexity	Dimensions
<code>bitField0</code>	<code>boolean</code>	<code>real</code>	<code>1</code>
<code>bitField1</code>	<code>boolean</code>	<code>real</code>	<code>1</code>
<code>bitField2</code>	<code>boolean</code>	<code>real</code>	<code>1</code>

Name	Data Type	Complexity	Dimensions
bitField3	boolean	real	1
bitField4	boolean	real	1
bitField5	boolean	real	1

- **Data scope** — Imported
- **Header file** — `busSpecification.h`. This file contains `myBus`, which defines C bit-field data types for the bus elements.

```
typedef struct myBus
{
 unsigned int bitField0 : 1;
 unsigned int bitField1 : 1;
 unsigned int bitField2 : 1;
 unsigned int bitField3 : 1;
 unsigned int bitField4 : 1;
 unsigned int bitField5 : 1;
} myBus;
```

### Size Mismatch Between Simulink and Target Hardware Data Types

When a Simulink data type and the corresponding target hardware data type differ in size, a SIL or PIL simulation produces an error. This size mismatch can occur if you map a Simulink data type to the target hardware data type through definitions in an imported header file. For example, if you create a data type alias, `T_BOOL`, which is a `Simulink.AliasType` object with these properties:

- **Base type** — `boolean`.
- **Mode** — `Built in`, `boolean`.
- **Data scope** — Imported.
- **Header file** — `myDefinitions.h`. This file defines `T_BOOL` as an enumerated data type:

```
typedef enum _BOOL_TYPE
{
 FALSE = 0,
 TRUE = 1
} BOOL_TYPE;

typedef BOOL_TYPE T_BOOL;
```

In this case, the compiler for the target hardware determines the size of `T_BOOL`, which can differ from the size of the Simulink data type, `boolean`.

### SIL Simulations with Target-Specific Custom Code

Target-specific custom code that is not portable for execution on your development computer can produce compilation or run-time failures during a SIL simulation.

For example, SIL does not support the use of custom code that explicitly casts pointers to integer-type variables that are smaller than the length of a pointer variable on your development computer. Consider using one of these alternatives:

- Run a PIL simulation.

- If you have custom code that casts pointers to a 32-bit integer type, for your development computer, set up a PIL target connectivity configuration that uses a toolchain that is configured to build a 32-bit binary application.

### Sample Time Differences in Simulation Data Inspector Comparisons

If you use the Simulation Data Inspector to compare logged model outputs from normal and SIL or PIL simulations, the sample times of the outputs might differ. You can still use the Simulation Data Inspector to verify that the outputs match numerically.

## Top-Model SIL/PIL Limitations

### Top-Model Root-Level Logging

Top-model SIL/PIL supports signal logging for signals connected to root-level inports and outports. The C API is not required. Root-level logging has the following limitations:

- The characteristics of the logged data such as data type, sample time, and dimensions must match the characteristics of the root-level inports and outports (rather than the characteristics of the connected signal).

In some cases, there can be differences in data type and dimensions between the signal being logged and the root inport or outport that the signal is connected to. Consider the following examples.

- If a signal being logged has matrix dimensions [1x5] but the outport connected to the signal has vector dimensions (5), then the data logged during a SIL or PIL simulation has vector dimensions (5).
- If a signal being logged has scalar dimensions but the outport connected to the signal has matrix dimensions [1x1], then the data logged during a SIL or PIL simulation has matrix dimensions [1x1].
- Signals connected to duplicated inports are not logged during SIL/PIL simulation. No warning is issued.

During normal simulation, signals connected directly to duplicated inports are logged.

- The Signal Logging Selector / `DataLoggingOverride` override mechanism is not supported.
- Normal and SIL/PIL simulations log bus signals with names that are different when all of the following conditions apply:
  - The `SaveOutput` or `SignalLogging` configuration parameter is on.
  - The names of the elements in the bus signal are different from the corresponding names in the bus object. For example, when the `InheritFromInputs` parameter for a Bus Creator block is set to 'on'.
- The software inserts the suffix `_wrapper` for *output logging* if the save format is `Structure` or `Structure with time` and you run the `sim` command without specifying the single-output format. The software adds `_wrapper` to the block name for signals in `yout`. If the save format is `Array`, the software does not add the suffix. For example:

```
>> yout.signals
ans =
 values: [11x1 double]
```

```

dimensions: 1
 label: 'SignalLogging'
 blockName: 'sillogging_wrapper/OutputLogging'

```

To avoid this behavior, run command-line simulations with the `sim` command specifying the single-output format. See “Run Simulations Programmatically”.

### Callback Support

SIL/PIL does not support the callbacks (model or block) `StartFcn` and `StopFcn`.

---

**Note** Top-model SIL/PIL supports the callback `InitFcn`.

---

### Incremental Build

When you start a top-model SIL/PIL simulation, the software regenerates code if it detects changes to your model. The software detects changes by using a checksum for the model. The software does not detect changes that you make to:

- The `HeaderFile` property of a `Simulink.AliasType` object
- Legacy S-functions

If you make these changes, build (**Ctrl-B**) your model again before starting the next PIL simulation.

## Model Block SIL/PIL Limitations

### Top-Model Code Testing

The following limitations apply:

- Because model arguments do not apply to a top model, when the **Code interface** block parameter is set to `Top model`, the software does not support the **Model arguments** block parameter.
- Conditional execution does not apply to a top model. If a Model block is set up to execute conditionally and the **Code interface** block parameter is set to `'Top model'`, the software produces an error when you run a SIL or PIL simulation.
- For sample time independent models, you must set **Configuration Parameters > Solver > Periodic sample time constraint** to `Ensure sample time independent`.

### Conditionally Executed Subsystem

You see an error if:

- You place your Model block, in either SIL or PIL simulation mode, in a conditionally executed subsystem and the referenced model is multirate (that is, has multiple sample times). Single-rate, referenced models (with only a single sample time) are not affected.
- Your Model block, in either SIL or PIL simulation mode, has blocks that depend on absolute time **and** is conditionally executed.

### Outputs with Constant Sample Time

If the block parameter **Code interface** is `Top model`, Model block SIL/PIL supports outputs with constant sample time.

### **Noninlined S-Functions**

Model-block SIL/PIL simulations do not support noninlined S-functions.

### **Referenced Models That Use Same Target Connectivity Configuration**

Consider a top model with two or more Model blocks that reference models that use the same target connectivity configuration. If the Model blocks are in PIL mode simultaneously, you cannot run a simulation of the top model. An error occurs.

### **SIL and PIL Instances of a Referenced Model**

Consider a top model that contains two instances of a Model block that reference the same model. If one instance is in SIL mode and the other instance is in PIL mode, you cannot run a simulation of the top model. An error occurs.

## **Subsystem Block SIL/PIL Limitations**

### **Atomic Subsystem Workflow Limitations**

The workflow described in “Test Atomic Subsystem Generated Code” on page 82-18 does not support:

- These subsystem types:
  - Virtual
  - Function-call
  - Stateflow
  - For Each
  - Action
  - Initialize Function
  - Reset Function
  - Terminate Function
  - Simulink Function
- The 'Compact' option for `ERTFilePackagingFormat` if `PreserveStaticInFcnDecl` is set to 'on'.
- Subsystems that generate in-lined code. The subsystem block parameter `RTWSystemCode` must be 'Nonreusable function' or 'Reusable function'.
- Subsystems that contain:
  - Referenced models.
  - Simulink Function blocks.
  - Data Store Memory, Data Store Read, and Data Store Write blocks.
- The LDRA tool suite and the BullseyeCoverage tool for code coverage analysis.
- Virtual buses at the subsystem interface.

The results from model and SIL or PIL simulations might differ numerically if:

- The subsystem uses non-finite numbers, for example, `NaN` and `Inf`.

- The subsystem and the parent model have multiple sample rates and rate transitions.
- A lookup table block in the subsystem is connected to a Prelookup block across the subsystem boundary.

### **Variant Condition Propagation with Variant Source and Variant Sink Blocks**

SIL/PIL block simulations do not support the propagation of variant conditions across component boundaries.

### **PIL Block Mux**

The PIL block supports mux signals, except mixed data-type mux signals that expand into individual signals during a right-click subsystem build.

### **Code Coverage**

SIL block simulations do not support the generation of code coverage results. PIL block support for code coverage depends on your target connectivity configuration and third-party product support.

### **Subsystem with Inherited Sample Time Blocks**

When you create a SIL/PIL block from a subsystem that has blocks with inherited sample times, the generated code and SIL/PIL wrapper acquire the sample time of the original parent model. If you use the SIL/PIL block in a context that does not allow explicit sample times, for example, within a triggered subsystem, you see an error.

Try one of these workarounds:

- Before you create the SIL/PIL block, in the parent model, set **Configuration Parameters > Solver > Periodic sample time constraint** to **Ensure sample time independent**.
- Using the subsystem, create a Model block that is independent of sample time. With this block, run Model block SIL/PIL simulations.

## **See Also**

### **Related Examples**

- “SIL and PIL Simulations” on page 82-2
- “Choose a SIL or PIL Approach” on page 82-11

## Test Generated Code with SIL and PIL Simulations

Test numerical equivalence between model components and production code that you generate from the components by using software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations.

With a SIL simulation, you test source code on your development computer. With a PIL simulation, you test the compiled object code that you intend to deploy in production by running the object code on real target hardware or an instruction set simulator. To determine whether model components and generated code are numerically equivalent, compare SIL and PIL results against normal mode results.

There are three ways of running SIL and PIL simulations. You can use the top model, Model blocks, or SIL and PIL blocks that you create from a subsystem. See “Choose a SIL or PIL Approach” on page 82-11.

### Target Connectivity Configuration for PIL

Before you can run PIL simulations, you must configure target connectivity. The target connectivity configuration enables the PIL simulation to:

- Build the target application.
- Download, start, and stop the application on the target.
- Support communication between Simulink and the target.

To produce a target connectivity configuration, you can use the supplied target connectivity API. For details, see “Create PIL Target Connectivity Configuration for Simulink” on page 82-40.

For supported hardware, you can use target support packages. For details, see “Embedded Coder Supported Hardware”.

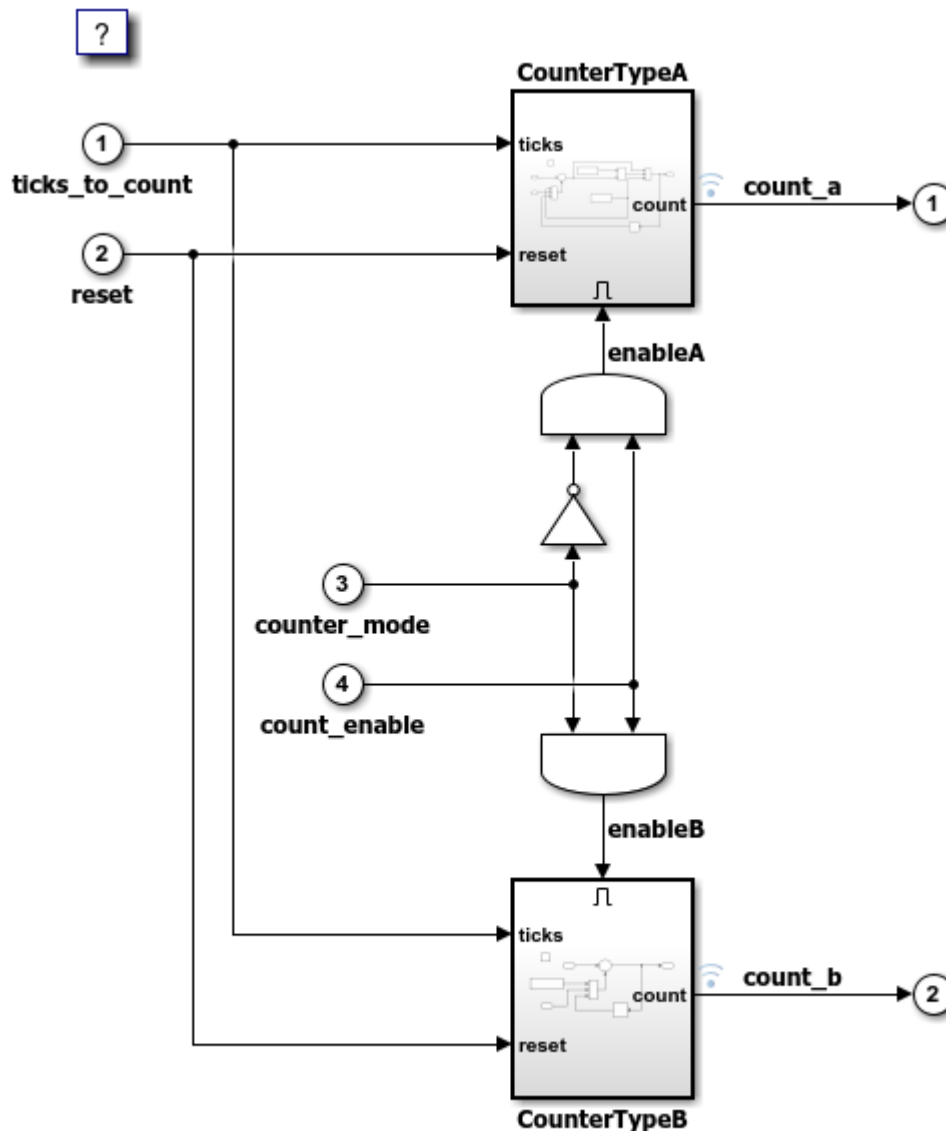

### SIL or PIL Simulation with a Top Model

Test generated model code by running a top-model SIL or PIL simulation. With this approach:

- You test code generated from the top model, which uses the standalone code interface.
- You configure the model to load test vectors or stimulus inputs from the MATLAB workspace.
- You can easily switch the top model between the normal, SIL, and PIL simulation modes.

Open a simple counter top model.

```
model='rtwdemo_sil_topmodel';
close_system(model,0)
open_system(model)
```

Copyright 1994-2021 The MathWorks, Inc.

To focus on numerical equivalence testing, turn off:

- Model coverage
- Code coverage
- Execution time profiling

```
set_param(gcs, 'RecordCoverage', 'off');
coverageSettings = get_param(model, 'CodeCoverageSettings');
coverageSettings.CoverageTool='None';
set_param(model, 'CodeCoverageSettings', coverageSettings);
set_param(model, 'CodeExecutionProfiling', 'off');
```

Configure the input stimulus data.

```
[ticks_to_count, reset, counter_mode, count_enable] = ...
 rtwdemo_sil_topmodel_data(T);
```

Configure logging options in the model.

```
set_param(model, 'LoadExternalInput', 'on');
set_param(model, 'ExternalInput', 'ticks_to_count, reset, counter_mode, count_enable');
set_param(model, 'SignalLogging', 'on');
set_param(model, 'SignalLoggingName', 'logsOut');
set_param(model, 'SaveOutput', 'on')
```

Run a normal mode simulation.

```
set_param(model, 'SimulationMode', 'normal')
sim_output = sim(model, 10);
yout_normal = [sim_output.yout.signals(1).values sim_output.yout.signals(2).values];
```

Run a top-model SIL simulation.

```
set_param(model, 'SimulationMode', 'Software-in-the-Loop (SIL)')
sim_output = sim(model, 10);
yout_sil = [sim_output.yout.signals(1).values sim_output.yout.signals(2).values];
```

```
Starting build procedure for: rtwdemo_sil_topmodel
Successful completion of build procedure for: rtwdemo_sil_topmodel
```

Build Summary

Top model targets built:

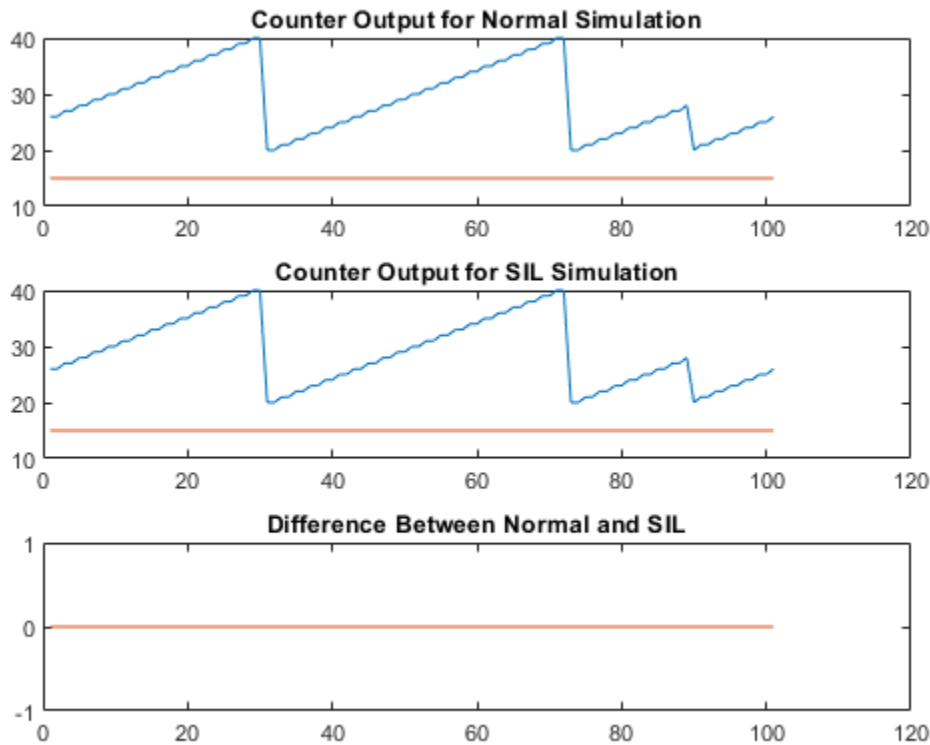

Model	Action	Rebuild Reason
rtwdemo_sil_topmodel	Code generated and compiled	Code generation information file does not exist

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 24.171s
Preparing to start SIL simulation ...
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Updating code generation report with SIL files ...
Starting SIL simulation for component: rtwdemo_sil_topmodel
Application stopped
Stopping SIL simulation for component: rtwdemo_sil_topmodel
```

Unless up-to-date code for this model exists, new code is generated and compiled. The generated code runs as a separate process on your computer.

Plot and compare the results of the normal and SIL simulations. Observe that the results match.

```
fig1 = figure;
subplot(3,1,1), plot(yout_normal), title('Counter Output for Normal Simulation')
subplot(3,1,2), plot(yout_sil), title('Counter Output for SIL Simulation')
subplot(3,1,3), plot(yout_normal-yout_sil), ...
 title('Difference Between Normal and SIL');
```

Clean up.

```
close_system(model,0);
if ishandle(fig1), close(fig1), end
clear fig1
simResults = {'yout_sil','yout_normal','model','T',...
 'ticks_to_count','reset'};
save([model '_results'],simResults{:});
clear(simResults{:},'simResults')
```

### SIL or PIL Simulation with a Model Block

Test generated model code by using a test harness model that runs a Model block in SIL mode. With this approach:

- You can test code that is generated from a top model or a referenced model. The code from the top model uses the standalone code interface. The code from the referenced model uses the model reference code interface. For more information, see “Code Interfaces for SIL and PIL” on page 82-5.
- You use a test harness model or a system model to provide test vector or stimulus inputs.
- You can easily switch a Model block between the normal, SIL, and PIL simulation modes.

Open an example model that has two Model blocks which reference the same model. In a simulation, you run one Model block in SIL mode and the other Model block in normal mode.

```
model='rtwdemo_sil_modelblock';
open_system(model);
```

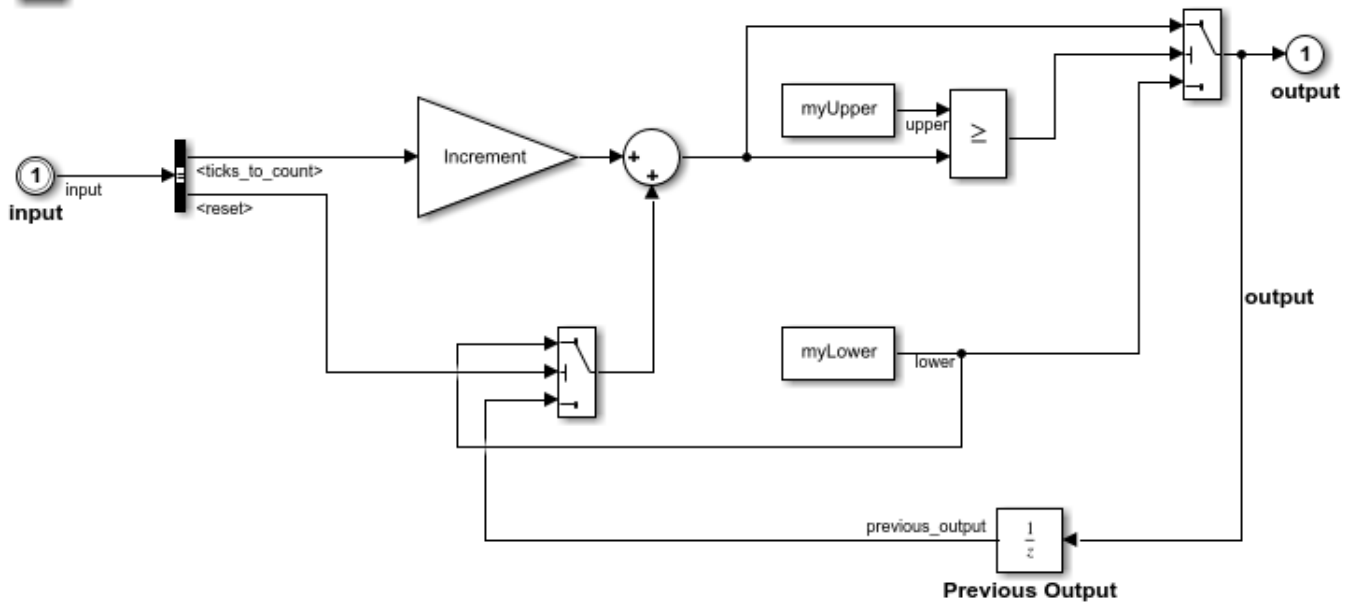

Copyright 2008-2020 The MathWorks, Inc.

Turn off:

- Code coverage
- Execution time profiling

```
coverageSettings = get_param(model, 'CodeCoverageSettings');
coverageSettings.CoverageTool='None';
set_param(model, 'CodeCoverageSettings',coverageSettings);
open_system('rtwdemo_sil_modelblock')
set_param('rtwdemo_sil_modelblock', 'CodeExecutionProfiling','off');
open_system('rtwdemo_sil_counter')
set_param('rtwdemo_sil_counter', 'CodeExecutionProfiling','off');
currentFolder=pwd;
save_system('rtwdemo_sil_counter', fullfile(currentFolder,'rtwdemo_sil_counter.slx'))
```

Copyright 1994-2020 The MathWorks, Inc.

Configure state logging for the models.

```
set_param('rtwdemo_sil_counter', 'SaveFormat','Dataset');
save_system('rtwdemo_sil_counter', fullfile(currentFolder,'rtwdemo_sil_counter.slx'))
set_param(model, 'SaveFormat','Dataset');
set_param(model, 'SaveState','on');
set_param(model, 'StateSaveName', 'xout');
```

### Test Top-Model Code

For the Model block in SIL mode, specify generation of top-model code, which uses the standalone code interface.

```
set_param([model '/CounterA'], 'CodeInterface', 'Top model');
```

Run a simulation of the test harness model.

```
out = sim(model,20);

Starting build procedure for: rtwdemo_sil_counter
Successful completion of build procedure for: rtwdemo_sil_counter
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_sil_counter	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 18.979s

```

Preparing to start SIL simulation ...
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Updating code generation report with SIL files ...
Starting SIL simulation for component: rtwdemo_sil_counter
Application stopped
Stopping SIL simulation for component: rtwdemo_sil_counter

```

The model block in SIL mode runs as a separate process on your computer. In the working folder, you see that standalone code is generated for the referenced model unless generated code from a previous build exists.

Compare the behavior of Model blocks in normal and SIL modes. The results match.

```

yout = out.logsOut;
yout_sil = yout.get('counterA').Values.Data;
yout_normal = yout.get('counterB').Values.Data;
fig1 = figure;
subplot(3,1,1), plot(yout_normal), title('Counter Output for Normal Simulation')
subplot(3,1,2), ...
 plot(yout_sil), title('Counter Output for Model Block SIL (Top-Model) Simulation')
subplot(3,1,3), plot(yout_normal-yout_sil), ...
 title('Difference Between Normal and SIL');

```

Compare the logged states of Model blocks from normal and SIL mode simulations.

```

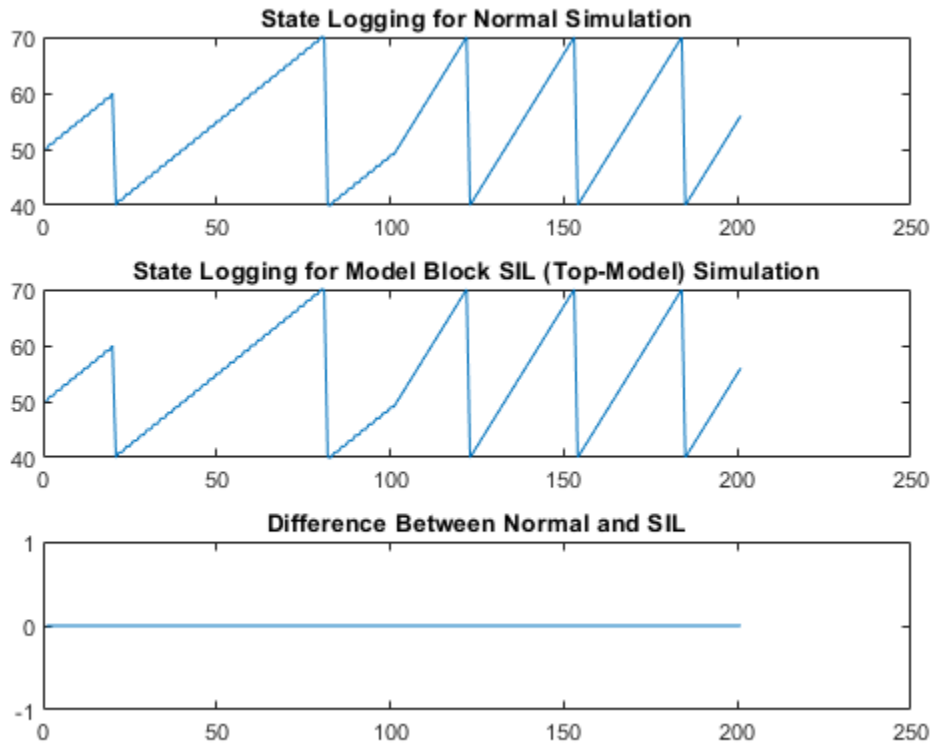

xout = out.xout;
xout_sil = xout{1}.Values.Data;

```

```

xout_normal = xout{2}.Values.Data;
fig1 = figure;
subplot(3,1,1), plot(xout_sil), title('State Logging for Normal Simulation')
subplot(3,1,2), ...
 plot(xout_normal), title('State Logging for Model Block SIL (Top-Model) Simulation')
subplot(3,1,3), plot(xout_normal-xout_sil), ...
 title('Difference Between Normal and SIL');

```

### Test Model Reference Code

For the Model block in SIL mode, specify generation of referenced model code, which uses the model reference code interface.

```
set_param([model '/CounterA'], 'CodeInterface', 'Model reference');
```

Run a simulation of the test harness model.

```
out2 = sim(model,20);
```

```

Starting serial model reference code generation build
Starting build procedure for: rtwdemo_sil_counter
Successful completion of build procedure for: rtwdemo_sil_counter

```

Build Summary

Code generation targets built:

Model	Action	Rebuild Reason
-------	--------	----------------

```
=====
rtwdemo_sil_counter Code generated and compiled rtwdemo_sil_counter.c does not exist.
```

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 14.837s
Preparing to start SIL simulation ...
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Updating code generation report with SIL files ...
Starting SIL simulation for component: rtwdemo_sil_counter
Application stopped
Stopping SIL simulation for component: rtwdemo_sil_counter
```

The model block in SIL mode runs as a separate process on your computer. In the working folder, you see that model reference code is generated unless code from a previous build exists.

Compare the behavior of Model blocks in normal and SIL modes. The results match.

```
yout2 = out2.logsOut;
yout2_sil = yout2.get('counterA').Values.Data;
yout2_normal = yout2.get('counterB').Values.Data;
fig1 = figure;
subplot(3,1,1), plot(yout2_normal), title('Counter Output for Normal Simulation')
subplot(3,1,2), ...
 plot(yout2_sil), title('Counter Output for Model Block SIL (Model Reference) Simulation')
subplot(3,1,3), plot(yout2_normal-yout2_sil), ...
 title('Difference Between Normal and SIL');
```

Compare the logged states of Model blocks from normal and SIL mode simulations.

```
xout2 = out.xout;
xout2_sil = xout2{1}.Values.Data;
xout2_normal = xout2{2}.Values.Data;
fig1 = figure;
subplot(3,1,1), plot(xout2_sil), title('State Logging for Normal Simulation')
subplot(3,1,2), ...
 plot(xout2_normal), title('State Logging for Model Block SIL (Model Reference) Simulation')
subplot(3,1,3), plot(xout2_normal-xout2_sil), ...
 title('Difference Between Normal and SIL');
```

Clean up.

```
close_system(model,0);
if ishandle(fig1), close(fig1), end, clear fig1
simResults={'out','yout','yout_sil','yout_normal', ...
 'out2','yout2','yout2_sil','yout2_normal', ...
 'SilCounterBus','T','reset','ticks_to_count','Increment'};
save([model '_results'],simResults{:});
clear(simResults{:},'simResults')
```

### SIL or PIL Block Simulation

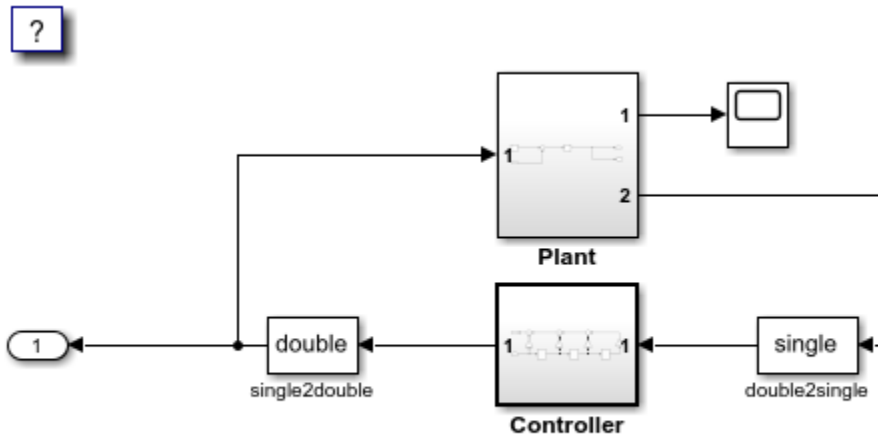

Test generated subsystem code by using a SIL or PIL block in a simulation. With this approach:

- You test code generated from subsystems, which uses the standalone code interface.

- You provide a test harness or a system model to supply test vector or stimulus inputs.
- You replace your original subsystem with the generated SIL or PIL block.

Open a simple model, which consists of a control algorithm and a plant model in a closed loop. The control algorithm regulates the output from the plant.

```
model='rtwdemo_sil_block';
close_system(model,0)
open_system(model)
```

Copyright 2004-2020 The MathWorks, Inc.

Run a normal mode simulation

```
out = sim(model,10);
yout_normal = out.yout;
clear out
```

Configure the build process to create the SIL block for testing.

```
set_param(model, 'CreateSILPILBlock', 'SIL');
```

To test the behavior on production hardware, specify a PIL block.

To create the SIL block, generate code for the control algorithm subsystem. You see the SIL block at the end of the build process. Its input and output ports match those of the control algorithm subsystem.

```
close_system('untitled',0);
slbuild([model '/Controller'])

Starting build procedure for: Controller
Successful completion of build procedure for: Controller
Creating SIL block ...
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
Controller	Code generated and compiled	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 32.974s

Alternatively, you can right-click the subsystem and select C/C++ Code > Build This Subsystem. In the dialog box that opens, click Build.

To perform a SIL simulation of the controller and plant model in a closed loop, replace the original control algorithm with the new SIL block. To avoid losing your original subsystem, do not save your model in this state.

```
controllerBlock = [model '/Controller'];
blockPosition = get_param(controllerBlock, 'Position');
delete_block(controllerBlock);
add_block('untitled/Controller', [controllerBlock '(SIL)', ...
 'Position', blockPosition);
close_system('untitled', 0);
clear controllerBlock blockPosition
```

Run the SIL simulation.

```
out = sim(model, 10);

Preparing to start SIL block simulation: <a href="matlab: targets_hyperlink_manager('run',6)
Starting SIL simulation for component: rtwdemo_sil_block
Application stopped
Stopping SIL simulation for component: rtwdemo_sil_block
```

The control algorithm uses single-precision, floating-point arithmetic. You can expect the order of magnitude for differences between SIL and normal simulations to be close to the machine precision for single-precision data.

Define an error tolerance for SIL simulation results that is based on the machine precision for the single-precision, normal simulation results.

```
machine_precision = eps(single(yout_normal));
tolerance = 4 * machine_precision;
```

Compare normal and SIL simulation results. In the third plot, the differences between the simulations lie well within the defined error tolerance.

```
yout_sil = out.yout;
tout = out.tout;
fig1 = figure;
subplot(3,1,1), plot(yout_normal), title('Controller Output for Normal Simulation')
subplot(3,1,2), plot(yout_sil), title('Controller Output for SIL Simulation')
```

```
subplot(3,1,3), plot(tout,abs(yout_normal-yout_sil),'g-'), tout,tolerance,'r-'), ...
 title('Normal and SIL Difference and Error Tolerance');
```

Clean up.

```
close_system(model,0);
if ishandle(fig1), close(fig1), end
clear fig1
simResults={'out','yout_sil','yout_normal','tout','machine_precision'};
save([model '_results'],simResults{:});
clear(simResults{:},'simResults')
```

### Hardware Implementation Settings

When you run a SIL simulation, you must configure your hardware implementation settings (characteristics such as native word sizes) to allow compilation for your development computer. These settings can differ from the hardware implementation settings that you use when building the model for your production hardware. To avoid the need to change hardware implementation settings

between SIL and PIL simulations, enable portable word sizes. For more information, see “Configure Hardware Implementation Settings” on page 82-20.

## Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation

Implement a communication channel for processor-in-the-loop (PIL) simulation.

The communication channel enables exchange of data between different processes. The communication channel supports capabilities that require the exchange of data between the Simulink® software environment that runs on your development computer (host) and deployed code that runs on target hardware. For example, a PIL simulation.

You learn about the `rtiostream` interface and how it provides a generic communication channel that you can implement in the form of target connectivity drivers for different connection types. This example describes how to use the default TCP/IP implementation.

Two entities, Station A and Station B, use the `rtiostream` interface to set up a communication channel and exchange data. For this example, Station A and Station B are configured within the same process on your desktop computer.

The target connectivity drivers support an on-target PIL simulation. In the simulation, Station A and Station B represent the target and host computers that exchange data via the communication channel. On the host side, the target connectivity driver is implemented as a shared library that is loaded and called from within the MATLAB® product. On the target side, the driver is source code or a library that is linked to the application that runs on the target.

Additionally, you can:

- Configure your own target-side driver for TCP/IP to operate with the default host-side TCP/IP driver.
- Configure the supplied host-side driver for serial communications.
- Implement custom target connectivity drivers, for example, by using CAN or USB for host and target sides of the communication channel.

See also “Test Generated Code with SIL and PIL Simulations” on page 82-90 and “Configure Processor-In-The-Loop (PIL) for a Custom Target” on page 82-109.

### View Source Code for the Default TCP/IP Implementation

The file `rtiostream_tcpip.c` implements client-side and server-side TCP/IP communication. A startup parameter configures the driver to operate in either client or server mode. You can use this source file as a starting point for a custom implementation. Each side of the communication channel requires only one or the other of the server or client implementations. If the client and server drivers run on different architectures, consider placing the driver code for each architecture in a separate source file.

The header file `rtiostream.h` contains prototypes for the functions `rtIOStreamOpen/Send/Recv/Close`. Include it (using `#include`) for custom implementations.

Extract the location of TCP/IP driver source code.

```
rtiostream_src_dir=fullfile(matlabroot,'toolbox','coder','rtiostream','src');
tcpip_dir=fullfile(rtiostream_src_dir,'rtiostreamtcpip');
```

View `rtiostream_tcpip.c`.

```
edit(fullfile(tcpip_dir, 'rtiostream_tcpip.c'));
```

View `rtiostream.h`.

```
edit(fullfile(rtiostream_src_dir, 'rtiostream.h'));
```

### Location of Shared Library Files

To access the target connectivity drivers from the MATLAB product, you must compile them to a shared library. The shared library must be located on your system path. A shared library for the default TCP/IP drivers is located in `matlabroot/bin/$ARCH` (`$ARCH` is your system architecture, for example, `win64`).

The shared library filename extension and location depends on your operating system.

```
[~, ~, sharedLibExt] = coder.BuildConfig.getStdLibInfo;
```

Identify the shared library for Station A and Station B.

```
libTcpip = ['libmwrrtiostreamtcpip' sharedLibExt];
disp(libTcpip)
```

```
libmwrrtiostreamtcpip.dll
```

### Test the Target Connectivity Drivers

If you are implementing a custom target connectivity driver, it is helpful to test it from within the MATLAB product. The following example shows how to load the default TCP/IP target connectivity drivers and use them for data exchange between Station A and Station B.

To access the drivers, you can use the MEX-file `rtiostream_wrapper`. With this MEX-file, you can load the shared library and access the `rtiostream` functions to open and close an `rtiostream` channel, and send and receive data.

Station A and Station B run on the host computer. Station A is configured as a TCP/IP server and Station B as a TCP/IP client. For host to target communication, you typically configure the host as a TCP/IP client and the target as a TCP/IP server.

Choose a port number for TCP.

```
if usejava('jvm')
 % Find a free port
 tempSocket = java.net.ServerSocket(0);
 port = num2str(tempSocket.getLocalPort);
 tempSocket.close;
else
 % Use a hard-coded port
 port = '14646';
end
```

Open the Station A `rtiostream` as a TCP/IP server.

```
stationA = rtiostream_wrapper(libTcpip, 'open', ...
 '-client', '0', ...
 '-blocking', '0', ...
 '-port', port);
```

If the communication channel opens, the return value is a handle to the connection. A return value of -1 indicates an error.

Check the return value.

```
assert(stationA!=-1)
```

Open the Station B rtiostream as a TCP/IP client.

```
stationB = rtiostream_wrapper(libTcpi, 'open', ...
 '-client', '1', ...
 '-blocking', '0', ...
 '-port', port, ...
 '-hostname', 'localhost');
```

If the communication channel opens, the return value is a handle to the connection. A return value of -1 indicates an error.

Check the return value.

```
assert(stationB!=-1)
```

### Send Data from Station B to Station A

The target connectivity drivers send a stream of data in 8-bit bytes. For processors that are not byte-addressable, the data is sent in the smallest addressable word size.

Send message data from Station B to Station A.

```
msgOut = uint8('Station A, this is Station B. Are you there? OVER');
```

```
[retVal, sizeSent] = rtiostream_wrapper(libTcpi, ...
 'send', ...
 stationB, ...
 msgOut, ...
 length(msgOut));
```

A return value of zero indicates success.

```
assert(retVal==0);
```

Make sure that bytes in the message were sent.

```
assert(sizeSent==length(msgOut));
```

Allow time for data transmission to be completed.

```
pause(0.2)
```

Receive data in Station A.

```
[retVal, msgRecvd, sizeRecvd] = rtiostream_wrapper(libTcpi, ...
 'recv', ...
 stationA, ...
 100);
```

A return value of zero indicates success.

```
assert(retVal==0);
```

Make sure that bytes in the message were received.

```
assert(sizeRecvd==sizeSent);
```

Display the received data.

```
disp(char(msgRecvd))
```

```
Station A, this is Station B. Are you there? OVER
```

### Send a Response from Station A to Station B

Send response data from Station A to Station B.

```
msgOut = uint8('Station B, this is Station A. Yes, I'm here! OVER. ');
[~, sizeSent] = rtiostream_wrapper(libTcpi, ... %#ok
 'send', ...
 stationA, ...
 msgOut, ...
 length(msgOut));
```

Allow time for data transmission to be completed.

```
pause(0.2)
```

Receive data in Station B.

```
[~, msgRecvd, sizeRecvd] = rtiostream_wrapper(libTcpi, ... %#ok
 'recv', ...
 stationB, ...
 100);
```

Display the received data.

```
disp(char(msgRecvd))
```

```
Station B, this is Station A. Yes, I'm here! OVER.
```

### Close Connection and Unload Shared Libraries

Close rtiostream on Station B.

```
retVal = rtiostream_wrapper(libTcpi, 'close', stationB);
```

A return value of zero indicates success.

```
assert(retVal==0);
```

Close rtiostream on Station A.

```
retVal = rtiostream_wrapper(libTcpi, 'close', stationA);
```

A return value of zero indicates success.

```
assert(retVal==0)
```

Unload the shared library.

```
rtiostream_wrapper(libTcpi, 'unloadlibrary');
```

### Host-Side Driver for Serial Communications

You can use the supplied host-side driver for serial communications as an alternative to the drivers for TCP/IP. To configure the serial driver, see `rtiostream_wrapper` in the Embedded Coder® reference documentation.

### Configure Your Own Target-Side Driver

If your target has an Ethernet connection and you have a TCP/IP stack available, follow these steps:

- 1 Write a wrapper for your TCP/IP stack that makes it available via the `rtiostream` interface defined in `rtiostream.h`.
- 2 Write a test application for your target that sends and receives some data.
- 3 Use the `rtiostream_wrapper` MEX-file and host-side TCP/IP driver to test your driver software that is running on the target.
- 4 When you have a working target-side driver, include the driver source files in the build for your automatically generated code.

You can configure your target-side driver to operate only as a TCP/IP server because the default host-side driver for PIL is configured as a TCP/IP client.

If you need to use a communications channel that is not already supported on the host-side, write drivers for host and target. In this case, you can still use the `rtiostream_wrapper` MEX-file for testing your `rtiostream` drivers.

### Configure Your Own Host-Side Driver

You can implement the target connectivity drivers by using different communication channels. For example, you can implement host-target communications via a special serial connection, which requires that you provide drivers for the host and target.

On the host side, you can test the drivers by using the `rtiostream_wrapper` MEX-file. If your driver includes diagnostic output from `printf` statements and `rtiostream_wrapper` loads the shared library, you must replace the `printf` statements with `mexPrintf` statements.

When you have a working host-side device driver, you must make it available within the Simulink software environment. For PIL simulation, register the shared host-side shared library via `sl_customization`.

## Configure Processor-In-The-Loop (PIL) for a Custom Target

Create a target connectivity configuration by using target connectivity APIs. With a target connectivity configuration, you can run processor-in-the-loop (PIL) simulations on custom embedded hardware.

You learn how to:

- Adapt the build process to support PIL simulations.
- Configure a tool for downloading and starting execution of a PIL executable on your target hardware.
- Configure a communication channel between host and target to support PIL simulation on the target hardware.

Start with a model configured for software-in-the-loop (SIL) simulation. This example guides you through the process of creating a target connectivity configuration so that you can simulate the model in PIL mode. The example runs entirely on your host computer. You can follow the same steps to create a connectivity configuration for your own embedded target hardware.

See also “Test Generated Code with SIL and PIL Simulations” on page 82-90 and “Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation” on page 82-104.

### Preliminaries

Later in this example, you will add a folder to the search path. Create the folder path.

```
sl_customization_path = fullfile(matlabroot,...
 'toolbox',...
 'rtw',...
 'rtwdemos',...
 'pil_demo');
```

If this folder is already on the search path, remove it.

```
if strfind(path,sl_customization_path)
 rmpath(sl_customization_path)
end
```

Reset customizations.

```
sl_refresh_customizations
```

Create a temporary folder (in your system's temporary folder) for the build and inspection process.

```
currentDir = pwd;
rtwdemodir();
```

### Test Generated Code with SIL Simulation

Simulate a model configured for SIL. Verify the generated code compiled for your host computer by comparing the SIL simulation behavior with the normal simulation behavior.

Make sure that the example model is newly opened.

```
close_system('rtwdemo_sil_modelblock',0);
close_system('rtwdemo_sil_counter',0)
open_system('rtwdemo_sil_modelblock')
```

The CounterA Model block displays the text (SIL), which indicates that its referenced model is configured for SIL simulation.

Run a simulation of the system.

```
set_param('rtwdemo_sil_modelblock','StopTime','10');
sim('rtwdemo_sil_modelblock');

Starting build procedure for model: rtwdemo_sil_counter
Successful completion of build procedure for model: rtwdemo_sil_counter
Preparing to start SIL simulation ...
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
Updating code generation report with SIL files ...
Starting SIL simulation for component: rtwdemo_sil_counter
Stopping SIL simulation for component: rtwdemo_sil_counter
```

### Target Connectivity Configuration

Start work on a target connectivity configuration for PIL.

Make a local copy of the target connectivity configuration classes.

```
src_dir = ...
 fullfile(matlabroot,'toolbox','coder','simulinkcoder','+coder','+mypil');
if exist(fullfile('.','+mypil'),'dir')
 rmdir('+mypil','s')
end
mkdir +mypil
copyfile(fullfile(src_dir,'Launcher.m'), '+mypil');
copyfile(fullfile(src_dir,'TargetApplicationFramework.m'), '+mypil');
copyfile(fullfile(src_dir,'ConnectivityConfig.m'), '+mypil');
```

Make the copied files writable.

```
fileattrib(fullfile('+mypil','*'),'w');
```

Update the package name to reflect the new location of the files.

```
coder.mypil.Utils.UpdateClassName(...
 './+mypil/ConnectivityConfig.m',...
 'coder.mypil',...
 'mypil');
```

Verify that you now have a folder +mypil in the current folder, which has the files Launcher.m, TargetApplicationFramework.m, and ConnectivityConfig.m.

```
dir './+mypil'
```

.	Launcher.m
..	TargetApplicationFramework.m
ConnectivityConfig.m	

## Review Code to Launch the PIL Executable

The class that configures a tool for launching the PIL executable is `mypil.Launcher`. Open this class in the editor.

```
edit(which('mypil.Launcher'))
```

Review the content of this file. The method `setArgString` supplies additional command-line parameters to the executable. These parameters can include a TCP/IP port number. For an embedded processor implementation, you can choose to hard-code these settings.

## Configure the Overall Target Connectivity Configuration

View the class `mypil.ConnectivityConfig`.

```
edit(which('mypil.ConnectivityConfig'))
```

Review the content of this file. You should be able to identify:

- The creation of an instance of `rtw.connectivity.RtIOStreamHostCommunicator` that configures the host side of the TCP/IP communications channel.
- A call to the `setArgString` method of `Launcher` that configures the target side of the TCP/IP communications channel.
- A call to `setTimer` that configures a timer for execution time measurement

To define your own target-specific timer for execution time profiling, you must use the Code Replacement Library to specify a replacement for the function `code_profile_read_timer`. Use a command-line API or the `crtool` user interface.

## Review the Target-Side Communications Drivers

View the file `rtiostream_tcpip.c`.

```
rtiostreamtcpip_dir=fullfile(matlabroot,'toolbox','coder','rtiostream','src',...
 'rtiostreamtcpip');
edit(fullfile(rtiostreamtcpip_dir,'rtiostream_tcpip.c'))
```

Scroll down to the end of this file. See that this file contains a TCP/IP implementation of the functions `rtIOStreamOpen`, `rtIOStreamSend`, and `rtIOStreamRecv`. These functions are required for the target hardware to communicate with your host computer. You must provide an implementation for each of these functions that is specific to your target hardware and communication channel.

## Add Target-Side Communications Drivers to the Connectivity Configuration

The class that configures additional files to include in the build is `mypil.TargetApplicationFramework`. Open this class in the editor.

```
edit(which('mypil.TargetApplicationFramework'))
```

## Use `sl_customization` to Register the Target Connectivity Configuration

To use the new target connectivity configuration, you must provide an `sl_customization` file. The `sl_customization` file registers your new target connectivity configuration and specifies the required conditions for its use. The conditions specified in this file can include the name of your system target file and your hardware implementation settings.

You can view the `sl_customization` file. For this example, you do not have to make changes to the file.

```
edit(fullfile(sl_customization_path, 'sl_customization.m'))
```

Add the `sl_customization` folder to the search path and refresh the customizations.

```
addpath(sl_customization_path);
sl_refresh_customizations;
```

### Test Generated Code with PIL Simulation

Run the PIL simulation.

```
close_system('rtwdemo_sil_modelblock',0)
open_system('rtwdemo_sil_modelblock')
set_param('rtwdemo_sil_modelblock/CounterA', 'SimulationMode', 'processor-in-the-loop (pil)');
set_param('rtwdemo_sil_modelblock', 'StopTime', '10');
sim('rtwdemo_sil_modelblock');

Starting build procedure for model: rtwdemo_sil_counter
Generated code for 'rtwdemo_sil_counter' is up to date because no structural, parameter or c
Successful completion of build procedure for model: rtwdemo_sil_counter
Connectivity configuration for referenced model "rtwdemo_sil_counter": My PIL Example ###
EXECUTING METHOD SETARGSTRING
SETARGSTRING called from line 71 of ConnectivityConfig.m
Preparing to start PIL simulation ...
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
Updating code generation report with PIL files ...
Starting application: 'rtwdemo_sil_counter_ert_rtw\pil\rtwdemo_sil_counter.exe'
Starting PIL simulation
Started new process, pid = 14132
Stopping PIL simulation
Terminated process, pid = 14132
```

Review the preceding messages. Confirm that the simulation ran without errors. You have now implemented a target connectivity configuration for PIL. You can use the same APIs to implement a connectivity configuration for your own combination of embedded processor, download tool, and communications channel.

### Cleanup

Remove the search path for this example.

```
rmpath(sl_customization_path)
```

Reset customizations.

```
sl_refresh_customizations
```

Close the models.

```
close_system('rtwdemo_sil_modelblock',0)
close_system('rtwdemo_sil_counter',0)
```

```
rtwdemoclean;
cd(currentDir)
```

## Field-Oriented Control of Permanent Magnet Synchronous Machine

This example shows the basic workflow and key APIs for generating C code from a motor control algorithm, and for verifying its compiled behavior and execution time. You will use Processor-in-the-loop (PIL) simulation to gain confidence that the C code will perform as expected when you integrate it with embedded software that interfaces with the motor hardware. Although this workflow uses a motor control application for a specific processor, you can apply this workflow to virtually any application or processor.

We use a Field-Oriented Control algorithm for a Permanent Magnet Synchronous Machine to show this workflow. This control technique is common in motor drive systems for hybrid electric vehicles, manufacturing machinery, and industrial automation.

### Overview

In this example, generate and verify C code from a control algorithm model, which you can integrate with additional embedded software required to interface to motor hardware.

You will use a simulation environment to model and verify the behavior of a closed-loop motor control system. Once the control system behavior is within specification, you will generate C code from the controller model. After inspecting the code, you will assess its functional behavior and execution time using processor-in-the-loop (PIL) testing.

To facilitate PIL testing, you will select test signals to exercise the controller model and establish reference outputs. You will review an example PIL implementation for a Texas Instruments™ F28335 processor that communicates with Simulink® on the host computer over a serial connection. You can use this example as a starting point to create a PIL implementation for your own processor. You will run the controller model in PIL mode to measure execution time and verify execution behavior of the code running on the embedded processor against the simulation reference outputs.

In the final implementation on the embedded processor, you would integrate the generated controller C code with additional embedded software, such as peripherals and interrupts, required to interface with the motor hardware.

### Notes

- Simscape™ Electrical is required for system simulation in the section "Verify Behavior through System Simulation." It is not required for other tasks.
- The Texas Instruments™ F28335 PIL implementation is a reference approach that you can apply to virtually any processor. However, if you wish to use this implementation directly, you will need additional support files, compilers, and tools from Texas Instruments™. You can find more information about those in "Create PIL Implementation and Register with Simulink®" section of this example. This reference PIL implementation does not require the Texas Instrument C2000™ Embedded Target feature of Embedded Coder®, but C2000™ users are encouraged to install Texas Instruments C2000 Support Package using Add-On Explorer.

### Verify Behavior through System Simulation

In this section, you will verify the controller in a closed loop system simulation.

The system model test bench consists of test inputs, the embedded processor, the power electronics and motor hardware, and visualizations. You can use the system model to exercise the controller and explore its expected behavior. You can use the following commands to execute the model and plot logged signals.

```

open_system('rtwdemo_pmsmfoc_system')
out_system = sim('rtwdemo_pmsmfoc_system')
rtwdemo_pmsmfoc_plotsignals(out_system.logout)

out_system =
 Simulink.SimulationOutput:
 logout: [1x1 Simulink.SimulationData.Dataset]

 SimulationMetadata: [1x1 Simulink.SimulationMetadata]
 ErrorMessage: [0x0 char]

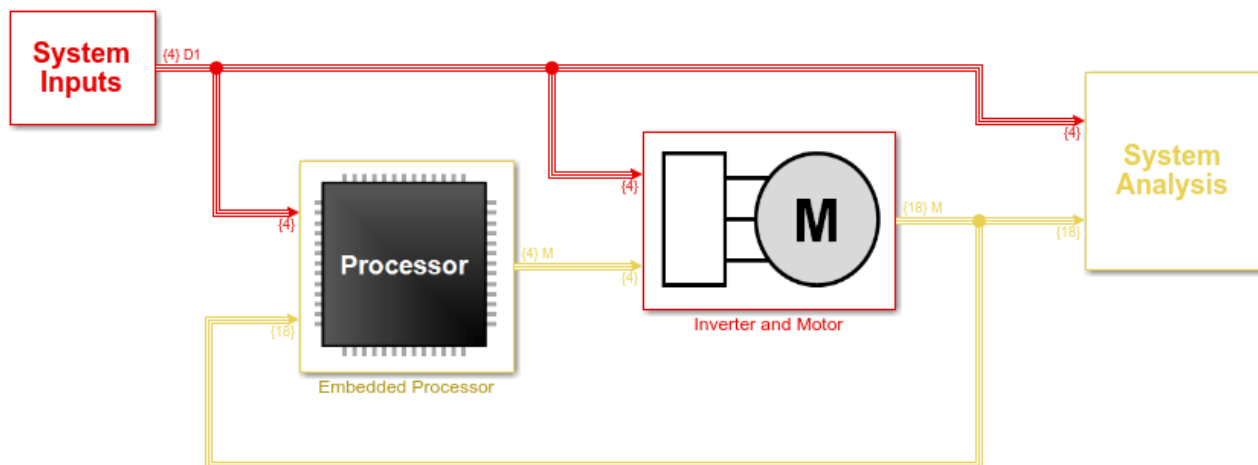

```

?

## Field-Oriented Control of Permanent Magnet Synchronous Machine System Test Bench

Model Description: Field-Oriented Control of Permanent Magnet Synchronous Machine

Demonstrates a Field-Oriented Control algorithm with Space Vector Modulation for a Permanent Magnet Synchronous Machine (PMSM). The test bench can be used to evaluate the system performance. Examples include turning the motor on, searching for a valid rotor position, transitioning to closed loop operation, and changing speed and torque during closed loop control. The Embedded Processor subsystem contains the controller algorithm (which supports C code generation) as well as simulation models of peripherals.

Copyright 2010-2020 The MathWorks, Inc.

The plots show that the motor is stationary until the `motor_on` signal is true. The motor then spins in an open loop until a known position is detected, which is indicated by the encoder index pulse. The controller then transitions to closed loop operation and the motor reaches a steady state speed.

### Explore Model Architecture

In this section, you will explore the model architecture including how data is specified, how the controller is partitioned from the test bench, and how controller is scheduled. This architecture facilitates system simulation, algorithmic code generation, and PIL testing.

A data definition file creates the MATLAB® data required for simulation and code generation. This data file is automatically run within the `PreLoadFcn` callback of the system test bench model.

```
edit('rtwdemo_pmsmfoc_data.m')
```

Within the system test bench model, the embedded processor is modeled as a combination of the peripherals and the controller software.

```
open_system('rtwdemo_pmsmfoc_system/Embedded Processor')
```

## Embedded Processor

Models hardware on the embedded processor, including the controller algorithm software specification and peripherals.

The controller software is specified in a separate model. Within this model, the Mode\_Scheduler subsystem uses Stateflow® to schedule different modes of operation of the Motor\_Control algorithm.

```
open_system('rtwdemo_pmsmfoc')
```

## Controller Algorithm for Permanent Magnet Synchronous Machine

### Model Description: Controller Algorithm for Permanent Magnet Synchronous Machine

Specifies controller software component for Permanent Magnet Synchronous Machine (PMSM) using Field-Oriented Control. The sensors bus/structure contains values returned by the Analog to Digital Converter (ADC) and quadrature encoder peripherals. The controller outputs compare values used by the Pulse Width Modulators (PWMs) to generate the phase voltages.

Copyright 2010-2020 The MathWorks, Inc.

Within the Motor\_Control subsystem, sensor signals are converted to engineering units and passed to the core controller algorithm. The controller algorithm calculates voltages. The voltages are then converted to a driver signal.

```
open_system('rtwdemo_pmsmfoc/Motor_Control')
```

## Motor Control

This layer converts driver units to engineering units, executes the control law, and calculates compare values used by the PWM driver. The sensors bus/structure contains values returned by the Analog to Digital Converter (ADC) and quadrature encoder peripherals. The controller outputs compare values used by the Pulse Width Modulators (PWMs) to generate the phase voltages.

The primary control law is a field-oriented controller. The controller has a low rate outer loop that controls the speed, and a higher rate inner loop that controls the current.

```
open_system('rtwdemo_pmsmfoc/Motor_Control/Field_Oriented_Controller')
```

## Field Oriented Controller

The Velocity Controller outer loop is executed as a multiple of the Current Control loop time. You can view the MATLAB® variables, which specify these sample times:

```
fprintf('High rate sample time = %f seconds\n', ctrlConst.TsHi)
fprintf('Low rate sample time = %f seconds\n', ctrlConst.TsLo)
```

```
High rate sample time = 0.000040 seconds
Low rate sample time = 0.005000 seconds
```

Notice that the highest rate in the controller algorithm is 25 kHz.

```
fprintf('High rate frequency = %5.0f Hz\n', 1/ctrlConst.TsHi)
```

```
High rate frequency = 25000 Hz
```

### Generate Controller C Code for Integration into Embedded Application

In this section, you will generate and visually inspect the C code function for the controller.

To ease integration, the controller model is configured in single-tasking mode so that the generated code can be invoked using one function call. This function handles the lower and higher rates. The generated controller function must be executed at the high rate sample time.

The function prototype is specified in the model configuration parameters and the input and output ports are passed as arguments. You can view the function specification for the controller algorithm.

```
mdlFcn = RTW.getFunctionSpecification('rtwdemo_pmsmfoc');
disp(mdlFcn.getPreview('init'))
disp(mdlFcn.getPreview('step'))

Controller_Init ()
error = Controller (motor_on, command_type, current_request, * sensors, * pwm_compare)
```

Through use of a global structure in the generated code, you can access the field-oriented controller proportional and integral gains. This global structure is specified in the data definition file.

```
disp(ctrlParams.Value)
disp(ctrlParams.CoderInfo)

 Current_P: 10
 Current_I: 10000
 Velocity_P: 0.0050
 Velocity_I: 0.0150
 Position_P: 0.1000
 Position_I: 0.6000
 StartupAcceleration: 1
 StartupCurrent: 0.2000
 RampToStopVelocity: 20
 AdcZeroOffsetDriverUnits: 2.2523e+03
 AdcDriverUnitsToAmps: 0.0049
 EncoderToMechanicalZeroOffsetRads: 0
 PmsmPolePairs: 4

Simulink.CoderInfo
 StorageClass: 'ExportedGlobal'
 Identifier: ''
 Alignment: -1
```

You generate C code from the model as follows.

```
slbuild('rtwdemo_pmsmfoc')

Starting build procedure for: rtwdemo_pmsmfoc
Successful completion of build procedure for: rtwdemo_pmsmfoc

Build Summary

Top model targets built:

Model Action Rebuild Reason
=====
rtwdemo_pmsmfoc Code generated and compiled Code generation information file does not exist.

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 59.217s
```

Use the generated report to inspect the generated C code file and verify that the correct step and initialization functions were generated. Also verify that the parameter structure was created as a global variable.

## Establish Reference Behavior for Controller Model

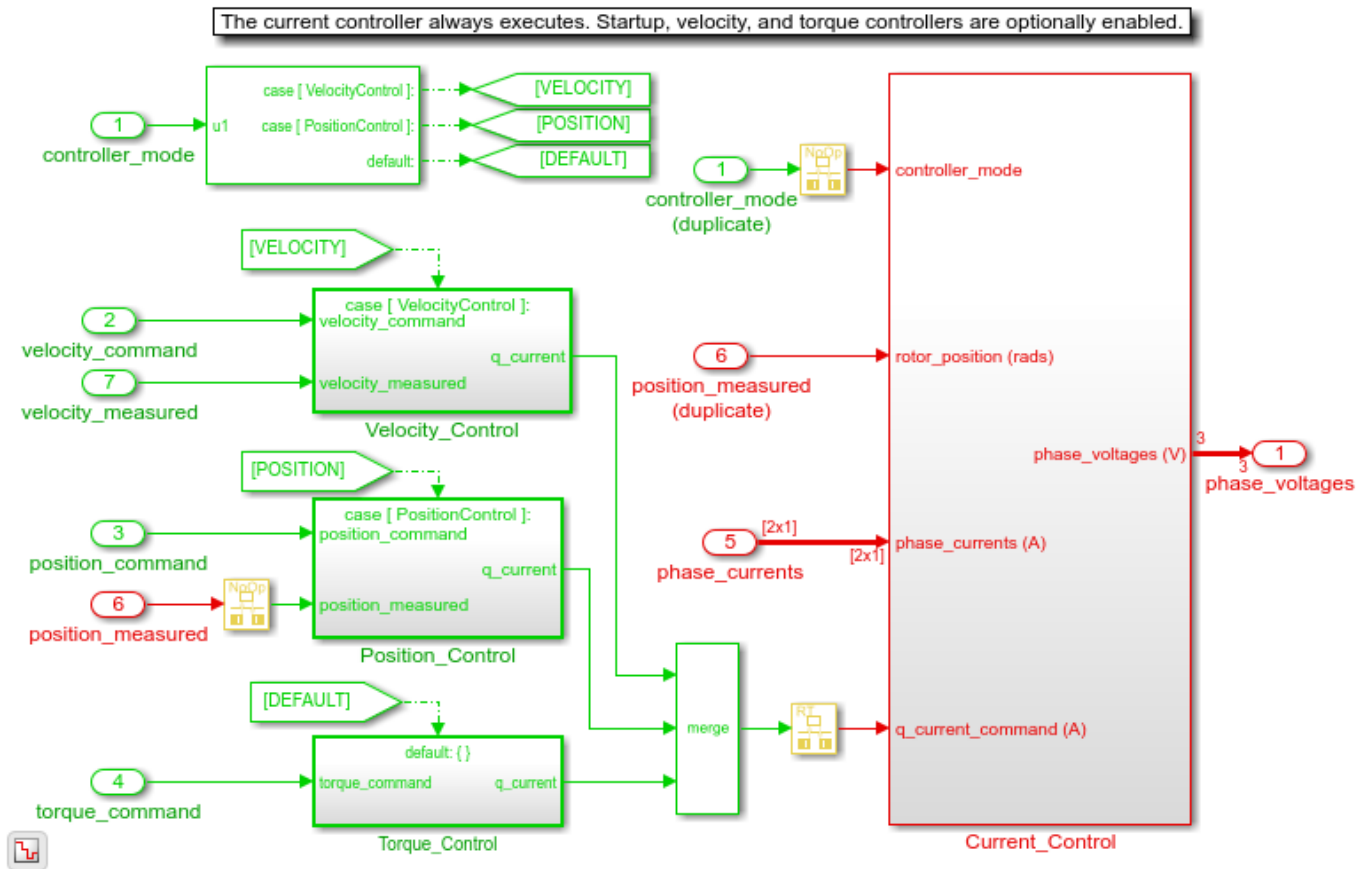

In this section, you will establish test inputs and a reference output to help verify behavior and profile execution time during PIL testing. You will make a local copy of the controller model then load a set of test input signals that exercise the different modes within the controller. You will then configure the controller model to attach these logged signals to input ports, execute the controller model, and log the output port signal to the workspace.

Configuration parameters of the controller model used to establish the reference behavior and test environment will change as described below. Blocks and parameters used to specify the controller model's design and generate production code will not change. However, to avoid modifying any part of the installed controller model, save the model and change its name to `rtwdemo_pmsmfoc_local.slx`.

```
save_system('rtwdemo_pmsmfoc','rtwdemo_pmsmfoc_local.slx')
close_system('rtwdemo_pmsmfoc_system',0);
close_system('rtwdemo_pmsmfoc',0);
```

omCallMethod failed on slmsgviewer.renameTab

## Field Oriented Controller

To profile execution times, select a set of test inputs that will execute the paths of interest within the controller. One way to acquire these test inputs and reference output is to log them from the system simulation model.

```

in.motor_on = out_system.logout.getElement('motor_on').Values;
in.command_type = out_system.logout.getElement('command_type').Values;
in.command_value = out_system.logout.getElement('command_value').Values;
in.sensors = out_system.logout.getElement('sensors').Values;
display(in)

```

```
in =
```

```
struct with fields:
```

```

 motor_on: [1x1 timeseries]
 command_type: [1x1 timeseries]
 command_value: [1x1 timeseries]
 sensors: [1x1 struct]

```

These signals can now be attached to the input ports and imported into the controller model such that it can execute directly and independently from the system model. An advantage of this approach is that the controller model can be tested and verified as a standalone component, facilitating reuse and integration with other system models or closed-loop test benches. To elaborate, or prepare, the controller model for testing, change its Configuration Parameters to attach input signals and log signals in the MATLAB® workspace. These changes can be made graphically in the model's Configuration Parameters dialog, or programmatically as shown below.

```

set_param('rtwdemo_pmsmfoc_local',...
 'LoadExternalInput', 'on',...
 'ExternalInput', 'in.motor_on, in.command_type, in.command_value, in.sensors',...
 'StopTime', '0.06',...
 'ZeroInternalMemoryAtStartup', 'on',...
 'SimulationMode', 'normal')
save_system('rtwdemo_pmsmfoc_local.slx')

```

You can now execute the controller model and plot the signal associated with the PWM Compare output port.

```

out = sim('rtwdemo_pmsmfoc_local')
controller_mode = out.logout.getElement('controller_mode').Values;
pwm_compare_ref = out.logout.getElement('pwm_compare').Values;
rtwdemo_pmsmfoc_plotpwmcompare(controller_mode, pwm_compare_ref)

```

```
out =
```

```

Simulink.SimulationOutput:
 logout: [1x1 Simulink.SimulationData.Dataset]

SimulationMetadata: [1x1 Simulink.SimulationMetadata]
 ErrorMessage: [0x0 char]

```

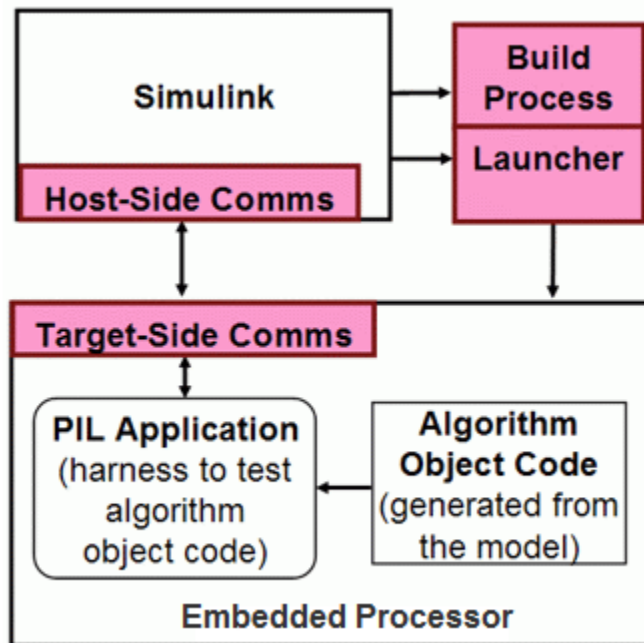

The logged output will be used as the reference behavior for PIL testing.

Notice that the plot is annotated with information about the mode of the controller at each time step. This mode information will be useful when interpreting execution profiling information.

### Create PIL Implementation

In this section, you will study and use an example PIL implementation. You will begin by reviewing prerequisite help documentation from Embedded Coder®. You will then copy the example PIL implementation into your local directory and register it with Simulink®. You will review the approach used to develop the PIL implementation and can explore the associated files to gain additional insight. If you are using a Spectrum Digital Inc. eZdsp F28335 board with Code Composer v4 and a serial connection, you will be able to configure this PIL implementation to directly work with the controller model. If you are using a different processor, you can use this PIL implementation as a starting point to create your own implementation.

The fundamentals of creating a custom PIL implementation are described in “Create PIL Target Connectivity Configuration for Simulink” on page 82-40 . You should familiarize yourself with the basic concept of using the rtiostream API to facilitate communication between Simulink® (host-side) and the embedded processor (target-side) during PIL testing. Note that Embedded Coder® provides host-side drivers for the default TCP/IP implementation (for all platforms supported by Simulink®) as well as a Windows® only version for serial communication. Building the generated code is accomplished using a makefile as described in “Customize Template Makefiles” . To create a PIL implementation you will need to perform several tasks in the embedded environment including writing a target-side communications driver, writing a makefile to build the generated code, and automating download and execution of the built executable.

Using the above approach, a PIL implementation was created for a Spectrum Digital Inc. eZdsp F28335 board. Below is a summary of the target connectivity API components used in this implementation.

- **Host-Side Communication** - The host-side connectivity driver is configured to use serial communication.
- **Target-Side Communication** - The target-side communication is achieved using a handwritten serial implementation of the `rtiostream` functions as well as timer access functions.
- **Build Process** - A makefile based approach is used to build the executable application.
- **Launcher** - Downloading and running the executable is accomplished using the Debug Server Scripting (DSS) utility of Code Composer Studio™ v4 (CCSv4).

The PIL implementation was iteratively developed in three stages. Below is a description of these stages and the tasks performed in these stages. You may find it helpful to follow a similar approach when developing your own PIL implementation

### Stage 1: Create serial communication application with CCSv4

- Install CCSv4 and verify that it can connect with the F28335 eZdsp board.
- Write an embedded application that sends and receives serial data.
- Test the serial communication between the host computer and the embedded application.
- Identify the commands and options for the compiler, linker, and archiver to build the application using a makefile.
- Download and run the application from a Windows® Command Prompt using the DSS utility.

### Stage 2: Implement and test embedded serial `rtiostream` and launch automation with MATLAB®

- Extend the serial application to implement the `rtiostream` API functions for echoing data. Write the `rtIOStreamOpen` to perform general board initialization, including configuring the serial port.

- Verify sending and receiving serial data with the embedded processor from MATLAB® using the `rtiostream_wrapper` function.
- Download and run the application from MATLAB® using the system command to call the DSS utility.

### Stage 3: Implement and test connectivity configuration with Simulink®

- Create a connectivity configuration class to configure the host-side serial communication, specify which target-side code files from the `rtiostream` application should be included in the build process, specify how to access a timer that will be used to collect profiling data, and integrate calling the DSS utility to launch the embedded application.
- Create a tool specification makefile (`target_tools.mk`) which specifies the commands and options for the compiler, linker, and archiver. This makefile is included by the template makefile (`target_tools.mk`).
- Create a template makefile (`ec_target.tmf`) that includes `target_tools.mk`.
- Identify parameters which may be installation dependent and store them as MATLAB® preferences.
- Create a Simulink® customization file which specifies when the PIL implementation is valid

The files associated with this PIL implementation are included with Embedded Coder®, but are not on the MATLAB® path. To explore these files, you can copy them into a local directory. You can register this PIL implementation by adding this directory to the MATLAB® path and refreshing the Simulink® customizations.

```
%copyfile(fullfile(matlabroot,'toolbox','rtw','rtwdemos','examplePilF28335'),'examplePilF28335',
addpath(genpath(fullfile(matlabroot,'toolbox','rtw','rtwdemos','examplePilF28335'))))
sl_refresh_customizations
```

MATLAB® preferences are used to specify path information and the host serial COM port number. If you are using this PIL implementation directly, you must specify these preferences as appropriate for your configuration.

Note that the `TI_F28xxx_SysSWDir` preference points to a directory provided by Texas Instruments™ in their **C2000™ Experimenter Kit Application Software** (`sprc675.zip`). These files are not included with Embedded Coder®.

```
setpref('examplePilF28335','examplePilF28335Dir', fullfile(matlabroot,'toolbox','rtw','rtwdemos',
setpref('examplePilF28335','CCSRootDir', 'C:\Program Files\Texas Instruments\ccsv4');
setpref('examplePilF28335','TI_F28xxx_SysSWDir', 'C:\Program Files\Texas Instruments\TI_F28xxx_9
setpref('examplePilF28335','targetConfigFile', fullfile(matlabroot,'toolbox','rtw','rtwdemos',
setpref('examplePilF28335','baudRate', 115200);
setpref('examplePilF28335','cpuClockRateMHz', 150);
setpref('examplePilF28335','boardConfigPLL', 10);
setpref('examplePilF28335','COMPort', 'COM4');
```

The PIL implementation is now ready to be used.

### Prepare Controller Model for PIL Testing

In this section you will configure the controller model to use the PIL implementation. You will review the customization file used to register the PIL implementation, set the configuration parameters of the model to use the PIL implementation, and enable logging controller outputs and execution profiling data.

When you begin a simulation in PIL mode, Simulink® will check if any of the registered PIL implementations are valid. A customization file specifies which configuration parameters correspond to a valid PIL implementation. You can explore the customization file for this implementation by invoking the following command.

```
edit(fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'examplePilF28335', 'sl_customization.m'));
```

Notice that this file specifies setting for the hardware device and the template makefile which are required to use this PIL implementation. You can modify the configuration parameters in the controller model to match these settings. These changes can be made graphically in the model's Configuration Parameters dialog, or programmatically as shown below.

```
set_param('rtwdemo_pmsmfoc_local', ...
 'ProdHWDeviceType', 'Texas Instruments->C2000', ...
 'TemplateMakefile', 'ec_target.tmf', ...
 'GenCodeOnly', 'off', ...
 'SimulationMode', 'processor-in-the-loop (pil)')
```

You can specify collecting execution profiling information during PIL testing by logging the simulation output values as the variable `pilOut` and logging the execution profiling information as the variable `executionProfile`. These changes can be made graphically in the model's Configuration Parameters dialog, or programmatically as shown below.

```
set_param('rtwdemo_pmsmfoc_local', ...
 'CodeExecutionProfiling', 'on', ...
 'CodeExecutionProfileVariable', 'executionProfile', ...
 'CodeProfilingSaveOptions', 'AllData');
save_system('rtwdemo_pmsmfoc_local.slx')
```

The controller model is now ready to be run in PIL mode.

### Test Behavior and Execution Time of Generated Code

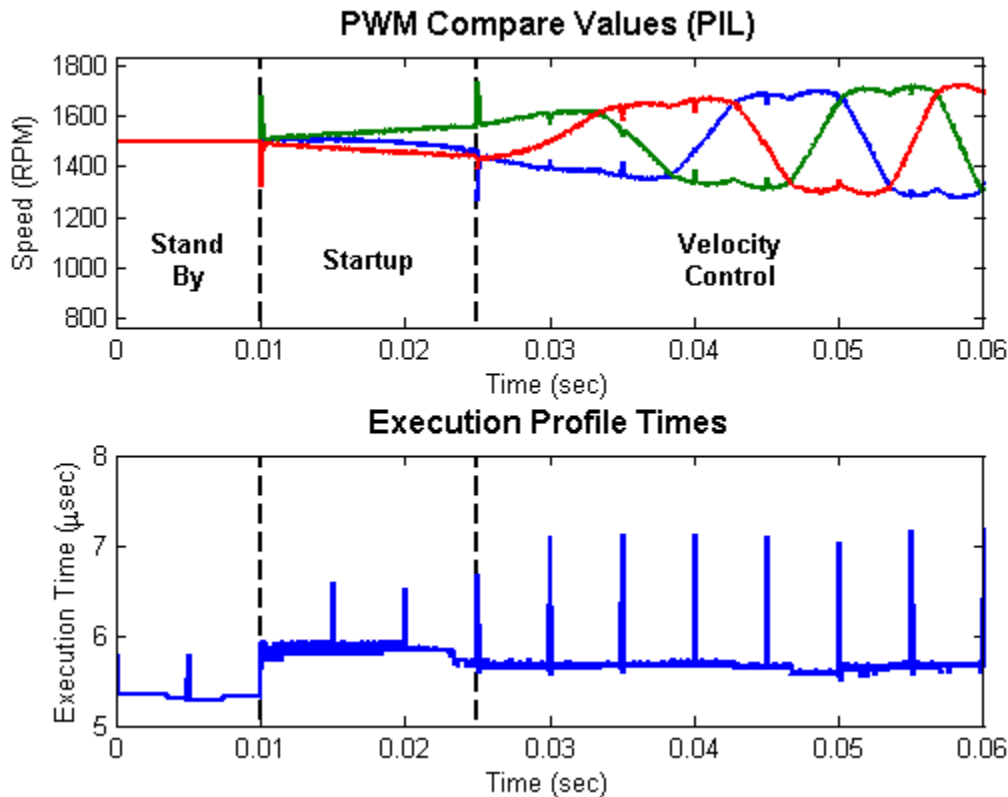

In this section you will run the controller model in PIL mode and explore the behavioral and execution profiling results. You will verify that the behavior of the compiled controller code matches the reference simulation behavior, and then verify that the execution of the code meets timing requirements.

You can run the model and plot the PIL simulation results. When you start the model for the first time, Embedded Coder® will generate code for the algorithm, link the algorithm code with the serial communication interface code, build the embedded application, download the application to the board, and begin the on-target simulation. Note that during subsequent PIL simulations, code is only regenerated if the model changes. Due to the overhead associated with the serial communication interface, the PIL simulation may run slower than the model in normal mode.

The MATLAB® commands below are intentionally commented out as they require connection to hardware and use of embedded development tools described previously. If you have the hardware connected and embedded development tools installed, uncomment and execute these lines to run the model, plot the results, and verify the behavior is numerically equivalent to the simulation running in normal mode. Otherwise, continue reviewing this section to learn about PIL execution analysis options.

```
% UNCOMMENT THE BELOW LINES TO RUN THE SIMULATION AND PLOT THE RESULTS
% if exist('slprj','dir'), rmdir('slprj','s'); end
% out = sim('rtwdemo_pmsmfoc_local')
```

```
% pwm_compare_pil = out.logsout.getElement('pwm_compare').Values;
% rtdemo_pmsmfoc_plotpwmcompare_pil(controller_mode, pwm_compare_pil, executionProfile)
```

The upper plot is the output of the controller, PWM Compare. Note that the outputs in PIL mode look the same as the outputs of the simulation in normal mode shown in the section "Establish Reference Behavior for Controller Model". You can subtract the outputs of normal mode simulation from the PIL mode simulation output to verify that they are numerically equivalent:

```
% UNCOMMENT THE BELOW LINE TO VERIFY NUMERICAL EQUIVALENCE OF THE OUTPUTS
% pilErrorWithRespectToReference = sum(abs(pwm_compare_pil.Data - pwm_compare_pil.Data))

pilErrorWithRespectToReference =
```

```
0 0 0
```

The lower plot is the amount of time spent executing the controller model at each simulation time step. The "Stand By" state requires the least time. Small periodic spikes in execution time occur because the controller is multi-rate and single tasking. The periodic spikes correspond to the time required to run both the base rate and 5 millisecond rate code in the same task.

Since the controller must be executed at 25 kHz on the embedded processor, the algorithm must complete its execution within 40 microseconds (minus additional headroom requirements by other code, which may also be executing on the final application.) The profiling results indicate that the algorithm will execute within the time allotted for this configuration of the embedded environment.

The generated code is now verified to provide numerically equivalent results and meets the execution timing requirements for this test case.

```
close_system('rtwdemo_pmsmfoc_local',0);
close_system('power_util',0);
```

The MATLAB® preferences used in this PIL implementation are persistent between MATLAB® sessions. If you want to remove these preferences, run the following commands.

```
rmpref('examplePilF28335');
rmexamplePilF28335hooks();
```

### **Conclusion**

This example showed system level simulation and algorithmic code generation using a Field-Oriented Control algorithm for a Permanent Magnet Synchronous Machine to explore functional behavior of the controller algorithm. It also showed a general approach for target integration, functional testing, and execution profiling for any embedded processor. Once the algorithm was behaviorally correct, code was generated from the controller model, tested on the target processor and profiled. The algorithm code is now verified and can be integrated with embedded software that interfaces with the motor hardware for further testing.

## Check Configuration

Use the `cgv.Config` class to check model settings for a SIL or PIL simulation. You can review your model configuration and determine the settings that you must change. By default, `cgv.Config` changes configuration parameter values to the value that it recommends, but does not save the model. Alternatively, you can:

- Change configuration parameter values to the values that `cgv.Config` recommends, and save the model. Specify this approach using the `SaveModel` property.
- List the values that `cgv.Config` recommends for the configuration parameters, but not change the configuration parameters or the model. Specify this approach using the `ReportOnly` property.

---

### Note

- Execution in the target environment can require additional modifications to configuration parameter values or the model.
  - Do not use referenced configuration sets in models that you are changing using `cgv.Config`. If the model uses a referenced configuration set, update the model with a copy of the configuration set. Use the `getRefConfigSet` method of the `Simulink.ConfigSetRef` class.
  - If you use `cgv.Config` on a model that executes a callback function, the callback function can change configuration parameter values each time the model loads. The callback function can revert changes that `cgv.Config`. For more information, see “Callbacks for Customized Model Behavior”.
- 

To verify that your model is configured for SIL or PIL:

- 1 Construct a `cgv.Config` object that changes the configuration parameter values without saving the model.
- 2 Determine and change the configuration parameter values that the object recommends using the `configModel` method.
- 3 Display a report of the changes that `configModel` makes.
- 4 Review the changes.
- 5 To apply the changes to your model, save the model.

- “Configure and Run SIL Simulation” on page 82-15
- “Verify Numerical Equivalence with CGV” on page 82-132
- “Verify Numerical Equivalence Between Two Modes of Execution of a Model” on page 82-133

## Verify Numerical Equivalence with CGV

Before verifying numerical equivalence:

- Configure your model for SIL or PIL simulation.
- Use the `cgv.Config` class of the CGV API to verify the model configuration for SIL or PIL simulation.
- Configure your model for code generation. For more information, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 46-2.
- Save your model. If you modify a model without saving it, CGV can issue an error.

To verify numerical equivalence:

- Set up the tests for the first execution environment. For example, simulation.
- Use `run` to run the tests for the first execution environment.
- Set up the tests for the second execution environment. For example, top-model PIL.
- Use `cgv.CGV.run` to run the tests for the second execution environment.
- Use `getOutputData` to get the output data for each execution environment.
- Use `getSavedSignals` to display the signal names in the output data. (optional)
- Build a list of signal names for input to other `cgv.CGV` methods. (optional)
- Use `createToleranceFile` to create a file correlating tolerance information with output signal names. (optional)
- Use `compare` to compare the output signals of the first and second execution environments for numerical equivalence.

---

**Note** Simulink Test is a separate product that provides additional capabilities for SIL and PIL testing, for example, test sequence construction and test management.

---

# Verify Numerical Equivalence Between Two Modes of Execution of a Model

## In this section...

“Configure the Model” on page 82-133  
 “Execute the Model” on page 82-133  
 “Compare All Output Signals” on page 82-134  
 “Compare Individual Output Signals” on page 82-135  
 “Plot Output Signals” on page 82-136

The following example describes configuring, executing, and comparing the results of the `rtwdemo_cgv` model in normal and software-in-the-loop (SIL) simulation modes.

## Configure the Model

The first task for verifying numerical equivalence is to check the configuration of your model.

- 1 Open the `rtwdemo_cgv` model.

```
cgvModel = 'rtwdemo_cgv';
load_system(cgvModel);
```

- 2 Save the model to a working directory.

```
save_system(cgvModel, fullfile(pwd, cgvModel));
close_system(cgvModel); % avoid original model shadowing saved model
```

- 3 Use the `cgv.Config` to create a `cgv.Config` object. Specify parameters that check and modify configuration parameter values and save the model for top-model SIL mode of execution.

```
cgvCfg = cgv.Config('rtwdemo_cgv', 'connectivity', 'sil', 'SaveModel', 'on');
```

- 4 Use the `configModel` method to review your model configuration and to change the settings to configure your model for SIL. When `'connectivity'` is set to `'sil'`, the system target file is automatically set to `'ert.tlc'`. If you specified the parameter/value pair, (`'SaveModel'`, `'on'`) when you created the `cgvCfg` object, the `cgv.Config.configModel` method saves the model.

---

**Note** CGV runs on models that are open. If you modify a model without saving it, CGV can issue an error.

---

```
cgvCfg.configModel(); % Evaluate, change, and save your model for SIL
```

- 5 Display a report of the changes that `cgv.Config.configModel` makes to the model.

```
cgvCfg.displayReport(); % In this example, this reports no changes
```

## Execute the Model

Use the CGV API to execute the model in two modes. The two modes in this example are normal mode simulation and SIL mode. In each execution of the model, the CGV object for each mode captures the output data and writes the data to a file.

- 1 If you have not already done so, follow the steps described in “Configure the Model” on page 82-133.

- 2 Create a `cgv.CGV` object that specifies the `rtwdemo_cgv` model in normal mode simulation.

```
cgvSim = cgv.CGV(cgvModel, 'connectivity', 'sim');
```

---

**Note** When the top model is set to normal simulation mode, the CGV API sets referenced models in PIL mode to accelerator mode.

---

- 3 Provide the input file to the `cgvSim` object.

```
cgvSim.addInputData(1, [cgvModel '_data']);
```

- 4 Before execution of the model, specify the MATLAB files to execute or MAT-files to load. This step is optional.

```
cgvSim.addPostLoadFiles({'[cgvModel '_init.m']});
```

- 5 Specify a location where the object writes all output data and metadata files for execution. This step is optional.

```
cgvSim.setOutputDir('cgv_output');
```

- 6 Execute the model.

```
result1 = cgvSim.run();
```

- 7 Get the output data associated with the input data.

```
outputDataSim = cgvSim.getOutputData(1);
```

- 8 For the next mode of execution, SIL, repeat steps 2-7.

```
cgvSil = cgv.CGV(cgvModel, 'Connectivity', 'sil');
cgvSil.addInputData(1, [cgvModel '_data']);
cgvSil.addPostLoadFiles({'[cgvModel '_init.m']});
cgvSil.setOutputDir('cgv_output');
result2 = cgvSil.run();
```

## Compare All Output Signals

After setting up and running the test, compare the outputs by doing the following:

- 1 If you have not already done so, configure and test the model, as described in “Configure the Model” on page 82-133 and “Execute the Model” on page 82-133.

- 2 Test that the execution result of the model:

```
if ~result1 || ~result2
 error('Execution of model failed.');
```

```
end
```

- 3 Use the `getOutputData` method to get the output data from the `cgv.CGV` objects.

```
simData = cgvSim.getOutputData(1);
silData = cgvSil.getOutputData(1);
```

- 4 Display a list of signals by name using the `getSavedSignals` method.

```
cgvSim.getSavedSignals(simData);
```

- 5 Using the list of signals, build a list of signals in a cell array of character vectors. The signal list can contain a number of signals.

```
signalList = {'simData.getElement(4).Values.Data'};
```

- 6 Use the `createToleranceFile` method to create a file, in this example, `'localtol'`, correlating tolerance information with output signal names.

```
toleranceList = {'absolute', 0.5};
cgv.CGV.createToleranceFile('localtol', signalList, toleranceList);
```

- 7 Compare the output data signals. By default, the `compare` method looks at all signals which have a common name between both executions. If a tolerance file is present, `cgv.CGV.compare` uses the associated tolerance for a specific signal during comparison; otherwise the tolerance is zero. In this example, the `'Plot'` parameter is set to `'mismatch'`. Therefore, only mismatched signals produce a plot.

```
[matchNames, ~, mismatchNames, ~] = ...
 cgv.CGV.compare(simData, silData, 'Plot', 'mismatch', ...
 'Tolerancefile', 'localtol');
fprintf('%d Signals match, %d Signals mismatch\n', ...
 length(matchNames), length(mismatchNames));
disp('Mismatched Signal Names:');
disp(mismatchNames);
```

At the MATLAB command line, you see:

```
14 Signals match, 1 Signals mismatch
Mismatched Signal Names:
 'simData.getElement(4).Values.Data'
```

A plot results from the signal mismatch.

The lower plot displays the numeric difference between the results.

## Compare Individual Output Signals

After setting up and running the test, compare the outputs of individual signals by doing the following:

- 1 If you have not already done so, configure and test the model, as described in “Configure the Model” on page 82-133 and “Execute the Model” on page 82-133.

- 2 Use the `getOutputData` method to get the output data from the `cgv.CGV` objects.

```
simData = cgvSim.getOutputData(1);
silData = cgvSil.getOutputData(1);
```

- 3 Use the `getSavedSignals` method to display the output data signal names. Build a list of specific signal names in a cell array of character vectors. The signal list can contain a number of signals.

```
cgv.CGV.getSavedSignals(simData);

signalList = {'simData.getElement(3).Values.hil.mid0.lo1.Data', ...
'simData.getElement(3).Values.hil.mid0.lo2.Data', ...
'simData.getElement(2).Values.Data(:,3)'};
```

- 4 Use the specified signals as input to the `compare` method to compare the signals from separate runs.

```
[matchNames, ~, mismatchNames, ~] = ...
 cgv.CGV.compare(simData, silData, 'Plot', 'mismatch', ...
 'signals', signalList);
fprintf('%d Signals match, %d Signals mismatch\n', ...
 length(matchNames), length(mismatchNames));
if ~isempty(mismatchNames)
 disp('Mismatched Signal Names:');
 disp(mismatchNames);
end
```

At the MATLAB command line, the result is:

```
3 Signals match, 0 Signals mismatch
```

## Plot Output Signals

After setting up and running the test, use the `plot` method to plot output signals.

- 1 If you have not already done so, configure and test the model, as described in “Configure the Model” on page 82-133 and “Execute the Model” on page 82-133.

- 2 Use the `getOutputData` method to get the output data from the `cgv.CGV` objects.

```
simData = cgvSim.getOutputData(1);
```

- 3 Use the `getSavedSignals` method to display the output data signal names. Build a list of specific signal names in a cell array of character vectors. The signal list can contain a number of signals.

```
cgv.CGV.getSavedSignals(simData);
signalList = {'simData.getElement(2).Values.Data(:,1)'};
```

- 4 Use the specified signal list as input to the `plot` method to compare the signals from separate runs.

```
[signalNames, signalFigures] = cgv.CGV.plot(simData, ...
 'Signals', signalList);
```

## Numerical Consistency of Model and Generated Code Simulation Results

### In this section...

“Numerical Consistency” on page 83-2

“Numerical Consistency in Complex Systems” on page 83-2

“Reasons for Block-Level Numerical Differences” on page 83-4

### Numerical Consistency

In the Model-Based Design workflow, you use MathWorks products to generate code for numerical applications that employ fixed-point and floating-point arithmetic.

- To develop models, you use MATLAB, Simulink, and Stateflow.
- To generate source code, you use Simulink Coder and Embedded Coder.
- To test numerical equivalence between your model and generated code, you compare model and generated code simulation results. For example, normal mode simulation results compared with software-in-the-loop (SIL) simulation results.

The results from the model and generated code simulations are numerically consistent if:

- In fixed-point applications, the results agree in a bit-wise comparison.
- In floating-point applications, the results agree with an error tolerance that you specify.

Use the Simulation Data Inspector to compare results. To determine whether discrepancies exist or are significant, you can specify absolute and relative tolerance values:

- For fixed-point applications, you can specify an absolute tolerance of zero.
- For floating-point applications, you can specify tolerance with respect to a reference value or signal. The choice of reference depends on your application. Consider these examples:
  - An algorithm that solves a linear algebraic equation by iterative, feed-forward error calculations. You can specify tolerance with respect to `eps`.
  - A Proportional-Integral-Derivative (PID) controller for a closed-loop system. For transient behavior, you can specify tolerance with criteria from a standard. For steady-state behavior, you can specify tolerance with reference to the PID controller characteristics.

Programmatically, you can specify absolute and relative tolerance values through the `absTol` and `relTol` properties of the `Simulink.sdi.Signal` object.

### Numerical Consistency in Complex Systems

For complex systems, numerical differences between model and generated code simulations can be a result of block-level differences propagating through the system. If you observe numerical differences at the system level:

- 1 Identify blocks for which block-level numerical differences exceed the error tolerance.
- 2 Investigate each identified block.

Consider the following plant-controller model.

- T produces reference or test signals.
- C is the controller component. The controller output is the plant input. C can be a Model block that comprises multiple Model blocks.
- P is the plant component. The plant output is subtracted from the reference signal to produce the controller input.

To test numerical equivalence between the model controller and the generated code version:

- 1 Run the model in normal mode, and, using the Simulation Data Inspector, record the output of C.
- 2 Specify SIL mode for C. Rerun the simulation, recording the output of C.
- 3 Using the Simulation Data Inspector, compare normal and SIL mode outputs with reference to your specified error tolerance.

If the Simulation Data Inspector comparison indicates a match, the model and generated code results are numerically consistent.

If the normal and SIL mode outputs do not match:

- 1 Within C, enable signal logging for block outputs.
- 2 Run the model in normal mode.
- 3 Rerun the simulation with C in SIL mode.

- 4 Using the Simulation Data Inspector, compare the logged output signals with reference to your specified error tolerance. See “Compare Simulation Data”.
- 5 Identify blocks for which normal and SIL mode output differences exceed the error tolerance.
- 6 Analyze each identified block and look for the cause. For example, the generated code might use a different math library than MATLAB.

---

**Note** If the comparison of a large number of signals is required, you can automate the workflow with Simulink Test. See “SIL Verification for a Subsystem” (Simulink Test).

---

## Reasons for Block-Level Numerical Differences

In fixed-point and floating-point application development, there are factors that can affect numerical agreement between block-level results from model and generated code simulations.

Some factors can affect both fixed-point and floating-point applications. For example, the use of:

- Code generation optimization.
- Custom code.
- Code replacement library entries whose results differ from MATLAB results.
- Code replacement libraries that implement different algorithms.

Other factors affect only floating-point applications. For example:

- Numerical soundness of algorithm.
- Algorithm sensitivity to input.
- Closed loop and open loop behavior.

## Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution

MATLAB Coder supports software-in-the-loop (SIL) and processor-in-the-loop (PIL) execution, which enables you to verify production-ready source code and compiled object code. With these execution modes, you can reuse test vectors developed for your MATLAB functions to verify the numerical behavior of library code.

In SIL execution, through a MATLAB SIL interface, the software compiles and runs library code on your development computer. In PIL execution, through a MATLAB PIL interface, the software cross-compiles and runs production object code on a target processor or an equivalent instruction set simulator. Before you run a PIL execution, you must set up a PIL connectivity configuration for your target.

The workflow for generating and verifying code is:

- 1 Set up MATLAB Coder.
- 2 Fix errors detected at design time.
- 3 Generate MEX function.
- 4 Test MEX function.
- 5 Generate C/C++ library code.
- 6 Verify generated C/C++ code through SIL or PIL execution — requires Embedded Coder license.

In step 4, you verify code that is generated for execution within MATLAB. However, this code is different from the standalone code generated for libraries. In step 6, with an Embedded Coder license, you use SIL or PIL execution to verify the standalone code.

For more information, use the following table.

## Software-in-the-Loop Execution with the MATLAB Coder App

Use software-in-the-loop (SIL) execution to verify the numerical behavior of the generated C/C++ code with reference to your original MATLAB functions.

- 1 To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
- 2 To open your project, click , and then click **Open existing project**. Select the project. For example, `kalman_filter01.prj`.
- 3 On the **Generate Code** page, click the **Generate** arrow .
- 4 In the **Generate** dialog box:
  - a Set **Build type** to `Static Library` or `Dynamic Library`.
  - b In the **Output file name** field, use the default value. For example, `kalman01`.
  - c Specify **Language**.
  - d Clear the **Generate code only** check box.
  - e In the **Hardware Board** field, use the default value (`MATLAB Host Computer`).

You do not have to specify the **Toolchain** setting. By default, the MATLAB Coder app locates an installed toolchain.

- 5 To generate the C or C++ code, click **Generate**.
- 6 Click **Verify Code**.
- 7 In the command field, specify the test file that calls the original MATLAB functions, for example, `test01_ui.m`.
- 8 If required, select the **Enable source-level debugging for SIL** check box.
- 9 To start the SIL execution, click **Run Generated Code**.

The MATLAB Coder app:

- Generates a standalone library, for example, `codegen\lib\kalman01`.
  - Generates SIL interface code, for example, `codegen\lib\kalman01\sil`.
  - Runs the test file, replacing calls to the MATLAB function with calls to the generated code in the library.
  - Displays messages from the SIL execution in the **Test Output** tab.
- 10 Verify that the results from the SIL execution match the results from the original MATLAB functions.
  - 11 To terminate the SIL execution process, click **Stop SIL Verification**. Alternatively, on the **Test Output** tab, click the link that follows `To terminate execution`.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

## Software-in-the-Loop Execution From Command Line

Use software-in-the-loop (SIL) execution to verify the numerical behavior of the generated C/C++ code with reference to your original MATLAB functions.

To set up and start a SIL execution from the command line:

- 1 Create a `coder.EmbeddedCodeConfig` object.
- 2 Configure the object for SIL.
- 3 Use the `codegen` function to generate library code for your MATLAB function and the SIL interface.
- 4 Use the `coder.runTest` function to run the test file for your original MATLAB function.

To terminate the SIL execution, use the `clear function_sil` or `clear mex` command.

The following example shows how you can set up and run a SIL execution from the command line.

### SIL Execution of Code Generated for a Kalman Estimator

#### 1 Copy MATLAB code for Kalman estimator

From `docroot\toolbox\coder\examples\kalman`, copy the following files to your working folder:

- `kalman01.m` — MATLAB function for the Kalman estimator
- `test01_ui.m` — MATLAB file to test `kalman01.m`
- `plot_trajectory.m` — File that plots actual target trajectory and Kalman estimator output
- `position.mat` — Input data

```
src_dir = ...
 fullfile(docroot, 'toolbox', 'coder', 'examples', 'kalman');

copyfile(fullfile(src_dir, 'kalman01.m'), '.')
copyfile(fullfile(src_dir, 'test01_ui.m'), '.')
copyfile(fullfile(src_dir, 'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir, 'position.mat'), '.')
```

For a description of the Kalman estimator in this example, see “Generate C Code at the Command Line”.

#### 2 Configure SIL execution

- a From your working folder, create a `coder.EmbeddedCodeConfig` object.

```
config = coder.config('lib');
config.GenerateReport = true; % Optional, documents code in HTML report
```

- b Configure the object for SIL.

```
config.VerificationMode = 'SIL';

% Check that production hardware setting is the default
% i.e. 'Generic->MATLAB Host Computer'
disp(config.HardwareImplementation.ProdHWDeviceType);
```

- c If required, enable the Microsoft Visual Studio debugger for SIL execution:

```
config.SILDebugging = true;
```

### 3 Generate code and run SIL execution

Generate library code for the `kalman01` MATLAB function and the SIL interface, and run the MATLAB test file, `test01_ui`. The test file uses `kalman01_sil`, the generated SIL interface for `kalman01`.

```
codegen -config config -args {zeros(2,1)} kalman01 -test test01_ui
```

The software creates the following output folders:

- `codegen\lib\kalman01` — Standalone code for `kalman01`.
- `codegen\lib\kalman01\sil` — SIL interface code for `kalman01`.

Verify that the output of this run matches the output from the original `kalman01.m` function.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

### 4 Debug code during SIL execution

If you enable the Microsoft Visual Studio debugger, then running the test file opens the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `kalman01_initialize` and `kalman01` functions.

You can use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

- a Remove all breakpoints.
- b Click the **Continue** button (F5).

The SIL execution runs to completion.

### 5 Terminate SIL execution

Terminate the SIL execution process.

```
clear kalman01_sil;
```

You can also use the command `clear mex`, which clears MEX functions from memory.

---

**Note** Suppose that the MATLAB current working directory (the folder that `pwd` displays) is a UNC path (for example, `\\server\a\b\c`) on a Windows platform. If you launch a SIL executable from this path, the location where the SIL executable is launched can be unpredictable and different from the MATLAB current working directory (for example, `C:\Windows`).

---

To fix this issue, use a mapped network drive for the UNC path as your MATLAB current working directory.

---

### More About

- “Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution” on page 84-2

## Debug Generated Code During SIL Execution

If a SIL execution fails or you notice differences between the outputs of your original functions and the generated code, you can rerun the SIL execution with a debugger enabled. By inserting breakpoints, you can observe the behavior of code sections, which might help you to understand the cause of the problem.

For a SIL execution failure, you can also view information from the standard output and standard error streams in the MATLAB Command Window. For example:

- Output from `printf` statements in your code.
- If you enable run-time error detection, messages sent to `stderr`.
- Some low-level system messages.

---

**Note** During a SIL execution, the SIL application redirects the `stdout` and `stderr` streams. When the application terminates, the MATLAB Command Window displays the information from the redirected streams. The SIL application also provides a basic signal handler, which captures the POSIX signals `SIGFPE`, `SIGILL`, `SIGABRT`, and `SIGSEV`. For this signal handler, the SIL application includes the file `signal.h`.

---

This table gives information about debugger support.

Operating System	Supported Debuggers
Windows	Microsoft Visual Studio IDE.
	Visual Studio Code with MinGW GDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package, which you can download from MATLAB Central File Exchange.
macOS	LLDB.
	Visual Studio Code with LLDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package, which you can download from MATLAB Central File Exchange.
Linux	GNU Data Display Debugger (DDD).
	Visual Studio Code with GDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package, which you can download from MATLAB Central File Exchange.

---

**Note** You can perform SIL debugging only if the MATLAB product family supports your Microsoft Visual C++, Xcode, or GNU GCC compiler. For more information, see supported compilers.

---

To run a SIL execution with debugging enabled:

- 1 On the **Generate Code** page, click **Verify Code**.
- 2 Select the **Enable source-level debugging for SIL** check box.
- 3 Click **Run Generated Code**.

On a Windows computer, your `user_fn.c` or `user_fn.cpp` file opens, for example, in the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `user_fn_initialize` and `user_fn` functions.

```

kalman01.c
/*
 * File: kalman01_initialize.c
 *
 * MATLAB Coder version : 2.7
 * C/C++ source code generated on : 19-May-2014 10:51:32
 */

/* Include Files */
#include "rt_nonfinite.h"
#include "kalman01.h"
#include "kalman01_initialize.h"

/* Function Definitions */

/*
 * Arguments : void
 * Return Type : void
 */
void kalman01_initialize(void)
{
 rt_InitInfAndNaN(8U);
 kalman01_init();
}

/*
 * File trailer for kalman01_initialize.c
 */

```

You can now use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

- 1 Remove all breakpoints.
- 2 Click the **Continue** button (**F5**).

The SIL execution runs to completion.

- 3 To terminate the SIL execution process, on the **Test Output** tab, click the link that follows To terminate execution, for example, clear `kalman01_sil`.

The Microsoft Visual Studio IDE closes automatically.

---

**Note** If you select **Debug > Stop Debugging**, the SIL execution times out with the following error message:

Communications error: failed to send data to the target. There might be multiple reasons for this failure.

...  
...

## Create PIL Target Connectivity Configuration for MATLAB

### In this section...

“Target Connectivity Configurations for PIL” on page 84-12

“Create a Target Connectivity API Implementation” on page 84-12

“Register Target Connectivity Configuration” on page 84-14

“Verify Target Connectivity Configuration” on page 84-14

### Target Connectivity Configurations for PIL

Use target connectivity configurations and the target connectivity API to customize processor-in-the-loop (PIL) execution for your target environments.

Through a target connectivity configuration, you specify:

- A target connectivity configuration name for a target connectivity API implementation.
- Settings that define compatible MATLAB code. For example, the code that is generated for a particular hardware implementation.

A PIL execution requires a target connectivity PIL API implementation that integrates third-party tools for:

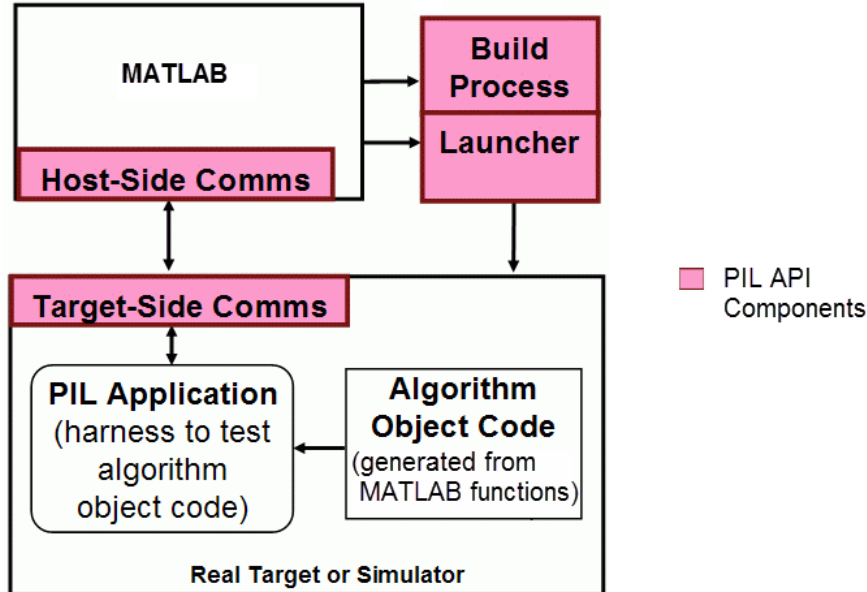

- Building the PIL application that runs on the target hardware
- Downloading, starting, and stopping the application on the target
- Communicating between MATLAB and the target

You can have many different connectivity configurations for PIL execution. Register a connectivity configuration with MATLAB by creating an `rtwTargetInfo.m` file and placing it on the MATLAB search path.

In a PIL execution, the software determines which of the available connectivity configurations to use. The software looks for a connectivity configuration that is compatible with the MATLAB code under test. If the software finds multiple or no compatible connectivity configurations, the software generates an error message with information about resolving the problem.

### Create a Target Connectivity API Implementation

This diagram shows the components of the PIL target connectivity API.

You must provide implementations of the three API components:

- Build API — Specify a toolchain approach for building generated code.
- Launcher API — Control how MATLAB starts and stops the PIL executable.
- Communications API — Customize connectivity between MATLAB and the PIL target. Embedded Coder provides host-side support for TCP/IP and serial communications, which you can adapt for other protocols.

These steps outline how you create a target connectivity API implementation. The example code shown in the steps is taken from the `ConnectivityConfig.m` file used in “Processor-in-the-Loop Execution From Command Line” on page 84-25.

**1** Create a subclass of `rtw.connectivity.Config`.

```
ConnectivityConfig < rtw.connectivity.Config
```

**2** In the subclass:

- Instantiate `rtw.connectivity.MakefileBuilder`, which configures the build process.

```
builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
 targetApplicationFramework, ...
 exeExtension);
```

- Create a subclass of `rtw.connectivity.Launcher`, which downloads and executes the application using a third-party tool.

```
launcher = mypil.Launcher(componentArgs, builder);
```

**3** Configure your `rtiostream` API implementation of the host-target communications on page 84-16 channel.

- For the target side, you must provide the driver code for communications, for example, code for TCP/IP or serial communications. To integrate this code into the build process, create a subclass of `rtw.pil.RtIOStreamApplicationFramework`.

- For the host side, you can use a supplied library for TCP/IP or serial communications. Instantiate `rtw.connectivity.RtIOStreamHostCommunicator`, which loads and initializes the library that you specify.

```
hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(...
 componentArgs, ...
 launcher, ...
 rtiostreamLib);
```

- 4 If you require execution-time profiling for generated code, create a timer object that provides details of the hardware-specific timer and associated source files. See “Specify Hardware Timer” on page 84-19.
- 5 If you require stack usage profiling for generated code, specify a driver implementation that obtains stack usage data from the target hardware. The driver must return the value of the stack register. If you do not specify a driver, the PIL simulation tries to use a default generic driver. See “Implement Driver to Obtain Stack Usage Data During PIL Execution” on page 77-17.

## Register Target Connectivity Configuration

To register a target connectivity API implementation as a target connectivity configuration in MATLAB:

- 1 Create or update an `rtwTargetInfo.m` file. In this file:
  - Create a target connectivity configuration object that specifies, for example, the configuration name for a target connectivity API implementation and compatible MATLAB code.
  - Invoke `registerTargetInfo`.
- 2 Add the folder containing `rtwTargetInfo.m` to the search path and refresh the MATLAB Coder library registration information.

For more information, see `rtw.connectivity.ConfigRegistry`.

## Verify Target Connectivity Configuration

To verify your target connectivity configuration early on and independently of your algorithm development and code generation, use the `piltest` function. With the function, you can run a suite of tests. The function:

- Runs the MATLAB function and performs PIL executions.
- Compares results and produces errors if it detects differences.

For an example, see “PIL Execution of Code Generated for a Kalman Estimator” on page 84-25.

## Host-Target Communication for MATLAB PIL Execution

### In this section...

“Communications rtiostream API” on page 84-16

“Synchronize Host and Target” on page 84-17

“Test an rtiostream Driver” on page 84-17

“Troubleshooting Host-Target Communication” on page 84-17

This section provides information about using the `rtiostream` API for communication between your development computer and target hardware during PIL execution.

### Communications rtiostream API

The `rtiostream` API supports communications for the target connectivity API. Use the `rtiostream` API to implement a communication channel that enables data exchange between different processes.

PIL verification requires a host-target communications channel. This communications channel comprises driver code that runs on the host and target. The `rtiostream` API defines the signature of target-side and host-side functions that must be implemented by this driver code.

The API is independent of the physical layer that sends the data. Possible physical layers include RS232, Ethernet, or Controller Area Network (CAN).

A full `rtiostream` implementation requires both host-side and target-side drivers. Code generation software includes host-side drivers for the default TCP/IP implementation as well as a version for serial communications. To use:

- The TCP/IP `rtiostream` communications channel, you must provide, or obtain from a third party, target-specific TCP/IP device drivers.
- The serial communications channel, you must provide, or obtain from a third party, target-specific serial device drivers.

For other communication channels and platforms, the code generation software does not provide default implementations. You must provide both the host-side and the target-side drivers.

The `rtiostream` API comprises the following functions:

- `rtIOStreamOpen`
- `rtIOStreamSend`
- `rtIOStreamRecv`
- `rtIOStreamClose`

For information about:

- Using `rtiostream` functions in a connectivity implementation, see “Create a Target Connectivity API Implementation” on page 84-12.
- Testing the `rtiostream` shared library methods from MATLAB code, see `rtiostream_wrapper`.
- Debugging and verifying the behavior of custom `rtiostream` interface implementations, see “Test an `rtiostream` Driver” on page 84-17 and `rtiostreamtest`.

## Synchronize Host and Target

If you use the `rtiostream` API to implement the communications channel, the host and target must be synchronized, which prevents MATLAB from transmitting and receiving data before the target application is fully initialized.

To synchronize the host and target for TCP/IP `rtiostream` implementations, use the `setInitCommsTimeout` method from `rtw.connectivity.RtIOStreamHostCommunicator`. This approach works well for connection-oriented TCP/IP `rtiostream` implementations because MATLAB automatically waits until the target server is running.

With other `rtiostream` implementations, for example, serial, the MATLAB side of the `rtiostream` connection opens without waiting for the target to be fully initialized. In this case, you must make your `Launcher` implementation wait until the target application is fully initialized. Use one of the following approaches to synchronize your host and target:

- Add a pause at the end of the `Launcher` implementation that makes the `Launcher` wait until target initialization is complete.
- In the `Launcher` implementation, use third-party downloader or debugger APIs that wait until target initialization is complete.
- Implement a handshaking mechanism in the `Launcher` / `rtiostream` implementation that confirms completion of target initialization.

## Test an rtiostream Driver

Use a test suite to debug and verify the behavior of custom `rtiostream` interface implementations.

The test suite can help you to:

- Reduce the time required for integrating custom hardware that does not have built-in `rtiostream` support.
- Reduce the time required for testing custom `rtiostream` drivers.
- Analyze the performance of custom `rtiostream` drivers.

The test suite consists of two parts. One part is an application that runs on the target hardware. The other part runs in MATLAB. For details, see `rtiostreamtest`.

## Troubleshooting Host-Target Communication

To display communication I/O information during PIL execution, in the MATLAB Coder app, on the **All Settings** tab, set **SIL/PIL Verbosity** to `On`. Or, in a `coder.EmbeddedCodeConfig` object, set the `SILPILVerbosity` property to `true`.

By default, **SIL/PIL Verbosity** is set to `Off`.

For SIL execution with **SIL/PIL Verbosity** set to `On`, the app displays I/O information for communication that occurs between MATLAB and the target application that runs as a separate process on your development computer.

## Specify Hardware Timer

For processor-in-the-loop (PIL) code execution profiling, you must create a timer object that provides details of the hardware-specific timer and associated source files. You can use the **Code Replacement Tool** or the code replacement library API to specify this hardware-specific timer.

To specify the timer with the Code Replacement Tool:

- 1** Open the Code Replacement Tool. In the Command Window, enter `crtool`.
- 2** Create a new code replacement table. Select **File > New table**.
- 3** Create a new function entry. Under **Tables List**, right-click the new table. Then, from the context-menu, select **New entry > Function**.
- 4** In the middle view, select the new unnamed function.
- 5** On the **Mapping Information** pane:
  - a** From the **Function** drop-down list, select `code_profile_read_timer`.
  - b** Specify the count direction for your timer. For example, from the **Count direction** drop-down list, select **Up**.
  - c** In the **Ticks per second** field, specify the number of ticks per second for your timer, for example, `1e+09`.

The default value is 0. In this case, the software reports time measurements in terms of ticks, not seconds.

- d** In the **Conceptual function** section, from the **Data type** list, select `uint8`, `uint16`, `uint32`, or `uint64`.
- e** In the **Function prototype** section, in the **Name** field, specify a replacement function name, for example, `MyTimer`.
- f** Click **Apply**.

- g** To validate the function entry, click **Validate entry**.
- 6** On the **Build Information** pane, specify the required build information. See Specify build information in “Define Code Replacement Library Optimizations” on page 69-36.
- 7** Save the table (**Ctrl+S**). When you save the table for the first time, use the Save As dialog box to specify the file name and location.

You must save the table in a location that is on the MATLAB search path. For example, you can save this file in the folder for your subclass of `rtw.connectivity.Config`.

The software stores your timer information as a code replacement library table.

- 8** Assuming you save the table as `MyCrlTable.m`, in your subclass of `rtw.connectivity.Config`, add the following line:

```
setTimer(this, MyCrlTable)
```

## Custom Toolchain Directives Required for Code Execution Profiling

If you use a custom toolchain for building a processor-in-the-loop (PIL) target application that supports code execution profiling, in the toolchain definition file, you must provide these compiler directives:

- `CompileFlag` — Specify the flag that C or C++ compiler uses to compile source files without linking. For example, if the compiler in the toolchain is GNU C or C++, set the directive to `-c`.
- `PreprocessFile` — Specify the flag that C or C++ compiler uses to preprocess the source files without running other compiler stages. For example, if the compiler in the toolchain is GNU C or C++, set the directive to `-E`.

This section from a toolchain definition file example shows how you can use the `setDirective` method to provide the directives.

```
tc = coder.make.ToolchainInfo('BuildArtifact','nmake makefile');
tc.Name = 'My Toolchain Name';
tc.Platform = 'win64';
tc.SupportedVersion = '14';
...
% -----
% C Compiler
% -----
tool = tc.getBuildTool('C Compiler');
tool.setName('My C Compiler');
...
tool.setDirective('CompileFlag','-c');
tool.setDirective('PreprocessFile','-E');
...
```

## Processor-in-the-Loop Execution with the MATLAB Coder App

Use processor-in-the-loop (PIL) execution to verify the numerical behavior of cross-compiled object code with reference to your original MATLAB functions.

Before you run a PIL execution, you must define a target connectivity configuration. In “Processor-in-the-Loop Execution From Command Line” on page 84-25, steps 1 and 2 of the example “PIL Execution of Code Generated for a Kalman Estimator” on page 84-25 show how you can set up and register a connectivity configuration for PIL execution on your development computer.

- 1 To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
- 2 To open your project, click , and then click `Open existing project`. Select the project. For example, `kalman_filter.prj`.
- 3 On the **Generate Code** page, click the **Generate** arrow .
- 4 In the **Generate** dialog box:
  - a Set **Build type** to `Static Library` or `Dynamic Library`.
  - b In the **Output file name** field, use the default value. For example, `kalman01`.
  - c Clear the **Generate code only** check box.
  - d From the **Hardware Board** drop-down list, select `None - Select device below`.
  - e In the **Device** fields, specify vendor and type. These settings must match the target hardware settings in the `rtwTargetInfo.m` file of your target connectivity configuration. For host-based PIL, select settings that match your host computer. For example:
    - For a Windows 64-bit system, set **Device vendor** to `Intel` and **Device type** to `x86-64 (Windows64)`. In addition, set **Enable long long** to `Yes`.
    - For a Linux 64-bit system, set **Device vendor** to `Intel` and **Device type** to `x86-64 (Linux 64)`.
    - For a Mac OS X system, set **Device vendor** to `Intel` and **Device type** to `x86-64 (Mac OS X)`.

You do not have to specify the **Toolchain** setting. By default, the MATLAB Coder app locates an installed toolchain.

- 5 To generate the C or C++ code, click **Generate**.
- 6 Click **Verify Code**.
- 7 In the command field, specify the test file that calls the original MATLAB functions, for example, `test01_ui.m`.
- 8 To start the PIL execution, click **Run Generated Code**.

The MATLAB Coder app:

- Generates a standalone library, for example, `codegen\lib\kalman01`.
- Generates PIL interface code, for example, `codegen\lib\kalman01\pil`.
- Runs the test file, replacing calls to the MATLAB function with calls to the generated code in the library.

- Displays messages from the PIL execution in the **Test Output** tab.
- 9** Verify that the results from the PIL execution match the results from the original MATLAB functions.
- 10** To terminate the PIL execution process, click **Stop PIL Verification**. Alternatively, on the **Test Output** tab, click the link that follows To terminate execution.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

### More About

- “Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution” on page 84-2

## Processor-in-the-Loop Execution From Command Line

Use processor-in-the-loop (PIL) execution to verify code that you intend to deploy in production.

To set up and start a PIL execution from the command line:

- 1 Create, register, and verify your target connectivity configuration.
- 2 Create a `coder.EmbeddedCodeConfig` object.
- 3 Configure the object for PIL.
- 4 Use the `codegen` function to generate library code for your MATLAB function and the PIL interface.
- 5 Use the `coder.runTest` function to run the test file for your original MATLAB function.

To terminate the PIL execution, use the `clear function_pil` or `clear mex` command.

The following example shows how you can use line commands to set up and run a PIL execution on your development computer.

### PIL Execution of Code Generated for a Kalman Estimator

#### 1 Create a target connectivity API implementation

- a In your current working folder, make a local copy of the connectivity classes.

```
src_dir = ...
 fullfile(matlabroot, 'toolbox', 'coder', 'simulinkcoder', '+coder', '+mypil');
if exist(fullfile('.', '+mypil'), 'dir')
 rmdir('+mypil', 's')
end
mkdir +mypil
copyfile(fullfile(src_dir, 'Launcher.m'), '+mypil');
copyfile(fullfile(src_dir, 'TargetApplicationFramework.m'), '+mypil');
copyfile(fullfile(src_dir, 'ConnectivityConfig.m'), '+mypil');
```

- b Make the copied files writable.

```
fileattrib(fullfile('+mypil', '*'), '+w');
```

- c Update the package name to reflect the new location of the files.

```
coder.mypil.Utils.UpdateClassName(...
 './+mypil/ConnectivityConfig.m', ...
 'coder.mypil', ...
 'mypil');
```

- d Check that you now have a folder `+mypil` in the current folder, which includes three files, `Launcher.m`, `TargetApplicationFramework.m`, and `ConnectivityConfig.m`.

```
dir './+mypil'
```

- e Review the code that starts the PIL application. The `mypil.Launcher` class configures a tool for starting the PIL executable. Open this class in the editor.

```
edit(which('mypil.Launcher'))
```

Review the content of this file. For example, consider the `setArgString` method. This method allows additional command line parameters to be supplied to the application. These parameters can include a TCP/IP port number. For an embedded processor implementation, you might have to hard code these settings.

- f The class `mypil.ConnectivityConfig` configures target connectivity.

```
edit(which('mypil.ConnectivityConfig'))
```

Review the content of this file. For example:

- The creation of an instance of `rtw.connectivity.RtIOStreamHostCommunicator` that configures the host side of the TCP/IP communications channel.
- A call to the `setArgString` method of `Launcher` that configures the target side of the TCP/IP communications channel.
- A call to `setTimer` that configures a timer for execution time measurement. To define your own target-specific timer for execution time profiling, you must use the Code Replacement Library to specify a replacement for the function `code_profile_read_timer`.

**g** Review the target-side communication drivers.

```
rtiostreamtcpip_dir=fullfile(matlabroot,'toolbox','coder','rtiostream','src',...
 'rtiostreamtcpip');
edit(fullfile(rtiostreamtcpip_dir,'rtiostream_tcpip.c'))
```

Scroll down to the end of this file. The file contains a TCP/IP implementation of the functions `rtIOStreamOpen`, `rtIOStreamSend`, and `rtIOStreamRecv`. These functions are required for target communication with the host. For each of these functions, you must provide an implementation that is specific to your target hardware and communication channel.

The `mypil.TargetApplicationFramework` class adds target-side communication drivers to the connectivity configuration.

```
edit(which('mypil.TargetApplicationFramework'))
```

The file specifies additional files to include in the build.

## 2 Register a target connectivity configuration

Use an `rtwTargetInfo.m` file to:

- Create a target connectivity configuration object.
- Invoke `registerTargetInfo`, which registers the target connectivity configuration.

The target connectivity configuration object specifies, for example:

- The configuration name and associated API implementation. See `rtw.connectivity.ConfigRegistry`.
- A toolchain for your target hardware. This example assumes that the target hardware is your host computer, and uses the toolchain supplied for host-based PIL verification. For information about toolchains, see “Custom Toolchain Registration”.

**a** Insert the following code into your `rtwTargetInfo.m` file, and save the file in the current working folder or in a folder that is on the MATLAB search path:

```
function rtwTargetInfo(tr)
% Register PIL connectivity config: mypil.ConnectivityConfig

tr.registerTargetInfo(@loc_createConfig);

% local function
function config = loc_createConfig

% Create object for connectivity configuration
config = rtw.connectivity.ConfigRegistry;
% Assign connectivity configuration name
config.ConfigName = 'My PIL Example';
```

```

% Associate the connectivity configuration with the connectivity
% API implementation
config.ConfigClass = 'mypil.ConnectivityConfig';

% Specify toolchains for host-based PIL
config.Toolchain = rtw.connectivity.Utils.getHostToolchainNames;

% Through the HardwareBoard and TargetHWDeviceType properties,
% define compatible code for the target connectivity configuration
config.HardwareBoard = {}; % Any hardware board
config.TargetHWDeviceType = {'Generic->32-bit x86 compatible' ...
 'Generic->Custom' ...
 'Intel->x86-64 (Windows64)', ...
 'Intel->x86-64 (Mac OS X)', ...
 'Intel->x86-64 (Linux 64)'};

```

- b** Refresh the MATLAB Coder library registration information.

```
RTW.TargetRegistry.getInstance('reset');
```

### 3 Verify target connectivity configuration

Use the supplied `piltest` function to verify your target connectivity configuration.

- a** Create a `coder.EmbeddedCodeConfig` object for verifying the target connectivity configuration.

```
configVerify = coder.config('lib');
```

- b** Specify the manufacturer and test hardware type. For example, PIL execution on a 64-bit Windows development computer requires:

```
configVerify.HardwareImplementation.TargetHWDeviceType = ...
 'Intel->x86-64 (Windows64)';
configVerify.HardwareImplementation.ProdLongLongMode = true;
```

- c** Run `piltest`.

```
piltest(configVerify, 'ConfigParam', {'ProdLongLongMode'})
```

### 4 Copy MATLAB code for Kalman estimator

Copy the MATLAB code to your working folder.

```
src_dir = ...
 fullfile(docroot, 'toolbox', 'coder', 'examples', 'kalman');

copyfile(fullfile(src_dir, 'kalman01.m'), '.')
copyfile(fullfile(src_dir, 'test01_ui.m'), '.')
copyfile(fullfile(src_dir, 'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir, 'position.mat'), '.')

```

For a description of the Kalman estimator in this example, see “Generate C Code at the Command Line”.

### 5 Configure the PIL execution

- a** Create a `coder.EmbeddedCodeConfig` object.

```
config = coder.config('lib');
```

- b** Configure the object for PIL.

```
config.VerificationMode = 'PIL';
```

- c** Specify production hardware, which must match one of the test hardware settings in `rtwTargetInfo.m`. For PIL execution on your development computer, specify settings that match the computer. For example, if your computer is a Windows 64-bit system, specify:

```
config.HardwareImplementation.ProdHWDeviceType =...
 'Intel->x86-64 (Windows64)';
config.HardwareImplementation.ProdLongLongMode = true;
```

For a Linux 64-bit system, set `ProdHWDeviceType` to `'Intel->x86-64 (Linux 64)'`.

For a Mac OS X system, set `ProdHWDeviceType` to `'Intel->x86-64 (Mac OS X)'`.

## 6 Generate code and run PIL execution

Generate library code for the `kalman01` MATLAB function and the PIL interface, and run the MATLAB test file, `test01_ui`. The test file uses `kalman01_pil`, the generated PIL interface for `kalman01`.

```
codegen -config config -args {zeros(2,1)} kalman01 -test test01_ui
```

The software creates the following output folders:

- `codegen\lib\kalman01` — Standalone code for `kalman01`.
- `codegen\lib\kalman01\pil` — PIL interface code for `kalman01`.

Verify that the output of this run matches the output from the original `kalman01.m` function.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

## 7 Terminate PIL execution

Terminate the PIL execution process.

```
clear kalman01_pil;
```

### More About

- “Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution” on page 84-2

## Verification of Code Generation Assumptions

The settings on the **More Settings > Hardware** tab specify target behavior, which result in the implementation of implicit assumptions in the generated code. Incorrect settings can lead to:

- Suboptimal code
- Code execution failure, incorrect code output, and nondeterministic code behavior

At the start of a processor-in-the-loop (PIL) execution, the software verifies the **Hardware** tab settings with reference to the target hardware. The software checks:

- The correctness of settings. For example, the integer bit length in the **Sizes > int** field.
- Whether the settings are optimized. For example, the rounding of signed integer division in the **Signed integer division rounds to** field.

If required, the software generates warnings and errors.

## SIL/PIL Execution Support and Limitations

Feature		Supported
Output types	Static library	Yes
	Dynamic library	Yes
	Executable	No
Languages	C	Yes
	C++	Yes
Interface types	Inputs	Yes
	Outputs	Yes
	Constant inputs	Yes
	Global data	<p>Yes. SIL and PIL execution supports four types of storage classes on page 92-2 for MATLAB Coder global variables. The synchronization of global data between MATLAB and the SIL or PIL application depends on the type of storage class that you specify:</p> <ul style="list-style-type: none"> <li>• <code>ExportedGlobal</code> (default) — The synchronization of global data between MATLAB and a SIL or PIL application is identical to the synchronization between MATLAB and a MEX function.</li> <li>• <code>ExportedDefine</code> — There is no synchronization of global data between MATLAB and the SIL or PIL application. The application uses the values of the global variables in MATLAB at the time of code generation.</li> <li>• <code>ImportedExtern</code> and <code>ImportedExternPointer</code> — There is no synchronization of global data between MATLAB and the SIL or PIL application. The application uses initial values of global variables, which you specify in the external code. If the global variables are not initialized in the external code, the SIL or PIL execution results are undefined.</li> </ul>
	Constant global data	Yes
	Reentrant code	Yes
	Multiple entry points	Yes
Data types	Basic types	Yes
	Enumerated types	Yes
	Structures	Yes

Feature		Supported
	Complex data	Yes
	Fixed-point data	Yes
	Multiword fixed-point data	SIL only
	char arrays	Yes
	Empty values	Yes
	Cell arrays	Yes
Size	Scalars	Yes
	Fixed-size arrays	Yes
	Static variable-size arrays	Yes
	Dynamic variable-size arrays	Yes

## Speed Up SIL/PIL Execution by Disabling Constant Input Checking and Global Data Synchronization

By default, a SIL or PIL execution performs constant input checking and global data synchronization. Constant input checking compares the value that a test file provides for a constant input argument with the value specified at code generation time. If the values do not match, an error occurs. Global data synchronization makes the values of global variables in the SIL or PIL execution environment consistent with the values in the MATLAB workspace. If a global variable is constant and its value in the SIL or PIL execution environment differs from its value in the MATLAB workspace, an error occurs.

It is possible to speed up a SIL or PIL execution by disabling constant input checking or global data synchronization. However, if you disable these features, the SIL or PIL execution results might differ from the results in MATLAB.

### Disable Constant Input Checking or Global Data Synchronization at the Command Line

In a coder .EmbeddedCodeConfig object that you configured for SIL or PIL execution:

- To disable constant input checking, set the `SILPILCheckConstantInputs` property to `false`. For example, for an object `cfg`, use this code:

```
cfg.SILPILCheckConstantInputs = false;
```

- To disable global data synchronization, set the `SILPILSyncGlobalData` property to `false`. For example, for an object `cfg`, use this code:

```
cfg.SILPILSyncGlobalData = false;
```

### Disable Constant Input Checking or Global Data Synchronization in the MATLAB Coder App

In the settings for a project that you set up for SIL or PIL execution, on the **Debugging** tab:

- To disable constant input checking, set **Check constant inputs in SIL/PIL** to **No**.
- To disable global data synchronization, set **Synchronize global data in SIL/PIL** to **No**.

## SIL and PIL Verification for Deployment on Raspberry Pi

This example shows how to verify the generated code by using the software-in-the-loop (SIL) and processor-in-the-loop (PIL) executions. In this example, the PIL execution uses a Raspberry Pi® hardware board.

### Run MATLAB Code

This example uses these supporting files:

- `kalman01.m` contains the MATLAB® function `kalman01` for the Kalman estimator.
- `position.mat` contains the input data about the trajectory of an object.
- `test01_ui.m` is a MATLAB script that loads the input data from `position.mat` into the workspace, calls `kalman01` to estimate the object location by using the Kalman filtering algorithm, and finally calls the `plot_trajectory` function that plots both the actual trajectory of the object and the Kalman estimate.
- `plot_trajectory.m` contains the `plot_trajectory` function described above.

To test the MATLAB code, run the script `test01_ui`.

```
test01_ui
```

```
Current plot held
```

```
Current plot released
```

In the plot that is displayed, you see that the Kalman estimate closely follows the actual trajectory of the object. The test data includes two sudden shifts or discontinuities in position. These discontinuities check that the Kalman filter can quickly readjust its estimate and get back to tracking the object accurately.

For more information, see “C Code Generation for a MATLAB Kalman Filtering Algorithm”.

### Software-in-the-Loop (SIL) Execution

In SIL execution, through a MATLAB SIL interface, the code generator compiles and runs library code on your development computer.

#### Configure SIL Execution

Create a `coder.EmbeddedCodeConfig` object to generate a static C library. Set the `VerificationMode` property to 'SIL'. Optionally, enable the Microsoft® Visual Studio® debugger for SIL execution.

```
config = coder.config('lib');
config.VerificationMode = 'SIL';
% config.SILDebugging = true;
```

Check that the production hardware setting is set to the default value 'Generic->MATLAB Host Computer'.

```
disp(config.HardwareImplementation.ProdHWDeviceType);
```

```
Generic->MATLAB Host Computer
```

#### Generate Static Library and Run SIL Execution

Use the `codegen` command with the configuration object `config` to generate a static C library and the SIL interface for the `kalman01` function. To perform SIL execution, you can simply call the generated SIL interface `kalman01_sil` at the MATLAB command line.

In the `codegen` command, the `-test` option enables you to run the test script `test01_ui` with calls to the `kalman01` function replaced by calls to the generated SIL interface `kalman01_sil`.

```
codegen -config config -args {zeros(2,1)} kalman01 -report -test test01_ui
```

```
Code generation successful: View report
```

```
Running test file: 'test01_ui' with MEX function 'kalman01_sil.mexw64'.
```

```
Current plot held
```

```
Starting SIL execution for 'kalman01'
```

```
 To terminate execution: clear kalman01_sil
```

Current plot released

The code generator creates these output folders:

- `codegen\lib\kalman01` — Static library for `kalman01`.
- `codegen\lib\kalman01\sil` — SIL interface code for `kalman01`.

Observe that the output of this run matches the output from the `kalman01` MATLAB function.

### Debug Code During SIL Execution

If you enable the Microsoft Visual Studio debugger, then running the test file opens the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `kalman01_initialize` and `kalman01` functions.

You can use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

- Remove all breakpoints.
- Click the Continue button (**F5**).

The SIL execution runs to completion.

### Terminate SIL Execution

Terminate the SIL execution process.

```
clear kalman01_sil;
Stopping SIL execution for 'kalman01'
```

You can also use the command `clear mex`, which clears MEX functions from memory.

### Usage Notes for Windows® platform

Usage notes for SIL execution on a Windows platform:

- The Windows Firewall can potentially block a SIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.
- Suppose that the MATLAB current working directory (the folder that `pwd` displays) is a UNC path (for example, `\\server\a\b\c`) on a Windows platform. If you launch a SIL executable from this path, the location where the SIL executable is launched can be unpredictable and different from the MATLAB current working directory (for example, `C:\Windows`). To fix this issue, use a mapped network drive for the UNC path as your MATLAB current working directory.

### Processor-in-the-Loop (PIL) Execution

In PIL execution, through a MATLAB PIL interface, the code generator cross-compiles and runs production object code on a target processor or an equivalent instruction set simulator. Before you run a PIL execution, you must set up a PIL connectivity configuration for your target. In this example, the PIL execution uses a Raspberry Pi® hardware board.

### Configure PIL Execution

Create a `coder.EmbeddedCodeConfig` object to generate a static C library. Set the `VerificationMode` property to `'PIL'`. Set the `Hardware` property to a hardware board configuration object for Raspberry Pi.

```
config = coder.config('lib');
config.VerificationMode = 'PIL';
config.Hardware = coder.hardware('Raspberry Pi');
```

If you are to your Raspberry Pi hardware board for the first time, you must also specify the `Username`, `DeviceAddress`, and `Password` properties of the `config.Hardware` parameter.

### Generate Static Library and Run PIL Execution

Use the `codegen` command with the configuration object `config` to generate a static C library and the PIL interface for the `kalman01` function. To perform PIL execution, you can simply call the generated PIL interface `kalman01_pil` at the MATLAB command line.

In the `codegen` command, the `-test` option enables you to run the test script `test01_ui` with calls to the `kalman01` function replaced by calls to the generated PIL interface `kalman01_pil`.

```
codegen -config config -args {zeros(2,1)} kalman01 -report -test test01_ui
```

```
Connectivity configuration for function 'kalman01': 'Raspberry Pi'
Location of the generated elf : /home/pi/MATLAB_ws/R2021b/C/Users/aghosh/Documents/Examples/ecod
Code generation successful: View report
```

```

Running test file: 'test01_ui' with MEX function 'kalman01_pil.mexw64'.
Current plot held
Connectivity configuration for function 'kalman01': 'Raspberry Pi'
Starting application: 'codegen\lib\kalman01\pil\kalman01.elf'
 To terminate execution: clear kalman01_pil
Launching application kalman01.elf...

```

Current plot released

The code generator creates these output folders:

- codegen\lib\kalman01 — Static library for kalman01.
- codegen\lib\kalman01\pil — PIL interface code for kalman01.

Observe that the output of this run matches the output from the kalman01 MATLAB function.

The Windows Firewall can potentially block a PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

### Terminate PIL Execution

Terminate the PIL execution process.

```
clear kalman01_pil;
```

```
Host application produced the following standard output (stdout) and standard error (stderr)
```

You can also use the command `clear mex`, which clears MEX functions from memory.

# Software-in-the-loop Execution For MATLAB Function with Multiple Signatures

## In this section...

“Generate Multisignature SIL MEX File for an Entry-Point Function” on page 84-39

“Generate Multisignature SIL MEX File for Multiple Entry-Point Functions” on page 84-40

For MATLAB function with multiple signatures, software-in-the-loop (SIL) enables you to verify the generated C/C++ code by using a SIL MEX file that supports multiple signatures. This feature enables you to generate one SIL MEX file for verification instead of generating separate SIL MEX files for each signature.

## Generate Multisignature SIL MEX File for an Entry-Point Function

### 1 MATLAB code for myAdd function

Copy the MATLAB code of one entry-point function `myAdd`, and save it in your working directory.

The entry-point function, `myAdd`, returns the sum of two values.

```
function y = myAdd(a,b)
%#codegen
y = a+b;
end
```

### 2 Configure SIL execution

Create a `coder.EmbeddedCodeConfig` object and configure the object for SIL.

```
cfg = coder.config('lib');
cfg.VerificationMode = "SIL";
```

### 3 Generate code using codegen command

The `codegen` command generates a SIL MEX file `myAdd_sil` that works with three different data types: `double`, `int8`, and `vector of doubles`. You specify the entry-point function followed by `-args` for each signature of the entry-point function.

```
codegen -config cfg myAdd-args {1,2} -args {int8(2),int8(3)} -args {1:10,1:10} -report
```

### 4 Run generated SIL MEX file myAdd\_sil

At the command prompt, call the generated SIL MEX file `myAdd_sil`. Make sure that the values you pass to `myAdd_sil` match the input properties that you specified in the `codegen` command.

```
myAdd_sil(3,4)
ans =
 7

myAdd_sil(int8(5),int8(6))
ans =
 int8
```

```

11
myAdd_sil(1:10,2:11)
ans =
 3 5 7 9 11 13 15 17 19 21

```

Running the MATLAB function `myAdd` with these input values produces the same output. These test cases verify that `myAdd` and `myAdd_sil` have the same behavior.

## 5 Terminate SIL execution

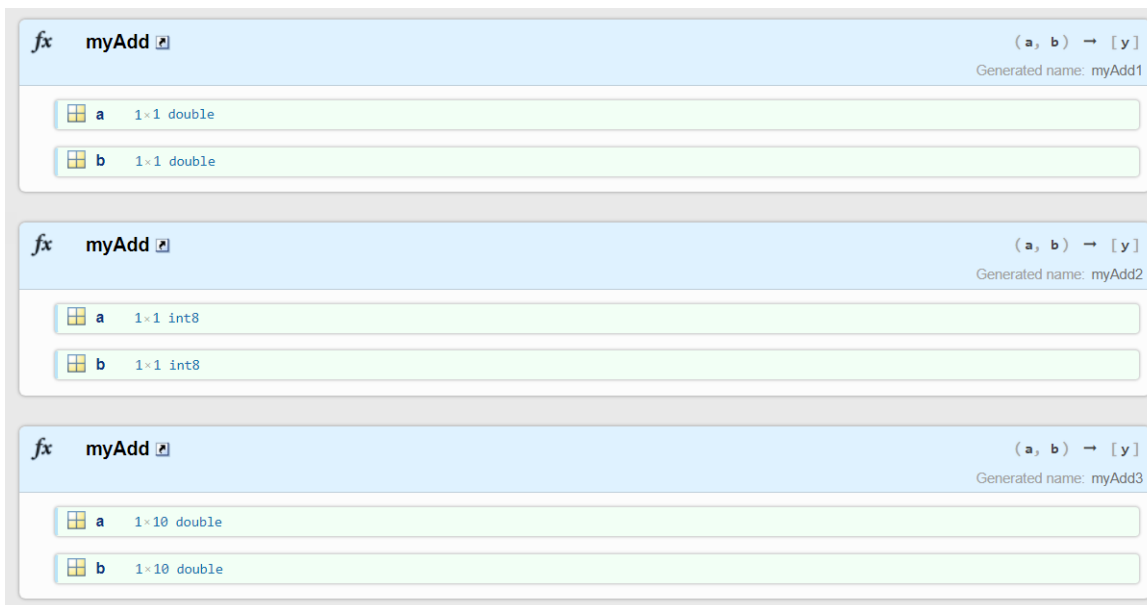

Terminate the SIL execution process.

```
clear myAdd_sil;
```

You can also use the command `clear mex`, which clears MEX files from memory.

## 6 Entry Point Summary Report

In the generated code, different signatures are mapped to versioned entry-point functions `myAdd1`, `myAdd2`, and `myAdd3` as shown in the figure.

## Generate Multisignature SIL MEX File for Multiple Entry-Point Functions

### 1 MATLAB code for myAdd and myMul functions

Copy the MATLAB codes of two entry-point functions, `myAdd` and `myMul` and save it in your working directory.

The first entry-point function, `myAdd`, returns the sum of two values:

```
function y = myAdd(a,b)
%#codegen
```

```
y = a+b;
end
```

The second entry-point function, `myMul`, returns the multiplication of two values:

```
function y = myMul(a,b)
%#codegen
y = a*b;
end
```

## 2 Configure SIL execution

Create a `coder.EmbeddedCodeConfig` object and configure the object for SIL.

```
cfg = coder.config('lib');
cfg.VerificationMode = "SIL";
```

## 3 Generate code using `codegen` command

The `codegen` command generates a SIL MEX file `myMath_sil` for the signatures that you specified in the `codegen` command. The SIL MEX file `myMath_sil` works for `myAdd` and `myMul` with two different data types: `double`, and `int8`. You specify the entry-point function followed by `-args` for each signature of the entry-point function.

```
codegen -config cfg myAdd.m -args {1,2} -args {int8(1),int8(2)} myMul.m -args {1,2} -args {in
```

## 4 Run generated SIL MEX file `myMath_sil`

At the command prompt, call the generated SIL MEX file `myMath_sil`. Make sure that the values you pass to `myMath_sil` match the input properties that you specified in the `codegen` command.

```
myMath_sil("myAdd",3,4)
```

```
ans =
```

```
7
```

```
myMath_sil("myAdd",int8(5),int8(6))
```

```
ans =
```

```
int8
```

```
11
```

```
myMath_sil("myMul",3,4)
```

```
ans =
```

```
12
```

```
myMath_sil("myMul",int8(5),int8(6))
```

```
ans =
```

```
int8
```

```
30
```

Running the MATLAB function `myAdd` and `myMul` with these input values produces the same output. These test cases verify that `myAdd`, `myMul` and the generated SIL MEX file `myMath_sil` have the same behavior.

## 5 Terminate SIL execution

Terminate the SIL execution process.

```
clear myMath_sil;
```

You can also use the command `clear mex`, which clears MEX files from memory.

## 6 Entry Point Summary Report

In the generated code, different signatures are mapped to versioned entry-point functions `myAdd1`, `myAdd2`, `myMul1` and `myMul2` as shown in the figure.

The figure displays four function signatures from the Entry Point Summary Report, each with its generated name and input/output types:

- myAdd1**: Signature `(a, b) -> [y]`. Inputs: `a` (1x1 double), `b` (1x1 double). Generated name: `myAdd1`.
- myAdd2**: Signature `(a, b) -> [y]`. Inputs: `a` (1x1 int8), `b` (1x1 int8). Generated name: `myAdd2`.
- myMul2**: Signature `(a, b) -> [y]`. Inputs: `a` (1x1 int16), `b` (1x1 int16). Generated name: `myMul2`.
- myMul1**: Signature `(a, b) -> [y]`. Inputs: `a` (1x1 double), `b` (1x1 double). Generated name: `myMul1`.

Example main file provides information about how to use entry-points in your application. “Incorporate Generated Code Using an Example Main Function”, helps to generate example main.c file.

**Note** You can implement the multisignature PIL MEX for an entry-point function and multiple entry-point functions in the same way that the multisignature SIL MEX is implemented.

## Limitations

The multisignature SIL MEX and PIL MEX generation does not have graphical user interface (GUI) support.

## Simulink Code Coverage Metrics

### In this section...

“Statement Coverage” on page 85-2

“Condition Coverage” on page 85-2

“Decision Coverage” on page 85-3

“Modified Condition/Decision Coverage (MCDC)” on page 85-4

“Cyclomatic Complexity” on page 85-4

“Relational Boundary Coverage” on page 85-5

If you have a Simulink Coverage license, you can run a SIL or PIL simulation that produces code coverage metrics for generated model code. The simulation performs several types of code coverage analysis.

### Statement Coverage

Statement coverage measures the number of source code statements that execute when the code runs. Use this type of coverage to determine whether every statement in the program has been invoked at least once.

The percentage of statement coverage is represented by the following equation:

$$\text{Statement coverage} = (\text{Number of executed statements} / \text{Total number of statements}) * 100$$

#### Statement Coverage Example

This code snippet contains five statements. To achieve 100% statement coverage, you need at least one test with positive  $x$  values, one test with negative  $x$  values, and one test with  $x$  values of zero.

```
if (x > 0)
 printf("x is positive");
else if (x < 0)
 printf("x is negative");
else
 printf("x is 0");
```

### Condition Coverage

Condition coverage analyzes statements that include conditions in source code. Conditions are C/C++ Boolean expressions that contain relation operators (<, >, <=, or >=), equation operators (!= or ==), or logical negation operators (!), but that do not contain logical operators (&& or ||). This type of coverage determines whether every condition has been evaluated to all possible outcomes at least once.

The percentage of condition coverage is represented by the following equation:

$$\text{Condition coverage} = (\text{Number of executed condition outcomes} / \text{Total number of condition outcomes}) * 100$$

## Condition Coverage Example

In this expression:

```
y = x<=5 || x!=7;
```

there are two conditions:

```
x<=5
x!=7
```

To achieve 100% condition coverage, your test cases need to demonstrate a true and false outcome for both conditions. For example, a test case where  $x$  is equal to 4 demonstrates a true case for both conditions, and a case where  $x$  is equal to 7 demonstrates a false case for both conditions.

## Decision Coverage

Decision coverage analyzes statements that represent decisions in source code. Decisions are Boolean expressions composed of conditions and one or more of the logical C/C++ operators `&&` or `||`. Conditions within branching constructs (if/else, while, and do-while) are decisions. Decision coverage determines the percentage of the total number of decision outcomes the code exercises during execution. Use this type of coverage to determine whether all decisions, including branches, in your code are tested.

---

**Note** The decision coverage definition for DO-178C compliance differs from the Simulink Coverage definition. For decision coverage compliance with DO-178C, in the Configuration Parameters, set the **Structural Coverage Level** to Condition Decision for Boolean expressions not containing `&&` or `||` operators.

---

The percentage of decision coverage is represented by the following equation:

$$\text{Decision coverage} = (\text{Number of executed decision outcomes} / \text{Total number of decision outcomes}) * 100$$

## Decision Coverage Example

This code snippet contains three decisions:

```
y = x<=5 && x!=7; // decision #1

if(x > 0) // decision #2
 printf("decision #2 is true");
else if(x < 0 && y) // decision #3
 printf("decision #3 is true");
else
 printf("decisions #2 and #3 are false");
```

To achieve 100% decision coverage, your test cases must demonstrate a true and false outcome for each decision.

## Modified Condition/Decision Coverage (MCDC)

Modified condition/decision coverage (MCDC) analyzes whether the conditions within decisions independently affect the decision outcome during execution. To achieve 100% MCDC, your test cases must demonstrate:

- All conditions within decisions have been evaluated to all possible outcomes at least once.
- Every condition within a decision independently affects the outcome of the decision.

The percentage of MCDC is represented by the following equation:

$$\text{MCDC coverage} = (\text{Number of conditions evaluated to all possible outcomes affecting the outcome of the decision} / \text{Total number of conditions within the decisions}) * 100$$

### Modified Condition/Decision Coverage Example

For this decision:

```
X || (Y && Z)
```

the following set of test cases delivers 100% MCDC coverage.

	X	Y	Z
Test case #1	0	0	1
Test case #2	0	1	0
Test case #3	0	1	1
Test case #4	1	0	1

In order to demonstrate that the conditions Y and Z can independently affect the decision outcome, the condition X must be false for those test cases. If the condition X is true, then the decision is already known to be true. Therefore, the conditions Y and Z would not affect the decision outcome.

## Cyclomatic Complexity

Cyclomatic complexity measures the structural complexity of code by using the McCabe complexity measure. To compute the cyclomatic complexity of code, code coverage uses this formula:

$$c = \sum_{1}^{N} (o_n - 1)$$

$N$  is the number of decisions in the code.  $o_n$  is the number of outcomes for the  $n^{\text{th}}$  decision point. Code coverage adds 1 to the complexity number for each C/C++ function.

### Coverage Example

For this code snippet, the cyclomatic complexity is 3:

```
void evalNum(int x)
{
 if (x > 0) // decision #1
 printf("x is positive");
 else if (x < 0) // decision #2
```

```
 printf("x is negative");
else
 printf("x is 0");
}
```

The code contains one function that has two decision points. Each decision point has two outcomes. Using the preceding formula,  $N$  is 2,  $o_1$  is 2, and  $o_2$  is 2. Code coverage uses the formula with these decisions and outcomes and adds 1 for the function. The cyclomatic complexity for this code snippet is:

$$c = (o_1 - 1) + (o_2 - 1) + 1 = (2 - 1) + (2 - 1) + 1 = 3$$

## Relational Boundary Coverage

Relational boundary code coverage examines code that has relational operations. Relational boundary code coverage metrics align with those for model coverage, as described in “Relational Boundary Coverage” (Simulink Coverage). Fixed-point values in your model are integers during code coverage.

### Related Examples

- “Code Coverage for Models in Software-in-the-Loop (SIL) Mode and Processor-in-the-Loop (PIL) Mode” on page 85-6

## Code Coverage for Models in Software-in-the-Loop (SIL) Mode and Processor-in-the-Loop (PIL) Mode

If you have Embedded Coder and Simulink Coverage, you can analyze coverage for generated code during a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation.

### In this section...

“Enable SIL or PIL Code Coverage for a Model” on page 85-6

“Review the Coverage Results for Models in SIL or PIL Mode” on page 85-6

“Limitations” on page 85-7

### Enable SIL or PIL Code Coverage for a Model

To record SIL or PIL code coverage for a model:

- 1 Ensure you have a supported compiler installed. For a list of supported compilers, see Supported and Compatible Compilers.
- 2 In the Configuration Parameters dialog box, on the left pane, click **Code Generation**. From the list, select **Verification**.
- 3 Under **Code profiling**, set **Measure function execution times** to Off.
- 4 Under **Code coverage for SIL or PIL**, set **Third-party tool** to None (use Simulink Coverage).
- 5 Enable coverage for a model in SIL or PIL mode or a reference model in SIL or PIL mode. For more information about enabling coverage, see “Specify Coverage Options” (Simulink Coverage).
- 6 Run a SIL or PIL simulation.

---

**Note** The **Coverage (Run)** button in the Coverage toolstrip forces a Normal mode simulation for the top-level model and does not yield SIL or PIL code coverage.

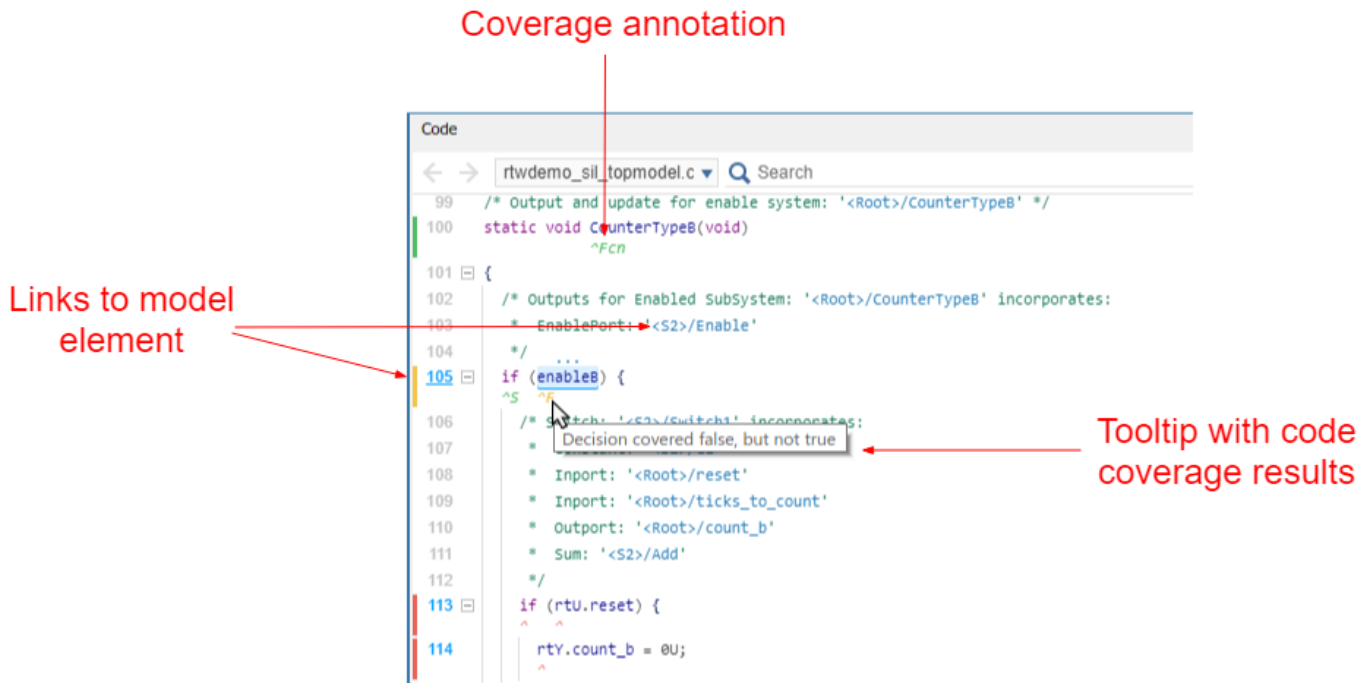

---

To run a SIL or PIL simulation:

- a In the Simulink window, click **Apps** and then click **SIL/PIL Manager**.
- b In the **SIL/PIL** tab, click **Automated Verification > SIL/PIL Simulation Only**.
- c Click **Run SIL/PIL**.

### Review the Coverage Results for Models in SIL or PIL Mode

To view the code coverage information in the Code view, from the drop-down list to the right of the search box, select **Show code coverage**. If the option is disabled, then on the **Coverage** tab, click **Coverage Highlighting**. The code displays highlighting and annotations that show code coverage information. You can navigate from the code to the associated model blocks by using the links in the line numbers, code elements, and comments.

At the bottom of the Code view, the coverage section shows a summary of the code coverage report.

## Limitations

Coverage for models in SIL and PIL mode has these limitations:

- The model must meet the requirements listed in “Enable SIL or PIL Code Coverage for a Model” on page 85-6.
- Code coverage results must not include external C/C++ files in read-only folders.
- The **Coverage (Run)** button in the Coverage toolstrip forces a Normal simulation and will not yield SIL or PIL code coverage.

## **See Also**

### **Related Examples**

- “Custom Toolchain Directives Required for Code Coverage and Execution Profiling” on page 82-64
- “Software-in-the-Loop Code Coverage” (Simulink Coverage)
- “SIL/PIL Manager Verification Workflow” on page 82-72

## Configure Code Coverage with Third-Party Tools

During a top-model or Model block SIL or PIL simulation, you can collect code coverage metrics for generated code using a third-party tool. Embedded Coder supports the following tools:

- The LDRA tool suite from LDRA Software Technology. For information about installing and using this tool, go to [www.ldra.com](http://www.ldra.com).

The software supports LDRA code coverage for SIL and PIL.

- BullseyeCoverage from Bullseye Testing Technology. For information about installing and using this tool, go to [www.bullseye.com](http://www.bullseye.com).

The software supports BullseyeCoverage code coverage for SIL and, in certain cases, PIL.

---

**Note** SIL and PIL simulation support for BullseyeCoverage will be removed in a future release.

---

To configure a code coverage tool for a top-model or Model block SIL or PIL simulation, in the Configuration Parameters dialog box, select the **Verification** pane:

- 1 From the **Third-party tool** drop-down list, select a tool, for example, BullseyeCoverage or LDRAcover or LDRA tool suite.
- 2 Click **Configure** to open the Code Coverage Settings dialog box.
- 3 In the **Installation folder** field, specify the location where your coverage tool is installed. If you click **Browse**, the Select Installation Folder dialog box opens, which allows you to navigate to the folder where your coverage tool is installed. The software detects and displays the tool version.

By default, the following parameters are enabled:

- **Code coverage for this model** — Generate coverage data for the current (top) model.
- **Code coverage for referenced models** — Generate data for models referenced by the current (top) model.

If your top model has Model blocks, these parameters of the top model override the corresponding parameters of referenced models.

**4** Click **OK**.

With the LDRA tool suite:

- The evaluation of cumulative code coverage begins from the point when you last added a new file to the existing set of source files. For example, existing code coverage results are deleted when you:
  - Run a simulation with a new model using the existing code generation folder.
  - Run a simulation that results in additional source code files being instrumented.
- If you switch between SIL and PIL simulations of a model, the software generates separate cumulative code coverage results for the SIL and PIL simulations.

For a model in a reference hierarchy, the software does not support simultaneous function execution time measurement and code coverage.

## View Code Coverage Information at the End of SIL or PIL Simulations

### In this section...

“View LDRA Tool Suite Results” on page 85-11

“View BullseyeCoverage Results” on page 85-11

If you configure third-party code coverage for a SIL or PIL simulation, when the simulation is complete, the code generation report opens automatically and you see hyperlinks in the Command Window.

### View LDRA Tool Suite Results

If you specified the LDRA tool suite, you see three links in the Command Window:

```
...
Starting SIL simulation for component: rtwdemo_sil_topmodel
Stopping SIL simulation for component: rtwdemo_sil_topmodel
Starting analysis of coverage data
Use the following links to view code coverage results:
 LDRAcover or LDRA tool suite GUI
 LDRAcover or LDRA tool suite Code Coverage Overview Report
 HTML code generation report with code coverage annotations
Completed code coverage analysis
>>
```

To open the LDRA GUI, click the `LDRAcover or LDRA tool suite GUI` link.

To open the LDRA report with your Web browser, click the `LDRAcover or LDRA tool suite Code Coverage Overview Report` link. For information about using the report, refer to the LDRA documentation.

LDRA analysis results for all code in the current code generation folder belong to a set. In this set, you can find analysis results for models that share the same code generation folder. The `LDRAcover or LDRA tool suite Code Coverage Overview Report` link identifies the location of the LDRA analysis results, which is determined by:

- The LDRA tool suite configuration.
- The name of the LDRA tool suite set associated with the current code generation folder.

To view summary data and code annotations with coverage information in the code generation report, click the `HTML code generation report with code coverage annotations` link. To view the code coverage information in the Code view, from the drop-down list to the right of the search box, select **Show code coverage**.

### View BullseyeCoverage Results

---

**Note** SIL and PIL simulation support for BullseyeCoverage will be removed in a future release.

---

If you specified the BullseyeCoverage tool, you see two links in the Command Window:

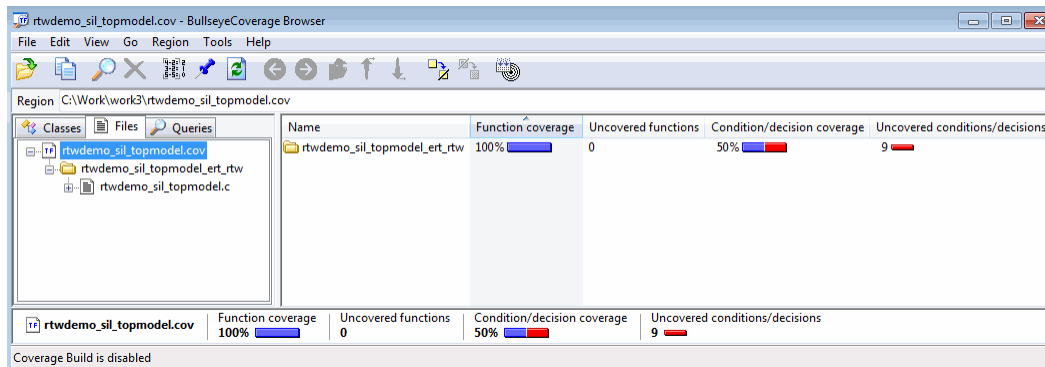

```
Starting SIL simulation for component: rtwdemo_sil_topmodel
Stopping SIL simulation for component: rtwdemo_sil_topmodel
```

```

Processing code coverage data
Use the following links to view code coverage results:
 BullseyeCoverage browser (coverage for last run)
 HTML code generation report (cumulative coverage)
Completed code coverage analysis
>>

```

To view the coverage report using the BullseyeCoverage Browser, click the BullseyeCoverage browser (coverage for last run) link.

The BullseyeCoverage Browser shows coverage data for instrumented files associated with your latest top-model simulation. The coverage data shown in the browser is not cumulative and pertains only to the most recent simulation. For information about the BullseyeCoverage Browser, go to [www.bullseye.com](http://www.bullseye.com).

To view summary data and code annotations with coverage information in the code generation report, click the **HTML code generation report (cumulative coverage)** link. To view the code coverage information in the Code view, from the drop-down list to the right of the search box, select **Show code coverage**.

## See Also

### Related Examples

- “Configure Code Coverage with Third-Party Tools” on page 85-9
- “Collect Code Coverage Metrics with a Third-Party Tool” on page 85-25
- “Code Coverage Summary and Annotations” on page 85-15

## Configure Code Coverage Programmatically

For a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation, you can configure third-party code coverage analysis by using command-line APIs.

### Set Up Third Party Code Coverage From Command Line

For BullseyeCoverage, you can use this workflow:

- 1 Using `get_param`, retrieve the object containing coverage settings for the current model. For example:

```
covSettings = get_param(gcs, 'CodeCoverageSettings')
```

```
covSettings =
```

```
CodeCoverageSettings with properties:
```

```
 TopModelCoverage: 'off'
 ReferencedModelCoverage: 'off'
 CoverageTool: 'None'
```

The property `TopModelCoverage` determines whether the software generates code coverage data for just the top model, while `ReferencedModelCoverage` determines whether the software generates coverage data for models referenced by the top model. If neither property is 'on', the code generator does not produce code coverage data during a SIL or PIL simulation.

When you save your model, the properties `TopModelCoverage`, `ReferencedModelCoverage`, and `CoverageTool` are also saved.

- 2 Check the class of `covSettings`.

```
class(covSettings)
```

```
ans =
```

```
 'coder.coverage.CodeCoverageSettings'
```

- 3 Turn on BullseyeCoverage code coverage analysis for the top model and referenced models.

```
covSettings.TopModelCoverage='on';
covSettings.ReferencedModelCoverage='on';
covSettings.CoverageTool='BullseyeCoverage';
```

To specify the LDRA tool suite as the code coverage tool, set the property `CoverageTool` to 'LDRAcover or LDRA tool suite'.

- 4 Using `set_param`, apply the new coverage settings to the model.

```
set_param(gcs, 'CodeCoverageSettings', covSettings);
```

- 5 Assuming the third-party code coverage tool is installed, specify the installation path.

```
coder.coverage.BullseyeCoverage.setPath('C:\Program Files\BullseyeCoverage')
```

For the LDRA tool suite, use `coder.coverage.LDRA.setPath('C:\...')`.

- 6 Check that the path is saved as a preference.

```
coder.coverage.BullseyeCoverage.getPath
```

For the LDRA tool suite, use `coder.coverage.LDRA.getPath`.

## Code Coverage for Model That Uses Configuration Reference

If your model uses a configuration set that is not attached to the model, for example, a configuration reference, then the **Configure** button is dimmed in the Configuration Parameters dialog box. You cannot open the Code Coverage Settings dialog box and you must use line commands to specify code coverage settings.

To configure third-party code coverage analysis for a model that uses a configuration reference:

- 1 Get the active configuration set from the model.

```
cs = getActiveConfigSet(gcs)
```

- 2 Retrieve the current code coverage settings.

```
covSettings = get_param(cs, 'CodeCoverageSettings')
```

- 3 Specify the code coverage settings that you require. For example:

```
covSettings.TopModelCoverage = 'on';
covSettings.ReferencedModelCoverage='on';
covSettings.CoverageTool='BullseyeCoverage';
```

- 4 Get the configuration set that is specified by the configuration reference.

```
csBase = cs.getRefConfigSet
```

- 5 Apply the required code coverage settings to the referenced configuration set.

```
set_param(csBase, 'CodeCoverageSettings', covSettings);
```

The active configuration set for the model contains the code coverage settings that you require.

## Code Coverage Summary and Annotations

In this section...
“LDRA Tool Suite Coverage” on page 85-15
“BullseyeCoverage Information” on page 85-17

If you specify a code coverage tool for a SIL or PIL simulation, the software provides summary data and code annotations with coverage information in the Code view. Each code annotation is associated with a code feature and indicates the nature of the feature coverage during code execution. The Code view also allows you to navigate easily between blocks in your model and the corresponding sections in the source code.

### LDRA Tool Suite Coverage

The cumulative coverage data in the Code view is derived from instrumented files associated with your latest top-model simulation **and** coverage data collected from simulations with other top models that share referenced models with your current top model.

The software provides LDRA tool suite annotations in the Code view to help you to review code coverage.

---

**Note** Do not use the Code view alone to verify that you have achieved your coverage goals. You must refer to the LDRA report.

---

In the Code view, the color of each bar and annotations shows the amount of coverage of the corresponding line of code or code feature. Green indicates full coverage, yellow indicates partial coverage, and red indicates no coverage.

```

104 */
105 if (enableB) {
106 /* Switch: '<S2>/Switch1' incorporates:
107 * Constant: '<S2>/C1'
108 * Inport: '<Root>/reset'
109 * Inport: '<Root>/ticks_to_count'
110 * Output: '<Root>/count_b'
111 * Sum: '<S2>/Add'
112 */
113 if (rtU.reset) {
114 rtY.count_b = 0U;
115 }
116
117 rtY.count_b = (uint8_T)(uint32_T)((uint32_T)rtU.ticks_to_count + (uint32_T)
118 rtY.count_b);
119
120 /* End of Switch: '<S2>/Switch1' */
121 }

```

Place your cursor over the annotation `^b` to see a tooltip. the tooltip indicates which branch destinations are covered and which are not covered.

```

104 */
105 if (enableB) {
106 /* Switch: Branch destinations covered <line>c<column>: 123c3; branch destinations not covered: 105c16
107 * Constant: '<S2>/C1'
108 * Inport: '<Root>/reset'
109 * Inport: '<Root>/ticks_to_count'
110 * Output: '<Root>/count_b'
111 * Sum: '<S2>/Add'
112 */
113 if (rtU.reset) {
114 rtY.count_b = 0U;
115 }

```

This table describes the LDRA code annotations that you might see in the Code view produced by SIL and PIL simulations.

Code feature	Annotation symbol	What happened during simulation
Function	Fcn	Function <i>name</i> returned through this exit point.
	=>	Function <i>name</i> never returned through this exit point.
Branch/condition	=>	Condition not encountered.
	=>t	Condition evaluated true only.
	=>f	Condition evaluated false only.
	tf	Condition evaluated both true and false.
Branch/decision	=>	Branch never encountered.
	=>b	Branch to at least one destination covered and branch to at least one other destination not covered.
	b	Branch fully exercised.
Modified Condition/Decision Coverage (MC/DC)	=>mc	Condition did not independently affect outcome of decision.
	mc	Condition independently affected outcome of decision.
Statement	•	Statements associated with line covered.
	•	Not all statements associated with line covered.
Code that is reformatted by LDRA tool suite and does not match the original source code. For example, source code with <code>#include</code> statements to include other files, and source code with <code>#define</code> statements for macros.  For detailed coverage information, refer to the LDRA report.	=> $\Sigma$	Zero coverage — probes within source code line or files included by source code line not exercised.
	=> $\Sigma$	Coverage probes within source code line or any included file partially exercised.
	$\Sigma$	Coverage probes within source code line or included files fully exercised.

## BullseyeCoverage Information

The cumulative coverage data in the Code view is derived from instrumented files associated with your latest top-model simulation **and** coverage data collected from simulations with other top models that share referenced models with your current top model.

The software provides BullseyeCoverage annotations in the Code view to help you to review code coverage.

In the Code view, the color of each bar and annotations shows the amount of coverage of the corresponding line of code or code feature. Green indicates full coverage, yellow indicates partial coverage, and red indicates no coverage.

```

=>F 105 if (enableB) {
106 /* Switch: '<S2>/Switch1' incorporates:
107 * Constant: '<S2>/C1'
108 * Inport: '<Root>/reset'
109 * Inport: '<Root>/ticks_to_count'
110 * Outport: '<Root>/count_b'
111 * Sum: '<S2>/Add'
112 */

```

This table describes the BullseyeCoverage code annotations that you might see in a code generation report produced by a SIL simulation.

Code feature	Annotation symbol	What happened during simulation
Decision	=>	Decision not executed.
	TF	Decision evaluated both true and false.
	=>T	Decision evaluated true only.
	=>F	Decision evaluated false only.
Function	=>	Function not called.
	Fcn	Function called.
Switch label	=>	Switch command not used.
	Sw	Switch command used.
Constant	k	Decision or condition was constant, which did not allow any variation in coverage.
Condition	=>	Condition not encountered.
	tf	Condition evaluated both true and false.
	=>t	Condition evaluated true only.
	=>f	Condition evaluated false only.
Try	=>	Try block never completed.
	Try	Try block covered.
Catch	=>	Catch block not covered.
	Cat	Catch block covered.

## Code Coverage Tool Support

Embedded Coder code coverage provides the following support for BullseyeCoverage and the LDRA tool suite.

Operating system	BullseyeCoverage		LDRA Tool Suite	
	Version supported	Compiler supported	Version supported	Compiler supported
Windows	8.15.41	Microsoft Visual C++ (MSVC)	9.8.4	<ul style="list-style-type: none"> <li>• Microsoft Visual C++ (MSVC)</li> <li>• LCC</li> <li>• MinGW</li> </ul>
Linux	8.15.41	gcc	9.8.4	gcc
Mac	Not supported		Not supported	

### See Also

### Related Examples

- “Configure Code Coverage with Third-Party Tools” on page 85-9
- “Select and Configure C or C++ Compiler”

## Tips and Limitations

### Model Build and SIL/PIL Blocks Not Supported

Code coverage does not support:

- The model build process, for example, the Ctrl+B command.
- SIL or PIL blocks.

Code coverage settings are ignored by the Ctrl+B command and SIL or PIL blocks.

### BullseyeCoverage License Wait

When you build your model, you might have to wait for a BullseyeCoverage license. If you want to see information about the wait, before you build your model, in the Configuration Parameters dialog box, select **Verbose build**.

---

**Note** SIL and PIL simulation support for BullseyeCoverage will be removed in a future release.

---

### Current Working Folder Cannot be UNC Path

If your MATLAB current working folder is a Universal Naming Convention (UNC) path, code coverage fails.

### Characters in matlabroot and File Path

If `matlabroot` or the path to your generated files contains a space or the . (period) character, code coverage might fail.

### Header Files with Identical Names

Consider a model that is configured for LDRA code coverage. During the build process, if the software detects two header files with the same name in the folder for generated code, the software generates an error.

### Code Coverage for Source Files in Shared Utility Folders

The software supports code coverage for source files generated in shared utility folders. If you configure code coverage for a model that uses shared utility code generation, when you build the model, you also build all source files in the shared utilities folder with code coverage enabled.

Whenever you build a model, the code coverage settings of the model must be consistent with source files that you previously built in the shared utilities folder. Otherwise, the software reports that code in the shared utilities folder is inconsistent with the current model configuration and must be rebuilt. For example, if you run a SIL simulation for a model with code coverage enabled and then run a SIL simulation for another model with code coverage disabled, the software must rebuild all source files in the shared utilities folder.

## BullseyeCoverage Behavior with Inline Macros

The BullseyeCoverage tool, by default, does not provide code coverage data for inline macros.

For example, if a model generates a file `slprj/ert/_sharedutils/rt_SATURATE.h` that contains the macro

```
#define rt_SATURATE(sig,ll,ul) (((sig) >= (ul)) ? (ul) : (((sig) <= (ll)) ? (ll) : (sig)))
```

and the macro is in `sat_ert_rtw/sat.c`, then the coverage report provides a measurement for `sat.c`, but no coverage data for the conditions within the macro `rt_SATURATE`.

To configure the BullseyeCoverage tool to provide code coverage data for inline macros:

- 1 Open the BullseyeCoverage Browser.
- 2 Select **Tools > Options** to open the Options dialog box.
- 3 On the **Build** tab, select the **Instrument macro expansions** check box.
- 4 Click **OK**.
- 5 Rerun your simulation.

Alternatively, you can add the text `-macro` to the BullseyeCoverage configuration file. For more information, go to [www.bullseye.com/help](http://www.bullseye.com/help).

---

**Note** SIL and PIL simulation support for BullseyeCoverage will be removed in a future release.

---

## SIL and PIL Simulations with Open LDRA GUI

If you enable LDRA code coverage, you must verify that the LDRA tool suite GUI is not open when you run your SIL or PIL simulation. If the set name in the GUI differs from the set name used by the SIL or PIL simulation, the SIL or PIL simulation fails.

## Minor SIL and PIL Differences for LDRA Tool Suite

The target connectivity API supports LDRA code coverage for top-model and Model block PIL.

There are minor differences in the code coverage information collected during SIL and PIL simulations. In particular, with PIL, the software does not explicitly show function exit point coverage. However, you can infer the coverage of function exit points by examining statement coverage.

## PIL Zero Coverage LDRA Annotations

For a PIL simulation with LDRA code coverage specified, recorded coverage for some source files might be zero. In this case, the software provides summary information indicating that:

- There is coverage to measure.
- The coverage is zero.

You do not see information for individual probes on each line. The displayed summary information has an associated annotation tooltip:

0 out of *N* coverage probes were exercised (detailed breakdown unavailable)

## PIL Support for BullseyeCoverage

Code coverage with BullseyeCoverage is available for top-model and Model block PIL provided your PIL application can write directly to the host file system. Your target for the PIL application must provide `fopen` and `fread` access to the host file system.

If code coverage is not available when you run the PIL application on your target hardware, you might be able to collect code coverage measurements by running the PIL application on an instruction set simulator that supports direct file I/O with the host file system.

---

**Note** SIL and PIL simulation support for BullseyeCoverage will be removed in a future release.

---

## Modify Legacy Code

If you modify legacy code and rerun a SIL or PIL simulation, the legacy code is recompiled. However, the code from the model may be up-to-date. In this case, the code generation report is not updated and does not show the modified legacy code. Instead, the code coverage information for the modified legacy code is displayed with reference to the original legacy code. You must regenerate the report. For more information, see “Generate Code Generation Report” on page 51-5.

## Collect Code Coverage Metrics with a Third-Party Tool

If Simulink® Coverage™ is installed, you can collect code coverage metrics during a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation - see “Collect Coverage for Code” (Simulink Coverage). In this example, you can collect code coverage metrics with a third-party tool, i.e., BullseyeCoverage or LDRA tool suite. You must install the third-party tool - see “Code Coverage Tool Support” on page 85-20.

This screen shot shows a code coverage report obtained by running a SIL simulation with a code coverage tool enabled. The annotations depend on the code coverage tool that you specify.

```

162 /* Model step function */
 • 163 void rtwdemo_sil_topmodel_step(void)
164 {
165 /* Logic: '<Root>/Logical Operator2' incorporates:
166 * Inport: '<Root>/count_enable'
167 * Inport: '<Root>/counter_mode'
168 * Logic: '<Root>/Logical Operator'
169 */
 • 170 enableA = ((!rtU.counter_mode) && rtU.count_enable);
 ^
 ^
 ^
 ^
 ^
171
 • 172 /* Outputs for Enabled SubSystem: '<Root>/CounterTypeA' */
 CounterTypeA();

 /* End of Outputs for SubSystem: '<Root>/CounterTypeA' */

176
177 /* Logic: '<Root>/Logical Operator1' incorporates:
178 * Inport: '<Root>/count_enable'
179 * Inport: '<Root>/counter_mode'
180 */
 • 181 enableB = (rtU.counter_mode && rtU.count_enable);
 ^
 ^
 ^
 ^
 ^
182
 • 183 /* Outputs for Enabled SubSystem: '<Root>/CounterTypeB' */
 CounterTypeB();

 /* End of Outputs for SubSystem: '<Root>/CounterTypeB' */

 • 187 }
 ^

```

Annotations in the code include:

- Line 170: `enableA = ((!rtU.counter_mode) && rtU.count_enable);` with annotations `=>mc`, `=>t`, `=>b`, `=>mc`, and `=>t`.
- Line 181: `enableB = (rtU.counter_mode && rtU.count_enable);` with annotations `=>mc`, `=>f`, `=>b`, `=>mc`, and `=>`.
- Line 187: `}` with annotation `Fcn`.

Callout boxes:

- Condition evaluated true, but not false:** Points to the `=>t` annotation on line 170.
- MC/DC: condition did not independently affect outcome of decision:** Points to the `=>mc` annotation on line 170.
- Function rtwdemo\_sil\_topmodel\_step returned via this exit point:** Points to the `Fcn` annotation on line 187.

In this example, you measure model coverage during normal mode simulation and repeat the same simulation in SIL mode to measure code coverage. By using the hyperlinks in the model coverage and code coverage reports, you can compare model coverage and code coverage results.

For SIL and PIL simulation examples, see “Test Generated Code with SIL and PIL Simulations” on page 82-90.

**Initial Setup**

Make sure the model is newly opened.

```
model='rtwdemo_sil_topmodel';
close_system(model,0)
open_system(model)
```

Copyright 1994-2020 The MathWorks, Inc.

Remove existing build folders.

```
buildFolder=RTW.getBuildDir(model);
if exist(buildFolder.BuildDirectory,'dir')
 rmdir(buildFolder.BuildDirectory,'s');
end
```

Configure generation of model coverage report.

```
set_param(model, 'RecordCoverage', 'on')
clear covCumulativeData
```

Set up the stimulus data.

```
T=0.1; % sample time
[ticks_to_count, reset, counter_mode, count_enable, ...
 counter_mode_values_run1, counter_mode_values_run2, ...
 count_enable_values_run1, count_enable_values_run2] = ...
 rtwdemo_sil_topmodel_data(T);
```

### Run a Simulation in Normal Mode

The model is configured to collect model coverage metrics. When a simulation is complete, the model coverage report opens. Use the coverage display window to navigate from blocks in the model to the corresponding sections of the coverage report.

```
counter_mode.signals.values = counter_mode_values_run1;
count_enable.signals.values = count_enable_values_run1;
set_param(model, 'SimulationMode', 'normal');
```

Set up Simulation Data Inspector for interactive viewing and comparison of simulation results.

```
Simulink.sdi.view;
Simulink.sdi.clear;
```

Run the simulation.

```
simout_normal_run1 = sim(model, 'ReturnWorkspaceOutputs', 'on');
```

Capture the results.

```
Simulink.sdi.createRun('Run 1 (normal mode)', 'namevalue',...
 {'simout_normal_run1'}, {simout_normal_run1});
```

### Run a Second Simulation in Normal Mode

For the first simulation, the report shows that the achieved coverage is less than 100%. Run a second simulation with different input signals that increase the level of MC/DC coverage to 100%. Note that the model coverage report is configured to show cumulative coverage across both simulation runs.

```
counter_mode.signals.values = counter_mode_values_run2;
count_enable.signals.values = count_enable_values_run2;
set_param(model, 'SimulationMode', 'normal');
```

```
simout_normal_run2 = sim(model, 'ReturnWorkspaceOutputs', 'on');
```

```
Simulink.sdi.createRun('Run 2 (normal mode)', 'namevalue',...
 {'simout_normal_run2'}, {simout_normal_run2});
```

### Configure the Model to Measure Code Coverage

Before running a SIL simulation, check the availability of third-party tools, and configure the model to collect code coverage metrics. If a third-party tool is not available, the model uses Simulink® Verification and Validation™.

```
covToolPath = '';
ldraPath = coder.coverage.LDRA.getPath;
bullseyePath = coder.coverage.BullseyeCoverage.getPath;

coverageSettings = get_param(model, 'CodeCoverageSettings');
coverageSettings.TopModelCoverage='on';
if ~isempty(ldraPath)
```

```

 coverageSettings.CoverageTool='LDRAcover or LDRA tool suite';
elseif ~isempty(bullseyePath)
 coverageSettings.CoverageTool='BullseyeCoverage';
else
 coverageSettings.CoverageTool='None';
end
set_param(model, 'CodeCoverageSettings', coverageSettings);

```

### Run Simulations in SIL Mode

The normal mode simulations produce coverage metrics for the model. With a SIL simulation, you can apply the same input stimulus signals to the generated code and measure code coverage.

Run the first simulation in SIL mode.

```

counter_mode.signals.values = counter_mode_values_run1;
count_enable.signals.values = count_enable_values_run1;
set_param(model, 'SimulationMode', 'software-in-the-loop');
set_param(model, 'CodeExecutionProfiling', 'off');
set_param(model, 'CodeProfilingInstrumentation', 'off');
simout_sil_run1 = sim(model, 'ReturnWorkspaceOutputs', 'on');
Simulink.sdi.createRun('Run 1 (SIL mode)', 'namevalue', ...
 {'simout_sil_run1'}, {simout_sil_run1});

Starting build procedure for: rtwdemo_sil_topmodel
Successful completion of build procedure for: rtwdemo_sil_topmodel

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_sil_topmodel	Code generated and compiled	Code generation information file does not exist

```

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 44.156s
Preparing to start SIL simulation ...
Building with 'MinGW64 Compiler (C)'.
MEX completed successfully.
Updating code generation report with SIL files ...
Starting SIL simulation for component: rtwdemo_sil_topmodel
Stopping SIL simulation for component: rtwdemo_sil_topmodel
Completed code coverage analysis

```

Run the second simulation in SIL mode.

```

counter_mode.signals.values = counter_mode_values_run2;
count_enable.signals.values = count_enable_values_run2;
set_param(model, 'SimulationMode', 'software-in-the-loop');
set_param(model, 'CodeExecutionProfiling', 'off');
set_param(model, 'CodeProfilingInstrumentation', 'off');

Simulink.sdi.createRun('Run 2 (SIL mode)', 'namevalue', ...
 {'simout_sil_run2'}, {simout_sil_run2});

Starting build procedure for: rtwdemo_sil_topmodel
Generated code for 'rtwdemo_sil_topmodel' is up to date because no structural, parameter or
Successful completion of build procedure for: rtwdemo_sil_topmodel

```

### Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_sil_topmodel	Code compiled	Compilation artifacts were out of date.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 3.656s
Preparing to start SIL simulation ...
Starting SIL simulation for component: rtwdemo_sil_topmodel
Stopping SIL simulation for component: rtwdemo_sil_topmodel
Completed code coverage analysis
```

When a simulation is complete, click the link in the Command Window to open the code coverage report and view the cumulative code coverage results. The link is available only if you have a third-party tool installed.

Use hyperlinks in the code coverage report to go to corresponding locations in the block diagram. Then, by using the coverage display window, you can open corresponding sections of the model coverage report. Compare model coverage and code coverage results.

The Simulation Data Inspector opens automatically, allowing interactive viewing and analysis of the results. Use the Compare and Inspect panes to confirm that the SIL and normal mode logged signals are identical for both runs.

### Concluding Remarks

In this example, you:

- Collected model coverage metrics during a normal mode simulation.
- Collected code coverage metrics during a SIL simulation.
- Navigated between the code coverage and model coverage reports.
- Cross-checked metrics from both reports.

## Customize Generated ASAP2 File

### In this section...

“About ASAP2 File Customization” on page 86-2  
 “ASAP2 File Structure on the MATLAB Path” on page 86-2  
 “Customize the Contents of the ASAP2 File” on page 86-2  
 “ASAP2 Templates” on page 86-3  
 “Customize Computation Method Names” on page 86-5  
 “Suppress Computation Methods for FIX\_AXIS” on page 86-5

### About ASAP2 File Customization

The Embedded Coder product provides a number of Target Language Compiler (TLC) files to enable you to customize the ASAP2 file generated from a Simulink model.

### ASAP2 File Structure on the MATLAB Path

The ASAP2 related files are organized within the folders identified below:

- TLC files for generating ASAP2 file

The *matlabroot*/rtw/c/tlc/mw (open) folder contains TLC files that generate ASAP2 files, *asamlib.tlc*, *asap2lib.tlc*, *asap2main.tlc*, and *asap2grouplib.tlc*. These files are included by the setting of model configuration parameter **System target file**. (See “System Target Files Supporting ASAP2” on page 60-2.)

- ASAP2 target files

The *matlabroot*/toolbox/rtw/targets/asap2/asap2 (open) folder contains the ASAP2 system target file and other control files.

- Customizable TLC files

The *matlabroot*/toolbox/rtw/targets/asap2/asap2/user (open) folder contains files that you can modify to customize the content of your ASAP2 files.

- ASAP2 templates

The *matlabroot*/toolbox/rtw/targets/asap2/asap2/user/templates (open) folder contains templates that define each type of CHARACTERISTIC in the ASAP2 file.

### Customize the Contents of the ASAP2 File

The ASAP2 related TLC files enable you to customize the appearance of the ASAP2 file generated from a Simulink model. Most customization is done by modifying or adding to the files contained in the *matlabroot*/toolbox/rtw/targets/asap2/asap2/user (open) folder. This section refers to this folder as the *asap2/user* folder.

The user-customizable files provided are divided into two groups:

- The *static* files define the parts of the ASAP2 file that are related to the environment in which the generated code is used. They describe information specific to the user or project. The static files are not model dependent.
- The *dynamic* files define the parts of the ASAP2 file that are generated based on the structure of the source model.

The procedure for customizing the ASAP2 file is as follows:

- 1 Make a copy of the `asap2/user` folder before making modifications.
- 2 Remove the old `asap2/user` folder from the MATLAB path, or add the new `asap2/user` folder to the MATLAB path above the old folder. The MATLAB session uses the ASAP2 setup file, `asap2setup.tlc`, in the new folder.

`asap2setup.tlc` specifies the folders and files to include in the TLC path during the ASAP2 file generation process. Modify `asap2setup.tlc` to control the folders and folders included in the TLC path.

- 3 Modify the static parts of the ASAP2 file. These include
  - Project and header symbols, which are specified in `asap2setup.tlc`
  - Static sections of the file, such as file header and tail, `A2ML`, `MOD_COMMON`, and so on. These are specified in `asap2userlib.tlc`.
  - Specify the appearance of the dynamic contents of the ASAP2 file by modifying the existing ASAP2 templates or by defining new ASAP2 templates. Sections of the ASAP2 file affected include

`RECORD_LAYOUT`: modify parts of the ASAP2 template files.

`CHARACTERISTIC`: modify parts of the ASAP2 template files. For more information on modifying the appearance of `CHARACTERISTIC` records, see “ASAP2 Templates” on page 86-3.

- `MEASUREMENT`: These are specified in `asap2userlib.tlc`.
- `COMPU_METHOD`: These are specified in `asap2userlib.tlc`.

## ASAP2 Templates

The appearance of `CHARACTERISTIC` records in the ASAP2 file is controlled using a different template for each type of `CHARACTERISTIC`. The `asap2/user` folder contains template definition files for scalars, 1-D Lookup Table blocks and 2-D Lookup Table blocks. You can modify these template definition files, or you can create additional templates as required.

The procedure for creating a new ASAP2 template is as follows:

- 1 Create a template definition file. See “Create Template Definition Files” on page 86-3.
- 2 Include the template definition file in the TLC path. The path is specified in the ASAP2 setup file, `asap2setup.tlc`.

### Create Template Definition Files

This section describes the components that make up an ASAP2 template definition file. This description is in the form of code examples from `asap2lookup1d.tlc`, the template definition file for the `Lookup1D` template. This template corresponds to the `Lookup1D` parameter group.

---

**Note** When creating a new template, use the corresponding parameter group name in place of `Lookup1D` in the code shown.

---

### Template Registration Function

The input argument is the name of the parameter group associated with this template:

```
%<LibASAP2RegisterTemplate("Lookup1D")>
```

### RECORD\_LAYOUT Name Definition Function

Record layout names (aliases) can be arbitrarily specified for each data type. This function is used by the other components of this file.

```
%function ASAP2UserFcnRecordLayoutAlias_Lookup1D(dtId) void
 %switch dtId
 %case tSS_UINT8
 %return "Lookup1D_UBYTE"
 ...
 %endswitch
%endfunction
```

### Function to Write RECORD\_LAYOUT Definitions

This function writes `RECORD_LAYOUT` definitions associated with this template. The function is called by the built-in functions involved in the ASAP2 file generation process. The function name must be defined as shown, with the template name after the underscore:

```
%function ASAP2UserFcnWriteRecordLayout_Lookup1D() Output
 /begin RECORD_LAYOUT
 %<ASAP2UserFcnRecordLayoutAlias_Lookup1D(tSS_UINT8)>
 ...
 /end RECORD_LAYOUT
%endfunction
```

### Function to Write the CHARACTERISTIC

This function writes the `CHARACTERISTIC` associated with this template. The function is called by the built-in functions involved in the ASAP2 file generation process. The function name must be defined as shown, with the template name after the underscore.

The input argument to this function is a pointer to a parameter group record. The example shown is for a `Lookup1D` parameter group that has two members. The references to the associated `x` and `y` data records are obtained from the parameter group record as shown.

This function calls a number of built-in functions to obtain the required information. For example, `LibASAP2GetSymbol` returns the symbol (name) for the specified data record:

```
%function ASAP2UserFcnWriteCharacteristic_Lookup1D(paramGroup)
Output
 %assign xParam = paramGroup.Member[0].Reference
 %assign yParam = paramGroup.Member[1].Reference
 %assign dtId = LibASAP2GetDataTypeId(xParam)
 /begin CHARACTERISTIC
 /* Name */ %<LibASAP2GetSymbol(xParam)>
 /* Long identifier */ %<LibASAP2GetLongID(xParam)>
```

```

 ...
 /end CHARACTERISTIC
%endfunction

```

## Customize Computation Method Names

In generated ASAP2 files, computation methods translate the electronic control unit (ECU) internal representation of measurement and calibration quantities into a physical model oriented representation. Simulink Coder software provides the ability to customize the names of computation methods. You can provide names that are more intuitive, enhancing ASAP2 file readability, or names that meet organizational requirements.

To customize computation method names, use the MATLAB function `getCompuMethodName`, which is defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m`.

The `getCompuMethodName` function constructs a computation method name. The function prototype is

```
cmName = getCompuMethodName(dataTypeName, cmUnits)
```

where *dataTypeName* is the name of the data type associated with the computation method, *cmUnits* is the units as specified in the `Unit` property of a `Simulink.Parameter` or `Simulink.Signal` object (for example, rpm or m/s), and *cmName* returns the constructed computation method name.

The default constructed name returned by the function has the format

```
<localPrefix><datatype>_<cmUnits>
```

where

- `<local_Prefix>` is a local prefix, `CM_`, defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m`.
- `<datatype>` and `<cmUnits>` are the arguments you specified to the `getCompuMethodName` function.

Additionally, in the generated ASAP2 file, the constructed name is prefixed with `<ASAP2CompuMethodName_Prefix>`, a model prefix defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/asap2setup.tlc`.

For example, if you call the `getCompuMethodName` function with the *dataTypeName* argument 'int16' and the *cmUnits* argument 'm/s', and generate an ASAP2 file for a model named `myModel`, the computation method name would appear in the generated file as follows:

```

/begin COMPU_METHOD
 /* Name of CompuMethod */ myModel_CM_int16_m_s
 /* Units */ "m/s"
 ...
/end COMPU_METHOD

```

## Suppress Computation Methods for FIX\_AXIS

Versions 1.51 and later of the ASAP2 specification state that for certain cases of lookup table axis descriptions (integer data type and no doc units), a computation method is not required and the

Conversion Method parameter must be set to the value `NO_COMPU_METHOD`. You can control whether or not computation methods are suppressed when not required using the Target Language Compiler (TLC) option `ASAP2GenNoCompuMethod`. This TLC option is disabled by default. If you enable the option, ASAP2 file generation does not generate computation methods for lookup table axis descriptions when not required, and instead generates the value `NO_COMPU_METHOD`. For example:

```
/begin CHARACTERISTIC
/* Name */
luld_fix_axisTable_data
...
/begin AXIS_DESCR
 ...
 /* Conversion Method */
 NO_COMPU_METHOD
 ...
/end CHARACTERISTIC
```

The `ASAP2GenNoCompuMethod` option is defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/asap2setup.tlc`.

## Control Build Process Compiling and Linking

After generating code for a model, the build process determines whether to compile and link an executable program. Various factors guide this determination:

- **Generate code only** option

When you select this option, the code generator produces code for the model, including a makefile.

- **Generate makefile** option

When you clear this option, the code generator does not produce a makefile for the model. You must specify post code generation processing, including compilation and linking, as a user-defined command, as explained in “Customize Post-Code-Generation Build Processing” on page 87-7.

- **Makefile-only target**

The Microsoft Visual C++ Project Makefile versions of the `grt` and Embedded Coder target configurations generate a Visual C++ project makefile (`model.mak`). To build an executable, you must open `model.mak` in the Visual C++ IDE and compile and link the model code.

- **HOST template makefile variable**

The template makefile variable `HOST` identifies the type of system upon which your executable is intended to run. The variable can be set to one of three possible values: `PC`, `UNIX`, or `ANY`.

By default, `HOST` is set to `UNIX` in template makefiles designed for use with The Open Group UNIX platforms (such as `grt_unix.tmf`), and to `PC` in the template makefiles designed for use with development systems for the PC (such as `grt_vc.tmf`).

If the Simulink software is running on the same type of system as the system specified by the `HOST` variable, then the executable is built. Otherwise,

- If `HOST = ANY`, an executable is still built. This option is useful when you want to cross-compile a program for a system other than the one that the Simulink software is running on.
- Otherwise, processing stops after generating the model code and the makefile; the following message is displayed on the MATLAB command line.

```
Make will not be invoked - template makefile is for a different host
```

## Control Library Location and Naming During Build

When you generate precompiled, non-precompiled, and model reference libraries, you can control the library location and library name by using configuration parameters. These parameters control values in generated makefiles during model builds:

- For build processes that use the toolchain approach, control the generated library location by using the `TargetPreCompLibLocation` configuration parameter.
- For build processes that use the template makefile approach, control the generated library location by using the `TargetPreCompLibLocation` configuration parameter and control the generated library name by using the `TargetLibSuffix` configuration parameter.

### Library Control Parameters

Use the library control parameters to:

- Specify the location of precompiled libraries, such as blockset libraries or the Simulink Coder block library. Typically, a target has cross-compiled versions of these libraries and places them in a target-specific folder.
- Control the suffix applied to library file names (for example, `_target.a` or `_target.lib`).

Targets can set the parameters inside the system target file (STF) select callback. For example:

```
function mytarget_select_callback_handler(varargin)
 hDig=varargin{1};
 hSrc=varargin{2};
 slConfigUISetVal(hDig, hSrc, 'TargetPreCompLibLocation',...
 'c:\mytarget\precomplibs');
 slConfigUISetVal(hDig, hSrc, 'TargetLibSuffix',...
 '_target.library');
```

The TMF has corresponding expansion tokens:

```
|>EXPAND_LIBRARY_LOCATION<|
|>EXPAND_LIBRARY_SUFFIX<|
```

Alternatively, you can use a call to the `set_param` function. For example:

```
set_param(model,'TargetPreCompLibLocation',...
 'c:\mytarget\precomplibs');
```

---

**Note** If your model contains referenced models, you can use the make option `USE_MDLREF_LIBPATHS` to control whether libraries used by the referenced models are copied to the build folder of the parent model. For more information, see “Location of Model Reference Libraries” on page 87-5.

---

### Identify Library File Type for Toolchain Approach

The toolchain approach for model builds does not use the value of the `TargetLibSuffix` configuration parameter to select the library file name *suffix* and *extension*.

With the toolchain approach, the final binary name is composed of the *modelname*, the *compilername*, and the *extension* provided by the build tool description in the toolchain definition:

```
model_compilername.extension
```

You can identify the static library file name extension from the build tool description in the toolchain definition. To get this information for the default toolchain, use this procedure:

- 1 Get the default toolchain name. For example, enter:

```
tc_name = coder.make.getDefaultToolchain()
```

- 2 Get the default toolchain handle. For example, enter:

```
tc = coder.make.getToolchainInfoFromRegistry(tc_name)
```

- 3 Get the handle to the toolchain object. For example, enter:

```
tool_archiver = tc.getBuildTool('Archiver');
```

- 4 Get the extension. For example, enter:

```
ext_archiver = tool_archiver.getFileExtension('Static Library');
```

---

**Note** If you do not set the `TargetLibSuffix` parameter, template makefile and toolchain approaches produce the same static library file name *extension*.

---

## Specify the Location of Precompiled Libraries

Use the `TargetPreCompLibLocation` configuration parameter to:

- Override the precompiled library location specified in the `rtwmakecfg.m` file (see “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 87-17 for details)
- Precompile and distribute target-specific versions of product libraries (for example, the DSP System Toolbox product)

For a precompiled library, such as a blockset library or the Simulink Coder block library, the location specified in `rtwmakecfg.m` is typically a location specific to the blockset or the Simulink Coder product. The code generator expects that the library exists in this location and links against the library during builds.

For some applications, such as custom targets, it is preferable to locate the precompiled libraries in a target-specific or other alternate location rather than in the location specified in `rtwmakecfg.m`. For a custom target, the code generator expects that the target-specific cross-compiler creates the library, and you place the library in the target-specific location. Compile and place libraries supported by the target in the target-specific location, so they can be used during the build process.

You can set up the `TargetPreCompLibLocation` parameter in its select callback. The path that you specify for the parameter must be a fully qualified, absolute path to the library location. Relative paths are not supported. For example:

```
slConfigUISetVal(hDlg, hSrc, 'TargetPreCompLibLocation',...
'c:\mytarget\precomplibs');
```

Alternatively, you set the parameter with a call to the `set_param` function. For example:

```
set_param(model, 'TargetPreCompLibLocation',...
'c:\mytarget\precomplibs');
```

During makefile generation, the build process replaces the tokens with the location from the `rtwmakecfg.m` file. For example, if the library name in the `rtwmakecfg.m` file is `'rtwlib'`, the template makefile build approach expands the token from:

```
LIBS += |>EXPAND_LIBRARY_LOCATION<|\|>EXPAND_LIBRARY_NAME<|\
_target.library
```

to:

```
LIBS += c:\mytarget\precomplibs\rtwlib_target.library
```

By default, `TargetPreCompLibLocation` is an empty character vector. The build process uses the location in `rtwmakecfg.m` for the token replacement.

## Location of Model Reference Libraries

The build process assigns a path such as `../slprj/grt/sub/sub_rtwlib.lib` to `MODELREF_LINK_LIBS`. The build process uses the path to gain access to the library file at link time.

## Control the Suffix Applied to Library File Names

With the template makefile approach for model builds, use the `TargetLibSuffix` configuration parameter to control the suffix applied to library names (for example, `_target.lib` or `_target.a`). The specified suffix scheme must include a period (.). You can apply `TargetLibSuffix` to the following libraries:

- Libraries on which a target depends, as specified in the `rtwmakecfg.m` API. You can use `TargetLibSuffix` to change the suffix of both precompiled and non-precompiled libraries configured from the `rtwmakecfg` API. For details, see “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 87-17.

In this case, a target can set the parameter in its select callback. For example:

```
slConfigUISetVal(hDlg, hSrc, 'TargetLibSuffix',...
'_target.library');
```

Alternatively, you can use a call to the `set_param` function. For example:

```
set_param(model, 'TargetLibSuffix', '_target.library');
```

During the TMF-to-makefile conversion, the build process replaces the token `|>EXPAND_LIBRARY_SUFFIX<|` with the specified suffix. For example, if the library name specified in the `rtwmakecfg.m` file is `'rtwlib'`, the TMF expands from:

```
LIBS += |>EXPAND_LIBRARY_LOCATION<|\|>EXPAND_LIBRARY_NAME<|\
|>EXPAND_LIBRARY_SUFFIX<|
```

to:

```
LIBS += c:\mytarget\precomplibs\rtwlib_target.library
```

By default, `TargetLibSuffix` is set to an empty character vector. In this case, the build process replaces the token `|>EXPAND_LIBRARY_SUFFIX<|` with an empty character vector.

- Model libraries created with model reference. For these cases, associated makefile variables do not require the `|>EXPAND_LIBRARY_SUFFIX<|` token. Instead, the build process includes `TargetLibSuffix` implicitly. For example, for a top model named `topmodel` with referenced models named `refmodel1` and `refmodel2`, the TMF of the top model is expanded from:

```
MODELLIB = |>MODELLIB<|
MODELREF_LINK_LIBS = |>MODELREF_LINK_LIBS<|
```

to:

```
MODELLIB = topmodellib_target.library
MODELREF_LINK_LIBS = \
refmodell_rtwlib_target.library refmodel2_rtwlib_target.library
```

By default, the `TargetLibSuffix` parameter is an empty character vector. In this case, the build process chooses a default suffix for these three tokens using a file extension of `.lib` on Windows hosts and `.a` on UNIX hosts. For model reference libraries, the default suffix also includes `_rtwlib`. For example, on a Windows host, the expanded makefile values are:

```
MODELLIB = topmodellib.lib
MODELREF_LINK_LIBS = refmodell_rtwlib.lib refmodel2_rtwlib.lib
```

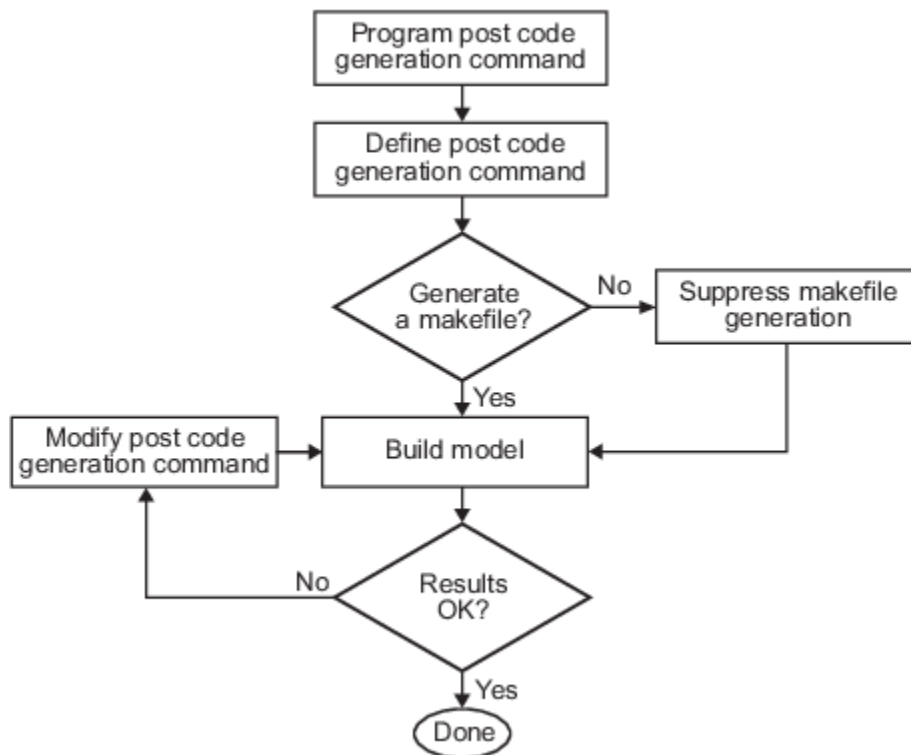

## Customize Post-Code-Generation Build Processing

The code generator provides a set of tools, including a build information object, you can use to customize build processing that occurs after code generation. You can use such customizations for target development or the integration of third-party tools into your application development environment.

### Workflow for Setting Up Customizations

The following figure and the steps that follow show the general workflow for setting up post-code-generation customizations.

- 1 Program the post code generation command on page 87-8.
- 2 Define the post code generation command on page 87-9.
- 3 Suppress makefile generation on page 87-11, if applicable.
- 4 Build the model.
- 5 Modify the command and rebuild the model until the build results are acceptable.

### Build Information Object

At the start of a model build, the build process logs the following build option and dependency information to a temporary build information object:

- Compiler options
- Preprocessor identifier definitions

- Linker options
- Source files and paths
- Include files and paths
- Precompiled external libraries

You can retrieve information from and add information to this object by using an extensive set of functions. For a list of available functions and detailed function descriptions, see “Build Process Customization”. “Program a Post Code Generation Command” on page 87-8 explains how to use the functions to control post code generation build processing.

## Program a Post Code Generation Command

For certain applications, you could want to control aspects of the build process after the code generation. For example, you can use this approach if you develop your own target, or you want to apply an analysis tool to the generated code before continuing with the build process. You can apply this level of control to the build process by programming and then defining a post code generation command.

A post code generation command is a MATLAB language file that typically calls functions that get data from or add data to the build information object of the model. You can program the command as a script or function.

If you program the command as a:	Then the:
Script	Script can gain access to the model name and the build information directly
Function	Function can pass the model name and the build information as arguments

If your post code generation command calls user-defined functions, make sure that the functions are on the MATLAB path. If the build process cannot find a function you use in your command, the build process errors out.

You can then call a combination of build information functions, as listed in “Build Process Customization”, to customize the post code generation build processing of the model.

The following example shows a fragment of a post code generation command that gets the file names and paths of the source and include files generated for a model for analysis.

```
function analyzegencode(buildInfo)
% Get the names and paths of source and include files
% generated for the model and then analyze them.

% buildInfo - build information for my model.

% Define cell array to hold data.
MyBuildInfo={};

% Get source file information.
MyBuildInfo.srcfiles=getSourceFiles(buildInfo, true, true);
MyBuildInfo.srcpaths=getSourcePaths(buildInfo, true);

% Get include (header) file information.
MyBuildInfo.incfiles=getIncludeFiles(buildInfo, true, true);
MyBuildInfo.incpaths=getIncludePaths(buildInfo, true);
```

```
% Analyze generated code.
.
.
.
```

## Define a Post Code Generation Command

After you program a post code generation command, inform the build process that the command exists and to add it to the build processing of the model. Define the command with the `PostCodeGenCommand` model configuration parameter. When you define a post code generation command, the build process evaluates the command after generating and writing the generated code to disk and before generating a makefile.

As the following syntax lines show, the arguments that you specify when setting the configuration parameter varies depending on whether you program the command as a script, function, or set of functions.

---

**Note** When defining the command as a function, you can specify an arbitrary number of input arguments. To pass the name and build information of the model to the function, specify identifiers `modelName` and `buildInfo` as arguments.

---

### Script

```
set_param(model, 'PostCodeGenCommand',...
'pcgScriptName');
```

### Function

```
set_param(model, 'PostCodeGenCommand',...
'pcgFunctionName(modelName)');
```

### Multiple Functions

```
pcgFunctions=...
'pcgFunction1Name(modelName);...
pcgFunction2Name(buildInfo)';
set_param(model, 'PostCodeGenCommand',...
pcgFunctions);
```

The following call to `set_param` defines `PostCodGenCommand` to evaluate the function `analyzegencode`.

```
set_param(model, 'PostCodeGenCommand',...
'analyzegencode(buildInfo)');
```

## Customize Build Process with PostCodeGenCommand and Relocate Generated Code to an External Environment

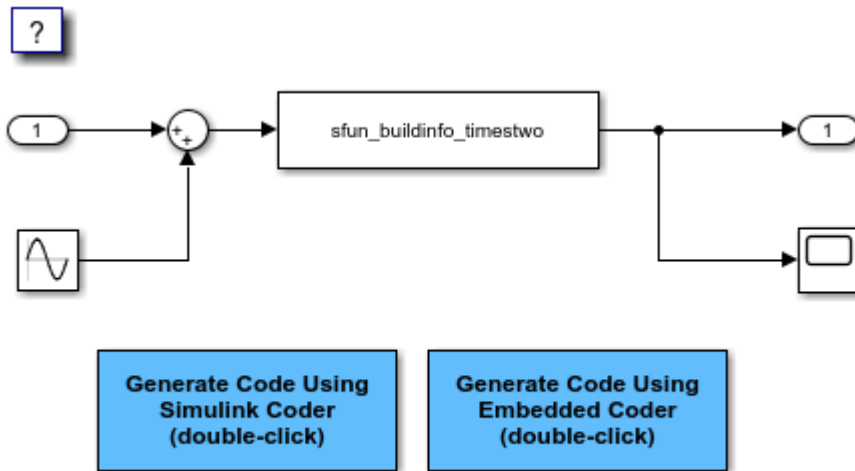

This example shows how to use the build information programming interface and the model configuration parameter **Post code generation command** (`PostCodeGenCommand`) to customize the build process. For this example, **Post code generation command** is set to `rtwdemo_buildinfo_data`. The build process invokes that function after code generation.

The example also shows how to use build configuration function `rtwmakecfg.m`.

## Open Example Model

Open the example model `rtwdemo_buildinfo`.

```
open_system('rtwdemo_buildinfo');
```

Copyright 1994-2020 The MathWorks, Inc.

## Generate Code from Model

Generate code. The code generator produces the file `BuildInfo.html`, which documents the build information object.

## Examine the Build Process Customizations and Output

Examine the build process customizations and the post code generation query of the build information object. In a Web browser, open the file `BuildInfo.html`. The file provides hyperlinks that you can use to examine the code produced for the model. Alternatively, in the MATLAB Command Window:

- To view the function configured to execute during the post code generation stage of the build process, enter:

```
get_param('rtwdemo_buildinfo','PostCodeGenCommand');
```

- To study the programming interface for the build information object, enter:

```
rtwdemo_buildinfo_data(buildInfo);
```

- To study how the example uses the `rtwmakecfg` function, enter:

```
edit rtwmakecfg.m;
```

- To view the build information object data that the build process saves in the `buildInfo.mat` file, open the file `rtwdemo_<target>_rtw\buildInfo.mat`.
- To view the contents of the post code generation function `rtwdemo_buildinfo_data.m`, enter:

```
edit rtwdemo_buildinfo_data.m;
```

At the end of the file, the function calls `packNGo` to package the source and object files that the build information object identifies for relocation.

- “Use `rtwmakecfg.m` API to Customize Generated Makefiles”
- “Relocate or Share Generated Code”

## Suppress Makefile Generation

The code generator lets you suppress makefile generation during the build process. For example, you can use this support when you integrate tools into the build process that do not use makefiles.

To instruct the code generator not to produce a makefile, do one of the following:

- Clear the **Generate makefile** option on the **Code Generation** pane of the Configuration Parameters dialog box.
- Set the value of the configuration parameter `GenerateMakefile` to `off`.

When you suppress makefile generation,

- You cannot explicitly specify a make command or template makefile.
- Specify your own instructions for a post code generation processing, including compilation and linking, in a post code generation command as explained in “Program a Post Code Generation Command” on page 87-8 and “Define a Post Code Generation Command” on page 87-9.

## See Also

`RTW.BuildInfo`

## Configure Generated Code with TLC

You can use the Target Language Compiler (TLC) to fine-tune your generated code. TLC supports extended code generation variables and options in addition to parameters available on the **Code Generation** pane on the Configuration Parameters dialog box. There are two ways to set TLC variables and options, as described in this section.

---

**Note** Do not customize TLC files in the folder *matlabroot/rtw/c/tlc* even though the capability exists to do so. It is possible that such TLC customizations are not applied during the code generation process. Such customizations can lead to unpredictable results.

---

### Assigning Target Language Compiler Variables

The `%assign` statement lets you assign a value to a TLC variable, as in:

```
%assign MaxStackSize = 4096
```

This assignment is also known as creating a *parameter name/parameter value pair*.

For a description of the `%assign` statement, see “Target Language Compiler Directives”. Write your `%assign` statements in the Configure RTW code generation settings section of the system target file.

The following table lists the code generation variables you can set with the `%assign` statement.

## Target Language Compiler Optional Variables

Variable	Description
MaxStackSize= <i>N</i>	<p>When the <b>Enable local block outputs</b> check box is selected, the total allocation size of local variables that are declared by block outputs in the model cannot exceed <b>MaxStackSize</b> (in bytes). <b>MaxStackSize</b> can be a positive integer. If the total size of local block output variables exceeds this maximum, the remaining block output variables are allocated in global, rather than local, memory. The default value for <b>MaxStackSize</b> is <code>rtInf</code>, that is, unlimited stack size.</p> <p><b>Note:</b> Local variables in the generated code from sources other than local block outputs, such as from a Stateflow diagram or MATLAB Function block, and stack usage from sources such as function calls and context switching are not included in the <b>MaxStackSize</b> calculation. For overall executable stack usage metrics, do a target-specific measurement by using run-time (empirical) analysis or static (code path) analysis with object code.</p>
MaxStackVariableSize= <i>N</i>	<p>When the <b>Enable local block outputs</b> check box is selected, this selection limits the size of a local block output variable declared in the code to <i>N</i> bytes, where <math>N &gt; 0</math>. A variable whose size exceeds <b>MaxStackVariableSize</b> is allocated in global, rather than local, memory. The default is 4096.</p>
RemoveFixptWordSizeChecks= <i>value</i>	<p>For a model that uses fixed-point data types, control the generation of preprocessor directives that perform fixed-point word size checks. If <i>value</i> is:</p> <ul style="list-style-type: none"> <li>• 0, generate the preprocessor directives. The generated code contains fixed-point word size checks.</li> <li>• 1, suppress the generation of the preprocessor directives. The generated code does not contain fixed-point word size checks.</li> </ul> <p>You can also suppress the generation of the preprocessor directives by running this command:</p> <pre>set_param(gcs, 'TLCOptions', ...             '-aRemoveFixptWordSizeChecks=1')</pre> <p>If you generate code that does not contain the fixed-point word size checks, you can use processor-in-the-loop (PIL) simulations that check <b>Hardware Implementation</b> settings with reference to the target hardware. For more information, see “Verification of Code Generation Assumptions” on page 82-67.</p>

Variable	Description
WarnNonSaturatedBlocks= <i>value</i>	<p>Flag to control display of overflow warnings for blocks that have saturation capability, but have it turned off (not selected) in their dialog box. Options include:</p> <ul style="list-style-type: none"><li>• 0 — Warning is not displayed.</li><li>• 1 — Displays one warning for the model during code generation</li><li>• 2 — Displays one warning that contains a list of offending blocks</li></ul>

## Set Target Language Compiler Options

You can specify TLC command-line options for code generation using the model parameter `TLCOptions` in a `set_param` function call. For information about these options, see “Specify TLC for Code Generation” and “Configure TLC”.

## Use makecfg to Customize Generated Makefiles for S-Functions

With the toolchain or template makefile approach for building code, you can customize generated makefiles for S-functions. Through the customization, you can specify additional items for the S-function build process:

- Source files and folders
- Include files and folders
- Library names
- Preprocessor macro definitions
- Compiler flags
- Link objects

To customize the generated makefile:

- 1 In the S-function MEX file folder that contains your S-function components, create a `makecfg.m` or `specificSFunction_makecfg.m` file. If you create a `makecfg.m` file, it is active for any S-function in the S-function MEX file folder that the model uses. A `specificSFunction_makecfg.m` file is active only if the model uses the corresponding S-function.
- 2 In the file that you create, use `RTW.BuildInfo` functions to specify additional items for the S-function build process. For example, you can use:
  - `addCompileFlags` to specify compiler options.
  - `addDefines` to specify preprocessor macro definitions.
- 3 Save the created file.

After code generation, in the S-function MEX file folder, the code generator searches for `makecfg.m` and `specificSFunction_makecfg.m` files. If the files are present, the code generator uses these files to customize the generated makefile, `model.mk`.

For example, consider a folder that contains `signalConvert.mexa64` (S-function binary file) and `signalConvert.tlc` (inlined S-function implementation) after the TLC phase of the build process. The S-function requires an additional source code file, `filterV1.c`, which is located in `anotherFolder`. You can create a file, `signalConvert_makecfg.m`, that uses `RTW.BuildInfo` functions to specify `filterV1.c` for the build process.

```
function signalConvert_makecfg(objBuildInfo)

absolutePath = fullfile('${START_DIR}', 'anotherFolder');
addSourceFiles(objBuildInfo, 'filterV1.c', absolutePath);
```

- “Use rtwmakecfg.m API to Customize Generated Makefiles”

## Use rtwmakecfg.m API to Customize Generated Makefiles

---

**Note** To customize generated makefiles for S-functions, MathWorks recommends the use of the `makecfg` approach instead of the `rtwmakecfg` function. For more information, see “Use `makecfg` to Customize Generated Makefiles for S-Functions” on page 87-15.

---

Both the toolchain approach and the template makefile approach for builds let you add the following items to generated makefiles:

- Source folders
- Include folders
- Library names
- Module objects

### About the `rtwmakecfg` Function

Using an `rtwmakecfg` function, you add this information to the makefile during the build operation for S-functions. The `rtwmakecfg` function is useful when specifying added sources and libraries to build a model that contains one or more of your S-function blocks.

To add information pertaining to an S-function to the makefile:

- 1 Create the MATLAB language `rtwmakecfg` function in the `rtwmakecfg.m` file. The code generator associates this file with your S-function based on its folder location. “Create the `rtwmakecfg` Function” on page 87-17 describes the requirements for the `rtwmakecfg` function and the data it returns.
- 2 If you are using the template makefile approach, modify the TMF of your target such that it supports macro expansion for the information that the `rtwmakecfg` function returns. “Modify the Template Makefile for `rtwmakecfg`” on page 87-19 describes the required modifications. If you are using the toolchain approach, the information that the `rtwmakecfg` function returns is used by the generated makefile; no further configuration is required.

After the TLC phase of the build process, when generating a makefile, the code generator searches for an `rtwmakecfg.m` file in the folder that contains the S-function MEX file. If it finds the file, the build process calls the `rtwmakecfg` function.

### Create the `rtwmakecfg` Function

Create the `rtwmakecfg.m` file containing the `rtwmakecfg` function in the same folder as your S-function component (a MEX-file with a platform-dependent extension, such as `.mexext` on Microsoft Windows systems). The function must return a structured array that contains these fields.

Field	Description
<code>makeInfo.includePath</code>	A cell array that specifies additional include folder names, organized as a row vector. The build process expands the folder names into include instructions in the generated makefile.

Field	Description
<code>makeInfo.sourcePath</code>	A cell array that specifies additional source folder names, organized as a row vector. Include the folder names of files entered into the <b>S-function modules</b> field on the S-Function Block Parameters dialog box or into the <code>SFunctionModules</code> parameter of the block if they are not in the same folder as the S-function. The build process expands the folder names into make rules in the generated makefile.
<code>makeInfo.sources</code>	A cell array that specifies additional source file names (C or C++), organized as a row vector. Do not include the name of the S-function or files entered into the <b>S-function modules</b> field on the S-Function Block Parameters dialog box or into the <code>SFunctionModules</code> parameter of the block. The build process expands the file names into make variables that contain the source files. Specify only file names (with extension). Specify path information with the <code>sourcePath</code> field.
<code>makeInfo.linkLibsObjs</code>	A cell array that specifies additional, fully qualified paths to object or library files against which the generated code links. The build process does not compile the specified objects and libraries. However, it includes them when linking the final executable. This inclusion can be useful for incorporating libraries that you do not want the build process to recompile or for which the source files are not available. You can also use this element to integrate source files from languages other than C and C++. This integration is possible if you first create a C compatible object file or library outside of the build process.
<code>makeInfo.precompile</code>	A Boolean flag that indicates whether the libraries specified in the <code>rtwmakecfg.m</code> file exist in a specified location ( <code>precompile==1</code> ) or if you must create the libraries in the build folder during the build process ( <code>precompile==0</code> ).
<code>makeInfo.library</code>	A structure array that specifies additional run-time libraries and module objects, organized as a row vector. The build process expands the information into make rules in the generated makefile. For a list of the library fields, see the next table.

The `makeInfo.library` field consists of the following elements.

Element	Description
<code>makeInfo.library(n).Name</code>	A character array that specifies the name of the library (without an extension).
<code>makeInfo.library(n).Location</code>	A character array that specifies the folder in which the library is located when precompiled. For more information, see the description of <code>makeInfo.precompile</code> in the preceding table. A target can use the <code>TargetPreCompLibLocation</code> parameter to override this value. See “Specify the Location of Precompiled Libraries”.
<code>makeInfo.library(n).Modules</code>	A cell array that specifies the C or C++ source file base names (without an extension) that comprise the library. Do not include the file extension. The makefile appends the object extension.

---

**Note** The `makeInfo.library` field must fully specify each library and how to build it. The modules list in the `makeInfo.library(n).Modules` element cannot be empty. To specify a link-only library, use the `makeInfo.linkLibsObjs` field instead.

---

**Example:**

```
disp(['Running rtwmakecfg from folder: ',pwd]);
makeInfo.includePath = { fullfile(pwd, 'somedir2') };
makeInfo.sourcePath = {fullfile(pwd, 'somedir2'), fullfile(pwd, 'somedir3')};
makeInfo.sources = { 'src1.c', 'src2.cpp'};
makeInfo.linkLibsObjs = { fullfile(pwd, 'somedir3', 'src3.object'),...
 fullfile(pwd, 'somedir4', 'mylib.library')};

makeInfo.precompile = 1;
makeInfo.library(1).Name = 'myprecompiledlib';
makeInfo.library(1).Location = fullfile(pwd,'somedir2','lib');
makeInfo.library(1).Modules = {'srcfile1' 'srcfile2' 'srcfile3' };
```

---

**Note** If a path that you specify in the `rtwmakecfg.m` API contains spaces, the build process does not convert the path to its nonspace equivalent. If the build environments you intend to support do not support spaces in paths, refer to “Build Process Support for Folder Names”.

---

## Modify the Template Makefile for rtwmakecfg

To expand the information that an `rtwmakecfg` function generates, modify the following sections in the TMF of your target:

- Include Path
- C Flags and/or Additional Libraries
- Rules

It is possible that these TMF code examples do not apply to your make utility. For additional examples, see the GRT or ERT TMFs located in *matlabroot/toolbox/coder/compile/tmf*.

### Add Folder Names to the Makefile Include Path

The following TMF code example adds folder names to the include path in the generated makefile:

```
ADD_INCLUDES = \
|>START_EXPAND_INCLUDES<| -I|>EXPAND_DIR_NAME<| \
|>END_EXPAND_INCLUDES<|
```

Also, the `ADD_INCLUDES` macro must be added to the `INCLUDES` line.

```
INCLUDES = -I. -I.. $(ADD_INCLUDES) $(USER_INCLUDES)
```

### Add Library Names to the Makefile

The following TMF code example adds library names to the generated makefile.

```
LIBS =
|>START_PRECOMP_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME<|.a |>END_PRECOMP_LIBRARIES<|
|>START_EXPAND_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME<|.a |>END_EXPAND_LIBRARIES<|
```

For more information, see “Control Library Location and Naming During Build” on page 87-3.

## Add Rules to the Makefile

The TMF code example adds rules to the generated makefile.

```
|>START_EXPAND_RULES<|
$(BLD)/%.o: |>EXPAND_DIR_NAME<|/%.c $(SRC)/$(MAKEFILE) rtw_proj.tmw
@$(BLANK)
@echo ### "|>EXPAND_DIR_NAME<|*.c"
$(CC) $(CFLAGS) $(APP_CFLAGS) -o (BLD)(DIRCHAR)$.o \
|>EXPAND_DIR_NAME<|$(DIRCHAR)$.c > (BLD)(DIRCHAR)$.lst
|>END_EXPAND_RULES<|

|>START_EXPAND_LIBRARIES<|MODULES_|>EXPAND_LIBRARY_NAME<| = \
|>START_EXPAND_MODULES<| |>EXPAND_MODULE_NAME<|.o \
|>END_EXPAND_MODULES<|

|>EXPAND_LIBRARY_NAME<|.a : $(MAKEFILE) rtw_proj.tmw
$(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
@$(BLANK)
@echo ### Creating $@
$(AR) -r $@ $(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
|>END_EXPAND_LIBRARIES<|

|>START_PRECOMP_LIBRARIES<|MODULES_|>EXPAND_LIBRARY_NAME<| = \
|>START_EXPAND_MODULES<| |>EXPAND_MODULE_NAME<|.o \
|>END_EXPAND_MODULES<|

|>EXPAND_LIBRARY_NAME<|.a : $(MAKEFILE) rtw_proj.tmw
$(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
@$(BLANK)
@echo ### Creating $@
$(AR) -r $@ $(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
|>END_PRECOMP_LIBRARIES<|
```

## Register Custom Toolchain and Build Executable

This example shows how to register and use a toolchain to build an executable file. This example uses the Intel® compiler. However, the concepts and programming interface apply for other toolchains. Once you register a toolchain, you can configure a model such that the code generator uses the toolchain to build an executable file for the model.

### Toolchain

A toolchain is a collection of tools required to compile and link code for a specified platform. A toolchain consists of multiple tools, such as a compiler, linker, and archiver. You can configure the tools in a toolchain with multiple options and group tool specifications into types of configurations.

### Create a New Folder and Copy Relevant Files

The following code creates a folder in your current working folder (pwd). The new folder contains files for this example. If you do not want to affect the current folder, or cannot generate files in this folder, change your working folder before invoking the command.

```
copyfile(fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'toolchain_demo'), 'toolchain_demo', 'f')
cd toolchain_demo
```

### Open a Model

Open the `rtwdemo_counter` model. By default, this model is configured to use the Generic Real-Time Target (GRT) configuration and the toolchain approach for building an executable file. The capability demonstrated in this example is available for models configured to use the toolchain approach.

```
model = 'rtwdemo_counter';
open_system(model)
```

Copyright 1994-2020 The MathWorks, Inc.

## Choose a Toolchain

Open the **Configuration Parameters** dialog box. Select **Code Generation**. The **Toolchain settings** section contains parameters for configuring a toolchain. From the **Toolchain** drop-down list, select the toolchain installed on your development system for building an executable file from the code generated from your model.

By default, the **Faster Runs** build configuration is selected. Click **Show settings** to see the toolchain flags specified for building the generated code. Choose a build configuration based on your current application development goal.

Close the **Configuration Parameters** dialog box.

## Create a ToolchainInfo Object

This example shows how you can register a custom toolchain and add it as a selectable **Toolchain** option.

The first step to registering a custom toolchain is to create a `ToolchainInfo` object that contains information about the toolchain. Methods are available to set toolchain specifications. You can share a `ToolchainInfo` object across installations.

Open the toolchain definition file for an Intel compiler. This file creates a `ToolchainInfo` object that contains information about the Intel toolchain on a 64-bit Windows® platform.

```
edit intel_tc
type intel_tc

function tc = intel_tc
%INTEL_TC Creates an Intel v18 ToolchainInfo object.
% This file can be used as a template to define other toolchains on Windows.

% Copyright 2012-2019 The MathWorks, Inc.

tc = coder.make.ToolchainInfo('BuildArtifact', 'nmake makefile');
tc.Name = 'Intel v18 | nmake makefile (64-bit Windows)';
tc.Platform = 'win64';
tc.SupportedVersion = '18';

tc.addAttribute('TransformPathsWithSpaces');
tc.addAttribute('RequiresCommandFile');
tc.addAttribute('RequiresBatchFile');

% -----
% Setup
% -----
% Below we are using %ICPP_COMPILER18% as root folder where Intel Compiler is installed.
% You can either set an environment variable or give full path to the
% compilervars.bat file

debugFlag.CppCompiler = '$(CPPDEBUG)';
debugFlag.Linker = '$(LDDEBUG)';
debugFlag.CppLinker = '$(CPPLDDEBUG)';
debugFlag.Archiver = '$(ARDEBUG)';

% Set the toolchain flags for 'Faster Builds' build configuration

cfg = tc.getBuildConfiguration('Faster Builds');
cfg.setOption('C Compiler', horzcat(cCompilerOpts, optimsOff0pts));
cfg.setOption('C++ Compiler', horzcat(cppCompilerOpts, optimsOff0pts));
cfg.setOption('Linker', linkerOpts);
cfg.setOption('C++ Linker', linkerOpts);
cfg.setOption('Shared Library Linker', sharedLinkerOpts);
cfg.setOption('Archiver', archiverOpts);

% Set the toolchain flags for 'Faster Runs' build configuration

cfg = tc.getBuildConfiguration('Faster Runs');
cfg.setOption('C Compiler', horzcat(cCompilerOpts, optimsOn0pts));
cfg.setOption('C++ Compiler', horzcat(cppCompilerOpts, optimsOn0pts));
cfg.setOption('Linker', linkerOpts);
cfg.setOption('C++ Linker', linkerOpts);
cfg.setOption('Shared Library Linker', sharedLinkerOpts);
cfg.setOption('Archiver', archiverOpts);

% Set the toolchain flags for 'Debug' build configuration

cfg = tc.getBuildConfiguration('Debug');
cfg.setOption('C Compiler', horzcat(cCompilerOpts, optimsOff0pts, debugFlag.CCompiler));
cfg.setOption('C++ Compiler', horzcat(cppCompilerOpts, optimsOff0pts, debugFlag.CppCompiler));
cfg.setOption('Linker', horzcat(linkerOpts, debugFlag.Linker));
cfg.setOption('C++ Linker', horzcat(linkerOpts, debugFlag.CppLinker));
cfg.setOption('Shared Library Linker', horzcat(sharedLinkerOpts, debugFlag.Linker));
cfg.setOption('Archiver', horzcat(archiverOpts, debugFlag.Archiver));

tc.setBuildConfigurationOption('all', 'Make Tool', '-f $(MAKEFILE)');

```

You can display the errors and warnings in the diagnostics messages pane from builds generated by custom compilers. For more information, see “Diagnostic Message Pane”.

Run the toolchain definition file to generate the ToolchainInfo object.

```
tc = intel_tc;
```

Save the ToolchainInfo object tc to a MAT file.

```
save intel_tc tc
```

## Register the Custom Toolchain

After you create the `ToolchainInfo` object for the new toolchain, register it. Register a toolchain in `RTW.TargetRegistry`. To register the toolchain, write an `rtwTargetInfo.m` file. Then, add that file to the MATLAB path so the system loads it automatically.

```
type rtwTargetInfo

function rtwTargetInfo(tr)
%RTWTARGETINFO Registration file for custom toolchains.

% Copyright 2012-2019 The MathWorks, Inc.

tr.registerTargetInfo(@loc_createToolchain);

end

% -----
% Create the ToolchainInfoRegistry entries
% -----
function config = loc_createToolchain

config(1) = coder.make.ToolchainInfoRegistry;
config(1).Name = 'Intel v18 | nmake makefile (64-bit Windows)';
config(1).FileName = fullfile(fileparts(mfilename('fullpath')), 'intel_tc.mat');
config(1).TargetHWDeviceType = {'*'};
config(1).Platform = {computer('arch')};

end
```

Reset the `TargetRegistry` to use the new `rtwTargetInfo.m` file.

```
RTW.TargetRegistry.getInstance('reset');
```

## Choose the Custom Toolchain

Reopen the **Configuration Parameters** dialog box. Click **Toolchain**. You should see the new toolchain in the list. Select the Intel v18 toolchain.

Programmatically, you can accomplish the same task with the following commands:

```
cs = getActiveConfigSet(model);
set_param(cs, 'Toolchain', tc.Name)
```

Verify your selection.

```
toolchain = get_param(cs, 'Toolchain')

toolchain =

 'Intel v18 | nmake makefile (64-bit Windows)'
```

## Build the Model Using the Custom Toolchain

You can now build the model with the new custom toolchain.

Note: If you do not have the Intel toolchain installed, you can use the following command to generate the code and makefile only.

```
set_param(cs, 'GenCodeOnly', 'on')
```

Build the model to generate the code and makefile that uses the new toolchain.

```
slbuild(model)
```

```
Starting build procedure for: rtwdemo_counter
Successful completion of code generation for: rtwdemo_counter
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_counter	Code generated	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 26.094s

Obtain the build directory information.

```
dirInfo = RTW.getBuildDir(model);
```

Examine the generated makefile.

```
type(fullfile(dirInfo.BuildDirectory, [model '.mk']))
```

```

```

### Restore

You can optionally remove the folder you created earlier.

```

cd ..
rmdir('toolchain_demo', 's')

```

Reset the TargetRegistry to remove the toolchain that you registered above.

```

RTW.TargetRegistry.getInstance('reset');

```

Close the model.

```

close_system(model, 0)

```

Clear the variables introduced in the workspace.

```

clear INC K LIMIT RESET model tc cs toolchain

```

## Customize Build Process with `STF_make_rtw_hook` File

The build process lets you supply optional custom code in hook methods that are executed at specified points in the code generation and make process. You can use hook methods to add target-specific actions to the build process.

### `STF_make_rtw_hook` File

You can modify hook methods in a file generically referred to as `STF_make_rtw_hook.m`, where `STF` is the name of a system target file, such as `ert` or `mytarget`. This file implements a function, `STF_make_rtw_hook`, that dispatches to a specific action, depending on the `hookMethod` argument passed in.

The build process calls `STF_make_rtw_hook`, passing in the `hookMethod` argument and other arguments. You implement only those hook methods that your build process requires.

If your model contains reference models, you can implement an `STF_make_rtw_hook.m` for each reference model as required. The build process calls each `STF_make_rtw_hook` for reference models, processing these files recursively (in dependency order).

### Conventions for Using the `STF_make_rtw_hook` File

For the build process to call the `STF_make_rtw_hook`, check that the following conditions are met:

- The `STF_make_rtw_hook.m` file is on the MATLAB path.
- The file name is the name of your system target file (`STF`), appended to the text `_make_rtw_hook.m`. For example, if you generate code with a custom system target file `mytarget.tlc`, name your hook file `mytarget_make_rtw_hook.m`, and name the hook function implemented within the file `mytarget_make_rtw_hook`.
- The hook function implemented in the file uses the function prototype described in “`STF_make_rtw_hook.m` Function Prototype and Arguments” on page 87-35.

### `STF_make_rtw_hook.m` Function Prototype and Arguments

The function prototype for `STF_make_rtw_hook` is:

```
function STF_make_rtw_hook(hookMethod, modelName, rtwRoot, templateMakefile,
 buildOpts, buildArgs, buildInfo)
```

The arguments are defined as:

- `hookMethod`: Character vector specifying the stage of build process from which the `STF_make_rtw_hook` function is called. The following flow chart summarizes the build process, highlighting the hook points. Valid values for `hookMethod` are `'entry'`, `'before_tlc'`, `'after_tlc'`, `'before_make'`, `'after_make'`, `'exit'`, and `'error'`. The `STF_make_rtw_hook` function dispatches to the relevant code with a `switch` statement.

- `modelName`: Character vector specifying the name of the model. Valid at all stages of the build process.
- `rtwRoot`: Reserved.
- `templateMakefile`: Name of template makefile.
- `buildOpts`: A MATLAB structure that contains the Boolean field `codeWasUpToDate`. Valid for the `'before_make'`, `'after_make'`, and `'exit'` stages only.
- `buildArgs`: Character vector containing the argument to `make_rtw`. When you invoke the build process, `buildArgs` is copied from the argument following `"make_rtw"` in the **Configuration Parameters + Code Generation + Make command** field.

For example, the following make arguments from the **Make command** field

```
make_rtw VAR1=0 VAR2=4
```

generate the following:

```
% make -f untitled.mk VAR1=0 VAR2=4
```

The `buildArgs` argument does not apply for toolchain approach builds because these builds do not allow adding make arguments to the `make_rtw` call. On the compiler command line, to provide custom definitions (for example, `VAR1=0 VAR2=4`) that apply for both TMF approach and toolchain approach builds, use the **Configuration Parameters > Code Generation > Custom Code > Defines** field.

- `buildInfo`: The `RTW.BuildInfo` object that contains information for compiling and linking generated code. Available only for the `'after_tlc'`, `'before_make'`, `'after_make'`, and `'exit'` stages. The information in the object at the end of the `'after_tlc'` stage might not be complete. In later stages, the `'before_make'` and `'after_make'` hook methods can also add information to the object. For more information about using the `RTW.BuildInfo` object, see “Code Compilation Customization”.

## Applications for STF\_make\_rtw\_hook.m

This section shows how you can use the `STF_make_rtw_hook.m` hook methods.

In general, use the `'entry'` hook to initialize the build process, for example, to change or validate settings before code is generated. One application for the `'entry'` hook is to rerun the auto-configuration script that initially ran at target selection time to compare model parameters before and after the script executes, for validation purposes.

The other hook points, `'before_tlc'`, `'after_tlc'`, `'before_make'`, `'after_make'`, `'exit'`, and `'error'` are useful for interfacing with external tool chains, source control tools, and other environment tools.

For example, you can use the `STF_make_rtw_hook.m` file at a stage after `'entry'` to obtain the path to the build folder. At the `'exit'` stage, you can then locate generated code files within the build folder and check them into your version control system. You can use `'error'` to clean up static or global data used by the hook function when an error occurs during code generation or the build process.

---

**Note** The build process temporarily changes the MATLAB working folder to the build folder for stages `'before_make'`, `'after_make'`, `'exit'`, and `'error'`. Your `STF_make_rtw_hook.m` file must not make incorrect assumptions about the location of the build folder. At a point after the `'entry'` stage, you can obtain the path to the build folder. In the following MATLAB code example, the build folder path is returned as a character vector to the variable `buildDirPath`.

```
buildDirPath = rtwprivate('get_makertwsettings',gcs,'BuildDirectory');
```

---

**Note** Do not use the `STF_make_rtw_hook.m` file to change the model configuration. For example, do not use a hook method to:

- Switch between model variants.
- Call the `set_param` function.

Changing the model configuration might produce unexpected code generation results.

---

## Control Code Regeneration Using STF\_make\_rtw\_hook.m

When you rebuild a model, by default, the build process performs checks to determine whether changes to the model or relevant settings require regeneration of the top model code. (For details on

the criteria, see “Control Regeneration of Top Model Code” on page 56-35.) If the checks determine that top model code generation is required, the build process fully regenerates and compiles the model code. If the checks indicate that the top model generated code is current with respect to the model, and model settings do not require full regeneration, the build process omits regeneration of the top model code.

Regardless of whether the top model code is regenerated, the build process subsequently calls the build process hooks, including *STF\_make\_rtw\_hook* functions and the post code generation command. The following mechanisms allow you to perform actions related to code regeneration in the *STF\_make\_rtw\_hook* functions:

- To force code regeneration, use the following function call from the 'entry' hook:

```
rtw.targetNeedsCodeGen('set', true);
```

- In hooks from 'before\_tlc' through 'exit', the *buildOpts* structure passed to the hook has a Boolean field *codeWasUpToDate*. The field is set to *true* if model code was up to date and code was not regenerated, or *false* if code was not up to date and code was regenerated. You can customize hook actions based on the value of this field. For example:

```
...
case 'before_tlc'
 if buildOpts.codeWasUpToDate
 %Perform hook actions for up to date model
 else
 %Perform hook actions for full code generation
 end
end
...
```

## Use *STF\_make\_rtw\_hook.m* for Your Build Procedure

To create a custom *STF\_make\_rtw\_hook* hook file for your build procedure, copy and edit the example *ert\_make\_rtw\_hook.m* file, which is located in the folder *matlabroot/toolbox/coder/embeddedcoder* (open), as follows:

- 1 Copy *ert\_make\_rtw\_hook.m* to a folder in the MATLAB path. Rename it in accordance with the naming conventions described in “Conventions for Using the *STF\_make\_rtw\_hook* File” on page 87-35. For example, to use it with the GRT target *grt.tlc*, rename it to *grt\_make\_rtw\_hook.m*.
- 2 Rename the *ert\_make\_rtw\_hook* function within the file to match the file name.
- 3 Implement the hooks that you require by adding code to case statements within the *switch hookMethod* statement.

## Hook Method *after\_tlc*

The *after\_tlc* hook method is available solely for backwards compatibility.

The format of the generated code during the *after\_tlc* stage is not the final format.

### Related Examples

- “Customize Build Process with *sl\_customization.m*” on page 87-39

## Customize Build Process with `sl_customization.m`

The Simulink customization file `sl_customization.m` is a mechanism that allows you to use MATLAB to customize the build process interface. The Simulink software reads the `sl_customization.m` file, if present on the MATLAB path, when it starts and the customizations specified in the file are applied to the Simulink session. For more information on the `sl_customization.m` customization file, see “Register Customizations with Simulink”.

### The `sl_customization.m` File

The `sl_customization.m` file can be used to register installation-specific hook functions to be invoked during the build process. The hook functions that you register through `sl_customization.m` complement System Target File (STF) hooks (described in “Customize Build Process with `STF_make_rtw_hook` File” on page 87-35) and post-code generation commands (described in “Customize Post-Code-Generation Build Processing” on page 87-7).

The following figure shows the relationship between installation-level hooks and the other available mechanisms for customizing the build process.

## Register Build Process Hook Functions Using `sl_customization.m`

To register installation-level hook functions that are invoked during the build process, you create a MATLAB function called `sl_customization.m` and include it on the MATLAB path of the Simulink installation that you want to customize. The `sl_customization` function accepts one argument: a handle to a customization manager object. For example,

```
function sl_customization(cm)
```

As a starting point for your customizations, the `sl_customization` function must first get the default (factory) customizations, using the following assignment statement:

```
hObj = cm.RTWBuildCustomizer;
```

You then invoke methods to register your customizations. The customization manager object includes the following method for registering build process hook customizations:

- `addUserHook(hObj, hookType, hook)`

Registers the MATLAB hook script or function specified by `hook` for the build process stage represented by `hookType`. The valid values for `hookType` are `'entry'`, `'before_tlc'`, `'after_tlc'`, `'before_make'`, `'after_make'`, and `'exit'`.

Use this method to register installation-specific hook functions in your instance of the `sl_customization` function.

The Simulink software reads the `sl_customization.m` file when it starts. If you subsequently change the file, you must restart the Simulink session or enter the following command in the Command Window to enable the changes:

```
sl_refresh_customizations
```

## Variables Available for `sl_customization.m` Hook Functions

The following variables are available for `sl_customization.m` hook functions to use:

- `modelName` — The name of the Simulink model (valid for all stages)
- `dependencyObject` — An object containing the dependencies of the generated code (valid only for the `'after_make'` stage)

A hook script can directly access the valid variables. A hook function can pass the valid variables as arguments to the function. For example:

```
hObj.addUserHook('after_make', 'afterMakeFunction(modelName,dependencyObject)');
```

## Example of Build Process Customization with `sl_customization.m`

The `sl_customization.m` file shown in the example, **`sl_customization.m` for Build Process Customizations**, uses the `addUserHook` method to specify installation-specific build process hooks to be invoked at the `'entry'` and `'after_tlc'` stages of the build process. For the hook function source code, see the **`CustomRTWEntryHook.m`** and **`CustomRTWPostProcessHook.m`** examples.

### Example 87.1. `sl_customization.m` for Build Process Customizations

```
function sl_customization(cm)
% Register user customizations

% Get default (factory) customizations
hObj = cm.RTWBuildCustomizer;

% Register build process hooks
hObj.addUserHook('entry', 'CustomRTWEntryHook(modelName)');
hObj.addUserHook('after_tlc', 'CustomRTWPostProcessHook(modelName)');

end
```

### Example 87.2. `CustomRTWEntryHook.m`

```
function [str, status] = CustomRTWEntryHook(modelName)
str = sprintf('Custom entry hook for model ''%s.''',modelName);
disp(str)
status =1;
```

### Example 87.3. `CustomRTWPostProcessHook.m`

```
function [str, status] = CustomRTWPostProcessHook(modelName)
str = sprintf('Custom post process hook for model ''%s.''',modelName);
```

```
disp(str)
status =1;
```

If you include the above three files on the MATLAB path of the Simulink installation that you want to customize, the coded hook function messages appear in the displayed output for builds. For example, if you open the ERT-based model `rtwdemo_udt`, open the **Code Generation** pane of the Configuration Parameters dialog box, and press **Ctrl+B** to initiate a build, the following messages are displayed:

```
>> rtwdemo_udt

Starting build procedure for model: rtwdemo_udt
Custom entry hook for model 'rtwdemo_udt.'
Custom post process hook for model 'rtwdemo_udt.'
Successful completion of build procedure for model: rtwdemo_udt
>>
```

## Replace STF\_rtw\_info\_hook Supplied Target Data

Prior to MATLAB Release 14, custom targets supplied target-specific information with a hook file (referred to as *STF\_rtw\_info\_hook.m*). The *STF\_rtw\_info\_hook* specified properties such as word sizes for integer data types (for example, char, short, int, and long), and C implementation-specific properties of the custom target.

The *STF\_rtw\_info\_hook* mechanism has been replaced by the **Hardware Implementation** pane of the Configuration Parameters dialog box. Using this dialog box, you can specify properties that were formerly specified in your *STF\_rtw\_info\_hook* file.

For backward compatibility, existing *STF\_rtw\_info\_hook* files are available. However, you should convert your target and models to use of the **Hardware Implementation** pane. See “Configure Production and Test Hardware”.

## Custom Targets

A custom target is a software package that you create to deploy MATLAB and Simulink designs to target hardware. Using the package, you can perform tasks to optimize, prototype, verify, and deploy an application to your hardware. This table lists tasks that you can perform.

Task	See
Generate code for a specific processor.	“Customize System Target Files” on page 88-18 “Target Platform Device Customization”
Optimize generated code by using a processor-specific code-replacement library.	“Code Replacement”
Integrate real-time operating systems and device drivers.	“Device Drivers” on page 88-71
Build, deploy, download, and run the application on target hardware.	“Generated Code Compilation”
Tune parameters and monitor target application signals during an external mode simulation.	“External Mode Simulation by Using XCP Communication” on page 57-7 “Customize XCP Server Software” on page 57-42
Perform code execution profiling through a processor-in-the-loop (PIL) simulation.	“Code Execution Profiling with SIL and PIL” on page 76-2 “Set Up PIL Connectivity by Using target Package” on page 82-50
Test numerical equivalence between your MATLAB code or Simulink model and the generated code by running a PIL simulation.	“Set Up PIL Connectivity by Using target Package” on page 82-50 “Configure and Run PIL Simulation” on page 82-26

You can also create custom targets that are based on MathWorks reference targets. For example, see:

- “Embedded Coder Support Package for ARM Cortex-A Processors”
- “Embedded Coder Support Package for ARM Cortex-M Processors”

- “Support C++ Class Interface Control”

## Sample Custom Targets

There are technical solutions on the MathWorks Web site that you can use as a starting point to create your own target solution. The solutions provide guides to the following tasks for creating custom targets:

- Methods of embedding code onto a custom processor
- Creating a system target file
- Customizing the makefile and main file
- Adding compiler, chip, and board specific information
- Integrating legacy code and device drivers
- Creating blocks and libraries
- Implementing processor-in-the-loop (PIL) testing.

Consider these options:

- Download the embedded targets development guide zip file from this web page:

Is there an example guide on developing an embedded target...?

The zip file provides example files and a guide to developing a custom embedded target. The guide is divided into two parts, one on creating a generic custom target and another on creating a target for the Freescale™ S12X processor using the Cosmic Compiler.

Read the example guide along with this document to understand the tasks for developing embedded targets.

- For more detailed example files for specific processors, see:
  - Is there an example Freescale S12X target... using the Cosmic Compiler?
  - Is there an example Freescale S12X target... using the CodeWarrior Compiler?

These example kits contain example models, code generation files, and instruction guides on generating and testing code for the processor. The Cosmic example illustrates the use of the target connectivity API for processor-in-the-loop (PIL) testing. The CodeWarrior example does not have PIL but shows CAN Calibration Protocol (CCP) and Simulink external mode.

The intent of the example kits is to provide working examples that you can use as a base to create your own target solution. The intent is not to provide a full featured and maintained Embedded Target product like those provided by MathWorks or third-party products, as listed on the Embedded Coder Hardware Support Web page.

- You can watch a video that shows an overview of the example kit [www.mathworks.com/videos/programming-the-freescale-s12x-target-68811.html](http://www.mathworks.com/videos/programming-the-freescale-s12x-target-68811.html).
- For an example target for the ARM9 (STR9) processor, see [Is there an example ARM9 \(STR9\) target... using the GNU ARM Compiler and Hitex STR9-comStick?](#)

If you have questions on specific targets, email [mytarget@mathworks.com](mailto:mytarget@mathworks.com).

The example kits and this document describe Embedded Coder features such as customized ert system target files and processor-in-the-loop testing, but you can study the examples as a starting point for use with Simulink Coder targets.

## Target Development Folders, Files, and Builds

Target development mechanics work with a number of folder and file types. The following topics provide the information to develop custom targets, configure folder usage, and use custom targets in the build process.

### Folder and File Naming Conventions

You can use a single folder for your custom target files, or if desired you can use subfolders, for example containing files associated with specific development environments or tools.

For a custom target implementation, the recommended folder and file naming conventions are

- Use *only* lowercase in folder names, filenames, and extensions.
- Do not embed spaces in folder names. Spaces in folder names cause errors with many third-party development environments.
- Include desired folders in the MATLAB path
- Do *not* place your custom target folder anywhere in the MATLAB folder tree (that is, in or under the *matlabroot* folder). If you place your folder under *matlabroot* you risk losing your work if you install a new MATLAB version (or reinstall the current version).

The following sections explain how to organize your target folders and files and add them to your MATLAB path. They also provide high-level descriptions of the files.

In this document, *mytarget* is a placeholder name that represents folders and files that use the target's name. The names *dev\_tool1*, *dev\_tool2*, and so on represent subfolders containing files associated with development environments or tools. This document describes an example structure where the folder *mytarget* contains subfolders for *mytarget*, *blocks*, *dev\_tool1*, *dev\_tool2*. The top level folder *mytarget* is the *target root folder*.

### Components of a Custom Target

- “Overview” on page 88-5
- “Code Components” on page 88-6
- “Control Files” on page 88-7

#### Overview

The components of a custom target are files located in a hierarchy of folders. The top-level folder in this structure is called the *target root folder*. The target root folder and its contents are named, organized, and located on the MATLAB path according to conventions described in “Folder and File Naming Conventions” on page 88-5.

The components of a custom target include

- Code components: C source code that supervises and supports execution of generated model code.
- Control files:
  - A system target file to control the code generation process.

- File(s) to control the building of an executable from the generated code. In a traditional make-based environment, a template makefile (TMF) generates a makefile for this purpose. Another approach is to generate project files in support of a modern integrated development environment (IDE) such as the Freescale Semiconductor CodeWarrior IDE.
- Hook files: Optional TLC and MATLAB program files that can be invoked at well-defined stages of the build process. Hook files let you customize the build process and communicate information between various phases of the process.
- Other target files: Files that let you integrate your target into the MATLAB environment. For example, you can provide an `info.xml` file to make your target block libraries and examples available from a MATLAB session.

The next sections introduce key concepts and terminology you need to know to develop each component. References to more detailed information sources are provided.

## Code Components

An executable program containing code generated from a Simulink model consists of a number of code modules and data structures. These fall into two categories: application components and execution support files.

### Application Components

Application components are those which are specific to a particular model; they implement the functions represented by the blocks in the model. Application components are not specific to the target. Application components include

- Modules generated from the model
- User-written blocks (S-functions)
- Parameters of the model that are visible, and can be interfaced to, external code

### Execution Support Files

A number of code modules and data structures, referred to collectively as the *execution support files*, are responsible for managing and supporting the execution of the generated program. The execution support files modules are not automatically generated. Depending on the requirements of your target, you must implement certain parts of the execution support files. Execution Support Files summarizes the execution support files.

### Execution Support Files

You Provide...	The Code Generator Provides...
Customized main program	Generic main program
Timer interrupt handler to run model	Execution engine and integration solver (called by timer interrupt handler)
Other interrupt handlers	Example interrupt handlers (Asynchronous Interrupt blocks)
Device drivers	Example device drivers
Data logging, parameter tuning, signal monitoring, and external mode support	Data logging, parameter tuning, signal monitoring, and external mode APIs

## User-Written Execution Support Files

The code generator provides most of the execution support files. Depending on the requirements of your target, you must implement some or all of the following elements:

- A timer *interrupt service routine* (ISR). The timer runs at the program's base sample rate. The timer ISR is responsible for operations that must be completed within a single clock period, such as computing the current output sample. The timer ISR usually calls the `rt_OneStep` function.

If you are targeting a real-time operating system (RTOS), your generated code usually executes under control of the timing and task management mechanisms provided by the RTOS. In this case, you may not have to implement a timer ISR.

- The *main program*. Your main program initializes the blocks in the model, installs the timer ISR, and executes a background task or loop. The timer periodically interrupts the main loop. If the main program is designed to run for a finite amount of time, it is also responsible for cleanup operations — such as memory deallocation and masking the timer interrupt — before terminating the program.

If you are targeting a real-time operating system (RTOS), your main program most likely spawns tasks (corresponding to the sample rates used in the model) whose execution is timed and controlled by the RTOS.

Your main program typically is based on a generated or static main program. For details on the structure of the execution support files, code execution, and guidelines for customizing main programs, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 68-2.

- *Device drivers*. Drivers communicate with I/O devices on your target hardware. In production code, device drivers are normally implemented as inlined S-functions.
- *Other interrupt handlers*. If your models need to support asynchronous events, such as hardware generated interrupts and asynchronous read and write operations, you must supply interrupt handlers. The Interrupt Templates library provides examples.
- *Data logging, parameter tuning, signal monitoring, and external mode support*. It is atypical to implement rapid prototyping features such as external mode support in an embedded target. However, it is possible to support these features by using standard code generator APIs. See “Calibration and Measurement” for details.

## Control Files

The code generation and build process is directed by a number of TLC and MATLAB files collectively called *control files*. This section introduces and summarizes the main control files.

### Top-Level Control File (`make_rtw`)

The build process is initiated when you press **Ctrl+B**. At this point, the build process parses the **Make command** field of the **Code Generation** pane of the Configuration Parameters dialog box, expecting to find the name of a MATLAB command that controls the build process (as well as optional arguments to that command). The default command is `make_rtw`, and the default top-level control file for the build process is `make_rtw.m`.

---

**Note** `make_rtw` is an internal MATLAB command used by the build process. Normally, target developers do not need detailed knowledge of how `make_rtw` works. (The details for target developers are described in “Target Development and the Build Process” on page 88-13.) You should not invoke `make_rtw` directly from MATLAB code, and you should not customize `make_rtw.m`.

---

The `make_rtw.m` file contains the logic required to execute your target-specific control files, including a number of hook points for execution of your custom code. `make_rtw` does the following:

- Passes optional arguments in to the build process
- Performs required preprocessing before code generation
- Executes the system target file to perform code generation (and optional HTML report generation)
- Processes the TMF to generate a makefile
- Invokes a make utility to execute the makefile and build an executable
- Performs required post-processing (such as generating calibration data files or downloading the generated executable to the target)

### System Target File

The Target Language Compiler (TLC) generates target-specific C or C++ code from a partial description of your Simulink block diagram (`model.rtw`). The Target Language Compiler reads `model.rtw` and executes a program consisting of several target files (`.tlc` files.) The system target file, at the top level of this program, controls the code generation process. The output of this process is a number of source files, which are fed to your development system's make utility.

You need to create a customized system target file to set code generation parameters for your target. You should copy, rename, and modify the standard ERT system target file (`matlabroot/rtw/c/ert/ert.tlc`).

The detailed structure of the system target file is described in “Customize System Target Files” on page 88-18.

---

**Note** The system target file selects whether the target supports the toolchain approach or template makefile approach for code generation. See “Customize System Target Files” on page 88-18.

---

### Template Makefile (TMF)

A TMF provides information about your model and your development system. The build process uses this information to create a makefile (`.mk` file) that builds an executable program.

Some targets implement more than one TMF, in order to support multiple development environments (for example, two or more cross-compilers) or multiple modes of code generation (for example, generating a binary executable versus generating a project file for your compiler).

The Embedded Coder software provides a large number of TMFs suitable for different types of development computer systems. These TMFs are located in `matlabroot/toolbox/coder/compile/tmf`. The standard TMFs are described in “Template Makefiles and Make Options”.

The detailed structure of the TMF is described in “Customize Template Makefiles” on page 88-43.

---

**Note** The system target file selects whether the target supports the toolchain approach or template makefile approach for code generation. See “Customize System Target Files” on page 88-18.

---

## Hook Files

The build process allows you to supply optional *hook files* that are executed at specified points in the code generation and make process. You can use hook files to add target-specific actions to the build process.

The hook files must follow well-defined naming and location requirements. “Folder and File Naming Conventions” on page 88-5 describes these requirements.

## Key Folders Under Target Root (mytarget)

- “Target Root Folder (mytarget)” on page 88-9
- “Target Folder (mytarget/mytarget)” on page 88-9
- “Target Block Folder (mytarget/blocks)” on page 88-9
- “Development Tools Folder (mytarget/dev\_tool1, mytarget/dev\_tool2)” on page 88-10
- “Target Source Code Folder (mytarget/src)” on page 88-10

### Target Root Folder (mytarget)

This folder contains the key subfolders for the target (see “Folder and File Naming Conventions” on page 88-5). You can also locate miscellaneous files (such as a `readme` file) in the target root folder. The following sections describe required and optional subfolders and their contents.

### Target Folder (mytarget/mytarget)

This folder contains files that are central to the target, such as the system target file (STF) and template makefile (TMF). “Key Files in Target Folder (mytarget/mytarget)” on page 88-11 summarizes the files that should be stored in `mytarget/mytarget`, and provides pointers to detailed information about these files.

---

**Note** `mytarget/mytarget` should be on the MATLAB path.

---

### Target Block Folder (mytarget/blocks)

If your target includes device drivers or other blocks, locate the block implementation files in this folder. `mytarget/blocks` contains

- Compiled block MEX-files
- Source code for the blocks
- TLC inlining files for the blocks
- Library models for the blocks (if you provide your blocks in one or more libraries)

---

**Note** `mytarget/blocks` should be on the MATLAB path.

---

You can also store example models and supporting files in `mytarget/blocks`. Alternatively, you can create a `mytarget/mytargetdemos` folder, which should also be on the MATLAB path.

To display your blocks in the standard Simulink Library Browser and/or integrate your example models into the MATLAB session environment, you can create the files described below and store them in `mytarget/blocks`.

### **mytarget/blocks/slblocks.m**

This file allows a group of blocks to be integrated into the Simulink Library and Simulink Library Browser.

#### **Example 88.1. Example slblocks.m File**

```
function blkStruct = slblocks
% Information for "Blocksets and Toolboxes" subsystem
blkStruct.Name = sprintf('Embedded Target\n for MYTARGET');
blkStruct.OpenFcn = 'mytargetlib';
blkStruct.MaskDisplay = 'disp(''MYTARGET'')';

% Information for Simulink Library Browser
Browser(1).Library = 'mytargetlib';
Browser(1).Name = 'Embedded Target for MYTARGET';
Browser(1).IsFlat = 1;% Is this library "flat" (i.e. no subsystems)?

blkStruct.Browser = Browser;
```

### **mytarget/blocks/demos.xml**

This file provides information about the components, organization, and location of example models. MATLAB software uses this information to place the example in the MATLAB session environment.

#### **Example 88.2. Example demos.xml File**

```
<?xml version="1.0" encoding="utf-8"?>
<demos>
 <name>Embedded Target for MYTARGET</name>
 <type>simulink</type>
 <icon>$toolbox/matlab/icons/boardicon.gif</icon>
 <description source = "file">mytarget_overview.html</description>

 <demosession>
 <label>Multirate model</label>
 <demoitem>
 <label>MYTARGET demo</label>
 <file>mytarget_overview.html</file>
 <callback>mytarget_model</callback>
 </demoitem>
 </demosession>
</demos>
```

### **Development Tools Folder (mytarget/dev\_tool1, mytarget/dev\_tool2)**

These folders contain files associated with specific development environments or tools (`dev_tool1`, `dev_tool2`, etc.). Normally, your target supports at least one such development environment and invokes its compiler, linker, and other utilities during the build process. `mytarget/dev_tool1` includes linker command files, startup code, hook functions, and other files required to support this process.

For each development environment, you should provide a separate folder.

### **Target Source Code Folder (mytarget/src)**

This folder is optional. If the complexity of your target requires it, you can use `mytarget/src` to store common source code and configuration code (such as boot and startup code).

## Key Files in Target Folder (mytarget/mytarget)

- “Introduction” on page 88-11
- “mytarget.tlc” on page 88-11
- “mytarget.tmf” on page 88-11
- “mytarget\_genfiles.tlc” on page 88-11
- “mytarget\_main.c” on page 88-12
- “STF\_make\_rtw\_hook.m” on page 88-12
- “STF\_rtw\_info\_hook.m (obsolete)” on page 88-12
- “info.xml” on page 88-12
- “mytarget\_overview.html” on page 88-12

### Introduction

The target folder `mytarget/mytarget` contains key files in your target implementation. These include the system target file, template makefile, main program module, and optional M and TLC hook files that let you add target-specific actions to the build process. The following sections describe the key target folder files.

### mytarget.tlc

`mytarget.tlc` is the system target file. Functions of the system target file include

- Making the target visible in the System Target File Browser
- Definition of code generation options for the target (inherited and target-specific)
- Providing an entry point for the top-level control of the TLC code generation process

You should base your system target file on `ert.tlc`, the system target file provided by Embedded Coder software.

“Customize System Target Files” on page 88-18 gives detailed information on the structure of the system target file, and also gives instructions on how to customize a system target file to

- Display your target in the System Target File Browser
- Add your own target options to the Configuration Parameters dialog box
- Tailor the code generation and build process to the requirements of your target

### mytarget.tmf

`mytarget.tmf` is the template makefile for building an executable for your target.

For basic information on the structure and operation of template makefiles, see “Customize Template Makefiles” on page 88-43.

### mytarget\_genfiles.tlc

This file is optional. `mytarget_genfiles.tlc` is useful as a central file from which to invoke target-specific TLC files that generate additional files as part of your target build process. For example, your target may create sub-makefiles or project files for a development environment, or command scripts for a debugger to do automatic downloads. See “Using `mytarget_genfiles.tlc`” on page 88-30 for details.

## mytarget\_main.c

A main program module is required for your target. To provide a main module, you can either

- Modify the `rt_main.c` or `rt_cppclass_main.cpp` module provided by the software
- Generate `mytarget_main.c` or `.cpp` during the build process

For a description of the operation of main programs, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 68-2. The section also contains guidelines for generating and modifying a main program module.

## STF\_make\_rtw\_hook.m

`STF_make_rtw_hook.m` is an optional hook file that you can use to invoke target-specific functions or executables at specified points in the build process. `STF_make_rtw_hook.m` implements a function that dispatches to a specific action depending on the `method` argument that is passed into it.

“Customize Build Process with `STF_make_rtw_hook` File” describes the operation of the `STF_make_rtw_hook.m` hook file in detail.

## STF\_rtw\_info\_hook.m (obsolete)

Prior to Release 14, custom targets supplied target-specific information with a hook file (referred to as `STF_rtw_info_hook.m`). The `STF_rtw_info_hook` specified properties such as word sizes for integer data types (for example, `char`, `short`, `int`, and `long`), and C implementation-specific properties of the custom target.

The `STF_rtw_info_hook` mechanism has been replaced by the **Hardware Implementation** pane of the Configuration Parameters dialog box. Using this dialog box, you can specify the properties that were formerly specified in your `STF_rtw_info_hook` file.

For backward compatibility, existing `STF_rtw_info_hook` files are still available. However, you should convert your target and models to use the **Hardware Implementation** pane. See “Configure Run-Time Environment Options”.

## info.xml

This file provides information to MATLAB software that specifies where to display the target toolbox in the MATLAB session environment. For more information, see “Display Custom Documentation”.

## mytarget\_overview.html

By convention, this file serves as home page for the target examples.

The `<description>` field in `demos.xml` should point to `mytarget_overview.html` (see “mytarget/blocks/demos.xml” on page 88-10).

### Example mytarget\_overview.html File

```

<html>
<head><title>Embedded Target for MYTARGET</title></head><body>
<p style="color:#990000; font-weight:bold; font-size:x-large">Embedded Target
for MYTARGET Example Model</p>

<p>This example provides a simple model that allows you to generate an executable
for a supported target board. You can then download and run the executable and
set breakpoints to study and monitor the execution behavior.</p>

```

```
</body>
</html>
```

## Additional Files for Externally Developed Targets

- “Introduction” on page 88-13
- “mytarget/mytarget/mytarget\_setup.m” on page 88-13
- “mytarget/mytarget/doc” on page 88-13

### Introduction

If you are developing an embedded target that is not installed into the MATLAB tree, you should provide a target setup script and target documentation within `mytarget/mytarget`, for the convenience of your users. The following sections describe the required materials and where to place them.

### mytarget/mytarget/mytarget\_setup.m

This file script adds paths for your target to the MATLAB path. Your documentation should instruct users to run the script when installing the target.

You should include a call to the MATLAB function `savepath` in your `mytarget_setup.m` script. This function saves the added paths, so users need to run `mytarget_setup.m` only once.

The following code is an example `mytarget_setup.m` file.

```
function mytarget_setup()
curpath = pwd;
tgtpath = curpath(1:end-length('\mytarget'));
addpath(fullfile(tgtpath, 'mytarget'));
addpath(fullfile(tgtpath, 'dev_tool1'));
addpath(fullfile(tgtpath, 'blocks'));
addpath(fullfile(tgtpath, 'mytargetdemos'));
savepath;
disp('MYTARGET Target Path Setup Complete.');
```

### mytarget/mytarget/doc

You should put the documentation related to your target in the folder `mytarget/mytarget/doc`.

## Target Development and the Build Process

- “About the Build Process” on page 88-13
- “Build Process Phases and Information Passing” on page 88-14
- “Additional Information Passing Techniques” on page 88-15

### About the Build Process

To develop an embedded target, you need a thorough understanding of the build process. Your embedded target uses the build process and may require you to modify or customize the process. A general overview of code generation and the build process is given in “Code Generation” and “Build Process”.

This section supplements that overview with a description of the build process as customized by the Embedded Coder software. The emphasis is on points in the process where customization hooks are available and on passing information between different phases of the process.

This section concludes with “Additional Information Passing Techniques” on page 88-15, describing assorted tips and tricks for passing information during the build process.

### Build Process Phases and Information Passing

It is important to understand where (and when) the build process obtains required information. Sources of information include

- The *model*.rtw file, which provides information about the generating model. The information in *model*.rtw is available to target TLC files.
- The code generation panes of the Configuration Parameters dialog box. Options (both general and target-specific) are provided through check boxes, menus, and edit fields. You can associate options with TLC variables in the *rtwoptions* data structure. Use the **Configuration Parameters > Code Generation > Custom Code > Code information > Defines** field to define makefile tokens .
- The selected toolchain (for toolchain approach builds) or selected template makefile .tmf (for template makefile approach builds); these generate the model-specific makefile.
- Environment variables on the host computer. Environment variables provide additional information about installed development tools.
- Other target-specific files such as target-related TLC files, linker command files, or project files.

It is also important to understand the several phases of the build process and how to pass information between the phases. The build process comprises several high-level phases:

- Execution of the top-level file (*slbuild.m*) to sequence through the build process for a target
- Conversion of the model into the TLC input file (*model*.rtw)
- Generation of the target code by the TLC compiler
- Compilation of the generated code with *make* or other utilities
- Transmission of the final generated executable to the target hardware with a debugger or download utility

It is helpful to think of each phase of the process as a different “environment” that maintains its own data. These environments include

- MATLAB code execution environment (MATLAB)
- Simulink
- Target Language Compiler execution environment
- makefile
- Development environments such as and IDE or debugger

In each environment, you might get information from the various sources mentioned above. For example, during the TLC phase, execute MATLAB file might execute to obtain information from the MATLAB environment. Also, a given phase may generate information for a subsequent phase.

See “Key Files in Target Folder (mytarget/mytarget)” on page 88-11 for details on the available MATLAB file and TLC hooks for information passing, with code examples.

## Additional Information Passing Techniques

This section describes a number of useful techniques for passing information among different phases of the build process.

### tlcvariable Field in rtwoptions Structure

Parameters on the code generation panes of the Configuration Parameters dialog box can be associated with a TLC variable, and specified in the `tlcvariable` field of the option's entry in the `rtwoptions` structure. The variable value is passed on the command line when TLC is invoked. This provides a way to make code generation parameters and their values available in the TLC phase.

See “System Target File Structure” on page 88-18 for further information.

### makevariable Field in rtwoptions Structure

You can associate code generation parameters with a template makefile token, that you specify in the `makevariable` field of the option's entry in the `rtwoptions` structure. If a token of the same name as the `makevariable` name exists in the TMF, the token is updated with the option value when the final makefile is created. If the token does not exist in the TMF, the `makevariable` is passed in on the command line when make is invoked. Thus, in either case, the `makevariable` is available to the makefile.

See “System Target File Structure” on page 88-18 for further information.

### Accessing Host Environment Variables

You can access host shell environment variables at the MATLAB command line by entering the `getenv` command. For example:

```
getenv ('MSDEVDIR')
```

```
ans =
```

```
D:\Applications\Microsoft Visual Studio\Common\MSDev98
```

To access the same information from TLC, use the `FEVAL` directive to invoke `getenv`.

```
%assign eVar = FEVAL("getenv", "<varname>")
```

### Supplying Development Environment Information to Your Template Makefile

An embedded target must tie the build process to target-specific development tools installed on a host computer. For the make process to run these tools, the TMF must be able to determine the name of the tools, the path to the compiler, linker, and other utilities, and possibly the host operating system environment variable settings.

Require the end user to modify the target TMF. The user enters path information (such as the location of a compiler executable), and possibly host operating system environment variables, as make variables. This allows the TMF to be tailored to specific needs.

### Using MATLAB Application Data

Application data provides a way for applications to save and retrieve data stored with the GUI. This technique enables you to create what is essentially a user-defined property for an object, and use this property to store data for use in the build process. For more information, see `setappdata` and `getappdata`.

The following code examples illustrates the use of application data to pass information to TLC.

This file, `tlc2appdata.m`, stores the data passed in as application data under the name passed in (`appDataName`).

```
function k = tlc2appdata(appDataName,data)
 disp([mfilename,': ',appDataName,' ', data]);
 setappdata(0,appDataName,data);
 k = 0; % TLC expects a return value for FEVAL.
```

The following sample TLC file uses the FEVAL directive to invoke `tlc2appdata.m` to store arbitrary application data, under the name `z80`.

```
%% test.tlc
%%
%assign myApp = "z80"
%assign myData = "314159"
%assign dummy = FEVAL("tlc2appdata",myApp,myData)
```

To test this technique:

- 1 Create the `tlc2appdata.m` file as shown. Check that `tlc2appdata.m` is stored in a folder on the MATLAB path.
- 2 Create the TLC file as shown. Save it as `test.tlc`.
- 3 Enter the following command at the MATLAB prompt to execute the TLC file:

```
tlc test.tlc
```

- 4 Get the application data at the MATLAB prompt:

```
k = getappdata(0,'z80')
```

The function returns the value 314159.

- 5 Enter the following command.

```
who
```

Note that application data is not stored in the MATLAB workspace. Also observe that the `z80` data is not visible. Using application data in this way has the advantage that it does not clutter the MATLAB workspace. Also, it helps prevent you from accidentally deleting your data, since it is not stored directly in your workspace.

A real-world use of application data might be to collect information from the `model.rtw` file and store it for use later in the build process.

### Adding Block-Specific Information to the Makefile

The `rtwmakecfg` mechanism provides a method for inlined S-functions such as driver blocks to add information to the makefile. This mechanism is described in “Use `rtwmakecfg.m` API to Customize Generated Makefiles”.

## **See Also**

### **More About**

- “Custom Targets”

## Customize System Target Files

This section provides information on the structure of the system target file, guidelines for customizing a system target file, and a basic tutorial that helps you to produce a skeletal system target file.

### Control Code Generation With the System Target File

The system target file controls the code generation stage of the build process. The system target file also lets you control the presentation of your target to the end user. The system target file provides

- Definitions of variables that are fundamental to the build process, such as the value for the CodeFormat TLC variable
- The main entry point to the top-level TLC program that generates code
- Target information for display in the System Target File Browser
- A mechanism for defining target-specific code generation options (and other parameters related to the build process) and for displaying them in the Configuration Parameters dialog box
- A mechanism for inheriting options from another target (such as the Embedded Real-Time (ERT) target)

Note that, although the system target file is a Target Language Compiler (TLC) file, it contains embedded MATLAB code. Before creating or modifying a system target file, you should acquire a working knowledge of TLC and of the MATLAB language. “Target Language Compiler” and “Scripts vs. Functions” describe the features and syntax of both the TLC and MATLAB languages.

While reading this section, you may want to refer to the system target files provided with the code generator. Most of these files are stored in the target-specific folders under *matlabroot*/rtw/c (open). Additional system target files are stored under *matlabroot*/toolbox/rtw/targets (open).

### System Target File Naming and Location Conventions

A system target file must be located in a folder on the MATLAB path for the target to be displayed in the System Target File Browser and invoked in the build process. Follow the location and naming conventions for system target files and related target files given in “Folder and File Naming Conventions” on page 88-5.

### System Target File Structure

- “Overview” on page 88-19
- “Header Comments” on page 88-20
- “TLC Configuration Variables” on page 88-21
- “TLC Program Entry Point and Related %includes” on page 88-21
- “RTW\_OPTIONS Section” on page 88-22
- “rtwgensettings Structure” on page 88-22
- “Additional Code Generation Options” on page 88-24
- “Model Reference Considerations” on page 88-24

## Overview

This section is a guide to the structure and contents of a system target file. The following listing shows the general structure of a system target file. Note that this is not a complete code listing of a system target file. The listing consists of excerpts from each of the sections that make up a system target file.

```

%%-----
%% Header Comments Section
%%-----
%% SYSTLC: Example Real-Time Target
%% TMF: my_target.tmf MAKE: make_rtw
%% Initial comments contain directives for STF Browser.
%% Documentation, date, copyright, and other info may follow.
 ...
%selectfile NULL_FILE
 ...
%%-----
%% TLC Configuration Variables Section
%%-----
%% Assign code format, language, target type.
%%
%assign CodeFormat = "Embedded-C"
%assign TargetType = "RT"
%assign Language = "C"
%%
%%-----
%% TLC Program Entry Point
%%-----
%% Call entry point function.
%include "codegenentry.tlc"
%%
%%-----
%% (OPTIONAL) Generate Files for Build Process
%%-----
%include "mytarget_genfiles.tlc"
%%-----
%% RTW_OPTIONS Section
%%-----
/%
BEGIN_RTW_OPTIONS
%% Define rtwoptions structure array. This array defines target-specific
%% code generation variables, and controls how they are displayed.
rtwoptions(1).prompt = 'example code generation options';
 ...
rtwoptions(6).prompt = 'Show eliminated blocks';
rtwoptions(6).type = 'Checkbox';
 ...
%-----%
% Configure RTW code generation settings %
%-----%
 ...
%%-----
%% rtwgensettings Structure
%%-----
%% Define suffix text for naming build folder here.
rtwgensettings.BuildDirSuffix = '_mytarget_rtw'
%% Callback compatibility declaration
rtwgensettings.Version = '1';

%% (OPTIONAL) target inheritance declaration
rtwgensettings.DerivedFrom = 'ert.tlc';
%% (OPTIONAL) other rtwGenSettings fields...
 ...
END_RTW_OPTIONS
%/
%%-----
%% targetComponentClass - MATHWORKS INTERNAL USE ONLY
%% REMOVE NEXT SECTION FROM USER_DEFINED CUSTOM TARGETS
%%-----

```

```

/%
BEGIN_CONFIGSET_TARGET_COMPONENT
targetComponentClass = 'Simulink.ERTTargetCC';
END_CONFIGSET_TARGET_COMPONENT
%/

```

If you are creating a custom target based on an existing system target file, you must remove the `targetComponentClass` section (bounded by the directives `BEGIN_CONFIGSET_TARGET_COMPONENT` and `END_CONFIGSET_TARGET_COMPONENT`). This section is reserved for the use of targets developed internally by MathWorks.

## Header Comments

These lines at the head of the file are formatted as TLC comments. They provide required information to the System Target File Browser and to the build process. Note that you must place the browser comments at the head of the file, before other comments or TLC statements.

The presence of the comments enables the code generator to detect system target files. When the System Target File Browser is opened, the code generator scans the MATLAB path for TLC files that have formatted header comments. The comments contain the following directives:

- **SYSTLC**: The descriptor that appears in the browser.
- **TMF**: Name of the template makefile (TMF) to use during build process. When the target is selected, this filename is displayed in the “Template makefile” field of the **Code Generation** pane of the Configuration Parameters dialog box.
- **MAKE**: make command to use during build process. When the target is selected, this command is displayed in the **Make command** field of the **Code Generation** pane of the Configuration Parameters dialog box.

The following header comments are from `matlabroot/rtw/c/ert/ert.tlc`.

```

%% SYSTLC: Embedded Coder TMF: ert_default_tmf MAKE: make_rtw
%% SYSTLC: Create Visual C/C++ Solution File for Embedded Coder\
%% TMF: RTW.MSVCCBuild MAKE: make_rtw
.
.
.

```

Each comment can only contain a maximum of two lines.

If you do not specify the TMF field in the system target file, the file is still valid. To change the value for the `TemplateMakefile` parameter, you can instead use the callback function specified by `rtwgensettings.SelectCallback`.

You can also use the callback function specified by `rtwgensettings.SelectCallback` to change the value for external mode parameters, `ExtMode`, `ExtModeTransport`, `ExtModeMexFile`, or `ExtModeIntrrfLevel`.

You can specify more than one group of directives in the header comments. Each such group is displayed as a different target configuration in the System Target File Browser. In the above example, the first two lines of code specify the default configuration of the ERT target. The next two lines specify a configuration that creates and builds a Microsoft Visual C++ Solution (.sln) file. The figure below shows how these configurations appear in the System Target File Browser.

System Target File:	Description:
asap2.tlc	ASAM-ASAP2 Data Definition Target
autosar.tlc	AUTOSAR
ert.tlc	Embedded Coder
ert.tlc	Create Visual C/C++ Solution File for Embedd
ert_shrllib.tlc	Embedded Coder (host-based shared library ta
grt.tlc	Generic Real-Time Target
grt.tlc	Create Visual C/C++ Solution File for Simuli
idelink_ert.tlc	IDE Link ERT
idelink_grt.tlc	IDE Link GRT
my_ert_target.tlc	My ERT-based Target
my_ert_target.tlc	Create Visual C/C++ Solution File for Embedd
realtime.tlc	Run on Target Hardware
rsim.tlc	Rapid Simulation Target

See “Create a Custom Target Configuration” on page 88-32 for an example of customized header comments.

### TLC Configuration Variables

This section of the system target file assigns global TLC variables that relate to the overall code generation process.

For an embedded target, in most cases you should simply use the global TLC variable settings used by the ERT target (`ert.tlc`). It is especially important that your system target file use the 'Embedded-C' value for the `CodeFormat` TLC variable and uses the corresponding `rtwgensettings.DerivedFrom = 'ert.tlc'` in the `RTW_OPTIONS` section of the TLC file. Verify that values are assigned to the following variables:

- **CodeFormat:** The `CodeFormat` TLC variable selects generated code features. The 'Embedded-C' value for this variable is used by the ERT target. Your ERT-based target should specify 'Embedded-C' as the value for `CodeFormat`. This selection is designed for production code, minimal memory usage, static memory allocation, and a simplified interface to generated code.

For information on other values for the `CodeFormat` TLC variable, see “Compare System Target File Support Across Products”.

- **Language:** The only valid value is `C`, which enables support for C or C++ code generation as specified by the configuration parameter `TargetLang`.
- **TargetType:** The code generator defines the preprocessor symbols `RT` and `NRT` to distinguish simulation code from real-time code. These symbols are used in conditional compilation. The `TargetType` variable determines whether `RT` or `NRT` is defined.

Most targets are intended to generate real-time code. They assign `TargetType` as follows.

```
%assign TargetType = "RT"
```

Some targets, such as the model reference simulation target, accelerated simulation target, `RSim` target, and S-function target, generate code for use in nonreal time only. Such targets assign `TargetType` as follows.

```
%assign TargetType = "NRT"
```

### TLC Program Entry Point and Related `%includes`

The code generation process normally begins with `codegenentry.tlc`. The system target file invokes `codegenentry.tlc` as follows.

```
%include "codegenentry.tlc"
```

---

**Note** `codegenentry.tlc` and the lower-level TLC files assume that `CodeFormat`, `TargetType`, and `Language` have been assigned. Set these variables before including `codegenentry.tlc`.

---

If you need to implement target-specific code generation features, you should include the TLC file `mytarget_genfiles.tlc` in your system target file. This file provides a mechanism for executing custom TLC code before and after invoking `codegenentry.tlc`. For information on this mechanism, see

- “Using `mytarget_genfiles.tlc`” on page 88-30 for an example of custom TLC code for execution after the main code generation entry point.
- “Target Development and the Build Process” on page 88-13 for general information on the build process, and for information on other build process customization hooks.

Another way to customize the code generation process is to call lower-level functions (normally invoked by `codegenentry.tlc`) directly, and include your own TLC functions at each stage of the process. This approach should be taken with caution. See “TLC Files” for more information.

The lower-level functions called by `codegenentry.tlc` are

- `genmap.tlc`: maps block names to corresponding language-specific block target files.
- `commonsetup.tlc`: sets up global variables.
- `commonentry.tlc`: starts the process of generating code.

### RTW\_OPTIONS Section

The `RTW_OPTIONS` section is bounded by the directives:

```
/%
 BEGIN_RTW_OPTIONS
 .
 .
 .
 END_RTW_OPTIONS
%/
```

The first part of the `RTW_OPTIONS` section defines an array of `rtwoptions` structures. This structure is discussed in “Using `rtwoptions` to Display Custom Target Options” on page 88-24.

The second part of the `RTW_OPTIONS` section defines `rtwgensettings`, a structure defining the build folder name and other settings for the code generation process. See “`rtwgensettings` Structure” on page 88-22 for information about `rtwgensettings`.

### `rtwgensettings` Structure

The final part of the system target file defines the `rtwgensettings` structure. This structure stores information that is written to the `model.rtw` file and used by the build process. The `rtwgensettings` fields of most interest to target developers are

- `rtwgensettings.Version`: Use this property to enable `rtwoptions` callbacks and to use the Callback API in `rtwgensettings.SelectCallback`.

---

**Note** To use callbacks, you *must* set:

```
rtwgensettings.Version = '1';
```

---

Add the statement above to the **Configure RTW code generation settings** section of the system target file.

- `rtwgensettings.DerivedFrom`: This structure field defines the system target file from which options are to be inherited. See “Inheriting Target Options” on page 88-29.
- `rtwgensettings.SelectCallback`: This structure field specifies a `SelectCallback` function. You must set `rtwgensettings.Version = '1'`; or your callback will be ignored. `SelectCallback` is associated with the target rather than with any of its individual options. The `SelectCallback` function is triggered when you:
  - Load the model.
  - Update any configuration settings in the Configuration Parameters dialog box.
  - Build the model.

The `SelectCallback` function is useful for setting up (or disabling) configuration parameters specific to the target.

The following code installs a `SelectCallback` function:

```
rtwgensettings.SelectCallback = 'my_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions.

---

**Note** If you have developed a custom target and you want it to be compatible with model referencing, you must implement a `SelectCallback` function to declare model reference compatibility. See “Support Model Referencing” on page 88-60.

---

- `rtwgensettings.ActivateCallback`: this property specifies an `ActivateCallback` function. The `ActivateCallback` function is triggered when the active configuration set of the model changes. This could happen during model loading, and also when the user changes the active configuration set.

The following code installs an `ActivateCallback` function:

```
rtwgensettings.ActivateCallback = 'my_activate_callback_handler(hDlg,hSrc)';
```

The arguments to the `ActivateCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions.

- `rtwgensettings.PostApplyCallback`: this property specifies a `PostApplyCallback` function. The `PostApplyCallback` function is triggered when the user clicks the **Apply** or **OK** button after editing options in the Configuration Parameters dialog box. The `PostApplyCallback` function is called after the changes have been applied to the configuration set.

The following code installs an `PostApplyCallback` function:

```
rtwgensettings.PostApplyCallback = 'my_postapply_callback_handler(hDlg,hSrc)';
```

The arguments to the `PostApplyCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions.

- `rtwgensettings.BuildDirSuffix`: To identify the build folder created by the build process, most system target files define a folder name suffix. To form the name of the build folder, the build process appends the suffix defined in the `rtwgensettings.BuildDirSuffix` field to the model name. You can modify the suffix by specifying a new string value for `rtwgensettings.BuildDirSuffix`. For example:

```
rtwgensettings.BuildDirSuffix = '_mytarget_rtw'
```

The build process creates a build folder named `model_mytarget_rtw`. For more information, see “Build Process Folders” on page 49-31.

Do *not* use a function to specify the new string value. For example:

```
rtwgensettings.BuildDirSuffix = my_get_build_suffix(bdroot);
```

### Additional Code Generation Options

“Configure Generated Code with TLC” describes additional TLC code generation variables. End users of a target can assign these variables by entering a MATLAB command of the form

```
set_param(modelName, 'TLCOptions', '-aVariable=val');
```

(For more information, see “Specify TLC for Code Generation”.)

However, the preferred approach is to assign these variables in the system target file using statements of the form:

```
%assign Variable = val
```

For readability, we recommend that you add such assignments in the section of the system target file after the comment **Configure RTW code generation settings**.

### Model Reference Considerations

See “Support Model Referencing” on page 88-60 for important information on system target file and other modifications you may need to make to support the code generator model referencing features.

## Define and Display Custom Target Options

- “Using `rtwoptions` to Display Custom Target Options” on page 88-24
- “Example System Target File With Customized `rtwoptions`” on page 88-28
- “Inheriting Target Options” on page 88-29

### Using `rtwoptions` to Display Custom Target Options

You control the options to display in the **Code Generation** pane in the Configuration Parameters dialog box by customizing the `rtwoptions` structure in your system target file.

The fields of the `rtwoptions` structure define variables and associated user interface elements to be displayed in the Configuration Parameters dialog box. Using the `rtwoptions` structure array, you can define target-specific options displayed in the dialog box and organize options into categories. You can also write callback functions to specify how these options are processed.

When the **Code Generation** pane opens, the `rtwoptions` structure array is scanned and the listed options are displayed. Each option is represented by an assigned user interface element (check box, edit field, menu, or push button), which displays the current option value.

The user interface elements can be in an enabled or disabled (appears dimmed) state. If an option is enabled, the user can change the option value. If an option is disabled, the option uses the default value and the user cannot change the option value.

You can also use the `rtwoptions` structure array to define special NonUI elements that cause callback functions to be executed, but that are not displayed in the **Code Generation** pane. See “NonUI Elements” on page 88-28.

The elements of the `rtwoptions` structure array are organized into groups. Each group of items begins with a header element of type `Category`. The default field of a `Category` header must contain a count of the remaining elements in the category.

The `Category` header is followed by options to be displayed on the **Code Generation** pane. The header in each category is followed by one or more option definition elements.

Each category of target options corresponds to options listed under **Code Generation** in the Configuration Parameters dialog box.

The table `rtwoptions` Structure Fields Summary summarizes the fields of the `rtwoptions` structure.

### Example `rtwoptions` Structure

The following `rtwoptions` structure is excerpted from an example system target file, `matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo/usertarget.tlc`. The code defines an `rtwoptions` structure array. The default field of the first (header) element is set to 4, indicating the number of elements that follow the header.

```

rtwoptions(1).prompt = 'userPreferred target options (I)';
rtwoptions(1).type = 'Category';
rtwoptions(1).enable = 'on';
rtwoptions(1).default = 4; % number of items under this category
 % excluding this one.
rtwoptions(1).popupstrings = ''; % At the first item, user has to
rtwoptions(1).tlcvariable = ''; % initialize all supported fields
rtwoptions(1).tooltip = '';
rtwoptions(1).callback = '';
rtwoptions(1).makevariable = '';

rtwoptions(2).prompt = 'Execution Mode';
rtwoptions(2).type = 'Popup';
rtwoptions(2).default = 'Real-Time';
rtwoptions(2).popupstrings = 'Real-Time|UserDefined';
rtwoptions(2).tlcvariable = 'tlcvariable1';
rtwoptions(2).tooltip = ['See this text as tooltip'];

rtwoptions(3).prompt = 'Log Execution Time';
rtwoptions(3).type = 'Checkbox';
rtwoptions(3).default = 'on';
rtwoptions(3).tlcvariable = 'RL32LogTETModifier';
rtwoptions(3).tooltip = ['']; % no tooltip

rtwoptions(4).prompt = 'Real-Time Interrupt Source';
rtwoptions(4).type = 'Popup';
rtwoptions(4).default = 'Timer';
rtwoptions(4).popupstrings = 'Timer|5|6|7|8|9|10|11|12|13|14|15';
rtwoptions(4).tlcvariable = 'tlcvariable3';
rtwoptions(4).callback = 'usertargetcallback(hDlG, hSrc, ''tlcvariable3'')';
rtwoptions(4).tooltip = [''];
rtwoptions(4).tooltip = ['See TLC file for how to use reserved '...

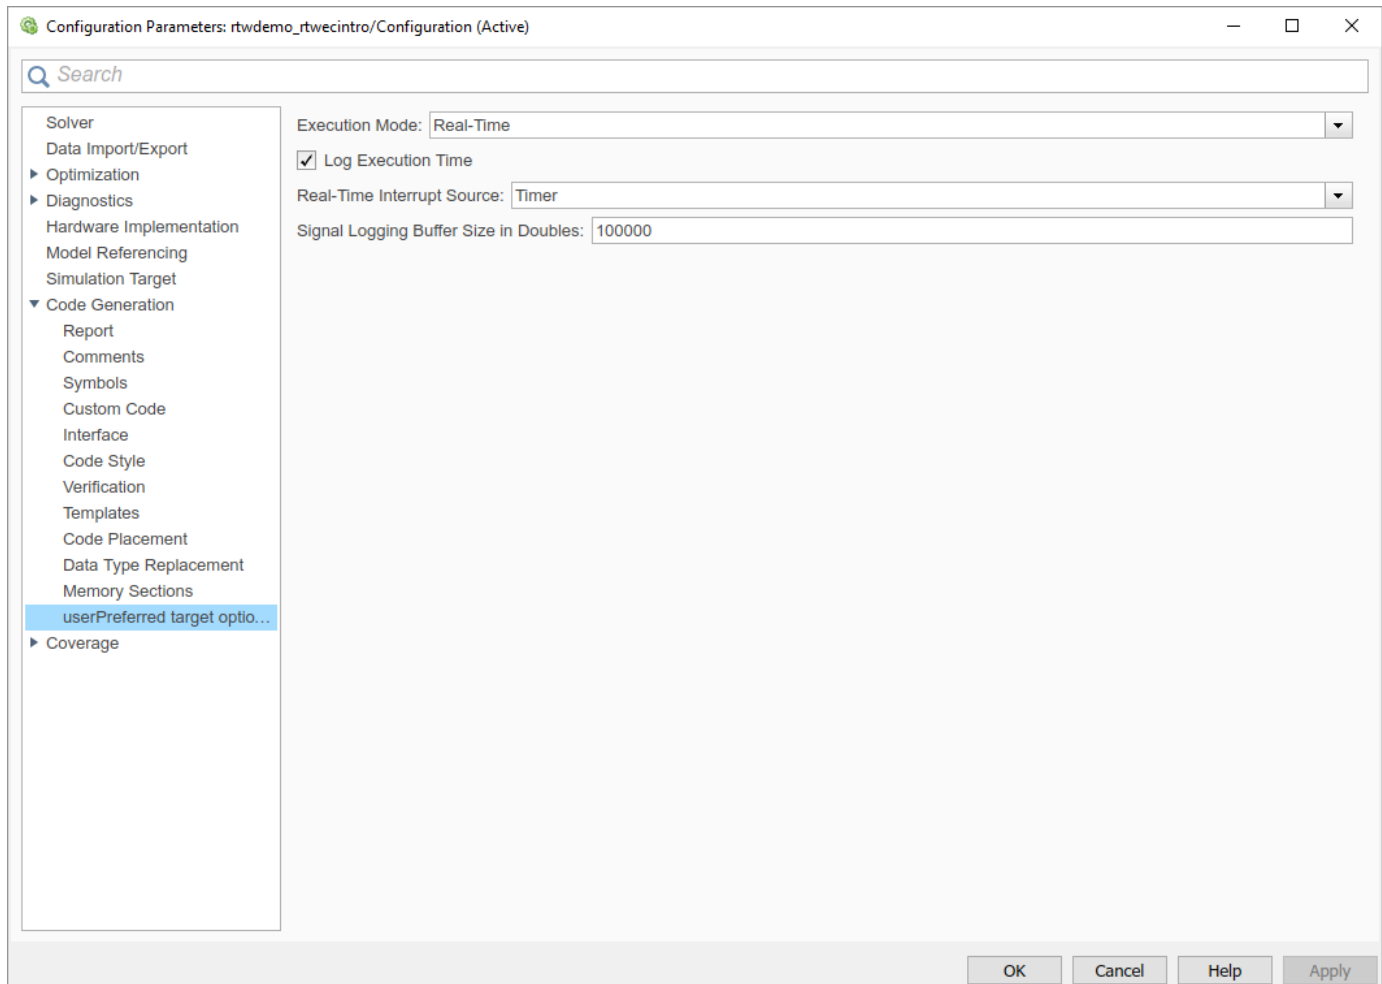

```

```

 ' keyword 'hdlg'', and 'hSrc''.');
...
rtwoptions(5).prompt = 'Signal Logging Buffer Size in Doubles';
rtwoptions(5).type = 'Edit';
rtwoptions(5).default = '100000';
rtwoptions(5).tlcvariable = 'tlcvariable2';
rtwoptions(5).tooltip = [''];

```

The first element adds a **userPreferred target options (I)** pane under **Code Generation** in the Configuration Parameters dialog box. The pane displays the options defined in `rtwoptions(2)`, `rtwoptions(3)`, `rtwoptions(4)`, and `rtwoptions(5)`.

If you want to define a large number of options, you can define multiple **Category** groups within a single system target file.

Note the `rtwoptions` structure and callbacks are written in MATLAB code, although they are embedded in a TLC file. To verify the syntax of your `rtwoptions` structure definitions and code, you can execute the commands at the MATLAB prompt by copying and pasting them to the MATLAB Command Window.

To learn more about `usertarget.tlc` and the example callback files provided with it, see “Example System Target File With Customized `rtwoptions`” on page 88-28. For more examples of target-specific `rtwoptions` definitions, see the `target.tlc` files under `matlabroot/rtw/c` (open).

rtwoptions Structure Fields Summary lists the fields of the `rtwoptions` structure.

### rtwoptions Structure Fields Summary

Field Name	Description
<code>callback</code>	For examples of callback usage, see “Example System Target File With Customized <code>rtwoptions</code> ” on page 88-28.
<code>closecallback</code> (obsolete)	Do not use <code>closecallback</code> . Use <code>rtwgensettings.PostApplyCallback</code> instead (see “ <code>rtwgensettings</code> Structure” on page 88-22).  <code>closecallback</code> is ignored.  For examples of callback usage, see “Example System Target File With Customized <code>rtwoptions</code> ” on page 88-28.
<code>default</code>	Default value of the option (empty if the <code>type</code> is <code>Pushbutton</code> ).
<code>enable</code>	Must be 'on' or 'off'. If 'on', the option is displayed as an enabled item; otherwise, as a disabled item.
<code>makevariable</code>	Template makefile token (if any) associated with the option. The <code>makevariable</code> is expanded during processing of the template makefile. See “Template Makefile Tokens” on page 88-43.
<code>modelReferenceParameter-Check</code>	Specifies whether the option must have the same value in a referenced model and its parent model. If this field is unspecified or has the value 'on' the option values must be same. If the field is specified and has the value 'off' the option values can differ. See “Controlling Configuration Option Value Agreement” on page 88-62.
<code>NonUI</code>	Element that is not displayed, but is used to invoke a close or open callback. See “NonUI Elements” on page 88-28.
<code>opencallback</code> (obsolete)	Do not use <code>opencallback</code> . Use <code>rtwgensettings.SelectCallback</code> instead (see “ <code>rtwgensettings</code> Structure” on page 88-22).  For examples of callback usage, see “Example System Target File With Customized <code>rtwoptions</code> ” on page 88-28.
<code>popupstrings</code>	If <code>type</code> is <code>Popup</code> , <code>popupstrings</code> defines the items in the menu. Items are delimited by the " " (vertical bar) character. The following example defines the items of the <b>MAT-file variable name modifier</b> menu used by the GRT target.  'rt_ _rt none'
<code>prompt</code>	Label for the option.
<code>tlcvariable</code>	Name of TLC variable associated with the option.
<code>tooltip</code>	Help text displayed when mouse is over the item.
<code>type</code>	Type of element: <code>Checkbox</code> , <code>Edit</code> , <code>NonUI</code> , <code>Popup</code> , <code>Pushbutton</code> , or <code>Category</code> .

### NonUI Elements

Elements of the `rtwoptions` array that have type `NonUI` exist solely to invoke callbacks. A `NonUI` element is not displayed in the Configuration Parameters dialog box. You can use a `NonUI` element if you want to execute a callback that is not associated with a user interface element, when the dialog box opens or closes. See the next section, “Example System Target File With Customized `rtwoptions`” on page 88-28 for an example.

---

**Note** The default value of an element of type `NonUI` or `Edit` determines the set of values allowed for that element.

- If the default value is '0' or '1':
    - For type `NonUI`, the element stores a Boolean value.
    - For type `Edit`, the element stores a value of type `int32`.
  - If the default value contains an integer other than '0' or '1', the element stores a value of type `int32`.
  - If the default value does not contain an integer, the element is evaluated as a character vector.
- 

### Example System Target File With Customized `rtwoptions`

A working system target file, with MATLAB file callback functions, has been provided as an example of how to use the `rtwoptions` structure to display and process custom options on the **Code Generation** pane. The examples are compatible with the callback API.

The example target files are in the folder (open):

```
matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo
```

The example target files include:

- `usertarget.tlc`: The example system target file. This file illustrates how to define custom menus, check boxes, and edit fields. The file also illustrates the use of callbacks.
- `usertargetcallback.m`: A MATLAB file callback invoked by a menu.

Refer to the example files while reading this section. The example system target file, `usertarget.tlc`, illustrates the use of `rtwoptions` to display the following custom target options:

- The **Execution Mode** menu.
- The **Log Execution Time** check box.
- The **Real-Time Interrupt Source** menu. The menu executes a callback defined in an external file, `usertargetcallback.m`. The TLC variable associated with the menu is passed in to the callback, which displays the menu's current value.
- The edit field **Signal Logging Buffer Size in Doubles**.

Try studying the example code while interacting with the example target options in the Configuration Parameters dialog box. To interact with the example target file,

- 1 Make `matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo` (open) your working folder.
- 2 Open a model of your choice.

- 3 Open the Configuration Parameters dialog box and select the **Code Generation** pane.
- 4 Click **Browse**. The System Target File Browser opens. Select `usertarget.tlc`. Then click **OK**.
- 5 Observe that the **Code Generation** pane contains a custom sub-tab: **userPreferred target options (I)**.
- 6 As you interact with the options in this category and open and close the Configuration Parameters dialog box, observe the messages displayed in the MATLAB Command Window. These messages are printed from code in the system target file, or from callbacks invoked from the system target file.

### Inheriting Target Options

`ert.tlc` provides a basic set of Embedded Coder code generation options. If your target is based on `ert.tlc`, your system target file should normally inherit the options defined in ERT.

Use the `rtwgensettings.DerivedFrom` field in the `rtwgensettings` structure to define the system target file from which options are to be inherited. You should convert your custom target to use this mechanism as follows.

Set the `rtwgensettings.DerivedFrom` field value as in the following example:

```
rtwgensettings.DerivedFrom = 'stf.tlc';
```

where `stf` is the name of the system target file from which options are to be inherited. For example:

```
rtwgensettings.DerivedFrom = 'ert.tlc';
```

When the Configuration Parameters dialog box executes this line of code, it includes the options from `stf.tlc` automatically. If `stf.tlc` is a MathWorks internal system target file that has been converted to a new layout, the dialog box displays the inherited options using the new layout.

### Handling Unsupported Options

If your target does not support all of the options inherited from `ert.tlc`, you should detect unsupported option settings and display a warning or error message. In some cases, if a user has selected an option your target does not support, you may need to abort the build process. For example, if your target does not support the **Generate an example main program** option, the build process should not be allowed to proceed if that option is selected.

Even though your target may not support all inherited ERT options, it is required that the ERT options are retained in the **Code Generation** pane of the Configuration Parameters dialog box. Do not simply remove unsupported options from the `rtwoptions` structure in the system target file. Options must be in the dialog box to be scanned by the code generator when it performs optimizations.

For example, you may want to prevent users from turning off the **Single output/update function** option. It may seem reasonable to remove this option from the dialog box and simply assign the TLC variable `CombineOutputUpdateFcns` to `on`. However, if the option is not included in the dialog box, the code generator assumes that output and update functions are *not* to be combined. Less efficient code is generated as a result.

## Tips and Techniques for Customizing Your System Target File

- “Introduction” on page 88-30

- “Required and Recommended %includes” on page 88-30
- “Handling Aliases for Target Option Values” on page 88-31
- “Supporting Multiple Development Environments” on page 88-32
- “Updating Your Custom System Target File” on page 88-32

## Introduction

The following sections include information on techniques for customizing your system target file, including:

- How to invoke custom TLC code from your system target file
- Approaches to supporting multiple development environments
- Considerations for when you update your system target file

## Required and Recommended %includes

If you need to implement target-specific code generation features, we recommend that your system target file include the TLC file `mytarget_genfiles.tlc`.

Once your system target file has set up the required TLC environment, you must include `codegenentry.tlc` to start the standard code generation process.

`mytarget_genfiles.tlc` provides a mechanism for executing custom TLC code after the main code generation entry point. See “Using `mytarget_genfiles.tlc`” on page 88-30.

## Using `mytarget_genfiles.tlc`

`mytarget_genfiles.tlc` (optional) is useful as a central file from which to invoke target-specific TLC files that generate additional files as part of your target build process. For example, your target may create sub-makefiles or project files for a development environment, or command scripts for a debugger to do automatic downloads.

The build process can then invoke these generated files either directly from the make process or after the executable is created. This is done with the `STF_make_rtw_hook.m` mechanism, as described in “Customize Build Process with `STF_make_rtw_hook` File”.

The following TLC code shows an example `mytarget_genfiles.tlc` file.

```
%selectfile NULL_FILE

%assign ModelName = CompiledModel.Name

%% Create Debugger script
%assign model_script_file = "%<ModelName>.cfg"
%assign script_file = "debugger_script_template.tlc"

%if RTWVerbose
 %selectfile STDOUT
 ### Creating %<model_script_file>
 %selectfile NULL_FILE
%endif

%include "%<script_file>"
%openfile bld_file = "%<model_script_file>"
```

```
%<CreateDebuggerScript(>
%closefile bld_file
```

### Handling Aliases for Target Option Values

This section describes utility functions that can be used to detect and resolve alias values or legacy values when testing user-specified values for the target device type (`ProdHWDeviceType`) and the code replacement library (`CodeReplacementLibrary`).

#### RTW.isHWDeviceTypeEq

To test if two target device type values represent the same hardware device, invoke the following function:

```
result = RTW.isHWDeviceTypeEq(type1, type2)
```

where *type1* and *type2* are character vectors containing target device type values or aliases.

The `RTW.isHWDeviceTypeEq` function returns true if *type1* and *type2* are character vectors representing the same hardware device. For example, the following call returns true:

```
RTW.isHWDeviceTypeEq('Specified', 'Generic->Custom')
```

For a description of the target device type option `ProdHWDeviceType`, see the command-line information for the **Hardware Implementation** pane parameters “Device vendor” and “Device type”.

#### RTW.resolveHWDeviceType

To return the device type value for a hardware device, given a value that might be an alias or legacy value, invoke the following function:

```
result = RTW.resolveHWDeviceType(type)
```

where *type* is a character vector containing a target device type value or alias.

The `RTW.resolveHWDeviceType` function returns the device type value of the device. For example, the following calls both return 'Generic->Custom':

```
RTW.resolveHWDeviceType('Specified')
RTW.resolveHWDeviceType('Generic->Custom')
```

For a description of the target device type option `ProdHWDeviceType`, see the command-line information for the **Hardware Implementation** pane parameters “Device vendor” and “Device type”.

#### RTW.isTfLEq

To test if two code replacement library (CRL) names represent the same CRL, invoke the following function:

```
result = RTW.isTfLEq(name1, name2)
```

where *name1* and *name2* are character vectors containing CRL values or aliases.

The `RTW.isTfLEq` function returns true if *name1* and *name2* are character vectors representing the same code replacement library. For example, the following call returns true:

```
RTW.isTfLEq('GNU', 'GNU C99 extensions')
```

For a description of the `CodeReplacementLibrary` parameter, see “Code replacement library”.

### **RTW.resolveTflName**

To return the CRL value for a code replacement library, given a value that might be an alias or legacy value, invoke the following function:

```
result = RTW.resolveTflName(name)
```

where *name* is a character vector containing a CRL value or alias.

The `RTW.resolveTflName` function returns the value of the referenced code replacement library. For example, the following calls both return 'GNU C99 extensions':

```
RTW.resolveTflName('GNU')
RTW.resolveTflName('GNU C99 extensions')
```

For a description of the `CodeReplacementLibrary` parameter, see “Code replacement library”.

## **Supporting Multiple Development Environments**

Your target may require support for multiple development environments (for example, two or more cross-compilers) or multiple modes of code generation (for example, generating a binary executable versus generating a project file for your compiler).

One approach to this requirement is to implement multiple system target files. Each system target file invokes a template makefile for the development environment. This amounts to providing two separate targets.

## **Updating Your Custom System Target File**

Updating your custom system target file can impact the option values of a model that you load that uses the updated system target file. If you disable an option, the updated system target file uses the default value for that option. If a model has a different value for that option, when you load the model with the updated system target file, the value from the model is discarded and the system target file uses the default value instead.

## **Create a Custom Target Configuration**

- “Introduction” on page 88-32
- “my\_ert\_target Overview” on page 88-33
- “Creating Target Folders” on page 88-34
- “Create ERT-Based, Toolchain Compliant System Target File” on page 88-35
- “Create ERT-Based Template MakeFile” on page 88-39
- “Create Test Model and S-Function” on page 88-40
- “Verify Target Operation” on page 88-41

### **Introduction**

This tutorial can supplement the example target guides described in “Sample Custom Targets” on page 88-3. For an introduction and example files, try the example targets first.

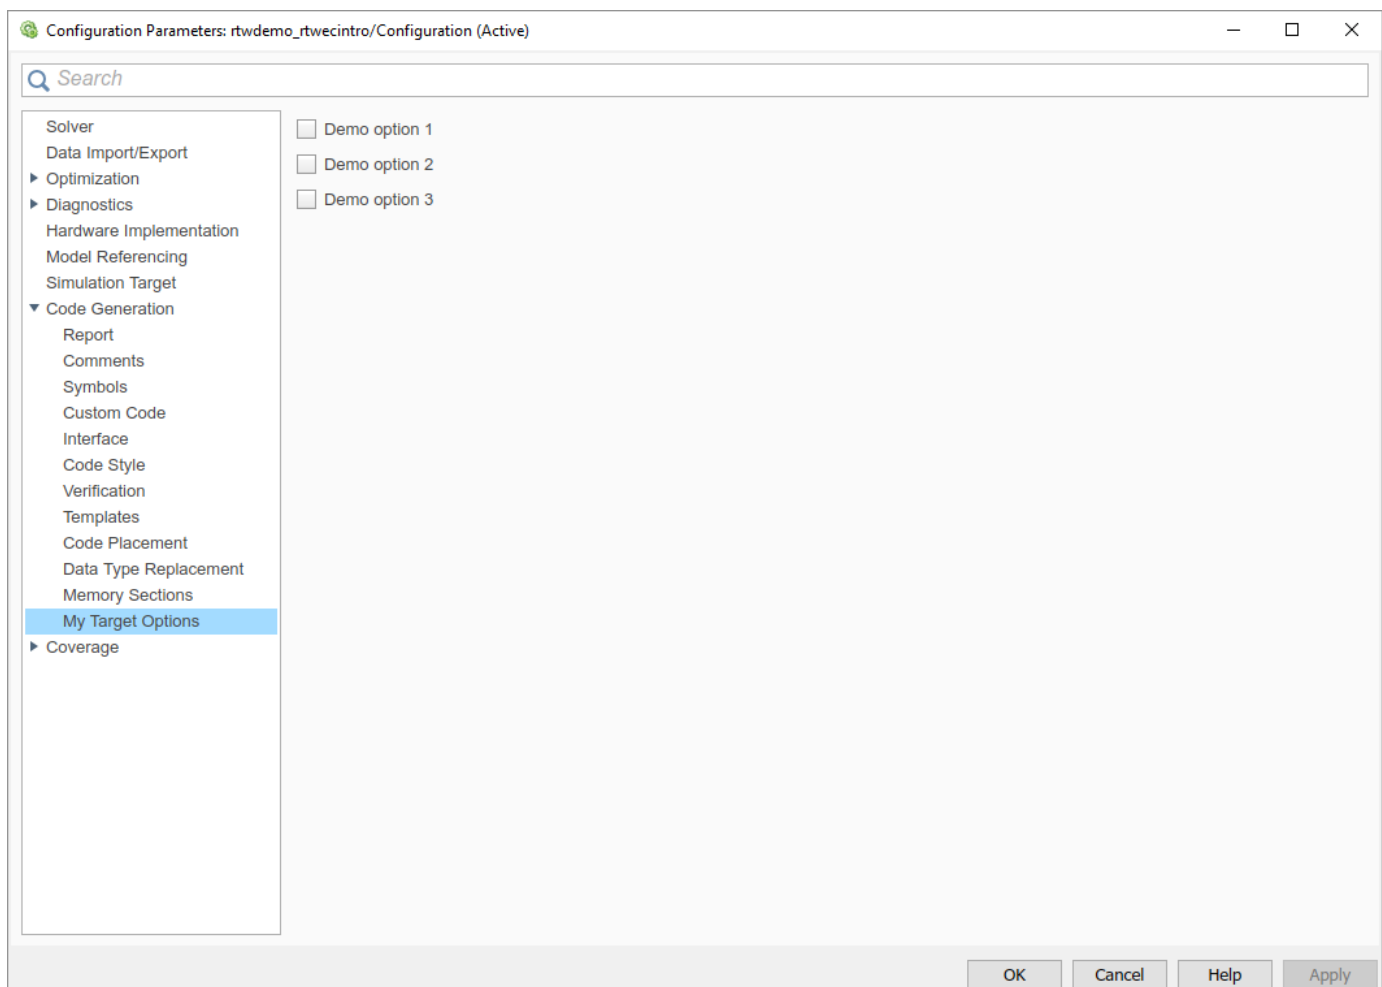

This tutorial guided you through the process of creating an ERT-based target, `my_ert_target`. This exercise illustrates several tasks, which are typical for creating a custom target:

- Setting up target folders and modifying the MATLAB path.
- Making modifications to a standard system target file and TMF such that the custom target is visible in the System Target File Browser, inherits ERT options, displays target-specific options, and generates code with the default host-based compiler.
- Testing the build process with the custom target, using a simple model that incorporates an inlined S-function.

During this exercise, you implement an operational, but skeletal, ERT-based target. This target can be useful as a starting point in a complete implementation of a custom embedded target.

### my\_ert\_target Overview

In the following sections, you create a skeletal target, `my_ert_target`. The target inherits and supports the standard options of the ERT target and displays additional target-specific options in the Configuration Parameters dialog box (see “Target-Specific Options for `my_ert_target`” on page 88-33).

### Target-Specific Options for my\_ert\_target

`my_ert_target` supports a toolchain-based build, generating code and executables that run on the host system. `my_ert_target` uses the `lcc` compiler on a Microsoft Windows platform. The chosen

compiler is readily available and is distributed with the code generator. On a Microsoft Windows platform, if you use a different compiler, you can set up `lcc` temporarily as your default compiler through the following MATLAB command:

```
mex -setup
```

The software displays links for supported compilers that are installed on your computer. Click the `lcc` link.

---

**Note** On Linux systems, make sure that you have an installed C compiler. If so, you can use Linux folder syntax to complete this exercise.

`my_ert_target` can also support template makefile-based builds. For more information about using this target with the template makefile approach, see “Create ERT-Based Template MakeFile” on page 88-39.

---

You can test `my_ert_target` with a model that is compatible with the ERT target (see “Configure a System Target File” on page 47-2). Generated programs operate identically to ERT generated programs.

To simplify the testing of your target, test with `targetmodel`, a very simple fixed-step model (see “Create Test Model and S-Function” on page 88-40). The S-Function block in `targetmodel` uses the source code from the `timestwo` example, and generates fully inlined code. See “S-Function Examples” and “Inline S-Functions with TLC” for further discussion of the `timestwo` example S-function.

### Creating Target Folders

Create folders to store the target files and add them to the MATLAB path, following the recommended conventions (see “Folder and File Naming Conventions” on page 88-5). You also create a folder to store the test model, S-function, and generated code.

This example assumes that your target and model folders are located within the folder `c:/work`. Do not place your target and model folders within the MATLAB folder tree (that is, in or under the `matlabroot` folder).

To create the folders and make them accessible:

- 1 Create a target root folder, `my_ert_target`. From the MATLAB Command Window on a Windows platform, enter:

```
cd c:/work
mkdir my_ert_target
```

- 2 Within the target root folder, create a subfolder to store your target files.

```
mkdir my_ert_target/my_ert_target
```

- 3 Add these folders to your MATLAB path.

```
addpath c:/work/my_ert_target
addpath c:/work/my_ert_target/my_ert_target
```

- 4 Create a folder, `my_targetmodel`, to store the test model, S-function, and generated code.

```
mkdir my_targetmodel
```

## Create ERT-Based, Toolchain Compliant System Target File

Create a system target file for your target by copying and modifying the standard system target file for the ERT target. Then, validate the system target file by viewing the new target in the System Target File Browser and in the Configuration Parameters dialog box.

### Editing the System Target File

To edit the system target file, use these steps:

- 1 Change your working folder to the folder you created in “Creating Target Folders” on page 88-34.

```
cd c:/work/my_ert_target/my_ert_target
```

- 2 Place a copy of `matlabroot/rtw/c/ert/ert.tlc` in `c:/work/my_ert_target/my_ert_target` and rename it to `my_ert_target.tlc`. The file `ert.tlc` is the system target file for the ERT target.
- 3 Open `my_ert_target.tlc` in a text editor of your choice.
- 4 Customize the system target file, replacing the header comment lines with directives that make your system target file visible in the System Target File Browser and define the associated TMF, make command, and external mode interface file (if any). For more information about these directives, see “Header Comments” on page 88-20 .

Replace the header comments in `my_ert_target.tlc` with the following header comments.

```
%% SYSTLC: My ERT-based Target TMF: my_ert_target_lcc.tmf MAKE: make_rtw
```

- 5 The file `my_ert_target.tlc` inherits the standard ERT options, using the mechanism described in “Inheriting Target Options” on page 88-29. Therefore, the existing `rtwoptions` structure definition is superfluous. Edit the `RTW_OPTIONS` section such that it includes only the following code.

```
/%
BEGIN_RTW_OPTIONS

%-----%
% Configure RTW code generation settings %
%-----%

rtwgenSettings.BuildDirSuffix = '_ert_rtw';

END_RTW_OPTIONS
%/
```

- 6 Delete the code after the end of the `RTW_OPTIONS` section, which is delimited by the directives `BEGIN_CONFIGSET_TARGET_COMPONENT` and `END_CONFIGSET_TARGET_COMPONENT`. This code is for use only by internal MathWorks developers.
- 7 Modify the build folder suffix in the `rtwgenSettings` structure in accordance with the conventions described in “`rtwgenSettings` Structure” on page 88-22.

To set the suffix to a character vector for the `_my_ert_target` custom target, change the line

```
rtwgenSettings.BuildDirSuffix = '_ert_rtw'
```

to

```
rtwgenSettings.BuildDirSuffix = '_my_ert_target_rtw'
```

- 8 Modify the `rtwgenSettings` structure to inherit options from the ERT target and declare Release 14 or later compatibility as described in “`rtwgenSettings` Structure” on page 88-22. Add the following code to the `rtwgenSettings` definition:

```
rtwgensettings.DerivedFrom = 'ert.tlc';
rtwgensettings.Version = '1';
```

- 9 Add an `rtwoptions` structure that defines a target-specific options category with three check boxes just after the `BEGIN_RTW_OPTIONS` directive. The following code shows the complete `RTW_OPTIONS` section, including the previous `rtwgenSettings` changes.

```
/%
BEGIN_RTW_OPTIONS

rtwoptions(1).prompt = 'My Target Options';
rtwoptions(1).type = 'Category';
rtwoptions(1).enable = 'on';
rtwoptions(1).default = 3; % number of items under this category
 % excluding this one.

rtwoptions(1).popupstrings = '';
rtwoptions(1).tlcvariable = '';
rtwoptions(1).tooltip = '';
rtwoptions(1).callback = '';
rtwoptions(1).makevariable = '';

rtwoptions(2).prompt = 'Demo option 1';
rtwoptions(2).type = 'Checkbox';
rtwoptions(2).default = 'off';
rtwoptions(2).tlcvariable = 'DummyOpt1';
rtwoptions(2).makevariable = '';
rtwoptions(2).tooltip = ['Demo option1 (non-functional)'];
rtwoptions(2).callback = '';

rtwoptions(3).prompt = 'Demo option 2';
rtwoptions(3).type = 'Checkbox';
rtwoptions(3).default = 'off';
rtwoptions(3).tlcvariable = 'DummyOpt2';
rtwoptions(3).makevariable = '';
rtwoptions(3).tooltip = ['Demo option2 (non-functional)'];
rtwoptions(3).callback = '';

rtwoptions(4).prompt = 'Demo option 3';
rtwoptions(4).type = 'Checkbox';
rtwoptions(4).default = 'off';
rtwoptions(4).tlcvariable = 'DummyOpt3';
rtwoptions(4).makevariable = '';
rtwoptions(4).tooltip = ['Demo option3 (non-functional)'];
rtwoptions(4).callback = '';

%-----%
% Configure RTW code generation settings %
%-----%

rtwgensettings.BuildDirSuffix = '_my_ert_target_rtw';
rtwgensettings.DerivedFrom = 'ert.tlc';
rtwgensettings.Version = '1';
rtwgensettings.SelectCallback = 'enableToolchainCompliant(hSrc, hDlg)';
%SelectCallback provides toolchain approach support, but requires custom function
%Omit this SelectCallback if using the template makefile approach

END_RTW_OPTIONS
%/
```

- 10 Save your changes to `my_ert_target.tlc` and close the file.

### Create ToolchainCompliant Function

To enable builds using the toolchain approach, you create a function that corresponds to the `SelectCallback` near the end of the custom system target file. This function sets properties for toolchain compliance.

```
function enableToolchainCompliant(hSrc, hDlg)
% The following parameters enable toolchain compliance.
slConfigUISetVal(hDlg, hSrc, 'UseToolchainInfoCompliant', 'on');
```

```

slConfigUISetVal(hDlg, hSrc, 'GenerateMakefile','on');

% The following parameters are not required for toolchain compliance.
% But, it is recommended practice to set these default values and
% disable the parameters (as shown).
slConfigUISetVal(hDlg, hSrc, 'RTWCompilerOptimization','off');
slConfigUISetVal(hDlg, hSrc, 'MakeCommand','make_rtw');
slConfigUISetEnabled(hDlg, hSrc, 'RTWCompilerOptimization',false);
slConfigUISetEnabled(hDlg, hSrc, 'MakeCommand',false);
hSrc.refreshDialog;
end

```

**Note** If you are using the template makefile approach, omit calling the function enabling toolchain compliance from your system target file. Instead, use the information in “Create ERT-Based Template MakeFile” on page 88-39.

### Viewing the System Target File

At this point, you can verify that the target inherits and displays ERT options as follows:

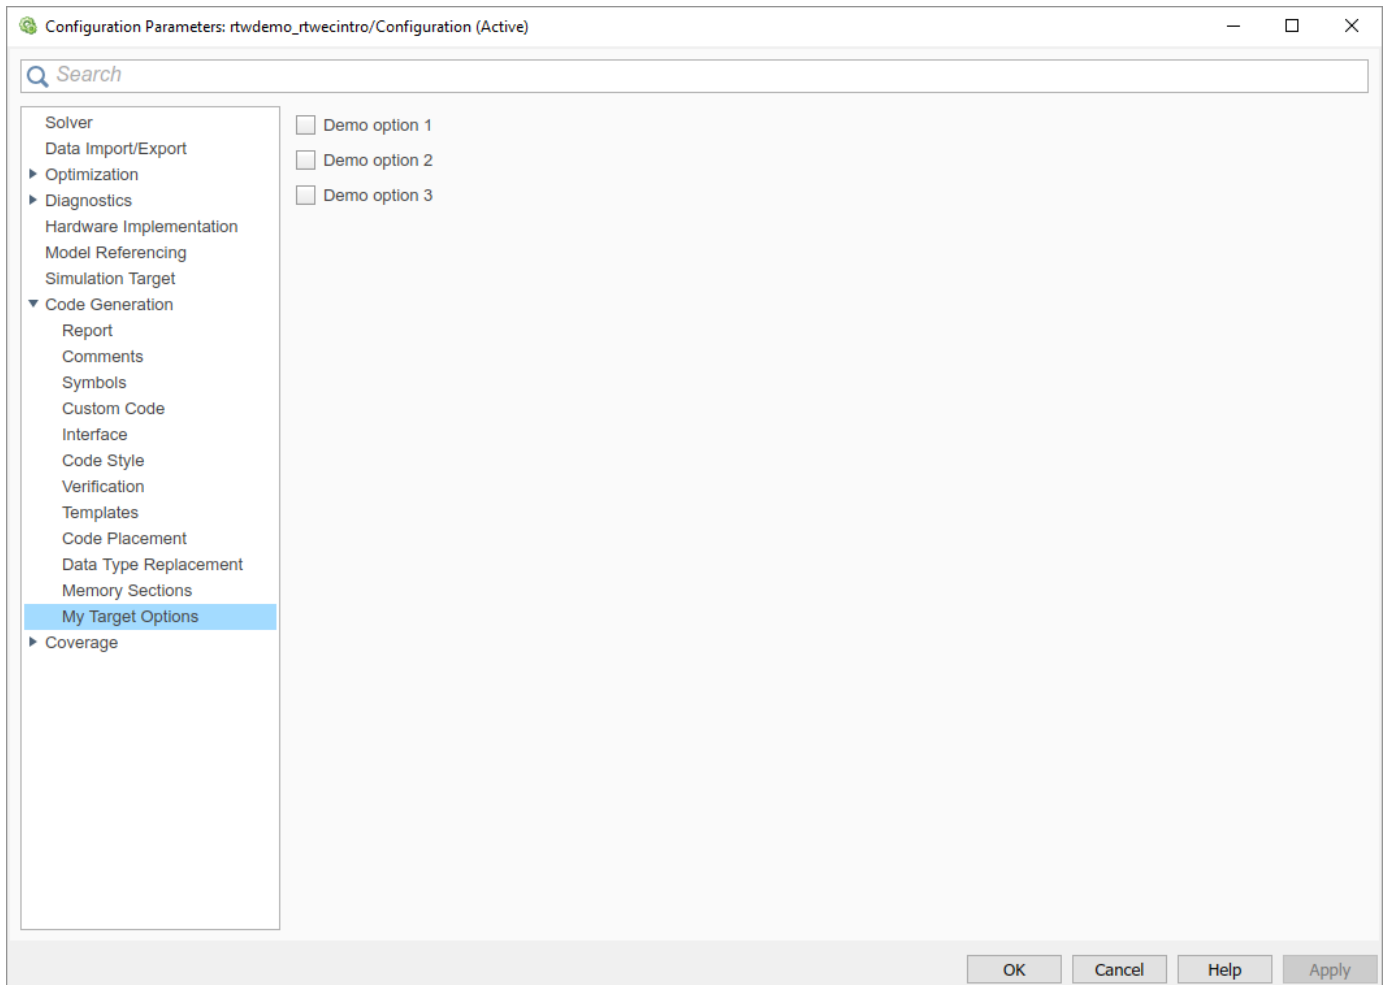

- 1 Create a new model.
- 2 Open the Model Explorer or the Configuration Parameters dialog box.
- 3 Select the **Code Generation** pane.
- 4 Click **Browse** to open the System Target File browser.
- 5 In the file browser, scroll through the list of targets to find the new target, `my_ert_target.tlc`. (This step assumes that your MATLAB path contains `c:/work/my_ert_target/my_ert_target`, as previously set in “Creating Target Folders” on page 88-34.)
- 6 Select My ERT-based Target and click **OK**.

- 7 The **Code Generation** pane now shows that the model is configured for the `my_ert_target.tlc` target. The **System target file**, **Language**, **Toolchain**, and **Build configuration** fields should appear:

- 8 Select the **My Target Options** pane. The target displays the three check box options defined in the `rtwoptions` structure.

- 9 Select the **Code Generation** pane and reopen the System Target File Browser.
- 10 Select the Embedded Coder target (`ert.tlc`). The target displays the standard ERT options.
- 11 Close the model. You do not need to save it.

The system target file for the skeletal target is complete. If you are using the toolchain approach, you are ready to invoke the build process for your target.

If you prefer to use the template makefile approach, the reference to a TMF, `my_ert_target_lcc.tmf`, in the system target file header comments prevents you from invoking the build process for your target until the TMF file is in place. First, you must create a `my_ert_target_lcc.tmf` file.

### Create ERT-Based Template MakeFile

If you are using the toolchain makefile approach with a toolchain compliant custom target, omit the steps that apply to the template makefile approach. (Skip this section.)

If you are using the template makefile approach, follow the steps that apply to a template makefile and omit calling the function that enables toolchain-compliance from your system target file, which is described in “Create ERT-Based, Toolchain Compliant System Target File” on page 88-35.

Create a template makefile for your target by copying and modifying a supplied ERT template makefile. Select the template makefile that fits your target best. This example uses `ert_lcc64.tmf`, but you can also use `ert_vcx64.tmf` or `ert_unix.tmf`.

- 1 Make sure that your working folder is still set to the target file folder you created previously in “Creating Target Folders” on page 88-34.

```
c:/work/my_ert_target/my_ert_target
```

- 2 Place a copy of `matlabroot/toolbox/coder/compile/tmf/ert_lcc64.tmf` in `c:/work/my_ert_target/my_ert_target` and rename it `my_ert_target_lcc.tmf`. The file `ert_lcc64.tmf` is the ERT compiler-specific template makefile for the LCC compiler.

- 3 Open `my_ert_target_lcc.tmf` in a text editor.

- 4 Change the `SYS_TARGET_FILE` parameter so that the file reference for your `.tlc` file is generated in the make file. Change the line

```
SYS_TARGET_FILE = any
```

```
to
```

```
SYS_TARGET_FILE = my_ert_target.tlc
```

- 5 Save changes to `my_ert_target_lcc.tmf` and close the file.

Your target can now generate code and build a host-based executable. In the next sections, you create a test model and test the build process using `my_ert_target`.

### Create Test Model and S-Function

In this section, you build a simple test model for later use in code generation:

- 1 Set your working folder to `c:/work/my_targetmodel`.

```
cd c:/work/my_targetmodel
```

For the remainder of this tutorial, `my_targetmodel` is assumed to be the working folder. Your target writes the output files of the code generation process into a build folder within the working folder. When inlined code is generated for the `timestwo` S-function, the build process looks for the TLC implementation of the S-function in the working folder.

- 2 Copy the following C and TLC files for the `timestwo` S-function to your working folder:

- `matlabroot/toolbox/simulink/simdemos/simfeatures/src/timestwo.c`
- `matlabroot/toolbox/simulink/simdemos/simfeatures/tlc_c/timestwo.tlc`

- 3 Build the `timestwo` MEX-file in `c:/work/my_targetmodel`.

```
mex timestwo.c
```

- 4 Create the following model, using an S-Function block from the Simulink User-Defined Functions library. Save the model in your working folder as `targetmodel`.

- 5 Double-click the S-Function block to open the Block Parameters dialog box. Enter the S-function name `timestwo`. Click **OK**. The block is now bound to the `timestwo` MEX-file.

- 6 Open Model Explorer or the Configuration Parameters dialog box and select the **Solver** pane.
- 7 Set the solver **Type** to `fixed-step` and click **Apply**.
- 8 Save the model.
- 9 Open the scope and run a simulation. Verify that the `timestwo` S-function multiplies its input by 2.0.

Keep the `targetmodel` model open for use in the next section, in which you generate code using the test model.

### Verify Target Operation

In this section you configure `targetmodel` for the `my_ert_target` custom target, and use the target to generate code and build an executable:

- 1 In the Configuration Parameters dialog box, select the **Code Generation** pane.
- 2 Click **Browse** to open the System Target File Browser.
- 3 In the Browser, select `My ERT-based Target` and click **OK**.
- 4 The Configuration Parameters dialog box now displays the **Code Generation** pane for `my_ert_target`.
- 5 Select the **Code Generation > Report** pane and select the **Create code generation report** option.
- 6 Click **Apply** and save the model. The model is configured for `my_ert_target`.
- 7 Build the model. If the build succeeds, the MATLAB Command Window displays the message below.

```
Created executable: ../targetmodel.exe
Successful completion of build procedure for model:
targetmodel
```

Your working folder contains the `targetmodel.exe` file and the build folder, `targetmodel_my_ert_target_rtw`, which contains generated code and other files. The working folder also contains an `s\prj` folder, used internally by the build process.

The code generator also creates a code generation report.

- 8 To view the generated code, on the **C Code** tab, click **View Code**. In the **Contents** pane of the code generation report, click the `targetmodel.c` link.
- 9 In `targetmodel.c`, locate the model step function, `targetmodel_step`. Observe the following code.

```
/* S-Function Block: <Root>/S-Function */
/* Multiply input by two */
targetmodel_B.SFunction = targetmodel_B.SineWave * 2.0;
```

The presence of this code confirms that the `my_ert_target` custom target has generated an inlined output computation for the S-Function block in the model.

## Customize Template Makefiles

To configure or customize a template makefile (TMF), you should be familiar with how the `make` command works and how it processes a makefile (.mk file). You should also understand makefile build rules. For information on these topics, refer to the documentation provided with the `make` utility that you use.

### Template Makefiles and Tokens

A template makefile contains tokens. The build process expands the tokens and creates makefiles:

- `model.mk` -- Compiles and links code generated from model components.
- `rtwshared.mk` -- Compiles generated shared utility code.

The makefiles (`model_or_sharedutils.mk`) use commands that are specific to your development computer.

### Template Makefile Tokens

The `make_rtw` command (or a different command provided with some targets) directs the process of generating `model_or_sharedutils.mk`. The `make_rtw` command processes the TMF specified on the **Code Generation** pane of the Configuration Parameters dialog box. `make_rtw` copies the TMF, line by line, expanding each token encountered. Template Makefile Tokens Expanded by `make_rtw` lists the tokens and their expansions.

These tokens are used in several ways by the expanded makefile:

- To control the conditional behavior in the makefile. The conditionals are used to control the source file lists, library names, target to be built, and other build-related information.
- To provide the macro definitions for compiling the files, for example, `-DINTEGER_CODE=1`.

### Template Makefile Tokens Expanded by make\_rtw

Token	Expansion
<b>General purpose</b>	
>ADDITIONAL_LDFLAGS<	Linker flags automatically added by blocks.
>ALT_MATLAB_BIN<	Alternate full pathname for the MATLAB executable; value is different than value for MATLAB_BIN token when the full pathname contains spaces.
>ALT_MATLAB_ROOT<	Alternate full pathname for the MATLAB installation; value is different than value for MATLAB_ROOT token when the full pathname contains spaces.
>BUILDARGS<	Options passed to make_rtw. This token is provided so that the contents of your <i>model_or_sharedutils.mk</i> file change when you change the build arguments, thus forcing an update of modules when your build options change.
>COMBINE_OUTPUT_UPDATE_FCNS<	True (1) when you select model configuration parameter <b>Single output/update function</b> , otherwise False (0). Used for the macro definition <code>-DONESTEPFCN=1</code> .
>COMPILE_FLAGS_OTHER<	<p>Compiler flags in a group other than 'OPTS', 'OPT_OPTS', and 'OPTIMIZATION_FLAGS'. The build process produces a warning if  &gt;COMPILE_FLAGS_OTHER&lt;  is absent and these conditions apply:</p> <ul style="list-style-type: none"> <li>• The build information contains a compiler flag that is not in 'OPTS', 'OPT_OPTS', or 'OPTIMIZATION_FLAGS'.</li> <li>• The compiler flag is not in the template makefile.</li> </ul>
>COMPUTER<	Computer type. See the MATLAB computer command.

Token	Expansion
>DEFINES_OTHER<	<p>Preprocessor macro definitions in a group other than 'OPTS', 'OPT_OPTS', 'OPTIMIZATION_FLAGS', and 'Custom'.</p> <p>A preprocessor macro definition in 'OPTS', 'OPT_OPTS', 'OPTIMIZATION_FLAGS', or 'Custom' that has a corresponding variable/token pair in the template makefile is not expanded in <code>DEFINES_OTHER</code>. This behavior helps to avoid the provision of duplicate preprocessor macro definitions.</p> <p>For example, some template makefiles contain these statements:</p> <pre>... NUMST =  &gt;NUMST&lt;  ... CPP_REQ_DEFINES1 = ... -DNUMST=\$(NUMST) ...</pre> <p>If the template makefile contains the variable/token pair <code>NUMST =  &gt;NUMST&lt; </code> and <code>NUMST</code> is a preprocessor macro definition in <code>buildInfo</code>, then the build process does not expand it in <code>DEFINES_OTHER</code>.</p> <p>The build process produces a warning if <code> &gt;DEFINES_OTHER&lt; </code> is absent and these conditions apply:</p> <ul style="list-style-type: none"> <li>The build information contains a preprocessor macro definition that is not in 'OPTS', 'OPT_OPTS', 'OPTIMIZATION_FLAGS', or 'Custom'.</li> <li>The preprocessor macro definition, for example, <code>NUMST</code>, is not in the template makefile.</li> </ul>
>EXPAND_LIBRARY_LOCATION<	Location of precompiled library file. The <code>TargetPreCompLibLocation</code> configuration parameter can override this setting. For examples, see “Control Library Location and Naming During Build”.
>EXPAND_LIBRARY_NAME<	Library name. For examples, see “Control Library Location and Naming During Build” and “Modify the Template Makefile for <code>rtwmakecfg</code> ”.
>EXPAND_LIBRARY_SUFFIX<	Library suffix. The <code>TargetLibSuffix</code> configuration parameter can override this setting. For examples, see “Control Library Location and Naming During Build”.
>EXT_MODE<  (Not required for R2018a and later provided template makefile specifies <code>TOOLCHAIN_NAME</code> )	True (1) to enable generation of external mode support code, otherwise False (0).
>EXTMODE_TRANSPORT<  (Not required for R2018a and later provided template makefile specifies <code>TOOLCHAIN_NAME</code> )	Index of transport mechanism (for example, <code>tcpip</code> , <code>serial</code> ) for external mode.

Token	Expansion
>EXTMODE_STATIC<  (Not required for R2018a and later provided template makefile specifies TOOLCHAIN_NAME)	True (1) if static memory allocation is selected for external mode. False (0) if dynamic memory allocation is selected.
>EXTMODE_STATIC_SIZE<  (Not required for R2018a and later provided template makefile specifies TOOLCHAIN_NAME)	Size of static memory allocation buffer for external mode.
>GENERATE_ERT_S_FUNCTION<	True (1) when model configuration parameter <b>Create block</b> is set to SIL, otherwise False (0). Used for control of the makefile target of the build.
>INCLUDE_MDL_TERMINATE_FCN<	True (1) when model configuration parameter <b>Terminate function required</b> is selected, otherwise False (0). Used for the macro definition <code>-DTERMFCN==1</code> .
>INTEGER_CODE<	True (1) when model configuration parameter <b>Support floating-point numbers</b> is cleared, otherwise False (0). INTEGER_CODE is a required macro definition when compiling the source code and is used when selecting precompiled libraries to link against.
>MAKEFILE_NAME<	<i>model_or_sharedutils.mk</i> — The name of the makefile that was created from the TMF.
>MAT_FILE<	True (1) when model configuration parameter <b>MAT-file logging</b> is selected, otherwise False (0). MAT_FILE is a required macro definition when compiling the source code and also is used to include logging code in the build process.
>MATLAB_BIN<	Location of the MATLAB executable program.
>MATLAB_ROOT<	Path to where MATLAB is installed.
>MEM_ALLOC<	RT_MALLOC or RT_STATIC. Indicates how memory is to be allocated.
>MEXEXT<	MEX-file extension. See the MATLAB mexext command.
>MODEL_MODULES<	Additional generated source modules. For example, you can split a large model into two files, <i>model.c</i> and <i>model1.c</i> . In this case, this token expands to <i>model1.c</i> .
>MODEL_MODULES_OBJ<	Object filenames (.obj) corresponding to additional generated source modules.
>MODEL_NAME<	Name of the Simulink block diagram currently being built.
>MULTITASKING<	True (1) if solver mode is multitasking, otherwise False (0).
>NCSTATES<	Number of continuous states.
>NUMST<	Number of sample times in the model.
>RELEASE_VERSION<	The MATLAB release version.
>S_FUNCTIONS_LIB<	List of S-function libraries available for linking.
>SOLVER<	Solver source filename, for example, <i>ode3.c</i> .
>SOLVER_OBJ<	Solver object (.obj) filename, for example, <i>ode3.obj</i> .
>START_DIR<	Code generation folder at the start of the build.

Token	Expansion
>TARGET_LANG_EXT<	c when model configuration parameter <b>Language</b> is set to C, cpp when <b>Language</b> is set to C++. Used in the makefile to control the extension on generated source files.
>TID01EQ<	True (1) if sampling rates of the continuous task and the first discrete task are equal, otherwise False (0).
<b>S-function and build information support</b>	
<b>Note</b> For examples of the tokens in this section, see “Modify the Template Makefile for rtwmakecfg”.	
>START_EXPAND_INCLUDES<   >EXPAND_DIR_NAME<   >END_EXPAND_INCLUDES<	List of folder names to add to the include path. Additionally, the ADD_INCLUDES macro must be added to the INCLUDES line.
>START_EXPAND_LIBRARIES<   >EXPAND_LIBRARY_NAME<   >END_EXPAND_LIBRARIES<	List of library names.
>START_EXPAND_MODULES<   >EXPAND_MODULE_NAME<   >END_EXPAND_MODULES<	Library module names within  >START_EXPAND_LIBRARIES<  and  >START_PRECOMP_LIBRARIES<  library lists.
>START_EXPAND_RULES<   >EXPAND_DIR_NAME<   >END_EXPAND_RULES<	Makefile rules.
>START_PRECOMP_LIBRARIES<   >EXPAND_LIBRARY_NAME<   >END_PRECOMP_LIBRARIES<	List of precompiled library names.
<b>Model reference support</b>	
<b>Note</b> For examples of the tokens in this section, see “Providing Model Referencing Support in the TMF” on page 88-60.	
>MODELLIB<	Name of the library file generated for the current model.
>MODELREFS<	List of models referenced by the top model.
>MODELREF_LINK_LIBS<	List of referenced model libraries against which the top model links.
>MODELREF_LINK_RSPFILE_NAME<	Name of a response file against which the top model links. This token is valid only for build environments that support linker response files. For an example of its use, see <i>matlabroot/toolbox/coder/compile/tmf/grt_vcx64.tmf</i> .
>MODELREF_TARGET_TYPE<	Type of target being built. Possible values are <ul style="list-style-type: none"> <li>• NONE: Standalone model or top model referencing other models</li> <li>• RTW: Model reference target build</li> <li>• SIM: Model reference simulation target build</li> </ul>

Token	Expansion
>RELATIVE_PATH_TO_ANCHOR<	Relative path, from the location of the generated makefile, to the MATLAB working folder.

These tokens are expanded by substitution of parameter values known to the build process. For example, if the source model contains blocks with two different sample times, the TMF statement

```
NUMST = |>NUMST<|
```

expands to:

```
NUMST = 2
```

In addition to the above, `make_rtw` expands tokens from other sources:

- Target-specific tokens defined in the target options of the Configuration Parameters dialog box
- Structures in the `rtwoptions` section of the system target file. Structures in the `rtwoptions` structure array that contain the field `makevariable` are expanded.

The following example is extracted from `matlabroot/rtw/c/grt/grt.tlc`. The section starting with `BEGIN_RTW_OPTIONS` contains MATLAB code that sets up `rtwoptions`. The following directive causes the `|>EXT_MODE<|` token to be expanded to 1 (on) or 0 (off), depending on how you set the external mode options.

```
rtwoptions(2).makevariable = 'EXT_MODE'
```

## Invoke the make Utility

- “make Command” on page 88-48
- “make Utility Versions” on page 88-49

### make Command

After creating `model_or_sharedutils.mk` from your TMF, the build process invokes a `make` command. To invoke `make`, the build process issues this command.

```
makecommand -f model_or_sharedutils.mk
```

`makecommand` is defined by the `MAKECMD` macro in your system target file TMF (see “Structure of the Template Makefile” on page 88-49). You can specify additional options to `make` by using the model configuration parameter **Make command**. (See the sections “Specify a Make Command” and “Template Makefiles and Make Options”.)

For example, specifying `OPT_OPTS=-02` in the **Make command** field causes `make_rtw` to generate the following `make` command.

```
makecommand -f model_or_sharedutils.mk OPT_OPTS=-02
```

A comment at the top of the TMF specifies the available `make` command options. If these options do not provide you with enough flexibility, you can configure your own TMF.

## make Utility Versions

The make utility lets you control nearly every aspect of building your real-time program. There are several different versions of make available. The code generator provides the Free Software Foundation GNU make for both UNIX<sup>7</sup> and PC platforms in platform-specific subfolders under

*matlabroot/bin*

It is possible to use other versions of make with the code generator, although GNU Make is recommended. To be compatible with the code generator, verify that your version of make supports the following command format.

```
makecommand -f model_or_sharedutils.mk
```

## Structure of the Template Makefile

A TMF has multiple sections, including the following:

- **Abstract** — Describes what the makefile targets. Here is a representative abstract from the ERT TMFs in *matlabroot/toolbox/coder/compile/tmf*:

```
Abstract:
Template makefile for building a Windows-based stand-alone embedded
real-time version of Simulink model using generated C code and the
Microsoft Visual C/C++ compiler for x64.
#
Note that this template is automatically customized by the build
procedure to create "<model>.mk"
#
The following defines can be used to modify the behavior of the
build:
OPT_OPTS - Optimization option. See DEFAULT_OPT_OPTS in
vctools.mak for default.
OPTS - User specific options.
CPP_OPTS - C++ compiler options.
USER_SRCS - Additional user sources, such as files needed by
S-functions.
USER_INCLUDES - Additional include paths
(i.e. USER_INCLUDES="-Iwhere-ever -Iwhere-ever2")
#
To enable debugging:
set DEBUG_BUILD = 1, which will trigger OPTS=-Zi (may vary with
compiler version, see compiler doc)
#
This template makefile is designed to be used with a system target
file that contains 'rtwgensettings.BuildDirSuffix' see ert.tlc
```

- **Macros read by make\_rtw section** — Defines macros that tell make\_rtw how to process the TMF. Here is a representative Macros read by make\_rtw section from the GRT TMFs in *matlabroot/toolbox/coder/compile/tmf*:

```
#----- Macros read by make_rtw -----
#
The following macros are read by the build procedure:
#
MAKECMD - This is the command used to invoke the make utility
HOST - What platform this template makefile is targeted for
(i.e. PC or UNIX)
BUILD - Invoke make from the build procedure (yes/no)?
SYS_TARGET_FILE - Name of system target file.
#
MAKECMD = nmake
HOST = PC
```

<sup>7</sup> UNIX is a registered trademark of The Open Group in the United States and other countries.

```

BUILD = yes
SYS_TARGET_FILE = any
BUILD_SUCCESS = ^#^#^# Created

Opt in to simplified format by specifying compatible Toolchain
TOOLCHAIN_NAME = [\
 "Microsoft Visual C++ 2019 v16.0 | nmake (64-bit Windows)", \
 "Microsoft Visual C++ 2017 v15.0 | nmake (64-bit Windows)", \
 "Microsoft Visual C++ 2015 v14.0 | nmake (64-bit Windows)"]

```

The macros in this section might include:

- **MAKECMD** — Specifies the command used to invoke the make utility. For example, if **MAKECMD** = **mymake**, then the make command invoked is

```
mymake -f model_or_sharedutils.mk
```

- **HOST** — Specifies the platform targeted by this TMF. This can be **PC**, **UNIX**, *computer\_name* (see the **MATLAB** **computer** command), or **ANY**.
- **BUILD** — Instructs **make\_rtw** whether or not it should invoke **make** from the build procedure. Specify **yes** or **no**.
- **SYS\_TARGET\_FILE** — Specifies the name of the system target file or the value **any**. This is used for consistency checking by **make\_rtw** to verify the system target file specified in the **Target selection** panel of the **Code Generation** pane of the Configuration Parameters dialog box. If you specify **any**, you can use the TMF with any system target file.
- **BUILD\_SUCCESS** — When the makefile creates a static library, it produces the **BUILD\_SUCCESS** string as defined, for example, by this rule in **ert\_vcx64.tmf**:

```

$(PRODUCT) : $(OBJS) $(LIBS) $(MODELREF_LINK_LIBS)
 @cmd /C "echo ### Linking ..."
 $(LD) $(LD_FLAGS) $(LIBS) \
 @$$(CMD_FILE) @$$(MODELREF_LINK_RSPFILE) -dll -def:$(MODEL).def -out:$@
 @cmd /C "echo $(BUILD_SUCCESS) dynamically linked library $(PRODUCT)"

```

When the build process finds the **BUILD\_SUCCESS** string, it polls for the existence of the updated static library file. The build process does not link the library file to the executable file until the build process can confirm the presence of the library file, with an updated timestamp, on the file system.

If the build process does not find **BUILD\_SUCCESS** in the compilation log, then the build process assumes that the updated library archive is available on the file system. If required, the build process links the library to the executable file.

- **Tokens expanded by make\_rtw section** — Defines the tokens that **make\_rtw** expands. Here is a brief excerpt from a representative **Tokens expanded by make\_rtw section** from the ERT TMFs in *matlabroot/toolbox/coder/compile/tmf/*:

```

#----- Tokens expanded by make_rtw -----
#
The following tokens, when wrapped with "|>" and "<|" are expanded by the
build procedure.
#
MODEL_NAME - Name of the Simulink block diagram
MODEL_MODULES - Any additional generated source modules
MAKEFILE_NAME - Name of makefile created from template makefile <model>.mk
MATLAB_ROOT - Path to where MATLAB is installed.
...

MODEL = |>MODEL_NAME<|
MODULES = |>MODEL_MODULES<|
PRODUCT = |>PRODUCT<|
MAKEFILE = |>MAKEFILE_NAME<|

```

```
MATLAB_ROOT = |>MATLAB_ROOT<|
...
```

For more information about TMF tokens, see [Template Makefile Tokens Expanded by make\\_rtw](#).

- Subsequent sections vary based on compiler, host, and target. Some common sections include `Model` and `reference models`, `External mode`, `Tool Specifications` or `Tool Definitions`, `Include Path`, `C Flags`, `Additional Libraries`, and `Source Files`.
- `Rules` section — Contains the make rules used in building an executable from the generated source code. The build rules are typically specific to your version of make. The `Rules` section might be followed by related sections such as `Dependencies`.

## Customize and Create Template Makefiles

- “Introduction” on page 88-51
- “Setting Up a Template Makefile” on page 88-51
- “Using Macros and Pattern Matching Expressions in a Template Makefile” on page 88-51
- “Customizing Generated Makefiles with `rtwmakecfg`” on page 88-53
- “Supporting Continuous Time in Custom Targets” on page 88-53
- “Model Reference Considerations” on page 88-54
- “Timeout Error When Building Shared Utility Code with Custom Template Makefile” on page 88-54

### Introduction

This section describes the mechanics of setting up a custom template makefile (TMF) and incorporating it into the build process. It also discusses techniques for modifying a TMF and MATLAB file mechanisms associated with the TMF.

Before creating a custom TMF, you should read “Folder and File Naming Conventions” on page 88-5 to understand the folder structure and MATLAB path requirements for custom targets.

### Setting Up a Template Makefile

To customize or create a new TMF, copy an existing GRT or ERT TMF from `matlabroot/toolbox/coder/compile/tmf`.

Place the copy in the same folder as the associated system target file. Usually, this is the `mytarget/mytarget` folder within the target folder structure. Then, rename your TMF (for example, `mytarget.tmf`) and modify it.

To allow the build process to locate and select your TMF, you must provide information in the system target file header (see “System Target File Structure” on page 88-18). For a target that implements a single TMF, the standard way to specify the TMF to be used in the build process is to use the `TMF` directive of the system target file header.

```
TMF: mytarget.tmf
```

### Using Macros and Pattern Matching Expressions in a Template Makefile

This section shows, through an example, how to use macros and file-pattern-matching expressions in a TMF to generate commands in `model_or_sharedutils.mk`.

The `make` utility processes `model_or_sharedutils.mk` and generates a set of commands based upon dependency rules defined in `model_or_sharedutils.mk`. After `make` generates the set of commands for building or rebuilding `test`, `make` executes them.

For example, to build a program called `test`, `make` must link the object files. However, if the object files don't exist or are out of date, `make` must compile the source code. Thus there is a dependency between source and object files.

Each version of `make` differs slightly in its features and how rules are defined. For example, consider a program called `test` that gets created from two sources, `file1.c` and `file2.c`. Using most versions of `make`, the dependency rules would be

```
test: file1.o file2.o
 cc -o test file1.o file2.o

file1.o: file1.c
 cc -c file1.c

file2.o: file2.c
 cc -c file2.c
```

In this example, a UNIX<sup>8</sup> environment is assumed. In a PC environment the file extensions and compile and link commands are different.

In processing the first rule

```
test: file1.o file2.o
```

`make` sees that to build `test`, it needs to build `file1.o` and `file2.o`. To build `file1.o`, `make` processes the rule

```
file1.o: file1.c
```

If `file1.o` doesn't exist, or if `file1.o` is older than `file1.c`, `make` compiles `file1.c`.

The format of TMFs follows the above example. Our TMFs use additional features of `make` such as macros and file-pattern-matching expressions. In most versions of `make`, a macro is defined with

```
MACRO_NAME = value
```

References to macros are made with `$(MACRO_NAME)`. When `make` sees this form of expression, it substitutes `value` for `$(MACRO_NAME)`.

You can use pattern matching expressions to make the dependency rules more general. For example, using GNU<sup>9</sup> Make, you could replace the two "`file1.o: file1.c`" and "`file2.o: file2.c`" rules with the single rule

```
%.o : %.c
 cc -c $<
```

Note that `$<` in the previous example is a special macro that equates to the dependency file (that is, `file1.c` or `file2.c`). Thus, using macros and the "%" pattern matching character, the previous example can be reduced to

---

8 UNIX is a registered trademark of The Open Group in the United States and other countries.

9 GNU is a registered trademark of the Free Software Foundation.

```

SRCS = file1.c file2.c
OBJS = $(SRCS:.c=.o)

test: $(OBJS)
 cc -o $@ $(OBJS)

%.o : %.c
 cc -c $<

```

Note that the `$@` macro above is another special macro that equates to the name of the current dependency target, in this case `test`.

This example generates the list of objects (`OBJS`) from the list of sources (`SRCS`) by using the text substitution feature for macro expansion. It replaces the source file extension (for example, `.c`) with the object file extension (`.o`). This example also generalized the build rule for the program, `test`, to use the special "`$@`" macro.

### Customizing Generated Makefiles with `rtwmakecfg`

TMFs provide tokens that let you add the following items to generated makefiles:

- Source folders
- Include folders
- Run-time library names
- Run-time module objects

S-functions can add this information to the makefile by using an `rtwmakecfg.m` file function. This function is particularly useful when building a model that contains one or more of your S-Function blocks, such as device driver blocks.

To add information pertaining to an S-function to the makefile,

- 1 Create the function `rtwmakecfg` in file `rtwmakecfg.m`. The code generator associates this file with your S-function based on its folder location.
- 2 Modify your target's TMF such that it supports macro expansion for the information returned by `rtwmakecfg` functions.

After the TLC phase of the build process, when generating a makefile from the TMF, the build process searches for an `rtwmakecfg.m` file in the folder that contains the S-function component. If it finds the file, the build process calls the `rtwmakecfg` function. For more information, see "Use `rtwmakecfg.m` API to Customize Generated Makefiles".

### Supporting Continuous Time in Custom Targets

If you want your custom ERT-based target to support continuous time, you must update your template makefile (TMF) and the static main program module (for example, `mytarget_main.c`) for your target.

#### Template Makefile Modifications

Add the `NCSTATES` token expansion after the `NUMST` token expansion, as follows:

```

NUMST = |>NUMST<|
NCSTATES = |>NCSTATES<|

```

In addition, add NCSTATES to the CPP\_REQ\_DEFINES macro, as in the following example:

```
CPP_REQ_DEFINES = -DMODEL=$(MODEL) -DNUMST=$(NUMST) -DNCSTATES=$(NCSTATES) \
-DMAT_FILE=$(MAT_FILE) \
-DINTEGER_CODE=$(INTEGER_CODE) \
-DONESTEPFCN=$(ONESTEPFCN) -DTERMFCN=$(TERMFCN) \
-DHAVESTDIO \
-DMULTI_INSTANCE_CODE=$(MULTI_INSTANCE_CODE) \
```

### Modifications to Main Program Module

The main program module defines a static main function that manages task scheduling for the supported tasking modes of single- and multiple-rate models. NUMST (the number of sample times in the model) determines whether the main function calls multirate or single-rate code. However, when a model uses continuous time, do not rely on NUMST directly.

When the model has continuous time and the flag TID01EQ is true, both continuous time and the fastest discrete time are treated as one rate in generated code. The code associated with the fastest discrete rate is guarded by a major time step check. When the model has only two rates, and TID01EQ is true, the generated code has a single-rate call interface.

To support models that have continuous time, update the static main module to take TID01EQ into account, as follows:

- 1 Before NUMST is referenced in the file, add the following code:

```
#if defined(TID01EQ) && TID01EQ == 1 && NCSTATES == 0
#define DISC_NUMST (NUMST - 1)
#else
#define DISC_NUMST NUMST
#endif
```

- 2 Replace instances of NUMST in the file by DISC\_NUMST.

### Model Reference Considerations

See “Support Model Referencing” on page 88-60 for important information on TMF modifications you may need to make to support the code generator model referencing features.

---

**Note** If you are using a TMF without the variable MODELREFS, the file might have been used with a previous release of Simulink software. If you want your TMF to support model referencing, add MODELREFS to the make file.

---

### Timeout Error When Building Shared Utility Code with Custom Template Makefile

If the build process uses a custom template makefile to create a makefile for the shared utility code, the build process produces a timeout error when all of these conditions apply:

- The configuration parameter GenCodeOnly is 'off'.
- The BUILD\_SUCCESS message is output during the make call to rtwshared.mk.
- The make call to rtwshared.mk does not update the final product (typically rtwshared.lib).

To avoid the error, update the custom template makefile so that the make call generates the BUILD\_SUCCESS message only when the final product is generated (as identified by the make variable PRODUCT). Alternatively, if the build process does not use the generated makefile, disable makefile generation by setting the configuration parameter GenerateMakefile to 'off'.

- [“Customize System Target Files”](#)
- [“Custom Target Optional Features”](#)
- [“Support Toolchain Approach with Custom Target”](#)

## Custom Target Optional Features

This section describes how to configure a custom embedded target to support these optional features.

To ...	Use Target Configuration Parameters ...	For more information, see ...
Indicate a custom target is toolchain-compliant	UseToolchainInfoCompliant GenerateMakefile	“Support Toolchain Approach with Custom Target”
Build a model that includes referenced models and uses a custom target	ModelReferenceCompliant ParMdlRefBuildCompliant (parallel build support)	“Support Model Referencing”
Control the compiler optimization level building generated code for a custom target	CompOptLevelCompliant	“Support Compiler Optimization Level Control”
Control C function prototypes of initialize and step functions that are generated for a model that uses a custom target	ModelStepFunctionPrototypeControlCompliant (ERT only)	“Support C Function Prototype Control”
Control C++ class interfaces that are generated for a model that uses a custom target	CPPClassGenCompliant (ERT only)	“Support C++ Class Interface Control”
Enable concurrent execution of multiple tasks on a multicore platform for a model that uses a custom target	ConcurrentExecutionCompliant	“Support Concurrent Execution of Multiple Tasks”

The required configuration changes are modifications to your system target file, and in some cases also modifications to your template makefile (TMF) or your custom static main program.

The API for system target file callbacks provides a function `SelectCallback` for use in system target files. `SelectCallback` is associated with the target rather than with its individual options. If you implement a `SelectCallback` function for a target, it is triggered whenever the user selects the target in the System Target File Browser.

The API provides the functions `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` for controlling custom target configuration options from a user-written `SelectCallback` function. (For function descriptions and examples, see the function reference pages.)

The general requirements for supporting one of the optional features include:

- To support model referencing or compiler optimization level control, the target must be derived from the GRT or the ERT target. To support C function prototype control or C++ class interface control, the target must be derived from the ERT target.
- The system target file must declare feature compliance by including one of the target configuration parameters listed above in a `SelectCallback` function call.

- Additional changes such as TMF modifications or static main program modifications may be required, depending on the feature. See the detailed steps in the subsections for individual features.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

## Support Toolchain Approach with Custom Target

This section describes how to configure a custom system target file to support builds with the toolchain approach.

In the Configuration Parameters dialog box, on the Code Generation pane of, you can set the build controls for the toolchain approach or the template makefile approach. The model configuration parameters that contribute to determining which build controls appear include these parameters.

Model Parameter	Value	Notes
UseToolchainInfoCompliant	on	For toolchain approach, set this parameter to 'on'. For TMF approach, set this parameter to 'off'.
GenerateMakefile	on	For toolchain approach, set this parameter to 'on'.

When the dialog box detects that the selected target has these properties, the dialog box recognizes the target as toolchain-compliant and displays the build controls for the toolchain approach.

Because the custom target file cannot set these properties directly, use a `SelectCallback` function in the custom target file to set the properties. The `SelectCallback` function call in the `RTW_OPTION` section of the TLC file can take the form:

```
rtwgensettings.SelectCallback = 'enableToolchainCompliant(hSrc, hDlg)';
```

A corresponding callback function can contain:

```
function enableToolchainCompliant(hSrc, hDlg)
% The following parameters enable toolchain compliance.
slConfigUISetVal(hDlg, hSrc, 'UseToolchainInfoCompliant', 'on');
slConfigUISetVal(hDlg, hSrc, 'GenerateMakefile', 'on');

% The following parameters are not required for toolchain compliance.
% But, it is recommended practice to set these default values and
% disable the parameters (as shown).
slConfigUISetVal(hDlg, hSrc, 'RTWCompilerOptimization', 'off');
slConfigUISetVal(hDlg, hSrc, 'MakeCommand', 'make_rtw');
slConfigUISetEnabled(hDlg, hSrc, 'RTWCompilerOptimization', false);
slConfigUISetEnabled(hDlg, hSrc, 'MakeCommand', false);
hSrc.refreshDialog;
end
```

When you select your custom target, the configuration parameters dialog box displays the toolchain approach build controls. For an example, see “Create a Custom Target Configuration” on page 88-32.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

## Support Model Referencing

If you want to use a custom system target file for building a model that has referenced models, you must configure the custom system target file to support model referencing.

### Requirements for Model Referencing with a Custom System Target File

To build a model that references other models:

- Use a custom system target file that is derived from a GRT or ERT system target file.
- The custom system target file must declare model reference compliance -- see “Declaring Model Referencing Compliance” on page 88-60.
- The template makefile must define some entities that support model referencing -- see “Providing Model Referencing Support in the TMF” on page 88-60.

### Declaring Model Referencing Compliance

To declare model reference compliance for your target, you must implement a callback function that sets the `ModelReferenceCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your system target file. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following system target file code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in system target file callback functions. They should be passed in without alteration.

Your callback function should set the `ModelReferenceCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ModelReferenceCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ModelReferenceCompliant',false);
hSrc.refreshDialog;
```

If you might use the target to build models containing large model reference hierarchies, consider configuring the target to support parallel builds, as discussed in “Reduce Build Time for Referenced Models by Using Parallel Builds”.

To configure a target for parallel builds, your callback function must also set the `ParMdlRefBuildCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ParMdlRefBuildCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ParMdlRefBuildCompliant',false);
hSrc.refreshDialog;
```

For more information about the system target file callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

### Providing Model Referencing Support in the TMF

To configure the template makefile (TMF) for model referencing:

- 1 Add the following make variables and tokens to be expanded when the makefile is generated:

```

MODELREFS = |>MODELREFS<|
MODELLIB = |>MODELLIB<|
MODELREF_LINK_LIBS = |>MODELREF_LINK_LIBS<|
MODELREF_LINK_RSPFILE = |>MODELREF_LINK_RSPFILE_NAME<|
RELATIVE_PATH_TO_ANCHOR = |>RELATIVE_PATH_TO_ANCHOR<|
MODELREF_TARGET_TYPE = |>MODELREF_TARGET_TYPE<|

```

The following code excerpt shows how makefile tokens are expanded for a referenced model.

```

MODELREFS =
MODELLIB = engine3200cc_rtwlib.a
MODELREF_LINK_LIBS =
MODELREF_LINK_RSPFILE =
RELATIVE_PATH_TO_ANCHOR = ../../..
MODELREF_TARGET_TYPE = RTW

```

The following code excerpt shows how makefile tokens are expanded for the top model that references the referenced model.

```

MODELREFS = engine3200cc transmission
MODELLIB =
MODELREF_LINK_LIBS = engine3200cc_rtwlib.a transmission_rtwlib.a
MODELREF_LINK_RSPFILE =
RELATIVE_PATH_TO_ANCHOR = ..
MODELREF_TARGET_TYPE = NONE

```

Token	Expands to
MODELREFS for the top model	List of referenced model names.
MODELLIB	Name of the library generated for the model.
MODELREF_LINK_LIBS token for the top model	List of referenced model libraries that the top model links against.
MODELREF_LINK_RSPFILE token for the top model	Name of a response file that the top model links against. This token is valid only for build environments that support linker response files. For an example of its use, see <i>matlabroot/toolbox/coder/compile/tmf/grt_vcx64.tmf</i> .
RELATIVE_PATH_TO_ANCHOR	Relative path, from the location of the generated makefile, to the MATLAB working folder.
MODELREF_TARGET_TYPE	Signifies the type of target being built. Possible values are <ul style="list-style-type: none"> <li>• NONE: Standalone model or top model referencing other models</li> <li>• RTW: Model reference target build</li> <li>• SIM: Model reference simulation target build</li> </ul>

- 2 Add the RELATIVE\_PATH\_TO\_ANCHOR include path to the overall INCLUDES variable.

```

INCLUDES = -I. -I$(RELATIVE_PATH_TO_ANCHOR) $(ADD_INCLUDES) \
$(USER_INCLUDES) $(SHARED_INCLUDES)

```

- 3 Change the SRCS variable in your TMF so that it initially lists only common modules. Additional modules are then appended conditionally, as described in the next step. For example, change

```
SRCS = $(MODEL).c $(MODULES) ert_main.c $(ADD_SRCS) $(EXT_SRC)
```

to

```
SRCS = $(MODULES)
```

- 4 Create variables to define the final target of the makefile. You can remove variables that may have existed for defining the final target. For example, remove

```
PROGRAM = ../$(MODEL)
```

and replace it with

```
ifeq ($(MODELREF_TARGET_TYPE), NONE)
Top model for RTW
PRODUCT = $(RELATIVE_PATH_TO_ANCHOR)/$(MODEL)
BIN_SETTING = $(LD) $(LD_FLAGS) -o $(PRODUCT) $(SYSLIBS)
BUILD_PRODUCT_TYPE = "executable"
ERT based targets
SRCS += $(MODEL).c ert_main.c $(EXT_SRC)
GRT based targets
SRCS += $(MODEL).c grt_main.c rt_sim.c $(EXT_SRC) $(SOLVER)
else
sub-model for RTW
PRODUCT = $(MODELLIB)
BUILD_PRODUCT_TYPE = "library"
endif
```

---

**Note** If the template makefile is associated with a toolchain, remove `$(MODEL).c` or `$(MODEL).$(TARGET_LANG_EXT)` from the SRCS list.

---

- 5 Create rules for the final target of the makefile (replace existing final target rules). For example:

```
ifeq ($(MODELREF_TARGET_TYPE), NONE)
Top model for RTW
$(PRODUCT) : $(OBJS) $(LIBS) $(MODELREF_LINK_LIBS)
 $(BIN_SETTING) $(LINK_OBJS) $(MODELREF_LINK_LIBS)
 $(LIBS)
 @echo "### Created $(BUILD_PRODUCT_TYPE): $@"
else
sub-model for RTW
$(PRODUCT) : $(OBJS) $(LIBS)
 @rm -f $(MODELLIB)
 $(ar) ruvs $(MODELLIB) $(LINK_OBJS)
 @echo "### Created $(MODELLIB)"
 @echo "### Created $(BUILD_PRODUCT_TYPE): $@"
endif
```

- 6 Create a rule to allow referenced models to compile files that reside in the MATLAB working folder (pwd).

```
%.o : $(RELATIVE_PATH_TO_ANCHOR)/%.c
 $(CC) -c $(CFLAGS) $<
```

---

**Note** If you are using a TMF without the variable `MODELREFS`, the file might have been used with a previous release of Simulink software. If you want your TMF to support model referencing, add either variable `MODELREFS` to the make file.

---

## Controlling Configuration Option Value Agreement

By default, the value of a configuration option defined in the system target file for a TLC-based custom target must be the same in a referenced model and its parent model. To relax this requirement, include the `modelReferenceParameterCheck` field in the `rtwoptions` structure element that defines the configuration option, and set the value of the field to `'off'`. For example:

```

rtwoptions(2).prompt = 'My Custom Parameter';
rtwoptions(2).type = 'Checkbox';
rtwoptions(2).default = 'on';
rtwoptions(2).modelReferenceParameterCheck = 'on';
rtwoptions(2).tlcvariable = 'mytlcvariable';
...

```

The configuration option **My Custom Parameter** can differ in a referenced model and its parent model. See “Customize System Target Files” on page 88-18 for information about TLC-based system target files, and *rtwoptions* Structure Fields Summary for a list of *rtwoptions* fields.

## Preventing Resource Conflicts (Optional)

Hook files are optional TLC and MATLAB program files that are invoked at well-defined stages of the build process. Hook files let you customize the build process and communicate information between various phases of the process.

If you are adapting your custom target for code generation compatibility with model reference features, consider adding checks to your hook files for handling referenced models differently than top models to prevent resource conflicts.

For example, consider adding the following check to your *STF\_make\_rtw\_hook.m* file:

```

% Check if this is a referenced model
mdlRefTargetType = get_param(codeGenModelName, 'ModelReferenceTargetType');
isNotModelRefTarget = strcmp(mdlRefTargetType, 'NONE'); % NONE, SIM, or RTW
if isNotModelRefTarget
 % code that is specific to the top model
else
 % code that is specific to the referenced model
end

```

You may need to do a similar check in your TLC code.

```

%if !IsModelReferenceTarget()
 %% code that is specific to the top model
%else
 %% code that is specific to the referenced model
%endif

```

## Support Compiler Optimization Level Control

This section describes how to configure a custom embedded target to support compiler optimization level control. Without the described modifications, you cannot use model configuration parameter **Compiler optimization level** to control the compiler optimization level for building generated code. For more information about compiler optimization level control, see “Compiler optimization level”.

### About Compiler Optimization Level Control and Custom Targets

The requirements for supporting compiler optimization level control are as follows:

- The target must be derived from the GRT target or the ERT target.
- The system target file must declare compiler optimization level control compliance, as described in “Declaring Compiler Optimization Level Control Compliance” on page 88-64.
- The target makefile must honor the setting for model configuration parameter **Compiler optimization level**, as described in “Providing Compiler Optimization Level Control Support in the Target Makefile” on page 88-65.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

### Declaring Compiler Optimization Level Control Compliance

To declare compiler optimization level control compliance for your target, you must implement a callback function that sets the `CompOptLevelCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your system target file. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following system target file code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in system target file callback functions. They should be passed in without alteration.

Your callback function should set the `CompOptLevelCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'CompOptLevelCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'CompOptLevelCompliant',false);
hSrc.refreshDialog;
```

For more information about the system target file callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `CompOptLevelCompliant` target configuration parameter is set to on, the **Compiler optimization level** parameter is displayed in the **Code Generation** pane of the Configuration Parameters dialog box for your model.

## Providing Compiler Optimization Level Control Support in the Target Makefile

As part of supporting compiler optimization level control for your target, you must modify the target makefile to honor the setting for model configuration parameter **Compiler optimization level**. Use a GRT or ERT target provided by MathWorks as a model for making the modifications.

## Support C Function Prototype Control

This section describes how to configure a custom embedded target to support function prototype control. Without the described modifications, you will not be able to use available interfaces for customizing entry-point function interfaces. For more information, see “Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113.

### About C Function Prototype Control and Custom Targets

The requirements for supporting C function prototype control are as follows:

- The system target file must be derived from the ERT system target file.
- The system target file must declare C function prototype control compliance, as described in “Declaring C Function Prototype Control Compliance” on page 88-66.
- If your system target file uses a custom static main program, and if a nondefault function prototype control configuration is associated with a model, the static main program must call the function prototype controlled initialize and step functions, as described in “Providing C Function Prototype Control Support in the Custom Static Main Program” on page 88-67.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

### Declaring C Function Prototype Control Compliance

To declare C function prototype control compliance for your target, you must implement a callback function that sets the `ModelStepFunctionPrototypeControlCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your system target file. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following system target file code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in system target file callback functions. They should be passed in without alteration.

Your callback function should set the `ModelStepFunctionPrototypeControlCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ModelStepFunctionPrototypeControlCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ModelStepFunctionPrototypeControlCompliant',false);
hSrc.refreshDialog;
```

For more information about the system target file callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `ModelStepFunctionPrototypeControlCompliant` target configuration parameter is set to `on`, you can use the Configure C Step Function Interface dialog box to control the function prototype of the base-rate step function generated for a rate-based model.

## Providing C Function Prototype Control Support in the Custom Static Main Program

If your target uses a custom static main program, and if a nondefault function prototype control configuration is associated with a model, you must update the static main program to call the function prototype controlled initialize and step functions. You can do this in either of the following ways:

- 1 Manually adapt your static main program to declare model data and call the function prototype controlled initialize and step functions.
- 2 Generate your main program by selecting model configuration parameter **Generate an example main program**. The generated main program declares model data and calls the function prototype controlled initialize and step function.

## Support C++ Class Interface Control

This section describes how to configure a custom embedded target to support C++ class interface control. Without the described modifications, you will not be able to use C++ class code interface packaging to generate and configure C++ class interfaces to model code. For more information about C++ class interface control, see “Interactively Configure C++ Interface” on page 41-2.

### About C++ Class Interface Control and Custom Targets

The requirements for supporting C++ class interface control are as follows:

- The target must be derived from the ERT system target file.
- The system target file must declare C++ class interface control compliance, as described in “Declaring C++ Class Interface Control Compliance” on page 88-68.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

### Declaring C++ Class Interface Control Compliance

To declare C++ class interface control compliance for your target, you must implement a callback function that sets the `CPPClassGenCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your system target file. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following system target file code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in system target file callback functions. They should be passed in without alteration.

Your callback function should set the `CPPClassGenCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'CPPClassGenCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'CPPClassGenCompliant',false);
hSrc.refreshDialog;
```

For more information about the system target file callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `CPPClassGenCompliant` target configuration parameter is set to `on`, you can use the C++ class code interface packaging to generate and configure C++ class interfaces to model code.

### Providing C++ Class Interface Control Support in the Custom Static Main Program

Selecting C++ class code interface packaging for your model enables model configuration parameter **Generate an example main program**. When you select this parameter, the code generator produces an example main program, `ert_main.cpp`. The generated example main program declares model data and calls the C++ class interface configured model step method, and illustrates how the generated code can be deployed.

To customize the build process and disable generation and inclusion of an example main program, see the `setTargetProvidesMain` function. Disabling example main generation permits including a custom main program.

- [“Custom Targets”](#)
- [“Sample Custom Targets”](#)
- [“Customize System Target Files”](#)

## Support Concurrent Execution of Multiple Tasks

If a custom embedded target must support concurrent execution of multiple tasks on a multicore platform, the target must declare support for concurrent execution by setting the target configuration option `ConcurrentExecutionCompliant`. Otherwise, you will not be able to configure a multicore target model for concurrent execution.

If `ConcurrentExecutionCompliant` is not already configured for your custom target, you can set the option in the following ways:

- Include the following code directly in your system target file (*mytarget.tlc*):

```
rtwgensettings.SelectCallback = 'slConfigUISetVal(hDlg,hSrc,...
 ''ConcurrentExecutionCompliant'',''on'');';
rtwgensettings.ActivateCallback = 'slConfigUISetVal(hDlg,hSrc,...
 ''ConcurrentExecutionCompliant'',''on'');';
```

- Implement a callback function that sets the `ConcurrentExecutionCompliant` option, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your system target file. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following system target file code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in system target file callback functions. They should be passed in without alteration.

Your callback function should set the `ConcurrentExecutionCompliant` option as follows:

```
slConfigUISetVal(hDlg,hSrc,'ConcurrentExecutionCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ConcurrentExecutionCompliant',false);
hSrc.refreshDialog;
```

For more information about the system target file callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `ConcurrentExecutionCompliant` target configuration option is set to 'on', you can select the custom target and configure your multicore target model for concurrent execution.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

## Device Drivers

Device drivers that communicate with target hardware are essential to many real-time development projects.

You can integrate existing C (or C++) device driver functions into Simulink models by using the Legacy Code Tool. When you use the code generator to generate code from a model, the Legacy Code Tool can insert a call to your C function into the generated code. For details, see “Import Calls to External Code into Generated Code with Legacy Code Tool” and “Integrate C Functions into Simulink Models with Legacy Code Tool”.

# Build Configurations for Embedded Targets in Embedded Coder

---

## Model Setup

### In this section...

“Block Selection” on page 89-2

“Configure Target Hardware Resources” on page 89-2

### Block Selection

You can create models for targeting the same way you create other Simulink models—by combining standard blocks and C-MEX S-functions.

You can use blocks from the following sources:

- The Embedded Coder Support Packages.
- The Embedded Targets library (`embeddedtargetslib`) in the Embedded Coder product.
- Blocks from the System Toolboxes products
- Custom blocks

Avoid using blocks that do not generate code, including the following blocks.

Block Name/Category	Library	Description
Scope	Simulink, DSP System Toolbox software	Provides oscilloscope view of your output. Do not use the <b>Save data to workspace</b> option on the <b>Data history</b> pane in the Scope Parameters dialog.
To Workspace	Simulink	Return data to your MATLAB workspace.
From Workspace	Simulink	Send data to your model from your MATLAB workspace.
Spectrum Scope	DSP System Toolbox	Compute and display the short-time FFT of a signal. It has internal buffering that can slow your process without adding value.
To File	Simulink	Send data to a file on your host machine.
From File	Simulink	Get data from a file on your host machine.
Triggered to Workspace	DSP System Toolbox	Send data to your MATLAB workspace.
Signal To Workspace	DSP System Toolbox	Send a signal to your MATLAB workspace.
Signal From Workspace	DSP System Toolbox	Get a signal from your MATLAB workspace.
Triggered Signal From Workspace	DSP System Toolbox	Get a signal from your MATLAB workspace.
To Wave device	DSP System Toolbox	Send data to a <code>.wav</code> device.
From Wave device	DSP System Toolbox	Get data from a <code>.wav</code> device.

### Configure Target Hardware Resources

To configure your Simulink model for your target hardware and toolchain:

- 1** In the Configuration Parameters dialog box, select **Hardware Implementation**, and then specify your **Hardware board**.

Specifying a **Hardware board** automatically sets many **Code Generation** parameters to values appropriate for the hardware.

- 2** On the **Target Hardware Resources** tab, review the other parameters.
- 3** (Optional) In the Configuration Parameters dialog box, select **Code Generation**, and then review and modify other code generation features for your model.
- 4** Click **Apply**, and save the changes to your model.

## Replace Code for Embedded Targets

### In this section...

“Using a Processor-Specific Code Replacement Library to Optimize Code” on page 90-2

“Process of Determining Optimization Effects Using Real-Time Profiling Capability” on page 90-2

### Using a Processor-Specific Code Replacement Library to Optimize Code

You can optimize the code the code generator produces for a specific processor by configuring the code generator to use a code replacement library (CRL) during code generation. If you have an Embedded Coder license, you can develop and apply custom code replacement libraries.

For more information about replacing code, using code replacement libraries that MathWorks provides, see “What Is Code Replacement?” on page 54-2 and “Replace Code Generated from Simulink Models” on page 54-8. For information about developing code replacement libraries, see “What Is Code Replacement Customization?” on page 69-3 and “Develop a Code Replacement Library” on page 69-20.

### Process of Determining Optimization Effects Using Real-Time Profiling Capability

You can use the real-time profiling capability to examine the results of applying the processor-specific library functions and operators to your generated code. After you select a processor-specific code replacement library, use the real-time execution profiling capability to examine the change in program execution time.

Use the following process to evaluate the effects of applying a processor-specific code replacement library when you generate code:

- 1 Enable real-time profiling in your model. Refer to “Code Execution Profiling”.
- 2 Generate code for your project without specifying a code replacement library (the default **Code replacement library** setting is None).
- 3 Profile the code, and save the report.
- 4 Rebuild your project using a processor-specific code replacement library.
- 5 Profile the code, and save the second report.
- 6 Compare the profile report from running your application with the processor-specific library selected to the profile results in the first report with no code replacement library selected.

For an example of verifying the code optimization, search help for “Optimizing Embedded Code via Code Replacement Library” and select the example that matches your IDE.

## Specify Comment Style for C/C++ Code

### In this section...

“Specify Comment Style Using the MATLAB Coder App” on page 91-2

“Specify Comment Style Using the Command-Line Interface” on page 91-2

If you have an Embedded Coder, you can specify the comment style for C/C++ code generated from MATLAB code. Specify single-line style to generate single-line comments preceded by `//`. Specify multiline style to generate single-line or multiline comments delimited by `/*` and `*/`. Single-line style is the default for C++ code generation. Multiline style is the default for C code generation. For C code generation, select single-line comment style only if your compiler supports it.

### Specify Comment Style Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3 Click **More Settings**.
- 4 On the **Code Appearance** tab, select the **Include comments** check box if it is not already selected. By default, the **Include comments** check box is selected.
- 5 Set **Comment Style** to one of the following options.

Value	Description
Auto(Use standard comment style of the target language)	For C, generate multiline comments. For C++, generate single-line comments. (default)
Single-line (Use C++-style comments)	Generate single-line comments preceded by <code>//</code> .
Multi-line (Use C-style comments)	Generate single-line or multiline comments delimited by <code>/*</code> and <code>*/</code> .

### Specify Comment Style Using the Command-Line Interface

- 1 Create a code configuration object for C/C++ code generation. For example, create a configuration object for C/C++ static library generation:

```
cfg = coder.config('lib', 'ecoder', true);
```

- 2 Set the `CommentStyle` property to one of the following values:

Value	Description
'Auto'	For C, generate multiline comments. For C++, generate single-line comments. (default)
'Single-line'	Generate single-line comments preceded by <code>//</code> .

Value	Description
'Multi-line'	Generate single-line or multiline comments delimited by /* and */.

For example, this code sets the comment style to single-line style:

```
cfg.CommentStyle='Single-line';
```

`coder.EmbeddedCodeConfig`

## More About

- “Configure Build Settings”

## Specify Indent Style for C/C++ Code

### In this section...

“Specify Indent Style Using the MATLAB Coder App” on page 91-4

“Specify Indent Style Using the Command-Line Interface” on page 91-5

If you have an Embedded Coder license, you can control the indent style and indent size in C/C++ code generated from MATLAB code. Indent style controls the placement of braces. Indent size controls the number of characters per indentation level.

You can specify the K&R indent style or the Allman indent style. Both styles:

- Place the function opening and closing braces on their own lines at the same indentation level as the function header.
- Indent code within the function according to the indent size.
- For blocks within a function, place closing braces on a new line at the same indentation level as the control statement.
- Indent code within a block according to the indent size.

The K&R style and the Allman style differ in their placement of the opening brace for a control statement. If you want the opening brace on the same line as its control statement, select the K&R style. Here is code that has the K&R indent style:

```
void addone(const double x[6], double z[6])
{
 int i;
 for (i = 0; i < 6; i++) {
 z[i] = x[i] + 1.0;
 }
}
```

If you want the opening brace on its own line, select the Allman style. Here is code that has the Allman indent style:

```
void addone(const double x[6], double z[6])
{
 int i;
 for (i = 0; i < 6; i++)
 {
 z[i] = x[i] + 1.0;
 }
}
```

### Specify Indent Style Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)

- Executable (.exe)
- 3 Click **More Settings**.
  - 4 On the **All Settings** tab, under **Advanced**, set **Indent style** to K&R or Allman.
  - 5 On the **All Settings** tab, under **Advanced**, set **Indent size** to an integer from 2 to 8.

## Specify Indent Style Using the Command-Line Interface

- 1 Create a code configuration object for 'lib', 'dll', or 'exe'. For example:

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

- 2 Set the `IndentStyle` property to 'K&R' or 'Allman'. For example:

```
cfg.IndentStyle = 'Allman';
```

- 3 Set the `IndentSize` property to an integer from 2 to 8. For example:

```
cfg.IndentSize = 4;
```

- “Configure Build Settings”

## Generate Custom File and Function Banners for C/C++ Code

When you generate C and C++ code from MATLAB code, you can use a code generation template (CGT) file to specify custom:

- File banners
- Function Banners
- File trailers
- Comments before code sections

This example shows how you can create your own CGT file and customize it to generate your own file and function banners.

- 1 Create a local copy of the default CGT file for MATLAB Coder and rename it. The default CGT file is `matlabcoder_default_template.cgt` in the `matlabroot/toolbox/coder/matlabcoder/templates/` folder.
- 2 Store the copy in a folder that is outside of the MATLAB folder structure, but on the MATLAB path. If necessary, add the folder to the MATLAB path. If you intend to use the CGT file with a custom target, locate the CGT file in a folder under your target root folder. If the file is not on the MATLAB path, specify a full path to the file when adding the file to your configuration.
- 3 View the default template and generated output. For example, here is the default File Banner section:

```

%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<FileBanner style="classic">
File: %<FileName>

MATLAB Coder version : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>

```

When you generate code using this default, the file banner looks similar to this file banner:

```

/*
 * File: coderand.c
 *
 * MATLAB Coder version : 2.7
 * C/C++ source code generated on : 06-Apr-2014 14:34:15
 */

```

- 4 Edit your local copy of the CGT file. You can change the default values and add your own custom tokens. For example, here is the File Banner section with the style changed to `box` and a custom token `myCustomToken`:

```

%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.

```

```
%%
<FileBanner style="box">
File: %<FileName>

My custom token : %<myCustomToken>

MATLAB Coder version : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>
```

For more information, see “Code Generation Template Files for MATLAB Code” on page 91-9.

- 5 Create a configuration object for generation of a C static library for an embedded target.

```
% Create configuration object for an embedded target
cfgObj = coder.config('lib','ecoder',true);
```

- 6 Create a MATLABCodeTemplate object from your CGT file and add it to the configuration object.

```
% Specify the custom CGT file
CGTFile = 'myCGTFile.cgt';
% Use custom template
cfgObj.CodeTemplate = coder.MATLABCodeTemplate(CGTFile);
```

- 7 Assign values for custom tokens that you added to the template. For example, assign the value 'myValue' to the myCustomToken token that you added in a previous step.

```
cfgObj.CodeTemplate.setTokenValue('myCustomToken','myValue');
```

- 8 Make sure that generation of comments is enabled. Otherwise, the code generator does not produce file or function banners.

```
cfgObj.GenerateComments=true;
```

- 9 Generate code using the configuration object that you created.

```
codegen -config cfgObj coderand
```

- 10 View the changes to the generated file banner. For example, here is the file banner for coderand.c using the customized CGT file:

```
/* File: coderand.c */
/* My custom token : myValue */
/* MATLAB Coder version : 2.7 */
/* C/C++ source code generated on : 06-Apr-2014 14:42:55 */
/*****
```

Changes to a CGT file do not affect the generated code unless you create a MATLABCodeTemplate object from the modified CGT file, and then add it to the configuration object. If you modify the CGT File, myCGTFile.cgt, used in the previous example, you must repeat these steps:

- 1 Create a MATLABCodeTemplate object from myCGTFile.cgt and add it to the configuration object.

```
CGTFile = 'myCGTFile.cgt';
cfgObj.CodeTemplate = coder.MATLABCodeTemplate(CGTFile);
```

- 2 Assign the value 'myValue' to the myCustomToken token.

```
cfgObj.CodeTemplate.setTokenValue('myCustomToken','myValue');
```

- 3 Generate code.

```
codegen -config cfgObj coderand
```

- “Code Generation Template Files for MATLAB Code” on page 91-9

## Code Generation Template Files for MATLAB Code

In this section...
“Default CGT File” on page 91-9
“CGT File Structure” on page 91-9
“Components of the CGT File Sections” on page 91-10

A code generation template (CGT) file defines the sections in generated code that you can customize using comments and tokens. Using a code generation template (CGT) file for the generation of C and C++ code from MATLAB code, you can specify custom file banners and function banners for generated code. File banners are comment sections in the header and trailer sections of a generated file. Function banners are comment sections for each function in the generated code. You can also customize comments before code sections. Use these banners to:

- Add a company copyright statement.
- Specify a special version symbol for your configuration management system.
- Remove timestamps.
- Add other custom information to your generated files.

For information on creating, customizing, and using a CGT file, see “Generate Custom File and Function Banners for C/C++ Code” on page 91-6.

### Default CGT File

You can base your custom template on the default CGT file, `matlabcoder_default_template.cgt`, in the `matlabroot/toolbox/coder/matlabcoder/templates/` folder.

---

**Note** If you choose not to customize banners for your generated code, the default template is used for code generation.

---

### CGT File Structure

A CGT file consists of 13 optional sections.

#### File Banner Section

Contains comments and tokens for use in generating a custom file banner.

#### Function Banner Section

Contains comments and tokens for use in generating a custom function banner.

#### Shared Utility Function Banner

Contains comments and tokens for use in generating custom banners for shared utility functions.

#### File Trailer Section

Contains comments for use in generating a custom trailer banner.

**Include Files Banner**

Contains comments for use in generating a custom banner for the include files section.

**Type Definitions**

Contains comments for use in generating a custom banner for the type definitions section.

**Named Constants**

Contains comments for use in generating a custom banner for the named constants section.

**Variable Declarations**

Contains comments for use in generating a custom banner for the variable declarations section.

**Variable Definitions**

Contains comments for use in generating a custom banner for the variable definitions section.

**Function Declarations**

Contains comments for use in generating a custom banner for the function declarations section.

**Function Definitions**

Contains comments for use in generating a custom banner for the function definitions section.

**Custom Source Code**

Contains comments for use in generating a custom banner for the custom source code section.

**Custom Header Code**

Contains comments for use in generating a custom banner for the custom header code section.

**Components of the CGT File Sections**

Each CGT file section is defined by open and close tags.

<b>CGT File Section</b>	<b>Open Tag</b>	<b>Close Tag</b>
"File Banner" on page 91-13	<FileBanner>	</FileBanner>
"Function Banner Section" on page 91-9	<FunctionBanner>	</FunctionBanner>
"Shared Utility Function Banner" on page 91-9	<SharedUtilityBanner>	</SharedUtilityBanner>
"File Trailer Section" on page 91-9	<FileTrailer>	</FileTrailer>
"Include Files Banner" on page 91-10	<IncludeFilesBanner>	</IncludeFilesBanner>

CGT File Section	Open Tag	Close Tag
"Type Definitions" on page 91-10	<TypeDefinitionsBanner>	</TypeDefinitionsBanner>
"Named Constants" on page 91-10	<NamedConstantsBanner>	</NamedConstantsBanner>
"Variable Declarations" on page 91-10	<VariableDeclarationsBanner>	</VariableDeclarationsBanner>
"Variable Definitions" on page 91-10	<VariableDefinitionsBanner>	</VariableDefinitionsBanner>
"Function Declarations" on page 91-10	<FunctionDeclarationsBanner>	</FunctionDeclarationsBanner>
"Function Definitions" on page 91-10	<FunctionDefinitionsBanner>	</FunctionDefinitionsBanner>
"Custom Source Code" on page 91-10	<CustomSourceCodeBanner>	</CustomSourceCodeBanner>
"Custom Header Code" on page 91-10	<CustomHeaderCodeBanner>	</CustomHeaderCodeBanner>

You can customize your banners by including tokens and comments between the open and close tags for each section. Tokens are replaced with values in the generated code. The following rules apply to tokens in your CGT file:

- You can have only one token per line.
- Token values must not contain a '\t' for formatting.

---

**Note** In the contents of your banner, C comment indicators, `'/*' or '*/'`, can introduce an error in the generated code.

---

An open tag includes tag attributes. Enclose the value of the attribute in double quotes. The attributes available for an open tag are:

- `width`: specifies the width of the file or function banner comments in the generated code. The default value is 80.
- `style`: specifies the boundary for the file or function banner comments in the generated code.

The open tag syntax is:

```
<OpenTag style = "style_value" width = "num_width">
```

There are five options for the banner style. The `CommentStyle` and `TargetLang` configuration object properties determine the use of C or C++ comment style. The built-in style options for the `style` attribute are:

- `classic`

Using C style comments

```
/* single line comments */
```

```
/*
 * multiple line comments
 * second line
 */
```

Using C++ style comments

```
// single line comments

//
// multiple line comments
// second line
//
```

- box

Using C style comments

```
/* banner contents */
```

Using C++ style comments

```
// banner contents //
```

- open\_box

Using C style comments

```
/* banner contents */
```

Using C++ style comments

```
// banner contents //
```

- doxygen

Using C style comments

```
/** single line comments */

/**
 * multiple line comments
 * second line
 */
```

Using C++ style comments

```
///single line comments

///
/// multiple line comments
///second line
///
```

- doxygen Qt

Using C style comments

```

/! single line comments */

/!
 * multiple line comments
 * second line
 */

```

Using C++ style comments

```

//!single line comments

//!
//! multiple line comments
//!second line
//!

```

## File Banner

This section contains comments and tokens for use in generating a custom file banner that precedes the generated C and C++ code. If you omit the file banner section from the CGT file, the code generator does not generate a file banner in the generated code. The file banner section provided in the default CGT file is:

```

%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<FileBanner style="classic">
File: %<FileName>

MATLAB Coder version : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>

```

## Summary of Tokens for File Banner Generation

FileName	Name of the generated file (for example, "kalman.c")
SourceGeneratedOn	Timestamp of generated file
MATLABCoderVersion	Version of MATLAB Coder
EmbeddedCoderVersion	Version of Embedded Coder
HardwareSelection	Selected target
OutputType	Type of output (for example, lib, exe, or dll)

## Function Banner

This section contains comments and tokens for use in generating a custom function banner that precedes a generated C or C++ function. If you omit the function banner section from the CGT file, the code generator does not generate function banners. The function banner section provided in the default CGT file is:

```

%%
%% Custom Function Banner section (optional)
%% Customize function banners by using the following predefined tokens:
%% %<FunctionName>, %<FunctionDescription>, %<FunctionPrototype>
%% %<Arguments>, %<ReturnType>
%%
<FunctionBanner style="classic">
%<FunctionPrototype>
%<FunctionDescription>
Arguments : %<Arguments>
Return Type : %<ReturnType>
</FunctionBanner>

```

**Summary of Tokens for Function Banner Generation**

FunctionName	Name of function
FunctionDescription	Short abstract about the function  If the configuration parameter MATLABFcnDesc is true, the function description appears in the function banner. Otherwise, the code generator treats the function description as user comments.
FunctionPrototype	MATLAB function prototype  The function prototype appears in the function banner only if the MATLABSourceComments configuration parameter is true.
Arguments	List of function arguments
ReturnType	Return type of function

**Shared Utility Banner**

This section contains comments and tokens for use in generating a custom shared utility function banner that precedes a generated C or C++ shared utility function. If you omit the shared utility function banner section from the CGT file, the code generator does not generate shared utility function banners. The shared utility function banner section provided in the default CGT file is:

```

%%
%% Custom Shared Utility Function Banner section (optional)
%% Customize shared utility function banners by using the following
%% predefined tokens:
%% %<FunctionName>, %<FunctionDescription>
%% %<Arguments>, %<ReturnType>
%%
<SharedUtilityBanner style="classic">
Arguments : %<Arguments>
Return Type : %<ReturnType>
</SharedUtilityBanner>

```

**Summary of Tokens for Shared Utility Function Banner Generation**

FunctionName	Name of function
FunctionDescription	Short abstract about the function
Arguments	List of function arguments
ReturnType	Return type of function

## File Trailer

The file trailer section contains comments for generating a custom file trailer that follows the generated C or C++ code. If you omit the file trailer section from the CGT file, the code generator does not generate a file trailer. The file trailer section provided in the default CGT file is:

```

%%
%% Custom file trailer section (optional)
%% You can use any of the predefined tokens used for File Banner
%%
<FileTrailer style="classic">
File trailer for %<FileName>

[EOF]
</FileTrailer>

```

Tokens for the file banner are available for the file trailer. See Summary of Tokens for File Banner Generation.

## Include Files Banner

The include files banner section contains comments for generating a custom banner that precedes the include files section in the generated code. If you omit the include files banner section from the CGT file, the code generator does not generate a banner for this section. The include files banner section provided in the default CGT file is:

```

<IncludeFilesBanner style="classic">
Include Files
</IncludeFilesBanner>

```

## Type Definitions Banner

The type definitions banner section contains comments for generating a custom banner that precedes the type definitions section in the generated code. If you omit the type definitions banner section from the CGT file, the code generator does not generate a banner for this section. The type definitions banner section provided in the default CGT file is:

```

<TypeDefinitionsBanner style="classic">
Type Definitions
</TypeDefinitionsBanner>

```

## Named Constants Banner

The named constants banner section contains comments for generating a custom banner that precedes the named constants section in the generated code. If you omit the named constants banner section from the CGT file, the code generator does not generate a banner for this section. The named constants banner section provided in the default CGT file is:

```

<NamedConstantsBanner style="classic">
Named Constants
</NamedConstantsBanner>

```

## Variable Declarations

The variable declarations banner section contains comments for generating a custom banner that precedes the variable declarations section in the generated code. If you omit the variable declarations banner section from the CGT file, the code generator does not generate a banner for this section. The variable declarations banner section provided in the default CGT file is:

```
<VariableDeclarationsBanner style="classic">
Variable Declarations
</VariableDeclarationsBanner>
```

### **Variable Definitions**

The variable definitions banner section contains comments for generating a custom banner that precedes the variable definitions section in the generated code. If you omit the variable definitions banner section from the CGT file, the code generator does not generate a banner for this section. The variable definitions banner section provided in the default CGT file is:

```
<VariableDefinitionsBanner style="classic">
Variable Definitions
</VariableDefinitionsBanner>
```

### **Function Declarations**

The function declarations banner section contains comments for generating a custom banner that precedes the function declarations section in the generated code. If you omit the function declarations banner section from the CGT file, the code generator does not generate a banner for this section. The function declarations banner section provided in the default CGT file is:

```
<functionDeclarationsBanner style="classic">
Function Declarations
</FunctionDeclarationsBanner>
```

### **Function Definitions**

The function definitions banner section contains comments for generating a custom banner that precedes the function definitions section in the generated code. If you omit the function definitions banner section from the CGT file, the code generator does not generate a banner for this section. The function definitions banner section provided in the default CGT file is:

```
<FunctionDefinitionsBanner style="classic">
Function Definitions
</FunctionDefinitionsBanner>
```

### **Custom Source Code**

The custom source code banner section contains comments for generating a custom banner that precedes the custom source code section in the generated code. If you omit the custom source code banner section from the CGT file, the code generator does not generate a banner for this section. The custom source code banner section provided in the default CGT file is:

```
<CustomSourceCodeBanner style="classic">
Custom Source Code
</CustomSourceCodeBanner>
```

### **Custom Header Code**

The custom header code banner section contains comments for generating a custom banner that precedes the custom header code section in the generated code. If you omit the custom header code banner section from the CGT file, the code generator does not generate a banner for this section. The custom header code banner section provided in the default CGT file is:

```
<CustomHeaderCodeBanner style="classic">
Custom Header Code
</CustomHeaderCodeBanner>
```

## **More About**

- “Generate Custom File and Function Banners for C/C++ Code” on page 91-6

## Customize Generated Identifiers

### In this section...

“Customize Identifiers by Using the MATLAB Coder App” on page 91-18

“Customize Generated Identifiers by Using the Command-Line Interface” on page 91-19

If you have Embedded Coder, you can customize the identifiers in C/C++ code generated from MATLAB code. For each kind of identifier that you want to customize, set the appropriate identifier format parameter to a macro that specifies the format of the generated identifiers. The macro can include:

- Valid C or C++ language identifiers (a-z, A-Z, \_, 0-9).
- The tokens listed in the following table. \$M is required.

Token	Description
\$M	Code generator inserts name mangling text to avoid naming collisions.  Required.
\$N	Code generator inserts the name of the object (global variable, global type, local function, local temporary variable, or constant macro) for which the identifier is generated. Improves readability of generated code.  Required.
\$R	Code generator inserts the root project name into identifier, replacing unsupported characters with the underscore ( _ ) character.

### Customize Identifiers by Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library
  - Dynamic Library
  - Executable
- 3 Click **More Settings**.
- 4 On the **Code Appearance** tab, under **Identifier Format**, for each kind of identifier that you want to customize, enter the macro.

Parameter	Default Macro
<b>Global variables</b>	\$M\$N
<b>Global types</b>	\$M\$N
<b>Field name of global types</b>	\$M\$N
<b>Local functions</b>	\$M\$N
<b>Local temporary variables</b>	\$M\$N

Parameter	Default Macro
Constant macros	\$M\$N
EMX Array Types	emxArray_ \$M\$N
EMX Array Utility Functions	emx\$M\$N

For example, suppose that **Global variables** has the value `glob_ $M$N`. For a global variable named `g`, when name mangling is not required, the generated identifier is `glob_g`. If name mangling is required, the generated identifier includes the name mangling text.

## Customize Generated Identifiers by Using the Command-Line Interface

- 1 Create a code configuration object for a library or executable program. For example:

```
cfg = coder.config('lib','ecoder',true);
```
- 2 For each kind of identifier that you want to customize, specify the macro as a character vector.

Parameter	Description	Default Macro
CustomSymbolStrGlobalVar	Global variables	' \$M\$N '
CustomSymbolStrType	Global types	' \$M\$N '
CustomSymbolStrField	Field name of global types	' \$M\$N '
CustomSymbolStrFcn	Local functions	' \$M\$N '
CustomSymbolStrTmpVar	Local temporary variables	' \$M\$N '
CustomSymbolStrMacro	Constant macros	' \$M\$N '
CustomSymbolStrEMXArray	EMX Array Types	'emxArray_ \$M\$N '
CustomSymbolStrEMXArrayFcn	EMX Array Utility Functions	'emx\$M\$N '

For example:

```
cfg.CustomSymbolStrGlobalVar = 'glob_ MN';
```

For a global variable named `g`, when name mangling is not required, the generated identifier is `glob_g`. If name mangling is required, the generated identifier includes the name mangling text.

## Customize C/C++ File Names Generated from MATLAB Code

### In this section...

“Customize File Names by Using the MATLAB Coder App” on page 91-20

“Customize Generated File Names by Using the Command-Line Interface” on page 91-20

If you have Embedded Coder, you can customize the file names of the C/C++ code generated from MATLAB code. By changing the file names, you can avoid name clashes when integrating different C/C++ code projects together. Customize the file names by setting the file name format parameter `CustomFileNameStr` to a macro. The macro can include:

- Valid file name characters.
- The tokens listed in the following table. `$M` and `$N` are required.

Token	Description
<code>\$M</code>	Code generator inserts name mangling text to avoid naming collisions. Required.
<code>\$N</code>	Code generator inserts the non-customized file name. Required.
<code>\$R</code>	Code generator inserts the root project name into the file name, replacing unsupported characters with the underscore ( <code>_</code> ) character.

By default, the macro is set to `$N$M`.

### Customize File Names by Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library
  - Dynamic Library
  - Executable
- 3 Click **More Settings**.
- 4 Enter the macro on the **Code Appearance** tab, next to **Generated source and header files**:

For example, suppose you set the macro to the value `ec_ $N$M`. For an entry-point function called `foo`, when name mangling is not required, the generated file name for `foo` becomes `ec_ foo`. If name mangling is required, the generated file name includes the name mangling text.

### Customize Generated File Names by Using the Command-Line Interface

- 1 Create a code generation configuration object for a library or executable program. For example:
 

```
cfg = coder.config('lib', 'ecoder', true);
```

- 2 Specify the file name macro as a character vector in the `CustomFileNameStr` object property. For example:

```
cfg.CustomFileNameStr = 'ec_$$M$M';
```

For an entry-point function called `foo`, when name mangling is not required, the generated file name for `foo` becomes `ec_foo`. If name mangling is required, the generated file name includes the name mangling text.

## Control Signed Left Shifts in Generated Code

### In this section...

“Control Signed Left Shifts Using the MATLAB Coder App” on page 91-22

“Control Signed Left Shifts Using the Command-Line Interface” on page 91-22

If you have an Embedded Coder license, you can control whether MATLAB Coder replaces multiplications by powers of two with signed left bitwise shifts. Some coding standards, such as MISRA, do not allow bitwise operations on signed integers.

By default, MATLAB Coder replaces multiplication by powers of two with signed left shifts. Here is an example of generated C code that uses a signed left shift for multiplication by eight.

```
i <<= 3;
```

To increase the likelihood of generating MISRA C:2012 compliant code, disable the replacement of multiplication by powers of two with signed left shifts. Here is an example of generated C code that does not use a signed left shift for multiplication by eight:

```
i = i * 8;
```

### Control Signed Left Shifts Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3 Click **More Settings**.
- 4 On the **Code Appearance** tab, select or clear the **Use signed shift left for fixed-point operations and multiplication by powers of 2** check box.

### Control Signed Left Shifts Using the Command-Line Interface

- 1 Create a code configuration object for 'lib', 'dll', or 'exe'. For example:

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

- 2 Set the EnableSignedLeftShifts property to true or false. For example:

```
cfg.EnableSignedLeftShifts = false;
```

## Control Data Type Casts in Generated Code

### In this section...

“Specify Casting Mode Using the MATLAB Coder App” on page 91-24

“Specify Casting Mode Using the Command-Line Interface” on page 91-24

If you have an Embedded Coder license, you can control data type casts in C/C++ code generated from MATLAB code. You can specify one of the following casting modes.

Casting Mode	Description
Nominal	<p>Nominal casting mode is the default casting mode. Generated C/C++ code uses the default C compiler data type casting. When you do not have special data type information requirements, choose this option. Here is an example of code generated using nominal casting mode:</p> <pre data-bbox="865 835 1166 1115"> short addone(short x) {     int i;     i = x + 1;     if (i &gt; 32767) {         i = 32767;     }      return (short)i; } </pre>
Standards Compliant	<p>Generated C/C++ code has data type casts that conform to MISRA standards. The MISRA data type casting eliminates common MISRA standard violations, including address arithmetic and assignment. It reduces 10.1, 10.2, 10.3, and 10.4 violations. Here is an example of code generated using standards-compliant casting mode:</p> <pre data-bbox="865 1381 1198 1661"> short addone(short x) {     int i;     i = (int)x + (int)1;     if (i &gt; (int)32767) {         i = (int)32767;     }      return (short)i; } </pre>

Casting Mode	Description
Explicit	<p>Generated C/C++ code has explicit data type casts. Explicit data type casts provide information about the amount of memory that the variable uses and the level of precision for calculations using the variable. Here is an example of code generated using explicit casting mode:</p> <pre>short addone(short x) {     int i;     i = (int)x + 1;     if (i &gt; 32767) {         i = 32767;     }      return (short)i; }</pre>

## Specify Casting Mode Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3 Click **More Settings**.
- 4 On the **All Settings** tab, under **Advanced**, set **Casting mode** to one of the following values:
  - Nominal
  - Standards Compliant
  - Explicit

## Specify Casting Mode Using the Command-Line Interface

- 1 Create a code configuration object for 'lib', 'dll', or 'exe'. For example:

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

- 2 Set the `CastingMode` property to one of the following values:

- 'Nominal'
- 'Standards'
- 'Explicit'

For example:

```
cfg.CastingMode = 'Standards';
```

## Simplify Multiply Operations for Array Indexing in Loops

If you use Embedded Coder to generate C/C++ code from MATLAB code, you can enable an optimization that simplifies array indexing in loops in the generated code. When possible, for array indices in loops, this optimization replaces multiply operations with add operations. Multiply operations can be expensive. This optimization, referred to as strength reduction, is useful when the C/C++ compiler on the target platform does not optimize the array indexing.

Here is code generated without the optimization:

```
for (i = 0; i < 10; i++) {
 z[5 * (1 + i) - 1] = x[5 * (1 + i)];
}
```

Here is code generated with the optimization:

```
for (b_i = 0; b_i < 10; b_i++) {
 z[i + 4] = x[i + 5];
 i += 5;
}
```

By default, the strength reduction optimization is disabled. To enable it:

- At the command line, set the configuration object parameter `EnableStrengthReduction` to `true`.
- In the MATLAB Coder app, project build settings, on the **All Settings** tab, set **Simplify array indexing** to Yes.

Even when the optimization replaces the multiply operations in the generated code, it is possible that the C/C++ compiler can generate multiply instructions.

## Generate SIMD Code for MATLAB Functions

You can generate single instruction, multiple data (SIMD) code from certain MATLAB functions by using Intel SSE and, if you have Embedded Coder, Intel AVX technology. SIMD is a computing paradigm in which a single instruction processes multiple data. Many modern processors have SIMD instructions that, for example, perform several additions or multiplications at once. For computationally intensive operations among supported functions, SIMD intrinsics can significantly improve the performance of the generated code on Intel platforms.

### MATLAB Functions That Support SIMD Code

When certain conditions are met, you can generate SIMD code by using Intel SSE or Intel AVX technology. The following table lists MATLAB functions that support SIMD code generation. The table also details the conditions under which the support is available.

MATLAB Function	Conditions
plus	<ul style="list-style-type: none"> <li>For AVX, SSE, and FMA, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For AVX2, SSE4.1, and SSE2, the input signal has a data type of <code>single</code>, <code>double</code>, <code>int8</code>, <code>int16</code>, <code>int32</code> or <code>int64</code>.</li> <li>For AVX512F, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For integer data types, the value of <b>Saturate on integer overflow</b> is set to <code>No</code>.</li> </ul>
minus	<ul style="list-style-type: none"> <li>For AVX, SSE, and FMA, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For AVX2, SSE4.1, and SSE2, the input signal has a data type of <code>single</code>, <code>double</code>, <code>int8</code>, <code>int16</code>, <code>int32</code> or <code>int64</code>.</li> <li>For AVX512F, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For integer data types, the value of <b>Saturate on integer overflow</b> is set to <code>No</code>.</li> </ul>
times	<ul style="list-style-type: none"> <li>For AVX, SSE, and FMA, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For AVX2, SSE4.1, and SSE2, the input signal has a data type of <code>single</code>, <code>double</code>, <code>int16</code>, or <code>int32</code>.</li> <li>For AVX512F, the input signal has a data type of <code>single</code> or <code>double</code>.</li> <li>For integer data types, the value of <b>Saturate on integer overflow</b> is set to <code>No</code>.</li> </ul>
rdivide	The input signal has a data type of <code>single</code> or <code>double</code> .

MATLAB Function	Conditions
sqrt	The input signal has a data type of single or double.
ceil	<ul style="list-style-type: none"> <li>• For AVX2, AVX, SSE4.1, SSE2, and SSE, the input signal has a data type of single or double.</li> <li>• AVX512F is not supported.</li> </ul>
floor	<ul style="list-style-type: none"> <li>• For AVX2, AVX, SSE4.1, SSE2, and SSE, the input signal has a data type of single or double.</li> <li>• AVX512F is not supported.</li> </ul>
max	<ul style="list-style-type: none"> <li>• The input signal has a data type of single or double.</li> <li>• The value of the <b>Support nonfinite numbers</b> parameter is set to off.</li> </ul>
min	<ul style="list-style-type: none"> <li>• The input signal has a data type of single or double.</li> <li>• The value of the <b>Support nonfinite numbers</b> parameter is set to off.</li> </ul>
sum	<ul style="list-style-type: none"> <li>• For AVX, SSE, and FMA, the input signal has a data type of single or double.</li> <li>• For AVX2, SSE4.1, and SSE2, the input signal has a data type of single, double, int8, int16, int32 or int64.</li> <li>• For AVX512F, the input signal has a data type of single or double.</li> <li>• The <b>Optimize reductions</b> configuration parameter is set to on.</li> <li>• For integer data types, the value of <b>Saturate on integer overflow</b> is set to No.</li> </ul>
prod	<ul style="list-style-type: none"> <li>• For AVX, SSE, and FMA, the input signal has a data type of single or double.</li> <li>• For AVX2, SSE4.1, and SSE2, the input signal has a data type of single, double, int16, or int32.</li> <li>• For AVX512F, the input signal has a data type of single or double.</li> <li>• The <b>Optimize reductions</b> configuration parameter is set to on.</li> <li>• For integer data types, the value of <b>Saturate on integer overflow</b> is set to No.</li> </ul>

MATLAB Function	Conditions
bitand	<ul style="list-style-type: none"> <li>For SSE2, the input signal has a data type of int8, int16, int32, or int64.</li> <li>For AVX2, and AVX512F, the input signal has a data type of int8, int16, int32, or int64.</li> </ul>
bitor	<ul style="list-style-type: none"> <li>For SSE2, the input signal has a data type of int8, int16, int32, or int64.</li> <li>For AVX2, and AVX512F, the input signal has a data type of int8, int16, int32, or int64.</li> </ul>
bitxor	<ul style="list-style-type: none"> <li>For SSE2, the input signal has a data type of int8, int16, int32, or int64.</li> <li>For AVX2, and AVX512F, the input signal has a data type of int8, int16, int32, or int64.</li> </ul>
bitshift	<ul style="list-style-type: none"> <li>The input signal has a data type of int32.</li> </ul>

If you have a DSP System Toolbox, you can generate SIMD code from certain MATLAB System objects. For more information, see “System objects in DSP System Toolbox that Support SIMD Code Generation” (DSP System Toolbox).

## Generate SIMD Code Versus Plain C Code

Consider the MATLAB function `dynamic`. This function consists of addition and multiplication operations between the variable-size arrays `A` and `B`. These arrays have a data type of `single` and an upper bound of  $100 \times 100$ .

```
function C = dynamic(A, B)
 assert(all(size(A) <= [100 100]));
 assert(all(size(B) <= [100 100]));
 assert(isa(A, 'single'));
 assert(isa(B, 'single'));

 C = zeros(size(A), 'like', A);
 for i = 1:numel(A)
 C(i) = (A(i) .* B(i)) + (A(i) .* B(i));
 end
end
```

To generate plain C code at the command line:

- 1 For C library code generation, create a code generation configuration object.

```
cfg = coder.config('lib');
```

- 2 To generate a static library in the default location, `codegen\lib\dynamic`, use the `codegen` function `t`.

```
codegen('-config', cfg, 'dynamic');
```

- 3 In the list of generated files, click `dynamic.c`. In the plain (non-SIMD) C code, each loop iteration produces one result.

```
void dynamic(const float A_data[], const int A_size[2], const float B_data[],
 const int B_size[2], float C_data[], int C_size[2])
{
```

```

float C_data_tmp;
int i;
int loop_ub;
(void)B_size;
C_size[0] = (signed char)A_size[0];
C_size[1] = (signed char)A_size[1];
loop_ub = (signed char)A_size[0] * (signed char)A_size[1];
if (0 <= loop_ub - 1) {
 memset(&C_data[0], 0, loop_ub * sizeof(float));
}
loop_ub = A_size[0] * A_size[1];
for (i = 0; i < loop_ub; i++) {
 C_data_tmp = A_data[i] * B_data[i];
 C_data[i] = C_data_tmp + C_data_tmp;
}
}

```

To generate SIMD C code at the command line:

- 1 For C library code generation, use the `coder.config` function to create a code generation configuration object.

```
cfg = coder.config('lib');
```

- 2 Set the `coder.HardwareImplementation` object `TargetHWDeviceType` property to 'Intel->x86-64 (Linux 64)' or 'Intel->x86-64 (Windows64)'.

```
cfg.HardwareImplementation.TargetHWDeviceType = 'Intel->x86-64 (Windows64)';
```

- 3 Set the `coder.HardwareImplementation` object `ProdHWDeviceType` property to 'Intel->x86-64 (Linux 64)' or 'Intel->x86-64 (Windows64)'.

```
cfg.HardwareImplementation.ProdHWDeviceType = 'Intel->x86-64 (Windows64)';
```

If you are using the MATLAB Coder app to generate code:

- Set the **Hardware Board** parameter to None-Select device below.
  - Set the **Device vendor** parameter to Intel, AMD, or Generic.
  - Set the **Device type** to x86-64 (Linux 64), x86-64 (Windows64), or MATLAB Host Computer.
- 4 Set the `InstructionSetExtensions` property to an instruction set extension that your processor supports. This example uses SSE2 for Windows.

```
cfg.InstructionSetExtensions = 'SSE2';
```

The library that you choose depends on which instruction set extension your processor supports. If you use Embedded Coder, you can also select from the instruction sets SSE, SSE4.1, AVX, AVX2, FMA, and AVX512F.

For more information, see <https://www.intel.com/content/www/us/en/support/articles/000005779/processors.html>.

If you are using the MATLAB Coder app to generate code, on the **Speed** tab, set the **Leverage target hardware instruction set extensions** parameter to an instruction set that your processor supports.

- 5 Optionally, select the `OptimizeReductions` parameter to generate SIMD code for reduction operations such as sum and product functions.

```
cfg.OptimizeReductions = 'on';
```

If you are using the MATLAB Coder app to generate code, on the **Speed** tab, select the **Optimize reductions** parameter.

- 6 Use the `codegen` function to generate a static library in the default location, `codegen\lib\dynamic`.

```
codegen('-config', cfg, 'dynamic');
```

- 7 In the list of generated files, click `dynamic.c`.

```
void dynamic(const float A_data[], const int A_size[2], const float B_data[],
 const int B_size[2], float C_data[], int C_size[2])
{
 __m128 r;
 float C_data_tmp;
 int i;
 int loop_ub;
 int scalarLB;
 int vectorUB;
 (void)B_size;
 C_size[0] = (signed char)A_size[0];
 C_size[1] = (signed char)A_size[1];
 loop_ub = (signed char)A_size[0] * (signed char)A_size[1];
 if (0 <= loop_ub - 1) {
 memset(&C_data[0], 0, loop_ub * sizeof(float));
 }
 loop_ub = A_size[0] * A_size[1];
 scalarLB = (loop_ub / 4) << 2;
 vectorUB = scalarLB - 4;
 for (i = 0; i <= vectorUB; i += 4) {
 r = _mm_mul_ps(_mm_loadu_ps(&A_data[i]), _mm_loadu_ps(&B_data[i]));
 _mm_storeu_ps(&C_data[i], _mm_add_ps(r, r));
 }
 for (i = scalarLB; i < loop_ub; i++) {
 C_data_tmp = A_data[i] * B_data[i];
 C_data[i] = C_data_tmp + C_data_tmp;
 }
}
```

The SIMD instructions are the intrinsic functions that start with the identifier `_mm`. These functions process multiple data in a single iteration of the loop because the loop increments by four for single data types. For double data types, the loop increments by two. For MATLAB code that processes more data and is more computationally intensive, than the code in this example, the presence of SIMD instructions can significantly speed up the code execution time.

The second `for` loop is in the generated code because the `for` loop that contains SIMD code must be divisible by four for single data types. The second loop processes the remainder of the data.

For a list of a Intel intrinsic functions for supported MATLAB functions, see <https://www.intel.com/content/www/us/en/docs/intrinsics-guide/index.html>.

## Limitations

The generated code does not contain SIMD code when the MATLAB code meets these conditions:

- Scalar operations outside a loop. For example, if `a`, `b`, and `c` are scalars, the generated code does not contain SIMD code for an operation such as `c=a+b`.
- Indirectly indexed arrays or matrices. For example, if `A`, `B`, `C`, and `D` are vectors, the generated code does not contain SIMD code for an operation such as `D(A)=C(A)+B(A)`.
- Parallel `for`-Loops (`parfor`). The `parfor` loop does not contain SIMD code, but loops within the body of the `parfor` loop might contain SIMD code.

- Polyspace does not support analysis of generated code that includes SIMD instructions. Disable SIMD code generation by setting the **Leverage target hardware instruction set extensions** parameter to None.
- Reduction operations that operate on floating-point values when support for nonfinite numbers is enabled. To generate SIMD code for reduction operations that operate on floating-point values, in the MATLAB Coder app, set **Support nonfinite numbers** to No. Or, in a code generation configuration object, set the `SupportNonFinite` property to `false`.

## Generate C/C++ Code with Improved MISRA Compliance

The Motor Industry Software Reliability Association (MISRA)<sup>10</sup> has established “Guidelines for the Use of the C Language in Critical Systems” (MISRA C). When you generate code from MATLAB code, if you have Embedded Coder, you can configure certain code generation parameters to increase the likelihood of generating C and C++ code that comply with the MISRA C:2012 and MISRA C++:2008 guidelines.

The following describes the separate command line and app workflows.

### Configure Code Generation Configuration Object Properties

- 1 Create an Embedded Coder code generation configuration object.

```
cfg = coder.config('lib', 'ecoder', true);
```

- 2 Set the properties listed in the table to the values for improved MISRA compliance.

Property	Value for Improved MISRA Compliance
CastingMode	'Standards'
CppNamespace	Any valid namespace name for C++
DataTypeReplacement	'CoderTypedefs'
DynamicMemoryAllocation	'Off'
EnableRuntimeRecursion	false
EnableSignedLeftShifts	false
EnableSignedRightShifts	false
GenerateDefaultInSwitch	true
ParenthesesLevel	'Maximum'
TargetLangStandard	'C99 (ISO)' for C, 'C++03 (ISO)' for C++

To set these properties in one step, use `coder.setupMISRAConfig`.

```
coder.setupMISRAConfig(cfg);
```

Alternatively, set properties individually. For example:

```
cfg.CastingMode = 'Standards';
```

If the `CppNamespace` property is unset, and the `TargetLang` property is 'C++', then `coder.setupMISRAConfig` sets the `CppNamespace` property to a default character vector, 'Codegen'. Modify this value to a namespace name that is particular to your project.

- 3 Pass the configuration object to `codegen` by using the `-config` option.

```
codegen myFunction -config cfg ...
```

<sup>10</sup> MISRA and MISRA C are registered trademarks of HORIBA MIRA Ltd., held on behalf of the MISRA Consortium.

## Configure MATLAB Coder App Settings

- 1 On the **Generate Code** page, set **Build type** to Source Code, Static Library, Dynamic Library, or Executable.
- 2 Click **More Settings**.
- 3 Click **MISRA Compliance**.

The app displays the settings that might impact MISRA compliance.

Use the following settings to improve MISRA compliance of generated code.

Setting	Current Value	Recommended Value
Dynamic memory allocation	For arrays with max size at or above thres...	Never
Enable run-time recursion	Yes	No
Use signed shift left for fixed-point ...	Yes	No
Allow right shifts on signed integers	Yes	No
Casting mode	Nominal	Standards Compliant
Data Type Replacement	Use built-in C data types in the generated ...	Use MathWorks typedefs in the generated
Parentheses	Nominal (Optimize for readability)	Maximum (Specify precedence with parer
Always generate a default case for s...	No	Yes

Set to Recommended Values

- 4 To set all of these settings to the recommended values, click **Set to Recommended Values**.

To modify an individual setting, click **All Settings**, and then search for the setting.

## Additional Settings for MISRA C++ Compliance

By default, the C++ code that you generate uses a custom type definition for `bool` to maximize compatibility with certain precompiled libraries. This custom type definition can cause violations for MISRA C++:2008 Rule 5-0-13 and Rule 5-3-1.

To use the built-in `bool` type in generated C++ code, and avoid these violations, change the **Hardware Board** setting in the configuration object from MATLAB Host Computer. To see how to change this setting in the App, see “Access Hardware Implementation Properties with a Dialog Box”. For example, for code generation and build on a 64-bit Windows platform, change the **Hardware Board** to `None - Select device below`, and then set **Device vendor** to `Intel` and **Device type** to `x86-64 (Windows64)`.

## Customize Data Type Replacement

While generating C/C++ code from MATLAB code, the **Data Type Replacement** option enables you to use built-in C data types or MathWorks typedefs in the generated code. Code generation supports these data types for custom renaming: double, single, uint8, uint16, uint32, uint64, int8, int16, int32, int64, char, and logical.

The **Data Type Replacement** option is available in the **Generate Code** window (**More Settings**), on the **Code Appearance** tab. You can select one of these options:

- Use built-in C data types in the generated code
- Use MathWorks typedefs in the generated code

**Note** The code generator does not replace variable-size character arrays with `char*` type strings in the generated code.

If you have Embedded Coder installed, you can specify custom names for MATLAB built-in data types in the generated C/C++ code. For example, you can customize double as `Custom_Double`.

## Specify Custom Data Type Names by Using the MATLAB Coder App

To specify custom names for the MATLAB data types:

- 1 Open the MATLAB Coder app.
- 2 Navigate to the **Generate Code** step.
- 3 Click **More Settings**.
- 4 In the **Code Appearance** tab, select **Enable custom data type replacement** under **Custom Data Type Replacement**.
- 5 The table lists the name of the supported data types. Specify your custom names for these data types and press **Enter**. The specified custom names replace the built-in data type names in the generated code. If you do not specify a custom name, the code generator uses a default name.

## Specify Custom Data Type Names by Using the Command-Line Interface

Use the `EnableCustomReplacementTypes` and `ReplacementTypes` properties in an Embedded Coder configuration object when you generate code by using `codegen`.

- 1 Write a MATLAB function from which you can generate code. This example uses the function `myAdd` that returns the sum of its inputs.

```
function c = myAdd(a,b)
c = a + b;
end
```

- 2 Create a code configuration object for generation of a static library.

```
cfg = coder.config('lib','ecoder',true);
```

- 3 Set the `EnableCustomReplacementTypes` property to `true`.

```
cfg.EnableCustomReplacementTypes = true;
```

- 4 Specify custom name for the data types. Here, the built-in data type name `uint8` is customized to `Custom_Uint8`.

```
cfg.ReplacementTypes.uint8 = "Custom_Uint8";
```

- 5 Generate code by using `codegen` and `-config` option.

```
codegen myAdd.m -args {1,uint8(1)} -config cfg -report
```

## More About

- “Import Custom Data Type Definitions from External Header Files” on page 91-38

## Import Custom Data Type Definitions from External Header Files

By default, MATLAB Coder uses the predefined data types in the generated code. You can use customized data type names by importing custom type definitions from external header files. You can then use your own type definitions in the generated C/C++ code. If you have existing legacy code, you can integrate that code, in the generated C/C++ code. You can import a header file by using either the MATLAB Coder app or the command-line interface.

### Import Custom Types by Using the MATLAB Coder App

To import custom types from external header files:

- 1 Open the MATLAB Coder app and proceed to the **Generate Code** page.
- 2 Click **More Settings**.
- 3 In the **Code Appearance** tab, select **Enable custom data type replacement**.
- 4 Specify your custom names for the data types in **Enable custom data type replacement** table and press **Enter**.
- 5 Select the **Import custom types from external header files** check box.

- 6 In the **Header files** text field, enter a semicolon-separated list of external header file names and press **Enter**. For example, `myHeader1.h;myHeader2.h;myHeader3.h`.

## Import Custom Types by Using the Command-Line Interface

Use the `ReplacementTypes.IsExtern` and `ReplacementTypes.HeaderFiles` properties in a `coder.EmbeddedCodeConfig` object when you generate code by using `codegen`.

- 1 Create a code configuration object for generation of a static library.

```
cfg = coder.config('lib','ecoder',true);
```

- 2 Specify custom names for the data types. For example, `double` is named as `Custom_Double` and `int8` is named as `Custom_Int8` in the code.

```
cfg.EnableCustomReplacementTypes = true;
cfg.ReplacementTypes.double = "Custom_Double";
cfg.ReplacementTypes.int8 = "Custom_Int8";
```

- 3 Specify configuration properties for importing the external header files.

```
% Include single header file
```

```
cfg.ReplacementTypes.IsExtern = true;
cfg.ReplacementTypes.HeaderFiles = "myHeader.h";
cfg.CustomInclude = 'C:\myFiles'; % Include path of the header file
```

```
% Include multiple header files
```

```
cfg.ReplacementTypes.IsExtern = true;
cfg.ReplacementTypes.HeaderFiles = "myHeader1.h;myHeader2.h;myHeader3.h";
cfg.CustomInclude = 'C:\Program Files\MATLAB\myFiles'; % Include path of the header files
```

For more information on `CustomInclude`, see “Configure Build by Using the Configuration Object”.

- 4 Generate code by using `codegen` and the `-config` option.

```
codegen myAdd.m -args {1,int8(1)} -config cfg -report
```

## MATLAB Code Patterns That Require a Nonempty Initialize Function in Generated Code

### Issue

When generating standalone code from MATLAB code, you choose not to generate the initialize function:

- In a `coder.EmbeddedCodeConfig` object, `IncludeInitializeFcn` is set to `false`.
- Alternatively, in the MATLAB Coder app, on the **All Settings** tab, **Initialize Function Required** is set to **No**.

Also, you ensure that the custom code to appear in the generated initialize function is empty:

- In a `coder.EmbeddedCodeConfig` object, `CustomInitializer` is set to `''`.
- Alternatively, in the MATLAB Coder app, on the **Custom Code** tab, **Custom C Code for Generated Files** for initialize function is empty.

You still get this error message:

```
The initialize function is not empty, but the IncludeInitializeFcn configuration setting requests the initialize function be omitted.
```

### Solution

In certain situations, the code generator determines that the initialize function must be nonempty and produces code for the initialize function. This code generation can occur even if the custom code for the initialize function that you specify is empty. Not including this generated code in the initialize function causes the generated entry-point functions to operate on an invalid state. In such situations, if you choose to not generate the initialize function, the code generator produces an error message.

To fix this issue, include the initialize function in your generated code by doing one of the following:

- In a `coder.EmbeddedCodeConfig` object, set `IncludeInitializeFcn` to `true` (this value is the default value).
- In the MATLAB Coder app, on the **All Settings** tab, set **Initialize Function Required** to **Yes** (this setting is the default setting).

Examples of MATLAB code patterns that require a nonempty initialize function in the generated code are:

- Your MATLAB code contains an operation that can generate nonfinite values (`Inf` or `NaN`). For example, define a MATLAB function `foo` that calls `factorial`. The `factorial` function grows quickly and returns `Inf` for inputs greater than a certain threshold. For an input of type `double`, the threshold is 170. Executing `factorial(171)` in MATLAB returns `Inf`.

```
function y = foo(a)
y = factorial(a);
end
```

Generate a static library for `foo`. In the `coder.EmbeddedCodeConfig` object `cfg`, set the parameter `CustomInitializer` to an empty character array. Set the parameter `IncludeInitializeFcn` to `true`. These values are the default values for the parameters.

```

cfg = coder.config('lib');

cfg.CustomInitializer = ''; %These are the default values
cfg.IncludeInitializeFcn = true;

codegen -config cfg foo -args {1}

```

The code generator automatically produces a nonempty initialize function `foo_initialize` that calls supporting code for nonfinite data. This function calls `rt_InitInfAndNaN`, which is defined in another generated file `rt_nonfinite.c`.

```

/* Include Files */
#include "foo_initialize.h"
#include "foo.h"
#include "foo_data.h"
#include "rt_nonfinite.h"

/* Function Definitions */

/*
 * Arguments : void
 * Return Type : void
 */
void foo_initialize(void)
{
 rt_InitInfAndNaN();
 isInitialized_foo = true;
}

/*
 * File trailer for foo_initialize.c
 *
 * [EOF]
 */

```

- Your MATLAB code uses `global` or `persistent` variables. For example, define this MATLAB function:

```

function y = bar
global g
y = g;
end

```

Generate a static library for `bar`. Specify the initial value of `g` as 1. In the `coder.EmbeddedCodeConfig` object `cfg`, set the parameter `CustomInitializer` to an empty character array. Set the parameter `IncludeInitializeFcn` to `true`. These values are the default values for the parameters.

```

cfg = coder.config('lib');

cfg.CustomInitializer = ''; %These are the default values
cfg.IncludeInitializeFcn = true;

codegen -config cfg -globals {'g',1} bar

```

The code generator automatically produces a nonempty initialize function `bar_initialize` that initializes `g`.

```
/* Include Files */
#include "bar_initialize.h"
#include "bar.h"
#include "bar_data.h"

/* Function Definitions */

/*
 * Arguments : void
 * Return Type : void
 */
void bar_initialize(void)
{
 g = 1.0;
 isInitialized_bar = true;
}

/*
 * File trailer for bar_initialize.c
 *
 * [EOF]
 */
```

# Storage Classes for Code Generation from MATLAB Code

---

- “Storage Classes for Code Generation from MATLAB Code” on page 92-2
- “Control Declarations and Definitions of Global Variables in Code Generated from MATLAB Code” on page 92-4

## Storage Classes for Code Generation from MATLAB Code

If you have an Embedded Coder license, you can use storage classes to control the declaration and definition of a global variable in the generated C/C++ code.

In the context of code generation, a storage class is a specification that determines the declaration and definition of a variable in the generated code. For code generation, the term storage class is not the same as the C language term storage class specifier.

Storage classes help you to integrate generated code with external code. You can make a generated variable visible to external code. You can also make variables declared in the external code visible to the generated code. For code generation from MATLAB code, you can use storage classes with global variables only. The storage class determines:

- The file placement of a global variable declaration and definition.
- Whether the global variable is imported from external code or exported for use by external code.

To assign a storage class to a global variable, in your MATLAB code, use the `coder.storageClass` function. Only when you use an Embedded Coder project or configuration object for generation of C/C++ libraries or executables does the code generator recognize `coder.storageClass` calls.

The syntax for `coder.storageClass` is:

```
coder.storageClass(global_name, storage_class)
```

`global_name` is the name of a global variable, specified as a character vector. `global_name` must be a compile-time constant.

`storage_class` can be one of the following values.

Storage Class	Description
'ExportedGlobal'	<ul style="list-style-type: none"> <li>• Defines the variable in the Variable Definitions section of the C file <code>entry_point_name.c</code>.</li> <li>• Declares the variable as an extern in the Variable Declarations section of the header file <code>entry_point_name.h</code></li> <li>• Initializes the variable in the function <code>entry_point_name_initialize.h</code>.</li> </ul>
'ExportedDefine'	Declares the variable with a <code>#define</code> directive in the Exported data define section of the header file <code>entry_point_name.h</code> .
'ImportedExtern'	Declares the variable as an extern in the Variable Declarations section of the header file <code>entry_point_name_data.h</code> . The external code must supply the variable definition.
'ImportedExternPointer'	Declares the variable as an extern pointer in the Variable Declarations section of the header file <code>entry_point_name_data.h</code> . The external code must define a valid pointer variable.

Storage classes have these requirements and limitations:

- Assign the storage class to a global variable in a function that declares the global variable. You do not have to assign the storage class in more than one function.
- After you assign a storage class to a global variable, you cannot assign a different storage class to that global variable.
- You cannot assign a storage class to a constant global variable.
- A global variable with an `ExportedDefine` storage class must be a scalar but not a complex or multi-word scalar. The global variable must only be read and not written to in the code.

If you do not assign a storage class to a global variable, except for the declaration location, the variable behaves like it has an `'ExportedGlobal'` storage class. For an `'ExportedGlobal'` storage class, the global variable is declared in the file `entry_point_name.h`. When the global variable does not have a storage class, the variable is declared in the file `entry_point_name_data.h`.

- “Generate Code for Global Data”

## Control Declarations and Definitions of Global Variables in Code Generated from MATLAB Code

This example uses storage classes to control the declarations and definitions of global variables in C/C++ code generated from MATLAB code. Using storage classes helps you to interface generated code with external code.

This example requires an Embedded Coder license.

Write a function `addglobals` that adds four global variables. Declare the global variables in the function.

```
function y = addglobals %#codegen
% Define the global variables.
global u;
global v;
global x;
global z;

% Assign the storage classes.
coder.storageClass('u','ExportedGlobal');
coder.storageClass('v','ImportedExtern');
coder.storageClass('x','ImportedExternPointer');
coder.storageClass('z','ExportedDefine');
y = u + v + x + z;
end
```

Create a file `c:\myfiles\myfile.c` that defines and initializes the imported global variables `u` and `v`.

```
#include <stdio.h>

/* Variable definitions for imported variables */
double v = 1.0;
double *x = &v;
```

Create a code configuration object. Configure the code generation parameters to include `myfile.c`. For output type `'lib'`, or if you generate source code only, you can generate code without providing this file. Otherwise, you must provide this file.

```
cfg = coder.config('dll','ecoder', true);
cfg.CustomSource = 'myfile.c';
cfg.CustomInclude = 'c:\myfiles';
```

Generate the code. This example uses the `-globals` argument to specify the types and initial values of the global variables `u`, `v`, `x`, and `z`. Alternatively, you can define global variables in the MATLAB global workspace. For the imported global variables `v` and `x`, the code generator uses the initial values only to determine the type.

```
codegen -config cfg -globals {'u', 1, 'v', 2, 'x', 3, 'z', 4} addglobals -report
```

From the initial values 1, 2, 3, and 4 `codegen` determines that `u`, `v`, `x` and `z` have type `double`. `codegen` defines and declares the exported global variables `u` and `z`. It generates code that initializes `u` to 1.0 and `z` to 4.0. `codegen` declares the imported global variables `v` and `x`. It does not define these variables or generate code that initializes them. `myfile.c` provides the code that defines and initializes `v` and `x`.

To view the code generated for the global variables, open the report. Click the **View report** link.

View the definition for the exported global `z` in the `Exported data define` section in `addglobals.h`.

```
/* Definition for custom storage class: ExportedDefine */
#define z 4.0
```

View the definition and declaration for the exported global `u`.

- `u` is defined in the `Variable Definitions` section in `addglobals.c`.

```
/* Variable Definitions */
/* Definition for custom storage class: ExportedGlobal */
double u;
```

- `u` is declared as `extern` in the `Variable Declarations` section in `addglobals.h`.

```
/* Variable Declarations */
/* Declaration for custom storage class: ExportedGlobal */
extern double u;
```

- `u` is initialized in `addglobals_initialize.c`.

```
/* Include Files */
#include "addglobals_initialize.h"
#include "addglobals.h"
#include "addglobals_data.h"

/* Function Definitions */

/*
 * Arguments : void
 * Return Type : void
 */
void addglobals_initialize(void)
{
 u = 1.0;
 isInitialized_addglobals = true;
}
```

View the definition and declaration for the imported external global `v` and the imported external global pointer `x`.

`v` and `x` are declared as `extern` in the `Variable Declarations` section in `addglobals_data.h`.

```
/* Variable Declarations */
/* Declaration for custom storage class: ImportedExtern */
extern double v;
```

```
/* Declaration for custom storage class: ImportedExternPointer */
extern double *x;
```

## Highlight Potential Data Type Issues in a Report

### In this section...

“Enable Highlight Option Using the MATLAB Coder App” on page 93-2

“Enable Highlight Option Using the Command Line Interface” on page 93-2

If you have Embedded Coder, you have the option to highlight potential data types issues in the code generation report for standalone code generated from MATLAB code. If you enable this option, on the **Code Insights** tab, the report identifies single-precision and double-precision operations in the generated C/C++ code. If you have Fixed-Point Designer, the report also identifies expensive fixed-point operations.

To view potential data type issues in a code generation report:

- 1 Click the **Code Insights** tab.
- 2 Expand the **Potential data type issues** section.
- 3 Expand the data type issues section that you want to see.

For example, this report identifies MATLAB code that results in double-precision operations in the generated code.

The option to highlight potential data type issues is disabled by default.

### Enable Highlight Option Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3 Click **More Settings**.
- 4 On the **Debugging** tab, select the **Always create a report** and **Highlight potential data type issues** check boxes.

### Enable Highlight Option Using the Command Line Interface

- 1 Create an embedded code configuration object for 'lib', 'dll', or 'exe':
 

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

- 2 Set the `GenerateReport` and `HighlightPotentialDataTypeIssues` configuration object properties to `true`:

```
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
```

## See Also

- “Find and Address Cumbersome Operations” on page 93-5
- “Find and Address Expensive Rounding” on page 93-5
- “Find and Address Expensive Comparison Operations” on page 93-6
- “Find and Address Multiword Operations” on page 93-7

### Data Type Issues Overview

When you generate C code from MATLAB code, you can highlight potential data type issues in the C code generation report. The report highlights MATLAB code that requires single-precision, double-precision, or expensive fixed-point operations. The expensive fixed-point operations checks require a Fixed-Point Designer.

- The double-precision check highlights expressions that result in a double-precision operation. When trying to achieve a strict-single or fixed-point design, manual inspection of code can be time-consuming and error prone.

For a strict-single precision design, specify a language standard that supports single-precision implementations. To change the library for a project, during the Generate Code step, in the project settings dialog box, on the **Custom Code** tab, set the **Language standard** to C99 (ISO).

- The single-precision check highlights expressions that result in a single operation.
- The expensive fixed-point operations check identifies optimization opportunities for fixed-point code. It highlights expressions in the MATLAB code that require cumbersome multiplication or division, expensive rounding, expensive comparison, or multiword operations. For more information on optimizing generated fixed-point code, see “Tips for Making Generated Code More Efficient” (Fixed-Point Designer).

### Enable Highlighting of Potential Data Type Issues

#### Enable the highlight option using the MATLAB Coder app

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3 Click **More Settings**.
- 4 On the **Debugging** tab, select the **Always create a report** and **Highlight potential data type issues** check boxes.

## Enable the highlight option using the command-line interface

- 1 Create an embedded code configuration object for 'lib', 'dll', or 'exe':

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

- 2 Set the GenerateReport and HighlightPotentialDataTypeIssues configuration object properties to true:

```
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
```

## Find and Address Cumbersome Operations

Cumbersome operations usually occur due to an insufficient range of output. Avoid inputs to a multiply or divide operation that have word lengths larger than the base integer type of your processor. Software can process operations with larger word lengths, but this approach requires more code and runs slower.

This example requires Embedded Coder and Fixed-Point Designer. The target word length for the processor in this example is 64.

- 1 Create the function myMul.

```
function out = myMul(in1, in2)
 out = fi(in1*in2, 1, 64, 0);
end
```

- 2 Generate code for myMul.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
fm = fimath('ProductMode', 'SpecifyPrecision', 'ProductWordLength', 64);
codegen -config cfg myMul -args {fi(1, 1, 64, 4, fm), fi(1, 1, 64, 4, fm)}
```

- 3 Click **View report**.

- 4 In the code generation report, click the **Code Insights** tab.

- 5 Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.

The report flags the expression `in1 * in2`. To resolve the issue, modify the data types of `in1` and `in2` so that the word length of the product does not exceed the target word length of 64.

## Find and Address Expensive Rounding

Traditional handwritten code, especially for control applications, almost always uses "no effort" rounding. For example, for unsigned integers and two's complement signed integers, shifting right and dropping the bits is equivalent to rounding to floor. To get results comparable to, or better than, what you expect from traditional handwritten code, use the floor rounding method.

This example requires Embedded Coder and Fixed-Point Designer.

- 1 Create the function `myRounding`.

```
function [quot] = myRounding(in1, in2)
 quot = in1 / in2;
end
```

- 2 Generate code for `myRounding`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myRounding -args {fi(1, 1, 16, 2), fi(1, 1, 16, 4)}
```

- 3 Click **View report**.

- 4 In the code generation report, click the **Code Insights** tab.

- 5 Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.

SUMMARY	ALL MESSAGES (0)	BUILD LOGS	CODE INSIGHTS (1)	VARIABLES
<div style="border: 1px solid #ccc; padding: 5px;"> <div style="background-color: #f0f0f0; padding: 2px;"> <span>⊞</span> <span>📄</span> Potential data type issues (1) <i>MATLAB code that requires single-precision, double-precision, or expensive fixed-point operations.</i> </div> <div style="padding: 2px;"> <span>⊞</span> <span>📄</span> Expensive fixed-point operations           <ul style="list-style-type: none"> <li><span>↳</span> <span>📄</span> myRounding 2: quot = in1 / in2;</li> </ul> </div> </div>				

The division operation `in1/in2` uses the default rounding method, nearest. Changing the rounding method to `Floor` provides a more efficient implementation.

## Find and Address Expensive Comparison Operations

Comparison operations generate extra code when a casting operation is required to do the comparison. For example, before comparing an unsigned integer to a signed integer, one of the inputs must be cast to the signedness of the other. Consider optimizing the data types of the input arguments so that a cast is not required in the generated code.

This example requires Embedded Coder and Fixed-Point Designer.

- 1 Create the function `myRelop`.

```
function out = myRelop(in1, in2)
 out = in1 > in2;
end
```

- 2 Generate code for `myRelop`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myRelop -args {fi(1, 1, 14, 3, 1), fi(1, 0, 14, 3, 1)}
```

- 3 Click **View report**.

- 4 In the code generation report, click the **Code Insights** tab.

- 5 Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.

SUMMARY	ALL MESSAGES (0)	BUILD LOGS	CODE INSIGHTS (1)	VARIABLES
<div style="border: 1px solid #ccc; padding: 5px;"> <div style="background-color: #f0f0f0; padding: 2px;"> <span>⊞</span> <span>📄</span> Potential data type issues (1) <i>MATLAB code that requires single-precision, double-precision, or expensive fixed-point operations.</i> </div> <div style="padding: 2px;"> <span>⊞</span> <span>📄</span> Expensive fixed-point operations           <ul style="list-style-type: none"> <li><span>↳</span> <span>📄</span> myRelop 2: out = in1 &gt; in2;</li> </ul> </div> </div>				

The first input argument, `in1`, is signed, while `in2` is unsigned. Extra code is generated because a cast must occur before the two inputs can be compared.

Change the signedness and scaling of one of the inputs to generate more efficient code.

## Find and Address Multiword Operations

Multiword operations can be inefficient on hardware. When an operation has an input or output data type larger than the largest word size of your processor, the generated code contains multiword operations. You can avoid multiword operations in the generated code by specifying local `fimath` properties for variables. You can also manually specify input and output word lengths of operations that generate multiword code.

This example requires Embedded Coder and Fixed-Point Designer. In this example, the target word length is 64.

- 1 Create the function `myMul`.

```
function out = myMul(in1, in2)
 out = in1 * in2;
end
```

- 2 Generate code for `myMul`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypesIssues = true;
codegen -config cfg myMul -args {fi(1, 1, 33, 4), fi(1, 1, 32, 4)}
```

- 3 Click **View report**.

In the code generation report, click the **Code Insights** tab.

- 5 Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.

- 6 The report flags the `in1 * in2` operation in line 2 of `myMul`. In the code pane, pause over `in1`, `in2`, and the expression `in1 * in2`. You see that:
  - The word length of `in1` is 33 bits and the word length of `in2` is 32 bits.
  - The word length of the expression `in1 * in2` is 65 bits.

The software detects a multiword operation because the word length 65 is larger than the target word length of 64.

- 7 To resolve this issue, modify the data types of `in1` and `in2` so that the word length of the product does not exceed the target word length. Alternatively, specify the `ProductMode` property of the local `fimath` object.

## PIL Execution with ARM Cortex-A at the Command Line

This example shows how to set up a PIL execution to verify generated code at the command line.

You can use processor-in-the-loop (PIL) executions to verify generated code that you deploy to target hardware by using a MATLAB Coder procedure. You can profile algorithm performance and speed for your generated code. To verify generated code with the MATLAB Coder app, you must have an Embedded Coder license.

This PIL execution is available with these hardware support packages. To use the PIL execution, install one of these support packages.

- Embedded Coder Support Package for BeagleBone® Black Hardware
- Embedded Coder Support Package for ARM Cortex®-A Processors

In the Command Window, select the hardware for PIL execution.

```
hw = coder.hardware('ARM Cortex-A9 (QEMU)')
```

```
hw =
```

```
Hardware with properties:
```

```
 Name: 'ARM Cortex-A9 (QEMU)'
 CPUClockRate: 1000
```

When using the BeagleBone hardware, more hardware properties are supported (Username, Password, and DeviceAddress). Set these properties based on your specific hardware or application.

```
hw = coder.hardware('BeagleBone Black')
```

```
hw =
```

```
Hardware with properties:
```

```
 Name: 'BeagleBone Black'
 CPUClockRate: 1000
 Password: 'root'
 Username: 'admin'
 DeviceAddress: '192.168.1.10'
```

Add the hardware to the MATLAB Coder configuration object.

```
cfg = coder.config('lib','ecoder',true);
cfg.VerificationMode = 'PIL';
cfg.Hardware = hw;
```

Generate PIL code for a function, `averaging_filter`.

```
codegen -config cfg averaging_filter -args {zeros(1,16)}
```

For more information on the `averaging_filter` function, see “Generate Code for an Averaging Filter”.

For another example of PIL verification, see the “Processor-in-the-Loop Verification of MATLAB Functions” (Embedded Coder Support Package for ARM Cortex-A Processors) page in the

documentation of the Embedded Coder Support Package for ARM Cortex-A Processors. To install the Embedded Coder Support Package for ARM Cortex-A Processors, see “Embedded Coder Supported Hardware”.

## PIL Execution with ARM Cortex-A by Using the MATLAB Coder App

You can use processor-in-the-loop (PIL) executions to verify generated code that you deploy to target hardware by using a MATLAB Coder procedure. You can profile algorithm performance and speed for your generated code. To verify generated code with the MATLAB Coder app, you must have an Embedded Coder license.

This PIL execution is available with these hardware support packages. To use the PIL execution, install one of these support packages.

- Embedded Coder Support Package for BeagleBone Black Hardware
- Embedded Coder Support Package for ARM Cortex-A Processors

You can set up PIL execution with the MATLAB Coder app.

To configure the build type and hardware board:

- 1** On the **Generate Code** page, in the **Generate** dialog box:
  - Set the **Build type** to `Static Library`.
  - Clear the **Generate code only** check box.
  - Set the **Hardware Board** to `BeagleBone Black` or `ARM Cortex-A9 (QEMU)`.
- 2** If necessary, modify the settings for your board. To modify the settings, click **More Settings**, and then click **Hardware**.
- 3** To generate the library, click **Generate**.
- 4** Set up your PIL execution. Click **Verify Code** to open the **Verify Code** dialog box.

Because the hardware board is not MATLAB Host Computer, the **Verify Code** dialog box is configured for PIL execution.

In the **Verify Code** dialog box:

- Enter the name of the test file to use for PIL execution.
  - Select **Generated code**.
- 5** To start the PIL execution, click **Run Generated Code**.
  - 6** To stop the PIL execution, click **Stop**.

For another example of PIL verification, see the "Processor-in-the-Loop Verification of MATLAB Functions" page in the documentation of the Embedded Coder Support Package for ARM Cortex-A Processors. Install the support package to view the documentation.

## Interactively Trace Between MATLAB Code and Generated C/C++ Code

This example shows how to trace between MATLAB source code and the generated C/C++ code. Tracing between source code and generated code helps you to:

- Understand how the code generator implemented your algorithm.
- Debug issues in the generated code.
- Evaluate the quality of the generated code.

If you have Embedded Coder and enable production of a code generation report with traceability, you can view MATLAB source code and generated C/C++ code next to each other. As you move your pointer over code, you can follow highlighted traces to the corresponding generated code or source MATLAB code.

### Create the MATLAB Source Code

To illustrate interactive traceability, this example produces a report for generation of a C static library for a MATLAB function `lpsolve` that solves the linear program:

- maximize  $y = c*x$
- subject to  $A*x \leq b$
- where  $x \geq 0$  and  $b \geq 0$

#### `lpsolve`

```
%Attempts to solve the linear program:
%
% maximize y = c*x
% subject to: A*x <= b,
% where x >= 0 and b >= 0
%
% using the dictionary form of the simplex algorithm.
%
% c must be a double, real row vector.
% b must be a double, real column vector.
% A must be a double, real, non-empty matrix with
% size(A) = [length(b),length(c)].
%
% Compare to
% x = linprog(-c(:),A,b,[],[],zeros(length(c),1))
% y = c*x
%
% Copyright 2011-2018 The MathWorks, Inc.

function [x,y] = lpsolve(c,A,b)
%#codegen
narginchk(3,3);
m = int32(size(A,1));
n = int32(size(A,2));
if ~validInputs(c,A,b)
 % Something is wrong with the inputs. Return NaNs.
 x = nan(n,1);
```

```

 y = nan;
 return
 end
 cn = c;
 nIdx = 1:n; % indices of non-basic variables
 bIdx = n + (1:m); % indices of basic variables
 % Perform iterations.
 j = findPivotColumn(cn,nIdx);
 unbounded = false;
 while j > 0 && ~unbounded
 [i,r] = findPivotRow(j,A,b);
 if i == 0 || isinf(r)
 unbounded = true;
 else
 b(i) = r;
 % Take account of the variables entering and leaving the basis.
 entering = nIdx(j);
 leaving = bIdx(i);
 bIdx(i) = entering;
 nIdx(j) = leaving;
 [cn,A,b] = pivot(cn,A,b,i,j);
 j = findPivotColumn(cn,nIdx);
 end
 end
 % Construct the solution.
 if unbounded
 x = nan(n,1);
 y = inf;
 else
 x = zeros(n,1);
 y = 0;
 for k = 1:m
 j = bIdx(k);
 if j <= n
 x(j) = b(k);
 y = y + c(j)*x(j);
 end
 end
 end
end

%-----

function p = validInputs(c,A,b)
coder.inline('never');
% All inputs must be double.
p = isa(c,'double') && isa(A,'double') && isa(b,'double');
% All inputs must be real.
p = p && isreal(c) && isreal(A) && isreal(b);
% A must be a non-empty matrix.
p = p && ismatrix(A) && ~isempty(A);
% c must be a row-vector with length = size(A,2).
p = p && isrow(c) && size(c,2) == size(A,2);
% b must be a column-vector with length = size(A,1).
p = p && iscolumn(b) && size(b,1) == size(A,1);
% The elements of b must be non-negative.
p = p && all(b(:) >= 0);

%-----

```

```

function [c,A,b] = pivot(c,A,b,i,j)
% Pivot on element i,j.
coder.inline('never');
m = int32(size(A,1));
aij = A(i,j);
A(i,j) = 1;
A(i,:) = A(i,+)/aij;
for k = 1:m
 if k ~= i
 akj = A(k,j);
 A(k,j) = 0;
 A(k,:) = A(k,:) - akj*A(i,:);
 b(k) = b(k) - akj*b(i);
 end
end
cj = c(j);
c(j) = 0;
c = c - cj*A(i,:);

%-----

function j = findPivotColumn(c,idx)
% Find a suitable variable to enter the basis using the smallest
% subscript rule to prevent cycling.
coder.inline('never');
j = int32(0);
nc = int32(numel(c));
lastidx = int32(0);
for k = 1:nc
 if c(k) > 0 && (lastidx < 1 || idx(k) < lastidx)
 j = k;
 lastidx = idx(k);
 end
end

%-----

function [i,r] = findPivotRow(j,A,b)
% Find the pivot row in column j of A and also return r = b(i)/A(i,j).
coder.inline('never');
r = inf;
i = int32(0);
nb = int32(numel(b));
for k = 1:nb
 if A(k,j) > 0
 rtmp = b(k)/A(k,j);
 if rtmp < r
 r = rtmp;
 i = k;
 end
 end
end

%-----

```

The example also uses a test function `lpsolve_test` that calls `lpsolve` with representative input values.

## lpsolve\_test

```
% Test function for lpsolve
%
% Copyright 2011-2018 The MathWorks, Inc.
```

```
function lpsolve_test()
c = [2 3 1 1];
A = [2 3 1 -1;1 0 2 1;0 2 1 1];
b = [27;9;18];
[x,y] = lpsolve(c,A,b);
x % display x
y % display y
```

Copy `lpsolve.m` and `lpsolve_test.m` to a writable folder.

```
copyfile(fullfile(docroot, 'toolbox', 'ecoder', 'examples', 'lpsolve.m'))
copyfile(fullfile(docroot, 'toolbox', 'ecoder', 'examples', 'lpsolve_test.m'))
```

## Prepare for Code Generation

Before you generate C/C++ code, it is a best practice to screen your MATLAB code for code generation readiness.

```
coder.screener('lpsolve')
```

The code generation readiness report indicates that `lpsolve` is suitable for code generation.

It is also a best practice to check for run-time issues by generating and testing a MEX function.

- To specify the types of the inputs arguments, pass representative input values to the `codegen -args` option. Alternatively, because you have a test function, you can use `coder.getArgTypes` to determine the types.
- To generate and test a MEX function, use the `-test` option.

```
c = [2 3 1 1];
A = [2 3 1 -1;1 0 2 1;0 2 1 1];
b = [27;9;18];
codegen lpsolve -args {c A b} -test lpsolve_test
```

Running test file: 'lpsolve\_test' with MEX function 'lpsolve\_mex'.

```
x =
```

```
5
7
0
4
```

```
y =
```

```
35
```

codegen successfully generates and runs the MEX function.

## Produce a Code Generation Report with Traceability

To generate a report that has interactive traceability:

- Create a `coder.EmbeddedCodeConfig` object. The `EnableTraceability` property controls traceability. By default, the `EnableTraceability` property is `true`.
- Specify the types of the input arguments by passing representative input values to the `-args` option.
- Enable production of a code generation report by using the `-report` option.

```
cfg = coder.config('lib', 'ecoder', true);
codegen -config cfg lpsolve -args {c A b} -report
```

## Access Trace Mode in the Report

To open the code generation report, click **View report**.

In the code pane, you see `lpsolve.m`.

To enable tracing, on the **Report** tab, click **Trace Code**.

You see the MATLAB source code and the generated C code next to each other.

```

37 unbounded = false;
38 while j > 0 && ~unbounded
39 [i,r] = findPivotRow(j,A,b);
40 if i == 0 || isinf(r)
41 unbounded = true;
42 else
43 b(i) = r;
44 % Take account of the variables entering and leaving
45 entering = nIdx(j);
46 leaving = bIdx(i);
47 bIdx(i) = entering;
48 nIdx(j) = leaving;
49 [cn,A,b] = pivot(cn,A,b,i,j);
50 j = findPivotColumn(cn,nIdx);
51 end
52 end
53 % Construct the solution.
54 if unbounded
55 x = nan(n,1);
56 y = inf;
57 else
58 x = zeros(n,1);
59 y = 0;
60 for k = 1:m
61 j = bIdx(k);
62 if j <= n
13
14 /* Function Declarations */
15 static int findPivotColumn(const double c[4], const int idx[
16 static void findPivotRow(int j, const double A[12], const do
17 double *r);
18 static void pivot(double c[4], double A[12], double b[3], in
19 static boolean_T validInputs(const double b[3]);
20
21 /* Function Definitions */
22
23 /*
24 * Find a suitable variable to enter the basis using the sma
25 * subscript rule to prevent cycling.
26 * Arguments : const double c[4]
27 const int idx[4]
28
29 222 unbounded = false;
223 while ((j > 0) && (!unbounded)) {
224 findPivotRow(j, A, b, &i, &r);
225 if ((i == 0) || rtIsInf(r)) {
226 unbounded = true;
227 } else {
228 b[i - 1] = r;
229
230 /* Take account of the variables entering
231
232 lastidx = 0;

```

You see this symbol that tells you that the highlighted MATLAB code has one trace that is not in view.

You see the corresponding C code in a separate window in the C code pane.

- 2 In the C code pane, scroll down until you see the C code that corresponds to the while loop.

```

36 j = findPivotColumn(cn,nIdx);
37 unbounded = false;
38 while j > 0 && ~unbounded
39 [i,r] = findPivotRow(j,A,b);
40 if i == 0 || isinf(r)
41 unbounded = true;
42 else
43 b(i) = r;
44 % Take account of the variables entering and leaving
45 entering = nIdx(j);
46 leaving = bIdx(i);
47 bIdx(i) = entering;
48 nIdx(j) = leaving;
49 [cn,A,b] = pivot(cn,A,b,i,j);
50 j = findPivotColumn(cn,nIdx);
51 end
52 end
53 % Construct the solution.
54 if unbounded
55 x = nan(n,1);
220
221 j = findPivotColumn(c, iv0);
222 unbounded = false;
223 while ((j > 0) && (!unbounded)) {
224 findPivotRow(j, A, b, &i, &r);
225 if ((i == 0) || rtIsInf(r)) {
226 unbounded = true;
227 } else {
228 b[i - 1] = r;
229
230 /* Take account of the variables entering and lea
231 leaving = bIdx[i - 1];
232 bIdx[i - 1] = nIdx[j - 1];
233 nIdx[j - 1] = leaving;
234 pivot(cn, A, b, i, j);
235 j = findPivotColumn(cn, nIdx);
236 }
237
238

```

- 3 In the MATLAB code, move your pointer over different syntax elements in the while loop. Highlight variables, expressions, and code blocks.

When you move your pointer over expressions that are part of larger expressions, different shades of purple help you to find the relevant expression in the corresponding C code. For example, at line 43, pause over `i`.

```

43 b(i) = r;
44 % Take account of the variables entering and leaving
45 entering = nIdx(j);
46 leaving = bIdx(i);
47 bIdx(i) = entering;
224 findPivotRow(j,
225 if ((i == 0) ||
226 unbounded = tr
227 } else {
228 b[i - 1] = r;

```

- 4 In the MATLAB code, move your pointer back to the while-loop that starts at line 38. When the entire loop is highlighted in purple, select it by clicking. When you move your pointer outside of the trace, the yellow highlighting identifies the selected trace.

```

38 while j > 0 && ~unbounded
39 [i,r] = findPivotRow(j,A,b);
40 if i == 0 || isinf(r)
41 unbounded = true;
42 else
43 b(i) = r;
44 % Take account of the variables entering and leaving
45 entering = nIdx(j);
46 leaving = bIdx(i);
47 bIdx(i) = entering;
48 nIdx(j) = leaving;
49 [cn,A,b] = pivot(cn,A,b,i,j);
50 j = findPivotColumn(cn,nIdx);
51 end
52 end
53 % Construct the solution.
54 if unbounded
55 x = nan(n,1);
56 y = inf;
57 else
58 x = zeros(n,1);

```

```

217 for (j = 0; j < 4; j++) {
218 iv0[j] = 1 + j;
219 }
220
221 j = findPivotColumn(c, iv0);
222 unbounded = false;
223 while ((j > 0) && (!unbounded)) {
224 findPivotRow(j, A, b, &i, &r);
225 if ((i == 0) || rtIsInf(r)) {
226 unbounded = true;
227 } else {
228 b[i - 1] = r;
229
230 /* Take account of the variables
231 leaving = bIdx[i - 1];
232 bIdx[i - 1] = nIdx[j - 1];
233 nIdx[j - 1] = leaving;
234 pivot(cn, A, b, i, j);
235 j = findPivotColumn(cn, nIdx);
236 }
237 }

```

To clear the selection, press **Esc** or select different code.

## View Multiple Traces

When code traces to more than one place in the corresponding source or generated code:

- If you pause over the code that you are tracing, at the top of the code pane, you see the number of traces.
- If some traces are not in view, you see a symbol that tells you how many traces are out of view.

- In the code pane, if you select the code that you want to trace, at the top of the code pane, you can select the trace that you want to see.

In the report for `lpsolve`, view multiple traces.

- 1 Pause over line 36.

At the top of the code pane, you see that line 36 has two traces.

- 2 Select line 36.

At the top of the code pane, you see the location of the first trace.

- 3 To list all traces, click the arrow to the right of the traces.

## View Traces to Different Files

In the code generation report for `lpsolve`, all traces from the MATLAB code go to one C file `lpsolve.c`. If MATLAB code traces to multiple C files, above the C code, you see a symbol such as

that provides the number of additional files in which you can find a trace. If you click the symbol, you can select the file that you want to see. If you select the MATLAB code, then you can select the trace that you want to see.

Likewise, above the MATLAB source code, a symbol such as  indicates that the highlighted C code traces to multiple MATLAB files.

## Switch the Locations of the Source and Generated Code

- 1 To view `lpsolve.c` on the left side of the code pane, in the list of generated files, click `lpsolve.c`.
- 2 To view the MATLAB code on the left side of the code pane, click a MATLAB function, for example, `lpsolve`.

## Enable Code Tooltips and Links

When you are not in trace mode:

- In the MATLAB code, if you point to a variable or expression, a tooltip provides information such as the type.
- In the C code, links go to other parts of the code such as type or function definitions.

When you are in trace mode, to enable MATLAB code tooltips and C code links, hold down **Ctrl**. MATLAB code tooltips are available only for a selected MATLAB function.

In the report for `lpsolve`, view type information for a variable.

- 1 In the **MATLAB Source** pane, select `pivot`.
- 2 In the code pane, hold down **Ctrl** and pause over the input argument `i`.

---

**Note** On a Macintosh platform, use the **Command** key instead of **Ctrl**.

---

## Disable Traceability

To produce a code generation report that does not include traceability:

- In a `coder.EmbeddedCodeConfig` object, set the `EnableTraceability` property to `false`.
- In the MATLAB Coder app, set **Enable code traceability** to **No**.

## Polyspace Verification of C/C++ Code Generated by MATLAB Coder

To check for run-time errors in C/C++ code generated from MATLAB code, you can use Polyspace Code Prover. To check for defects, you can use Polyspace Bug Finder. If you have Polyspace and Embedded Coder, Polyspace is integrated into the MATLAB Coder workflow.

- In the MATLAB Coder app, you can run Polyspace analysis without additional setup.
- At the command line, after code generation with `codegen`, you can run Polyspace analysis on the generated code by providing the code generation output folder to `pslinkrun`.

### Run Polyspace Analysis in the MATLAB Coder App

- 1 Generate standalone C/C++ code (a static library, dynamically linked library, or executable program).
- 2 On the **Generate Code** page, click **Polyspace**.
- 3 Select the options. See “Configure Advanced Polyspace Options in MATLAB Coder App” (Polyspace Code Prover).
- 4 Click **Run**.

The app logs the analysis output on the **Polyspace Log** tab and opens the Polyspace user interface.

### Run Polyspace Analysis on Code Generated by `codegen`

- 1 Create a `pslinkoptions` object for verification of code generated by MATLAB Coder.
- 2 As needed, change object properties:
  - In the `ResultDir` property, specify the name of the folder for the Polyspace results.
  - In the `VerificationMode` property, specify the Polyspace verification product.
- 3 Run the verification by using `pslinkrun`. Provide the `pslinkoptions` object and the folder that contains the generated code.
- 4 To view verification results, open the Polyspace user interface.

For example, suppose that you generated a static library for the MATLAB function `myFunction` and that the code generation output folder is `codegen/lib/myFunction`. To run Polyspace Code Prover on the generated code, use this code:

```
opts = pslinkoptions('codegen');
opts.ResultDir = 'polyspace';
opts.VerificationMode = 'CodeProver';
pslinkrun('-codegenfolder', 'codegen/lib/myFunction', opts);
polyspaceCodeProver('polyspace/myFunction.psprj');
```

You can also set the `VerificationMode` property to `'BugFinder'` and view verification results by using `polyspaceBugFinder`.

### Review Analysis Results

In the **Results List** pane of the Polyspace user interface, review the run-time checks. See whether you can trace the issues back to the original MATLAB code. See “Interactively Trace Between MATLAB Code and Generated C/C++ Code” on page 93-12.

For example, an operation in the C code might overflow because Polyspace assumes an unbounded range for a function input. Consider specifying a constraint on the input and reanalyzing the code with Polyspace. See “Run Polyspace on C/C++ Code Generated from MATLAB Code” (Polyspace Code Prover).
