© COPYRIGHT 2011–2022 by The MathWorks, Inc.

The software described in this document is furnished under a license agreement. The software may be used or copied only under the terms of the license agreement. No part of this manual may be photocopied or reproduced in any form without prior written consent from The MathWorks, Inc.

FEDERAL ACQUISITION: This provision applies to all acquisitions of the Program and Documentation by, for, or through the federal government of the United States. By accepting delivery of the Program or Documentation, the government hereby agrees that this software or documentation qualifies as commercial computer software or commercial computer software documentation as such terms are used or defined in FAR 12.212, DFARS Part 227.72, and DFARS 252.227-7014. Accordingly, the terms and conditions of this Agreement and only those rights specified in this Agreement, shall pertain to and govern the use, modification, reproduction, release, performance, display, and disclosure of the Program and Documentation by the federal government (or other entity acquiring for or through the federal government) and shall supersede any conflicting contractual terms or conditions. If this License fails to meet the government's needs or is inconsistent in any respect with federal procurement law, the government agrees to return the Program and Documentation, unused, to The MathWorks, Inc.

Trademarks

MATLAB and Simulink are registered trademarks of The MathWorks, Inc. See www.mathworks.com/trademarks for a list of additional trademarks. Other product or brand names may be trademarks or registered trademarks of their respective holders.

Patents

MathWorks products are protected by one or more U.S. patents. Please see www.mathworks.com/patents for more information.

Revision History

April 2011	Online only	New for Version 6.0 (Release 2011a)
September 2011	Online only	Revised for Version 6.1 (Release 2011b)
March 2012	Online only	Revised for Version 6.2 (Release 2012a)
September 2012	Online only	Revised for Version 6.3 (Release 2012b)
March 2013	Online only	Revised for Version 6.4 (Release 2013a)
September 2013	Online only	Revised for Version 6.5 (Release 2013b)
March 2014	Online only	Revised for Version 6.6 (Release 2014a)
October 2014	Online only	Revised for Version 6.7 (Release 2014b)
March 2015	Online only	Revised for Version 6.8 (Release 2015a)
September 2015	Online only	Revised for Version 6.9 (Release 2015b)
October 2015	Online only	Rereleased for Version 6.8.1 (Release 2015aSP1)
March 2016	Online only	Revised for Version 6.10 (Release 2016a)
September 2016	Online only	Revised for Version 6.11 (Release 2016b)
March 2017	Online only	Revised for Version 6.12 (Release 2017a)
September 2017	Online only	Revised for Version 6.13 (Release 2017b)
March 2018	Online only	Revised for Version 7.0 (Release 2018a)
September 2018	Online only	Revised for Version 7.1 (Release 2018b)
March 2019	Online only	Revised for Version 7.2 (Release 2019a)
September 2019	Online only	Revised for Version 7.3 (Release 2019b)
March 2020	Online only	Revised for Version 7.4 (Release 2020a)
September 2020	Online only	Revised for Version 7.5 (Release 2020b)
March 2021	Online only	Revised for Version 7.6 (Release 2021a)
September 2021	Online only	Revised for Version 7.7 (Release 2021b)
March 2022	Online only	Revised for Version 7.8 (Release 2022a)

Check Bug Reports for Issues and Fixes

Software is inherently complex and is not free of errors. The output of a code generator might contain bugs, some of which are not detected by a compiler. MathWorks reports critical known bugs brought to its attention on its Bug Report system at www.mathworks.com/support/bugreports/. In the search bar, type the phrase "Incorrect Code Generation" to obtain a report of known bugs that produce code that might compile and execute, but still produce wrong answers. To save a search, click Save Search.

The bug reports are an integral part of the documentation for each release. Examine periodically all bug reports for a release, as such reports may identify inconsistencies between the actual behavior of a release you are using and the behavior described in this documentation.

In addition to reviewing bug reports, you should implement a verification and validation strategy to identify potential bugs in your design, code, and tools.

Model Architecture and Design

Software Deployment Fundamentals

1

Software Deployment Concepts	1-2
Component Models	1-2
Platforms	1-2
Platform Specifications	1-4
Platform Middleware	1-5
Platform Service Data Communication Methods	1-7
Component Platform Interfaces	1-8
Choose Software Deployment Workflow	1-10
Code Generation Environment Customization	1-11
Component Deployment	1-13
Identify Requirements	1-14
Create C Code Interface Definitions	1-16
Develop Component Model	1-19
Deploy and Integrate Generated Code	1-24
Decompose Software Problem	1-28
Map Embedded System Architecture to Simulink Modeling Environment	1-29
Modeling Algorithms	1-29
Modeling Interfaces	1-30
Modeling Systems	1-32
Modeling Target Platform Environments	1-33
Embedded Coder Supported Hardware	1-36

Components

2

Component Model Design for Deployment	2-2
Subcomponents	2-2
Utilities	2-2

Model Single-Core, Single-Tasking Platform Execution	2-4
Model Single-Core, Multitasking Platform Execution	2-7
Model Concurrent Execution for Symmetric Multicore CPU Platforms	2-10
Model Explicit Function Invocation with Atomic Subsystems	2-15
Model Explicit Function Invocation with Function-Call Subsystems	2-18
Periodic and Aperiodic Function Interfaces	2-21
Rate-Based Components	2-21
Function-Call-Based Components	2-22
Periodic and Aperiodic Function Interface Configuration	2-24
Startup, Reset, and Shutdown Function Interfaces	2-25
Generate Code for Initialize and Terminate Events	2-26
Generate Code for Reset Events	2-29
Event Names and Code Aggregation	2-31
Limitation	2-32
Receive and Send Communication Interfaces	2-34
Message Communication Interfaces	2-36
Generate C++ Messages to Communicate Data Between Simulink and an Operating System or Middleware	2-36
Generate C++ Messages to Communicate Data Between Simulink Components	2-40
Generate C Messages to Communicate Data Between Simulink Components	2-45
Use Handwritten Code to Integrate C++ Messages with POSIX ...	2-52
Client-Server Communication Interfaces	2-59
Implementation Options for Simulink Functions and Function Callers	2-59
Choose a Modeling Pattern	2-59
Specify Function Scope	2-60
Decide Whether to Generate Export Function Code	2-61
Configure Function Code Interface	2-61
Uncalled Simulink Function Blocks	2-61
Requirements	2-61
Limitations	2-62
Client-Server C Code Communication Example	2-62
Client-Server C++ Code Communication Example	2-67
Device Driver I/O	2-73
Data Transfer Interfaces	2-75
Nonvolatile Memory Interfaces	2-76
Nonvolatile Memory Direct Access Interfaces	2-76
Nonvolatile Memory Service Interfaces	2-76

Parameter Tuning Interfaces	2-78
Measurement Interfaces	2-80
Multi-Instantiation	2-82

Subsystems in Simulink Coder

3

Generate Code and Executables for Individual Subsystems	3-2
Subsystem Build Limitations	3-3
Generate Inlined Subsystem Code	3-5
Configure Subsystem to Inline Code	3-5
Exceptions to Inlining	3-6
See Also	3-6
Generate Subsystem Code as Separate Function and Files	3-7
Subsystem Function Dependence	3-7
Generate Subsystem as a Reusable Function	3-7
Generate Subsystem as a Nonreusable Function	3-8

Subsystems in Embedded Coder

4

Generate Predictable Function Interface to Match Graphical Block Interface	4-2

Referenced Models in Simulink Coder

5

Generate Code for Model Reference Hierarchy	5-2
Model Reference Technology	5-2
Generate Code for Model Reference Hierarchy	5-2
Working with Code Generation Folders	5-6
Build Model Reference Targets	5-7
Set Configuration Parameters for Code Generation of Model Hierarchies	5-9
Configuration Parameter Requirements	5-9
Configuration Parameters Changed During Code Generation	5-11
Naming Requirements	5-12
Custom Target Requirements	5-12
Miscellaneous Considerations	5-12

Convert Subsystem to Referenced Model and Generate Code	5-14
Configure Code Mappings	5-14
Convert Subsystem to Referenced Model	5-14
Copy Code Mappings After Subsystem Conversion	5-16
Review Generated Code	5-16
Generate Reusable Code from Model Reference Hierarchy	5-17
Storage Classes for Parameters and Signals Used in Model Blocks	5-20
Storage Classes for Parameters in Model Blocks	5-20
Storage Classes for Signals in Model Blocks	5-21
Signal Name Mismatches Across Model Reference Boundary	5-21
Code Generation Limitations for Model Reference	5-23
Storage Class Limitations	5-23
Data Logging Limitations	5-23
State Initialization Limitations	5-23
Model Reuse Limitations	5-23
S-Functions Limitations	5-24
Subsystems Limitations	5-24
Targets Limitation	5-24
Conditional Models Limitation	5-24
Simulink Cache Files for Incremental Code Generation	5-25
Contents of Simulink Cache Files	5-25
Share Code Generation Artifacts	5-25
Specify Instance-Specific Parameter Values for Reusable Referenced Model	5-28
Pass Parameter Data to Referenced Model Entry-Point Functions as Arguments	5-28
Control Data Types of Model Arguments and Argument Values	5-50
Generated Functions in a Model Reference Hierarchy	5-52
Generated Functions in a Top Model	5-52
Generated Functions in a Referenced Model	5-53

Combined Models in Simulink Coder

6

Combine Code Generated for Multiple Models	6-2
Considerations for Combining Code for Different Models	6-2
Control Ownership of Data	6-3
Combine Code Generated for Multiple Models or Multiple Instances of a Model	6-3
Function Reuse in Generated Code	6-5
File Packaging for Models (Code and Data)	6-10

What Is Code Reuse?	7-2
What Is Reentrant Code?	7-3
Choose a Componentization Technique for Code Reuse	7-4
Simulink Function Blocks and Code Generation	7-6
Why Generate Code from Simulink Function Blocks and Function Callers?	7-6
Implementation Options	7-6
Choose a Modeling Pattern	7-6
Specify Function Scope	7-8
Decide Whether to Generate Export Function Code	7-8
Specify Function Code Interface Customizations	7-8
Uncalled Simulink Function Blocks	7-8
Requirements	7-9
Limitations	7-9
Generate and Call Reusable Function Code	7-9
Generate Code for a Simulink Function and Function Caller	7-15
Generate Reentrant Code from Top Models	7-18
Generate Reentrant, Multi-Instance Code	7-18
Share Data Between Instances	7-21
Generate Reentrant Code from Simulink Function Blocks	7-23
Identify Requirements	7-23
Create Model	7-23
Configure Model and Model Elements	7-25
Generate and Inspect C Code	7-27
Generate and Inspect C++ Code	7-29
Limitations	7-31
Generate Reentrant Code from Subsystems	7-33
Function Reuse in Generated Code	7-34
Limitations	7-38
Generate Reusable Code from Library Subsystems Shared Across Models	7-41
What Is a Reusable Library Subsystem?	7-41
Reusable Library Subsystem Code Placement and Naming	7-41
Configure Reusable Library Subsystem	7-42
Configure Models That Include Reusable Library Subsystems	7-42
Generate Reusable Code for Subsystems Shared Across Models	7-43
Generate Reusable Code from Stateflow Atomic Subcharts	7-50
Generate Reusable Code for Linked Atomic Subcharts	7-50
Generate Reusable Code for Unlinked Atomic Subcharts	7-50
Generate Reusable Code for Unit Testing	7-51
Generate Shared Utility Code	7-56
When to Generate Shared Utility Code	7-56

Configure Naming of Generated Functions	7-56
Control Placement of Shared Utility Code	7-57
Control Placement of rtwtypes.h for Shared Utility Code	7-58
Avoid Duplicate Header Files for Exported Data	7-58
Reduce Shared Utility Code Generation with Incremental Builds ..	7-58
Manage the Shared Utility Code Checksum	7-59
Generate Shared Utility Code for Fixed-Point Functions	7-64
Generate Shared Utility Code for Custom Data Types	7-66
Shared Constant Parameters for Code Reuse	7-68
Suppress Shared Constants in the Generated Code	7-69
Determine Why Subsystem Code Is Not Reused	7-71
Review Subsystems Section of HTML Code Generation Report	7-71
Compare Subsystem Checksum Data	7-71

Library-Based Code Generation

8

Library-Based Code Generation for Reusable Library Subsystems	
.....	8-2
Example Model and Library	8-2
Configure Reusable Library Subsystems	8-3
Specify Unique Function Interface Names	8-3
Configure and Manage Function Interfaces	8-4
Build the Library	8-7
Generate Code from Model Containing a Reusable Library Subsystem	
Instance	8-8
Verify Code Generated from Reusable Library Subsystems	8-9
Limitations	8-10

Configure Model Parameters for Simulink Coder

9

Configure Run-Time Environment Options	9-2
Configure Production and Test Hardware	9-2
Production Hardware Considerations	9-7
Test Hardware Considerations	9-8
Example Production Hardware Setting That Affects Normal Mode	
Simulation	9-8
Register New Hardware Devices	9-11
Specify Hardware Implementation for New Device	9-11
Specify Hardware Implementation That Persists Over MATLAB	
Sessions	9-12
Create Hardware Implementation by Modifying Existing	
Implementation	9-12

Create Hardware Implementation by Reusing Existing Implementation	9-12
Validate Hardware Device Data	9-13
Export Hardware Device Data	9-14
Create Alternative Identifier for Target Object	9-14
Upgrade Data Definitions for Hardware Devices	9-15

Model Protection in Simulink Coder

10

Protect Models to Conceal Contents	10-2
Prepare the Parent Model	10-2
Protect the Referenced Model	10-3
Protected Model Requirements and Limitations	10-6
Code Generation Requirements and Limitations	10-7
Nested Protected Model Requirements and Limitations	10-7
Create Protected Models with Multiple Targets	10-9
Test Protected Models	10-10
Package and Share Protected Models	10-12
Harness Model	10-12
MAT-File with Base Workspace Definitions	10-12
Simulink Data Dictionary	10-13
Protected Model File Contents	10-13
Specify Custom Obfuscators for Protected Models	10-16
Define Callbacks for Protected Models	10-17
Creating Callbacks	10-17
Defining Callback Code	10-17
Create a Protected Model with Callbacks	10-18
Sign a Protected Model	10-19
Sign Your Protected Model	10-19
Best Practices for Creating Protected Models	10-21
Coordinate Settings with the User of Your Protected Model	10-21
Minimize the Model External Interface	10-21
Contents to Include in Your Protected Model	10-23

Stateflow Blocks in Simulink Coder

11

Code Generation of Stateflow Blocks	11-2
Comparison of Code Generation Methods	11-2

Generate Code from Atomic Subcharts	11-5
Generate Reusable Code for Unlinked Atomic Subcharts	11-5
Generate Reusable Code for Linked Atomic Subcharts	11-5
Inline State Functions in Generated Code	11-7
Inlined Generated Code for State Functions	11-7
How to Set the State Function Inline Option	11-8
Best Practices for Controlling State Function Inlining	11-8
Air-Fuel Ratio Control System with Stateflow Charts	11-10

12 Block Authoring and Code Generation for Simulink Coder

S-Functions and Code Generation	12-2
Types of S-Functions	12-2
Files Required for Implementing Noninlined and Inlined S-Functions	12-4
Guidelines for Writing S-Functions that Support Code Generation	12-4
Import Calls to External Code into Generated Code with Legacy Code Tool	12-6
Legacy Code Tool and Code Generation	12-6
Generate Inlined S-Function Files for Code Generation	12-6
Apply Code Style Settings to Legacy Functions	12-7
Address Dependencies on Files in Different Locations	12-8
Deploy S-Functions for Simulation and Code Generation	12-8
Integrate External C++ Objects	12-8
Legacy Code Tool Examples	12-11
Integrate External C Functions That Pass Input Arguments By Value Versus Address	12-11
Integrate External C Functions That Pass the Output Argument As a Return Argument	12-14
Integrate External C++ Object Methods	12-16
Integrate External C Functions That Pass Input and Output Arguments as Parameters with a Fixed-Point Data Type	12-18
Integrate External C Functions That Pass Input and Output Arguments as Signals with a Fixed-Point Data Type	12-21
Integrate External C Functions with Instance-Specific Persistent Memory	12-23
Integrate External C Functions That Use Structure Arguments ...	12-25
Integrate External C Functions That Pass Input and Output Arguments as Signals with Complex Data	12-28
Integrate External C Functions That Pass Arguments That Have Inherited Dimensions	12-30
Integrate External C Functions That Pass Arguments as Multi- Dimensional Signals	12-33
Integrate External C Functions That Implement Start and Terminate Actions	12-35

Integrate External C Functions That Implement N-Dimensional Table Lookups	12-37
Integrate External C Functions That Pass Arguments as Multi-Dimensional Signals	12-40
Integrate External C Functions with a Block Sample Time Specified, Inherited, and Parameterized	12-42
Integrate External C Functions That Pass Input and Output Arguments as Parameters with a Fixed-Point Data Type	12-47
Integrate External C Functions That Implement N-Dimensional Table Lookups	12-50
Integrate External C++ Object Methods	12-53
External Code Integration Examples	12-56
Integrate External C++ Code into a Model Using S-Functions ...	12-56
Insert External C and C++ Code Into Stateflow Charts for Code Generation	12-57
Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters	12-58
Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters	12-60
Insert External C++ Code Into Stateflow Charts for Code Generation	12-62
Generate S-Function from Subsystem	12-64
Macro Parameters	12-66
S-Functions That Support Expression Folding	12-68
Categories of Output Expressions	12-68
Acceptance or Denial of Requests for Input Expressions	12-71
Expression Folding in a TLC Block Implementation	12-73
S-Functions That Specify Port Scope and Reusability	12-77
S-Functions That Specify Sample Time Inheritance Rules	12-81
S-Functions for Code Reuse	12-85
S-Functions for Multirate Multitasking Environments	12-90
About S-Functions for Multirate Multitasking Environments	12-90
Rate Grouping Support in S-Functions	12-90
Create Multitasking, Multirate, Port-Based Sample Time S-Functions	12-90
Write Noninlined S-Function	12-95
Guidelines for Writing Noninlined S-Functions	12-95
Noninlined S-Function Parameter Type Limitations	12-96
Write Wrapper S-Function and TLC Files	12-97
MEX S-Function Wrapper	12-97
TLC S-Function Wrapper	12-100
Code Overhead for Noninlined S-Functions	12-100
Inline a Wrapper S-Function	12-101

The Inlined Code	12-103
Write Fully Inlined S-Functions	12-104
Multiport S-Function	12-104
Guidelines for Writing Inlined S-Functions	12-104
Write Fully Inlined S-Functions with mdlRTW Routine	12-106
S-Function RTWdata	12-106
Direct-Index Lookup Table Algorithm	12-107
Direct-Index Lookup Table Example	12-108
Error Handling	12-109
User Data Caching	12-109
mdlRTW Usage	12-109

What is the Target Language Compiler?

13

Target Language Compiler Basics	13-2
Target Language Compiler Overview	13-2
Overview of the TLC Process	13-2
Overview of the Code Generation Process	13-4
Why Use the Target Language Compiler?	13-6
Customizing Output	13-6
Inlining S-Functions	13-6
Defining Advanced Storage Classes	13-6
The Advantages of Inlining S-Functions	13-8
When To Avoid Inlining	13-8
Inlining Process	13-8
Search Algorithm for Locating TLC Files	13-9
Availability for Inlining and Noninlining	13-9

Getting Started

TLC Error Handling

A

TLC Error Handling	A-2
Error Reporting	A-2
Generating Errors from TLC Files	A-2
Using TLC Error Messages to Troubleshoot	A-4
%closefile or %selectfile or %flushfile argument must be a valid open file	A-4
%define no longer supported, use %function instead	A-4
%error directive: text	A-4

%exit directive: text	A-4
%filescope has already been used in this file	A-4
%trace directive: text	A-5
%warning directive: text	A-5
A %implements directive must appear within a block template file and must match the %language and type specified	A-5
A %switch statement can only have one %default	A-5
A language choice must be made using the %language directive prior to using GENERATE or GENERATE_TYPE	A-5
A non-homogeneous vector was passed to GENERATE_FORMATTED_VALUE	A-5
Ambiguous reference to identifier — must use array index to refer to one of multiple scopes	A-6
An %if statement can only have one %else	A-6
Argument to identifier must be a string	A-6
Arguments to directive must be records	A-7
Arguments to TLC from the MATLAB command line must be strings	A-7
Assertion failed	A-7
Assignment to scope identifier is only allowed when using the + operator to add members	A-7
Attempt to define a function identifier on top of an existing variable or function	A-7
Attempt to divide by zero	A-7
Bad cast - unable to cast this expression to type	A-7
Bad directory (dirname) in O: filename	A-8
builtin was expecting expression of type type, got one of type type	A-8
Cannot %undef any builtin functions or variables	A-8
Cannot convert string your_string to a number	A-8
Changing value of identifier from the RTW file	A-8
Error opening filename	A-8
Error writing to file error	A-8
Errors occurred — aborting	A-8
Expansion directives %<> cannot be nested	A-8
Expansion directives %<> cannot span multiple lines; use \ at end of line	A-9
Extra arguments to the function-name built-in function were ignored (Warning)	A-9
File name too long (directory =dirname, name =filename)	A-9
format is not a legal format value	A-9
Function argument mismatch; function function_name expects number arguments	A-9
Function reached the end and did not return a value	A-10
Function values are not allowed	A-10
Identifier identifier multiply defined. Second and succeeding definitions ignored.	A-10
Identifier identifier used on a %foreach statement was already in scope (Warning)	A-10
Illegal use of eval (i.e., %<...>)	A-10
Indices may not be negative	A-10
Indices must be constant integral numbers	A-10
Invalid handle	A-10
Invalid identifier range, the leading strings string1 and string2 must match	A-10

Invalid identifier range, the lower bound (bound) must be less than the upper bound (bound)	A-11
Invalid type for unary operator	A-11
Invalid type type	A-11
It is illegal to return a function from a function	A-11
Named value identifier already exists within this scope-identifier; use %assign to change the value	A-11
No %case statement(s) seen yet, statement ignored	A-11
Only double and character arrays can be converted from MATLAB to TLC. This can occur if the MATLAB function does not return a value (see %matlab)	A-11
Only one output is allowed from the TLC	A-12
Only strings of length 1 can be assigned using the [] notation	A-12
Only strings or cells of strings may be used as the argument to Query and ExecString	A-12
Only vectors of the same length as the existing vector value can be assigned using the [] notation	A-12
Output file identifier opened with %openfile was not closed	A-12
Ranges, identifier ranges, and repeat values cannot be repeated	A-12
String cannot modify the setting for the command line switch '-switch'	A-12
string is not a recognized user defined property of this handle	A-12
Syntax error	A-13
The %break directive can only appear within a %foreach, %for, %roll, or %switch statement	A-13
The %case and %default directives can only be used within the %switch statement	A-13
The %continue directive can only appear within a %foreach, %for, or %roll statement	A-13
The %foreach statement expects a constant numeric argument	A-13
The %if statement expects a constant numeric argument	A-13
The %implements directive expects a string or string vector as the list of languages	A-13
The %implements directive specifies type as the type where type was expected	A-14
The %implements language does not match the language currently being generated (language)	A-14
The %return statement can only appear within the body of a function	A-14
The == and != operators can only be used to compare values of the same type	A-14
The argument for %openfile must be a valid string	A-14
The argument for %with must be a valid scope	A-14
The argument for an [] operation must be a repeated scope symbol, a vector, or a matrix	A-14
The argument to %addincludepath must be a valid string	A-15
The argument to %include must be a valid string	A-15
The begin directive must be in the same file as the corresponding end directive.	A-15
The begin directive on this line has no matching end directive	A-15
The construct %matlab function_name(...) construct is illegal in standalone tlc	A-15
The FEVAL() function can accept only 2-dimensional arrays from MATLAB, not number dimensions	A-16
The FEVAL() function can accept vectors of numbers or strings only when calling MATLAB	A-16

The FEVAL() function requires the name of a function to call	A-16
The final argument to %roll must be a valid block scope	A-16
The first argument of a ? : operator must be a Boolean expression	A-16
The first argument to GENERATE or GENERATE_TYPE must be a valid scope	A-16
The function name requires at least number arguments	A-16
The GENERATE function requires at least 2 arguments	A-16
The GENERATE_TYPE function requires at least 3 arguments	A-16
The ISINF(), ISNAN(), ISFINITE(), REAL(), and IMAG() functions expect a real or complex valued argument	A-17
The language being implemented cannot be changed within a block template file	A-17
The language being implemented has changed from old-language to new-language (Warning)	A-17
The left-hand side of a . operator must be a valid scope identifier	A-17
The left-hand side of an assignment must be a simple expression comprised of ., [], and identifiers	A-17
The number of columns specified (specified-columns) did not match the actual number of columns in the rows (actual-columns)	A-17
The number of rows specified (specified-rows) did not match the actual number of rows seen in the matrix (actual-rows)	A-17
The operator_name operator only works on Boolean arguments	A-18
The operator_name operator only works on integral arguments	A-18
The operator_name operator only works on numeric arguments	A-18
The return value from the RollHeader function must be a string	A-18
The roll argument to %roll must be a nonempty vector of numbers or ranges	A-18
The second value in a Range must be greater than the first value	A-18
The specified index (index) was out of the range 0 - number-of-elements - 1	A-18
The STRINGOF built-in function expects a vector of numbers as its argument	A-19
The SYSNAME built-in function expects an input string of the form xxx/yyy	A-19
The threshold on a %roll statement must be a single number	A-19
The use of feature is being deprecated and will not be supported in future versions of TLC. See the TLC manual for alternatives.	A-19
The WILL_ROLL built in function expects a range vector and an integer threshold	A-19
There are no more free contexts. Use tlc('close', HANDLE) to free up a context	A-19
There was no type associated with the given block for GENERATE	A-19
This assignment would overwrite an identifier-value pair from the RTW file. To avoid this error either qualify the left-hand side, or choose another identifier.	A-20
TLC has leaked number symbols. You may have created a cyclic record. If this not the case then please report this leak to The MathWorks.	A-20
Unable to find identifier within the scope-identifier scope	A-20
Unable to open %include file filename	A-20
Unable to open block template file filename from GENERATE or GENERATE_TYPE	A-20
Unable to open output file filename	A-21
Undefined identifier identifier_name	A-21
Unknown type type in CAST expression	A-21

Unrecognized command line switch passed to string: switch	A-21
Unrecognized directive directive-name seen	A-21
Unrecognized type output-type for function	A-22
Unterminated multiline comment.	A-22
Unterminated string	A-22
Usage: tlc [options] file	A-22
Use of feature incurs a performance hit, please see TLC manual for possible workarounds.	A-22
Value of type type cannot be compared	A-22
Values of specified_type type cannot be expanded	A-22
Values of type Special, Macro Expansion, Function, File, Full Identifier, and Index cannot be converted to MATLAB variables	A-23
When appending to a buffer stream, the variable must be a string	A-23
TLC Function Library Error Messages	A-23

Step 3: Configure Model for Generating Preprocessor Conditionals	26-27
Step 4: Review Generated Code	26-28
Limitations	26-31
Generate Preprocessor Conditionals for Variant Systems	26-32
Define Variant Controls	26-32
Configure Model for Generating Preprocessor Conditional Directives	26-33
Special Considerations for Generating Preprocessor Conditionals	26-33
Generate Variant Control Macros in Same Header File	26-34
Represent Variant Source and Sink Blocks in Generated Code ...	26-37
Represent Variant Source and Variant Sink Blocks in Simulink ...	26-37
Specify Conditions That Control Variant Choice Selection	26-40
Review the Generated Code	26-41
Generate Code with Zero Active Variant Controls	26-43

Configure Dimension Variants for S-Function Blocks	26-45
Generate Code from an S-Function Block with Dimension Variants	26-46
S-Function That Supports Forward and Backward Propagation of Symbolic Dimensions	26-51
Represent Variant Condition Values of Enumerated Type in Generated Code	26-53
Use Enumerated Type Derived From Built-In Integer	26-53
Use In-Memory Enumerated Type Derived From Simulink.IntEnumType	26-56
Options to Represent Variant Parameters in Generated Code	26-57
Limitations	26-57
Overview of Variant Parameters	26-57
Choice of Values in Generated Code	26-57
Types of Variables in Generated Code	26-58
Storage Classes for Different Variant Activation Times	26-58
Symbolic Dimensions in Generated Code	26-59
Generate C Code for Variant Parameters	26-60
Generate Code for Variant Subsystem with Child Subsystems of Different Output Signal Dimensions	26-65
Example Model	26-65
Simulate Model	26-65
Generate Code	26-66
Use Variant Subsystem To Generate Code That Uses C Preprocessor Conditionals	26-68
Use Variant Models to Generate Code That Uses C Preprocessor Conditionals	26-73

Timers in Simulink Coder

27

Absolute and Elapsed Time Computation	27-2
About Timers	27-2
Timers for Periodic and Asynchronous Tasks	27-2
Allocation of Timers	27-2
Integer Timers in Generated Code	27-3
Elapsed Time Counters in Triggered Subsystems	27-3
Access Timers Programmatically	27-4
About Timer APIs	27-4
C API for S-Functions	27-4
TLC API for Code Generation	27-6
Generate Code for an Elapsed Time Counter	27-7
Absolute Time Limitations	27-10

Time-Based Scheduling and Code Generation	28-2
Sample Time Considerations	28-2
Tasking Modes	28-2
Model Execution and Rate Transitions	28-3
Execution During Simulink Model Simulation	28-4
Model Execution in Real Time	28-4
Single-Tasking Versus Multitasking Operation	28-4
Modeling for Single-Tasking Execution	28-6
Single-Tasking Mode	28-6
Build a Program for Single-Tasking Execution	28-6
Single-Tasking Execution	28-6
Modeling for Multitasking Execution	28-9
Multitasking and Pseudomultitasking Modes	28-9
Build a Program for Multitasking Execution	28-11
Execute Multitasking Models	28-11
Multitasking Execution	28-12
Handle Rate Transitions	28-16
Rate Transitions	28-16
Data Transfer Problems	28-17
Data Transfer Assumptions	28-17
Rate Transition Block Options	28-18
Automatic Rate Transition	28-19
Visualize Inserted Rate Transition Blocks	28-20
Periodic Sample Rate Transitions	28-22
Protect Data Integrity with volatile Keyword	28-26
Separate Rate Transition Block Code and Data from Algorithm Code and Data	28-26
Configure Time-Based Scheduling	28-33
Configure Start and Stop Times	28-33
Configure the Solver Type	28-33
Configure the Tasking Mode	28-33
Time-Based Scheduling Example Models	28-35
Optimize Memory Usage for Time Counters	28-35
Single-Rate Modeling (Bare Board, No OS)	28-40
Multirate Modeling in Single-Tasking Mode (Bare Board, no OS) .	28-41
Multirate Modeling in Multitasking Mode (Bare Board, no OS) . . .	28-41
Multirate Modeling in Multitasking Mode (VxWorks® OS)	28-43
Trade Determinism and Data Integrity to Improve System Performance	28-43

Asynchronous Events	29-2
Asynchronous Support	29-2
Block Library for Calls to an Example Real-Time Operating System	29-2
Examples and Additional Information	29-3
Generate Interrupt Service Routines	29-4
Connecting the Async Interrupt Block	29-4
Requirements and Restrictions	29-4
Performance Considerations	29-5
Dual-Model Approach for Developing Real-Time Systems that Include ISRs	29-5
Dual-Model Approach: Simulation	29-6
Dual-Model Approach: Code Generation	29-6
Spawn and Synchronize Execution of RTOS Task	29-11
Pass Asynchronous Events in RTOS as Input to a Referenced Model	29-29
Rate Transitions and Asynchronous Blocks	29-35
About Rate Transitions and Asynchronous Blocks	29-35
Handle Rate Transitions for Asynchronous Tasks	29-36
Handle Multiple Asynchronous Interrupts	29-36
Protect Data Integrity with volatile Keyword	29-38
Timers in Asynchronous Tasks	29-39
Create a Customized Asynchronous Library	29-41
About Implementing Asynchronous Blocks	29-41
Async Interrupt Block Implementation	29-41
Task Sync Block Implementation	29-44
asynclib.tlc Support Library	29-46
Import Asynchronous Event Data for Simulation	29-48
Capabilities	29-48
Input Data Format	29-48
Example	29-48
Asynchronous Support Limitations	29-51
Asynchronous Task Priority	29-51
Convert an Asynchronous Subsystem into a Model Reference	29-51

Use Discrete and Continuous Time	30-2
Support for Discrete and Continuous Time Blocks	30-2

Support for Continuous Solvers	30-2
Support for Stop Time	30-2

Optimize Multirate Multitasking Execution for RTOS Run-Time

Environments	30-4
Use rtmStepTask	30-4
Schedule Code for Real-time Model without an RTOS	30-4
Schedule Code for Multirate Multitasking on an RTOS	30-5
Suppress Redundant Scheduling Calls	30-5

Representing a Software Architecture by Creating Code Generation Definitions

31

Define Storage Classes, Memory Sections, and Function Templates for Software Architecture

.....	31-2
Create Code Definitions for Use in the Code Mappings Editor	31-2
Create Code Definitions for External Data Objects	31-2
Use Package Code Definitions in Embedded Coder Dictionaries ...	31-3
Constrain Use of Storage Class Code Mappings	31-3
Deploy Code Generation Definitions to Users	31-3
Interact with Code Generation Definitions Programmatically	31-3

Create Code Definitions Programmatically

Deploy Code Generation Definitions

.....	31-10
Share Code Generation Definitions Between Multiple Models and Users	31-10
Dictionary Usage for Models Created with Different Versions of Simulink	31-10
Configure Default Code Mapping in a Shared Dictionary	31-10
Share Embedded Coder Dictionary Definition Between Models ...	31-12
Migrate Definitions from Model File to Shared Data Dictionary ..	31-14
Use Data Dictionary to Store Code Definitions but Not Design Data	31-16

Generate Code to Conform to Software Architecture by Sharing and Copying Default Settings Between Models

.....	31-18
Share Common Code Generation Settings among Multiple Models	31-18
Copy Code Generation Settings to New Models	31-19

Manage an Embedded Coder Dictionary

.....	31-21
Share Available Code Definitions with New Models	31-21
Migrate Package Definitions to Embedded Coder Dictionary to Use in Code Mappings	31-21
Change Code Generation Definitions	31-22

Migration of Memory Section and Shared Utility Settings from Configuration Parameters to Code Mappings

.....	31-25
Effects of Migration	31-25
Considerations Before Migrating	31-25

Considerations After Migrating	31-26
Flexible Storage Class for Different Model Hierarchy Contexts ..	31-28
Separation of Code Definitions from Model-Specific Data and Function Configurations	31-31
Manage Code Specifications in One Location	31-31
Apply Definitions to Model Elements with Flexibility	31-31
Generate Standardized Code from Multiple Models	31-32
Generate Code for Different Platforms	31-33

Data, Function, and File Definition

32 | **Configuring Data and Functions in the Generated Code**

C Code Generation Configuration for Model Interface Elements	32-2
Migration	32-2
Code Definitions	32-3
Data Default Configurations	32-3
Function Default Configurations	32-6
Configurations for Individual Data Elements and Functions	32-8
Configure Data	32-9
Configure Functions	32-10
Code Definition and Mapping Limitations and Considerations ...	32-11
Limitations	32-11
Default Code Mapping Constraints	32-11
Unresolved Code Definitions	32-12
Model Editing Operations and Individual Data Element Code Mappings	32-12
Storage Classes and Reentrant, Multi-Instance Models and Components	32-13
Copy Code Mappings When Converting Subsystems to Referenced Models	32-14
Configure Default C Code Generation for Categories of Data Elements and Functions	32-15
Set Up Example Environment	32-15
Configure Default Code Generation for Data	32-16
Configure Default Code Generation for Functions	32-20
Configure Model Elements for Code Generation with Definitions Stored in Shared Data Dictionary	32-22
Configure Default Data and Function Code Generation Programmatically	32-24
Configure Root-Level Inport Blocks for C Code Generation	32-30
Choose Customization Options for Inport Interface	32-30

Configure Default Code Generation Settings for Root-Level Inports	32-31
Configure Code Generation Settings for Individual Root-Level Inports	32-33
Configure Code Generation Settings for Root-Level Inports Programmatically	32-35
Choose Storage Class and Storage Class Properties for Root-Level Inports	32-38
Configure Root-Level Output Blocks for C Code Generation	32-41
Choose Customization Options for Outport Interface	32-41
Configure Default Code Generation Settings for Root-Level Outports	32-42
Configure Code Generation Settings for Individual Root-Level Outports	32-44
Configure Code Generation Settings for Root-Level Outports Programmatically	32-45
Choose Storage Class and Storage Class Properties for Root-Level Outports	32-47
Configure Signal Data for C Code Generation	32-50
Choose Code Configuration Options for Signals	32-50
Add Signals to Model Code Mappings	32-51
Configure Default Code Generation Settings for Signals	32-53
Configure Code Generation Settings for Individual Signals	32-54
Remove Signals from Model Code Mappings	32-56
Configure Code Generation Settings for Signals Programmatically	32-56
Choose Storage Class and Storage Class Properties for Signals . .	32-58
Configure Parameters for C Code Generation	32-61
Choose Customization Options for Parameters	32-62
Configure Default Code Generation Settings for Parameters	32-63
Configure Code Generation for Individual Parameters	32-65
Organize Parameter Data into a Structure by Using Struct Storage Class	32-67
Configure Code Generation Settings for Parameters Programmatically	32-69
Choose Storage Class and Storage Class Properties for Model Parameters	32-71
Configure Block States for C Code Generation	32-74
Choose Code Configuration Options for States	32-74
Configure Default Code Generation Settings for States	32-75
Configure Code Generation Settings for Individual States	32-76
Configure Code Generation Settings for States Programmatically	32-78
Choose Storage Class and Storage Class Properties for States . . .	32-79
Configure Data Stores for C Code Generation	32-82
Choose Customization Options for Data Stores	32-82
Configure Default Code Generation Settings for Data Stores	32-83
Configure Code Generation for Individual Data Stores	32-85
Configure Code Generation Settings for Data Stores Programmatically	32-87

Choose Storage Class and Storage Class Properties for Data Stores	32-89
Manage Multiple Code Mappings for a Model	32-92
Configure Alternative Code Mappings by Using Configuration Sets	32-92
Activate Code Mappings in the Simulink Editor	32-93
Create and Activate Code Mappings Programmatically	32-94
Code Mappings and Embedded Coder Dictionary	32-94
Configure Model Data Interface for C Code Generation	32-96
Migration of Model Data Configurations to Code Mappings	32-103
Effects of Migration	32-103
Considerations Before Migrating	32-104
Copy Blocks and Signal Lines Between Models	32-107
Switch Between GRT- and ERT-Based System Target Files	32-108
Workflow Changes	32-109
Dimension Preservation of Multidimensional Arrays	32-110
Dimension Preservation in Generated Code	32-110
Difference in Dimension Preservation Between MATLAB and C ..	32-110
Configure Generated C Function Interface for Model Entry-Point Functions	32-113
What Is an Entry-Point Function?	32-113
Types of Generated Entry-Point Functions	32-113
Configure Whether Entry-Point Functions Are Reusable	32-115
Choose an Approach for Configuring Generated C Function Interfaces	32-117
Configure Default Code Generation Settings for a Function Category	32-117
Configure Names for Individual C Entry-Point Functions	32-118
Configure Name and Arguments for Individual Step Functions ..	32-119
Configure Code Generation Settings for C Entry-Point Functions Programmatically	32-127
How to Interface with Generated Entry-Point Functions	32-128
C Function Interface Customization Limitations	32-128
Configure Multi-Instance Code Generation	32-130
Configure a Top Model for Multi-Instance Code Generation	32-130
Configure a Referenced Model for Multi-Instance Code Generation	32-130
Configure Data Interfaces	32-131
Configure Default Code Generation for Data	32-131
Override Default Data Interface for Individual Data Elements ...	32-131
Configure Entry-Point Function Interfaces	32-132
Define Function Customization Templates	32-132
Configure Default Code Generation for Entry-Point Functions ...	32-132
Override Default Code Generation for Entry-Point Functions ...	32-132
Configure Internal Data	32-134
Configure Default Representation of Internal Data	32-134

Override Default Representation for Individual Internal Data Elements	32-134
Configure Subsystem Function Packaging and Interface	32-135

Data Representation in Simulink Coder

33

Preserve Variables in Generated Code	33-2
Access Signal, State, and Parameter Data During Execution	33-2
Configure Data Accessibility	33-15
Limitations	33-16
Access Signal, State, and Parameter Data During Execution	33-17
Data Structures in the Generated Code	33-31
Standard Data Structures	33-31
Real-Time Model Data Structure	33-32
How Generated Code Exchanges Data with an Environment	33-35
Data Interfaces in the Generated Code	33-35
Configure Data Interface	33-42
Control Data and Function Interface in Generated Code	33-44
Control Type Names, Field Names, and Variable Names of Standard I/O Structures (Embedded Coder)	33-44
Control Names of Generated Entry-Point Functions (Embedded Coder)	33-44
Control Data Interface for Nonreentrant Code	33-44
Control Data Interface for Reentrant Code	33-46
Prevent Unintended Changes to the Interface	33-46
Reduce Number of Arguments by Using Structures	33-47
Control Data Types of Arguments	33-48
Promote Data Item to the Interface	33-48
How Generated Code Stores Internal Signal, State, and Parameter Data	33-49
Internal Data in the Generated Code	33-49
Local Variables in the Generated Code	33-64
Appearance of Test Points in the Generated Code	33-65
Appearance of Workspace Variables in the Generated Code	33-65
Promote Internal Data to the Interface	33-65
Control Default Representation of Internal Data (Embedded Coder)	33-67
Choose Data Configuration Approach	33-70
Data Element Categories	33-70
Where to Store Data Elements Used by Your Model	33-71
When to Configure a Data Element for Code Generation	33-71
Configure a Data Element for Code Generation	33-72

Choose Storage Class for Controlling Data Representation in Generated Code	33-75
Storage Class Properties	33-75
Default Storage Class	33-75
Built-in and Predefined Storage Classes	33-75
Auto	33-77
Default	33-77
Model Default	33-77
Dictionary Default	33-77
ExportedGlobal	33-78
ImportedExtern, ImportedExternPointer	33-78
Bitfield	33-79
CompilerFlag	33-79
Const, Volatile, and ConstVolatile	33-79
Define, ImportedDefine	33-80
ExportToFile	33-80
FileScope	33-81
GetSet	33-81
ImportFromFile	33-82
Localizable	33-82
Reusable	33-83
Struct	33-83
MultiInstance	33-83
ParamStruct, SignalStruct	33-84
Storage Class Limitations	33-84
 Use Enumerated Data in Generated Code	 33-85
Enumerated Data Types	33-85
Specify Integer Data Type for Enumeration	33-85
Customize Enumerated Data Type	33-86
Control Enumerated Type Implementation in Generated Code ...	33-90
Type Casting for Enumerations	33-91
Enumerated Type Limitations	33-91
 Data Stores in Generated Code	 33-93
About Data Stores	33-93
Generate Code for Data Store Memory Blocks	33-93
Storage Classes for Data Store Memory Blocks	33-94
Data Store Buffering in Generated Code	33-95
Data Stores Shared by Instances of a Reusable Model	33-98
Structures in Generated Code Using Data Stores	33-98
 Specify Single-Precision Data Type for Embedded Application ..	 33-102
Use single Data Type as Default for Underspecified Types	33-102
 Tune Phase Parameter of Sine Wave Block During Code Execution	 33-105
 Switch Between Output Waveforms During Code Execution for Waveform Generator Block	 33-107
 Create Tunable Calibration Parameter in the Generated Code ..	 33-110
Represent Block Parameter as Tunable Global Variable	33-110
Apply Storage Class When Block Parameter Refers to Numeric MATLAB Variable	33-113

Create Storage Class That Represents Calibration Parameters (Embedded Coder)	33-113
Initialize Parameter Value From System Constant or Other Macro (Embedded Coder)	33-116
Code Generation Impact of Storage Location for Parameter Objects	33-117
Configure Accessibility of Signal Data	33-118
Programmatic Interfaces for Tuning Parameters	33-118
Set Tunable Parameter Minimum and Maximum Values	33-118
Considerations for Other Modeling Goals	33-119
Limitations for Block Parameter Tunability in Generated Code	33-120
Tunable Expression Limitations	33-120
Linear Block Parameter Tunability	33-121
Parameter Structures	33-122
Code Generation of Parameter Objects With Expression Values	33-123
Considerations and Limitations	33-123
Expression Preservation	33-123
Configure Packaging of Parameter Arguments in Generated Code	
.....	33-125
Code Generation Behavior	33-125
Limitations	33-128
Parameter Data Types in the Generated Code	33-129
Significance of Parameter Data Types	33-129
Typecasts Due to Parameter Data Type Mismatches	33-129
Considerations for Other Modeling Patterns	33-130
Generate Efficient Code by Specifying Data Types for Block Parameters	33-133
Eliminate Unnecessary Typecasts and Shifts by Matching Data Types	33-133
Reduce Memory Consumption by Storing Parameter Value in Small Data Type	33-135
Reuse Parameter Data in Different Data Type Contexts	33-141
Organize Data into Structures in Generated Code	33-145
Techniques to Create Structures	33-148
Default Application of Structured Storage Class	33-149
Direct Application of Structured Storage Class	33-150
Nonvirtual Buses and Parameter Structures	33-150
Combine Techniques to Work Around Limitations	33-157
Arrays of Structures	33-158
Structure Padding	33-158
Limitations	33-158
Switch Between Sets of Parameter Values During Simulation and Code Execution	33-159
Design Data Interface by Configuring Inport and Outport Blocks	33-167

Generate Efficient Code for Bus Signals	33-171
Code Efficiency for Bus Signals	33-171
Set Bus Diagnostics	33-171
Optimize Virtual and Nonvirtual Buses	33-172
Control Signal and State Initialization in the Generated Code ..	33-174
Signal and State Initialization in the Generated Code	33-174
Generate Tunable Initial Conditions	33-175
Generate Tunable Initial Condition Structure for Bus Signal	33-179
Initialization of Signal, State, and Parameter Data in the Generated Code	33-185
Static Initialization and Dynamic Initialization	33-185
Real-World Ground Initialization Requiring Nonzero Bit Pattern .	33-185
Initialization of Signal and State Data	33-186
Initialization of Parameter Data	33-187
Data Initialization in the Generated Code	33-187
Modeling Goals	33-192
Optimize Speed and Size of Signal Processing Algorithm by Using Fixed-Point Data	33-194
Optimize Generated Code Using Fixed-Point Data with Simulink, Stateflow, and MATLAB	33-195
Declare Workspace Variables as Tunable Parameters Using the Model Parameter Configuration Dialog Box	33-196
Declare Existing Workspace Variables as Tunable Parameters ..	33-196
Declare New Tunable Parameters	33-196
Set Tunable Parameter Code Generation Options	33-197
Programmatically Declare Workspace Variables as Tunable Parameters	33-197
Share Data Between Code Generated from Simulink, Stateflow, and MATLAB	33-199
Air-Fuel Ratio Control System with Fixed-Point Data	33-201

Data Definition and Declaration Management in Embedded Coder

34

Control Placement of Global Data Definitions and Declarations in Generated Files	34-2
Organize Data to Support Component-Based, Team-Oriented Model Development	34-5
Specify Default Placement	34-7
Override Default Placement for Individual Data Items	34-8
Prevent Name Clashes by Configuring Data Item as static	34-8
Code Generation Impact of Storage Location for Parameter Objects	34-8
Specify Default #include Syntax for Data Header Files	34-8

Data Types in Embedded Coder

35

Control Data Type Names in Generated Code 35-2

- Control Names of Primitive Data Types 35-2
- Control Names of Structure Types 35-9
- Generate Code That Reuses Data Types From External Code 35-9
- Create Data Type Alias in the Generated Code 35-9
- Create a Named Fixed-Point Data Type in the Generated Code ... 35-14
- Rename Data Type Object 35-17
- Display Signal Data Types on Block Diagram 35-17
- Limitations 35-17

Control File Placement of Custom Data Types 35-19

- Data Scope and Header File 35-19
- Macro Guards 35-20

Replace and Rename Data Types to Conform to Coding Standards

- 35-22
- Inspect External C Code 35-22
- Explore Example Model and Default Generated Code 35-22
- Reuse External Data Type Definitions 35-23
- Create Meaningful Data Type Aliases for Individual Data Items ... 35-24
- Create Single Point of Definition for Primitive Types 35-25
- Permanently Store Data Type Objects 35-26
- Create and Maintain Objects Corresponding to Multiple C typedef Statements 35-26

Exchange Structured and Enumerated Data Between Generated and External Code 35-27

- Inspect External Code 35-27
- Create Simulink Model 35-28
- Configure Generated Code to Write Output Data to Existing Structure Variable 35-29
- Configure Generated Code to Define Parameter Data 35-31
- Generate, Compile, and Inspect Code 35-32
- Replace Data Type Names Throughout Model 35-32

Specify Boolean and Data Type Limit Identifiers 35-34

- Data Type Limit Identifiers 35-34
- Boolean Identifiers 35-34
- Boolean and Data Type Limit Identifier Header Files 35-35

36

MPT Data Object Properties 36-2
 Specify Persistence Level for Signals and Parameters 36-10

Storage Classes in Embedded Coder

37

Reuse Parameter Data from External Code in the Generated Code 37-2

Import Parameter Data with Conditionally Compiled Dimension Length 37-6

Access Structured Data Through a Pointer That External Code Defines 37-10

Create Storage Classes by Using the Custom Storage Class Designer 37-14

- Create and Apply a Storage Class 37-14
- Modify a Built-In Storage Class 37-17
- Control Data Representation by Configuring Storage Class Properties 37-17
- Avoid Errors During Code Generation by Validating Storage Class Configuration 37-20
- Make Storage Classes Available Outside the Current Folder 37-20
- Make Storage Classes Available in the Code Mappings Editor 37-21
- Share Storage Class Between Packages 37-21
- Control Appearance of Storage Class Drop-Down List 37-21
- Protect Custom Storage Class Definitions 37-22
- Further Customize Generated Code by Writing TLC Code 37-22

Finely Control Data Representation by Writing TLC Code for a Storage Class 37-23

- Create Custom Attributes Class for Storage Class 37-23
- Write TLC Code for Storage Class 37-23
- Create Storage Class by Using Custom Storage Class Designer .. 37-23

Access Data Through Functions with Storage Class GetSet 37-25

- Access Legacy Data Using Get and Set Functions 37-25
- Use GetSet with Vector Data 37-28
- Use GetSet with Structured Data 37-31
- Use GetSet with Matrix Data 37-35
- Specify Header File or Function Naming Scheme for Data Items . 37-39
- Access Scalar and Array Data Through Macro Instead of Function Call 37-40
- GetSet Storage Class Restrictions 37-40

Access Data Through Functions by Using Storage Classes in Embedded Coder Dictionary	37-41
Access Legacy Data by Value	37-41
Access Legacy Data by Pointer	37-43
Integrate External Application Code with Code Generated from PID Controller	37-45
Configure Generated Code According to Interface Control Document Specifications	37-54
Generate Local Variables with Localizable Storage Class	37-62
Example Model	37-62
Generate Code with Localizable Storage Class	37-62
Generate Code Without Localizable Storage Class	37-63
Additional Information	37-64

Data Object Wizard in Embedded Coder

38

Create Data Objects for Code Generation with Data Object Wizard	38-2
--	-------------

Entry-Point Functions and Scheduling in Simulink Coder

39

Configure Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks	39-2
Configure Generated C Function Interface for Global Simulink Function Block	39-2
Configure Generated C Function Interface for Exported Scoped Simulink Function Block	39-4
Configure Generated C++ Function Interface for Exported Scoped Simulink Function Block	39-6
Simulink Function Code Interface Limitations	39-7
Generate C++ Class Interface to Model or Subsystem Code	39-9
Generate C++ Class Interface to Model Code	39-9
Generate C++ Class Interface to Nonvirtual Subsystem Code ...	39-10
C++ Class Interface Limitations	39-10
Execution of Code Generated from a Model	39-12
Program Execution	39-12
Program Timing	39-13
External Mode Communication	39-13
Data Logging in Single-Tasking and Multitasking Model Execution	39-14
Non-Real-Time Single-Tasking Systems	39-14
Non-Real-Time Multitasking Systems	39-15

Real-Time Single-Tasking Systems	39-16
Real-Time Multitasking Systems	39-17
Multitasking Systems Using Real-Time Tasking Primitives	39-18
Rapid Prototyping and Embedded Model Execution Differences ..	39-19
Rapid Prototyping Model Functions	39-21

Function and Class Interfaces in Embedded Coder

40

Generate Modular Function Code for Nonvirtual Subsystems	40-2
About Nonvirtual Subsystem Code Generation	40-2
Configure Subsystem for Generating Modular Function Code	40-2
Modular Function Code for Nonvirtual Subsystems	40-5
Partition Functions in Generated Code	40-8
Nonvirtual Subsystem Modular Function Code Limitations	40-17
Generate Reentrant, Multi-Instance Code	40-19
Generate Code for String Blocks by Using the Standard C++ String Library	40-23
Configure Deployment Types for Model Hierarchy	40-26
Set Up Test Harness and Model Hierarchy	40-26
Specify Deployment Types for the Models	40-27
Generate and Inspect Code	40-29

Configure C++ Class Interface

41

Interactively Configure C++ Interface	41-2
Interactive Workflow Overview	41-2
Open Environment	41-2
Configure Model as Class	41-4
Configure Model Data Elements as Class Members	41-5
Configure Model Functions as Class Methods	41-14
Generate C++ Class Interface	41-22
Considerations and Limitations	41-23
Programmatically Configure C++ Interface	41-25
Programmatic Workflow Overview	41-25
Open Environment	41-25
Configure Model as Class	41-27
Configure Model Data Elements as Class Members	41-28
Configure Model Functions as Class Methods	41-37
Generate C++ Class Interface	41-42
Considerations and Limitations	41-43
Configure C++ Class Interface for Rate-Based Models	41-45

Memory Sections in Embedded Coder

42

Control Data and Function Placement in Memory by Inserting	
Pragmas	42-2
Insert Pragmas by Using Memory Sections	42-2
Configure Pragma to Surround Groups of Definitions	42-6
Override Default Memory Placement for Individual Data Elements	42-6
Choose Where to Create and Store Memory Section Definition	42-7
Share Memory Section Definition Between Models	42-7
Override Default Memory Placement for Subsystem Functions and Data	42-7
Share Memory Section Between Packages (Package Memory Sections Only)	42-9
Control Appearance of Memory Section Drop-Down List (Package Memory Sections Only)	42-10
Protect Definitions of Package Memory Sections (Package Memory Sections Only)	42-10
Limitations	42-10
Insert Pragmas for Functions and Data in Generated Code	42-11
Protect Global Data with const and volatile Type Qualifiers	42-13
Maintain const Correctness for Arguments of Entry-Point Functions	42-13
Incorrect Results or Undefined Behavior When Passing Volatile Data to a Generated Function	42-13

Array Layout

43

Column-Major Layout to Row-Major Layout Conversion of Models with Lookup Table Blocks	43-2
Interpolation Algorithm for Row-Major Array Layout	43-9
Interpolation with Subtable Selection Algorithm for Row-Major Array Layout	43-15
Direct Lookup Table Algorithm for Row-Major Array Layout	43-21
Generate Row-Major Code for S-Functions	43-28
Row-Major Algorithms for Row-Major Array Layout	43-31

Generate Row-Major Code for Model That Contains a MATLAB Function Block	43-34
Row-Major Code Generation	43-34
Mixed-Majority Code Generation	43-35

Preserve Dimensions

44

Preserve Dimensions of Multidimensional Arrays in Generated Code	44-2
Configure Default Model Data Elements to Preserve Dimensions ..	44-2
Configure Individual Model Data Elements to Preserve Dimensions	44-3
Storage Classes Supported to Preserve Dimensions	44-4
Preserve Dimensions for New Storage Classes	44-4
Limitations	44-5
Preserve Dimensions of Bus Elements in Generated Code	44-6

Code Generation

Configuration for Simulink Coder

45

Code Generation Configuration	45-2
Open the Model Configuration for Code Generation	45-2
Configuration Tools	45-2
Configure Code Generation Parameters for Model Programmatically	45-4
Modify Parameters to Support Execution efficiency	45-4
Configure Model from Command Line	45-6
Use Configuration Reference to Select Code Generation Target ..	45-11
Check Model and Configuration for Code Generation	45-16
Check Model for Code Efficiency with Model Advisor	45-16
Check Model During Code Generation by using the Code Generation Advisor	45-16
Application Objectives Using Code Generation Advisor	45-18
High-Level Code Generation Objectives	45-18
Configure Model for Code Generation Objectives Using Code Generation Advisor	45-19

Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box	45-19
Simulink Coder Model Advisor Checks for Standards and Code Efficiency	45-21
Configure Code Comments	45-22
Include MATLAB Code as Comments in Generated Code	45-23
Include MATLAB Code as Comments in the Generated Code	45-23
Location of Comments in Generated Code	45-23
Include MATLAB User Comments in Generated Code	45-25
Limitations of MATLAB Source Code as Comments	45-26
Construction of Generated Identifiers	45-27
Identifier Name Collisions and Mangling	45-28
Identifier Name Collisions with Referenced Models	45-28
Specify Identifier Length to Avoid Naming Collisions	45-29
Specify Reserved Names for Generated Identifiers	45-30
Reserved Keywords	45-31
C Reserved Keywords	45-31
C++ Reserved Keywords	45-31
Reserved Keywords for Code Generation	45-32
Code Generation Code Replacement Library Keywords	45-32
Configure Model for Debugging	45-34

Configuration in Embedded Coder

46

Configure Model for Code Generation Objectives by Using Code Generation Advisor	46-2
High-Level Code Generation Objectives	46-2
Specify Objectives in Referenced Models	46-3
Configure Model Using Code Generation Advisor	46-3
Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box	46-4
Configure Code Generation Objectives Programmatically	46-7
Check Model and Configuration for Code Generation	46-8
Check Model During Code Generation by Using the Code Generation Advisor	46-8
Embedded Coder Model Advisor Checks for Standards, Guidelines, and Code Efficiency	46-9
Create Custom Code Generation Objectives	46-10
Specify Parameters in Custom Objectives	46-10

Specify Checks in Custom Objectives	46-10
Determine Checks and Parameters in Existing Objectives	46-11
Steps to Create Custom Objectives	46-12
Configuration Variations	46-14
Configure and Optimize Model with Configuration Wizard Blocks	46-15
Configuration Wizard Block Library	46-15
Add a Configuration Wizard Block	46-16
Use Configuration Wizard Blocks to Configure Your Model	46-17
Create a Custom Configuration Wizard Block	46-17
Aircraft Position Radar Model	46-22

System Target File Configuration

47

Configure a System Target File	47-2
Select a Solver That Supports Code Generation	47-2
Select a System Target File from STF Browser	47-2
Select a System Target File Programmatically	47-3
Develop Custom System Target Files	47-4
Configure STF-Related Code Generation Parameters	47-5
Specify Generated Code Interfaces	47-5
Configure Numeric Data Support	47-8
Configure Time Value Support	47-8
Configure Noninlined S-Function Support	47-9
Configure Model Function Generation and Argument Passing	47-9
Configure Code Reuse Support	47-10
Configure a Code Replacement Library	47-12
Configure Standard Math Library for Target System	47-13
Compare System Target File Support Across Products	47-16
Compare Product System Target Files	47-17
Compare Code Styles and STF Support	47-19
Compare Generated Code Features by Product	47-20
Compare Generated Code Features by STF	47-22

Internationalization Support in Embedded Coder

48

Internationalization and Code Generation	48-2
Locale Settings	48-2
Prepare to Generate Code for Mixed Languages and Locales	48-2
Character Set Limitations	48-2

XML Escape Sequence Replacements	48-3
CGT Files and XML Escape Sequence Replacements	48-3
Generate and Review Code with Mixed Languages and Mixed Locales	48-3

Source Code Generation in Simulink Coder

49

Review the Generated Code	49-13
Generate an Executable	49-14
Key Points	49-14
 Configure Data Interface	 49-16
About This Example	49-16
Declare Data	49-16
Use Data Objects	49-17
Add New Data Objects	49-19
Enable Data Objects for Generated Code	49-19
Effects of Simulation on Data Typing	49-20
Manage Data	49-21
Key Points	49-22
 Call External C Functions	 49-23
About This Example	49-23
Include External C Functions in a Model	49-23
Create a Block That Calls a C Function	49-23
Validate External Code in the Simulink Environment	49-25
Validate C Code as Part of a Model	49-26
Call a C Function from Generated Code	49-27
Key Points	49-27
 Reload Generated Code	 49-29
 Manage Build Process Folders	 49-30
File Generation Control Parameters	49-30
Build Process Folders	49-31

Manage Build Process Files	49-34
model.bat	49-38
model.h	49-38
rtwtypes.h	49-39
Manage Build Process File Dependencies	49-41
System Header Files	49-42
Code Generator Header Files	49-44
Add Build Process Dependencies	49-50
File Dependency Information for the Build Process	49-50
Folder Dependency Information for the Build Process	49-52
Build Process Support for Folder Names	49-55
Folder Names with Spaces	49-55
Troubleshooting Errors When Folder Names Have Spaces	49-57
Folder Names with Special Characters	49-58
Very Long Folder Paths	49-58
Code Generation of Matrices and Arrays	49-60
Array Storage in Computer Memory	49-60
Code Generator Matrix Parameters	49-62
Internal Data Storage for Complex Number Arrays	49-64
Unsupported Blocks for Row-Major Code Generation	49-64
Limitations for Row-Major Code Generation	49-65
Cross-Release Shared Utility Code Reuse	49-66
Workflow to Reuse Shared Utility Code	49-66
Required Editing for Shared Utility Code Reuse	49-67
Cross-Release Code Integration	49-68
Workflow	49-68
Limitations	49-70
Simulink.Bus Support	49-71
Root-Level I/O Through Global Variables in Generated Code	49-72
Communicate Between Current and Previous Release Components Through Global Data Stores	49-74
Parameter Tuning	49-75
Use Multiple Instances of Code Generated from Reusable Referenced Model	49-76
Compare Simulation Behavior of Model Component in Current Release and Generated Code from Previous Release	49-77
Import AUTOSAR Code from Previous Releases	49-78
Integration of Code from Multiple Folders	49-79
Integrate Generated Code by Using Cross-Release Workflow	49-82
Use Protected Models from Previous Releases to Perform SIL Testing and Generate Code	49-90
Compile Code in Another Development Environment	49-96
Generate Code and Simulate Models in a Project	49-99

Generate Code and Simulate Models Programmatically with Project	49-102
Code Generation for Deep Learning Simulink Model That Performs Lane and Vehicle Detection	49-107

Source Code Generation in Embedded Coder

50

Generate Code Using Embedded Coder	50-2
Generate Code by Using the Quick Start Tool	50-9
Quick Start Model Analysis	50-9
Configuration Parameter Changes for Models That Have a Configuration Reference	50-10
Next Steps	50-11
Manage File Packaging of Generated Code Modules	50-12
Generated Code Modules	50-12
User-Written Code Modules	50-14
Customize Generated Code Modules	50-14
Tutorial for Generating C Code from a Control Algorithm for an Embedded System	50-17
Third-Party Software	50-17
Prepare a Control Algorithm Model for C Code Generation	50-18
Configure Data Interface in the Generated Code	50-29
Partition Functions in Generated Code	50-38
Call External C Code from Model and Generated Code	50-47
Build Integrated Code Outside the Simulink Environment	50-52
Test Generated Code	50-57
Evaluate Performance of the Generated Code	50-63
Install and Use Cygwin and Eclipse	50-67

Report Generation in Embedded Coder

51

Reports for Code Generation	51-2
HTML Code Generation Report Content	51-2
HTML Code Generation Report Location	51-2

HTML Code Generation Report for Referenced Models	51-2
HTML Code Generation Report Extensions	51-3
Generate Code Generation Report	51-5
Configure Model	51-5
Generate Report	51-5
Share Report	51-5
Limitation	51-6
Generate Code Generation Report Programmatically	51-7
Web View of Model in Code Generation Report	51-10
Generate HTML Code Generation Report with Model Web View ..	51-10
Model Web View Limitations	51-12
Analyze the Generated Code Interface	51-13
Code Interface Report Overview	51-13
Generating a Code Interface Report	51-13
Navigating Code Interface Report Subsections	51-15
Interpreting the Entry-Point Functions Subsection	51-16
Interpreting the Inports and Outports Subsections	51-19
Interpreting the Interface Parameters Subsection	51-20
Interpreting the Data Stores Subsection	51-21
Code Interface Report Limitations	51-21
Static Code Metrics	51-23
Static Code Metrics	51-23
Static Code Metrics Analysis	51-23
View Static Code Metrics and Definitions Within the Generated Code	
.....	51-25
Static Code Metrics Report Limitations	51-25
Generate Static Code Metrics Report for Simulink Model	51-26
Generating a Static Code Metrics Report for Code Generated from	
 MATLAB Code	51-30
Example Static Code Metrics Report	51-30
Requirements for Running Static Code Metrics Analysis After Code	
Generation	51-32
Running Static Code Metrics at Code Generation Time	51-32
Analyze Code Replacements in Generated Code	51-33
Document Generated Code with Simulink Report Generator	51-35
Generate Code for the Model	51-35
Open the Report Generator	51-36
Set Report Name, Location, and Format	51-38
Include Models and Subsystems in a Report	51-39
Customize the Report	51-39
Generate the Report	51-40
Get Code Description of Generated Code	51-41
Get Generated Type and Name of Inport Structures	51-48

Customize Code Comments to Enhance Readability and Traceability	52-2
.....	
Add Custom Comments for Variables in the Generated Code	52-3
Embed Handwritten Comments for Signals or Parameters	52-3
Generate Dynamic Comments Based on Data Properties	52-3
Add Global Comments in the Generated Code	52-5
Use a Simulink DocBlock to Add a Comment	52-5
Use a Simulink Annotation to Add a Comment	52-7
Use Sorted Notes to Add Comments	52-8
Limitations	52-9
Customize Generated Identifier Naming Rules	52-10
Apply Naming Rules to Identifiers Globally	52-10
Apply Custom Naming Conventions to Identifiers	52-11
Identifier Format Control	52-17
Control Case by Using Token Decorators	52-20
Modify Identifiers by Using Regular Expression Decorators	52-21
Control Formatting of Identifiers	52-22
Control Name Mangling in Generated Identifiers	52-24
Minimize Name Mangling	52-24
Avoid Identifier Name Collisions with Referenced Models	52-25
Use Model Advisor to Detect Identifier Names Changed During Code Generation	52-25
Maintain Traceability for Generated Identifiers	52-26
Exceptions to Identifier Formatting Conventions	52-27
Identifier Format Control Parameters Limitations	52-28
Control Parentheses in Generated Code	52-30
Control Use of Parentheses	52-30
Optimize Code by Reordering Commutable Operands	52-32
Example Model	52-32
Generate Code	52-32
Generate Code with Optimization	52-32
Suppress Generation of Default Cases for Unreachable Stateflow Switch Statements	52-34
Example	52-34
Generate Code with Default Cases for Unreachable Stateflow Switch Statements	52-36
Suppress Default Cases for Unreachable Stateflow Switch Statements	52-36

Replace Multiplication by Powers of Two with Signed Bitwise Shifts	
.....	52-37
Example	52-37
Generate Code with Signed Bitwise Shifts	52-37
Generate Code with Multiplication by Powers of Two	52-37
Generate Code Containing Right Shifts on Signed Integers	52-39
Example Model	52-39
Generate Code Containing Right Shifts on Signed Integers	52-39
Generate Code That Does Not Allow Right Shifts on Signed Integers	
.....	52-39
Control Cast Expressions in Generated Code	52-41
Enable Nominal Casting Mode and Generate Code	52-41
Enable Standards Compliant Casting Mode and Generate Code ..	52-42
Enable Explicit Casting Mode and Generate Code	52-43
Customize Code Organization and Format	52-45
Custom File Processing Components	52-45
Custom File Processing Configuration	52-46
Specify Templates For Code Generation	52-47
Code Generation Template (CGT) Files	52-48
Default CGT file	52-48
CGT File Structure	52-48
Built-In Tokens and Sections	52-49
Subsections	52-50
Format Generated Code Files by Using Templates	52-52
Custom File Processing (CFP) Templates	52-54
Custom File Processing (CFP) Template Structure	52-54
Generate Additional Files Required to Interface with an Application	
.....	52-55
Change the Organization of a Generated File	52-57
Customize Generated File Names	52-59
Generate Source and Header Files with a Custom File Processing	
(CFP) Template	52-61
Generate Code with a CFP Template	52-61
Analysis of the Example CFP Template and Generated Code	52-62
Generate a Custom Section	52-65
Custom Tokens	52-66
Comparison of a Template and Its Generated File	52-67
Template and Generated File	52-67
Code Template API Summary	52-70
Generate Custom File and Function Banners	52-73
Create a Custom File and Function Banner Template	52-73

Customize a Code Generation Template (CGT) File for File and Function Banner Generation	52-74
Template Symbols and Rules	52-80
Introduction	52-80
Template Symbol Groups	52-80
Template Symbols	52-82
Rules for Modifying or Creating a Template	52-84
Annotate Code for Justifying Polyspace Checks	52-85
Enhance Readability of Code for Flow Charts	52-94
Appearance of Generated Code for Flow Charts	52-94
Convert If-Elseif-Else Code to Switch-Case Statements	52-96
Example of Converting Code to Switch-Case Statements	52-98
Enhance Code Readability for MATLAB Function Blocks	52-104
Requirements for Using Readability Optimizations	52-104
Converting If-Elseif-Else Code to Switch-Case Statements	52-104
Example of Converting Code for If-Elseif-Else Decision Logic to Switch- Case Statements	52-106
Improve Data Coherency in Generated Code	52-110
Example Model	52-110
Generate Code Without Parameter Enabled	52-110
Generate Code With Parameter Enabled	52-111

Tune Parameters Interactively During Rapid Simulation	65-21
Rapid Simulation Target Limitations	65-22
Run Rapid Simulations Over a Range of Parameter Values	65-24
Run Batch Simulations Without Recompiling Generated Code	65-30
Use MAT-Files to Feed Data to Inport Blocks for Rapid Simulations	65-35
Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target	65-40
About the S-Function Target	65-40
Create S-Function Blocks from a Subsystem	65-42
Tunable Parameters in Generated S-Functions	65-45
System Target File	65-46
Checksums and the S-Function Target	65-46
Generated S-Function Compatibility	65-47
S-Function Target Limitations	65-47

Desktops in Embedded Coder

66

Package Generated Code as Shared Libraries	66-2
About Generated Shared Libraries	66-2
Generate Shared Library Version of Model Code	66-2
Create Application Code to Use Shared Library	66-3
Shared Library Limitations	66-6

67

Deploy Algorithm Model for Real-Time Rapid Prototyping	67-2
About Real-Time Rapid Prototyping	67-2
Goals of Real-Time Rapid Prototyping	67-2
Refine Code With Real-Time Rapid Prototyping	67-2
Deploy Environment Model for Real-Time Hardware-In-the-Loop (HIL) Simulation	67-4
About Hardware-In-the-Loop Simulation	67-4
Set Up and Run HIL Simulations	67-4
Untrusted Custom Code, Custom Targets, and Callbacks	67-6

Real-Time and Embedded Systems in Embedded Coder

68

Deploy Generated Standalone Executable Programs To Target Hardware	68-2
Generate a Standalone Program	68-2
Standalone Program Components	68-2
Main Program	68-3
rt_OneStep and Scheduling Considerations	68-4
Static Main Program Module	68-8
Rate Grouping Compliance and Compatibility Issues	68-12
Generate Code That Dereferences Data from a Literal Memory Address	68-15
Generate Main Program for Deployment to Bare-Metal Target Hardware	68-24
Deploy Generated Component Software to Application Target Platforms	68-26
Interface to an Example Real-Time Multitasking System	68-26

Code Replacement Customization for Simulink Models in Embedded Coder

69

What Is Code Replacement Customization?	69-3
Code Replacement Match and Replacement Process	69-3
Code Replacement Customization Limitations	69-3
Code You Can Replace From Simulink Models	69-6
Math Functions - Simulink Support	69-6
Math Functions - Stateflow Support	69-11
Memory Functions	69-14

Nonfinite Functions	69-15
Mutex and Semaphore Functions	69-15
Operators	69-16
Develop a Code Replacement Library	69-20
Quick Start Code Replacement Library Development - Simulink	69-21
Semaphore and Mutex Function Replacement	69-30
Identify Code Replacement Library Requirements	69-35
What Is a Code Replacement Library?	69-35
What Functions Can Be Optimized with a Code Replacement Library?	69-35
How to Develop a Code Replacement Library	69-35
Identify Basic Requirements	69-35
Define Code Replacement Library Optimizations	69-36
Interactively Develop a Code Replacement Library	69-36
Programmatically Develop a Code Replacement Library	69-39
Register Code Replacement Library	69-51
Interactively Develop and Load a Registration file	69-51
Programmatically Develop and Load a Registration File	69-52
Verify Code Replacement Library	69-55
Verify Library Structure	69-55
Verify Library Replacement	69-55
Verify Library Performance	69-56
Deploy Code Replacement Library	69-57
Troubleshoot Code Replacement Library Registration	69-58
Troubleshoot Code Replacement Misses	69-59
Miss Reason Messages	69-59
Analyze and Correct Code Replacement Misses	69-60
Math Function Code Replacement	69-64
Interactively Develop a Code Replacement Library	69-64
Programmatically Develop a Code Replacement Library	69-66
Generate Code by Using Math Code Replacement Library	69-69
Buffer Index Calculation Code Replacement	69-71
Interactively Develop a Code Replacement Library	69-71
Programmatically Develop a Code Replacement Library	69-72
Generate Code by Using Circular Index Code Replacement Library	69-75
Memory Function Code Replacement	69-78
Interactively Develop a Code Replacement Library	69-78
Programmatically Develop a Code Replacement Library	69-80

Nonfinite Function Code Replacement	69-83
Interactively Develop a Code Replacement Library	69-83
Programmatically Develop a Code Replacement Library	69-85
Algorithm-Based Code Replacement	69-88
Interactively Develop a Code Replacement Library	69-88
Programmatically Develop a Code Replacement Library	69-90
Lookup Table Function Code Replacement	69-94
Lookup Table Function Signatures	69-94
Interactively Develop a Code Replacement Library	69-97
Programatically develop a code replacement library	69-99
Generate Code by Using Lookup Table Code Replacement Library	69-102
Data Alignment for Code Replacement	69-105
Code Replacement Data Alignment	69-105
Specify Data Alignment Requirements for Function Arguments .	69-105
Provide Data Alignment Specifications for Compilers	69-106
Basic Example of Code Replacement Data Alignment	69-109
Replace MATLAB Functions with Custom Code by Using the coder.replace Function	69-112
Interactively Develop a Code Replacement Library	69-112
Programmatically Develop a Code Replacement Library	69-114
Replace coder.ceval Calls to External Functions	69-118
Example Files	69-118
Interactively Develop a Code Replacement Library	69-119
Programmatically Develop a Code Replacement Library	69-121
Custom Function Code Replacement	69-125
Interactively Develop a Code Replacement Library	69-125
Programmatically Develop a Code Replacement Library	69-126
Generate Code by Using Custom Function Code Replacement ..	69-129
Reserved Identifiers and Code Replacement	69-131
Customize Match and Replacement Process	69-132
Customize Code Match and Replacement for Functions	69-133
Customize Code Match and Replacement for Nonscalar Operations	69-135
Customize Code Match and Replacement for Scalar Operations .	69-138
Scalar Operator Code Replacement	69-143
Interactively Develop a Code Replacement Library	69-143
Programmatically Develop a Code Replacement Library	69-145
Addition and Subtraction Algorithm Types for Code Replacement	69-148
Algorithm Options	69-148
Algorithm Classification	69-148
Limitations	69-149

Replace Addition and Subtraction Operator Code	69-151
Interactively Develop a Code Replacement Library	69-151
Programmatically Develop a Code Replacement Library	69-153
Generate Code using Addition and Subtraction Operator Code Replacement Library	69-155
Matrix Multiplication Operation to MathWorks BLAS Code	
Replacement	69-158
Interactively Develop a Code Replacement Library	69-158
Programmatically Develop a Code Replacement Library	69-160
Convert a Matrix Multiplication Operation to MathWorks BLAS Through Code Replacement	69-165
Matrix Multiplication Operation to ANSI/ISO C BLAS Code	
Replacement	69-168
Interactively Develop a Code Replacement Library	69-168
Programmatically Develop a Code Replacement Library	69-170
Small Matrix Operation to Processor Code Replacement	69-175
Interactively Develop a Code Replacement Library	69-175
Programmatically Develop a Code Replacement Library	69-177
Generate Code to Optimize Performance of a Small Matrix Operation for Processor-Specific Intrinsic Function	69-180
Remap Operator Output to Function Input	69-183
Fixed-Point Operator Code Replacement	69-186
Common Ways to Match Fixed-Point Operator Entries	69-186
Fixed-Point Numbers and Arithmetic	69-187
Addition	69-188
Subtraction	69-188
Multiplication	69-189
Division	69-189
Data Type Conversion (Cast)	69-190
Shift	69-190
Binary-Point-Only Scaling Code Replacement	69-192
Programmatically Develop a Code Replacement Library	69-193
Slope Bias Scaling Code Replacement	69-197
Programmatically Develop a Code Replacement Library	69-198
Net Slope Scaling Code Replacement	69-203
Interactively Develop a Code Replacement Library	69-203
Programmatically Develop a Code Replacement Library	69-205
Equal Slope and Zero Net Bias Code Replacement	69-210
Interactively Develop a Code Replacement Library	69-210
Programmatically Develop a Code Replacement Library	69-212
Data Type Conversions (Casts) and Operator Code Replacement	
.....	69-216
Interactively Develop a Code Replacement Library	69-216
Programmatically Develop a Code Replacement Library	69-218

Shift Left Operations and Code Replacement	69-222
Interactively Develop a Code Replacement Library	69-222
Programmatically Develop a Code Replacement Library	69-224
Optimize Generated Code by Using Multiple Code Replacement Libraries	69-227

70

Code Replacement Customization for MATLAB Code

What Is Code Replacement Customization?	70-3
Code Replacement Match and Replacement Process	70-3
Code Replacement Customization Limitations	70-3
Code You Can Replace from MATLAB Code	70-5
Math Functions	70-5
Memory Functions	70-8
Operators	70-9
Develop a Code Replacement Library	70-13
Quick Start Library Development	70-14
Identify Code Replacement Library Requirements	70-21
What Is a Code Replacement Library?	70-21
What Functions Can Be Optimized with a Code Replacement Library?	
.....	70-21
How to Develop a Code Replacement Library	70-21
Identify Basic Requirements	70-21
Define Code Replacement Library Optimizations	70-23
Interactively Develop a Code Replacement Library	70-23
Programmatically Develop a Code Replacement Library	70-26
Register Code Replacement Library	70-38
Interactively Develop and Load a Registration file	70-38
Programmatically Develop and Load a Registration File	70-39
Troubleshoot Code Replacement Library Registration	70-42
Verify Code Replacement Library	70-43
Verify Library Structure	70-43
Verify Library Replacement	70-43
Verify Library Performance	70-44
Review Code Replacements	70-44
Troubleshoot Code Replacement Misses	70-47
Miss Reason Messages	70-47
Analyze and Correct Code Replacement Misses	70-48
Deploy Code Replacement Library	70-50

Math Function Code Replacement	70-51
Interactively Develop a Code Replacement Library	70-51
Programmatically Develop a Code Replacement Library	70-53
Memory Function Code Replacement	70-57
Interactively Develop a Code Replacement Library	70-57
Programmatically Develop a Code Replacement Library	70-59
Specify In-Place Code Replacement	70-62
Interactively Develop a Code Replacement Library	70-62
Programmatically Develop a Code Replacement Library	70-64
Data Alignment for Code Replacement	70-67
Code Replacement Data Alignment	70-67
Specify Data Alignment Requirements for Function Arguments ..	70-67
Provide Data Alignment Specifications for Compilers	70-69
Specify Data Alignment in MATLAB Code for Imported Data	70-72
Array Layout and Code Replacement	70-73
Allow Shape Agnostic Match	70-75
User Interface Method- Code Replacement Tool	70-75
Programmatic Method	70-76
Limitations	70-78
Replace MATLAB Functions with Custom Code by Using the coder.replace Function	70-79
Interactively Develop a Code Replacement Library	70-79
Programmatically Develop a Code Replacement Library	70-81
Replace coder.ceval Calls to External Functions	70-85
Example Files	70-85
Interactively Develop a Code Replacement Library	70-86
Programmatically Develop a Code Replacement Library	70-88
Reserved Identifiers and Code Replacement	70-92
Customize Match and Replacement Process	70-93
Customize Match and Replacement Process for Operators	70-94
Scalar Operator Code Replacement	70-99
Interactively Develop a Code Replacement Library	70-99
Programmatically Develop a Code Replacement Library	70-101
Addition and Subtraction Operator Code Replacement	70-104
Algorithm Options	70-104
Algorithm Classification	70-104
Interactively Develop a Code Replacement Library	70-105
Programmatically Develop a Code Replacement Library	70-108
Limitations	70-110
Small Matrix Operation to Processor Code Replacement	70-111
Interactively Develop a Code Replacement Library	70-111
Programmatically Develop a Code Replacement Library	70-113

Matrix Multiplication Operation to MathWorks BLAS Code Replacement	70-117
Interactively Develop a Code Replacement Library	70-117
Programmatically Develop a Code Replacement Library	70-119
Matrix Multiplication Operation to ANSI/ISO C BLAS Code Replacement	70-125
Interactively Develop a Code Replacement Library	70-125
Programmatically Develop a Code Replacement Library	70-127
Remap Operator Output to Function Input	70-132
Fixed-Point Operator Code Replacement	70-134
Common Ways to Match Fixed-Point Operator Entries	70-134
Fixed-Point Numbers and Arithmetic	70-135
Addition	70-136
Subtraction	70-136
Multiplication	70-137
Division	70-137
Data Type Conversion (Cast)	70-138
Shift	70-138
Binary-Point-Only Scaling Code Replacement	70-140
Programmatically Develop a Code Replacement Library	70-141
Slope Bias Scaling Code Replacement	70-145
Programmatically Develop a Code Replacement Library	70-146
Net Slope Scaling Code Replacement	70-151
Interactively Develop a Code Replacement Library	70-151
Programmatically Develop a Code Replacement Library	70-153
Equal Slope and Zero Net Bias Code Replacement	70-158
Interactively Develop a Code Replacement Library	70-158
Programmatically Develop a Code Replacement Library	70-160
Data Type Conversions (Casts) and Operator Code Replacement	70-164
Interactively Develop a Code Replacement Library	70-164
Programmatically Develop a Code Replacement Library	70-166
Shift Left Operations and Code Replacement	70-170
Interactively Develop a Code Replacement Library	70-170
Programmatically Develop a Code Replacement Library	70-172
Optimize Generated Code by Developing and Using Code Replacement Libraries - MATLAB	70-175

Optimizations for Generated Code in Simulink Coder

Increase Code Generation Speed	71-3
Build a Model in Increments	71-3
Build Large Model Reference Hierarchies in Parallel	71-3
Minimize Memory Requirements During Code Generation	71-4
Generate Only Code	71-4
Suppress Creation of a Code Generation Report	71-4
Control Compiler Optimizations	71-6
Optimize Generated Code with Code Efficiency Tools and Techniques	
.....	71-7
Use the Model Advisor to Optimize a Model for Code Generation ..	71-7
Design Tips for Optimizing Generated Code for Stateflow Objects	
.....	71-7
Additional Optimization Techniques	71-8
Control Memory Allocation for Time Counters	71-10
Execution Profiling for Generated Code	71-11
Optimize Generated Code by Combining Multiple for Constructs	
.....	71-13
Subnormal Number Execution Speed	71-16
Simulation Time With and Without Subnormal Numbers	71-17
Flush Subnormal Numbers to Zero	71-17
Remove Code for Out-of-Range Floating Point to Integer Conversions	
.....	71-20
Remove Code That Maps NaN to Integer Zero	71-23
Disable Nonfinite Checks or Inlining for Math Functions	71-26
Fold Expressions	71-31
Minimize Computations and Storage for Intermediate Results at Block Outputs	71-35
Expression Folding	71-35
Example Model	71-35
Generate Code	71-35
Enable Optimization	71-36
Generate Code with Optimization	71-36
Inline Invariant Signals	71-38
Optimize Generated Code Using Inline Invariant Signals	71-38

Inline Numeric Values of Block Parameters	71-41
Configure Loop Unrolling Threshold	71-46
Use memcpy Function to Optimize Generated Code for Vector	
Assignments	71-48
Example Model	71-48
Generate Code	71-49
Generate Code with Optimization	71-50
Generate Target Optimizations Within Algorithm Code	71-51
Remove Code for Blocks That Have No Effect on Computational	
Results	71-52
Eliminate Dead Code Paths in Generated Code	71-56
Floating-Point Multiplication to Handle a Net Slope Correction .	71-59
Use Conditional Input Branch Execution	71-62
Optimize Generated Code for Complex Signals	71-66
Speed Up Linear Algebra in Code Generated from a MATLAB	
Function Block	71-68
Specify LAPACK Library	71-68
Write LAPACK Callback Class	71-68
Generate LAPACK Calls by Specifying a LAPACK Callback Class ..	71-69
Locate LAPACK Library in Execution Environment	71-70
Speed Up Matrix Operations in Code Generated from a MATLAB	
Function Block	71-71
Specify BLAS Library	71-71
Write BLAS Callback Class	71-71
Generate BLAS Calls by Specifying a BLAS Callback Class	71-73
Locate BLAS Library in Execution Environment	71-73
Usage Notes and Limitations for OpenBLAS Library	71-74
Speed Up Fast Fourier Transforms in Code Generated from a	
MATLAB Function Block	71-75
Install an FFTW Library	71-75
Write FFT Callback Class	71-75
Generate FFTW Calls by Specifying an FFT Callback Class	71-76
Synchronize Multithreaded FFTW Planning in Code Generated from	
a MATLAB Function Block	71-78
Prerequisites	71-78
Create a Model with a MATLAB Function Block That Calls an FFT	
Function	71-78
Write Supporting C Code	71-79
Create an FFT Library Callback Class	71-79
Configure Code Generation Parameters and Build the Model	71-80

Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block	71-82
Provide Upper Bounds for Variable-Size Arrays	71-82
Disable Dynamic Memory Allocation for MATLAB Function Blocks	71-82
Modify the Dynamic Memory Allocation Threshold	71-82
Optimize Memory Usage for Time Counters	71-84
Optimize Generated Code Using Boolean Data for Logical Signals	71-89
Reduce Memory Usage for Boolean and State Configuration Variables	71-92
Customize Stack Space Allocation	71-93
Optimize Generated Code Using memset Function	71-95
Vector Operation Optimization	71-99
Enable and Reuse Local Block Outputs in Generated Code	71-102
Example Model	71-102
Generate Code Without Optimization	71-102
Enable Local Block Outputs and Generate Code	71-103
Reuse Local Block Outputs and Generate Code	71-104
Generate SIMD Code from Simulink Blocks	71-105
Blocks That Support SIMD Code Generation	71-105
Generate SIMD Code Compared to Plain C Code	71-107
Limitations	71-109
Optimize Code for Reduction Operations by Using SIMD	71-110

Configuration in Embedded Coder

72

Set Hardware Implementation Parameters	72-2
---	-------------

Data Copy Reduction in Embedded Coder

73

Optimize Global Variable Usage	73-2
Use Global to Hold Temporary Results	73-2
Minimize Global Data Access	73-6
Reuse Global Block Outputs in the Generated Code	73-12
Virtualized Output Ports Optimization	73-15

Specify Buffer Reuse for Signals in a Path	73-17
Specify Buffer Reuse for MATLAB Function Blocks in a Path	73-25
Example Model	73-25
Generate Code with Optimization	73-25
Remove Data Copies by Reordering Block Operations in the Generated Code	73-27
Example Model	73-27
Generate Code without Optimization	73-27
Generate Code with Optimization	73-29
Data Copy Reduction for Data Store Read and Data Store Write Blocks	73-32
Reduce Data Copies for Bus Assignment Blocks in Generated Code	73-36
Example Model	73-36
Generate Code Without Optimization	73-36
Generate Code with Optimization	73-37
Optimize Generated Code by Using Signal Labels to Guide Buffer Reuse	73-39
Example Model	73-39
Generate Code Without Optimization	73-39
Generate Code with Optimization	73-40
Using Label-Based Reuse Versus Reusable Storage Classes	73-40

Execution Speed in Embedded Coder

74

Reduce Memory Usage for Signals	74-2
Remove Zero Initialization Code	74-3
Remove Zero Initialization Code for Internal Data	74-3
Remove Initialization Code from Root-Level Inports and Outports Set to Zero	74-5
Additional Information	74-7
Simplify Multiply Operations in Array Indexing	74-8
Example Model	74-8
Generate Code	74-8
Generate Code with Optimization	74-9
Replace boolean with Specific Integer Data Type	74-11
Example Model	74-11
Generate Code That Contains the Default boolean Data Type	74-11
Generate Code That Contains the Target boolean Data Type	74-12
Remove Code from Tunable Parameter Expressions That Saturate Against Integer Overflow	74-14

Remove Code That Guards Against Division Exceptions for Integers and Fixed-Point Data	74-17
Optimize Generated Code by Consolidating Redundant If-Else Statements	74-21
Optimize Generated Code for Fixed-Point Data Operations	74-25
Unroll Parallel for-Loop That Has Small Number of Iterations ...	74-27
Optimize Generated Code by Developing and Using Code Replacement Libraries - Simulink	74-30
Improve Execution Efficiency by Reordering Block Operations in the Generated Code	74-51
Optimize SIMD Code by Performing Fused Multiply Add Operations	74-61
Speed Up for-Loop Implementation in Code Generated by Using parfor	74-65
How parfor-Loops Improve Execution Speed	74-65
When to Use parfor-Loops	74-65
When Not to Use parfor-Loops	74-65
Write Code by Using parfor-Loops	74-66

Memory Usage in Embedded Coder

75

Optimize Generated Code Using Minimum and Maximum Values	75-2
Configure Your Model	75-2
Optimize Generated Code Using Specified Minimum and Maximum Values	75-3
Limitations	75-6
Reduce Global Variables in Nonreusable Subsystem Functions ...	75-8
Generate void-void Function	75-8
Generate Function with Arguments	75-9
Optimize Generated Code by Packing Boolean Data into Bitfields	75-11
Optimize Generated Code by Passing Reusable Subsystem Outputs as Individual Arguments	75-14
Convert Data Copies to Pointer Assignments	75-18
Reuse Buffers of Different Sizes and Dimensions	75-22
Remove Reset and Disable Functions from the Generated Code .	75-29
Example Model	75-29

Generate Code	75-30
Enable Optimization	75-30
Control Operator Type in Generated Code	75-32

Code Execution and Stack Usage Profiling in Embedded Coder

76

Code Execution Profiling with SIL and PIL	76-2
Configure Code Execution Profiling	76-2
Control Profiling Granularity	76-3
View and Compare Code Execution Times	76-6
Run SIL Simulation That Generates Execution-Time Metrics	76-6
Code Execution Profiling Report Sections	76-8
View Code Execution Profiles for Multiple Model Blocks	76-14
Compare Code Execution-Time Performance Against Baseline ...	76-16
Visualize Task Scheduling	76-16
Analyze Code Execution Data	76-18
Remove Instrumentation Overheads from Execution Time Measurements	76-20
Approach for Estimating and Removing Instrumentation Overhead	76-20
Remove Instrumentation Overheads by Using target Package ...	76-21
Remove Instrumentation Overheads by Using Functions from rtw.connectivity.Config	76-22
Retrieve Benchmark Results	76-23
Capture Main Profiling Metrics on Target Hardware	76-25
Tips and Limitations	76-27
Triggered Model Block	76-27
Outliers in Execution-Time Profiles	76-27
Hardware-Specific Timer	76-28
Effect of Instrumentation Code on Instruction Cycle	76-28
Task Context Switching Due to Preemption	76-28
Subsystem Code Reuse	76-28
Cannot Load Execution-Time Measurements from Previous Release	76-29
Stack Usage Profiling for Code Generated from Simulink Models	76-30
Benefits of Dynamic Stack Usage Profiling	76-30
Configure Stack Usage Profiling	76-30
Observe Stack Usage of Generated Code	76-31
Implement Driver to Obtain Stack Usage Data During PIL Simulation	76-36

Code Execution Profiling for MATLAB Coder

77

Execution Time Profiling for SIL and PIL	77-2
Generate Execution Time Profile	77-3
View Execution Times	77-4
Code Execution Profiling Report	77-4
Visualize Task Scheduling	77-8
Analyze Execution Time Data	77-9
Extract Execution Time Data for Kalman Estimator Code	77-9
Stack Usage Profiling for Code Generated From MATLAB Code ..	77-13
Benefits of Dynamic Stack Usage Profiling	77-13
Generate Stack Usage Profile	77-13
View Stack Usage Profile From SIL Execution	77-14
Implement Driver to Obtain Stack Usage Data During PIL Execution	77-17
Removal of Unused Class Properties in the Generated C/C++ Code	77-19
Preserve Unused Class Properties by using MATLAB Coder App ..	77-19
Preserve Unused Class Properties at the Command Line	77-19
Usage Notes and Limitations	77-20

Verification

Simulation and Code Comparison in Simulink Coder

78

Simulation and Code Comparison	78-2
Configure Signal Data for Logging	78-2
Log Simulation Data	78-3
Run Executable and Load Data	78-4
Visualize and Compare Results	78-5
Compare States for Simulation and Code Generation	78-7

Code Tracing in Embedded Coder

79

Verify Generated Code by Using Code Tracing	79-2
Traceable Elements	79-2
Traceability in Generated Code	79-3

Traceability Tags	79-5
Operator Traceability	79-6
Traceability Limitations	79-7
Trace Simulink Model Elements in Generated Code	79-8
Code-to-Model Traceability	79-8
Model-to-Code Traceability	79-10
Trace Stateflow Elements in Generated Code	79-12
Inline Traceability for Stateflow Elements	79-12
Bidirectional Traceability for States and Transitions	79-13
Bidirectional Traceability for State Transition Tables	79-15
Bidirectional Traceability for Truth Table Blocks	79-17
Bidirectional Traceability for Graphical Functions	79-19
Code-to-Model Traceability for Events	79-19
Model-to-Code Traceability for Junctions	79-20
Format of Traceability Comments for Stateflow Elements	79-21
Link Generated Code to Requirements	79-24
Reload Existing Traceability Information	79-28
Customize Traceability Reports	79-30
Generate a Traceability Matrix	79-31
Trace Generated Code to Blocks	79-33
Use Traceability in MATLAB Function Blocks	79-35
Extent of Traceability in MATLAB Function Blocks	79-35
Traceability Requirements	79-35
Using Traceability in a MATLAB Function Block	79-35

Component Verification in Embedded Coder

Model Architecture and Design

Software Deployment Fundamentals

Software Deployment Concepts

Component Models

A component model is a top-level model that represents an application algorithm. From a component model, the code generator produces code that has a well-defined programming interface for interacting with other platform environment software. Embedded Coder software produces component model code that you can deploy to run on or integrate as part of an embedded system platform.

A component model:

- Is a construct that you can design and configure such that the code generated for the component aligns with platform requirements.
- Publishes its interface to interact with other platform environment software.
- Can include subcomponents, such as reference models and subsystems, that interact within the context of the parent component model.
- Can be part of a system composition.

High-level requirements of component models can include:

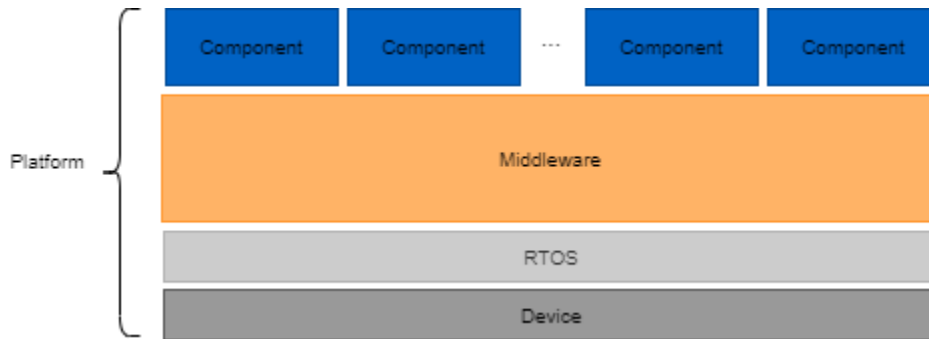

- Startup and shutdown events
- Periodic and aperiodic execution
- Communication services that safely handle access to data, including data that is shared by tasks or threads that execute concurrently
- Nonvolatile memory service
- Timer services
- Programming interface customizations for accessing data

For more information about developing component models for deployment, see:

- “Components”
- “Subcomponents and Utilities”
- “External Code Import”

- “Standards, Guidelines, and Block Usage”
- “Modeling Patterns for C Code Constructs”
- “Blocks for Embedded Targets”
- “Software Component Modeling”

Platforms

A platform is the environment consisting of the device and software on which your deployed software runs. As this figure shows, the software might include a real-time operating system (RTOS), middleware, and other component code.

Target platforms for embedded system applications vary in complexity. A platform consists of a combination of the parts listed in this table.

Parts of Platform Environment	Examples
Device	<ul style="list-style-type: none"> • Development computer • Rapid-prototyping board • Microprocessor • Microcontroller • FPGA • ASIC
Processor cores	<ul style="list-style-type: none"> • Single • Multiple
Processing	<ul style="list-style-type: none"> • Single • Multiple
Operating system	<ul style="list-style-type: none"> • General-purpose operating system • Real-time operating system (RTOS) • None (bare metal)
Scheduling	<ul style="list-style-type: none"> • Periodic, single-tasking • Periodic, multitasking • Asynchronous • Initialize, reset, terminate
Middleware	<ul style="list-style-type: none"> • Scheduling support • Communication • Data management • Authentication • Other services or capabilities not offered by operating system
Application algorithm code	<ul style="list-style-type: none"> • Generated from a model • External code

To ensure an optimized and accurate model design and to accurately configure the model for code generation, you or someone else contributing to your project must identify the parts, characteristics, and requirements for your application to interface with the target platform.

Platform Specifications

A platform specification informs the code generator about platform requirements, such as:

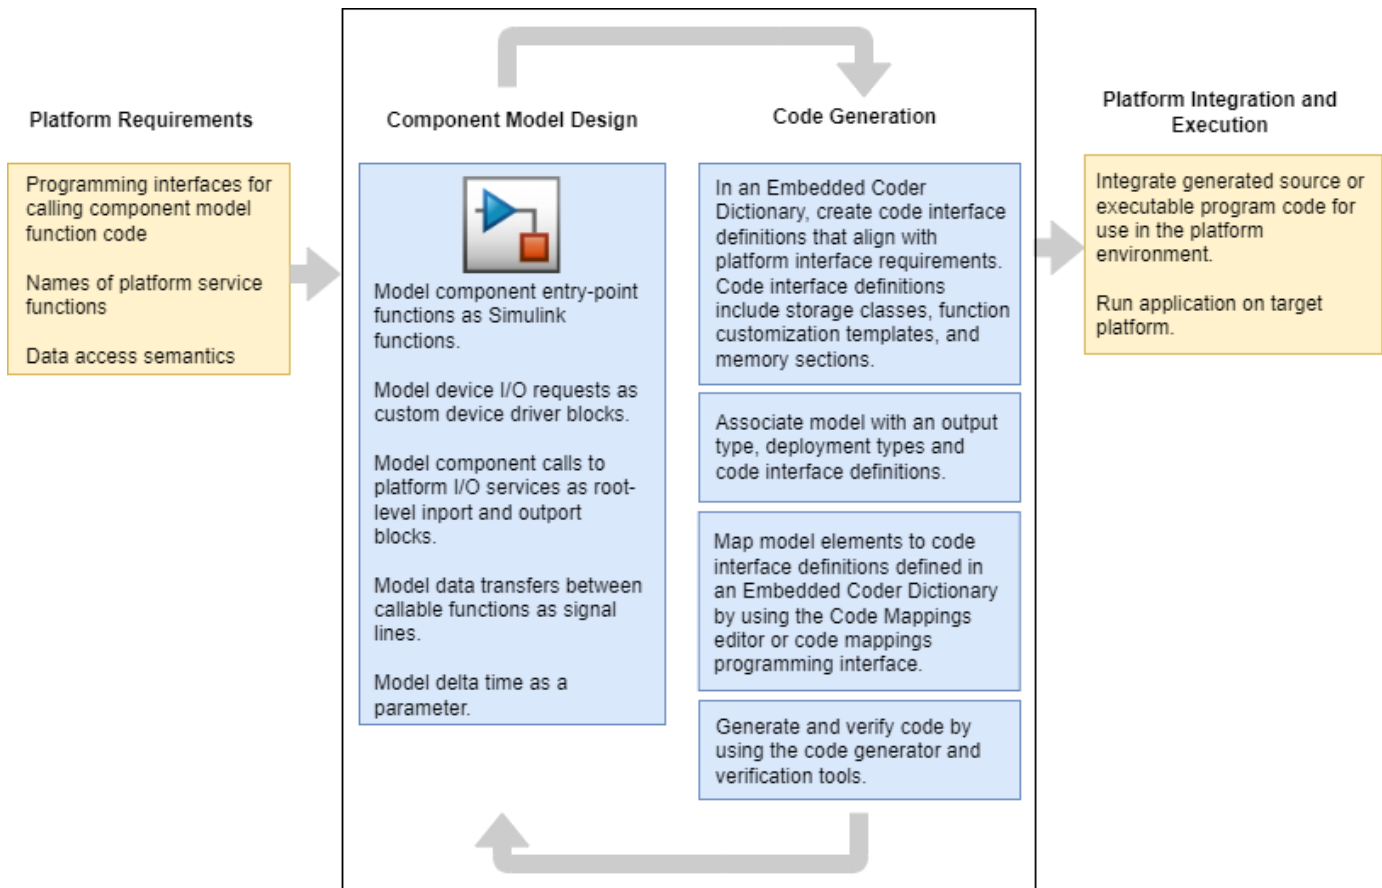

- How to name function entry points (callable functions)
- Names of service functions that your application can call
- Data communication methods, which define an interface contract between platform services and generated code

You make the code generator aware of the platform requirements by using a combination of:

- Modeling elements in your component model
- Code interface definitions (storage classes and function customization templates) in an Embedded Coder Dictionary
- Code interface configurations in your component model code mappings

This figure shows the relationship between:

- Platform requirements (the input to the component deployment process)
- Platform specification (how you use Simulink and Embedded Coder tooling to communicate the platform requirements to the code generator)
- Platform integration and execution (what you do with the code generator output)

Platform Middleware

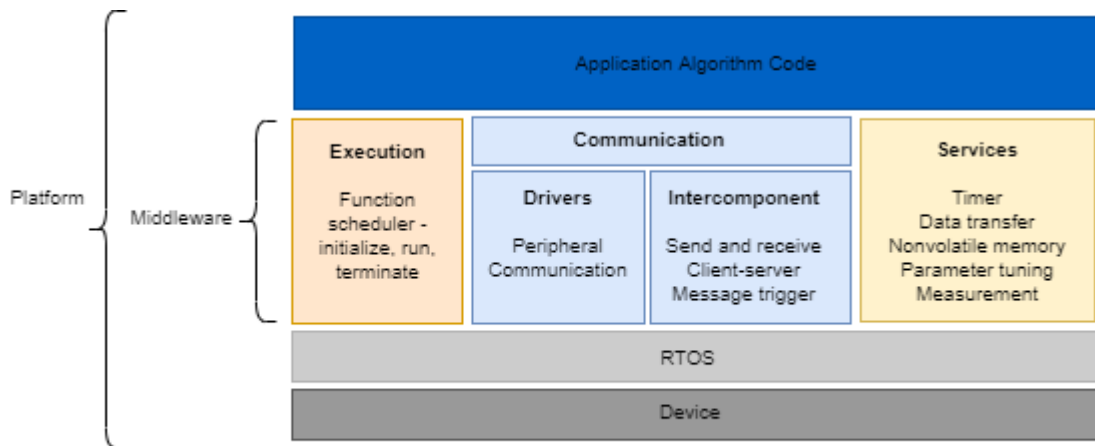

Platform middleware is a collection of services that supplements tasks performed by an operating system to support the execution of applications. For example, a platform schedules generated application code by using scheduling and data transfer services.

If you design and configure a component model according to recommended guidelines, the code generator produces code that aligns with integration requirements of a specific platform. To generate and deploy such code, you must consider platform middleware requirements as you design the component model and define and configure code interfaces.

The middleware of a platform can consist of these types of services:

- Scheduling and task execution services
- Communication services, including support for device driver, send-receive, client-server, and message-trigger communication
- Optional services, such as timer, data transfer, nonvolatile memory, parameter tuning, and measurement services

This figure shows layers of platform middleware services for a platform.

Embedded system applications typically interact with middleware that consists of these services.

Service	Description
Scheduling	Selects a task to execute based on a sample time (period/offset) or an event and execution order. Goals of the service include maximizing throughput, minimizing wait time, minimizing latency, maximizing fairness, and meeting deadlines.
Data receive	Receives input data from another component or from nonvolatile memory.
Data send	Sends output data to other components or to nonvolatile memory.
Data transfer	Handles sharing of data between callable functions. The service takes complete ownership of this data including the setting of initial values.
Nonvolatile memory	Reads data from and writes data to nonvolatile memory.
Timer	Implements aspects of time, such as timer resolution, absolute time, and elapsed time (function step size).
Parameter tuning	Enables access to and the ability to change parameter values while an application executes.
Measurement	Enables access to and the ability to read signal data while an application executes.

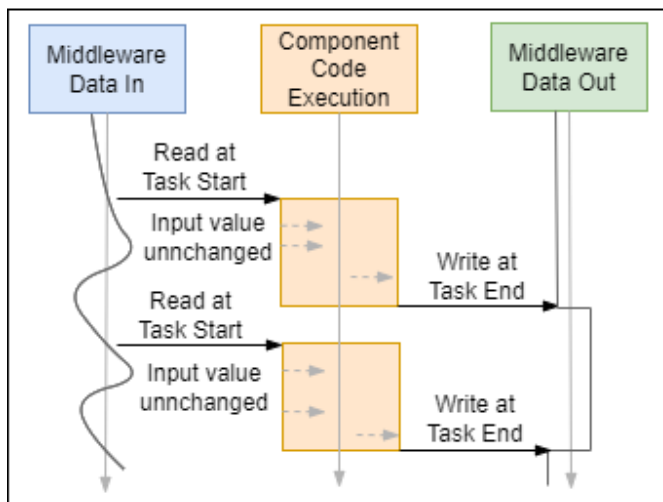

To interact with a service, a component model must include specific model elements that represent an interface to the service. In some cases, you might also need to configure the model elements in a specific way. For example, you can represent the interface for data receive service by using a root-level inport that is configured with a storage class.

The modeling guidelines that are provided in the Component Deployment Guidelines for Embedded Coder Support Package describe how to represent interfaces for the different services in component models intended for function platform deployment.

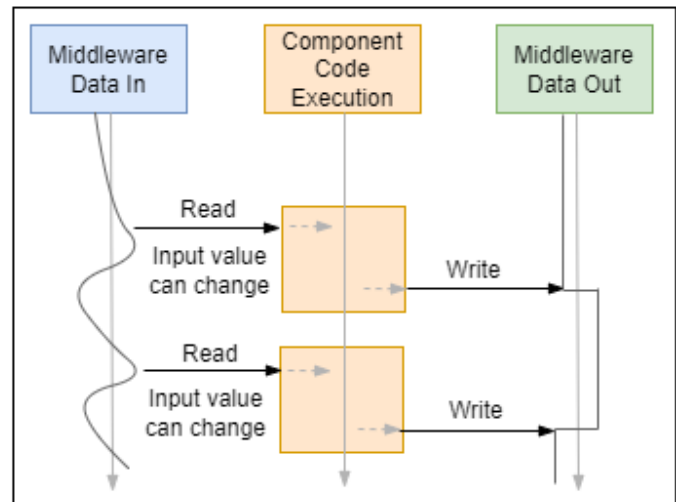

Platform Service Data Communication Methods

When designing a component model, for some platform services, you must consider data communication methods that the platform services use. Data communication methods are direct-access, outside-execution, and during-execution. These methods coordinate the communication of data for tasks, including concurrent access to data. The direct-access method specifies that a component accesses data directly from memory provided by the platform services. This figure shows differences between the outside-execution and during-execution communication methods.

Platform Outside-Execution Behavior

Platform During-Execution Behavior

For each data communication method, this table describes the platform service behavior and the expected corresponding behavior of generated code that uses a service that applies the data communication method.

Data Communication Method	Platform Service Behavior	Generated Code Behavior
Direct access	<ul style="list-style-type: none"> Provides generated functions that have direct access to data that is stored in platform memory. Memory is persistent for the duration of a power cycle. Assumes that generated functions do not access a memory buffer concurrently. Does not apply data concurrency safeguards. Maximizes performance. 	Communicates with other functions directly by using memory that the platform manages.

Data Communication Method	Platform Service Behavior	Generated Code Behavior
Outside execution	<ul style="list-style-type: none"> • Applies data concurrency safeguards. • Communicates data to other functions outside (before and after) function execution. • Favors memory optimizations over data freshness. 	<ul style="list-style-type: none"> • Communicates with other functions indirectly. • Interacts with memory provided by the platform.
During execution	<ul style="list-style-type: none"> • Applies data concurrency safeguards. • Communicates data to other functions immediately during function execution. • Favors data freshness over memory usage. 	<ul style="list-style-type: none"> • Communicates with other functions indirectly. • Interacts with platform services by using its local memory.

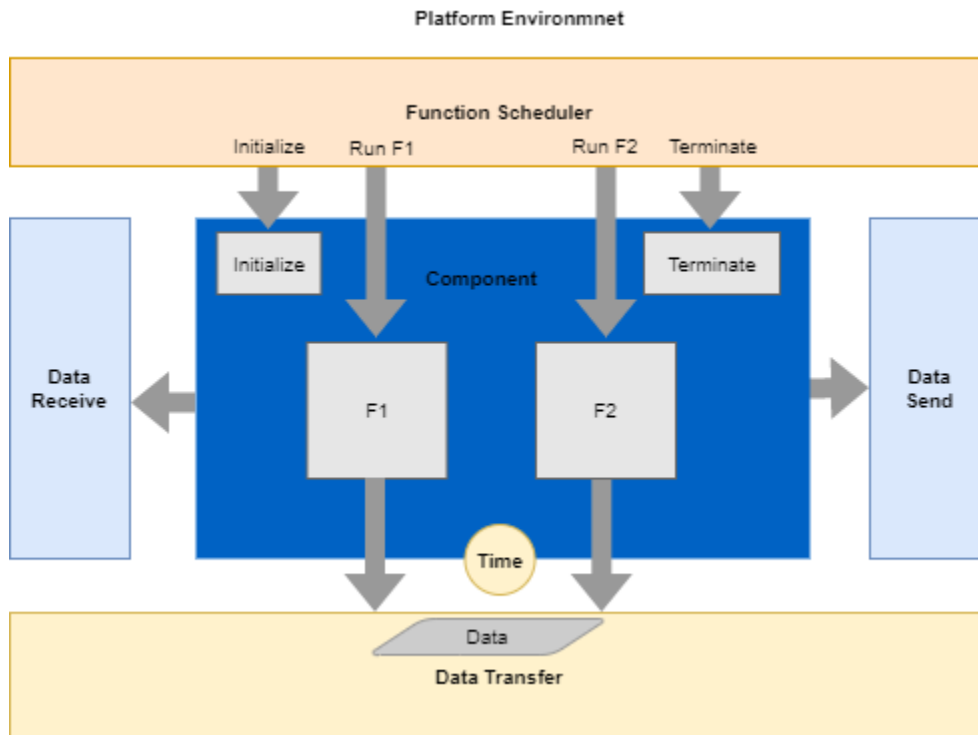

Design your component model and configure model data elements based on the data communication methods that the platform services apply.

Component Platform Interfaces

Design a component model such that the code generator produces code that is prepared to integrate and interface with middleware and other component code that runs on your target platform. For example, for function platform deployment, modeling guidelines provided in the Component Deployment Guidelines for Embedded Coder Support Package identify model elements and model element configurations for target platform execution, communication, and other service requirements. When you design and configure a component based on the guidelines:

- The code generator produces a collection of callable entry-point functions that align with platform scheduler service calls.
- Within the generated function code, calls to platform service functions align with the service programming interfaces.
- The generated function code honors data communication methods that platform services use.

This figure shows the interaction between a component and platform services in a platform execution environment.

The arrows indicate the direction of function interface calls. The platform function scheduler calls component entry-point functions: `Initialize`, `F1`, `F2`, and `Terminate`. The component calls platform services to read input, write output, transfer data between callable functions, and get time values.

Choose Software Deployment Workflow

Embedded Coder provides capabilities for customizing the code generation environment for a project and for deploying component software generated from Simulink models.

Choose the workflow that aligns with your goal (customization, component deployment, or both). For more information, see “Code Generation Environment Customization” on page 1-11 and “Component Deployment” on page 1-13.

Code Generation Environment Customization

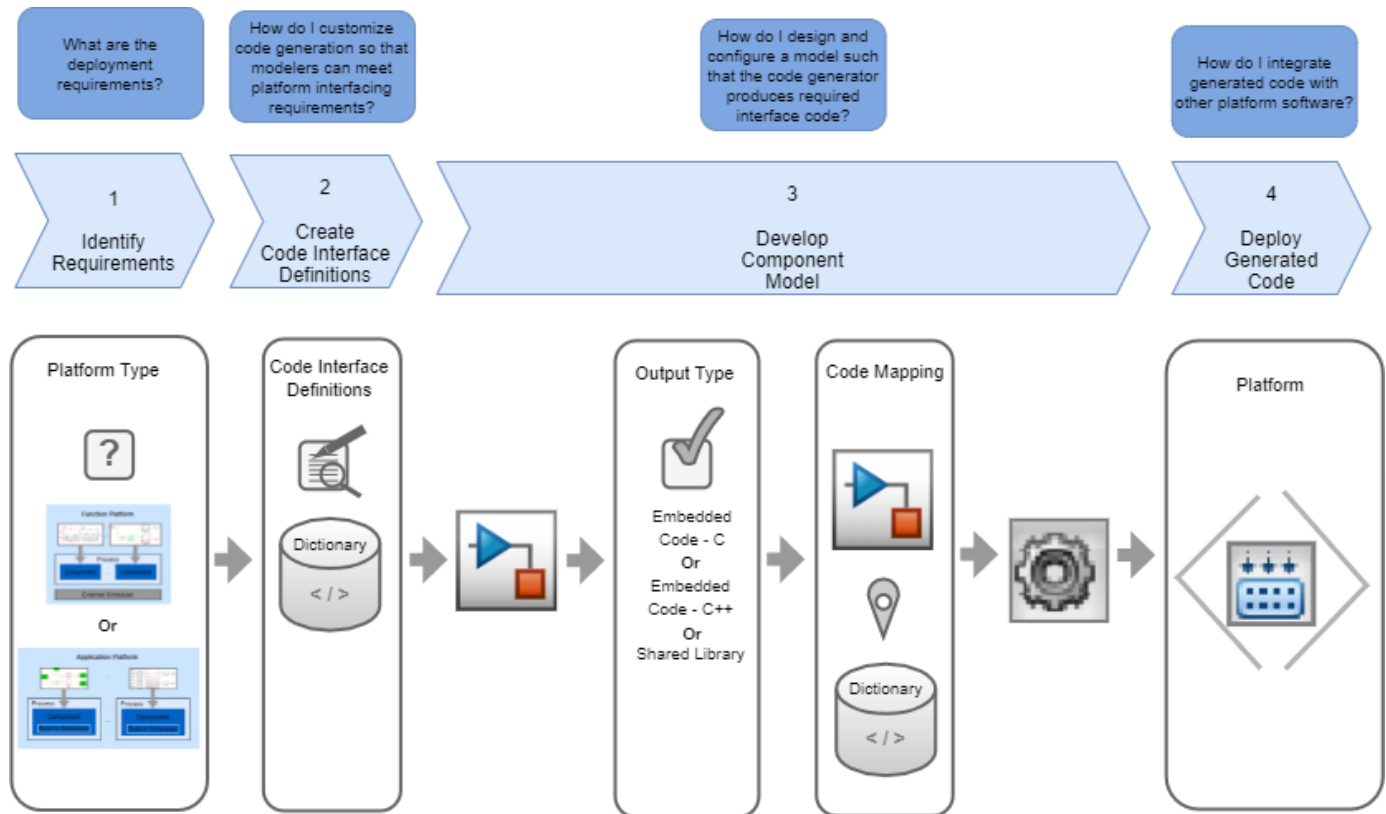

If you are responsible for customizing the code generation environment for a component deployment project or for component deployment across an organization, consider these options.

Customization Goal	Description	More Information
Data representation	Customize how the code generator stores data, including matrices and arrays. Control the naming and placement of data types in generated code.	"Data Representation"
Code interface definitions	Create data, function, and memory section code generation definitions (for example, storage classes) for standardization and software architecture conformance.	"Code Interface Definitions"
Code replacement	Create and maintain code replacement libraries that control how and when the code generator replaces code that it generates for functions and operators.	"Code Replacement Customization"
Model configuration settings	Establish standard model configuration parameter settings that define how the code generator produces and compiles code from models.	"Model Configuration Set Customization"
Custom blocks	Define code generation behavior for custom blocks by developing S-functions.	"Code Generation for Custom Blocks"
Target Language Compiler	Use the Target Language Compiler to customize generated code, inline code generated for S-function blocks, and generate additional or different types of files.	"Target Language Compiler"
Target platform devices	For a target platform device, select a system target file that specifies required target platform environment and code features, use the <code>target</code> package to extend the range of hardware that the code generator supports, and configure the code generator to use code replacement libraries.	"Target Platform Device Customization"
Code compilation	Customize the compilation stage of the build process by using a toolchain or template makefile approach.	"Code Compilation Customization"

Customization Goal	Description	More Information
Custom software for target hardware	Create software that supports the deployment of MATLAB® and Simulink designs to hardware platforms. Register custom toolchains for the build process, customize XCP server software for target hardware, and create a target hardware application that checks the validity of code generation assumptions. Use the target package to extend the range of supported hardware and provide connectivity between Simulink and your target hardware for external mode and processor-in-the-loop (PIL) simulations.	“Custom Software for Target Hardware”

Component Deployment

Simulink provides capabilities for designing and deploying component models as generated code that behaves in a target platform environment the same way as the model during simulation. This figure shows the steps required for component deployment by using Simulink and Embedded Coder.

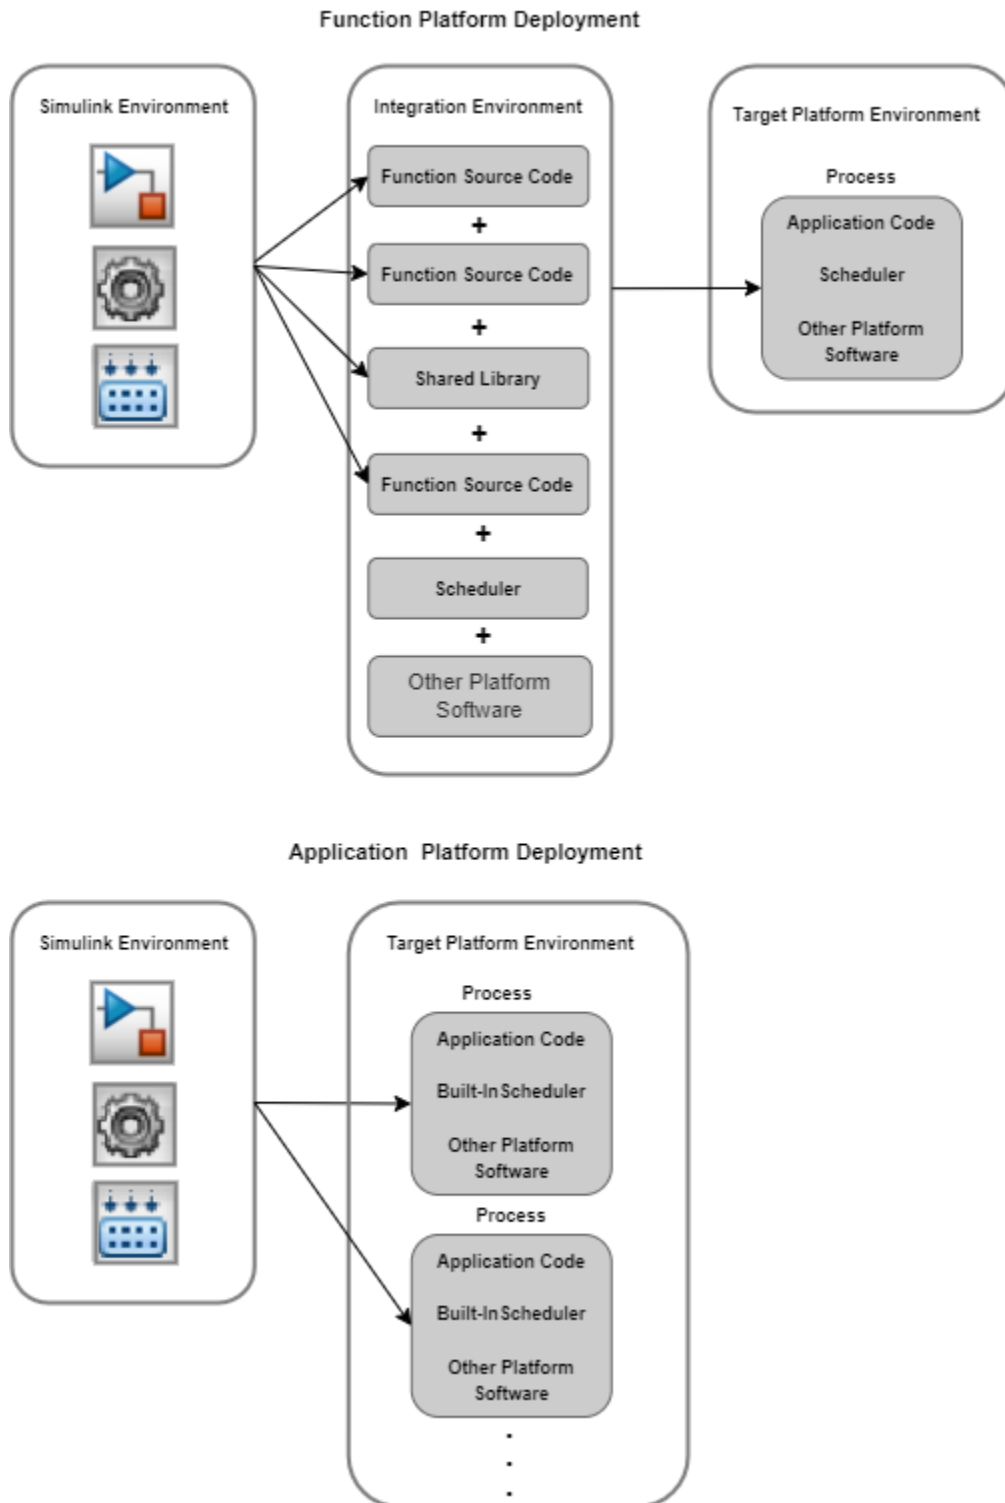

Step	Goal
Identify requirements	Assess project requirements and identify the platform type for your deployment.
Create code interface definitions	Create a specification that informs the code generator about interface code requirements for the target platform environment.
Develop component model	Design a component model, associate the model with a platform definition, and generate and verify component code.

Step	Goal
Deploy generated code	Deploy generated source code modules for integration with external application and platform source code. Deploy generated source code modules or executable programs. Deploy generated executable programs to run as standalone executable programs in a single-process environment or for integration with other applications in a multiprocessing environment.

Identify Requirements

Identify the requirements for your project. The requirements help you identify the type of platform deployment. Embedded Coder provides tools to deploy component models as generated code for function platform deployment or application platform deployment. The first consideration is which type of platform deployment meets scheduling and other needs of your project.

This figure shows a primary difference between the two types of platform deployment. Function platform deployment requires integration of generated function code with an external scheduler and other platform software. When you generate code for application platform deployment, the resulting code includes a built-in scheduler and can be built into a deployable executable program.

Code that you generate for an application platform can run on a single-process or multiprocess architecture as part of a real-time or non-real-time application. For a single-process architecture, the generated code is optimized for a specific target device and meets hard real-time requirements.

Multiprocess deployment addresses requirements of high-throughput and distributed execution applications.

This table lists requirements and conditions that apply to each platform type. Use the information in the table to identify the platform that best aligns with your application requirements.

Requirements and Conditions	Platform Type
<ul style="list-style-type: none"> • You generate C source code. • You deploy the C source code module generated for a component model. • You hand off the generated component code for integration with an external platform scheduler and other platform services. • The integrated code runs on a single-process architecture. 	Function
<ul style="list-style-type: none"> • You generate C or C++ source code. • You deploy a generated executable program to run on a single- or multiprocess architecture as part of a real-time or non-real-time application. • The generated code for a model replicates the simulation scheduler and optimizes the scheduling code for single-tasking, rate-monotonic multitasking, or concurrent execution, depending on the model configuration. • For single-process architectures, the generated code is optimized for a specific target device. • You are deploying code to a single-process architecture for rapid prototyping, hardware-in-the-loop (HIL) simulation, or production code that runs as a complete, hard real-time application. • You are deploying code to a multiprocess architecture for an application that requires high throughput or distributed execution. 	Application

For more information about assessing project requirements, see “Map Embedded System Architecture to Simulink Modeling Environment” on page 1-29.

Create C Code Interface Definitions

For C code generation, code interface definitions inform the code generator about requirements for the appearance, placement, and behavior of component interface code. To generate component interface code that aligns with specific target platform requirements, you or someone in your organization must define a platform definition. Embedded Coder provides predefined platform definitions for generating application executable programs, which include scheduling support, and shared libraries. You can create definitions for function and application platforms.

After researching code interface requirements, you create code interface definitions by using the Embedded Coder Dictionary. Types of code definitions that you should create depends on your project requirements and deployment goal. You can create these types of definitions:

- Memory sections
- Storage classes
- Function customization templates

The code generator uses the code definitions as a specification for producing interfaces that appear in the generated C code as:

- Entry-point function prototypes for periodic or aperiodic execution functions
- Entry-point function prototypes for initialize, reset, and terminate functions
- Variable assignments
- Get and set data access functions

For information about using the Embedded Coder Dictionary and Custom Storage Class Designer, see “Code Interface Definitions”.

Research for Code Interface Requirements

Research the required component interactions with your target platform. Identify sources of input and required output. Determine what the code for interfacing with other platform resources must look like and how it must behave. For example, does your model or generated code need to exchange data with platform software? If so, map inputs, outputs, and parameters to the external function interface. Typical function interfaces involve function arguments and return values, global variables, and access functions.

This list of questions can help you identify interface requirements that are relevant to component deployment.

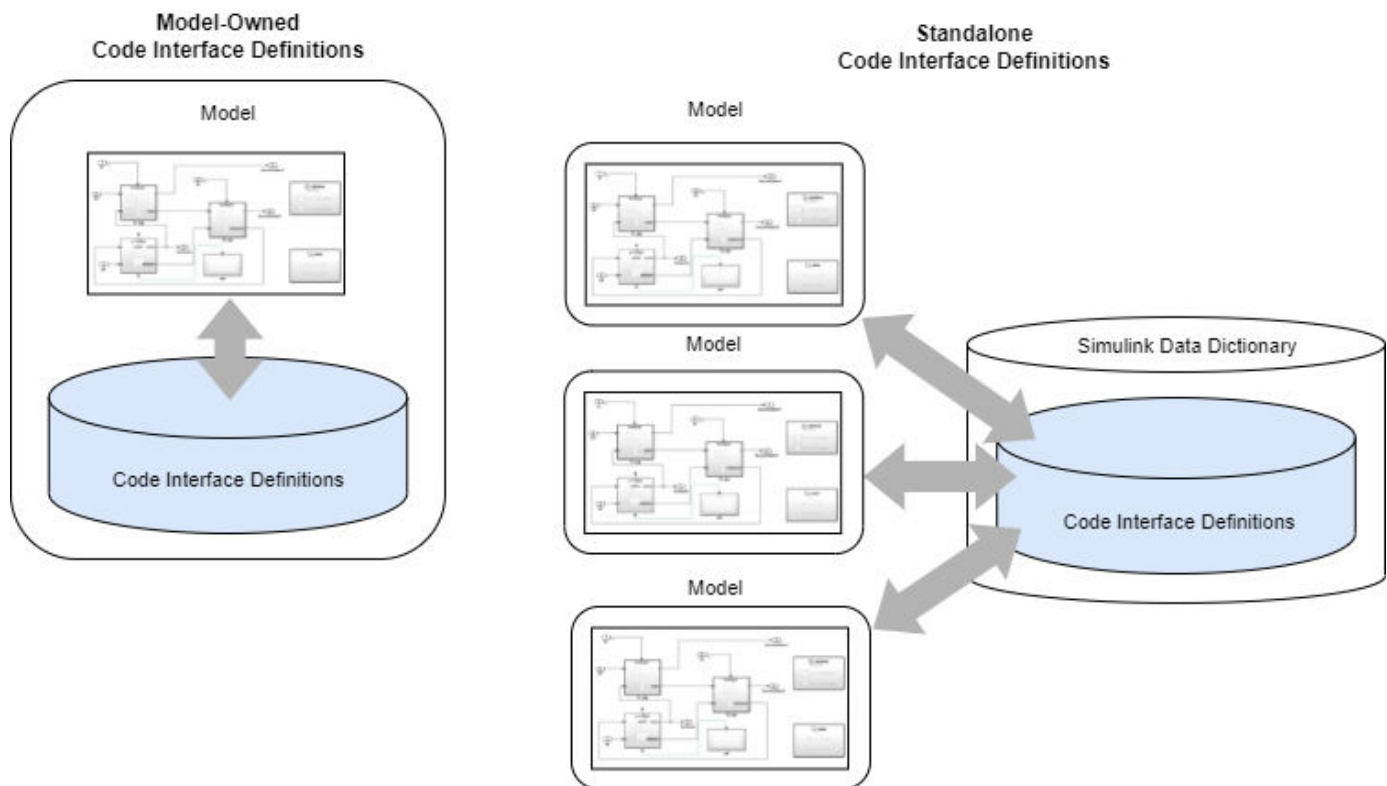

- What platform software will the component interact with? For example, does the platform software include an operating system? What platform middleware services are available?
- Does the platform expect the component to handle startup or shutdown events?
- Does the platform have naming requirements for entry-point functions that it calls to initiate component execution?
- What are the names of the service functions that a component needs to call to use platform services?
- What methods (semantics) do platform services use for handling concurrent access to data when communicating with components?
- Does the platform expect component input and output to be represented as arrays, structures, or enumerated types? In the Simulink environment, you can represent these types as vectors, buses, and IntEnum, respectively.
- Is fixed-point support required? If you use the Simulink fixed-point interface, you can scale and specify offsets.
- Does the platform software use company-specific data types? If yes and you have Embedded Coder software, create alias types to represent those types. The code generator uses the alias types in the code that it produces. For example, once defined, you can specify an alias type in a function prototype, for a temporary variable, or for block output.
- Does the component need to exchange data by using shared memory? If yes, define and use memory sections.
- Does the platform require that component code optimize memory usage when sending data?
- Does the platform require access to variables that represent component parameters or signal data for tuning or measurement purposes? If so, how does the platform expect the data to be represented in component code? Does the data need to reside in a specific header file?
- Does the platform architecture support single-processing only or multiprocessing as well?

- Does the platform application code consist of multiple component source code modules developed independently and integrated manually with a platform function scheduler? Or, is the platform application code a generated executable program that runs a standalone executable program on the platform device (single-processing) or as a collection of executable programs that run concurrently in a multiprocessing architecture?

For some projects, these requirements are captured in an interface control document (ICD). An ICD provides the details about the interfaces between application components and between application components and platform services.

Options for Code Definition Storage

Code interface definitions for a component model can reside within a model (model-owned) or in a Simulink data dictionary (standalone).

Model-Owned Code Interface Definitions

By default, Simulink associates a component model with model-owned code interface definitions. Model-owned code interface definitions apply to the owner component model only. You can customize these definitions. Use model-owned code interface definitions for models of smaller scope and that do not share interface requirements with other component models. To customize the default model-owned coder dictionary, on the Embedded Coder app toolstrip, click **Code Interface > Embedded Coder Dictionary**.

Standalone Code Interface Definitions

Standalone code interface definitions:

- Reside within a Simulink data dictionary.
- Are independent of the component. The model and dictionary that contains the definitions are separate entities.
- Can be associated with multiple component models.

The separation of the model and code interface definitions enables you to:

- Standardize code generated from models designed across your organization for a specific target platform.
- Generate code that meets requirements of different target platforms from a model.

Because the dictionary that contains code interface definitions and the model are separate entities, the dictionary must be linked to the model. Depending on how you create the dictionary, the link might be set up automatically (see “Deploy Code Generation Definitions” on page 31-10). Once a component model is associated code interface definitions, you can map model interface elements to storage classes and function customization templates.

To create standalone code interface definitions, in the Model Explorer, click **New > Create Embedded Coder Dictionary** or in the Configuration Parameters dialog box, click the **New** button to the right of the **External coder dictionary** parameter.

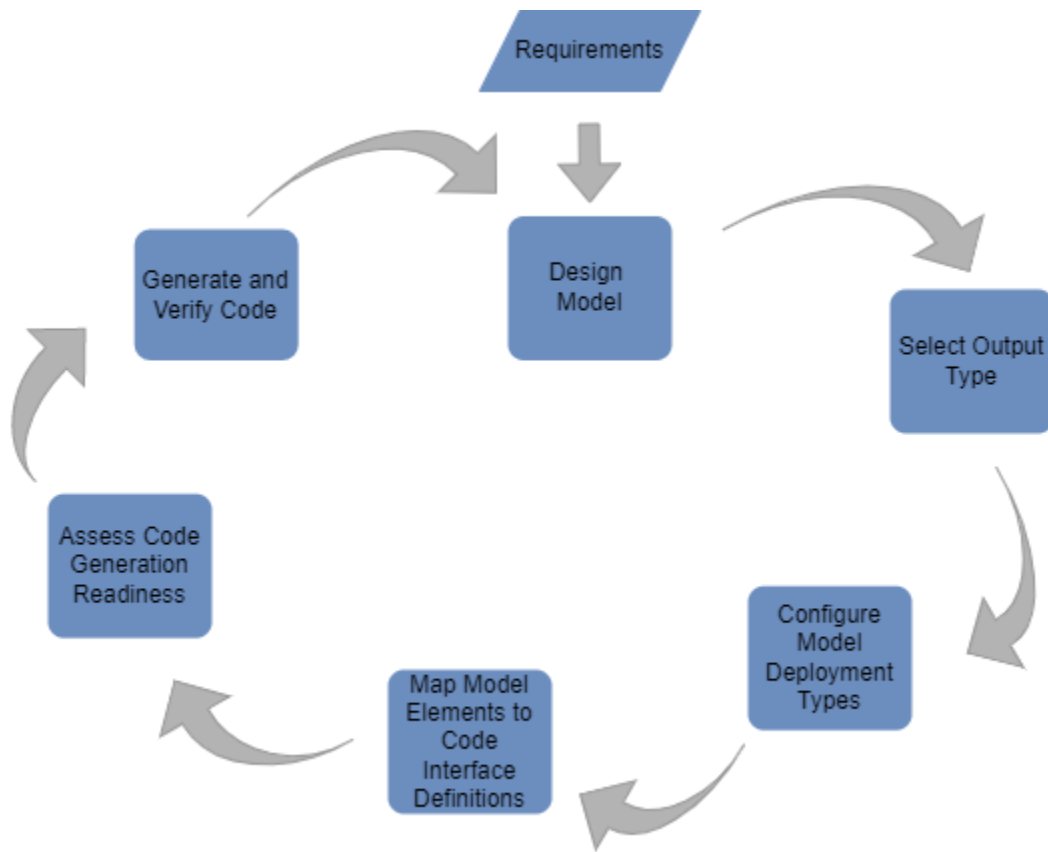

Code Interface Definitions for Data Objects

To create code definitions for data objects that you store in the base workspace or in a Simulink data dictionary, use the Custom Storage Class designer to create a definition in a package. For these data objects, you apply code generation settings to the data object instead of applying them in the mapping of a model. When an item in a model uses the data object and its code generation settings, the code mapping for the item reflects the specification of the data object.

If you want to use the same code generation definition in model code mappings and in data objects, you do not need to store one copy of the definition in an Embedded Coder Dictionary and another copy in a package. Instead, store the definition in a package (by using the Custom Storage Class Designer). Then, configure one or more Embedded Coder Dictionaries to refer to the definition in the package. When you want to make changes to the definition, you make the changes in only one place, the package.

Develop Component Model

This figure shows the steps for developing a component model that you intend to deploy as generated code.

To develop a component model for deployment, iterate through these steps until the generated code meets interface requirements.

Step	Goal
Design model	Decompose algorithm into subcomponents and identify relevant utilities. Choose and implement a modeling style and modeling patterns that align with how you intend to deploy the generated component code. Apply relevant component modeling guidelines.
Select output type	Select an output type for code generation. Depending on the deployment goals for a model, an output type specifies one or a combination of the system target file to apply, programming language of the output, or platform middleware, such as AUTOSAR or DDS. For information about AUTOSAR or DDS, see “AUTOSAR Blockset” and “DDS Blockset”.
Configure model deployment types	Specify a deployment type (component or subcomponent) for each model in your component model hierarchy. Often, you can accept default deployment type settings.

Step	Goal
Map model elements to code interface definitions	Map model elements to interface definitions that correspond to the selected output type. For example, for the C language, available interface definitions are defined in the Embedded Coder Dictionary associated with the model. The mappings serve as an interface configuration, informing the code generator about appearance, placement, and behavior requirements of the code for model elements.
Assess code generation readiness	Use the Model Advisor to check whether the component model is ready for code generation. Use the Code Generation Advisor to check and configure a model for code generation application objectives, such as traceability or debugging.
Generate and verify code	Generate code and confirm that the output meets the interface requirements.

Component modeling guidelines and tooling facilitate development of component models that you intend to deploy as:

- C function source code modules that are integrated with a platform function scheduler and other platform services that run in a single-processing environment.
- Standalone executable program that replicates the simulation scheduler and optimizes scheduling code for single-tasking, rate-monotonic multitasking, or concurrent execution, depending on the model configuration. The executable program runs as a single-process or multiprocess application. Code for a single-process application is intended to run on a specific target device.

When deploying a component model to a function platform, you develop each component model in isolation. Then, you or someone else in your organization integrates the generated function code into a complete application program at the source code level.

For function platform deployments, the Component Deployment Guidelines for Embedded Coder Support Package provides guidelines and tools to help produce code that aligns with these aspects of the platform services:

- Interface of generated callable entry-point functions
- Interface of calls to service interface functions
- Data communication methods

Design Model

You can design models for code generation where the code generator uses code interface mappings to produce code that aligns with a target platform environment.

To start the design work for a component deployment project, partition the project into components and subcomponents. Also identify potential utilities.

Deployment Type	Description
Component	Top-level model that represents an application algorithm. The composition of a component can include subcomponents, such as reference models and subsystems that interact within the context of the parent component model. A component can be part of a system composition. From a component, the code generator can produce code that interacts with other platform environment software. The code generator produces component model code that you can deploy to run on an embedded system platform or integrate as part of an embedded system platform.
Subcomponent	Part of an algorithm that is captured within a component model and runs as part of the model. You model a subcomponent as a reference model, subsystem, or linked subsystem. The parent component gains access to subcomponent code by using subcomponent entry points. Code generated for subcomponents is not accessible to the target platform environment. The code generated for a subcomponent is dependent on code for the parent component model. If a subcomponent uses shared data and runs in multiple execution contexts, the subcomponent code must use data transfer services prescribed by the target platform.
Utility	<p>Reusable function that a program can call from a location in the code without knowing the target platform environment. You model a utility as a library subsystem that adheres to specific modeling constraints. The code generator uses the constraints to produce code that is free of platform context requirements. Include utilities in model compositions when you want to:</p> <ul style="list-style-type: none"> • Generate code for a set of reusable components that models can share • Lock down the interface for a subsystem • Make a model the owner of its generated code
Simulation only component	A model, such as a plant model or test harness, used to simulate component models.

High-level requirements of a component model can include:

- Startup and shutdown events
- Periodic and aperiodic sample rates
- Communication services that safely handle access to data, including data that is shared by tasks or threads that execute concurrently
- Nonvolatile memory services
- Time and delta time services
- Programming interface customizations for accessing data

The deployment type of a model determines how the model constructs map to platform interfaces and the rules for peer interaction and scope for data and function accessibility for models in the hierarchy. For each model in the hierarchy, you select a deployment type based on the role of the model.

Choose and implement a modeling style and modeling patterns that align with how you intend to deploy the generated component code. Apply relevant component modeling guidelines. The Component Modeling Guidelines for Embedded Coder Support Package provides component

modeling guidelines for function platform deployment. The guidelines help you design component models from which the code generator produces code that can integrate and interface with middleware and other component code that runs on your target platform. The guidelines identify model elements and model element code configurations for target platform execution, communication, and other service requirements. When you design and configure a component based on the component modeling guidelines:

- The code generator produces a collection of callable entry-point functions that align with platform scheduler service calls.
- Within the generated function code, calls to platform service functions align with the service programming interfaces.
- The generated function code honors data communication methods that platform services use.

For more information, see “Architecture and Component Design”.

Select Output Type

When using the coder app, before you generate code for the loaded component model, you must select an output type. Available output types are listed in the toolstrip **Output** menu. For more information, see “Select Output Type” on page 1-23.

Configure Model Deployment Types

A model deployment type determines rules for peer interaction and scope for data and function accessibility for models in the model hierarchy. For each model in the hierarchy, you select a deployment type based on the role of the model.

Role of Model	Deployment Type
Publish execution, communication, and service code interfaces according to the specified output type so the component can interact with other components in the target platform environment.	Component
Referenced by and runs as part of the parent component model. Execution and communication interfaces are accessible within the context of the parent component model only. Generated code is not accessible to the target platform environment.	Subcomponent

In the Embedded Coder app toolstrip, the **Deployment Type** field shows the deployment type of the currently loaded model. You can use that field to change the deployment type. To review or set the deployment types for models throughout the model hierarchy, from the **Deployment Type** menu, select **Set Up Deployment Type for Model Hierarchy**. For more information, see “Configure Deployment Types for Model Hierarchy” on page 40-26.

Map Model Elements to Code Interface Definitions

After you associate a component model with a platform definition, you can map model interface elements to storage classes and function customization templates by using the Code Mappings editor or code mappings programming interface. See:

- “C Code Generation Configuration for Model Interface Elements” on page 32-2
- **Code Mappings Editor - C**
- `coder.mapping.api.CodeMapping`

- “Interactively Configure C++ Interface” on page 41-2
- “Programmatically Configure C++ Interface” on page 41-25
- `coder.mapping.api.CodeMappingCPP`

Assess Code Generation Readiness

Verify that your component model is ready for code generation by using the Model Advisor and Code Generation Advisor. The Model Advisor checks to assess readiness to generate code. General Embedded Coder checks are available in Embedded Coder and checks for function platform deployment are available as part of the Component Deployment Guidelines for Embedded Coder Support Package.

The Code Generation Advisor checks and configures your model for code generation application objectives such as traceability or debugging.

For information about using Model Advisor, see:

- “Check Your Model Using the Model Advisor”
- “Embedded Coder Checks”
- Component Deployment Guidelines for Embedded Coder Support Package

For information about using the Code Generation Advisor, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 46-2.

Generate and Verify Code

Generate code. To verify whether the code aligns with code interface requirements, use the code view pane in the coder app and the generated Code Interface Report. Several other tools are available for other types of verification, such as profiling code execution, testing for numeric equivalence between simulations and code execution, and checking for unintended functionality.

For more information, see:

- “Code Generation”
- “Verification, Testing, and Certification”

Deploy and Integrate Generated Code

After you generate and verify code, deploy it. The steps involved with deploying generated code depends on whether you are deploying to a function or application platform.

Platform Type	Deployment Goals
Function	Integrate generated source code module with other code that runs on the platform.

Platform Type	Deployment Goals
Application	<ul style="list-style-type: none"> • Run generated executable program on the platform as a standalone application. • Integrate generated executable program to run with other application code on the platform. • Customize generated source code to integrate with other application code that runs on the platform. In this case, you might use the generated example <code>main</code> as a starting point for developing a custom <code>main</code> program.

For an application platform, by default, the code generator produces an example application `main` function that you can customize. For function platform deployment, you must integrate your generated code with an external `main` program. You might choose to do the same for source code that you generated for an application platform. For an embedded system, the `main` function:

- Defines function interfaces (function prototypes).
- Includes files that declare external data.
- Defines extern data.
- Initializes data.
- Calls simulated or actual hardware.
- Calls algorithmic functions.

Integrate Generated Component Code with Platform Code

To integrate generated component code with a `main` function and other platform and application code, you must:

- Match the data and function interfaces of the generated code with other interfaces of existing system code.
- Connect input data.
- Connect output data.
- Access other data, such as block state values, local parameters, and time.

Design and configure the component model such that generated code aligns with the code interfaces of the target platform code. For example, if your platform code defines a global variable for storing output data and the generated code reads that data as input, you can configure the corresponding inport so that the generated code interacts with the existing variable. The platform environment that calls the entry-point functions must provide input signal data and, depending on your application, scheduling information. The generated algorithm calculates output data that the calling environment can use. The platform environment and the algorithm can exchange this data by using global variables or formal parameters (arguments). The set of input and output data and the data access mechanisms constitute the interfaces of the entry-point functions. When you understand the code interfaces and how to control them, you can:

- Generate code that can be called by other component code and platform services.
- Write code that calls the generated code.
- Generate reusable (reentrant) code that you can call multiple times in a single application.
- Integrate the generated code with other, external code in your application.

In a model, root-level inports and outports represent the primary inputs and outputs of the component algorithm. By default, the code generator aggregates this input and output data into standard structures. For examples, see “Configure Generated Code According to Interface Control Document Specifications” on page 37-54 and “Integrate External Application Code with Code Generated from PID Controller” on page 37-45.

For more information, see “Deployment, Integration, and Supported Hardware”.

Review Generated Interface Code

Confirm that the code generator produces expected interface code by reviewing the Code Interface Report. The report describes the generated code interface, including interface information for:

- Each component model entry-point function (function name, prototype, timing information, arguments, return value, and header file)
- Each model root-level inport and root-level outport (block name, code identifier, data type, scaling information, and dimensions)
- Tunable parameters that are associated with the model (data store source, code identifier, data type, scaling information, and dimensions)
- Global data stores and data stores with non-auto storage that are associated with the model

Configure the code generator to produce a Code Interface Report as part of the generated HTML report.

For more information about the report, see “Analyze the Generated Code Interface” on page 51-13.

Get Meta Information About Generated Code

By default, the code generator creates a code descriptor file (`codedescriptor.dmr`) in the build folder. That file contains meta information about the generated code, including:

- Data interfaces (inports, outports, parameters, data stores, and internal data)
- Function interfaces (initialize, output, update, and terminate)
- Execution information for the data and function interfaces, such as timing requirements
- Model hierarchy information and information for referenced models

You can use the code descriptor programming interface to get access to the contents of the code descriptor file and use the results to confirm that generated interfaces meet integration requirements. You can also use the programming interface to provide input to tools that generate interfaces for platform services.

For more information, see “Get Code Description of Generated Code” on page 51-41 and `coder.codedescriptor.CodeDescriptor` class.

Identify and Package Files for Deployment

For function platform deployment, after you review and, if necessary, refine the code interfaces generated for a component model, identify files required to build the integrated code. If you use an application build system outside of the Simulink environment, you can package the generated files and required support files that MathWorks® provides into a zip file by using the `packNGo` utility. That utility finds and packages the files that you need to build an executable image. Then, you can relocate the zip file to another development environment, such as a dedicated application build system.

For more information about the packNGo, see “Relocate or Share Generated Code” on page 56-42 and packNGo.

Build integrate Code Into an Executable Program

Build integrated code. Embedded Coder provides extensive capabilities for customizing the build process. For example:

- Choose between a build process that generates makefiles that support custom toolchains or one that uses an existing template makefile with a toolchain that you specify. See “Approaches for Building Code Generated from Simulink Models” on page 56-11.
- Control compiler optimizations. See “Control Compiler Optimizations” on page 71-6.
- Reduce build time by building referenced models in parallel. See “Reduce Build Time for Referenced Models by Using Parallel Builds” on page 56-37.
- Customize build processing that occurs after code generation to include third-party tools. See “Customize Post-Code-Generation Build Processing” on page 87-7.
- Compile code in another development environment. See “Compile Code in Another Development Environment” on page 49-96.

Decompose Software Problem

A step in the component assessment process is to break down your software problem into smaller parts. You can represent each part as a separate component. Smaller components:

- Facilitate separation of concerns.
- Are easier to work with.
- Enable parallel development.
- Promote reuse.

When assessing a component for reuse, consider whether the component is:

- Reusable as is.
- Reusable with slight variations.
- Expected to be volatile.

If you have access to System Composer™, you can use that software to graphically represent software components as you decompose the software problem and design a software architecture. For more information, see “Author Architecture Models” (System Composer).

As part of the decomposition process, identify data and execution dependencies, such as ports, function-call interfaces, and parameters that require tuning and signal data that must be measured during program execution.

For multicore scenarios, the code generator assumes that:

- Target hardware includes two or more cores.
- System initialization occurs on one core.
- Services assign tasks to a core statically. Tasks do not switch between cores.
- Tasks can communicate within and across cores during run time.

This figure illustrates these assumptions. The tasks in the figure represent instances of entry-point functions running in a multi-core target platform environment.

Embedded Coder Supported Hardware

Embedded Coder generates ANSI/ISO C and C++ code that can be compiled and executed on a processor by manually integrating the generated code with the RTOS, I/O devices, and build tools for your processor.

Embedded Coder provides support packages that help to automate integration, execution, and verification of generated code for the processors and devices in this table.

Support Package	Vendor	Earliest Release Available	Last Release Available
Analog Devices DSPs	Analog Devices®	R2013a	R2015b

Components

Component Model Design for Deployment

A component model is a top-level model that represents an application algorithm. From a component model, the code generator produces code that has a programming interface for interacting with other platform environment software. Embedded Coder® software produces component model code that you can deploy to run on or integrate as part of an embedded system platform.

When deploying a component model to a function platform, you develop each component model in isolation. Then, you or someone else in your organization integrates the generated function code into a complete application program at the source code level.

The composition of a component model can include subcomponents and utilities. Depending on the platform that you configure for a component model, you might need to configure the deployment type of each model in the component model hierarchy. The deployment type determines how model constructs map to platform interfaces and the rules for peer interaction and scope for data and function accessibility for models in the hierarchy. For each model in the hierarchy, you select a deployment type based on the role of the model.

Role of Model	Deployment Type
Publish execution, communication, and service code interfaces according to the specified platform definition so the component can interact with other components in the target platform environment.	Component
Referenced by and runs as part of the parent component model. Execution and communication interfaces are accessible within the context of the parent component model only. Generated code is not accessible to the target platform environment.	Subcomponent

When designing a component model that communicates with the platform code, consider and account for the communication methods used by the platform software and Simulink semantics. For more information, see “Platform Service Data Communication Methods” on page 1-7.

Subcomponents

A subcomponent is part of an algorithm that is captured within a component model and runs as part of a component model. You model a subcomponent as a reference model, subsystem, or linked subsystem. The parent component gains access to subcomponent code by using subcomponent entry points. Code generated for subcomponents is not accessible to the target platform environment. The code generated for a subcomponent is dependent on code for the parent component model. If a subcomponent shares data with other subcomponents, the subcomponent code must use data transfer services prescribed by the target platform.

For guidance on choosing an approach for modeling subcomponents, see “Component-Based Modeling”.

Utilities

A utility is a reusable function that a program can call from any location in the code without considering the target platform environment. You model a utility as a library subsystem that adheres to specific modeling constraints. The code generator uses the constraints to produce code that is free of platform context requirements.

Include utilities in model compositions when you want to:

- Generate code that models can share.
- Lock down the interface for a subsystem.
- Make a model the owner of its generated code.

For more information, see “Library-Based Code Generation for Reusable Library Subsystems” on page 8-2.

Model Single-Core, Single-Tasking Platform Execution

This example shows a model designed and configured for embedded system code generation intended to execute on a single-core, single-tasking platform. The application algorithm is captured in a single model hierarchy, making it possible to use Simulink® time-based, single-task scheduling to simulate the model and execute the generated code.

Periodic Multirate Model Set Up for Single-Tasking Execution

Open the example model `rtwdemo_multirate_singletasking`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.

- Sample times for Inport blocks In1_1s and In2_2s are set to 1 and 2 seconds, respectively.
- To provide clean partitioning of rates, sample times for subsystems SS1 and SS2 are set to 1.

Relevant Model Configuration Parameter Settings

- **Type** set to Fixed-step.
- **Solver** set to discrete (no continuous states).
- **Treat each discrete rate as a separate task** cleared.

Scheduling

Simulink® simulates the model based on the model configuration. Code generated from the model implements the same execution semantics. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, single-tasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

The generated code schedules subrates in the model. In this example, the rate for Inport block In2_2s, the green rate, is a subrate. The generated code properly transfers data between tasks running at the different rates.

Benefits of implicit rate grouping:

- Simulink does not impose architectural constraints on the model.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, the model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates based on single-tasking execution semantics.

Your execution framework can communicate with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

Generate Code and Report

Open the **Embedded Coder** app. Then, generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point function `rtwdemo_multirate_singletasking_step`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_multirate_singletasking.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_multirate_singletasking.h` declares model data structures and a public interface to the model entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

- 1 Include the generated header file by adding directive `#include rtwdemo_multirate_singletasking.h`.
- 2 Write input data to the generated code for model Inport blocks.
- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.In1_1s` of data type `real_T` with dimension of 1
- `rtU.In2_2s` of data type `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_multirate_singletasking_initialize(void)`. At startup, call this function once.

- Output and update entry-point (step) function, `void rtwdemo_multirate_singletasking_step(void)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.

Output ports:

- `rtY.Out1` of data type `real_T` with dimension of 1
- `rtY.Out2` of data type `real_T` with dimension of 1

Model Single-Core, Multitasking Platform Execution

Use Simulink® time-based, multitask scheduling to simulate and generate code for an application algorithm captured in a single model hierarchy. The model is designed and configured for an embedded system intended to execute on a single-core, multitasking platform. The model simulates and the generated code executes based on the model configuration and a rate monotonic scheduling algorithm.

Periodic Multirate Model Set Up for Multitasking Execution

Open the example model `rtwdemo_multirate_multitasking`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.

- Sample times for Inport blocks In1_1s and In2_2s are set to 1 and 2 seconds, respectively.
- To provide a clear partitioning of rates, sample times for subsystems SS1 and SS2 are set to 1.
- The Rate Transition block models an explicit rate transition. Alternatively, instruct Simulink to insert Rate Transition blocks for you by selecting model configuration parameter **Automatically handle rate transition for data transfer**.

Relevant Model Configuration Parameter Settings

- **Type** set to Fixed-step.
- **Solver** set to discrete (no continuous states).
- **Treat each discrete rate as a separate task** selected.

Scheduling

Simulink® simulates the model based on the model configuration. Code that this model generates implements the same execution semantics. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, multitasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate. Yellow represents the mixture of the two rates.

The generated code schedules subrates in the model. In this example, the rate for Inport block In2_2s, the green rate, is a substrate. The generated code properly transfers data between tasks that run at the different rates.

Benefits of implicit rate grouping:

- Simulink does not impose architectural constraints on the model. Create a model without imposing software architecture constraints within the model.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, the model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates based on multitasking execution semantics.

Simulink enforces data transfer constraints to achieve rate-monotonic scheduling:

- Data transfers occur between a single read task and a single write task.
- When data transfers between two tasks, only one task can preempt the other task.
- For periodic tasks, a task with a faster rate has a higher priority than a task with a slower rate. In addition, a task with the faster rate, preempts a task with a slower rate.
- Tasks run on a single processor.
- Time slicing, use of a defined time period during which a task can run in a preemptive multitasking system, is not allowed.
- Processes do not crash and restart, especially during data transfers between tasks.
- Read and write operations on byte-sized variables are atomic.

Your execution framework communicates with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

Generate Code and Report

Open the **Embedded Coder** app. Then, generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point functions `rtwdemo_multirate_multitasking_step0` and `rtwdemo_multirate_multitasking_step1`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_multirate_multitasking.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_multirate_multitasking.h` declares model data structures and a public interface to the model entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

- 1 Include the generated header file by adding directive `#include rtwdemo_multirate_multitasking.h`.
- 2 Write input data to the generated code for model Inport blocks.
- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.In1_1s` of data type `real_T` with dimension of 1
- `rtU.In2_2s` of data type `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_multirate_multitasking_initialize(void)`. At startup, call this function once.
- Output and update entry-point (step) function, `void rtwdemo_multirate_multitasking_step0(void)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.
- Output and update entry-point function, `void rtwdemo_multirate_multitasking_step1(void)`. Call this function periodically at the second fastest rate in the model. For this model, call the function every two seconds. To achieve real-time execution, attach this function to a timer.

Output ports:

- `rtY.Out1` of data type `real_T` with dimension of 1
- `rtY.Out2` of data type `real_T` with dimension of 1

Model Concurrent Execution for Symmetric Multicore CPU Platforms

Use Simulink® time-based, multitask scheduling to simulate and generate code for an application algorithm captured in a single model hierarchy. The model is designed and configured for an embedded system intended to execute on a symmetric multicore, multitasking platform.

Periodic Multirate Model Set Up for Multitasking Concurrent Execution

Open the example model `rtwdemo_concurrent_execution`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.

Simulink supports simulating concurrent task execution by assigning partitions of a model to tasks that you designate to run concurrently on multicore hardware. Use an implicit or explicit approach to designating partitions.

Simulink implicit partitioning:

- Partitions the model based on sample times specified in the model.
- Assigns a task to each sample rate and designates that the tasks run concurrently.
- Controls the granularity of partitions. For example, you cannot split a sample rate into multiple tasks.
- Does not impose modeling constraints.
- Provides ready-to-use hardware solutions, such as solutions that the Simulink® Real-Time™ product produces.
- Is not relevant to standalone production code generation due to the lack of control over partition granularity.

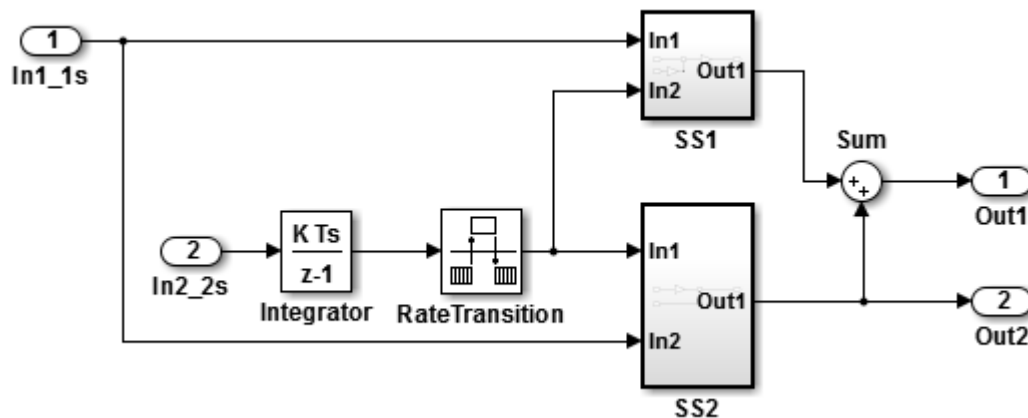

Explicit partitioning:

- Use Model and Subsystem blocks to partition the model.

- Create an arbitrary number of tasks.
- Simulink assigns each partition to a task.
- Simulink imposes modeling constraints.
- Control the granularity of partitions.
- Split a sample rate into multiple tasks.
- Assign partitions to different processor cores.
- Is for standalone production code generation due to the level of control you have over granularity of partitions.

This example shows explicit partitioning.

Consider the following periodic multirate model that is set up for multitasking execution.

- Sample times for Inport blocks In1_1s and In2_2s are set to 1 and 2 seconds, respectively.
- To provide a clear partitioning of rates, sample times for models SS1 and SS2 are set to 1.
- The Rate Transition block explicitly models a rate transition.

To support concurrent execution of tasks in a multicore run-time environment, the preceding model was modified:

- The Integrator block is in a Model block configured with a fixed-step discrete solver and a step size of two seconds.
- Subsystems SS1 and SS2 were converted to Model blocks configured with a fixed-step discrete solver and a step size of one second.
- The Sum block is in a Model block configured with a fixed-step discrete solver and a step size of one second. Another option for the Sum block is to place it in SS1 or SS2 and compute its value coincident with the Model block. For concurrent execution of tasks, only connection blocks, Model blocks, and Subsystem blocks can be at the root level of a model.
- The Rate Transition block was removed.

Relevant Model Configuration Parameter Settings

- **Type** set to Fixed-step.
- **Solver** set to discrete (no continuous states).

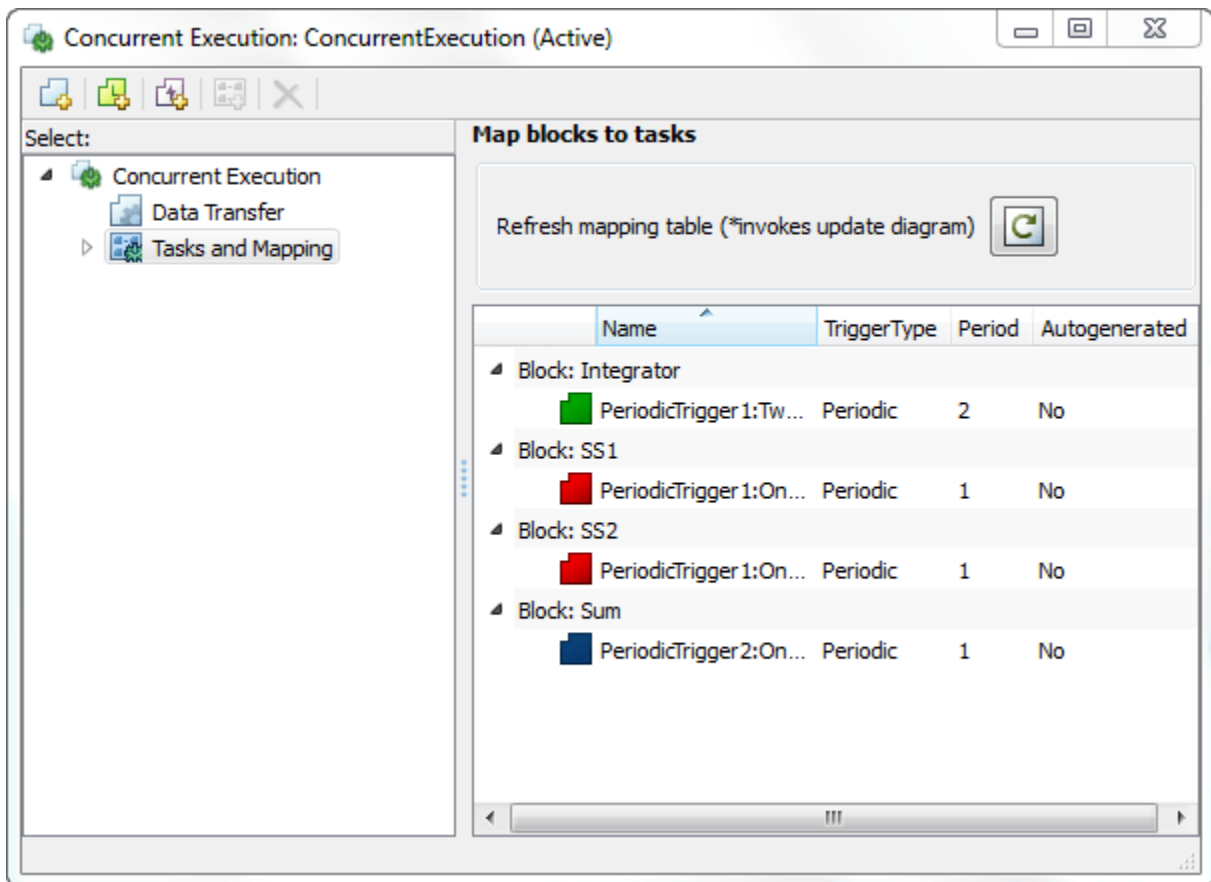

- **Treat each discrete rate as a separate task** selected.
- **Automatically handle rate transition for data transfer** selected. Necessary because Rate Transition block was removed.
- **Allow tasks to execute concurrently on target** selected.

Concurrent Execution Parameter Settings

Open the Concurrent Execution dialog box by clicking **Configure Tasks** on the Configuration Parameters **Solver** pane. Selecting parameter **Allow tasks to execute concurrently on target** enables the **Configure Tasks** button.

When selected, parameter **Enable explicit model partitioning for concurrent behavior** enables concurrent execution options for the top-level model.

Click **Tasks and Mapping** to review the tasks and mapping.

Simulink creates a default mapping for each partition (Model block) by assigning each partition to a separate task. Simulink designates that each partition executes concurrently and simulates latency effects that data communication between processor cores imposes. This dialog box displays a mapping consisting of partitions spread across two independent periodic triggers: SS1, SS2, and Sum mapped to periodic trigger 1 and Integrator mapped to periodic trigger 2.

Scheduling

Simulink® simulates the model based on the model configuration. Code generated from the model implements the same execution semantics. Simulink propagates and uses the Inport block sample times to order block execution based on a multicore, multitasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

The generated code schedules subrates in the model. In this example, the rate for Inport block In2_2s, the green rate, is a subrate. The generated code properly transfers data between the rates.

Benefits of implicit Simulink rate grouping:

- Simulink does not impose architectural constraints on the model. Create a model without imposing software architecture constraints within it.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates, based on multitasking execution semantics.

Simulink enforces data transfer constraints:

- Data transfers occur between a single read task and a single write task.
- Tasks run on a single processor.
- Processes do not stop or restart, especially during data transfers between tasks.
- Read and write operations on byte-sized variables are atomic.

Your execution framework can communicate with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by indirectly calling entry-point functions `PeriodicTrigger1_OneSecond_step`, `PeriodicTrigger1_TwoSecond_step`, and `PeriodicTrigger2_OneSecond_step` with the function `rtwdemo_concurrent_execution_step`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_concurrent_execution.c` contains entry points for the code that implements the model algorithm. This file includes the rate and task scheduling code.
- `rtwdemo_concurrent_execution.h` declares model data structures and a public interface to the model entry points and data structures.
- `model_reference_types.h` contains type definitions for timing bridges. These type definitions are generated for a model reference target or a model containing Model blocks.

- `rtw_windows.h` declares mutex and semaphore function prototypes that the generated code uses for concurrent execution on Microsoft® Windows® platforms.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

- 1 Include the generated header file by adding directive `#include rtwdemo_concurrent_execution.h`.
- 2 Write input data to the generated code for model Inport blocks.
- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Outport blocks.

Input ports:

- `In1_1s` of data type `real_T` with dimension of 1
- `In2_2s` of data type `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_concurrent_execution_initialize(void)`. At startup, call this function once.
- Output and update entry-point (step) function, `void PeriodicTrigger1_OneSecond_step(void)`. Call this function periodically for one of two tasks that require scheduling at the fastest rate in the model. For this model, call the function every second.
- Output and update entry-point function, `void PeriodicTrigger1_TwoSecond_step(void)`. Call this function periodically at the second fastest rate in the model. For this model, call the function every two seconds.
- Output and update entry-point function, `void PeriodicTrigger2_OneSecond_step(void)`. Call this function periodically for the second task that requires scheduling at the fastest rate in the model. For this model, call the function every second.

To achieve real-time execution, define a task or thread for each entry-point step function. Trigger execution of each function based on a timer that has the same rate as the given function. The operating system schedules the tasks across cores dynamically or based on your mapping of tasks to cores.

Output ports:

- `Out1_1s` of data type `real_T` with dimension 1
- `Out2_1s` of data type `real_T` with dimension 1

Model Explicit Function Invocation with Atomic Subsystems

Deploy embedded system code from Simulink® models by partitioning a model into multiple atomic subsystems that you build separately.

Atomic Subsystem Model

Open the example model `rtwdemo_explicitinvocation_atomicsubsys`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.

This model partitions an algorithm into two atomic subsystems: **Rate1s** and **Rate2s**. Subsystem **Rate1s** is configured with a sample time of 1 second. Subsystem **Rate2s** is configured with a sample time of 2 seconds.

Relevant Model Configuration Parameter Settings

- **Type** set to Fixed-step.
- **Solver** set to discrete (no continuous states).
- **Treat each discrete rate as a separate task** cleared.

Scheduling

Simulink® simulates the model based on the model configuration. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, single-tasking execution platform.

For this example, the sample time legend shows implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

Based on rate-monotonic scheduling, your application code (execution framework) must transfer data between subsystems **Rate2s** and **Rate1s** at a frequency of 2 seconds with the priority of 1 second. That is, the generated function transfers data in the 1 second task every other time prior to executing code for subsystem **Rate1s**.

Your execution framework must schedule the generated function code and handle the data transfers between them. This is an advantage for multirate models because the generated code does not assume scheduling or data transfer semantics. However, the execution framework must handle data transfers explicitly.

Generate Code and Report

Generate a single callable function for each subsystem without connections between them. Multiple ways are available to generate code for a subsystem, including from the subsystem context menu.

- 1 Open the **Embedded Coder** app.
- 2 Right-click a subsystem block.
- 3 Click **C/C++ Code > Build This Subsystem**.

The example model generates a report.

Review Generated Code

Review the generated code in the **Code** view or the code generation report.

- `ert_main.c` is an example main program (execution framework) for the subsystem. This code controls model code execution by calling entry-point function `Rate1s_step` or `Rate2s_step`. Use this file as a starting point for coding your execution framework.
- `Rate1s.c` and `Rate2s.c` contain entry points for the code that implements subsystem `Rate1s` and `Rate2s`, respectively. This file includes the rate and task scheduling code.
- `Rate1s.h` and `Rate2s.h` declare model data structures and a public interface to subsystem entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

- 1 Include the generated header file by adding directive `#include rtwdemo_explicitinvocation_atomicsusys.h`.
- 2 Write input data to the generated code for model Inport blocks.
- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Outport blocks.

Input ports, `Rate1s`:

- `rtU.In1` of type `real_T` with dimension of 1
- `rtU.In2` of type `real_T` with dimension of 1

Entry-point functions, `Rate1s`:

- Initialize entry-point function, `void Rate1s_initialize(void)`. At startup, call this function once.
- Output and update entry-point (step) function, `void Rate1s_step(void)`. Call this function periodically, every second.

- Termination function, `void Rate1s_terminate(void)`. Call this function once from your shutdown code.

Output ports, `Rate1s`:

- `rtY.Out1` of type `real_T` with dimension of 1
- `rtY.Out2` of type `real_T` with dimension of 1

Input ports, `Rate2s`:

- `rtU.In1` of type `real_T` with dimension of 1

Entry-point functions, `Rate2s`:

- Initialize entry-point function, `void Rate2s_initialize(void)`. Call this function once at startup.
- Output and update entry-point (step), `void Rate2s_step(void)`. Call this function periodically, every 2 seconds.
- Termination function, `void Rate2s_terminate(void)`. Call this function once from your shutdown code.

Output ports, `Rate2s`:

- `rtY.Out1` of type `real_T` with dimension of 1

- “Customize Code Organization and Format” on page 52-45

Model Explicit Function Invocation with Function-Call Subsystems

Deploy embedded system code from Simulink® models by partitioning a model into function-call subsystems that you build separately.

Function-Call Subsystem Model

Open the example model `rtwdemo_explicitinvocation_funccallsubsys`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.

This model partitions an algorithm into three function-call subsystems: `Rate1s`, `Rate2s`, and `DataBuffer`. Use function-call subsystems to model multirate systems explicitly.

Subsystems `Rate1s` and `DataBuffer` use a sample time of 1 second. Subsystem `Rate2s` uses a sample time of 2 seconds.

This model design is referred to as export function modeling. Simulink constrains the model to function-call subsystems at the root level. The driving Inport block specifies the function name.

Relevant Model Configuration Parameter Settings

- **Type** set to Fixed-step.
- **Solver** set to discrete (no continuous states).
- **Treat each discrete rate as a separate task** selected. Simulink applies multitasking execution because the model uses multiple sample rates.

Scheduling

Simulink® simulates the model based on the model configuration. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, multitasking execution platform.

In the sample time legend, red identifies the fastest discrete rate. Magenta identifies rates inherited from exported functions, indicating their execution is outside the context of Simulink scheduling.

Your execution framework must schedule the generated function code and transfer data between functions.

Your execution framework needs to schedule the generated function code and handle data transfers between functions. The generated code is simple and you control the order of execution.

Generate Code and Report

Open the **Embedded Coder** app. Then, generate code and a code generation report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize, execute, and terminate the generated code.
- `rtwdemo_explicitinvocation_funccallsubsys.c` calls the initialization function and exported functions for subsystems `Rate1s`, `Rate2s`, and `DataBuffer`.
- `rtwdemo_explicitinvocation_funccallsubsys.h` declares model data structures and a public interface to the exported entry point functions and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

- 1 Include the generated header files by adding directives `#include Rate1s.h`, `#include DataBuffer.h`, and `#include Rate2s.h`.
- 2 Write input data to the generated code for model Inport blocks.
- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.In1_1s` of type `real_T` with dimension of 1
- `rtU.In2_2s` of type `real_T` with dimension of 1

Entry-point functions:

- Initialize entry-point function, `void rtwdemo_explicitinvocation_funccallsubsys_initialize(void)`. At startup, call this function once.

- Exported function, `void CallEvery1s(void)`. Call this function as needed.
- Exported function, `void CallEvery1s(void)`. Call this function as needed.
- Exported function, `void CallEvery2sAt1sPriority(void)`. Call this function as needed.

Output ports:

- `rtY.Out1` of type `real_T` with dimension of 1
- `rtY.Out2` of type `real_T` with dimension of 1

More About

Periodic and Aperiodic Function Interfaces

A target platform initiates execution of a component by calling execution entry-point functions generated for the model. The execution entry-point functions that implement component behavior can be periodic or aperiodic. The code that the code generator produces for a component model depends on the modeling styles and periodic rates represented in the model. You represent periodic and aperiodic entry-point functions in a model by using a combination of two modeling styles: rate-based and function-call- (export-function) based.

This table lists conditions that might prompt you to choose each modeling style.

Rate-Based Modeling Style Conditions	Function-Call Based Modeling Style Conditions
<ul style="list-style-type: none"> Assumes rate monotonic scheduling. Code generator produces a unique entry-point function for each rate represented in the model. Sample time is design data. It is not an implementation consideration. Can generate reusable code from multiple instances of a model. 	<ul style="list-style-type: none"> A function represents the entry-point function for a server. A function exchanges data with multiple other functions. A function represents a periodic entry-point function that has a rate that is not a multiple of the fastest rate used by the component. A function represents a periodic entry-point function that other events also trigger. Multiple functions represent periodic entry-point functions that are triggered at the same period.

If you want a component to support multiple instantiation, you cannot model periodic functions as function-call subsystems. Use rate-based modeling.

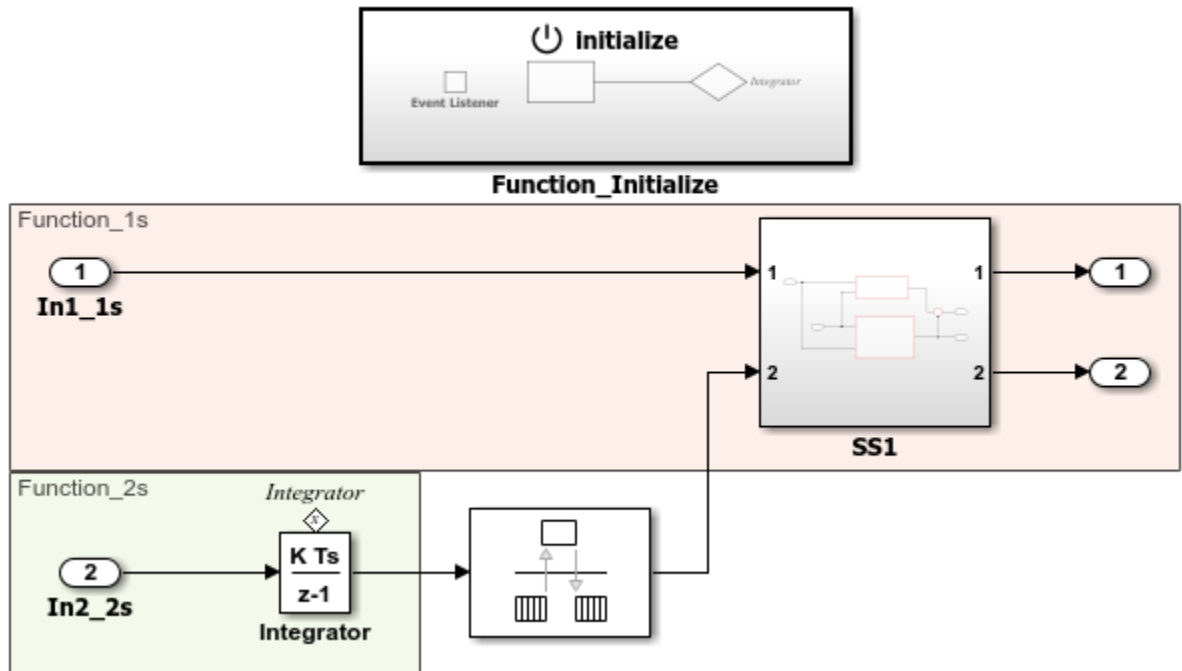

For more information about modeling execution behavior, see “Rate-Based Components” on page 2-21 and “Function-Call-Based Components” on page 2-22.

For options to configure the function prototype for generated periodic and aperiodic execution entry-point functions, see “Periodic and Aperiodic Function Interface Configuration” on page 2-24.

Rate-Based Components

A rate-based model represents periodic entry-point functions by using unique periodic rates.

This example model shows a rate-based implementation of a component. The model implements periodic entry-point functions by using the rates 1 second and 2 seconds. An Initialize Function block initializes the component.

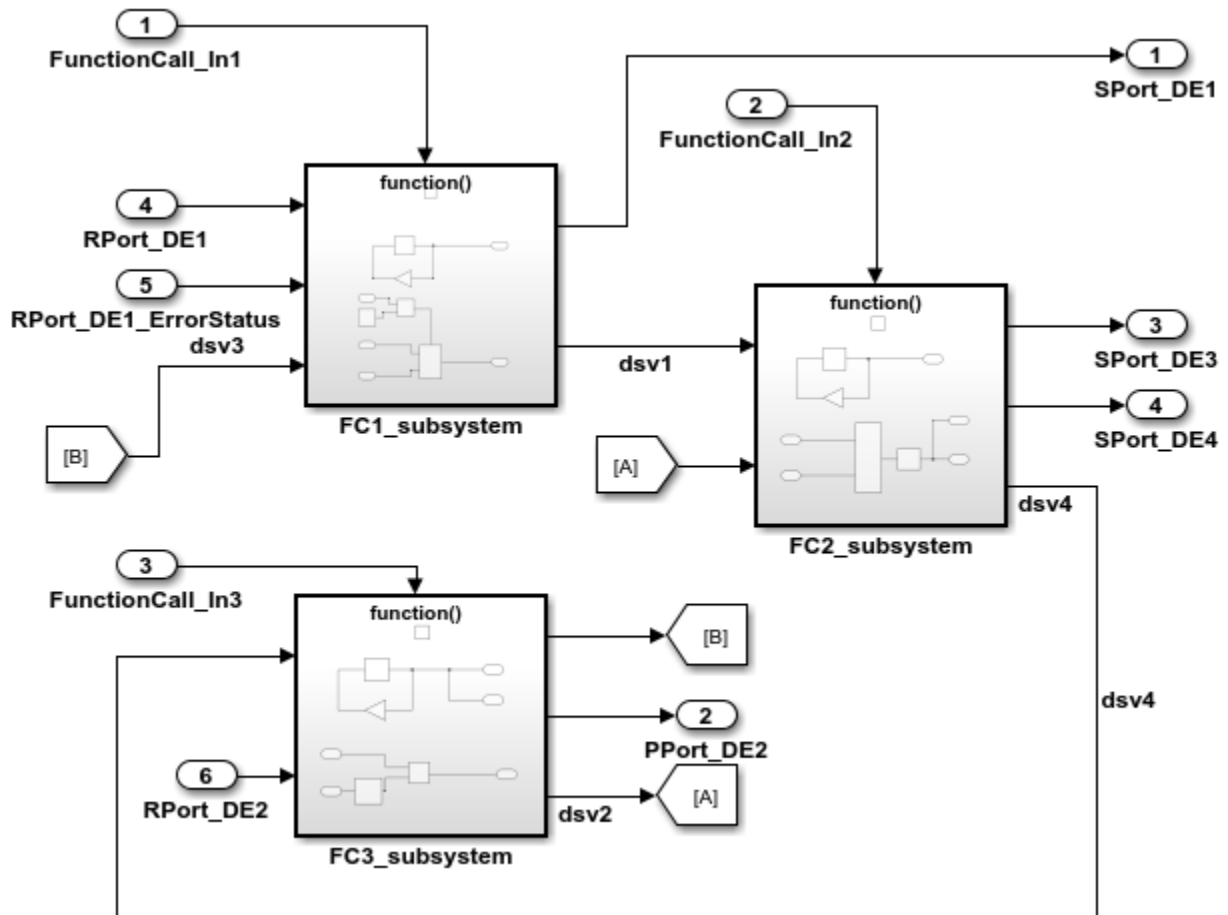

When you generate code for a rate-based component model, the C code contains rate-grouped step entry-point functions, one function for each discrete rate in the model. The platform function scheduler calls the generated periodic step functions.

You can design a rate-based component model to represent periodic and aperiodic entry-point functions. For example, in the JMAAB-B type beta architecture, an asynchronous trigger entry-point function interacts with periodic rate-based entry-point functions.

Function-Call-Based Components

You can represent a function-call- (export-function) based component as a function-call subsystem. For function-call-based models, the code generator produces code for independent functions that execute at a periodic rate or aperiodically in response to events. You can integrate the independent function code with other platform code, including the function scheduler and other platform services.

This example model shows a function-call-based implementation of a component. The model uses three Function-Call Subsystem blocks, FC1_subsystem, FC1_subsystem, and FC3_subsystem, which have periodic rates to implement three periodic entry-point functions. Signal lines that connect the Function-Call Subsystem blocks, dsv1, dsv2, dsv3, and dsv4, represent data transfers.

When you generate code for a function-call-based implementation, the code includes a callable model entry-point function for each function represented in the top model. Unless you define and configure the interface otherwise, the code generator uses the name of the function-call subsystem input port as the name of the callable entry-point function. You can override the default naming by defining a function customization template in an Embedded Coder Dictionary and configuring the function name in the model code mappings.

You can control how the code generator packages the code for a function-call-based implementation. For example, by using subsystem block parameter **Function packaging**, you can specify whether the code generator inlines the function code for a subsystem or produces separate function code that passes I/O as global data. When inlined, the code generator uses the name of the function-call subsystem input port to name the entry-point function. When producing separate function code, the code generator names the function based on the settings of other parameters, such as **File name options**.

For more information, see “Generate Component Source Code for Export to External Code Base” on page 55-40, “Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113, and “Interactively Configure C++ Interface” on page 41-2.

Periodic and Aperiodic Function Interface Configuration

The code generator produces several types of entry-point functions for model functions (see “Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113). As an example, a component model that includes two periodic function-call subsystems and an aperiodic function-call subsystem, the code generator produces three callable entry-point functions for initiating component execution:

- *model_step0* - function for the first periodic rate
- *model_step1* - function for the second periodic rate
- *function* - aperiodic function, where *function* is the name of the Inport block for a function call subsystem or label of the signal line connecting the Inport and subsystem

Customize the entry-point function prototypes to align with function calls initiated by the platform function scheduler by applying one of these approaches:

- For the model, in the Code Mappings editor or by using the code mappings programming interface, configure the function name and arguments for each model execution function individually.
- Define a function customization template for execution functions in the Embedded Coder Dictionary (see “Code Interface Definitions”). Then, for the model, in the Code Mappings editor or by using the code mappings programming interface, configure the code generator to use that template for model execution functions.

For more information, see “Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113.

Startup, Reset, and Shutdown Function Interfaces

Applications sometimes require logic that executes during system initialization, reset, and termination sequences. To model startup, reset, and shutdown processing in a component model, use the Initialize Function, Reset Function, and Terminate Function blocks. You can use the blocks anywhere in a model hierarchy.

The Initialize Function, Reset Function, and Terminate Function blocks can control execution of a component in response to initialize, reset, or terminate events. Examples of when to generate code that responds to these events include:

- Starting and stopping a component.
- Calculating initial conditions.
- Saving and restoring state from nonvolatile memory.
- Generating reset entry-point functions that respond to external events.

You can place the blocks at different levels of a model hierarchy. Each nonvirtual subsystem can have its own set of initialize, reset, and terminate functions. In a lower-level model, Simulink aggregates the content of the functions with corresponding instances in the parent model.

The Initialize Function and Terminate Function blocks contain an Event Listener block. To specify the event type of the function—*Initialize*, *Reset*, or *Terminate*—use the **Event type** parameter of the Event Listener block. The function block reads or writes the state of conditions for other blocks. By default, the Initialize Function block initializes block state with the State Writer block. The Terminate Function block saves the block state by using the State Reader block. When the function is triggered by an initialize or terminate event, the function writes the value of the state variable or reads the value from the specified block.

Component models can use the Initialize Function, Reset Function, and Terminate Function blocks to model complex startup, reset, and shutdown sequences. The subsystems work with various modeling styles. Software-in-the-loop (SIL) simulation of initialize, reset, or terminate functions works with function-call modeling only.

The code generator produces initialization and termination code differently than reset code. For initialization and termination code, the code generator includes your component initialization and termination code in the default entry-point functions, *model_initialize* and *model_terminate*. The code generator produces reset code only if you model reset behavior.

For example, consider a component model that includes these elements:

- An Initialize Function block
- Two Reset Function blocks that specify event names `tooHighReset` and `tooLowReset`
- A Terminate Function block

For this scenario, the code generator produces four callable entry-point functions that respond to platform function calls triggered by events:

- *model_initialize* - initialization function
- *model_tooHighReset* - reset function for `tooHighReset` event
- *model_tooLowReset* - reset function, for `tooLowReset` event
- *model_terminate* - terminate function

Customize the entry-point function names to align with function calls initiated by the platform function scheduler by applying one of these approaches:

- For the model, in the Code Mappings editor or by using the code mappings programming interface, configure the function name for model initialize, reset, and terminate functions individually.
- Define a function customization template for the initialize, reset, and terminate functions in the Embedded Coder Dictionary. Then, for the model, in the Code Mappings editor or by using the code mappings programming interface, configure the code generator to use that template for the model event-triggered functions.

Generate Code for Initialize and Terminate Events

When you generate code for a component that includes Initialize Function and Terminate Function blocks, the code generator:

- Includes initialize event code with default initialize code in entry-point function `model_initialize`.
- Includes terminate event code with default terminate code in entry-point function `model_terminate`.

Consider the model `rtwdemo_irt_base`.

For this model, the code generator produces initialize and terminate entry-point functions that other code can interface with.

```
void rtwdemo_irt_base_initialize(void)
void rtwdemo_irt_base_terminate(void)
```

This code appears in the generated file `rtwdemo_irt_base.c`. The initialize function, `rtwdemo_irt_base_initialize`:

- Initializes an error status.
- Allocates memory for block I/O and state parameters.
- Sets the output value
- Sets the initial condition for the discrete integrator.

The terminate function, `rtwdemo_irt_base_terminate`, requires no code.

This code assumes that support for nonfinite numbers and MAT-file logging is disabled.

```
void rtwdemo_irt_base_initialize(void)
{
    rtmSetErrorStatus(rtwdemo_irt_base_M, (NULL));

    (void) memset((void *)&rtwdemo_irt_base_DW, 0,
```

```

        sizeof(DW_rtwdemo_irt_base_T));

    rtwdemo_irt_base_Y.Out1 = 0.0;

    rtwdemo_irt_base_DW.DiscreteIntegrator_DSTATE = 0.0;
}

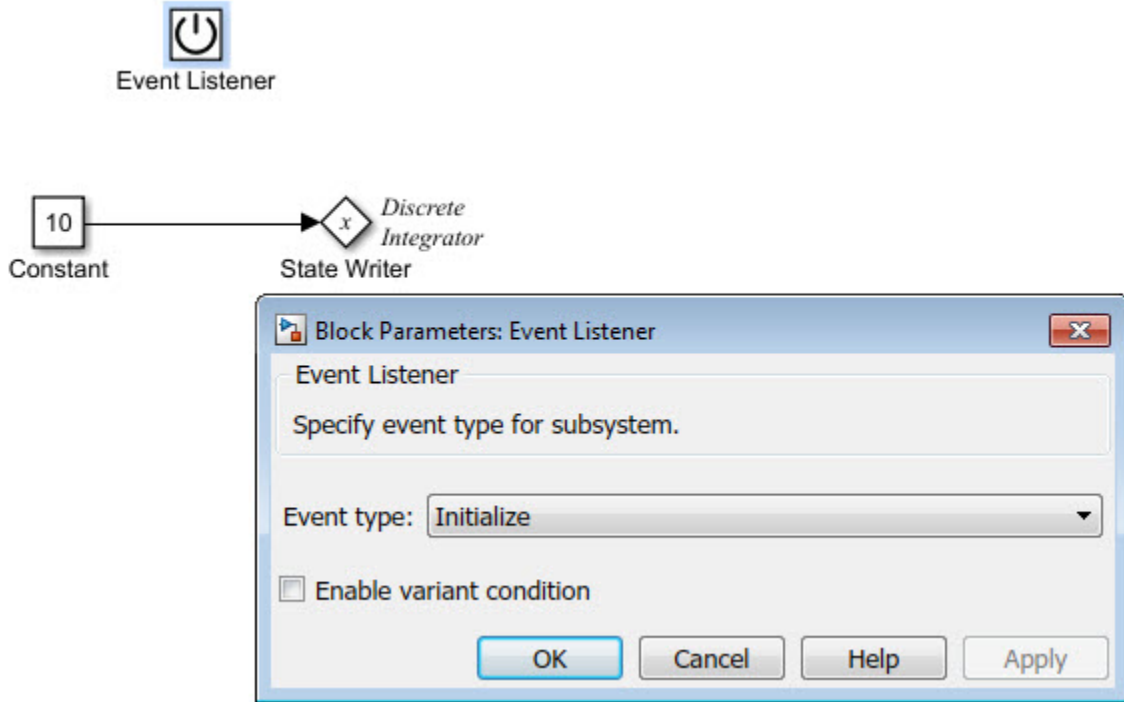

void rtwdemo_irt_base_terminate(void)
{
    /* (no terminate code required) */
}

```

Add Initialize Function and Terminate Function blocks to the model (see `rtwdemo_irt_initterm`). The Initialize Function block uses the State Writer block to set the initial condition of a Discrete Integrator block. The Terminate Function block includes a State Reader block, which reads the state of the Discrete Integrator block.

Parameter **Event type** for the Event Listener block for the initialize and terminate functions is set to **Initialize** and **Terminate**, respectively. The initialize function uses the State Writer block to initialize the input value for the Discrete Integrator block to 10. The terminate function uses the State Reader block to read the state of the Discrete Integrator block.

The code generator includes the event code that it produces for the Initialize Function and Terminate Function blocks with standard initialize and terminate code in entry-point functions

`rtwdemo_irt_initterm_initialize` and `rtwdemo_irt_initterm_terminate`. This code assumes that support for nonfinite numbers and MAT-file logging is disabled.

```
void rtwdemo_irt_initterm_initialize(void)
{
    rtmSetErrorStatus(rtwdemo_irt_initterm_M, (NULL));

    (void) memset((void *)&rtwdemo_irt__initterm_DW, 0,
                 sizeof(DW_rtwdemo_irt__initterm_T));

    rtwdemo_irt_initterm_Y.Out1 = 0.0;

    rtwdemo_irt_initterm_DW.DiscreteIntegrator_DSTATE = 10.0;
}

void rtwdemo_irt__initterm_terminate(void)
{
    /* (no terminate code required) */
}
```

Generate Code for Reset Events

Generate code that responds to a reset event by including an Initialize Function or Terminate Function block in a modeling component. Configure the block for a reset by setting the **Event type** parameter of its Event Listener block to **Reset**. Also set the **Event name** parameter. The default name is **reset**.

The code generator produces a reset entry-point function *only* if you model reset behavior. If a component contains multiple reset specifications, the code that the code generator produces depends on whether reset functions share an event name. For a given component hierarchy:

- For reset functions with unique event names, the code generator produces a separate entry-point function for each named event. The name of each function is the name of the corresponding event.
- For reset functions that share an event name, the code generator aggregates the reset code into one entry-point function. The code for the reset functions appears in order, starting with the lowest level (innermost) of the component hierarchy and ending with the root (outermost). The name of the function is `model_reset`. For more information, see “Event Names and Code Aggregation”.

Consider the model `rtwdemo_irt_reset`, which includes a Reset Function block derived from an Initialize Function block.

The **Event type** and **Event name** parameters of the Event Listener block are set to **Reset** and **reset**, respectively. The function uses the State Writer block to reset the input value for the Discrete Integrator block to 5.

The code generator produces reset function `rtwdemo_irt_reset_reset`.

```
void rtwdemo_irt_reset_reset(void)
{
    rtwdemo_irt_reset_DW.DiscreteIntegrator_DSTATE = 5.0;
}
```

Event Names and Code Aggregation

Use the Initialize Function and Terminate Function blocks to define multiple initialize, reset, and terminate functions for a component hierarchy. Define only one initialize function and one terminate function per hierarchy level. You can define multiple reset functions for a hierarchy level. The event names that you configure for the functions at a given level must be unique.

When producing code, the code generator aggregates code for functions that have a given event name across the entire component hierarchy into one entry-point function. The code for reset functions appears in order, starting with the lowest level (innermost) of the component hierarchy and ending with the root (outermost). The code generator uses the event name to name the function.

For example, the model `rtwdemo_irt_shared` includes a subsystem that replicates the initialize, reset, and terminate functions that are in the parent model.

Although the model includes multiple copies of the initialize, reset, and terminate functions, the code generator produces one entry-point function for reset (`rtwdemo_irt_shared_reset`), one for initialize (`rtwdemo_irt_shared_initialize`), and one for terminate (`rtwdemo_irt_shared_terminate`). Within each entry-point function, after listing code for blocks

configured with an initial condition (*model_P.block_IC*), the code generator orders code for components, starting with the lowest level of the hierarchy and ending with the root.

```
.
.
.
void rtwdemo_irt_shared_reset(void)
{
    rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 5.0;

    rtwdemo_irt_shared_DW.Integrator2_DSTATE = 5.0;
}
.
.
.
void rtwdemo_irt_shared_initialize(void)
{
    rtmSetErrorStatus(rtwdemo_irt_shared_M, (NULL));

    (void) memset(((void *)&rtwdemo_irt_shared_DW), 0,
        sizeof(DW_rtwdemo_irt_shared_T));

    rtwdemo_irt_shared_Y.Out1 = 0.0;

    rtwdemo_irt_shared_DW.Integrator1_DSTATE = 0.0;

    rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 2.0;

    rtwdemo_irt_shared_DW.Integrator2_DSTATE = 10.0;
.
.
.
void rtwdemo_irt_shared_terminate(void)
{
    /* (no terminate code required) */
}
```

If you rename the event configured for the subsystem reset function to `reset_02`, the code generator produces two reset entry-point functions, `rtwdemo_irt_shared_reset` and `rtwdemo_irt_shared_reset_02`.

```
void rtwdemo_irt_shared_reset(void)
{
    rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 5.0;
}

void rtwdemo_irt_shared_reset_02(void)
{
    rtwdemo_irt_shared_DW.Integrator2_DSTATE = 5.0;
}
```

Limitation

You cannot generate code from a harness model—a root model that contains a Model block, which exposes initialize, reset, or terminate function ports.

Receive and Send Communication Interfaces

Within a platform environment, a component receives data from and sends data to other components by calling the platform data receive and data send services. To represent calls to the data receive and data send services in a component model and configure the relevant data elements for code generation:

- 1 In the component model:
 - Represent a data receive request by using a root-level inport (In Bus Element or Inport block).
 - Represent a data send request by using a root-level outport (Out Bus Element or Outport block).
- 2 For function platform deployment, when the root-level inports and outports communicate with platform services that use the during-execution communication method and concurrent data access is possible, create a memory buffer to hold the value that the function receives constant during function execution by using the Safeguard block that is provided in the Component Deployment Guidelines for Embedded Coder Support Package. Insert and connect the safeguard mechanism to:
 - The output port of the component model root-level inport
 - The input port of the component model root-level outport
- 3 If you have not already done so, open the Embedded Coder app.
- 4 In the Code Mappings editor or by using the code mappings programming interface, configure the code interfaces for the root-level inport and outport. At a minimum, set these properties:
 - **Storage Class**, which controls the appearance and placement of the data element in the generated code.
 - **Identifier**, which names the model element in the generated code. The code generator uses the identifier in names constructed for access functions.
 - **GetFunction** or **SetFunction**, which specifies the naming rule for the name of the platform data receive or data send service function.

For root-level inports and outports intended to use during-execution communication, use the `DuringExecution` storage class that is provided in the Component Deployment Guidelines for Embedded Coder Support Package.

For a list of storage classes supported by Embedded Coder, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.

A best practice is to represent communication I/O ports at the root-level of a component model by using In Bus Element and Out Bus Element blocks.

- As a named signal interface, these blocks reduce wiring in the model and avoid issues with port reordering.
- As a structured data type, these blocks enable use of arrays of buses.

To represent a bus as a signal interface, use an In Bus Element or Out Bus Element block that has the **Bus virtuality** attribute set to `virtual`. Virtual buses provide a way to group signals so that you can access them as a whole or select specific signals. A virtual bus consisting of one signal is equivalent to using an Inport or Outport block.

To enforce the composition of a bus interface, use a bus object. A bus object specifies the architectural properties of a bus, such as element names, hierarchy, order, and data types. A bus object is analogous to a structure definition in C. The object defines members of the bus but does not create the bus.

To reduce the number of function arguments that are passed to a reference model in the generated code, choose one of these options for configuring a In Bus Element:

- Set the block **Bus virtuality** attribute to `nonvirtual` and, in the model code mappings, for the inport, set the storage class.
- Set the block **Bus virtuality** attribute to `virtual` or `inherited` and, in the model code mappings, for the inport, set the storage class to `Default`.

If you have a requirement to represent root-level I/O in the generated code as a structured data type, model the inport or outport as a nonvirtual bus. The data type of a nonvirtual bus must be a `Simulink.Bus` object that is defined in the model base workspace or data dictionary.

Message Communication Interfaces

Within a platform environment, a Simulink component model can communicate with platform software or with other Simulink component models by using message-based communication. Generate C++ component code for message-based communication with platform software. Generate C++ or C component code for message-based communication with other component models.

Generate C++ Messages to Communicate Data Between Simulink and an Operating System or Middleware

To generate C++ code that supports message communication between Simulink top models and external applications, use the Simulink Messages & Events Library Send and Receive blocks. Generating code from a top model to facilitate messages passed outside of the Simulink environment enables your modeled application to communicate in a distributed system that uses an external message protocol service, commonly referred to as an operating system or middleware (for example, DDS, ROS, SOMEIP, or POSIX messages).

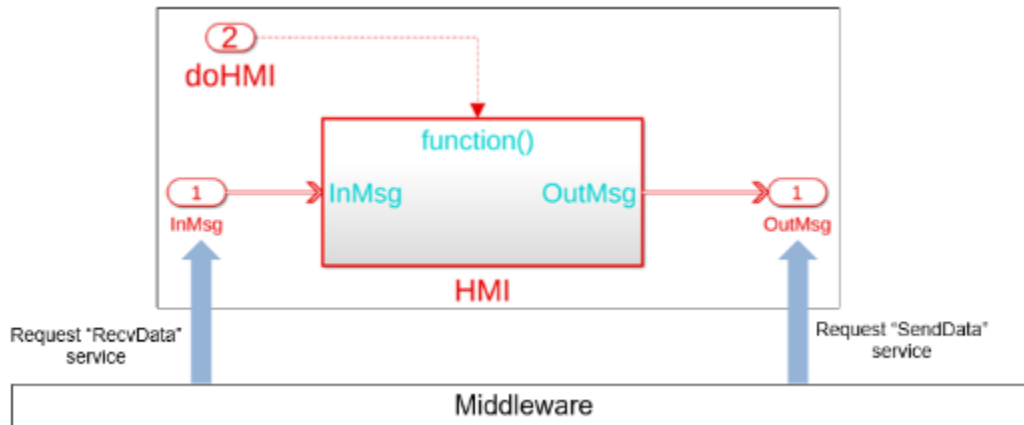

Simulink top models pass messages by:

- Top models contain message blocks to communicate outside the Simulink environment. If a top model contains a Send block directly connected to a root Output port block, the block converts its signals into messages and passes them outside the Simulink environment. If a top model contains a Receive block directly connected to a root Input port block, the block converts the received messages into signals.
- The external message protocol manages the message communication according to its own standard, that is, policies that control capacity, order of delivery, and other quality of service (QoS) behavior.

To generate C++ messages to communicate between Simulink top models and an operating system or middleware, prepare your model, generate code, and integrate that code with your selected operating system or middleware.

Prepare Model

To set up your model so that it can pass messages with an operating system or middleware, configure the model as a top model that has at least one message block, either a Send block connected to a root Output port block or a Receive block connected to a root Input port block. The top model can then connect to your selected operating system or middleware through the message blocks:

Within a model, the message ports are connected as shown:

Generate Code

To generate C++ code from a model:

- 1 In the Apps gallery, click **Embedded Coder**.
- 2 In the Configuration Parameters dialog box, set these parameters:
 - In the **Code Generation** pane, set the **Language** to C++.
 - In the **Interface** pane, set **Code interface packaging** to C++ class.
 - In the **Templates** pane, select Generate an example main program.
- 3 Generate code. On the **C++ Code** tab, click **Build**.
- 4 View the generated code. On the **C++ Code** tab, click **View Code**.

Integrate Code

To integrate the generated C++ code from your model with your selected operating system or middleware use handwritten code to implement send and receive message classes and application code that uses those classes to pass messages. Specifically:

- 1 If you use your own main, create concrete subclasses from the generated abstract classes shown in `RecvData_<T>.h` and `SendData<T>.h`. If you use the generated example main program, concrete subclasses are provided in the file.
- 2 Implement the class functions `SendData` and `RecvData` to call into your selected operating system or middleware to send and receive messages.

- 3 Create an instance of your implemented send and receive message classes (send and receive objects).
- 4 Create an instance of the model class by using the instances of each message class (send and receive objects) as arguments in the model constructor.
- 5 Send and receive messages as required by your application. Manage the lifetime of the message queues. The queues must be in a state ready to accept messages prior to the first step of the model.

To integrate the generated code with a platform main program:

- 1 Open the generated example main program or create your own. If you use the generated example main program, the concrete subclasses `RecvData_real_T` and `SendData_real_T` are in the file. If you create your own main, create concrete subclasses in your application code:

```

class mHMIHandlerRecvData_real_T : public RecvData_real_T{
public:
    void RecvData(real_T* data, int32_T length, int32_T* status)
    {
        // Add receive data Logic here
    }
};

static mHMIHandlerRecvData_real_T InMsgRecvData_arg;
class mHMIHandlerSendData_real_T : public SendData_real_T{
public:
    void SendData(const real_T* data, int32_T length, int32_T* status)
    {
        // Add send data Logic here
    }
};

static mHMIHandlerSendData_real_T OutMsgSendData_arg;
static mHMIHandler mHMI_Obj(InMsgRecvData_arg, OutMsgSendData_arg);

int_T main(int_T argc, const char *argv[])
{
    // Unused arguments
    (void)(argc);
    (void)(argv);

    // Initialize model
    mHMI_Obj.initialize();
    while (rtmGetErrorStatus(mHMI_Obj.getRTM()) == (NULL)) {
        // Perform application tasks here.
    }

    // Terminate model
    mHMI_Obj.terminate();
    return 0;
}

```

- 2 To receive messages, manually write the implementation of the generated receive class. Implement the class function `RecvData` to call into your selected operating system or middleware to receive messages.

An example implementation for POSIX is:

```

class mHMIHandlerRecvData_real_T: public RecvData_real_T {
public:
void RecvData(real_T* data, int32_T length, int32_T* status)
{
    // Use POSIX API mq_receive to receive messages
    unsigned int priority = 1;
    *status = mq_receive(msgQueue, (char *)data, length, &priority);
}
};

```

Create a receive object.

```
static mHMIHandlerRecvData_real_T InMsgRecvData_arg;
```

- 3** To send messages, manually write the implementation of the generated send class. Implement the class function `SendData` to call into your selected operating system or middleware to send messages.

An example implementation for POSIX is:

```

class mHMIHandlerSendData_real_T : public SendData_real_T {
public:
void SendData(const real_T* data, int32_T length, int32_T* status)
{
    // Use the POSIX API mq_send to send messages
    unsigned int priority = 1;
    *status = mq_send(msgQueue, (char*)data, length, priority);
}
};

```

Create a send object.

```
static mHMIHandlerSendData_real_T OutMsgSendData_arg;
```

Create an instance of the model class by using your send and receive objects as arguments in the model constructor.

```
static mHMIHandler mHMI_Obj(InMsgRecvData_arg, OutMsgSendData_arg);
```

- 4** Send and receive messages as required by your application and maintain the lifetime of the message queue.

An example implementation for POSIX is:

```

int_T main(int_T argc, const char *argv[])
{
    // Unused arguments
    (void)(argc);
    (void)(argv);

    //Initialize model
    mHMI_obj.initialize();

    // Open POSIX queue
    mqd_t msgQueue = mq_open("/PosixMQ_Example", O_RDONLY);
    if (msgQueue == -1)
    {
        printf("mq_open failed\n");
        exit(1);
    }
}

```

```
    }  
  
    // Send and Receive messages  
    while (rtmGetErrorStatus(mHMI_Obj.getRTM()) == (NULL)) {  
        //perform application tasks here.  
        rt_OneStep();  
    }  
  
    // Close POSIX queue  
    mq_close(msgQueue);  
  
    // Terminate model  
    mHMI_Obj.terminat():  
    return 0;  
}
```

For a more complex POSIX integration example, see “Use Handwritten Code to Integrate C++ Messages with POSIX” on page 2-52

Considerations and Limitations

- Handwritten code is the only supported integration technique.
- You must select the model configuration parameter **Generate an example main program**. Applications that require a static main are not supported.
- You cannot configure function prototype control (FPC) for a top model that has root message ports.

Generate C++ Messages to Communicate Data Between Simulink Components

To generate C++ code that supports message-based communication between model components in the Simulink environment, use the Simulink Messages & Events Library blocks Send and Receive. To customize the communication, use the Queue block (from the same library) to set parameters for capacity, sorting policy (LIFO, FIFO, and priority), and overwriting policy (behavior when the queue exceeds capacity). You can generate C++ code for GRT-based system target files by using Simulink Coder or for ERT-based system target files by using Embedded Coder.

Messages are an effective communication technique for distributed and complex systems that you can model within Simulink.

How to Prepare Models in Simulink for Message-Based Communication

In Simulink, model message-based communication between model components:

- 1 Create a model that contains a Send block (referenced model).
- 2 Create a model that contains a Receive block (referenced model).
- 3 Create a model that has two Model blocks (top model).
 - Set the first Model block to the model that contains the Send block (model from step 1).
 - Set the second Model block to the model that contains the Receive block (model from step 2).
- 4 When you run the model, a queue generates in the top model above the message line. A queue, explicit or implicit, controls the message communication. You can use the generated queue or you can add a Queue block in the top model to explicitly specify communication parameters.

How Model Components Pass Messages and How the Code Implements the Behavior

Referenced models pass messages:

- 1 In the model that contains the Send block, the Send block converts signals into messages.
- 2 The top model that contains the queue manages messages according to parameters that define capacity, order of delivery, and other quality of service (QoS) metrics.
- 3 In the model that contains the Receive block, the Receive block converts messages back to signals.

In the generated C++ code, the top model facilitates the connection between the send and receive referenced models by establishing a set interface that the referenced models can access independently of one another.

The generated C++ code implements message behavior:

- 1 A service is created at each model boundary. A service contains a reference to the top model and an entry point function, referred to as a service function, for referenced models to use to pass messages to the top model.
- 2 The top model initializes each service to create a connection to each referenced model.
- 3 The referenced models invoke service functions to pass messages to the top model.

C++ Code Generation Example

This example generates and examines C++ code from the model provided in “Establish Message Send and Receive Interfaces Between Software Components”.

Copyright 2019 The MathWorks, Inc.

Generate C++ Code:

- 1 Open the model.
- 2 In the Apps gallery, click **Embedded Coder**.
- 3 For each model (top and both referenced models), in the Configuration Parameters dialog box, set these parameters:

- In the Code Generation pane, set **Language** to C++.
- In the Interface pane, set **Code interface packaging** to C++ class.

Save the model.

- 4 Generate code. On the **C++ Code** tab, click **Build**.

- 5 View the generated code. On the **C++ Code** tab, click **View Code**.

Examine C++ Code:

- 1 A service is created at each model boundary. In C++, services are represented as objects that hold an instance of the top model and a service function that referenced models invoke to pass messages.
 - a To view the creation of the services, open the top model C++ file `MessageSendReceiveDefaultBufferModel.cpp`. View the constructor method.

```
// Constructor
MessageSendReceiveDefaultBufferModelModelClass::
  MessageSendReceiveDefaultBufferModelModelClass():
  MessageSendReceiveDefaultBuff_B()
  ,MessageSendReceiveDefaultBuf_DW()
  ,ReceiveComponentRecvData(*this)
  ,SendComponentSendData(*this)
  ,Receive_ComponentMDLOBJ0(get_ReceiveComponentRecvData())
  ,Send_ComponentMDLOBJ1(get_SendComponentSendData())
  ,MessageSendReceiveDefaultBuf_M()
{
  // Currently there is no constructor body generated.
}
```

The constructor methods, `ReceiveComponentRecvData(*this)` and `SendComponentSendData(*this)`, create the receive and send service objects respectively by taking as an argument a reference to the instance of the top model. Each service object saves a reference to the top model and defines the message interface (the service functions `RecvData` and `SendData`).

- b To view the receive and send service classes, open the top model header file `MessageSendReceiveDefaultBufferModel.h`, and view the following section.

```

// Forward declaration
class MessageSendReceiveDefaultBufferModelModelClass;
class
  MessageSendReceiveDefaultBufferModelModelClassMessa_ReceiveComponent_RecvDataT
  : public RecvData_real_T
{
private:
  MessageSendReceiveDefaultBufferModelModelClass & aProvider;
public:
  MessageSendReceiveDefaultBufferModelModelClassMessa_ReceiveComponent_RecvDataT
    (MessageSendReceiveDefaultBufferModelModelClass & aProvider);
  virtual void RecvData(real_T *data, int32_T length, int32_T *status);
};

class
  MessageSendReceiveDefaultBufferModelModelClassMessa_ReceiveComponent_SendDataT
  : public SendData_real_T
{
private:
  MessageSendReceiveDefaultBufferModelModelClass & aProvider;
public:
  MessageSendReceiveDefaultBufferModelModelClassMessa_ReceiveComponent_SendDataT
    (MessageSendReceiveDefaultBufferModelModelClass & aProvider);
  virtual void SendData(const real_T *data, int32_T length, int32_T *status);
};

```

- 2 The top model initializes each service to create a connection to each referenced model. To view the initialization, open the top model C++ file `MessageSendReceiveDefaultBufferModel.cpp`. View the constructor method.

```

// Constructor
MessageSendReceiveDefaultBufferModelModelClass::
  MessageSendReceiveDefaultBufferModelModelClass():
  MessageSendReceiveDefaultBuff_B()
  ,MessageSendReceiveDefaultBuf_DW()
  ,ReceiveComponentRecvData(*this)
  ,SendComponentSendData(*this)
  ,Receive_ComponentMDL0BJ0(get_ReceiveComponentRecvData())
  ,Send_ComponentMDL0BJ1(get_SendComponentSendData())
  ,MessageSendReceiveDefaultBuf_M()
{
  // Currently there is no constructor body generated.
}

```

The constructor method

`Receive_ComponentMDL0BJ0(get_ReceiveComponentRecvData())`, passes a reference to the receive service to the receive referenced model. The constructor method, `Send_ComponentMDL0BJ1(get_SendComponentSendData())`, passes a reference to the send service to the send referenced model.

- 3 The referenced models invoke service functions to pass messages to the top model. In C++, referenced models invoke the top model (common ancestor, if in a hierarchy) service functions to send or receive messages (specifically, a referenced model invokes the abstract service method (`RecvData` or `SendData`) from the interface created in step 2). The abstract interface classes are emitted to a shared folder. The implementation of the service functions in each service is defined in the top model C++ file.

- a To view the abstract interface class to send messages, open from the shared folder the header file `SendData_real_T.h`.

```
class SendData_real_T
{
public:
    virtual void SendData(const real_T *data, int32_T length, int32_T *status) = 0;
};
```

- b To view the implementation of the service function to send messages, open the top model C++ file `MessageSendReceiveDefaultBufferModel.cpp`.

```
// Model step function
void MessageSendReceiveDefaultBufferModelModelClass::
    Messa_ReceiveComponent_SendData(const real_T *data, int32_T length, int32_T
    *status_ptr) // Explicit Task: ExplicitTask0
{
    UNUSED_PARAMETER(length);
```

- c To view how the send referenced model invokes the service function, open its C++ file `mSend.cpp`. In the step function, the model invokes the service function to send messages to the top model and receives back a return status.

```
// Send: '<Root>/Send'
Out1SendData.SendData(&rtb_SineWave, sizeof(real_T), &status);
```

- d To view the abstract interface class to receive messages, open from the shared folder the header file `RecvData_real_T.h`.

```
class RecvData_real_T
{
public:
    virtual void RecvData(real_T *data, int32_T length, int32_T *status) = 0;
};
```

- e To view the implementation of the service function to receive messages, open top model C++ file `MessageSendReceiveDefaultBufferModel.cpp`.

```
// Model step function
void MessageSendReceiveDefaultBufferModelModelClass::
    Messa_ReceiveComponent_RecvData(real_T *data, int32_T length, int32_T
    *status_ptr) // Explicit Task: ExplicitTask0
{
    UNUSED_PARAMETER(length);
```

- f To view how the receive referenced model invokes the service function, open its C++ file `mRecieve.cpp`. In the step function, the model invokes the service function to receive messages and a status from the top model.

```

// Output and update for referenced model: 'mReceive'
void mReceiveModelClass::step(real_T *rty_Out1)
{
    int32_T status = 1;

    // Receive: '<Root>/Receive'
    status = 1;
    InRecvData.RecvData(rty_Out1, sizeof(real_T), &status);
}

```

Considerations and Limitations

- C++ code support is available for GRT-based system target files by using the Simulink Coder App.
- C++ code support is available for ERT-based system target files by using the Embedded Coder App.
- To generate code, for top and referenced models, select the same language (C++) and the same system target file.
- You cannot configure function prototype control (FPC) for a top model that has root message ports.
- External models and variant models are not supported.
- Software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations are not supported.

Generate C Messages to Communicate Data Between Simulink Components

To generate C code that supports message-based communication between model components in the Simulink environment, use the Simulink Messages & Events Library blocks Send and Receive. To customize the communication, use the Queue block (from the same library) to set parameters for capacity, sorting policy (LIFO, FIFO, and priority), and overwriting policy (behavior when the queue exceeds capacity). You can generate C code for GRT-based system target files by using Simulink Coder or for ERT-based system target files by using Embedded Coder.

Messages are an effective communication technique for distributed and complex systems that you can model within Simulink.

How to Prepare Models in Simulink for Message-Based Communication

In Simulink, you can model message-based communication between model components:

- 1 Create a model that contains a Send block (referenced model).
- 2 Create a model that contains a Receive block (referenced model).
- 3 Create a model that has two Model blocks (top model).
 - Set the first Model block to the model that contains the Send block (model from step 1).
 - Set the second Model block to the model that contains the Receive block (model from step 2).
- 4 When you run the model, a queue generates in the top model above the message line. A queue, explicit or implicit, controls the message communication. You can use the generated queue or you can add a Queue block in the top model to explicitly specify communication parameters.

How Model Components Pass Messages and How the Code Implements the Behavior

Referenced models pass messages:

- 1 In the model that contains the Send block, the Send block converts signals into messages.
- 2 The top model that contains the queue manages messages according to parameters that define capacity, order of delivery, and other quality of service (QoS) metrics.
- 3 In the model that contains the Receive block, the Receive block converts messages back to signals.

In the generated C code, the top model facilitates the connection between the send and receive referenced models by establishing a set interface that the referenced models can access independently of one another.

The generated C code implements message behavior:

- 1 A service is created at each model boundary. A service contains a reference to the top model and an entry point function, referred to as a service function, for referenced models to use to pass messages to the top model.
- 2 The top model initializes each service to create a connection to each referenced model.
- 3 The referenced models invoke service functions to pass messages to the top model.

C Code Generation Example

This example generates and examines C code from the model provided in “Establish Message Send and Receive Interfaces Between Software Components”.

Copyright 2019 The MathWorks, Inc.

Generate C Code:

- 1 Open the model.
- 2 In the Apps gallery, click **Embedded Coder**.
- 3 For each model (top and both referenced models), in the Configuration Parameters dialog box, in the Code Generation pane, set **Language** to C and save the model.
- 4 Generate code. On the **C Code** tab, click **Build**.
- 5 View the generated code. On the **C Code** tab, click **View Code**.

Examine C Code:

- 1 A service is created at each model boundary. In C, referenced models represent services as DWork. The service provides a pointer to an instance of the top model and a service function that referenced models invoke to pass messages.

- a To view the service to send messages, open the send referenced model header file `mSend.h`. View the DWork allocation.

```

/* Block states (default storage) for model 'mSend' */
typedef struct {
    SendData_real_T Out1_SendData;    /* synthesized block */
    real_T lastSin;                   /* '<S1>/Sine Wave' */
    real_T lastCos;                   /* '<S1>/Sine Wave' */
    int32_T systemEnable;             /* '<S1>/Sine Wave' */
} DW_mSend_f_T;

```

- b To view the send message data type, if the data type is shareable (for example, built-in data types, imported bus types, or exported bus types that have a specified data type) the information is located in a shared header file. If the data type is not shareable, the information is located the model header file `mSend.h`. For this example, view the shareable data type by opening the shared header file `SendData_real_T.h`.

```

typedef struct {
    void *host;
    void (*SendData)(void *, const real_T *, int32_T, int32_T *);
} SendData_real_T;

```

- c To view the service to receive messages, open the receive referenced model header file, `mReceive.h`. View the DWork allocation.

```

/* Block states (default storage) for model 'mReceive' */
typedef struct {
    RecvData_real_T In_RecvData;     /* synthesized block */
} DW_mReceive_f_T;

```

- d To view the received messages data type, if the data type is shareable (for example, built-in data types, imported bus types, or exported bus types that have a specified data type) the information is located in a shared header file. If the data type is not shareable the information is located the model header file, `mReceive.h`. For this example, view the shareable data type by opening the shared header file `RecvData_real_T.h`.

```

typedef struct {
    void *host;
    void (*RecvData)(void *, real_T *, int32_T, int32_T *);
} RecvData_real_T;

```

- 2 The top model initializes each service to create a connection to each referenced model. In C, the top model initializes each referenced model DWork. To view the initialization, open the top model C file `MessageSendReceiveDefaultBufferModel.c`.

```

/* Model initialize function */
void MessageSendReceiveDefaultBufferModel_initialize(void)
{
    /* Registration code */

    /* states (dwork) */
    MessageSendReceiveDefaultBuf_DW.SendComponent_InstanceData.rtdw.Out1_SendData.SendData
    = Messa_ReceiveComponent_SendData;
    MessageSendReceiveDefaultBuf_DW.SendComponent_InstanceData.rtdw.Out1_SendData.host
    = MessageSendReceiveDefaultBuf_M;
    MessageSendReceiveDefaultBuf_DW.ReceiveComponent_InstanceData.rtdw.In_RecvData.RecvData
    = Messa_ReceiveComponent_RecvData;
    MessageSendReceiveDefaultBuf_DW.ReceiveComponent_InstanceData.rtdw.In_RecvData.host
    = MessageSendReceiveDefaultBuf_M;
}

```

- 3 The referenced models invoke service functions to pass messages to the top model. In C, a referenced model invokes a service function by dereferencing the service function pointer and passing a pointer to the instance of the top model. You can view the prototypes of the service functions in the top model header file. You can view the referenced model invocations of those service functions in the referenced model C files.
 - a To view the prototype of the service function to send messages, open the top model header file, `MessageSendReceiveDefaultBufferModel.h`.

```

/* Exported entry point function */
extern void Messa_ReceiveComponent_SendData(void *host, const real_T *data,
    int32_T length, int32_T *status_ptr);

```

- b To view the implementation of the service function to send messages, open the top model C file, `MessageSendReceiveDefaultBufferModel.c`.

```

/* Model step function */
void Messa_ReceiveComponent_SendData(void *host, const real_T *data, int32_T
    length, int32_T *status_ptr) /* Explicit Task: ExplicitTask0 */
{
    UNUSED_PARAMETER(host);
    UNUSED_PARAMETER(length);

    /* DiscreteEventSubgraph generated from: '<Root>/Receive Component' */
    *status_ptr = Messa_ReceiveComponent_SendData_l(data);
}

```

```

static int32_T Messa_ReceiveComponent_SendData_1(const real_T *data)
{
    int32_T status = 1;
    Msg_real_T msg;

    /* DiscreteEventSubgraph generated from: '<Root>/Receive Component' */
    msg = MessageSendReceiveDefaultBufferModel_createMsg(data);

    /* Queue generated from: '<Root>/Receive Component' incorporates:
     * DiscreteEventSubgraph generated from: '<Root>/Receive Component'
     */
    if (MessageSendReceiveDefaultBuff_1
        (&MessageSendReceiveDefaultBuf_DW.Queue_InsertedFor_ReceiveCompon, &msg))
    {
        status = 0;
    }

    /* End of Queue generated from: '<Root>/Receive Component' */
    return status;
}

```

- c To view how the send referenced model invokes the service function, open the C file for the model `mSend.c`. In the step function, the model invokes the service to send instance data and a message to the top model and receives back a return status.

```

/* Send: '<Root>/Send' */
if (localDW->Out1_SendData.SendData != NULL) {
    localDW->Out1_SendData.SendData(localDW->Out1_SendData.host, &rtb_SineWave,
        sizeof(real_T), &status);
}

```

- d To view the prototype of the service function to receive messages, open the top model header file `MessageSendReceiveDefaultBufferModel.h`.

```

/* Exported entry point function */
extern void Messa_ReceiveComponent_RecvData(void *host, real_T *data, int32_T
    length, int32_T *status_ptr);

```

- e To view the implementation of the service function to receive messages, open the top model C file `MessageSendReceiveDefaultBufferModel.c`.

```

/* Model step function */
void Messa_ReceiveComponent_RecvData(void *host, real_T *data, int32_T length,
    int32_T *status_ptr) /* Explicit Task: ExplicitTask0 */
{
    UNUSED_PARAMETER(host);
    UNUSED_PARAMETER(length);

    /* DiscreteEventSubgraph generated from: '<Root>/Receive Component' */
    *status_ptr = Messa_ReceiveComponent_RecvData_1(data);
}

```

```

static int32_T Messa_ReceiveComponent_RecvDa_l(real_T *data)
{
    int32_T status = 1;
    Msg_real_T msg;

    /* Queue generated from: '<Root>/Receive Component' incorporates:
     * DiscreteEventSubgraph generated from: '<Root>/Receive Component'
     */
    if (MessageSendReceiveDefaultBuf_lh
        (&MessageSendReceiveDefaultBuf_DW.Queue_InsertedFor_ReceiveCompon, &msg))
    {
        status = 0;
        *data = msg.fData;
    }

    /* End of Queue generated from: '<Root>/Receive Component' */
    return status;
}

```

- f To view how the receive referenced model invokes the service function, open the C file for the model `mReceive.c`. In the step function, the model invokes the service to receive a message payload and a return status.

```

/* Output and update for referenced model: 'mReceive' */
void mReceive(real_T *rty_Out1, DW_mReceive_f_T *localDW)
{
    int32_T status = 1;

    /* Receive: '<Root>/Receive' */
    status = 1;
    if (localDW->In_RecvData.RecvData != NULL) {
        localDW->In_RecvData.RecvData(localDW->In_RecvData.host, rty_Out1, sizeof
            (real_T), &status);
    }

    /* End of Receive: '<Root>/Receive' */
}

```

Considerations and Limitations

- C code support is available for GRT-based system target files by using the Simulink Coder App.
- C code support is available for ERT-based system target files by using the Embedded Coder App.
- To generate code, for top and referenced models, select the same language (C) and the same system target file.
- You cannot configure function prototype control (FPC) for a top model that has root message ports.
- External models and variant models are not supported.
- Software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations are not supported.

Use Handwritten Code to Integrate C++ Messages with POSIX

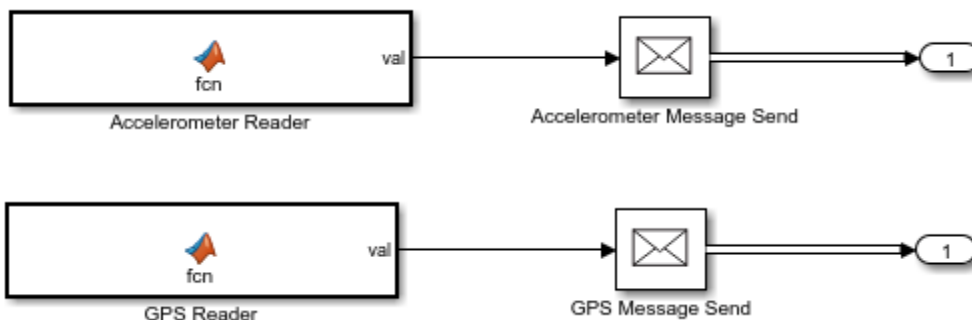

This example shows how to integrate generated C++ code with POSIX to facilitate message communication. The example application is a multisensor positioning system designed to estimate the position of a vehicle. The multisensor positioning system is composed of two components: sensors (multiple models) and an estimation model. The outlined workflow shows how to prepare each component, generate code, and integrate the generated code to pass messages between system components. This example assumes you are familiar with using messages in the Simulink environment. For more information, see “Generate C++ Messages to Communicate Data Between Simulink and an Operating System or Middleware” on page 2-36.

Sensor Models

The first component in the multisensor positioning system is the sensors. The positioning system uses an accelerometer and a GPS sensor to estimate the vehicle position. Each sensor model is composed of a Function block, Send block, and Output port. Each sensor model sends messages to the estimation model by using POSIX messages.

Prepare Models

Open the sensor models `rtwdemo_accel_send` and `rtwdemo_gps_send`.

For each model, perform these steps:

- 1 In the Apps Gallery, click **Embedded Coder**.
- 2 On the toolstrip, set the **Stop time** to 100 seconds. The stop time defines the duration of the data collection when estimating the vehicle position.
- 3 In the model, open the Block Parameters for the Function block and set the **Sample time** to 0.01.

Generate Code

1. For each sensor model, in the Configuration Parameters dialog box, set these parameters:
 - On the **Code Generation** pane, set **Language** to C++. Set **Build configuration** to Specify and add `-lrt` to the **C++ Linker**.
 - On the **Interface** pane, set **Code interface packaging** to C++ class and **Multi-instance code error diagnostic** to none. Under Advanced parameters, select MAT-file logging.
2. Generate code. On the **C++ Code** tab, click **Build**.

Integrate Code

To integrate the generated C++ code from each sensor model with POSIX, hand write the implementation of the send class and generated main program (or create your own). This example provides a customized main program with an implemented send class. To integrate the code from each sensor model, replace the generated main file with the customized main file.

Review the customized main file for each sensor:

1. The customized main file for each sensor is implemented in the same way. As an example, open the customized main file `rtwdemo_accel_send_ert_main_customized.cpp`.

2. Review the implemented send class:

- The send class function, `SendData`, calls into the POSIX API (`mq_send`) to send messages.
- To provide access to a message queue, a POSIX message queue is added as a class variable and a set method is implemented to set the queue.

```
class accelSendModelClassSendData_real_T : public SendData_real_T{
    mqd_t msgQueue;

public:
    // Use POSIX to send messages
    void SendData(const real_T* data, int32_T length, int32_T* status)
    {
        unsigned int priority = 1;
        *status = mq_send(msgQueue, (char*)data, length, priority);
    }

    // Set method for class POSIX queue
    void SetMQ(mqd_t mq)
    {
        msgQueue = mq;
    }
};
```

After the send class implementation, an instance of the send class (a send object) is created. The send object is then attached to the sensor model to enable the sensor to send messages to the estimate model.

```
// Create send object
static accelSendModelClassSendData_real_T Out1SendData_arg;

// Attach send object to sensor model to send messages
static accelSendModelClass rtObj( Out1SendData_arg);
```

3. Review the added POSIX queue behavior functions. The main function uses these functions to open and close the POSIX queue.

```
mqd_t openMQ(const char *name, int flags, int maxmsg, int msgsize)
{
    struct mq_attr attr;
    attr.mq_flags = 0;
    attr.mq_maxmsg = maxmsg;
    attr.mq_msgsize = msgsize;

    mqd_t msgQueue = mq_open(name, flags, 0664, &attr);
```

```
        if (msgQueue < 0) {
            printf("mq_open failed\n");
            exit(1);
        }

        return msgQueue;
    }

void closeMQ(mqd_t msgQueue)
{
    mq_close(msgQueue);
}
```

4. Review the main function. The implemented main function uses the previously defined class and queue functions to send messages and to manage the POSIX message queue. The main function performs the following:

- Opens a POSIX message queue.
- Sends messages.
- Closes the POSIX queue.

```
int_T main(int_T argc, const char *argv[])
{
    // Unused arguments
    (void)(argc);
    (void)(argv);

    // Initialize model
    rtObj.initialize();

    // Open POSIX message queue
    mqd_t msgQueue = openMQ("/PosixMQ_accel", O_CREAT | O_WRONLY, 2, 16);
    Out1SendData_arg.SetMQ(msgQueue);

    // Send messages
    while (rtmGetErrorStatus(rtObj.getRTM()) == (NULL)) {
        rt_OneStep();
    }

    // Matfile logging
    rt_StopDataLogging(MATFILE, rtObj.getRTM()->rtwLogInfo);

    // Disable rt_OneStep() here

    // Close POSIX message queue
    closeMQ(msgQueue);

    return 0;
}
```

Estimate Model

The second component is the estimate model. The estimate model receives messages that have input data from the sensor models and calculates the estimated position of the vehicle.

Prepare Model

Open the model `rtwdemo_pos_estimate`.

- 1 In the Apps Gallery, click **Embedded Coder**.
- 2 On the toolbar, set the **Stop time** to 100 seconds.
- 3 In the model, double-click to open each inport. In the Block Parameters, set **Data type** to double, **Port dimensions** to 3, and **Sample time** to 0.01.
- 4 Open each Message Receive block. Clear the **Use internal queue** parameter to enable the model to use a POSIX message queue.
- 5 Open the Function block and view the implementation of the estimation algorithm.

Generate Code

1. In the Configuration Parameters dialog box, set these parameters:
 - On the **Code Generation** pane, set **Language** to C++. Set **Build configuration** to Specify and add `-lrt` to the **C++ Linker**.
 - On the **Interface** pane, set **Code interface packaging** to C++ class and set **Multi-instance code error diagnostic** to none. Under Advanced parameters, select MAT-file logging.
2. Generate code. On the **C++ Code** tab, click **Build**.

Integrate Code

To integrate the generated C++ code from the estimate model with POSIX, hand write the implementation of the receive class and generated main program (or create your own). The estimate model receives messages from the sensor models and calculates an estimated position of the vehicle. This examples provides a customized main program with an implemented receive class. To integrate the code from the estimate model, replace the generated main file with the customized main file.

Review the customized main file:

1. Open the customized main file `rtwdemo_pos_estimate_ert_main_customized.cpp`.
2. Review the implemented receive class:
 - The receive class function, `RecvData`, calls into the POSIX API (`mq_receive`) to receive messages.

- To provide access to a message queue, a POSIX message queue is added as a class variable and a set method is implemented to set the queue.

```
class positionEstimateModelClassRecvData_real_T : public RecvData_real_T{
    mqd_t msgQueue;

    public:
    // Uses POSIX API mq_receive to receive messages
    void RecvData(real_T* data, int32_T length, int32_T* status)
    {
        // Add receive data logic here
        unsigned int priority = 1;
        *status = mq_receive(msgQueue, (char *)data, length, &priority);
    }

    // Set method for class POSIX queue
    void SetMQ(mqd_t mq)
    {
        msgQueue = mq;
    }
};
```

After the receive class implementation, an instance of the receive class (a receive object) is created for each sensor model. The receive objects are then attached to the estimate model to enable the model to receive messages from each sensor.

```
// Create receive objects
static positionEstimateModelClassRecvData_real_T In1RecvData_arg;
static positionEstimateModelClassRecvData_real_T In2RecvData_arg;

// Attach receive objects to estimate model to receive messages
static positionEstimateModelClass rtObj( In1RecvData_arg, In2RecvData_arg);
```

3. Review the added POSIX queue behavior functions. The main function uses these functions to open, close, and unlink the POSIX queue.

```
mqd_t openMQ(const char *name, int flags, int maxmsg, int msgsize)
{
    struct mq_attr attr;
    attr.mq_flags = 0;
    attr.mq_maxmsg = maxmsg;
    attr.mq_msgsize = msgsize;

    mqd_t msgQueue = mq_open(name, flags, 0664, &attr);

    if (msgQueue < 0) {
        printf("mq_open failed\n");
        exit(1);
    }

    return msgQueue;
}

void closeMQ(mqd_t msgQueue)
{
    mq_close(msgQueue);
}

void unlinkMQ(const char *name)
{

```

```

    if (mq_unlink(name) < 0) {
        printf("mq_unlink failed\n");
        exit(1);
    }
}

```

4. Review the main function. The implemented main function uses the previously defined class and queue functions to receive messages and to manage the POSIX queue. The main function performs the following:

- Opens a POSIX message queue.
- Receives messages.
- Closes the POSIX queue.

```

int_T main(int_T argc, const char *argv[])
{
    // Unused arguments
    (void)(argc);
    (void)(argv);

    // Initialize model
    rtObj.initialize();

    // Open POSIX message queues
    mqd_t msgQueueAccel = openMQ("/PosixMQ_accel", 0_CREAT | 0_RDONLY, 2, 16);
    mqd_t msgQueueGPS = openMQ("/PosixMQ_gpspos", 0_CREAT | 0_RDONLY, 2, 16);

    In1RecvData_arg.SetMQ(msgQueueAccel);
    In2RecvData_arg.SetMQ(msgQueueGPS);

    // Receive messages
    while (rtmGetErrorStatus(rtObj.getRTM()) == (NULL)) {
        rt_OneStep();
    }

    // Matfile logging
    rt_StopDataLogging(MATFILE, rtObj.getRTM()->rtwLogInfo);

    // Disable rt_OneStep() here

    // Close POSIX message queues
    closeMQ(msgQueueAccel);
    closeMQ(msgQueueGPS);

    unlinkMQ("/PosixMQ_accel");
    unlinkMQ("/PosixMQ_gpspos");

    return 0;
}

```

Execute Multisensor Positioning System

To execute the multisensor positioning system, rebuild and run the executables for all models. To view results, run the provided build script `rtwdemo_positioning_system_script`. An example of results is shown in this figure.

Client-Server Communication Interfaces

Components in a platform environment can communicate by using client-server communication. To model client-server communication, use the Simulink Function and Function Caller blocks. A Simulink Function block represents a shared resource. You define the logic as a resource in a Simulink Function block, which separates the function interface (name and arguments) from the logic implementation. Function callers (Function Caller blocks, MATLAB Function blocks, and Stateflow charts) can use the function logic at different levels of the model hierarchy.

The Simulink Function block shares states between function callers. The code generator produces one function. If the Simulink Function block contains blocks that have states, such as a delay or memory, the states persist between function callers.

Implementation Options for Simulink Functions and Function Callers

Choose how to implement Simulink functions and function callers based on your code generation requirements. Considerations include:

- How you represent a function and function callers in a model
- Scope of a function
- Whether to export a function from a model
- Function code interface customizations
- Code generation requirements
- Code generation limitations

Choose a Modeling Pattern

To choose a modeling pattern for client-server communication, review the function definition code and corresponding model elements in this table. The table shows C code for a function that multiplies an input value times two and a Simulink Function block that can represent that function in a component model.

Function Definition	Modeling Element
<pre>codegen-folder/subsystem.c #include "timestwo_sf.h" #include "ex_slfunc_comp_sf.h" #include "ex_slfunc_comp_sf_private.h" void timestwo_sf(real_T rtu_x, real_T *rty_y) { *rty_y = 2.0 * rtu_x; }</pre>	<p>Simulink Function block</p> 

A Simulink function caller invokes a function defined with a Simulink Function block. From anywhere in a model or chart hierarchy, you can call a function defined with a Simulink Function block by using one of these modeling elements.

Function Call	Modeling Element
<pre> codegen-folder/model.c void ex_slfunc_comp_sf_step(void) { real_T rtb_FunctionCaller1; timestwo_sf(ex_slfunc_comp_sf_U.In1, &rtb_FunctionCaller1); ex_slfunc_comp_sf_Y.Out1 = rtb_FunctionCaller1; . . . </pre>	Function Caller block  <p>The diagram shows a rectangular block labeled 'FunctionCaller1'. Inside the block, the text 'caller timestwo_sf()' is visible. An input port on the left is labeled 'x' and is connected to a signal source block containing the number '1'. An output port on the right is labeled 'y' and is connected to a signal destination block containing the number '1'.</p>
<pre> codegen-folder/model.c void ex_slfunc_comp_gf_step(void) { real_T rtb_y1_l; timestwo_gf(ex_slfunc_comp_gf_U.In4, &rtb_y1_l); ex_slfunc_comp_gf_Y.Out4 = rtb_y1_l; . . . </pre>	Stateflow® chart transition  <p>The diagram shows a yellow rounded rectangular transition block. An input port on the left is labeled 'x1' and is connected to a signal source block containing the number '4'. Inside the block, the text '(y1=timestwo_gf(x1);)' is visible. An output port on the right is labeled 'y1' and is connected to a signal destination block containing the number '4'.</p>
<pre> codegen-folder/model.c void ex_slfunc_comp_mf_step(void) { real_T rtb_y; timestwo_mf(ex_slfunc_comp_mf_U.In3, &rtb_y); ex_slfunc_comp_mf_Y.Out3 = rtb_y; . . . </pre>	MATLAB Function block  <p>The diagram shows a rectangular block labeled 'fcn'. An input port on the left is labeled 'x' and is connected to a signal source block containing the number '3'. An output port on the right is labeled 'y' and is connected to a signal destination block containing the number '3'.</p>

For more information about modeling choices, see “Simulink Functions Overview”.

Specify Function Scope

Specify the scope of a Simulink function that you define with a Simulink Function block to be global or scoped.

- Global --- The code generator places code for a global function in source and header files that are separate from model code files (for example, *function.c* and *function.h*). The separate files make the function code available for sharing between function callers.
- Scoped --- The code generator places code for a scoped function in model code files (*model.c* and *model.h*). To call a scoped function in the context of a model, the function caller must be at the same level as the function in the model hierarchy, or one or more levels below.

To create a library of functions that are accessible from anywhere in the generated model code, set up each function as a scoped Simulink Function block. Place each scoped function within a virtual subsystem at the root level of a model.

For more information, see “Scoped, Global, and Port-Scoped Simulink Function Blocks Overview”.

Decide Whether to Generate Export Function Code

Function code is more reusable when you generate it as standalone, atomic components. Design the functions in the context of export-function models.

For information, see “Generate Component Source Code for Export to External Code Base” on page 55-40 and “Export-Function Models Overview”.

Configure Function Code Interface

Simplify integration of the generated function code with external code by configuring generated function code interfaces for Simulink Function and Function Caller blocks. You can configure the function interfaces for:

- Global Simulink Function blocks
- Scoped Simulink Function blocks that are at the root level of a model

For more information, see “Configure Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-2.

Uncalled Simulink Function Blocks

If you use a Simulink Function block in a rate-based model and do not call that function, the code generator treats the Simulink Function block as a constant and does not produce function code. For example, this can occur during model development, when you are ready to define a function, but are not ready to identify a caller.

To identify such blocks in a rate-based model, display sample time colors during simulation (see “View Sample Time Information”). By default, Constant blocks appear magenta. Because the code generator considers uncalled Simulink Function blocks constants during simulation, they appear magenta.

Requirements

- Within a model hierarchy, function names are unique. If the code generator finds multiple functions with the same name, it issues an error. Change the name of one of the functions and delete the `s_lprj` folder.
- The signature (for example, the arguments and argument data types) for a function and function callers must match.
 - If the code generator finds the function first and the signature of a function caller does not match, the code generator issues an error. Change the function caller signature to match the signature of the Simulink Function block or delete the `s_lprj` folder.
 - If the code generator finds a function caller first and the signature of the function does not match, the code generator issues a warning message. Change the signature of the function or function caller so that the signatures match.
- In a Simulink Function block definition, do not define input and output signals for Argument Inport and Argument Outport blocks by using a storage class.

- Do not specify Argument Inport and Argument Outport blocks as test points.
- If you specify the data type of input and output signals for Argument Inport and Argument Outport blocks as a `Simulink.IntEnumType`, `Simulink.AliasType`, or `Simulink.Bus`, set the `DataScope` property to `Imported` or `Exported`.
- A function interface and function callers must match in data type, complexity, dimension, and number of arguments.

Limitations

- To generate code from a model that includes scoped Simulink functions, the model must be an export-function model. The code generator does not support rate-based models that include scoped Simulink functions.
- You can use a Simulink Function block to define a scoped function in a referenced model. You cannot generate code for an export-function model that uses a Function Caller block in an atomic subsystem to invoke that function.
- You can invoke a C++ function that the code generator produces from a Simulink Function block by using code generated from a Stateflow chart. Due to current scope limitations for generated C++ functions, you must invoke those functions with code generated from a Function Caller block.
- Simulink functions and function callers do not honor the `MaxStackSize` parameter.
- Code generation for a C++ class interface supports scoped Simulink functions only.

Client-Server C Code Communication Example

This example shows how to use the Simulink Function and Function Caller blocks to generate client-server communication code. The code generator produces a local server function and a global server function that complies with code requirements so that existing external code can call the function. The code generator also produces calls to the server functions. The call to the global server function shows that the global function is reused (shared).

Code requirements for the global function are:

- Function names start with prefix `func_`.
- Names of input arguments are of the form `xn`, where *n* is a unique integer value.
- Names of output arguments are of the form `yn`, where *n* is a unique integer value.
- Input and output arguments are integers (`int`) and are passed by reference. The native integer size of the target hardware is 32 bits.

You create a function that calls the generated server function code. Then, you construct and configure a model to match the code requirements.

Inspect External Code That Calls Server Functions

In your code generation root folder, create the files `call_times2.h` and `call_times2.c`. If you prefer, you can copy the files from `matlabroot\help\toolbox\ecoder\examples`.

```
call_times2.h
```

```
typedef int my_int;
```

```
call_times2.c
```

```
#include "call_times2.h"

void call_times2(void)
{
    int times2result;

    func_times2(x1, &y1);

    printf('Times 2 Value:', y1);
}
```

This C code calls global server function `func_times2`. The function multiplies an integer input value `x1` by 2 and returns the result as `y1`.

Create Model

Open the example model `ex_slfunc_comp`, which is available in the folder `matlabroot\help\toolbox\ecoder\examples`. The model includes two Simulink functions modeled as Simulink Function blocks, `func_times2` and `func_times3`, and a call to each function. As indicated in the model, the visibility of the Simulink Function block for `func_times2` is set to `global`. That visibility setting makes the function code accessible to other code, including external code that you want to integrate with the generated code. The visibility for `func_times3` is set to `scoped`.

If you configure the model for the code generator to use the GRT or ERT system target file with **File packaging format** set to `Modular`, the code generator produces function code for the model.

For more information, see “Generate Code for a Simulink Function and Function Caller” on page 7-15.

Configure Generated Code to Reuse Custom Data Type

The example assumes that the generated code runs on target hardware using a native integer size of 32 bits. The external code represents integers by using data type `my_int`, which is an alias of `int`. Configure the code generator to use `my_int` in place of the data type that the code generator uses by default, which is `int32_T`.

- 1 Create a `Simulink.AliasType` object to represent the custom data type `my_int`.

```
my_int = Simulink.AliasType
```

```
my_int =
```

```
AliasType with properties:
```

```
Description: ''
DataScope: 'Auto'
HeaderFile: ''
BaseType: 'double'
```

- 2 Set the alias type properties. Enter a description, set the scope to **Imported**, specify the header file that includes the type definition, and associate the alias type with the Simulink base type `int32`.

```
my_int.Description='Custom 32-bit int representation';
my_int.DataScope='Imported';
my_int.HeaderFile='call_times2.h';
my_int.BaseType='int32';
```

```
my_int
```

```
AliasType with properties:
```

```
Description: 'Custom 32-bit int representation'
DataScope: 'Imported'
HeaderFile: 'call_times2.h'
BaseType: 'int32'
```

- 3 Configure the code generator to replace instances of type `int32_T` with `my_int`. In the Configuration Parameters dialog box, open the **Code Generation Data Type Replacement** pane.
 - Select **Replace data type names in the generated code**.
 - In the **Data type names** table, enter `my_int` for the replacement name for `int32`.

Configure Server Functions

For external code to call a global server function, configure the corresponding Simulink Function block to have global visibility and an interface that matches what is expected by the external callers.

- 1 Open the block that represents the `times2` function.

- 2 Configure the function name and visibility by setting Trigger Port block parameters. For example, the code requirements specify that the function name start with the prefix `func_`.
 - Set **Function name** to `func_times2`.
 - Set **Function visibility** to `global`.

- 3 Configure the function input and output arguments by setting Argument Inport and Argument Outport block parameters. For example, the code requirements specify that argument names be of the form xn and yn . The requirements also specify that arguments be type `my_int`.
 - On the **Main** tab, set **Argument name** to `x1` (input) and `y1` (output).
 - On the **Signal Attributes** tab, set **Data type** to `int32`. With the data type replacement that you specified previously, `int32` appears in the generated code as `my_int`.
- 4 Configure the Simulink Function block code interface. At the top level of the model, right-click the block representing global function `func_times2`. From the context menu, select **C/C++ Code > Configure C/C++ Function Interface**.
 - Set **C/C++ function name** to `func_times2`.
 - Set **C/C++ return argument** to `void`.
 - Set **C/C++ Identifier Name** for argument `x1` to `x1`.
 - Set **C/C++ Identifier Name** for argument `y1` to `y1`.

If the dialog box lists output argument `y1` before input argument `x1`, reorder the arguments by dragging the row for `x1` above the row for `y1`.

Configure Local Server Function

Configure a Simulink Function block that represents a local server function to use scoped visibility. Based on code requirements, you might also have to configure the function name, input and output argument names and types, and the function interface.

- 1 Open the block that represents the `times3` function.
- 2 Configure the function name and visibility by setting Trigger Port block parameters. For example, the code requirements specify that the function name start with the prefix `func_`.
 - Set **Function name** to `func_times3`.
 - Set **Function visibility** to `scoped`.
- 3 Configure the function input and output arguments by setting Argument Inport and Argument Outport block parameters. For example, the code requirements specify that argument names be of the form xn and yn . The requirements also specify that arguments be type `my_int`.
 - On the **Main** tab, set **Argument name** to `x1` (input) and `y1` (output).
 - On the **Signal Attributes** tab, set **Data type** to `int32`. With the data type replacement that you specified previously, `int32` appears in the generated code as `my_int`.
- 4 Configure the Simulink Function block code interface. At the top level of the model, right-click the scoped function `func_times3`. From the menu, select **C/C++ Code > Configure C/C++ Function Interface**. In this case, the code generator controls naming the function and arguments. The function name combines the name of the root model and the function name that you specify for the trigger port of the Simulink Function block. In this example, the name is `ex_slfunc_comp_func_times3`.

You can set **C/C++ return argument** to the argument name that you specify for the Argument Outport block or `void`. For this example, set it to `void`.

For arguments, the code generator prepends `rtu_` (input) or `rty_` (output) to the argument name that you specify for the Argument Inport block.

If the dialog box lists output argument `y1` before input argument `x1`, reorder the arguments by dragging the row for `x1` above the row for `y1`.

Configure Function Callers

For each function caller, configure Function Caller block parameters:

- Set **Function prototype** to `y1 = func_times2(x1)`.
- Set **Input argument specifications** to `int32(1)`.
- Set **Output argument specifications** to `int32(1)`.

Generate and Inspect Code

Generate code for the model.

- Global server function code

Source code for global server function `func_times2` is in the build folder in subsystem file, `func_times2.c`.

```
#include "func_times2.h"

/* Include model header file for global data */
#include "ex_slfunc_comp.h"
#include "ex_slfunc_comp_private.h"

void func_times2(my_int x1, my_int *y1)
{
    *y1 = x1 << 1;
}
```

- Local server function code

The code generator places the definition for the local (scoped) function `func_times3` in file build folder in file `ex_slfunc_comp.c`.

```
void ex_slfunc_comp_func_times3(my_int rtu_x1, my_int *rty_y1)
{
    *rty_y1 = 3 * rtu_x1;
}
```

- Calls to generated functions

The model execution (step) function, in model file `ex_slfunc_comp.c`, calls the two Simulink functions: global function `func_times2` and local function `ex_slfunc_comp_func_times3`. The name `ex_slfunc_comp_func_times3` reflects the scope of the local function by combining the name of the model and the name of the function.

```
void ex_slfunc_comp_step(void)
{
    my_int rtb_FunctionCaller2;

    func_times2(ex_slfunc_comp_U.In1, &rtb_FunctionCaller2);

    ex_slfunc_comp_Y.Out1 = rtb_FunctionCaller2;

    ex_slfunc_comp_func_times3(ex_slfunc_comp_U.In2, &rtb_FunctionCaller2);

    ex_slfunc_comp_Y.Out2 = rtb_functionCaller2;
}
```

- Entry-point declaration for local server function

The model header file `ex_slfunc_comp.h` includes an extern declaration for function `ex_slfunc_comp_func_times3`. That statement declares the function entry point.

```
extern void ex_slfunc_comp_func_times3(my_int rtu_x1, my_int *rty_y1);
```

- Include statements for global server function

The model header file `ex_slfunc_comp.h` lists include statements for the global function `func_times2`.

```
#include "func_times2_private.h"
#include "func_times2.h"
```

- Local macros and data for global server function

The subsystem header file `func_times2_private.h` defines macros and includes header files that declare data and functions for the global server function, `func_times2`.

```
#ifndef RTW_HEADER_func_times2_private_h_
#define RTW_HEADER_func_times2_private_h_
#ifndef ex_slfunc_comp_COMMON_INCLUDES_
#define ex_slfunc_comp_COMMON_INCLUDES_
#include "rtwtypes.h"
#endif
#endif
```

- Entry-point declaration for global server function

The shared header file `func_times2.h`, in the shared utilities folder `slprj/stf/_sharedutils`, lists shared type includes for `rtwtypes.h`. The file also includes an extern declaration for the global server function, `func_times2`. That statement declares the function entry point.

```
#ifndef RTW_HEADER_func_times2_
#define RTW_HEADER_func_times2_

#include "rtwtypes.h"

extern void func_times2(my_int rtu_x1, my_int *rty_y1);

#endif
```

Client-Server C++ Code Communication Example

You can generate C++ code to support client-server communication by generating abstract classes for modeled client and server components. This type of code generation is supported for models that use scoped function ports as described in “Call Simulink Functions in Other Models Using Function Ports”. After code generation, you must then handwrite code to implement the generated classes. The basic workflow is the following:

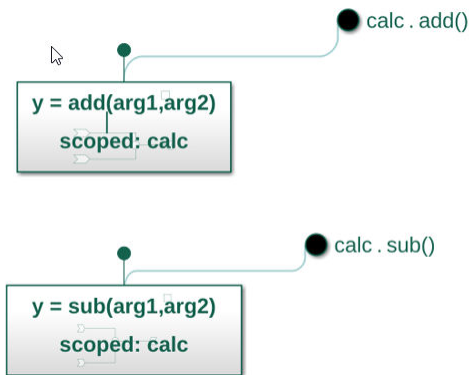

- 1 Create your own main file. In the program, create concrete methods from the generated abstract pure virtual methods shown in the example as `add` and `sub`.
- 2 Implement the class functions `add` and `sub` to call into your selected middleware to publish and subscribe data.

- 3 Create an instance of your implemented client and server scoped function port classes.
- 4 Create an instance of the model class by using the instances of each scoped function port class as arguments in the model constructor.

For example, the following modelled client requests the services of add and sub:

The corresponding modelled server provides these services:

The resulting generated code, as shown in the header files, is the following:

Generated Client-Server Code

Client Code	Server Code
<pre> // Class declaration for model calc_client class calc_client final { // public data and function members public: // External inputs (root inport signals with default storage) struct ExtU_calc_client_T { real_T calc_add_p; real_T calc_sub_p; real_T Input; real_T Input1; real_T Input2; real_T Input3; }; // External outputs (root outports fed by signals with default storage) struct ExtY_calc_client_T { real_T Output; real_T Output1; }; // Real-time Model Data Structure struct RT_MODEL_calc_client_T { const char_T * volatile errorStatus; }; ... // Real-Time Model get method calc_client::RT_MODEL_calc_client_T * getRTM(); // Constructor calc_client(calcT &calc_arg); // Root inports set method void setExternalInputs(const ExtU_calc_client_T *pExtU_calc_client_T) { calc_client_U = *pExtU_calc_client_T; } // Root outports get method const ExtY_calc_client_T &getExternalOutputs() const { return calc_client_Y; } // model initialize function static void initialize(); // model step function void doAdd(); // model step function void doSub(); </pre>	<pre> // Class declaration for model calc_server // Forward declaration class calc_server; class calc_servercalcT : public calcT { // public data and function members public: calc_servercalcT(calc_server &Provider); void add(real_T u2, real_T u1, real_T *y); void sub(real_T u2, real_T u1, real_T *y); // External inputs (root inports) struct ExtU_calc_server_T { real_T Input; real_T Input1; real_T Input2; real_T Input3; }; // External outputs (root outports) struct ExtY_calc_server_T { real_T Output; real_T Output1; }; // Real-time Model Data Structure struct RT_MODEL_calc_server_T { const char_T * volatile errorStatus; }; ... // Real-Time Model get method calc_servercalcT &getRTM(); // Constructor calc_servercalcT(calc_server &Provider); // Root inports set method void setExternalInputs(const ExtU_calc_server_T *pExtU_calc_server_T) { calc_servercalcT_U = *pExtU_calc_server_T; } // Root outports get method const ExtY_calc_server_T &getExternalOutputs() const { return calc_servercalcT_Y; } // model initialize function static void initialize(); // model step function void doAdd(); // model step function void doSub(); </pre>

Client Code	Server Code
<pre data-bbox="248 321 803 737">// model terminate function static void terminate(); ... // private data and function members private: // External inputs ExtU_calc_client_T calc_client_U; // External outputs ExtY_calc_client_T calc_client_Y; calcT &calc; // Real-Time Model RT_MODEL_calc_client_T calc_client_M; };</pre>	

To implement these abstract classes, you must handwrite the code. The following is a POSIX implementation example:

Implemented Client-Server Code

Client Code	Server Code
<pre> class mCalcModelClasscalcT : public calcT{ public: mCalcModelClasscalcT() { clnt = clnt_create (host, COMPUTE, if (clnt == NULL) { clnt_pcreateerror (host); exit (1); } } void add(int32_T arg0, int32_T arg1, int32_T* arg2) { int32_T *result_1; operands add_6_arg; // Do data marshaling into struct add_6_arg.num1 = arg0; add_6_arg.num2 = arg1; result_1 = add_6(&add_6_arg, clnt); if (result_1 == (int *) NULL) { clnt_perror (clnt, "call failed"); } // Marshal the result *arg2 = *result_1; } void sub(int32_T arg0, int32_T arg1, int32_T* arg2) { int32_T *result_2; operands sub_6_arg; sub_6_arg.num1 = arg0; sub_6_arg.num2 = arg1; result_2 = sub_6(&sub_6_arg, clnt); if (result_2 == (int *) NULL) { clnt_perror (clnt, "call failed"); } *arg2 = *result_2; } private: CLIENT *clnt; }; static mCalcModelClasscalcT calc_arg; static mCalcModelClass mCalc_Obj(calc_arg); </pre>	<pre> static mServer mCalcSvr_Obj; int * add_6_svc(operands *argp, struct svc_req *rqstp) { static int result; mCalcSvr_Obj.get_calc().add(argp->num1, argp->num2, &result); return &result; } int * sub_6_svc(operands *argp, struct svc_req *rqstp) { static int result; mCalcSvr_Obj.get_calc().sub(argp->num1, argp->num2, &result); return &result; } </pre>

Client-server communication uses the same modeling pattern as messages by generating an abstract interface that can be elaborated on for each scoped function service port. For additional information, see “Message Communication Interfaces” on page 2-36.

Device Driver I/O

Device drivers interact with hardware directly. They depend on characteristics of the hardware. For example, a device driver for an analog-to-digital converter initializes, reads data from, and writes data to hardware registers. Hardware differences and dependencies concern data type size, endianness, shift operations, compiler directives, and optimized function and operator support. Other application code interfaces with device drivers by using a programming interface and data mapped to specific memory addresses. Typically, simulation on a development computer is not possible. Reading from and writing to a register during simulation on a development computer produces unexpected and unwanted results.

Device drivers for communication protocols and target hardware are essential to real-time development projects. For example, you can have a working device driver that you want to integrate with algorithmic code that reads data from and writes data to an I/O device that the driver supports. The code generator can produce a single set of application source files from an algorithm model and integrated driver code written in C or C++.

This figure shows an application that requires integration of existing driver code for hardware devices. The core software algorithms and logic can be a combination of code modules for external reusable algorithms integrated into the Simulink environment and code generated as part of an overall model design.

Integrate device driver code in a component model by using one of these methods:

- Import driver function code into a C Caller block.
- Generate an S-function, compile and link the generated S-function, and create a mask for calling the generated S-function by using the Legacy Code Tool.

Data Transfer Interfaces

Within a platform environment, callable functions that are within a component exchange data by calling the platform data transfer service. To represent calls to a platform data transfer service in a component model and configure the relevant data elements for code generation:

- 1 In the component model, represent a data transfer by using a signal line that connects the communicating functions.
- 2 For function platform deployment, if the platform service that handles the data transfers uses during-execution data access, create a memory buffer to hold the value that a function receives constant during function execution by using the Safeguard block that is provided in the Component Deployment Guidelines for Embedded Coder Support Package. Insert and connect the safeguard mechanism to:
 - The output port of the root-level inport in the receiving function
 - The input port of the root-level outport in the sending function
- 3 If you have not already done so, open the Embedded Coder app.
- 4 Add the signal line that connects the function components to the model code mappings.
 - a In the component model, select the signal that connects the functions.
 - b Pause on the ellipsis that appears above or below the signal line to open the action bar. Click the **Add Signal** button.

In the Code Mappings editor, on the **Signals/States** tab, the Signals node expands and lists the signal that you added.

- 5 In the Code Mappings editor or by using the code mappings programming interface, configure the code interface for the signal line. At a minimum, set these properties:
 - **Storage Class**, which controls the appearance and placement of the signal data in the generated code
 - **Identifier**, which names the model element in the generated code. The code generator uses the identifier in names constructed for access functions.
 - **GetFunction** and **SetFunction**, which specifies naming rules for the names of the platform data transfer service functions

For signal lines that represent a service that uses during-execution communication, use the `DuringExecution` storage class that is provided in the Component Deployment Guidelines for Embedded Coder Support Package.

- “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75

Nonvolatile Memory Interfaces

Typically, a component accesses nonvolatile memory during component startup or shutdown. Within a platform environment, a component can gain access to nonvolatile memory directly or by using a nonvolatile memory service.

Nonvolatile Memory Direct Access Interfaces

To gain access to nonvolatile memory directly, without using a platform service, and configure the relevant data elements for code generation:

- 1 In the component model:
 - Represent a direct memory read with an inport (Inport or In Bus Element block) connected to an Initialize Function block.
 - Represent a direct memory write with an outport (Outport or Out Bus Element block) connected to a Terminate Function block.
- 2 If the nonvolatile memory data access occurs during function execution, connect a safeguard block to root-level inport or outport as described in “Receive and Send Communication Interfaces” on page 2-34.
- 3 If you have not already done so, open the Embedded Coder app.
- 4 In the Code Mappings editor, configure the code interfaces for the inport and outport that are connected to the Initialize Function and Terminate Function blocks. At a minimum, set these properties:
 - **Storage Class**, which controls the appearance and placement of the signal data in the generated code.
 - **Identifier**, which names the model element in the generated code. The code generator uses the identifier in names constructed for access functions.
 - **GetFunction** or **SetFunction**, which specifies the naming rule for the name of the platform get or set method that handles the read or write operation

Set **Storage Class** to GetSet.

For more information about the GetSet storage class, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.

- 5 In the Code Mappings editor or by using the code mappings programming interface, configure the prototypes for the initialize and terminate entry-point functions. For more information, see “Configure Generated C Function Interface for Model Entry-Point Functions” on page 32-113.

Nonvolatile Memory Service Interfaces

To represent use of a platform nonvolatile memory service in a component model and configure the relevant data elements for code generation:

- 1 In the model:
 - Represent the platform service by using a Simulink Function block.
 - Access the service by using a Function Caller block.

- 2 Configure the function prototype generated for the blocks to align with platform requirements by using the Code Mappings editor or the code mappings programming interface. See “Configure Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-2.

- “Configure Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-2

Parameter Tuning Interfaces

Some components require interface support for tunable parameters, which enable you to change the parameter value that is stored in memory during program execution. For example, you might use a tunable parameter to determine an optimal value by changing the value and monitoring the results or to adapt an algorithm to different execution conditions. An example of a block parameter value that you might want to be tunable is a the **Gain** parameter of the Gain block.

To represent a parameter in a component model and configure the parameter to be tunable in generated code:

- 1 Set up the parameter data for the model. For example, you might define MATLAB variables in the model or base workspace.
- 2 In the Model Explorer, convert MATLAB variables that represent the parameters to `Simulink.Parameter` objects.
- 3 In the Embedded Coder app, open the Code Mappings editor. In the **C Code** tab, select **Code Interface > Default Code Mappings**. The Code Mappings editor opens to the **Data Defaults** tab.
- 4 Expand the **Parameters** category.
- 5 Check the link text to the right of **Model parameters** . That link text informs you whether parameters are configured to be inlined or tunable. If the text is 'Auto' will be inlined, click it.
- 6 In the Model Configuration Parameters dialog box, set parameter **Default parameter behavior** to Tunable. In the Code Mappings editor, the link text changes to 'Auto' will be tunable.
- 7 In the Code Mappings editor or by using the code mappings programming interface, configure the code interface for the model parameters to be tuned. At a minimum, set these properties:
 - **Storage Class**, which controls the appearance and placement of the state or signal data in the generated code.
 - **Identifier**, which names the model element in the generated code.

For a list of storage classes supported by Embedded Coder, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.

Alternatively, you can use these programming interfaces to tune parameters without using external model:

- C application programming interface (API)
- Target Language Compiler programming interface

After you configure the parameter interface, you can:

- Set up and run external mode simulations that use a communication channel between Simulink on your development computer (host) and your generated program executable that runs on the target platform by using the Run on Custom Hardware app.
- Generate and customize an ASAP2 file and a Calibration Data Format (CDF) file by using the **Generate Calibration Files** tool.

Measurement Interfaces

Some components require interface support for viewing and analyzing signal and state data during program execution. For example, you might use the Simulation Data Inspector to produce plots and maps of the data for comparing run results that show model behavior.

To represent signal and state data in a component model and configure the signals and states for measurement in generated code:

- 1 Set up the signal and state data for the model design.
- 2 In the Embedded Coder app, open the Code Mappings editor. In the **C Code** tab, select **Code Interface > Individual Code Mappings**. The Code Mappings editor opens to the **Functions** tab.
- 3 Click the **Signals/States** tab.
- 4 Add the signal lines that you want to measure to the model code mappings.
 - a In the component model, select the signal.
 - b Pause on the ellipsis that appears above or below the signal line to open the action bar. Click the **Add Signal** button.

In the Code Mappings editor, on the **Signals/States** tab, the Signals node expands and lists the signal that you added.

- 5 In the Code Mappings editor or by using the code mappings programming interface, configure the code interface for the model states and the signal lines that you added. At a minimum, set these properties:
 - **Storage Class**, which controls the appearance and placement of the state or signal data in the generated code
 - **Identifier**, which names the model element in the generated code.

For a list of storage classes supported by Embedded Coder, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 33-75.

Alternatively, you can use these programming interfaces to visualize and analyze signal and state data without using external mode:

- C application programming interface (API)
- Target Language Compiler programming interface

After you configure the signal and state interfaces, you can:

- Set up and run external mode simulations that use a communication channel between Simulink on your development computer (host) and your generated program executable that runs on the target platform by using the Run on Custom Hardware app
- Generate and customize an ASAP2 file and a Calibration Data Format (CDF) file by using the **Generate Calibration Files** tool.

Multi-Instantiation

You can model multi-instance rate-based component models in Simulink. For example, you can:

- Configure a model as a multi-instance component by setting model configuration parameter “Code interface packaging” to `Reusable function`.
- Generate C code with reentrant functions and multi-instance calls to platform services. You can access external I/O, tunable parameters, and per-instance memory, and use reusable subsystems in multi-instance mode.
- Verify multi-instance C code by using software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations.

Subsystems in Simulink Coder

- “Generate Code and Executables for Individual Subsystems” on page 3-2
- “Generate Inlined Subsystem Code” on page 3-5
- “Generate Subsystem Code as Separate Function and Files” on page 3-7

Generate Code and Executables for Individual Subsystems

You can generate code and build a standalone executable for a subsystem within a model. When you generate code for an individual subsystem, the code generation and build process uses the code generation and build parameters of the root model.

- 1 Open a model with a subsystem, such as `rtwdemo_atomic`.

```
open_system('rtwdemo_atomic')
```

Copyright 1994-2020 The MathWorks, Inc.

- 2 Open Simulink Coder or Embedded Coder.

If you are using Embedded Coder, from the **C Code** tab, click **View Code** to open the **Code View** editor.
- 3 Right-click the Subsystem block. From the context menu, click **Block Parameters (Subsystem)**. From the **Block Parameters: SS1** window, open the **Code Generation** tab.
- 4 Use the **Function name options** and **File name options** parameters to control the names of the generated functions and files. Set the **Function name options** parameter to Auto so that the code generator uses the name of the subsystem in the generated file names.
- 5 Right-click the Subsystem block. From the context menu, select **C/C++ Code > Build This Subsystem**.
- 6 To configure properties such as the name, class, and storage class of variables (or data objects) that are referenced as block parameters in the subsystem, convert the subsystem to a Model block. Configure the properties through the Code Mappings editor.

For more information on tunable and inlined parameters and storage classes, see “Create Tunable Calibration Parameter in the Generated Code” on page 33-110.

The build process displays status messages in the MATLAB Command Window. When the build is complete, the generated executable is in your working folder. The name of the generated executable is *subsystem.exe* (on PC platforms) or *subsystem* (on The Open Group UNIX® platforms). *subsystem* is the name of the source Subsystem block. In this example, the Subsystem block is named SS1.

The generated code is in a build subfolder named *subsystem_target_rtw*. *subsystem* is the name of the source subsystem block and *target* is the name of the target configuration.

- 7 (Optional) Generate an S-function by right-clicking the Subsystem block and selecting **C/C++ Code > Generate S-Function** from the context menu. For more information on S-functions, see “Generate S-Function from Subsystem”.

Subsystem Build Limitations

These limitations apply to building subsystems:

- A subsystem build does not support a subsystem that has a function-call trigger input or a function-call output.
- When you build a subsystem that includes an Outport block for which the **Data type** parameter specifies a bus object, you must address errors that result from setting signal labels. To configure the software to display these errors, in the Configuration Parameters dialog box for the parent model, on the **Diagnostics > Connectivity** pane, set the **Signal label mismatch** parameter to **error**.
- When a subsystem is in a triggered or function-call subsystem, the right-click build process might fail if the subsystem code is not sample-time independent. To determine whether a subsystem is sample-time independent:
 - 1 Copy all blocks in the subsystem to an empty model.
 - 2 In the Configuration Parameters dialog box, on the **Solver** pane, set:
 - a **Type** to **Fixed-step**.
 - b **Periodic sample time constraint** to **Ensure sample time independent**.
 - c Click **Apply**.
 - 3 Update the model. If the model is sample-time dependent, Simulink generates an error in the process of updating the diagram.
- When you use the right-click build process for a subsystem, the code generator attempts to use the subsystem name for generated code files. In some cases, there can be a conflict with the name that you specify when you set, for example, **File name options** to **Use function name** or **Function name options** to **Use subsystem name**. You see an error:

```
The subsystem 'model/subsys'
is trying to generate code to an reserved file (subsys) for
the model 'subsys'...
```

To resolve the error, modify one of the conflicting file names so that the names are unique.

- In a subsystem build warning, the subsystem block path hyperlink that is created references a temporary model block path instead of the actual model block path. In the Diagnostic Viewer, clicking the subsystem hyperlink does not take you to the block. In the Command Window, you see a message:

```
...
No system or file called 'subsystemName' found.
...
```

Generate Inlined Subsystem Code

To inline subsystem code with your model code, configure a nonvirtual subsystem. In the Subsystem Block Parameters dialog box, the **Function packaging** parameter specifies the format of the subsystem generated code. This parameter has these settings:

- Auto
- Inline
- Nonreusable function
- Reusable function

The code generator can generate inlined code for the **Auto** and **Inline** settings. The inline setting directs the code generator to inline the subsystem code unconditionally.

The default **Auto** setting directs the code generator to generate the most efficient code for the subsystem based on the type and number of instances of the subsystem that exist in the model. When there is only one instance of a subsystem, the **Auto** setting inlines the subsystem code. In Embedded Coder, when there are multiple instances of a subsystem that are not too complex, the **Auto** setting inlines the code for each subsystem. Otherwise, the **Auto** setting generates a single copy of the function (as a reusable function). For a function-call subsystem that has multiple callers, the **Auto** setting generates subsystem code that is consistent with the **Nonreusable function** setting.

Configure Subsystem to Inline Code

- 1 Open a model with a subsystem, such as `rtwdemo_atomic`.

```
open_system('rtwdemo_atomic')
```

Copyright 1994-2020 The MathWorks, Inc.

- 2 Open Simulink Coder or Embedded Coder.

If you are using Embedded Coder, from the **C Code** tab, click **View Code** to open the **Code View** editor.

- 3 Right-click the Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
- 4 In the Subsystem Parameters dialog box, verify that **Treat as atomic unit** is selected. This option makes the subsystem nonvirtual. When the subsystem is nonvirtual, the **Function packaging** option is available on the **Code Generation** tab.
- 5 Click the **Code Generation** tab and select Auto or Inline from the **Function packaging** parameter.
- 6 Click **Apply** and close the dialog box.

The border of the subsystem thickens, indicating that it is nonvirtual.

- 7 Generate code from the model. The code generator inlines subsystem code within `rtwdemo_atomic.c`. You can identify this code by system and block identification tags, such as:

```
/* Atomic SubSystem Block: <Root>/AtomicSubsys1 */
```

Exceptions to Inlining

There are certain cases in which the code generator does not inline a nonvirtual subsystem, even though you select the **Inline** setting.

- If a noninlined S-function calls a function-call subsystem, the code generator ignores the **Inline** setting. Because noninlined S-functions use function pointers to make function calls, the code generator must generate a function with all arguments present.
- In a feedback loop involving function-call subsystems, the code generator generates a function instead of inlined code for one of the subsystems. Based on the internal, sorted order of the subsystems, the code generator selects which subsystem to generate a function.
- If an S-function, an Async Interrupt, or a Task Sync block that has the option `SS_OPTION_FORCE_NONINLINED_FCNCALL` set to `TRUE` calls a subsystem, the code generator generates a function instead of inlined code for the subsystem. The VxWorks® block library (`vxlib1`) contains the user-defined Async Interrupt and Task Sync blocks.¹

The **Function packaging** parameter is disabled in Simulink Function blocks.

Generate Subsystem Code as Separate Function and Files

You can configure an atomic subsystem to generate code to a separate function and file. This results in code that is more modular and enables you to unit test code for individual subsystems.

The **Function packaging** Subsystem block parameter has two settings that cause a subsystem to generate code as a separate function. The **Reusable** function option generates a function that passes I/O, states, and parameters as function arguments. The **Nonreusable** function option generates a function that passes I/O, states, and parameters as a combination of function arguments and global data structures.

Subsystem Function Dependence

When generating code for a subsystem, the code can reference global data structures of the model, even if the subsystem function code is in a separate file. Each subsystem code file contains `include` directives and comments describing the dependencies. The code generator checks for cyclic file dependencies and produces warnings about them at build time. For descriptions of how the code generator packages code, see “Manage Build Process File Dependencies”.

To generate subsystem function code that is independent of the code generated for the parent model, place the subsystem in a library and configure it as a reusable subsystem, as described in “Generate Reusable Code from Library Subsystems Shared Across Models” on page 7-41.

If you have Embedded Coder, you can generate code for library consisting of reusable subsystems that have different function interfaces. For more information, see “Library-Based Code Generation for Reusable Library Subsystems” on page 8-2.

Generate Subsystem as a Reusable Function

- 1 Open a model with a subsystem, such as `rtwdemo_atomic`.

Copyright 1994-2020 The MathWorks, Inc.

If you are using Embedded Coder, from the **C Code** tab, click **View Code** to open the **Code View** editor.

- 2 Right-click the Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
- 3 In the Subsystem Parameters dialog box, verify that **Treat as atomic unit** is selected. With that parameter selected, on the **Code Generation** tab, the **Function packaging** parameter is available.
- 4 Click the **Code Generation** tab and select Reusable function from the **Function packaging** parameter. This enables two parameters:
 - The **Function name options** parameter controls the naming of the generated function.
 - The **File name options** parameter controls the naming of the generated file.
- 5 Set the **File name options** parameter to Use subsystem name.
- 6 Click **Apply** and close the dialog box.
- 7 If you are using Embedded Coder, open the Configuration Parameters dialog box. Verify that the model configuration parameter **File packaging format** is set to Modular.
- 8 Generate the code.

```
#include "SS1.h"

/* Include model header file for global data */
#include "rtwdemo_atomic.h"
#include "rtwdemo_atomic_private.h"

/* Outputs for atomic system: '<Root>/SS1' */
real_T myfun(DW_myfun_T *localDW)
{
    /* DiscreteIntegrator: '<S1>/Integrator' */
    return localDW->Integrator_DSTATE;
}

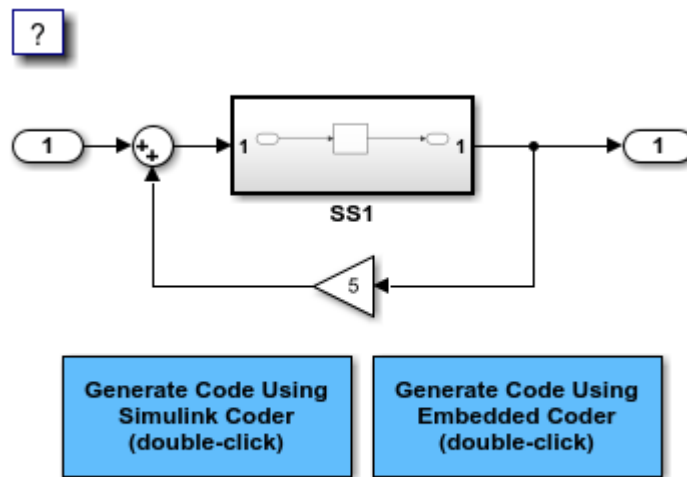

/* Update for atomic system: '<Root>/SS1' */
void myfun_Update(real_T rtu_In1, DW_myfun_T *localDW)
{
    /* Update for DiscreteIntegrator: '<S1>/Integrator' */
    localDW->Integrator_DSTATE += rtu_In1;
}
```

The reusable function `myfun` passes in inputs and states as arguments to the subsystem function.

For more information, see “Generate Reentrant Code from Subsystems” on page 7-33 and “Generate Reusable Code from Library Subsystems Shared Across Models” on page 7-41.

Generate Subsystem as a Nonreusable Function

- 1 Open a model with a subsystem, such as `rtwdemo_atomic`.

Copyright 1994-2020 The MathWorks, Inc.

If you are using Embedded Coder, from the **C Code** tab, click **View Code** to open the **Code View** editor.

- 2 Right-click the Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
- 3 In the Subsystem Parameters dialog box, verify that **Treat as atomic unit** is selected. With that parameter selected, on the **Code Generation** tab, the **Function packaging** parameter is available.
- 4 Click the **Code Generation** tab and select **Nonreusable** function from the **Function packaging** parameter. This enables two parameters:
 - The **Function name options** parameter controls the naming of the generated function.
 - The **File name options** parameter controls the naming of the generated file.
- 5 Set the **File name options** parameter to **Use subsystem name**.

If you are using Embedded Coder, verify that the **Function interface** parameter is set to **void_void**. For more information, see "Generate Predictable Function Interface to Match Graphical Block Interface" on page 4-2.

- 6 Click **Apply** and close the dialog box.
- 7 If you are using Embedded Coder, open the Configuration Parameters dialog box. Verify that the model configuration parameter **File packaging format** is set to **Modular**.
- 8 Generate the code.

```
#include "SS1.h"

/* Include model header file for global data */
#include "rtwdemo_atomic.h"
#include "rtwdemo_atomic_private.h"

/* Outputs for atomic system: '<Root>/SS1' */
void myfun(void)
{
    /* Output: '<Root>/Out1' incorporates:
```

```
    * DiscreteIntegrator: '<S1>/Integrator'  
    */  
    rtwdemo_atomic_Y.Out1 = rtwdemo_atomic_DW.Integrator_DSTATE;  
}  
  
/* Update for atomic system: '<Root>/SS1' */  
void myfun_Update(void)  
{  
    /* Update for DiscreteIntegrator: '<S1>/Integrator' */  
    rtwdemo_atomic_DW.Integrator_DSTATE += rtwdemo_atomic_B.Sum;  
}
```

The nonreusable function `myfun` passes in inputs and states through the global data structures `rtwdemo_atomic_Y` and `rtwdemo_atomic_DW`.

Subsystems in Embedded Coder

Generate Predictable Function Interface to Match Graphical Block Interface

You can generate code for a nonreusable subsystem that has a predictable function interface. A predictable interface can be useful for debugging and testing your code and integrating it with external applications. The generated code with a predictable function interface is more readable.

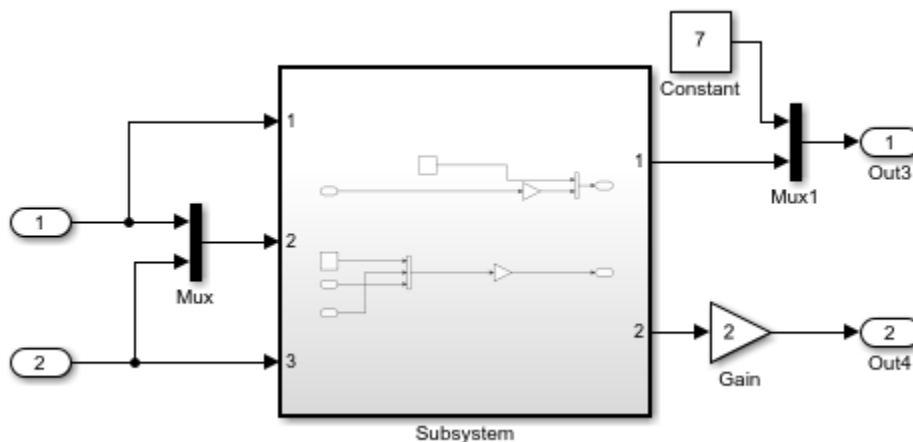

When you specify block parameter **Function interface** as **Allow arguments (Match graphical interface)**, the generated function interface matches the subsystem graphical block interface. For example, if a subsystem has two Inports and one Outport, the function interface generates two arguments for the Inports and one function argument for the Outport. The order of the arguments is determined by the port index. The function interface is predictable and does not change.

When you generate code for a nonreusable subsystem by using the block parameter **Function interface** set to **Allow arguments (Optimized)**, the code generator generates a subsystem function interface that passes data through arguments. The function arguments might not match the subsystem graphical block interface.

This example shows how the generated code is different when you specify **Function interface** as **Allow arguments (Optimized)** and **Allow arguments (Match graphical interface)**.

Generate Function Interface That Has Optimized Arguments

1. Open the example model `ex_mux_allow_arguments`. The subsystem in the model contains three inputs and two outputs.

2. Right-click the subsystem and select **Block Parameters (Subsystem)** from the context menu. Alternatively, click in the subsystem to open the Block Parameters dialog box in the **Property Inspector** pane.

These preset settings are required to generate expected code:

- In the **Main** tab, the block parameter **Treat as atomic unit** is selected.
- In the **Code Generation** tab, **Function packaging** is **Nonreusable function** and **Function interface** is **Allow arguments (Optimized)**.

3. Open the **Embedded Coder** app. Click **Build**.

The generated code in `ex_mux_allow_arguments.c` file contains a subsystem function interface with arguments:

```
/* Output and update for atomic system: '<Root>/Subsystem' */
static void FPCSS_Mux(real_T rtu_In1, real_T rtu_In2, real_T rty_Out2[4])
{
    /* Constant: '<S1>/Constant1' */
    rtDW.Constant1 = 5.0;

    /* Gain: '<S1>/Gain4' */
    rtDW.Gain4 = 10.0 * rtu_In1;

    /* Gain: '<S1>/Gain1' incorporates:
     * Constant: '<S1>/Constant'
     */
    rty_Out2[0] = 150.0;
    rty_Out2[1] = 15.0 * rtu_In2;
    rty_Out2[2] = 15.0 * rtu_In1;
    rty_Out2[3] = 15.0 * rtu_In2;
}
```

The `Allow arguments (Optimized)` specification leads to optimized generated code by reducing global RAM. The function interface has some inputs and outputs as function arguments. The generated function interface does not match the subsystem graphical block interface.

Generate Function Interface That Has Arguments Matching Graphical Interface

1. In the example model `ex_mux_allow_arguments`, open the Subsystem Block Parameters dialog box.
2. On the **Code Generation** tab, specify **Function interface** as `Allow arguments (Match graphical interface)` and click **Apply**.
3. Generate code for the model.

The generated code in `ex_mux_allow_arguments.c` file contains a subsystem function interface with arguments that match the subsystem graphical block interface:

```
/* Output and update for atomic system: '<Root>/Subsystem' */
static void FPCSS_Mux(real_T rtu_In1, const real_T rtu_In2[2], real_T rtu_In3,
                    real_T rty_Out1[2], real_T rty_Out2[4])
{
    /* SignalConversion generated from: '<S1>/Out1' incorporates:
     * Constant: '<S1>/Constant1'
     * Gain: '<S1>/Gain4'
     */
    rty_Out1[0] = 5.0;
    rty_Out1[1] = 10.0 * rtu_In1;

    /* Gain: '<S1>/Gain1' incorporates:
     * Constant: '<S1>/Constant'
     */
    rty_Out2[0] = 150.0;
```

```
    rty_Out2[1] = 15.0 * rtu_In3;  
    rty_Out2[2] = 15.0 * rtu_In2[0];  
    rty_Out2[3] = 15.0 * rtu_In2[1];  
}
```

The `Allow arguments (Match graphical interface)` specification generates a predictable interface and maps the function arguments to the graphical interface of the Subsystem block. Arrays as part of the function arguments account for the combination of input or output signals that the Mux block uses.

For the Enabled, Triggered, or Resettable Subsystem with the `Allow arguments (Match graphical interface)` specification, the generated function contains arguments corresponding to each Enable, Trigger block, and Reset block present within that subsystem.

Limitations

- The **Function interface** set as `Allow arguments (Match graphical interface)` specification is not applicable to context menu option **C/C++ > Build this Subsystem**.
- You cannot control the argument names.

Generate Code for Model Reference Hierarchy

To achieve incremental loading of models, incremental code generation, modular development of referenced models, and code reuse, you can generate code for the model reference hierarchy.

You can include one model inside another model by using a Model block. Each instance of a Model block is a model reference. For simulation and code generation, blocks within a referenced model execute together as a unit. The model that contains a referenced model is a parent model. A collection of parent and referenced models constitutes a model hierarchy.

Model Reference Technology

When you generate code for a referenced model hierarchy, the code generator produces a standalone executable for the top model and a library module called a model reference target for each referenced model. When the code executes, the top model executable invokes the model reference targets to compute the referenced model output. Model reference targets are sometimes called *Simulink Coder targets*.

Do not confuse a model reference target (Simulink Coder target) with these other types of targets:

- Target hardware — A platform for which the Simulink Coder software generates code.
- System target file — A file that instructs the Simulink Coder software how to generate code for particular purpose.
- Rapid Simulation target (RSim) — A system target file that is part of the Simulink Coder product.
- Simulation target — A MEX file that implements a referenced model, which is executed by using Simulink Accelerator™ software.

The code generator places the code for the top model in a hierarchy in the code generation folder and places the code for referenced models in an `s\prj` folder. Subfolders in `s\prj` are separate places for different types of files. For folder information, see “Manage Build Process Folders”.

By default, the Simulink Coder uses *incremental code generation*. When generating code, the software compares structural checksums of referenced model files to the generated code files to determine whether to regenerate model reference targets. To control when rebuilds occur, use the configuration parameter **Model Referencing > Rebuild**. For details, see “Rebuild”.

The Simulink Coder software also uses *incremental loading*. The code for a referenced model is not loaded into memory until the code for its parent model executes and requires the outputs of the referenced model. Simulink Coder then loads the referenced model target and executes the code. Once loaded, the target remains in memory until it is no longer used.

If you have Embedded Coder, custom targets must declare themselves as compliant with the model reference if they support Model blocks. For more information, see “Support Model Referencing” on page 88-60.

Generate Code for Model Reference Hierarchy

This example shows how to reference an existing model and generate code for the model reference hierarchy.

Create Model Reference Hierarchy

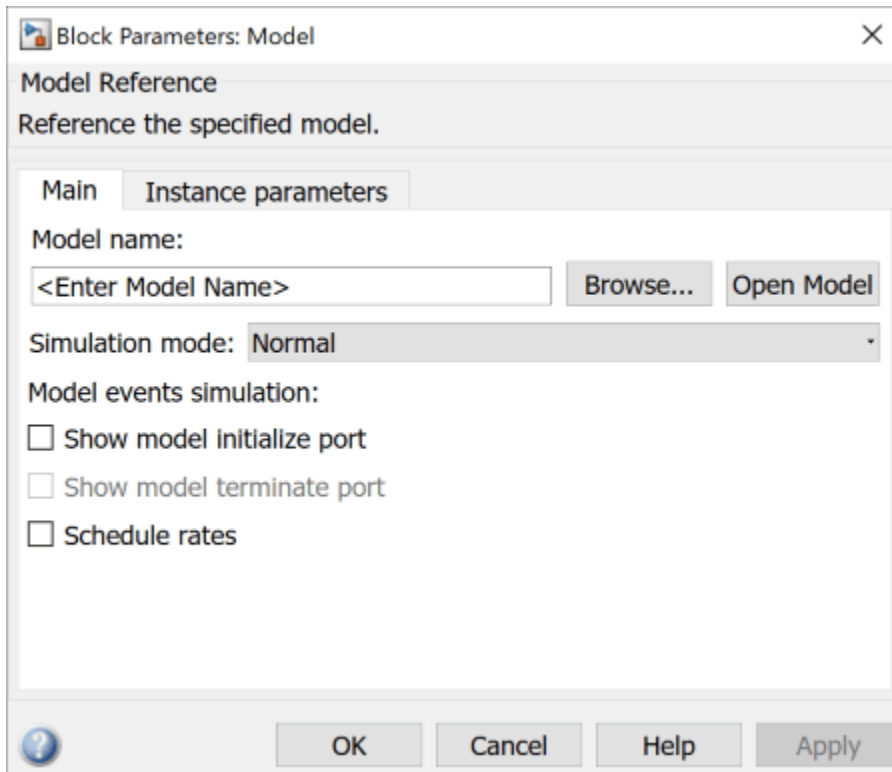

1. Open an existing model, for example the `ex_model_arg_ref` model. This model represents a reusable algorithm. This is a GRT model. If you have Embedded Coder, change the model configuration parameter **System target file** to `ert.tlc`.

```
open_system('ex_model_arg_ref');
```

Copyright 2021 The MathWorks, Inc.

2. A referenced model must specify that it is available to be referenced and whether it can be referenced just once or multiple times. Specify the model configuration parameter “Total number of instances allowed per top model” as **One** or **Multiple**. By default, **Total number of instances allowed per top model** is set to **Multiple**.
3. Create a new model that you want as a top model in the model reference hierarchy. The top model refers to other models as referenced models or multiple instances of a referenced model.
4. Add Inports and Outports to the top model as required. To add a referenced model, use the Model block.
5. The new block is initially unresolved because it does not specify a referenced model. To open the block parameters dialog box, double-click the Model block or use the context menu of the Model block.

6. Enter the name of the referenced model in the **Model name** field. This name must contain fewer than 60 characters, exclusive of the `.slx` suffix.

7. Click **OK**. If the referenced model contains root-level inputs or outputs, the Model block displays corresponding input and output ports.

8. Create another instance of the Model block so that the top model looks like model:

```
open_system('ex_model_arg');
```

Copyright 2021 The MathWorks, Inc.

9. Name the model `ex_model_arg` and save the model.

You can also convert a subsystem to a referenced model. For more details, see “Convert Subsystems to Referenced Models”.

Generate Code for Model Reference Hierarchy

1. Verify that the model configuration parameter Solver selection **Type** is set to **Fixed-step** for the top model and the referenced model. To open the respective Configuration Parameters dialog boxes, on the **Modeling** tab, select **Model Settings** for the respective models.

For a model reference hierarchy that has multiple referenced models, you can access the **Model Settings** of the referenced model that is open and the top model through this menu. To access the **Model Settings** of another referenced model in the model hierarchy, open the referenced model to access this menu.

2. For the top model, open the **C Code** tab by selecting either **Simulink Coder** app or **Embedded Coder** app. To generate code for the model reference hierarchy, click the **Build** button.

The Simulink Coder build process generates and compiles code. The current folder now contains new files and a new folder.

- `ex_model_arg_grt_rtw` — The build folder containing the generated code for the top model.
- `slprj > grt > ex_model_arg_ref` — The folder containing the generated code for the referenced model.
- `ex_model_arg.exe` — The executable created by the build process.
- `ex_model_arg.slxc` — The Simulink cache file for the top model.
- `ex_model_arg_ref.slxc` — The Simulink cache file for the referenced model.

For more information about the configuration parameter requirements, see “Set Configuration Parameters for Code Generation of Model Hierarchies”.

View Generated Code in Code Generation Report

To view the generated code, in the **C Code** tab, select **Open Report**. The code generation report contains hyperlinks to all the files generated for the model reference hierarchy.

To open the generated code for the referenced model, click the referenced model hyperlink under the **Referenced Models** section on the left pane.

To navigate back to the top model, click the **Go Backward** button on the top-left corner of the code generation report window.

Working with Code Generation Folders

Model reference code is generated in your code generation folder. Simulation target code is generated in your simulation cache folder. Due to the two different folders, there are constraints on:

- When and where you build model reference targets.
- How you access the model reference targets.

You can store the models referenced by Model blocks anywhere on the MATLAB path. A top model can include models stored on different file systems or in different folders. The simulation targets and generated code derived from these models cannot be stored on different file systems or in different folders. To allow code reuse, you must set up models referenced by a top model to simulate and generate model reference target code in a single code generation folder.

If you reference the same model from several top models, each stored in a different folder, you must choose one of these approaches:

- Work with the same code generation folder and be sure that the models are on your path.
- Allow separate code generation folders, simulation targets, and Simulink Coder targets to be generated in each folder in which you work.

The second approach requires maintenance of several instances of the model reference code. It is possible for generated code to become redundant, for example, when you make changes to the referenced model. To minimize code regeneration of referenced models, choose a specific code generation folder for all sessions.

Build Model Reference Targets

The code generator produces a model reference target directly from the Simulink model. The code generator generates or regenerates model reference targets, for example, when they require an update.

When you execute the `slbuild` command by using arguments in the MATLAB Command Window, Simulink and Simulink Coder can generate a simulation target for an accelerator mode referenced model and a model reference target for a referenced model.

The code generator produces only one model reference target for multiple instances of a referenced model. For more information, see “Generate Reentrant Code from Subsystems”.

Reduce Change Checking Time

You can reduce the time that Simulink and Simulink Coder spend checking whether model reference targets need to be rebuilt by setting configuration parameter values:

- In the top model, consider setting the model configuration parameter **Model Referencing > Rebuild** to **If any changes in known dependencies detected**.
- In the referenced models throughout the hierarchy, set the configuration parameter **Diagnostics > Data Validity > Signal resolution** to **Explicit only** or **None**.

These parameter values exist in a referenced model configuration set, not in the individual Model block. Setting either value for an instance of a referenced model sets it for the instances of that model.

Set Configuration Parameters for Code Generation of Model Hierarchies

A model reference hierarchy must satisfy various Simulink Coder requirements, as described in this topic. A model referencing hierarchy to be processed by the Simulink Coder software must also satisfy:

- The Simulink requirements listed in:
 - “Set Configuration Parameters for Model Hierarchies”
 - “Model Reference Interface and Boundary”
- The Simulink limitations listed in “Signal Requirements and Limitations”
- The Simulink Coder limitations listed in “Code Generation Limitations for Model Reference” on page 5-23

Configuration Parameter Requirements

A referenced model uses a configuration set in the same way a top model does. By default, every model in a hierarchy has its own configuration set, which it uses in the same way that it would if the model executed independently.

Because each model can have its own configuration set, configuration parameter values can be different in different models. Furthermore, some parameter values are intrinsically incompatible with model referencing. The response of the code generator to an inconsistent or unusable configuration parameter depends on the parameter:

- Where a parameter inconsistency has no significance, the code generator ignores or resolves the inconsistency without posting a warning.
- Where a nontrivial and possibly acceptable solution exists to an inconsistent parameter, the code generator resolves the conflict silently; resolves it with a warning; or generates an error.
- If an acceptable resolution is not possible, the code generator produces an error. You must then change parameter values to eliminate the issue.

When a model reference hierarchy contains many referenced models that have incompatible parameter values, or a changed parameter value must propagate to many referenced models, manually eliminating configuration parameter incompatibilities can be time-consuming. You can control or eliminate such overhead by using configuration references to assign an externally stored configuration set to multiple models. For more information, see “Share a Configuration with Multiple Models”.

To select a code generation target for a model reference hierarchy without modifying the individual models, use a configuration reference in the Simulink data dictionary. For more information, see “Use Configuration Reference to Select Code Generation Target” on page 45-11.

The following tables list configuration parameters that can cause problems if set in certain ways, or if set differently in a referenced model than in a parent model. Where possible, the code generator resolves violations of these requirements, but most cases require you to make changes to parameters in your models.

Configuration Requirements for Model Referencing with System Target Files

Dialog Box Pane	Option	Requirement
Solver	Start time	Some system target files require the start time of models to be zero.
Hardware Implementation	All options	Values must be the same for top and referenced models.
Code Generation	System target file	Must be the same for top and referenced models.
	Language	Must be the same for top and referenced models.
	Generate code only	Must be the same for top and referenced models.
Identifiers	Maximum identifier length	Cannot be longer for a referenced model than for its parent model.
Interface	Code replacement library	Must be the same for top and referenced models.
	ASAP2 interface	Can be on or off in a top model, but must be off in a referenced model. If it is not off, the code generator temporarily sets it to off during code generation.

Configuration Requirements for Model Referencing with ERT System Target Files (Requires Embedded Coder)

Dialog Box Pane	Option	Requirement
Identifiers	Global variables Global types Subsystem methods Local temporary variables Constant macros	\$R token must be included.
	Signal naming	Must be the same for top and referenced models.
	M-function	If specified, must be the same for top and referenced models.
	Parameter naming	Must be the same for top and referenced models.
Interface	#define naming	Must be the same for top and referenced models.
	Ignore custom storage classes	Must be the same for top and referenced models.
	Support floating-point numbers	Must be the same for top and referenced models.
	Support non-finite numbers	If off for top model, must be off for referenced models.
	Support complex numbers	If off for top model, must be off for referenced models.
Remove error status field in real-time model data structure	If on for top model, must be on for referenced models.	
Code Placement	Use owner from data object for data definition placement	Must be the same for top and referenced models.
	Signal display level	Must be the same for top and referenced models.
	Parameter tune level	Must be the same for top and referenced models.

Configuration Parameters Changed During Code Generation

For referenced models, if these **Configuration Parameters > Code Generation > Identifiers** parameters have settings that do not contain a \$R token (which represents the name of the referenced model), code generation prepends the \$R token to the identifier format:

- **Global variables** (CustomSymbolStrGlobalVar)
- **Global types** (CustomSymbolStrType)
- **Subsystem methods** (CustomSymbolStrFcn)
- **Constant macros** (CustomSymbolStrMacro)

You can use the Model Advisor to identify models in a model referencing hierarchy for which code generation changes configuration parameter settings.

- 1 In the Simulink Editor, from the **Modeling** tab, select **Model Advisor**.
- 2 Expand **By Task > Model Referencing**.
- 3 Run the **Check code generation identifier formats used for model reference** check.

If a script that operates on generated code uses identifier formats that code generation changes, then update the script to use the updated identifier format (which includes an appended \$R token).

For more information about identifiers, see “Identifier Format Control” on page 52-17.

Naming Requirements

Within a model that uses model referencing, names of the constituent models cannot collide. When you generate code from a model that uses model referencing, the **Maximum identifier length** parameter must be large enough to accommodate the root model name and the name-mangling text. A code generation error occurs if **Maximum identifier length** is not large enough.

When a name conflict occurs between a symbol within the scope of a higher-level model and a symbol within the scope of a referenced model, the symbol from the referenced model is preserved. The code generator performs name mangling on the symbol from the higher-level model.

Embedded Coder Naming Requirements

The Embedded Coder product lets you control the formatting of generated symbols in much greater detail. When generating code with an ERT target from a model that uses model referencing:

- The \$R token (in addition to the \$M token) must be included in the **Identifier format control** parameter specifications except for **Shared utilities identifier format**.
- The **Maximum identifier length** must be large enough to accommodate full expansions of the \$R and \$M tokens.

For more information, see “Model Configuration Parameters: Code Generation Identifiers”.

Custom Target Requirements

If you have Embedded Coder, a custom target must meet various requirements to support model referencing. For details, see “Support Model Referencing” on page 88-60.

Miscellaneous Considerations

Minimize occurrences of algebraic loops by selecting the **Minimize algebraic loop occurrences** parameter on the **Model Referencing** pane. The setting of this option affects only generation of code from the model. For more information about direct feed through, see “Algebraic Loop Concepts”.

Use the **Integer rounding mode** parameter on your model's blocks to simulate the rounding behavior of the C compiler that you intend to use to compile code generated from the model. This setting appears on the **Signal Attributes** pane of the parameter dialog boxes of blocks that can perform signed integer arithmetic, such as the Product, Matrix Multiply and n-D Lookup Table blocks.

For most blocks, the value of **Integer rounding mode** completely defines rounding behavior. For blocks that support fixed-point data and the Simplest rounding mode, the value of **Signed integer division rounds to** also affects rounding. For details, see “Rounding” (Fixed-Point Designer).

Convert Subsystem to Referenced Model and Generate Code

Converting subsystems to referenced models enhances incremental code generation, modular development of referenced models, and code reuse. Many large models use a combination of referenced models and subsystems.

To convert a Subsystem block to a Model block, use any of these methods:

- In the Simulink Editor, select a Subsystem block. On the Simulink Toolstrip, the **Subsystem Block** tab, select **Convert > Model Block**.
- In the MATLAB Command Window, use the `Simulink.SubSystem.convertToModelReference` function with the `'UseConversionAdvisor'` argument set to `true`.

Before you convert a subsystem to a referenced model:

- 1 Configure the Subsystem block as an atomic subsystem. In the Subsystem Block Parameters, select the **Treat as atomic unit** property.

An atomic subsystem executes as a unit relative to the parent model. Subsystem execution does not interleave with parent block execution. This property makes it possible to extract subsystems for use as standalone models and as functions in the generated code.

- 2 Set the model configuration parameter **Signal resolution** to `Explicit only` or `None`.

You can map a storage class to a category of model data elements or to an individual element by using the Code Mappings editor or the Code Mappings API (`coder.mapping.api.CodeMapping`). Then, use the Code Mappings editor or the API to specify code configurations settings specific for that storage class, such as header files, definition files, and memory sections. If your model contains code mappings, you can migrate the code mappings when you convert a subsystem to a referenced model. For more information, see **Code Mappings Editor - C**.

Configure Code Mappings

- 1 Open the example model `rtwdemo_roll`.

```
rtwdemo_roll
```
- 2 On the Simulink toolstrip, the **Apps** tab, select the **Embedded Coder** or **Simulink Coder** app.
- 3 In the **C Code** tab, click **Code Interface > Default Code Mappings**. This option pins the Code Mappings editor.
- 4 Map a storage class to a category of model data element. In the Code Mappings editor, select the **Data Defaults** tab. For the Inports category, specify the **Storage Class** as `ExportedGlobal`.

Alternatively, to configure the default mapping for Inports, in the MATLAB Command Window, enter:

```
roll_mapping = coder.mapping.api.get('rtwdemo_roll');
setDataDefault(roll_mapping, 'Inports', 'StorageClass', 'ExportedGlobal');
```

Convert Subsystem to Referenced Model

- 1 To convert a subsystem to a referenced model, open the **Model Reference Conversion Advisor**. Select the subsystem `HeadingMode`. On the **Subsystem Block** tab, select **Convert > Model Block**.

The Model Reference Conversion Advisor enables you to interactively specify conversion parameters and fix issues that the advisor finds.

- 2 Review the autopopulated model name. If needed, you can update this name.
- 3 To make the conversion process faster, select the **Fix errors automatically (if possible)**. This option fixes some conversion issues. You do not control the fixes.
- 4 To copy the code mappings specified for the model, select the **Copy code mappings** option. This option migrates the code mappings from the parent model to the newly converted referenced model. By default, this option is cleared.
- 5 Click **Convert**.

The Model Reference Conversion Advisor steps through each of the checks. Address any issues that the advisor reports. After the Model Reference Conversion Advisor successfully completes the conversion, it replaces the Subsystem block with a Model block that references the new model.

Alternatively, to convert a subsystem to a referenced model, in the MATLAB Command Window, enter:

```
Simulink.SubSystem.convertToModelReference(...
    'rtwdemo_roll/HeadingMode', ...
    'HeadingMode', ...
    'AutoFix',true,...
    'ReplaceSubsystem',true,...
    'CopyCodeMappings',true);
```

Copy Code Mappings After Subsystem Conversion

If you want to copy the code mappings from the parent model to the referenced model and you did not previously select the **Copy code mappings** option in the Model Reference Conversion Advisor, in the MATLAB Command Window, enter:

```
roll_mapping = coder.mapping.api.get('rtwdemo_roll');
roll_sc = getDataDefault(roll_mapping, 'Inports', 'StorageClass');

mode_mapping = coder.mapping.api.get('HeadingMode');
setDataDefault(mode_mapping, 'Inports', 'StorageClass', roll_sc);
```

Review Generated Code

For the `rtwdemo_roll` model which contains the referenced model `HeadingMode`, open the **C Code** tab. To generate code for the model reference hierarchy, click **Build**.

The Simulink Coder build process generates and compiles code. The current folder now contains new files and a new folder.

Folder or File	Purpose
<code>rtwdemo_roll_grt_rtw</code>	The build folder containing the generated code for the top model.
<code>slprj > grt > Heading Mode</code>	The build folder containing the generated code for the referenced model.
<code>rtwdemo_roll.exe</code>	The executable created by the build process.
<code>rtwdemo_roll.slxc</code>	The Simulink cache file for the top model.
<code>HeadingMode.slxc</code>	The Simulink cache file for the referenced model.

Generate Reusable Code from Model Reference Hierarchy

A reusable subsystem function that has input or output connected to the root Inport or Outport block of a referenced model can impact code reuse. It can prevent you from reusing atomic subsystems in a reference model context in the same way you might reuse the subsystems in a standalone model.

This example shows how to generate reusable code when you have a reusable subsystem referenced inside Model block.

Generate Reusable Code for Subsystem

1. Convert these blocks into a subsystem. Drag a box to outline the subsystem that you want to create. From the **Multiple** tab on the Simulink Editor toolstrip, select **Create Subsystem**.

Copyright 2021 The MathWorks, Inc.

2. Make these changes to the Subsystem block parameters:

- Select “Treat as atomic unit”.
- On the **Code Generation** tab, set “Function packaging” to Reusable function.

3. Create a model that includes three instances of the preceding subsystem.

Copyright 2021 The MathWorks, Inc.

4. Set the model configuration parameter “Default parameter behavior” to Inlined.

5. To build the model and generate code, press **Ctrl+B**.

The code generator optimizes the code by generating one copy of the function for the reused subsystem in the `model.c` file.

```
void ex_codeReuseThreeSubsys_Subsystem1(real_T rtu_In1,
    B_Subsystem1_ex_codeReuseThreeSubsys_T *localB)
{
    /* Gain: '<S1>/Gain' */
    localB->Gain = 3.0 * rtu_In1;
}
```

Generate Reusable Code for Subsystem in Referenced Model

1. Create a top model by using a Model block that references the preceding model that has three instances of the reusable subsystem.

Copyright 2021 The MathWorks, Inc.

2. Generate code for the top model. The code generator generates three different function signatures in the `slprj` folder.

```
/* Output and update for atomic system: '<Root>/Subsystem 1' */
void ex_codeReuseThreeSubsys_Subsystem1(const real_T *rtu_In1,
    B_Subsystem1_ex_codeReuseThreeSubsys_T *localB)
{
    /* Gain: '<S1>/Gain' */
    localB->Gain = 3.0 * *rtu_In1;
}

/* Output and update for atomic system: '<Root>/Subsystem 2' */
void ex_codeReuseThreeSubsys_Subsystem2(real_T rtu_In1,
    B_Subsystem2_ex_codeReuseThreeSubsys_T *localB)
{
    /* Gain: '<S2>/Gain' */
    localB->Gain = 3.0 * rtu_In1;
}

/* Output and update for atomic system: '<Root>/Subsystem 3' */
void ex_codeReuseThreeSubsys_Subsystem3(real_T rtu_In1, real_T *rty_Out1)
{
    /* Gain: '<S3>/Gain' */
    *rty_Out1 = 3.0 * rtu_In1;
}
```

3. To enable the subsystem functions for code reuse, insert Signal Conversion blocks into the referenced model. Place one block between the Inport and Subsystem 1 and another block between Subsystem 3 and the Output.

Copyright 2021 The MathWorks, Inc.

If the subsystem has a Merge block with initial conditions, do not add a Signal Conversion block. Instead, add a Bias block to obtain a reusable function.

4. Select the model configuration parameter “Pass fixed-size scalar root inputs by value for code generation”.

5. Generate code for the top model. The code generator generates a single reusable function in the `slprj` folder.

```
void ex_codeReuseSubsysSigConvert_Subsystem1(real_T rtu_In1,
      B_Subsystem1_ex_codeReuseSubsysSigConvert_T *localB,
      P_Subsystem1_ex_codeReuseSubsysSigConvert_T *localP)
{
    /* Gain: '<S1>/Gain' */
    localB->Gain = localP->Gain_Gain * rtu_In1;
}
```

Storage Classes for Parameters and Signals Used in Model Blocks

To transfer data between your referenced model and top model, use signals and parameters. You can also use parameters to integrate external data into the model reference hierarchy. To include one model inside another model and create a model reference hierarchy, use a Model block.

You can apply a storage class to a data item in a model, such as signal or parameter, to:

- Make the data item appear in the generated code as a global symbol, typically a global variable.
- Prevent optimizations such as **Default parameter behavior** and **Signal storage reuse** from eliminating the data item from the generated code.

For examples, see “C Code Generation Configuration for Model Interface Elements” on page 32-2.

You can map a storage class to a category of model data elements or to an individual element by using the Code Mappings editor or the Code Mappings API (`coder.mapping.api.CodeMapping`). You can specify code configurations settings specific to that storage class, such as header files, definition files, and memory sections using the Code Mappings editor or the API. For more information, see **Code Mappings Editor - C**.

Storage Classes for Parameters in Model Blocks

Models containing Model blocks can use storage classes for parameters to interface with external code. Storage classes, with the exception of `Auto`, are tunable. The supported storage classes include:

- Predefined storage classes in Simulink Coder and Embedded Coder
- A new storage class created by using the Embedded Coder Dictionary

For limitations on Embedded Coder storage classes, see “Storage Class Limitations”.

The restrictions on parameters in referenced models are:

- Tunable parameters are not supported for noninlined S-functions.
- Tunable parameters set through the Model Parameter Configuration dialog box are ignored.

Concerning how global tunable parameters are declared, defined, and used in code generated for targets, consider:

- A global tunable parameter is a parameter in the base workspace that has a storage class other than `Auto`.
- An `extern` declaration is generated for models that use a given parameter.
- If a parameter is exported, the top model defines (allocates memory for) the parameter whether the top model uses the parameter or not.
- Global parameters are accessed directly as global memory. They are not passed as arguments to the functions that are generated for the referenced models.
- In a referenced model that sets the default storage class for a category of parameter data to `Default` in the Code Mapping editor, symbols for `Model default` parameters are generated by using unstructured variables (`rtP_XXX`) instead of being written into the `model_P` structure. You can then compile each referenced model independently.

Parameters that you use as Model block arguments must be defined in the referenced model workspace. For details, see “Parameterize Instances of a Reusable Referenced Model”.

Storage Classes for Signals in Model Blocks

Models containing Model blocks can use signals of storage class `Auto`.

A global signal is a signal that has a storage class other than `Auto`. The supported storage classes include:

- Predefined storage classes in Simulink Coder and Embedded Coder
- A new storage class created by using Embedded Coder Dictionary

If you have Embedded Coder, you can create a global signal by using a storage class defined in the Embedded Coder Dictionary that has **Storage Type** set as `Unstructured` or by creating a storage in the Embedded Coder Dictionary that has **Storage Type** set as `Unstructured`.

These signals are distinct from individual signals that use the storage class `Model default`. When you set the default storage class of the corresponding data category to `Default` in the Code Mapping editor, these signals are treated as test points that have the `Auto` storage class.

When you declare signals as global, be aware of how the signal data is handled. Global signals are declared, defined, and used as follows:

- An `extern` declaration is generated for models that use a global signal.
As a result, if a signal crosses a Model block boundary, the top model and the referenced model both generate `extern` declarations for the signal.
- For an exported signal, the top model defines (allocates memory for) the signal, whether or not the top model itself uses the signal.
- Global signals used by a referenced model are accessed directly as global memory. They are not passed as arguments to the functions that are generated for the referenced models.

Storage classes that you create by using the Embedded Coder Dictionary also follow the preceding rules for the top model.

Note In a referenced model, you cannot use the storage class that you create by using the Embedded Coder Dictionary on root-level Inports and Outports.

Certain storage classes have limited support for use with model reference. See “Storage Class Limitations”.

Signal Name Mismatches Across Model Reference Boundary

Within a parent model, the name and storage class for a signal entering or leaving a Model block might not match those of the signal attached to the root inport or outport within that referenced model. Because referenced models are compiled independently without regard to a parent model, they cannot adapt to the possible variations in how parent models label and store signals.

The code generator accepts cases where input and output signals in a referenced model have the `Auto` storage class. When such signals are test pointed or are global, certain restrictions apply. This

table describes how mismatches in signal labels and storage classes between parent and referenced models are handled by the software.

Relationships of Signals and Storage Classes Across Model Reference Boundary

Storage Class in Referenced Model	Storage Class in Parent Model	Signal Passing Method	Signal Mismatch Checking
Auto	Non-Auto	Function argument	Signal label mismatch
Model default (when the Code Mapping editor specifies Default storage class) or resolved to Signal Object	Non-Auto	Function argument	Signal label mismatch
Non-Auto	Auto	Global variable	None
Non-Auto	Non-Auto	Global variable	One of the storage classes must be Auto (otherwise there is an error)

These signal resolution rules apply to code generation:

- If the storage class of a root input or output signal in a referenced model is `Auto` or `Model default` (when you set the storage class of the corresponding data category to `Default` in the Code Mapping editor), the signal is passed as a function argument. When such a signal is `Non-Auto` or resolves to a `Simulink.Signal` object in the parent model, the **Signal label mismatch** diagnostic is applied.
- If a root input or output signal in a referenced model is global, the signal is communicated by using direct memory access (global variable). The corresponding signal in the parent model must be `Auto`.
- You cannot use a storage class that you create by using the Embedded Coder Dictionary in a referenced model.

You can set the model configuration parameter **Signal label mismatch** diagnostic to error, warning, or none.

Code Generation Limitations for Model Reference

Code generation limitations for model references influence how you properly set up the model reference hierarchy for code generation.

In addition to these limitations, a model reference hierarchy used for code generation must satisfy:

- The Simulink requirements and limitations listed in:
 - “Configuration Requirements for All Referenced Model Simulation”
 - “Model Reference Requirements and Limitations”
 - “Model Reference Interface and Boundary”
- The Simulink Coder requirements applicable to the code generation target, as listed in “Configuration Parameter Requirements” on page 5-9.

Storage Class Limitations

If you have Embedded Coder, some restrictions exist on grouped storage classes in referenced models. For details, see “Storage Class Limitations”.

Data Logging Limitations

- To Workspace blocks and Scope blocks are ignored when Simulink Coder generates code for a referenced model. The resulting code is the same as if the blocks did not exist. In some cases for models with Scope block and MAT-file logging enabled, the code generator produces an extra PWork in the model's DWork structure.
- Code generated for referenced models cannot log data to MAT-files. If you enable data logging for a referenced model, Simulink Coder disables the option before code generation and re-enables it afterward.
- If you log states for a model that contains referenced models, the ordering of the states in the output is determined by block sorted order, and might not match between simulation output and generated code MAT-file logging output.

State Initialization Limitations

When a top model uses the model configuration parameter **Initial state** to specify initial conditions, Simulink Coder does not initialize the discrete states of the referenced models during code generation.

Model Reuse Limitations

If a referenced model used for code generation has at least one of the following characteristics, the model must specify the model configuration parameter **Total number of instances allowed per top model** as One. Other instances of the model can exist in the hierarchy. If you do not set the parameter to One, or more than one instance of the model exists in the hierarchy, an error occurs. The characteristics are:

- The model references another model that has been set to a single instance.
- The model contains an internal signal or state that has a storage class that is not supported for multi-instance models. You must set the storage class to `Auto` or `Model default` for internal

signals and states. The default storage class for internal data must be a multi-instance storage class.

- The model uses at least one of these Stateflow constructs:
 - Machine-parented data
 - Machine-parented events
 - Exported Stateflow graphical functions
- The model contains an S-function that is:
 - Inlined but you have not set the option `SS_OPTION_WORKS_WITH_CODE_REUSE`
 - Not inlined
- The model contains a function-call subsystem that:
 - The Simulink engine forces to be a function
 - Is called by a wide signal

S-Functions Limitations

- A referenced model cannot use noninlined S-functions generated by Simulink Coder.
- The Simulink Coder S-function target does not support model referencing.

For additional information, see “S-Functions in Referenced Models”.

Subsystems Limitations

If you generate code for an atomic subsystem as a reusable function, inputs or outputs that connect the subsystem to a referenced model might prevent code reuse, as described in “Generate Reentrant Code from Subsystems”.

Targets Limitation

The Simulink Coder S-function target does not support model referencing.

Conditional Models Limitation

When a model contains a trigger or enable port, you cannot generate standalone Simulink Coder code.

Simulink Cache Files for Incremental Code Generation

Share the generated code for various target types between team members inside an organization by using Simulink cache files. When you generate code from a Simulink model hierarchy, each referenced model has an associated Simulink cache file. These files have an `.slxc` file extension. The cache files contain artifacts from the build that can reduce the time required for successive model simulation and code generation. Simulink cache files are generated when you simulate models in accelerator or rapid accelerator mode or generate code for models. For more information, see “Share Simulink Cache Files for Faster Simulation”.

Contents of Simulink Cache Files

At the end of a build, the code generator packages the artifacts and generated code for the model hierarchy in the Simulink cache files. The cached artifacts include:

- Shared utilities
- All files under the `slprj\system_target_file\model_name`
- `model_name_rtw_system_target_file` folder for the top model
- Any binaries generated for the top model

You cannot modify the contents of the Simulink cache files. If you update the build artifacts inside the `slprj` folder, the Simulink cache file picks up these updates during the next build cycle.

Share Code Generation Artifacts

If you are involved in team development of large models that reference other models, use Simulink cache files to synchronize builds and share generated code artifacts to enhance incremental code generation. You can leverage Simulink cache files to avoid unnecessary code generation.

For example, assume that you collaborate with your team members by using a source control system and your models are built every night in a continuous integration system.

- 1 Open your model. For example, `rtwdemo_mdltreftop`.

```
model = 'rtwdemo_mdltreftop';
open_system(model)
```

- 2 Build the model. On the **C Code** tab, click **Build**.

Observe the Simulink cache files generated for all referenced models. The `rtwdemo_mdltreftop` model is a referenced model in `rtwdemo_mdltreftop`.

Simulink stores cache files in the folder specified by the **Simulation cache folder** preference.

To see all supported configurations, double-click the cache file. The Simulink cache report contains information related to each release, platform, and list of packaged targets.

Simulink cache for `rtwdemo_mdltreftop`

This Simulink cache contains derived files for the following releases and platforms:

R2019b : win64

Code generation

Target	Build Type	Folder Structure
grt	Top model	Model specific

OK

Alternatively, to get the contents of the Simulink cache file in a MATLAB table, use the `slxcinfo` function.

- 3 Submit your models to the source control system. The continuous integration system builds the models overnight and updates the existing Simulink cache files.

Note Because Simulink cache files are derived files, do not submit them to source control. If you share Simulink cache files by storing them in a source control system, you cannot diff or merge different versions of these files.

- 4 Assume your team member made some changes to the model and submitted the changes to the source control system. When you want to work with the model hierarchy, fetch these files:

- Design files (model and associated files) from the source control system.
 - Simulink cache files from the continuous integration system.
- 5** Make your changes to the model.
 - 6** Build the model. The code generator extracts code generation artifacts stored in the Simulink cache files from the overnight build and avoids unnecessary rebuilds and code regeneration.

The time to build the model and generate code is less than the first time that you built the model.

Note To unpack the simulation and code generation targets from the Simulink cache files without updating, simulating, or generating code for the model hierarchy, use the `slxcunpack` function.

- 7** Submit your updated model files to the source control system.

Specify Instance-Specific Parameter Values for Reusable Referenced Model

When you use model referencing to break a large system into components, each component is a separate model. You can reuse a component by referring to it with multiple Model blocks. Each Model block is an instance of the component. You can then configure a block parameter (such as the **Gain** parameter of a Gain block) to use either the same value or a different value for each instance of the component. To use different values, create and use a model argument to set the value of the block parameter.

When you generate code from a model hierarchy that uses model arguments, the arguments appear in the code as formal parameters of the referenced model entry-point functions, such as the output (step) function. The generated code then passes the instance-specific parameter values, which you specify in each Model block, to the corresponding function calls.

Whether you use or do not use model arguments, you can use storage classes to configure block parameters to appear in the generated code as tunable global variables. You can also use storage classes to generate tunable model argument values, which the generated code stores in memory and passes to the function calls. You can then change the values during execution.

Pass Parameter Data to Referenced Model Entry-Point Functions as Arguments

Configure a referenced model to accept parameter data through formal parameters of the generated model entry-point function. This technique enables you to specify a different parameter value for each instance (Model block) of the referenced model.

Configure Referenced Model to Use Model Arguments

Open the model `ex_arg_code_ref`. This model represents a reusable algorithm.

```
open_system('ex_arg_code_ref')
```

Copyright 2021 The MathWorks, Inc.

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data editor, in the data table, use the **Data Type** column to set the data type of the Inport block to `single`. Due to data type inheritance, the other signals in the model use the same data type.

Select the **Parameters** tab.

In the model, select the Gain block.

In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to `gainArg`.

Next to `gainArg`, click the action button (3 vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter` and **Location** to `Model Workspace`. Click **Create**.

In the property dialog box, set **Value** to a number, for example, `3.17`. Click **OK**.

Use the Model Data Editor to set the **Numerator** parameter by using a `Simulink.Parameter` object named `coeffArg` whose value is `1.05`. As with `gainArg`, store the parameter object in the model workspace.

In the Model Data Editor, click the **Show/refresh additional information** button.

Use the **Filter contents** box to find each parameter object (`gainArg` and `coeffArg`). For each object, select the check box in the **Argument** column.

Source	Name	Value	Data Type	Min	Max	Dimensions	Unit	Argument
Model Workspace	coeffArg	1.05	auto	[]	[]	[1 1]		<input checked="" type="checkbox"/>
Model Workspace	gainArg	3.17	auto	[]	[]	[1 1]		<input checked="" type="checkbox"/>

Save the `ex_arg_code_ref` model.

Alternatively, at the command prompt, you can use these commands to configure the blocks and the parameter objects:

```
set_param('ex_arg_code_ref/In1', 'OutDataTypeStr', 'single')

set_param('ex_arg_code_ref/Gain', 'Gain', 'gainArg')
modelWorkspace = get_param('ex_arg_code_ref', 'ModelWorkspace');
assignin(modelWorkspace, 'gainArg', Simulink.Parameter(3.17));

set_param('ex_arg_code_ref/Discrete Filter', 'Numerator', 'coeffArg')
assignin(modelWorkspace, 'coeffArg', Simulink.Parameter(1.05));

set_param('ex_arg_code_ref', 'ParameterArgumentNames', 'coeffArg, gainArg')

save_system('ex_arg_code_ref')
```

Specify Instance-Specific Parameter Values in Model Blocks

Open the model `ex_arg_code`. This model uses multiple instances (Model blocks) of the reusable algorithm.

```
open_system('ex_arg_code')
```

Copyright 2021 The MathWorks, Inc.

In the model, open the Model Data Editor **Parameters** tab (**Modeling > Model Data Editor**). The Model Data Editor shows four rows that correspond to the model arguments, `coeffArg` and `gainArg`, that you can specify for the two Model blocks.

Use the Model Data Editor to set values for the model arguments in Model. For example, use the values in the figure. For Model1, do not specify a value for the model arguments. By default, a model argument uses the last value specified below it in the model hierarchy (indicated by the value from below).

Model Data Editor								
Inports/Outports Signals Data Stores States Parameters								
Design <input type="text" value="Filter contents"/>								
Source	Name	Value	Data Type	Min	Max	Dimensions	Unit	Argument
Model	<code>coeffArg</code>	0.98						<input type="checkbox"/>
Model	<code>gainArg</code>	2.98						<input type="checkbox"/>
Model1	<code>coeffArg</code>	<from below>						<input type="checkbox"/>
Model1	<code>gainArg</code>	<from below>						<input type="checkbox"/>

Alternatively, at the command prompt, you can use this command to set the values for Model:

```
instSpecParams = get_param('ex_arg_code/Model','InstanceParameters');
instSpecParams(1).Value = '.98';
instSpecParams(2).Value = '2.98';
set_param('ex_arg_code/Model','InstanceParameters',instSpecParams);
```

Generate code from the top model.

```
slbuild('ex_arg_code')
```

```

Model	Action	Rebuild Reason
ex_arg_code_ref	Code generated and compiled	ex_arg_code_ref.c does not exist.

Top model targets built:

Model	Action	Rebuild Reason
ex_arg_code	Code generated and compiled	Code generation information file does not exist.

2 of 2 models built (0 models already up to date)

Build duration: 0h 0m 43.158s

The file `ex_arg_code_ref.c` defines the referenced model entry-point function, `ex_arg_code_ref`. The function has two formal parameters, `rtp_coeffArg` and `rtp_gainArg`, that correspond to the model arguments, `coeffArg` and `gainArg`. The formal parameters use the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```
file = fullfile('slprj','grt','ex_arg_code_ref','ex_arg_code_ref.c');
rtwdemodbtype(file,'/* Output and update for referenced model:',...
    'real32_T rtp_gainArg',1,1)

/* Output and update for referenced model: 'ex_arg_code_ref' */
void ex_arg_code_ref(const real32_T *rtu_In1, real32_T *rty_Out1, real32_T
    rtp_coeffArg, real32_T rtp_gainArg, DW_ex_arg_code_ref_f_T *
    localDW)
{
    real32_T rtb_Sum;

    /* Sum: '<Root>/Sum' incorporates:
     * UnitDelay: '<Root>/Unit Delay'
     */
    rtb_Sum = *rtu_In1 + localDW->UnitDelay_DSTATE;

    /* Gain: '<Root>/Gain' */
    rtb_Sum *= rtp_gainArg;

    /* DiscreteFilter: '<Root>/Discrete Filter' */
    localDW->DiscreteFilter_tmp = rtb_Sum - 0.5F * localDW->DiscreteFilter_states;
    *rty_Out1 = rtp_coeffArg * localDW->DiscreteFilter_tmp;

    /* Update for UnitDelay: '<Root>/Unit Delay' */
    localDW->UnitDelay_DSTATE = rtb_Sum;

    /* Update for DiscreteFilter: '<Root>/Discrete Filter' */
    localDW->DiscreteFilter_states = localDW->DiscreteFilter_tmp;
}

/* Model initialize function */
void ex_arg_code_ref_initialize(const char_T **rt_errorStatus,
    RT_MODEL_ex_arg_code_ref_T *const ex_arg_code_ref_M, DW_ex_arg_code_ref_f_T
    *localDW)
{
    /* Registration code */
}
```

```

/* initialize error status */
rtmSetErrorStatusPointer(ex_arg_code_ref_M, rt_errorStatus);

/* states (dwork) */
(void) memset((void *)localDW, 0,
              sizeof(DW_ex_arg_code_ref_f_T));
}

```

The file `ex_arg_code.c` contains the definition of the top model entry-point function, `ex_arg_code`. This function calls the referenced model entry-point function, `ex_arg_code_ref`, and uses the model argument values that you specified (such as 1.11 and 3.34) as the values of `rtp_coeffArg` and `rtp_gainArg`.

```

file = fullfile('ex_arg_code_grt_rtw', 'ex_arg_code.c');

}

/* Model terminate function */
void ex_arg_code_terminate(void)
{
/* (no terminate code required) */
}

```

The formal parameters use the data type `real32_T` (single) because:

- 1 The block parameters in `ex_arg_code_ref` determine their data types through internal rules. For example, in the Gain block dialog box, on the **Parameter Attributes** tab, **Parameter data type** is set to **Inherit: Inherit via internal rule** (the default). In this case, the internal rule chooses the same data type as the input and output signals, `single`.
- 2 The model arguments in the model workspace use context-sensitive data typing because the value of the `DataType` property is set to `auto` (the default). With this setting, the model arguments use the same data type as the block parameters, `single`.
- 3 The formal parameters in the generated code use the same data type as the model arguments, `single`.

Generate Tunable Argument Values

You can configure the instance-specific values in the Model blocks to appear in the generated code as tunable global variables. This technique enables you to store the parameter values for each instance in memory and to tune the values during code execution.

In the top model `ex_arg_code`, select the Model Data Editor **Parameters** tab.

Use the Model Data Editor to set the values of the model arguments according to this figure.

	Source ^	Name	Value
	Model	coeffArg	coeffForInst1
	Model	gainArg	gainForInst1
	Model1	coeffArg	coeffForInst2
	Model1	gainArg	gainForInst2

View the contents of the `ex_arg_code_ref` model workspace in Model Explorer.

Copy `gainArg` and `coeffArg` from the `ex_arg_code_ref` model workspace to the base workspace.

Rename `gainArg` as `gainForInst1`. Rename `coeffArg` as `coeffForInst1`.

```

gainForInst1 = getVariable(modelWorkspace, 'gainArg');
gainForInst1 = copy(gainForInst1);
coeffForInst1 = getVariable(modelWorkspace, 'coeffArg');
coeffForInst1 = copy(coeffForInst1);

```

Copy `gainForInst1` and `coeffForInst1` as `gainForInst2` and `coeffForInst2`.

```
gainForInst2 = copy(gainForInst1);
coeffForInst2 = copy(coeffForInst1);
```

Set the instance-specific parameter values by using the `Value` property of the parameter objects in the base workspace.

```
gainForInst1.Value = 2.98;
coeffForInst1.Value = 0.98;
```

```
gainForInst2.Value = 3.34;
coeffForInst2.Value = 1.11;
```

For each new parameter object, on the **Code Generation** tab, set `StorageClass` to `ExportedGlobal`. This setting causes the parameter objects to appear in the generated code as tunable global variables.

```
gainForInst1.StorageClass = 'ExportedGlobal';
coeffForInst1.StorageClass = 'ExportedGlobal';
gainForInst2.StorageClass = 'ExportedGlobal';
coeffForInst2.StorageClass = 'ExportedGlobal';
```

```
instSpecParams = get_param('ex_arg_code/Model', 'InstanceParameters');
instSpecParams(1).Value = 'coeffForInst1';
instSpecParams(2).Value = 'gainForInst1';
instSpecParams1 = get_param('ex_arg_code/Model1', 'InstanceParameters');
instSpecParams1(1).Value = 'coeffForInst2';
instSpecParams1(2).Value = 'gainForInst2';
set_param('ex_arg_code/Model', 'InstanceParameters', instSpecParams);
set_param('ex_arg_code/Model1', 'InstanceParameters', instSpecParams1);
```

Generate code from the top model.

```
slbuild('ex_arg_code')
```

```
### Starting serial model reference code generation build
### Model reference code generation target for ex_arg_code_ref is up to date.
### Starting build procedure for: ex_arg_code

{
/* (no terminate code required) */
}

```

The global variables in the generated code use the data type `real32_T` (single) because:

- 1 The parameter objects in the base workspace use context-sensitive data typing because the `DataType` property is set to `auto` (the default). With this setting, the parameter objects in the base workspace use the same data type as the model arguments, `single`.
- 2 The global variables in the generated code use the same data type as the parameter objects in the base workspace.

Group Multiple Model Arguments into Single Structure

Use the Model Explorer to copy `gainArg` and `coeffArg` from the `ex_arg_code_ref` model workspace into the base workspace.

```

temp = getVariable(modelWorkspace, 'gainArg');
gainArg = copy(temp);
temp = getVariable(modelWorkspace, 'coeffArg');
coeffArg = copy(temp);

```

At the command prompt, combine these two parameter objects into a structure, `structArg`.

```

structArg = Simulink.Parameter(struct('gain', gainArg.Value, ...
    'coeff', coeffArg.Value));

```

Use the Model Explorer to move `structArg` into the model workspace.

```

assignin(modelWorkspace, 'structArg', copy(structArg));
clear structArg gainArg coeffArg

```

In the **Contents** pane, configure `structArg` as the only model argument.

```

set_param('ex_arg_code_ref', 'ParameterArgumentNames', 'structArg')

```

The screenshot shows the 'Contents of: Model Workspace* (only)' pane. The 'Column View' is set to 'Data Objects'. A table lists the objects in the workspace:

Name	Value	Argument	DataType	Dimension
coeffArg	1.05	<input type="checkbox"/>	auto	[1 1]
gainArg	3.17	<input type="checkbox"/>	auto	[1 1]
structArg	<1x1 struct>	<input checked="" type="checkbox"/>	struct	[1 1]

In the `ex_arg_code_ref` model, select the Model Data Editor **Parameters** tab.

Use the Model Data Editor to set the value of the **Gain** parameter to `structArg.gain` and the value of the **Numerator** parameter to `structArg.coeff`. Save the model.

```
set_param('ex_arg_code_ref/Gain', 'Gain', 'structArg.gain')
set_param('ex_arg_code_ref/Discrete Filter', ...
    'Numerator', 'structArg.coeff')
save_system('ex_arg_code_ref')
```

At the command prompt, combine the four parameter objects in the base workspace into two structures. Each structure stores the parameter values for one instance of `ex_arg_code_ref`.

```
structForInst1 = Simulink.Parameter(struct('gain', gainForInst1.Value, ...
    'coeff', coeffForInst1.Value));

structForInst2 = Simulink.Parameter(struct('gain', gainForInst2.Value, ...
    'coeff', coeffForInst2.Value));
```

In the top model `ex_arg_code`, use the Model Data Editor to set the argument values according to this figure.

Model Data				
Inports/Outputs	Signals	Data Stores	States	Parameters
Design [Icons]				
Source	Name	Value		
Model	structArg	structForInst1		
Model1	structArg	structForInst2		

```
instSpecParams = get_param('ex_arg_code/Model', 'InstanceParameters');
instSpecParams(1).Value = 'structForInst1';
instSpecParams1 = get_param('ex_arg_code/Model1', 'InstanceParameters');
instSpecParams1(1).Value = 'structForInst2';
set_param('ex_arg_code/Model', 'InstanceParameters', instSpecParams);
set_param('ex_arg_code/Model1', 'InstanceParameters', instSpecParams1);
```

Click the **Show/refresh additional information** button.

For the new parameter objects `structForInst1` and `structForInst2`, use the Model Explorer to apply the storage class `ExportedGlobal`.

```
structForInst1.StorageClass = 'ExportedGlobal';
structForInst2.StorageClass = 'ExportedGlobal';
```

At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object. The hierarchy of elements in the object matches the hierarchy of the structure fields. The default name of the object is `s1Bus1`.

```
Simulink.Bus.createObject(structForInst1.Value);
```

Rename the bus object as `myParamStructType` by copying it.

```
myParamStructType = copy(s1Bus1);
```

In the Model Data Editor for `ex_arg_code`, use the Data Type column to set the data type of `structForInst1` and `structForInst2` to `Bus: myParamStructType`.

```
structForInst1.DataType = 'Bus: myParamStructType';
structForInst2.DataType = 'Bus: myParamStructType';
```

Source	Name	Value	Data Type	Min	Max	Dimensions	Unit	Argument
Model Workspace	structArg	<1x1 struct>	Bus: myParamStructType	[]	[]	[1 1]		<input checked="" type="checkbox"/>

```
temp = getVariable(modelWorkspace, 'structArg');
temp = copy(temp);
temp.DataType = 'Bus: myParamStructType';
assignin(modelWorkspace, 'structArg', copy(temp));
```

Save the `ex_arg_code_ref` model.

```
save_system('ex_arg_code_ref')
```

When you use structures to group parameter values, you cannot take advantage of context-sensitive data typing to control the data types of the fields of the structures (for example, the fields of `structForInst1`). However, you can use the properties of the bus object to control the field data types.

At the command prompt, set the data type of the elements in the bus object to `single`. The corresponding fields in the structures (such as `structForInst1` and `structArg`) use the same data type.

```
myParamStructType.Elements(1).DataType = 'single';
myParamStructType.Elements(2).DataType = 'single';
```

Generate code from the top model, `ex_arg_code`.

```
slbuild('ex_arg_code')
```

```
### Starting serial model reference code generation build
### Successfully updated the model reference code generation target for: ex_arg_code_ref
### Starting build procedure for: ex_arg_code
### Successful completion of build procedure for: ex_arg_code
```

Build Summary

Code generation targets built:

Model	Action	Rebuild Reason
ex_arg_code_ref	Code generated and compiled	Model or library ex_arg_code_ref has changed.

Top model targets built:

Model	Action	Rebuild Reason
ex_arg_code	Code generated and compiled	Referenced models were updated.

```
2 of 2 models built (0 models already up to date)
Build duration: 0h 1m 1.594s
```

The file `ex_arg_code_types.h` defines the structure type `myParamStructType`, which corresponds to the Simulink.Bus object.

```
file = fullfile('ex_arg_code_grt_rtw','ex_arg_code_types.h');
rtwdemodbtype(file,'typedef struct {' myParamStructType;',1,1)
```

```
typedef struct {
    real32_T gain;
    real32_T coeff;
} myParamStructType;
```

In the file `ex_arg_code_ref.c`, the referenced model entry-point function has a formal parameter, `rtp_structArg`, that correspond to the model argument `structArg`.

```
file = fullfile('slprj','grt','ex_arg_code_ref','ex_arg_code_ref.c');
rtwdemodbtype(file,'/* Output and update for referenced model:',...
    '*rtp_structArg)',1,1)

/* Output and update for referenced model: 'ex_arg_code_ref' */
void ex_arg_code_ref(const real32_T *rtu_In1, real32_T *rty_Out1, const
    myParamStructType *rtp_structArg, DW_ex_arg_code_ref_f_T
    *localDW)
{
    real32_T rtb_Sum;

    /* Sum: '<Root>/Sum' incorporates:
     * UnitDelay: '<Root>/Unit Delay'
     */
    rtb_Sum = *rtu_In1 + localDW->UnitDelay_DSTATE;

    /* Gain: '<Root>/Gain' */
    rtb_Sum *= rtp_structArg->gain;

    /* DiscreteFilter: '<Root>/Discrete Filter' */
    localDW->DiscreteFilter_tmp = rtb_Sum - 0.5F * localDW->DiscreteFilter_states;
    *rty_Out1 = rtp_structArg->coeff * localDW->DiscreteFilter_tmp;

    /* Update for UnitDelay: '<Root>/Unit Delay' */
    localDW->UnitDelay_DSTATE = rtb_Sum;

    /* Update for DiscreteFilter: '<Root>/Discrete Filter' */
    localDW->DiscreteFilter_states = localDW->DiscreteFilter_tmp;
}

/* Model initialize function */
void ex_arg_code_ref_initialize(const char_T **rt_errorStatus,
    RT_MODEL_ex_arg_code_ref_T *const ex_arg_code_ref_M, DW_ex_arg_code_ref_f_T
    *localDW)

Control Data Types of Model Arguments and Argument Values

When you use model arguments, you can apply a data type to:

- The block parameters that use the arguments (for certain blocks, such as those in the Discrete library).
- The arguments in the referenced model workspace.
- The argument values that you specify in Model blocks.

To generate efficient code by eliminating unnecessary typecasts and C shifts, consider using inherited and context-sensitive data typing to match the data types.

- In the model workspace, use a MATLAB variable whose data type is `double` or a parameter object whose `DataType` property is set to `auto`. In this case, the variable or object uses the same data type as the block parameter.
- When you set the argument values in Model blocks, take advantage of context-sensitive data typing. To set an argument value, use an untyped value.
 - A literal number such as `15.23`. Do not use a typed expression such as `single(15.23)`.
 - A MATLAB variable whose data type is `double`.
 - A `Simulink.Parameter` object whose `DataType` property is set to `auto`.

In these cases, the number, variable, or object uses the same data type as the model argument in the referenced model workspace. If you also configure the model argument to use context-sensitive data typing, you can control the data types of the block parameter, the argument, and the argument value by specifying the type only for the block parameter.

For basic information about controlling parameter data types, see “Parameter Data Types in the Generated Code” on page 33-129.

Use Model Argument in Different Data Type Contexts

If you use a model argument to set multiple block parameter values, and the data types of the block parameters differ, you cannot use context-sensitive data typing (`double` or `auto`) for the argument in the model workspace. You must explicitly specify a data type for the argument. For example, if the argument in the model workspace is a parameter object (such as `Simulink.Parameter`), set the `DataType` property to a value other than `auto`. For more information about this situation, see “Reuse Parameter Data in Different Data Type Contexts” on page 33-141.

In this case, you can continue to take advantage of context-sensitive data typing to control the data type of the argument values that you specify in Model blocks. Each argument value uses the data type that you specify for the corresponding argument in the model workspace.

Generated Functions in a Model Reference Hierarchy

When you generate code for a model, the code generator creates a subfolder `<model>_grt_rtw` (Simulink Coder) or a subfolder `<model>_ert_rtw` (Embedded Coder) in your current working folder and places source code files in this folder. The generated code is in these two primary files:

- `<model>.c` — This file contains the algorithm code. The generated code is mainly comprised of model data and model entry-point functions that are accessible to a caller by including the `<model>.h` file. You can call the generated model entry-point functions from external code or from a version of the generated `main` function that you modify.
- `<model>.h` — This file contains the extern declarations for block outputs, continuous states, model output, entry points, and timing data. For more information about data structures, see “Data Structures in the Generated Code” on page 33-31.

When you generate code for a referenced model hierarchy, the code generator places the code for the top model in the subfolder `<model>_grt_rtw` (Simulink Coder) or the subfolder `<model>_ert_rtw` (Embedded Coder) in your current working folder and places the code for referenced models in an `slprj` folder.

Generated Functions in a Top Model

In a model reference hierarchy, the code generator commonly produces these functions for a top model.

Function Name	Description
<code><model>_step</code>	Execution function that contains the output and update code for the blocks in a Simulink model. This function calls the referenced model function. The code generator produces this function by default. To generate separate functions for output and update code, clear the model configuration parameter Single output/update function . For more information, see <code>model_step</code> .
<code><model>_initialize</code>	Initialization function that executes the initialization code for a Simulink model. The code generator calls this function once at the start of the application code. This function might call the <code><ref_model>_Init</code> function of a referenced model to initialize states and <code><ref_model>_initialize</code> for zero initialization. For more information, see <code>model_initialize</code> .
<code><model>_terminate</code>	Termination function that contains the code to turn off a system. For ERT-based models, you can suppress generation of this function by clearing the model configuration parameter Terminate function required . For more information, see <code>model_terminate</code> .

Generated Functions in a Referenced Model

The functions generated for a referenced model are internal functions used by the code generator. These functions are not intended to interface with external code. In a model reference hierarchy, the code generator commonly produces these functions for a referenced model.

Function Name	Description
<code><ref_model>_Init</code>	Initialization function in a referenced model that is called from a top model entry-point function <code><model>_initialize</code> . The <code><model>_initialize</code> of the top model initializes the code for the model reference hierarchy and calls the <code><ref_model>_Init</code> of the child model to initialize the states to their initial condition.
<code><ref_model></code>	Execution function that serves a similar purpose as <code><model>_step</code> of a top model but is not an entry-point function for the external code. The two functions differ in terms of the scope. The <code><ref_model></code> function computes the outputs from internal state and updates that state. The <code><model>_step</code> does the same but calls the individual <code><ref_model></code> function of the referenced models.
<code><ref_model>_initialize</code>	Initialization function that executes the initialization code for a referenced model. The code generator calls this function from a top model entry-point function <code><model>_initialize</code> . The <code><model>_initialize</code> of the top model initializes the code for the model reference hierarchy and calls the <code><ref_model>_initialize</code> of the child model to zero-initialize the referenced model code.

- “File Packaging for Models (Code and Data)” on page 6-10

Combine Code Generated for Multiple Models

To combine code, which the code generator produces for multiple models or multiple instances of a model, into one executable program, use these techniques:

- Model reference hierarchy. See “Model Reference Basics” and “Generate Code for Model Reference Hierarchy”.
- If you have Embedded Coder software, interface the code for multiple models to a common harness program. From the harness program, call the entry-point functions generated for each model. The `ert.tlc` system target file has restrictions, related to embedded processing that might be incompatible with your application.
- Generate reusable, multi-instance code that is reentrant. See “Combine Code Generated for Multiple Models or Multiple Instances of a Model” on page 6-3.

Note The S-function system target (`rtwsfcn.tlc`) does not support combining code generated for multiple models.

To combine models for simulation and code generation, consider using model referencing. Model referencing helps with:

- Symbol naming consistency
- Required scheduling of the overall algorithm
- Model configuration consistency

Considerations for Combining Code for Different Models

If you combine code generated for different models that is, without using referenced models, consider the following:

- Data is global. Symbol (name) clashes can result.
- Configuration parameter settings for the models must match, including settings such as hardware word sizes.
- Reuse and sharing of code can be suboptimal (for example, duplicate code for shared utility functions, scheduling, and solvers).
- Scheduling can be more complex (for example, models can have periodic sample times that are not multiples of each other, making scheduling from a common timer interrupt more complicated)
- For plant models that use continuous time and state, the continuous time signals connecting models are not handled by a single solver like continuous time signals within a model, which can lead to subtle, numeric differences.

Share Data Across Models

Use unidirectional signal connections between models. These connections affect the order in which models are called. For example, if you use an output signal from `modelA` as input to `modelB`, the `modelA` output computation is called first.

Timing Issues

When combining code generated for multiple models or multiple instances of a model:

- Configure the models by using the same solver mode (single-tasking or multitasking).
- If the models use continuous states, configure the models by using the same solver.

If the base rates for the models differ, the main program (such as `rt_malloc_main.c`) must set up the timer interrupt to occur at the greatest common divisor rate of the models. The main program calls each model at a time interval.

Data Logging and External Mode Support

A multiple-model program can log data to separate MAT-files for each model.

Only one of the models in a multiple-model program can use external mode.

Control Ownership of Data

If you have Embedded Coder software, you can specify an owner for individual data items such as signals, parameters, and states. The owner of a data item generates the definition, the memory allocation and initialization, for the data item. For example, if you apply a storage class to a `Simulink.Signal` object so that it appears as a global variable in the generated code, specify one of the combined models as the owner of the object. The code generated for that model defines the variable.

If you use model referencing, you can modularize the generated code and establish clear ownership of data when you work in a team.

If you do not use model referencing, you can prevent generation of duplicate definitions for a data item. For example, suppose you store a `Simulink.Parameter` object in the base workspace and apply the storage class `ExportedGlobal`. If you generate code from two separate models that use the object, each model generates a definition for the corresponding global variable. Instead, you can specify an owner for the object so that only the owner generates a definition.

To specify an owner for a data item:

- 1 Apply a storage class to the data item. See “Organize Parameter Data into a Structure by Using Struct Storage Class” on page 32-67.
- 2 Configure the owner of the data item by specifying a value for the **Owner** property.
- 3 Select the model configuration parameter **Use owner from data object for data definition placement**.

For more information about controlling ownership and file placement of data definitions and declarations, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 34-2.

Combine Code Generated for Multiple Models or Multiple Instances of a Model

For each model that you are combining code for, generate the code.

- 1 Set the system target file to a GRT- or ERT-based system target file. The system target file for the models that you combine must be the same.
- 2 If you intend to have multiple instances of that model in the application, set the model configuration parameter **Code interface packaging** to `Reusable` function. If you specified

an ERT-based system target file, optionally, you can set the model configuration parameter **Use dynamic memory allocation for model initialization**, depending on whether you want to statically or dynamically allocate the memory for each instance of the model.

- 3** Generate source code. The code generator includes an allocation function in the generated file *model.c*. The allocation function dynamically allocates model data for each instance of the model.

After generating source code for each model:

- 1** Compile the code for each model that you are combining.
- 2** Combine the makefiles generated for the models into one makefile.
- 3** Create a combined simulation engine by modifying a main program, such as *rt_malloc_main.c*. The main program initializes and calls the code generated for each model.
- 4** Run the makefile. The makefile links the object files and the main program to an executable program.

Function Reuse in Generated Code

This example shows how to configure an atomic subsystem for generating reusable code. To specify that the code generated for a subsystem execute as an atomic unit, on the Block Parameters dialog box, select the **Treat as atomic unit** parameter. That parameter enables the **Function Packaging** parameter on the **Code Generation** tab. The **Function Packaging** parameter has these four settings:

- **Inline**: Inline the subsystem code
- **Nonreusable function**: Function with I/O passed as global data
- **Reusable function**: Function with I/O passed as function arguments
- **Auto**: Let Simulink Coder optimize based on context

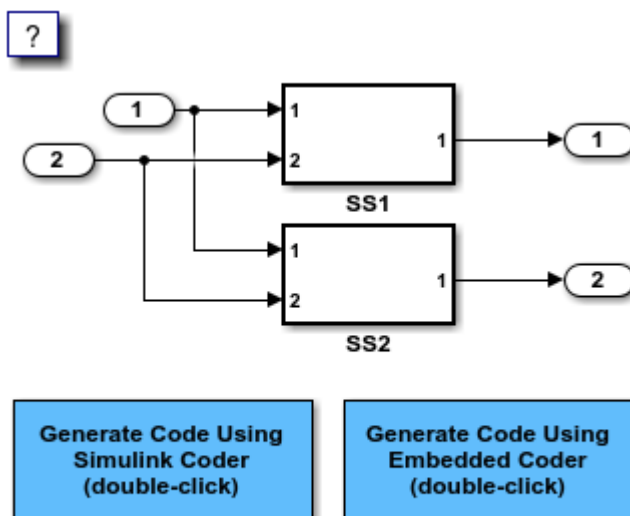

The **Reusable function** and **Auto** settings permit the code generator to reuse subsystem code. The **Reusable function** and **Nonreusable function** settings enable the **Function name options**, **Function name**, and **File name options** parameters.

If you have an Embedded Coder license, you can configure a nonreusable subsystem to accept arguments.

Example Model

The `rtwdemo_ssreuse` model contains two identical subsystems, SS1 and SS2. For these subsystems, the **Function packaging** parameter is set to **Reusable function**, and the **Function name** parameter is `myfun`. The subsystems are parameterized masked subsystems. To see the contents of the masked subsystems, right-click the subsystem blocks and select **Mask > Look Under Mask**.

```
model = 'rtwdemo_ssreuse';
open_system(model);
```

Generate and Inspect Code

Create a temporary folder for the build and inspection process. Open the **Simulink Coder** or **Embedded Coder** app. Then, generate and inspect the code.

```
currentDir=pwd;
[~,cgDir]=rtwdemodir();
slbuild(model)

### Starting build procedure for: rtwdemo_ssreuse
### Successful completion of build procedure for: rtwdemo_ssreuse

Build Summary

     * Sum: '<S1>/Sum'
     */
    rtwdemo_ssreuse_Y.Out1 = look1_binlx(Out1_tmp, rtwdemo_ssreuse_P.T1Break,
        rtwdemo_ssreuse_P.T1Data, 10U);

    /* End of Outputs for SubSystem: '<Root>/SS1' */

    /* Outputs for Atomic SubSystem: '<Root>/SS2' */
    /* Output: '<Root>/Out2' incorporates:
     * Lookup_n-D: '<S2>/Lookup Table'
     */
    rtwdemo_ssreuse_Y.Out2 = look1_binlx(Out1_tmp, rtwdemo_ssreuse_P.T2Break,
        rtwdemo_ssreuse_P.T2Data, 10U);
```

```

    /* End of Outputs for SubSystem: '<Root>/SS2' */
}

```

In the model step function, the subsystem code is inlined.

Change the **Function Packaging** parameter to Nonreusable function. For SS2, change the **Function name** parameter to myfun2.

```

set_param('rtwdemo_ssreuse/SS1','RTWSystemCode','Nonreusable function')
set_param('rtwdemo_ssreuse/SS2','RTWSystemCode','Nonreusable function')
set_param('rtwdemo_ssreuse/SS2','RTWFcnName','myfun2')

```

Generate and inspect the code.

```

slbuild(model)

### Starting build procedure for: rtwdemo_ssreuse
### Successful completion of build procedure for: rtwdemo_ssreuse

Build Summary

Top model targets built:

Model          Action          Rebuild Reason
=====
rtwdemo_ssreuse Code generated and compiled Generated code was out of date.

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 25.443s

cfile=fullfile(cgDir, 'rtwdemo_ssreuse_grt_rtw', 'rtwdemo_ssreuse.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_ssreuse_step(void)
{
    /* Outputs for Atomic SubSystem: '<Root>/SS1' */
    myfun();

    /* End of Outputs for SubSystem: '<Root>/SS1' */

    /* Outputs for Atomic SubSystem: '<Root>/SS2' */
    myfun2();

    /* End of Outputs for SubSystem: '<Root>/SS2' */
}

```

The model step function contains calls to the functions myfun and myfun2. These functions have a void-void interface.

Change the **Function Packaging** parameter to Auto.

```

set_param('rtwdemo_ssreuse/SS1','RTWSystemCode','Auto')
set_param('rtwdemo_ssreuse/SS2','RTWSystemCode','Auto')

```

For the auto setting, Simulink Coder chooses the optimal format. For this model, the optimal format is a reusable function.

Close the model and clean up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

File Packaging for Models (Code and Data)

This example shows how referenced models provide system interface encapsulation and incremental code generation. You can reference one model from another model (one or more times), and aspects of the referenced model are fixed: input/output signal types, parameter types, and sample times. Therefore, you can modularize your design and perform incremental code generation.

The code generator partitions data and functions of a referenced model into its own set of files, independent of its parent model. In this example, the referenced model `rtwdemo_mdrefbot` is referenced three times. For simulation and code generation, the model is incrementally generated, which means `rtwdemo_mdrefbot` builds the first time, but not on subsequent builds, unless you change `rtwdemo_mdrefbot`.

```
open_system('rtwdemo_mdrefbot')
```

Copyright 1994-2020 The MathWorks, Inc.

- 1 Generate and inspect the code.
- 2 Change the value of one of the constant inputs in `rtwdemo_mdrefbot`.
- 3 Generate code. The code generator does not reproduce code for reference model `rtwdemo_mdrefbot`.

```
bdclose('rtwdemo_mdrefbot');
```

Code Reuse for Simulink Coder

What Is Code Reuse?

Code reuse is a programming technique that reduces time and resources to develop software. When you develop code for reuse, the code serves multiple purposes. The technique involves modularization, which enables multiple individuals to develop code for various system components independently and in parallel. The technique also simplifies software distribution.

A software library is an example of code reuse. A library can contain code for several functions, each having specific behavior. To use a library, you need to know only the interface, which is the specification for calling the library functions.

Reusable code can be reentrant. You can invoke, interrupt, and reinvoke reentrant code. Reentrant code resides in shared memory. Instances of data associated with each use of the code are unique and preserved. Multiple calls to a reusable, reentrant function, for example, can access the function code with each call maintaining a unique data set.

Applications of code reuse include:

- Team-based development.
- Switching between implementations of a function.
- Intellectual property protection.
- Overriding library behavior with a custom implementation.
- Implementing a library that is based on standard library functions.
- Unit testing.
- Execution speed improvement.

The code generator supports code reuse and reentrancy. You can use key Simulink componentization techniques to partition a model into design components that you simulate, generate code for, and verify independently. You can save individual components as subsystems, libraries, referenced models, or combinations of these elements from which you can generate code. For example, the code generator produces reusable function code from library subsystems and export-function models.

More About

- “What Is Reentrant Code?” on page 7-3
- “Choose a Componentization Technique for Code Reuse” on page 7-4

What Is Reentrant Code?

Reentrant (multi-instance) code is a reusable routine that multiple programs can invoke, interrupt, and reinvoked simultaneously. When you want to reuse code, but associate each instance of the shared code with unique, preserved data, use reentrant code. For example, consider this figure that shows four instances of function `sensor_read`. Although the function algorithm is the same in each case, the data associated with each instance varies and is relative to the sensor position.

To make generated code for a model component reentrant, you configure the component such that model entry-point functions receive root-level input and output data as arguments. How you configure the component depends on the modeling style or technique that you apply.

Choose a Componentization Technique for Code Reuse

Key componentization techniques that you can use with Simulink and the code generator to produce reusable code include:

- Referenced models
- Subsystems
- Library subsystems
- Combinations of models, subsystems, and library subsystems

Choose componentization techniques based on your code reuse goals.

Goal	Referenced Model	Subsystem in Model	Subsystem in Library
Design for explicit code reuse.	√	√	√
Facilitate parallel team development.	√	√	√
Reuse function within a model or across models.	√		
Reduce build time by generating reusable code incrementally.	√		
Verify reusable code with SIL or PIL simulation.	√		
Optimize generated code by configuring code generator to detect opportunities for code reuse.	√	√	√
Maximize reuse with context-dependent behavior.		√	√
Develop a frequently used, and infrequently changed, utility function.			√

Simulink Function Blocks and Code Generation

Why Generate Code from Simulink Function Blocks and Function Callers?

Simulink Function blocks provide a mechanism for generating C or C++ code for modeling components that represent shared resources. You define the logic as a resource in a Simulink Function block, which separates the function interface (name and arguments) from the implementation of the logic. Function callers (Function Caller blocks, MATLAB Function blocks, and Stateflow charts) can then reuse the function logic at different levels of the model hierarchy.

Simulink Function blocks provide an alternative to reusable subsystems. For example, a consideration for using a Simulink Function block instead of a subsystem block is that a Simulink Function block shares states between function callers. The code generator produces one function. If the Simulink Function block contains blocks that have states, such as a delay or memory, the states persist between function callers. The order of the function calls is an important consideration.

Reusable functions that the code generator produces from subsystems do not share states. The code generator produces one function for multiple instances of the subsystem as an optimization. If that subsystem contains blocks that have states, the code generator produces one function, but passes a different state variable to each instance. The instances do not share states.

Other uses of Simulink Function blocks and callers include:

- Nesting calls to a function.
- Calling a function defined in one modeling component from another modeling component.
- Generating functions that are globally accessible or scoped.
- Producing code for a client and server application.

Implementation Options

Choose how to implement Simulink functions and function callers based on your code generation requirements. Considerations include:

- How you represent a function and function callers in a model
- Scope of a function
- Whether to export a function from a model (requires Embedded Coder)
- Function code interface customizations (requires Embedded Coder)
- Code generation requirements
- Code generation limitations

Choose a Modeling Pattern

This table shows C code for a function that multiplies an input value times two and a Simulink Function block that can represent that function in a Simulink model.

Function Definition	Modeling Element
<pre> codegen-<i>folder</i>/subsystem.c #include "timestwo_sf.h" #include "ex_slfunc_comp_sf.h" #include "ex_slfunc_comp_sf_private.h" void timestwo_sf(real_T rtu_x, real_T *rty_y) { *rty_y = 2.0 * rtu_x; } </pre>	Simulink Function block 

A Simulink function caller invokes a function defined with a Simulink Function block. From anywhere in a model or chart hierarchy, you can call a function defined with a Simulink Function block by using one of these modeling elements:

Function Call	Modeling Element
<pre> codegen-<i>folder</i>/model.c void ex_slfunc_comp_sf_step(void) { real_T rtb_FunctionCaller1; timestwo_sf(ex_slfunc_comp_sf_U.In1, &rtb_FunctionCaller1); ex_slfunc_comp_sf_Y.Out1 = rtb_FunctionCaller1; . . } </pre>	Function Caller block 
<pre> codegen-<i>folder</i>/model.c void ex_slfunc_comp_gf_step(void) { real_T rtb_y1_l; timestwo_gf(ex_slfunc_comp_gf_U.In4, &rtb_y1_l); ex_slfunc_comp_gf_Y.Out4 = rtb_y1_l; . . } </pre>	Stateflow chart transition 
<pre> codegen-<i>folder</i>/model.c void ex_slfunc_comp_mf_step(void) { real_T rtb_y; timestwo_mf(ex_slfunc_comp_mf_U.In3, &rtb_y); ex_slfunc_comp_mf_Y.Out3 = rtb_y; . . } </pre>	MATLAB Function block 

For more information about modeling choices, see “Simulink Functions Overview”.

Specify Function Scope

A function that you define with a Simulink Function block can be global or scoped.

- Global--The code generator places code for a global function in source and header files that are separate from model code files (for example, *function.c* and *function.h*). The separate files make the function code available for sharing between function callers.
- Scoped--The code generator places code for a scoped function in model code files (*model.c* and *model.h*). To call a scoped function in the context of a model, the function caller must be at the same level as the function in the model hierarchy, or one or more levels below.

To create a library of functions that are accessible from anywhere in the generated model code, set up each function as a scoped Simulink Function block. Place each scoped function within a virtual subsystem at the root level of a model.

For more information, see and “Scoped, Global, and Port-Scoped Simulink Function Blocks Overview”.

Decide Whether to Generate Export Function Code

Although you can use Simulink Function blocks in a single top-model design, function code is more reusable when you generate it as standalone, atomic components. You do that by designing the functions in the context of export-function models.

For information, see “Generate Component Source Code for Export to External Code Base” on page 55-40 and “Export-Function Models Overview”.

Specify Function Code Interface Customizations

With Embedded Coder, simplify integration of generated code with external code by customizing generated function code interfaces for Simulink Function and Function Caller blocks. You can customize the function interfaces for:

- Global Simulink Function blocks
- Scoped Simulink Function blocks that are at the root level of a model

For more information, see “Configure Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-2.

Uncalled Simulink Function Blocks

If you use a Simulink Function block in a rate-based model and do not call that function, the code generator treats the Simulink Function block as a constant and does not produce function code. For example, this can occur during model development when you are ready to define a function, but are not ready to identify a caller.

To identify such blocks in a rate-based model, display sample time colors during simulation. By default, Constant blocks appear magenta. Because the code generator considers uncalled Simulink Function blocks constants during simulation, they appear magenta.

Requirements

- Within a model hierarchy, function names are unique. If the code generator finds multiple functions with the same name, it issues an error. Change the name of one of the functions and delete the `s\prj` folder.
- The signature (for example, the arguments and argument data types) for a function and function callers must match.
 - If the code generator finds the function first and the signature of a function caller does not match, the code generator issues an error. Change the function caller signature to match the signature of the Simulink Function block or delete the `s\prj` folder.
 - If the code generator finds a function caller first and the signature of the function does not match, the code generator issues a warning message. Change the signature of the function or function caller so that the signatures match.
- In a Simulink Function block definition, do not define input and output signals for Argument Inport and Argument Outport blocks with a storage class.
- Do not specify Argument Inport and Argument Outport blocks as test points.
- If you specify the data type of input and output signals for Argument Inport and Argument Outport blocks as a `Simulink.IntEnumType`, `Simulink.AliasType`, or `Simulink.Bus`, set the `DataScope` property to `Imported` or `Exported`.
- A function interface and function callers must agree in data type, complexity, dimension, and number of arguments.

Limitations

- To generate code from a model that includes scoped Simulink functions, the model must be an export-function model. The code generator does not support rate-based models that include scoped Simulink functions.
- You can use a Simulink Function block to define a scoped function in a referenced model. However, you cannot generate code for an export-function model that uses a Function Caller block in an atomic subsystem to invoke that function.
- You can invoke a C++ function that the code generator produces from a Simulink Function block with code generated from a Stateflow chart. Due to current scope limitations for generated C++ functions, you must invoke those functions with code generated from a Function Caller block.
- Simulink functions and function callers do not honor the `MaxStackSize` parameter.
- Code generation for a C++ class interface supports scoped Simulink functions only.

Generate and Call Reusable Function Code

This example shows how to use the Simulink Function and Function Caller blocks to generate reusable function code. The code generator produces a global function, which complies with code requirements so that existing external code can call the function and a local function. The code generator also produces calls to global and local functions. The call to the global function shows that the global function is reused (shared).

Code requirements for the global function are:

- Function names start with prefix `func_`.

- Names of input arguments are of the form x_n , where n is a unique integer value.
- Names of output arguments are of the form y_n , where n is a unique integer value.
- Input and output arguments are integers (int) and are passed by reference. The native integer size of the target hardware is 32 bits.

You create a function that calls the generated reusable function code. Then, you construct and configure a model to match the code requirements.

Some of the features used in this example, such as data type aliasing and replacement, require Embedded Coder software.

Inspect External Code That Calls Reusable Function

In your code generation root folder, create the files `call_times2.h` and `call_times2.c`. If you prefer, you can copy the files from `matlabroot\help\toolbox\ecoder\examples`.

```
call_times2.h
typedef int my_int;

call_times2.c
#include "call_times2.h"

void call_times2(void)
{
    int times2result;

    func_times2(x1, &y1);

    printf('Times 2 Value:', y1);
}
```

This C code calls reusable function `func_times2`. The function multiplies an integer input value `x1` by 2 and returns the result as `y1`.

Create Model

Open the example model `ex_slfunc_comp`, which is available in the folder `matlabroot\help\toolbox\ecoder\examples`. The model includes two Simulink functions modeled as Simulink Function blocks, `func_times2` and `func_times3`, and a call to each function. As indicated in the model, the visibility of the Simulink Function block for `func_times2` is set to `global`. That visibility setting makes the function code accessible to other code, including external code that you want to integrate with the generated code. The visibility for `func_times3` is set to `scoped`.

If you configure the model with the GRT system target file or the ERT system target file with **File packaging format** set to **Modular**, the code generator produces function code for the model.

For more information, see “Generate Code for a Simulink Function and Function Caller” on page 7-15.

Configure Generated Code to Reuse Custom Data Type

The example assumes that the generated code runs on target hardware with a native integer size of 32 bits. The external code represents integers with data type `my_int`, which is an alias of `int`. Configure the code generator to use `my_int` in place of the data type that the code generator uses by default, which is `int32_T`.

- 1 Create a `Simulink.AliasType` object to represent the custom data type `my_int`.

```
my_int = Simulink.AliasType
```

```
my_int =
```

```
AliasType with properties:
```

```
Description: ''
DataScope: 'Auto'
HeaderFile: ''
BaseType: 'double'
```

- 2 Set the alias type properties. Enter a description, set the scope to **Imported**, specify the header file that includes the type definition, and associate the alias type with the Simulink base type `int32`.

```
my_int.Description='Custom 32-bit int representation';
my_int.DataScope='Imported';
my_int.HeaderFile='call_times2.h';
my_int.BaseType='int32';
```

```
my_int
```

```
AliasType with properties:
```

```
Description: 'Custom 32-bit int representation'
```

```
DataScope: 'Imported'
HeaderFile: 'call_times2.h'
BaseType: 'int32'
```

- Configure the code generator to replace instances of type `int32_T` with `my_int`. In the Configuration Parameters dialog box, open the **Code Generation Data Type Replacement** pane.
 - Select **Replace data type names in the generated code**.
 - In the **Data type names** table, enter `my_int` for the replacement name for `int32`.

Configure Reusable, Global Function

For external code to call a global function, configure the corresponding Simulink Function block to have global visibility and an interface that matches what is expected by the external callers.

- Open the block that represents the `times2` function.

- Configure the function name and visibility by setting Trigger Port block parameters. For example, the code requirements specify that the function name start with the prefix `func_`.
 - Set **Function name** to `func_times2`.
 - Set **Function visibility** to `global`.
- Configure the function input and output arguments by setting Argument Inport and Argument Outport block parameters. For example, the code requirements specify that argument names be of the form `xn` and `yn`. The requirements also specify that arguments be type `my_int`.
 - On the **Main** tab, set **Argument name** to `x1` (input) and `y1` (output).
 - On the **Signal Attributes** tab, set **Data type** to `int32`. With the data type replacement that you specified previously, `int32` appears in the generated code as `myint`.
- Configure the Simulink Function block code interface. At the top level of the model, right-click the block representing global function `func_times2`. From the context menu, select **C/C++ CodeConfigure C/C++ Function Interface**.
 - Set **C/C++ function name** to `func_times2`.
 - Set **C/C++ return argument** to `void`.
 - Set **C/C++ Identifier Name** for argument `x1` to `x1`.
 - Set **C/C++ Identifier Name** for argument `y1` to `y1`.

If the dialog box lists output argument `y1` before input argument `x1`, reorder the arguments by dragging the row for `x1` above the row for `y1`.

Configure Local Function

Configure a Simulink Function block that represents a local function with scoped visibility. Based on code requirements, you might also have to configure the function name, input and output argument names and types, and the function interface.

- 1 Open the block that represents the `times3` function.
- 2 Configure the function name and visibility by setting Trigger Port block parameters. For example, the code requirements specify that the function name start with the prefix `func_`.
 - Set **Function name** to `func_times3`.
 - Set **Function visibility** to `scoped`.
- 3 Configure the function input and output arguments by setting Argument Inport and Argument Outport block parameters. For example, the code requirements specify that argument names be of the form `xn` and `yn`. The requirements also specify that arguments be type `my_int`.
 - On the **Main** tab, set **Argument name** to `x1` (input) and `y1` (output).
 - On the **Signal Attributes** tab, set **Data type** to `int32`. With the data type replacement that you specified previously, `int32` appears in the generated code as `my_int`.
- 4 Configure the Simulink Function block code interface. At the top level of the model, right-click the scoped function `func_times3`. From the menu, select **C/C++ CodeConfigure C/C++ Function Interface**. In this case, the code generator controls naming the function and arguments. The function name combines the name of the root model and the function name that you specify for the trigger port of the Simulink Function block. In this example, the name is `ex_slfunc_comp_func_times3`.

You can set **C/C++ return argument** to the argument name that you specify for the Argument Outport block or `void`. For this example, set it to `void`.

For arguments, the code generator prepends `rtu_` (input) or `rty_` (output) to the argument name that you specify for the Argument Inport block.

If the dialog box lists output argument `y1` before input argument `x1`, reorder the arguments by dragging the row for `x1` above the row for `y1`.

Configure Function Callers

For each function caller, configure Function Caller block parameters:

- Set **Function prototype** to `y1 = func_times2(x1)`.
- Set **Input argument specifications** to `int32(1)`.
- Set **Output argument specifications** to `int32(1)`.

Generate and Inspect Code

Generate code for the model.

- Global function code

Source code for the global, reusable function `func_times2` is in the build folder in subsystem file, `func_times2.c`.

```
#include "func_times2.h"
```

```

/* Include model header file for global data */
#include "ex_slfunc_comp.h"
#include "ex_slfunc_comp_private.h"

```

```

void func_times2(my_int x1, my_int *y1)
{
    *y1 = x1 << 1;
}

```

- Local function code

The code generator places the definition for the local (scoped) function `func_times3` in file build folder in file `ex_slfunc_comp.c`.

```

void ex_slfunc_comp_func_times3(my_int rtu_x1, my_int *rty_y1)
{
    *rty_y1 = 3 * rtu_x1;
}

```

- Calls to generated functions

The model execution (step) function, in model file `ex_slfunc_comp.c`, calls the two Simulink functions: global function `func_times2` and local function `ex_slfunc_comp_func_times3`. The name `ex_slfunc_comp_func_times3` reflects the scope of the local function by combining the name of the model and the name of the function.

```

void ex_slfunc_comp_step(void)
{
    my_int rtb_FunctionCaller2;

    func_times2(ex_slfunc_comp_U.In1, &rtb_FunctionCaller2);

    ex_slfunc_comp_Y.Out1 = rtb_FunctionCaller2;

    ex_slfunc_comp_func_times3(ex_slfunc_comp_U.In2, &rtb_FunctionCaller2);

    ex_slfunc_comp_Y.Out2 = rtb_functionCaller2;
    .
    .
    .
}

```

- Entry-point declaration for local function

The model header file `ex_slfunc_comp.h` includes an `extern` declaration for function `ex_slfunc_comp_func_times3`. That statement declares the function entry point.

```
extern void ex_slfunc_comp_func_times3(my_int rtu_x1, my_int *rty_y1);
```

- Include statements for global function

The model header file `ex_slfunc_comp.h` lists include statements for the global function `func_times2`.

```

#include "func_times2_private.h"
#include "func_times2.h"

```

- Local macros and data for global function

The subsystem header file `func_times2_private.h` defines macros and includes header files that declare data and functions for the global function, `func_times2`.

```

#ifndef RTW_HEADER_func_times2_private_h_
#define RTW_HEADER_func_times2_private_h_

```

```
#ifndef ex_slfunc_comp_COMMON_INCLUDES_
#define ex_slfunc_comp_COMMON_INCLUDES_
#include "rtwtypes.h"
#endif
#endif
```

- Entry-point declaration for global function

The shared header file `func_times2.h`, in the shared utilities folder `slprj/stf/_sharedutils`, lists shared type includes for `rtwtypes.h`. The file also includes an extern declaration for the global function, `func_times2`. That statement declares the function entry point.

```
#ifndef RTW_HEADER_func_times2_
#define RTW_HEADER_func_times2_

#include "rtwtypes.h"

extern void func_times2(my_int rtu_x1, my_int *rty_y1);

#endif
```

Generate Code for a Simulink Function and Function Caller

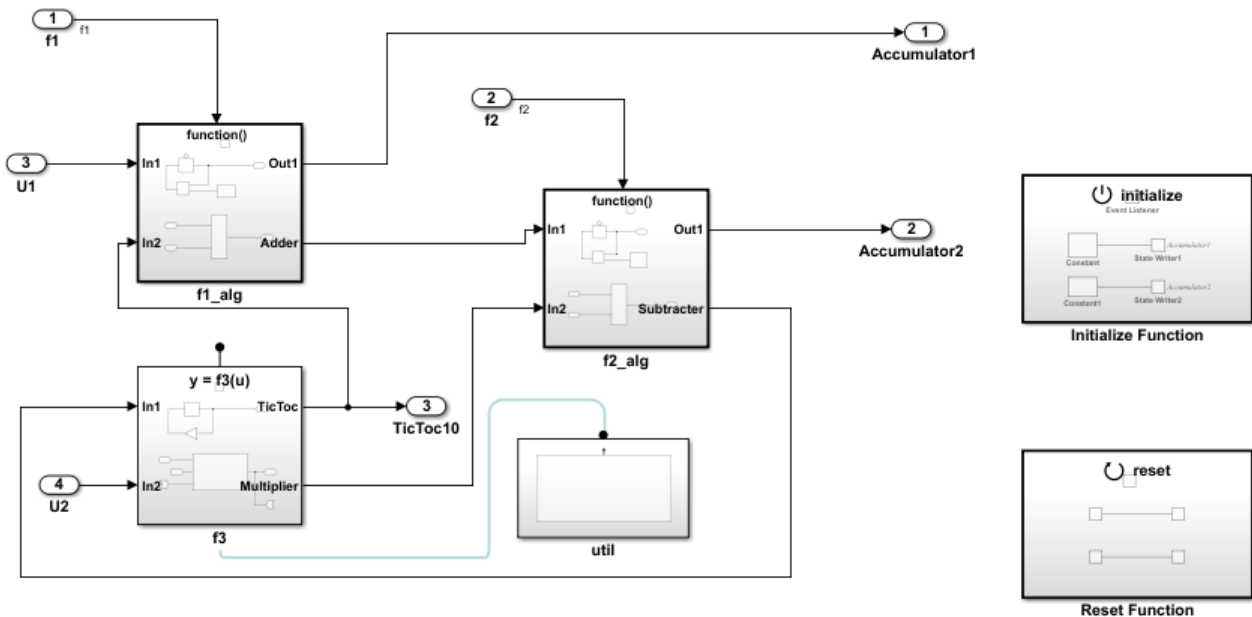

This example shows how to generate C code for Simulink Function and Function Caller blocks and displays the relevant generated code.

Open the example model `rtwdemo_export_functions`. The model uses Stateflow software, but this example reviews only the code generated from the referenced models.

Generate Code for Function Definition

- 1 To view the contents of the subsystem, double-click `rtwdemo_functions`. The Simulink Function block is the `f3` subsystem defined as $y = f3(u)$.

Copyright 2014-2016 The MathWorks, Inc.

- 2 Generate code.

The code generator creates `rtwdemo_functions.c`. This file contains the function definition and function initialization code.

- Initialization code for function `f3`:

```
void f3_Init(void)
{
    rtDWork.Delay_DSTATE = 1;
}
```

- Code for function `f3`:

```
void f3(real_T rtu_u, real_T *rty_y)
{
    rtY.TicToc10 = rtDWork.Delay_DSTATE;

    rtDWork.Delay_DSTATE = (int8_T)(int32_T)-(int32_T)rtY.TicToc10;

    adder_h(rtB.Subtract, rtU.U2, rtu_u, rtB.FunctionCaller);

    *rty_y = rtB.FunctionCaller;
}

void adder_h(real_T rtu_u1,
             real_T rtu_u2,
             real_T rtu_u3,
```

```

        real_T *rty_y)
    {
        *rty_y = (rtu_u1 + rtu_u2) + rtu_u3;
    }

```

- The shared header file `f3.h` contains the entry point declaration for function `f3`.

```

#include "rtwtypes.h"

extern void f3(real_T rtu_u, real_T *rty_y);

```

Generate Code for Function Caller

- 1 In the `rtwdemo_export_functions` model, double-click `rtwdemo_caller` to view the contents of the caller subsystem.
- 2 Generate code.

The code generator creates the files `rtwdemo_caller.h` and `rtwdemo_caller.c` in the folder `rtwdemo_caller_ert_rtw`.

`rtwdemo_caller.h` includes the shared header file, `f3.h`, which contains the function entry-point declaration.

`rtwdemo_caller.c` calls function `f3`.

```

void rtwdemo_caller_t_10tic(const real_T *rtu_u,
                           real_T *rty_y)
{
    f3(*rtu_u, rty_y);
}

```

Generate Reentrant Code from Top Models

By default, for top models, the code generator produces code that is not reentrant. Entry-point functions have a void-void interface. Code communicates with other code by sharing access to global data structures that reside in shared memory.

For applications that can benefit from reuse and require that each use or instance of the code maintains its own unique data, configure a model such that the code generator produces reentrant code. To generate reentrant code, set the model configuration parameter “Code interface packaging” to `Reusable` function. If you are using Embedded Coder and generating C++ code, alternatively, you can set the parameter to `C++ class`. In both cases, the code generator:

- Packages model data, such as block I/O, DWork vectors, and parameters, in the real-time model data structure (`rtModel`).
- Passes the real-time model data structure as an input argument, by reference, to generated model entry-point functions.
- Passes root-level input and output arguments to generated model entry-point functions as individual arguments.
- Allocates memory for model data structures statically.
- Exports the real-time model data structure in the generated header file `model.h`.

Apply additional diagnostic and code generation control by setting these model configuration parameters:

- To select the severity level for diagnostic messages that the code generator displays when a model does not meet requirements for multi-instance code, set parameter “Multi-instance code error diagnostic” to `None`, `Warning`, or `Error`. Set the parameter to `Error` unless you need to alter the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code.
- To control how the generated code passes root-level model input and output to the reusable execution (step) function (requires Embedded Coder), set parameter “Pass root-level I/O as” to `Individual arguments`, `Structure reference`, or `Part of model data structure`.

When you set “Code interface packaging” to `Reusable` function, the code generator packages model data (such as block I/O, Dwork, and parameters) into the real-time model data structure, and passes the model structure to generated model entry-point functions. If you set “Pass root-level I/O as” to `Part of model data structure`, the code generator packages root-level model input and output into the real-time model data structure also.

- To reduce memory usage by omitting the error status field from the real-time model data structure (requires Embedded Coder), select model configuration parameter **Remove error status field in real-time model data structure**.
- To include a function in the generated file `model.c` that uses `malloc` to dynamically allocate memory for model instance data (requires Embedded Coder), select model configuration parameter **Use dynamic memory allocation for model initialization**. If you do not select this parameter, the generated code statically allocates memory for model data structures.

Generate Reentrant, Multi-Instance Code

This example shows you how to configure a model for reentrant, multi-instance code generation. Multiple programs can use reentrant code simultaneously. When you configure a model for

reentrancy, the execution (step) entry-point function uses root-level input and output arguments instead of global data structures. After examining the configuration settings, generate and review the generated code.

Open the Model

Open the model `rtwdemo_reusable`. The model contains two root Inport blocks and a root Output block.

```
model='rtwdemo_reusable';
open_system(model);
```

Copyright 1994-2020 The MathWorks, Inc.

Save a copy of the model to a writable location.

```
currentDir=pwd;
[~,cgDir] = rtwdemodir();
```

Examine Relevant Model Configuration Parameter Settings

1. Open the **Embedded Coder** app.
2. Open the Model Configuration Parameters dialog box.
3. Model configuration parameter **System target file** is set to `ert.tlc`. Although you can generate reentrant code for a model configured with **System target file** set to `grt.tlc`, ERT and ERT-based system target files provide more control over how the code passes root-level I/O.
4. Open the **Code Generation > Interface** pane and explore relevant model configuration parameter settings.
 - **Code interface packaging** is set to `Reusable` function. This parameter setting instructs the code generator to produce reusable, multi-instance code.
 - Setting of `Reusable` function displays parameter **Multi-instance code error diagnostic**. That parameter is set to `Error`, indicating that the code generator abort if the model violates requirements for generating multi-instance code.
 - **Pass root-level I/O as** is set to `Part of model data structure`. This setting packages root-level model input and output into the real-time model data structure (`rtModel`), which is an optimized data structure that replaces `SimStruct` as the top-level data structure for a model.

- **Remove error status field in real-time model data structure** is selected. This parameter setting reduces memory usage by omitting the error status field from the generated real-time model data structure.

Generate and Review Code

```
slbuild(model);
```

```
### Starting build procedure for: rtwdemo_reusable
### Successful completion of build procedure for: rtwdemo_reusable
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_reusable	Code generated and compiled	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 17.385s

Review the Generated Code

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point function `rtwdemo_reusable_step`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_reusable.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_reusable.h` declare model data structures and a public interface to the model entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework.

1. Include the generated header file by adding directive `#include rtwdemo_reusable.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for the model Outport block.

Input ports:

- `<Root>/In1` of data `real_T` with dimension of 1
- `<Root>/In2` of data `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_reusable_initialize(RT_MODEL *const rtM)`. At startup, call this function once.

- Output and update (step) entry-point function, `void rtwdemo_reusable_step(RT_MODEL *const rtM)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.

Output port:

- `<Root>/Out1` of data type `real_T` with dimension of 1

Examine the Step Function

Examine the `rtwdemo_reusable_step` function code in `rtwdemo_reusable.c`.

```
cfile = fullfile(cgDir, 'rtwdemo_reusable_ert_rtw', 'rtwdemo_reusable.c');
rtwdemodbtype(cfile, /* Model step function', /* Model initialize function ', 1, 0);
```

```
/* Model step function */
void rtwdemo_reusable_step(RT_MODEL *const rtM)
{
    D_Work *rtDWork = rtM->dwork;
    ExternalInputs *rtU = (ExternalInputs *) rtM->inputs;
    ExternalOutputs *rtY = (ExternalOutputs *) rtM->outputs;

    /* Output: '<Root>/Out1' incorporates:
     * UnitDelay: '<Root>/Delay'
     */
    rtY->Out1 = rtDWork->Delay_DSTATE;

    /* Gain: '<Root>/Gain' incorporates:
     * Inport: '<Root>/In1'
     * Inport: '<Root>/In2'
     * Sum: '<Root>/Sum'
     * UnitDelay: '<Root>/Delay'
     */
    rtDWork->Delay_DSTATE = (rtU->In1 + rtU->In2) * rtP.k1;
}
```

The code generator passes model data to the `rtwdemo_reusable_step` function as part of the real-time model data structure. Try different settings for model configuration parameters **Code interface packaging** and **Pass root-level I/O** and regenerate code. Observe how the function prototype changes.

Close the Model and Report

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Share Data Between Instances

When your code calls a reentrant model entry-point function multiple times, each call represents an instance of the model. By default, the code generator generates code that assumes each instance reads from and writes to a separate copy of the signals, block states, and parameters in the model.

- To share a piece of parameter data between the instances (for example, to share a setpoint for a reusable PID control algorithm), use a parameter object, such as `Simulink.Parameter`. Then, configure the parameter with a storage class other than `Auto` or in the Code Mappings editor, set the default storage class for the corresponding category of parameter data `Default` (the default setting) to `Model default`. The parameter object appears in the code as a global symbol, such as a global variable, that the function accesses directly. For more information, see “C Code Generation Configuration for Model Interface Elements”.
- To share a piece of nonparameter data between the instances (for example, to share a fault indication or an accumulator), use a data store. You can configure the data store to appear in the code as a global symbol, such as a global variable, that the function accesses directly. Create a global data store by using a `Simulink.Signal` object or use a Data Store Memory block and select block parameter **Share across model instances**. For more information, see “Model Global Data by Creating Data Stores” and Data Store Memory.

Generate Reentrant Code from Simulink Function Blocks

If you are using Embedded Coder, you can generate reusable, reentrant code by representing an algorithm as a scoped Simulink Function block. Examples of when to generate reentrant code from Simulink Function blocks are when a function shares state between function callers within a model or for client/server applications. You can generate code that is highly modularized by using multiple instances of a shared Simulink Function block in an export-function model. The code generator produces function code and associates each use or call to the function with instance-specific data. The scope of the function depends on whether you place the function at the root level of model or in a subsystem.

The code generator produces reentrant function code when you configure a:

- Top model with model configuration parameter “Code interface packaging” set to **Reusable function** or **C++ class** (C++ only).
- Referenced model with “Total number of instances allowed per top model” set to **Multiple**.

Call a function represented by a scoped Simulink Function block from one level above, at the same level, or from a level below the level of the function definition. You can scope a function in an atomic or nonvirtual subsystem, but function call accessibility is limited to the same level or below of the hierarchy. The function name does not have to be unique.

Identify Requirements

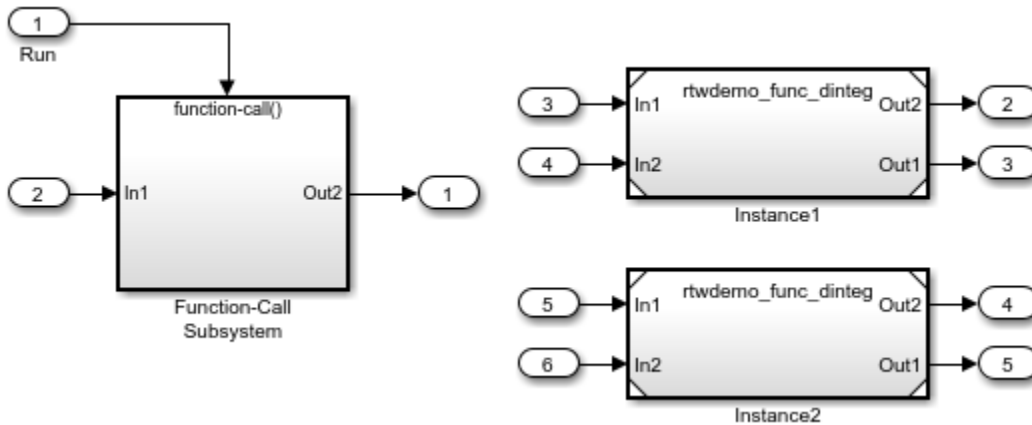

Before and while you design your model, consider:

- How many instances of each function are required?
- Do you need to restrict call sites for a function to the model containing the function definition?
- Do you need for a function to interface with signals in the local environment, but keep those signals hidden from callers?
- Do functions need to communicate directly with each other?
- Do functions need to connect to external I/O?
- Do you need to log function output?

Create Model

Use the example model component `rtwdemo_comp` to see how to use Simulink Function blocks to generate reentrant C code. Use example model `rtwdemo_comp_cpp` if you prefer to generate C++ code. Open the model and examine the model hierarchy.

The top level of the model includes a function-call subsystem and two instances of a referenced model.

The referenced model, `rtwdemo_func_dinteg`, consists of a Simulink Function block that defines function `multiinstfunc` and subsystem `subsys_calc`.

The subsystem consists of a Simulink Function block. This use of a Simulink Function block shows how you can limit the scope of the function that the block defines to the model that contains the subsystem. The code generator produces function code for `func_calc` and associates each call to the function with instance-specific data. The data includes states, such as data stored in memory.

The Simulink Function block that defines function `multiinstfunc` uses a Function Caller block to invoke function `func_calc`. That Simulink Function block also shows that it can interface to signals in the local environment of the block through Inport and Outport blocks.

At the top level of model `rtwdemo_comp`, the function-call subsystem uses Function Caller blocks to invoke the two instances of function `multiinstfunc`. The code generator produces function code and associates each call with instance-specific data.

Configure Model and Model Elements

Configure Simulink Function Blocks

Configure the Simulink Function blocks by setting parameters for the function Trigger Port block. For the code generator to produce reentrant code from Simulink Function blocks:

- Configure block instances with the same function name.
- Set block parameter **Function visibility** to `scoped`.

In the example, the function name for the Simulink Function blocks in the two instances of the referenced model `rtwdemo_func_dinteg` is specified as `multiinstfunc`.

Configure Function Caller Blocks

Configure the Function Caller blocks. For each of the blocks, set block parameter **Function prototype**. Start typing a prototype. For example, type `y`. Prototype options, based on function definitions in the model, appear in a selection list. Select the prototype that corresponds to each function call.

For this example, the prototypes are configured as follows:

- In the function-call subsystem, the prototypes for the function callers are configured as `y = Instance1.multiinstfunc(u)` and `y = Instance2.multiinstfunc(u)`. The `Instancen` prefix identifies each function invocation uniquely and associates the invocation with its own data set.
- The function caller in function `multiinstfunc` is configured with the prototype `y = subsystem_calc.func_calc(u)`. The prefix `subsystem_calc` identifies the subsystem that contains the function definition.

For the example, the input and output argument specifications and sample time retain default settings.

Subsystem Configuration

Configuration changes are not required for the subsystem in the example model. When you include a Simulink Function block in a subsystem, the code generator

- Scopes the function to the model that includes the subsystem.
- Treats the subsystem as an atomic unit.

Configure Referenced Model

Configure the referenced model that includes a Simulink Function block:

- In the Block Parameters dialog box, set parameter **Model name** to the referenced model file name. For this example, the model name is `rtwdemo_func_dinteg.slx`.
- Set model configuration parameter **Total number of instances allowed per top model** to `Multiple`.
- To generate a C++ class interface for the reference model, set model configuration parameter **Language** to `C++` and parameter **Code interface packaging** to `C++ class`.

Optionally, you can customize model entry-point function interfaces. You can specify entry-point function names. For the execution (step) entry-point function you can configure the function name and arguments. Custom entry-point function interfaces can minimize changes to existing external code that you integrate with the generated code. The example uses the default function interfaces. See “Configure Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-2.

Configure Top Model

Configure the top model for a model component. If you want the model component (that is, the top model) to be reusable, set model configuration parameter **Code interface packaging** to **Reusable function**. If you are generating C++ code, you can set this parameter to **C++ class**. In either case, also:

- Set model configuration parameter **Multi-instance code error diagnostic** to **Error**.
- Set model configuration parameter **Pass root-level I/O as** to **Part of model data structure**.

Optionally, you can customize model entry-point function interfaces. You can specify entry-point function names. For the execution (step) entry-point function you can configure the function name and arguments. Custom entry-point function interfaces can minimize changes to existing external code that you integrate with the generated code. The example uses the default function interfaces. See “Configure Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-2.

Generate and Inspect C Code

Generate C code for the model.

- Function code for multi-instance Simulink Function block

When you place a scoped Simulink Function block in a referenced model that you use multiple times in another model, the code generator places the function code in the *model.c* file for the referenced model. For this example, the code generator places function code for *multiinstfunc* in *slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.c*.

```
real_T rtwdemo_func_dinteg_multiinstfunc(RT_MODEL_rtwdemo_func_dinteg_T * const
    rtwdemo_func_dinteg_M, const real_T rtu_u)
{
    real_T rtb_TmpLatchAtInOutputport1;
    real_T rtb_TmpLatchAtIn2Outputport1;
    real_T rty_y_0;

    rtb_TmpLatchAtInOutputport1 =
        *rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextInport.rtu_In1;

    rtb_TmpLatchAtIn2Outputport1 =
        *rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextInport.rtu_In2;

    *rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextOutputport.rty_Out2 = 2.0 *
        rtb_TmpLatchAtInOutputport1;

    rtwdemo_func_dinteg_func_calc(rtwdemo_func_dinteg_M, rtb_TmpLatchAtIn2Outputport1,
        rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextOutputport.rty_Out1);

    rty_y_0 = rtwdemo_func_dinteg_M->dwork.DiscreteIntegrator_DSTATE;

    rtwdemo_func_dinteg_M->dwork.DiscreteIntegrator_DSTATE += 0.1 * rtu_u;
    return rty_y_0;
}
```

- Function code for a Simulink Function block defined in a subsystem

The code generator places the function code for a Simulink Function block that you define in a subsystem in the *model.c* file for the model that contains the subsystem. For this example, the code generator places the function code for *func_calc* in *slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.c*.

```

void rtwdemo_func_dinteg_func_calc(RT_MODEL_rtwdemo_func_dinteg_T * const
rtwdemo_func_dinteg_M, real_T rtu_u, real_T *rty_y)
{
    rtwdemo_func_dinteg_M->dwork.calcMem =
        rtwdemo_func_dinteg_M->dwork.UnitDelay_DSTATE;

    *rty_y = rtwdemo_func_dinteg_M->dwork.UnitDelay_DSTATE;

    rtwdemo_func_dinteg_M->dwork.UnitDelay_DSTATE = rtu_u * 0.07;
}

```

- Structure that stores multi-instance data for reusable functions

The code generator uses a structure similar to the real-time model (RT_MODEL) data structure to store the multi-instance data associated with a reusable function. The code generator defines the structure in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.h`.

```
typedef struct rtwdemo_func_dinteg_tag_RTM RT_MODEL_rtwdemo_func_dinteg_T;
```

- Initialization code for multi-instance referenced model

For each instance of a referenced model that includes the same scoped Simulink Function block, the code generator produces initialization and startup function code. A single copy of the initialization code is defined in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.c`.

```

void rtwdemo_func_dinteg_Start(RT_MODEL_rtwdemo_func_dinteg_T *const
rtwdemo_func_dinteg_M, const real_T *rtu_In1, const real_T *rtu_In2, real_T
*rty_Out2, real_T *rty_Out1)
{
    rtwdemo_func_dinteg_M->rtwdemo_func_dintegrttextInport.rtu_In1 = rtu_In1;
    rtwdemo_func_dinteg_M->rtwdemo_func_dintegrttextInport.rtu_In2 = rtu_In2;
    rtwdemo_func_dinteg_M->rtwdemo_func_dintegrttextOutport.rty_Out2 = rty_Out2;
    rtwdemo_func_dinteg_M->rtwdemo_func_dintegrttextOutport.rty_Out1 = rty_Out1;
}

void rtwdemo_func_dinteg_initialize(const char_T **rt_errorStatus,
RT_MODEL_rtwdemo_func_dinteg_T *const rtwdemo_func_dinteg_M)
{
    {
        rtmSetErrorStatusPointer(rtwdemo_func_dinteg_M, rt_errorStatus);
    }
}

```

The initialization code is called for each instance of a referenced model that contains the same Simulink Function block. That code is in file `rtwdemo_comp.c` in the build folder.

```

.
.
.
rtwdemo_func_dinteg_initialize(rtmGetErrorStatusPointer(rtwdemo_comp_M),
(&(rtwdemo_comp_M->Instance1)));

rtwdemo_func_dinteg_initialize(rtmGetErrorStatusPointer(rtwdemo_comp_M),
(&(rtwdemo_comp_M->Instance2)));

rtwdemo_func_dinteg_Start((&(rtwdemo_comp_M->Instance1)), &rtU->In2, &rtU->In3,
&rtY->Out2, &rtY->Out3);

rtwdemo_func_dinteg_Start((&(rtwdemo_comp_M->Instance2)), &rtU->In4, &rtU->In5,
&rtY->Out4, &rtY->Out5);
}

```

- Top model entry-point function declarations

The model header file `rtwdemo_comp.h` includes extern declarations for top model initialize, terminate, and execution (run) entry-point functions.

```
extern void rtwdemo_comp_initialize(RT_MODEL_rtwdemo_comp_T *const
rtwdemo_comp_M);
```

```
extern void Run(RT_MODEL_rtwdemo_comp_T *const rtwdemo_comp_M);
```

- Reference model entry-point function declarations

Header file `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.h` includes extern declarations for reference model entry-point functions.

```
extern void rtwdemo_func_dinteg_initialize(const char_T **rt_errorStatus,
    RT_MODEL_rtwdemo_func_dinteg_T *const rtwdemo_func_dinteg_M);
extern real_T rtwdemo_func_dinteg_multiinstfunc(RT_MODEL_rtwdemo_func_dinteg_T *
    const rtwdemo_func_dinteg_M, const real_T rtu_u);
extern void rtwdemo_func_dinteg_Start(RT_MODEL_rtwdemo_func_dinteg_T *const
    rtwdemo_func_dinteg_M, const real_T *rtu_In1, const real_T *rtu_In2, real_T
    *rty_Out2, real_T *rty_Out1);
```

Generate and Inspect C++ Code

Generate C++ code for the model.

- Function code for multi-instance Simulink Function block

When you place a scoped Simulink Function block in a referenced model that you use multiple times in another model, the code generator places the function code in the `model.cpp` file for the referenced model. For this example, the code generator places function code for `multiinstfunc` in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.cpp`.

```
real_T rtwdemo_func_dintegModelClass::multiinstfunc(const real_T rtu_u)
{
    real_T rtb_TmpLatchAtInOutputport1;
    real_T rtb_TmpLatchAtIn2Outputport1;
    real_T rty_y_0;

    rtb_TmpLatchAtInOutputport1 = *rtwdemo_func_dinteg_cprtrtu_In1;

    rtb_TmpLatchAtIn2Outputport1 = *rtwdemo_func_dinteg_cprtrtu_In2;

    *rtwdemo_func_dinteg_crtrty_Out2 = 2.0 * rtb_TmpLatchAtInOutputport1;

    rtwdemo_func_dinteg_c_func_calc(rtb_TmpLatchAtIn2Outputport1,
        rtwdemo_func_dinteg_crtrty_Out1);

    rty_y_0 = rtwdemo_func_dinteg_cpprtDW.DiscreteIntegrator_DSTATE;

    rtwdemo_func_dinteg_cpprtDW.DiscreteIntegrator_DSTATE += 0.1 * rtu_u;
    return rty_y_0;
}
```

- Function code for a Simulink Function block defined in a subsystem

The code generator places the function code for a Simulink Function block that you define in a subsystem in `model.cpp` for the model that contains the subsystem. For this example, the code generator places the function code for `func_calc` in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.cpp`.

```
void rtwdemo_func_dintegModelClass::rtwdemo_func_dinteg_c_func_calc(real_T rtu_u,
    real_T *rty_y)
{
    rtwdemo_func_dinteg_cpprtDW.calcMem =
        rtwdemo_func_dinteg_cpprtDW.UnitDelay_DSTATE;

    *rty_y = rtwdemo_func_dinteg_cpprtDW.UnitDelay_DSTATE;

    rtwdemo_func_dinteg_cpprtDW.UnitDelay_DSTATE = rtu_u * 0.07;
}
```

- Structure that stores multi-instance data for reusable functions

The code generator uses a structure similar to the real-time model (RT_MODEL) data structure to store the multi-instance data associated with a Reusable function. The code generator defines the structure in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.h`.

```
typedef struct rtwdemo_func_dinteg_cpp_tag_RTM rtwdemo_func_dinteg_cp_RT_MODEL;
```

- Initialization code for multi-instance referenced model

For each instance of a referenced model that includes the same scoped Simulink Function block, the code generator produces initialization and startup function code. A single copy of the initialization code is defined in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.cpp`.

```
void rtwdemo_func_dintegModelClass::start(real_T *rtu_In1, real_T *rtu_In2,
    real_T *rty_Out2, real_T *rty_Out1)
{
    rtwdemo_func_dinteg_cp_rtrtu_In1 = rtu_In1;
    rtwdemo_func_dinteg_cp_rtrtu_In2 = rtu_In2;
    rtwdemo_func_dinteg_cr_rty_Out2 = rty_Out2;
    rtwdemo_func_dinteg_cr_rty_Out1 = rty_Out1;
}
.
.
.
void rtwdemo_func_dintegModelClass::initializeRTM()
{
    (void) memset((void *)(&rtwdemo_func_dinteg_cp_rtm), 0,
        sizeof(rtwdemo_func_dinteg_cp_RT_MODEL));
}
}
```

The initialization code is called for each instance of a referenced model that contains the same Simulink Function block. That code is in file `rtwdemo_comp_cpp.cpp` in the build folder.

```
.
.
.
```

```
Instance1MDL0BJ0.initializeRTM();

Instance1MDL0BJ0.setErrorStatusPointer(rtmGetErrorStatusPointer((&rtM)));
Instance1MDL0BJ0.initialize();

Instance2MDL0BJ1.initializeRTM();

Instance2MDL0BJ1.setErrorStatusPointer(rtmGetErrorStatusPointer((&rtM)));

Instance1MDL0BJ0.start(&rtU.In2, &rtU.In3, &rtY.Out2, &rtY.Out3);

Instance2MDL0BJ1.start(&rtwU.In4, &rtwU.In5, &rtY.Out4, &rtY.Out5);
}
```

- Top model class declaration

The model header file `rtwdemo_comp_cpp.h` includes the class declaration for the top model.

```
class rtwdemo_compModelClass {
public:
    ExtU rtU;

    ExtY rtY;

    void initialize();

    void Run();

    rtwdemo_compModelClass();
};
```

```

~rtwdemo_compModelClass();

RT_MODEL * getRTM();

private:
RT_MODEL rtM;

rtwdemo_func_dintegModelClass Instance1MDL0BJ0;
rtwdemo_func_dintegModelClass Instance2MDL0BJ1;
};

```

- Reference model class declaration

Header file `s\prj\ert\rtwdemo_func_dinteg\rtwdemo_func_dinteg_cpp.h` includes the class declaration for the reference model.

```

class rtwdemo_func_dintegModelClass {
public:
real_T multiinstfunc(const real_T rtu_u);

void start(real_T *rtu_In1, real_T *rtu_In2, real_T *rty_Out2, real_T
*rty_Out1);

rtwdemo_func_dintegModelClass();
~rtwdemo_func_dintegModelClass();

rtwdemo_func_dinteg_cp_RT_MODEL * getRTM();

void initializeRTM();

void setErrorStatusPointer(const char_T **rt_errorStatus);

private:
rtwdemo_func_dinteg_cpp_DW rtwdemo_func_dinteg_cpprtDW;

const real_T *rtwdemo_func_dinteg_cprrtu_In1;
const real_T *rtwdemo_func_dinteg_cprrtu_In2;
real_T *rtwdemo_func_dinteg_crtrty_Out2;
real_T *rtwdemo_func_dinteg_crtrty_Out1;

rtwdemo_func_dinteg_cp_RT_MODEL rtwdemo_func_dinteg_cpprtM;

void rtwdemo_func_dinteg_c_func_calc(real_T rtu_u, real_T *rty_y);
};

```

Limitations

These code generation limitations apply to export-function models that include multiple instances of a Simulink Function block.

- You must set the model configuration parameter **Pass root-level I/O as to Part of model data structure**.
- Generated code is compatible with single-threaded execution only. To avoid race conditions for shared signal data, invoke instances of the function code from the same execution thread.
- You cannot:
 - Generate code if the export-function model includes model variants.
 - Call the generated code from a Stateflow chart.
 - Enable the external mode data exchange interface.

Generate Reentrant Code from Subsystems

You can reduce the amount of code that the code generator produces for identical atomic subsystems by configuring the subsystems as reusable functions that pass data as arguments (for example, `rtB_*` for block input and output, `rtDW_*` for continuous states, and `rtP_*` for parameters) . By default, the code generator produces subsystem code that communicates with other code by sharing access to global data structures that reside in shared memory. By passing data as arguments, the code can be reentrant. Each instance of the code maintains its own unique data.

To configure subsystems for reusability and reentrancy, configure mask and block parameters of the identical subsystems the same way. The code generator performs a checksum to determine whether subsystems are identical and whether the code is reusable. If the code is reusable, the code generator produces a single instance of reusable, reentrant function code.

To configure the subsystem block parameters:

- 1 If a subsystem is virtual, select block parameter “Treat as atomic unit” to enable function packaging parameters.
- 2 Set block parameter “Function packaging” to **Reusable function**. The code generator produces a separate function with arguments for each subsystem. Selecting **Reusable function** also enables additional parameters that you can use to control the names of the function and file that the code generator produces for the subsystem code.
- 3 Select a value for block parameter “Function name options”. To generate reusable, reentrant code, specify the same setting for identical subsystems.
 - To let the code generator determine the function name, select **Auto**.
 - To use the subsystem name or, for a library block, the name of the library block, select **Use subsystem name**.
 - To display block parameter “Function name” and enter a unique, valid C/C++ function name, select **User specified**.

If multiple instances of an identical subsystem exist within a model reference hierarchy, select **Auto**.

If you are using Embedded Coder, you can use identifier format controls. See “Identifier Format Control” on page 52-17.

- 4 Set “File name options”. To generate reusable, reentrant code, specify the same setting for identical subsystems.
 - To let the code generator determine file naming select **Auto**.
 - To use the subsystem name or, for a library block, the name of the library block select **Use subsystem name**.
 - To use the function name, as specified by block parameter **Function name options** select **Use function name**.
 - To display block parameter “File name (no extension)” and enter a file name, excluding the extension (for example, `.c` or `.cpp`) select **User specified**.

Other considerations:

- If multiple instances of an identical subsystem exist within a model reference hierarchy, select **Auto**.

- If the code generator does not generate a separate file for a subsystem, the function code is placed in the file generated from the subsystem's parent system. If the parent is the model itself, the code generator places the function code in *model.c* or *model.cpp*.
- If your generated code is under source control, specify a value other than **Auto**. This specification prevents the generated file name from changing when you modify and rebuild the model.
- If you select **Use subsystem name**, the code generator mangles the subsystem file name if the model contains Model blocks, or if a model reference target is being generated for the model. In these situations, the code generator uses the file name *modelsubsystem.c*.

If subsystem A has mask parameter b and K and subsystem B has mask parameters c and K, code reuse is not possible. The code generator produces separate functions for subsystems A and B. If you set block parameters for subsystems A and B differently, code reuse is not possible.

Function Reuse in Generated Code

This example shows how to configure an atomic subsystem for generating reusable code. To specify that the code generated for a subsystem execute as an atomic unit, on the Block Parameters dialog box, select the **Treat as atomic unit** parameter. That parameter enables the **Function Packaging** parameter on the **Code Generation** tab. The **Function Packaging** parameter has these four settings:

- **Inline**: Inline the subsystem code
- **Nonreusable function**: Function with I/O passed as global data
- **Reusable function**: Function with I/O passed as function arguments
- **Auto**: Let Simulink Coder optimize based on context

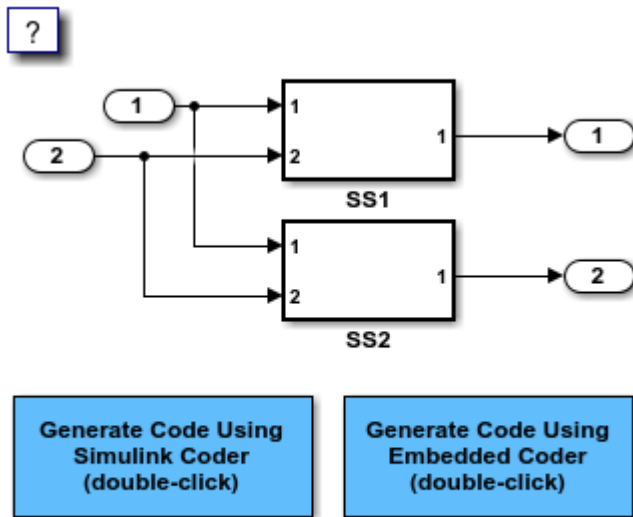

The **Reusable function** and **Auto** settings permit the code generator to reuse subsystem code. The **Reusable function** and **Nonreusable function** settings enable the **Function name options**, **Function name**, and **File name options** parameters.

If you have an Embedded Coder license, you can configure a nonreusable subsystem to accept arguments.

Example Model

The `rtwdemo_ssreuse` model contains two identical subsystems, SS1 and SS2. For these subsystems, the **Function packaging** parameter is set to **Reusable function**, and the **Function name** parameter is `myfun`. The subsystems are parameterized masked subsystems. To see the contents of the masked subsystems, right-click the subsystem blocks and select **Mask > Look Under Mask**.

```
model = 'rtwdemo_ssreuse';
open_system(model);
```

}

```

In the model step function, there are two calls to the reusable function, `myfun`. The mask parameters, `T1Break`, `T1Data`, `T2Break`, and `T2Data`, are function arguments.

Change the **Function Packaging** parameter to **Inline**.

```

set_param('rtwdemo_ssreuse/SS1','RTWSystemCode','Inline')
set_param('rtwdemo_ssreuse/SS2','RTWSystemCode','Inline')

```

Generate and inspect the code.

```

slbuild(model)

cfile=fullfile(cgDir, 'rtwdemo_ssreuse_grt_rtw', 'rtwdemo_ssreuse.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_ssreuse_step(void)
{
    real_T Out1_tmp;

    /* Outputs for Atomic SubSystem: '<Root>/SS2' */
    /* Outputs for Atomic SubSystem: '<Root>/SS1' */

```

```

/* Sum: '<S1>/Sum' incorporates:
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 * Sum: '<S2>/Sum'
 */
Out1_tmp = rtwdemo_ssreuse_U.In1 + rtwdemo_ssreuse_U.In2;

/* End of Outputs for SubSystem: '<Root>/SS2' */

/* Output: '<Root>/Out1' incorporates:
 * Lookup_n-D: '<S1>/Lookup Table'
 * Sum: '<S1>/Sum'
 */
rtwdemo_ssreuse_Y.Out1 = look1_binlx(Out1_tmp, rtwdemo_ssreuse_P.T1Break,
    rtwdemo_ssreuse_P.T1Data, 10U);

/* End of Outputs for SubSystem: '<Root>/SS1' */

/* Outputs for Atomic SubSystem: '<Root>/SS2' */
/* Output: '<Root>/Out2' incorporates:
 * Lookup_n-D: '<S2>/Lookup Table'
 */
rtwdemo_ssreuse_Y.Out2 = look1_binlx(Out1_tmp, rtwdemo_ssreuse_P.T2Break,
    rtwdemo_ssreuse_P.T2Data, 10U);

/* End of Outputs for SubSystem: '<Root>/SS2' */
}

```

In the model step function, the subsystem code is inlined.

Change the **Function Packaging** parameter to **Nonreusable function**. For SS2, change the **Function name** parameter to **myfun2**.

```

set_param('rtwdemo_ssreuse/SS1','RTWSystemCode','Nonreusable function')
set_param('rtwdemo_ssreuse/SS2','RTWSystemCode','Nonreusable function')
set_param('rtwdemo_ssreuse/SS2','RTWFcnName','myfun2')

```

Generate and inspect the code.

```
slbuild(model)
```

```

### Starting build procedure for: rtwdemo_ssreuse
### Successful completion of build procedure for: rtwdemo_ssreuse

```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_ssreuse	Code generated and compiled	Generated code was out of date.

```

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 25.443s

```

```

cfile=fullfile(cgDir, 'rtwdemo_ssreuse_grt_rtw', 'rtwdemo_ssreuse.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);

```

```
/* Model step function */
```

```

void rtwdemo_ssreuse_step(void)
{
    /* Outputs for Atomic SubSystem: '<Root>/SS1' */
    myfun();

    /* End of Outputs for SubSystem: '<Root>/SS1' */

    /* Outputs for Atomic SubSystem: '<Root>/SS2' */
    myfun2();

    /* End of Outputs for SubSystem: '<Root>/SS2' */
}

```

The model step function contains calls to the functions `myfun` and `myfun2`. These functions have a void-void interface.

Change the **Function Packaging** parameter to **Auto**.

```

set_param('rtwdemo_ssreuse/SS1', 'RTWSystemCode', 'Auto')
set_param('rtwdemo_ssreuse/SS2', 'RTWSystemCode', 'Auto')

```

For the `auto` setting, Simulink Coder chooses the optimal format. For this model, the optimal format is a reusable function.

Close the model and clean up.

```

bdclose(model)
rtwdemoclean;
cd(currentDir)

```

Limitations

- The code generator uses a checksum to determine whether subsystems are identical and reusable. Subsystem code is not reused if:
 - In blocks and data objects, you use symbols to specify dimensions.
 - A port has different sample times, data types, complexity, frame status, or dimensions across subsystems.
 - The output of a subsystem is marked as a global signal.
 - Subsystems contain identical blocks with different names or parameter settings.
 - The output of a subsystem is connected to a Merge block, and the output of the Merge block is configured with a custom storage class that is implemented in the C code as nonaddressable memory (for example, `BitField`).
 - The input of a subsystem is nonscalar and is configured with a custom storage class that is implemented in the C code as nonaddressable memory.
 - A masked subsystem has a parameter that is nonscalar and is configured with a custom storage class that is implemented in the C code as nonaddressable memory.
 - A function-call subsystem uses mask parameters when you set the model configuration parameter “Default parameter behavior” to `Tunable`. To reuse the masked function-call subsystem, place it inside a new atomic subsystem without a mask. Then move the Trigger block from the masked subsystem into the atomic subsystem.
 - A block in a subsystem uses a partially tunable expression. Some partially tunable expressions disable code reuse.

Partially tunable expressions are expressions that contain one or more tunable variables and an expression that is not tunable. For example, suppose that you create the tunable variable *K* with value 15.23 and the tunable variable *P* with value [5;7;9]. The expression *K+P'* is a partially tunable expression because the expression *P'* is not tunable. For more information about tunable expression limitations, see “Tunable Expression Limitations”.

- For subsystems that contain S-function blocks that are reusable, the blocks must meet the requirements listed in “S-Functions for Code Reuse” on page 12-85.
- If you select **Reusable function**, and the code generator determines that you cannot reuse the code for a subsystem, it generates a separate function that is not reused. The code generation report might show that the separate function is reusable, even if only one subsystem uses it. If you prefer that the code generator inline subsystem code in such cases (rather than deployed as functions), set “Function packaging” to **Auto**.
- If a reusable subsystem uses a shared local data store and you configure default mapping for model data elements, leave the default storage class mapping for category **Shared local data stores** set to **Default**.
- Use of these blocks in a subsystem can prevent the subsystem code from being reused:
 - Scope blocks (with data logging enabled)
 - S-Function blocks that fail to meet certain criteria (see “S-Functions for Code Reuse” on page 12-85)
 - To File blocks (with data logging enabled)
 - To Workspace blocks (with data logging enabled)
- For reusable library subsystems (subsystems shared across reference models), the code generator uses a checksum to determine whether subsystems are identical. The code generator places the reusable library subsystem code in the shared utilities folder, and the reusable code is independent of the generated code of the top model or the reference model. For example, the reusable library subsystem code does not include *model.h* or *model_types.h*.

Reusable code that the code generator places in the shared utilities folder and is dependent on the model code does not compile. If the code generator determines that the reusable library subsystem code is dependent on the model code, the reusable subsystem code is not placed in the shared utilities folder. The code generator produces code that is dependent on the model code when the reusable library subsystem:

- Contains a block that uses time-related functionality, such as a Step block, or continuous time or multirate blocks.
- Contains one or more Model blocks.
- Contains a subsystem that is not inlined or a reusable library subsystem.
- Contains a signal or parameter with a storage class that places the data declaration in a file under *model_ert_rtw* (For example, **ExportedGlobal** storage class places data in *model.c*)
- Contains a user-defined storage class like Enumeration, Simulink.Signal, Simulink.Parameter, and so on where **Data Scope** is not set to **Exported**. The code generator might place the type definition in *model_types.h*.
- Is a variant subsystem that generates preprocessor conditionals. The code generator places preprocessor directives that define the variant objects in *model_types.h*
- You cannot reuse a subsystem if there are multiple instances of the same subsystem in the model and one subsystem is fed by a Constant block but the other subsystem is not. To work around this limitation, insert a Signal Conversion block before the subsystems.

- Two reusable subsystems that have different checksums cannot share the same function in the generated code. When you specify the same function name for both subsystems in **Block Parameters (Subsystem) > Code Generation > Function name:**
 - If the subsystems are library-linked, the code generator mangles the function name to generate unique function names. The code generator uses the subsystem naming rules to generate the function names.
 - If the subsystems are not library-linked, the code generator issues an error.

The preceding limitations also apply for library-based code generation. For more information, see “Library-Based Code Generation for Reusable Library Subsystems” on page 8-2.

Generate Reusable Code from Library Subsystems Shared Across Models

What Is a Reusable Library Subsystem?

A reusable library subsystem is a subsystem included in a library that is configured for reuse. You must define a subsystem in a library and configure it for reuse to reuse the subsystem across models.

To reuse common functionality, you can include multiple instances of a subsystem:

- Within a single model, which is a top model or part of model reference hierarchy
- Across multiple referenced models in a model reference hierarchy
- Across multiple top models that contain Model blocks
- Across multiple top models that do not include Model blocks

The code generator uses checksums to determine reusability. There are cases when the code generator cannot reuse subsystem code.

For incremental code generation, if the reusable library subsystem changes, a rebuild of itself and its parents occurs. During the build, if a matching function is not found, a new instance of the reusable function is generated into the shared utilities folder. If a different matching function is found from previous builds, that function is used, and a new reusable function is not emitted.

For subsequent builds, unused files are not replaced or deleted from your folder. During development of a model, when many obsolete shared functions exist in the shared utilities folder, you can delete the folder and regenerate the code. If all instances of a reusable library subsystem are removed from a model reference hierarchy and you regenerate the code, the obsolete shared functions remain in the shared utilities folder until you delete them.

If a model changes such that the change might cause different generated code for the subsystem, a new reusable function is generated. For example, model configuration parameters that modify code comments might cause different generated code for the subsystem even if the reusable library subsystem did not change.

Embedded Coder users can generate code from a library that contains subsystems are configured for reuse. For more information, see “Library-Based Code Generation for Reusable Library Subsystems” on page 8-2.

Reusable Library Subsystem Code Placement and Naming

The generated code of a reusable library subsystem is independent of the generated code of the model. Code for the reusable library subsystem is generated to the shared utility folder, `s\prj/target/_sharedutils`, instead of the model reference hierarchy folders. The generated code for the supporting types, which are generated to the `.h` file, are also in the shared utilities folder.

For unique naming, reusable function names have a checksum appended to the reusable library subsystem name. For example, the code and files for a subsystem, `SS1`, which links to a reusable library subsystem, `RLS`, might be:

- Function name: `RLS_mgdj_lngd`

- File name: `RLS_mgdj\nd.c` and `RLS_mgdj\nd.h`

Configure Reusable Library Subsystem

Set the Subsystem parameters as listed here:

- Select **Treat as an atomic unit**.
- On the **Code Generation** tab:
 - Set **Function packaging** to `Reusable function`.
 - Set the **Function name options**

and **File name options** parameters to one of the following combinations:

- Set **Function name options** and **File name options** to `Auto`.
- Set **Function name options** to `Use subsystem name` and **File name options** to `Use function name`.
- Set **Function name options** to `User specified` and **File name options** to `Auto` or `Use function name`.
- Set **Function name options** to `User specified` and **File name options** to `User specified`. Set the same value for the **Function name** and **File name** parameters.

In a model reference hierarchy, if an instance of the reusable library subsystem is in the top model, then on the **Model Referencing** pane of the Configuration Parameters dialog box, you must select the **Pass fixed-size scalar root input by value for code generation** parameter. If you do not select the parameter, a separate shared function is generated for the reusable library subsystem instance in the top model, and a reusable function is generated for instances in the referenced models.

If a reusable library subsystem is connected to the root Output, reuse does not happen with identical subsystems that are not connected to the root Output. However, you can set **Pass reusable system outputs as** to `Individual arguments` on the **Optimizations** pane to make sure that reuse occurs between these subsystems. This parameter requires an Embedded Coder license.

For more information on creating a library, see “Custom Libraries”. For an example of creating a reusable library subsystem, see “Generate Reusable Code for Subsystems Shared Across Models”.

Configure Models That Include Reusable Library Subsystems

For a model to use a reusable library subsystem, you must configure the model differently depending on whether the model is a reference model or top model. If the subsystem is in a referenced model hierarchy, set the configuration parameter, “Shared code placement” to `Auto`. Otherwise, for each model that uses the subsystem, set the model configuration parameter **Shared code placement** to `Shared location`.

If a reusable library subsystem uses a shared local data store and you configure default mapping for model data elements, leave the default storage class mapping for category **Shared local data stores** set to **Default**.

Generate Reusable Code for Subsystems Shared Across Models

This example shows how to configure a reusable library subsystem and generate a reusable function for a subsystem shared across referenced models. The result is reusable code for the subsystem, which is generated to the shared utility folder (`slprj/target/_sharedutils`).

- “Create a reusable library subsystem.” on page 7-43
- “Create the example model.” on page 7-46
- “Set configuration parameters of the top model.” on page 7-47
- “Create and propagate a configuration reference.” on page 7-47
- “Generate and view the code.” on page 7-48

Create a reusable library subsystem.

- 1 In the Simulink Editor, on the **Simulation** tab, select **New > Library**. Select **Blank Library** from the Simulink Start Page window. Open `rtwdemo_ssreuse` to copy and paste subsystem `SS1` into the Library Editor. This action loads the variables for `SS1` into the base workspace. Rename the subsystem block to `RLS`.

- 2 Click the Subsystem block and press **Ctrl+U** to view the contents of subsystem RLS.

- 3 To configure the subsystem, in the Library editor, right-click RLS. In the context menu, select **Block Parameters (Subsystem)**. In the Subsystem Parameters dialog box, choose the following options:
 - Select **Treat as an atomic unit**.
 - On the **Code Generation** tab:
 - Set **Function packaging** to Reusable function.
 - Set **Function name options** to User specified and verify that the **Function name** is set to myfun.
 - Set **File name options** to Auto.
- 4 Click **Apply** and **OK**.
- 5 Save the reusable library subsystem as ssreuselib, which creates a file, ssreuselib.slx.

Create the example model.

- 1 Create a model which includes one instance of RLS from `ssreuselib`. Name this subsystem SS1. Add another subsystem and name it SS2. Name the model `ex_model1`.

- 2 Create another model which includes one instance of RLS from `ssreuselib`. Name this subsystem SS1. Add another subsystem and name it SS3. Name the model `ex_model2`.

- 3 Create a top model with two model blocks that reference `ex_model1` and `ex_model2`. Save the top model as `ex_md1ref_ssreuse`.

Set configuration parameters of the top model.

- 1 With model `ex_mdhref_ssreuse` open in the Simulink Editor, on the **C Code** tab, click **Settings** to open the Configuration Parameters dialog box.
- 2 On the **Solver** pane, specify the **Type** as Fixed-step.
- 3 On the **Model Referencing** pane, click the ellipsis to view the advanced parameters. Then, select **Pass fixed-size scalar root inputs by value for code generation**.
- 4 On the **Code Generation > Report** pane, select **Create code generation report** and **Open report automatically**.
- 5 On the **Code Generation > Interface** pane, set the “Shared code placement” to Shared location.
- 6 On the **Code Generation > Identifiers** pane, set the **Maximum identifier length** to 256. This step is optional.
- 7 Click **Apply** and **OK**.

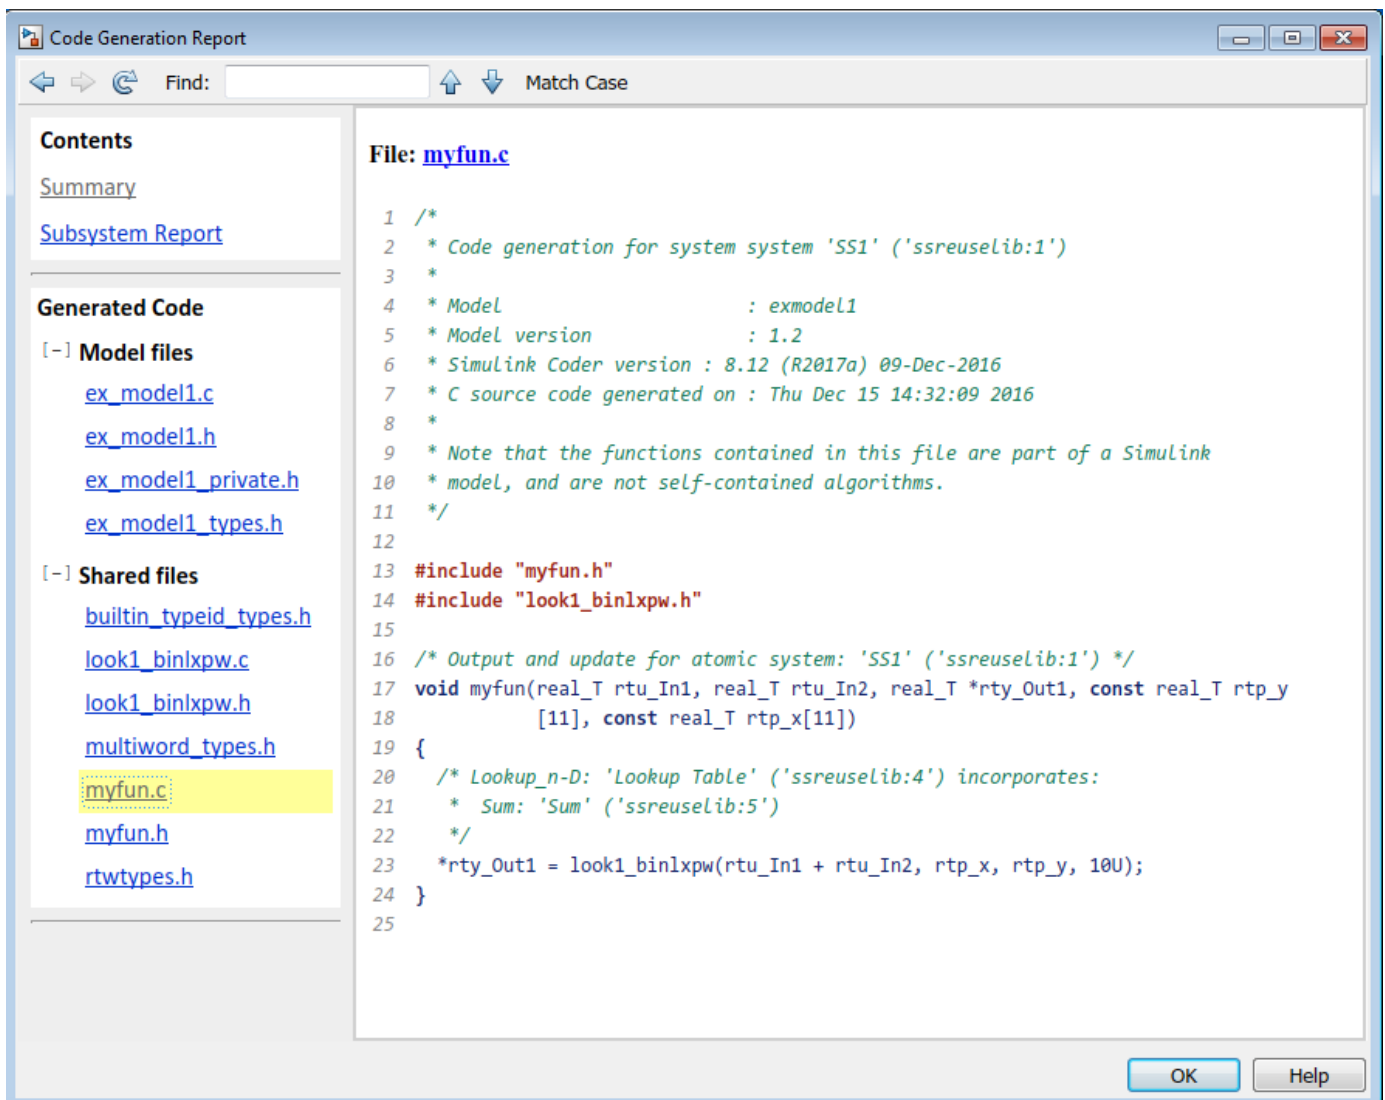

Create and propagate a configuration reference.

- 1 In the Simulink Editor, on the **Modeling** tab, click **Model Explorer** to open the Model Explorer. In the left navigation column of the Model Explorer, expand the `ex_mdhref_ssreuse` node.
- 2 Select the Configurations node below the `ex_mdhref_ssreuse` node. In the **Contents** pane, right-click **Configuration** and select **Convert to Configuration Reference**.
- 3 In the Convert Active Configuration to Reference dialog box, click **OK**. This action converts the model configuration set to a configuration reference, `Simulink.ConfigSetRef`, and creates the configuration reference object, `configSetObj`, in the base workspace.
- 4 In the left navigation column, right-click **Reference (Active)** and select **Propagate to Referenced Models**.
- 5 In the Configuration Reference Propagation to Referenced Models dialog box, select the referenced models in the list. Click **Propagate**.

Now, the top model and referenced models use the same configuration reference, Reference (Active), which points to a model configuration reference object, configSetObj, in the base workspace. When you save your model, you also need to export the configSetObj to a MAT-file.

Generate and view the code.

- 1 To generate code, in the Simulink Editor, press **Ctrl+B**. After the code is generated, the code generation report opens.
- 2 To view the code generation report for a referenced model, in the left navigation pane, in the **Referenced Models** section, select `ex_model1`. The code generation report displays the generated files for `ex_model1`.
- 3 In the left navigation pane, expand the **Shared files**. The code generator uses the reusable library subsystem name. The code for subsystem SS1 is in `myfun.c` and `myfun.h`.

- 4 Click **Back** and navigate to the `ex_model2` code generation report. `ex_model2` uses the same source code, `myfun.c` and `myfun.h`, as the code for `ex_model1`. Your subsystem function and file names will be different.

Generate Reusable Code from Stateflow Atomic Subcharts

Generate Reusable Code for Linked Atomic Subcharts

To specify code generation parameters for linked atomic subcharts from the same library:

- 1 Open the library model that contains your atomic subchart.
- 2 Unlock the library.
- 3 Right-click the library chart and select **Block Parameters**.
- 4 In the dialog box, specify the following parameters:
 - a On the **Main** tab, select parameter **Treat as atomic unit**.
 - b On the **Code Generation** tab, set parameter **Function packaging** to Reusable function.
 - c Set **File name options** to User specified.
 - d For **File name**, enter the name of the file without an extension.
 - e Click **OK** to apply the changes.
- 5 (OPTIONAL) Customize the generated function names for atomic subcharts:
 - a Set model configuration parameter **System target file** to `ert.tlc`.
 - b For model configuration parameter **Subsystem methods**, specify the format of the function names using a combination of the following naming rule tokens:
 - \$R — root model name
 - \$F — type of interface function for the atomic subchart
 - \$N — block name
 - \$H — subsystem index
 - \$M — name-mangling text
 - c Click **OK** to apply the changes.

When you generate code for your model, a separate file stores the code for linked atomic subcharts from the same library.

Generate Reusable Code for Unlinked Atomic Subcharts

To specify code generation parameters for an unlinked atomic subchart:

- 1 In your chart, right-click the atomic subchart and select **Properties**.
- 2 In the dialog box, specify the following properties:
 - a Set property **Code generation function packaging** to Reusable function.
 - b Set **Code generation file name options** to User specified.
 - c For **Code generation file name**, enter the name of the file without extension.
 - d Click **OK** to apply the changes.
- 3 (OPTIONAL) Customize the generated function names for atomic subcharts:

- a Set model configuration parameter **System target file** to `ert.tlc`.
- b For model configuration parameter **Subsystem methods**, specify the format of the function names using a combination of the following naming rule tokens:
 - `$R` — root model name
 - `$F` — type of interface function for the atomic subchart
 - `$N` — block name
 - `$H` — subsystem index
 - `$M` — name-mangling text
- c Click **OK** to apply the changes.

When you generate code for your model, a separate file stores the code for the atomic subchart. For more information, see “Generate Code from Atomic Subcharts” on page 11-5.

Generate Reusable Code for Unit Testing

Convert a State to an Atomic Subchart

To convert state A to an atomic subchart, right-click the state and select **Group & Subchart > Atomic Subchart**. State A changes to an atomic subchart:

Set Up a Standalone C File for the Atomic Subchart

- 1 Open the properties dialog box for A.
- 2 Set property **Code generation function packaging** to Reusable function.
- 3 Set **Code generation file name options** to User specified.
- 4 For **Code generation file name**, enter saturator as the name of the file.
- 5 Click **OK**.

Set Up the Code Generation Report

- 1 Set model configuration parameter **System target file** to `ert.tlc`.

- 2 Select model configuration parameters **Create code generation report** and **Open report automatically**.
- 3 Select parameters **Code-to-model** and **Model-to-code**.
- 4 Click **Apply**.

Customize the Generated Function Names

- 1 Set model configuration parameter **Subsystem methods** to the format scheme $\$R\$N\$M\F , where:
 - $\$R$ is the root model name.
 - $\$N$ is the block name.
 - $\$M$ is the mangle token.
 - $\$F$ is the type of interface function for the atomic subchart.

For more information, see “Subsystem methods”.

- 2 Click **Apply**.

Generate Code for Only the Atomic Subchart

To generate code for your model, press **Ctrl+B**. In the code generation report that appears, you see a separate file that contains the generated code for the atomic subchart.

To inspect the code for `saturation.c`, click the hyperlink in the report to see the following code:

Line 28 shows that the during function generated for the atomic subchart has the name `ex_reuse_states_A_during`. This name follows the format scheme `RNMF` specified for **Subsystem methods**:

- `$R` is the root model name, `ex_reuse_states`.
- `$N` is the block name, `A`.
- `$M` is the mangle token, which is empty.

- \$F is the type of interface function for the atomic subchart, during.

Note The line numbers shown can differ from the numbers that appear in your code generation report.

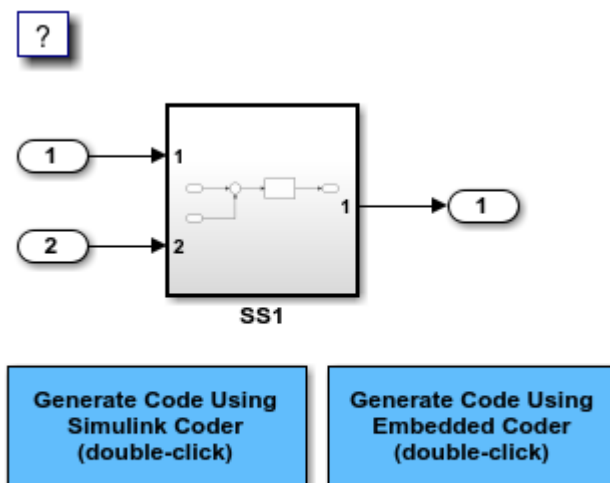

File Packaging for Atomic Subsystems (Code Only)

This model shows how to partition an atomic subsystem into its own source file. Once a subsystem is specified as atomic, on the Subsystem Block Parameter dialog, on the **Code Generation** tab, you can specify how the subsystem is represented in the generated code using the **Function packaging** parameter:

- **Inline**: an Inlined function
- **Function**: function with I/O passed as global data
- **Reusable function**: function with I/O passed as function arguments
- **Auto**: Simulink Coder optimizes based on context

With the **Function** and **Reusable function** options, you can specify a function and file name with **Function name** and **File name**, respectively. In the model, `rtwdemo_filepart`, `SS1` subsystem is configured as **Reusable function** with function name `myfun` and file name `myfile`.

```
open_system('rtwdemo_filepart')
```

Copyright 1994-2020 The MathWorks, Inc.

This capability only partitions the code for a subsystem. The data is declared and owned by the parent model. For full system encapsulation (i.e., data and functions), use Model Reference.

```
bdclose('rtwdemo_filepart');
```

Generate Shared Utility Code

When to Generate Shared Utility Code

Blocks in a model can require common functionality to implement their algorithms. Consider modularizing this functionality into standalone support or helper functions. This approach can be more efficient than inlining the code for the functionality for each block instance. To decide about using a library or a shared utility, consider:

- Packaging functions that can have multiple callers into a library when the functions are defined statically. That is, before you use the code generator to produce code for your model, the function source code exists in a file.
- Packaging functions that can have multiple callers as shared utilities (produced during code generation) when the functions cannot be defined statically. For example, several model- and block-specific properties specify which functions are used and their behavior. Also, these properties determine type definitions (for example, `typedef`) in shared utility header files. The number of possible combinations of properties that determine unique behavior make it impractical to define statically the possible function files before code generation.

Configure Naming of Generated Functions

Configure a default naming rule for generated shared utility functions by using one of these methods.

Configuration	Action
A new model or an existing model for which you have mapped default customization settings by using the Code Mappings Editor - C or code mappings programming interface	In the Embedded Coder Dictionary , define a function customization template that specifies a custom function naming rule. Then, in the Code Mappings editor or by using the code mappings programming interface, map the Shared utility function category to that template. For more information, see “Configure Default C Code Generation for Categories of Data Elements and Functions” on page 32-15.
A model created in a release earlier than R2018a and that has not been configured with the Code Mappings Editor - C or code mappings programming interface	Set the model configuration parameter Shared utilities identifier format (<code>CustomSymbolsStrUtil</code>) to a custom function naming rule. For more information, see “Identifier Format Control” on page 52-17.

Once you use the **Code Mappings Editor - C** or code mappings programming interface to configure a model, setting model configuration parameter **Shared utilities identifier format** does not impact code generation. This setting is not applicable for models configured with these specifications.

System Target File	Programming Language
<code>ert.tlc</code>	C++
<code>autosar.tlc</code>	C
<code>autosar_adaptive.tlc</code>	C++

The naming rule for shared utility functions must include the conditional checksum token `$.C`. To customize the length of the checksum that the code generator produces, use parameter **Shared**

checksum length (SharedChecksumLength) . Increasing the length of the checksum reduces the probability of clashes.

This example shows the customization of shared utility function names for C code generation.

- 1 Open the example model `rtwdemo_configdefaults` and the **Embedded Coder** app.
- 2 Set model configuration parameter **Shared code placement** to `Shared location`.
- 3 Open the Embedded Coder Dictionary. On the **C Code** tab, select **Code Interface > Embedded Coder Dictionary**.
- 4 On the **Function Customization Template** tab, below the table, click **Create** to add a new function customization template.
- 5 For the function customization template, specify these configurations:
 - **Name:** `exSharedUtility`
 - **Function Name:** `mymodel_$$N$$C`

You can customize this format by using a string. You must include token `$$C`.
- 6 Open the Code Mappings editor. On the **C Code** tab, select **Code Interface > Default Code Mappings**.
- 7 On the **Function Defaults** tab, for the **Shared Utility** category, configure **Function Customization Template** as `exSharedUtility`.
- 8 Generate code and a code generation report.
- 9 In the left navigation pane of the report, review the list of generated files for shared utilities under **Shared files**.

Control Placement of Shared Utility Code

Control placement of shared utility code with the model configuration parameter **Shared code placement**. The default option value is `Auto`. For this setting, the code generator places required code for fixed-point and other utilities in the `model.c` file, the `model.cpp` file, or a separate file in the build folder (for example, `vdp_grt_rtw`) if a model does not contain existing shared utility code or one of these blocks:

- Model blocks
- Simulink Function blocks
- Function Caller blocks
- Calls to Simulink Functions from Stateflow or MATLAB Function blocks
- Stateflow graphical functions when you select parameter **Export Chart Level Functions**

If a model contains one or more of the preceding blocks, the code generator creates and uses a shared utilities folder within `slprj`. The naming convention for shared utility folders is `slprj/target/_sharedutils`. `target` is `sim` for simulations with Model blocks or the name of the system target file for code generation.

```
slprj/sim/_sharedutils      % folder used with simulation
slprj/grt/_sharedutils     % folder used with grt.tlc STF
slprj/ert/_sharedutils     % folder used with ert.tlc STF
slprj/mytarget/_sharedutils % folder used with mytarget.tlc STF
```

To force a model build to use the `slprj` folder for shared utility generation, even when the current model does not contain existing shared utility code or one of the preceding blocks, set parameter **Shared code placement** to `Shared location`. The code generator places utilities under the `slprj` folder rather than in the normal build folder. This setting is useful when you are manually combining code from several models, because it prevents symbol collisions between the models.

Control Placement of `rtwtypes.h` for Shared Utility Code

The generated `rtwtypes.h` header file provides fundamental type definitions, `#define` statements, and enumerations. For more information, see “`rtwtypes.h`” on page 49-39.

Control placement of `rtwtypes.h` file by selecting whether the build process uses the shared utilities folder. If the model build uses a shared utilities folder, the build process places `rtwtypes.h` in `slprj/target/_sharedutils`. Otherwise, the software places `rtwtypes.h` in `model_target_rtw`.

Adding a model to a model hierarchy or changing an existing model in the hierarchy can result in updates to the shared `rtwtypes.h` file during code generation. If updates occur, recompile and, depending on your development process, reverify previously generated code. To minimize updates to the `rtwtypes.h` file, make the following changes in the Configuration Parameters dialog box:

- Select model configuration parameter **Support: complex numbers** even if the model does not currently use complex data types. Selecting this parameter protects against a future requirement to add support for complex data types when integrating code.
- Clear parameter **Support non-inlined S-functions**. If you use noninlined S-functions in the model, this option generates an error.
- Clear parameter **Classic call interface**. This parameter setting disables use of the GRT system target file.

Avoid Duplicate Header Files for Exported Data

Exported header files appear in the shared utility folder when:

- You control the file placement of declarations for signals, parameters, and states by defining and applying storage classes.
- The code generator places utility code in a shared location.

For example, you can specify a header file for data by using:

- A storage class that you define in the **Embedded Coder Dictionary** and map to categories of model data in the **Code Mappings Editor - C**.
- The **Code Generation** tab in a Signal Properties dialog box.
- The `HeaderFile` property of a data object. Data objects are objects of the classes `Simulink.Signal` and `Simulink.Parameter`.

If you want the declaration to appear in the file `model.h`, it is a best practice to leave the header file name unspecified. By default, the code generator places data declarations in `model.h`.

If you specify `model.h` as the header file name, and if the code generator places utility code in a shared location, you cannot generate code from the model. The code generator cannot create the file `model.h` in both the model build folder and the shared utility folder.

Reduce Shared Utility Code Generation with Incremental Builds

You can specify that the model build generates C source files in a shared utilities folder. See “Generate Shared Utility Code”. These files include C source files that contain function definitions and header files that contain macro definitions. For this discussion, the term functions means functions and macros.

Blocks within the same model and blocks in different models can use a shared function when you use model reference or when you build multiple standalone models from the same start build folder. The code generator produces the code for a given function only once for the block that first triggers code generation. As the product determines the requirement to generate function code for subsequent blocks, it performs a file existence check. If the file exists, the model build does not regenerate the function. The shared utility code mechanism requires that a given function and file name represent the same functional behavior regardless of which block or model generates the function. To satisfy this requirement:

- Model properties that determine function behavior contribute to the shared utility checksum or determine the function and file name.
- Block properties that determine the function behavior also determine the function and file name.

During compilation, makefile rules for the shared utilities folder select compilation of only new C files and incrementally archive the object file into the shared utility library, `rtwshared.lib`, or `rtwshared.a`. Incremental compilation also occurs.

Manage the Shared Utility Code Checksum

When you set the model configuration parameter **Shared code placement** to `Shared location` or when the model contains Model blocks, the code generator places shared code in the shared utilities folder. The build process generates a shared utilities checksum of the code generation configuration for the shared code.

During subsequent code generation, if the checksum file `slprj/target/_sharedutils/checksummap.mat` exists relative to the current folder, the code generator reads that file. The code generator verifies that the current model that you are building has configuration properties that match the checksum of properties from the shared utility model. If mismatches occur between the properties defined in `checksummap.mat` and the current model properties, you see an error. Use the error message to manage the checksum (for example, diagnose and resolve the configuration issues with the current model).

View the Shared Utility Checksum Hash Table

It is helpful to view the property values that contribute to the checksum. This example uses the `rtwdemo_lct_start_term.slx` model. To load the `checksum.mat` file into MATLAB and view the `targetInfoStruct` that defines the checksum-related properties:

- 1 Open the `rtwdemo_lct_start_term.slx` model. In the Command Window, type:

```
rtwdemo_lct_start_term
```

- 2 Create and move to a new working folder.

```
mkdir C:\Temp\demo
cd C:\Temp\demo
```

- 3 Save a copy of the model in the folder.

- 4 Build the model, which is set up to produce shared utilities.

- a On the **Apps** tab, under **Code Generation**, click **Simulink Coder**.
- b On the **C Code** tab, in the **Generate Code** section, click the **Build** button.

- 5 Move to the `_sharedutils` folder created by the build process.

```
cd C:\Temp\demo\slprj\grt\_sharedutils
```

6 Load the `checksummap.mat` file into MATLAB.

```
load checksummap
```

7 Display the contents of `hashTbl.targetInfoStruct` and examine the checksum-related property values.

```
hashTbl.targetInfoStruct
```

For this example, the Command Window displays `hashTbl.targetInfoStruct` for the shared utilities that you generated from the model:

```
ans =
```

```
struct with fields:
```

```

Relate the Shared Utility Checksum to Configuration Parameters

Examine the `targetInfoStruct` hash table from the shared utility model. Some key-value pairs relate directly to a model property. Other pairs relate to groups of properties.

The following table describes the key-value pairs.

Key Names	Model Properties
ShiftRightIntArith	TargetShiftRightIntArith
ProdShiftRightIntArith	ProdShiftRightIntArith
Endianess	TargetEndianess
ProdEndianess	ProdEndianess
wordlengths	TargetBitPerChar, TargetBitPerShort, TargetBitPerInt, TargetBitPerLong, TargetBitPerLongLong, TargetBitPerFloat, TargetBitPerDouble, TargetWordSize, TargetBitPerPointer, TargetBitPerSizeT, TargetBitPerPtrDiffT
Prodwordlengths	ProdBitPerChar, ProdBitPerShort, ProdBitPerInt, ProdBitPerLong, ProdBitPerLongLong, ProdBitPerFloat, ProdBitPerDouble, ProdWordSize, ProdBitPerPointer, ProdBitPerSizeT, ProdBitPerPtrDiffT

Generate Shared Utility Code for Fixed-Point Functions

An important set of generated functions that the model build places in the shared utility folder are the fixed-point support functions. Based on model and block properties, there are many possible versions of fixed-point utilities functions that make it impractical to provide a complete set as static files. Generating only the required fixed-point utility functions during the code generation process is an efficient alternative.

The shared utility checksum mechanism makes sure that several critical properties are identical for models that use the shared utilities. For the fixed-point functions, there are additional properties that determine function behavior. The mechanism codes these properties into the functions and file names to maintain requirements. The additional properties include:

Category	Function/Property
Block properties	<ul style="list-style-type: none"> Fixed-point operation that the block performs Fixed-point data type and scaling (Slope, Bias) of function inputs and outputs Overflow handling mode (Saturation, Wrap) Rounding Mode (Floor, Ceil, Zero)
Model properties	<code>get_param(bdroot, 'NoFixptDivByZeroProtection')</code>

The property-based naming convention for the fixed-point utilities is as follows:

```
operation + [zero protection] + output data type + output bits +
[input1 data] + input1 bits + [input2 data type + input2 bits] +
[shift direction] + [saturate mode] + [round mode]
```

The file names shown are examples of generated fixed-point utility files. The function or macro names in the file are identical to the file name without the extension.

```
FIX2FIX_U12_U16.c
FIX2FIX_S9_S9_SR99.c
ACCUM_POS_S30_S30.h
MUL_S30_S30_S16.h
div_nzp_s16s32_floor.c
div_s32_sat_floor.c
```

For these examples, the table shows how the respective fields correspond.

The ACCUM_POS example uses the output variable as one of the input variables. So, the file and macro name only contain the output and second input.

The second div example has identical data type and bits for both inputs and the output. So, the file and function name only include the output.

Operation	FIX2FIX	FIX2FIX	ACCUM_POS	MUL	div	div
Zero protection	NULL	NULL	NULL	NULL	_nzp	NULL
Output data type	_U	_S	_S	_S	_s	_s
Output bits	12	9	30	30	16	32
Input data type	_U	_S	_S	_S [and _S]	s	NULL
Input bits	16	9	30	30 [and 16]	32	NULL

Operation	FIX2FIX	FIX2FIX	ACCUM_POS	MUL	div	div
Shift direction	NULL	SR99	NULL	NULL	NULL	NULL
Saturate mode	NULL	NULL	NULL	NULL	NULL	_sat
Round mode	NULL	NULL	NULL	NULL	_floor	_floor

Generate Shared Utility Code for Custom Data Types

By default, if a model employs a custom data type (such as a `Simulink.AliasType` object or an enumeration class), the code generator places the corresponding type definition (`typedef`) in the `model_types.h` file. When you generate code from multiple models, each model duplicates the type definition. These duplicate definitions can prevent you from compiling the bodies of generated code together.

However, you can configure the code generator to place a single type definition in a header file in the `_sharedutils` folder. Then, when you generate code from a model, if the type definition already exists in the `_sharedutils` folder, the code generator does not duplicate the definition, but instead reuses it through inclusion (`#include`).

Through this mechanism, you can share:

- Simulink data type objects that you instantiate from the classes `Simulink.AliasType`, `Simulink.Bus`, and `Simulink.NumericType`. For basic information about creating and using these objects, see “Control Data Type Names in Generated Code” on page 35-2 and `Simulink.Bus`.
- Enumerations that you define, for example, by authoring an `enum` class in a script file or by using the function `Simulink.defineIntEnumType`. For basic information about defining enumerations in Simulink, see “Use Enumerated Data in Simulink Models”.

To share a custom data type across multiple models:

- 1 Define the data type. For example, create the `Simulink.AliasType` object.
- 2 Set data scope and header file properties to specific values that enable sharing.

For a data type object, set the `DataScope` property to `'Exported'` and, optionally, specify the header file name through the `HeaderFile` property.

For an enumeration that you define as an `enum` class in a script file, implement the `getDataScope` method (with return value `'Exported'`) and, optionally, implement the `getHeaderFile` method.

For an enumeration that you define by using the `Simulink.defineIntEnumType` function, set the `'DataScope'` pair argument to `'Exported'` and, optionally, specify the `'HeaderFile'` pair argument

- 3 Use the data type in the models.
- 4 Before generating code from each model, set the model configuration parameter **Shared code placement** to `Shared` location.
- 5 Generate code from the models.

Note You can configure the definition of the custom data type to appear in a header file in the `_sharedutils` folder. The shared utility functions that the model build generates into the `_sharedutils` folder do not use the custom data type name. Only model code located in code folders for each model uses the custom data type name.

Shared Constant Parameters for Code Reuse

You can share the generated code for constant parameters across models if either of the following conditions applies:

- Constant parameters are shared in a model reference hierarchy.
- The model configuration parameter “Shared code placement” is set to `Shared location`.

If you do not want to generate shared constants, and model configuration parameter **Shared code placement** is set to `Shared location`, set parameter `GenerateSharedConstants` to `off`. For example, to turn off shared constants for the current model, in the Command Window, type the following.

```
set_param(gcs, 'GenerateSharedConstants', 'off');
```

When the model configuration parameter `GenerateSharedConstants` is set to `off`, the code generator generates the constant parameters shared across the model reference hierarchy in a shared location, in the `s\prj\target_sharedutils` folder but outside the `const_params.c` file. The code generator defines the individual constant parameters in the reusable library subsystem files individually.

When the model configuration parameter `GenerateSharedConstants` is set to `on`, the code generator produces shared constant parameters individually and places them in the file `const_params.c`. The code generator places that file in the shared utilities folder `s\prj\target_sharedutils`.

For example, if a constant has multiple uses within a model reference hierarchy where the top model is named `topmod`, the code for the shared constant is as follows:

- In the shared utility folder, `s\prj\grt_sharedutils`, the constant parameters are defined in `const_params.c` and named `rtCP_pooled_` appended to a unique checksum:

```
extern const real_T rtCP_pooled_lfcjjmohiecj[7];
const real_T rtCP_pooled_lfcjjmohiecj[7] = { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0 };

extern const real_T rtCP_pooled_ppphohdbfcba[7];
const real_T rtCP_pooled_ppphohdbfcba[7] = { 7.0, 6.0, 5.0, 4.0, 3.0, 2.0, 1.0 };
```

- In `top_model_private.h` or in a referenced model, `ref_model_private.h`, for better readability, the constants are renamed as follows:

```
extern const real_T rtCP_pooled_lfcjjmohiecj[7];
extern const real_T rtCP_pooled_ppphohdbfcba[7];

#define rtCP_Constant_Value    rtCP_pooled_lfcjjmohiecj /* Expression: [1 2 3 4 5 6 7]
 * Referred by: '<Root>/Constant' */
#define rtCP_Gain_Gain        rtCP_pooled_ppphohdbfcba /* Expression: [7 6 5 4 3 2 1]
 * Referred by: '<Root>/Gain' */
```

- In `topmod.c` or `refmod.c`, the call site might be:

```
for (i = 0; i < 7; i++) {
    topmod_Y.Out1[i] = (topmod_U.In1 + rtCP_Constant_Value[i]) * rtCP_Gain_Gain[i];
}
```

The code generator attempts to generate constants as individual constants to the `const_params.c` file in the shared utilities folder. If a model contains a parameter that the code generator cannot inline directly (for example, an array parameter), the code defines a structure type that represents the data. This structure uses the `const` storage type qualifier, so some build toolchains can optimize the assembly code further.

The declaration of the structure, `ConstParam_model`, is in `model.h`.

Suppress Shared Constants in the Generated Code

You can choose whether the code generator produces shared constants and shared functions. You might want to be able to keep the code and data separate between subsystems, or you might find that sharing constants results in a memory shortage during code generation.

You can change this setting programmatically by using the parameter `GenerateSharedConstants` with `set_param` and `get_param`.

In the following example, when `GenerateSharedConstants` is set to on, the code generator defines the constant values in the `_sharedutils` folder in the `const_params.c` file. When `GenerateSharedConstants` is set to off, the code generator defines the constant values in a nonshared area, in the `model_ert_rtw` file in the `model_data.c` file.

Open the model `rtwdemo_throttlecntrl`:

Verify that model configuration parameter “Shared code placement” is set to Shared location. If the parameter is set to Auto, the code generator ignores setting `GenerateSharedConstants`. If you try to set the parameter value, an error message appears. By default, value `GenerateSharedConstants` is selected.

In the Command Window, set `GenerateSharedConstants` to on:

```
>> set_param('rtwdemo_throttlecntrl', 'GenerateSharedConstants', 'on')
```

You see the shared constant definitions in the folder `slprj/grt/_sharedutils`, in the file `const_params.c`:

```
extern const real_T rtCP_pooled_H4eTKtECwveN[9];
const real_T rtCP_pooled_H4eTKtECwveN[9] = { 1.0, 0.75, 0.6, 0.0, 0.0, 0.0, 0.6,
  0.75, 1.0 };

extern const real_T rtCP_pooled_SghuHxKVKGHD[9];
const real_T rtCP_pooled_SghuHxKVKGHD[9] = { -1.0, -0.5, -0.25, -0.05, 0.0, 0.05,
  0.25, 0.5, 1.0 };

extern const real_T rtCP_pooled_WqWb2t17NA2R[7];
const real_T rtCP_pooled_WqWb2t17NA2R[7] = { -1.0, -0.25, -0.01, 0.0, 0.01, 0.25,
  1.0 };

extern const real_T rtCP_pooled_Ygnal0wM3c14[7];
const real_T rtCP_pooled_Ygnal0wM3c14[7] = { 1.0, 0.25, 0.0, 0.0, 0.0, 0.25, 1.0
};
```

In the Command Window, set `GenerateSharedConstants` to off:

```
>> set_param('rtwdemo_throttletcntrl','GenerateSharedConstants','off')
```

You can see the unshared constants in the folder `rtwdemo_throttletcntrl_grt_rtw`, in the file `rtwdemo_throttletcntrl_data.c`:

```
/* Constant parameters (auto storage) */
const ConstP_rtwdemo_throttletcntrl_T rtwdemo_throttletcntrl_ConstP = {
  /* Pooled Parameter (Expression: P_OutMap)
   * Referenced by:
   *   '<S2>/Proportional Gain Shape'
   *   '<S3>/Proportional Gain Shape'
   */
  { 1.0, 0.25, 0.0, 0.0, 0.0, 0.25, 1.0 },

  /* Pooled Parameter (Expression: P_InErrMap)
   * Referenced by:
   *   '<S2>/Proportional Gain Shape'
   *   '<S3>/Proportional Gain Shape'
   */
  { -1.0, -0.25, -0.01, 0.0, 0.01, 0.25, 1.0 },

  /* Pooled Parameter (Expression: I_OutMap)
   * Referenced by:
   *   '<S2>/Integral Gain Shape'
   *   '<S3>/Integral Gain Shape'
   */
  { 1.0, 0.75, 0.6, 0.0, 0.0, 0.0, 0.6, 0.75, 1.0 },

  /* Pooled Parameter (Expression: I_InErrMap)
   * Referenced by:
   *   '<S2>/Integral Gain Shape'
   *   '<S3>/Integral Gain Shape'
   */
  { -1.0, -0.5, -0.25, -0.05, 0.0, 0.05, 0.25, 0.5, 1.0 }
};
```

Shared constant Parameters Limitations

The code generator does not produce shared constants for a model when:

- The model has a code replacement library (CRL) that is specified for data alignment.
- The **Memory Section** for constants is `MemVolatile` or `MemConstVolatile`.
- The parameter `GenerateSharedConstants` is set to off.

Individual constants are not shared, if:

- A constant is referenced by a non-inlined S-function.
- A constant has a user-defined type where **Data Scope** is not set to `Exported`.

More About

- “Generate Reentrant Code from Subsystems” on page 7-33
- “Generate Reusable Code from Library Subsystems Shared Across Models”

Determine Why Subsystem Code Is Not Reused

Due to the limitations described in “Generate Reentrant Code from Subsystems”, the code generator might not reuse generated code as you expect. To determine why code generated for a subsystem is not reused:

- 1 Review the Subsystems section of the code generation report.
- 2 Compare subsystem checksum data.

Review Subsystems Section of HTML Code Generation Report

If the code generator does not generate code for a subsystem as reusable code, and you configured the subsystem as reusable, examine the Subsystems section of the code generation report (see “Generate Code Generation Report”). The Subsystems section contains:

- A table that summarizes how nonvirtual subsystems were converted to generated code.
- Diagnostic information that describes why subsystems were not generated as reusable code.

The Subsystems section also maps noninlined subsystems in the model to functions or reused functions in the generated code. For an example, open and build the `rtwdemo_atomic` model.

Compare Subsystem Checksum Data

You can determine why subsystem code is not reused by comparing subsystem checksum data. The code generator determines whether subsystems are identical by comparing subsystem checksums, as noted in “Limitations”. For subsystem reuse across referenced models, this procedure might not flag every difference.

Consider the model, `rtwdemo_ssreuse`. `SS1` and `SS2` are instances of the same subsystem. In both instances the subsystem block parameter **Function packaging** is set to `Reusable function`.

Use the method `Simulink.SubSystem.getChecksum` to get the checksum for a subsystem. Review the results to determine why code is not reused.

- 1 Open the model `rtwdemo_ssreuse`. Save a copy of the model in a folder where you have write access.
- 2 Associate the subsystems `SS1` and `SS2` with `gcb`. For each of the subsystems, in the model window, select the subsystem. While the subsystem is selected, in the Command Window, enter:

```
SS1 = gcb;
```

```
SS2 = gcb;
```

- 3 Use the method `Simulink.SubSystem.getChecksum` to get the checksum for each subsystem. This method returns two output values: the checksum value and details on the input used to compute the checksum.

```
[chksum1, chksum1_details] = ...
Simulink.SubSystem.getChecksum(SS1);
[chksum2, chksum2_details] = ...
Simulink.SubSystem.getChecksum(SS2);
```

- 4 Compare the two checksum values. The values should be equal based on the subsystem configurations.

```
isequal(chksum1, chksum2)
ans =
     1
```

- 5 To use `Simulink.SubSystem.getChecksum` to determine why the checksums of two subsystems differ, change the data type mode of the output port of SS1 so that it differs from that of SS2.

- a Look under the mask of SS1. Right-click the subsystem. In the context menu, select **Mask > Look Under Mask**.
- b In the block diagram of the subsystem, double-click the Lookup Table block to open the Subsystem Parameters dialog box.
- c Click **Data Types**.
- d Select block parameter **Saturate on integer overflow** and click **OK**.

- 6 Get the checksum for SS1. Compare the checksums for the two subsystems. This time, the checksums are not equal.

```
[chksum1, chksum1_details] = ...
Simulink.SubSystem.getChecksum(SS1);
isequal(chksum1, chksum2)
ans =
     0
```

- 7 After you determine that the checksums are different, find out why. The Simulink engine uses information, such as signal data types, some block parameter values, and block connectivity information, to compute the checksums. To determine why checksums are different, compare the data that computes the checksum values. You can get this information from the second value returned by `Simulink.SubSystem.getChecksum`, which is a structure array with four fields.

Look at the structure `chksum1_details`.

```
chksum1_details

chksum1_details =
    ContentsChecksum: [1x1 struct]
    InterfaceChecksum: [1x1 struct]
    ContentsChecksumItems: [287x1 struct]
    InterfaceChecksumItems: [53x1 struct]
```

`ContentsChecksum` and `InterfaceChecksum` are component checksums of the subsystem checksum. The remaining two fields, `ContentsChecksumItems` and `InterfaceChecksumItems`, contain the checksum details.

- 8 Determine whether a difference exists in the subsystem contents, interface, or both. For example:

```

isequal(chksum1_details.ContentsChecksum.Value,...
        chksum2_details.ContentsChecksum.Value)
ans =
    0
isequal(chksum1_details.InterfaceChecksum.Value,...
        chksum2_details.InterfaceChecksum.Value)
ans =
    1

```

In this case, differences exist in the content.

- 9** Write a script like this script to find the differences.

```

idxForCDiffs=[];
for idx = 1:length(chksum1_details.ContentsChecksumItems)
    if (~strcmp(chksum1_details.ContentsChecksumItems(idx).Identifier, ...
               chksum2_details.ContentsChecksumItems(idx).Identifier))
        disp(['Identifiers different for contents item ', num2str(idx)]);
        idxForCDiffs=[idxForCDiffs, idx];
    end
    if (ischar(chksum1_details.ContentsChecksumItems(idx).Value))
        if (~strcmp(chksum1_details.ContentsChecksumItems(idx).Value, ...
                   chksum2_details.ContentsChecksumItems(idx).Value))
            disp(['Character vector values different for contents item ', num2str(idx)]);
            idxForCDiffs=[idxForCDiffs, idx];
        end
    end
    if (isnumeric(chksum1_details.ContentsChecksumItems(idx).Value))
        if (chksum1_details.ContentsChecksumItems(idx).Value ~= ...
            chksum2_details.ContentsChecksumItems(idx).Value)
            disp(['Numeric values different for contents item ', num2str(idx)]);
            idxForCDiffs=[idxForCDiffs, idx];
        end
    end
end
end

```

- 10** Run the script. The example assumes that you named the script `check_details`.

```

check_details
Character vector values different for contents item 202

```

The results indicate that differences exist for index item 202 in the subsystem contents.

- 11** Use the returned index values to get the handle, identifier, and value details for each difference found.

```

chksum1_details.ContentsChecksumItems(202)

ans =

    Handle: 'rtwdemo_ssreuse/SS1/Lookup Table'
    Identifier: 'SaturateOnIntegerOverflow'
    Value: 'on'

```

The details identify the Lookup Table block parameter **Saturate on integer overflow** as the focus for debugging a subsystem reuse issue.

Library-Based Code Generation

Library-Based Code Generation for Reusable Library Subsystems

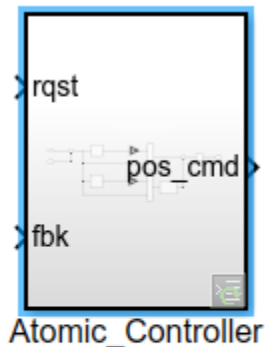

Library-based code generation provides a way of generating code for a set of reusable components that models can share. For each top-level reusable library subsystem, you specify a set of function interfaces that lock down the subsystem interface. A function interface consists of the subsystem input and output block parameter settings and the model configuration parameter settings.

Function interfaces are independent models that you save with an accompanying library. Before generating code for a model containing instances of the reusable library subsystem, you generate code for the library. Library-based code generation makes the library the owner of the code. To make the individual models the owner of the code, you can generate code for reusable library subsystems to the shared utilities folder. For more information, see “Generate Reusable Code from Library Subsystems Shared Across Models” on page 7-41.

Example Model and Library

To show how to use function interfaces and library-based code generation, this example uses the model `rtwdemo_libcodegen_md1` and library `rtwdemo_libcodegen_lib`. The model contains two instances of the reusable library subsystem `Atomic_Controller`. For `Atomic_Controller_Single`, the input signal data type is `single`. For `Atomic_Controller_Double`, the input signal data type is `double`. To open the model and library files, at the MATLAB command prompt, enter:

```
rtwdemo_libcodegen_md1  
rtwdemo_libcodegen_lib
```

Copyright 2018 The MathWorks, Inc.

Copyright 2018 The MathWorks, Inc.

Configure Reusable Library Subsystems

To perform library-based code generation, you must configure the library subsystem as reusable.

- 1 In the Subsystem block parameters dialog box, select “Treat as atomic unit”.
- 2 In the Subsystem block parameters dialog box, on the **Code Generation** tab, set the “Function packaging” parameter to Reusable function.

Specify Unique Function Interface Names

Each function interface corresponding to the same reusable library subsystem must have a unique name. To specify a unique name, follow these steps:

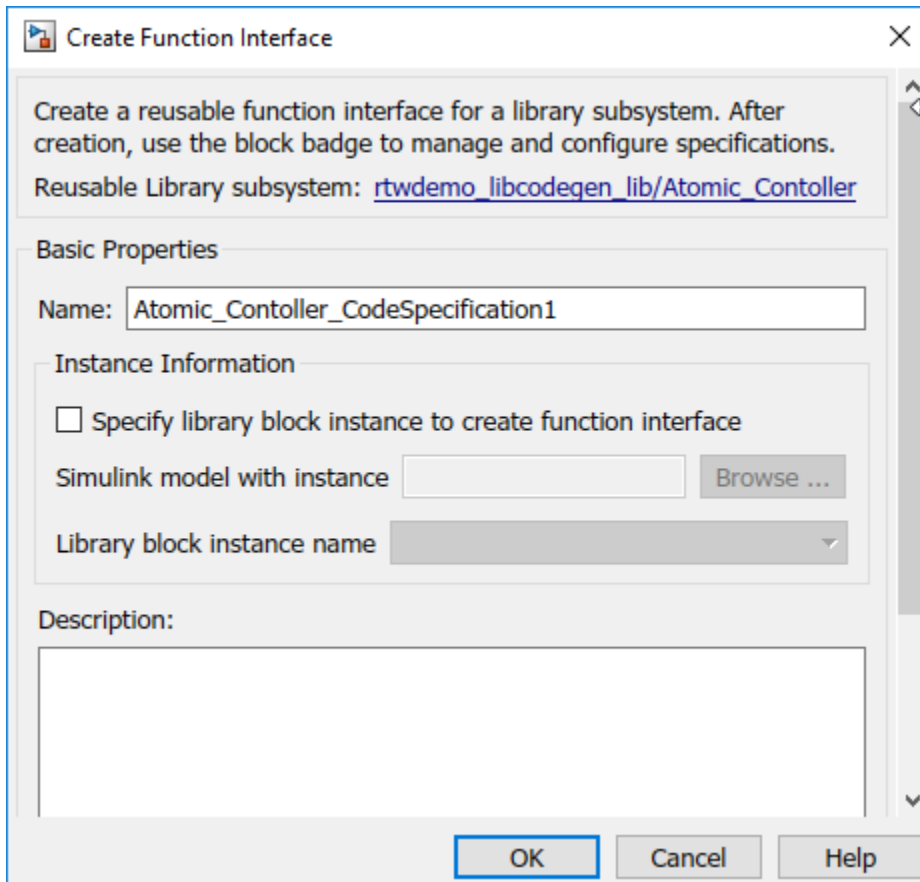

- 1 In the Subsystem block parameters dialog box, on the **Code Generation** tab, set the **Function name options** parameter to User specified.
- 2 For the **Function name** parameter, specify the \$R and \$N tokens. The \$R token represents the function interface name. The \$N token represents the subsystem name.
- 3 In the **Create Function Interface** dialog box, for the **Name** parameter, specify a name that describes the context.
- 4 Set the **File name option** parameter to Auto or Use function name.

Configure and Manage Function Interfaces

The model `rtwdemo_libcodegen_md1` contains two instances of the reusable library subsystem `Atomic_Controller`. Each instance represents a function interface. In the library `rtwdemo_libcodegen_lib`, right-click the badge at the lower rightmost side of the reusable library subsystem `Atomic_Controller`. Select **Manage Function Interfaces**. The two function interfaces have the names `Single` and `Double` because `Atomic_Controller` takes `single` and `double` data types.

To create function interfaces, in a library, right-click a subsystem and select **C/C++ Function Interfaces > Create Function Interface**. Specify a function interface **Name**.

Then, to configure the function interfaces, choose one of the following methods.

Specify a Function Interface from Model

To create function interfaces from linked instances of the reusable library subsystem:

- 1 In the library, right-click the badge at the lower rightmost side of the reusable library subsystem and select **Create Function Interface**. In the dialog box, select the **Specify library block instance to create function interface** parameter.
- 2 For the **Simulink model with instance** parameter, select the model that contains the subsystem.
- 3 For the **Library block instance name** parameter, select the subsystem.
- 4 Click **OK** and close the **Create Function Interface** dialog box.
- 5 For each function interface, repeat the preceding steps.

Note You can create a function interface from within a model that contains an instance of a linked reusable library subsystem. You must be in the Code perspective. To open the Code perspective, from the **apps** menu, select **Embedded Coder**. If the subsystem has function interfaces, a badge appears at the lower-right corner of the subsystem. Right-click the badge and select **Create Function Interface**. If the subsystem does not have function interfaces, right-click the subsystem, and select **C/C++ Function Interfaces > Create Function Interface**.

Export and Configure an Existing Function Interface

To export and configure the function interface as an independent model:

- 1** In the library, right-click the badge at the lower rightmost side of the reusable library subsystem and select **Manage Function Interfaces**.
- 2** Select the function interfaces that you want to modify.
- 3** Click **Export**.
- 4** In the **Save As** window, specify the current working folder. An exported function interface is a .slx file that has the function interface name plus the appendix `_export`.
- 5** Open the exported model. Make your changes to the subsystem input and output block parameter settings and model configuration parameter settings. Save the model.
- 6** In the library, right-click the reusable library subsystem and select **C/C++ Function Interfaces > Create Function Interface**. Specify a function interface **Name**.
- 7** For the **Simulink model with instance** parameter, select the exported model that is in the current working folder.
- 8** For the **Library block instance name** parameter, select the subsystem.
- 9** Click **OK** and close the **Create Function Interface** dialog box.

Configure Function Interfaces from Within a Library

- 1** In the library, right-click the badge at the lower rightmost side of the subsystem and select **Configure Function Interface**.
- 2** In the **Configure Function Interface** dialog box, for the subsystem inputs and outputs, specify values for the **Data Type**, **Dimensions**, and **Signal Type** parameters. To modify other subsystem input and output parameter settings, follow the export method in the preceding section.

- 3 To modify the model configuration parameters, click the gear button and make the changes. Click **Apply**. Close the Configuration Parameters dialog box.
- 4 To replace a function interface with an existing one from an instance model, select **Regenerate Using Instance**.
- 5 Specify values for the **Simulink model with instance** and **Library block instance name** parameters. Click **Regenerate**.
- 6 Click **Apply** and close the **Configure Function Interface** dialog box.

Build the Library

After you specify function interfaces for the subsystems in your library, generate code for the library. Before generating code for your model, you must generate code for the library. The code generator packages the library code as a separate C library. The generated code for the library is in a folder corresponding to your hardware settings (for example, IntelWin64). The library code folder has the same name as the library and must be at the same hierarchical level as the library.

To generate code, check that the library is unlocked. Open the **Embedded Coder** app and click **Build Library**.

When you generate code for the `rtwdemo_libcodegen_lib` library, the `rtwdemo_libcodegen_lib` folder contains these `.c` and `.h` files:

- `Atomic_Controller_Single.h`
- `Atomic_Controller_Single.c`

- `Atomic_Controller_Double.h`
- `Atomic_Controller_Double.c`

These functions names are representative of the $\$N\R specification for the **Function name options** and **Function name** parameters on the Subsystem block parameters dialog box.

A `_shared` folder contains code for shared utilities (for example, fixed-point utilities and Lookup Table and MATLAB function blocks), supplementary files, and exported parameters and types.

When you generate code for a model that contains an instance of a reusable library subsystem that can use the pregenerated library code, the model links to the library code. The code generator uses a checksum to determine reusability. The generated code for the model must be in the same folder as the library. At the MATLAB command line, enter:

```
Simulink.fileGenControl('set', 'CodeGenFolderStructure', ...  
    Simulink.filegen.CodeGenFolderStructure.TargetEnvironmentSubfolder);
```

For more information, see `Simulink.fileGenControl`.

If the model is unable to use the library code, you can specify whether or not Embedded Coder produces a warning or an error during code generation. In the Configuration Parameters dialog box, set the **Behavior when pregenerated library subsystem code is missing** diagnostic parameter setting.

You can generate code for a library but not execute a makefile by entering these commands:

```
library='rtwdemo_libcodegen_lib'  
set_param(library, 'GenCodeOnly', 'on')  
slbuild(library)
```

Note You can generate code for a library consisting of reusable subsystems that contain S-functions. To avoid uncompatible code, in the TLC function corresponding to the S-function, avoid directing the code generator to interact with model files, such as `model.c`, `model.h`, and `model_types.h`.

Generate Code from Model Containing a Reusable Library Subsystem Instance

To generate code from a model that contains an instance of a reusable library subsystem for which you want to use the library code:

- 1 Set the model configuration parameter **Shared code placement** to `Shared location`.
- 2 Specify a setting for the “Behavior when pregenerated library subsystem code is missing” parameter or leave the default setting, which is warning.
- 3 In the Configuration Parameters dialog box, the parameter settings on the **Code Generation** panes must all be identical to each other. If the settings are different, you might get a warning, error, or neither depending on the setting of the **Behavior when pregenerated library subsystem code is missing** parameter.
- 4 If a reusable library subsystem uses a shared local data store and you configure default mapping for model data elements, leave the default storage class mapping for category **Shared local data stores** set to **Default**.

Here is the generated C code for `rtwdemo_libcodegen_mdl`.

```

/* Model step function */
void rtwdemo_libcodegen_md1_step(void)
{
  /* Outputs for Atomic SubSystem: '<Root>/Atomic_Controller_Double' */

  /* Inport: '<Root>/pos_rqst' incorporates:
   * Inport: '<Root>/fbk_1'
   * Outport: '<Root>/pos_cmd_one'
   */
  Atomic_Controller_Double(pos_rqst1, rtU.fbk_1, &rtY.pos_cmd_one,
    &rtDW.Atomic_Controller_Double);

  /* End of Outputs for SubSystem: '<Root>/Atomic_Controller_Double' */

  /* Outputs for Atomic SubSystem: '<Root>/Atomic_Controller_Single' */

  /* Inport: '<Root>/pos_rqst1' incorporates:
   * Inport: '<Root>/fbk_2'
   * Outport: '<Root>/pos_cmd_two'
   */
  Atomic_Controller_Single(pos_rqst2, rtU.fbk_2, &rtY.pos_cmd_two,
    &rtDW.Atomic_Controller_Single);

  /* End of Outputs for SubSystem: '<Root>/Atomic_Controller_Single' */
}

```

The code contains calls to the `Atomic_Controller_Single` and `Atomic_Controller_Double` functions. The generated code pulls the function definitions from the pregenerated library code.

Verify Code Generated from Reusable Library Subsystems

Verification Workflow

If you have Simulink Test™ software, you can verify code that you generate from reusable library subsystems. Use this workflow:

- 1 Create a test harness in a library for a unique subsystem and function interface pair.
- 2 With the SIL/PIL Manager:
 - a Run normal mode and software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations of the subsystem.
 - b Compare numerical results in the Simulation Data Inspector.
 - c View the Simulink Coverage™ analysis report.

For more information, see “Test Library Blocks” (Simulink Test).

Verification Workflow Limitations

The verification workflow does not support:

- Function-Call Subsystem blocks.
- Triggered Subsystem blocks or subsystems that use zero-crossing events.
- Function interfaces where the number of Inports/Outports does not match the number of Inports/Outports in the graphical interface.

- Parameters that use the `ExportToFile` storage class.
- Subsystems with Outport blocks that are fed by Mux or Demux blocks.
- Virtual buses that are passed as Inport blocks.
- Data Store Memory blocks that use the `ExportedGlobal` storage class.
- Blocks where data is initialized outside the subsystem code, for example, the Width block.
- Code coverage highlighting and annotation.
- Signal and state data logging.

For such cases, you can create a model that contains an instance of the reusable library subsystem and use the SIL/PIL Manager to run SIL or PIL simulations.

Limitations

Because the code generator uses a checksum to determine reusability, the same limitations that apply to generating code for models that share reusable library subsystems apply to library-based code generation. See “Limitations” on page 7-38. These limitations also apply:

- You cannot specify a function interface on a reusable library subsystem that is within another reusable library subsystem.
- Only ERT and ERT-derived system target files support library-based code generation.
- Each function interface that corresponds to the same reusable library subsystem must be unique.
- On Windows platform, avoid naming the library `lib.slx` as doing so may interfere with the static library compilation process.
- When you generate code from a library, the code generator only generates code for top-level reusable subsystems in the library. The top-level library subsystem can be instantiated at any level in a client model and the instance in the client model reuses library code if it finds any.
- A library subsystem cannot reuse code if it is inside an Enabled Subsystem block with the Enable block parameter, **States when enabling**, set to `reset`.

Configure Model Parameters for Simulink Coder

- “Configure Run-Time Environment Options” on page 9-2
- “Register New Hardware Devices” on page 9-11

Configure Run-Time Environment Options

When you use Simulink software to create and execute a model and use the code generator to produce C or C++ code, consider your configuration for up to three run-time environments:

- The MATLAB development computer run-time environment that runs MathWorks software during application development.
- The production hardware run-time environment in which you deploy an application when it is put into production.
- The test hardware run-time environment in which you test an application under development before deployment.

One run-time environment can serve in multiple capacities, but the run-time environments remain conceptually distinct. Often, the MATLAB development computer is the test hardware. Typically, the production hardware is different from, and less powerful than, the MATLAB development or the test hardware. Many types of production hardware can do little more than run a downloaded executable file.

Provide information about the production hardware board and the compiler that you use with it when:

- You use Simulink software to simulate a model for which you later generate code
- You use the code generator to produce code for deployment on *production* hardware

The software uses the board and compiler information to get bit-true agreement for the results of integer and fixed-point operations performed in simulation and in code generated for the production hardware. The code generator uses the information to create code that executes with maximum efficiency.

When you generate code for testing on *test* hardware, provide information about the test hardware board and the compiler that you use. The code generator uses this information to create code that provides bit-true agreement between results from:

- Integer and fixed-point operations performed in simulation
- Generated code run on the production hardware
- Generated code run on the test hardware

You can achieve bit-true agreement for results even if the production and test hardware are different. Where the C standard does not completely define behavior, the compilers for the two types of hardware can use different defaults.

Configure Production and Test Hardware

You can specify model simulation or code generation for a specific hardware board and its device type. For example, you can set the data size, byte ordering, and compiler behavior, such as integer rounding. You can configure:

- The production hardware and the compiler that you use with it. This information affects simulation and code generation. See “Example Production Hardware Setting That Affects Normal Mode Simulation” on page 9-8.
- The test hardware and the compiler that you use with it. This information affects only code generation.

Configure production hardware by selecting **Configuration Parameters > Hardware Implementation**. By default, the Hardware Implementation pane lists **Hardware board**, **Device vendor**, and **Device type** parameter fields only. Unless you have installed hardware support packages, **Hardware board** lists values None or Determine by Code Generation system target file, and Get Hardware Support Packages. After installing a hardware support package, the list also includes the corresponding hardware board name. If you select a hardware board name, parameters for that board appear. To set device details, such as data size and byte ordering, click **Device details**.

Configure test hardware on the **Configuration Parameters > Hardware Implementation > Advanced parameters** pane. To enable parameters for configuring test hardware details, disable the **Configuration Parameters > Hardware Implementation > Advanced parameters > Test hardware is the same as production hardware** parameter. Code generated for test hardware executes in the environment specified by the test hardware parameters. The code behaves as if it were executing in the environment specified for the production hardware. For more information, see “Test Hardware Considerations” on page 9-8.

Default values and properties appear as initial values in the **Hardware Implementation** pane when:

- You specify a **System target file** in the **Code Generation** pane.
- The system target file specifies a default microprocessor and its hardware properties.

You cannot change parameters that have only one possible value. Parameters that have more than one possible value provide a list of valid values. If you specify hardware properties manually in **Hardware Implementation** pane, verify that these values are consistent with the system target file. Otherwise, the generated code can fail to compile or execute, or can execute but produce incorrect results.

Hardware implementation parameters describe hardware and compiler properties to MATLAB software. The code generator uses the information to produce code for the run-time environment that runs as efficiently as possible. The generated code gives bit-true agreement for the results of integer and fixed-point operations in simulation, production code, and test code.

For details about specific parameters, see “Hardware Implementation Pane”. To see an example of **Hardware Implementation** pane capabilities, see the `rtwdemo_targetsettings` example model. For details related to configuring a hardware implementation, see:

- “Specify Hardware Board” on page 9-3
- “Specify Device Vendor” on page 9-4
- “Specify the Device Type” on page 9-4
- “Set Bit Lengths for Device Data Types” on page 9-5
- “Set Byte Ordering for Device” on page 9-5
- “Set Quotient Rounding Behavior for Signed Integer Division” on page 9-6
- “Set Arithmetic Right Shift Behavior for Signed Integers” on page 9-6
- “Update Release 14 Hardware Configuration” on page 9-7

Specify Hardware Board

Specify the hardware board that runs the code generated from your model. Select a value for **Configuration Parameters > Hardware Implementation > Hardware board**.

The Hardware Implementation pane identifies the system target file selected on **Configuration Parameters > Code Generation**.

To configure test hardware, use the **Configuration Parameters > Hardware Implementation > Advanced parameters** pane.

To enable parameters for configuring test hardware details, set ProdEqTarget to off.

Ways to Specify the Hardware Board

If	Select
The menu <i>includes</i> the name of the hardware board that you want to use.	The name of that hardware board. If you select a hardware board name, parameters for that board appear.
The menu <i>does not include</i> the name of the hardware board that you want to use.	Get Hardware Support Packages. That value opens the Support Package Installer. Install the support package that you want. After you install the support package, the menu includes relevant hardware board names.
The model configuration <i>uses</i> system target file <code>ert.tlc</code> , <code>realtime.tlc</code> , or <code>autosar.tlc</code> .	None. No hardware board is specified for the hardware implementation.
The model configuration <i>does not use</i> system target file <code>ert.tlc</code> , <code>realtime.tlc</code> , or <code>autosar.tlc</code> .	Determine by Code Generation system target file. The code generator uses the specified system target file to determine the hardware implementation.

Specify Device Vendor

To specify the vendor of the microprocessor of the hardware device, use the **Device vendor** parameter. Your selection determines the available microprocessors in the **Device type** menu. If the vendor name does not appear, select Custom Processor. Then, use the **Device type** parameter to specify the microprocessor.

- For complete lists of **Device vendor** and **Device type** values, see “Device vendor” and “Device type”.
- To add **Device vendor** and **Device type** values to the default set that is displayed on the **Hardware Implementation** pane, see “Register New Hardware Devices” on page 9-11.

Specify the Device Type

To specify the microprocessor name from the supported devices listed for your **Device vendor** selection, use the **Device type** parameter. If the microprocessor does not appear in the menu, change **Device vendor** to Custom Processor. Then, specify device details for your custom device.

If you select a device type for which the system target file specifies default hardware properties, the properties appear as initial values. You cannot change the value of parameters with only one possible selection. Parameters that have more than one possible value provide a menu. Select values for your hardware.

Set Bit Lengths for Device Data Types

The **Number of bits** parameters describe the **native word size** of the microprocessor and the bit lengths of **char**, **short**, **int**, and **long** data. For code generation to succeed:

- The bit lengths must be such that **char** <= **short** <= **int** <= **long**.
- Bit lengths must be multiples of 8, with a maximum of 32.
- The bit length for **long** data must not be less than 32.

The `rtwtypes.h` file defines integer type names. The values that you provide must be consistent with the word sizes as defined in the compiler `limits.h` header file. The code generator maps its integer type names to the corresponding Simulink integer type names.

If no ANSI® C type with a matching word size is available, but a larger ANSI C type is available, the code generator uses the larger type for `int8_T`, `uint8_T`, `int16_T`, `uint16_T`, `int32_T`, and `uint32_T`. When the code generator uses a larger type, the resulting logged values (for example, MAT-file logging) can have different data types than logged values for simulation.

An application can use an integer data of length from 1 (unsigned) or 2 (signed) bits up 32 bits. If the integer length matches the length of an available type, the code generator uses that type. If a matching type is not available, the code generator uses the smallest available type that can hold the data, generating code that does not use unnecessary higher-order bits. For example, on hardware that supports 8-bit, 16-bit, and 32-bit integers, for a signal specified as 24 bits, the code generator implements the data as an `int32_T` or `uint32_T`.

Code that uses emulated integer data is not maximally efficient. This code can be useful during application development for emulating integer lengths that are available only on production hardware. Emulation does not affect the results of execution.

During code generation, the software checks the compatibility of model data types with the data types that you specify for production hardware.

- If none of the lengths that you specify for production hardware integers is 32 bits, the software generates an error.
- If the lengths of data types that the model uses are smaller than the available production hardware integer lengths, the software generates a warning.

Mapping of Integer Types from Code Generator to Simulink

Code Generator Integer Type	Simulink Integer Type
<code>boolean_T</code>	<code>boolean</code>
<code>int8_T</code>	<code>int8</code>
<code>uint8_T</code>	<code>uint8</code>
<code>int16_T</code>	<code>int16</code>
<code>uint16_T</code>	<code>uint16</code>
<code>int32_T</code>	<code>int32</code>
<code>uint32_T</code>	<code>uint32</code>

Set Byte Ordering for Device

The **Byte ordering** parameter specifies whether the hardware uses **Big Endian** (most significant byte first) or **Little Endian** (least significant byte first) byte ordering. If left as **Unspecified**, the

code generator produces code that determines the endianness of the hardware. This setting is the least efficient.

Set Quotient Rounding Behavior for Signed Integer Division

ANSI C does not completely define the quotient rounding technique for compilers to use when dividing one signed integer by another. So, the behavior is implementation-dependent. If both integers are positive, or both are negative, the quotient must round down. If either integer is positive and the other is negative, the quotient can round up or down.

The **Signed integer division rounds to** parameter instructs the code generator about how the compiler rounds the result of signed integer division. Providing this information does not change the operation of the compiler. It only describes that behavior to the code generator, which uses the information to optimize code generated for signed integer division. The parameter values are:

- **Zero** — If the quotient is between two integers, the compiler chooses the integer that is closer to zero as the result.
- **Floor** — If the quotient is between two integers, the compiler chooses the integer that is closer to negative infinity.
- **Undefined** — If **Zero** or **Floor** do not describe the compiler behavior or if that behavior is unknown, choose this value.

Avoid selecting **Undefined**. When the code generator does not know the signed integer division rounding behavior of the compiler, the model build generates extra code.

The compiler quotient rounding behavior varies according to these values.

You can obtain the compiler implementation for signed integer division rounding from the compiler documentation. If documentation is not available, you can determine this behavior by experiment.

Example Quotient Rounding for Zero, Floor, and Undefined

N	D	Ideal N/D	Zero	Floor	Undefined
33	4	8.25	8	8	8
-33	4	-8.25	-8	-9	-8 or -9
33	-4	-8.25	-8	-9	-8 or -9
-33	-4	8.25	8	8	8 or 9

Set Arithmetic Right Shift Behavior for Signed Integers

ANSI C does not define the behavior of right shifts on negative integers for compilers. So, the behavior is implementation-dependent. The **Shift right on a signed integer as arithmetic shift** option instructs the code generator about how the compiler implements right shifts on negative integers. Providing this information does not change the operation of the compiler. It only describes that behavior to the code generator, which uses the information to optimize the code generated for arithmetic right shifts.

If the C compiler implements a signed integer right shift as an arithmetic right shift, select the option. Otherwise, clear the option. An arithmetic right shift fills bits vacated by the right shift with the value of the most significant bit, which indicates the sign of the number in two's-complement notation. The option is selected by default. If your compiler handles right shifts as arithmetic shifts, this setting is preferred.

- When you select the option, the code generator produces efficient code whenever the Simulink model performs arithmetic shifts on signed integers.
- When the option is cleared, the code generator produces fully portable but less efficient code to implement right arithmetic shifts.

You can obtain the compiler implementation for arithmetic right shifts from the compiler documentation. If documentation is not available, you can determine this behavior by experiment.

Update Release 14 Hardware Configuration

If your model was created before Release 14 and you have not updated the model, the **Configure current execution hardware device** parameter (TargetUnknown) value is 'on' by default.

To update your model, clear the box for **Configuration Parameters > Hardware Implementation > Advanced parameters > Test hardware > Configure test hardware**. Or in the Command Window, type:

```
cs = getActiveConfigSet('your_model_name');
set_param(cs, 'TargetUnknown', 'off');
```

This update to your model:

- Enables the **Test Hardware is the same as production hardware** parameter (ProdEqTarget), setting the parameter to 'on'.
- Copies the **Production device vendor and type** parameter (ProdHWDeviceType) value to the **Test device vendor and type** parameter (TargetHWDeviceType).

To complete the update:

- 1 Clear the box for **Configuration Parameters > Hardware Implementation > Advanced parameters > Test hardware > Test Hardware is the same as production hardware**. Apply this step only if your production and test hardware are different.
- 2 Set the parameters in **Configuration Parameters > Hardware implementation > Advanced parameters** to match your production and test systems.
- 3 Save the model.

Production Hardware Considerations

When you configure production hardware, consider these points:

- Production hardware can have word sizes and other hardware characteristics that differ from the MATLAB development computer. You can prototype code on hardware that is different from the production hardware or the MATLAB development computer. When producing code, the code generator accounts for these differences.
- The Simulink product uses some of the information in the production hardware configuration. That information enables simulations without code generation to give the same results as executing generated code. For example, the results can detect error conditions that arise on the production hardware, such as hardware overflow.
- The code generator produces code that provides bit-true agreement with Simulink results for integer and fixed-point operations. Generated code that emulates unavailable data lengths runs less efficiently than without emulation. The emulation does not affect bit-true agreement with Simulink for integer and fixed-point results.

- If you change run-time environments during application development, before generating or regenerating code, reconfigure the hardware implementation parameters for the new run-time environment. When code executes on hardware for which it was not generated, bit-true agreement is not always achieved for results of integer and fixed-point operations in simulation, production code, and test code.
- To compile code generated from the model, use the **Integer rounding mode** parameter on model blocks to simulate the rounding behavior of the C compiler that you intend. This setting appears on the **Signal Attributes** pane in the parameter dialog boxes of blocks that can perform signed integer arithmetic, such as the Product, Matrix Multiply and n-D Lookup Table blocks.
- For most blocks, the value of **Integer rounding mode** completely defines rounding behavior. For blocks that support fixed-point data and the simplest rounding mode, the value of **Signed integer division rounds to** also affects rounding. For details, see “Precision” (Fixed-Point Designer).
- When models contain Model blocks, configure models that they reference to use identical hardware settings.

Test Hardware Considerations

By default, the test hardware configuration is the same as the configuration for the production hardware. You can use the generated code for testing in an environment that is identical to the production environment.

If the test and production environments differ, you can generate code that runs on test hardware as if it were running on production hardware:

- 1 To enable test hardware parameters, clear the box for **Configuration Parameters > Hardware Implementation > Advanced parameters > Test hardware > Test hardware is the same as production hardware**. Or, in the Command Window type:

```
cs = getActiveConfigSet('your_model_name');
set_param(cs, 'ProdEqTarget', 'off');
```

- 2 Specify device type details through the test hardware (Target*) parameters.

If you select a system target file that specifies a default microprocessor and its hardware properties, these default values and properties appear as initial values.

Parameters with only one possible value cannot be changed. If you modify hardware properties, check that their values are consistent with the system target file. Otherwise, the generated code can fail to compile or execute, or can execute but produce incorrect results.

Example Production Hardware Setting That Affects Normal Mode Simulation

Changing some production hardware settings, for example, `ProdLongLongMode` and `ProdIntDivRoundTo`, can affect normal mode simulation results. The following example simulates an adder with four inputs. In the first simulation, `ProdLongLongMode` is disabled. In the second simulation, `ProdLongLongMode` is enabled. In the plot of simulation outputs, you observe small differences between output values in the time step range 125–175.

```
model = 'hwSettingEffect';
new_system(model)
open_system(model)
```

```
% Create adder
```

```

pos = [140 140 200 340];
add_block('simulink/Math Operations/Add', ...
    [model '/sum_int32'], ...
    'Inputs','+++', ...
    'SaturateOnIntegerOverflow', ...
    'on', ...
    'Position', ...
    pos)

pos = [75 155 105 175];
add_block('built-in/Inport',[model '/In1'],'Position',pos)
set_param([model '/In1'], 'OutDataTypeStr', ...
    'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In1/1','sum_int32/1')

pos = [75 205 105 225];
add_block('built-in/Inport',[model '/In2'],'Position',pos)
set_param([model '/In2'], 'OutDataTypeStr', ...
    'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In2/1','sum_int32/2')

pos = [75 255 105 275];
add_block('built-in/Inport',[model '/In3'],'Position',pos)
set_param([model '/In3'], 'OutDataTypeStr', ...
    'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In3/1','sum_int32/3')

pos = [75 305 105 325];
add_block('built-in/Inport',[model '/In4'],'Position',pos)
set_param([model '/In4'], 'OutDataTypeStr', ...
    'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In4/1','sum_int32/4')

pos = [275 230 305 250];
add_block('built-in/Outport',[model '/Out1'],'Position',pos)
add_line(model, 'sum_int32/1','Out1/1')

% Specify input data
t = 0:200;
peakValue = 1.5e9;
in1 = peakValue * sin(t*2*pi/100);
in2 = peakValue * cos(t*2*pi/70);
in3 = -peakValue * sin(t*2*pi/40);
in4 = -peakValue * cos(t*2*pi/30);
set = Simulink.SimulationData.Dataset;
set = set.addElement(1, timeseries(int32(in1),t,'Name','sig1'));
set = set.addElement(2, timeseries(int32(in2),t,'Name','sig2'));
set = set.addElement(3, timeseries(int32(in3),t,'Name','sig3'));
set = set.addElement(4, timeseries(int32(in4),t,'Name','sig4'));

set_param(model, 'LoadExternalInput', 'on');
set_param(model, 'ExternalInput', 'set');

set_param(model, 'StopTime', '50');

% Disable production hardware setting and run first simulation
set_param(model, 'ProdLongLongMode', 'off');
[~, ~, y1] = sim(model, 200);

% Enable production hardware setting and run second simulation
set_param(model, 'ProdLongLongMode', 'on');
[~, ~, y2] = sim(model, 200);

plot([y1 y2]);
figure(gcf);

```

The difference in behavior is due to the accumulator data type in the Sum block. The **Accumulator data type** block parameter is set to `Inherit`: `Inherit` via internal rule. For this example, the resulting accumulator data type is 64 bits wide if the use of the C long long data type is enabled. Otherwise, it is 32 bits wide. Depending on the input values for the sum block, the 32-bit

accumulator can saturate when the 64-bit accumulator does not. Therefore, normal mode behavior can depend on the `ProdLongLongMode` setting. In both cases, the normal mode behavior and production hardware behavior matches bitwise.

- “Device vendor”
- “Device type”
- “Precision” (Fixed-Point Designer)

Register New Hardware Devices

On the **Hardware Implementation** pane, you can specify parameters that describe target hardware and compiler properties for MATLAB software, which enables you to:

- Observe target hardware during model simulations.
- Generate optimized code for production or test hardware.
- Directly test or deploy generated code on target hardware.

The **Hardware Implementation** pane supports a range of target hardware. To extend the range, register new hardware devices by using the `target.Processor` and `target.LanguageImplementation` classes.

Specify Hardware Implementation for New Device

To register a new hardware device:

- 1 Create a `target.Processor` object for the new hardware device.

```
myProc = target.create('Processor', ...
    'Name', 'MyProcessor', ...
    'Manufacturer', 'MyManufacturer');
```

- 2 Create a `target.LanguageImplementation` object for language implementation details.

```
myLanguageImplementation = target.create('LanguageImplementation', ...
    'Name', 'MyProcessorImplementation');
```

- 3 Specify language implementation details.

```
myLanguageImplementation.Endianess = target.Endianess.Little;

myLanguageImplementation.AtomicIntegerSize = 64;
myLanguageImplementation.AtomicFloatSize = 64;
myLanguageImplementation.WordSize = 64;

myLanguageImplementation.DataTypes.Char.Size = 8;
myLanguageImplementation.DataTypes.Short.Size = 16;
myLanguageImplementation.DataTypes.Int.Size = 32;
myLanguageImplementation.DataTypes.Long.Size = 64;
myLanguageImplementation.DataTypes.LongLong.IsSupported = true;
myLanguageImplementation.DataTypes.LongLong.Size = 64;
myLanguageImplementation.DataTypes.Float.Size = 32;
myLanguageImplementation.DataTypes.Double.Size = 64;

myLanguageImplementation.DataTypes.Pointer.Size = 32;

myLanguageImplementation.DataTypes.SizeT.Size = 64;
myLanguageImplementation.DataTypes.PtrDiffT.Size = 64;
```

- 4 Associate the language implementation with the hardware device.

```
myProc.LanguageImplementations = myLanguageImplementation;
```

- 5 Add the `target.Processor` object to an internal database.

```
objectsAdded = target.add(myProc);
```

On the **Hardware Implementation** pane, you can now set **Device vendor** and **Device type** to `MyManufacturer` and `MyProcessor` respectively.

Specify Hardware Implementation That Persists Over MATLAB Sessions

By default, when you add the target object to the internal database, the target data is available only for the current MATLAB session. You can specify target data persistence over MATLAB sessions.

- 1 Create a `target.Processor` object for a new hardware device.

```
myProc = target.create('Processor', ...
    'Name', 'MyProcessor', ...
    'Manufacturer', 'MyManufacturer');
```

```
existingImplementation = target.get('LanguageImplementation', ...
    'ARM Compatible-ARM Cortex');
```

```
myProc.LanguageImplementations = existingImplementation;
```

- 2 Add the `target.Processor` object to an internal database and specify persistence of target data over MATLAB sessions.

```
objectsAdded = target.add(myProc, 'UserInstall', true);
```

- 3 You can remove the object from the internal database.

```
target.remove(objectsAdded);
```

Create Hardware Implementation by Modifying Existing Implementation

If an existing hardware implementation contains most of the values that you want in a new hardware implementation, you can quickly create the new implementation by creating and modifying a copy of the existing implementation.

- 1 Create a `target.Processor` object for the new hardware device.

```
myProc = target.create('Processor', ...
    'Name', 'MyProcessor', ...
    'Manufacturer', 'MyManufacturer');
```

- 2 Create a `target.LanguageImplementation` object that copies an existing language implementation.

```
myCopiedImplementation = target.create('LanguageImplementation', ...
    'Name', 'MyCopiedImplementation', ...
    'Copy', 'Atmel-AVR');
```

- 3 Specify the required language implementation details. For example, byte ordering.

```
myCopiedImplementation.Endianness = target.Endianness.Big;
```

- 4 Associate the language implementation with the hardware device.

```
myProc.LanguageImplementations = myCopiedImplementation;
```

- 5 Add the `target.Processor` object to an internal database.

```
objectsAdded = target.add(myProc);
```

Create Hardware Implementation by Reusing Existing Implementation

If your hardware device requires the same hardware implementation as an existing implementation, you can reuse the existing implementation.

- 1 Create a `target.Processor` object for the new hardware device.

```
myProc = target.create('Processor', ...
                      'Name', 'MyProcessor', ...
                      'Manufacturer', 'MyManufacturer');
```

- 2 Retrieve the existing implementation by using the identifier for the device vendor and type, for example, 'ARM Compatible-ARM Cortex'.

```
existingImplementation = target.get('LanguageImplementation', ...
                                  'ARM Compatible-ARM Cortex');
```

- 3 Associate the language implementation with the hardware device.

```
myProc.LanguageImplementations = existingImplementation;
```

- 4 Add the target.Processor object to an internal database.

```
objectsAdded = target.add(myProc);
```

Validate Hardware Device Data

To validate the data integrity of target objects, use the `IsValid` property or `validate` method of the `target.Object` base class.

Consider an example where you create a `target.Processor` object and associate an existing language implementation with the object.

```
myProcessor = target.create('Processor');
myProcessor.LanguageImplementations = target.get('LanguageImplementation', ...
                                                'ARM Compatible-ARM Cortex');
```

To validate the created object, run `myProcessor.IsValid` or `myProcessor.validate()`.

```
myProcessor.IsValid
```

```
ans =
    logical
     0
```

```
myProcessor.validate()
```

```
Error using target.Processor/validate
Target data validation failed.
* Undefined property "Name" in "Processor" object.
* Undefined identifier in "Processor" object.
```

The validation fails because these `target.Processor` properties are not specified:

- **Name** — Processor name
- **Id** — Object identifier

You can specify a processor name, which also specifies the object identifier.

```
myProcessor.Name = 'MyProcessor';
```

Check the validity of `myProcessor`.

```
myProcessor.IsValid
```

```
ans =
    logical
     1
```

The validity of the object is established.

Note When you use the `target.add` function to register a target object, the software also checks the validity of the object.

Export Hardware Device Data

You can share previously created hardware device data across computers and users.

For this example, specify a hardware device and add it to an internal database.

```
myProc = target.create('Processor', ...
    'Name', 'MyProcessor', ...
    'Manufacturer', 'MyManufacturer');
existingImplementation = target.get('LanguageImplementation', ...
    'ARM Compatible-ARM Cortex');
myProc.LanguageImplementations = existingImplementation;
objectsAdded = target.add(myProc);
```

To create a function for sharing the hardware device data, run:

```
target.export(myProc, 'FileName', 'exportMyProcFunction')
```

The `target.export` function creates `exportMyProcFunction.m` in the current working folder.

```
function registeredObjects = exportMyProcFunction(varargin)
% This function was generated using target data export.

% Create target.Processor "MyManufacturer-MyProcessor"
processor = target.create("Processor");
processor.LanguageImplementations(1) = ...
    target.get("LanguageImplementation", "ARM Compatible-ARM Cortex");
processor.Manufacturer = "MyManufacturer";
processor.Name = "MyProcessor";

% Add the target objects to MATLAB memory
registeredObjects = target.add(processor, varargin{:});
```

Now, you can use the generated function to share the hardware device data in your database across computers and users. For example, on another computer, run this command.

```
objectsAdded = exportMyProcFunction;
```

The generated function recreates the `target.Processor` object, `MyManufacturer-MyProcessor`, and adds it to an internal database.

Create Alternative Identifier for Target Object

To create alternative identifiers for target objects, use the `target.Alias` class.

For example, if a `target.Processor` object has a long class identifier, you can create a `target.Alias` object that provides a short identifier for the `target.Processor` object.

- 1 Retrieve the `target.Processor` object.

```
processorObj = target.get('Processor', ...
    'Analog Devices-ADSP-CM40x (ARM Cortex-M)');
```

- 2 Use the `target.create` function to create a `target.Alias` object.

```
aliasProcessorObj = target.create('Alias');
```

- 3 Use `target.Alias` object properties to specify the alternative identifier and original target object.

- ```
aliasProcessorObj.Name = 'myShortName';
aliasProcessorObj.For = processorObj;
```
- 4** Add the target.Alias object to an internal database.
- ```
target.add(aliasProcessorObj);
```
- 5** To retrieve the original target.Processor object, run:
- ```
target.get('Processor', 'myShortName');
```

## Upgrade Data Definitions for Hardware Devices

To upgrade existing hardware device definitions that are specified through `rtwTargetInfo.m` or `sl_customization.m` files, use the `target.upgrade` function.

### rtwTargetInfo.m File

Suppose you have the hardware device definition in an `rtwTargetInfo.m` file:

```
function rtwTargetInfo(tr)

 % Add registration function handle to the Target Registry
 tr.registerTargetInfo(@loc_register_hardware);
end

function hw = loc_register_hardware
 hw = RTW.HWDeviceRegistry;
 hw.Vendor = 'MyManufacturer';
 hw.Type = 'MyDevice';
 hw.Alias = {};
 hw.Platform = {'Prod', 'Target'};
 hw.setWordSizes([8 16 32 64 64 64 64 64 64 64]);
 hw.Endianess = 'Little';
 hw.IntDivRoundTo = 'Zero';
 hw.ShiftRightIntArith = true;
 hw.LargestAtomicInteger = 'Long';
 hw.LargestAtomicFloat = 'Double';
end
```

To upgrade the data definitions contained in the file, run:

```
target.upgrade('rtwTargetInfo', 'myPathTo/rtwTargetInfo.m');
```

In the current folder, the function creates this `registerUpgradedTargets.m` file:

```
function processor = registerUpgradedTargets(varargin)
% This function was generated using target data export.

 % Create target.LanguageImplementation 'MyManufacturer-MyDevice'
 languageimplementation = target.create('LanguageImplementation');
 languageimplementation.AtomicFloatSize = 64;
 languageimplementation.AtomicIntegerSize = 64;
 languageimplementation.DataTypes.Char.Size = 8;
 languageimplementation.DataTypes.Double.Size = 64;
 languageimplementation.DataTypes.Float.Size = 64;
 languageimplementation.DataTypes.Half.IsSupported = false;
 languageimplementation.DataTypes.Half.Size = 16;
 languageimplementation.DataTypes.Int.Size = 32;
 languageimplementation.DataTypes.Long.Size = 64;
 languageimplementation.DataTypes.LongLong.IsSupported = false;
 languageimplementation.DataTypes.LongLong.Size = 64;
 languageimplementation.DataTypes.Pointer.Size = 64;
 languageimplementation.DataTypes.PtrDiffT.Size = 64;
 languageimplementation.DataTypes.Short.Size = 16;
 languageimplementation.DataTypes.SizeT.Size = 64;
 languageimplementation.Name = 'MyManufacturer-MyDevice';
 languageimplementation.WordSize = 64;
```

```

 % Create target.Processor 'MyManufacturer-MyDevice'
 processor = target.create('Processor');
 processor.LanguageImplementations(1) = languageimplementation;
 processor.Manufacturer = 'MyManufacturer';
 processor.Name = 'MyDevice';

 % Add the target objects to MATLAB memory
 target.add(processor, varargin{:});
end

```

To register the hardware device with MATLAB, run:

```
registerUpgradedTargets()
```

If you want the registration to persist across MATLAB sessions, run:

```
registerUpgradedTargets('UserInstall', true)
```

### sl\_customization.m File

Suppose you have multiple hardware device definitions in an `sl_customization.m` file:

```

function sl_customization(cm)
 % sl_customization function to register a device
 % vendor and type with Simulink.
 % Copy or rename this file to sl_customization.m.
 cm.registerTargetInfo(@loc_register_device);
 cm.registerTargetInfo(@loc_register_device2);
 cm.registerTargetInfo(@loc_createConfig);

 cm.registerTargetInfo(@locRegisterTfl);
 cm.CodeCoverageTools.add('DummyCoverageToolForTesting',...
 'HDummyCovTool',...
 'A Coverage Tool Vendor');
end

function thisDev = loc_register_device
 thisDev = RTW.HWDeviceRegistry;
 thisDev.Vendor = 'MyDevVendor';
 thisDev.Type = 'MyDevType';
 thisDev.Alias = {};
 thisDev.Platform = {'Prod', 'Target'};
 thisDev.setWordSizes([8 16 32 32 32]);
 thisDev.LargestAtomicInteger = 'Char';
 thisDev.LargestAtomicFloat = 'None';
 thisDev.Endianess = 'Unspecified';
 thisDev.IntDivRoundTo = 'Undefined';
 thisDev.ShiftRightIntArith = true;
 thisDev.setEnabled({'IntDivRoundTo'});
end

function thisDev = loc_register_device2
 thisDev = RTW.HWDeviceRegistry;
 thisDev.Vendor = 'MyDevVendor';
 thisDev.Type = 'MyDevType2';
 thisDev.Alias = {};
 thisDev.Platform = {'Prod', 'Target'};
 thisDev.setWordSizes([8 16 32 32 32]);
 thisDev.LargestAtomicInteger = 'Char';
 thisDev.LargestAtomicFloat = 'None';
 thisDev.Endianess = 'Unspecified';
 thisDev.IntDivRoundTo = 'Undefined';
 thisDev.ShiftRightIntArith = true;
 thisDev.setEnabled({'IntDivRoundTo'});
end

% local function
function config = loc_createConfig
 config = rtw.connectivity.ConfigRegistry;
 config.ConfigName = 'Infineon->C16x, XC16x';
 config.ConfigClass = 'pi_slcust.HostDemoConfig1';

```

```

config.SystemTargetFile = {'custom_target.tlc'};
config.TemplateMakefile = {'custom_target.tmf'};
config.TargetHWDeviceType = {'Infineon->C16x, XC16x'};
end

function thisTfl = locRegisterTfl
thisTfl(1) = RTW.TflRegistry;
thisTfl(1).Name = 'myTFL1';
thisTfl(1).Description = 'Test';
thisTfl(1).TableList = {'tfl_table_Sum',...
 'tfl_table_Product',...
 }; % Sum includes Add and Subtract
thisTfl(1).BaseTfl = 'ANSI_C';
thisTfl(1).TargetHWDeviceType = {'*'};
end

```

To upgrade the `RTW.HWDeviceRegistry` data definitions in the file, run:

```
target.upgrade('sl_customization', 'myPathTo/sl_customization.m')
```

In the current folder, the function creates this `registerUpgradedTargets.m` file:

```

function targetObjects = registerUpgradedTargets(varargin)
% This function was generated using target data export.

% Create target.LanguageImplementation 'MyDevVendor-MyDevType'
languageimplementation = target.create('LanguageImplementation');
languageimplementation.AtomicIntegerSize = 8;
languageimplementation.DataTypes.Char.Size = 8;
languageimplementation.DataTypes.Double.Size = 64;
languageimplementation.DataTypes.Float.Size = 32;
languageimplementation.DataTypes.Half.IsSupported = false;
languageimplementation.DataTypes.Half.Size = 16;
languageimplementation.DataTypes.Int.Size = 32;
languageimplementation.DataTypes.Long.Size = 32;
languageimplementation.DataTypes.LongLong.IsSupported = false;
languageimplementation.DataTypes.LongLong.Size = 64;
languageimplementation.DataTypes.Pointer.Size = 32;
languageimplementation.DataTypes.PtrDiffT.Size = 32;
languageimplementation.DataTypes.Short.Size = 16;
languageimplementation.DataTypes.SizeT.Size = 32;
languageimplementation.Endianess = target.Endianess.Unspecified;
languageimplementation.Name = 'MyDevVendor-MyDevType';
languageimplementation.WordSize = 32;

% Create target.Processor 'MyDevVendor-MyDevType'
processor = target.create('Processor');
processor.LanguageImplementations(1) = languageimplementation;
processor.Manufacturer = 'MyDevVendor';
processor.Name = 'MyDevType';

% Create target.LanguageImplementation 'MyDevVendor-MyDevType2'
languageimplementation2 = target.create('LanguageImplementation');
languageimplementation2.AtomicIntegerSize = 8;
languageimplementation2.DataTypes.Char.Size = 8;
languageimplementation2.DataTypes.Double.Size = 64;
languageimplementation2.DataTypes.Float.Size = 32;
languageimplementation2.DataTypes.Half.IsSupported = false;
languageimplementation2.DataTypes.Half.Size = 16;
languageimplementation2.DataTypes.Int.Size = 32;
languageimplementation2.DataTypes.Long.Size = 32;
languageimplementation2.DataTypes.LongLong.IsSupported = false;
languageimplementation2.DataTypes.LongLong.Size = 64;
languageimplementation2.DataTypes.Pointer.Size = 32;
languageimplementation2.DataTypes.PtrDiffT.Size = 32;
languageimplementation2.DataTypes.Short.Size = 16;
languageimplementation2.DataTypes.SizeT.Size = 32;
languageimplementation2.Endianess = target.Endianess.Unspecified;
languageimplementation2.Name = 'MyDevVendor-MyDevType2';
languageimplementation2.WordSize = 32;

% Create target.Processor 'MyDevVendor-MyDevType2'

```

```
processor2 = target.create('Processor');
processor2.LanguageImplementations(1) = languageimplementation2;
processor2.Manufacturer = 'MyDevVendor';
processor2.Name = 'MyDevType2';

targetObjects = [processor, processor2];

% Add the target objects to MATLAB memory
target.add(targetObjects, varargin{:});
end
```

To register the hardware device definitions with MATLAB, run:

```
registerUpgradedTargets()
```

If you want the registration to persist across MATLAB sessions, run:

```
registerUpgradedTargets('UserInstall', true)
```

- “Best Practices for Creating Protected Models” on page 10-21

## Protect Models to Conceal Contents

When you want to share a model with a third-party without revealing intellectual property, protect the model. Protecting a model conceals the implementation details of the original model by compiling it into a referenced model. The protected model includes derived files to support the optional functionalities that you specify.

When you protect a model, you can allow the user of the protected model to:

- Open a read-only web view of the model, including model contents and block parameters.
- Simulate the model in accelerator (default), rapid accelerator, and normal modes.
- Generate code for a model that includes the protected model.
- Generate HDL code for a model that includes the protected model.
- Generate code for the protected model through the standalone interface, if you have Embedded Coder and specify an ERT-based system target file for the model.

You can optionally password-protect each option. If you choose password protection for one of these options, the software protects the supporting files by using AES-256 encryption.

When you create a protected model:

- Simulink creates and stores a protected version of the model in a file that has the same name as the source model, with an `.slxp` extension.
- The original model file, with the `.slx` extension, does not change. If you protect the model through a Model block, that Model block does not change.
- Optionally, Simulink creates a project archive (`.mlproj`) that contains the protected model, a harness model for the protected model, and additional supporting files.

This example shows how to create a protected model from a referenced model for read-only viewing, simulation, or code generation.

### Prepare the Parent Model

Configure the Model blocks in the parent model to refer to the original referenced model. This step prevents the Model blocks from becoming protected references when you create the protected model.

- 1 Open the parent model that references the model you want to protect. For this example, open the model `sldemo_mdhref_basic`.
- 2 To run the workflow, create a local copy of the model `sldemo_mdhref_counter` that you want to protect. You can then create a local copy of the parent model `sldemo_mdhref_basic`. You must save the parent model in the same folder as the referenced model.
- 3 Open the `sldemo_mdhref_basic` model that you saved locally. Make sure that the Model blocks CounterA, CounterB, and CounterC reference the `sldemo_mdhref_counter` model that you saved locally.
- 4 For each Model block, open the Block Parameters dialog box and specify the extension `.slx` in the **Model name** field. When both the model and the protected model exist in the same folder, `.slxp` takes precedence over `.slx`. If you do not specify an extension, then the original Model block in the model refers to the protected model instead of the original model. Click **OK**.

## Protect the Referenced Model

- 1 In the `sldemo_mdhref_basic` model, click any of the three Model blocks. On the Simulink Toolstrip **Model Block** tab, click **Protect**.

The screenshot shows the 'Create Protected Model' dialog box for the model 'sldemo\_mdhref\_counter'. The dialog is titled 'Create Protected Model: sldemo\_mdhref\_counter' and has a close button (X) in the top right corner. It contains the following sections and controls:

- Description:** 'Create a protected model (.slxp) that allows read-only view, simulation, and code generation of the model with optional password protection.'
- Allow user of protected model to:**
  - Open read-only view of model: Includes 'Enter password (optional)' and 'Re-enter password (option...)' fields.
  - Simulate: Includes 'Enter password (optional)' and 'Re-enter password (option...)' fields.
  - Use generated code: Includes 'Enter password (optional)' and 'Re-enter password (option...)' fields.
  - Content type: A dropdown menu set to 'Obfuscated source code'.
  - Use generated HDL code: Includes 'Enter password (optional)' and 'Re-enter password (option...)' fields.
- Tunable parameters for simulation:**
  - Options for saving protected model:**
    - Destination folder: A text field containing 'H:\my\_models' and a 'Browse...' button.
    - Contents: A dropdown menu set to 'Protected model (.slxp) and dependencies in a project'.
    - Create harness model for protected model.
    - Name of project archive (.mlproj): A text field containing 'sldemo\_mdhref\_counter\_protected'.
- Buttons:** A question mark icon, a 'Create' button, a 'Cancel' button, and a 'Help' button.

- 2 In the Create Protected Model dialog box, select the **Simulate** and **Use generated code** check boxes. These options allow the protected model user to simulate and generate code for a model that references the protected model. If you want to password-protect the functionality of the protected model, enter a password with a minimum of four characters. Each option can have a unique password.
- 3 If you have Embedded Coder and specify an ERT-based system target file (for example, `ert.tlc`) for the model, the **Code interface** field is visible.

In this example, `sldemo_mdhref_basic` does not specify an ERT-based system target file, therefore the **Code interface** options are not available in the Create Protected Model dialog box.

From the **Code interface** drop-down list, select one of these options:

- **Model reference** — Specifies code access through the model reference code interface, which allows use of the protected model within a model reference hierarchy. Users of the

protected model can generate code from a parent model that contains the protected model. Users can run Model block SIL/PIL simulations with the protected model.

- **Top model** — Specifies code access through the standalone interface. Users of the protected model can run Model block SIL/PIL simulations with the protected model.
- 4 From the **Content type** list, select **Obfuscated source code** to conceal the source code purpose and logic of the protected model. For more information on the model protection options, see “Content type”.
  - 5 Expand the **Tunable parameters for simulation** section and select the parameters that you want the protected model user to be able to tune during simulation.

For code generation, parameters with non-auto storage classes are tunable. For more information, see “Storage Classes for Parameters and Signals Used in Model Blocks”.

- 6 In the **Destination folder** box, specify the folder path for the protected model. The default value is the current working folder.
- 7 To automatically collect, create, and package supporting files with the protected model, set **Contents** to **Protected Model (.slxp)** and **dependencies in a project**.

---

**Note** Before sharing the project, check whether the project contains the necessary supporting files. If supporting files are missing, simulating or generating code for the related harness model can help identify them. Add the missing dependencies to the project and update the harness model as needed.

---

- 8 Setting **Contents** to **Protected Model (.slxp)** and **dependencies in a project** selects the **Create harness model for protected model** check box. The harness model is included in the project and provides an isolated environment for the Model block that references the protected model.

- 9 To further customize your protected model, you can:
  - Specify a custom obfuscator for code obfuscation. See “Specify Custom Obfuscators for Protected Models” on page 10-16.
  - Specify multiple code generation targets. See “Create Protected Models with Multiple Targets” on page 10-9.
  - Define callbacks for the protected model. See “Define Callbacks for Protected Models” on page 10-17.
- 10 Click **Create**.

A project archive (.mlproj) that contains the protected model, harness model, and supporting files appears in the specified destination folder. To test the protected model, extract the contents

of the project archive by double-clicking it in the Current Folder browser and specifying the destination folder. Alternatively, right-click on the project archive and click **Extract Here**. The project opens, and the extracted files are in a new folder named after the project archive.

- 11 When you create the protected model from the Simulink Editor, a protected model report is generated and included as part of the protected model. For this example, to view the protected model report, double-click the protected model or right-click the protected-model badge icon on the block in the harness model and select **Display Report**.

The screenshot shows a window titled "Protected Model report" with a search bar and "Match Case" option. The left sidebar shows a "Contents" panel with "Summary" selected. The main area displays the "Summary for sldemo\_mdref\_counter" report, which includes two tables: "Environment" and "Supported functionality".

### Environment

Environment information for protected model "sldemo\_mdref\_counter"

|                              |                          |
|------------------------------|--------------------------|
| Model Version                | 1.78                     |
| Simulink version             | 10.1                     |
| Simulink Coder Version       | 9.3 (R2020a) 18-Nov-2019 |
| Protected model generated on | Tue Jan 7 14:33:52 2020  |
| Platform                     | win64                    |

### Supported functionality

Supported functionality for protected model "sldemo\_mdref\_counter"

|                             |                        |
|-----------------------------|------------------------|
| Read-only view support      | Off                    |
| Simulation support          | On                     |
| Code generation support     | On                     |
| HDL Code generation support | Off                    |
| Concurrent tasking support  | Off                    |
| Code interface              | Model reference        |
| Target                      | grt                    |
| Obfuscation                 | On                     |
| Generated code content type | Obfuscated source code |

Buttons for "OK" and "Help" are visible at the bottom right of the window.

The report contains:

- A **Summary**, including the following tables:
  - **Environment**, providing the Simulink version and other product versions and the platform used to create the protected model.
  - **Supported functionality**, reporting On, Off, or On with password protection for each possible functionality that the protected model supports. If you configure your protected model for multiple targets, this table includes a list of supported targets.
- An **Interface Report**, including model interface information such as input and output specifications, exported function information, interface parameters, and data stores.

The report does not contain other sections that appear in a code generation report for non-protected models, such as a code metrics report and traceability report, because these reports include more information about the model's design.

- 12 You can test the protected model to compare it to the original model. For more information, see “Test Protected Models” on page 10-10.
- 13 To use the protected model in a model hierarchy, reference it through a Model block such as the one included in the harness model. The **Simulation mode** for Model blocks that reference a protected model is set to **Accelerator**. You cannot change the mode. For more information, see “Reference Protected Models from Third Parties”.

### Other Methods of Protecting Models

To create a protected model from the current model, use one of these options:

- On the Simulink Toolstrip **Simulation** tab, click the **Save** button arrow, then select **Protected Model**.
- On the Simulink Toolstrip **C Code** tab, click the **Share** button arrow, then select **Generate Protected Model**.

To programmatically create a protected model, use the `Simulink.ModelReference.protect` function.

### Protected Model Requirements and Limitations

When you create a protected model, consider these following requirements:

- You must have a Simulink Coder or HDL Coder™ license to create a protected model.
- The model must be available on the MATLAB path.
- The model cannot have unsaved changes.
- The model uses the configuration that is active during protection. You cannot change the configuration of a protected model.
- If the model contains variants, the protected model includes only the variant that is active during protection.
- The model protection process does not preserve callbacks. For more information on creating callbacks for use with a protected model, see “Define Callbacks for Protected Models” on page 10-17
- Do not rename the protected model or change its suffix. If you do so, the model is unusable until you restore its original name and suffix.
- Use a unique name for the model and for models that it references. If a protected model references a model that shares a name with either a different protected model or a different model within the hierarchy of another protected model, there are limitations for using the protected models. If a top model references two protected models that have such a naming conflict, you cannot protect the top model, generate code for the top model, or simulate the top model in software-in-the-loop (SIL), processor-in-the-loop (PIL), or rapid accelerator modes.
- If your model includes a non-inlined S-function, use a unique name for the .MEX file. If there is a name conflict with a different .MEX file on the MATLAB path, you cannot simulate the protected model.

The model must also meet the requirements listed in “Model Reference Requirements and Limitations”.

## Code Generation Requirements and Limitations

To create a protected model that supports code generation, your model must meet these requirements:

- The protected model must use normal, accelerator, software-in-the-loop (SIL), or processor-in-the-loop (PIL) modes and a single target.
- The protected model must not include non-inlined S-functions.
- Do not select the **Code Generation > Verification > Measure function execution time** check box. If you have this option selected when you protect your model, the software turns off the parameter and displays a warning.
- Protected referenced models must support code generation without password protection.
- The protected model must be compatible with the **Content type** of each protected referenced model. This table provides compatibility information.

### Code Generation Content Type Compatibility

| Protected Parent Model Content Type          | Compatible Protected Referenced Model Content Types                                                                                                                                    |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Binaries                                     | <ul style="list-style-type: none"> <li>• Binaries</li> <li>• Obfuscated source code</li> </ul>                                                                                         |
| Binaries with 'ObfuscateCode' set to 'false' | <ul style="list-style-type: none"> <li>• Binaries</li> <li>• Binaries with 'ObfuscateCode' set to 'false'</li> <li>• Obfuscated source code</li> <li>• Readable source code</li> </ul> |
| Obfuscated source code                       | <ul style="list-style-type: none"> <li>• Obfuscated source code</li> </ul>                                                                                                             |
| Readable source code                         | <ul style="list-style-type: none"> <li>• Obfuscated source code</li> <li>• Readable source code</li> </ul>                                                                             |

When the **Content type** of the protected parent model and protected referenced models do not match, code generation applies the **Content type** that provides the higher level of protection. For example, a protected parent model set for **Binaries** generates **Binaries** for protected referenced models that are set to **Obfuscated source code**. A protected parent model set for **Readable source code** generates **Obfuscated source code** for protected referenced models that are set to **Obfuscated source code**.

To avoid an error during code generation of a model that includes the protected model:

- The protected model name must be unique from other model names in the same model reference hierarchy.
- The interfaces must match.
- The parameters must be compatible.

## Nested Protected Model Requirements and Limitations

To enable a recipient of your protected model to protect a model that references it, your protected model must:

- Support accelerator mode. You must select **Simulate** in the Create Protected Model dialog box or set 'Mode' to 'Accelerator' or 'CodeGeneration' using the `Simulink.ModelReference.protect` function.
- Use the default 'CodeInterface' setting: 'Model reference'.
- Not use password protection for simulation.
- Not have callbacks.
- Support without password protection the operations that the protected parent model is intended to support.
- Use a **Content type** that is compatible with the intended **Content type** of the protected parent model if the protected parent model is intended to support code generation. For a list of compatible **Content type** options, see the table in the preceding section.
- Use the same compiler as the protected parent model is intended to use.
- Not reference a model that shares a name with either a different protected model or a different model within the hierarchy of another protected model.

If the model that you want to protect references a protected model, the referenced protected model must meet the preceding requirements.

When you protect a model that references a protected model, you must specify the tunable parameters of the referenced protected model as tunable for the model you are protecting.

---

**Note** A protected model that you create with the **Use generated HDL code** option selected allows encryption and support for simulation and HDL code generation from a model that references the protected model. You cannot obfuscate the HDL source code, have callbacks, or use nested protected models with this option. To learn more about HDL code generation limitations, see “Protected Model Restrictions for HDL Code Generation” (HDL Coder).

### More About

- “Package and Share Protected Models” on page 10-12
- “Specify Custom Obfuscators for Protected Models” on page 10-16
- “Create Protected Models with Multiple Targets” on page 10-9
- “Define Callbacks for Protected Models” on page 10-17

## Create Protected Models with Multiple Targets

You can create a protected model that supports multiple code generation targets. This example shows how to use command-line functions to create a protected model that supports code generation for GRT and ERT targets.

- 1 Load a model and save a local copy. This model is configured for a GRT target.

```
openExample('sldemo_mdref_counter');
save_system('sldemo_mdref_counter','mdref_counter.slx');
```

- 2 Add a required password for modifying a protected model. If you do not add a password, you are prompted to set a password when you create a modifiable, protected model.

```
Simulink.ModelReference.ProtectedModel.setPasswordForModify(...
'mdref_counter','password');
```

- 3 Create a modifiable, protected model with support for code generation.

```
Simulink.ModelReference.protect('mdref_counter','Mode',...
'CodeGeneration','Modifiable',true,'Report',true);
```

- 4 Get a list of targets that the protected model supports.

```
st = Simulink.ProtectedModel.getSupportedTargets('mdref_counter')

st =

 'grt' 'sim'
```

- 5 Configure the unprotected model to support an ERT target.

```
set_param('mdref_counter','SystemTargetFile','ert.tlc');
save_system('mdref_counter');
```

- 6 Add support to the protected model for the ERT target. You are prompted for the modification password.

```
Simulink.ProtectedModel.addTarget('mdref_counter');
```

- 7 Verify that the list of supported targets now includes the ERT target.

```
st = Simulink.ProtectedModel.getSupportedTargets('mdref_counter')

st =

 'ert' 'grt' 'sim'
```

- “Protect Models to Conceal Contents” on page 10-2

## Test Protected Models

To test a protected model that you created, compare the output of the protected model to the output of the original model. Because you supply the protected model from the original model, both the original and the protected model might exist on the MATLAB path. In the parent model, if the Model block **Model name** parameter names the model without providing a suffix, the protected model takes precedence over the unprotected model. To override this default when testing the output, in the Model block **Model name** parameter, specify the file name with the extension of the unprotected model, `.slx`.

To compare the unprotected and protected versions of a Model block, use the Simulation Data Inspector. This example uses `sldemo_mdhref_basic` and the protected model, `sldemo_mdhref_counter.slxp`, which is created in “Protect Models to Conceal Contents” on page 10-2.

- 1 If it is not already open, open `sldemo_mdhref_basic`.  

```
openExample('sldemo_mdhref_basic');
```
- 2 Enable logging for the output signal of the Model block, CounterA. In the Configuration Parameters dialog box, in the **Data Import/Export** pane, select the **Signal logging** parameter. Click **Apply** and **OK**.
- 3 Right-click the output signal. From the context menu, select **Properties**. In the Signal Properties dialog box, select **Log signal data**. Click **Apply** and **OK**. For more information, see “Export Signal Data Using Signal Logging”.
- 4 Right-click the CounterA block. From the context menu, select **Block Parameters (ModelReference)**. In the Block Parameters dialog box, specify the **Model name** parameter with the name of the unprotected model and the extension, `sldemo_mdhref_counter.slx`. Click **Apply** and **OK**. Repeat this step for CounterB block and CounterC block.
- 5 Simulate the model. When the simulation is complete, click the **Data Inspector** button to open the Simulation Data Inspector.
- 6 In the Simulation Data Inspector, rename the run to indicate that it is for the unprotected model.
- 7 In the Simulink Editor, right-click the CounterA block. From the context menu, select **Block Parameters (ModelReference)**. In the Block Parameters dialog box, specify the **Model name** parameter with the name of the protected model, `sldemo_mdhref_counter.slxp`. A badge icon appears on the Model block. Repeat this step for CounterB block and CounterC block.
- 8 Simulate the model, which now refers to the protected model. When the simulation is complete, a new run appears in the Simulation Data Inspector.
- 9 In the Simulation Data Inspector, rename the new run to indicate that it is for the protected model.
- 10 In the Simulation Data Inspector, click the **Compare** tab. From the **Baseline** and **Compare To** lists, select the runs from the unprotected and protected model, respectively. To compare the runs, click **Compare Runs**. For more information about comparing runs, see “Compare Simulation Data”.

### **More About**

- “Protect Models to Conceal Contents” on page 10-2
- “Package and Share Protected Models” on page 10-12

## Package and Share Protected Models

When you protect a model, you can automatically create and package the following contents in a project archive (.mlproj) for easy sharing:

- Protected model file (.slxp)
- Harness model file
- MAT-file with base workspace definitions
- Data dictionary pruned to relevant definitions
- Other supporting files

In the Create Protected Model dialog box, set **Contents** to Protected model (.slxp) and dependencies in a project.

---

**Note** Before sharing the project, check whether the project contains the necessary supporting files. If supporting files are missing, simulating or generating code for the related harness model can help identify them. Add the missing dependencies to the project and update the harness model as needed.

---

Alternatively, you can use one of these options to deliver the protected model package:

- Create a project archive to share a project that contains the protected model file and supporting files. For more information, see “Create a Project from a Model” and “Share Projects”.
- Provide the protected model file and supporting files as separate files.
- Combine the files into a ZIP or other container file.
- Provide the files in some other standard or proprietary format specified by the receiver.

Whichever approach you use to deliver a protected model, include information on how to retrieve the original files.

### Harness Model

You can create a harness model when you create your protected model. The harness model contains a Model block that references the protected model. A third-party can use the Model block to reference your protected model. The harness model is set up for simulation of the protected model.

### MAT-File with Base Workspace Definitions

Referenced models can use object definitions or tunable parameters that are defined in the MATLAB base workspace. These variables are not saved with the model. When you protect a model, you must obtain the definitions of required base workspace entities and ship them with the model.

For example, if the model uses the following base workspace variables, they must be saved to a MAT-file:

- Global tunable parameter
- Global data store
- The following objects used by a signal that connects to a root-level model Inport or Outport:

- `Simulink.Signal`
- `Simulink.Bus`
- `Simulink.Alias`
- `Simulink.NumericType` that is an alias

To determine the required base workspace definitions and save them to a MAT-file, see “Explore Protected Model Capabilities”. Before executing the protected model as a part of a third-party model, the receiver of the protected model must load the MAT-file.

## Simulink Data Dictionary

Referenced models can use data definitions from a data dictionary, which are not saved with the model. When you protect a model that uses a data dictionary, package and ship the data dictionary with the protected model.

## Protected Model File Contents

A protected model file (`.slxp`) consists of the derived files that support the options that you selected when you created the protected model. The derived files are unpacked when you or a third-party use the protected model in simulation. You do not need to package these derived files with the protected model.

If you created a protected model for simulation only and the referencing model is in `Normal` mode, after simulation, the `model_msp.mexext` file is placed in the build folder. The derived files that are unpacked depends on the support that you enabled when creating the protected model.

**Protected Model Derived Files**

| Supported Functionality                                                                                        | Derived Files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Created a protected model for simulation only and the referencing model is in Normal mode                      | The <i>model_msp.mexext</i> file is placed in the build folder. If the model uses a noninlined S-function directly or indirectly, the S-function MEX-files are placed in the build folder.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Specify Custom Obfuscators for Protected Models

When creating a protected model, you can specify your own postprocessing function for files that the protected model creation process generates. Before packaging the protected model files, this function is called by the `Simulink.ModelReference.protect` function. You can use this functionality to run your own custom obfuscator on the generated files by following these steps:

- 1 Create your postprocessing function. Use this function to call your custom obfuscator. The function must be on the MATLAB path and accept a `Simulink.ModelReference.ProtectedModel.HookInfo` object as an input variable.
- 2 In your function, get the files and exported symbol information that your custom obfuscator requires to process the protected model files. To get the files and information, access the properties of your function input variable. The variable is a `Simulink.ModelReference.ProtectedModel.HookInfo` object with the following properties:
  - `SourceFiles`
  - `NonSourceFiles`
  - `ExportedSymbols`
- 3 Pass the protected model file information to your custom obfuscator. The following is an example of a postprocessing function for custom obfuscation:

```
function myHook(protectedModelInfo)

 % Get source file list information.
 srcFileList = protectedModelInfo.SourceFiles;
 disp('### Obfuscating...');
 for i=1:length(srcFileList)
 disp(['### Obfuscator: Processing ' srcFileList{i} '...']);
 % call to custom obfuscator
 customObfuscator(srcFileList{i});
 end
end
```

- 4 Specify your postprocessing function when creating the protected model:

```
Simulink.ModelReference.protect('myModel, ...
 'Mode', ...
 'CodeGeneration', ...
 'CustomPostProcessingHook', ...
 @(protectedModelInfo)myHook(protectedModelInfo))
```

The protected model creator can also enable obfuscation of simulation target code and generated code through the `'ObfuscateCode'` option of the `Simulink.ModelReference.protect` function. Your custom obfuscator runs only on the generated code and not on the simulation target code or the generated HDL code. If both obfuscators are in use, the custom obfuscator is the last to run on the generated code before the files are packaged.

## Define Callbacks for Protected Models

When you create a protected model, you can customize its behavior by defining callbacks. Callbacks specify code that executes when you view, simulate, or generate code for the protected model. You cannot have protected model callbacks with HDL code generation support enabled for a protected model. To learn more about HDL code generation limitations, see “Protected Model Restrictions for HDL Code Generation” (HDL Coder).

A protected model user cannot view or modify a callback. If a model references a protected model with callbacks, you cannot protect the model.

To create a protected model with callbacks:

- 1 Define `Simulink.ProtectedModel.Callback` objects for each callback.
- 2 To create your protected model, call the `Simulink.ModelReference.protect` function. Use the 'Callbacks' option to specify a cell array of callbacks to include in the protected model.

### Creating Callbacks

To create and define a protected model callback, create a `Simulink.ProtectedModel.Callback` object. Callback objects specify:

- The code to execute for the callback. The code can be a character vector of MATLAB commands or a script on the MATLAB path.
- The event that triggers the callback. The event can be 'PreAccess' or 'Build'.
- The protected model functionality that the event applies to. The functionality can be 'CODEGEN', 'SIM', 'VIEW', or 'AUTO'. If you select 'AUTO', and the event is 'PreAccess', the callback applies to each functionality. If you select 'AUTO', and the event is 'Build', the callback applies only to 'CODEGEN' functionality. If you do not select a functionality, the default behavior is 'AUTO'.
- The option to override the protected model build process. This option applies only to 'CODEGEN' functionality.

You can create only one callback per event and per functionality.

### Defining Callback Code

You can define the code for a callback by using either a character vector of MATLAB commands or a script on the MATLAB path. When you write callback code, follow these guidelines:

- Callbacks must use MATLAB code (.m or .p).
- The code can include protected model functions or a MATLAB command that does not require loading the model.
- Callback code must not call out to external utilities unless those utilities are available in the environment where the protected model is used.
- Callback code cannot reference the source protected model unless you are using protected model functions.

You can use the `Simulink.ProtectedModel.getCallbackInfo` function in callback code to get information on the protected model. The function returns a

`Simulink.ProtectedModel.CallbackInfo` object that provides the protected model name and the names of submodels. If the callback is specified for 'CODEGEN' functionality and 'Build' event, the object provides the target identifier and model code interface type ('Top model' or 'Model reference').

## Create a Protected Model with Callbacks

This example creates a protected model with a callback for code generation.

- 1 On the MATLAB path, create a callback script, `pm_callback.m`, containing:

```
s1 = 'Code interface is: ';
cbinfoobj = Simulink.ProtectedModel.getCallbackInfo(...
 'sldemo_mdref_counter', 'Build', 'CODEGEN');
disp([s1 cbinfoobj.CodeInterface]);
```

- 2 Create a callback that uses the script.

```
pmCallback = Simulink.ProtectedModel.Callback('Build', ...
 'CODEGEN', 'pm_callback.m');
```

- 3 Create the protected model and specify the code generation callback.

```
Simulink.ModelReference.protect('sldemo_mdref_counter', ...
 'Mode', 'CodeGeneration', 'Callbacks', {pmCallback})
```

- 4 Build the protected model. Before the build, the callback displays the code interface.

```
slbuild('sldemo_mdref_basic')
```

## Sign a Protected Model

A *digital signature* is a method of verifying information about the origin of a digital message or file. You can digitally sign a protected model to allow the user of the model to verify:

- That the model was created by you, the publisher that signed the model.
- That the model was not changed after you signed it.

By using digital signature validation, the recipient can detect issues, such as an unfamiliar publisher or a tampered model, before opening or executing a protected model.

These parties interact in the digital signing workflow:

- The creator of the protected model
- The recipient who uses the protected model
- An external certificate authority (CA) that the creator and the recipient trust

To exchange a protected model with certificate validation, they use this workflow:

- 1** The certificate authority provides a digital certificate, which proves that a public key belongs to the creator of the model. The certificate authority also provides the corresponding public certificate to the model recipient.
- 2** The creator signs the protected model by using the private key that corresponds to the public key in the certificate. The creator sends the signed protected model to the recipient.
- 3** The recipient verifies the signature on the protected model. Verification compares the signature on the model to the certificate attached to the model and to the certificate of the CA. Verification fails if:
  - The protected model was changed after it was signed.
  - The protected model was not signed.
  - The protected model was signed with an expired certificate.
  - The protected model was self-signed with a certificate issued by the author.
  - The protected model was signed with a missing or invalid certificate.
  - The certificate of the CA is missing in your system or is invalid.

As the model creator, you generate a public-private key pair and obtain a certificate for the public key from the CA. Then, you create a PKCS #12 file (.pfx file or .p12 file) that includes the private key and the certificate. Because the PKCS #12 file contains the private key, it is typically password-protected. Follow this workflow to sign your protected model before you send it to the recipient.

### Sign Your Protected Model

To sign a protected model, use a certificate that is issued to you by a certificate authority (CA) that you and the user of the model both trust. If you sign a protected model using a self-signed certificate or a certificate issued by an internal CA, the recipient's system must trust the certificate for the signature validation to succeed. Using a self-signed certificate to sign protected models is not recommended.

- 1** Locate the PKCS #12 file that you or your organization created from the private key and the certificate. The file must have a .pfx or .p12 extension.

**2** Protect the model that you want to sign. The protected version of the model has the extension `.slxp`.

**3** Provide the password for the PKCS #12 file.

```
Simulink.ModelReference.ProtectedModel.setPasswordForCertificate('certificate_file.pfx',...
'password');
```

**4** Sign the model by using the PKCS #12 file.

```
Simulink.ProtectedModel.sign('protected_model.slxp','certificate_file.pfx');
```

Your protected model is now signed with the PKCS #12 file. Do not change the protected model after you sign it. If you or another party changes the signed protected model, verification of the signature fails and the protected model cannot be used.

The recipient can verify the protected model by using the function `Simulink.ProtectedModel.verifySignature` or by selecting the Simulink preference `Verify digital signature of protected model before opening`. For more information, see “Reference Protected Models from Third Parties”.

## Best Practices for Creating Protected Models

When you want to conceal the implementation details of a model that you share with a third party, create a protected model. Instead of including your original model files, the protected model includes derived files to support the functionalities that you specify. To create a protected model that supports functionalities that your user requires and that includes minimal information about your model, follow these best practices. The settings that you choose for the model before and during protection specify what the user of the protected model can do with it. Consider the trade-offs of different design options. To support additional functionalities, the protected model must include more content and therefore, more elements of your design might be visible. Because the protected model uses derived artifacts from a compiled model reference, you cannot change the model after you protect it.

### Coordinate Settings with the User of Your Protected Model

When you develop a model that you will protect, coordinate with the user of the protected model to choose settings that allow their system to reference your protected model. After you protect your model, you cannot modify options such as configuration parameter settings to make your protected model compatible with a parent model. Before you protect your model, configure it to use compatible options.

#### Choose a Unique Model Name

You cannot change the name of your protected model after you protect it. To avoid name conflicts, choose a model name that is unique from other models in the system. Choose a model name that does not conflict with other models within your user's model hierarchy. Use the name to save your source (unprotected) model before you protect it.

#### Configure Model Parameters

Before you protect your model, choose configuration parameter settings by coordinating with the user of your protected model. When the parent model references your protected model, the configuration parameters of the models must be compatible. For example, if you set the parameter **Solver** to **Variable-step** for your protected model, the model that references your protected model must have **Solver** set to **Variable-step**. If your model contains multiple configuration sets, the protected model uses the configuration set that is active when you protect the model. To minimize parameter incompatibilities, send your model configuration set to the user of your protected model so that they can use the configuration for their parent model. For more information, see “Share a Configuration with Multiple Models”.

### Minimize the Model External Interface

Except for input and output ports, minimize the number of design elements that provide an interface into your model. To allow interfacing with external components, the protected model does not protect those design elements. For the following items, consider these alternative options that allow protection.

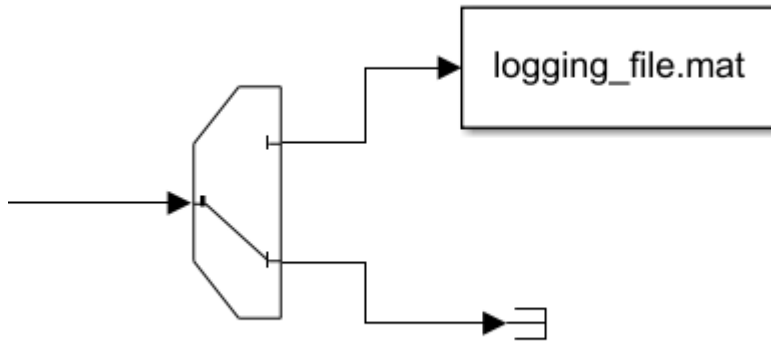

- **Tunable Parameters** — Minimize the number of tunable parameters in the code that use a storage class other than `Auto` or `Localizable`. Parameters that use a global storage class in your model's generated code are visible in the code for the protected model. If the user of your protected model requires access to tunable parameters, agree on a list of the parameters that the protected model provides. For more information, see “C Code Generation Configuration for Model Interface Elements”.

- **Data Objects** — Data objects, including parameter and signal data objects, data type objects, and bus objects, that you store externally are not protected. Include only data objects that the user of the protected model requires access to. Use the data objects to monitor signals and calibrate parameters while you develop your model. After calibration, specify values for the parameters, and then inline them. For more information, see “Data Objects”.
- **Data Stores** — Do not use global data stores on signal objects. Global data stores can make data visible across referenced models. Instead, use inports and outports to communicate data across model references. You can use Data Store Memory blocks as data stores that are local to your model. For more information, see “Local and Global Data Stores”.
- **Model Arguments** — Minimize the number of arguments that your model uses. When your protected model uses arguments, the user of your protected model must specify values for the arguments in the parent model. These data items are visible to the user of your protected model. For each model argument that your model uses, communicate the argument specifications to the user of your protected model.
- **Simulink Functions** — Consider the scope of Simulink functions that your model uses. When a Simulink function has a global scope or is scoped at the root level of your model, it provides a visible interface with your protected model. If you do not want a Simulink function to interface into your protected model, consider specifying a scope within a subsystem of your model. For more information, see “Scoped Simulink Function Blocks in Subsystems”.
- **Logging Blocks** — Do not use block-based logging in your protected model. To File blocks and To Workspace blocks that use the `Timeseries` format function in protected models, and therefore make the logged data visible to the protected model user. Signal logging, and other options that use the signal selector, do not work for signals inside a protected model.
- **Noninlined S-functions** — Consider the content of noninlined S-functions that your model uses. When you protect a model that contains a noninlined S-function, the MEX files that you write for the S-function are placed in the protected model build folder and are visible to the user of your protected model.

### **Design Options in Your Protected Model**

If you want to use one of the preceding design elements while you develop your model, but the element is not required by the user of the model, you can use variants to exclude the design element from your protected model. An example is using a To File block during testing to log data that the user of the protected model does not require access to. To exclude the block by using variants:

- 1** Insert a variant block, such as a Manual Variant Sink block, on the signal that leads to the To File block.
- 2** Connect the first output of the variant block to the To File block.
- 3** Connect the second output of the variant block to a Terminator block to terminate the signal.
- 4** To log the signal while testing the model, activate the first variant output.
- 5** To protect the model without using the logging block, activate the second variant output. The protected model uses only the active variant, so the signal is terminated without being logged.

## Contents to Include in Your Protected Model

### Model Protection Options

When you specify functionalities for your protected model, the protected model includes artifacts to support those functionalities. Limiting the included artifacts enables you to control what contents are visible to the user of your model or to an external attacker that wants to view or change your model without permission. Consider the trade-offs of different design options. To support additional functionalities, the protected model must include more content and therefore, more elements of your design might be visible. Coordinate with the user of your model to agree on what functionalities they require. Specify support for only those functionalities.

- **Obfuscated source code** — Use this option when the user of your protected model must compile the generated source code. The protected model includes an obfuscated version of the generated source code. It behaves the same as your source code but is more difficult to understand for the model user and potential attackers.
- **Compiled code** — Use this option when the user of your protected model can use the compiled library from your protected model. The protected model includes the binary files and header files compiled from your generated source code. It does not include the source code. This option prevents the user of your model and potential attackers from accessing the model's generated source code.
- **Password protection** — Use this option to support some functionality for your protected model's user and protect the supporting files from external attackers. For each option that you specify a password, the derived files that support that option are protected by using AES-256 encryption. Before executing each functionality, the protected model prompts the user for a password. Coordinate with the user of your protected model to choose the password for each option. If your protected model is referenced by a parent model that will also be protected, do not password-protect functionalities that the parent protected model will support.
- **Digital signature** — Sign your protected model by using a certificate to protect the recipient from using the model if it has been changed by an external attacker. When you sign your model, the user of the model can verify that the protected model is published by you and did not change after you signed it. After you sign the model, if it is changed, a user cannot use it. Make sure that the user's computer storage of trusted certificates has the certificate from the certificate authority that certified your certificate.

## **Interface Report**

When you create a protected model, the generated protected model report includes an interface report. The interface report includes information about input and output specifications, exported functions, interface parameters, and data stores. Use the interface report as a reference to communicate with the user of your protected model.

## **Create a Harness Model**

When you create a protected model, you have the option to create a harness model that references your protected model. Use the harness model to define information that the user requires to interface your protected model with their system. The harness contains the same configuration set that your protected model uses. In the harness model, you can include data definitions that your protected model uses.

# Stateflow Blocks in Simulink Coder

---

- “Code Generation of Stateflow Blocks” on page 11-2
- “Generate Code from Atomic Subcharts” on page 11-5
- “Inline State Functions in Generated Code” on page 11-7
- “Air-Fuel Ratio Control System with Stateflow Charts” on page 11-10

## Code Generation of Stateflow Blocks

The code generator produces code for Stateflow blocks for rapid prototyping. If you have an Embedded Coder license, you can generate production code for Stateflow blocks.

### Comparison of Code Generation Methods

The following sections compare two ways of generating code.

#### Code Generation Without Atomic Subcharts

You generate code for the entire model in one file and look through that entire file to find code for a specific part of the chart.

## Code Generation With Atomic Subcharts

You specify code generation parameters so that code for an atomic subchart appears in a separate file. This method of code generation enables unit testing for a specific part of a chart. You can avoid searching through unrelated code and focus only on the part that interests you.

**Note** Unreachable Stateflow states are optimized out and are not included in the generated code.

## **See Also**

### **Related Examples**

- “Generate Code from Atomic Subcharts” on page 11-5
- “Generate C or C++ Code from Stateflow Blocks” (Stateflow)

## Generate Code from Atomic Subcharts

To unit test a Stateflow chart in a Simulink model, first break the chart into smaller, independent components by using atomic subcharts. When you generate code for your chart, a separate file stores the code for the atomic subchart. Generating reusable code from atomic subcharts is useful for testing individual parts of your Stateflow chart. For more information, see “Create Reusable Subcomponents by Using Atomic Subcharts” (Stateflow).

### Generate Reusable Code for Unlinked Atomic Subcharts

To specify code generation parameters for an unlinked atomic subchart:

- 1 In your chart, right-click the atomic subchart and select **Properties**.
- 2 In the dialog box, specify these parameters:
  - a Set **Code generation function packaging** to Reusable function.
  - b Set **Code generation file name options** to User specified.
  - c For **Code generation file name**, enter the name of the file with no extension.
- 3 Open the Configuration Parameters dialog box.
- 4 In the **Code Generation** pane, set the **System target file** parameter to `ert.tlc`.
- 5 (OPTIONAL) Customize the generated function names for atomic subcharts. In the **Code Generation > Identifiers** pane, set the **Subsystem methods** parameter. Specify the format of the function names by using a combination of these tokens:
  - \$R — root model name
  - \$F — type of interface function for the atomic subchart
  - \$N — block name
  - \$H — subsystem index
  - \$M — name-mangling text

For more information, see “Generate Separate Code for an Atomic Subchart” (Stateflow).

### Generate Reusable Code for Linked Atomic Subcharts

To specify code generation parameters for linked atomic subcharts from the same library:

- 1 Open the library model that contains your atomic subchart.
- 2 Unlock the library.
- 3 Right-click the library chart and select **Block Parameters**.
- 4 In the dialog box, specify these parameters:
  - a On the **Main** tab, select **Treat as atomic unit**.
  - b On the **Code Generation** tab, set **Function packaging** to Reusable function.
  - c Set **File name options** to User specified.
  - d For **File name**, enter the name of the file with no extension.
- 5 In the **Code Generation** tab, set the **System target file** parameter to `ert.tlc`.

- 6** (OPTIONAL) Customize the generated function names for atomic subcharts. In the **Code Generation > Identifiers** tab, set the **Subsystem methods** parameter. Specify the format of the function names by using a combination of these tokens:
- \$R — root model name
  - \$F — type of interface function for the atomic subchart
  - \$N — block name
  - \$H — subsystem index
  - \$M — name-mangling text

When you generate code for your model, a separate file stores the code for linked atomic subcharts from the same library.

## Inline State Functions in Generated Code

| In this section...                                                    |
|-----------------------------------------------------------------------|
| “Inlined Generated Code for State Functions” on page 11-7             |
| “How to Set the State Function Inline Option” on page 11-8            |
| “Best Practices for Controlling State Function Inlining” on page 11-8 |

### Inlined Generated Code for State Functions

By default, the code generator uses an internal heuristic to determine whether to inline generated code for state functions. The heuristic takes into consideration an inlining threshold. As code grows and shrinks in size, generated code for state functions can be unpredictable.

If your model includes Stateflow objects and you have rigorous requirements for traceability between generated code and the corresponding state functions, you can override the default behavior. Use the state property `Function Inline Option` to explicitly force or prevent inlining of state functions.

#### What Happens When You Force Inlining

If you force inlining for a state, the code generator inlines code for state actions into the parent function. The parent function contains code for executing the state actions, outer transitions, and flow charts. It does not include code for empty state actions.

#### What Happens When You Prevent Inlining

If you prevent inlining for a state, the code generator produces these static functions for state *foo*.

| Function                        | Description                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>enter_atomic_foo</code>   | Marks <i>foo</i> active and performs entry actions.                                                                                                                                                                                                                                                                                                                                                      |
| <code>enter_internal_foo</code> | Calls default paths.                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>inner_default_foo</code>  | Executes flow charts that originate when an inner transition and default transition reach the same junction inside a state.<br><br>The code generator produces this function only when the flow chart is complex enough to exceed the inlining threshold.<br><br>In generated code, Stateflow software calls this function from both the <code>enter_internal_foo</code> and <code>foo</code> functions. |
| <code>foo</code>                | Checks for valid outer transitions and if none, performs during actions.                                                                                                                                                                                                                                                                                                                                 |
| <code>exit_atomic_foo</code>    | Performs exit actions and marks <i>foo</i> inactive.                                                                                                                                                                                                                                                                                                                                                     |
| <code>exit_internal_foo</code>  | Performs exit actions of the child substates and then exits <i>foo</i> .                                                                                                                                                                                                                                                                                                                                 |

Suppose the following chart is in model M.

If you prevent inlining for state A, the code generator produces this code.

```
static void M_inner_default_A(void);
static void M_exit_atomic_A(void);
static void M_A(void);
static void M_enter_atomic_A(void);
static void M_enter_internal_A(void);
```

## How to Set the State Function Inline Option

To set the function inlining property for a state:

- 1 Right-click inside the state and, from the context menu, select **Properties**.

The State properties dialog box opens.

- 2 For property **Function Inline Option**, select one of these values.

| Value    | Behavior                                                                                                                                                                  |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inline   | Forces inlining of state functions into the parent function, as long as the function is not part of a recursion. See “What Happens When You Force Inlining” on page 11-7. |
| Function | Prevents inlining of state functions. Generates up to six static functions for the state. See “What Happens When You Prevent Inlining” on page 11-7.                      |
| Auto     | Uses internal heuristics to determine whether or not to inline the state functions.                                                                                       |

- 3 Click **Apply**.

## Best Practices for Controlling State Function Inlining

| To                                                                                                               | Set Function Inline Option Property To   |
|------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| Generate a separate function for each action of a state and a separate function for each action of its substates | Function for the state and each substate |

| <b>To</b>                                                                                                            | <b>Set Function Inline Option Property To</b>       |
|----------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|
| Generate a separate function for each action of a state, but include code for the associated action of its substates | Function for the state and Inline for each substate |

## Air-Fuel Ratio Control System with Stateflow Charts

Generate code for an air-fuel ratio control system designed with Simulink® and Stateflow®.

Figures 1, 2, and 3 show relevant portions of the `sldemo_fuelsys` model, a closed-loop system containing a plant and controller. The plant validates the controller in simulation early in the design cycle. In this example, you generate code for the relevant controller subsystem, "fuel\_rate\_control". Figure 1 shows the top-level simulation model.

Use the command `rtwdemo_fuelsys` to open model `sldemo_fuelsys`. Then, compile the model to see the signal data types.

```
rtwdemo_fuelsys
sldemo_fuelsys([],[],[],'compile');
sldemo_fuelsys([],[],[],'term');
```

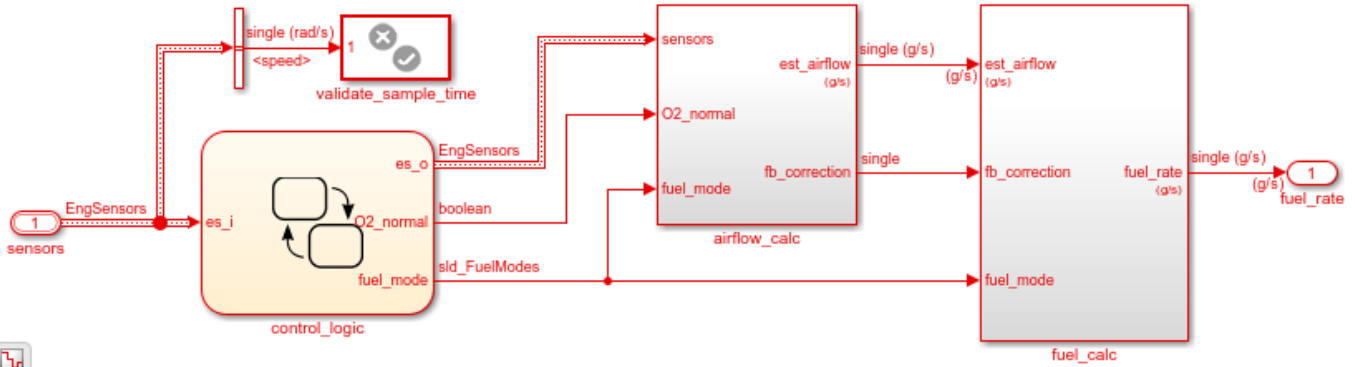

**Figure 1: Top-level model of the plant and controller**

The air-fuel ratio control system is comprised of Simulink® and Stateflow®. The control system is the portion of the model for which you generate code.

```
open_system('sldemo_fuelsys/fuel_rate_control');
```

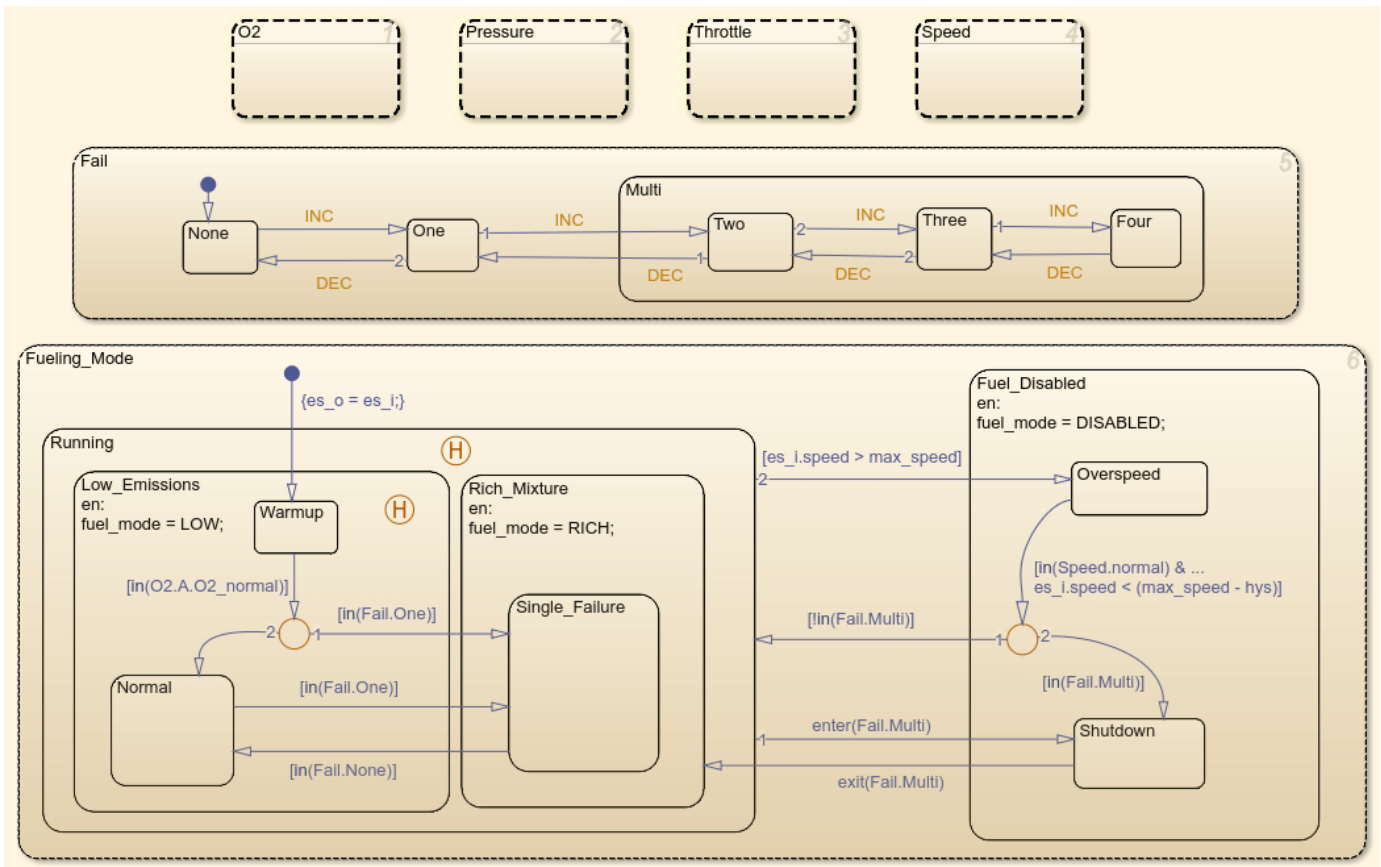

### Fuel Rate Control Subsystem

**Figure 2: The air-fuel ratio controller subsystem**

The control logic is a Stateflow® chart that specifies the different modes of operation.

```
open_system('sldemo_fuelsys/fuel_rate_control/control_logic');
```

**Figure 3: Air-fuel rate controller logic**

Close these windows.

```

close_system('sldemo_fuelsys/fuel_rate_control/airflow_calc');
close_system('sldemo_fuelsys/fuel_rate_control/fuel_calc');
close_system('sldemo_fuelsys/fuel_rate_control/control_logic');
hDemo.rt=sfroot;hDemo.m=hDemo.rt.find('-isa','Simulink.BlockDiagram');
hDemo.c=hDemo.m.find('-isa','Stateflow.Chart','-and','Name','control_logic');
hDemo.c.visible=false;
close_system('sldemo_fuelsys/fuel_rate_control');

```

### Configure and Build the Model with Embedded Coder®

To configure and build production ANSI® C/C++ code for the model, set model configuration parameter **System target file** to `ert.tlc` (Embedded Real-Time (ERT)). You can set the **System target file** parameter programmatically.

```
rtwconfiguredemo('sldemo_fuelsys','ERT');
```

Generate and inspect the code. You can navigate to the relevant code segments interactively by using **Previous** and **Next** buttons. From the chart context menu (right-click the Stateflow® block), select **C/C++ Code > Navigate to C/C++ Code**. Programmatically, use the `rtwtrace` utility.

```

slbuild('sldemo_fuelsys/fuel_rate_control');
rtwtrace('sldemo_fuelsys/fuel_rate_control/control_logic')

Starting build procedure for: fuel_rate_control
Successful completion of build procedure for: fuel_rate_control

```

Build Summary

Top model targets built:

| Model             | Action                      | Rebuild Reason                                   |
|-------------------|-----------------------------|--------------------------------------------------|
| fuel_rate_control | Code generated and compiled | Code generation information file does not exist. |

Build duration: 0h 0m 57.439s

ans =

```
'&sid=sldemo_fuelsys:107&inputLocs={"data": [{"file": "fuel_rate_control.c", "line": ["21", "10"]}]}'
```

View the air-fuel ratio control logic in the generated code.

```

rtwdemodbtype('fuel_rate_control_ert_rtw/fuel_rate_control.c',...
 /* Function for Chart:', 'case IN_Warmup:',1,0);

/* Function for Chart: '<S1>/control_logic' */
static void Fueling_Mode(const int32_T *sfEvent)
{
 switch (rtDWork.bitsForTID0.is_Fueling_Mode) {
 case IN_Fuel_Disabled:
 rtDWork.fuel_mode = DISABLED;
 switch (rtDWork.bitsForTID0.is_Fuel_Disabled) {
 case IN_Overspeed:
 /* Inport: '<Root>/sensors' */
 if ((rtDWork.bitsForTID0.is_Speed == IN_normal) && (rtU.sensors.speed <

```

```

 603.0F)) {
if (rtDWork.bitsForTID0.is_Fail != IN_Multi) {
 rtDWork.bitsForTID0.is_Fuel_Disabled = IN_NO_ACTIVE_CHILD;
 rtDWork.bitsForTID0.is_Fueling_Mode = IN_Running;

 /* The fuel is actively controlled while in this state. */
 switch (rtDWork.bitsForTID0.was_Running) {
 case IN_Low_Emissions:
 rtDWork.bitsForTID0.is_Running = IN_Low_Emissions;
 rtDWork.bitsForTID0.was_Running = IN_Low_Emissions;
 rtDWork.fuel_mode = LOW;
 switch (rtDWork.bitsForTID0.was_Low_Emissions) {
 case IN_Normal:
 rtDWork.bitsForTID0.is_Low_Emissions = IN_Normal;
 rtDWork.bitsForTID0.was_Low_Emissions = IN_Normal;

 /* All sensors are in correct operating modes, so effective closed-loop mixture control
 break;

```

Close the model and code generation report.

```

clear hDemo;
rtwdemoclean;
close_system('sldemo_fuelsys',0);

```

## S-Functions and Code Generation

You use S-functions to extend Simulink support for simulation and code generation. For example, you can use them to:

- Represent custom algorithms
- Interface existing external code with Simulink model and the generated code
- Represent device drivers for interfacing with hardware
- Generate highly optimized code for embedded systems
- Verify code generated for a subsystem as part of a Simulink simulation

The application program interface (API) for writing S-functions allows you to implement generic algorithms in the Simulink environment with a great deal of flexibility. If you intend to use S-functions in a model for code generation, the level of flexibility can vary. For example, it is not possible to access the MATLAB workspace from an S-function that you use with the code generator. This topic explains conditions to be aware of for using S-functions. However, using the techniques presented in this topic, you can create S-functions for most applications that work with the generated code.

Although S-functions provide a generic and flexible solution for implementing complex algorithms in a model, the underlying API incurs overhead in terms of memory and computation resources. Most often the additional resources are acceptable for real-time rapid prototyping systems. Often, though, additional resources are unavailable in real-time embedded applications. You can minimize memory and computational requirements by using the Target Language Compiler technology provided with the code generator to inline your S-functions. If you are producing an S-function for existing external code, consider using the Legacy Code Tool to generate your S-function and relevant TLC file.

This topic assumes that you understand the following concepts:

- Level-2 S-functions
- Target Language Compiler (TLC) scripting
- How the code generator produces and builds C/C++ code

---

**Notes** This information is for code generator users. Even if you do not currently use the code generator, follow these practices when writing S-functions, especially if you are creating general-purpose S-functions.

---

### Types of S-Functions

Examples for which you might choose to implement an S-function for simulation and code generation include:

- 1 “I’m not concerned with efficiency. I want to write one version of my algorithm and have it work in the Simulink and code generator products automatically.”
- 2 “I want to implement a highly optimized algorithm in the Simulink and code generator products that looks like a built-in block and generates efficient code.”
- 3 “I have a lot of hand-written code that I need to interface. I want to call my function from the Simulink and code generator products efficiently.”

Respectively, the preceding situations map to the following MathWorks terminology:

- 1 Noninlined S-function
- 2 Inlined S-function
- 3 Auto-generated S-function for external code

### Noninlined S-Functions

A noninlined S-function is a C or C++ MEX S-function that is treated identically by the Simulink engine and generated code. In general, you implement your algorithm once according to the S-function API. The Simulink engine and generated code call the S-function routines (for example, `mdlOutputs`) during model execution.

Additional memory and computation resources are required for each instance of a noninlined S-Function block. However, this routine of incorporating algorithms into models and code generation applications is typical during the prototyping phase of a project where efficiency is not important. The advantage gained by forgoing efficiency is the ability to change model parameters and structures rapidly.

Writing a noninlined S-function does not involve TLC coding. Noninlined S-functions are the default case for the build process in the sense that once you build a MEX S-function in your model, there is no additional preparation before pressing **Ctrl+B** to build your model.

Some restrictions exist concerning the names and locations of noninlined S-function files when generating makefiles. See “Write Noninlined S-Function” on page 12-95.

### Inlined S-Functions

For S-functions to work in the Simulink environment, some overhead code is generated. When the code generator produces code from models that contain S-functions (without `sfunction.tlc` files), it embeds some of this overhead code in the generated code. If you want to optimize your real-time code and eliminate some of the overhead code, you must *inline* (or embed) your S-functions. This involves writing a TLC (`sfunction.tlc`) file that eliminates overhead code from the generated code. The Target Language Compiler processes `sfunction.tlc` files to define how to inline your S-function algorithm in the generated code.

---

**Note** Do not confuse the term *inline* with the C++ *inline* keyword. Inline means to specify text in place of the call to the general S-function API routines (for example, `mdlOutputs`). For example, when a TLC file is used to inline an S-function, the generated code contains the C/ C++ code that normally appears within the S-function routines and the S-function itself that has been removed from the build process.

---

A fully inlined S-function builds your algorithm (block) into generated code in a manner that is indistinguishable from a built-in block. Typically, a fully inlined S-function requires you to implement your algorithm twice: once for the Simulink model (C/C++ MEX S-function) and once for code generation (TLC file). The complexity of the TLC file depends on the complexity of your algorithm and the level of efficiency you try to achieve in the generated code. TLC files vary from simple to complex in structure. See “Inlining S-Functions”.

### Auto-generated S-Functions for Legacy or Custom Code

If you need to invoke hand-written C/C++ code in your model, consider using the Simulink Legacy Code Tool. The Legacy Code Tool can automate the generation of a fully inlined S-function and a corresponding TLC file based on information that you register in a Legacy Code Tool data structure.

For more information, see “Integrate C Functions Using Legacy Code Tool” and see “Import Calls to External Code into Generated Code with Legacy Code Tool” on page 12-6.

## Files Required for Implementing Noninlined and Inlined S-Functions

This topic briefly describes what files and functions you need to create noninlined and inlined S-functions.

- Noninlined S-functions require the C or C++ MEX S-function source code (*sfunction.c* or *sfunction.cpp*).
- Fully inlined S-functions require an *sfunction.tlc* file. Fully inlined S-functions produce the optimal code for a parameterized S-function. This is an S-function that operates in a specific mode dependent upon fixed S-function parameters that do not change during model execution. For a given operating mode, the *sfunction.tlc* file specifies the exact code that is generated to implement the algorithm for that mode. For example, the direct-index lookup table S-function in “Write Fully Inlined S-Functions with mdlRTW Routine” on page 12-106 contains two operating modes — one for evenly spaced *x*-data and one for unevenly spaced *x*-data.

---

**Note** Fully inlined S-functions that are generated to invoke legacy or custom C/C++ code also require an *sfunction.tlc* file, which is generated by Legacy Code Tool.

---

Fully inlined S-functions might require the placement of the mdlRTW routine in your S-function MEX-file *sfunction.c* or *sfunction.cpp*. The mdlRTW routine lets you place information in *model.rtw.model.rtw*. *model.rtw* is the record file that specifies a model, and which the code generator invokes the Target Language Compiler to process before executing *sfunction.tlc* when generating code.

Including a mdlRTW routine is useful when you want to introduce non-tunable parameters into your TLC file. Such parameters are used to determine which operating mode is active in a given instance of the S-function. Based on this information, the TLC file for the S-function can generate highly efficient, optimal code for that operating mode.

## Guidelines for Writing S-Functions that Support Code Generation

- You can use C/C++ MEX, MATLAB language, and Fortran MEX S-functions with code generation.
- You can inline S-functions for code generation by providing an inlining TLC file. See S-Function Inlining in “Target Language Compiler”. MATLAB and Fortran MEX S-functions must be inlined. C/C++ MEX S-functions can be inlined for code efficiency, or noninlined.
- To automatically generate a fully inlined C MEX S-function for invoking legacy or custom code, use the Legacy Code Tool. For more information, see “Integrate C Functions Using Legacy Code Tool” and see “Import Calls to External Code into Generated Code with Legacy Code Tool”.
- If code efficiency is not an overriding consideration, for example, if you are rapid prototyping, you can choose not to inline a C/C++ MEX S-function. For more information, see “Write Noninlined S-Function” on page 12-95.

### Legacy Code Tool and Code Generation

You can use the Simulink Legacy Code Tool to generate fully inlined C MEX S-functions for legacy or custom code. The S-functions are optimized for embedded components, such as device drivers and lookup tables, and they call existing C or C++ functions.

**Note** The Legacy Code Tool can interface with C++ functions, but not C++ objects. To work around this issue so that the tool can interface with C++ objects, see “Legacy Code Tool Limitations”.

You can use the tool to:

- Compile and build the generated S-function for simulation.
- Generate a masked S-Function block that is configured to call the existing external code.

If you want to include these types of S-functions in models for which you intend to generate code, use the tool to generate a TLC block file. The TLC block file specifies how the generated code for a model calls the existing C or C++ function.

If the S-function depends on files in folders other than the folder containing the S-function dynamically loadable executable file, use the tool to generate an *sFunction\_makecfg.m* or *rtwmakecfg.m* file for the S-function. Generating the file maintains those dependencies when you build a model that includes the S-function. For example, for some applications, such as custom targets, you might want to locate files in a target-specific location. The build process looks for *sFunction\_makecfg.m* or *rtwmakecfg.m* in the same folder as the S-function dynamically loadable executable and calls the function in the file.

For more information, see “Integrate C Functions Using Legacy Code Tool”.

### Generate Inlined S-Function Files for Code Generation

Depending on the code generation requirements of your application, to generate code for a model that uses the S-function, do either of the following:

- Generate one *.cpp* file for the inlined S-function. In the Legacy Code Tool data structure, set the value of the `Options.singleCPPMexFile` field to `true` before generating the S-function source file from your existing C function. For example:

```
def.Options.singleCPPMexFile = true;
legacy_code('sfcn_cmex_generate', def);
```

- Generate a source file and a TLC block file for the inlined S-function. For example:

```
def.Options.singleCPPMexFile = false;
legacy_code('sfcn_cmex_generate', def);
legacy_code('sfcn_tlc_generate', def);
```

### singleCPPMexFile Limitations

You cannot set the `singleCPPMexFile` field to `true` if

- `Options.language='C++'`
- You use one of the following Simulink objects with the `IsAlias` property set to `true`:
  - `Simulink.Bus`
  - `Simulink.AliasType`
  - `Simulink.NumericType`
- The Legacy Code Tool function specification includes a `void*` or `void**` to represent scalar work data for a state argument
- `HeaderFiles` field of the Legacy Code Tool structure specifies multiple header files

### Apply Code Style Settings to Legacy Functions

To apply the model configuration parameters for code style to a legacy function:

- 1 Initialize the Legacy Code Tool data structure. For example:

```
def = legacy_code('initialize');
```

- 2 In the data structure, set the value of the `Options.singleCPPMexFile` field to `true`. For example:

```
def.Options.singleCPPMexFile = true;
```

To check the setting, enter:

```
def.Options.singleCPPMexFile
```

### singleCPPMexFile Limitations

You cannot set the `singleCPPMexFile` field to `true` if

- `Options.language='C++'`
- You use one of the following Simulink objects with the `IsAlias` property set to `true`:
  - `Simulink.Bus`
  - `Simulink.AliasType`
  - `Simulink.NumericType`
- The Legacy Code Tool function specification includes a `void*` or `void**` to represent scalar work data for a state argument
- `HeaderFiles` field of the Legacy Code Tool structure specifies multiple header files

## Address Dependencies on Files in Different Locations

By default, the Legacy Code Tool assumes that files on which an S-function depends reside in the same folder as the dynamically loadable executable file for the S-function. If your S-function depends on files that reside elsewhere and you are using the template makefile build process, generate an *sFunction\_makecfg.m* or *rtwmakecfg.m* file for the S-function. For example, you might generate this file if your Legacy Code Tool data structure defines compilation resources as path names.

To generate the *sFunction\_makecfg.m* or *rtwmakecfg.m* file, call the `legacy_code` function with `'sfcn_makecfg_generate'` or `'rtwmakecfg_generate'` as the first argument, and the name of the Legacy Code Tool data structure as the second argument. For example:

```
legacy_code('sfcn_makecfg_generate', lct_spec);
```

If you use multiple registration files in the same folder and generate an S-function for each file with a single call to `legacy_code`, the call to `legacy_code` that specifies `'sfcn_makecfg_generate'` or `'rtwmakecfg_generate'` must be common to all registration files. For more information, see “Handling Multiple Registration Files”.

For example, if you define `defs` as an array of Legacy Code Tool structures, you call `legacy_code` with `'sfcn_makecfg_generate'` once.

```
defs = [defs1(:);defs2(:);defs3(:)];
legacy_code('sfcn_makecfg_generate', defs);
```

For more information, see “Build Support for S-Functions”.

## Deploy S-Functions for Simulation and Code Generation

You can deploy the S-functions that you generate with the Legacy Code Tool so that other people can use them. To deploy an S-function for simulation and code generation, share the following files:

- Registration file
- Compiled dynamically loadable executable
- TLC block file
- *sFunction\_makecfg.m* or *rtwmakecfg.m* file
- Header, source, and include files on which the generated S-function depends

When you use these deployed files:

- Before using the deployed files in a Simulink model, add the folder that contains the S-function files to the MATLAB path.
- If the Legacy Code Tool data structure registers required files as absolute paths and the location of the files changes, regenerate the *sFunction\_makecfg.m* or *rtwmakecfg.m* file.

## Integrate External C++ Objects

The Legacy Code Tool can interface with C++ functions, but not C++ objects. Using the previous example as a starting point, here is an example of how you can work around this limitation.

- Modify the class definition for `adder` in a new file `adder_cpp.hpp`. Add three new macros that dynamically allocate a new `adder` object, invoke the method `add_one()`, and free the memory

allocated. Each macro takes a pointer to an `adder` object. Because each function called by the Legacy Code Tool must have a C-like signature, the pointer is cached and passed as a `void*`. Then you must explicitly cast to `adder*` in the macro. The new class definition for `adder`:

```
#ifndef _ADDER_CPP_
#define _ADDER_CPP_

class adder {
private:
 int int_state;
public:
 adder(): int_state(0) {};
 int add_one(int increment);
 int get_val() {return int_state;};
};

// Method wrappers implemented as macros
#define createAdder(work1) \
 *(work1) = new adder

#define deleteAdder(work1) \
 delete(static_cast<adder*>(*(work1)))

#define adderOutput(work1, u1) \
 (static_cast<adder*> ((work1)))->add_one(u1)

#endif /* _ADDER_CPP_ */
```

- Update `adder_cpp.cpp`. With the class modification, instead of one global instance, each generated S-function manages its own `adder` object.

```
#include "adder_cpp.hpp"

int adder::add_one(int increment)
{
 int_state += increment;
 return int_state;
}
```

- Update `rtwdemo_sfun_adder_cpp.cpp` with the following changes:
  - `StartFcnSpec` calls the macro that allocates a new `adder` object and caches the pointer.
 

```
def.StartFcnSpec = 'createAdder(void **work1)';
```
  - `OutputFcnSpec` calls the macro that invokes the method `add_one()` and provides the S-function specific `adder` pointer object.
 

```
def.OutputFcnSpec = 'int32 y1 = adderOutput(void *work1, int32 u1)';
```
  - `TerminateFcnSpec` calls the macro that frees the memory.
 

```
def.TerminateFcnSpec = 'deleteAdder(void **work1)';
```

## Legacy Code Tool Examples

You can use the Simulink Legacy Code Tool to generate fully inlined C MEX S-functions for legacy or custom code. The S-functions are optimized for embedded components, such as device drivers and lookup tables, and they call existing C or C++ functions. These examples show how to use the Legacy Code Tool to integrate a variety of external functions.

### Integrate External C Functions That Pass Input Arguments By Value Versus Address

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their input arguments by value versus address.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

#### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototypes of the legacy functions being called in this example are:

- `FLT filterV1(const FLT signal, const FLT prevSignal, const FLT gain)`
- `FLT filterV2(const FLT* signal, const FLT prevSignal, const FLT gain)`

FLT is a typedef to float. The legacy source code is in the files `your_types.h`, `myfilter.h`, `filterV1.c`, and `filterV2.c`.

Note the difference in the `OutputFcnSpec` defined in the two structures; the first case specifies that the first input argument is passed by value, while the second case specifies pass by pointer.

```

defs = [];

% rtwdemo_sfunk_filterV1
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfunk_filterV1';
def.OutputFcnSpec = 'single y1 = filterV1(single u1, single u2, single p1)';
def.HeaderFiles = {'myfilter.h'};
def.SourceFiles = {'filterV1.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfunk_filterV2
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfunk_filterV2';
def.OutputFcnSpec = 'single y1 = filterV2(single u1[], single u2, single p1)';

```

```
def.HeaderFiles = {'myfilter.h'};
def.SourceFiles = {'filterV2.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];
```

### Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-functions call the legacy functions in simulation. The source code for the S-functions is in the files `rtwdemo_sfun_filterV1.c` and `rtwdemo_sfun_filterV2.c`.

```
legacy_code('sfcn_cmex_generate', defs);
```

### Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```
Start Compiling rtwdemo_sfun_filterV1
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('rtwdemo_sfun_filterV1.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_filterV1
Exit

Start Compiling rtwdemo_sfun_filterV2
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('rtwdemo_sfun_filterV2.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_filterV2
Exit
```

### Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function `legacy_code()` again with the first input set to 'sfcn\_tlc\_generate' to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are `rtwdemo_sfun_filterV1.tlc` and `rtwdemo_sfun_filterV2.tlc`.

```
legacy_code('sfcn_tlc_generate', defs);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block files, you can call the function `legacy_code()` again with the first input set to 'rtwmakecfg\_generate' to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and

you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', defs);
```

### Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model.

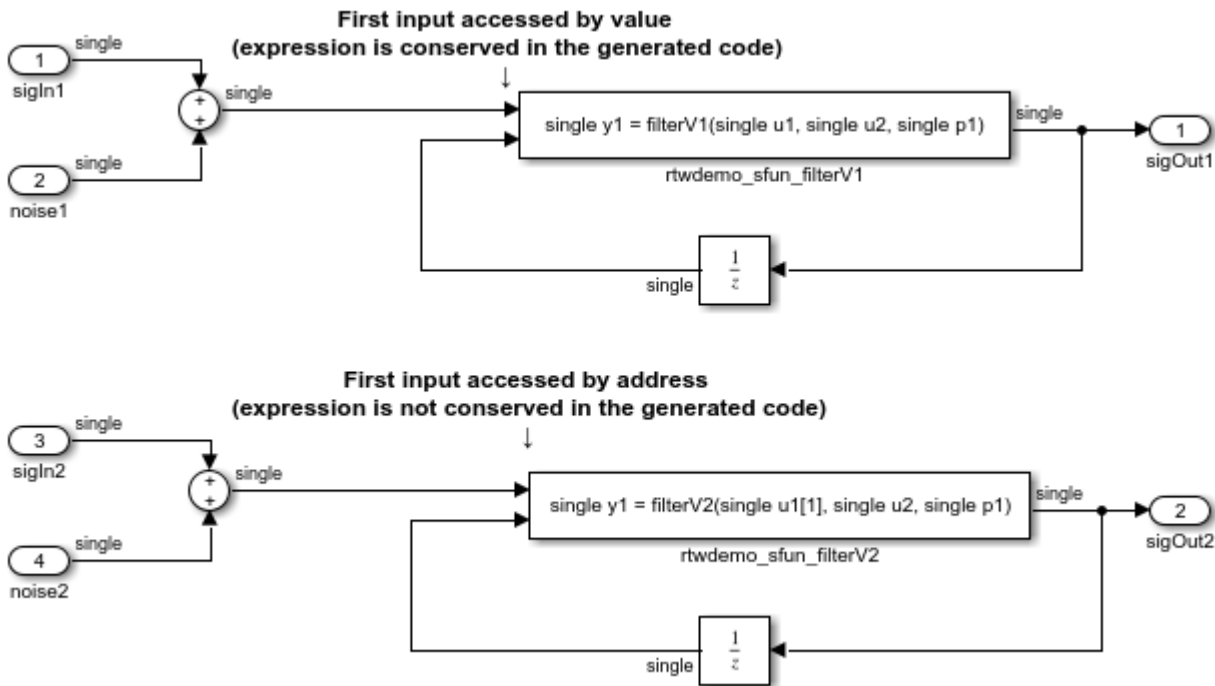

```
legacy_code('slblock_generate', defs);
```

### Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_filter` shows integration of the model with the legacy code. The subsystem `TestFilter` serves as a harness for the calls to the legacy C functions via the generate S-functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_filter')
open_system('rtwdemo_lct_filter/TestFilter')
sim('rtwdemo_lct_filter')
```

## Integrate External C Functions That Pass the Output Argument As a Return Argument

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their output as a return argument.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
FLT gainScalar(const FLT in, const FLT gain)
```

FLT is a typedef to float. The legacy source code is in the files `your_types.h`, `gain.h`, and `gainScalar.c`.

```
% rtwdemo_sfun_gain_scalar
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_gain_scalar';
```

```
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_gain_scalar.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
Start Compiling rtwdemo_sfun_gain_scalar
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_gain_scalar.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_gain_scalar
Exit
```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to 'sfcn\_tlc\_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_gain_scalar.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to 'rtwmakecfg\_generate' to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

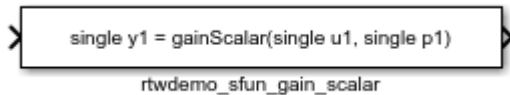

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to 'slblock\_generate' to generate a masked S-function block that calls that S-

function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

### Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_gain` shows integration of the model with the legacy code. The subsystem `TestGain` serves as a harness for the call to the legacy C function via the generate S-function.

```
open_system('rtwdemo_lct_gain')
open_system('rtwdemo_lct_gain/TestGain')
sim('rtwdemo_lct_gain')
```

## Integrate External C++ Object Methods

Integrate legacy C++ object methods by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C++ MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a block TLC file and optional `rtwmakecfg.m` file that calls the legacy code during code generation.

### Provide the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The definition of the legacy C++ class in this example is:

```
class adder {
private:
 int int_state;
public:
 adder();
 int add_one(int increment);
 int get_val();
};
```

The legacy source code is in the files `adder_cpp.h` and `adder_cpp.cpp`.

```

% rtwdemo_sfun_adder_cpp
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_adder_cpp';
def.StartFcnSpec = 'createAdder()';
def.OutputFcnSpec = 'int32 y1 = adderOutput(int32 u1)';
def.TerminateFcnSpec = 'deleteAdder()';
def.HeaderFiles = {'adder_cpp.h'};
def.SourceFiles = {'adder_cpp.cpp'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
def.Options.language = 'C++';
def.Options.useTlcWithAccel = false;

```

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_adder_cpp.cpp`.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```

Start Compiling rtwdemo_sfun_adder_cpp
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019'.
MEX completed successfully.
 mex('rtwdemo_sfun_adder_cpp.cpp', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\
Building with 'Microsoft Visual C++ 2019'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_adder_cpp
Exit

```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again. Set the first input to 'sfcn\_tlc\_generate' to generate a TLC block file that supports code generation through Simulink® Coder™. If the TLC block file is not created and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_adder_cpp.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an rtwmakecfg.m File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again. Set the first input to 'rtwmakecfg\_generate' to generate an `rtwmakecfg.m` file that supports code generation through Simulink® Coder™. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

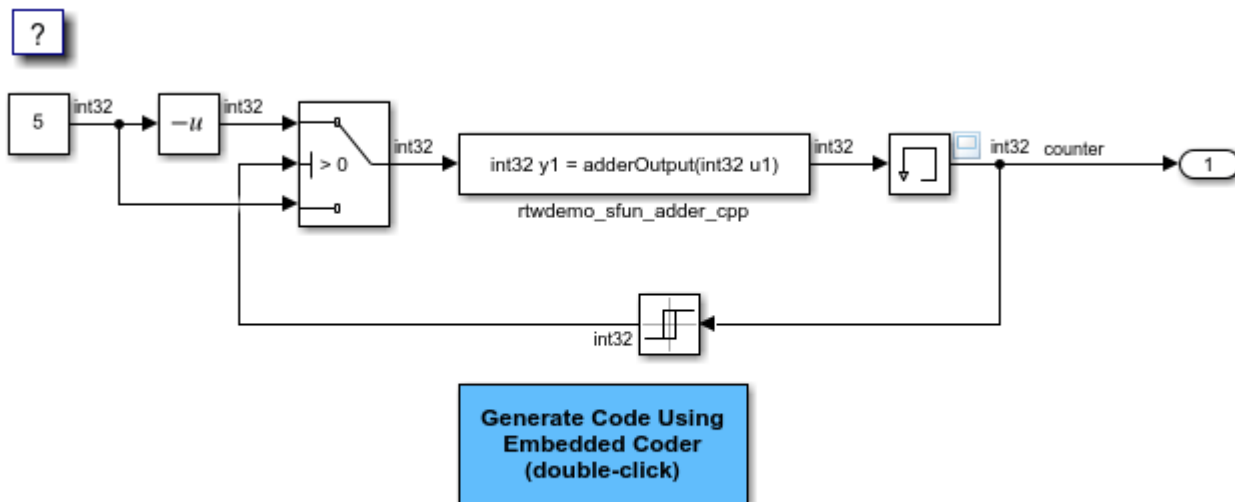

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again. Set the first input to `'slblock_generate'` to generate a masked S-function block that is configured to call that S-function. The software places the block in a new model. You can copy the block to an existing model.

```
% legacy_code('slblock_generate', def);
```

### Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_cpp` shows integration with the legacy code.

```
open_system('rtwdemo_lct_cpp')
sim('rtwdemo_lct_cpp')
```

Copyright 1990-2020 The MathWorks, Inc.

## Integrate External C Functions That Pass Input and Output Arguments as Parameters with a Fixed-Point Data Type

Integrate legacy C functions that pass their inputs and outputs by using parameters of a fixed-point data type with the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

## Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
myFixpt timesS16(const myFixpt in1, const myFixpt in2, const uint8_T fracLength)
```

`myFixpt` is logically a fixed point data type, which is physically a typedef to a 16-bit integer:

```
myFixpt = Simulink.NumericType;
myFixpt.DataTypeMode = 'Fixed-point: binary point scaling';
myFixpt.Signed = true;
myFixpt.WordLength = 16;
myFixpt.FractionLength = 10;
myFixpt.IsAlias = true;
myFixpt.HeaderFile = 'timesFixpt.h';
```

The legacy source code is in the files `timesFixpt.h`, and `timesS16.c`.

```
% rtwdemo_sfun_gain_fixpt
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_gain_fixpt';
def.OutputFcnSpec = 'myFixpt y1 = timesS16(myFixpt u1, myFixpt p1, uint8 p2)';
def.HeaderFiles = {'timesFixpt.h'};
def.SourceFiles = {'timesS16.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

## Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_gain_fixpt.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

## Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
Start Compiling rtwdemo_sfun_gain_fixpt
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('rtwdemo_sfun_gain_fixpt.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\T
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_gain_fixpt
Exit
```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again. Set the first input to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_gain_fixpt.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

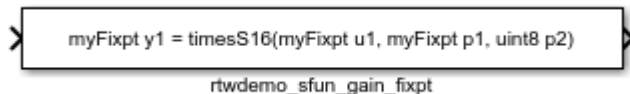

After you create the TLC block file, you can call the function `legacy_code()` again. Set the first input to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file that supports code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again. Set the first input to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. You can copy the block to an existing model.

```
legacy_code('slblock_generate', def);
```

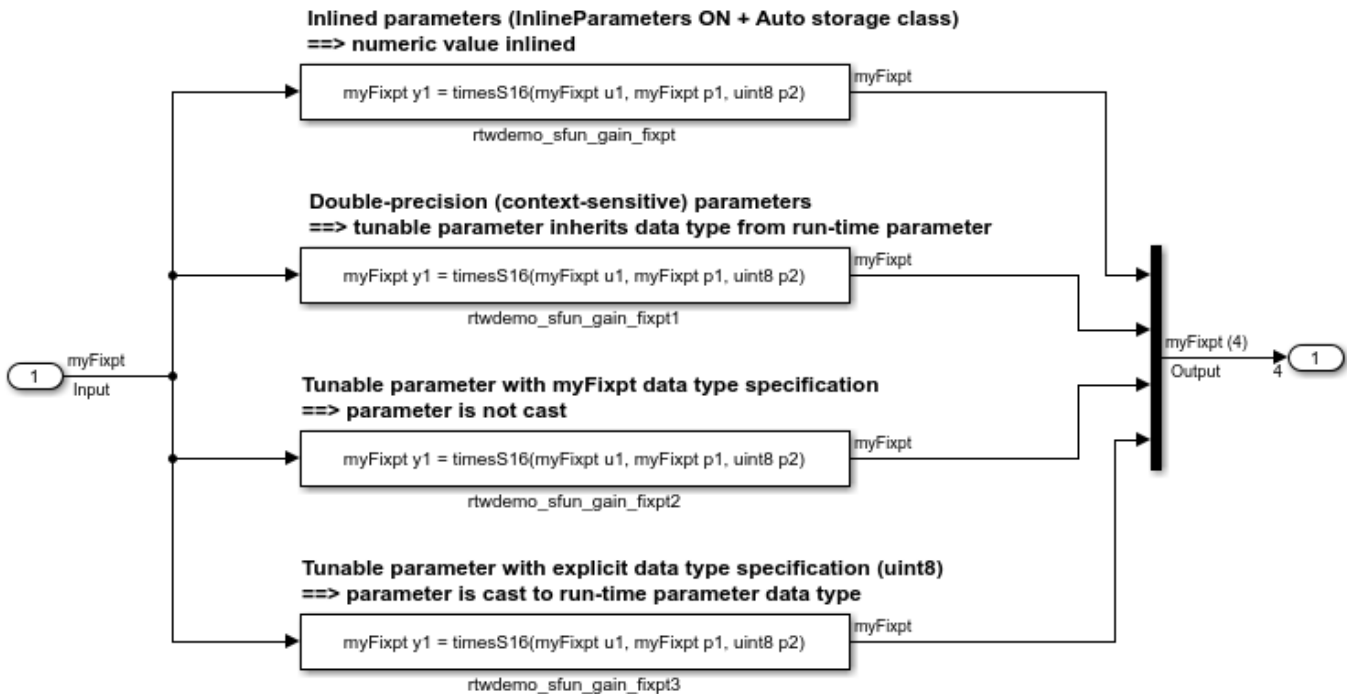

### Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_fixpt_params` shows integration of the model with the legacy code. The subsystem `TestFixpt` serves as a harness for the call to the legacy C function via the generated S-function.

```
open_system('rtwdemo_lct_fixpt_params')
open_system('rtwdemo_lct_fixpt_params/TestFixpt')
sim('rtwdemo_lct_fixpt_params')
```

## Integrate External C Functions That Pass Input and Output Arguments as Signals with a Fixed-Point Data Type

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their inputs and outputs by using parameters of fixed-point data type.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
myFixpt timesS16(const myFixpt in1, const myFixpt in2, const uint8_T fracLength)
```

`myFixpt` is logically a fixed-point data type, which is physically a typedef to a 16-bit integer:

```
myFixpt = Simulink.NumericType;
myFixpt.DataTypeMode = 'Fixed-point: binary point scaling';
myFixpt.Signed = true;
```

```
myFixpt.WordLength = 16;
myFixpt.FractionLength = 10;
myFixpt.IsAlias = true;
myFixpt.HeaderFile = 'timesFixpt.h';
```

The legacy source code is in the files `timesFixpt.h`, and `timesS16.c`.

```
% rtwdemo_sfun_times_s16
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_times_s16';
def.OutputFcnSpec = 'myFixpt y1 = timesS16(myFixpt u1, myFixpt u2, uint8 p1)';
def.HeaderFiles = {'timesFixpt.h'};
def.SourceFiles = {'timesS16.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument `def`, call the function `legacy_code()` again with the first input set to `'sfcn_cmex_generate'`. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_times_s16.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to `'compile'`.

```
legacy_code('compile', def);
```

```
Start Compiling rtwdemo_sfun_times_s16
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC...
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('rtwdemo_sfun_times_s16.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP...
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_times_s16
Exit
```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_times_s16.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and

you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

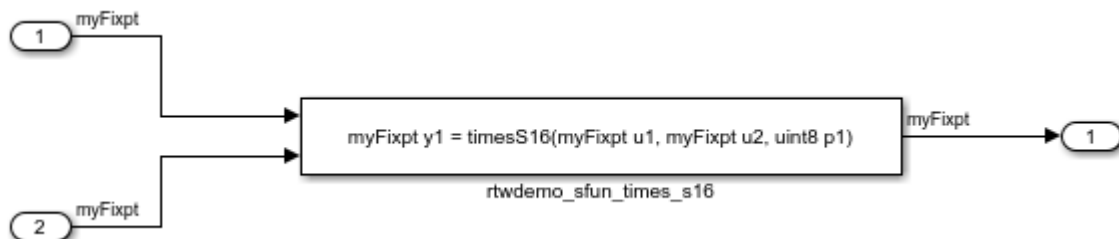

```
legacy_code('slblock_generate', def);
```

### Show the Integration of the Model with Legacy Code

The model `rtwdemo_lct_fixpt_signals` shows integration of the model with the legacy code. The subsystem `TestFixpt` serves as a harness for the call to the legacy C function via the generated S-function.

```
open_system('rtwdemo_lct_fixpt_signals')
open_system('rtwdemo_lct_fixpt_signals/TestFixpt')
sim('rtwdemo_lct_fixpt_signals')
```

## Integrate External C Functions with Instance-Specific Persistent Memory

Integrate legacy C functions that use instance-specific persistent memory by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

## Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototypes of the legacy functions being called in this example are:

```
void memory_bus_init(COUNTERBUS *mem, int32_T upper_sat, int32_T lower_sat);
```

```
void memory_bus_step(COUNTERBUS *input, COUNTERBUS *mem, COUNTERBUS *output);
```

`mem` is an instance-specific persistent memory for applying a one integration step delay. `COUNTERBUS` is a struct typedef defined in `counterbus.h` and implemented with a `Simulink.Bus` object in the base workspace. The legacy source code is in the files `memory_bus.h`, and `memory_bus.c`.

```
evalin('base','load rtwdemo_lct_data.mat')

% rtwdemo_sfun_work
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_work';
def.InitializeConditionsFcnSpec = ...
 'void memory_bus_init(COUNTERBUS work1[1], int32 p1, int32 p2)';
def.OutputFcnSpec = ...
 'void memory_bus_step(COUNTERBUS u1[1], COUNTERBUS work1[1], COUNTERBUS y1[1])';
def.HeaderFiles = {'memory_bus.h'};
def.SourceFiles = {'memory_bus.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

## Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_work.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

## Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
Start Compiling rtwdemo_sfun_work
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('rtwdemo_sfun_work.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bd
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_work
Exit
```

## Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_work.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

## Generate an `rtwmakecfg.m` File for Code Generation

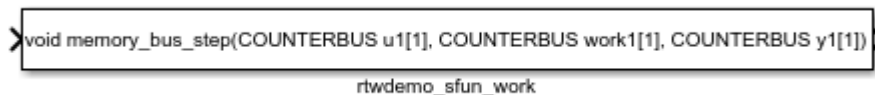

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

## Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

## Show the Integration of the Model with Legacy Code

The model `rtwdemo_lct_work` shows integration of the model with the legacy code. The subsystem `memory_bus` serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_work')
open_system('rtwdemo_lct_work/memory_bus')
sim('rtwdemo_lct_work')
```

## Integrate External C Functions That Use Structure Arguments

Integrate legacy C functions with structure arguments that use Simulink® buses with the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
counterbusFcn(COUNTERBUS *u1, int32_T u2, COUNTERBUS *y1, int32_T *y2)
```

COUNTERBUS is a struct typedef defined in `counterbus.h` and implemented with a `Simulink.Bus` object in the base workspace. The legacy source code is in the files `counterbus.h`, and `counterbus.c`.

```
evalin('base','load rtwdemo_lct_data.mat')

% rtwdemo_sfun_counterbus
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_counterbus';
def.OutputFcnSpec = ...
 'void counterbusFcn(COUNTERBUS u1[1], int32 u2, COUNTERBUS y1[1], int32 y2[1])';
def.HeaderFiles = {'counterbus.h'};
def.SourceFiles = {'counterbus.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_counterbus.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
Start Compiling rtwdemo_sfun_counterbus
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('rtwdemo_sfun_counterbus.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\T
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_counterbus
Exit
```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfuns_counterbus.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

### Show the Integration of the Model with Legacy Code

The model `rtwdemo_lct_bus` shows integration of the model with the legacy code. The subsystem `TestCounter` serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_bus')
open_system('rtwdemo_lct_bus/TestCounter')
sim('rtwdemo_lct_bus')
```

## Integrate External C Functions That Pass Input and Output Arguments as Signals with Complex Data

Integrate legacy C functions using complex signals with the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
void cplx_gain(creal_T *input, creal_T *gain, creal_T *output);
```

`creal_T` is the complex representation of a double. The legacy source code is in the files `cplxgain.h`, and `cplxgain.c`.

```
% rtwdemo_sfun_gain_scalar
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_cplx_gain';
def.OutputFcnSpec = ...
 ['void cplx_gain(complex<double> u1[1], ...
 'complex<double> p1[1], complex<double> y1[1])'];
def.HeaderFiles = {'cplxgain.h'};
def.SourceFiles = {'cplxgain.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_cplx_gain.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

## Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
Start Compiling rtwdemo_sfun_cplx_gain
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_cplx_gain.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TE
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_cplx_gain
Exit
```

## Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to 'sfcn\_tlc\_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_cplx_gain.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

## Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to 'rtwmakecfg\_generate' to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

## Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to 'slblock\_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

## Show the Integration of the Model with Legacy Code

The model `rtwdemo_lct_cplxgain` shows integration of the model with the legacy code. The subsystem `complex_gain` serves as a harness for the call to the legacy C function via the generate S-function.

```

if isempty(find_system('SearchDepth',0,'Name','rtwdemo_lct_cplxgain'))
 open_system('rtwdemo_lct_cplxgain')
 open_system('rtwdemo_lct_cplxgain/complex_gain')
 sim('rtwdemo_lct_cplxgain')
end

```

## Integrate External C Functions That Pass Arguments That Have Inherited Dimensions

This example shows how to use the Legacy Code Tool to integrate legacy C functions whose arguments have inherited dimensions.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototypes of the legacy functions being called in this example are:

- `void mat_add(real_T *u1, real_T *u2, int32_T nbRows, int32_T nbCols, real_T *y1)`
- `void mat_mult(real_T *u1, real_T *u2, int32_T nbRows1, int32_T nbCols1, int32_T nbCols2, real_T *y1)`

`real_T` is a typedef to `double`, and `int32_T` is a typedef to a 32-bit integer. The legacy source code is in the files `mat_ops.h`, and `mat_ops.c`.

```
defs = [];
```

```

% rtwdemo_sfuns_mat_add
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfuns_mat_add';
def.OutputFcnSpec = ['void mat_add(double u1[], double u2[], ' ...
 'int32 u3, int32 u4, double y1[size(u1,1)][size(u1,2)]];
def.HeaderFiles = {'mat_ops.h'};
def.SourceFiles = {'mat_ops.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];

```

```
% rtwdemo_sfuns_mat_mult
```

```

def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_mat_mult';
def.OutputFcnSpec = ['void mat_mult(double u1[p1][p2], double u2[p2][p3], ...
 'int32 p1, int32 p2, int32 p3, double y1[p1][p3)'];
def.HeaderFiles = {'mat_ops.h'};
def.SourceFiles = {'mat_ops.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];

```

### Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-functions call the legacy functions during simulation. The source code for the S-function is in the files `rtwdemo_sfun_mat_add.c` and `rtwdemo_sfun_mat_mult.c`.

```
legacy_code('sfcn_cmex_generate', defs);
```

### Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```

Start Compiling rtwdemo_sfun_mat_add
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_mat_add.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_mat_add
Exit

Start Compiling rtwdemo_sfun_mat_mult
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_mat_mult.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_mat_mult
Exit

```

### Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function `legacy_code()` again with the first input set to 'sfcn\_tlc\_generate' to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are `rtwdemo_sfun_mat_add.tlc` and `rtwdemo_sfun_mat_mult.tlc`.

```
legacy_code('sfcn_tlc_generate', defs);
```

### Generate an `rtwmakecfg.m` File for Code Generation

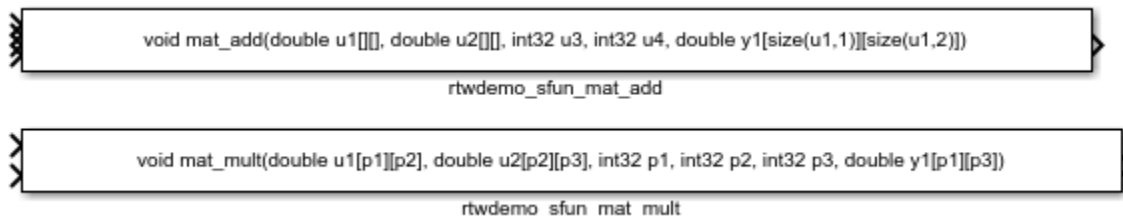

After you create the TLC block files, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', defs);
```

### Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model

```
legacy_code('slblock_generate', defs);
```

### Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_inherit_dims` shows integration of the model with the legacy code. The subsystem `TestMatOps` serves as a harness for the calls to the legacy C functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_inherit_dims')
open_system('rtwdemo_lct_inherit_dims/TestMatOps')
sim('rtwdemo_lct_inherit_dims')
```

## Integrate External C Functions That Pass Arguments as Multi-Dimensional Signals

This example shows how to use the Legacy Code Tool to integrate legacy C functions with multi-dimensional Signals.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
void array3d_add(real_T *y1, real_T *u1, real_T *u2, int32_T nbRows, int32_T nbCols, int32_T nbPages);
```

`real_T` is a typedef to `double`, and `int32_T` is a typedef to a 32-bit integer. The legacy source code is in the files `ndarray_ops.h`, and `ndarray_ops.c`.

```
% rtwdemo_sfun_ndarray_add
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_ndarray_add';
def.OutputFcnSpec = ...
```

```

 ['void array3d_add(double y1[size(u1,1)][size(u1,2)][size(u1,3)], ',...
 'double u1[][][], double u2[][][], ' ...
 'int32 size(u1,1), int32 size(u1,2), int32 size(u1,3))'];
def.HeaderFiles = {'ndarray_ops.h'};
def.SourceFiles = {'ndarray_ops.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};

```

y1 is a 3-D output signal of same dimensions as the 3-D input signal u1. Note that the last 3 arguments passed to the legacy function correspond to the number of element in each dimension of the 3-D input signal u1.

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_ndarray_add.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```

Start Compiling rtwdemo_sfun_ndarray_add
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('rtwdemo_sfun_ndarray_add.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_ndarray_add
Exit

```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to 'sfcn\_tlc\_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_ndarray_add.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to 'rtwmakecfg\_generate' to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

## Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to 'slblock\_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

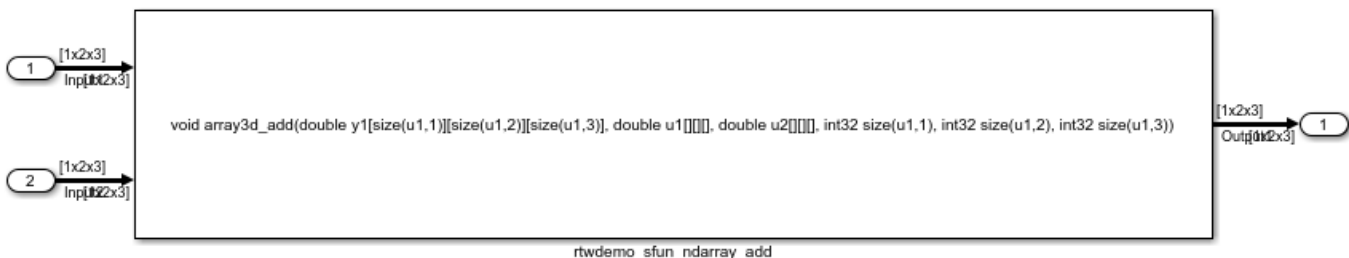

```
legacy_code('slblock_generate', def);
```

## Showing the Generated Integration with Legacy Code

The model `rtwdemo_lct_ndarray` shows integration of the model with the legacy code. The subsystem `ndarray_add` serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_ndarray')
open_system('rtwdemo_lct_ndarray/ndarray_add')
sim('rtwdemo_lct_ndarray')
```

## Integrate External C Functions That Implement Start and Terminate Actions

Integrate legacy C functions that have start and terminate actions by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototypes of the legacy functions being called in this example are:

- void initFaultCounter(unsigned int \*counter)
- void openLogFile(void \*\*fid)
- void incAndLogFaultCounter(void \*fid, unsigned int \*counter, double time)
- void closeLogFile(void \*\*fid)

The legacy source code is in the files `your_types.h`, `fault.h`, and `fault.c`.

```
% rtwdemo_sfun_fault
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_fault';
def.InitializeConditionsFcnSpec = 'initFaultCounter(uint32 work2[1])';
def.StartFcnSpec = 'openLogFile(void **work1)';
def.OutputFcnSpec = ...
 'incAndLogFaultCounter(void *work1, uint32 work2[1], double u1)';
def.TerminateFcnSpec = 'closeLogFile(void **work1)';
def.HeaderFiles = {'fault.h'};
def.SourceFiles = {'fault.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
def.Options.useTlcWithAccel = false;
```

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument `'def'`, call the function `legacy_code()` again with the first input set to `'sfcn_cmex_generate'`. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_fault.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to `'compile'`.

```
legacy_code('compile', def);
```

```
Start Compiling rtwdemo_sfun_fault
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('rtwdemo_sfun_fault.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\B
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_fault
Exit
```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_fault.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

## Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

## Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

## Showing the Generated Integration with Legacy Code

The model `rtwdemo_lct_start_term` shows integration of the model with the legacy code. The subsystem `TestFixpt` serves as a harness for the call to the legacy C function, and the scope compares the output of the function with the output of the built-in Simulink® product block; the results should be identical.

```
open_system('rtwdemo_lct_start_term')
open_system('rtwdemo_lct_start_term/TestFault')
sim('rtwdemo_lct_start_term')
```

## Integrate External C Functions That Implement N-Dimensional Table Lookups

Integrate legacy C functions that implement N-dimensional table lookups by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.

- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
FLT directLookupTableND(const FLT *tableND, const UINT32 nbDims, const UINT32 *tableDims,
const UINT32 *tableIdx)
```

FLT is a typedef to float, and UINT32 is a typedef to unsigned int32. The legacy source code is in the files `your_types.h`, `lookupTable.h`, and `directLookupTableND.c`.

```
defs = [];
evalin('base', 'load rtwdemo_lct_data.mat')
```

```
% rtwdemo_sfundlut3D
```

```
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfundlut3D';
def.OutputFcnSpec = 'single y1 = DirectLookupTable3D(single p1[][][][], uint32 p2[3], uint32 u1[3]);
def.HeaderFiles = {'lookupTable.h'};
def.SourceFiles = {'directLookupTableND.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];
```

```
% rtwdemo_sfundlut4D
```

```
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfundlut4D';
def.OutputFcnSpec = 'single y1 = DirectLookupTable4D(single p1[][][][][], uint32 p2[4], uint32 u1[4]);
def.HeaderFiles = {'lookupTable.h'};
def.SourceFiles = {'directLookupTableND.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];
```

### Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function `legacy_code()` again. Set the first input to 'sfcn\_cmex\_generate'. The S-functions call the legacy functions during simulation. The source code for the S-functions is in the files `rtwdemo_sfundlut3D.c` and `rtwdemo_sfundlut4D.c`.

```
legacy_code('sfcn_cmex_generate', defs);
```

### Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function `legacy_code()` again. Set the first input to 'compile'.

```
legacy_code('compile', defs);
```

```
Start Compiling rtwdemo_sfundlut3D
```

```

 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
 mex('rtwdemo_sfundlut3D.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfundlut3D
Exit

Start Compiling rtwdemo_sfundlut4D
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
 mex('rtwdemo_sfundlut4D.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfundlut4D
Exit

```

### Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function `legacy_code()` again. Set the first input to `'sfcn_tlc_generate'` to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are `rtwdemo_sfundlut3D.tlc` and `rtwdemo_sfundlut4D.tlc`.

```
legacy_code('sfcn_tlc_generate', defs);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block files, you can call the function `legacy_code()` again. Set the first input to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', defs);
```

### Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again. Set the first input to `'slblock_generate'` to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. You can copy the blocks to an existing model.

```
legacy_code('slblock_generate', defs);
```

## Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_lut` shows integration of the model with the legacy code. The subsystem `TestFixpt` serves as a harness for the call to the legacy C function, and the Display blocks compare the output of the function with the output of the built-in Simulink® lookup blocks. The results are identical.

```
open_system('rtwdemo_lct_lut')
open_system('rtwdemo_lct_lut/TestLut1')
sim('rtwdemo_lct_lut')
```

## Integrate External C Functions That Pass Arguments as Multi-Dimensional Signals

This example shows how to use the Legacy Code Tool to integrate legacy C functions with multi-dimensional Signals.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
void array3d_add(real_T *y1, real_T *u1, real_T *u2, int32_T nbRows, int32_T nbCols, int32_T nbPages);
```

real\_T is a typedef to double, and int32\_T is a typedef to a 32-bit integer. The legacy source code is in the files ndarray\_ops.h, and ndarray\_ops.c.

```
% rtwdemo_sfun_ndarray_add
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_ndarray_add';
def.OutputFcnSpec =...
 ['void array3d_add(double y1[size(u1,1)][size(u1,2)][size(u1,3)], ',...
 'double u1[][][], double u2[][][], ' ...
 'int32 size(u1,1), int32 size(u1,2), int32 size(u1,3))'];
def.HeaderFiles = {'ndarray_ops.h'};
def.SourceFiles = {'ndarray_ops.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

y1 is a 3-D output signal of same dimensions as the 3-D input signal u1. Note that the last 3 arguments passed to the legacy function correspond to the number of element in each dimension of the 3-D input signal u1.

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy\_code() again with the first input set to 'sfcn\_cmex\_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo\_sfun\_ndarray\_add.c.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy\_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
Start Compiling rtwdemo_sfun_ndarray_add
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('rtwdemo_sfun_ndarray_add.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_ndarray_add
Exit
```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy\_code() again with the first input set to 'sfcn\_tlc\_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo\_sfun\_ndarray\_add.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

### Showing the Generated Integration with Legacy Code

The model `rtwdemo_lct_ndarray` shows integration of the model with the legacy code. The subsystem `ndarray_add` serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_ndarray')
open_system('rtwdemo_lct_ndarray/ndarray_add')
sim('rtwdemo_lct_ndarray')
```

### Integrate External C Functions with a Block Sample Time Specified, Inherited, and Parameterized

This example shows how to use the Legacy Code Tool to integrate legacy C functions with the block's sample time specified, inherited and parameterized.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.

- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
FLT gainScalar(const FLT in, const FLT gain)
```

FLT is a typedef to float. The legacy source code is in the files `your_types.h`, `gain.h`, and `gainScalar.c`.

```
defs = [];

% rtwdemo_sfnc_st_inherited
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfnc_st_inherited';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfnc_st_fixed
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfnc_st_fixed';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
def.SampleTime = [2 1];
defs = [defs; def];

% rtwdemo_sfnc_st_parameterized
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfnc_st_parameterized';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
def.SampleTime = 'parameterized';
defs = [defs; def];
```

### Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function `legacy_code()` again with the first input set to 'sfnc\_cmex\_generate'. The S-functions call the legacy functions during simulation. The source code for the S-functions is in the files `rtwdemo_sfnc_st_inherited.c` and `rtwdemo_sfnc_st_fixed.c`. `rtwdemo_sfnc_st_parameterized.c`.

```
legacy_code('sfnc_cmex_generate', defs);
```

### Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```
Start Compiling rtwdemo_sfun_st_inherited
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_st_inherited.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_st_inherited
Exit

Start Compiling rtwdemo_sfun_st_fixed
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_st_fixed.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_st_fixed
Exit

Start Compiling rtwdemo_sfun_st_parameterized
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_st_parameterized.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_st_parameterized
Exit
```

### Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function `legacy_code()` again with the first input set to 'sfcn\_tlc\_generate' to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are `rtwdemo_sfun_st_inherited.tlc` and `rtwdemo_sfun_st_fixed.tlc`. `rtwdemo_sfun_st_parameterized.tlc`.

```
legacy_code('sfcn_tlc_generate', defs);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block files, you can call the function `legacy_code()` again with the first input set to 'rtwmakecfg\_generate' to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', defs);
```

## Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model.

```
legacy_code('slblock_generate', defs);
```

## Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_sampletime` shows integration of the model with the legacy code. The subsystem `sample_time` serves as a harness for the calls to the legacy C functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_sampletime')
open_system('rtwdemo_lct_sampletime/sample_time')
sim('rtwdemo_lct_sampletime')
```

## Integrate External C Functions That Pass Input and Output Arguments as Parameters with a Fixed-Point Data Type

Integrate legacy C functions that pass their inputs and outputs by using parameters of a fixed-point data type with the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using `'initialize'` as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
myFixpt timesS16(const myFixpt in1, const myFixpt in2, const uint8_T fracLength)
```

`myFixpt` is logically a fixed point data type, which is physically a typedef to a 16-bit integer:

```
myFixpt = Simulink.NumericType;
myFixpt.DataTypeMode = 'Fixed-point: binary point scaling';
myFixpt.Signed = true;
myFixpt.WordLength = 16;
myFixpt.FractionLength = 10;
myFixpt.IsAlias = true;
myFixpt.HeaderFile = 'timesFixpt.h';
```

The legacy source code is in the files `timesFixpt.h`, and `timesS16.c`.

```
% rtwdemo_sfun_gain_fixpt
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_gain_fixpt';
def.OutputFcnSpec = 'myFixpt y1 = timesS16(myFixpt u1, myFixpt p1, uint8 p2)';
def.HeaderFiles = {'timesFixpt.h'};
def.SourceFiles = {'timesS16.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument `'def'`, call the function `legacy_code()` again with the first input set to `'sfcn_cmex_generate'`. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_gain_fixpt.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
Start Compiling rtwdemo_sfun_gain_fixpt
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_gain_fixpt.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\T
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_gain_fixpt
Exit
```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again. Set the first input to 'sfcn\_tlc\_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_gain_fixpt.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an rtwmakecfg.m File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again. Set the first input to 'rtwmakecfg\_generate' to generate an `rtwmakecfg.m` file that supports code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again. Set the first input to 'slblock\_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. You can copy the block to an existing model.

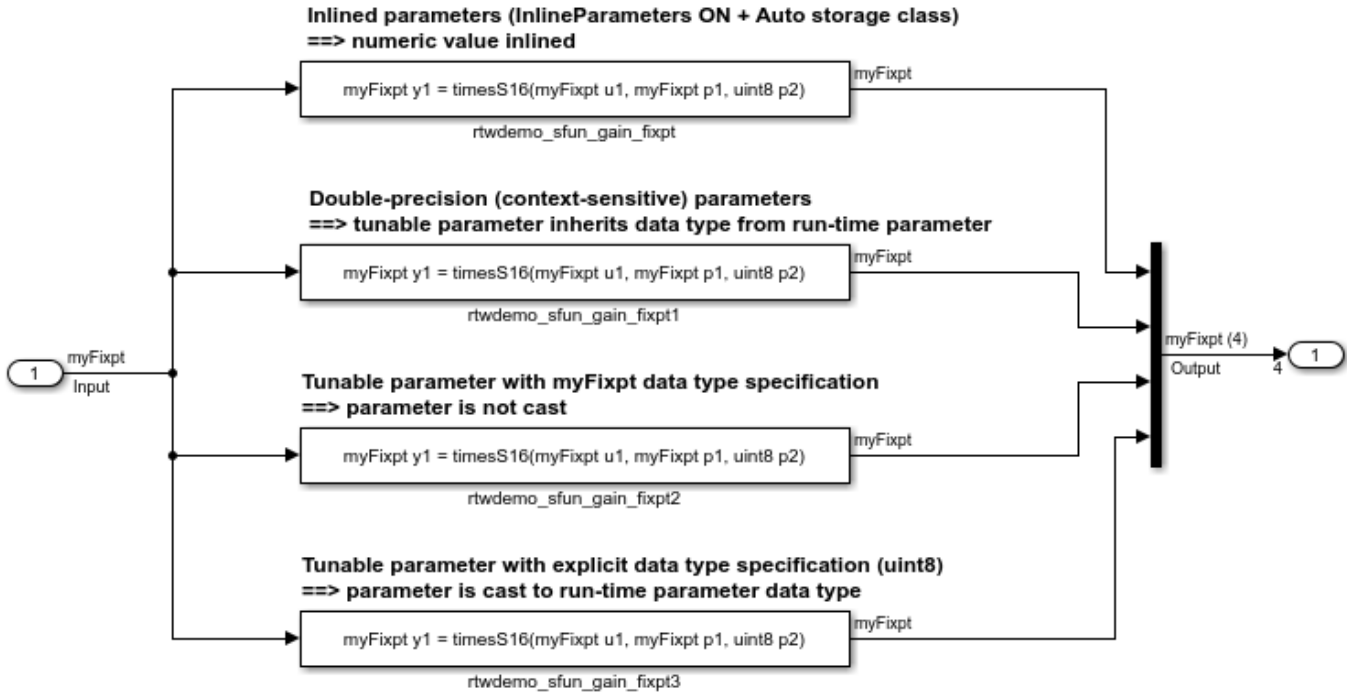

```
legacy_code('slblock_generate', def);
```

### Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_fixpt_params` shows integration of the model with the legacy code. The subsystem `TestFixpt` serves as a harness for the call to the legacy C function via the generated S-function.

```
open_system('rtwdemo_lct_fixpt_params')
open_system('rtwdemo_lct_fixpt_params/TestFixpt')
sim('rtwdemo_lct_fixpt_params')
```

## Integrate External C Functions That Implement N-Dimensional Table Lookups

Integrate legacy C functions that implement N-dimensional table lookups by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
FLT directLookupTableND(const FLT *tableND, const UINT32 nbDims, const UINT32 *tableDims,
const UINT32 *tableIdx)
```

FLT is a typedef to float, and UINT32 is a typedef to unsigned int32. The legacy source code is in the files `your_types.h`, `lookupTable.h`, and `directLookupTableND.c`.

```
defs = [];
evalin('base','load rtwdemo_lct_data.mat')
```

```
% rtwdemo_sfundlut3D
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfundlut3D';
def.OutputFcnSpec = 'single y1 = DirectLookupTable3D(single p1[][][], uint32 p2[3], uint32 u1[3]);
def.HeaderFiles = {'lookupTable.h'};
def.SourceFiles = {'directLookupTableND.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];
```

```
% rtwdemo_sfundlut4D
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfundlut4D';
def.OutputFcnSpec = 'single y1 = DirectLookupTable4D(single p1[][][][][], uint32 p2[4], uint32 u1[4]);
def.HeaderFiles = {'lookupTable.h'};
def.SourceFiles = {'directLookupTableND.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];
```

### Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function `legacy_code()` again. Set the first input to 'sfcn\_cmex\_generate'. The S-functions call

the legacy functions during simulation. The source code for the S-functions is in the files `rtwdemo_sfun_dlut3D.c` and `rtwdemo_sfun_dlut4D.c`.

```
legacy_code('sfcn_cmex_generate', defs);
```

### Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function `legacy_code()` again. Set the first input to `'compile'`.

```
legacy_code('compile', defs);
```

```
Start Compiling rtwdemo_sfun_dlut3D
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('rtwdemo_sfun_dlut3D.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_dlut3D
Exit

Start Compiling rtwdemo_sfun_dlut4D
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('rtwdemo_sfun_dlut4D.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_dlut4D
Exit
```

### Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function `legacy_code()` again. Set the first input to `'sfcn_tlc_generate'` to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are `rtwdemo_sfun_dlut3D.tlc` and `rtwdemo_sfun_dlut4D.tlc`.

```
legacy_code('sfcn_tlc_generate', defs);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block files, you can call the function `legacy_code()` again. Set the first input to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', defs);
```

### Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again. Set the first input to `'slblock_generate'` to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. You can copy the blocks to an existing model.

```
legacy_code('slblock_generate', defs);
```

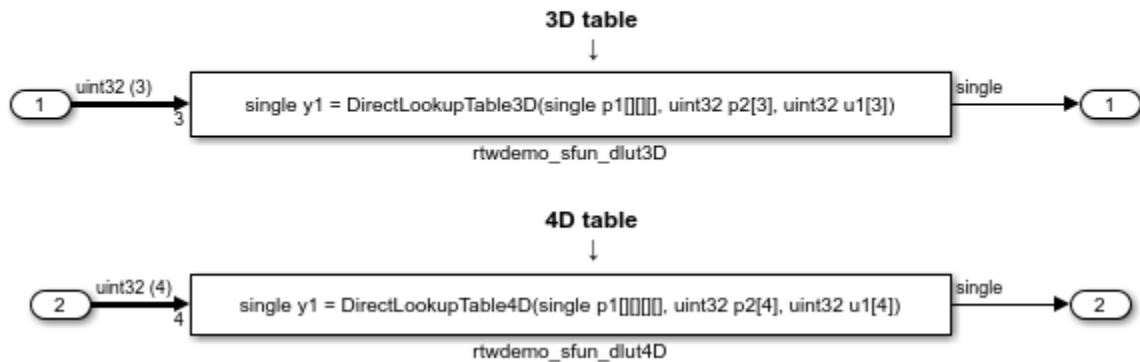

### Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_lut` shows integration of the model with the legacy code. The subsystem `TestFixpt` serves as a harness for the call to the legacy C function, and the Display blocks compare the output of the function with the output of the built-in Simulink® lookup blocks. The results are identical.

```
open_system('rtwdemo_lct_lut')
open_system('rtwdemo_lct_lut/TestLut1')
sim('rtwdemo_lct_lut')
```

```
LookUp Table are defined as:
>> LUT3D = single(reshape([1:4*5*6], [4 5 6]));
>> LUT4D = single(reshape([1:4*5*6*2], [4 5 6 2]));
```

- “Call External C Code from Model and Generated Code” on page 50-47

## Integrate External C++ Object Methods

Integrate legacy C++ object methods by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C++ MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a block TLC file and optional rtwmakecfg.m file that calls the legacy code during code generation.

### Provide the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. The definition of the legacy C++ class in this example is:

```
class adder {
private:
 int int_state;
public:
 adder();
 int add_one(int increment);
 int get_val();
};
```

The legacy source code is in the files `adder_cpp.h` and `adder_cpp.cpp`.

```
% rtwdemo_sfun_adder_cpp
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_adder_cpp';
def.StartFcnSpec = 'createAdder()';
def.OutputFcnSpec = 'int32 y1 = adderOutput(int32 u1)';
def.TerminateFcnSpec = 'deleteAdder()';
def.HeaderFiles = {'adder_cpp.h'};
def.SourceFiles = {'adder_cpp.cpp'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
def.Options.language = 'C++';
def.Options.useTlcWithAccel = false;
```

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_adder_cpp.cpp`.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
Start Compiling rtwdemo_sfun_adder_cpp
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC
Building with 'Microsoft Visual C++ 2019'.
MEX completed successfully.
 mex('rtwdemo_sfun_adder_cpp.cpp', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\
Building with 'Microsoft Visual C++ 2019'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_adder_cpp
Exit
```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again. Set the first input to `'sfcn_tlc_generate'` to generate a TLC block file that supports code generation through Simulink® Coder™. If the TLC block file is not created and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_adder_cpp.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again. Set the first input to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file that supports code generation through Simulink® Coder™. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

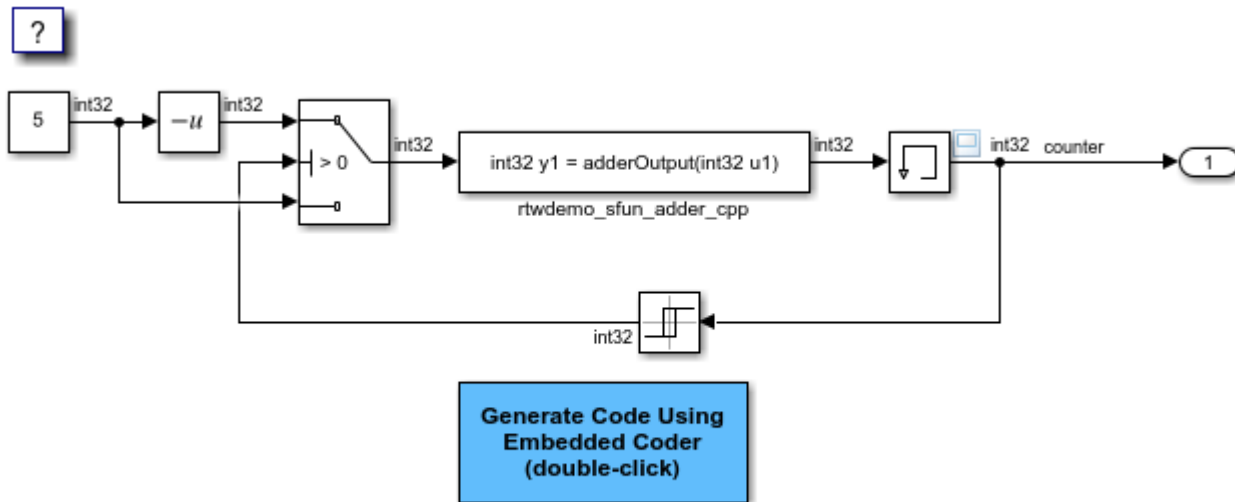

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again. Set the first input to `'slblock_generate'` to generate a masked S-function block that is configured to call that S-function. The software places the block in a new model. You can copy the block to an existing model.

```
% legacy_code('slblock_generate', def);
```

### Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_cpp` shows integration with the legacy code.

```
open_system('rtwdemo_lct_cpp')
sim('rtwdemo_lct_cpp')
```

## External Code Integration Examples

This topic shows various scenarios of external code integration.

### Integrate External C++ Code into a Model Using S-Functions

This example shows you how to integrate C++ code into a model by using S-functions.

#### Open Example Model

Open the example model `rtwdemo_cpp`.

```
open_system('rtwdemo_cpp');
```

Copyright 1994-2020 The MathWorks, Inc.

#### Configure C++ Compiler

1. In the MATLAB Command Window, enter this command:

```
mex -setup
```

2. When prompted, select a C++ compiler that is installed on your development computer.

#### Integrate C++ Code

You can integrate C++ code into a model by using S-functions.

1. Prepare the S-function source.

- Open `sfun_cppcount_cpp.cpp`
- Open `sfun_cppcount_cpp.h`

2. Open the **Simulink Coder** or **Embedded Coder** app.

3. Configure S-function source files and folders. Open the Model Configuration Parameter dialog box, navigate to the **Code Generation > Custom Code** pane, and add the S-function source files and include folders.

4. Inline the S-function to eliminate overhead of S-functions in the generated code.

Open `sfun_cppcount_cpp.tlc`

### Configure Model for C++ Code Generation

Set model configuration parameter **Language** to C++.

### Generate and review code.

Generate and review the C++ code.

### Related Topics

- “Programming Language Considerations”
- “C++ Language Support Limitations”

## Insert External C and C++ Code Into Stateflow Charts for Code Generation

This example shows how to use Stateflow® to integrate external code into a model.

### Open Model

```
model='rtwdemo_sfcustom';
open_system(model);
```

[▶ Build model using Simulink Coder](#)

Copyright 1994-2020 The MathWorks, Inc.

### Integrate Code

1. The example includes the custom header file `my_header.c` and the custom source file `my_function.c`.

```
%Open files my_header.h and my_function.c
eval('edit my_header.h')
eval('edit my_function.c')
```

2. On the Model Configuration Parameters dialog box **Simulation Target** pane, enter the custom source file and header file. Also enter additional include directories and source files.

In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the **Simulation Target** pane.

```
%Open Configuration Parameters dialog box
configSet = getActiveConfigSet(model);
openDialog(configSet);
```

3. To generate code, on the Model Configuration Parameters dialog box **Code Generation > Custom Code** pane, enter the same custom source file and header file. Also enter the same additional include directories and source files.

In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the **Code Generation > Custom Code** pane.

Open the **Code Generation > Custom Code** pane of the Model Configuration Parameters dialog box.

```
configSet = getActiveConfigSet(model);
openDialog(configSet);
```

### Generate Code

```
slbuild('rtwdemo_sfcustom')

Starting build procedure for: rtwdemo_sfcustom
Successful completion of build procedure for: rtwdemo_sfcustom
```

Build Summary

Top model targets built:

| Model            | Action                      | Rebuild Reason                                   |
|------------------|-----------------------------|--------------------------------------------------|
| rtwdemo_sfcustom | Code generated and compiled | Code generation information file does not exist. |

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 17.328s
```

### Call C Code from Stateflow

To call custom C code functions from Stateflow, use the same syntax as graphical function calls:

```
result = my_custom_function(in_args);
```

To call variables of structure type, use the dot notation: `result = my_var.my_field;`

### See Also

- “Configure Custom Code Settings for Simulation” (Stateflow)
- “Access Custom C++ Code in Stateflow Charts” (Stateflow)

### Close Model

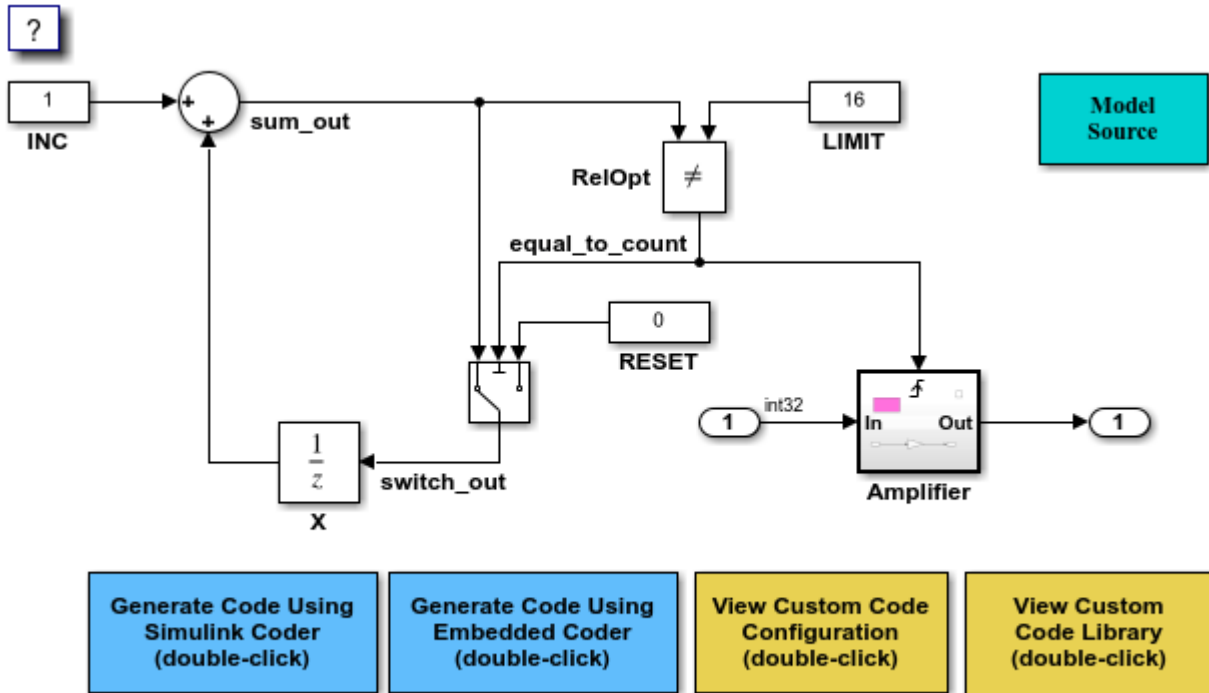

```
rtwdemoclean;
close_system('rtwdemo_sfcustom',0);
```

## Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model `rtwdemo_slcustcode`.

```
open_system('rtwdemo_slcustcode')
```

Copyright 1994-2020 The MathWorks, Inc.

2. Open the **Simulink Coder** or **Embedded Coder** app.

3. Open the Model Configuration Parameters dialog box and navigate to the **Custom Code** pane.

4. On the **Additional source code** tab, examine the settings for model configuration parameters **Additional code** and **Initialize code**.

- **Additional code** specifies a comment and sets the variable `GLOBAL_INT2` to -1.
- **Initialize code** initializes the variable `GLOBAL_INT2` to 1.

5. Close the dialog box.

6. Double-click the Model Source block. Block parameter **Top of Model Source** specifies that the code generator declare the variable `GLOBAL_INT1` and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.

7. Open the triggered subsystem **Amplifier**. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the **Amplifier** subsystem. The external code:

- Declares the pointer variable `*intPtr` and initializes it with the value of variable `GLOBAL_INT1`.
- Sets the pointer variable to -1 during execution.

- Resets the pointer variable to 0 before exiting.

8. Generate code and a code generation report.

9. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Additional code** configuration parameter and the second declaration with the Model Source block.

```
int_T GLOBAL_INT2 = -1;
```

```
int_T GLOBAL_INT1 = 0;
```

The Output function for the `Amplifier` subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Outputs block in the `Amplifier` subsystem.

```
int_T *intPtr = &GLOBAL_INT1;
```

```
*intPtr = -1;
```

```
rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;
```

```
*intPtr = 0;
```

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the **Initialize code** configuration parameter.

```
GLOBAL_INT2 = 1;
```

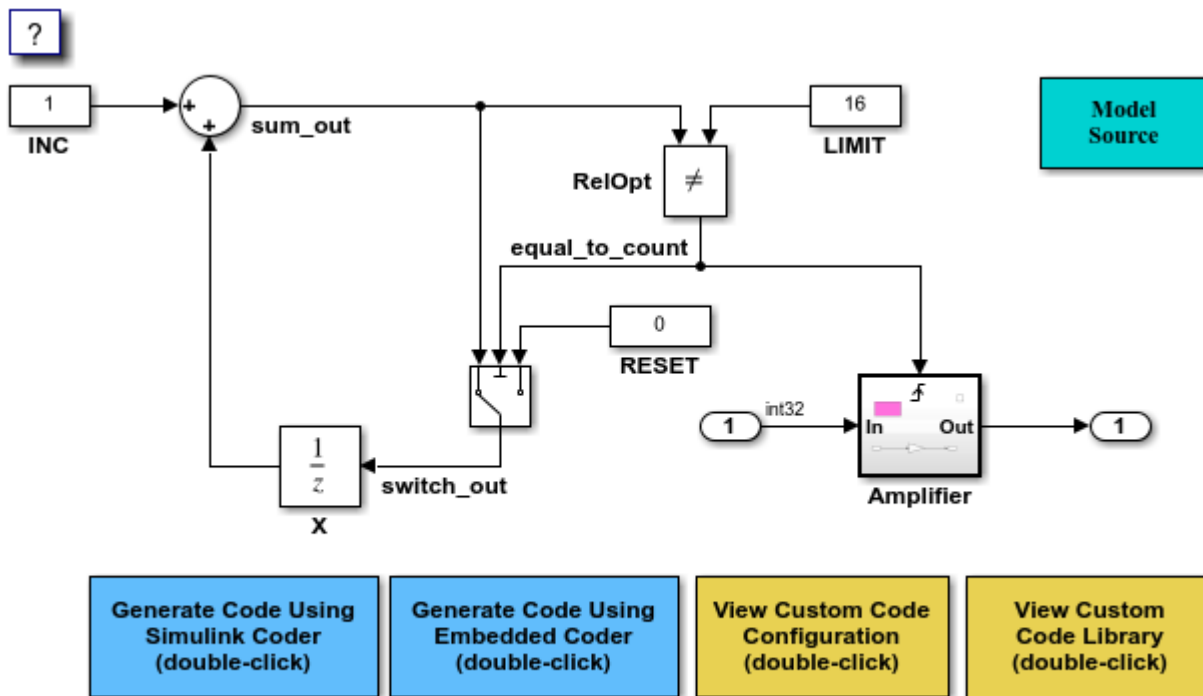

## Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model `rtwdemo_slcustcode`.

```
open_system('rtwdemo_slcustcode')
```

Copyright 1994-2020 The MathWorks, Inc.

2. Open the **Simulink Coder** or **Embedded Coder** app.
3. Open the Model Configuration Parameters dialog box and navigate to the **Custom Code** pane.
4. On the **Additional source code** tab, examine the settings for model configuration parameters **Additional code** and **Initialize code**.
  - **Additional code** specifies a comment and sets the variable GLOBAL\_INT2 to -1.
  - **Initialize code** initializes the variable GLOBAL\_INT2 to 1.
5. Close the dialog box.
6. Double-click the Model Source block. Block parameter **Top of Model Source** specifies that the code generator declare the variable GLOBAL\_INT1 and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.
7. Open the triggered subsystem **Amplifier**. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the **Amplifier** subsystem. The external code:
  - Declares the pointer variable `*intPtr` and initializes it with the value of variable GLOBAL\_INT1.
  - Sets the pointer variable to -1 during execution.
  - Resets the pointer variable to 0 before exiting.
8. Generate code and a code generation report.

9. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Additional code** configuration parameter and the second declaration with the Model Source block.

```
int_T GLOBAL_INT2 = -1;
```

```
int_T GLOBAL_INT1 = 0;
```

The Output function for the Amplifier subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Outputs block in the Amplifier subsystem.

```
int_T *intPtr = &GLOBAL_INT1;
```

```
*intPtr = -1;
```

```
rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;
```

```
*intPtr = 0;
```

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the **Initialize code** configuration parameter.

```
GLOBAL_INT2 = 1;
```

## Insert External C++ Code Into Stateflow Charts for Code Generation

This example shows how to use Stateflow® to integrate external C++ code into a model.

### Open Model

```
model='rtwdemo_sfcpp';
open_system(model);
```

Copyright 1994-2020 The MathWorks, Inc.

To setup a C++ compiler, on the command line, enter `mex -setup`.

### Integrate C++ Code

1. Create C-style wrapper functions or access macros for each method called from the C action language.

```
%Open example wrapper functions.
filename=fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'custom_cpp_src', 'adder_cpp.cpp');
eval('edit(filename)');
clear filename;

filename=fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'custom_cpp_src', 'adder_cpp.h');
eval('edit(filename)');
clear filename;
```

2. On the Configuration Parameters dialog box **Code Generation > Custom Code** pane, enter the S-Function source files and include directories.

```
%Open Configuration Parameters dialog box
configSet = getActiveConfigSet(model);
openDialog(configSet);
```

3. On the Configuration Parameters dialog box **Simulation Target > Custom Code** pane, enter the S-Function source files and include directories.

```
%Open Configuration Parameters dialog box
configSet = getActiveConfigSet(model);
openDialog(configSet);
```

### Generate C++ Code

On the Configuration Parameters dialog box **Code Generation** pane, set **Language** to C++. To generate code, select **Build**.

```
%Open Configuration Parameters dialog box
configSet = getActiveConfigSet(model);
openDialog(configSet);
clear model;
```

### See Also

- “Programming Language Considerations”
- “C++ Language Support Limitations”

### Close Model

```
rtwdemoclean;
close_system('rtwdemo_sfcpp',0);
```

## Generate S-Function from Subsystem

The **Generate S-function** menu option automates generating an S-function from a subsystem. The **Generate S-function** menu option presents parameters used within the subsystem and enables you to declare selected parameters as tunable.

For creating S-Function blocks from a subsystem, see “Create S-Function Blocks from a Subsystem” on page 65-42.

For example, consider `SourceSubsys`. The objective is to automatically extract `SourceSubsys` from the model and build an S-Function block from it. The workspace variable `K`, which is the gain factor of the Gain block within `SourceSubsys`, is declared and generated as a tunable variable.

To autogenerate an S-function from `SourceSubsys` that has tunable parameter `K`:

- 1 With the `SourceSubsys` model open, click the subsystem to select it.
- 2 Right-click the subsystem and select **C/C++ Code > Generate S-Function**.
- 3 In the **Generate S-Function** window you see variables or data objects that are referenced as block parameters in the subsystem. You can declare them as tunable.

The upper pane of the window displays these columns:

- **Variable Name:** Name of the parameter.
- **Class:** If the parameter is a workspace variable, its data type is displayed. If the parameter is a data object, its name and class is displayed.
- **Tunable:** Lets you select tunable parameters. To declare a parameter tunable, select the check box. In this example, the parameter `K` is declared tunable.

When you select a parameter in the upper pane, the lower pane shows the blocks that reference the parameter, and the parent system of each block.

- 4 After selecting tunable parameters, click the **Build** button. The build process initiates code generation and compilation of the S-function by using the S-function target. The **Create New Model** option is automatically enabled.
- 5 The build process displays status messages in the MATLAB Command Window. When the build is complete, the tunable parameters window closes and a new untitled model window opens.

- 6 The model window contains an S-Function block with the same name as the subsystem from which the block was generated (in this example, SourceSubsys). Optionally, you can save the generated model containing the generated block.

The generated code for the S-Function block is stored in the current working folder. These files are written to the top-level folder:

- *subsys\_sf.c* or *.cpp*, where *subsys* is the subsystem name (for example, SourceSubsys\_sf.c)
- *subsys\_sf.h*
- *subsys\_sf.mexext*, where *mexext* is a platform-dependent MEX-file extension (for example, SourceSubsys\_sf.mexw64)

The source code for the S-function is written to the subfolder *subsys\_sfcn\_rtw*. The top level *.c* or *.cpp* file is a stub file that contains an include directive that you can use to interface other C/C++ code to the generated code.

---

**Note** See “Required Files for S-Function Deployment” on page 65-41.

---

The generated S-Function block has inports and outports whose widths and sample times correspond to those of the original model.

The following code, from the `mdlOutputs` routine of the generated S-function code (in `SourceSubsys_sf.c`) shows how the tunable variable `K` is referenced by using calls to the MEX API.

```
static void mdlOutputs(SimStruct *S, int_T tid)
...

/* Gain: '<S1>/Gain' incorporates:
 * Sum: '<S1>/Sum'
 */
rtb_Gain_n[0] = (rtb_Product_p + (((const
real_T**)ssGetInputPortSignalPtrs(S, 2))[0])) * ((real_T
*)(mxGetData(K(S))));
rtb_Gain_n[1] = (rtb_Product_p + (((const
real_T**)ssGetInputPortSignalPtrs(S, 2))[1])) * ((real_T
*)(mxGetData(K(S))));
```

In automatic S-function generation, the **Use Value for Tunable Parameters** option is cleared or at the command line is set to `'off'`.

---

**Note** Use a MEX S-function wrapper only in the MATLAB version in which the wrapper is created.

---

## Macro Parameters

Suppose that you apply a storage class such as `Define` to a `Simulink.Parameter` object so that the parameter appears as a macro in the generated code. If you use the parameter object inside a subsystem from which you generate an ERT S-function, you cannot select the parameter object as a tunable parameter. Instead, the S-function code generator applies the custom storage class to the parameter object. This generation of macros in the S-function code enables you to generate S-functions from subsystems that contain variant elements, such as Variant Subsystem blocks, that you configure to produce preprocessor conditionals in the generated code. You cannot change the value of the parameter during simulation of the S-function.

To select the parameter object as a tunable parameter, apply a different storage class or create your own storage class. Storage classes that treat parameters as macros include `Define`, `ImportedDefine`, `CompilerFlag`, and storage classes that you create by setting **Data initialization** to `Macro` in the Custom Storage Class Designer. If you use a non-macro storage class, you cannot use the parameter object as a variant control variable and generate preprocessor conditionals.

If you apply a storage class that treats the parameter object as an imported macro, before you generate the ERT S-function, provide the macro definition. For example, suppose that you apply the storage class `ImportedDefine` to a `Simulink.Parameter` object and use the parameter object as a variant control variable in the subsystem. If you set the custom attribute `HeaderFile` to `'myHdr.h'`, when you generate the S-function, place the custom header file `myHdr.h` in the current folder. The generated S-function uses the macro value from your header file instead of the value from the `Value` property of the parameter object.

To use a macro that you define through a compiler option, for example by applying the storage class `CompilerFlag`, use the model configuration parameter **Code Generation > Custom Code > Code information > Defines** to specify the compiler option. For more information, see Code Generation Pane: Custom Code: Additional Build Information: Defines.

## S-Functions That Support Expression Folding

Use expression folding to increase the efficiency of code generated by your own inlined S-Function blocks, by calling macros provided in the S-Function API.

The S-Function API lets you specify whether a given S-Function block should nominally accept expressions at a given input port. A block should not always accept expressions. For example, if the address of the signal at the input is used, expressions should not be accepted at that input, because it is not possible to take the address of an expression.

The S-Function API also lets you specify whether an expression can represent the computations associated with a given output port. When you request an expression at a block's input or output port, the Simulink engine determines whether or not it can honor that request, given the block's context. For example, the engine might deny a block's request to output an expression if the destination block does not accept expressions at its input, if the destination block has an update function, or if multiple output destinations exist.

The decision to honor or deny a request to output an expression can also depend on the category of output expression the block uses.

To take advantage of expression folding in your S-functions, you should understand when to request acceptance and generation of expressions for specific blocks. You do not have to understand the algorithm by which the Simulink engine chooses to accept or deny these requests. However, if you want to trace between the model and the generated code, it is helpful to understand some of the more common situations that lead to denial of a request.

### Categories of Output Expressions

When you implement a C MEX S-function, you can specify whether the code corresponding to a block's output is to be generated as an expression. If the block generates an expression, you must specify that the expression is *constant*, *trivial*, or *generic*.

A *constant* output expression is a direct access to one of the block's parameters. For example, the output of a Constant block is defined as a constant expression because the output expression is simply a direct access to the block's `Value` parameter.

A *trivial* output expression is an expression that can be repeated, without a performance penalty, when the output port has multiple output destinations. For example, the output of a Unit Delay block is defined as a trivial expression because the output expression is simply a direct access to the block's state. Because the output expression does not have computations, it can be repeated more than once without degrading the performance of the generated code.

A *generic* output expression is an expression that should be assumed to have a performance penalty if repeated. As such, a generic output expression is not suitable for repeating when the output port has multiple output destinations. For instance, the output of a Sum block is a generic rather than a trivial expression because it is costly to recompute a Sum block output expression as an input to multiple blocks.

### Examples of Trivial and Generic Output Expressions

Consider this block diagram. The Delay block has multiple destinations, yet its output is designated as a trivial output expression, so that it can be used more than once without degrading the efficiency of the code.

This code excerpt shows the code generated from the Unit Delay block in this block diagram. The three root outputs are directly assigned from the state of the Unit Delay block, which is stored in a field of the global data structure `rtDWork`. Since the assignment is direct, without expressions, there is no performance penalty associated with using the trivial expression for multiple destinations.

```
void MdlOutputs(int_T tid)
{
 ...
 /* Outputport: <Root>/Out1 incorporates:
 * UnitDelay: <Root>/Unit Delay */
 rtY.Out1 = rtDWork.Unit_Delay_DSTATE;

 /* Outputport: <Root>/Out2 incorporates:
 * UnitDelay: <Root>/Unit Delay */
 rtY.Out2 = rtDWork.Unit_Delay_DSTATE;

 /* Outputport: <Root>/Out3 incorporates:
 * UnitDelay: <Root>/Unit Delay */
 rtY.Out3 = rtDWork.Unit_Delay_DSTATE;

 ...
}
```

The code generated shows how code is generated for Sum blocks with single and multiple destinations.

On the other hand, consider the Sum blocks in this model:

The upper Sum block in the model generates the signal labeled `non_triv`. Computation of this output signal involves two multiplications and an addition. If the Sum block's output were permitted to generate an expression even when the block had multiple destinations, the block's operations would be duplicated in the generated code. In this case, the generated expressions would proliferate to four multiplications and two additions. This would degrade the efficiency of the program.

Accordingly the output of the Sum block is not allowed to be an expression because it has multiple destinations.

The Simulink engine does not permit the output of the upper Sum block to be an expression because the signal `non_triv` is routed to two output destinations. Instead, the result of the multiplication and addition operations is stored in a temporary variable (`rtb_non_triv`) that is referenced twice in the statements that follow, as seen in the code excerpt below.

In contrast, the lower Sum block, which has only a single output destination (`Out2`), does generate an expression.

```
void MdlOutputs(int_T tid)
{
 /* local block i/o variables */
 real_T rtb_non_triv;
 real_T rtb_Sine_Wave;

 /* Sum: <Root>/Sum incorporates:
 * Gain: <Root>/Gain
 * Inport: <Root>/u1
 * Gain: <Root>/Gain1
 * Inport: <Root>/u2
 *
 * Regarding <Root>/Gain:
 * Gain value: rtP.Gain_Gain
 *
 * Regarding <Root>/Gain1:
 * Gain value: rtP.Gain1_Gain
 */
 rtb_non_triv = (rtP.Gain_Gain * rtU.u1) + (rtP.Gain1_Gain *
rtU.u2);

 /* Output: <Root>/Out1 */
 rtY.Out1 = rtb_non_triv;

 /* Sin Block: <Root>/Sine Wave */

 rtb_Sine_Wave = rtP.Sine_Wave_Amp *
 sin(rtP.Sine_Wave_Freq * rtmGetT(rtM_model) +
 rtP.Sine_Wave_Phase) + rtP.Sine_Wave_Bias;

 /* Output: <Root>/Out2 incorporates:
 * Sum: <Root>/Sum1
 */
 rtY.Out2 = (rtb_non_triv + rtb_Sine_Wave);
}
```

### Specify the Category of an Output Expression

The S-Function API provides macros that let you declare whether an output of a block should be an expression, and if so, to specify the category of the expression. This table specifies when to declare a block output to be a constant, trivial, or generic output expression.

#### Types of Output Expressions

| Category of Expression | When to Use                                                                                                                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Constant               | Use only if block output is a direct memory access to a block parameter.                                                                                                                                          |
| Trivial                | Use only if block output is an expression that can appear multiple times in the code without reducing efficiency (for example, a direct memory access to a field of the <code>DWork</code> vector, or a literal). |
| Generic                | Use if output is an expression, but not constant or trivial.                                                                                                                                                      |

You must declare outputs as expressions in the `mdlSetWorkWidths` function using macros defined in the S-Function API. The macros have the following arguments:

- `SimStruct *S`: pointer to the block's `SimStruct`.
- `int idx`: zero-based index of the output port.
- `bool value`: pass in `TRUE` if the port generates output expressions.

The following macros are available for setting an output to be a constant, trivial, or generic expression:

- `void ssSetOutputPortConstOutputExprInRTW(SimStruct *S, int idx, bool value)`
- `void ssSetOutputPortTrivialOutputExprInRTW(SimStruct *S, int idx, bool value)`
- `void ssSetOutputPortOutputExprInRTW(SimStruct *S, int idx, bool value)`

The following macros are available for querying the status set by prior calls to the macros above:

- `bool ssGetOutputPortConstOutputExprInRTW(SimStruct *S, int idx)`
- `bool ssGetOutputPortTrivialOutputExprInRTW(SimStruct *S, int idx)`
- `bool ssGetOutputPortOutputExprInRTW(SimStruct *S, int idx)`

The set of generic expressions is a superset of the set of trivial expressions, and the set of trivial expressions is a superset of the set of constant expressions.

Therefore, when you query an output that has been set to be a constant expression with `ssGetOutputPortTrivialOutputExprInRTW`, it returns `True`. A constant expression is considered a trivial expression because it is a direct memory access that can be repeated without degrading the efficiency of the generated code.

Similarly, an output that has been configured to be a constant or trivial expression returns `True` when queried for its status as a generic expression.

## Acceptance or Denial of Requests for Input Expressions

A block can request that its output be represented in code as an expression. Such a request can be denied if the destination block cannot accept expressions at its input port. Furthermore, conditions independent of the requesting block and its destination blocks can prevent acceptance of expressions.

A block should not be configured to accept expressions at its input port under the following conditions:

- The block must take the address of its input data. It is not possible to take the address of most types of input expressions.
- The code generated for the block references the input more than once (for example, the `Abs` or `Max` blocks). This would lead to duplication of a potentially complex expression and a subsequent degradation of code efficiency.

If a block refuses to accept expressions at an input port, then a block that is connected to that input port is not permitted to output a generic or trivial expression.

A request to output a constant expression is not denied, because there is no performance penalty for a constant expression, and the software can take the parameter's address.

### **S-Function API to Specify Input Expression Acceptance**

The S-Function API provides macros that let you:

- Specify whether a block input should accept nonconstant expressions (that is, trivial or generic expressions).
- Query whether a block input accepts nonconstant expressions.

By default, block inputs do not accept nonconstant expressions.

You should call the macros in your `mdlSetWorkWidths` function. The macros have these arguments:

- `SimStruct *S`: pointer to the block's `SimStruct`.
- `int idx`: zero-based index of the input port.
- `bool value`: pass in `TRUE` if the port accepts input expressions; otherwise pass in `FALSE`.

The macro available for specifying whether or not a block input should accept a nonconstant expression is:

```
void ssSetInputPortAcceptExprInRTW(SimStruct *S, int portIdx, bool value)
```

The corresponding macro available for querying the status set by any prior calls to `ssSetInputPortAcceptExprInRTW` is:

```
bool ssGetInputPortAcceptExprInRTW(SimStruct *S, int portIdx)
```

### **Denial of Block Requests to Output Expressions**

Even after a specific block requests that it be allowed to generate an output expression, that request can be denied for generic reasons. These reasons include, but are not limited to:

- The output expression is nontrivial, and the output has multiple destinations.
- The output expression is nonconstant, and the output is connected to at least one destination that does not accept expressions at its input port.
- The output is a test point.
- The output has been assigned an external storage class.
- The output must be stored using global data (for example is an input to a merge block or a block with states).
- The output signal is complex.

You do not need to consider these generic factors when deciding whether or not to utilize expression folding for a particular block. However, these rules can be helpful when you are examining generated code and analyzing cases where the expression folding optimization is suppressed.

## Expression Folding in a TLC Block Implementation

To take advantage of expression folding, modify the TLC block implementation of an inlined S-Function such that it informs the Simulink engine whether it generates or accepts expressions at its

- Input ports, as explained in “S-Function API to Specify Input Expression Acceptance” on page 12-72.
- Output ports, as explained in “Categories of Output Expressions” on page 12-68.

This topic discusses required modifications to the TLC implementation.

### Expression Folding Compliance

In the `BlockInstanceSetup` function of your S-function, register your block to be compliant with expression folding. Otherwise, expression folding requested or allowed at the block's outputs or inputs will be disabled, and temporary variables will be used.

To register expression folding compliance, call the TLC library function `LibBlockSetIsExpressionCompliant(block)`, which is defined in `matlabroot/rtw/c/tlc/lib/utillib.tlc`. For example:

```
%% Function: BlockInstanceSetup =====
%%
%function BlockInstanceSetup(block, system) void
 %%
 %<LibBlockSetIsExpressionCompliant(block)>
 %%
%endfunction
```

You can conditionally disable expression folding at the inputs and outputs of a block by making the call to this function conditionally.

If you override one of the TLC block implementations provided by the code generator with your own implementation, you should not make the preceding call until you have updated your implementation.

### Output Expressions

The `BlockOutputSignal` function is used to generate code for a scalar output expression or one element of a nonscalar output expression. If your block outputs an expression, you should add a `BlockOutputSignal` function. The prototype of the `BlockOutputSignal` is

```
%function BlockOutputSignal(block,system,portIdx,ucv,lcx,idx,retType) void
```

The arguments to `BlockOutputSignal` are these:

- `block`: the record for the block for which an output expression is being generated
- `system`: the record for the system containing the block
- `portIdx`: zero-based index of the output port for which an expression is being generated
- `ucv`: user control variable defining the output element for which code is being generated
- `lcx`: loop control variable defining the output element for which code is being generated
- `idx`: signal index defining the output element for which code is being generated
- `retType`: character vector defining the type of signal access desired:

"Signal" specifies the contents or address of the output signal

"SignalAddr" specifies the address of the output signal

The `BlockOutputSignal` function returns a character vector for the output signal or address. The character vector should enforce the precedence of the expression by using opening and terminating parentheses, unless the expression consists of a function call. The address of an expression can only be returned for a constant expression; it is the address of the parameter whose memory is being accessed. The code implementing the `BlockOutputSignal` function for the Constant block is:

```
%% Function: BlockOutputSignal =====
%% Abstract:
%% Return the reference to the parameter. This function *may*
%% be used by Simulink when optimizing the Block IO data structure.
%%
%%function BlockOutputSignal(block,system,portIdx,ucv,lcx,idx,retType) void
%switch retType
%case "Signal"
%return LibBlockParameter(Value,ucv,lcx,idx)
%case "SignalAddr"
%return LibBlockParameterAddr(Value,ucv,lcx,idx)
%default
%assign errTxt = "Unsupported return type: %<retType>"
%<LibBlockReportError(block,errTxt)>
%endswitch
%endfunction
```

The code implementing the `BlockOutputSignal` function for the Relational Operator block is:

```
%% Function: BlockOutputSignal =====
%% Abstract:
%% Return an output expression. This function *may*
%% be used by Simulink when optimizing the Block IO data structure.
%%
%%function BlockOutputSignal(block,system,portIdx,ucv,lcx,idx,retType) void
%switch retType
%case "Signal"
%assign logicOperator = ParamSettings.Operator
%if ISEQUAL(logicOperator, "~=")
%assign op = "!="
elseif ISEQUAL(logicOperator, "==") %assign op = "=="
%else
%assign op = logicOperator
%endif
%assign u0 = LibBlockInputSignal(0, ucv, lcx, idx)
%assign u1 = LibBlockInputSignal(1, ucv, lcx, idx)
%return "(%<u0> %<op> %<u1>)"
%default
%assign errTxt = "Unsupported return type: %<retType>"
%<LibBlockReportError(block,errTxt)>
%endswitch
%endfunction
```

### Expression Folding for Blocks with Multiple Outputs

When a block has a single output, the `Outputs` function in the block's TLC file is called only if the output port is not an expression. Otherwise, the `BlockOutputSignal` function is called.

If a block has multiple outputs, the `Outputs` function is called if any output port is not an expression. The `Outputs` function should guard against generating code for output ports that are expressions. This is achieved by guarding sections of code corresponding to individual output ports with calls to `LibBlockOutputSignalIsExpr()`.

For example, consider an S-Function with two inputs and two outputs, where

- The first output,  $y_0$ , is equal to two times the first input.
- The second output,  $y_1$ , is equal to four times the second input.

The `Outputs` and `BlockOutputSignal` functions for the S-function are shown in this code excerpt:

```

%% Function: BlockOutputSignal =====
%% Abstract:
%% Return an output expression. This function *may*
%% be used by Simulink when optimizing the Block IO data structure.
%%
%function BlockOutputSignal(block,system,portIdx,ucv,lcx,idx,retType) void
%switch retType
%case "Signal"
 %assign u = LibBlockInputSignal(portIdx, ucv, lcv, idx)
 %case "Signal"
 %if portIdx == 0
 %return "(2 * %<u>)"
 %elseif portIdx == 1
 %return "(4 * %<u>)"
 %endif
%default
%assign errTxt = "Unsupported return type: %<retType>"
 %<LibBlockReportError(block,errTxt)>
%endswitch
%endfunction
%%
%% Function: Outputs =====
%% Abstract:
%% Compute output signals of block
%%
%function Outputs(block,system) Output
%assign rollVars = ["U", "Y"]
%roll sigIdx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
%assign u0 = LibBlockInputSignal(0, "", lcv, sigIdx)
 %assign u1 = LibBlockInputSignal(1, "", lcv, sigIdx)
 %assign y0 = LibBlockOutputSignal(0, "", lcv, sigIdx)
 %assign y1 = LibBlockOutputSignal(1, "", lcv, sigIdx)
%if !LibBlockOutputSignalIsExpr(0)
 %<y0> = 2 * %<u0>;
%endif
%if !LibBlockOutputSignalIsExpr(1)
 %<y1> = 4 * %<u1>;
%endif
%endroll
%endfunction

```

### Comments for Blocks That Are Expression-Folding-Compliant

In the past, blocks preceded their outputs code with comments of the form

```
/* %<Type> Block: %<Name> */
```

When a block is expression-folding-compliant, the initial line shown above is generated automatically. Do not include the comment as part of the block's TLC implementation. Register additional information by using the `LibCacheBlockComment` function.

The `LibCacheBlockComment` function takes a character vector as an input, defining the body of the comment, except for the opening header, the final newline of a single or multiline comment, and the closing trailer.

The following TLC code illustrates registering a block comment. Note the use of the function `LibBlockParameterForComment`, which returns a character vector, suitable for a block comment, specifying the value of the block parameter.

```

%openfile commentBuf
 %c(*) Gain value: %<LibBlockParameterForComment(Gain)>
%closefile commentBuf
%<LibCacheBlockComment(block, commentBuf)>

```

- “S-Functions That Specify Port Scope and Reusability” on page 12-77
- “S-Functions That Specify Sample Time Inheritance Rules” on page 12-81
- “S-Functions for Code Reuse” on page 12-85

## S-Functions That Specify Port Scope and Reusability

You can use the following `SimStruct` macros in the `mdlInitializeSizes` method to specify the scope and reusability of the memory used for your S-function's input and output ports:

- `ssSetInputPortOptimOpts`: Specify the scope and reusability of the memory allocated to an S-function input port.
- `ssSetOutputPortOptimOpts`: Specify the scope and reusability of the memory allocated to an S-function output port.
- `ssSetInputPortOverWritable`: Specify whether one of your S-function's input ports can be overwritten by one of its output ports.
- `ssSetOutputPortOverwritesInputPort`: Specify whether an output port can share its memory buffer with an input port.

You declare an input or output as local or global, and indicate its reusability, by passing one of the following four options to the `ssSetInputPortOptimOpts` and `ssSetOutputPortOptimOpts` macros:

- `SS_NOT_REUSABLE_AND_GLOBAL`: Indicates that the input and output ports are stored in separate memory locations in the global block input and output structure.
- `SS_NOT_REUSABLE_AND_LOCAL`: Indicates that the code generator can declare individual local variables for the input and output ports.
- `SS_REUSABLE_AND_LOCAL`: Indicates that the code generator can reuse a single local variable for these input and output ports.
- `SS_REUSABLE_AND_GLOBAL`: Indicates that these input and output ports are stored in a single element in the global block input and output structure.

---

**Note** Marking an input or output port as a local variable does not imply that the code generator uses a local variable in the generated code. If your S-function accesses the inputs and outputs only in its `mdlOutputs` routine, the code generator declares the inputs and outputs as local variables. However, if the inputs and outputs are used elsewhere in the S-function, the code generator includes them in the global block input and output structure.

---

The reusability setting indicates if the memory associated with an input or output port can be overwritten. To reuse input and output port memory:

- 1 Indicate the ports are reusable using either the `SS_REUSABLE_AND_LOCAL` or `SS_REUSABLE_AND_GLOBAL` option in the `ssSetInputPortOptimOpts` and `ssSetOutputPortOptimOpts` macros.
- 2 Indicate the input port memory is overwritable using `ssSetInputPortOverWritable`.
- 3 If your S-function has multiple input and output ports, use `ssSetOutputPortOverwritesInputPort` to indicate which output and input ports share memory.

The following example shows how different scope and reusability settings affect the generated code. The following model contains an S-function block pointing to the C MEX S-function `matlabroot/toolbox/simulink/simdemos/simfeatures/src/sfun_directlook.c`, which models a direct 1-D lookup table.

The S-function's `mdlInitializeSizes` method declares the input port as reusable, local, and overwritable and the output port as reusable and local, as follows:

```
static void mdlInitializeSizes(SimStruct *S)
{
 /* snip */
 ssSetInputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);
 ssSetInputPortOverWritable(S, 0, TRUE);

 /* snip */
 ssSetOutputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);

 /* snip */
}
```

The generated code for this model stores the input and output signals in a single local variable `rtb_SFunction`, as shown in the following output function:

```
static void sl_directlook_output(int_T tid)
{
 /* local block i/o variables */
 real_T rtb_SFunction[2];

 /* Sin: '<Root>/Sine Wave' */
 rtb_SFunction[0] = sin(((real_T)sl_directlook_DWork.counter[0] +
 sl_directlook_P.SineWave_Offset) * 2.0 * 3.1415926535897931E+000 /
 sl_directlook_P.SineWave_NumSamp) * sl_directlook_P.SineWave_Amp[0] +
 sl_directlook_P.SineWave_Bias;
 rtb_SFunction[1] = sin(((real_T)sl_directlook_DWork.counter[1] +
 sl_directlook_P.SineWave_Offset) * 2.0 * 3.1415926535897931E+000 /
 sl_directlook_P.SineWave_NumSamp) * sl_directlook_P.SineWave_Amp[1] +

This table shows variations of the code generated for this model when using the generic real-time target (GRT). Each row explains a different setting for the scope and reusability of the S-function's input and output ports.

| Scope and reusability                                                              | S-function mdlInitializeSizes code                                                                                                                                           | Generated code                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

To check if the S-function input or output buffer reuse takes place, you can use `LibBlockInputSignalBufferDstPort` function.

## S-Functions That Specify Sample Time Inheritance Rules

For the Simulink engine to determine whether a model can inherit a sample time from a parent model, the S-functions in the model need to specify how they use sample times. You can specify this information by calling the macro `ssSetModelReferenceSampleTimeInheritanceRule` from `mdlInitializeSizes` or `mdlSetWorkWidths`. To use this macro:

- 1 Check whether the S-function calls any of these macros:
  - `ssGetSampleTime`
  - `ssGetInputPortSampleTime`
  - `ssGetOutputPortSampleTime`
  - `ssGetInputPortOffsetTime`
  - `ssGetOutputPortOffsetTime`
  - `ssGetInputPortSampleTimeIndex`
  - `ssGetOutputPortSampleTimeIndex`
- 2 Check for these in your S-function TLC code:
  - `LibBlockSampleTime`
  - `CompiledModel.SampleTime`
  - `LibBlockInputSignalSampleTime`
  - `LibBlockInputSignalOffsetTime`
  - `LibBlockOutputSignalSampleTime`
  - `LibBlockOutputSignalOffsetTime`
- 3 Depending on your search results, use `ssSetModelReferenceSampleTimeInheritanceRule` as indicated in this table.

| If...                                                                                                                  | Use...                                                                                                 | Example |

**Note** If an S-function does not set the `ssSetModelReferenceSampleTimeInheritanceRule` macro, by default the Simulink engine assumes that the S-function does not preclude the model containing that S-function from inheriting a sample time. However, the engine issues a warning indicating that the model includes S-functions for which this macro is not set.

You can use settings in the Configuration Parameters on the **Diagnostics > Sample Time** pane to control how the Simulink engine responds when it encounters S-functions that have unspecified sample time inheritance rules. Toggle the **Unspecified inheritability of sample time** diagnostic to none, warning, or error. The default is warning.

For information about Model block sample time inheritance, see “Referenced Model Sample Times”.

## S-Functions for Code Reuse

You can reuse the generated code for identical subsystems that occur in multiple instances within a model and across referenced models. For more information about code generation of subsystems for code reuse, see “Generate Subsystem Code as Separate Function and Files”.

### S-Function Code Reuse Requirements

To use S-function for code reuse for a subsystem, the S-function must meet these requirements:

- The S-function must be inlined.
- Code generated from the S-function must not use static variables.
- The S-function must initialize its pointer work vector in only `mdlStart` and not before.
- The S-function must not be a sink that logs data to the workspace.
- The S-function must register its parameters as run-time parameters in `mdlSetWorkWidths`. For this purpose, the S-function must not use `ssWriteRTWParameters` in its `mdlRTW` function.
- The S-function must not be a device driver.

Additionally, your S-function must set the `SS_OPTION_WORKS_WITH_CODE_REUSE` flag in the `ssSetOptions` function. This flag indicates that your S-function meets the requirements for subsystem code reuse. If the flag is set and your S-function does not meet the requirements, the code generator does not generate a reusable function and you see a warning.

### S-Functions Reused Across Models

You can place S-functions inside reusable library subsystems. In the S-function file, set both of these flags:

- `SS_OPTION_WORKS_WITH_CODE_REUSE` flag in the `ssSetOptions` function
- `ssSetSupportedForCodeReuseAcrossModels` set to 1 or true

If you use the `legacy_code` tool to generate your S-function, the S-function option `supportCodeReuseAcrossModels` specifies code reuse across models for the subsystem that contains the S-function.

Configure the S-function for code reuse across models only if the S-function does not access any model-specific data structures. This configuration is necessary because the generated code in `_sharedutils` folder is compiled separately from the generated code in `model_ert_rtw` folder. The reusable library subsystem code generated in the `_sharedutils` folder does not have access to types and macros that are declared in `model.h`. The reusable library subsystem code must be independent. For more information, see “Generate Reusable Code from Library Subsystems Shared Across Models”.

If your S-function uses custom functions defined in your external header files, add the “`LibAddtoSystemCustomIncludes(system, incFileName)`” function in your S-function's TLC file. For example, when you add `LibAddtoSystemCustomIncludes("company_math.h")` in your `.tlc` file, the reusable library subsystem code in the `_sharedutils` folder includes the `#company_math.h` header file.

1. Create a new MATLAB working folder. In the MATLAB Command Window, copy these external code files to your current MATLAB working folder:

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
copyfile(fullfile(matlabroot,'toolbox','rtw','rtwdemos','doubleIt.c'));
copyfile(fullfile(matlabroot,'toolbox','rtw','rtwdemos','doubleIt.h'));
```

2. Open example model `rtwdemo_sfcn_rls`. This example model uses two instances of the reusable library subsystem `rtwdemo_sfcn_rls_lib`. The S-function `sfun_mySrc` inside the reusable library subsystem uses external files `doubleIt.c` and `doubleIt.h`.

```
rtwdemo_sfcn_rls;
```

Copyright 2020 The MathWorks, Inc.

3. Generate the S-function code by using legacy code tool. Use these commands in your MATLAB Command window:

```
def = legacy_code('initialize');
def.SFunctionName = 'sfun_mySrc';
def.SourceFiles = {'doubleIt.c'};
def.HeaderFiles = {'doubleIt.h'};
def.OutputFcnSpec = 'double y1 = doubleIt(double u1)';
```

4. Specify the S-function for code reuse:

```
def.Options.supportCodeReuseAcrossModels = true;
```

5. Generate the S-function code TLC block file. Then compile the S-function.

```
legacy_code('sfcn_tlc_generate',def);
legacy_code('sfcn_cmex_generate', def);
legacy_code('compile', def);
```

```
Start Compiling sfun_mySrc
mex('-IC:\TEMP\Bdoc22a_1891349_13144\ibC86E06\16\tpca243cd3_a0a7_4832_8512_ffc13f7900ec\code
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('sfun_mySrc.c', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC86E06\16\tpca243cd3_a0a7_4832_8512_f
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling sfun_mySrc
Exit
```

6. The code generator creates the S-function file `sfun_mySrc.c` and its TLC file `sfun_mySrc.tlc` in your MATLAB working folder. In the `sfun_mySrc.c` file, the code generator adds these specifications:

```
file = fullfile('sfun_mySrc.c');
rtwdemodbtype(file, '* All options have the form SS_OPTION_<name>', ...
 'ssSetSupportedForCodeReuseAcrossModels(S, 1);', 1, 1);

 * All options have the form SS_OPTION_<name> and are documented in
 * matlabroot/simulink/include/simstruc.h. The options should be
 * bitwise or'd together as in
 * ssSetOptions(S, (SS_OPTION_name1 | SS_OPTION_name2))
 */
ssSetOptions(S,
 SS_OPTION_USE_TLC_WITH_ACCELERATOR |
 SS_OPTION_CAN_BE_CALLED_CONDITIONALLY |
 SS_OPTION_EXCEPTION_FREE_CODE |
 SS_OPTION_WORKS_WITH_CODE_REUSE |
 SS_OPTION_SFUNCTION_INLINED_FOR_RTW |
 SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME
);
ssSetSupportedForCodeReuseAcrossModels(S, 1);
```

In the `sfun_mySrc.c`, the `SS_OPTION_WORKS_WITH_CODE_REUSE` flag is set in the `ssSetOptions` function and `ssSetSupportedForCodeReuseAcrossModels` is set to true.

7. On the Simulink toolstrip, open the **Embedded Coder** or **Simulink Coder** app.

8. Generate code for the model. On the **C Code** tab, click **Build**.

```
evalc('slbuild(''rtwdemo_sfcn_rls'')');
```

The code generator produces a reusable function that can be reused across models in the `_sharedutils` folder. Models in a model reference hierarchy share this `_sharedutils` folder to reuse code. For this example, the reusable function is generated in the `slprj/grt/_sharedutils/sfunc.c` file:

```
file = fullfile('slprj', 'grt', '_sharedutils', 'sfunc.c');
rtwdemodbtype(file, 'Output and update for atomic system', ...
 'rtb_sfun_mySrc', 1, 1);

 * Output and update for atomic system:
 * 'ReusableSubsystem' ('rtwdemo_sfcn_rls_lib:60')
 * 'ReusableSubsystem' ('rtwdemo_sfcn_rls_lib:60')
 */
void sfunc(real_T rtu_In1, B_sfunc_T *localB, DW_sfunc_T *localDW)
{
 /* local block i/o variables */
 real_T rtb_sfun_mySrc;
```

### S-Functions Reused Within a Model

By default, S-functions inside a subsystem are not configured for code reuse within a model. You can specify the S-functions inside a subsystem for code reuse within a model. In the S-function file, set the `SS_OPTION_WORKS_WITH_CODE_REUSE` flag in the `ssSetOptions` function. This flag indicates that your S-function meets the requirements for subsystem code reuse and is configured for code

reuse. If the flag is set and your S-function does not meet the requirements, the code generator does not generate a reusable function and you see a warning.

1. Create a new MATLAB working folder and copy these external code files to your current MATLAB working folder:

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
copyfile(fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'doubleIt.c'));
copyfile(fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'doubleIt.h'));
```

2. For the example model `rtwdemo_sfcn_rls`, generate the S-function code by using legacy code tool. Do not include the S-function option `supportCodeReuseAcrossModels`. Use these commands in your MATLAB Command window:

```
def = legacy_code('initialize');
def.SFunctionName = 'sfun_mySrc';
def.SourceFiles = {'doubleIt.c'};
def.HeaderFiles = {'doubleIt.h'};
def.OutputFcnSpec = 'double y1 = doubleIt(double u1)';
```

3. Generate the S-function code TLC block file. Then compile the S-function.

```
legacy_code('sfcn_tlc_generate', def);
legacy_code('sfcn_cmex_generate', def);
legacy_code('compile', def);
```

```
Start Compiling sfun_mySrc
mex('-IC:\TEMP\Bdoc22a_1891349_13144\ibC86E06\16\tp1b4c279e_d328_424a_87fd_ba2aa37a15c8\code
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('sfun_mySrc.c', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC86E06\16\tp1b4c279e_d328_424a_87fd_b
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling sfun_mySrc
Exit
```

4. The code generator creates the S-function file `sfun_mySrc.c` and its TLC file `sfun_mySrc.tlc` in your MATLAB working folder.

```
file = fullfile('sfun_mySrc.c');
rtwdemodbtype(file, '* All options have the form SS_OPTION_<name>', ...
 'SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME', 1, 1);

* All options have the form SS_OPTION_<name> and are documented in
* matlabroot/simulink/include/simstruc.h. The options should be
* bitwise or'd together as in
* ssSetOptions(S, (SS_OPTION_name1 | SS_OPTION_name2))
*/
ssSetOptions(S,
 SS_OPTION_USE_TLC_WITH_ACCELERATOR |
 SS_OPTION_CAN_BE_CALLED_CONDITIONALLY |
 SS_OPTION_EXCEPTION_FREE_CODE |
 SS_OPTION_WORKS_WITH_CODE_REUSE |
 SS_OPTION_SFUNCTION_INLINED_FOR_RTW |
 SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME
```

In the `sfun_mySrc.c` file, the code generator adds `SS_OPTION_WORKS_WITH_CODE_REUSE` flag in the `ssSetOptions` function by default but does not include the `ssSetSupportedForCodeReuseAcrossModels` specification that prevents the S-function from being reused across models.

5. On the Simulink toolstrip, open the **Embedded Coder** or **Simulink Coder** app.

6. Generate code for the model. On the **C Code** tab, click **Build**.

```
evalc('slbuild(''rtwdemo_sfcn_rls'')');
```

The code generator produces a reusable function for the subsystem in the `rtwdemo_sfcn_rls.c` file, which is outside the `_sharedutils` folder. This code can be reused within the model but not across the model reference hierarchy:

```
file = fullfile('rtwdemo_sfcn_rls_grt_rtw','rtwdemo_sfcn_rls.c');
rtwdemodbtype(file,'void sfunc', ...
 'localDW->UnitDelay_DSTATE = rtb_sfun_mySrc;',1,1);

void sfunc_Init(DW_sfunc_T *localDW)
{
 /* InitializeConditions for UnitDelay: '<S1>/Unit Delay' */
 localDW->UnitDelay_DSTATE = 0.0;
}

/*
 * Output and update for atomic system:
 * '<Root>/ReusableSubsystem1'
 * '<Root>/ReusableSubsystem2'
 */
void sfunc(real_T rtu_In1, B_sfunc_T *localB, DW_sfunc_T *localDW)
{
 /* local block i/o variables */
 real_T rtb_sfun_mySrc;

 /* UnitDelay: '<S1>/Unit Delay' */
 localB->UnitDelay = localDW->UnitDelay_DSTATE;

 /* S-Function (sfun_mySrc): '<S1>/sfun_mySrc' */
 rtb_sfun_mySrc = doubleIt(rtu_In1);

 /* Update for UnitDelay: '<S1>/Unit Delay' */
 localDW->UnitDelay_DSTATE = rtb_sfun_mySrc;
}
```

## S-Functions for Multirate Multitasking Environments

### In this section...

“About S-Functions for Multirate Multitasking Environments” on page 12-90

“Rate Grouping Support in S-Functions” on page 12-90

“Create Multitasking, Multirate, Port-Based Sample Time S-Functions” on page 12-90

### About S-Functions for Multirate Multitasking Environments

S-functions can be used in models with multiple sample rates and deployed in multitasking target environments. Likewise, S-functions themselves can have multiple rates at which they operate. The code generator produces code for multirate multitasking models using an approach called *rate grouping*. In code generated for ERT-based targets, rate grouping generates separate *model\_step* functions for the base rate task and each subrate task in the model. Although rate grouping is a code generation feature found in ERT targets only, your S-functions can use it in other contexts when you code them as explained below.

### Rate Grouping Support in S-Functions

To take advantage of rate grouping, you must inline your multirate S-functions if you have not done so. You need to follow certain Target Language Compiler protocols to exploit rate grouping. Coding TLC to exploit rate grouping does not prevent your inlined S-functions from functioning properly in GRT. Likewise, your inlined S-functions will still generate valid ERT code even if you do not make them rate-grouping-compliant. If you do so, however, they will generate more efficient code for multirate models.

For instructions and examples of Target Language Compiler code illustrating how to create and upgrade S-functions to generate rate-grouping-compliant code, see “Rate Grouping Compliance and Compatibility Issues” on page 68-12.

For each multirate S-function that is not rate grouping-compliant, the code generator issues the following warning when you build:

```
Warning: Simulink Coder: Code of output function for multirate block
'<Root>/S-Function' is guarded by sample hit checks rather than being rate
grouped. This will generate the same code for all rates used by the block,
possibly generating dead code. To avoid dead code, you must update the TLC
file for the block.
```

You will also find a comment such as the following in code generated for each noncompliant S-function:

```
/* Because the output function of multirate block
<Root>/S-Function is not rate grouped,
the following code might contain unreachable blocks of code.
To avoid this, you must update your block TLC file. */
```

The words “update function” are substituted for “output function” in these warnings.

### Create Multitasking, Multirate, Port-Based Sample Time S-Functions

The following instructions show how to support both data determinism and data integrity in multirate S-functions. They do not cover cases where there is no determinism nor integrity. Support for frame-based processing does not affect the requirements.

---

**Note** The slow rates must be multiples of the fastest rate. The instructions do not apply when two rates being interfaced are not multiples or when the rates are not periodic.

---

### Rules for Properly Handling Fast-to-Slow Transitions

The rules that multirate S-functions should observe for inputs are

- The input should only be read at the rate that is associated with the input port sample time.
- Generally, the input data is written to DWork, and the DWork can then be accessed at the slower (downstream) rate.

The input can be read at every sample hit of the input rate and written into DWork memory, but this DWork memory cannot then be directly accessed by the slower rate. DWork memory that will be read by the slow rate must only be written by the fast rate when there is a *special sample hit*. A special sample hit occurs when both this input port rate and rate to which it is interfacing have a hit. Depending on their requirements and design, algorithms can process the data in several locations.

The rules that multirate S-functions should observe for outputs are

- The output should not be written by a rate other than the rate assigned to the output port, except in the optimized case described below.
- The output should always be written when the sample rate of the output port has a hit.

If these conditions are met, the S-Function block can specify that the input port and output port can both be made local and reusable.

You can include an optimization when little or no processing needs to be done on the data. In such cases, the input rate code can directly write to the output (instead of by using DWork) when there is a special sample hit. If you do this, however, you must declare the output port to be *global* and *not reusable*. This optimization results in one less memcopy but does introduce nonuniform processing requirements on the faster rate.

Whether you use this optimization or not, the most recent input data, as seen by the slower rate, is the value when both the faster and slower rate had their hits (and possible earlier input data as well, depending on the algorithm). Subsequent steps by the faster rate and the associated input data updates are not seen by the slower rate until the next hit for the slow rate occurs.

### Pseudocode Examples of Fast-to-Slow Rate Transition

The pseudocode below abstracts how you should write your C MEX code to handle fast-to-slow transitions, illustrating with an input rate of 0.1 second driving an output rate of one second. A similar approach can be taken when inlining the code. The block has following characteristics:

- File: `sfun_multirate_zoh.c`, Equation:  $y = u(t_{\text{slow}})$
- Input: local and reusable
- Output: local and reusable
- DirectFeedthrough: yes

```
OutputFcn
if (ssIsSampleHit("1")) {
 if (ssIsSpecialSampleHit("1")) {
 DWork = u;
 }
}
```

```

if (ssIsSampleHit("1")) {
 y = DWork;
}

```

An alternative, slightly optimized approach for simple algorithms:

- Input: local and reusable
- Output: global and not reusable because it needs to persist between special sample hits
- DirectFeedthrough: yes

```

OutputFcn
if (ssIsSampleHit(".1")) {
 if (ssIsSpecialSampleHit("1")) {
 y = u;
 }
}

```

Example adding a simple algorithm:

- File: `sfun_multirate_avg.c`; Equation:  $y = \text{average}(u)$
- Input: local and reusable
- Output: local and reusable
- DirectFeedthrough: yes

(Assume `DWork[0:10]` and `DWork[mycounter]` are initialized to zero)

```

OutputFcn
if (ssIsSampleHit(".1")) {
 /* In general, processing on 'u' could be done here,
 it runs on every hit of the fast rate. */
 DWork[DWork[mycounter]++] = u;
 if (ssIsSpecialSampleHit("1")) {
 /* In general, processing on DWork[0:10] can be done
 here, but it does cause the faster rate to have
 nonuniform processing requirements (every 10th hit,
 more code needs to be run).*/
 DWork[10] = sum(DWork[0:9])/10;
 DWork[mycounter] = 0;
 }
}
if (ssIsSampleHit("1")) {
 /* Processing on DWork[10] can be done here before
 outputting. This code runs on every hit of the
 slower task. */
 y = DWork[10];
}

```

### Rules for Properly Handling Slow-to-Fast Transitions

When output rates are faster than input rates, input should only be read at the rate that is associated with the input port sample time, observing the following rules:

- Always read input from the update function.
- Use no special sample hit checks when reading input.
- Write the input to a `DWork`.
- When there is a special sample hit between the rates, copy the `DWork` into a second `DWork` in the output function.
- Write the second `DWork` to the output at every hit of the output sample rate.

The block can request that the input port be made local but it cannot be set to reusable. The output port can be set to local and reusable.

As in the fast-to-slow transition case, the input should not be read by a rate other than the one assigned to the input port. Similarly, the output should not be written to at a rate other than the rate assigned to the output port.

An optimization can be made when the algorithm being implemented is only required to run at the slow rate. In such cases, you use only one DWork. The input still writes to the DWork in the update function. When there is a special sample hit between the rates, the output function copies the same DWork directly to the output. You must set the output port to be global and not reusable in this case. This optimization results in one less memcpy operation per special sample hit.

In either case, the data that the fast rate computations operate on is always delayed, that is, the data is from the previous step of the slow rate code.

### Pseudocode Examples of Slow-to-Fast Rate Transition

The pseudocode below abstracts what your S-function needs to do to handle slow-to-fast transitions, illustrating with an input rate of one second driving an output rate of 0.1 second. The block has following characteristics:

- File: `sfun_multirate_delay.c`, Equation:  $y = u(ts_{\text{slow}}-1)$
- Input: Set to local, will be local if output/update are combined (ERT) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: local and reusable
- DirectFeedthrough: no

```
OutputFcn
if (ssIsSampleHit(".1")) {
 if (ssIsSpecialSampleHit("1")) {
 DWork[1] = DWork[0];
 }
 y = DWork[1];
}
UpdateFcn
if (ssIsSampleHit("1")) {
 DWork[0] = u;
}
```

An alternative, optimized approach can be used by some algorithms:

- Input: Set to local, will be local if output/update are combined (ERT) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: global and not reusable because it needs to persist between special sample hits.
- DirectFeedthrough: no

```
OutputFcn
if (ssIsSampleHit(".1")) {
 if (ssIsSpecialSampleHit("1")) {
 y = DWork;
 }
}
UpdateFcn
if (ssIsSampleHit("1")) {
 DWork = u;
}
```

Example adding a simple algorithm:

- File: `sfun_multirate_modulate.c`, Equation:  $y = \sin(t_{\text{fast}}) + u(t_{\text{slow}} - 1)$
- Input: Set to local, will be local if output/update are combined (an ERT feature) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: local and reusable
- DirectFeedthrough: no

```
OutputFcn
if (ssIsSampleHit(".1")) {
 if (ssIsSpecialSampleHit("1")) {
 /* Processing not likely to be done here. It causes
 * the faster rate to have nonuniform processing
 * requirements (every 10th hit, more code needs to
 * be run).*/
 DWork[1] = DWork[0];
 }
 /* Processing done at fast rate */
 y = sin(ssGetTaskTime(".1")) + DWork[1];
}
UpdateFcn
if (ssIsSampleHit("1")) {
 /* Processing on 'u' can be done here. There is a delay of
 one slow rate period before the fast rate sees it.*/
 DWork[0] = u;}

```

## Write Noninlined S-Function

A noninlined S-function is a C or C++ MEX S-function that is treated identically by the Simulink engine and by the generated code. You implement your algorithm once according to the S-function API. The Simulink engine and generated code call the S-function routines (for example, `mdlOutputs`) during model execution.

Noninlined S-functions are identified by the absence of an `sfunction.tlc` file for your S-function. The file name varies depending on your platform. For example, on a 64-bit Microsoft® Windows® system, the file name is `sfunction.mexw64`. In the MATLAB Command Window, type `mexext` to see which extension your system uses.

### Guidelines for Writing Noninlined S-Functions

- The MEX-file cannot call MATLAB functions.
- If the MEX-file uses functions in the MATLAB External Interface libraries, include the header file `cg_sfun.h` instead of `mex.h` or `simulink.c`. For the header file `cg_sfun.h`, at the end of your S-function, include these lines:

```
#ifndef MATLAB_MEX_FILE /* Is this file being compiled as a MEX-file? */
#include "simulink.c" /* MEX-file interface mechanism */
#else
#include "cg_sfun.h" /* Code generation registration function */
#endif
```

- Use only the MATLAB API function that the code generator supports. The supported API functions are:
  - `mxGetDoubles`
  - `mxGetEps`
  - `mxGetInf`
  - `mxGetM`
  - `mxGetN`
  - `mxGetNaN`
  - `mxGetPr` (Not recommended. Use `mxGetDoubles` instead.)
  - `mxGetScalar`
  - `mxGetString`
  - `mxIsEmpty`
  - `mxIsFinite`
  - `mxIsInf`
- MEX library calls are not supported in generated code. To use such calls in the MEX-file and not in the generated code, add the following condition:

```
#ifndef MATLAB_MEX_FILE
#endif
```

- Use only full matrices that contain only real data.
- Do not specify a return value for calls to `mxGetString`. If you do specify a return value, the MEX-file does not compile. Instead, use the second input argument of the function, which returns a pointer to a character vector.

- Use the correct `#define s-function_name` statement. The S-function name that you specify must match the S-function file name.
- If possible, use the data types `real_T` and `int_T` instead of `double` and `int`. The data types `real_T` and `int_T` are more generic and can be used in multiple environments.
- Provide the build process with the names of the modules used to build the S-function. Use a template make file, the `set_param` function, or the `S-function modules` field of the S-Function block parameters dialog box. For example, suppose that you build your S-function with this command:

```
mex sfun_main.c sfun_module1.c sfun_module2.c
```

You can then use the following call to `set_param` to include the required modules:

```
set_param(sfun_block, "SFunctionModules", "sfun_module1 sfun_module2")
```

When you are ready to generate code, force the code generator to rebuild the top model. For more information, see “Control Regeneration of Top Model Code”.

## Noninlined S-Function Parameter Type Limitations

Parameters to noninlined S-functions can be of the following types only:

- Double precision
- Characters in scalars, vectors, or 2-D matrices

For more flexibility in the type of parameters that you can supply to S-functions or the operations in the S-function, inline your S-function and consider using an mdlRTW S-function routine.

Use of other functions from the MATLAB `matrix.h` API or other MATLAB APIs, such as `mex.h` and `mat.h`, are not supported. If you call unsupported APIs from an S-function source file, compiler errors occur. For details on supported MATLAB API functions, see the files `matlabroot/rtw/c/src/rt_matrix.h` and `matlabroot/rtw/c/src/rt_matrix.c`

If you use `mxGetPr` on an empty matrix, the function does not return `NULL`. It returns a random value. Therefore, you must protect calls to `mxGetPr` by using `mxIsEmpty`.

## Write Wrapper S-Function and TLC Files

Create S-functions that work seamlessly with the Simulink and code generator products by using the wrapper concept. You can:

- Interface your algorithms in Simulink models by writing MEX S-function wrappers (*sfunction.mex*).
- Direct the code generator to insert your algorithm into the generated code by creating a TLC S-function wrapper (*sfunction.tlc*).

### MEX S-Function Wrapper

Creating S-functions by using an S-function wrapper enables you to insert C/C++ code algorithms in Simulink models and the generated code with little or no change to your original C/C++ function. A MEX S-function wrapper is an S-function that calls code, which resides in another module.

---

**Note** Use a MEX S-function wrapper only in the MATLAB version in which you created the wrapper.

---

Suppose that you have an algorithm (that is, a C function) called `my_alg` that resides in the file `my_alg.c`. You can integrate `my_alg` into a Simulink model by creating a MEX S-function wrapper (for example, `wrapsfcn.c`). A Simulink model can then call `my_alg` from an S-Function block. The Simulink S-function contains a set of empty functions that the Simulink engine requires for various API related purposes. For example, although only `mdlOutputs` calls `my_alg`, the engine calls `mdlTerminate`, even though this S-function routine performs no action.

You can embed the call to `my_alg` in the generated code by creating a TLC S-function wrapper (for example, `wrapsfcn.tlc`). You can eliminate the empty function calls. You can avoid the overhead of executing the `mdlOutputs` function and you can then eliminate the `my_alg` function.

Wrapper S-functions are useful when you are creating algorithms that are procedural or when you are integrating legacy code into a Simulink model. If you want to create code that is:

- Interpretive in nature (that is, highly parameterized by operating modes)
- Heavily optimized (that is, no extra tests to decide what mode the code is operating in)

then you must create a fully inlined TLC file for your S-function.

The next figure shows the wrapper S-function concept.

Using an S-function wrapper to import algorithms into your Simulink model means that the S-function serves as an interface that calls your C/C++ algorithms from mdlOutputs. You can quickly integrate large standalone C/C++ programs into your model without having to change the code.

This sample model includes an S-function wrapper.

Two files are associated with the wrapsfcn block: the S-function wrapper and the C/C++ code that contains the algorithm. The first three statements:

- 1 Define the name of the S-function (what you enter in the Simulink S-Function block dialog box).

- 2 Specify that the S-function is using the level 2 format.
- 3 Provide access to the `SimStruct` data structure. `SimStruct` contains pointers to data used during simulation and code generation and defines macros that store data in and retrieve data from the `SimStruct`.

```
#define S_FUNCTION_NAME wrapsfcn
#define S_FUNCTION_LEVEL 2
#include "simstruc.h"

extern real_T my_alg(real_T u); /* Declare my_alg as extern */

/*
 * mdlInitializeSizes - initialize the sizes array
 */
static void mdlInitializeSizes(SimStruct *S)
{
 ssSetNumSFcnParams(S, 0); /*number of input arguments*/

 if (!ssSetNumInputPorts(S, 1)) return;
 ssSetInputPortWidth(S, 0, 1);
 ssSetInputPortDirectFeedThrough(S, 0, 1);

 if (!ssSetNumOutputPorts(S,1)) return;
 ssSetOutputPortWidth(S, 0, 1);

 ssSetNumSampleTimes(S, 1);
}

/*
 * mdlInitializeSampleTimes - indicate that this S-function runs
 * at the rate of the source (driving block)
 */
static void mdlInitializeSampleTimes(SimStruct *S)
{
 ssSetSampleTime(S, 0, INHERITED_SAMPLE_TIME);
 ssSetOffsetTime(S, 0, 0.0);
}

/*
 * mdlOutputs - compute the outputs by calling my_alg, which
 * resides in another module, my_alg.c
 */
static void mdlOutputs(SimStruct *S, int_T tid)
{
 InputRealPtrsType uPtrs = ssGetInputPortRealSignalPtrs(S,0);
 real_T *y = ssGetOutputPortRealSignal(S,0);
 *y = my_alg(*uPtrs[0]); /* Call my_alg in mdlOutputs */
}

/*
 * mdlTerminate - called when the simulation is terminated.
 */
static void mdlTerminate(SimStruct *S)
{
}

#ifdef MATLAB_MEX_FILE /* Is this file being compiled as a MEX-file? */
#include "simulink.c" /* MEX-file interface mechanism */
#else
#include "cg_sfun.h" /* Code generation registration function */
#endif
#endif
```

For more information, see “Templates for C S-Functions”.

The S-function routine `mdlOutputs` contains a function call to `my_alg`, which is the C function containing the algorithm that the S-function performs. For `my_alg.c`, the code is:

```

#ifdef MATLAB_MEX_FILE
#include "tmwtypes.h"
#else
#include "rtwtypes.h"
#endif
real_T my_alg(real_T u)
{
return(u * 2.0);
}

```

For more information, see “Manage Build Process File Dependencies”.

The wrapper S-function `wrapsfcn` calls `my_alg`, which computes  $u * 2.0$ . To build `wrapsfcn.mex`, use this command:

```
mex wrapsfcn.c my_alg.c
```

## TLC S-Function Wrapper

A TLC S-function wrapper is a TLC file that specifies how the code generator calls your code. For example, you can inline the call to `my_alg` in the `mdlOutputs` section of the generated code. In the “MEX S-Function Wrapper” example, the call to `my_alg` is embedded in the `mdlOutputs` section as:

```
*y = my_alg(*uPtrs[0]);
```

When you are creating a TLC S-function wrapper, the goal is to embed the same type of call in the generated code.

Look at how the code generator executes S-functions that are not inlined. A noninlined S-function is identified by the absence of the file `sfunction.tlc` and the existence of `sfunction.mex`. When generating code for a noninlined S-function, the code generator produces a call to `mdlOutputs` through a function pointer that, in this example, then calls `my_alg`.

The wrapper example contains one S-function, `wrapsfcn.mex`. You must compile and link an additional module, `my_alg`, with the generated code. At the MATLAB command prompt, enter:

```
set_param('wrapper/S-Function', 'SFunctionModules', 'my_alg')
```

## Code Overhead for Noninlined S-Functions

The code generated when using `grt.tlc` as the system target file *without* `wrapsfcn.tlc` is:

```
<Generated code comments for wrapper model with noninlined wrapsfcn S-function>
```

```

#include <math.h>
#include <string.h>
#include "wrapper.h"
#include "wrapper.prm"

/* Start the model */
void mdlStart(void)
{
/* (start code not required) */
}

/* Compute block outputs */
void mdlOutputs(int_T tid)
{
/* Sin Block: <Root>/Sin */
rtB.Sin = rtP.Sin.Amplitude *
sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

/* Level2 S-Function Block: <Root>/S-Function (wrapsfcn) */

```

```

{
 /* Noninlined S-functions create a SimStruct object and
 * generate a call to S-function routine mdlOutputs
 */
 SimStruct *rts = ssGetSFunction(rtS, 0);
 sfcnOutputs(rts, tid);
}

/* Outport Block: <Root>/Out */
rtY.Out = rtB.S_Function;
}

/* Perform model update */
void mdlUpdate(int_T tid)
{
 /* (update code not required) */
}

/* Terminate function */
void mdlTerminate(void)
{
 /* Level2 S-Function Block: <Root>/S-Function (wrapsfcn) */
 {
 /* Noninlined S-functions require a SimStruct object and
 * the call to S-function routine mdlTerminate
 */
 SimStruct *rts = ssGetSFunction(rtS, 0);
 sfcnTerminate(rts);
 }
}

#include "wrapper.reg"

/* [EOF] wrapper.c */

```

The `wrapper.reg` generated file contains the initialization of the `SimStruct` for the wrapper S-Function block. There is one child `SimStruct` for each S-Function block in your model. You can significantly reduce this overhead by creating a TLC wrapper for the S-function.

## Inline a Wrapper S-Function

The generated code makes the call to your S-function, `wrapsfcn.c`, in `mdlOutputs` by using this code:

```

SimStruct *rts = ssGetSFunction(rtS, 0);
sfcnOutputs(rts, tid);

```

This call has computational overhead associated with it. The Simulink engine creates a `SimStruct` data structure for the S-Function block. The code generator constructs a call through a function pointer to execute `mdlOutputs`, then `mdlOutputs` calls `my_alg`. By inlining the call to your C/C++ algorithm, `my_alg`, you can eliminate both the `SimStruct` and the extra function call, thereby improving the efficiency and reducing the size of the generated code.

Inlining a wrapper S-function requires an `sfunction.tlc` file for the S-function. The TLC file must contain the function call to `my_alg`. The figure shows the relationships between the algorithm, the wrapper S-function, and the `sfunction.tlc` file.

The `wrapsfcn.tlc` file tells Simulink Coder how to inline the call to `my_alg` using this statement.

To inline the call to `my_alg`, place your function call in an `sfunction.tlc` file with the same name as the S-function (in this example, `wrapsfcn.tlc`). The Target Language Compiler overrides the default method of placing calls to your S-function in the generated code.

This code is the TLC file `wrapsfcn.tlc` that inlines `wrapsfcn.c`:

```
%% File : wrapsfcn.tlc
%% Abstract:
%% Example inlined tlc file for S-function wrapsfcn.c
%%

implements "wrapsfcn" "C"

%% Function: BlockTypeSetup =====
%% Abstract:
%% Create function prototype in model.h as:
%% "extern real_T my_alg(real_T u);"
%%
%%function BlockTypeSetup(block, system) void
 %openfile buffer
 extern real_T my_alg(real_T u); /* This line is placed in wrapper.h */
 %closefile buffer
 %<LibCacheFunctionPrototype(buffer)>
%endfunction %% BlockTypeSetup

%% Function: Outputs =====
%% Abstract:
%% y = my_alg(u);
%%
%%function Outputs(block, system) Output
 /* %<Type> Block: %<Name> */
 %assign u = LibBlockInputSignal(0, "", "", 0)
 %assign y = LibBlockOutputSignal(0, "", "", 0)
 %% PROVIDE THE CALLING STATEMENT FOR "algorithm"
 %% The following line is expanded and placed in mdlOutputs within wrapper.c
 %<y> = my_alg(%<u>);

%endfunction %% Outputs
```

The first section of this code inlines the `wrapsfcn` S-Function block and generates the code in C:

```
implements "wrapsfcn" "C"
```

The next task is to inform the code generator that the routine `my_alg` must be declared as external in the generated `wrapper.h` file for any `wrapsfcn` S-Function blocks in the model. Do this declaration once for all `wrapsfcn` S-Function blocks by using the `BlockTypeSetup` function. In this function, you direct the Target Language Compiler to create a buffer and cache the `my_alg` as `extern` in the `wrapper.h` generated header file.

The final step is the inlining of the call to the function `my_alg`. The `Outputs` function inlines the call. In this function, you access the block input and output and place a direct call to `my_alg`. The call is embedded in `wrapper.c`.

## The Inlined Code

The code generated when you inline your wrapper S-function is similar to the default generated code. The `mdlTerminate` function does not contain a call to an empty function and the `mdlOutputs` function now directly calls `my_alg`.

```
void mdlOutputs(int_T tid)
{
 /* Sin Block: <Root>/Sin */
 rtB.Sin = rtP.Sin.Amplitude *
 sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

 /* S-Function Block: <Root>/S-Function */
 rtB.S_Function = my_alg(rtB.Sin); /* Inlined call to my_alg */

 /* Output Block: <Root>/Out */
 rtY.Out = rtB.S_Function;
}
```

`wrapper.reg` does not create a child `SimStruct` for the S-function because the generated code is calling `my_alg` directly, eliminating over 1 KB of memory usage.

- “Write Fully Inlined S-Functions”

## Write Fully Inlined S-Functions

A fully inlined S-function builds your algorithm (block) into generated code that you cannot distinguish from a built-in block. Typically, a fully inlined S-function requires you to implement your algorithm twice: once for the Simulink model (C/C++ MEX S-function) and once for code generation (TLC file).

Using the example in “Write Wrapper S-Function and TLC Files”, you can eliminate the call to `my_alg` entirely by specifying the explicit code (that is, `2.0 * u`) in `wrapsfcn.tlc`. While this can improve performance, if you are working with a large amount of C/C++ code, the task can be lengthy. You also have to maintain your algorithm in two places, the C/C++ S-function itself and the corresponding TLC file. Consider whether the performance gains might outweigh the disadvantages. To inline the algorithm used in this example, in the `Outputs` section of your `wrapsfcn.tlc` file, instead of writing:

```
%<y> = my_alg(%<u>);
```

Use:

```
%<y> = 2.0 * %<u>;
```

This code is the code produced in `mdlOutputs`:

```
void mdlOutputs(int_T tid)
{
 /* Sin Block: <Root>/Sin */
 rtB.Sin = rtP.Sin.Amplitude *
 sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

 /* S-Function Block: <Root>/S-Function */
 rtB.S_Function = 2.0 * rtB.Sin; /* Explicit embedding of algorithm */

 /* Output Block: <Root>/Out */
 rtY.Out = rtB.S_Function;
}
```

The Target Language Compiler replaces the call to `my_alg` with the algorithm itself.

## Multiport S-Function

A more advanced multiport inlined S-function example is `sfun_multiport.c` and `sfun_multiport.tlc`. This S-function illustrates how to create a fully inlined TLC file for an S-function that contains multiple ports.

## Guidelines for Writing Inlined S-Functions

- Consider using the block property `RTWdata` (see “S-Function RTWdata”). This property is a structure of character vectors that you can associate with a block. The code generator saves the structure with the model in the `model.rtw` file and makes the `.rtw` file more readable. For example in the MATLAB Command Window, suppose you enter these commands:

```
mydata.field1 = 'information for field1';
mydata.field2 = 'information for field2';
set_param(sfun_block, 'RTWdata', mydata);
```

The `.rtw` file that the code generator produces for the block includes the comments specified in the structure `mydata`.

- Consider using the `mdlRTW` function to inline your C MEX S-function in the generated code for:
  - Renaming tunable parameters in the generated code.
  - Introducing non-tunable parameters into a TLC file.

## **Related Examples**

- “Write Fully Inlined S-Functions with `mdlRTW` Routine”

## Write Fully Inlined S-Functions with mdlRTW Routine

You can inline more complex S-functions by using the S-function `mdlRTW` routine. The `mdlRTW` routine provides the code generation process with more information about how the S-function is to be inlined by creating a parameter record of a non-tunable parameter for use with a TLC file. The `mdlRTW` routine places information in the `model.rtw` file. The `mdlRTW` function is described in the text file `matlabroot/simulink/src/sfuntmpl_doc.c`.

To use the `mdlRTW` function, take steps to create a direct-index lookup S-function. Lookup tables are collections of ordered data points of a function. Typically, these tables use some interpolation scheme to approximate values of the associated function between known data points. To incorporate the example lookup table algorithm into a Simulink model, the first step is to write an S-function that executes the algorithm in `mdlOutputs`. To produce the most efficient code, the next step is to create a corresponding TLC file to eliminate computational overhead and improve the speed of the lookup computations.

The Simulink product provides support for general-purpose lookup 1-D, 2-D, and n-D algorithms. You can use these algorithms as they are or create a custom lookup table S-function to fit your requirements. You can create a 1-D lookup S-function, `sfun_directlook.c`, and its corresponding inlined `sfun_directlook.tlc` file (see “Target Language Compiler” for more details). You can:

- Error check of S-function parameters.
- Cache information for the S-function that does not change during model execution.
- Use the `mdlRTW` function to customize the code generator to produce the optimal code for a given set of block parameters.
- Create a TLC file for an S-function that either fully inlines the lookup table code or calls a wrapper function for the lookup table algorithm.

### S-Function RTWdata

`RTWdata` is a property of blocks, which can be used by the Target Language Compiler when inlining an S-function. `RTWdata` is a structure of character vectors that you can attach to a block. `RTWdata` is saved with the model and placed in the `model.rtw` file when you generate code. For example, this set of MATLAB commands:

```
mydata.field1 = 'information for field1';
mydata.field2 = 'information for field2';
set_param(gcf, 'RTWdata', mydata)
get_param(gcf, 'RTWdata')
```

produces this result:

```
ans =
 field1: 'information for field1'
 field2: 'information for field2'
```

The information for the associated S-Function block inside the `model.rtw` file is:

```
Block {
 Type "S-Function"
 RTWdata {
 field1 "information for field1"
 field2 "information for field2"
 }
}
```

---

**Note** RTWdata is saved in the model file for S-functions that are not linked to a library. However, RTWdata is **not persistent** for S-Function blocks that are linked to a library.

---

## Direct-Index Lookup Table Algorithm

The 1-D lookup table block provided in the Simulink library uses interpolation or extrapolation when computing outputs. In this example, you create a lookup table that directly indexes the output vector (y-data vector) based on the current input (x-data) point.

This direct 1-D lookup example computes an approximate solution  $p(x)$  to a partially known function  $f(x)$  at  $x=x_0$ , given data point pairs  $(x,y)$  in the form of an x-data vector and a y-data vector. For a given data pair (for example, the  $i$ 'th pair),  $y_i = f(x_i)$ . It is assumed that the x-data values are monotonically increasing. If  $x_0$  is outside the range of the x-data vector, the first or last point is returned.

The parameters to the S-function are:

XData, YData, XEvenlySpaced

XData and YData are double vectors of equal length representing the values of the unknown function. XDataEvenlySpaced is a scalar, 0.0 for false and 1.0 for true. If the XData vector is evenly spaced, XDataEvenlySpaced is 1.0 and more efficient code is generated.

The graph shows how the parameters XData=[1:6] and YData=[1,2,7,4,5,9] are handled. For example, if the input (x-value) to the S-Function block is 3, the output (y-value) is 7.

## Direct-Index Lookup Table Example

Improve the lookup table by inlining a direct-index S-function with a TLC file. This direct-index lookup table S-function does not require a TLC file. The example uses a TLC file for the direct-index lookup table S-function to reduce the code size and increase efficiency of the generated code.

Implementation of the direct-index algorithm with an inlined TLC file requires the S-function main module, `sfun_directlook.c` and a corresponding `lookup_index.c` module. The `lookup_index.c` module contains the `GetDirectLookupIndex` function that is used to locate the index in the XData for the current `x` input value when the XData is unevenly spaced. The `GetDirectLookupIndex` routine is called from the S-function and the generated code. The example uses the wrapper concept for sharing C/C++ code between Simulink MEX-files and the generated code.

If the XData is evenly spaced, then both the S-function main module and the generated code contain the lookup algorithm to compute the `y`-value of a given `x`-value because the algorithm is short.

The inlined TLC file is `sfun_directlook.tlc`, which is used to either perform a wrapper call or embed the optimal C/C++ code for the S-function. (See the example in “mdlRTW Usage”).

## Error Handling

In `sfun_directlook.tlc`, the `mdlCheckParameters` routine verifies that:

- The new parameter settings are valid.
- `XData` and `YData` are vectors of the same length containing real, finite numbers.
- `XDataEvenlySpaced` is a scalar.
- The `XData` vector is a monotonically increasing vector and evenly spaced.

The `mdlInitializeSizes` function explicitly calls `mdlCheckParameters` after it verifies the number of parameters passed to the S-function. After the Simulink engine calls `mdlInitializeSizes`, it then calls `mdlCheckParameters` whenever you change the parameters or reevaluate them.

## User Data Caching

In `sfun_directlook.tlc`, the `mdlStart` routine shows how to cache information that does not change during the simulation or while the generated code is executing. The example caches the value of the `XDataEvenlySpaced` parameter in `UserData`, a field of the `SimStruct`. The following line in `mdlInitializeSizes` instructs the Simulink engine to disallow changes to `XDataEvenlySpaced`.

```
ssSetSFcnParamTunable(S, iParam, SS_PRM_NOT_TUNABLE);
```

During execution, `mdlOutputs` accesses the value of `XDataEvenlySpaced` from `UserData` rather than calling the `mxGetPr` MATLAB API function.

## mdlRTW Usage

The code generator calls the `mdlRTW` routine while generating the `model.rtw` file. To produce optimal code for your Simulink model, you can add information to the `model.rtw` file about the mode in which your S-Function block is operating.

The example adds parameter settings to the `model.rtw` file. The parameter settings do not change during execution. In this case, the `XDataEvenlySpaced` S-function parameter cannot change during execution (`ssSetSFcnParamTunable` was specified as false (0) for it in `mdlInitializeSizes`). The parameter setting (`XSpacing`) uses the function `ssWriteRTWParamSettings`.

Because `xData` and `yData` are registered as run-time parameters in `mdlSetWorkWidths`, the code generator writes to the `model.rtw` file automatically.

Before examining the S-function and the inlined TLC file, consider the generated code for this model.

The model uses evenly spaced XData in the top S-Function block and unevenly spaced XData in the bottom S-Function block. When creating this model, specify the following commands for each S-Function block.

```
set_param('sfun_directlook_ex/S-Function','SFunctionModules','lookup_index')
set_param('sfun_directlook_ex/S-Function1','SFunctionModules','lookup_index')
```

The build process uses the module `lookup_index.c` when creating the executable.

When generating code for this model, the code generator uses the S-function `mdlRTW` method to generate a `model.rtw` file with the value `EvenlySpaced` for the `XSpacing` parameter for the top S-Function block and the value `UnEvenlySpaced` for the `XSpacing` parameter for the bottom S-Function block. The TLC-file uses the value of `XSpacing` to determine what algorithm to include in the generated code. The generated code contains the lookup algorithm when the XData is evenly spaced, but calls the `GetDirectLookupIndex` routine when the XData is unevenly spaced. The generated `model.c` or `model.cpp` code for the lookup table example model is similar to this code:

```
/*
 * sfun_directlook_ex.c
 *
 * Code generation for Simulink model
 * "sfun_directlook_ex.slx".
 *
 * ...
 */

#include "sfun_directlook_ex.h"
#include "sfun_directlook_ex_private.h"

/* External outputs (root outputs fed by signals with auto storage) */
ExtY_sfun_directlook_ex_T sfun_directlook_ex_Y;

/* Real-time model */
RT_MODEL_sfun_directlook_ex_T sfun_directlook_ex_M;

 &sfun_directlook_ex_M;

/* Model output function */
void sfun_directlook_ex_output(void)
{
 /* local block i/o variables */
 real_T rtb_SFunction;
 real_T rtb_SFunction1;

 /* Sin: '<Root>/Sine Wave' */
 rtb_SFunction1 = sin(sfun_directlook_ex_M->Timing.t[0]);
}
```

```

/* Code that is inlined for the top S-function block in the
 * sfun_directlook_ex model
 */
/* S-Function (sfun_directlook): '<Root>/S-Function' */
{
 const real_T *xData = sfun_directlook_ex_ConstP.SFunction_XData;
 const real_T *yData = sfun_directlook_ex_ConstP.SFunction_YData;
 real_T spacing = xData[1] - xData[0];
 if (rtb_SFunction1 <= xData[0]) {
 rtb_SFunction = yData[0];
 } else if (rtb_SFunction1 >= yData[20]) {
 rtb_SFunction = yData[20];
 } else {
 int_T idx = (int_T)((rtb_SFunction1 - xData[0]) / spacing);
 rtb_SFunction = yData[idx];
 }
}

/* Outport: '<Root>/Out1' */
sfun_directlook_ex_Y.Out1 = rtb_SFunction;

/* Code that is inlined for the bottom S-function block in the
 * sfun_directlook_ex model
 */
/* S-Function (sfun_directlook): '<Root>/S-Function1' */
{
 const real_T *xData = sfun_directlook_ex_ConstP.SFunction1_XData;
 const real_T *yData = sfun_directlook_ex_ConstP.SFunction1_YData;
 int_T idx;
 idx = GetDirectLookupIndex(xData, 5, rtb_SFunction1);
 rtb_SFunction1 = yData[idx];
}

/* Outport: '<Root>/Out2' */
sfun_directlook_ex_Y.Out2 = rtb_SFunction1;
}

/* Model update function */
void sfun_directlook_ex_update(void)
{
 /* signal main to stop simulation */
 {
 /* Sample time: [0.0s, 0.0s] */
 if ((rtmGetTFinal(sfun_directlook_ex_M)!=-1) &&
 !((rtmGetTFinal(sfun_directlook_ex_M)-sfun_directlook_ex_M->Timing.t[0])
 > sfun_directlook_ex_M->Timing.t[0] * (DBL_EPSILON))) {
 rtmSetErrorStatus(sfun_directlook_ex_M, "Simulation finished");
 }
 }

 /* Update absolute time for base rate */
 /* The "clockTick0" counts the number of times the code of this task has
 * been executed. The absolute time is the multiplication of "clockTick0"
 * and "Timing.stepSize0". Size of "clockTick0" ensures timer will not
 * overflow during the application lifespan selected.
 * Timer of this task consists of two 32 bit unsigned integers.
 * The two integers represent the low bits Timing.clockTick0 and the high bits
 * Timing.clockTickH0. When the low bit overflows to 0, the high bits increment.
 */
 if (!(++sfun_directlook_ex_M->Timing.clockTick0)) {
 ++sfun_directlook_ex_M->Timing.clockTickH0;
 }

 sfun_directlook_ex_M->Timing.t[0] = sfun_directlook_ex_M->Timing.clockTick0 *
 sfun_directlook_ex_M->Timing.stepSize0 +
 sfun_directlook_ex_M->Timing.clockTickH0 *
 sfun_directlook_ex_M->Timing.stepSize0 * 4294967296.0;
}
...

```

## Target Language Compiler Basics

### Target Language Compiler Overview

Target Language Compiler (TLC) is an integral part of the code generator. It enables you to customize generated code. Through customization, you can produce platform-specific code, or you can incorporate your own algorithmic changes for performance, code size, or compatibility with existing methods.

The TLC includes:

- Files corresponding to a subset of the provided Simulink blocks.
- Files for model-wide information that specify header and parameter information.

The TLC files are ASCII files that explicitly control the way that code is generated. By editing a TLC file, you can alter the way that the code is generated.

The Target Language Compiler provides a complete set of ready-to-use TLC files for generating ANSI C or C++ code. You can view the TLC files and make minor or extensive changes to them. This open environment provides tremendous flexibility for customizing the generated code.

For more information, see “Implement C/C++ S-Functions”, which describes how to write wrapped and fully inlined S-functions, with emphasis on the `mdlRTW()` function.

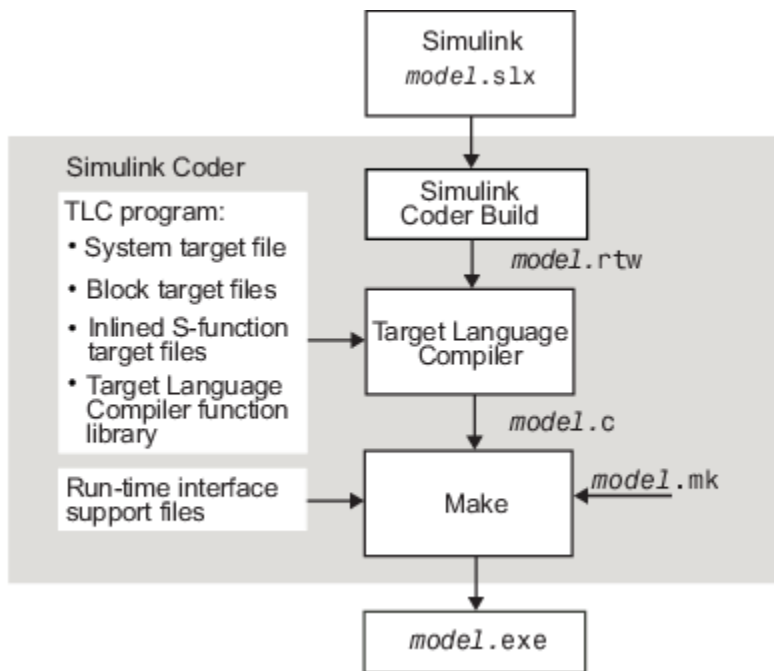

---

**Note** Do not customize TLC files in the folder `matlabroot/rtw/c/tlc`, even though the capability exists. Such TLC customizations might not be applied during the code generation process and can lead to unpredictable results.

---

### Overview of the TLC Process

This top-level diagram shows how the Target Language Compiler fits in with the code generation process.

The Target Language Compiler (TLC) is designed to convert the model description file *model.rtw* (or similar files) into target-specific code or text.

The Target Language Compiler transforms a representation of a Simulink block diagram, called *model.rtw*, into C or C++ code. The *model.rtw* file contains a partial representation of the model. The representation describes the execution semantics of the block diagram in a high-level language. For more information, see “*model.rtw* File and Scopes” on page 17-2.

After reading the *model.rtw* file, the Target Language Compiler generates its code based on target files, which specify particular code for each block, and model-wide files, which specify the overall code style. The TLC uses the target files and the *model.rtw* file to generate ANSI C or C++ code.

To create a target-specific application, the code generator requires a template makefile that specifies a C or C++ compiler and compiler options for the build process. The code generator transforms the template makefile into a target makefile (*model.mk*) by performing token expansion specific to a given model. The target makefile is a modified version of the generic *rt\_main* file (or *grt\_main*). You must modify *grt\_main* to conform to the target’s specific requirements, such as interrupt service routines. See “*Template Makefiles and Make Options*” and “*Customize Template Makefiles*”.

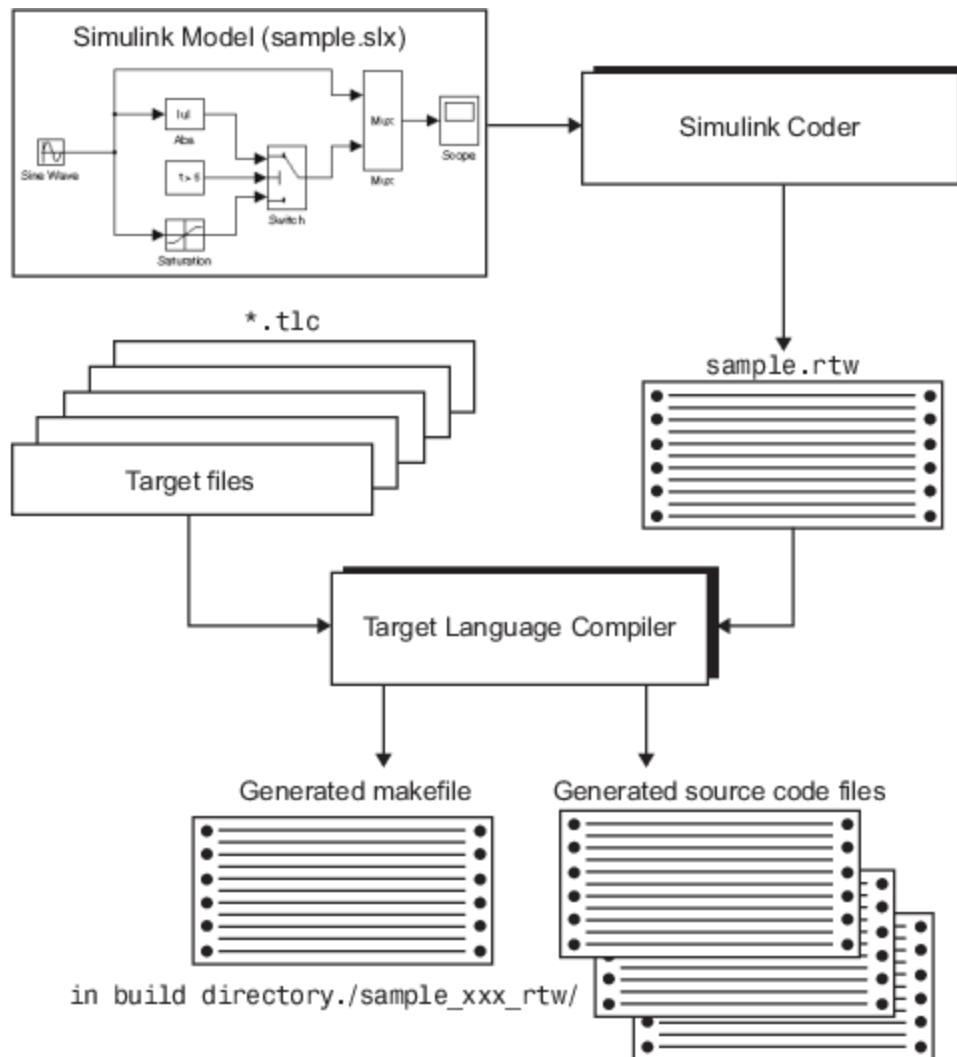

The Target Language Compiler has similarities with HTML, Perl, and MATLAB. It has markup syntax similar to HTML, the power and flexibility of Perl and other scripting languages, and the data handling power of MATLAB (TLC can invoke MATLAB functions). The code that TLC generated is highly optimized and fully commented. With TLC, you can generate code from linear, nonlinear, continuous, discrete, or hybrid Simulink models. The models can include Simulink blocks that are automatically converted to code. Exceptions are MATLAB function blocks and S-function blocks that invoke MATLAB files. The Target Language Compiler uses block target files to transform each block in the *model.rtw* file and a model-wide target file for global customization of the code.

You can incorporate C MEX S-functions, with the generated code into the program executable. You can write a target file for your C MEX S-function to inline the S-function (see “*Inline C MEX S-Functions*” on page 20-8), to improve performance by eliminating function calls to the S-function

itself and the memory overhead of the `SimStruct` of the S-function. Inlining an S-function incorporates the S-function block code into the generated code for the model. When a TLC target file is not present for the S-function, its C or C++ code file is invoked through a function call. See “Inline S-Functions” on page 20-2. You can also write target files for MATLAB language files or Fortran S-functions.

## Overview of the Code Generation Process

The Target Language Compiler works with its target files and the code generator output to produce code.

When generating code from a Simulink model, the first step in the automated process is to generate a `model.rtw` file. The `model.rtw` file includes the model-specific information required for generating code from the Simulink model. `model.rtw` is passed to the Target Language Compiler, which uses it in combination with a set of included system target files and block target files to generate the code.

Only the final executable file is written directly to the current folder. For other files created during code generation, including the `model.rtw` file, a build folder is used. This folder is created in the

current folder and is named *model\_target\_rtw*. *target* is the abbreviation for the target environment grt that is a generic real-time target.

Files placed in the build folder include:

- The body for the generated C or C++ source code (*model.c* or *model.cpp*)
- Header files (*model.h*)
- Header file *model\_private.h* defining parameters and data structures private to the generated code
- A makefile, *model.mk*, for building the application
- Additional files, described in “Manage Build Process Files”

## Why Use the Target Language Compiler?

If you simply need to produce ANSI C or C++ code from Simulink models, you do not need to know how to prepare files for the Target Language Compiler. If you need to customize the output, you must run the Target Language Compiler. With the Target Language Compiler, you can:

- Customize the set of options specified by your system target file.
- Inline the code for S-Function blocks.
- Generate additional or different types of files.

The MATLAB Function block and the Embedded Coder product facilitate code customization in a variety of ways. You might be able to accomplish what you need with them, without the need to write TLC files. However, you do need to prepare TLC files if you intend to inline S-functions.

See the following sections.

### Customizing Output

To produce customized output using the Target Language Compiler, it helps if you understand how blocks perform their functions, what data types are being manipulated, the structure of the `model.rtw` file, and how to modify target files to produce the desired output. Directives and Built-In Functions topics on “Target Language Compiler”, describe the target language directives and their associated constructs. You will use the Target Language Compiler directives and constructs to modify existing target files or create new ones, depending on your needs. See “TLC Files” on page 16-11 for more information about target files.

---

**Note** You should not customize TLC files in the folder `matlabroot/rtw/c/tlc` even though the capability exists to do so. Such TLC customizations might not be applied during the code generation process and can lead to unpredictable results.

---

### Inlining S-Functions

The Target Language Compiler provides a great deal of freedom for altering, optimizing, and enhancing the generated code. One of the most important TLC features is that it lets you inline S-functions that you write to add your own algorithms, device drivers, and custom blocks to a Simulink model.

To create an S-function, you write code following a well-defined application program interface (API). By default, the Target Language Compiler will generate noninlined code for S-functions that invokes them using this same API. This generalized interface incurs a fair amount of overhead due to the presence of a large data structure called the `SimStruct` for each instance of each S-Function block in your model. In addition, extra run-time overhead is involved whenever methods (functions) within your S-function are called. You can eliminate this overhead by using the Target Language Compiler to inline the S-function, by creating a TLC file named `sfunction_name.tlc` that generates source code for the S-function as if it were a built-in block. Inlining an S-function improves the efficiency of the generated code and reduces memory usage.

### Defining Advanced Storage Classes

Certain data layouts, such as nested structures, cannot be generated using the standard `Unstructured` and `FlatStructure` storage class types. You can define an *advanced storage class* if

you want to generate other types of data. Creating advanced storage classes requires understanding TLC programming and using a special advanced mode of the Custom Storage Class Designer. For more information, see “Finely Control Data Representation by Writing TLC Code for a Storage Class” on page 37-23. Note that this support requires an Embedded Coder license.

## The Advantages of Inlining S-Functions

The goals of generated code usually include compactness and speed. On the other hand, S-functions are run-time-loadable extension modules for adding block-level functionality to Simulink. As such, the S-function interface is optimized for flexibility in configuring and using blocks in a simulation environment with capability to allow run-time changes to a block's operation via parameters. These changes typically take the form of algorithm selection and numerical constants for the block algorithms.

While switching algorithms is a desirable feature in the design phase of a system, when the time comes to generate code, this type of flexibility is often dropped in favor of optimal calculation speed and code size. The Target Language Compiler is designed to allow the generation of code that is compact and fast by selectively generating only the code you need for one instance of a block's parameter set.

### When To Avoid Inlining

You might decide not to inline C MEX S-functions that have:

- Few or no numerical parameters.
- One algorithm that is already fixed in capability. For example, it has no optional modes or alternate algorithms.
- Support for only one data type.
- A significant or large code size in the `mdlOutputs()` function.
- Multiple instances of S-Function block in your models.

Whenever you encounter this situation, the effort of inlining the block might not improve execution speed and could actually increase the size of the generated code. The tradeoff is in the size of the block's body code generated for each instance versus the size of the child `SimStruct` created for each instance of a noninlined S-function in the generated code.

Alternatively, you can use a hybrid inlining method known as a C MEX wrapped S-function, where the block target file simply generates a call to a custom code function that the S-function itself also calls. This approach might be the optimal solution for code generation in the case of a large piece of existing code. See "Write Wrapper S-Function and TLC Files" for the procedure and an example of a wrapped S-function.

### Inlining Process

The strategy for improving code from blocks centers on determining what part of a block's operations are active and used in the generated code and what parts can be predetermined or left out.

In practice, this means the TLC code in the block target file will select an algorithm that is a subset of the algorithms contained in the S-function itself and then selectively hard-code numerical parameters that are not to be changed at run time. This reduces code memory size and results in code that is often much faster than its S-function counterpart when mode selection is a significant part of S-function processing. Additionally, function-call overhead is eliminated for inlined S-functions, as the code is generated directly in the body of the code unless there is an explicit call to a library function in the generated code.

The algorithm selections and parameters for each block are output in the initial phase of the code generation process from the registered S-function parameter set or the `mdlRTW()` function (if

present), which results in entries in the model's `.rtw` file for that block at code generation time. A file written in the target language for the block is then called to read the entries in the `model.rtw` file and compute the generated code for this instance of the block. This TLC code is contained in the block target file.

One special case for inlined S-functions is for the case of I/O blocks and drivers such as A/D converters or communications ports. For simulation, the I/O driver is typically coded in the S-function as a pure source, a pass-through, or a pure sink. In the generated code, however, an actual interface to the I/O device must be made, typically through direct coding with the common `_in()`, `_out()` functions, inlined assembly code, or a specific set of I/O library calls unique to the device and target environment.

## Search Algorithm for Locating TLC Files

The Target Language Compiler uses the following search order to locate TLC files:

- 1 Current folder.
- 2 Locations specified by `%addincludepath` directives. The compiler evaluates multiple `%addincludepath` directives from the *bottom up*.
- 3 Locations specified by `-I` options. The compiler evaluates multiple `-I` options from *right to left*.

For inlined S-function TLC files, the build process supports the following locations:

- The folder where the S-function executable (MEX or MATLAB) file is located.
- S-function folder subfolder `./tlc_c` (for C or C++ language targets).
- The current folder when the build process is initiated.

---

**Note** Note: Placing the inlined S-function TLC file elsewhere is not supported, even if the location is in the TLC include path.

---

The first target file encountered with the required name that implements the specified language is used in processing the S-function `model.rtw` file entry.

---

**Note** The compiler does *not* search the MATLAB path, and will not find a file that is available only on that path. The compiler searches only the locations described above.

---

## Availability for Inlining and Noninlining

S-functions can be written in MATLAB language, Fortran, C, and C++. TLC inlining of S-functions is available as indicated in this table.

**Inline TLC Support by S-Function Type**

<b>S-Function Type</b>	<b>Noninlining Supported</b>	<b>Inlining Supported</b>
MATLAB language	No	Yes
Fortran MEX	No	Yes
C	Yes	Yes
C++	Yes	Yes

- “Inlining S-Functions” on page 14-8

## Code Architecture

Before investigating the specific code generation pieces of the Target Language Compiler (TLC), consider how Target Language Compiler generates code for a simple model. From the next figure, you see that blocks place code into Mdl routines. This shows MdlOutputs.

```
static void simple_output(int_T tid)
{
 /* Sin Block: '<Root>/Sine Wave' */
 simple_B.SinWave_d = simple_P.SinWave_Amp *
 sin(simple_P.SinWave_Freq * simple_M->Timing.t[0] +
 simple_P.SinWave_Phase) + simple_P.SinWave_Bias;

 /* Gain: '<Root>/Gain' */
 simple_B.Gain_d = simple_B.SinWave_d * simple_P.Gain_Gain;

 /* Output: '<Root>/Out1' */
 simple_Y.Out1 = simple_B.Gain_d;
}
```

Blocks have inputs, outputs, parameters, states, plus other general properties. For example, block inputs and outputs are generally written to a block I/O structure (generated with identifiers of the type *model\_B*, where *model* is the model name). Block inputs can also come from the external input structure (*model\_U*) or the state structure when connected to a state port of an integrator (*model\_X*), or ground (*rtGround*) if unconnected or grounded. Block outputs can also go to the external output structure, (*model\_Y*). The following diagram shows the general block data mappings.

This discussion should give you a general sense of what the block object looks like. Now, you can look at specific pieces of the code generation process that are specific to the Target Language Compiler.

## Code Generation Process

The code generator invokes the Target Language Compiler after a model is compiled into a partial representation of the model (*model.rtw*) suitable for code generation. To generate code, the Target Language Compiler uses its library of functions to transform two classes of target files:

- System target files
- Block target files

System target files are used to specify the overall structure of the generated code, tailoring for specific target environments. Block target files are used to implement the functionality of Simulink blocks, including user-defined S-function blocks.

You can create block target files for C MEX, Fortran, and MATLAB language S-functions to fully inline block functionality into the body of the generated code. C MEX S-functions can be noninlined, wrapper-inlined, or fully inlined. Fortran S-functions must be wrapper-inlined or fully inlined.

## How TLC Determines S-Function Inlining Status

Whenever the Target Language Compiler encounters an entry for an S-function block in the *model.rtw* file, it must decide whether to generate a call to the S-function or to inline it.

Because they cannot use `SimStructs`, Fortran and MATLAB language S-functions must be inlined. This inlining can either be in the form of a full block target file or a one-line block target file that refers to a substitute C MEX S-function source file.

The Target Language Compiler selects a C MEX S-function for inlining if an explicit `mdlRTW()` function exists in the S-function code or if a target file for the current target language for the current block is in the TLC file search path. If a C MEX S-function has an explicit `mdlRTW()` function, there must be a corresponding target file or an error condition results.

The target file for an S-function must have the same root name as the S-function and must have the extension `.tlc`. For example, the target file for a C MEX S-function named `sfix_bitop` has the filename `sfix_bitop.tlc`.

## Inlined and Noninlined S-Function Code

This example focuses on a C MEX S-function named `sfix_bitop`. The code generation options are set to allow reuse of signal memory for signal lines that were not set as tunable signals.

The code generated for the bit-wise operator block reuses a temporary variable that is set up for the output of the sum block to save memory. This results in one very efficient line of code, as seen here.

```

/* Bitwise Logic Block: <Root>/Bitwise Logical Operator */
/* [input] OR 'F00F' */
rtb_temp2 |= 0xF00F;

```

Initialization or setup code is not required for this inlined block.

If this block were not inlined, the source code for the S-function itself with its various options would be added to the generated code base, memory would be allocated in the generated code for the block's `SimStruct` data, and calls to the S-function methods would be generated to initialize, run, and terminate the S-function code. To execute the `mdlOutputs` function of the S-function, code would be generated like this:

```

/* Level2 S-Function Block: <Root>/Bitwise Logical Operator (sfix_bitop) */
{
 SimStruct *rts = ssGetSFunction(rtS, 0);
 sfcnOutputs(rts, tid);
}

```

The entire `mdlOutputs` function is called and runs just as it does during simulation. That's not everything, though. There is also registration, initialization, and termination code for the noninlined S-function. The initialization and termination calls are similar to the fragment above. Then, the registration code for an S-function with just one inport and one output is 72 lines of C code generated as part of file `model_reg.h`.

```

/*Level2 S-Function Block: <Root>/Bitwise Logical Operator (sfix_bitop) */
{
 extern void untitled_sf(SimStruct *rts);
 SimStruct *rts = ssGetSFunction(rtS, 0);

 /* timing info */
 static time_T sfcnPeriod[1];
 static time_T sfcnOffset[1];
 static int_T sfcnTsMap[1];

 {
 int_T i;

 for(i = 0; i < 1; i++) {
 sfcnPeriod[i] = sfcnOffset[i] = 0.0;
 }
 }
 ssSetSampleTimePtr(rts, &sfcnPeriod[0]);
 ssSetOffsetTimePtr(rts, &sfcnOffset[0]);
 ssSetSampleTimeTaskIDPtr(rts, sfcnTsMap);
 ssSetMdlInfoPtr(rts, ssGetMdlInfoPtr(rtS));

 /* inputs */
 {
 static struct _ssPortInputs inputPortInfo[1];

 _ssSetNumInputPorts(rts, 1);
 ssSetPortInfoForInputs(rts, &inputPortInfo[0]);

 /* port 0 */
 {
 static real_T const *sfcnUPtrs[1];
 sfcnUPtrs[0] = &rtU.In1;
 ssSetInputPortSignalPtrs(rts, 0, (InputPtrsType)&sfcnUPtrs[0]);
 _ssSetInputPortNumDimensions(rts, 0, 1);
 ssSetInputPortWidth(rts, 0, 1);
 }
 }
}
.
.
.

```

This continues until S-function sizes and methods are declared, allocated, and initialized. The amount of registration code generated is essentially proportional to the number and size of the input ports and output ports.

A noninlined S-function will typically have a significant impact on the size of the generated code, whereas an inlined S-function can be close to the handwritten size and performance of the generated code.

## Target Language Compiler Process

To write TLC code for your S-function, you need to understand the Target Language Compiler process for code generation. As previously described, the Simulink software generates a *model.rtw* file that contains a partial representation of the execution semantics of the block diagram. The *model.rtw* file is an ASCII file that contains a data structure in the form of a nested set of TLC records. The records comprise property name/property value pairs. The Target Language Compiler reads the *model.rtw* file and converts it into an internal representation.

Next, the Target Language Compiler runs (interprets) the TLC files, starting first with the system target file, for example, *grt.tlc*. This is the entry point to the system TLC and block files, that is, other TLC files included in or generated from the TLC file passed to Target Language Compiler on its command line (*grt.tlc*). As the TLC code in the system and block target files is run, it uses, appends to, and modifies the existing property name/property value pairs and records initially loaded from the *model.rtw* file.

### model.rtw Structure

The structure of the *model.rtw* file mirrors the block diagram's structure:

- For each nonvirtual system in the model, there is a corresponding system record in the *model.rtw* file.
- For each nonvirtual block within a nonvirtual system, there is a block record in the *model.rtw* file in the corresponding system.

The basic structure of *model.rtw* is

```
CompiledModel {
 System {
 Block {
 DataInputPort {
 ...
 }
 DataOutputPort{
 ...
 }
 ParamSettings {
 ...
 }
 Parameter {
 ...
 }
 }
 }
}
```

### Operating Sequence

For each occurrence of a given block in the model, a corresponding block record exists in the *model.rtw* file. The system target file TLC code loops through block records and calls the functions in the corresponding block target file for that block type. For inlined S-functions, it calls the inlining TLC file.

There is a method for getting block-specific information (internal block information, as opposed to inputs, outputs, parameters, etc.) into the block record in the *model.rtw* file for a block by using the `mdlRTW` function in the C MEX function of the block.

Among other things, the `mdlRTW` function allows you to write out parameter settings (`ParamSettings`), that is, unique information pertaining to this block. For parameter settings in the block TLC file, direct accesses to these fields are made from the block TLC code and can be used to alter the generated code as desired.

## Inlining S-Functions

### Inlining an S-function

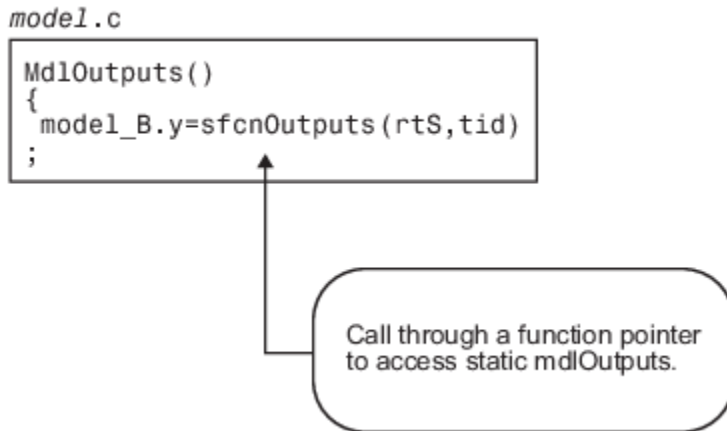

To inline an S-function means to provide a TLC file for an S-Function block that will replace the C, C++, Fortran, or MATLAB language version of the block that was used during simulation.

### Noninlined S-Function

If an inlining TLC file is not provided, most targets support the block by recompiling the C MEX S-function for the block. As discussed earlier, there is overhead in memory usage and speed when using a C/C++ coded S-function and a limited subset of `mx*` API calls supported within the code generator context. If you want the most efficient generated code, you must inline S-functions by writing a TLC file for them.

When the simulation needs to execute one of the functions for an S-function block, it calls the MEX-file for that function. When the code generator executes a noninlined S-function, it does so in a similar manner, as this diagram illustrates.

## Types of Inlining

It is helpful to define two categories of inlining:

- Fully inlined S-functions
- Wrapper inlined S-functions

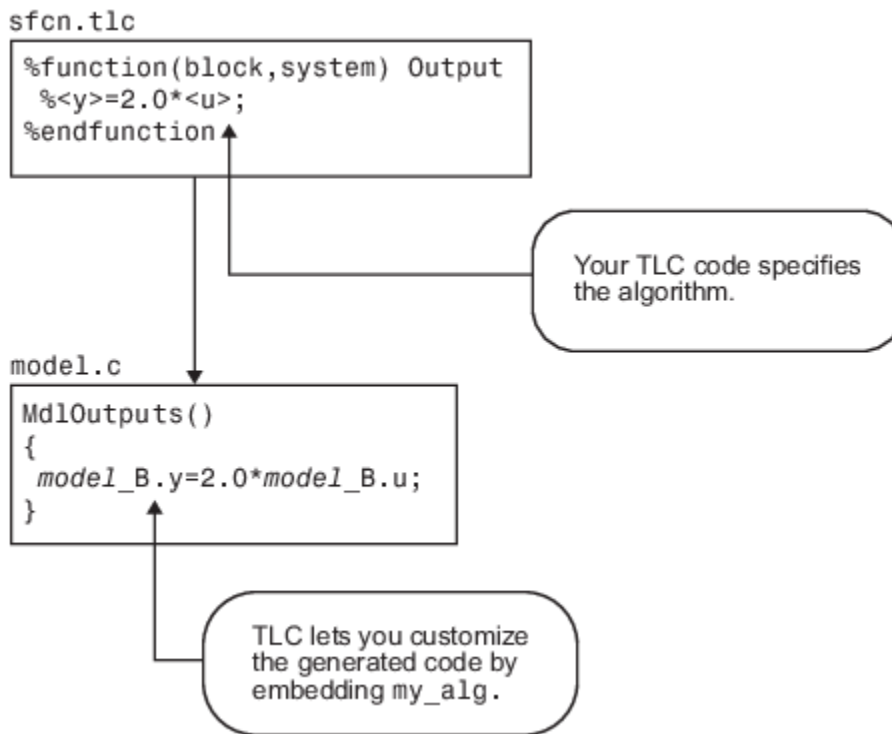

While both inline the S-function and remove the overhead of a noninlined S-function, the two approaches are different. The first example below, using `timestwo.tlc`, is considered a fully inlined TLC file, where the full implementation of the block is contained in the TLC file for the block.

The second example uses a wrapper TLC file. Instead of generating the algorithmic code in place, this example calls a C function that contains the body of code. There are several potential benefits for using the wrapper TLC file:

- It provides a way for the C MEX S-function and the generated code to share the C code. You do not need to write the code twice.
- The called C function is an optimized routine.
- Several of the blocks might exist in the model, and it is more efficient in terms of code size to have them call a function, as opposed to each creating identical algorithmic code.
- It provides a way to incorporate legacy C code seamlessly into generated code.

## Fully Inlined S-Function Example

Inlining an S-function provides a mechanism to directly embed code for an S-function block into the generated code for a model. Instead of calling into a separate source file via function pointers and maintaining a separate data structure (`SimStruct`) for it, the code appears “inlined” as the next figure shows.

The S-function `timestwo.c` provides a simple example of a fully inlined S-function. This block multiplies its input by 2 and outputs it. The C MEX version of the block is in the file `matlabroot/toolbox/simulink/simdemos/simfeatures/src/timestwo.c`, and the inlining TLC file for the block is `matlabroot/toolbox/simulink/simdemos/simfeatures/tlc_c/timestwo.tlc`.

### timestwo.tlc

```

%implements "timestwo" "C"

%% Function: Outputs =====
%%
%function Outputs(block, system) Output
/* %<Type> Block: %<Name> */
%%
/* Multiply input by two */
%assign rollVars = ["U", "Y"]
%roll idx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
%<LibBlockOutputSignal(0, "", lcv, idx)> = \
%<LibBlockInputSignal(0, "", lcv, idx)> * 2.0;
%endroll
%endfunction

```

### TLC Block Analysis

The `%implements` directive is required by TLC block files and is used by the Target Language Compiler to verify the block type and language supported by the block. The `%function` directive starts a function declaration and shows the name of the function, `Outputs`, and the arguments passed to it, `block` and `system`. These are the relevant records from the `model.rtw` file for this instance of the block.

The last piece of the prototype is `Output`. This means that any line that is not a TLC directive is output by the function to the current file that is selected in TLC. So, nondirective lines in the `Outputs` function become generated code for the block.

The most complicated piece of this TLC block example is the `%roll` directive. TLC uses this directive to provide automatic generation of `for` loops, depending on input/output widths and whether the inputs are contiguous in memory. This example uses the typical form of accessing outputs and inputs from within the body of the `roll`, using `LibBlockOutputSignal` and `LibBlockInputSignal` to access the outputs and inputs and perform the multiplication and assignment. Note that this TLC file supports any valid signal width.

The only function used to implement this block is `Outputs`. For more complicated blocks, other functions are declared as well. You can find examples of more complicated inlining TLC files in the folders `matlabroot/toolbox/simulink/simdemos/simfeatures/tlc_c` (open) and `matlabroot/toolbox/simulink/blocks/tlc_c` (open), and by looking at the code for built-in blocks in the folder `matlabroot/rtw/c/tlc/blocks` (open).

### The timestwo Model

This simple model uses the `timestwo` S-function and shows the `MdlOutputs` function from the generated `model.c` file, which contains the inlined S-function code.

### Model Outputs Code

```

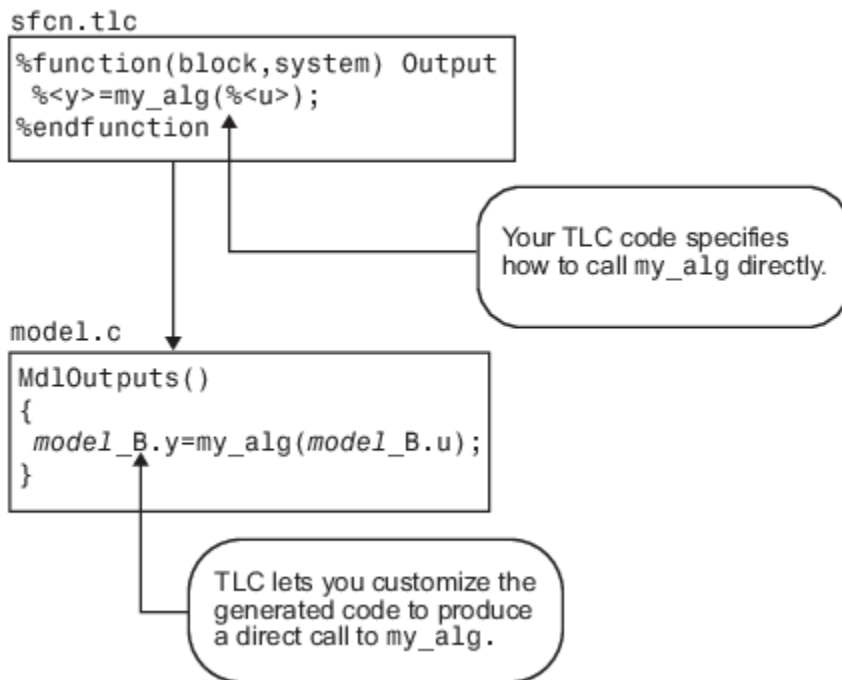

/* Model output function */
static void timestwo_ex_output(int_T tid)
{
 /* S-Function Block: <Root>/S-Function */
 /* Multiply input by two */
 timestwo_ex_B.timestwo_output = timestwo_ex_P.Constant_Value
 * 2.0;

 /* Output: '<Root>/Out1' */
 timestwo_ex_Y.Out1 = timestwo_ex_B.timestwo_output;
}

```

### Wrapper Inlined S-Function Example

The following diagram illustrates inlining an S-function as a wrapper. The algorithm is directly called from the generated model code, removing the S-function overhead but maintaining the user function.

This is the inlining TLC file for a wrapper version of the `timestwo` block.

```
%implements "timestwo" "C"

%% Function: BlockTypeSetup =====
%%
%function BlockTypeSetup(block, system) void
 %% Add function prototype to model's header file
 %<LibCacheFunctionPrototype...
 ("extern void mytimestwo(real_T* in,real_T* out,int_T els);">
 %% Add file that contains "myfile" to list of files to be compiled
 %<LibAddToModelSources("myfile")>
%endfunction

%% Function: Outputs =====
%%
%function Outputs(block, system) Output
 /* %<Type> Block: %<Name> */
 %assign outPtr = LibBlockOutputSignalAddr(0, "", "", 0)
 %assign inPtr = LibBlockInputSignalAddr(0, "", "", 0)
 %assign numEls = LibBlockOutputSignalWidth(0)
 /* Multiply input by two */
 mytimestwo(%<inPtr>,%<outPtr>,%<numEls>);
%endfunction
```

### Analysis

The function `BlockTypeSetup` is called once for each type of block in a model; it doesn't produce output directly like the `Outputs` function. Use `BlockTypeSetup` to include a function prototype in the `model.h` file and to tell the build process to compile an additional file, `myfile.c`.

Instead of performing the multiplication directly, the `Outputs` function now calls the function `mytimestwo`. All instances of this block in the model call the same function to perform the multiplication. The resulting model function, `MdlOutputs`, then becomes

```
static void timestwo_ex_output(int_T tid)
{
```

```
/* S-Function Block: <Root>/S-Function */
/* Multiply input by two */
mytimestwo(&model_B.Constant_Value,&model_B.S_Function,1);

/* Output Block: <Root>/Out1 */
model_Y.Out1 = model_B.S_Function;
}
```

## Advice About TLC Tutorials

The fastest and easiest way to understand the Target Language Compiler (TLC) is to run it, paying attention to how TLC scripts transform compiled Simulink models (*model.rtw* files) into source code. The tutorials highlight the principal reasons for and techniques of using TLC. The tutorials provide a number of TLC exercises, each one organized as a major section.

The example models, S-functions, and TLC files for the exercises are located in the folder *matlabroot/toolbox/rtw/rtwdemos/tlctutorial* (open). In this chapter, this folder is referred to as `tlctutorial`. Each example is located in a separate subfolder within `tlctutorial`. Within that subfolder, you can find solutions to the problem in a `solutions` subfolder.

---

**Note** Before you begin the tutorial, copy the entire `tlctutorial` folder to a local working folder. The files are together, and if you make mistakes or want fresh examples to try again, you can recopy files from the original `tlctutorial` folder.

---

Each tutorial exercise is limited in scope, requiring just a small amount of experimentation. The tutorial explains details about TLC that will help customize and optimize code for code generation projects.

---

**Note** You should not customize TLC files in the folder *matlabroot/rtw/c/tlc* even though the capability exists to do so. Such TLC customizations might not be applied during the code generation process and can lead to unpredictable results.

---

The tutorials progress in difficulty from basic to more advanced. To get the most out of them, you should be familiar with

- Working in the MATLAB environment
- Building Simulink models
- Using the code generator to produce code for target systems
- High-level language concepts (for example, C or Fortran programming)

If you encounter terms in the tutorials that you do not understand, it may be helpful to read “Code Generation Concepts” on page 16-7 to acquaint yourself with the basic goals and methods of TLC programming. Similarly, if you see TLC keywords, built-in functions, or directives that you would like to know more about, see the corresponding topics on “Target Language Compiler”.

The examples used in the tutorial are:

Example	Description
guide	Illustrative record file
timesN	An example C file S-function for multiplying an input by N
tlcdebug	An example using TLC Debugger
wrapper	Example TLC file for S-function <code>wrapsfcn.c</code>

## Read Record Files with TLC

### Tutorial Overview

**Objective:** Understand the structure of record files and learn how to parse them with TLC directives.

**Folder:** `matlabroot/toolbox/rtw/rtwdemos/tlctutorial/guide` (open)

In this tutorial you interpret a simple file of structured records with a series of TLC scripts. You will learn how records are structured, and how TLC `%assign` and `%<>` token expansion directives are used to process them. In addition, the tutorial illustrates loops using `%foreach`, and scoping using `%with`.

The tutorial includes these steps, which you should follow sequentially:

- 1 **Structure of Record Files** — Some background and a simple example
- 2 **Interpret Records** — Presenting contents of the record file
- 3 **Anatomy of a TLC Script** — Deconstructing the presentation
- 4 **Modify `read-guide.tlc`** — Experiment with TLC
- 5 **Pass and Use a Parameter**— Pass parameters from the command line to TLC files
- 6 **Review**

### Structure of Record Files

The code generator compiles models into a structured form called a record file, referred to as `model.rtw`. Such compiled model files are similar in syntax and organization to source model files, in that they contain a series of hierarchically nested records of the form

```
recordName {itemName itemValue}
```

Item names are alphabetic. Item values can be strings or numbers. Numeric values can be scalars, vectors, or matrices. Curly braces set off the contents of each record, which may contain one or more items, delimited by space, tab, or return characters.

In a `model.rtw` file, the top-level (first) record's name is `CompiledModel`. Each block is represented by a subrecord within it, identified by the block's name. TLC can parse well-formed record files, as this exercise illustrates.

The following listing is a valid record file that TLC can parse, although not one for which it can generate code. Comments are indicated by a pound sign (`#`):

```
#
File: guide.rtw Illustrative record file, which can't be used by Simulink
#
Note: string values MUST be in quotes
Top {
 Date "21-Aug-2008"
 Employee {
 FirstName "Arthur"
 LastName "Dent"
 Overhead 1.78
 PayRate 11.50
 GrossRate 0.0
 }
 NumProject 3
 Project {

```

```

 Name "Tea" # Alpha field Name, Top.Project[0].Name
 Difficulty 3 # Numeric field Top.Project[0].Difficulty
 } # End of first list item
Project { # Second list item, called Top.Project[1]
 Name "Gillian" # Alpha field Name, Top.Project[1].Name
 Difficulty 8 # Numeric field Top.Project[1].Difficulty
} # End of second list item
Project { # Third list item, called Top.Project[2]
 Name "Zaphod" # Alpha field Name, Top.Project[2].Name
 Difficulty 10 # Numeric field Top.Project[2].Difficulty
} # End of third list item
} # End of Top record and of file

```

As long as programmers know the names of records and fields, and their expected contents, they can compose TLC statements to read, parse, and manipulate record file data.

## Interpret Records

Here is the output from a TLC program script that reads `guide.rtw`, interprets its records, manipulates field data, and formats descriptions, which are directed to the MATLAB Command Window:

```

Using TLC you can:
* Directly access a field's value, e.g.
 %<Top.Date> -- evaluates to:
 "21-Aug-2008"

* Assign contents of a field to a variable, e.g.
 "%assign worker = Top.Employee.FirstName"
 worker expands to Top.Employee.FirstName = "Arthur"

* Concatenate string values, e.g.
 "%assign worker = worker + " " + Top.Employee.LastName"
 worker expands to worker + " " + Top.Employee.LastName = "Arthur Dent"

* Perform arithmetic operations, e.g.
 "%assign wageCost = Top.Employee.PayRate * Top.Employee.Overhead"
 wageCost expands to Top.Employee.PayRate * Top.Employee.Overhead <- 11.5 * 1.78 = 20.47

* Put variables into a field, e.g.
 Top.Employee.GrossRate starts at 0.0
 "%assign Top.Employee.GrossRate = wageCost"
 Top.Employee.GrossRate expands to wageCost = 20.47

* Index lists of values, e.g.
 "%assign projects = Top.Project[0].Name + ", " + Top.Project[1].Name..."
 "+ ", " + Top.Project[2].Name"
 projects expands to Top.Project[0].Name + ", " + Top.Project[1].Name
 + ", " + Top.Project[2].Name = Tea, Gillian, Zaphod

* Traverse and manipulate list data via loops, e.g.
 - At top of Loop, Project = Tea; Difficulty = 3
 - Bottom of Loop, i = 0; diffSum = 3.0
 - At top of Loop, Project = Gillian; Difficulty = 8
 - Bottom of Loop, i = 1; diffSum = 11.0
 - At top of Loop, Project = Zaphod; Difficulty = 10
 - Bottom of Loop, i = 2; diffSum = 21.0
 Average Project Difficulty expands to diffSum / Top.NumProject = 21.0 / 3 = 7.0

```

This output from `guide.rtw` was produced by invoking TLC from the MATLAB Command Window, executing a script called `read-guide.tlc`. Do this yourself now, by following these steps:

- 1 In MATLAB, change folder (`cd`) to your copy of `tlctutorial/guide` within your working folder.
- 2 To produce the output just listed, process `guide.rtw` with the TLC script `read-guide.tlc` by typing the following command:

```
tlc -v -r guide.rtw read-guide.tlc
```

Note command usage:

- The `-r` switch (for read) identifies the input data file, in this case `guide.rtw`.
- The TLC script handling the data file is specified by the last token typed.
- The `-v` switch (for verbose) directs output to the command window, unless the TLC file handles this itself.

## Anatomy of a TLC Script

You now dissect the script you just ran. Each “paragraph” of output from `guide.tlc` is discussed in sequence in the following brief sections:

- “Coding Conventions” on page 15-6 — Before you begin
- “File Header” on page 15-6 — Header info and a formatting directive
- “Token Expansion” on page 15-7— Evaluating field and variable identifiers
- “General Assignment” on page 15-7 — Using the `%assign` directive
- “String Processing Plus” on page 15-8 — Methods of assembling strings
- “Arithmetic Operations” on page 15-9 — Computations on fields and variables
- “Modify Records” on page 15-9 — Changing, copying, appending to records
- “Index Lists” on page 15-10 — Referencing list elements with subscripts
- “Loop Over Lists” on page 15-10 — Details on loop construction and behavior

## Coding Conventions

These are some basic TLC syntax and coding conventions:

<code>%% Comment</code>	TLC comment, which is not output
<code>/* comment */</code>	Comment, to be output
<code>%keyword</code>	TLC directive (keyword), start with “%”
<code>%&lt;expr&gt;</code>	TLC token operator
<code>.</code> (period)	Scoping operator, for example, <code>Top.Lev2.Lev3</code>
<code>...</code> (at end-of-line)	Statement continuation (line break is not output)
<code>\</code> (at end-of-line)	Statement continuation (line break is output)
<code>localvarIdentifier</code>	Local variables start in lowercase
<code>GlobalvarIdentifier</code>	Global variables start in uppercase
<code>RecordIdentifier</code>	Record identifiers start in uppercase
<code>EXISTS()</code>	TLC built-in functions are named in uppercase
	<b>Note:</b> TLC identifiers are case-sensitive.

For further information, see “TLC Coding Conventions” on page 20-17.

## File Header

The file `read-guide.tlc` begins with:

```
%% File: read-guide.tlc (This line is a TLC Comment, and will not print)
%%
%% To execute this file, type: tlc -v -r guide.rtw read-guide.tlc
%% Set format for displaying real values (default is "EXPONENTIAL")
%realformat "CONCISE"
```

- Lines 1 through 4 — Text on a line following the characters %% is treated as a comment (ignored, not interpreted or output).
- Line 5 — As explained in the text of the fourth line, is the TLC directive (keyword) %real format, which controls how subsequent floating-point numbers are formatted when displayed in output. Here we want to minimize the digits displayed.

### Token Expansion

The first section of output is produced by the script lines:

Using TLC you can:

\* Directly access a field's value, e.g.

```
%assign td = "%" + "<Top.Date>"
```

%<td> -- evaluates to:

```
"%<Top.Date>"
```

- Lines 1 and 2 — (and lines that contain no TLC directives or tokens) are simply echoed to the output stream, including leading and trailing spaces.
- Line 3 — Creates a variable named td and assigns the string value %<Top.Date> to it. The %assign directive creates new and modifies existing variables. Its general syntax is:

```
%assign ::variable = expression
```

The optional double colon prefix specifies that the variable being assigned to is a global variable. In its absence, TLC creates or modifies a local variable in the current scope.

- Line 4 — Displays

```
%<Top.Date> -- evaluates to:
```

The preceding line enables TLC to print %<Top.Date> without expanding it. It constructs the string by pasting together two literals.

```
%assign td = "%" + "<Top.Date>"
```

As discussed in "String Processing Plus" on page 15-8, the plus operator concatenates strings and adds numbers, vectors, matrices, and records.

- Line 5 — Evaluates (expands) the record Top.Date. More precisely, it evaluates the field Date which exists in scope Top. The syntax %<expr> causes expression expr (which can be a record, a variable, or a function) to be evaluated. This operation is sometimes referred to as an *eval*.

---

**Note** You cannot nest the %<expr> operator (that is, %<foo%<bar>> is not allowed).

---

---

**Note** When you use the %<expr> operator within quotation marks, for example, "%<Top.Date>", TLC expands the expression and then encloses the result in quotation marks. However, placing %assign within quotation marks, for example, "%assign foo = 3", simply echoes the statement enclosed in quotation marks to the output stream. No assignment results (the value of foo remains unchanged or undefined).

---

### General Assignment

The second section of output is produced by the script lines:

```
* Assign contents of a field to a variable, e.g.
%assign worker = Top.Employee.FirstName
"%assign worker = Top.Employee.FirstName"
worker expands to Top.Employee.FirstName = %<worker>
```

- Line 1 — Echoed to output.
- Line 2 — An assignment of field `FirstName` in the `Top.Employee` record scope to a new local variable called `worker`.
- Line 3 — Repeats the previous statement, producing output by enclosing it in quotation marks.
- Line 4 — Explains the following assignment and illustrates the token expansion. The token `%<worker>` expands to `Arthur`.

### String Processing Plus

The next section of the script illustrates string concatenation, one of the uses of the “+” operator:

```
* Concatenate string values, e.g.
%assign worker = worker + " " + Top.Employee.LastName
"%assign worker = worker + " " + Top.Employee.LastName"
worker expands to worker + " " + Top.Employee.LastName = "%<worker>"
```

- Line 1 — Echoed to output.
- Line 2 — Performs the concatenation.
- Line 3 — Echoes line 2 to the output.
- Line 4 — Describes the operation, in which a variable is concatenated to a field separated by a space character. An alternative way to do this, without using the `+` operator, is

```
%assign worker = "%<Top.Employee.FirstName> %<Top.Employee.LastName>"
```

The alternative method uses evals of fields and is equally efficient.

The `+` operator, which is associative, also works for numeric types, vectors, matrices, and records:

- Numeric Types — Add two expressions together; both operands must be numeric. For example:

Output:

```
* Numeric Type example, e.g.
Top.Employee.PayRate = 11.5
Top.Employee.Overhead = 1.78
td = Top.Employee.PayRate + Top.Employee.Overhead
td evaluates to 13.28
```

- Vectors — If the first argument is a vector and the second is a scalar value, TLC appends the scalar value to the vector. For example:

Output:

```
* Vector example, e.g.
v1 is [0, 1, 2, 3]
Top.Project[1].Difficulty is 8
v2 = v1 + Top.Project[1].Difficulty
v2 evaluates to: [0, 1, 2, 3, 8]
```

- **Matrices** — If the first argument is a matrix and the second is a vector of the same column-width as the matrix, TLC appends the vector as another row to the matrix. For example:

Output:

```
* Matrices example, e.g.
 mx1 is [[4, 5, 6, 7]; [8, 9, 10, 11]]
 v1 is [0, 1, 2, 3]
 mx = mx1 + v1
 mx evaluates to [[4, 5, 6, 7]; [8, 9, 10, 11]; [0, 1, 2, 3]]
```

- **Records** — If the first argument is a record, TLC adds the second argument as a parameter identifier (with its current value). For example:

Output:

```
* Record example, e.g.
 StartDate is August 28, 2008
 Top + StartDate
 Top.StartDate evaluates to August 28, 2008
```

## Arithmetic Operations

TLC provides a full complement of arithmetic operators for numeric data. In the next portion of our TLC script, two numeric fields are multiplied:

```
* Perform arithmetic operations, e.g.
%assign wageCost = Top.Employee.PayRate * Top.Employee.Overhead
"%assign wageCost = Top.Employee.PayRate * Top.Employee.Overhead"
wageCost expands to Top.Employee.PayRate * Top.Employee.Overhead ...
<- %<Top.Employee.PayRate> * %<Top.Employee.Overhead> = %<wageCost>
```

- Line 1 — Echoed to output.
- Line 2 — %assign statement that computes the value, which TLC stores in local variable `wageCost`.
- Line 3 — Echoes the operation in line 2.
- Lines 4 and 5 — Compose a single statement. The ellipsis (typed as three consecutive periods, for example, `...`) signals that a statement is continued on the following line, but if the statement has output, TLC does not insert a line break. To continue a statement and insert a line break, replace the ellipsis with a backslash (`\`).

## Modify Records

Once read into memory, you can modify and manipulate records just like variables you create by assignment. The next segment of `read-guide.tlc` replaces the value of record field `Top.Employee.GrossRate`:

```
* Put variables into a field, e.g.
%assign Top.Employee.GrossRate = wageCost
"%assign Top.Employee.GrossRate = wageCost"
Top.Employee.GrossRate expands to wageCost = %<Top.Employee.GrossRate>
```

Such changes to records are nonpersistent (because record files are inputs to TLC; other file types, such as C source code, are outputs), but can be useful.

You can use several TLC directives besides `%assign` to modify records:

<code>%createrecord</code>	Creates new top-level records, and might also specify subrecords within them, including name/value pairs.
<code>%addtorecord</code>	Adds fields to an existing record. The new fields can be name/value pairs or aliases to existing records.
<code>%mergerecord</code>	Combines one or more records. The first record contains itself plus copies of the other records' contents specified by the command, in sequence.
<code>%copyrecord</code>	Creates a new record as <code>%createrecord</code> does, except the components of the record come from the existing record you specify.
<code>%undef var</code>	Removes (deletes) <code>var</code> (a variable or a record) from scope. If <code>var</code> is a field in a record, TLC removes the field from the record. If <code>var</code> is a record array (list), TLC removes the first element of the array; the remaining elements remain accessible. You can remove only records you create with <code>%createrecord</code> or <code>%copyrecord</code> .

See “Target Language Compiler Directives” on page 18-2 for details on these directives.

## Index Lists

Record files can contain lists, or sequences of records having the same identifier. Our example contains a list of three records identified as `Project` within the `Top` scope. List references are indexed, numbered from 0, in the order in which they appear in the record file. Here is TLC code that compiles data from the `Name` field of the `Project` list:

```
* Index lists of values, e.g.
%assign projects = Top.Project[0].Name + ", " + Top.Project[1].Name...
+ ", " + Top.Project[2].Name
"%assign projects = Top.Project[0].Name + ", " + Top.Project[1].Name..."
"+ ", " + Top.Project[2].Name"
projects expands to Top.Project[0].Name + ", " + Top.Project[1].Name
+ ", " + Top.Project[2].Name = %<projects>
```

The `Scope.Record[n].Field` syntax is similar to that used in C to reference elements in an array of structures.

While explicit indexing, such as the above, is perfectly acceptable, it is often preferable to use a loop construct when traversing entire lists, as shown in “Loop Over Lists” on page 15-10.

## Loop Over Lists

By convention, the section of a record file that a list occupies is preceded by a record that indicates how many list elements are present. In `model.rtw` files, such parameters are declared as `NumIdent`, where `Ident` is the identifier used for records in the list that follows. In `guide.rtw`, the `Project` list looks like this:

```
NumProject 3 # Indicates length of following list
Project { # First list item, called Top.Project[0]
 Name "Tea" # Alpha field Name, Top.Project[0].Name
 Difficulty 3 # Numeric field Top.Project[0].Difficulty
} # End of first list item
Project { # Second list item, called Top.Project[1]
 Name "Gillian" # Alpha field Name, Top.Project[1].Name
 Difficulty 8 # Numeric field Top.Project[1].Difficulty
} # End of second list item
Project { # Third list item, called Top.Project[2]
 Name "Zaphod" # Alpha field Name, Top.Project[2].Name
```

```

 Difficulty 10 # Numeric field Top.Project[2].Difficulty
} # End of third list item

```

Thus, the value of `NumProject` describes how many `Project` records occur.

---

**Note** `model.rtw` files might also contain records that start with `Num` but are not list-size parameters. TLC does not require that list size parameters start with `Num`. Therefore you need to be cautious when interpreting `NumIdent` record identifiers. The built-in TLC function `SIZE()` can determine the number of records in a specified scope, hence the length of a list.

---

The last segment of `read-guide.tlc` uses a `%foreach` loop, controlled by the `NumProject` parameter, to iterate the `Project` list and manipulate its values.

```

* Traverse and manipulate list data via loops, e.g.
%assign diffSum = 0.0
%foreach i = Top.NumProject
- At top of Loop, Project = %<Top.Project[i].Name>; Difficulty = ...
%<Top.Project[i].Difficulty>
 %assign diffSum = diffSum + Top.Project[i].Difficulty
- Bottom of Loop, i = %<i>; diffSum = %<diffSum>
%endforeach
%assign avgDiff = diffSum / Top.NumProject
Average Project Difficulty expands to diffSum / Top.NumProject = %<diffSum> ...
/ %<Top.NumProject> = %<avgDiff>

```

As you may recall, the TLC output looks like this:

```

* Traverse and manipulate list data via loops, e.g.
- At top of Loop, Project = Tea; Difficulty = 3
- Bottom of Loop, i = 0; diffSum = 3.0
- At top of Loop, Project = Gillian; Difficulty = 8
- Bottom of Loop, i = 1; diffSum = 11.0
- At top of Loop, Project = Zaphod; Difficulty = 10
- Bottom of Loop, i = 2; diffSum = 21.0
Average Project Difficulty expands to diffSum / Top.NumProjects = 21.0 / 3 = 7.0

```

After initializing the summation variable `diffSum`, a `%foreach` loop is entered, with variable `i` declared as the loop counter, iterating up to `NumProject`. The scope of the loop is all statements encountered until the corresponding `%endforeach` is reached (`%foreach` loops may be nested).

---

**Note** Loop iterations implicitly start at zero and range to one less than the index that specifies the upper bound. The loop index is local to the loop body.

---

## Modify `read-guide.tlc`

Now that you have studied `read-guide.tlc`, it is time to modify it. This exercise introduces two important TLC facilities, *file control* and *scoping control*. You implement both within the `read-guide.tlc` script.

### File Control Basics

TLC scripts almost invariably produce output in the form of streams of characters. Output is normally directed to one or more buffers and files, collectively called *streams*. So far, you have directed output from `read-guide.tlc` to the MATLAB Command Window because you included the `-v` switch on the command line. Prove this by omitting `-v` when you run `read-guide.tlc`. Type

```
tlc -r guide.rtw read-guide.tlc
```

Nothing appears to happen. In fact, the script was executed, but output was directed to a null device (sometimes called the “bit bucket”).

There is one active output file, even if it is null. To specify, open, and close files, use the following TLC directives:

```
%openfile streamid ="filename" , "mode"
%closefile streamid
%selectfile streamid
```

If you do not give a file name, subsequent output flows to the memory buffer named by `streamid`. If you do not specify a mode, TLC opens the file for writing and deletes any existing content (subject to system-level file protection mechanisms). Valid mode identifiers are `a` (append) and `w` (write, the default). Enclose these characters in quotes.

The `%openfile` directive creates a file/buffer (in `w` mode), or opens an existing one (in `a` mode). Note the required equals sign for file specification. Multiple streams can be open for writing, but only one can be active at one time. To switch output streams, use the `%selectfile` directive. You do not need to close files until you are done with them.

The default output stream, which you can respecify with the stream ID `NULL_FILE`, is `null`. Another built-in stream is `STDOUT`. When activated using `%selectfile`, `STDOUT` directs output to the MATLAB Command Window.

---

**Note** The streams `NULL_FILE` and `STDOUT` are always open. Specifying them with `%openfile` generates errors. Use `%selectfile` to activate them.

---

The directive `%closefile` closes the current output file or buffer. Until an `%openfile` or a `%selectfile` directive is encountered, output goes to the previously opened stream (or, if none exists, to null). Use `%selectfile` to designate an open stream for reading or writing. In practice, many TLC scripts write pieces of output data to separate buffers, which are then selected in a sequence and their contents spooled to one or more files.

### Implement Output File Control

In your `tlctutorial/guide` folder, find the file `read-guide-file-src.tlc`. The supplied version of this file contains comments and three lines of text added. Edit this file to implement output file control, as follows:

- 1 Open `read-guide-file-src.tlc` in your text editor.
- 2 Save the file as `read-guide-file.tlc`.
- 3 Note five comment lines that begin with `%% ->`.

Under each of these comments, insert a TLC directive as indicated.

- 4 Save the edited file as `read-guide-file.tlc`.
- 5 Execute `read-guide-file.tlc` with the following command:

```
tlc -r guide.rtw read-guide-file.tlc
```

If you succeeded, TLC creates the file `guidetext.txt` which contains the expected output, and the MATLAB Command Window displays

```

*** Output being directed to file: guidetext.txt
*** We're almost done . . .
*** Processing completed.

```

If you did not see these messages, or if a text file was not produced, review the material and try again. If problems persist, inspect `read-guide-file.tlc` in the `guide/solutions` subfolder to see how you should specify file control.

## Scope Basics

“Structure of Record Files” on page 15-4 explains the hierarchical organization of records. Each record exists within a scope defined by the records in which it is nested. The example file, `guide.rtw`, contains the following scopes:

```

Top
Top.Employee
Top.Project[0]
Top.Project[1]
Top.Project[2]

```

To refer to a field or a record, specify its scoping, even if no other context that contains the identifier exists. For example, in `guide.rtw`, the field `FirstName` exists only in the scope `Top.Employee`. You must refer to it as `Top.Employee.FirstName` whenever accessing it.

When models present scopes that are deeply nested, this can lead to extremely long identifiers that are tedious and error prone to type. For example:

```
CompiledModel.BlockOutputs.BlockOutput.ReusedBlockOutput
```

This identifier has a scope that is long and has similar item names that you could easily enter incorrectly.

The `%with/%endwith` directive eases the burden of coding TLC scripts and clarifies their flow of control. The syntax is

```

%with RecordName
 [TLC statements]
%endwith

```

Every `%with` is eventually followed by an `%endwith`, and these pairs might be nested (but not overlapping). If `RecordName` is below the top level, you need not include the top-level scope in its description. For example, to make the current scope of `guide.rtw` `Top.Employee`, you can specify

```

%with Employee
 [TLC statements]
%endwith

```

Naturally, `%with Top.Employee` is also valid syntax. Once bracketed by `%with/%endwith`, record identifiers in TLC statements do not require you to specify their outer scope. However, note the following conditions :

- You can access records outside of the current `%with` scope, but you must qualify them fully (for example, using record name and fields).
- Whenever you make assignments to records inside a `%with` directive, you must qualify them fully.

## Change Scope Using %with

In the last segment of this exercise, you modify the TLC script by adding a `%with/%endwith` directive. You also need to edit record identifier names (but not those of local variables) to account for the changes of scope resulting from the `%with` directives.

- 1 Open the TLC script `read-guide-scope-src.tlc` in the text editor.
- 2 Save the file as `read-guide-scope.tlc`.
- 3 Note comment lines that commence with `%% ->`.

Under each of these comments, insert a TLC directive or modify statements already present, as indicated.

- 4 Save the edited file as `read-guide-scope.tlc`.
- 5 Execute `read-guide-scope.tlc` with the following command:

```
tlc -v -r guide.rtw read-guide-scope.tlc
```

The output should be exactly the same as from `read-guide.tlc`, except possibly for white space that you might have introduced by indenting sections of code inside `%with/%endwith` or by eliminating blank lines.

Fully specifying a scope inside a `%with` context is not an error; it is simply unnecessary. However, failing to fully specify its scope when assigning it to a record (for example, `%assign GrossRate = wageCost`) is invalid.

If errors result from running the script, review the discussion of scoping above and edit `read-guide-scope.tlc` to eliminate them. As a last resort, inspect `read-guide-scope.tlc` in the `/solutions` subfolder to see how you should have handled scoping in this exercise.

For additional information, see “Scopes in the model.rtw File” on page 17-2 and “Variable Scoping” on page 18-38.

## Pass and Use a Parameter

You can use the TLC commands and built-in functions to pass parameters from the command line to the TLC file being executed. The most general command switch is `-a`, which assigns arbitrary variables. For example:

```
tlc -r input.rtw -avar=1 -afoo="abc" vars.tlc
```

The result of passing this pair of strings via `-a` is the same as declaring and initializing local variables in the file being executed (here, `vars.tlc`). For example:

```
%assign var = 1
%assign foo = "abc"
```

You do not need to declare such variables in the TLC file, and they are available for use when set with `-a`. However, errors result if the code assigns undeclared variables that you do not specify with the `-a` switch when invoking the file. Also note that (in contrast to the `-r` switch) a space should not separate `-a` from the parameter you are declaring.

In the final section of this tutorial, you use the built-in function `GET_COMMAND_SWITCH()` to print the name of the record file being used in the TLC script, and provide a parameter to control whether or

not the code is suppressed. By default the code is executed, but is suppressed if the command line contains `-alist=0`:

- 1 Open the TLC script `read-guide-param-src.tlc` in your text editor.
- 2 Save the file as `read-guide-param.tlc`.
- 3 To enable your program to access the input filename from the command line, do the following:

- a Below the line `%selectfile STDOUT`, add the line:

```
%assign inputfile = GET_COMMAND_SWITCH ("r")
```

The `%assign` directive declares and sets variables. In this instance, it holds a string filename identifier. `GET_COMMAND_SWITCH()` returns whatever string argument follows a specified TLC command switch. You must use UPPERCASE for built-in function names.

- b Change the line `*** WORKING WITH RECORDFILE` to read as follows:

```
*** WORKING WITH RECORDFILE %<inputfile>
```

- 4 To control whether or not a section of TLC code is executed, do the following:

- a Below the line `%assign inputfile = GET_COMMAND_SWITCH ("r")`, add:

```
%if (!EXISTS(list))
 %assign list = 1
%endif
```

The program checks whether a `list` parameter has been declared, via the intrinsic (built-in) function `EXISTS()`. If no `list` variable exists, the program assigns one. This defines `list` and by default its value is `TRUE`.

- b Enclose lines of code within an `%if` block.

```
%if (list)
 * Assign contents of a field to a variable, e.g.
 %assign worker = FirstName
 "%assign worker = FirstName"
 worker expands to FirstName = %<worker>
%endif
```

Now the code to assign `worker` is sent to the output only when `list` is `TRUE`.

- c Save `read-guide-param.tlc`.

- 5 Execute `read-guide-param.tlc` and examine the output, using the command

```
tlc -r guide.rtw read-guide-param.tlc
```

This yields

```
*** WORKING WITH RECORDFILE [guide.rtw]
* Assign contents of a field to a variable, e.g.
 "%assign worker = FirstName"
 worker expands to FirstName = Arthur
***END
```

- 6 Execute `read-guide-param.tlc` with the command:

```
tlc -r guide.rtw -alist=0 read-guide-param.tlc
```

With the `-alist=0` switch, the output displays only the information outside of the `if` statement.

```
*** WORKING WITH RECORDFILE [guide.rtw]
***END
```

## Review

The preceding exercises examined the structure of record files, and expanded on how to use TLC directives. The following TLC directives are commonly used in TLC scripts (see “Target Language Compiler Directives” on page 18-2 for detailed descriptions):

<code>%addincludepath</code>	Enable TLC to find included files.
<code>%addtorecord</code>	Add fields to existing record. New fields can be name/value pairs or aliases to existing records.
<code>%assign</code>	Create or modify variables.
<code>%copyrecord</code>	Create new record and, if applicable, specify subrecords within them, including name/value pairs. The components of the record come from the existing record specified.
<code>%createrecord</code>	Create new top-level records and, if applicable, specify subrecords within them, including name/value pairs.
<code>%foreach/%endforeach</code>	Iterate loop variable from 0 to upper limit.
<code>%if/%endif</code>	Control whether code is executed, as in C.
<code>%include</code>	Insert one file into another, as in C.
<code>%mergerecord</code>	Combine one or more records. The first record contains itself plus copies of the other records contents specified by the command, in sequence.
<code>%selectfile</code>	Direct outputs to a stream or file.
<code>%undef var</code>	Remove (delete) <code>var</code> (a variable or a record) from scope. If <code>var</code> is a field in a record, TLC removes the field from the record. If <code>var</code> is a record array (list), TLC removes the first element of the array; the remaining elements remain accessible. Only records created via <code>%createrecord</code> or <code>%copyrecord</code> can be removed.
<code>%with/%endwith</code>	Add scope to simplify referencing blocks.

# Inline S-Functions with TLC

## timesN Tutorial Overview

**Objective:** To understand how TLC works with an S-function.

**Folder:** `matlabroot/toolbox/rtw/rtwdemos/tlctutorial/timesN` (open)

In this tutorial, you generate versions of C code for existing S-function `timesN`.

The tutorial includes these steps:

- 1 **Noninlined Code Generation** — Via SimStructs and generic API
- 2 **Why Use TLC to Inline S-Functions?** — Benefits of inlining
- 3 **Create an Inlined S-Function** — Via custom TLC code

A later tutorial provides information and practice with “wrapping” S-functions.

## Noninlined Code Generation

The tutorial folder `tlctutorial/timesN` in your working folder contains Simulink S-function `timesN.c`.

In this exercise, you generate noninlined code from the model `sfun_xN`.

- 1 Find the file `rename_timesN.tlc` in `tlctutorial/timesN`. Rename this file to `timesN.tlc`. This allows you to generate code.
- 2 In the MATLAB Command Window, create a MEX-file for the S-function:

```
mex timesN.c
```

This avoids picking up the version shipped with Simulink.

- 3 Open the model `sfun_xN`, which uses the `timesN` S-function. The block diagram looks like this.

- 4 Open the Configuration Parameters dialog box and select the **Solver** pane.
- 5 Set **Stop time** to `10.0`.
- 6 Set the **Solver Options**.
  - **Type** to Fixed-step
  - **Solver** to Discrete (no continuous states)
  - **Fixed-step size** to `0.01`
- 7 Select the **Optimization** pane, and make sure that **Default parameter behavior** is set to Tunable.

8 Select the **Code Generation > Comments** pane, and notice that **Include comments** is checked by default.

9 Select the **Code Generation** pane and check **Generate code only**.

Click **Apply**.

10 Press **Ctrl+B** to generate C code for the model.

11 Open the resulting file `sfun_xN_grt_rtw/sfun_xN.c` and view the `sfun_xN_output` portion, shown below.

```
/* Model output function */
static void sfun_xN_output(int_T tid)
{
 /* Sin: '<Root>/Sin' */
 sfun_xN_B.Sin = sin(sfun_xN_M->Timing.t[0] * sfun_xN_P.Sin_Freq +
 sfun_xN_P.Sin_Phase) * sfun_xN_P.Sin_Amp +
 sfun_xN_P.Sin_Bias;

 /* S-Function Block: <Root>/S-Function */
 /* Multiply input by 3.0 */
 sfun_xN_B.timesN_output = sfun_xN_B.Sin * 3.0;

 /* Outport: '<Root>/Out' */
 sfun_xN_Y.Out = sfun_xN_B.timesN_output;
 UNUSED_PARAMETER(tid);
}
```

Comments appear in the code because, in the **Code Generation > Comments** pane of the Configuration Parameters dialog box, **Include comments** is selected by default.

## Why Use TLC to Inline S-Functions?

The code generator includes a generic API that you can use to invoke user-written algorithms and drivers. The API includes a variety of callback functions — for initialization, output, derivatives, termination, and so on — as well as data structures. Once coded, these are instantiated in memory and invoked during execution via indirect function calls. Each invocation involves stack frames and other overhead that adds to execution time.

In a real-time environment, especially when many solution steps are involved, generic API calls can be unacceptably slow. The code generator can speed up S-functions in standalone applications that it generates by embedding user-written algorithms within auto-generated functions, rather than indirectly calling S-functions via the generic API. This form of optimization is called inlining. TLC inlines S-functions, resulting in faster, optimized code.

You should understand that TLC is not a substitute for writing C code S-functions. To invoke custom blocks within Simulink, you still have to write S-functions in C (or as MATLAB files), since simulations do not make use of TLC files. You can, however, prepare TLC files that inline specified S-functions to make your target code much more efficient.

## Create an Inlined S-Function

TLC creates an inlined S-function whenever it detects a `.tlc` file with the same name as an S-function. Assuming the `.tlc` file has the expected form, it directs construction of code that functionally duplicates the external S-function without incurring API overhead. See how this process works by completing the following steps:

- 1 If you have not done so already, find the file `rename_timesN.tlc` in `tlctutorial/timesN`. Rename this file to `timesN.tlc`, so you can use it to generate code. The executable portion of the file is

```
%implements "timesN" "C"

%% Function: Outputs =====
%%
%function Outputs(block, system) Output
 %assign gain =SFcnParamSettings.myGain
 /* %<Type> Block: %<Name> */
 %%
 /* Multiply input by %<gain> */
 %assign rollVars = ["U", "Y"]
 %roll idx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
 %<LibBlockOutputSignal(0, "", lcv, idx)> = \
 %<LibBlockInputSignal(0, "", lcv, idx)> * %<gain>;
 %endroll
%endfunction
```

- 2 Create the inline version of the S-function.
  - a On the **Optimization** pane of the Configuration Parameters dialog box, set **Default parameter behavior** to **Inlined**, and click **Apply**.
  - b Change the diagram's label from `model: sfun_xN` to `model: sfun_xN_ilp`.
  - c Save the model as `sfun_x2_ilp`.
  - d Press **Ctrl+B**. Source files are created in a new subfolder called `sfun_xN_ilp_grt_rtw`.
  - e Inspect the code in generated file `sfun_xN_ilp.c`:

```
/* Model output function */
static void sfun_xN_ilp_output(int_T tid)
{
 /* Sin: '<Root>/Sin' */
 sfun_xN_ilp_B.Sin = sin(sfun_xN_ilp_M->Timing.t[0]);

 /* S-Function Block: <Root>/S-Function */
 /* Multiply input by 3.0 */
 sfun_xN_ilp_B.timesN_output = sfun_xN_ilp_B.Sin * 3.0;

 /* Outport: '<Root>/Out' */
 sfun_xN_ilp_Y.Out = sfun_xN_ilp_B.timesN_output;
 UNUSED_PARAMETER(tid);
}
```

---

**Note** When the code generator produces code and builds executables, it creates or uses a specific subfolder (called the build folder) to hold source, object, and make files. By default, the build folder is named `model_grt_rtw`.

---

Notice that setting **Default parameter behavior** to **Inlined** did not change the code. This is because TLC inlines S-functions.

- 3 Continue the exercise by creating a standalone simulation.
  - a In the **Code Generation** pane of the Configuration Parameters dialog box, clear **Generate code only** and click **Apply**.
  - b In the **Data Import/Export** pane of the Configuration Parameters dialog box, check **Output**.

This specification causes the model's output data to be logged in your MATLAB workspace.

- c** Press **Ctrl+B** to generate code, compile, and link the model into an executable, named `sfun_xN_ilp.exe` (or, on UNIX systems, `sfun_xN_ilp`).
- d** Confirm that the `timesN.tlc` file produces expected output by running the standalone executable. To run it, in the MATLAB Command Window, type

```
!sfun_xN_ilp
```

The following response appears:

```
** starting the model **
** created sfun_xN_ilp.mat **
```

- e** View or plot the contents of the `sfun_xN_ilp.mat` file to verify that the standalone model generated sine output ranging from -3 to +3. In the MATLAB Command Window, type

```
load sfun_xN_ilp.mat
plot (rt_yout)
```

---

**Tip** For UNIX platforms, run the executable program in the Command Window with the syntax `!./executable_name`. If preferred, run the executable program from an OS shell with the syntax `./executable_name`. For more information, see “Run External Commands, Scripts, and Programs”.

## Explore Variable Names and Loop Rolling

### timesN Looping Tutorial Overview

**Objective:** This example shows how you can influence looping behavior of generated code.

**Folder:** `matlabroot/toolbox/rtw/rtwdemos/tlctutorial/timesN` (open)

Work with the model `sfun_xN` in `tlctutorial/timesN`. It has one source (a Sine Wave generator block), a times N gain block, an Out block, and a Scope block.

The tutorial guides you through following steps:

- 1 **Getting Started** — Set up the exercise and run the model
- 2 **Modify the Model** — Change the input width and see the results
- 3 **Change the Loop Rolling Threshold** — Change the threshold and see the results
- 4 **More About TLC Loop Rolling** — Parameterize loop behavior

### Getting Started

- 1 Make `tlctutorial/timesN` your current folder, so that you can use the files provided.

---

**Note** You must use or create a working folder outside of `matlabroot` for Simulink models you make. You cannot build models in source folders.

---

- 2 In the MATLAB Command Window, create a MEX-file for the S-function:

```
mex timesN.c
```

This avoids picking up the version shipped with Simulink.

---

**Note** An error might occur if you have not previously run `mex -setup`.

---

- 3 Open the model file `sfun_xN`.

- 4 View the previously generated code in `sfun_xN_grt_rtw/sfun_xN.c`. Note that no loops exist in the code. This is because the input and output signals are scalar.

### Modify the Model

- 1 Replace the Sine Wave block with a Constant block.
- 2 Set the parameter for the Constant block to `1:4`, and change the top label, `model: sfun_xN`, to `model: sfun_vec`.

- 3 Save the edited model as `sfun_vec` (in `tlctutorial/timesN`). The model now looks like this.

- 4 Because the Constant block generates a vector of values, this is a vectorized model. Generate code for the model and view the `/*Model output function */` section of `sfun_vec.c` in your editor to observe how variables and `for` loops are handled. This function appears as follows:

```

/* Model output function */
static void sfun_vec_output(int_T tid)
{
 /* S-Function Block: <Root>/S-Function */
 /* Multiply input by 3.0 */
 sfun_vec_B.timesN_output[0] = sfun_vec_P.Constant_Value[0] * 3.0;
 sfun_vec_B.timesN_output[1] = sfun_vec_P.Constant_Value[1] * 3.0;
 sfun_vec_B.timesN_output[2] = sfun_vec_P.Constant_Value[2] * 3.0;
 sfun_vec_B.timesN_output[3] = sfun_vec_P.Constant_Value[3] * 3.0;

 /* Outport: '<Root>/Out' */
 sfun_vec_Y.Out[0] = sfun_vec_B.timesN_output[0];
 sfun_vec_Y.Out[1] = sfun_vec_B.timesN_output[1];
 sfun_vec_Y.Out[2] = sfun_vec_B.timesN_output[2];
 sfun_vec_Y.Out[3] = sfun_vec_B.timesN_output[3];
 UNUSED_PARAMETER(tid);
}

```

Notice that there are four instances of the code that generates model outputs, corresponding to four iterations.

- 5 Set the parameter for the Constant block to 1:10, and save the model.
- 6 Generate code for the model and view the `/*Model output function */` section of `sfun_vec.c` in your editor to observe how variables and `for` loops are handled. This function appears as follows:

```

/* Model output function */
static void sfun_vec_output(int_T tid)
{
 /* S-Function Block: <Root>/S-Function */
 /* Multiply input by 3.0 */
 {
 int_T i1;
 const real_T *u0 = &sfun_vec_P.Constant_Value[0];
 real_T *y0 = sfun_vec_B.timesN_output;
 for (i1=0; i1 < 10; i1++) {
 y0[i1] = u0[i1] * 3.0;
 }
 }

 {
 int32_T i;
 for (i = 0; i < 10; i++) {
 /* Outport: '<Root>/Out' */
 sfun_vec_Y.Out[i] = sfun_vec_B.timesN_output[i];
 }
 }

 UNUSED_PARAMETER(tid);
}

```

Notice that:

- The code that generates model outputs gets “rolled” into a loop. This occurs by default when the number of iterations exceeds 5.
- Loop index `i1` runs from 0 to 9.
- Pointer `*y0` is used and initialized to the output signal array.

## Change the Loop Rolling Threshold

The code generator creates iterations or loops depending on the current value of the **Loop unrolling threshold** parameter.

The default value of **Loop unrolling threshold** is 5. To change looping behavior for blocks in a model:

- 1 On the **Optimization** pane of the Configuration Parameters dialog box, set **Loop unrolling threshold** to 12 and click Apply.

The parameter `RollThreshold` is now 12. Loops will be generated only when the width of signals passing through a block exceeds 12.

---

**Note** You cannot modify `RollThreshold` for specific blocks from the Configuration Parameters dialog box.

---

- 2 Press **Ctrl+B** to regenerate the output.
- 3 Inspect `sfun_vec.c`. It will look like this:

```
/* Model output function */
static void sfun_vec_output(int_T tid)
{
 /* S-Function Block: <Root>/S-Function */
 /* Multiply input by 3.0 */
 sfun_vec_B.timesN_output[0] = sfun_vec_P.Constant_Value[0] * 3.0;
 sfun_vec_B.timesN_output[1] = sfun_vec_P.Constant_Value[1] * 3.0;
 sfun_vec_B.timesN_output[2] = sfun_vec_P.Constant_Value[2] * 3.0;
 sfun_vec_B.timesN_output[3] = sfun_vec_P.Constant_Value[3] * 3.0;
 sfun_vec_B.timesN_output[4] = sfun_vec_P.Constant_Value[4] * 3.0;
 sfun_vec_B.timesN_output[5] = sfun_vec_P.Constant_Value[5] * 3.0;
 sfun_vec_B.timesN_output[6] = sfun_vec_P.Constant_Value[6] * 3.0;
 sfun_vec_B.timesN_output[7] = sfun_vec_P.Constant_Value[7] * 3.0;
 sfun_vec_B.timesN_output[8] = sfun_vec_P.Constant_Value[8] * 3.0;
 sfun_vec_B.timesN_output[9] = sfun_vec_P.Constant_Value[9] * 3.0;

 /* Output: '<Root>/Out' */
 sfun_vec_Y.Out[0] = sfun_vec_B.timesN_output[0];
 sfun_vec_Y.Out[1] = sfun_vec_B.timesN_output[1];
 sfun_vec_Y.Out[2] = sfun_vec_B.timesN_output[2];
 sfun_vec_Y.Out[3] = sfun_vec_B.timesN_output[3];
 sfun_vec_Y.Out[4] = sfun_vec_B.timesN_output[4];
 sfun_vec_Y.Out[5] = sfun_vec_B.timesN_output[5];
 sfun_vec_Y.Out[6] = sfun_vec_B.timesN_output[6];
 sfun_vec_Y.Out[7] = sfun_vec_B.timesN_output[7];
 sfun_vec_Y.Out[8] = sfun_vec_B.timesN_output[8];
 sfun_vec_Y.Out[9] = sfun_vec_B.timesN_output[9];
 UNUSED_PARAMETER(tid);
}
```

- 4 To activate loop rolling again, change the **Loop unrolling threshold** to 10 (or less) on the **Optimization** pane.

Loop rolling is an important TLC capability for optimizing generated code. Take some time to study and explore its implications before generating code for production requirements.

## More About TLC Loop Rolling

The following TLC `%roll` code is the `Outputs` function of `timesN.tlc`:

```
%function Outputs(block, system) Output
/* %<Type> Block: %<Name> */
%%
/* Multiply input by %<gain> */
%assign rollVars = ["U", "Y"]
%roll idx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
 %<LibBlockOutputSignal(0, "", lcv, idx)> = \
 %<LibBlockInputSignal(0, "", lcv, idx)> * %<gain>;
%endroll
%endfunction %% Outputs
```

### Arguments for %roll

The lines between `%roll` and `%endroll` may be either repeated or looped. The key to understanding the `%roll` directive is in its arguments:

```
%roll sigIdx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
```

Argument	Description
<code>sigIdx</code>	Specify the index into a (signal) vector that is used in the generated code. If the signal is scalar, when analyzing that block of the <code>model.rtw</code> file, TLC determines that only a single line of code is required. In this case, it sets <code>sigIdx</code> to 0 so as to access only the first element of a vector, and no loop is constructed.
<code>lcv</code>	A control variable generally specified in the <code>%roll</code> directive as <code>lcv = RollThreshold</code> . <code>RollThreshold</code> is a global (model-wide) threshold with the default value of 5. Therefore, whenever a block contains more than five contiguous androllable variables, TLC collapses the lines nested between <code>%roll</code> and <code>%endroll</code> into a loop. If fewer than five contiguousrollable variables exist, <code>%roll</code> does not create a loop and instead produces individual lines of code.
<code>block</code>	This tells TLC that it is operating on block objects. TLC code for S-functions use this argument.
<code>"Roller"</code>	This, specified in <code>rtw/c/tlc/roller.tlc</code> , formats the loop. Normally you pass this as is, but other loop control constructs are possible for advanced uses (see <code>LibBlockInputSignal</code> in "Input Signal Functions" on page 21-7).
<code>rollVars</code>	Tells TLC what types of items should be rolled: input signals, output signals, and/or parameters. You do not have to use all of them. In a previous line, <code>rollVars</code> is defined using <code>%assign</code> .  <pre>%assign rollVars = ["U", "Y"]</pre> <p>This list tells TLC that it is rolling through input signals (U) and output signals (Y). In cases where blocks specify an array of parameters instead of a scalar parameter, <code>rollvars</code> is specified as</p> <pre>%assign rollVars = ["U", "Y", "P"]</pre>

## Input Signals, Output Signals, and Parameters

Look at the lines that appear between `%roll` and `%endroll`:

```
%<LibBlockOutputSignal(0, "", lcv, idx)> = \
%<LibBlockInputSignal (0, "", lcv, idx)> * 2.0;
```

The TLC library functions `LibBlockInputSignal` and `LibBlockOutputSignal` expand to produce scalar or vector identifiers that are named and indexed. `LibBlockInputSignal`, `LibBlockOutputSignal`, and a number of related TLC functions are passed four canonical arguments:

Argument	Description
first argument — 0	Corresponds to the input port index for a given block. The first input port has index 0. The second input port has index 1, and so on.
second argument — " "	An index variable reserved for advanced use. For now, specify the second argument as an empty string. In advanced applications, you may define your own variable name to be used as an index with <code>%roll</code> . In such a case, TLC declares this variable as an integer in a location in the generated code.
third argument — lcv	As described previously, <code>lcv = RollThreshold</code> is set in <code>%roll</code> to indicate that a loop be constructed whenever <code>RollThreshold</code> (default value of 5) is exceeded.
fourth argument — sigIdx	Enables TLC to handle special cases. In the event that the <code>RollThreshold</code> is <i>not</i> exceeded (for example, if the block is only connected to a scalar input signal) TLC does not roll it into a loop. Instead, TLC provides an integer value for the index variable in a corresponding line of “inline” code. Whenever the <code>RollThreshold</code> is exceeded, TLC creates a <code>for</code> loop and uses an index variable to access inputs, outputs and parameters within the loop.

## Debug Your TLC Code

### tlcdebug Tutorial Overview

**Objective:** Introduces the TLC debugger. You will learn how to set breakpoints and familiarize yourself with TLC debugger commands.

**Folder:** `matlabroot/toolbox/rtw/rtwdemos/tlctutorial/tlcdebug` (open)

You can cause the TLC debugger to be invoked whenever the build process is invoked. In this tutorial, you use it to detect a bug in a `.tlc` file for a model called `simple_log`. The bug causes the generated code output from the standalone version of the model to differ from its simulation output. The tutorial guides you through following steps:

- 1 **Getting Started** — Run the model and inspect output
- 2 **Generate and Run Code from the Model** — Compare compiled results to original output
- 3 **Start the Debugger and Use Its Commands** — Things you can do with the debugger
- 4 **Debug `timesN.tlc`** — Find out what went wrong
- 5 **Fix the Bug and Verify** — Easy ways to fix bugs and verify fixes

### Getting Started

- 1 Copy the files from `tlctutorial/tlcdebug` to your current working directory.
- 2 In the MATLAB Command Window, create a MEX-file for the S-function:

```
mex timesN.c
```

This avoids picking up the version shipped with your Simulink software.

---

**Note** An error might occur if you have not previously run `mex -setup`.

---

- 3 Open the model `simple_log`. The model looks like this.

- 4 In the **Data Import/Export** pane of the Configuration Parameters dialog box, check **Time** and **Output**. This causes model variables to be logged to the MATLAB workspace.
- 5 Run the model. On the **Simulation** tab, click **Run**. Variables `tout` and `yout` appear in your MATLAB workspace.
- 6 Double-click `yout` in the **Workspace** pane of the MATLAB Command Window. The Variable Editor displays the 6x1 array output from `simple_log`. The display looks like this:

yout <6x1 double>						
	1	2	3	4	5	6
1	3					
2	0					
3	3					
4	0					
5	3					
6	0					

Column 1 contains discrete pulse output for six time steps (3s and 0s), collected at port out1.

Next, you generate a standalone version of `simple_log`. You execute it and compare its results to the output from Simulink displayed above.

---

**Note** For the purpose of this exercise, the TLC file provided, `timesN.tlc`, contains a bug. This version must be in the same folder as the model that uses it.

---

## Generate and Run Code from the Model

### 1 Press **Ctrl+B**.

The code generator produces, compiles, and links C source code. The MATLAB Command Window shows the progress of the build, which ends with these messages:

```
Created executable: simple_log.exe
Successful completion of build procedure
 for model: simple_log
```

### 2 Run the standalone model just created by typing

```
!simple_log
```

This results in the messages

```
** starting the model **
** created simple_log.mat **
```

### 3 Inspect results by placing the variables in your workspace. In the **Current Folder** pane, double-click `simple_log.mat`, then double-click `rt_yout` (the standalone version of variable `yout`) in the **Workspace** pane.

Compare `rt_yout` with `yout`. Do you notice differences? Can you surmise what caused values in `rt_yout` to change?

A look at the generated C code that TLC placed in your build folder (`simple_log_grt_rtw`) helps to identify the problem.

### 4 Edit `simple_log.c` and look at its `MdlOutputs` function, which should appear as shown below:

```
/* Model output function */
static void simple_log_output(void)
{
 /* DiscretePulseGenerator: '<Root>/Discrete Pulse Generator' */
 simple_log_B.DiscretePulseGenerator = (simple_log_DW.clockTickCounter < 1.0) &&
 (simple_log_DW.clockTickCounter >= 0) ? 1.0 : 0.0;
```

```
if (simple_log_DW.clockTickCounter >= 2.0 - 1.0) {
 simple_log_DW.clockTickCounter = 0;
} else {
 simple_log_DW.clockTickCounter++;
}

/* End of DiscretePulseGenerator: '<Root>/Discrete Pulse Generator' */

/* S-Function (timesN): '<Root>/Gain1st' incorporates:
 * Output: '<Root>/Out1'
 */
/* S-Function Block: <Root>/Gain1st */
/* Multiply input by 3.0 */
simple_log_Y.Out1 = simple_log_B.DiscretePulseGenerator * 1;
}
```

Note the line near the end:

```
simple_log_B.first_output = simple_log_B.DiscretePulseGenerator * 1;
```

How did the incorrect product get assigned to the output when it was supposed to receive a variable that alternates between 3.0 and 0.0? Use the debugger to find out.

## Start the Debugger and Use Its Commands

You use the TLC debugger to monitor the code generation process. As it is not invoked by default, you need to request the debugger explicitly.

- 1 Set up the TLC debugging environment and start to build the application:
  - a Select the **Configuration Parameters > Code Generation** pane, and select the options **Retain .rtw file** and **Start TLC debugger when generating code**. Click **OK**.
  - b Build the model.

The MATLAB Command Window describes the building process. The build stops at the `timesN.tlc` file and displays the command prompt:

```
TLC-DEBUG>
```

- 2 Type `help` to list the TLC debugger commands. Here are some things you can do in the debugger.

- View and query various entities in the TLC scope.

```
TLC-DEBUG> whos CompiledModel
TLC-DEBUG> print CompiledModel.NumSystems
TLC-DEBUG> print TYPE(CompiledModel.NumSystems)
```

- Examine the statements in your current context.

```
TLC-DEBUG> list
TLC-DEBUG> list 10,40
```

- Move to the next line of code.

```
TLC-DEBUG> next
```

- Step into a function.

```
TLC-DEBUG> step
```

- Assign a constant value to a variable, such as the input signal `%<u>`.

- ```
TLC-DEBUG> assign u = 5.0
```
- Set a breakpoint where you are or in some other part of the code.

```
TLC-DEBUG> break timesN.tlc:10
```
 - Execute until the next breakpoint.

```
TLC-DEBUG> continue
```
 - Clear breakpoints you have established.

```
TLC-DEBUG> clear 1
TLC-DEBUG> clear all
```
- 3** If you have tried the TLC debugger commands, execute the remaining code to finish the build process, then build `simple_log` again. The build stops at the `timesN.tlc` file and displays the command prompt:
- ```
TLC-DEBUG>
```

## Debug timesN.tlc

Now look around to find out what is wrong with the code:

- 1** Set a breakpoint on line 20 of `timesN.tlc`.

```
TLC-DEBUG> break timesN.tlc:20
```

- 2** Instruct the TLC debugger to advance to your breakpoint.

```
TLC-DEBUG> continue
```

TLC processes input, reports its progress, advances to line 20 in `timesN.tlc`, displays the line, and pauses.

```
Loading TLC function libraries

.
Breakpoint 1
00020: %roll idx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
```

- 3** Use the `whos` command to see the variables in the current scope.

```
TLC-DEBUG> whos
Variables within: <BLOCK_LOCAL>
gain Real
rollVars Vector
block Resolved
system Resolved
```

- 4** Inspect the variables using the `print` command (names are case sensitive).

```
TLC-DEBUG> print gain
3.0
```

```
TLC-DEBUG> print rollVars
[U, Y]
```

- 5** Execute one step.

```
TLC-DEBUG> step
00021: %<LibBlockOutputSignal(0, "", lcv, idx)> = \
```

- 6** Because it is a built-in function, advance via the `next` command.

```
TLC-DEBUG> next
.
00022: %<LibBlockInputSignal(0, "", lcv, idx)> * 1;
```

This is the origin of the C statement responsible for the erroneous constant output, `simple_log_B.first_output = simple_log_B.DiscretePulseGenerator * 1;`.

- 7 Abandon the build by quitting the TLC debugger. Type

```
TLC-DEBUG> quit
```

An error message is displayed showing that you stopped the build by using the TLC debugger quit command. Close the error window.

## Fix the Bug and Verify

The problem you identified is caused by evaluating a constant rather than a variable inside the TLC function `FcnEliminateUnnecessaryParams()`. This is a typical coding error and is easily repaired. Here is the code you need to fix.

```
%function Outputs(block, system) Output
 %assign gain = SFcnParamSettings.myGain
 /* %<Type> Block: %<Name> */
 %%
 /* Multiply input by %<gain> */
 %assign rollVars = ["U", "Y"]
 %roll idx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
 %<LibBlockOutputSignal(0, "", lcv, idx)> = \
 %<LibBlockInputSignal(0, "", lcv, idx)> * 1;
 %endroll
%endfunction

%% [EOF] timesN.tlc
```

- 1 To fix the coding error, edit `timesN.tlc`. The line

```
%<LibBlockInputSignal(0, "", lcv, idx)> * 1;
```

multiplies the evaluated input by 1. Change the line to

```
%<LibBlockInputSignal(0, "", lcv, idx)> * %<gain>;
```

Save `timesN.tlc`.

- 2 Build the standalone model again. Complete the build by typing `continue` at each TLC-DEBUG prompt.
- 3 Execute the standalone model by typing

```
!simple_log
```

A new version of `simple_log.mat` is created containing its output.

- 4 Load `simple_log.mat` and compare the workspace variable `rt_yout` with `yout`, as you did before. The values in the first column should now correspond.

## TLC Code Coverage to Aid Debugging

### tlcdebug Execute Tutorial Overview

**Objective:** Learn to use TLC coverage statistics to help identify bugs in TLC code.

**Folder:** `matlabroot/toolbox/rtw/rtwdemos/tlctutorial/tlcdebug` (open)

This tutorial teaches you how to determine whether your TLC code is being executed as expected. Here it uses the same model as for the previous tutorial. As you focus on understanding flow of control in processing TLC files, you don't need to compile and execute a standalone model, only to look at code. The tutorial proceeds as follows:

- 1 **Getting Started** — Why and how to analyze TLC coverage
- 2 **Open the Model and Generate Code** — Read a coverage log file

### Getting Started

The **Code Generation > Debug** pane provides the option **Start TLC coverage when generating code**. Selecting it results in a listing that documents how many times each line in your TLC source file was executed during code generation. The listing, `name.log` (where `name` is the filename of the TLC file being analyzed), is placed in your build folder.

---

**Note** A log file for every `.tlc` file invoked or included is generated in the build folder. Focus on `timesN.log`.

---

### Open the Model and Generate Code

- 1 Copy the folder `tlctutorial/tlcdebug/` to your working folder and `cd` to it. *Do this even though you already have copied it*, to be sure you have the version of `timesN.tlc` that has the bug.
- 2 In the MATLAB Command Window, create a MEX-file for the S-function.  

```
mex timesN.c
```

This avoids picking up the version shipped with your Simulink software.
- 3 Open the model `simple_log`.
- 4 In the **Code Generation** pane of the Configuration Parameters dialog box, check **Generate code only**.
- 5 In the **Code Generation > Debug** pane of the Configuration Parameters dialog box, select **Start TLC coverage when generating code**. (Do not select **Start TLC debugger when generating code**. Invoking the debugger is unnecessary.) Click **Apply**.
- 6 Press **Ctrl+B**. The usual messages appear in the MATLAB Command Window, and a build folder (`simple_log_grt_rtw`) is created in your working folder.
- 7 Enter the build folder. Find the file `timesN.log`, and copy it to your working folder, renaming it to `timesN_ilp.log` to prevent it from being overwritten.

- 8 Open the log file `timesN_ilp.log` in your editor. It looks almost like `timesN.tlc`, except for a number followed by a colon at the beginning of each line. This number represents the number of times TLC executed the line in generating code. The code for `Outputs()` should look like this:

```
0: %% Function: Outputs =====
0: %%
1: %function Outputs(block, system) Output
1: %assign gain =SFcnParamSettings.myGain
1: /* %<Type> Block: %<Name> */
0: %%
1: /* Multiply input by %<gain> */
1: %assign rollVars = ["U", "Y"]
1: %roll idx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
1: %<LibBlockOutputSignal(0, "", lcv, idx)> = \
1: %<LibBlockInputSignal(0, "", lcv, idx)> * 1;
0: %endroll
1:
0: %endfunction
```

Notice that comments were not executed. TLC statements were reached, which means they output to the generated C code as many times as the number prefixed to those lines.

Changing code generation options can cause a latent issue in generated source code. Systematically changing options and observing the resulting differences in TLC coverage can facilitate the process of discovering faulty code.

## Wrap User Code with TLC

### wrapper Tutorial Overview

**Objective:** Learn the architecture of wrapper S-functions and how to create an inlined wrapper S-function using TLC.

**Folder:** `matlabroot/toolbox/rtw/rtwdemos/tlctutorial/wrapper` (open)

Wrapper S-functions enable you to use existing C functions without fully rewriting them in the context of Simulink S-functions. Each wrapper you provide is an S-function “shell” that merely calls one or more existing, external functions. This tutorial explains and illustrates wrappers as follows:

- **Why Wrap User Code?** — Reason for building TLC wrapper functions
- **Getting Started** — Set up the wrapper exercise
- **Generate Code Without a Wrapper** — How the code generator handles external functions by default
- **Generate Code Using a Wrapper** — Bypass the API overhead

### Why Wrap User Code?

Many Simulink users want to build models incorporating algorithms that they have already coded, implemented, and tested in a high-level language. Typically, such code is brought into Simulink as S-functions. To generate an external application that integrates user code, you can take several approaches:

- You can construct an S-function from user code that hooks it to the Simulink generic API. This is the simplest approach, but sacrifices efficiency for standalone applications.
- You can inline the S-function, reimplementing it as a TLC file. This improves efficiency, but takes time and effort, can introduce errors into working code, and leads to two sets of code to maintain for each algorithm, unless you use the Legacy Code Tool (see “Import Calls to External Code into Generated Code with Legacy Code Tool”).
- You can inline the S-function via a TLC wrapper function. By doing so, you need to create only a small amount of TLC code, and the algorithm can remain coded in its existing form.

The next figure illustrates how S-function wrappers operate.

Wrapping a function eliminates the need to recode it, requiring only a bit of extra TLC code to integrate it. Wrappers also enable object modules or libraries to be used in S-functions. This may be the only way to deploy functions for which source code is unavailable, and also allows users to distribute models to others without divulging implementation details that may be proprietary.

For example, you might have an existing object file compiled for a processor on which Simulink does not run. You can write a dummy C S-function and use a TLC wrapper that calls the external function, despite not having its source code. You could similarly access functions in a library of algorithms optimized for the target processor. Accomplishing this requires making changes to a template makefile, or otherwise providing a means to link against the library.

**Note** Object files that lack source code and are created with Microsoft Visual C and Microsoft Visual C++<sup>®</sup> Compiler (MSVC) work only with MSVC.

The only restriction on S-function wrappers is for the number of block inputs and outputs match number of inputs and outputs of the wrapped external function. Wrapper code may include computations, but usually these are limited to transforming values (for example, scaling or reformatting) passed to and from the wrapped external functions.

## Getting Started

In the example folder, the “external function” is found in the file `my_alg.c`. You are also provided with a C S-function called `wrapsfcn.c` that integrates `my_alg.c` into Simulink. Set up the exercise as follows:

- 1 Make `tlctutorial/wrapper` your current folder.
- 2 In MATLAB, open the model `externalcode` from your working folder. The block diagram looks like this:

- 3 Activate the Scope block by double-clicking it.
- 4 Run the model (from the **Simulation** tab, or type **Ctrl+T**). You will get an error telling you that `wrapsfcn` does not exist. Can you figure out why?
- 5 The error occurs because a mex file does not exist for `wrapsfcn`. To rectify this, in the MATLAB Command Window type

```
mex wrapsfcn.c
```

---

**Note** An error might occur if you have not previously run `mex -setup`.

---

- 6 Run the simulation again with the S-function present.

The S-Function block multiplies its input by two. Looking at the Scope block, you see a sine wave that oscillates between -2.0 and 2.0. The variable `yout` that is created in your MATLAB workspace steps through these values.

In the remainder of the exercise, you build and run a standalone version of the model, then write some TLC code that allows the code generator to build a standalone executable that calls the S-function `my_alg.c` directly.

## Generate Code Without a Wrapper

Before creating a wrapper, generate code that uses the Simulink generic API. The first step is to build a standalone model.

- 1 On the **C Code** tab, click **Build**.

The code generator creates the standalone program in your working folder and places the source and object files in your build folder. The file will be called `externalcode.exe` on Microsoft Windows platforms or `externalcode` on UNIX platforms.

As it generates the program, the code generator reports its progress in the MATLAB Command Window. The final lines are:

```
Created executable: externalcode.exe
Successful completion of build procedure
for model: externalcode
```

- 2 Run the standalone program to see that it behaves the same as the Simulink version. There should not be differences.

```
!externalcode
```

```
** starting the model **
** created externalcode.mat **
```

- 3 Notice this line in `wrapsfcn.c`:

```
#include "my_alg.c"
```

This pulls in the external function. That function consists entirely of

```
/*
 * Copyright 1994-2002 The MathWorks, Inc.
 */
```

```
double my_alg(double u)
{
 return(u * 2.0);
}
```

Inspect the `mdlOutputs()` function of the code in `wrapsfcn.c` to see how the external function is called.

```
static void mdlOutputs(SimStruct *S, int tid)
{
 int_T i;
 InputRealPtrsType uPtrs = ssGetInputPortRealSignalPtrs(S,0);
 real_T *y = ssGetOutputPortRealSignal(S,0);
 int_T width = ssGetOutputPortWidth(S,0);

 *y = my_alg(*uPtrs[0]);
}
```

---

**Tip** For UNIX platforms, run the executable program in the Command Window with the syntax `!./executable_name`. If preferred, run the executable program from an OS shell with the syntax `./executable_name`. For more information, see “Run External Commands, Scripts, and Programs”.

---

Generally, functions to be wrapped are either included in the wrapper, as above, or, when object modules are being wrapped, resolved at link time.

## Generate Code Using a Wrapper

To create a wrapper for the external function `my_alg.c`, you need to construct a TLC file that embodies its calling function, `wrapsfcn.c`. The TLC file must generate C code that provides:

- A function prototype for the external function that returns a double, and passes the input double `u`.
- A function call to `my_alg()` in the outputs section of the code.

To create a wrapper for `my_alg()`, do the following:

- 1 Open the file `change_wrapsfcn.tlc` in your editor, and add lines of code where comments indicate to create a workable wrapper.
- 2 Save the edited file as `wrapsfcn.tlc`. It must have the same name as the S-function block that uses it or TLC is not called to inline code.
- 3 In MATLAB, open the model `externalcode` from your working folder. Activate the Scope block by double-clicking it, and run the model (from the **Simulation** tab, or type **Ctrl+T**). This gives you a baseline result.
- 4 Inform Simulink that your code has an external reference to be resolved. To update the model's parameters, in the MATLAB Command Window, do one of the following:

- Type

```
set_param('externalcode/S-Function','SFunctionModules','my_alg')
```

- In the S-Function block parameters dialog box, in the S-function modules field, specify 'my\_alg'.

- 5 Create the standalone application, by entering one of the following commands in the Command Window:

```
slbuild('my_alg','ForceTopModelBuild',true)
```

```
slbuild('my_alg','StandaloneCoderTarget','ForceTopModelBuild',true)
```

These commands force the code generator to rebuild the top model, which is required when you make changes associated with external or custom code.

Alternatively, you can force regeneration of top model code by deleting folders in the code generation folder, such as `slprj` or the generated model code folder.

For more information, see “Control Regeneration of Top Model Code”.

- 6 Run the new standalone application and verify that it yields identical results as in the scope window.

```
!externalcode
```

If you had problems building the application:

- Find the error messages and try to determine what files are at fault, paying attention to which step (code generation, compiling, linking) failed.
- Be sure you issued the `set_param()` command as specified above.
- Chances are that problems can be traced to your TLC file. It may be helpful to use TLC debugger to step through `wrapsfcn.tlc`.
- As a last resort, look at `wrapsfcn.tlc` in the `solutions/tlc_solution` folder, also listed below:

```
%% File : wrapsfcn.tlc
%% Abstract:
%% Example tlc file for S-function wrapsfcn.c
%%
%% Copyright 1994-2002 The MathWorks, Inc.
%%
%%
```

```

implements "wrapfcn" "C"

%% Function: BlockTypeSetup =====
%% Abstract:
%% Create function prototype in model.h as:
%% "extern double my_alg(double u);"
%%
%%function BlockTypeSetup(block, system) void
 %openfile buffer
 %% ASSIGNMENT: PROVIDE A LINE OF CODE AS A FUNCTION PROTOTYPE
 %% FOR "my_alg" AS DESCRIBED IN THE WRAPPER TLC ASSIGNMENT
 extern double my_alg(double u);

 %closefile buffer
 %<LibCacheFunctionPrototype(buffer)>
%endfunction %% BlockTypeSetup

%% Function: Outputs =====
%% Abstract:
%% y = my_alg(u);
%%
%%function Outputs(block, system) Output
 /* %<Type> Block: %<Name> */
 %assign u = LibBlockInputSignal(0, "", "", 0)
 %assign y = LibBlockOutputSignal(0, "", "", 0)
 %% PROVIDE THE CALLING STATEMENT FOR "wrapfcn"
 %<y> = my_alg(%<u>);
%endfunction %% Outputs

```

Look at the highlighted lines. Did you declare `my_alg()` as `extern double`? Did you call `my_alg()` with the expected input and output? Fix mistakes and rebuild the model.

## Build Process

### Build Process Overview

TLC compiles files written in the target language. The target language is an interpreted language and the compiler operates on source files every time it executes. You can change a target file and watch the effects of your change the next time you build a model. You do not need to recompile TLC binary or other large binary to see the changes.

Because the target language is an interpreted language, some statements might not be compiled or executed (and hence not checked by the compiler). For example:

```
%if 1
 Hello
%else
 %<Invalid_function_call()>
%endif
```

In this example, the `Invalid_function_call` statement is not executed. This example emphasizes that you should test TLC code with test cases that execute every line.

### Create and Use Target Language File

This example creates a target language file that generates specific text from a model. It shows the sequence of steps that you should follow in creating and using your own target language files.

#### Process

To begin, create the Simulink model shown in the next figure.

- 1 Save the new model in a working folder as `basic`.
- 2 Display the Configuration Parameters dialog box.
- 3 Select the **Solver** pane.
- 4 In the **Solver** pane:
  - a Select `Fixed-step` in the **Type** field.
  - b Select `discrete (no continuous states)` in the **Solver** field.
  - c Under **Additional options**, specify `0.1` in the **Fixed-step size** field. (Otherwise, the code generator posts a warning and supplies a value when you generate code.)
- 5 Click **Apply**.
- 6 Select the **Code Generation** pane.
- 7 Select **Retain .rtw file**, then click **Apply**. This step lets you inspect the contents of the `model.rtw` file after the build finishes.
- 8 Select **Generate code only**, then click **OK**.
- 9 Build the model.

The build process generates code in the `basic_grt_rtw` folder. You can see the progress in the MATLAB Command Window. When code generation is complete, following message is displayed:

```
Successful completion of code generation for model: basic
```

### The `slbuild` Command

Invoke `slbuild` by pressing **Ctrl+B** in the model window. However, some circumstances require you to execute `slbuild` directly from the MATLAB prompt.

To generate a `model.rtw` file from the MATLAB prompt, type:

```
slbuild('model')
```

You can specify other options to `slbuild` that build or rebuild model reference simulation targets or a stand-alone executable. For more information, type:

```
help slbuild
```

at the MATLAB prompt or see `slbuild` in the Simulink documentation.

### Viewing the `basic.rtw` File

A `model.rtw` file contains a hierarchy of labeled records and fields. Each record is delimited by brackets, and contains subordinate records and/or fields. The labels state the purpose of each record and field. The records and fields in the `model.rtw` file created for a model describe various details of the model and the Configuration Parameter settings that specify its context.

Open the file `./basic_grt_rtw/basic.rtw`, in MATLAB or a text editor.

### Create the Target File

---

**Note** The following exercise is provided to give a conceptual overview of how the `.rtw` file is used in the build process. The code generator does not support manually invoking TLC with a `.rtw` file created from an earlier build. Also, the contents of the `.rtw` file are undocumented and subject to change. The `basic.tlc` file shows how information is provided in a `.rtw` file that can be accessed by the TLC files and executed as part of the build process.

---

Next, create a `basic.tlc` file to act as a target file for this model. Instead of generating code, simply display some information about the model using this file. The concept is the same as used in code generation.

Create a file called `basic.tlc` in the folder containing `basic`. This file should contain the following lines:

```
%with CompiledModel

My model is called %<Name>.
It was generated on %<GeneratedOn>.
It has %<NumModelOutputs> output(s) and %<NumContStates> continuous state(s).

%endwith
```

---

**Note** In the build process, the `.tlc` file specified on the command line when TLC is invoked (for example, `grt.tlc`) is referred to as the System Target File (STF). It can be selected via the **System target file** browser option in the **Code Generation** pane of the Configuration Parameters dialog box.

---

In this example, you generate the `.rtw` file as part of the build process and then manually run TLC using the file `basic.tlc` as an example STF. `basic.tlc` illustrates (in a limited capacity) how `.rtw` file information is used to generate an example output. To do this, enter at the MATLAB prompt:

```
slbuild('basic')
tlc -r basic_grt_rtw/basic.rtw basic.tlc -v
```

The first line generates the `.rtw` file in the build folder `'basic_grt_rtw'`. This step is unnecessary because the file has already been generated in the previous step. However, it is useful if the model is changed and the operation has to be repeated.

The second line runs TLC on the file `basic.tlc`. The `-r` option tells TLC that it should use the file `basic.rtw` as the `.rtw` file. Note that a space must separate `-r` and the input filename. The `-v` option tells TLC to be verbose in reporting its activity.

The output of this pair of commands is (date will differ):

```
My model is called basic.
It was generated on Wed Jun 22 20:51:11 2005.
It has 1 output(s) and 0 continuous state(s).
```

You can also try changing the model (for instance, by using `rand(2,2)` as the value for the constant block) and then repeating the process to see how the output of TLC changes.

- “TLC Files” on page 16-11

## Configure TLC

### In this section...

“Set Command-Line Arguments” on page 16-5

“Configure for TLC Debugging” on page 16-6

### Set Command-Line Arguments

You can enter TLC command-line arguments from the MATLAB command line using the `set_param` command, the model parameter `TLCOptions`, and the TLC option `-a`. For example, to enter the TLC command-line string `-amyConfigVariable=1`, use the following MATLAB command:

```
set_param(modelName, 'TLCOptions', '-amyConfigVariable=1');
```

Using `-amyConfigVariable=1` is equivalent to coding the following in your target file:

```
%assign myConfigVariable = 1
```

Alternatively, you can configure the TLC code generation process by using the `-a` option on the TLC command line. That is, you must give the TLC command interactively.

You can repeatedly use the `-a` option.

For an example of how this process works, consider the following TLC code fragment:

```
%if !EXISTS(myConfigVariable)
 %assign myConfigVariable = 0
%endif
%if (myConfigVariable == 1)
 code fragment 1
%else
 code fragment 2
%endif
```

If you specify `-amyConfigVariable=1` in the command line, `code fragment 1` is generated; otherwise `code fragment 2` is generated. The `if` block starting with

```
%if !EXISTS(myConfigVariable)
```

serves to set the default value of `myConfigVariable` to 0, so that TLC does not generate an error if you forget to add `-amyConfigVariable` to the command line.

If you use the `-a` option to input a string variable, the variable must be enclosed in double quotation marks:

```
-aMyStringVariable="hello"
```

However, if the string contains white space, enclose the string within apostrophes and double quotation marks:

```
-aMyStringVariable="'hello world'"
```

Do this if apostrophes exist within the string, whether or not white space is included, and the apostrophes must be escaped (doubled):

```
-aMyStringVariable="'can't'"
```

## Configure for TLC Debugging

To configure TLC for debugging via the Configuration Parameters dialog box, search for the option **Start TLC debugger when generating code**. To activate TLC debugger, select **Start TLC debugger when generating code**. For more information, see “Using the TLC Debugger” on page 19-2 and the debugging topics in “Target Language Compiler”.

### Related Examples

- “Build Process” on page 16-2
- “TLC Files” on page 16-11

## Code Generation Concepts

TLC interprets a target language, which is a general programming language, and you can use it as such. It is important, however, to remember that TLC was designed for one purpose: to convert a *model.rtw* file to generated code. Thus, the target language provides many features that are useful for this task but does not provide some of the features that other languages like C and C++ provide.

You might find some of the following general programming examples useful to familiarize yourself with the basic constructs used within TLC.

### Output Streams

The typical “Hello World” example is rather simple in the target language. Type the following in a file named *hello.tlc*:

```
%selectfile STDOUT
Hello, World
```

To run this TLC program, type

```
tlc hello.tlc
```

at the MATLAB prompt.

This simple script illustrates some important concepts underlying the purpose (and hence the design) of TLC. Since the primary purpose of TLC is to generate code, it is output (or stream) oriented. It makes it easy to handle buffers of text and output them easily. In the above script, the `%selectfile` directive tells TLC to send any following text that it generates or does not recognize to the standard output device. Syntax that TLC recognizes begins with the `%` character. Because `Hello, World` is not recognized, it is sent directly to the output. You could easily change the output destination to be a file. Do not open the `STDOUT` stream, but select to write to the Command Window.

```
%openfile foo = "foo.txt"
%openfile bar = "bar.txt"
%selectfile foo
This line is in foo.
%selectfile STDOUT
Line has been output to foo.
%selectfile bar
This line is in bar.
%selectfile NULL_FILE
This line will not show up anywhere.
%selectfile STDOUT
About to close bar.
%closefile bar
%closefile foo
```

You can switch between buffers to display status messages. The semantics of the three directives `%openfile`, `%selectfile`, and `%closefile` are given in “Target Language Compiler Directives” on page 18-2.

### Variable Types

The absence of explicit type declarations for variables is another feature of TLC. See “Target Language Compiler” for more information on the implicit data types of variables.

## Records

One of the constructs most relevant to generating code from the *model.rtw* file is a record. A record is similar to a structure in C or a record in Pascal. The syntax of a record declaration is

```
%createrecord recVar { ...
 field1 value1 ...
 field2 value2 ...
 ...
 fieldN valueN ...
}
```

where *recVar* is the name of the record being declared, *fieldi* is a string, and *valuei* is the corresponding TLC value.

Records can have nested records, or subrecords, within them. The *model.rtw* file is essentially one large record, named `CompiledModel`, containing levels of subrecords.

Unlike MATLAB, TLC requires that you explicitly load function definitions not located in the same target file. In MATLAB, the line `A = myfunc(B)` causes MATLAB to automatically search for and load a MATLAB file or MEX-file named `myfunc`. TLC requires that you specifically include the file that defines the function using the `%addincludepath` directive.

TLC provides a `%with` directive that facilitates using records. See “Target Language Compiler Directives” on page 18-2.

---

**Note** The format and structure of the *model.rtw* file are subject to change from one release of the code generator to another.

---

A record read in from a file is changeable, like other records that you declare in a program. The record `CompiledModel` is modified many times during code generation. `CompiledModel` is the global record in the *model.rtw* file. It contains variables used for code generation, such as `NumNonvirtSubsystems`, `NumBlocks`. It is also appended during code generation with many new variables, options, and subrecords.

Functions such as `LibGetFormattedBlockPath` are provided in TLC libraries located in *matlabroot/rtw/c/tlc/lib/\*.tlc* (open). For a complete list of available functions, refer to TLC Function Library Reference on “Target Language Compiler”.

### Assign Values to Fields of Records

To assign a value to a field of a record, you must use a qualified variable expression. A qualified variable expression references a variable in one of the following forms:

- An identifier
- A qualified variable followed by “.” followed by an identifier, such as

```
var[2].b
```

- A qualified variable followed by a bracketed expression such as

```
var[expr]
```

## Record Aliases

In TLC, it is possible to create what is called an alias to a record. Aliases are similar to pointers to structures in C. You can create multiple aliases to a single record. Modifications to the aliased record are visible to every place that holds an alias.

The following code fragment illustrates the use of aliases:

```
%createrecord foo { field 1 }
%createrecord a { }
%createrecord b { }
%createrecord c { }

%addtorecord a foo foo
%addtorecord b foo foo
%addtorecord c foo { field 1 }

%% notice we are not changing field through a or b.
%assign foo.field = 2

ISALIAS(a.foo) = %<ISALIAS(a.foo)>
ISALIAS(b.foo) = %<ISALIAS(b.foo)>
ISALIAS(c.foo) = %<ISALIAS(c.foo)>

a.foo.field = %<a.foo.field>
b.foo.field = %<b.foo.field>
c.foo.field = %<c.foo.field>
%% note that c.foo.field is unchanged
```

Saving this script as `record_alias.tlc` and invoking it with

```
tlc -v record_alias.tlc
```

produces the output

```
ISALIAS(a.foo) = 1
ISALIAS(b.foo) = 1
ISALIAS(c.foo) = 0

a.foo.field = 2
b.foo.field = 2
c.foo.field = 1
```

When inside a function, it is possible to create an alias to a locally created record that is within the function. If the alias is returned from the function, it remains valid even after exiting the function, as in the following example:

```
%function func(value) Output
 %createrecord foo { field value }
 %createrecord a { foo foo }
 ISALIAS(a.foo) = %<ISALIAS(a.foo)>
 %return a.foo
%endfunction

%assign x = func(2)
ISALIAS(x) = %<ISALIAS(x)>
x = %<x>
x.field = %<x.field>
```

Saving this script as `alias_func.tlc` and invoking it with

```
tlc -v alias_func.tlc
```

produces the output

```
ISALIAS(a.foo) = 1
ISALIAS(x) = 1
x = { field 2 }
x.field = 2
```

As long as there is some reference to a record through an alias, that record is not deleted. This allows records to be used as return values from functions.

## TLC Files

### In this section...

“TLC Program” on page 16-11  
 “Available Target Files” on page 16-11  
 “Target File Usage” on page 16-12  
 “System Target Files” on page 16-13

## TLC Program

Target Language Compiler (TLC) works with the Simulink software to generate code.

A TLC program is a collection of ASCII files called scripts. Because TLC is an interpreted language, there are no object files. The single target file that calls (with the `%include` directive) other target files used for the program is called the entry point.

## Available Target Files

TLC interprets the set of target files to transform the partial representation of the Simulink model (`model.rtw`) into target-specific code.

Target files provide you with the flexibility to customize the code generated by the compiler. For example, if you use the available system target files, you produce generic C or C++ code from your Simulink model. This executable code is not platform-specific.

**Note** Do not customize TLC files even though the capability exists to do so. Such TLC customizations might not be applied during the code generation process and can lead to unpredictable results. Customize only the TLC files that you create.

The parameters in the target files are read from the `model.rtw` file and looked up by using block scoping rules. You can define additional parameters within the target files by using the `%assign` statement.

Use target language directives to write target files. “Target Language Compiler Directives” on page 18-2 provide complete descriptions of the block scope rules and the target language directives.

“model.rtw File and Scopes” on page 17-2 describes `model.rtw` file, which is useful for creating and modifying target files.

In the context of code generation, there are two types of target files:

- System target files

System target files determine the overall framework of code generation. They determine when blocks are executed, how data is logged, and so on.

- Block target files

Each block has a target file that determines what code should be generated for the block. The code can vary depending on the exact parameters of the block or the types of connections to it (e.g., wide vs. scalar input). For more information, see “Block Target File Methods” on page 20-21

### Model-Wide Target Files and System Target Files

You use model-wide target files on a model-wide basis. Model-wide target files provide basic information to TLC, which transforms the `model.rtw` file into target-specific code.

The system target file is the entry point for TLC. It is analogous to the `main()` routine of a C program. System target files oversee the entire code generation process. For example, the system target file `grt.tlc` sets up some variables for `codegenentry.tlc`, which is the entry point into the system target files. For a complete list of available system target files, see “Compare System Target File Support Across Products”.

## Target File Usage

Use the target files to:

- Inline an S-function

Inlining an S-function means writing a block target file that instructs TLC how to generate code for that S-Function block. The compiler can generate code for noninlined C MEX S-functions. If you inline a C MEX S-function, the compiler can generate more efficient code. Noninlined C MEX S-functions execute by using the S-function application program interface (API) and can be inefficient. You can inline a MATLAB file or Fortran S-function. TLC can generate code for the S-function in both cases.

- Customize the code generated for all models

You might want to instrument the generated code for profiling or make other changes to overall code generation for all models. To accomplish such changes, modify some of the system target files.

## System Target Files

The entire code generation process starts with the single system target file that you specify in the Configuration Parameters dialog box, on the **Code Generation** pane. Click the **Browse** button to activate the system target file browser for this purpose. A close examination of a system target file reveals how code generation occurs. This listing is a listing of the non-comment lines in `grt.tlc`, the target file to generate code for a generic real-time executable.

```
%selectfile NULL_FILE
%assign TargetType = "RT"
%assign Language = "C"
%assign MatFileLogging = 1
%include "codegenentry.tlc"
```

The three variables, `Language`, `TargetType`, and `MatFileLogging`, are global TLC variables that other functions use. Code generation is then initiated by the call to `codegenentry.tlc`, the main entry point for code generation.

If you want to modify overall code generation, you must change the system target file. After the initial setup, instead of calling `codegenentry.tlc`, you must call your own TLC files. This code shows an example system target file called `mygrt.tlc`.

```
%% Set up variables, etc.
%% Load my library functions
%% Note that mylib.tlc should %include funclib.tlc at the
%% beginning.
%include "mylib.tlc"
%include "commonsetup.tlc"

%% Next, you can include TLC files that you need for
%% preprocessing information about the model and to fill in
%% hooks. The following is an example of including a single
%% TLC file that contains custom hooks.
%include "myhooks.tlc"

%% Finally, call the code generator.
%include "commonentry.tlc"
```

Generated code is placed in a model or subsystem function. The relevant generated function names and their execution order are described in “Execution of Code Generated from a Model” and “Configure Generated C Function Interface for Model Entry-Point Functions”. During code generation, functions from each of the block target files are executed and the generated code is placed in model or subsystem functions.

## Data Handling with TLC

### In this section...

"Matrix Parameters" on page 16-14

"Code Generator Matrix Parameters" on page 16-14

### Matrix Parameters

MATLAB, Simulink, and the code generator use column-major ordering for array storage (1-D, 2-D, ...). The next element of an array in memory is accessed by incrementing the first index of the array. For example, these element pairs are stored sequentially in memory:  $A(i)$  and  $A(i+1)$ ,  $B(i, j)$  and  $B(i+1, j)$ ,  $C(i, j, k)$  and  $C(i+1, j, k)$ . For more information on the internal representation of MATLAB data, see "MATLAB Data".

### Code Generator Matrix Parameters

Simulink and code generator internal data storage formatting differs from MATLAB internal data storage formatting only in the storage of complex number arrays. In MATLAB, the real and imaginary parts are stored in separate arrays. In the Simulink and code generator products they are stored in an "interleaved" format, where the numbers in memory alternate real, imaginary, real, imaginary, and so forth. This convention allows efficient implementations of small signals on Simulink lines and for Mux blocks and other "virtual" signal manipulation blocks (that is, they do not actively copy their inputs, merely the references to them).

The compiled model file, *model.rtw*, represents matrices as strings in MATLAB syntax, with no implied storage format. This is so you can copy the string out of an *.rtw* file and paste it into MATLAB code and have it recognized by MATLAB.

TLC declares Simulink block matrix parameters as scalar or 1-D array variables

```
real_T scalar;
real_T mat[nRows * nCols];
```

where *real\_T* can be an arbitrary data type supported by Simulink, and match the variable type given in the model file.

For example, the 3-by-3 matrix in the Look-Up Table (2-D) block

```
1 2 3
4 5 6
7 8 9
```

is stored in *model.rtw* as

```
Parameter {
 Name "OutputValues"
 Value Matrix(3,3)
 [[1.0, 2.0, 3.0]; [4.0, 5.0, 6.0]; [7.0, 8.0, 9.0];]
 String "t"
 StringType "Variable"
 ASTNode {
 IsNonTerminal 0
 Op SL_NOT_INLINED
 }
}
```

```

 ModelParameterIdx 3
 }
}

```

and results in this definition in *model.h*

```

typedef struct Parameters_tag {
 real_T s1_Look_Up_Table_2_D_Table[9];
 /* Variable:s1_Look_Up_Table_2_D_Table
 * External Mode Tunable:yes
 * Referenced by block:
 * <S1>/Look-Up Table (2-D
 */

 [... other parameter definitions ...]
} Parameters;

```

The *model.h* file declares the actual storage for the matrix parameter and you can see that the format is column-major. That is, read down the columns, then across the rows.

```

Parameters model_P = {
 /* 3 x 3 matrix s1_Look_Up_Table_2_D_Table */
 { 1.0, 4.0, 7.0, 2.0, 5.0, 8.0, 3.0, 6.0, 9.0 },
 [... other parameter declarations ...]
};

```

TLC accesses matrix parameters via `LibBlockMatrixParameter` and `LibBlockMatrixParameterAddr`, where

`LibBlockMatrixParameter(OutputValues, "", "", 0, "", "", 1)` returns "*model\_P.s1\_Look\_Up\_Table\_2\_D\_Table[nRows]*" (automatically optimized from "[0+nRows\*1]") and

`LibBlockMatrixParameterAddr(OutputValues, "", "", 0, "", "", 1)` returns "&*model\_P.s1\_Look\_Up\_Table\_2\_D\_Table[nRows]*" for both inlined and noninlined block TLC code.

Matrix parameters are like other TLC parameters. Only those parameters explicitly accessed by a TLC library function during code generation are placed in the parameters structure. So, following the example, `s1_Look_Up_Table_2_D_Table` is not declared unless `LibBlockParameter` or `LibBlockParameterAddr` explicitly access it.

- “Data References in the *model.rtw* File” on page 17-9
- “Exception to Using the Library Functions that Access *model.rtw*” on page 17-11

## model.rtw File and Scopes

The code generation software creates a *model*.rtw file from your Simulink model. A *model*.rtw file is a partial representation of a model generated by the build process for use by the Target Language Compiler. It describes blocks, inputs, outputs, parameters, states, storage, and other model components and properties from the corresponding model file.

The generated *model*.rtw file is input to the Target Language Compiler. If you select **Retain .rtw file** from the **Configuration Parameters > Code Generation** pane, after building a model, you can view the *model*.rtw file that was generated.

A *model*.rtw file is implemented as an ASCII file of parameter-value pairs stored in a hierarchy of records. A parameter name/parameter value pair is specified as

```
ParameterName value
```

where ParameterName (also called an identifier) is the name of the TLC identifier and value is a string, scalar, vector, or matrix. For example, in the parameter name/parameter value pair

```
NumDataOutputPorts 1
```

NumDataOutputPorts is the identifier and 1 is its value.

A record is specified as

```
RecordName {
 .
 .
 .
}
```

A record contains parameter name/parameter value pairs and/or subrecords. For example, this record contains one parameter name/parameter value pair:

```
DataStores {
 NumDataStores 0
}
```

---

**Note** The structure of the *model*.rtw file is very likely to change between releases, which is a compelling reason to limit your access to *model*.rtw to the library functions documented under TLC Function Library Reference: “Target Language Compiler”. For additional information, see “Exception to Using the Library Functions that Access model.rtw” on page 17-11.

---

### Scopes in the model.rtw File

Each record creates a new scope. The *model*.rtw file uses curly braces { and } to open and close records (or scopes). Using scopes, you can access values within the *model*.rtw file.

The scope in this example begins with CompiledModel. Use periods (.) to access values within particular scopes. The format of *model*.rtw is

```
CompiledModel {
 Name "modelName" -- Example of a parameter-value
 ... pair (record field).
```

```

System {
 Block {
 Type "S-Function"
 Name "<S3>/S-Function"
 ...
 Parameter {
 Name "P1"
 Value Matrix(1,2) [[1, 2];]
 }
 ...
 Block {
 }
 }
 ...
 System {
 ...
 }
}

```

For example, to access `Name` within `CompiledModel`, you would use

```
CompiledModel.Name
```

Multiple records of the same name form a list where the index of the first record starts at 0. To access the above S-function block record, you would use

```
CompiledModel.System[0].Block[0]
```

To access the name field of this block, you would use

```
CompiledModel.System[0].Block[0].Name
```

To simplify this process, you can use the `%with` directive, which changes the current scope. For example:

```
%with CompiledModel.System[0].Block[0]
%assign blockName = Name
%endwith
```

`blockName` will have the value `"<S3>/S-Function"`.

When inlining S-function blocks, your S-function block record is scoped as though the above `%with` directive was done. In an inlined `.tlc` file, you should access fields without a fully qualified path.

The following code shows a more detailed scoping example where the `Block` record has several parameter-value pairs (`Type`, `Name`, `Identifier`, and so on), and three subrecords, each called `Parameter`. `Block` is a subrecord of `System`, which is a subrecord of `CompiledModel`. Note that the parameter names in this file changes from release to release.

### Related Examples

- “Data Object Information in model.rtw File” on page 17-5
- “Data References in the model.rtw File” on page 17-9

## Data Object Information in model.rtw File

You can obtain meta information about the generated code by accessing the *model.rtw* file in the build folder.

During the build process, the code generator writes information about Simulink signal and parameter data objects to the *model.rtw* file. An **Object** record with **CoderInfo** property information is written for each parameter or signal that meets certain conditions. These conditions are described in “Object Records for Parameters” on page 17-5 and “Object Records for Signals” on page 17-6.

The **Object** records contain the information corresponding to the associated data object. To access **Object** records, you must write Target Language Compiler code (see “Access Data Object Information by Using Target Language Compiler (TLC) Code” on page 17-7).

For some data, defining storage classes can be helpful. For more information, see “Finely Control Data Representation by Writing TLC Code for a Storage Class” on page 37-23. Embedded Coder is required.

---

**Note** These **Object** record examples are generated from the example model *rtwdemo\_configrpininterface*. The parameters and signals are individually configured by using the *ExportedGlobal* storage class.

---

### Object Records for Parameters

An **Object** record that has **CoderInfo** property information is included in the *ModelParameters* section of the *model.rtw* file for each parameter that meets these conditions:

- The parameter resolves to a *Simulink.Parameter* data object or to a parameter data object that comes from a class derived from the *Simulink.Parameter* class.
- The parameter symbol is preserved in the generated code. The symbol is preserved when the *CoderInfo.StorageClass* property of the data object is not set to *Auto* or if you set the storage class on the individual parameter by using the Code Mappings editors or the *coder.mapping.api.CodeMapping* object.

This example shows part of an **Object** record for a parameter.

```
ModelParameters {
 NumParameters 10
 ...
 Parameter {
 Identifier "K1"
 LogicalSrc P7
 WorkspaceVarName "K1"
 Protected no
 Tunable yes
 StorageClass "ExportedGlobal"
 Value [2]
 OriginalDataTypeIdx 2
 CGTypeIdx 36
 ContainerCGTypeIdx 42
 IsPublic 1
 ReferencedBy Matrix(1,4)
 }
 [[1, 0, 4, 2];]
 GraphicalRef Matrix(1,2)
 [[0, 10];]
 GraphicalSource [-1, -1]
 OwnerSysIdx [1, -1]
```

```

HasObject 1
Object {
 Package Simulink
 Class Parameter
 ObjectProperties {
 Value 2.0
 CoderInfo {
 Object {
 Package Simulink
 Class CoderInfo
 ObjectProperties {
 HasCoderInfo 1
 StorageClass "ExportedGlobal"
 TypeQualifier ""
 Alias ""
 Alignment -1
 IsCSCPackageOverridden 0
 CSCPackageName "Simulink"
 ParameterOrSignal "Parameter"
 CustomStorageClass "Default"
 CustomAttributes {
 Object {
 Package SimulinkCSC
 Class AttribClass_Simulink_Default
 ObjectProperties {
 }
 }
 }
 }
 }
 }
}
...
}

```

## Object Records for Signals

An Object record that has CoderInfo property information is included in either the ExternalOutputs, ExternalInputs, or BlockOutputs section of the *model.rtw* file for each signal (including root-level Inport and Outport blocks) whose symbol is preserved in the generated code. The symbol is preserved when the signal uses a storage class other than Auto and is individually mapped.

An Object record that has CoderInfo property information is included in the *model.rtw* file for each signal that preserves the signal symbol in the generated code and meets these conditions:

- The CoderInfo.StorageClass property of the data object is not set to Auto.
- The data object is individually mapped to a predefined storage class by using the Code Mappings editor or the `coder.mapping.api.CodeMapping` object.

If you configure the signal to be an unstructured global variable in the generated code, its validity and uniqueness are enforced and its symbol is preserved.

This example shows part of an Object record for a root-level Outport block.

```

ExternalOutputs {
 ...
 NumExternalOutputs 1
 ...
 ExternalOutput {
 ArgSrc Y0
 Block [1,3]
 BlockName "<Root>/Out1"
 GrSrc [0, 4]
 Identifier "output"
 StorageClass "ExportedGlobal"
 }
}

```

```

HasObject 1
Object {
 Package Simulink
 Class Signal
 ObjectProperties {
 CoderInfo {
 Object {
 Package Simulink
 Class CoderInfo
 ObjectProperties {
 HasCoderInfo 1
 StorageClass "ExportedGlobal"
 TypeQualifier ""
 Alias "output"
 Alignment -1
 IsCSCPackageOverridden 0
 CSCPackageName "Simulink"
 ParameterOrSignal "Signal"
 CustomStorageClass "Default"
 CustomAttributes {
 Object {
 Package SimulinkCSC
 Class AttribClass_Simulink_Default
 ObjectProperties {
 }
 }
 }
 }
 }
 }
}
...
}

```

## Access Data Object Information by Using Target Language Compiler (TLC) Code

Here, sample code shows how to access data object information from the *model.rtw* file by using TLC code.

### Access Parameter Object Records

This code fragment iterates over Parameter structures in the ModelParameters section of the *model.rtw* file. The code extracts information from parameter Object records.

```

%with CompiledModel.ModelParameters
%foreach modelParamIdx = NumParameters
%assign thisModelParam = Parameter[modelParamIdx]
%assign paramName = thisModelParam.Identifier
%if EXISTS("thisModelParam.Object.ObjectProperties")
%with thisModelParam.Object.ObjectProperties
%assign valueInObject = Value
%with CoderInfo.Object.ObjectProperties
%assign storageClassInObject = StorageClass
%endwith
%% *****
%% Access user-defined properties here
%% *****
%if EXISTS("MY_PROPERTY_NAME")
%assign userDefinedPropertyName = MY_PROPERTY_NAME
%endif
%% *****
%endwith
%endif
%endforeach
%endwith

```

## Access Signal Object Records

This code fragment iterates over `ExternalBlockOutput` structures in the `BlockOutputs` section of the `model.rtw` file. The code extracts information from signal `Object` records.

```
%with CompiledModel.BlockOutputs
%foreach blockOutputIdx = NumExternalBlockOutputs
%assign thisBlockOutput = ExternalBlockOutput[blockOutputIdx]
%assign signalName = thisBlockOutput.Identifier
%if EXISTS("thisBlockOutput.Object.ObjectProperties")
%with thisBlockOutput.Object.ObjectProperties
%with CoderInfo.Object.ObjectProperties
%assign storageClassInObject = StorageClass
%endwith \
%% *****\
%% Access user-defined properties here\
%% *****
%if EXISTS("MY_PROPERTY_NAME")
%assign userDefinedPropertyName = MY_PROPERTY_NAME
%endif
%% *****
%endwith
%endif
%endforeach
%endwith
```

## Data References in the model.rtw File

### Data Reference Overview

Some records in a *model.rtw* file, such as those corresponding to parameters and constant block I/O, can have extremely large data value vectors embedded in them. Such a vector can cause significant memory overhead during code generation because the values must be maintained as text in memory during this process.

To avoid such overhead, by default the Simulink software does not write out the entire data value vector into *model.rtw*. Instead, it writes a key called a data reference that can be used during code generation to access the data directly from Simulink. If the data is not mutated during code generation, it is efficiently streamed to disk when the actual code containing the data values is written out.

A data reference has the format `SLData(index)`, where *index* is a numeric value that tells Simulink which data is being referenced. TLC directives such as `GENERATE_FORMATTED_VALUE` store data references in unexpanded format in memory. When the generated code is written out to disk, the data values expand to the actual values. To access the data vector of the model parameter written to the `ModelParameters` record in the *model.rtw*, use the `LibGetParameterValue` function.

### Control Data Reference Threshold

By default, if you do not specify a value for the model configuration parameter `RTWDataReferencesMinSize`, the code generator assigns the value `-1` to the parameter. In this case, the code generator writes a data reference of a model parameter to the *model.rtw* file in place of a data vector. This optimization reduces the file read/write operations, which improves the code generation time. When you specify a positive value for the `RTWDataReferencesMinSize` parameter, the code generator uses the value as the threshold size based on which it writes data references to the *model.rtw* file in place of a data vector.

To change the maximum length of a vector that can appear literally in the file, use:

```
set_param(0, 'RTWDataReferencesMinSize', maxlen)
```

Simulink replaces a vector as long or longer than `maxlen` with a data reference when it creates *model.rtw*. Specify `maxlen` as an integer or as `inf`. Specifying `inf` disables data references. The complete value set of every vector, however long, then appears literally in *model.rtw* and occupies text memory during code generation.

Setting an explicit `maxlen` affects only the current MATLAB session. To set the value across sessions, include a `set_param` command in your `startup.m` file, or automate execution of the command when MATLAB launches.

### Expand Data References

You can explicitly expand a data reference by using the `GENERATE_FORMATTED_VALUE` built-in function with the optional third `expand` argument. Commands such as `FEVAL` may cause a data reference to be expanded to the full form.

## **Avoid Data Reference Expansion**

Either turning off data references completely or expanding select parameters in TLC can cause significant text memory overhead during the code generation process. During most common code generation tasks, it is unnecessary to have the expanded data vector in memory and pay the price of the additional overhead. Avoid expanded data vectors unless no alternative exists.

## **Restart Code Generation**

A *model.rtw* file that contains data references cannot be used in isolation to restart a custom code generation process. The data references within it become stale once the code generation process is completed. Attempting to start a code generation process using only this file may result in unpredictable behavior and memory segmentation faults.

## **See Also**

### **Related Examples**

- “Data Object Information in model.rtw File” on page 17-5
- “Exception to Using the Library Functions that Access model.rtw” on page 17-11

## Exception to Using the Library Functions that Access model.rtw

There are several library functions that provide access to block inputs, outputs, parameters, sample times, and other information. It is recommended that you use these library functions to access many of the parameter name/parameter values pairs in the block record, as opposed to accessing the parameter name/parameter value pairs directly from your block TLC code. For more information about using these functions (recommended method for accessing *model.rtw*), see “Target Language Compiler Library Functions Overview” on page 21-2.

An exception to using these functions is when you access parameter settings for a block. Parameter settings can be written out using the `mdlRTW` function of a C MEX S-function. They can contain data in the form of strings, scalar values, vectors, and matrices. They can be used to pass fixed values and information that is used to alter the generated code for a block or directly as values in the resulting code of a block.

### Example Exception to Using the Library Functions

The following example demonstrates accessing parameter settings for a block using the `mdlRTW` function of a C MEX S-function. For more details on using parameter settings, see “Inlining S-Functions” on page 14-8.

#### mdlRTW Function in C MEX S-Function Code

```
static void mdlRTW(SimStruct *S)
{
 if (!ssWriteRTWParamSettings(S, 1, SSWRITE_VALUE_QSTR, "Operator", "AND"))
 {
 ssSetErrorStatus(S,"Error writing parameter data to .rtw file");
 return;
 }
}
```

#### Resulting Block Record in model.rtw File

```
Block {
 Type "S-Function"
 Name "<Root>/S-Function"
 ...
 SFcnParamSettings {
 Operator "AND"
 }
}
```

#### TLC Code to Access the Parameter Settings

```
%function Outputs(block, system) Output
%%
%% Select Operator
%switch(SFcnParamSettings.Operator)
%case "AND"
 %assign LogicOp = "&"
 %break
 ...
%endswitch
%endfunction
```

## Caution Against Directly Accessing Record Fields

When functions in the block target file are called, they are passed to the block and system records for this instance as arguments. The first argument, `block`, is in scope, which means that variable names inside this instance's block record are accessible by name. For example:

```
%assign fast = SFcnParamSetting.Fast
```

Block target files could generate code for a given block by directly using the fields in the Block record for the block. This process is *not* recommended, for two reasons:

- The contents of the `model.rtw` file can change from release to release. This can cause block TLC files that access the `model.rtw` file directly to stop working.
- TLC library functions are provided that substantially reduce the amount of TLC code for implementing a block while handling the various configurations (widths, data types, etc.) a block might have. These library functions are provided by the system target files to provide access to inputs, outputs, parameters, and so on. Using these functions in a block TLC script makes it flexible enough to generate code for multiple instances or configurations of the block, as well as across releases. Exceptions to this do occur, however, such as when you want to directly access a field in the block's record. This happens with parameter settings, as discussed in "TLC Code to Access the Parameter Settings" on page 17-11.

# Directives and Built-In Functions

---

You control how code is generated from models largely through writing or modifying scripts that apply TLC directives and built-in functions. Use the following sections as your primary reference to the syntax and format of target language constructs, as well as the MATLAB `tlc` command itself.

- “Target Language Compiler Directives” on page 18-2
- “Command-Line Arguments” on page 18-48

## Target Language Compiler Directives

You control how code is generated from models largely through writing or modifying scripts that apply TLC directives and built-in functions. Use the following sections as your primary reference to the syntax and format of target language constructs, as well as the MATLAB `tlc` command itself.

A target language directive must be the first non-blank character on a line and begins with the `%` character. Lines beginning with `%%` are TLC comments, and are *not* passed to the output stream. Lines beginning with `/*` are C comments, and *are* passed to the output stream.

### Syntax

A target language file consists of a series of statements of either form:

- `[text | %<expression>]*`

The literal text is passed to the output stream unmodified, and expressions enclosed in `%< >` are evaluated before being written to output (stripped of `%< >`).

- `%keyword [argument1, argument2, ...]`

The `%keyword` represents one of the directives of Target Language Compiler, and `[argument1, argument2, ...]` represents expressions that define required parameters. For example, the statement

```
%assign sysNumber = sysIdx + 1
```

uses the `%assign` directive to define or change the value of the `sysNumber` parameter.

### Directives

The rest of this section shows the complete set of Target Language Compiler directives, and describes each directive in detail.

#### **%% text**

Single-line comment where `text` is the comment.

#### **/\* text\*/**

Single (or multiline) comment where `text` is the comment.

#### **%matlab**

Calls a MATLAB function that does not return a result. For example, `%matlab disp(2.718)`.

#### **%<expr>**

Target language expressions that are evaluated. For example, if you have a TLC variable that was created via `%assign varName = "foo"`, then `%<varName>` would expand to `foo`. Expressions can also be function calls, as in `%<FcnName(param1, param2)>`. On directive lines, TLC expressions need not be placed within the `%<>` syntax. Doing so causes a double evaluation. For example, `%if %<x> == 3` is processed by creating a hidden variable for the evaluated value of the variable `x`. The `%if` statement then evaluates this hidden variable and compares it against 3. The efficient way to do

this operation is to write `%if x == 3`. In MATLAB notation, this would equate to writing `if eval('x') == 3` as opposed to `if x = 3`. The exception to this is during an `%assign` for format control, as in

```
%assign str = "value is: %<var>"
```

**Note:** Nested evaluation expressions (e.g., `%<foo(%<expr>)>`) are not supported.

There is not a speed penalty for evaluations inside strings, such as

```
%assign x = "%<expr>"
```

Avoid evaluations outside strings, such as the following example.

```
%assign x = %<expr>
```

### **%if expr%elseif expr%else%endif**

Conditional inclusion, where the constant expression *expr* must evaluate to an integer. For example, the following code checks whether a parameter, *k*, has the numeric value 0.0 by executing a TLC library function to check for equality.

```
%if ISEQUAL(k, 0.0)
 <text and directives to be processed if k is 0.0>
%endif
```

In this and other directives, you do not have to expand variables or expressions using the `%<expr>` notation unless *expr* appears within a string. For example,

```
%if ISEQUAL(idx, "my_idx%<i>"), where idx and i are both strings.
```

As in other languages, logical evaluations do short-circuit (are halted when the result is known).

### **%switch expr %case expr %break %default %break %endswitch**

The `%switch` directive is similar to the C language `switch` statement. The expression *expr* should be of a type that can be compared for equality using the `==` operator. If the `%break` is not included after a `%case` statement, then it will fall through to the next statement.

### **%with %endwith**

`%with recordName` is a scoping operator. Use it to bring the named record into the current scope, to remain until the matching `%endwith` is encountered (`%with` directives can be nested as desired).

Note that on the left side of `%assign` statements contained within a `%with / %endwith` block, references to fields of records must be fully qualified (see "Assign Values to Fields of Records" on page 16-8), as in the following example.

```
%with CompiledModel
 %assign oldName = name
 %assign CompiledModel.name = "newname"
%endwith
```

### **%setcommandswitch string**

Changes the value of a command-line switch as specified by the argument string. Only the following switches are supported:

v, m, p, 0, d, r, I, a

The following example sets the verbosity level to 1.

```
%setcommandswitch "-v1"
```

See also "Command-Line Arguments" on page 18-48.

### **%assert expr**

Tests a value of a Boolean expression. If the expression evaluates to false, TLC issues an error message, a stack trace and exit; otherwise, the execution continues normally. To enable the evaluation of assertions outside the code generator environment, use the command-line option `-da`. When building from within the code generator, this flag is ignored, as it is superseded by the **Enable TLC assertion** check box on the **TLC process** section of the **Code Generation > Debug** pane. To control assertion handling from the MATLAB Command Window, use

```
set_param(model, 'TLCAssertion', 'on|off')
```

to set this flag on or off. Default is Off. To see the current setting, use

```
get_param(model, 'TLCAssertion')
```

### **%error %warning %trace %exit**

Flow control directives:

**%error *tokens***

The *tokens* are expanded and displayed.

**%warning *tokens***

The *tokens* are expanded and displayed.

**%trace *tokens***

The *tokens* are expanded and displayed only when the verbose output command-line option `-v` or `-v1` is specified.

**%exit *tokens***

The *tokens* are expanded, displayed, and TLC exits.

When reporting errors, use the following command if the error is produced by an incorrect configuration that the user needs to fix in the model.

```
%exit Error Message
```

If you are adding assert code (that is, code that should never be reached), use

```
%setcommandswitch "-v1" %% force TLC stack trace
%exit Assert message
```

### **%assign**

Creates identifiers (variables). The general form is

```
%assign [::]variable = expression
```

The `::` specifies that the variable being created is a global variable; otherwise, it is a local variable in the current scope (i.e., a local variable in the function).

If you need to format the variable, say, within a string based upon other TLC variables, then you should perform a double evaluation, as in

```
%assign nameInfo = "The name of this is %<Name>"
```

or alternately

```
%assign nameInfo = "The name of this is " + Name
```

To assign a value to a field of a record, you must use a qualified variable expression. See “Assign Values to Fields of Records” on page 16-8.

### **%createrecord**

Creates records in memory. This command accepts a list of one or more record specifications (e.g., { foo 27 }). Each record specification contains a list of zero or more name-value pairs (e.g., foo 27) that become the members of the record being created. The values themselves can be record specifications, as the following illustrates.

```
%createrecord NEW_RECORD { foo 1 ; SUB_RECORD {foo 2} }
%assign x = NEW_RECORD.foo /* x = 1 */
%assign y = NEW_RECORD.SUB_RECORD.foo /* y = 2 */
```

If more than one record specification follows a given record name, the set of record specifications constitutes an array of records.

```
%createrecord RECORD_ARRAY { foo 1 } ...
 { foo 2 } ...
 { bar 3 }
%assign x = RECORD_ARRAY[1].foo /* x = 2 */
%assign y = RECORD_ARRAY[2].bar /* y = 3 */
```

Note that you can create and index arrays of subrecords by specifying %createrecord with identically named subrecords, as follows:

```
%createrecord RECORD_ARRAY { SUB_RECORD { foo 1 } ...
 SUB_RECORD { foo 2 } ...
 SUB_RECORD { foo 3 } }
%assign x = RECORD_ARRAY.SUB_RECORD[1].foo /* x = 2 */
%assign y = RECORD_ARRAY.SUB_RECORD[2].foo /* y = 3 */
```

If the scope resolution operator (::) is the first token after the %createrecord token, the record is created in the global scope.

---

**Note** You should not create a record array by using %createrecord within a loop.

---

### **%addtorecord**

Adds fields to an existing record. The new fields can be name-value pairs or aliases to already existing records.

```
%addtorecord OLD_RECORD foo 1
```

If the new field being added is a record, then %addtorecord makes an alias to that record instead of a deep copy. To make a deep copy, use %copyrecord.

```
%createrecord NEW_RECORD { foo 1 }
%addtorecord OLD_RECORD NEW_RECORD_ALIAS NEW_RECORD
```

**%mergerecord**

Adds (or merges) one or more records into another. The first record will contain the results of the merge of the first record plus the contents of the other records specified by the command. The contents of the second (and subsequent) records are deep copied into the first (i.e., they are not references).

```
%mergerecord OLD_RECORD NEW_RECORD
```

If duplicate fields exist in the records being merged, the original record's fields are not overwritten.

**%copyrecord**

Makes a deep copy of an existing record. It creates a new record in a similar fashion to `%createrecord` except the components of the record are deep copied from the existing record. Aliases are replaced by copies.

```
%copyrecord NEW_RECORD OLD_RECORD
```

**%realformat**

Specifies how to format real variables. To format in exponential notation with 16 digits of precision, use

```
%realformat "EXPONENTIAL"
```

To format without loss of precision and minimal number of characters, use

```
%realformat "CONCISE"
```

When inlining S-functions, the format is set to `concise`. You can switch to `exponential`, but should switch it back to `concise` when done.

**%language**

This must appear before the first `GENERATE` or `GENERATE_TYPE` function call. This specifies the name of the language as a string, which is being generated as in `%language "C"`. Generally, this is added to your system target file.

The only valid value is `C` which enables support for C and C++ code generation as specified by the configuration parameter `TargetLang` (see "Language" for more information).

**%implements**

Placed within the `.tlc` file for a specific record type, when mapped via `%generatefile`. The syntax is `%implements "Type" "Language"`. When inlining an S-function in C or C++, this should be the first noncomment line in the file, as in

```
%implements "s_function_name" "C"
```

The next noncomment lines will be `%function` directives specifying the functionality of the S-function.

See the `%language` and `GENERATE` function descriptions for further information.

**%generatefile**

Provides a mapping between a record `Type` and functions contained in a file. Each record can have functions of the same name but different contents mapped to it (i.e., polymorphism). Generally, this is used to map a `Block` record `Type` to the `.tlc` file that implements the functionality of the block, as in

```
%generatefile "Sin" "sin_wave.tlc"
```

**%filescope**

Limits the scope of variables to the file in which they are defined. A `%filescope` directive anywhere in a file declares that variables in the file are visible only within that file. Note that this limitation also applies to files inserted, via the `%include` directive, into the file containing the `%filescope` directive.

You should not use the `%filescope` directive within functions or `GENERATE` functions.

`%filescope` is useful in conserving memory. Variables whose scope is limited by `%filescope` go out of scope when execution of the file containing them completes. This frees memory allocated to such variables. By contrast, global variables persist in memory throughout execution of the program.

**%include**

Use `%include "file.tlc"` to insert the specified target file at the current point.

The `%include` directives behave as if they were in a global context. For example,

```
%addincludepath "./sub1"
%addincludepath "./sub2"
```

in a `.tlc` file enables either subfolder to be referenced implicitly:

```
%include "file_in_sub1.tlc"
%include "file_in_sub2.tlc"
```

Use forward slashes for folder names, as they work on both UNIX and PC systems. However, if you do use back slashes in PC folder names, be sure to escape them, e.g., `"C:\\mytlc"`. Alternatively, you can express a PC folder name as a literal using the `L` format specifier, as in `L"C:\\mytlc"`.

**%addincludepath**

Use `%addincludepath "folder"` to add additional paths to be searched. Multiple `%addincludepath` directives can appear. The compiler evaluates multiple `%addincludepath` directives from the *bottom up*.

Using `%addincludepath` directives establishes a global context. For example,

```
%addincludepath "./sub1"
%addincludepath "./sub2"
```

in a `.tlc` file enables either subfolder to be referenced implicitly:

```
%include "file_in_sub1.tlc"
%include "file_in_sub2.tlc"
```

Use forward slashes for folder names, as they work on both UNIX and PC systems. However, if you do use back slashes in PC folder names, be sure to escape them, e.g., "C:\\myt1c". Alternatively, you can express a PC folder name as a literal using the L format specifier, as in L"C:\myt1c".

## **%roll %endroll**

Multiple inclusion plus intrinsic loop rolling based upon a specified threshold. This directive can be used by most Simulink blocks that have the concept of an overall block width that is usually the width of the signal passing through the block.

This example of the %roll directive is for a gain operation,  $y=u*k$ :

```
%function Outputs(block, system) Output
/* %<Type> Block: %<Name> */
%assign rollVars = ["U", "Y", "P"]
%roll sigIdx = RollRegions, lcv = RollThreshold, block,...
 "Roller", rollVars
 %assign y = LibBlockOutputSignal(0, "", lcv, sigIdx)
 %assign u = LibBlockInputSignal(0, "", lcv, sigIdx)
 %assign k = LibBlockParameter(Gain, "", lcv, sigIdx)
 %<y> = %<u> * %<k>;
%endroll
%endfunction
```

The %roll directive is similar to %foreach, except that it iterates the identifier (sigIdx in this example) over roll regions. Roll regions are computed by looking at the input signals and generating regions where the inputs are contiguous. For blocks, the variable RollRegions is automatically computed and placed in the Block record. An example of a roll regions vector is [0:19, 20:39], where there are two contiguous ranges of signals passing through the block. The first is 0:19 and the second is 20:39. Each roll region is either placed in a loop body (e.g., the C language for statement) or inlined, depending upon whether or not the length of the region is less than the roll threshold.

Each time through the %roll loop, sigIdx is an integer for the start of the current roll region or an offset relative to the overall block width when the current roll region is less than the roll threshold. The TLC global variable RollThreshold is the general model-wide value used to decide when to place a given roll region in a loop. When the decision is made to place a given region in a loop, the loop control variable is a valid identifier (e.g., "i"); otherwise it is "".

The block parameter is the current block that is being rolled. The "Roller" parameter specifies the name for internal GENERATE\_TYPE calls made by %roll. The default %roll handler is "Roller", which is responsible for setting up the default block loop rolling structures (e.g., a C for loop).

The rollVars (roll variables) are passed to "Roller" functions to create roll structures. The defined loop variables relative to a block are

**"U"**

The inputs to the block. It assumes you use LibBlockInputSignal(portIdx, "", lcv, sigIdx) to access each input, where portIdx starts at 0 for the first input port.

**"ui"**

Similar to "U", except only for specific input, *i*. The "u" must be lowercase or it will be interpreted as "U" above.

**"Y"**

The outputs of the block. It assumes you use LibBlockOutputSignal(portIdx, "", lcv, sigIdx) to access each output, where portIdx starts at 0 for the first output port.

"yi"

Similar to "Y", except only for specific output, *i*. The "y" must be lowercase or it will be interpreted as "Y" above.

"P"

The parameters of the block. It assumes you use `LibBlockParameter(name, "", lcv, sigIdx)` to access them.

"<param>/name"

Similar to "P", except specific for a specific *name*.

rwork

The RWork vectors of the block. It assumes you use `LibBlockRWork(name, "", lcv, sigIdx)` to access them.

"<rwork>/name"

Similar to RWork, except for a specific *name*.

dwork

The DWork vectors of the block. It assumes you use `LibBlockDWork(name, "", lcv, sigIdx)` to access them.

"<dwork>/name"

Similar to DWork, except for a specific *name*.

iwork

The IWork vectors of the block. It assumes you use `LibBlockIWork(name, "", lcv, sigIdx)` to access them.

"<iwork>/name"

Similar to IWork, except for a specific *name*.

pwork

The PWork vectors of the block. It assumes you use `LibBlockPWork(name, "", lcv, sigIdx)` to access them.

"<pwork>/name"

Similar to PWork, except for a specific *name*.

"Mode"

The mode vector. It assumes you use `LibBlockMode("", lcv, sigIdx)` to access it.

"PZC"

Previous zero-crossing state. It assumes you use `LibPrevZCState("", lcv, sigIdx)` to access it.

To roll your own vector based upon the block's roll regions, you need to walk a pointer to your vector. Assuming your vector is pointed to by the first PWork, called name,

```
datatype *buf = (datatype*)%<LibBlockPWork(name,"","",0)
%roll sigIdx = RollRegions, lcv = RollThreshold, block, ...
 "Roller", rollVars
 *buf++ = whatever;
%endroll
```

**Note:** In the above example, `sigIdx` and `lcv` are local to the body of the loop.

**%breakpoint**

Sets a breakpoint for the TLC debugger. See “%breakpoint Directive” on page 19-5.

**%function %return %endfunction**

A function that returns a value is defined as

```
%function name(optional-arguments)
 %return value
%endfunction
```

A void function does not produce output and is not required to return a value. It is defined as

```
%function name(optional-arguments) void
%endfunction
```

A function that produces outputs to the current stream and is not required to return a value is defined as

```
%function name(optional-arguments) Output
%endfunction
```

For block target files, you can add to your inlined .tlc file the following functions that are called by the model-wide target files during code generation.

```
%function BlockInstanceSetup(block,system) void
```

Called for each instance of the block within the model.

```
%function BlockTypeSetup(block,system) void
```

Called once for each block type that exists in the model.

```
%function Enable(block,system) Output
```

Use this if the block is placed within an enabled subsystem and has to take specific actions when the subsystem is enabled. Place within a subsystem enable routine.

```
%function Disable(block,system) Output
```

Use this if the block is placed within a disabled subsystem and has to take specific actions when the subsystem is disabled. Place within a subsystem disable routine.

```
%function Start(block,system) Output
```

Include this function if your block has startup initialization code that needs to be placed within MdlStart.

```
%function InitializeConditions(block,system) Output
```

Use this function if your block has state that needs to be initialized at the start of execution and when an enabled subsystem resets states. Place in MdlStart and/or subsystem initialization routines.

```
%function Outputs(block,system) Output
```

The primary function of your block. Place in MdlOutputs.

```
%function Update(block,system) Output
```

Use this function if your block has actions to be performed once per simulation loop, such as updating discrete states. Place in MdlUpdate.

```
%function Derivatives(block,system) Output
```

Use this function if your block has derivatives.

**%function ZeroCrossings(block,system) Output**

Use this function if your block does zero-crossing detection and has actions to be performed in `MdlZeroCrossings`.

**%function Terminate(block,system) Output**

Use this function if your block has actions that need to be in `MdlTerminate`.

**%foreach %endforeach**

Multiple inclusion that iterates from 0 to the `upperLimit - 1` constant integer expression. Each time through the loop, the `loopIdentifier`, (e.g., `x`) is assigned the current iteration value.

```
%foreach loopIdentifier = upperLimit
 %break -- use this to exit the loop
 %continue -- use this to skip the following code and
 continue to the next iteration
%endforeach
```

**Note:** The `upperLimit` expression is cast to a TLC integer value. The `loopIdentifier` is local to the loop body.

**%for**

Multiple inclusion directive with syntax

```
%for ident1 = const-exp1, const-exp2, ident2 = const-exp3
 %body
 %break
 %continue
 %endbody
%endfor
```

The first portion of the `%for` directive is identical to the `%foreach` statement. The `%break` and `%continue` directives act the same as they do in the `%foreach` directive. `const-exp2` is a Boolean expression that indicates whether the loop should be rolled (see `%roll` above).

If `const-exp2` evaluates to `TRUE`, `ident2` is assigned the value of `const-exp3`. Otherwise, `ident2` is assigned an empty string.

**Note:** `ident1` and `ident2` above are local to the loop body.

**%openfile %selectfile %closefile**

These are used to manage the files that are created. The syntax is

```
%openfile streamId="filename.ext" mode {open for writing}
%selectfile streamId {select an open file}
%closefile streamId {close an open file}
```

Note that the `"filename.ext"` is optional. If a filename is not specified, a variable (string buffer) named `streamId` is created containing the output. The mode argument is optional. If specified, it can be `"a"` for appending or `"w"` for writing.

Note that the special string `streamIdNULL_FILE` specifies no output. The special string `streamIdSTDOUT` specifies output to the terminal.

To create a buffer of text, use

```
%openfile buffer
text to be placed in the 'buffer' variable.
%closefile buffer
```

Now `buffer` contains the expanded text specified between the `%openfile` and `%closefile` directives.

### **%generate**

`%generate blk fn` is equivalent to `GENERATE(blk, fn)`.

`%generate blk fn type` is equivalent to `GENERATE(blk, fn, type)`.

See “GENERATE and GENERATE\_TYPE Functions” on page 18-24.

### **%undef**

`%undef var` removes the variable `var` from scope. If `var` is a field in a record, `%undef` removes that field from the record. If `var` is a record array, `%undef` removes the entire record array.

## **Comments**

You can place comments anywhere within a target file. To include comments, use the `/%...%/` or `%%` directives. For example:

```
/%
 Abstract: Return the field with [width], if field is wide
%/
```

or

```
%endfunction %% Outputs function
```

Use the `%%` construct for line-based comments. Characters from `%%` to the end of the line become a comment.

Non-directive lines, that is, lines that do not have `%` as their first non-blank character, are copied into the output buffer verbatim. For example,

```
/* Initialize sysNumber */
int sysNumber = 3;
```

copies both lines to the output buffer.

To include comments on lines that do not begin with the `%` character, you can use the `/%...%/` or `%%` comment directives. In these cases, the comments are not copied to the output buffer.

---

**Note** If a non-directive line appears within a function, it is not copied to the output buffer unless the function is an output function or you specifically select an output file using the `%selectfile` directive. For more information about functions, see “Target Language Functions” on page 18-45.

---

## Line Continuation

You can use the C language `\` character or the MATLAB sequence `...` to continue a line. If a directive is too long to fit conveniently on one line, this allows you to split the directive onto multiple lines. For example:

```
%roll sigIdx = RollRegions, lcv = RollThreshold, block,\
 "Roller", rollVars
```

or

```
%roll sigIdx = RollRegions, lcv = RollThreshold, block,...
 "Roller", rollVars
```

---

**Note** Use `\` to suppress line feeds to the output and the ellipsis `...` to indicate line continuation. Note that `\` and the ellipsis `...` cannot be used inside strings.

---

## Target Language Value Types

This table shows the types of values you can use within the context of expressions in your target language files. Expressions in the Target Language Compiler must use these types.

Value Type String	Example	Description
"Boolean"	<code>1==1</code>	Result of a comparison or other Boolean operator. The result will be <code>TLC_TRUE</code> or <code>TLC_FALSE</code> .
"Complex"	<code>3.0+5.0i</code>	64-bit double-precision complex number ( <code>double</code> on the target machine).
"Complex32"	<code>3.0F+5.0Fi</code>	32-bit single-precision complex number ( <code>float</code> on the target machine).
"File"	<code>%openfile x</code>	String buffer opened with <code>%openfile</code> .
"File"	<code>%openfile x = "out.c"</code>	File opened with <code>%openfile</code> .
"Function"	<code>%function foo...</code>	User-defined function and <code>TLC_FALSE</code> otherwise.
"Gaussian"	<code>3+5i</code>	32-bit integer imaginary number ( <code>int</code> on the target machine).
"Identifier"	<code>abc</code>	Identifier values can appear only within the <code>model.rtw</code> file and cannot appear in expressions (within the context of an expression, identifiers are interpreted as values). To compare against an identifier value, use a string; the identifier will be converted to a string.
"Matrix"	<code>Matrix (3,2) [ [ 1, 2]; [3 , 4]; [ 5, 6] ]</code>	Matrices are simply lists of vectors. The individual elements of the matrix do not need to be the same type, and can be any supported type except vectors or matrices. The <code>Matrix (3,2)</code> text in the example is optional.
"Number"	<code>15</code>	Integer number ( <code>int</code> on the target machine).
"Range"	<code>[1:5]</code>	Range of integers between 1 and 5, inclusive.

Value Type String	Example	Description
"Real"	3.14159	Floating-point number ( <code>double</code> on the target machine), including exponential notation.
"Real32"	3.14159F	32-bit single-precision floating-point number ( <code>float</code> on the target machine).
"Scope"	Block { ... }	Block record.
"Special"	FILE_EXISTS	Special built-in function, such as FILE_EXISTS.
"String"	"Hello, World"	ASCII character strings. In all contexts, two strings in a row are concatenated to form the final value, as in "Hello, " "World", which is combined to form "Hello, World". These strings include the ANSI C standard escape sequences such as <code>\n</code> , <code>\r</code> , <code>\t</code> , etc. Use of line continuation characters (i.e., <code>\</code> and <code>...</code> ) inside strings is illegal.
"Subsystem"	<sub1>	Subsystem identifier. Within the context of an expansion, be careful to escape the delimiters on a subsystem identifier, as in <code>%&lt;x == &lt;sub\&gt;&gt;</code> .
"Unsigned"	15U	32-bit unsigned integer ( <code>unsigned int</code> on the target machine).
"Unsigned Gaussian"	3U+5Ui	32-bit complex unsigned integer ( <code>unsigned int</code> on the target machine).
"Vector"	[1, 2] or BR Vector(2) [1, 2]	Vectors are lists of values. The individual elements of a vector do not need to be the same type, and can be of any supported type except vectors or matrices.

## Target Language Expressions

You can include an expression of the form `%<expression>` in a target file. The Target Language Compiler replaces `%<expression>` with a calculated replacement value based upon the type of the variables within the `%<>` operator. Integer constant expressions are folded and replaced with the resultant value; string constants are concatenated (e.g., two strings in a row "a" "b", are replaced with "ab").

```
%<expression> /* Evaluates the expression.
 * Operators include most standard C
 * operations on scalars. Array indexing
 * is required for certain parameters that
 * are block-scoped within the .rtw file.*/
```

Within the context of an expression, each identifier must evaluate to an identifier or function argument currently in scope. You can use the `%< >` directive on a line to perform text substitution. To include the `>` character within a replacement, you must escape it with a `\` character. For example:

```
%<x \> 1 ? "ABC" : "123">
```

Operators that need the `>` character to be escaped are the following:

Operator	Description	Example
>	greater than	y = %<x \> 2>;
>=	greater than or equal to	y = %<x \>= 3>;
>>	right shift	y = %<x \>\> 4>;

The table Target Language Expressions lists the operators that are allowed in expressions. In this table, expressions are listed in order from highest to lowest precedence. The horizontal lines distinguish the order of operations.

As in C expressions, conditional operators are short-circuited. If the expression includes a function call with effects, the effects are noticed as if the entire expression was not fully evaluated. For example:

```
%if EXISTS(foo) && foo == 3
```

If the first term of the expression evaluates to a Boolean false (i.e., `foo` does not exist), the second term (`foo == 3`) is not evaluated.

In the upcoming table, note that *numeric* is one of the following:

- Boolean
- Number
- Unsigned
- Real
- Real32
- Complex
- Complex32
- Gaussian
- UnsignedGaussian

Also, note that *integral* is one of the following:

- Number
- Unsigned
- Boolean

See “TLC Data Promotions” on page 18-18 for information on the promotions that result when the Target Language Compiler operates on mixed types of expressions.

## Target Language Expressions

Expression	Definition
constant	Constant parameter value. The value can be a vector or matrix.
variable-name	Valid in-scope variable name, including the local function scope, if any, and the global scope.
::variable-name	Used within a function to indicate that the function scope is ignored when the variable is looked up. This accesses the global scope.
expr[expr]	Index into an array parameter. Array indices range from 0 to N-1. This syntax is used to index into vectors, matrices, and repeated scope variables.
expr([expr[,expr]...])	Function call or macro expansion. The expression outside the parentheses is the function/macro name; the expressions inside are the arguments to the function or macro.  <b>Note:</b> Macros are text-based; they cannot be used within the same expression as other operators.
expr . expr	The first expression must have a valid scope; the second expression is a parameter name within that scope.
(expr)	Use ( ) to override the precedence of operations.
!expr	Logical negation (generates TLC_TRUE or TLC_FALSE). The argument must be numeric or Boolean.
-expr	Unary minus negates the expression. The argument must be numeric.
+expr	No effect; the operand must be numeric.
~expr	Bit-wise negation of the operand. The argument must be an integer.
expr * expr	Multiplies the two expressions; the operands must be numeric.
expr / expr	Divides the two expressions; the operands must be numeric.
expr % expr	Takes the integer modulo of the expressions; the operands must be integers.

Expression	Definition
<code>expr + expr</code>	<p>Works on numeric types, strings, vectors, matrices, and records as follows:</p> <p><b>Numeric types:</b> Add the two expressions; the operands must be numeric.</p> <p><b>Strings:</b> The strings are concatenated.</p> <p><b>Vectors:</b> If the first argument is a vector and the second is a scalar, the scalar is appended to the vector.</p> <p><b>Matrices:</b> If the first argument is a matrix and the second is a vector of the same column width as the matrix, the vector is appended as another row in the matrix.</p> <p><b>Records:</b> If the first argument is a record, the second argument is added as a parameter identifier (with its current value).</p> <p>Note that the addition operator is associative.</p>
<code>expr - expr</code>	Subtracts the two expressions; the operands must be numeric.
<code>expr &lt;&lt; expr</code>	Left-shifts the left operand by an amount equal to the right operand; the arguments must be integers.
<code>expr &gt;&gt; expr</code>	Right-shifts the left operand by an amount equal to the right operand; the arguments must be integers.
<code>expr &gt; expr</code>	Tests whether the first expression is greater than the second expression; the arguments must be numeric.
<code>expr &lt; expr</code>	Tests whether the first expression is less than the second expression; the arguments must be numeric.
<code>expr &gt;= expr</code>	Tests whether the first expression is greater than or equal to the second expression; the arguments must be numeric.
<code>expr &lt;= expr</code>	Tests whether the first expression is less than or equal to the second expression; the arguments must be numeric.
<code>expr == expr</code>	Tests whether the two expressions are equal.
<code>expr != expr</code>	Tests whether the two expressions are not equal.
<code>expr &amp; expr</code>	Performs the bit-wise AND of the two arguments; the arguments must be integers.
<code>expr ^ expr</code>	Performs the bit-wise XOR of the two arguments; the arguments must be integers.
<code>expr   expr</code>	Performs the bit-wise OR of the two arguments; the arguments must be integers.
<code>expr &amp;&amp; expr</code>	Performs the logical AND of the two arguments and returns <code>TLC_TRUE</code> or <code>TLC_FALSE</code> . This can be used on either numeric or Boolean arguments.

Expression	Definition
<code>expr    expr</code>	Performs the logical OR of the two arguments and returns <code>TLC_TRUE</code> or <code>TLC_FALSE</code> . This can be used on either numeric or Boolean arguments.
<code>expr ? expr : expr</code>	Tests the first expression for <code>TLC_TRUE</code> . If true, the first expression is returned; otherwise, the second expression is returned.
<code>expr , expr</code>	Returns the value of the second expression.

---

**Note** Relational operators (`<`, `=<`, `>`, `>=`, `!=`, `==`) can be used with nonfinite values.

You do not have to place expressions in the `%< > eval` format when they appear on directive lines. Doing so causes a double evaluation.

---

### TLC Data Promotions

When the Target Language Compiler operates on mixed types of expressions, it promotes the results to the common types indicated in the following table.

The table uses the following abbreviations:

<b>B</b>	Boolean
<b>N</b>	Number
<b>U</b>	Unsigned
<b>F</b>	Real32
<b>D</b>	Real
<b>G</b>	Gaussian
<b>UG</b>	UnsignedGaussian
<b>C32</b>	Complex32
<b>C</b>	Complex

The top row (in bold) and first column (in bold) show the types of expression used in the operation. The intersection of the row and column shows the resulting type of expressions.

For example, if the operation involves a Boolean expression (B) and an unsigned expression (U), the result will be an unsigned expression (U).

## Data Types Resulting from Expressions of Mixed Type

	<b>B</b>	<b>N</b>	<b>U</b>	<b>F</b>	<b>D</b>	<b>G</b>	<b>UG</b>	<b>C32</b>	<b>C</b>
<b>B</b>	B	N	U	F	D	G	UG	C32	C
<b>N</b>	N	N	U	F	D	G	UG	C32	C
<b>U</b>	U	U	U	F	D	UG	UG	C32	C
<b>F</b>	F	F	F	F	D	C32	C32	C32	C
<b>D</b>	D	D	D	D	D	C	C	C	C
<b>G</b>	G	G	UG	C32	C	G	UG	C32	C
<b>UG</b>	UG	UG	UG	C32	C	UG	UG	C32	C
<b>C32</b>	C32	C32	C32	C32	C	C32	C32	C32	C
<b>C</b>	C	C	C	C	C	C	C	C	C

## Formatting

By default, the Target Language Compiler outputs floating-point numbers in exponential notation with 16 digits of precision. To override the default, use the directive

```
%realformat string
```

If *string* is "EXPONENTIAL", the standard exponential notation with 16 digits of precision is used. If *string* is "CONCISE", the compiler uses internal heuristics to output the values in a more readable form while maintaining accuracy. The `%realformat` directive sets the default format for Real number output to the selected style for the remainder of processing or until it encounters another `%realformat` directive.

## Conditional Inclusion

The conditional inclusion directives are

```
%if constant-expression
%else
%elseif constant-expression
%endif
```

```
%switch constant-expression
%case constant-expression
%break
%default
%endswitch
```

### **%if**

The `constant-expression` must evaluate to an integer expression. It controls the inclusion of the following lines until it encounters an `%else`, `%elseif`, or `%endif` directive. If the `constant-expression` evaluates to 0, the lines following the directive are not included. If the `constant-expression` evaluates to an integer value other than 0, the lines following the `%if` directive are included until the `%endif`, `%elseif`, or `%else` directive.

When the compiler encounters an `%elseif` directive, and no prior `%if` or `%elseif` directive has evaluated to nonzero, the compiler evaluates the expression. If the value is 0, the lines following the

`%elseif` directive are not included. If the value is nonzero, the lines following the `%elseif` directive are included until the subsequent `%else`, `%elseif`, or `%endif` directive.

The `%else` directive begins the inclusion of source text if the previous `%elseif` statements or the original `%if` statement evaluates to 0; otherwise, it prevents the inclusion of subsequent lines up to and including the following `%endif`.

The constant-expression can contain any expression specified in “Target Language Expressions” on page 18-14.

### **%switch**

The `%switch` statement evaluates the constant expression and compares it to expressions appearing on `%case` selectors. If a match is found, the body of the `%case` is included; otherwise the `%default` is included.

`%case ... %default` bodies flow together, as in C, and `%break` must be used to exit the switch statement. `%break` exits the nearest enclosing `%switch`, `%foreach`, or `%for` loop in which it appears. For example,

```
%switch(type)
%case x
 /* Matches variable x. */
 /* Note: Any valid TLC type is allowed. */
%case "Sin"
 /* Matches Sin or falls through from case x. */
 %break
 /* Exits the switch. */
%case "gain"
 /* Matches gain. */
 %break
%default
 /* Does not match x, "Sin," or "gain." */
%endswitch
```

In general, this is a more readable form for the `%if/%elseif/%else` construction.

## **Multiple Inclusion**

### **%foreach**

The syntax of the `%foreach` multiple inclusion directive is

```
%foreach identifier = constant-expression
 %break
 %continue
%endforeach
```

The constant-expression must evaluate to an integer expression, which then determines the number of times to execute the `foreach` loop. The `identifier` increments from 0 to one less than the specified number. Within the `foreach` loop, you can use `x`, where `x` is the identifier, to access the identifier variable. `%break` and `%continue` are optional directives that you can include in the `%foreach` directive:

- Use `%break` to exit the nearest enclosing `%for`, `%foreach`, or `%switch` statement.

- Use `%continue` to begin the next iteration of a loop.

## `%for`

---

**Note** The `%for` directive is functional, but it is not recommended. Instead, use `%roll`, which provides the same capability in a more open way. The code generator does not use the `%for` construct.

---

The syntax of the `%for` multiple inclusion directive is

```
%for ident1 = const-exp1, const-exp2, ident2 = const-exp3
 %body
 %break
 %continue
 %endbody
%endfor
```

The first portion of the `%for` directive is identical to the `%foreach` statement in that it causes a loop to execute from 0 to N-1 times over the body of the loop. In the normal case, it includes only the lines between `%body` and `%endbody`, and the lines between the `%for` and `%body`, and ignores the lines between `%endbody` and `%endfor`.

The `%break` and `%continue` directives act the same as they do in the `%foreach` directive.

`const-exp2` is a Boolean expression that indicates whether the loop should be rolled. If `const-exp2` is true, `ident2` receives the value of `const-exp3`; otherwise it receives the null string. When the loop is rolled, the lines between the `%for` and the `%endfor` are included in the output exactly one time. `ident2` specifies the identifier to be used for testing whether the loop was rolled within the body. For example,

```
%for Index = <NumNonVirtualSubsystems>3, rollvar="i"
 {
 int i;

 for (i=0; i< %<NumNonVirtualSubsystems>; i++)
 {
 %body
 x[%<rollvar>] = system_name[%<rollvar>];
 %endbody
 }
 }
%endfor
```

If the number of nonvirtual subsystems (`NumNonVirtualSubsystems`) is greater than or equal to 3, the loop is rolled, causing the code within the loop to be generated exactly once. In this case, `Index = 0`.

If the loop is not rolled, the text before and after the body of the loop is ignored and the body is generated `NumNonVirtualSubsystems` times.

This mechanism gives each individual loop control over whether or not it should be rolled.

## **%roll**

The syntax of the `%roll` multiple inclusion directive is

```
%roll ident1 = roll-vector-exp, ident2 = threshold-exp, ...
 block-exp [, type-string [,exp-list]]
 %break
 %continue
%endroll
```

This statement uses the `roll-vector-exp` to expand the body of the `%roll` statement multiple times as in the `%foreach` statement. If a range is provided in the `roll-vector-exp` that range is larger than the `threshold-exp` expression, the loop will roll. When a loop rolls, the body of the loop is expanded once and the identifier (`ident2`) provided for the threshold expression is set to the name of the loop control variable. If no range is larger than the specified rolling threshold, this statement is identical to the `%foreach` statement. For example,

```
%roll Idx = [1 2 3:5, 6, 7:10], lcv = 10, ablock
%endroll
```

In this case, the body of the `%roll` statement expands 10 times, as in the `%foreach` statement, because there are no regions greater than or equal to 10. `Idx` counts from 1 to 10, and `lcv` is set to the null string, "".

When the Target Language Compiler determines that a given block will roll, it performs a `GENERATE_TYPE` function call to output the various pieces of the loop (other than the body). The default type used is `Roller`; you can override this type with a string that you specify. Extra arguments passed to the `%roll` statement are provided as arguments to these special-purpose functions. The called function is one of these four functions:

### **RollHeader(block, ...)**

This function is called once on the first section of this roll vector that will actually roll. It should return a string that is assigned to the `lcv` within the body of the `%roll` statement.

### **LoopHeader(block, StartIdx, Niterations, Nrolled, ...)**

This function is called once for each section that will roll prior to the body of the `%roll` statement.

### **LoopTrailer(block, Startidx, Niterations, Nrolled, ...)**

This function is called once for each section that will roll after the body of the `%roll` statement.

### **RollTrailer(block, ...)**

This function is called once at the end of the `%roll` statement if any of the ranges caused loop rolling.

These functions should output language-specific declarations, loop code, and so on as required to generate code for the loop.

An example of a `Roller.tlc` file is

```
%implements Roller "C"
%function RollHeader(block) Output
{
 int i;
 %return ("i")
}
```

```

%endfunction
%function LoopHeader(block,StartIdx,Niterations,Nrolled) Output
 for (i = %<StartIdx>; i < %<Niterations+StartIdx>; i++)
 {
%endfunction
%function LoopTrailer(block,StartIdx,Niterations,Nrolled) Output
 }
%endfunction
%function RollTrailer(block) Output
 }
%endfunction

```

---

**Note** The Target Language Compiler function library provided with the code generator has the capability to extract references to the block I/O and other code generator vectors that vastly simplify the body of the `%roll` statement. These functions include `LibBlockInputSignal`, `LibBlockOutputSignal`, `LibBlockParameter`, `LibBlockRWork`, `LibBlockIWork`, `LibBlockPWork`, `LibDeclareRollVars`, `LibBlockMatrixParameter`, `LibBlockParameterAddr`, `LibBlockContinuousState`, and `LibBlockDiscreteState`. (See the function reference pages in “Input Signal Functions” on page 21-7, “Output Signal Functions” on page 21-17, “Parameter Functions” on page 21-23, and “Block State and Work Vector Functions” on page 21-29.) This library also includes a default implementation of `Roller.tlc` as a “flat” roller.

---

Extending the former example to a loop that rolls,

```

%language "C"
%assign ablock = BLOCK { Name "Hi" }
%roll Idx = [1:20, 21, 22, 23:25, 26:46], lcv = 10, ablock
 Block[%<lcv == "" ? Idx : lcv>] *= 3.0;
%endroll

```

This Target Language Compiler code produces this output:

```

{
 int i;
 for (i = 1; i < 21; i++)
 {
 Block[i] *= 3.0;
 }
 Block[21] *= 3.0;
 Block[22] *= 3.0;
 Block[23] *= 3.0;
 Block[24] *= 3.0;
 Block[25] *= 3.0;
 for (i = 26; i < 47; i++)
 {
 Block[i] *= 3.0;
 }
}

```

## Object-Oriented Facility for Generating Target Code

The Target Language Compiler provides a simple object-oriented facility. The language directives are

```
%language string
%generatefile
%implements
```

This facility was designed specifically for customizing the code for Simulink blocks, but can be used for other purposes as well.

### **%language**

The `%language` directive specifies the target language being generated. It is required as a consistency check to verify the implementation files found for the language being generated. The `%language` directive must appear prior to the first `GENERATE` or `GENERATE_TYPE` built-in function call. `%language` specifies the language as a string. For example:

```
%language "C"
```

Simulink blocks have a `Type` parameter. This parameter is a string that specifies the type of the block, for example `"Sin"` or `"Gain"`. The object-oriented facility uses this type to search the path for a file that implements the block. By default the name of the file is the `Type` of the block with `.tlc` appended, so for example, if the `Type` is `"Sin"` the Compiler would search for `"Sin.tlc"` along the path. You can override this default filename using the `%generatefile` directive to specify the filename that you want to use to replace the default filename. For example,

```
%generatefile "Sin" "sin_wave.tlc"
```

The files that implement the block-specific code must contain an `%implements` directive indicating both the type and the language being implemented. The Target Language Compiler will produce an error if the `%implements` directive does not match as expected. For example,

```
%implements "Sin" "Pascal"
```

causes an error if the initial language choice was C.

You can use a single file to implement more than one target language by specifying the desired languages in a vector. For example,

```
%implements "Sin" "C"
```

Finally, you can implement several types using the wildcard (`*`) for the type field:

```
%implements * "C"
```

---

**Note** The use of the wildcard (`*`) is not recommended because it relaxes error checking for the `%implements` directive.

---

### **GENERATE and GENERATE\_TYPE Functions**

The Target Language Compiler has two built-in functions that dispatch object-oriented calls, `GENERATE` and `GENERATE_TYPE`. You can call a function appearing in an implementation file (from outside the specified file) only by using the `GENERATE` and `GENERATE_TYPE` special functions.

#### **GENERATE**

The `GENERATE` function takes two or more input arguments. The first argument must be a valid scope and the second a string containing the name of the function to call. The `GENERATE` function passes

the first block argument and any additional arguments specified to the function being called. The return argument is the value, if any, returned from the function being called. Note that the compiler automatically “scopes” or adds the first argument to the list of scopes searched as if it appears on a `%with` directive line. (See “Variable Scoping” on page 18-38.) This scope is removed when the function returns.

### **GENERATE\_TYPE**

The `GENERATE_TYPE` function takes three or more input arguments. It handles the first two arguments identically to the `GENERATE` function call. The third argument is the type; the type specified in the Simulink block is ignored. This facility is used to handle S-function code generation by the build process. That is, the block type is `S-function`, but the Target Language Compiler generates it as the specific S-function specified by `GENERATE_TYPE`. For example,

```
GENERATE_TYPE(block, "Output", "dp_read")
```

specifies that S-function `block` is of type `dp_read`.

The `block` argument and any additional arguments are passed to the function being called. Like the `GENERATE` built-in function, the compiler automatically scopes the first argument before the `GENERATE_TYPE` function is entered and then removes the scope on return.

Within the file containing `%implements`, function calls are looked up first within the file and then in the global scope. This makes it possible to have hidden helper functions used exclusively by the current object.

---

**Note** It is not an error for the `GENERATE` and `GENERATE_TYPE` directives to find no matching functions. This is to prevent requiring empty specifications for all aspects of block code generation. Use the `GENERATE_FUNCTION_EXISTS` or `GENERATE_TYPE_FUNCTION_EXISTS` directives to determine whether the specified function actually exists.

---

## **Output File Control**

The structure of the output file control construct is

```
%openfile string optional-equal-string optional-mode
%closefile id
%selectfile id
```

### **%openfile**

The `%openfile` directive opens a file or buffer for writing; the required string variable becomes a variable of type `file`. For example,

```
%openfile x /* Opens and selects x for writing. */
%openfile out = "out.h" /* Opens "out.h" for writing. */
```

### **%selectfile**

The `%selectfile` directive selects the file specified by the variable as the current output stream. Output goes to that file until another file is selected using `%selectfile`. For example,

```
%selectfile x /* Select file x for output. */
```

### **%closefile**

The `%closefile` directive closes the specified file or buffer. If the closed entity is the currently selected output stream, `%closefile` invokes `%selectfile` to reselect the previously selected output stream.

There are two possible cases that `%closefile` must handle:

- If the stream is a file, the associated variable is removed as if by `%undef`.
- If the stream is a buffer, the associated variable receives the text that has been output to the stream. For example,

```
%assign x = "" /* Creates an empty string. */
%openfile x
"hello, world"
%closefile x /* x = "hello, world\n"*/
```

If desired, you can append to an output file or string by using the optional mode, `a`, as in

```
%openfile "foo.c", "a" %% Opens foo.c for appending.
```

## **Input File Control**

The input file control directives are

```
%include string
%addincludepath string
```

### **%include**

The `%include` directive searches the path for the target file specified by `string` and includes the contents of the file inline at the point where the `%include` statement appears.

### **%addincludepath**

The `%addincludepath` directive adds an additional include path to be searched when the Target Language Compiler references `%include` or block target files. The syntax is

```
%addincludepath string
```

The `string` can be an absolute path or an explicit relative path. For example, to specify an absolute path, use

```
%addincludepath "C:\\folder1\\folder2" (PC)
%addincludepath "/folder1/folder2" (UNIX)
```

To specify a relative path, the path must explicitly start with `..`. For example,

```
%addincludepath "..\\folder2" (PC)
%addincludepath "../folder2" (UNIX)
```

Note that for PC, the backslashes must be escaped (doubled).

When an explicit relative path is specified, the folder that is added to the Target Language Compiler search path is created by concatenating the location of the target file that contains the `%addincludepath` directive and the explicit relative path.

The Target Language Compiler searches the folders in the following order for target or include files:

- 1 The current folder.
- 2 Include paths specified in `%addincludepath` directives. The compiler evaluates multiple `%addincludepath` directives from the *bottom up*.
- 3 Include paths specified at the command line via `-I`. The compiler evaluates multiple `-I` options from *right to left*.

Typically, `%addincludepath` directives should be specified in your system target file. Multiple `%addincludepath` directives will add multiple paths to the Target Language Compiler search path.

---

**Note** The compiler does *not* search the MATLAB path, and will not find a file that is available only on that path. The compiler searches only the locations described above.

---

## Asserts, Errors, Warnings, and Debug Messages

The related assert, error, warning, and debug message directives are

```
%assert expression
%error tokens
%warning tokens
%trace tokens
%exit tokens
```

These directives produce error, warning, or trace messages whenever a target file detects an error condition, or tracing is desired. The tokens following the directive on a line become part of the generated error or warning message.

The Target Language Compiler places messages generated by `%trace` onto `stderr` if and only if you specify the verbose mode switch (`-v`) to the Target Language Compiler. See “Command-Line Arguments” on page 18-48 for additional information about switches.

The `%assert` directive evaluates the expression and produces a stack trace if the expression evaluates to a Boolean `false`.

---

**Note** In order for `%assert` directives to be evaluated, **Enable TLC assertion** must be selected in the **TLC process** section of the **Code Generation > Debug** pane. The default action is for `%assert` directives not to be evaluated.

---

The `%exit` directive reports an error and stops further compilation.

## Built-In Functions and Values

The following table lists the built-in functions and values that are added to the list of parameters that appear in the `model.rtw` file. These Target Language Compiler functions and values are defined in uppercase so that they are visually distinct from other parameters in the `model.rtw` file, and, by convention, from user-defined parameters.

## TLC Built-In Functions and Values

Built-In Function Name	Expansion
CAST( <i>expr</i> , <i>expr</i> )	<p>The first expression must be a string that corresponds to one of the type names in the table “Target Language Value Types” on page 18-13, and the second expression will be cast to that type. A typical use might be to cast a variable to a real format as in</p> <pre>CAST("Real", variable-name)</pre> <p>An example of this is in working with parameter values for S-functions. To use them within C or C++ code, you need to typecast them to <code>real</code> so that a value such as 1 will be formatted as 1.0 (see also <code>%realformat</code>).</p>
EXISTS( <i>var</i> )	<p>If the <i>var</i> identifier is not currently in scope, the result is <code>TLC_FALSE</code>. If the identifier is in scope, the result is <code>TLC_TRUE</code>. <i>var</i> can be a single identifier or an expression involving the <code>.</code> and <code>[]</code> operators.</p>
FEVAL( <i>matlab-command</i> , <i>TLC-expressions</i> )	<p>Performs an evaluation in MATLAB. For example,</p> <pre>%assign result = FEVAL("sin",3.14159)</pre> <p>The <code>%matlab</code> directive can be used to call a MATLAB function that does not return a result. For example,</p> <pre>%matlab disp(2.718)</pre> <p><b>Note:</b> If the MATLAB function returns more than one value, TLC receives the first value only.</p>
FILE_EXISTS( <i>expr</i> )	<p><i>expr</i> must be a string. If a file by the name <i>expr</i> does not exist on the path, the result is <code>TLC_FALSE</code>. If a file by that name exists on the path, the result is <code>TLC_TRUE</code>.</p>
FORMAT( <i>realvalue</i> , <i>format</i> )	<p>The first expression is a Real value to format. The second expression is either <code>EXPONENTIAL</code> or <code>CONCISE</code>. Outputs the Real value in the designated format, where <code>EXPONENTIAL</code> uses exponential notation with 16 digits of precision, and <code>CONCISE</code> outputs the number in a more readable format while maintaining numerical accuracy.</p>
FIELDNAMES( <i>record</i> )	<p>Returns an array of strings containing the record field names associated with the record. Because it returns a sorted list of strings, the function is <math>O(n \cdot \log(n))</math>.</p>
GETFIELD( <i>record</i> , "fieldname")	<p>Returns the contents of the specified field name, if the field name is associated with the record. The function uses hash lookup, and therefore executes in constant time.</p>
GENERATE( <i>record</i> , function-name, ...)	<p>Executes function calls mapped to a specific record type (i.e., block record functions). For example, use this to execute the functions in the <code>.tlc</code> files for built-in blocks. Note that TLC automatically “scopes” or adds the first argument to the list of scopes searched as if it appears on a <code>%with</code> directive line.</p>
GENERATE_FILENAME( <i>type</i> )	<p>For the specified record type, does a <code>.tlc</code> file exist? Use this to see if the <code>GENERATE_TYPE</code> call will succeed.</p>

Built-In Function Name	Expansion
<b>GENERATE_FORMATTED_VALUE</b> (expr, string, expand)	<p>Returns a potentially multiline string that can be used to declare the value(s) of <code>expr</code> in the current target language. The second argument is a string that is used as the variable name in a descriptive comment on the first line of the return string. If the second argument is the empty string, "", then no descriptive comment is put into the output string. The third argument is a Boolean that when TRUE causes <code>expr</code> to be expanded into raw text before being output. <code>expand = TRUE</code> uses much more memory than the default (FALSE); set <code>expand = TRUE</code> only if the parameter text needs to be processed for some reason before being written to disk.</p> <p>For example,</p> <pre>static const unsigned char contents[] =  %assign value = GENERATE_FORMATTED_VALUE(SFcnParamSettings.CONTENTES, "", TLC_FALSE)  ;</pre> <p>yields this C code:</p> <pre>static const unsigned char contents[] = { 0U, 1U, 2U, 3U, 4U };</pre>
<b>GENERATE_FUNCTION_EXISTS</b> (record, function-name)	<p>Determines whether a given block function exists. The first expression is the same as the first argument to <b>GENERATE</b>, namely a block scoped variable containing a Type. The second expression is a string that should match the function name.</p>
<b>GENERATE_TYPE</b> (record, function-name, type, ...)	<p>Similar to <b>GENERATE</b>, except that <code>type</code> overrides the Type field of the record. Use this when executing functions mapped to specific S-function block records based upon the S-function name (i.e., the name becomes the type).</p>
<b>GENERATE_TYPE_FUNCTION_EXISTS</b> (record, function-name, type)	<p>Same as <b>GENERATE_FUNCTION_EXISTS</b> except that it overrides the Type built into the record.</p>
<b>GET_COMMAND_SWITCH</b>	<p>Returns the values of command-line switches. Only the following switches are supported:</p> <p><code>v, m, p, 0, d, dr, r, I, a</code></p> <p>See also "Command-Line Arguments" on page 18-48.</p>
<b>IDNUM(expr)</b>	<p><code>expr</code> must be a string. The result is a vector where the first element is a leading string, if any, and the second element is a number appearing at the end of the input string. For example,</p> <p><code>IDNUM("ABC123")</code> yields ["ABC", 123]</p>
<b>IMAG(expr)</b>	<p>Returns the imaginary part of a complex number.</p>
<b>INT8MAX</b>	<p>127</p>

Built-In Function Name	Expansion
INT8MIN	-128
INT16MAX	32767
INT16MIN	-32768
INT32MAX	2147483647
INT32MIN	-2147483648
INTMIN	Minimum integer value on host machine.
INTMAX	Maximum integer value on host machine.
ISALIAS(record)	Returns TLC_TRUE if the record is a reference (symbolic link) to a different record, and TLC_FALSE otherwise.
ISEQUAL(expr1, expr2)	Where the data types of both expressions are numeric: returns TLC_TRUE if the first expression contains the same value as the second expression; returns TLC_FALSE otherwise.  Where the data type of either expression is nonnumeric (e.g., string or record): returns TLC_TRUE if and only if both expressions have the same data type and contain the same value; returns TLC_FALSE otherwise.
ISEMPTY(expr)	Returns TLC_TRUE if the expression contains an empty string, vector, or record, and TLC_FALSE otherwise.
ISFIELD(record, "fieldname")	Returns TLC_TRUE if the field name is associated with the record, and TLC_FALSE otherwise.
ISINF(expr)	Returns TLC_TRUE if the value of the expression is <code>inf</code> , and TLC_FALSE otherwise.
ISNAN(expr)	Returns TLC_TRUE if the value of the expression is <code>NAN</code> , and TLC_FALSE otherwise.
ISFINITE(expr)	Returns TLC_TRUE if the value of the expression is not <code>+/- inf</code> or <code>NAN</code> , and TLC_FALSE otherwise.
ISSLPRMREF(param.value)	Returns a Boolean value indicating whether its argument is a reference to a Simulink parameter or not. This function supports parameter sharing with Simulink; using it can save memory and time during code generation. For example,  <pre>%if !ISSLPRMREF(param.Value)     assign param.Value = CAST("Real", param.Value) %endif</pre>
ISSUBSTRING(expr1, expr2)	Returns TLC_TRUE if the <code>expr2</code> is a substring of <code>expr1</code> , and TLC_FALSE otherwise. <code>expr1</code> and <code>expr2</code> must be a string.
NULL_FILE	A predefined file for no output that you can use as an argument to <code>%selectfile</code> to prevent output.
NUMTLCFILES	The number of target files used thus far in expansion.
OUTPUT_LINES	Returns the number of lines that have been written to the currently selected file or buffer. Does not work for <code>STDOUT</code> or <code>NULL_FILE</code> .
REAL(expr)	Returns the real part of a complex number.

Built-In Function Name	Expansion
REMOVEFIELD(record, "fieldname")	Removes the specified field from the contents of the record. Returns TLC_TRUE if the field was removed; otherwise returns TLC_FALSE.
ROLL_ITERATIONS()	Returns the number of times the current roll regions are looping or NULL if not inside a %roll construct.
SETFIELD(record, "fieldname", value)	Sets the contents of the field name associated with the record. Returns TLC_TRUE if the field was added; otherwise returns TLC_FALSE.
SIZE(expr[,expr])	Calculates the size of the first expression and generates a two-element row vector. If the second operand is specified, it is used as an integer index into this row vector; otherwise the entire row vector is returned. SIZE(x) applied to a scalar returns [1 1]. SIZE(x) applied to a scope returns the number of repeated entries of that scope type. For example, SIZE(Block) returns  [1,<number of blocks>]
SPRINTF(format,var,...)	Formats the data in variable var (and in any additional variable arguments) under control of the specified format string, and returns a string variable containing the values. Operates like the C library sprintf(), except that output is the return value rather than contained in an argument to sprintf.
STDOUT	A predefined file for stdout output. You can use this as an argument to %selectfile to force output to stdout.
STRING(expr)	Expands the expression into a string; the characters \, \n, and " are escaped by preceding them with \ (backslash). The ANSI escape sequences are translated into string form. If %<> is in the expression, it is escaped so that the enclosed string is not subject to further TLC interpretation.
STRINGOF(expr)	Accepts a vector of ASCII values and returns a string that is constructed by treating each element as the ASCII code for a single character. Used primarily for S-function string parameters.
STRNCMP(expr1, expr2, value)	Returns TLC_TRUE if the expr1 is same as the expr2 to the number of characters specified in value, and TLC_FALSE otherwise. expr1 and expr2 must be a string, and value must be a number.
STRNREP(expr1, expr2, expr3, value)	Accepts the string expr1 and returns a new string that replaces all instances of the substring expr2 present in expr1 with the string expr3 for the number of instances specified in value.
STRREP(expr1, expr2, expr3)	Accepts the string expr1 and returns a new string that replaces all instances of the substring expr2 present in expr1 with the string expr3.

Built-In Function Name	Expansion
SYSNAME( <i>expr</i> )	Looks for specially formatted strings of the form <i>&lt;x&gt;/y</i> and returns <i>x</i> and <i>y</i> as a two-element string vector. This is used to resolve subsystem names. For example,  <pre>%&lt;sysname("&lt;sub&gt;/Gain")&gt;</pre> returns  <pre>["sub", "Gain"]</pre> <p>In Block records, the name of the block is written <i>&lt;sys/blockname&gt;</i>, where <i>sys</i> is <i>S#</i> or <i>Root</i>. You can obtain the full path name by calling <code>LibGetBlockPath(block)</code>; this will include newlines and other troublesome characters that cause display difficulties. To obtain a full path name suitable for one-line comments but not identical to the Simulink path name, use <code>LibGetFormattedBlockPath(block)</code>.</p>
TLCFILES	Returns a vector containing the names of the target files included thus far in the expansion. Absolute paths are used. See also NUMTLCFILES.
TLC_FALSE	Boolean constant that equals a negative evaluated Boolean expression.
TLC_TRUE	Boolean constant that equals a positive evaluated Boolean expression.
TLC_TIME	Date and time of compilation.
TLC_VERSION	Version and date of the Target Language Compiler.
TYPE( <i>expr</i> )	Evaluates <i>expr</i> and determines the result type. The result of this function is a string that corresponds to the type of the given expression. See the <b>Value Type String</b> column in the table "Target Language Value Types" on page 18-13 for possible values.
UINT8MAX	255U
UINT16MAX	65535U
UINT32MAX	4294967295U
UINTMAX	Maximum unsigned integer value on host machine.
WHITE_SPACE( <i>expr</i> )	Accepts a string and returns 1 if the string contains only white-space characters ( , \t, \n, \r); returns 0 otherwise.
WILL_ROLL( <i>expr1</i> , <i>expr2</i> )	The first expression is a roll vector and the second expression is a roll threshold. This function returns <code>true</code> if the vector contains a range that will roll.

### FEVAL Function

The FEVAL built-in function calls MATLAB file functions and MEX-functions. The structure is

```
%assign result = FEVAL(matlab-function-name, rhs1, rhs2, ...
 rhs3, ...);
```

### Note

- Only a single left-side argument is allowed when you use FEVAL.

- If your MATLAB function evaluation leads to an error, the TLC compiler does not terminate but continues with the execution. The FEVAL directive returns an empty value to the TLC.
- For string operations, it is recommended to use string TLC directives instead of FEVAL functions.

This table shows the conversions that are made when you use FEVAL.

### MATLAB Conversions

TLC Type	MATLAB Type
"Boolean"	Boolean (scalar or matrix)
"Number"	Double (scalar or matrix)
"Real"	Double (scalar or matrix)
"Real32"	Double (scalar or matrix)
"Unsigned"	Double (scalar or matrix)
"String"	String
"Vector"	If the vector is homogeneous, it is converted to a MATLAB vector. If the vector is heterogeneous, it is converted to a MATLAB cell array.
"Gaussian"	Complex (scalar or matrix)
"UnsignedGaussian"	Complex (scalar or matrix)
"Complex"	Complex (scalar or matrix)
"Complex32"	Complex (scalar or matrix)
"Identifier"	String
"Subsystem"	String
"Range"	Expanded vector of Doubles
"Idrange"	Expanded vector of Doubles
"Matrix"	If the matrix is homogeneous, it is converted to a MATLAB matrix. If the matrix is heterogeneous, it is converted to a MATLAB cell array. (Cell arrays can be nested.)
"Scope" or "Record"	Structure with elements
Scope or Record alias	String containing fully qualified alias name
Scope or Record array	Cell array of structures
Other type not listed above	Conversion not supported

When values are returned from MATLAB, they are converted as shown in this table. Note that conversion of matrices with more than two dimensions is not supported, nor is conversion or downcast of 64-bit integer values.

**More Conversions**

<b>MATLAB Type</b>	<b>TLC Type</b>
String	String
Vector of Strings	Vector of Strings
Boolean (scalar or matrix)	Boolean (scalar or matrix)
INT8,INT16,INT32 (scalar or matrix)	Number (scalar or matrix)
INT64	Not supported
UINT64	Not supported
Complex INT8,INT16,INT32 (scalar or matrix)	Gaussian (scalar or matrix)
UINT8,UINT16,UINT32 (scalar or matrix)	Unsigned (scalar or matrix)
Complex UINT8,UINT16,UINT32 (scalar or matrix)	UnsignedGaussian (scalar or matrix)
Single precision	Real32 (scalar or matrix)
Complex single precision	Complex32 (scalar or matrix)
Double precision	Real (scalar or matrix)
Complex double precision	Complex (scalar or matrix)
Sparse matrix	Expanded to matrix of Doubles
Cell array of structures	Record array
Cell array of non-structures	Vector or matrix of types converted from the types of the elements
Cell array of structures and non-structures	Conversion not supported
Structure	Record
Object	Conversion not supported

Other value types are not currently supported.

As an example, this statement uses the FEVAL built-in function to call MATLAB to take the sine of the input argument.

```
%assign result = FEVAL("sin", 3.14159)
```

Variables (identifiers) can take on the following constant values. Note the suffix on the value .

<b>Constant Form</b>	<b>TLC Type</b>
1.0	"Real"
1.0[F/f]	"Real32"
1	"Number"
1[U u]	"Unsigned"
1.0i	"Complex"

Constant Form	TLC Type
l[Ui ui]	"UnsignedGaussian"
li	"Gaussian"
l.0[Fi fi]	"Complex32"

**Note** The suffix controls the Target Language Compiler type obtained from the constant.

This table shows Target Language Compiler constants and their equivalent MATLAB values.

TLC Constants	Equivalent MATLAB Value
rtInf, Inf, inf	+inf
rtMinusInf	-inf
rtNaN, NaN, nan	nan
rtInfi, Infi, infi	inf*i
rtMinusInfi	-inf*i
rtNaNi, NaNi, nani	nan*i

## TLC Reserved Constants

For double-precision values, the following are defined for infinite and not-a-number IEEE® values:

rtInf, inf, rtMinusInf, -inf, rtNaN, nan

For single-precision values, these constants apply:

rtInfF, InfF, rtMinusInfF, rtNaNF, NaNF

Their corresponding versions when complex are:

rtInfi, infi, rtMinusInfi, -infi, rtNaNi (for doubles)  
rtInfFi, InfFi, rtMinusInfFi, rtNaNFi, NaNFi (for singles)

For integer values, the following are defined:

INT8MIN, INT8MAX, INT16MIN, INT16MAX, INT32MIN, INT32MAX,  
UINT8MAX, UINT16MAX, UINT32MAX, INTMAX, INTMIN, UINTMAX

## Identifier Definition

To define or change identifiers (TLC variables), use the directive

```
%assign [::]expression = constant-expression
```

This directive introduces new identifiers (variables) or changes the values of existing ones. The left side can be a qualified reference to a variable using the `.` and `[]` operators, or it can be a single element of a vector or matrix. In the case of the matrix, only the single element is changed by the assignment.

The `%assign` directive inserts new identifiers into the local function scope, file function scope, generate file scope, or into the global scope. Identifiers introduced into the function scope are not

available within functions being called, and are removed upon return from the function. Identifiers inserted into the global scope are persistent. You can change existing identifiers by completely respecifying them. The constant expressions can include legal identifiers from the `.rtw` files. You can use `%undef` to delete identifiers in the same way that you use it to remove macros.

Within the scope of a function, variable assignments create new local variables unless you use the `::` scope resolution operator. In this example, the assignment creates a variable `foo`, local to the function, that will disappear when the function exits.

```
%function ...
...
%assign foo = 3
...
%endfunction
```

Note that `foo` is created even if a global `foo` already exists.

To create or change values in the global scope, you must use the scope resolution operator (`::`) to disambiguate, as in

```
%function ...
%assign foo = 3
%assign ::foo = foo
...
%endfunction
```

The scope resolution operator forces the compiler to assign the value of the local variable `foo`, 3, to the global variable `foo`.

---

**Note** It is an error to change a value from the code generator file without qualifying it with the scope. This example does not generate an error:

```
%assign CompiledModel.name = "newname" %% No error
```

This example generates an error:

```
%with CompiledModel
%assign name = "newname" %% Error %endwith
```

---

## Creating Records

Use the `%createrecord` directive to build new records in the current scope. For example, if you want to create a new record called `Rec` that contains two items (e.g., `Name "Name"` and `Type "t"`), use

```
%createrecord Rec { Name "Name"; Type "t" }
```

## Adding Records

Use the `%addtorecord` directive to add new records to existing records. For example, if you have a record called `Rec1` that contains a record called `Rec2`, and you want to add an additional `Rec2` to it, use

```
%addtorecord Rec1 Rec2 { Name "Name1"; Type "t1" }
```

This figure shows the result of adding the record to the existing one.

If you want to access the new record, you can use

```
%assign myname = Rec1.Rec2[1].Name
```

In this same example, if you want to add two records to the existing record, use

```
%addtorecord Rec1 Rec2 { Name "Name1"; Type "t1" }
%addtorecord Rec1 Rec2 { Name "Name2"; Type "t2" }
```

This produces

### Adding Parameters to an Existing Record

You can use the %assign directive to add a new parameter to an existing record. For example,

```
%addtorecord Block[Idx] N 500 /* Adds N with value 500 to Block */
%assign myn = Block[Idx].N /* Gets the value 500 */
```

adds a new parameter, N, at the end of an existing block with the name and current value of an existing variable, as shown in this figure. It returns the block value.

## Variable Scoping

This section discusses how the Target Language Compiler resolves references to variables (including records).

Scope, in this document, has two related meanings. First, scope is an attribute of a variable that defines its visibility and persistence. For example, a variable defined within the body of a function is visible only within that function, and it persists only as long as that function is executing. Such a variable has function (or local) scope. Each TLC variable has one (and only one) of the scopes described in “Scopes” on page 18-38.

The term scope also refers to a collection, or pool, of variables that have the same scope. At a given point in the execution of a TLC program, several scopes can exist. For example, during execution of a function, a function scope (the pool of variables local to the function) exists. In all cases, a global scope (the pool of global variables) also exists.

To resolve variable references, TLC maintains a search list of current scopes and searches them in a well-defined sequence. The search sequence is described in “How TLC Resolves Variable References” on page 18-42.

Dynamic scoping refers to the process by which TLC creates and deallocates variables and the scopes in which they exist. For example, variables in a function scope exist only while the defining function executes.

### Scopes

The following sections describe the possible scopes that a TLC variable can have.

#### Global Scope

By default, TLC variables have global scope. Global variables are visible to, and can be referenced by, code anywhere in a TLC program. Global variables persist throughout the execution of the TLC program. Global variables are said to belong to the global pool.

Note that the `CompiledModel` record of the `model.rtw` file has global scope. Therefore, you can access this structure from your TLC functions or files.

You can use the scope resolution operator (`::`) to explicitly reference or create global variables from within a function. See “The Scope Resolution Operator” on page 18-41 for examples.

Note that you can use the `%undef` directive to free memory used by global variables.

#### File Scope

Variables with file scope are visible only within the file in which they are created. To limit the scope of variables in this way, use the `%filescope` directive anywhere in the defining file.

In the following code fragment, the variables `fs1` and `fs2` have file scope. Note that the `%filescope` directive does not have to be positioned before the statements that create the variables.

```
%assign fs1 = 1
%filescope
%assign fs2 = 3
```

Variables whose scope is limited by `%filescope` go out of scope when execution of the file containing them completes. This lets you free memory allocated to such variables.

### Function (Local) Scope

Variables defined within the body of a function have function scope. That is, they are visible within and local to the defining function. For example, in the following code fragment, the variable `localv` is local to the function `foo`. The variable `x` is global.

```
%assign x = 3

%function foo(arg)
 %assign localv = 1
 %return x + localv
%endfunction
```

A local variable can have the same name as a global variable. To refer, within a function, to identically named local and global variables, you must use the scope resolution operator (`::`) to disambiguate the variable references. See “The Scope Resolution Operator” on page 18-41 for examples.

---

**Note** Functions themselves (as opposed to the variables defined within functions) have global scope. There is one exception: functions defined in generate scope are local to that scope. See “Generate Scope” on page 18-39.

---

### %with Scope

The `%with` directive adds a new scope, referred to as a *%with scope*, to the current list of scopes. This directive makes it easier to refer to block-scoped variables.

The structure of the `%with` directive is

```
%with expression
%endwith
```

For example, the directive

```
%with CompiledModel.System[sysidx]
 ...
%endwith
```

adds the `CompiledModel.System[sysidx]` scope to the search list. This scope is searched before anything else. You can then refer to the system name simply by

Name

instead of

```
CompiledModel.System[sysidx].Name
```

### Generate Scope

Generate scope is a special scope used by certain built-in functions that are designed to support code generation. These functions dispatch function calls that are mapped to a specific record type. This capability supports a type of polymorphism in which different record types are associated with functions (analogous to methods) of the same name. Typically, this feature is used to map `Block` records to functions that implement the functionality of different block types.

Functions that employ generate scope include `GENERATE`, `GENERATE_TYPE`, `GENERATE_FUNCTION_EXISTS`, and `GENERATE_TYPE_FUNCTION_EXISTS`. See “GENERATE and

GENERATE\_TYPE Functions” on page 18-24. This section discusses generate scope using the GENERATE built-in function as an example.

The syntax of the GENERATE function is

```
GENERATE(blk, fn)
```

The first argument (`blk`) to GENERATE is a valid record name. The second argument (`fn`) is the name of a function to be dispatched. When a function is dispatched through a GENERATE call, TLC automatically adds `blk` to the list of scopes that is searched when variable references are resolved. Thus the record (`blk`) is visible to the dispatched function as if an implicit `%with <blk>... %endwith` directive existed in the dispatched function.

In this context, the record named `blk` is said to be in generate scope.

Three TLC files, illustrating the use of generate scope, are listed below. The file `polymorph.tlc` creates two records representing two hypothetical block types, `MyBlock` and `YourBlock`. Each record type has an associated function named `aFunc`. The block-specific implementations of `aFunc` are contained in the files `MyBlock.tlc` and `YourBlock.tlc`.

Using GENERATE calls, `polymorph.tlc` dispatches to a function for each block type. Notice that the `aFunc` implementations can refer to the fields of `MyBlock` and `YourBlock`, because these records are in generate scope.

- The following listing shows `polymorph.tlc`:

```
%% polymorph.tlc

%language "C"

%%create records used as scopes within dispatched functions

%createrecord MyRecord { Type "MyBlock"; data 123 }
%createrecord YourRecord { Type "YourBlock"; theStuff 666 }

%% dispatch the functions thru the GENERATE call.

%% dispatch to MyBlock implementation
%<GENERATE(MyRecord, "aFunc")>

%% dispatch to YourBlock implementation
%<GENERATE(YourRecord, "aFunc")>

%% end of polymorph.tlc
```

- The following listing shows `MyBlock.tlc`:

```
%%MyBlock.tlc

%implements "MyBlock" "C"

%% aFunc is invoked thru a GENERATE call in polymorph.tlc.
%% MyRecord is in generate scope in this function.
%% Therefore, fields of MyRecord can be referenced without
%% qualification

%function aFunc(r) Output
%selectfile STDOUT
```

```
The value of MyRecord.data is: %<data>
%closefile STDOUT
%endfunction
```

```
%%end of MyBlock.tlc
```

- The following listing shows YourBlock.tlc:

```
%%YourBlock.tlc
```

```
%implements "YourBlock" "C"
```

```
%% aFunc is invoked thru a GENERATE call in polymorph.tlc.
%% YourRecord is in generate scope in this function.
%% Therefore, fields of YourRecord can be referenced without
%% qualification
```

```
%function aFunc(r) Output
%selectfile STDOUT
The value of YourRecord.theStuff is: %<theStuff>
%closefile STDOUT
%endfunction
```

```
%%end of YourBlock.tlc
```

The invocation and output of `polymorph.tlc`, as displayed in the MATLAB Command Window, are shown below:

```
tlc -v polymorph.tlc
```

```
The value of MyRecord.data is: 123
The value of YourRecord.theStuff is: 666
```

---

**Note** Functions defined in generate scope are local to that scope. This is an exception to the general rule that functions have global scope. In the above example, for instance, neither of the `aFunc` implementations has global scope.

---

## The Scope Resolution Operator

The scope resolution operator (`::`) is used to indicate that the global scope should be searched when a TLC function looks up a variable reference. The scope resolution operator is often used to change the value of global variables (or even create global variables) from within functions.

By using the scope resolution operator, you can resolve ambiguities that arise when a function references identically named local and global variables. In the following example, a global variable `foo` is created. In addition, the function `myfunc` creates and initializes a local variable named `foo`. The function `myfunc` explicitly references the global variable `foo` by using the scope resolution operator.

```
%assign foo = 3 %% this variable has global scope
.
.
.
%function myfunc(arg)
 %assign foo = 3 %% this variable has local scope
```

```
%assign ::foo = arg %% this changes the global variable foo
%endfunction
```

You can also use the scope resolution operator within a function to create global variables. The following function creates and initializes a global variable:

```
%function sideeffect(arg)
 %assign ::theglobal = arg %% this creates a global variable
%endfunction
```

### How TLC Resolves Variable References

This section discusses how the Target Language Compiler searches the existing scopes to resolve variable references.

#### Global Scope

In the simplest case, the Target Language Compiler resolves a variable reference by searching the global pool (including the `CompiledModel` structure).

#### %with Scope

You can modify the search list and search sequence by using the `%with` directive. For example, when you add the following construct,

```
%with CompiledModel.System[sysidx]
 ...
%endwith
```

the `System[sysidx]` scope is added to the search list. This scope is searched first, as shown by this picture.

This technique makes it simpler to access embedded definitions. Using the `%with` construct (as in the previous example), you can refer to the system name simply by

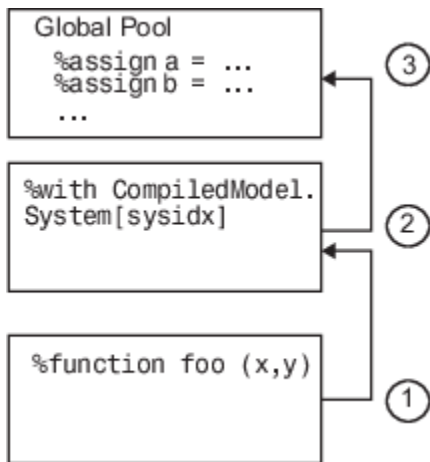

Name

instead of

`CompiledModel.System[sysidx].Name`

#### Function Scope

A function has its own scope. That scope is added to the previously described search list, as shown in this diagram.

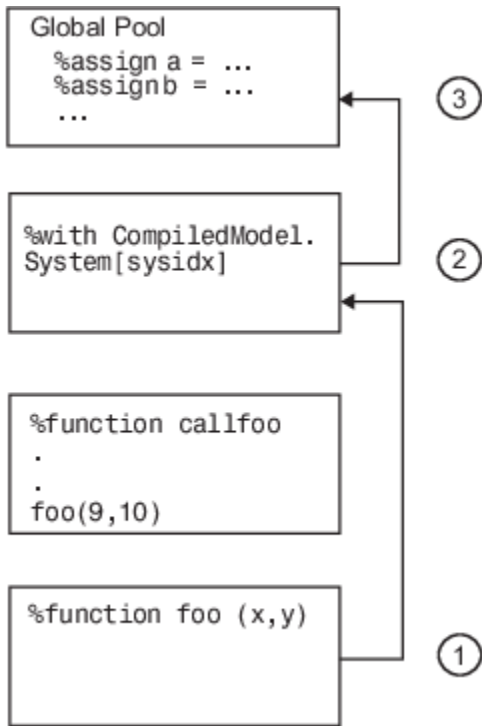

For example, in the following code fragment,

```
% with CompiledModel.System[sysidx]
...
 %assign a=foo(x,y)
...
%endwith
...
%function foo(a,b)
...
 assign myvar=Name
...
%endfunction
...
%<foo(1,2)>
```

If `Name` is not defined in `foo`, the assignment uses the value of `Name` from the previous scope, `CompiledModel.System[SysIdx].Name`.

In a nested function, only the innermost function scope is searched, together with the enclosing `%with` and global scopes, as shown in the following diagram:

**File Scope**

File scopes are searched before the global scope, as shown in the following diagram.

The rule for nested file scopes is similar to that for nested function scopes. In the case of nested file scopes, only the innermost nested file scope is searched.

## Target Language Functions

The target language function construct is

```
%function identifier (optional-arguments) [Output | void]
%return
%endfunction
```

Functions in the target language are recursive and have their own local variable space. Target language functions do not produce output unless they are output functions or explicitly use the `%openfile`, `%selectfile`, and `%closefile` directives.

A function optionally returns a value with the `%return` directive. The returned value can be a type defined in the table at “Target Language Value Types” on page 18-13.

In this example, a function, `name`, returns `x` if `x` and `y` are equal, or returns `z` if `x` and `y` are not equal:

```
%function name(x,y,z) void

%if x == y
 %return x
%else
 %return z
%endif

%endfunction
```

Function calls can appear in contexts where variables are allowed.

The `%with` statements that are in effect when a function is called are available to the function. Calls to other functions do not include the local scope of the function, but do include `%with` statements appearing within the function.

Assignments to variables within a function create new local variables and cannot change the value of global variables unless you use the scope resolution operator (`::`).

By default, a function returns a value and does not produce output. You can override this behavior by specifying the `Output` and `void` modifiers on the function declaration line, as in

```
%function foo() Output
...
%endfunction
```

In this case, the function continues to produce output to the currently open file, and is not required to return a value. You can use the `void` modifier to indicate that the function does not return a value and should not produce output, as in

```
%function foo() void
...
%endfunction
```

### Variable Scoping Within Functions

Within a function, the left-hand member of an `%assign` statement defaults to creating a local variable. A new entry is created in the function's block within the scope chain; it does not affect the other entries. An example appears in "Function Scope" on page 18-42.

You can override this default behavior by using `%assign` with the scope resolution operator (`::`).

When you introduce new scopes within a function, using `%with`, these new scopes are used during nested function calls, but the local scope for the function is not searched.

If a `%with` is included within a function, its associated scope is carried with nested function calls, as shown in the next figure.

### `%return`

The `%return` statement closes all `%with` statements appearing within the current function. In this example, the `%with` statement is automatically closed when the `%return` statement is encountered, removing the scope from the list of searched scopes:

```
%function foo(s)
 %with s
 %return(name)
 %endwith
%endfunction
```

The `%return` statement does not require a value. You can use `%return` to return from a function without a return value.

## Command-Line Arguments

### Target Language Compiler Switches

To call the Target Language Compiler, use

```
tlc [switch1 expr1 switch2 expr2 ...] filename.tlc
```

This table lists the switches you can use with the Target Language Compiler. Order does not makes a difference. Note that if you specify a switch more than once, the last one takes precedence.

### Target Language Compiler Switches

Switch	Meaning
-r <i>filename</i>	Reads a database file (such as an .rtw file). Repeat this option multiple times to load multiple database files into the Target Language Compiler. Omit this option for target language programs that do not depend on the database.
-v[ <i>number</i> ]	Sets the internal verbosity level to <i>number</i> . Omitting this option sets the verbosity level to 1.
-I <i>path</i>	Adds the specified folder to the list of paths to be searched for TLC files.
-O <i>path</i>	Specifies that the output produced should be placed in the designated folder, including files opened with %openfile and %closefile, and .log files created in debug mode. To place files in the current folder, use -O (use the capital letter O, not zero).
-m[ <i>number</i> ]	The <i>number</i> specifies the maximum number of errors to report. Without -m, the default is to report the first five errors. If the <i>number</i> argument is omitted on this option, 1 is assumed.
-x0	Parse TLC file only (do not execute).
-lint	Performs some simple checks for performance and obsolete features.
-p[ <i>number</i> ]	Prints a dot (.) indicating progress for every <i>number</i> of TLC primitive operations executed.
-d[a c f n o]	<p>Invokes the TLC's debug mode.</p> <ul style="list-style-type: none"> <li>-da makes TLC execute %assert directives. However, when using the build process, this flag is ignored, because it is superseded by the <b>Enable TLC assertion</b> check box in the <b>TLC process</b> section of the <b>Code Generation &gt; Debug</b> pane.</li> <li>-dc invokes the TLC command-line debugger.</li> <li>-df <i>filename</i> invokes the TLC debugger and runs the debugger script specified by <i>filename</i>. A debugger script is a text file containing valid debugger commands. TLC searches only the current working folder for the script file.</li> <li>-dn causes TLC to produce log files indicating which lines were and were not reached during compilation.</li> <li>-do disables the TLC debugging behavior.</li> </ul>
-dr	Checks for cyclic records (records that reference each other, a source of memory leaks).
-a[ <i>ident</i> ]= <i>expr</i>	Specifies an initial value, <i>expr</i> , for the identifier, <i>ident</i> , for some parameters; equivalent to the %assign command.

Switch	Meaning
-shadow[0 1]	<p>Enables a warning when an identifier-value pair of a record overwrites a local variable. The warning is disabled by default.</p> <p>-shadow0 disables the warning.</p> <p>-shadow1 enables the warning.</p>

As an example, the command line

```
tlc -r myModel.rtw -v grt.tlc
```

specifies that `myModel.rtw` should be read and used to process `grt.tlc` in verbose mode.

## Filenames and Search Paths

Target files have the `.tlc` extension. By default, block-level files have the same name as the Type of the block in which they appear. You can override the search path for target files with your own local versions. The Target Language Compiler finds target files along this path. If you specify additional search paths with the `-I` switch of the `tlc` command or via the `%addincludepath` directive, the search order is:

- 1 Current folder.
- 2 Include paths specified in `%addincludepath` directives. The compiler evaluates multiple `%addincludepath` directives from the *bottom up*.
- 3 Include paths specified at the command line via `-I`. The compiler evaluates multiple `-I` options from *right to left*.

---

**Note** The compiler does *not* search the MATLAB path, and will not find a file that is available only on that path. The compiler searches only the locations described above.

# Debugging TLC Files

---

The Target Language Compiler debugger is a command-line debugger that enables you to identify problems in executing TLC code. The following sections describe the facilities provided and provide examples of use.

- “Using the TLC Debugger” on page 19-2
- “TLC Coverage” on page 19-6
- “TLC Profiler” on page 19-9

## Using the TLC Debugger

The TLC debugger helps you identify programming errors in your TLC code. Using the debugger, you can execute TLC code line-by-line, analyze and/or change variables in a specified block scope, and view the TLC call stack. The TLC debugger has a command-line interface that provides commands similar to standard debugging tools such as `dbx` or `gdb`.

### Tips for Debugging TLC Code

Here are a few tips that will help you to debug your TLC code:

- 1 To see the full TLC call stack, place the following statement in your TLC code before the line that is pointed to by the error message. This will be helpful in narrowing down your problem.

```
%setcommandswitch "-v1"
```

- 2 To trace the value of a variable in a function, place the following statement in your TLC file:

```
%trace This is in my function %<variable>
```

Your message will appear when the Target Language Compiler is run with the `-v` command switch, but not otherwise. You can use `%warning` instead of `%trace` to print variables, but you will need to remove or comment out such lines after you are through debugging.

- 3 Use the TLC coverage log files to identify parts of your code that have not been reached.

### Invoking the Debugger

Use the TLC debugger to identify bugs and potential problems in your TLC files. To use the TLC debugger:

- 1 On the Configuration Parameters dialog box, select "Retain .rtw file". This prevents the `model.rtw` file from being deleted after code generation.
- 2 Select "Start TLC debugger when generating code" to invoke the TLC debugger when starting the code generation process.

Selecting **Start TLC debugger when generating code** is equivalent to specifying the TLC option `-dc` on the **Code Generation** pane of the Configuration Parameters dialog box.

- 3 Apply changes and start code generation by pressing **Ctrl+B**. This stops at the first line of executed TLC code, breaks into the TLC command-line debugger, and displays the following prompt:

```
TLC_DEBUG>
```

You can now set breakpoints, explore the contents of code generator files, and explore variables in your TLC file using `print`, `which`, or `whos`.

An alternative way to invoke the TLC debugger is from the MATLAB prompt. (This assumes you retained the `model.rtw` file in the project folder.) To avoid making mistakes, copy the `tlc` command output of the build process to the MATLAB Command Window, and issue it after appending `-dc` to that command line.

A complete list of command-line switches for the TLC debugger is available in the table "Target Language Compiler Switches" on page 18-48.

## TLC Debugger Command Summary

The table TLC Debugger Commands summarizes the TLC debugger commands.

To obtain more detailed help on individual commands, use the syntax

```
help command
```

from within the TLC debugger, as in this example:

```
TLC-DEBUG> help clear
```

You can abbreviate a TLC debugger command to its shortest unique form. For example,

```
TLC-DEBUG> break warning
```

can be abbreviated to

```
TLC-DEBUG> br warning
```

To view a complete list of TLC debugger commands, type `help` at the `TLC-DEBUG>` prompt.

## TLC Debugger Commands

Command	Description
assign variable=value	Change a variable in the running program.
break ["filename":]line error warning trace function	Set a breakpoint. See also "%breakpoint Directive" on page 19-5.
clear [breakpoint# all]	Remove a breakpoint.
condition [breakpoint#] [expression]	Attach a condition to a breakpoint.
continue ["filename":]line function	Continue from a breakpoint.
disable [breakpoint#]	Disable a breakpoint.
down [n]	Move down the stack.
enable [breakpoint#]	Enable a breakpoint.
finish	Break after completing the current function.
help [command]	Obtain help for a command.
ignore [breakpoint#]count	Set the ignore count of a breakpoint.
iostack	Display contents of I/O stack.
list start[,end]	List lines from the file from start to end.
loadstate "filename"	Load debugger breakpoint state from a file.
next	Single step without going into functions.
print expression	Print the value of a TLC expression. To print a record, you must specify a fully qualified scope such as <code>CompiledModel.System[0].Block[0]</code> .
quit	Quit the TLC debugger. You can also exit the debugger by typing <b>Ctrl+C</b> at the prompt.
run "filename"	Run a batch file of command-line debugger commands.
savestate "filename"	Save debugger breakpoint state to a file.
status	Display a list of active breakpoints.
step	Step into.
stop ["filename":]line error warning trace function	Set a breakpoint (same as break).
tbreak ["filename":]line function	Set a temporary breakpoint.
thread [n]	Change the active thread to thread #n (0 is the main program's thread number).
threads	List the currently active TLC execution threads.
tstop ["filename":]line function	Set a temporary breakpoint.
up [n]	Move up the stack.
where	Show the currently active execution chains.
which name	Look up the name and display what scope it comes from.
whos [:: expression]	List the variables in the given scope.

## **%breakpoint Directive**

As an alternative to the `break` command, you can embed breakpoints at locations in a TLC file by adding the directive

```
%breakpoint
```

## **Usage Notes**

When using `break` or `stop`, use

- `error` to break or stop on error
- `warn` to break or stop on warning
- `trace` to break or stop on trace

For example, if you need to break on error, use

```
TLC_DEBUG> break error
```

When using `clear`, get the status of breakpoints using `status` and clear specific breakpoints. For example

```
TLC-DEBUG> break "foo.tlc":46
TLC-DEBUG> break "foo.tlc":25
TLC-DEBUG> status
Breakpoints:
[1] break File: foo.tlc Line: 46
[2] break File: foo.tlc Line: 25
TLC-DEBUG> clear 2
```

In this example, `clear 2` clears the second breakpoint.

## TLC Coverage

### Using the TLC Coverage Option

The example in “Using the TLC Debugger” on page 19-2 used the debugger to detect a problem in one section of the TLC file. Because a test model may not cover all possible cases, there is a technique that traces the untested cases, the TLC coverage option.

The TLC coverage option provides an easier way to ascertain that the different code parts (not paths) in your code are exercised. To specify TLC coverage tracking, on the Configuration Parameters dialog box, select “Start TLC coverage when generating code”.

When you initiate TLC coverage, the Target Language Compiler produces a .log file for every target file (\*.tlc) used. These .log files are placed in project folder created for the model. Each .log file contains usage (count) information regarding how many times it encounters each line during execution. Each line begins with the number of times it is encountered, followed by a colon, followed by the code.

### Example .log File

Here is a log file that results from generating code for the example model `sfcn_demo_sdotproduct`, located in the folder `matlabroot/toolbox/simulink/simdemos/simfeatures` (open). This model inlines the `sdotproduct` S-function in TLC. The TLC file that implements the S-function is located in the folder `matlabroot/toolbox/simulink/simdemos/simfeatures/tlc_c` (open). The .log file for `sdotproduct.tlc` is `sdotproduct.log`, which is placed in your build folder. The contents of `sdotproduct.log` are similar to:

```
Source: E:\matlab\toolbox\simulink\simdemos\simfeatures\tlc_c\sdotproduct.tlc
0: %%
0: %% File : sdotproduct.tlc generated from sdotproduct.ttlc revision 1.6

0: %%
1: %assign yre = LibBlockOutputSignal(0, "", lcv, "%<tRealPart>%<idx>")
1: %assign yim = LibBlockOutputSignal(0, "", lcv, "%<tImagPart>%<idx>")
0: %%
1: %<FcnThriftdComplexConjMultiply(u0re, u0im, ulre, ulim, yre, yim, "+=")>\
0: %endroll
0: %endif
1: %if outputOverWritesInput
0: }
0: %endif
1:

```

```
0: %endfunction
1:
0: %% [EOF] sdotproduct.tlc
```

## Analyzing the Results

This structure makes it easy to identify branches not taken and to develop new tests that can exercise unused portions of the target files.

Looking at the `sdotproduct.log` file, you can see that the code has not been used to assign default values to parameters (e.g., the first part of the code for function `FcnThriftdComplexConjMultiply`). Using this log as a reference and creating models that exercise unexecuted lines, you can make sure that your code is more robust.

# TLC Profiler

## Using the Profiler

The TLC profiler collects timing statistics for TLC code. It collects execution time for functions, scripts, macros, and built-in functions. These results become the basis of HTML reports that are identical in format to MATLAB profiler reports. By analyzing the report, you can identify bottlenecks in your code that make code generation take longer.

On the Configuration Parameters dialog box, select "Profile TLC". Apply your changes and press **Ctrl +B**.

At the end of the TLC process, the build process creates the HTML summary and related files.

## Analyzing the Report

The profile report is generated into the build folder. To open the report, change folder (cd) to the build folder and open the file `model.html`, opening it in a browser window. Here is a sample of a TLC profiling report:

Summary | [Function Details](#)

## TLC Profile Report: Summary

Report generated 03-Aug-2012 20:10:52

Total recorded time: 2.98 s  
 Number of Builtins: 22  
 Number of Evals: 1  
 Number of Generate Scripts: 9  
 Number of Normal Functions: 131  
 Number of Output Functions: 66  
 Number of Scripts: 135  
 Number of Void Functions: 636  
 Clock precision: 0.00000004 s  
 Clock Speed: 2500 MHz

### Function List

Name	Time	Calls	Time/call	Self time	Loc
<a href="#">codegenentry.tlc</a>	2.97961910	100.0%	1 2.979619100000	0.01560010	0.5% <a href="#">C:/</a>
<a href="#">grt.tlc</a>	2.97961910	100.0%	1 2.979619100000	0.00000000	0.0% <a href="#">C:/</a>
<a href="#">commonsetup.tlc</a>	1.91881230	64.4%	1 1.918812300000	0.09360060	3.1% <a href="#">C:/</a>
<a href="#">funclib.tlc</a>	1.54440990	51.8%	1 1.544409900000	1.15440740	38.7% <a href="#">C:/</a>

The created report is fairly self-explanatory. Some points to note are

- Functions are sorted in descending order of their execution time.
- Self-time is the time spent in the function alone, not including the time spent in functions called by the function.
- Functions are hyperlinks that take you to the details related to that specific function.

The profiler report can be helpful when you have inlined S-functions in your model. You can use the profiler to compare time spent in specific user-written or `Lib` functions, and then modify your TLC code accordingly.

## Nonexecutable Directives

TLC considers the following directives to be nonexecutable lines. Therefore, these directives are not counted in TLC Profiler reports:

- `%filescope`
- `%else`
- `%endif`
- `%endforeach`
- `%endfor`
- `%endroll`
- `%endwith`
- `%body`
- `%endbody`
- `%endfunction`
- `%endswitch`
- `%default`
- Comment (`%%` or `/% text %/`)

## Improving Performance

Analyzing the profiler results also gives you an overview of which functions are used more often or are more expensive. Then, you can either improve those functions, or try alternative methods to improve code generation speed. Two points to consider are

- Reduce usage of `EXISTS`. Performing an `EXISTS` on a field is more costly than comparing the field to a value. When possible, create an inert default value for a field. Then, instead of doing an `EXISTS` on the entity, compare it against the default value.
- Reduce the use of one-line functions. One-line functions might be a bottleneck for code generation speed. When readability is not an issue, consider expanding the function.

# Inlining S-Functions

---

To wrap or to inline, that is the question. Once you have decided, the following sections explain how to go about it, using the `timestwo` S-function as a running example. Inlining works almost identically for C, C++, MATLAB file, and Fortran S-functions.

- “Inline S-Functions” on page 20-2
- “Inline C MEX S-Functions” on page 20-8
- “TLC Coding Conventions” on page 20-17
- “Block Target File Methods” on page 20-21
- “Loop Rolling” on page 20-27

## Inline S-Functions

Writing S-functions to be included in generated code involves requirements that go beyond writing S-functions used only for simulation. Before you proceed to inline an S-function make sure that it meets requirements and functions as you expect. For more information, see “S-Functions and Code Generation”. If your S-function is multirate, see “Time-Based Scheduling and Code Generation” and “Modeling for Multitasking Execution”, and “Rate Grouping Compliance and Compatibility Issues” on page 68-12.

### Inline S-Functions with Block Target Files

#### When to Inline S-Functions

With C MEX S-functions, non-ERT targets support calling the original C MEX code if the source code (.c file) is available when entering the build phase. For S-functions that are in Fortran or MATLAB language, you must inline them to have complete code generation for Simulink models that contain them. Additionally, once you have determined that you will inline an S-function, you must decide to make it either fully inlined or wrapped.

#### Fully Inlined S-Functions

The block target file for a fully inlined S-function is a self-contained definition of how to inline the block’s functionality directly into the various portions of the generated code — start code, output code, etc. This approach is most beneficial when there are many modes and data types supported for algorithms that are relatively small or when the code size is not significant.

#### Function-Based or Wrapped Code Generation

When the physical size of the code for a block becomes too large for inlining, the block target file is written to gather inputs, outputs, and parameters, and make a call to a function that you write to perform the block functionality. This has an advantage in generated code size when the code in the function is large or there are many instances of this block in a model. Of course, you should consider the overhead of the function call when weighing the option of fully inlining the block algorithm or generating function calls.

If you choose to go with function-based code generation, two more options need consideration:

- Write the functions once, put them in .c files, and have the TLC code’s `BlockTypeSetup` method specify external references to your support functions. Use `LibAddToModelSources` for names of the modules containing the supporting functions. This approach is usually done using one function per file to get the smallest executable possible.
- Write a more sophisticated TLC file. In addition to methods such as `Start` and `Outputs`, conditionally generate customized versions of functions (data types, widths, algorithms, and so on), in separate code generation buffers, to be written to a separate .c file. The file should contain only functions used by this model, instead of all possible functions.

Either approach can produce optimal code. The first option can result in hundreds of files if your S-function supports many data types, signal widths, and algorithm choices. The second approach is more difficult to write, but results in a more maintainable code generation library, and the code can be every bit as tight as the first approach.

For further information on wrapping, see “Wrapper Inlined S-Function Example” on page 14-11.

## Inline MATLAB File S-Functions

You can inline the functionality of MATLAB file S-functions in the generated code. The process for writing a block target file for a MATLAB file S-function is essentially identical to the process for writing a C MEX S-function.

---

**Note** While you can fully inline a MATLAB file S-function to improve performance, Simulink Accelerator or the code generator does not include a C or C++ API for the MATLAB Math Library. You therefore cannot call MATLAB Math Library functions from a TLC file.

---

The following example illustrates the equivalence of C MEX and MATLAB file S-functions for code generation. The S-function MATLAB file `timestwo.m` is equivalent to the C MEX S-function `timestwo`. The TLC file for the C MEX S-function `timestwo` works for the S-function MATLAB file `timestwo.m`. TLC is independent of the type of S-function because TLC requires only the root name of the S-function and not its type. In the case of `timestwo`, one line determines how the code generator implements the TLC file:

```
%implements "timestwo" "C"
```

To try this yourself:

- 1 Create the following sample model:

- 2 Copy the file `timestwo.m` from the folder `matlabroot/toolbox/simulink/simdemos/simfeatures` (open) to a temporary folder.
- 3 Copy the file `timestwo.tlc` from the folder `matlabroot/toolbox/simulink/simdemos/simfeatures/tlc_c` (open) to the same temporary folder.
- 4 In MATLAB, change folder (`cd`) to the temporary folder and make a Simulink model with an S-function block that calls `timestwo`.
- 5 On the **Signal Attributes** tab of the Inport Block Parameters dialog box, set the **Port dimensions** parameter to 5.

Simulink uses the MATLAB file S-function for simulation because the MATLAB search path finds `timestwo.m` in the current folder before finding the C MEX S-function `timestwo` in the `matlabpath`. Verify which S-function the code generator uses by typing the MATLAB command:

```
which timestwo
```

The answer is the MATLAB file S-function `timestwo.m` in the temporary folder.

In the generated code, the `timestwo.tlc` file inlines the MATLAB file S-function.

```

/* S-Function (timestwo): '<Root>/MATLAB S-Function' */
/* Multiply input by two */
{
 int_T i1;
 const real_T *u0 = ×two_B.Gain[0];
 real_T *y0 = ×two_Y.Out1[0];
 for (i1=0; i1 < 5; i1++) {

```

```

 y0[i1] = u0[i1] * 2.0;
 }
}

```

The output is the product of each input, `u0[i1]` times 2.0. The code generator uses this `Outputs` method from the block target file to generate code:

```

%function Outputs(block, system) Output
/* %<Type> Block: %<Name> */
%%
/* Multiply input by two */
%assign rollVars = ["U", "Y"]
%roll idx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
%<LibBlockOutputSignal(0, "", lcv, idx)> = \
%<LibBlockInputSignal(0, "", lcv, idx)> * 2.0;
%endroll
%endfunction

```

Alter these temporary copies of the MATLAB file S-function and the TLC file to see how they interact. Start out by just changing the comments in the TLC file and see the changes that appear in the generated code. Then, work up to algorithmic changes.

For more information on inlining C MEX S-Functions, see “Inline C MEX S-Functions” on page 20-8.

## Inline Fortran (F-MEX) S-Functions

The capabilities of Fortran MEX S-functions can be fully inlined using a TLC block target file. This interface can be illustrated with a Fortran MEX S-function that implements the `timestwo` function. Here is the sample Fortran S-function code:

```

```

Copy the preceding code into file `ftimestwo.for` in a convenient working folder.

Putting this into an S-function block in a simple model will illustrate the interface for inlining the S-function. Once your Fortran MEX environment is set up, prepare the code for use by compiling the S-function in a working folder along with the file `simulink.for` from the folder `matlabroot/simulink/src` (open). For more information about setting up your Fortran MEX environment, see “Create Level-2 Fortran S-Functions”.

Compile the code with the `mex` command at the MATLAB command line:

```
mex ftimestwo.for simulink.for
```

Now reference this block from a simple model set with a fixed-step solver and the `grt` target.

The TLC code for inlining this block is a modified form of `timestwo.tlc`. In your working folder, create a file named `ftimestwo.tlc` and put this code into it.

```

%implements "ftimestwo" "C"

%function Outputs(block, system) Output
/* %<Type> Block: %<Name> */
%%
/* Multiply input by two */
%assign rollVars = ["U", "Y"]
%roll idx = RollRegions, lcv = RollThreshold, block, ...
"Roller", rollVars
%<LibBlockOutputSignal(0, "", lcv, idx)> = \
%<LibBlockInputSignal(0, "", lcv, idx)> * 2.0;
%endroll
%endfunction

```

Now you can generate code for the `ftimestwo` Fortran MEX S-function. The resulting code fragment specific to `ftimestwo` is

```
/* S-Function Block: <Root>/F-MEX S-Function */
/* Multiply input by two */
rtB.F_MEX_S_Function = rtB.Gain * 2.0;
```

## Inline C MEX S-Functions

### Inline S-Function Overview

When a Simulink model contains an S-function and a corresponding TLC block target file exists for that S-function, the code generator inlines the S-function. Inlining an S-function can produce more efficient code by eliminating the S-function API layer from the generated code.

For S-functions that can perform a variety of tasks, inlining them gives you the opportunity to generate code only for the current mode of operation set for each instance of the block. As an example of this, if an S-function accepts an arbitrary signal width and loops through each element of the signal, you would want to generate inlined code that has loops when the signal has two or more elements, but generates a simple nonlooped calculation when the signal has just one element.

Level 1 C MEX S-functions (written to an older form of the S-function API) that are not inlined will cause the generated code to make calls to all of these functions even if the routine is empty for the particular S-function.

Function	Purpose
<code>mdlInitializeSizes</code>	Initialize the sizes array
<code>mdlInitializeSampleTimes</code>	Initialize the sample times array
<code>mdlInitializeConditions</code>	Initialize the states
<code>mdlOutputs</code>	Compute the outputs
<code>mdlUpdate</code>	Update discrete states
<code>mdlDerivatives</code>	Compute the derivatives of continuous states
<code>mdlTerminate</code>	Clean up when the simulation terminates

Level 2 C MEX S-functions (i.e., those written to the current S-function API) that are not inlined make calls to the above functions, with the following exceptions:

- `mdlInitializeConditions` is called only if `MDL_INITIALIZE_CONDITIONS` is declared with `#define`.
- `mdlStart` is called only if `MDL_START` is declared with `#define`.
- `mdlUpdate` is called only if `MDL_UPDATE` is declared with `#define`.
- `mdlDerivatives` is called only if `MDL_DERIVATIVES` is declared with `#define`.

By inlining an S-function, you can eliminate the calls to these possibly empty functions in the simulation loop. This can greatly improve the efficiency of the generated code.

To inline an S-function called *sfunc\_name*, you create a custom S-function block target file called *sfunc\_name.tlc* and place it in the same folder as the S-function MEX-file. Then, at build time, the target file is executed instead of setting up function calls into the S-function .c file. The S-function target file “inlines” the S-function by directing the Target Language Compiler to insert only the statements defined in the target file.

In general, inlining an S-function is especially useful when

- The time required to execute the contents of the S-function is small in comparison to the overhead required to call the S-function.

- Certain S-function routines are empty (e.g., mdlUpdate).
- The behavior of the S-function changes between simulation and code generation. For example, device driver I/O S-functions might read from the MATLAB workspace during simulation, but read from an actual hardware address in the generated code.

## S-Function Parameters

An S-function can write two different types of parameters into the *model.rtw* file for Target Language Compiler files to access:

- Parameter settings: These correspond to nontunable parameters (typically set from check boxes and menus on a masked S-function) that are written via the mdlRTW method of the S-function using `ssWriteRTWParamSettings`. The S-function TLC implementation file can then directly access the values of these parameter settings from the `SFcnParamSettings` record in the block.
- Tunable parameters: This class of parameters can be accessed when they are registered as run-time parameters within the S-function. Note that such tunable parameters are automatically written out to the *model.rtw* file. Within the TLC file for the S-function, you can access run-time parameters and their attributes using the `LibBlockParameter` library function and its variants.

For more information on how to create and use run-time parameters, see “Create and Update S-Function Run-Time Parameters”. Also see the example `sfcndemo_runtime` in the S-function examples for how to create and use the two classes of parameters. The example source files, which you can inspect and adapt, are

- `toolbox/simulink/simdemos/simfeatures/src/sfun_runtime1.c`
- `toolbox/simulink/simdemos/simfeatures/tlc_c/sfun_runtime1.tlc`
- `toolbox/simulink/simdemos/simfeatures/src/sfun_runtime2.c`
- `toolbox/simulink/simdemos/simfeatures/tlc_c/sfun_runtime2.tlc`
- `toolbox/simulink/simdemos/simfeatures/src/sfun_runtime3.c`
- `toolbox/simulink/simdemos/simfeatures/tlc_c/sfun_runtime3.tlc`

## Sample Code for S-Function

Suppose you have a simple S-function that mimics the Gain block, with one input, one output, and a scalar gain. That is,  $y = u * p$ . If the Simulink block’s name is `foo` and the name of the Level 2 S-function is `foogain`, the C MEX S-function must contain this code:

```
#define S_FUNCTION_NAME foogain
#define S_FUNCTION_LEVEL 2
#include "simstruc.h"
#define GAIN mxGetPr(ssGetSFcnParam(S,0))[0]

static void mdlInitializeSizes(SimStruct *S)
{
 ssSetNumContStates (S, 0);
 ssSetNumDiscStates (S, 0);

 if (!ssSetNumInputPorts(S, 1)) return;
 ssSetInputPortWidth (S, 0, 1);
 ssSetInputPortDirectFeedThrough(S, 0, 1);
}
```

```

 if (!ssSetNumOutputPorts(S, 1)) return;
 ssSetOutputPortWidth (S, 0, 1);

 ssSetNumSFcnParams (S, 1);
 ssSetNumSampleTimes (S, 0);
 ssSetNumIWork (S, 0);
 ssSetNumRWork (S, 0);
 ssSetNumPWork (S, 0);
}

static void
mdlOutputs(SimStruct *S, int_T tid)
{
 real_T *y = ssGetOutputPortRealSignal(S, 0);
 const InputRealPtrsType u = ssGetInputPortRealSignalPtrs(S, 0);

 y[0] = (*u)[0] * GAIN;
}

static void
mdlInitializeSampleTimes(SimStruct *S){}

static void
mdlTerminate(SimStruct *S) {}

#define MDL_RTW /* Change to #undef to remove function */
#if defined(MDL_RTW)&&(defined(MATLAB_MEX_FILE)||defined(NRT))
static void
mdlRTW (SimStruct *S)
{
 if (!ssWriteRTWParameters(S, 1,SSWRITE_VALUE_VECT,"Gain","",
 mxGetPr(ssGetSFcnParam(S,0)),1))
 {
 return;
 }
}
#endif

#ifdef MATLAB_MEX_FILE
#include "simulink.c"
#else
#include "cg_sfun.h"
#endif

```

The following two sections show the difference in the generated code for *model.c* containing noninlined and inlined versions of S-function *foogain*. The model contains no other Simulink blocks.

For more information about these S-function related C library functions, see “Configure C/C++ S-Function Features”. For information about how to generate code, see “Configure Model and Generate Code” and “Approaches for Building Code Generated from Simulink Models”.

### Comparison of Noninlined and Inlined Versions of *model.c*

Without a TLC file to define the S-function specifics, the code generator must call the MEX-file S-function through the S-function API. The following code is the *model.c* file for the noninlined S-function (i.e., no corresponding TLC file exists).

### Noninlined S-Function

```

/*
 * model.c
 .
 .
 .
 */
real_T untitled_RGND = 0.0; /* real_T ground */
/* Start the model */
void MdlStart(void)
{
 /* (no start code required) */
}
/* Compute block outputs */
void MdlOutputs(int_T tid)
{
 /* Level2 S-Function Block: <Root>/S-Function (foogain) */
 {
 SimStruct *rts = ssGetSFunction(rtS, 0);
 sfcnOutputs(rts, tid);
 }
}
/* Perform model update */
void MdlUpdate(int_T tid)
{
 /* (no update code required) */
}
/* Terminate function */
void MdlTerminate(void)
{
 /* Level2 S-Function Block: <Root>/S-Function (foogain) */
 {
 SimStruct *rts = ssGetSFunction(rtS, 0);
 sfcnTerminate(rts);
 }
}
#include "model_reg.h"
/* [EOF] model.c */

```

### Inlined S-Function

This code is *model.c* with the foogain S-function fully inlined:

```

/*
 * model.c
 .
 .
 .
 */
/* Start the model */
void MdlStart(void)
{
 /* (no start code required) */
}

/* Compute block outputs */
void MdlOutputs(int_T tid)

```

```

/* S-Function block: <Root>/S-Function */
/* NOTE: There are no calls to the S-function API in the inlined
 version of model.c. */
rtB.S_Function = 0.0 * rtP.S_Function_Gain;
}

/* Perform model update */
void MdlUpdate(int_T tid)
{
/* (no update code required) */
}

/* Terminate function */
void MdlTerminate(void)
{
/* (no terminate code required) */
}

#include "model_reg.h"

/* [EOF] model.c */

```

If you include this target file for this S-function block, the resulting *model.c* code is

```
rtB.S_Function = 0.0 * rtP.S_Function_Gain;
```

Including a TLC file drastically decreased the code size and increased the execution efficiency of the generated code. These notes highlight some information about the TLC code and the generated output:

- The TLC directive `%implements` is required by block target files, and must be the first executable statement in the block target file. This directive prevents the Target Language Compiler from executing an inappropriate target file for S-function `foogain`.
- The input to `foo` is `rtGROUND` (a Simulink Coder global equal to 0.0) because `foo` is the only block in the model and its input is unconnected.
- Including a TLC file for `foogain` eliminates the need for an S-function registration segment for `foogain`. This significantly reduces code size.
- The TLC code inlines the `gain` parameter when the build process is configured to inline parameter values. For example, if the S-function parameter is specified as 2.5 in the S-function dialog box, the TLC Outputs function generates

```
rtB.foo = input * 2.5;
```

- Use the `%generatefile` directive if your operating system has a filename size restriction and the name of the S-function is `foosfunction` (that exceeds the limit). In this case, you would include the following statement in the system target file (anywhere prior to a reference to this S-function block target file).

```
%generatefile foosfunction "foosfunc.tlc"
```

This statement tells the Target Language Compiler to open `foosfunc.tlc` instead of `foosfunction.tlc`.

## Comparison of Noninlined and Inlined Versions of `model_reg.h`

Inlining a Level 2 S-function significantly reduces the size of the `model_reg.h` code. Model registration functions are lengthy; much of the code has been eliminated in this example. The code below highlights the difference between the noninlined and inlined versions of `model_reg.h`; inlining eliminates this code:

```

/*
 * model_reg.h
 *
 */
/* Normal model initialization code independent of
 S-functions */

/* child S-Function registration */
ssSetNumSFunctions(rtS, 1);

/* register each child */
{
 static SimStruct childSFunctions[1];
 static SimStruct *childSFunctionPtrs[1];

 (void)memset((char_T *)&childSFunctions[0], 0,
 sizeof(childSFunctions));
 ssSetSFunctions(rtS, &childSFunctionPtrs[0]);
 {
 int_T i;

 for(i = 0; i < 1; i++) {
 ssSetSFunction(rtS, i, &childSFunctions[i]);
 }
 }

 /* Level2 S-Function Block: untitled/<Root>/S-Function
 (foogain) */
 {
 extern void foogain(SimStruct *rts);
 SimStruct *rts = ssGetSFunction(rtS, 0);

 /* timing info */
 static time_T sfcnPeriod[1];
 static time_T sfcnOffset[1];
 static int_T sfcnTsMap[1];

 {
 int_T i;

 for(i = 0; i < 1; i++) {
 sfcnPeriod[i] = sfcnOffset[i] = 0.0;
 }
 }
 ssSetSampleTimePtr(rts, &sfcnPeriod[0]);
 ssSetOffsetTimePtr(rts, &sfcnOffset[0]);
 ssSetSampleTimeTaskIDPtr(rts, sfcnTsMap);
 ssSetMdlInfoPtr(rts, ssGetMdlInfoPtr(rtS));

 /* inputs */
 {

```

```

static struct _ssPortInputs inputPortInfo[1];

_ssSetNumInputPorts(rts, 1);
ssSetPortInfoForInputs(rts, &inputPortInfo[0]);

/* port 0 */
{
 static real_T const *sfcnUPtrs[1];

 sfcnUPtrs[0] = &untitled_RGND;
 ssSetInputPortWidth(rts, 0, 1);
 ssSetInputPortSignalPtrs(rts, 0,
 (InputPtrsType)&sfcnUPtrs[0]);
}
}

/* outputs */
{
 static struct _ssPortOutputs outputPortInfo[1];
 _ssSetNumOutputPorts(rts, 1);
 ssSetPortInfoForOutputs(rts, &outputPortInfo[0]);
 ssSetOutputPortWidth(rts, 0, 1);
 ssSetOutputPortSignal(rts, 0, &rtB.S_Function);
}

/* path info */
ssSetModelName(rts, "S-Function");
ssSetPath(rts, "untitled/S-Function");
ssSetParentSS(rts, rtS);
ssSetRootSS(rts, ssGetRootSS(rtS));
ssSetVersion(rts, SIMSTRUCT_VERSION_LEVEL2);

/* parameters */
{
 static mxArray const *sfcnParams[1];

 ssSetSFcnParamsCount(rts, 1);
 ssSetSFcnParamsPtr(rts, &sfcnParams[0]);

 ssSetSFcnParam(rts, 0, &rtP.S_Function_P1Size[0]);
}

/* registration */
foogain(rts);

sfcnInitializeSizes(rts);
sfcnInitializeSampleTimes(rts);

/* adjust sample time */
ssSetSampleTime(rts, 0, 0.2);
ssSetOffsetTime(rts, 0, 0.0);
sfcnTsMap[0] = 0;

/* Update the InputPortReusable and BufferDstPort flags for
each input port */
ssSetInputPortReusable(rts, 0, 0);
ssSetInputPortBufferDstPort(rts, 0, -1);

```

```

 /* Update the OutputPortReusable flag of each output port */
 }
}

```

### A TLC File to Inline S-Function foogain

To avoid unnecessary calls to the S-function and to generate the minimum code required for the S-function, the following TLC file, `foogain.tlc`, is provided as an example.

```

implements "foogain" "C"

%function Outputs (block, system) Output
/* %<Type> block: %<Name> */
%%
%assign y = LibBlockOutputSignal (0, "", "", 0)
%assign u = LibBlockInputSignal (0, "", "", 0)
%assign p = LibBlockParameter (Gain, "", "", 0)
%<y> = %<u> * %<p>;
%endfunction

```

### Managing Block Instance Data with an Eye Toward Code Generation

Instance data is extra data or working memory that is unique to each instance of a block in a Simulink model. This does not include parameter or state data (which is stored in the model parameter and state vectors, respectively), but rather is used to cache intermediate results or derived representations of parameters and modes. One example of instance data is the buffer used by a transport delay block.

Allocating and using memory on an instance-by-instance basis can be done several ways in a Level 2 S-function: via `ssSetUserData`, work vectors (e.g., `ssSetRWorkValue`, `ssSetIWorkValue`), or data-typed work vectors known as `DWork` vectors. For the smallest effort in writing the S-function and block target file and for automatic conformance to both static and `malloc` instance data on targets such as `grt`, use data-typed work vectors when writing S-functions with instance data.

The advantages are twofold. In the first place, writing the S-function is more straightforward, in that memory allocations and frees are handled for you by Simulink. Secondly, the `DWork` vectors are written to the `model.rtw` file for you automatically, including the `DWork` name, data type, and size. This makes writing the block target file easier, because you do not have to write TLC code for allocating and freeing the `DWork` memory.

Additionally, if you want to bundle groups of `DWork` vectors into structures for passing to functions, you can populate the structure with pointers to `DWork` arrays in both your S-function `mdlStart` function and the block target file's `Start` method, achieving consistency between the S-function and the generated code's handling of data.

Finally, using a `DWork` makes it straightforward to create a specific version of code (data types, scalar vs. vectorized, etc.) for each block instance that matches the implementation in the S-function. Both implementations use `DWork` in the same way so that the inlined code can be used with the Simulink Accelerator software without changes to the C MEX S-function or the block target file.

### Using Inlined Code with the Simulink Accelerator Software

By default, the Simulink Accelerator software calls your C MEX S-function as part of an accelerated model simulation. If you prefer to have the accelerator inline your S-function before running the accelerated model, tell the accelerator to use your block target file to inline the S-function with the

`SS_OPTION_USE_TLC_WITH_ACCELERATOR` flag in the call to `ssSetOptions()` in the `mdlInitializeSizes` function of that S-function.

Note that memory and work vector size and usage must be the same for the TLC generated code and the C MEX S-function, or the Simulink Accelerator software cannot execute the inlined code properly. This is because the C MEX S-function is called to initialize the block and its work vectors, calling the `mdlInitializeSizes`, `mdlInitializeConditions`, `mdlCheckParameters`, `mdlProcessParameters`, and `mdlStart` functions. In the case of constant signal propagation, `mdlOutputs` is called from the C MEX S-function during the initialization phase of model execution.

During the time-stepping phase of accelerated model execution, the code generated by the `Output` and `Update` block TLC methods will execute, plus the `Derivatives` and zero-crossing methods if they exist. The `Start` method of the block target file is not used in generating code for an accelerated model.

- “Write Fully Inlined S-Functions with `mdlRTW` Routine”

## TLC Coding Conventions

These guidelines can help you apply programming style in each target file consistently.

### Begin Identifiers with Uppercase Letters

Identifiers in the file begin with an uppercase letter. For example,

```
NumModelInputs 1
NumModelOutputs 2
NumNonVirtBlocksInModel 42
DirectFeedthrough yes
NumContStates 10
```

Because a Name identifier may be promoted into the parent scope, block records that contain a Name identifier should start the name with an uppercase letter. For example, a block might contain

```
Block {
 :
 :
RWork [4, 0]
 :
NumRWorkDefines 4
RWorkDefine {
 Name "TimeStampA"
 Width 1
 StartIndex 0
}
}
```

Because the Name identifier within the RWorkDefine record is promoted to PrevT in its parent scope, it must start with an uppercase letter. The promotion of the Name identifier into the parent block scope is currently done for the Parameter, RWorkDefine, IWorkDefine, and PWorkDefine block records.

The Target Language Compiler assignment directive (%assign) generates a warning if you assign a value to an “unqualified” code generator identifier. For example,

```
%assign TID = 1
```

produces an error because the TID identifier is not qualified by Block. However, a “qualified” assignment does not generate a warning. For example,

```
%assign Block.TID = 1
```

does not generate a warning because the assignment contains a qualifier. The Target Language Compiler therefore assumes that the programmer is intentionally modifying an identifier.

### Begin Global Variable Assignments with Uppercase Letters

Global TLC variable assignments should start with uppercase letters. A global variable is a variable declared in a system target file (grt.tlc, mdlwide.tlc, mdlhdr.tlc, mdlbody.tlc, mdlreg.tlc, or mdlparam.tlc), or within a function that uses the operator. Global assignments have the same scope as code generator variables. An example of a global TLC variable defined in mdlwide.tlc is

```
%assign InlineParameters = 1
```

An example of a global reference in a function is

```
%function foo() void
 %assign ::GlobalIdx = ::GlobalIdx + 1
%endfunction
```

## Begin Local Variable Assignments with Lowercase Letters

Local TLC variable assignments should start with lowercase letters. A local TLC variable is a variable assigned inside a function. For example,

```
%assign numBlockStates = ContStates[0]
```

## Begin Functions Declared in block.tlc Files with Fcn

When you declare a function inside a `block.tlc` file, it should start with `Fcn`. For example,

```
%function FcnMyBlockFunc(...)
```

---

**Note** Functions declared inside a system file are global; functions declared inside a block file are local.

---

## Do Not Hard-Code Variables Defined in commonsetup.tlc

Because the code generator tracks use of variables and generates code based on usage, you should use access routines instead of directly using a variable. For example, you should not use the following in your TLC file:

```
x = %<tInf>;
```

You should use

```
x = %<LibRealNonFinite(inf)>;
```

Similarly, instead of using `%<tTID>`, use `%<LibTID()>`. For a complete list of functions, see TLC Function Library Reference in “Target Language Compiler”.

Simulink Coder global variables start with `rt` and Simulink Coder global functions start with `rt_`.

Avoid naming global variables in modules that start with `rt` or `rt_` because they might conflict with Simulink Coder global variables and functions. These TLC variables are declared in `commonsetup.tlc`.

This convention creates consistent variables throughout the target files. For example, the Gain block contains the following `Outputs` function.

```

Note c {
 %% Function: Outputs =====
 %% Abstract:
 %% Y = U * K
 %%
 %%function Outputs(block, system) Output
 /* %<Type> Block: %<Name> */ _____ } Note a
 %assign rollVars = ["U", "Y", "P"] _____ } Note e
Notes d,f {
 %roll sidIdx = RollRegions, lcv = RollThreshold, block,...
 "Roller", rollVars
 %assign y = LibBlockOutputSignal(0, "", lcv, sigIdx)
 %assign u = LibBlockInputSignal(0, "", lcv, sigIdx)
 %assign k = LibBlockParameter(Gain, "", lcv, sigIdx)
 %<y> = %<u> * %<k>;
 %endroll _____ } Note b
 %endfunction

```

### Notes about this TLC code

- The code section for each block begins with a comment specifying the block type and name.
- Include a blank line immediately after the end of the function to create consistent spacing between blocks in the output code.
- Try to stay within 80 columns per line for the function banner. You might set up an 80 column comment line at the top of each function. As an example, see `constant.tlc`.
- For consistency, use the variables `sysIdx` and `blkIdx` for system index and block index, respectively.
- Use the variable `rollVars` when using the `%roll` construct.
- When naming loop control variables, use `sigIdx` and `lcv` when looping over `RollRegions` and `xidx` and `xlcv` when looping over the states.

### Example: Output function in `gain.tlc`

```

%roll sigIdx = RollRegions, lcv = RollThreshold, ...
 block, "Roller", rollVars

```

### Example: InitializeConditions function in `linblock.tlc`

```

%roll xidx = [0:nStates-1], xlcv = RollThreshold,...
 block, "Roller", rollVars

```

## Conditional Inclusion in Library Files

The Target Language Compiler function library files are conditionally included with guard code so you can reference them multiple times using `%include` without worrying if they have previously been included. Follow this practice for TLC library files that you create.

The convention is to use a variable with the same name as the base filename, uppercase and with underscores attached at both ends. So, a file named `customlib.tlc` should have the variable `_CUSTOMLIB_` guarding it.

As an example, the main Target Language Compiler function library, `funclib.tlc`, contains this TLC code to prevent multiple inclusion:

```

%if EXISTS("_FUNCLIB_") == 0
%assign _FUNCLIB_ = 1

```

```
.
. .
. .
%endif %% _FUNCLIB_
```

## Code Defensively

As the code your TLC generates could be used in referenced models in unpredictable contexts, do not assume too much about name spaces. For example, when writing TLC code for a block and adding a typedef, guard it with `if/def`, as the following example illustrates:

```
%openfile tmpBuff
 #ifndef RESOLUTION_TYPEDEF

 typedef enum { LO_RES, HI_RES } Resolution;
 typedef struct { Resolution res; int8_T value; } Data;

 #define RESOLUTION_TYPEDEF
 #endif /* RESOLUTION_TYPEDEF */
%closefile tmpBuff

%<LibCacheTypedefs(tmpBuff)>;
```

## Block Target File Methods

### Block Functions Overview

Each block has a target file that determines what code should be generated for the block. The code can vary depending on the exact parameters of the block or the types of connections to it (e.g., wide vs. scalar input).

Within each block target file, block functions specify the code to be output for the block in the model's or subsystem's `start` function, `output` function, `update` function, and so on.

The functions declared inside each of the block target files are called by the system target files. In these tables, `block` refers to a Simulink block name (e.g., `gain` for the Gain block) and `system` refers to the subsystem in which the block resides. The first table lists the two functions that are used for preprocessing and setup. Neither of these functions outputs generated code.

- “`BlockInstanceSetup(block, system)`” on page 20-21
- “`BlockTypeSetup(block, system)`” on page 20-22

The following functions generate executable code that the code generator places appropriately:

- “`Enable(block, system)`” on page 20-23
- “`Disable(block, system)`” on page 20-23
- “`Start(block, system)`” on page 20-23
- “`InitializeConditions(block, system)`” on page 20-24
- “`Outputs(block, system)`” on page 20-24
- “`Update(block, system)`” on page 20-25
- “`Derivatives(block, system)`” on page 20-26
- “`Terminate(block, system)`” on page 20-26

In object-oriented programming terms, these functions are polymorphic in nature, because each block target file contains the same functions. The Target Language Compiler dynamically determines at run-time which block function to execute depending on the block's type. That is, the system file only specifies that the `Outputs` function, for example, is to be executed. The particular `Outputs` function is determined by the Target Language Compiler depending on the block's type.

To write a block target file, use these polymorphic block functions combined with the Target Language Compiler library functions. For a complete list of the Target Language Compiler library functions, see TLC Function Library Reference on “Target Language Compiler”.

### BlockInstanceSetup(block, system)

The `BlockInstanceSetup` function executes for the blocks that have this function defined in their target files in a model. For example, if a model includes 10 From Workspace blocks, then the `BlockInstanceSetup` function in `fromwks.tlc` executes 10 times, once for each From Workspace block instance. Use `BlockInstanceSetup` to generate code for each instance of a given block type.

See TLC Function Library Reference on “Target Language Compiler” for available utility processing functions to call from inside this block function. See the file `matlabroot/rtw/c/tlc/blocks/lookup2d.tlc` for an example of the `BlockInstanceSetup` function.

**Syntax**

```
BlockInstanceSetup(block, system) void
block = Reference to a Simulink block
system = Reference to a nonvirtual Simulink subsystem
```

This example uses `BlockInstanceSetup`:

```
%function BlockInstanceSetup(block, system) void
%if (block.InMask == "yes")
 %assign blockName = LibParentMaskBlockName(block)
%else
 %assign blockName = LibGetFormattedBlockPath(block)
%endif
%if (CodeFormat == "Embedded-C")
 %if !(ParamSettings.ColZeroTechnique == "NormalInterp" && ...
 ParamSettings.RowZeroTechnique == "NormalInterp")
 %selectfile STDOUT
```

Note: Removing repeated zero values from the X and Y axes will produce more efficient code for block: `%<blockName>`. To locate this block, type

```
open_system('%<blockName>')
```

at the MATLAB command prompt.

```
 %selectfile NULL_FILE
%endif
%endif
%endfunction
```

**BlockTypeSetup(block, system)**

`BlockTypeSetup` executes once per block type before code generation begins. That is, if 10 Lookup Table blocks exist in the model, the `BlockTypeSetup` function in `look_up.tlc` is called only one time. Use this function to perform general work for multiple blocks of a given type.

See TLC Function Library Reference on “Target Language Compiler” for a list of relevant functions to call from inside this block function. See `look_up.tlc` for an example of the `BlockTypeSetup` function.

**Syntax**

```
BlockTypeSetup(block, system) void
block = Reference to a Simulink block
system = Reference to a nonvirtual Simulink subsystem
```

As an example, given the S-function `foo`, which requires a `#define` and two function declarations in the header file, you could define:

```
%function BlockTypeSetup(block, system) void

%% Place a #define in the model's header file

%openfile buffer
#define A2D_CHANNEL 0
```

```

%closefile buffer

%<LibCacheDefine(buffer)>

%% Place function prototypes in the model's header file

%openfile buffer
 void start_a2d(void);
 void reset_a2d(void);
%closefile buffer

%<LibCacheFunctionPrototype(buffer)>
%endfunction

```

The remaining block functions execute once for each block in the model.

## Enable(block, system)

The code generator creates `Enable` functions for nonvirtual subsystem whenever a Simulink subsystem contains a block with an `Enable` function. Including the `Enable` function in a block's target file places the block's specific enable code in this subsystem `Enable` function. For example:

```

%% Function: Enable =====
%% Abstract:
%% Subsystem Enable code is required only for the discrete form
%% of the Sine Block. Setting the Boolean to TRUE causes the
%% Output function to resync its last values of cos(wt) and
%% sin(wt).
%%
%function Enable(block, system) Output
 %if LibIsDiscrete(TID)
 /* %<Type> Block: %<Name> */
 %<LibBlockIWork(SystemEnable, "", "", 0)> = (int_T) TRUE;

 %endif
%endfunction

```

## Disable(block, system)

Nonvirtual subsystem `Disable` functions are created whenever a Simulink subsystem contains a block with a `Disable` function. Including the `Disable` function in a block's target file places the block's specific disable code into this subsystem `Disable` function.

## Start(block, system)

Include a `Start` function to place code in the `Start` function. The code inside the `Start` function executes once and only once. Typically, you include a `Start` function to execute code once at the beginning of the simulation (e.g., initialize values in the work vectors) or code that does not need to be re-executed when the subsystem in which it resides is enabled. See `constant.tlc` for an example of the `Start` function.

```

%% Function: Start =====
%% Abstract:
%% Set the output to the constant parameter value if the block
%% output is visible in the model's start function scope, i.e.,

```

```

%% it is in the global rtB structure.
%%
%function Start(block, system) Output
 %if LibBlockOutputSignalIsInBlockIO(0)
 /* %<Type> Block: %<Name> */
 %assign rollVars = ["Y", "P"]
 %roll idx = RollRegions, lcv = RollThreshold, block, ...
 "Roller", rollVars
 %assign yr = LibBlockOutputSignal(0,"", lcv, ...
 "%<tRealPart>%<idx>")
 %assign pr = LibBlockParameter(Value, "", lcv, ...
 "%<tRealPart>%<idx>")
 %<yr> = %<pr>;
 %if LibBlockOutputSignalIsComplex(0)
 %assign yi = LibBlockOutputSignal(0, "", lcv, ...
 "%<tImagPart>%<idx>")
 %assign pi = LibBlockParameter(Value, "", lcv, ...
 "%<tImagPart>%<idx>")
 %<yi> = %<pi>;
 %endif
 %endif
%endroll
%endif
%endfunction %% Start

```

## InitializeConditions(block, system)

TLC code that is generated from the block's `InitializeConditions` function appears in one of two places. A nonvirtual subsystem contains an `Initialize` function when it is configured to reset states on enable. In this case, the TLC code generated by this block function is placed in the subsystem `Initialize` function, and the `start` function calls this subsystem `Initialize` function. If, however, the Simulink block resides in the root system or in a nonvirtual subsystem that does not require an `Initialize` function, the code generated from this block function is placed directly (inlined) into the `start` function.

There is a subtle difference between the block functions `Start` and `InitializeConditions`. Typically, you include a `Start` function to execute code that does not need to re-execute when the subsystem in which it resides is enabled. You include an `InitializeConditions` function to execute code that must re-execute when the subsystem in which it resides is enabled. For example:

```

%% Function: InitializeConditions =====
%%
%% Abstract: Invalidate the stored output and input in
%% rwork[1 2*blockWidth] by setting the time stamp stored
%% in rwork[0]) to rtInf.
%%
%function InitializeConditions(block, system) Output
 /* %<Type> Block: %<Name> */
 %<LibBlockRWork(PrevT, "", "", 0)> = %<LibRealNonFinite(inf)>;
%endfunction

```

## Outputs(block, system)

A block should generally include an `Outputs` function. The TLC code generated by a block's `Outputs` function is placed in one of two places. The code is placed directly in the model's `Outputs` function if the block does not reside in a nonvirtual subsystem, and in a subsystem's `Outputs` function if the block resides in a nonvirtual subsystem. For example:

```

%% Function: Outputs =====
%% Abstract:
%% Y[i] = fabs(U[i]) if U[i] is real or
%% Y[i] = sqrt(U[i].re^2 + U[i].im^2) if U[i] is complex.
%%
%function Outputs(block, system) Output
/* %<Type> Block: %<Name> */
%%
%assign inputIsComplex = LibBlockInputSignalIsComplex(0)
%assign RT_SQUARE = "RT_SQUARE"
%%
%assign rollVars = ["U", "Y"]
%if inputIsComplex
 %roll sigIdx = RollRegions, lcv = RollThreshold, ...
 block, "Roller", rollVars
 %%
 %assign ur = LibBlockInputSignal(0, "", lcv, ...
 "%<tRealPart>%<sigIdx>")
 %assign ui = LibBlockInputSignal(0, "", lcv, ...
 "%<tImagPart>%<sigIdx>")
 %%
 %assign y = LibBlockOutputSignal(0, "", lcv, sigIdx)
 %<y> = sqrt(%<RT_SQUARE>(%<ur>) + %<RT_SQUARE>(%<ui>));
%endroll
%else
 %roll sigIdx = RollRegions, lcv = RollThreshold, ...
 block, "Roller", rollVars
 %assign u = LibBlockInputSignal (0, "", lcv, sigIdx)
 %assign y = LibBlockOutputSignal(0, "", lcv, sigIdx)
 %<y> = fabs(%<u>);
%endroll
%endif
%endfunction

```

---

**Note** Zero-crossing reset code is placed in the `Outputs` function.

---

If you write TLC code to generate inlined code from an S-function, and if the TLC code contains an `Outputs` function, you must modify the TLC code if all of these conditions are true:

- An output port uses or inherits constant sample time. The output port has a constant value.
- The S-function is a multirate S-function or uses port-based sample times.

In this case, the TLC code must generate code for the constant-valued output port by using the function `OutputsForTID` instead of the function `Outputs`. For more information, see “Specifying Constant Sample Time (Inf) for a Port”.

## Update(block, system)

Include an `Update` function if the block has code that needs to be updated at each major time step. Code generated from this function is placed in either the model’s or the subsystem’s `Update` function, depending on whether or not the block resides in a nonvirtual subsystem. For example:

```

%% Function: Update =====
%% Abstract:

```

```
%% X[i] = U[i]
%%
%function Update(block, system) Output
/* %<Type> Block: %<Name> */
%assign rollVars = ["U", "Xd"]
%roll idx = RollRegions, lcv = RollThreshold, block, ...
 "Roller", rollVars
%assign u = LibBlockInputSignal(0, "", lcv, idx)
%assign x = LibBlockDiscreteState("", lcv, idx)
%<X> = %<U>;
%endroll
%endfunction %% Update
```

## Derivatives(block, system)

Include a `Derivatives` function when generating code to compute the block's continuous states. Code generated from this function is placed in either the model's or the subsystem's `Derivatives` function, depending on whether or not the block resides in a nonvirtual subsystem. See `integrat.tlc` for an example of the `Derivatives` function.

## Terminate(block, system)

Include a `Terminate` function to place code in `MdlTerminate`. User-defined S-function target files can use this function to save data, free memory, reset hardware on the target, and so on. See `tofile.tlc` for an example of the `Terminate` function.

### Related Examples

- “Loop Rolling” on page 20-27

## Loop Rolling

One of the optimization features of the Target Language Compiler is the intrinsic support for loop rolling. Based on a specified threshold, code generation for looping operations can be unrolled or left as a loop (rolled).

Coupled with loop rolling is the concept of noncontiguous signals. Consider the following model:

The input to the `timestwo` S-function comes from two arrays located at two different memory locations, one for the output of `source1` and one for the output of block `source2`. This is because of an optimization that makes the Mux block virtual, meaning that code is not explicitly generated for the Mux block and thus processor cycles are not spent evaluating it (i.e., it becomes a pure graphical convenience for the block diagram). So this is represented in the `model.rtw` file in this case as

```
Block {
 Type "S-Function"
 MaskType "S-function: timestwo"
 BlockIdx [0, 0, 2]
 SL_BlockIdx 2
 GrSrc [0, 1]
 ExprCommentInfo {
 SysIdxList []
 BlkIdxList []
 PortIdxList []
 }
 ExprCommentSrcIdx {
 SysIdx -1
 BlkIdx -1
 PortIdx -1
 }
 Name "<Root>/timestwo C-MEX S-Function"
 SLName "<Root>/timestwo \nC-MEX S-Function"
 Identifier timestwoCMEXSFunction
 TID 0
 RollRegions [0:19, 20:49]
 NumDataInputPorts 1
 DataInputPort {
 SignalSrc [b0@20, b1@30]
 SignalOffset [0:19, 0:29]
 Width 50
 RollRegions [0:19, 20:49]
 }
 NumDataOutputPorts 1
}
```

```

 DataOutputPort {
 SignalSrc [b2@50]
 SignalOffset [0:49]
 Width 50
 }
 Connections {
 InputPortContiguous [no]
 InputPortConnected [yes]
 OutputPortConnected [yes]
 OutputPortBeingMerged [no]
 DirectSrcConn [no]
 DirectDstConn [yes]
 DataOutputPort {
 NumConnPoints 1
 ConnPoint {
 SrcSignal [0, 50]
 DstBlockAndPortEl [0, 4, 0, 0]
 }
 }
 }
}
.
.
.

```

From this fragment of the *model.rtw* file you can see that the block and input port `RollRegion` entries are not just one number, but two groups of numbers. This denotes two groupings in memory for the input signal. The generated code looks like this:

```

/* S-Function Block: <Root>/timestwo C-MEX S-Function */
/* Multiply input by two */
{
 int_T i1;

 const real_T *u0 = &contig_sample_B.u[0];
 real_T *y0 = contig_sample_B.timestwoCMEXSFunction_m;

 for (i1=0; i1 < 20; i1++) {
 y0[i1] = u0[i1] * 2.0;
 }

 u0 = &contig_sample_B.u_o[0];
 y0 = &contig_sample_B.timestwoCMEXSFunction_m[20];

 for (i1=0; i1 < 30; i1++) {
 y0[i1] = u0[i1] * 2.0;
 }
}

```

Notice that two loops are generated and between them the input signal is redirected from the first base address, `&contig_sample_B.u[0]`, to the second base address of the signals, `&contig_sample_B.u_o[0]`. If you do not want to support this in your S-function or your generated code, you can use

```
ssSetInputPortRequiredContiguous(S, 1);
```

in the `mdlInitializeSizes` function to cause Simulink to implicitly generate code that performs a buffering operation. This option uses both extra memory and CPU cycles at run-time, but might be worth it if your algorithm performance increases enough to offset the overhead of the buffering.

Use the `%roll` directive to generate loops. See also “%roll” on page 18-22 for the reference entry for `%roll`, and “Input Signal Functions” on page 21-7 for a discussion on the behavior of `%roll`.

# TLC Function Library Reference

---

This chapter provides a set of Target Language Compiler functions that are useful for inlining S-functions. The TLC files contain many other library functions, but you should use only the functions that are documented in these reference pages for development. Undocumented functions can change significantly from release to release. “Obsolete Functions” on page 21-70 includes a table of obsolete functions and their replacements.

- “Target Language Compiler Library Functions Overview” on page 21-2

- “Advanced Functions” on page 21-72
- “Block Compatibility Functions” on page 21-77

## Target Language Compiler Library Functions Overview

There are several library functions that provide access to block inputs, outputs, parameters, sample times, and other information. It is recommended that you use these library functions to access many of the parameter name/parameter values pairs in the block record, as opposed to accessing the parameter name/parameter value pairs directly from your block TLC code.

The library functions simplify block TLC code and provide support for loop rolling, data types, and complex data. The functions also provide a layer to protect against changes that can occur to the contents of the *model.rtw* file.

An exception to using these functions is when you access parameter settings for a block. Parameter settings can be written out using the `mdlRTW` function of a C MEX S-function. They can contain data in the form of strings, scalar values, vectors, and matrices. They can be used to pass fixed values and information that is used to alter the generated code for a block or directly as values in the resulting code of a block. For more information about this exception, see “Exception to Using the Library Functions that Access *model.rtw*” on page 17-11.

## Target Language Compiler Function Conventions

You can find examples using these functions in *matlabroot/toolbox/simulink/blocks/tlc\_c* and *matlabroot/toolbox/simulink/simdemos/simfeatures/tlc\_c*. The corresponding MEX S-function source code is located in *matlabroot/simulink/src* or *matlabroot/toolbox/simulink/simdemos/simfeatures/src*. MATLAB file S-functions and the MEX-file executables (for example, *sfunction.mex\**) are located in *matlabroot/toolbox/simulink/blocks* or *matlabroot/toolbox/simulink/simdemos/simfeatures*.

### Common Function Arguments

Several functions take similar or identical arguments. To simplify the reference pages, some of these arguments are documented in detail here instead of in the reference pages.

Argument	Description
portIdx	Refers to an input or output port index, starting at 0. For example, the first input port of an S-function is 0.
ucv	User control variable. This is an advanced feature that overrides the lcv and sigIdx parameters. When used within an inlined S-function, it should generally be specified as "".
lcv	Loop control variable. This is generally generated by the %roll directive via the second %roll argument (e.g., lcv=RollThreshold) and should be passed directly to the library function. It contains either "", indicating that the current pass through the %roll is being inlined, or it is the name of a loop control variable such as "i", indicating that the current pass through the %roll is being placed in a loop. Outside the %roll directive, this is usually specified as "".

Argument	Description
sigIdxoridx	<p>Signal index. Sometimes referred to as the signal element index. When accessing specific elements of an input or output signal directly, the call to the various library routines should have <code>ucv=""</code>, <code>lcv=""</code>, and <code>sigIdx</code> equal to the desired integer signal index starting at 0. For complex signals, <code>sigIdx</code> can be an overloaded integer index specifying both whether the real or imaginary part is being accessed and which element. When you access these items inside a <code>%roll</code>, use the <code>sigIdx</code> generated by the <code>%roll</code> directive.</p> <p>Most functions that take a <code>sigIdx</code> argument accept it in an overloaded form, where <code>sigIdx</code> can be</p> <ul style="list-style-type: none"> <li>• An integer, e.g., 3. If the referenced signal is complex, then this refers to the identifier for the complex container. If the referenced signal is not complex, then this refers to the identifier.</li> <li>• An <code>id-num</code>, usually of the form (see “Overloading sigIdx” on page 21-4) <ul style="list-style-type: none"> <li><b>a</b> <code>"%&lt;tRealPart&gt;%&lt;idx&gt;"</code> (e.g., "re3"). The real part of the signal element. Usually <code>"%&lt;tRealPart&gt;%&lt;sigIdx&gt;"</code> when <code>sigIdx</code> is generated by the <code>%roll</code> directive.</li> <li><b>b</b> <code>"%&lt;tImagPart&gt;%&lt;idx&gt;"</code> (e.g., "im3"). The imaginary part of the signal element or "" if the signal is not complex. Usually <code>"%&lt;tImagPart&gt;%&lt;sigIdx&gt;"</code> when <code>sigIdx</code> is generated by the <code>%roll</code> directive.</li> </ul> </li> </ul> <p>Use the <code>idx</code> name when referring to a state or work vector.</p> <p>Functions that accept the three arguments <code>ucv</code>, <code>lcv</code>, <code>sigIdx</code> (or <code>idx</code>) are called differently depending upon whether or not they are used within a <code>%roll</code> directive. If they are used within a <code>%roll</code> directive, <code>ucv</code> is generally specified as "" and, <code>lcv</code> and <code>sigIdx</code> are the same as those specified in the <code>%roll</code> directive. If they are not used within a <code>%roll</code> directive, <code>ucv</code> and <code>lcv</code> are generally specified as "", and <code>sigIdx</code> specifies the index to access.</p>
paramIdx	Parameter index. Sometimes referred to as the parameter element index. The handling of this parameter is very similar to <code>sigIdx</code> above: it can be <code>#</code> , <code>re#</code> , or <code>im#</code> .
stateIdx	State index. Sometimes referred to as the state vector element index. It must evaluate to an integer where the first element starts at 0.

## Overloading sigIdx

The signal index (`sigIdx` sometimes written as `idx`) can be overloaded when passed to most library functions. Suppose you are interested in element 3 of a signal, and `ucv=""`, `lcv=""`. The following table shows

- Values of `sigIdx`
- Whether the signal being referenced is complex
- What the function that uses `sigIdx` returns
- An example of a returned variable
- Data type of the returned variable

Note that “container” in the following table refers to the object that encapsulates both the real and imaginary parts of the number, e.g., `creal_T`, defined in `tmwtypes.h`.

<b>sigIdx</b>	<b>Complex</b>	<b>Function Returns</b>	<b>Example</b>	<b>Data Type</b>
"re3"	Yes	Real part of element 3	<code>u0[2].re</code>	<code>real_T</code>
"im3"	Yes	Imaginary part of element 3	<code>u0[2].im</code>	<code>real_T</code>
"3"	Yes	Complex container of element 3	<code>u0[2]</code>	<code>creal_T</code>
3	Yes	Complex container of element 3	<code>u0[2]</code>	<code>creal_T</code>
"re3"	No	Element 3	<code>u0[2]</code>	<code>real_T</code>
"im3"	No	" "	N/A	N/A
"3"	No	Element 3	<code>u0[2]</code>	<code>real_T</code>
3	No	Element 3	<code>u0[2]</code>	<code>real_T</code>

Now suppose the following:

- 1 You are interested in element 3 of a signal.
- 2 (`ucv = "i" AND lcv == ""`) OR (`ucv = "" AND lcv = "i"`).

The following table shows values of `idx`, whether the signal is complex, and what the function that uses `idx` returns.

<b>sigIdx</b>	<b>Complex</b>	<b>Function Returns</b>
"re3"	Yes	Real part of element <i>i</i>
"im3"	Yes	Imaginary part of element <i>ii</i>
"3"	Yes	Complex container of element <i>i</i>
3	Yes	Complex container of element <i>i</i>
"re3"	No	Element <i>i</i>
"im3"	No	" "
"3"	No	Element <i>i</i>
3	No	Element <i>i</i>

### Notes

- The vector index is added only for wide signals.
- If `ucv` is not an empty string (""), then `ucv` is used instead of `sigIdx` in the above examples and both `lcv` and `sigIdx` are ignored.
- If `ucv` is empty but `lcv` is not empty, then the function returns `&y%<portIdx>[%<lcv>]` and `sigIdx` is ignored.
- It is assumed that the roller has declared and initialized the variables accessed inside the roller. The variables accessed inside the roller should be specified using `rollVars` as the argument to the `%roll` directive.

## **See Also**

### **Related Examples**

- “Target Language Compiler Library Functions Overview” on page 21-2

## Input Signal Functions

### LibBlockInputHasSymbolicWidth(portIdx)

Returns 1 (true) if the specified block input port index has symbolic dimensions. This function take the port index as an input argument.

See LibBlockInputHasSymbolicWidth in blkio\_api.tlc.

### LibBlockInputPortIndexMode(block, pidx)

#### Purpose

Determines the index mode of a block's input port.

#### Arguments

block — Block record

pidx — Port index

#### Returns

" " for a nonindex port, and "Zero-based" or "One-based" otherwise.

#### Description

If an input port of a block is set as an index port and its indexing base is marked as zero-based or one-based, this information is written into the *model.rtw* file. LibBlockInputPortIndexMode queries the indexing base to branch to different code according to what the input port indexing base is.

#### Example

```
%if LibBlockInputPortIndexMode(block, pidx) == "Zero-based"
...
%elseif LibBlockInputPortIndexMode(block, pidx) == "One-based"
...
%else
...
%endif
```

See LibBlockInputPortIndexMode in blkio\_lib.tlc.

### LibBlockInputPortIsContinuousQuantity(portIdx)

Returns whether the input port accepts a co-simulation signal. This function takes the port index as an input argument.

See LibBlockInputPortIsContinuousQuantity in blkio\_api.tlc.

## LibBlockInputSignal(portIdx, ucv, lcv, sigIdx)

Based on the input port number (`portIdx`), the user control variable (`ucv`), the loop control variable (`lcv`), the signal index (`sigIdx`), and where this input signal is coming from, `LibBlockInputSignal` returns the reference to a block input signal.

The returned string value is a valid `rvalue` (right-side value) for an expression. The block input signal can come from another block, a state vector, or an external input, or it can be a literal constant (e.g., 5.0).

---

**Note** Do not use `LibBlockInputSignal` to access the address of an input signal.

---

Because the returned value can be a literal constant, you should not use `LibBlockInputSignal` to access the address of an input signal. To access the address of an input signal, use `LibBlockInputSignalAddr`. Accessing the address of the signal via `LibBlockInputSignal` can result in a reference to a literal constant (e.g., 5.0).

For example, the following would *not* work.

```
%assign u = LibBlockInputSignal(0, "", lcv, sigIdx)
x = &%<u>;
```

If `%<u>` refers to an invariant signal with a value of 4.95, the statement (after being processed by the preprocessor) would be generated as

```
x = &4.95;
```

or, if the input signal sources to ground, the statement could come out as

```
x = &0.0;
```

Neither of these would compile.

Avoid such situations by using `LibBlockInputSignalAddr`.

```
%assign uAddr = LibBlockInputSignalAddr(0, "", lcv, sigIdx)
x = %<uAddr>;
```

The code generator tracks signals and parameters accessed by their addresses and declares them in addressable memory.

### Input Arguments

The following table summarizes the input arguments to `LibBlockInputSignal`.

## LibBlockInputSignal Arguments

Argument	Description
portIdx	Integer specifying the input port index (zero-based).  <b>Note:</b> For certain built-in blocks, portIdx can be a string identifying the port (such as "enable" or "trigger").
ucv	User control variable. Must be a string, either an indexing expression or "".
lcv	Loop control variable. Must be a string, either an indexing expression or "".
sigIdx	Either an integer literal or a string of the form  %<tRealPart>Integer %<tImagPart>Integer  For example, the following signifies the real part of the signal and the imaginary part of the signal starting at 5:  "%<tRealPart>5" "%<tImagPart>5"

### General Usage

Uses of LibBlockInputSignal fall into the categories described below.

#### Direct indexing

If ucv == "" and lcv == "", LibBlockInputSignal returns an indexing expression for the element specified by sigIdx.

#### Loop rolling/unrolling

In this case, lcv and sigIdx are generated by the %roll directive, and ucv must be "". A nonempty value for lcv is allowed only when generated by the %roll directive and when using the Roller TLC file (or a user supplied Roller TLC file that conforms to the same variable/signal offset handling). In addition, calls to LibBlockInputSignal with lcv should occur only when "U" or a specific input port (e.g., "u0") is passed to the %roll directive via the roll variables argument.

The following example shows a single input/single output port S-function.

```
%assign rollVars = ["U", "Y", "P"]
%roll sigIdx=RollRegions, lcv=RollThreshold, block, ...
 "Roller", rollVars
 %assign u = LibBlockInputSignal(0, "", lcv, sigIdx)
 %assign y = LibBlockOutputSignal(0, "", lcv, sigIdx)
 %assign p = LibBlockParameter(0, "", lcv, sigIdx)
 %<y> = %<p> * %<u>;
%endroll
```

With the %roll directive, sigIdx is the starting index of the current roll region and lcv is "" or an indexing variable. The following are examples of valid values:

```
LibBlockInputSignal(0, "", lcv, sigIdx) rtB.blockname[0]
LibBlockInputSignal(0, "", lcv, sigIdx) u[i]
```

In the first example, `LibBlockInputSignal` returns `rtB.blockname[2]` when the input port is connected to the output of another block, and

- The loop control variable (`lcv`) generated by the `%roll` directive is empty, indicating that the current roll region is below the roll threshold, and `sigIdx` is 0.
- The width of the input port is 1, indicating that this port is being scalar expanded.

If `sigIdx` is nonzero, then `rtB.blockname[sigIdx]` is returned. For example, if `sigIdx` is 3, then `rtB.blockname[3]` is returned.

In the second example, `LibBlockInputSignal` returns `u[i]` when the current roll region is above the roll threshold and the input port width is nonscalar (wide). In this case, the Roller TLC file sets up a local variable, `u`, to point to the input signal, and the code in the current `%roll` directive is placed within a `for` loop.

For another example, consider a block with multiple input ports where each port has a width greater than or equal to 1 and at least one port has width equal to 1. The following code sets the output signal to the sum of the squares of the input signals.

```
%assign y = LibBlockOutputSignal(0, "", "", 0)
%<y> = 0;

%assign rollVars = ["U"]
%foreach port = block.NumDataInputPorts - 1
 %roll sigIdx=RollRegions, lcv = RollThreshold, block, ...
 "Roller", rollVars
 %assign u = LibBlockInputSignal(port, "", lcv, sigIdx)
 %<y> += %<u> * %<u>;
 %endroll
%endforeach
```

Because the first parameter of `LibBlockInputSignal` is 0 indexed, you must index the `foreach` loop to start from 0 and end at `NumDataInputPorts-1`.

### User Control Variable (ucv) Handling

This is an advanced mode and generally not required by S-function authors.

If `ucv != ""`, `LibBlockInputSignal` returns an `rvalue` for the input signal using the user control variable indexing expression. The control variable indexing expression has the following form:

```
rvalue_id[%<ucv>]%<optional_real_or_imag_part>
```

To obtain `rvalue_id`, look at the integer part of `sigIdx`. You must specify `sigIdx` because the input to this block can be discontinuous, meaning that the input can come from several different memory areas (signal sources) and `sigIdx` is used to identify the area of interest for the `ucv`. You can also use `sigIdx` to determine whether the real or imaginary part of a signal is to be accessed.

You can obtain `optional_real_or_imag_part` from the string part of `sigIdx` (i.e., "re", or "im", or "").

Note that the value for `lcv` is ignored and `sigIdx` must point to the same element in the input signal to which the `ucv` initially points.

The handling of `ucv` with `LibBlockInputSignal` requires care. Consider a discontinuous input signal feeding an input port as in the following block diagram:

To use `ucv` in a robust manner, you must use the `%roll` directive with a roll threshold of 1 and a Roller TLC file that does not have loop header/trailer setup for this input signal. In addition, you need to use `ROLL_ITERATIONS` to determine the width of the current roll region, as in the following TLC code:

```
{
int i;

%assign rollVars = [""]
%assign threshold = 1
 %roll sigIdx=RollRegions, lcv=threshold, block, ...
 "FlatRoller", rollVars
 %assign u = LibBlockInputSignal(0, "i", "", sigIdx)
 %assign y = LibBlockOutputSignal(0, "i+%<sigIdx>", "", sigIdx)
 %assign p = LibBlockParameter(0, "i+%<sigIdx>", "", sigIdx)
 for (i = 0; i < %<ROLL_ITERATIONS(>); i++) {
 %<y> = %<p> * %<u>;
 }
%endroll
}
```

Note that the `FlatRoller` does not have loop header/trailer setup (`rollVars` is ignored). Its purpose is to walk the `RollRegions` of the block. Alternatively, you can force a contiguous input signal to your block by specifying

```
ssSetInputPortRequiredContiguous(S, port, TRUE)
```

in your S-function.

In this case, the TLC code simplifies to

```
{
%assign u = LibBlockInputSignal(0, "i", "", 0)
%assign y = LibBlockOutputSignal(0, "i", "", 0)
%assign p = LibBlockParameter(0, "i", "", 0)

for (i = 0; i < %<LibBlockInputSignalWidth(0)>; i++) {
 %<y> = %<p> * %<u>;
}
}
```

If you create your own roller and the indexing does not conform to the way the Roller TLC file provided by MathWorks operates, then must to use `ucv` instead of `lcv`.

## Handling Input Arguments: `ucv`, `lcv`, and `sigIdx`

Consider the following cases:

Function (Case 1, 2, 3,4)	Example Return Value
<code>LibBlockInputSignal(0, "i", "", sigIdx)</code>	<code>rtB.blockname[i]</code>
<code>LibBlockInputSignal(0, "i", "", sigIdx)</code>	<code>rtU.signame[i]</code>
<code>LibBlockInputSignal(0, "", lcv, sigIdx)</code>	<code>u0[i1]</code>
<code>LibBlockInputSignal(0, "", lcv, sigIdx)</code>	<code>rtB.blockname[0]</code>

The value returned depends on what the input signal is connected to in the block diagram and how the function is invoked (e.g., in a `%roll` or directly). In the above example,

- Cases 1 and 2 occur when an explicit call is made with the `ucv` set to "i".

Case 1 occurs when `sigIdx` points to the block I/O vector, i.e., the first element that "i" starts with. For example, if you initialize "i" to be starting at offset 5, then you should specify `sigIdx == 5`.

Case 2 occurs when `sigIdx` points to the external input vector, i.e., the first element that "i" starts with. For example, if you initialize "i" to start at offset 20, then you should specify `sigIdx == 20`.

- Cases 3 and 4 receive the same arguments, `lcv` and `sigIdx`; however, they produce different return values.

Case 3 occurs when `LibBlockInputSignal` is called within a `%roll` directive and the current roll region is being rolled (`lcv != ""`).

Case 4 occurs when `LibBlockInputSignal` is called within a `%roll` directive and the current roll region is not being rolled (`lcv == ""`).

When called within a `a%roll` directive, `LibBlockInputSignal` looks at `ucv`, `lcv`, and `sigIdx`, the current roll region, and the current roll threshold to determine the return value. The variable `ucv` has highest precedence, `lcv` has the next highest precedence, and `sigIdx` has the lowest precedence. That is, if `ucv` is specified, it is used (thus, when called in a `%roll` directive it is usually ""). If `ucv` is not specified, and if `lcv` and `sigIdx` are specified, the returned value depends on whether or not the current roll region is being placed in a for loop or being expanded. If the roll region is being placed in a loop, then `lcv` is used; otherwise, `sigIdx` is used.

A direct call to `LibBlockInputSignal` (inside or outside a `%roll` directive) uses `sigIdx` when `ucv` and `lcv` are specified as "".

For an example of `LibBlockInputSignal`, see `sfun_multiport.tlc`.

See also `blkio.lib.tlc`.

## `LibBlockInputSignalAddr(portIdx, ucv, lcv, sigIdx)`

Returns a string that provides the memory address of the specified block input port signal.

When you need an input signal address, you must use `LibBlockInputSignalAddr` instead of appending an "&" to the string returned by `LibBlockInputSignal`. For example,

`LibBlockInputSignal` can return a literal constant, such as 5 (i.e., an invariant input signal). The code generator tracks when `LibBlockInputSignalAddr` is called on an invariant signal and declares the signal as `const` data (which is addressable), instead of being placed as a literal constant in the generated code (which is not addressable).

Note that the last input argument, `sigIdx`, is not overloaded, which it is in `LibBlockInputSignal`. Hence, if the input signal is complex, the address of the complex container is returned.

### Example

To get the address of a wide input signal and pass it to a user function for processing, you could use

```
%assign uAddr = LibBlockInputSignalAddr(0, "", "", 0)
%assign y = LibBlockOutputSignal(0, "", "", 0)
%<y> = myfcn(%<uAddr>);
```

See `LibBlockInputSignalAddr` in `blkio.lib.tlc`.

### LibBlockInputSignalAliasedThruDataTypeName(portIdx, reim)

Returns the name of the aliased thru data type (e.g., `int_T`, ... `creal_T`) corresponding to the specified block input port. Specify the `reim` argument as "" (empty) if you want the complete signal type name.

For example, if `reim == ""` and the first output port is real and complex, the data type name placed in `dtname` is `creal_T`.

```
%assign dtname = LibBlockInputSignalDataTypeName(0, "")
```

Specify `reim` as `tRealPart` if you want the raw element type name. For example, if `reim == tRealPart` and the first output port is real and complex, the data type name returned is `real_T`.

```
%assign dtname = LibBlockOutputSignalDataTypeName(0, tRealPart)
```

See `LibBlockInputSignalAliasedThruDataTypeName` in `blkio.lib.tlc`.

### LibBlockInputSignalAllowScalarExpandedExpr(block, portIdx)

Allow the input signal to be an expression, even when an output signal is wide. This function takes the block record and the port index as input arguments. Call this function from within the `BlockInstanceSetup` function.

See `LibBlockInputSignalAllowScalarExpandedExpr` in `blkio_api.tlc`.

### LibBlockInputSignalASCIIEscapedUnitExpr(portIdx)

Returns the escaped name of the units corresponding to the specified block input port. This function takes the port index as an input argument.

See `LibBlockInputSignalASCIIEscapedUnitExpr` in `blkio_api.tlc`.

### **LibBlockInputSignalConnected(portIdx)**

Returns 1 if the specified input port is connected to a block other than the Ground block and 0 otherwise.

See `LibBlockInputSignalConnected` in `inblkio_api.tlc`.

### **LibBlockInputSignalDataTypeId(portIdx)**

Returns the numeric identifier (`id`) corresponding to the data type of the specified block input port.

If the input port signal is complex, `LibBlockInputSignalDataTypeId` returns the data type of the real part (or the imaginary part) of the signal.

See `LibBlockInputSignalDataTypeId` in `blkio.lib.tlc`.

### **LibBlockInputSignalDataTypeName(portIdx, reim)**

Returns the name of the data type (e.g., `int_T`, ... `creal_T`) corresponding to the specified block input port.

Specify the `reim` argument as `""` if you want the complete signal type name. For example, if `reim=""` and the first output port is real and complex, the data type name placed in `dtname` is `creal_T`.

```
%assign dtname = LibBlockInputSignalDataTypeName(0,"")
```

Specify the `reim` argument as `tRealPart` if you want the raw element type name. For example, if `reim=tRealPart` and the first output port is real and complex, the data type name returned is `real_T`.

```
%assign dtname = LibBlockInputSignalDataTypeName(0,tRealPart)
```

See `LibBlockInputSignalDataTypeName` in `blkio.lib.tlc`.

### **LibBlockInputSignalDimensions(portIdx)**

Returns the dimensions vector of the specified block input port, e.g., `[2,3]`.

See `LibBlockInputSignalDimensions` in `blkio_api.tlc`.

### **LibBlockInputSignalIsComplex(portIdx)**

Returns 1 if the specified block input port is complex, 0 otherwise.

See `LibBlockInputSignalIsComplex` in `blkio_api.tlc`.

### **LibBlockInputSignalIsExpr(portIdx)**

Returns 1 (true) if the input signal is an expression (versus a variable), and 0 (false) otherwise. This function takes the port index as an input argument.

See `LibBlockInputSignalIsExpr` in `blkio_api.tlc`.

**LibBlockInputSignalIsFrameData(portIdx)**

Returns 1 if the specified block input port is frame based, 0 otherwise.

See `LibBlockInputSignalIsFrameData` in `blkio_api.tlc`.

**LibBlockInputSignalIsTrivialExpr(portIdx)**

Returns 1 (true) if the input signal is a trivial expression (versus a variable), and 0 (false) otherwise. This function take the port index as an input argument.

See `LibBlockInputSignalIsTrivialExpr` in `blkio_api.tlc`.

**LibBlockInputSignalLocalSampleTimeIndex(portIdx)**

Returns the local sample time index corresponding to the specified block input port.

See `LibBlockInputSignalLocalSampleTimeIndex` in `blkio.lib.tlc`.

**LibBlockInputSignalNumDimensions(portIdx)**

Returns the number of dimensions of the specified block input port.

See `LibBlockInputSignalNumDimensions` in `blkio_api.tlc`.

**LibBlockInputSignalOffsetTime(portIdx)**

Returns the offset time corresponding to the specified block input port.

See `LibBlockInputSignalOffsetTime` in `blkio.lib.tlc`.

**LibBlockInputSignalSampleTime(portIdx)**

Returns the sample time corresponding to the specified block input port.

See `LibBlockInputSignalSampleTime` in `blkio.lib.tlc`.

**LibBlockInputSignalSampleTimeIndex(portIdx)**

Returns the sample time index corresponding to the specified block input port.

See `LibBlockInputSignalSampleTimeIndex` in `blkio.lib.tlc`.

**LibBlockInputSignalSymbolicDimensions(portIdx)**

Returns the number of dimensions of the specified block input port.

See `LibBlockInputSignalSymbolicDimensions(portIdx)` in `blkio.lib.tlc`.

### **LibBlockInputSignalSymbolicWidth(portIdx)**

Returns the symbolic width of the specified block input port.

See `LibBlockInputSignalSymbolicWidth(portIdx)` in `blkio.lib.tlc`.

### **LibBlockInputSignalWidth(portIdx)**

Returns the width of the specified block input port index.

See `LibBlockInputSignalWidth` in `blkio_api.tlc`.

### **LibBlockInputSignalUnitExpr(portIdx)**

Returns the name of the units corresponding to the specified block input port. This function takes the port index as an input argument.

See `LibBlockInputSignalUnitExpr` in `blkio_api.tlc`.

### **LibBlockInputSignalUnitId(portIdx)**

Returns the numeric identifier (id) corresponding to the units of the specified block input port. This function takes the port index as an input argument.

See `LibBlockInputSignalUnitId` in `blkio_api.tlc`.

See also `LibBlockInputSignalUnitExp` and `LibBlockOutputSignalUnitId` in `blkio_api.tlc`.

### **LibBlockNumInputPorts(block)**

Returns the number of data input ports of a block (excludes control ports).

See `LibBlockNumInputPorts` in `blocklib.tlc`.

## Output Signal Functions

### **LibBlockAssignOutputSignal(portIdx, ucv, lcv, sigIdx, rhs)**

Based on the output port number (`portIdx`), the user control variable (`ucv`), the loop control variable (`lcv`), the signal index (`sigIdx`), and the output signal destination, `LibBlockAssignOutputSignal` assigns a block's output to a specified right hand side value, (`rhs`).

See `LibBlockAssignOutputSignal` in `customstoragelib.tlc`.

### **LibBlockGetNumFcnCallOutputs(block)**

Returns the number of function call outputs for the specified block. This function takes the block record as an input argument.

See `LibBlockGetNumFcnCallOutputs` in `block_api.tlc`.

### **LibBlockGetNumFcnCallOutputsDsts(block)**

Returns the number of function call output destinations for the specified block. This function takes the block record as an input argument.

See `LibBlockGetNumFcnCallOutputDsts` in `block_api.tlc`.

### **LibBlockNumOutputPorts(block)**

Returns the number of data output ports of a block (excludes control and state ports).

See `LibBlockNumOutputPorts` in `blocklib.tlc`.

### **LibBlockOutputHasSymbolicWidth(portIdx)**

Returns 1 (true) if the specified block output port index has symbolic dimensions, and 0 (false) otherwise. This function takes the port index as an input argument.

See `LibBlockOutputHasSymbolicWidth` in `blkio_api.tlc`.

### **LibBlockOutputPortIndexMode(block, pidx)**

#### **Purpose**

Determines the index mode of a block's output port.

#### **Description**

If a block's output port is set as an index port and its indexing base is marked as zero-based or one-based, this information is written into the `model.rtw` file. `LibBlockOutputPortIndexMode` queries the indexing base to branch to different code according to what the output port indexing base is.

**Example**

```
%if LibBlockOutputPortIndexMode(block, idx) == "Zero-based"
 ...
%elseif LibBlockOutputPortIndexMode(block, idx) == "One-based"
 ...
%else
 ...
%endif
```

**Arguments**

block — Block record

pidx — Port index

**Returns**

"" for a nonindex port, and "Zero-based" or "One-based" otherwise.

See LibBlockOutputPortIndexMode in blkio.lib.tlc.

**LibBlockOutputPortIsContinuousQuantity(portIdx)**

Returns whether the output port represents a co-simulation signal. This function takes the port index as an input argument.

See LibBlockOutputPortIsContinuousQuantity in blkio\_api.tlc.

**LibBlockOutputSignal(portIdx, ucv, lcv, sigIdx)**

Based on the output port number (portIdx), the user control variable (ucv), the loop control variable (lcv), the signal index (sigIdx), and the output signal destination, LibBlockOutputSignal returns a reference to a block output signal.

The returned value is a valid lvalue (left-side value) for an expression. The block output destination can be a location in the block I/O vector (another block's input), the state vector, or an external output.

---

**Note** Do not use LibBlockOutputSignal to access the address of an output signal.

---

The code generator tracks when a variable (e.g., a signal or parameter) is accessed by its address. To access the address of an output signal, use LibBlockOutputSignalAddr as in the following example:

```
%assign yAddr = LibBlockOutputSignalAddr(0, "", lcv, sigIdx)
x = %<yAddr>;
```

See LibBlockOutputSignal in blkio.lib.tlc.

**LibBlockOutputSignalAddr(portIdx, ucv, lcv, sigIdx)**

Returns a string that provides the memory address of the specified block output port signal.

When an output signal address is required, you must use `LibBlockOutputSignalAddr` instead of taking the address that is returned by `LibBlockOutputSignal`. For example, `LibBlockOutputSignal` can return a literal constant, such as 5 (i.e., an invariant output signal). When `LibBlockOutputSignalAddr` is called on an invariant signal, the signal is declared as a `const` instead of being placed as a literal constant in the generated code.

Note that unlike `LibBlockOutputSignal`, the last argument, `sigIdx`, is not overloaded. Hence, if the output signal is complex, the address of the complex container is returned.

### Example

To get the address of a wide output signal and pass it to a user function for processing, you could use

```
%assign u = LibBlockOutputSignalAddr(0, "", "", 0)
%assign y = LibBlockOutputSignal(0, "", "", 0)
%<y> = myfcn (%<u>);
```

See `LibBlockOutputSignalAddr` in `blkio.lib.tlc`.

### LibBlockOutputSignalAliasedThruDataTypeName(portIdx, reim)

Returns the type name string (e.g., `int_T`, ... `creal_T`) of the aliased data type corresponding to the specified block output port.

Specify the `reim` argument as "" if you want the complete signal type name. For example, if `reim == ""` and the first output port is real and complex, the data type placed in `dtname` is `creal_T`:

```
%assign dtname = LibBlockOutputSignalAliasedThroughDataTypeName(0x,"")
```

Specify the `reim` argument as `tRealPart` if you want the raw element type name. For example, if `reim == tRealPart` and the first output port is real and complex, the data type name returned is `real_T`.

```
%assign dtname = LibBlockOutputSignalAliasedThroughDataTypeName(0,tRealPart)
```

See `LibBlockOutputSignalAliasedThruDataTypeName` in `blkio.lib.tlc`.

### LibBlockOutputSignalBeingMerged(portIdx)

Returns whether the specified output port is connected to a Merge block.

See `LibBlockOutputSignalBeingMerged` in `blkio_api.tlc`.

### LibBlockOutputSignalConnected(portIdx)

Returns 1 if the specified output port is connected to a block other than the Ground block and 0 otherwise.

See `LibBlockOutputSignalConnected` in `blkio_api.tlc`.

### LibBlockOutputSignalDataTypeId(portIdx)

Returns the numeric ID corresponding to the data type of the specified block output port.

If the output port signal is complex, `LibBlockOutputSignalDataTypeId` returns the data type of the real (or the imaginary) part of the signal.

See `LibBlockOutputSignalDataTypeId` in `blkio.lib.tlc`.

### **LibBlockOutputSignalDataTypeName(portIdx, reim)**

Returns the type name string (e.g., `int_T`, ... `creal_T`) of the data type corresponding to the specified block output port.

Specify the `reim` argument as `""` if you want the complete signal type name. For example, if `reim==""` and the first output port is real and complex, the data type name placed in `dtname` is `creal_T`.

```
%assign dtname = LibBlockOutputSignalDataTypeName(0x,"")
```

Specify the `reim` argument as `tRealPart` if you want the raw element type name. For example, if `reim==tRealPart` and the first output port is real and complex, the data type name returned is `real_T`.

```
%assign dtname = LibBlockOutputSignalDataTypeName(0,tRealPart)
```

See `LibBlockOutputSignalDataTypeName` in `blkio.lib.tlc`.

### **LibBlockOutputSignalDimensions(portIdx)**

Returns the dimensions of the specified block output port.

See `LibBlockOutputSignalDimensions` in `blkio_api.tlc`.

### **LibBlockOutputSignalIsComplex(portIdx)**

Returns 1 if the specified block output port is complex, 0 otherwise.

See `LibBlockOutputSignalIsComplex` in `blkio_api.tlc`.

### **LibBlockOutputSignalIsConstExpr(portIdx)**

Returns 1 (true) if the output signal is a constant expression, and 0 (false) otherwise. Note that a constant expression is constant even if a block output function calls it. This function takes the port index as an input argument.

See `LibBlockOutputSignalIsConstExpr` in `blkio_api.tlc`.

### **LibBlockOutputSignalIsExpr(portIdx)**

Returns 1 (true) if the output signal is an expression, and 0 (false) otherwise.

See `LibBlockOutputSignalIsExpr` in `blkio_api.tlc`.

### **LibBlockOutputSignalIsExprInOutputs(portIdx)**

Returns 1 (true) if the output signal is an expression in the outputs function, and 0 (false) otherwise. You can use this function as a low-level utility to get access to what the value will be when generating the block's output code. Use this function in the `BlockInstanceSetup` function. This function takes the port index as an input argument.

See `LibBlockOutputSignalIsExprInOutputs` in `blkio_api.tlc`.

### **LibBlockOutputSignalIsFrameData(portIdx)**

Returns 1 if the specified block output port is frame based, 0 otherwise.

See `LibBlockOutputSignalIsFrameData` in `blkio_api.tlc`.

### **LibBlockOutputSignalIsNonConstExpr(portIdx)**

Returns 1 (true) if the output signal is a non-constant expression, and 0 (false) otherwise. This function takes the port index as an input argument.

See `LibBlockOutputSignalIsNonConstExpr` in `blkio_api.tlc`.

### **LibBlockOutputSignalIsTrivialExpr(portIdx)**

Returns 1 (true) if the output signal is a trivial expression, and 0 (false) otherwise. This function takes the port index as an input argument.

See `LibBlockOutputSignalIsTrivialExpr` in `blkio_api.tlc`.

### **LibBlockOutputSignalLocalSampleTimeIndex(portIdx)**

Returns the local sample time index corresponding to the specified block output port.

See `LibBlockOutputSignalLocalSampleTimeIndex` in `blkio_api.tlc`.

### **LibBlockOutputSignalNumDimensions(portIdx)**

Returns the number of dimensions of the specified block output port.

See `LibBlockOutputSignalNumDimensions` in `blkio_api.tlc`.

### **LibBlockOutputSignalOffsetTime(portIdx)**

Returns the offset time corresponding to the specified block output port.

See `LibBlockOutputSignalOffsetTime` in `blkio_lib.tlc`.

### **LibBlockOutputSignalSampleTime(portIdx)**

Returns the sample time corresponding to the specified block output port.

See `LibBlockOutputSignalSampleTime` in `blkio.lib.tlc`.

### **LibBlockOutputSignalSampleTimeIndex(portIdx)**

Returns the sample time index corresponding to the specified block output port.

See `LibBlockOutputSignalSampleTimeIndex` in `blkio.lib.tlc`.

### **LibBlockOutputSignalSymbolicDimensions(portIdx)**

Returns the symbolic dimensions of specified block output port.

See `LibBlockOutputSignalSymbolicDimensions` in `blkio.lib.tlc`.

### **LibBlockOutputSignalSymbolicWidth(portIdx)**

Returns the symbolic width of specified block output port.

See `LibBlockOutputSignalSymbolicWidth` in `blkio.lib.tlc`.

### **LibBlockOutputSignalWidth(portIdx)**

Returns the width of the specified block output port.

See `LibBlockOutputSignalWidth` in `blkio_api.tlc`.

### **LibBlockOutputSignalUnitExpr(portIdx)**

Returns the type name string of the units corresponding to the specified output port. This function takes the port index as an input argument.

See `LibBlockOutputSignalUnitExpr` in `blkio_api.tlc`.

### **LibBlockOutputSignalUnitId(portIdx)**

Returns the numeric ID corresponding to the units of the specified block output port. This function takes the port index as an input argument.

See `LibBlockOutputSignalUnitId` in `blkio_api.tlc`.

## Parameter Functions

### LibBlockMatrixParameter

`LibBlockMatrixParameter(param, rucv, rlcV, ridX, cucv, clcv, cidX)` returns a matrix parameter for a block, given the row and column user control variables (`rucv`, `cucv`), loop control variables (`rlcv`, `clcv`), and indices (`ridx`, `cidx`). Generally, blocks should use `LibBlockParameter`. If you have a matrix parameter, you should write it as a column-major vector and access it via `LibBlockParameter`.

---

**Note** Loop rolling is currently not supported, and will generate an error if requested (i.e., if either `rlcv` or `clcv` is not equal to "").

---

The row and column index arguments are similar to the arguments for `LibBlockParameter`. The column index (`cidx`) is overloaded to handle complex numbers.

See `LibBlockMatrixParameter` in `paramlib.tlc`.

### LibBlockMatrixParameterAddr

`LibBlockMatrixParameterAddr(param, rucv, rlcV, ridX, cucv, clcv, cidX)` returns the address of a matrix parameter.

---

**Note** `LibBlockMatrixParameterAddr` returns the address of a matrix parameter. Loop rolling is not supported (i.e., `rlcv` and `clcv` should both be an empty string).

---

See `LibBlockMatrixParameterAddr` in `paramlib.tlc`.

### LibBlockMatrixParameterBaseAddr

`LibBlockMatrixParameterBaseAddr(param)` returns the base address of a matrix parameter.

See `LibBlockMatrixParameterBaseAddr` in `paramlib.tlc`.

### LibBlockParamSetting

`LibBlockParamSetting(bType, psType)` returns the string of a specified parameter setting for a specified block type. If you pass an empty block type into this function, the parameter setting will be assumed to be in the `ParamSettings` record of the block. If a nonempty block type is passed into the function, the parameter settings will be assumed to be in the `%<Btype>ParamSettings` record of that block.

See `LibBlockParamSetting` in `paramlib.tlc`.

### LibBlockParameter

Based on the parameter reference (`param`), the user control variable (`ucv`), the loop control variable (`lcV`), the signal index (`sigIdx`), and the state of parameter inlining, `LibBlockParameter(param,`

ucv, lcv, sigIdx) returns a reference to a block parameter. The returned value is a valid rvalue (right-side value for an expression). For example,

Case	Function Call	Can Produce
1	LibBlockParameter(Gain, "i", lcv, sigIdx)	rtP.blockname[i]
2	LibBlockParameter(Gain, "i", lcv, sigIdx)	rtP.blockname
3	LibBlockParameter(Gain, "", lcv, sigIdx)	p_Gain[i]
4	LibBlockParameter(Gain, "", lcv, sigIdx)	p_Gain
5	LibBlockParameter(Gain, "", lcv, sigIdx)	4.55
6	LibBlockParameter(Gain, "", lcv, sigIdx)	rtP.blockname.re
7	LibBlockParameter(Gain, "", lcv, sigIdx)	rtP.blockname.im

To illustrate the basic workings of LibBlockParameter, assume a noncomplex vector signal where Gain[0]=4.55:

```
LibBlockParameter(Gain, "", "i", 0)
```

Case	Rolling	Inline Parameter	Type	Result	Required in Memory
1	0	Yes	Scalar	4.55	No
2	1	Yes	Scalar	4.55	No
3	0	Yes	Vector	4.55	No
4	1	Yes	Vector	p_Gain[i]	Yes
5	0	No	Scalar	rtP.blk.Gain	No
6	0	No	Scalar	rtP.blk.Gain	No
7	0	No	Vector	rtP.blk.prm[0]	No
8	0	No	Vector	p.Gain[i]	Yes

Note Case 4. Even though Inline Parameter is Yes, the parameter must be placed in memory (RAM), because it is accessed inside a for loop.

---

**Note** LibBlockParameter also supports expressions when used with inlined parameters and parameter tuning.

---

For example, if the parameter field had the MATLAB expression '2\*a', LibBlockParameter would return the C expression '(2\*a)'. The list of functions supported by LibBlockParameter is determined by the functions FcnConvertNodeToExpr and FcnConvertIdToFcn. To enhance functionality, augment or update either of these functions.

Note that certain types of expressions are not supported, such as x\*y where both x and y are nonscalar expressions.

See the documentation about tunable parameters for more details on the exact functions and syntax that are supported.

**Warning**

Do not use `LibBlockParameter` to access the address of a parameter, or you may might erroneously reference a number (i.e., `&4.55`) when the parameter is inlined. You can avoid this situation by using `LibBlockParameterAddr`.

See `LibBlockParameter` in `paramlib.tlc`.

**LibBlockParameterAddr**

`LibBlockParameterAddr(param, ucv, lcv, idx)` returns the address of a block parameter.

Using `LibBlockParameterAddr` to access a parameter when the global `InlineParams` variable is equal to 1 will cause the variable to be declared `const` in RAM instead of being inlined.

Accessing the address of an expression when the expression has multiple tunable/rolled variables in it will result in an error.

See `LibBlockParameterAddr` in `paramlib.tlc`.

**LibBlockParameterBaseAddr**

`LibBlockParameterBaseAddr(param)` returns the base address of a block parameter.

Using `LibBlockParameterBaseAddr` to access a parameter when the global `InlineParams` variable is equal to one will cause the variable to be declared `const` in RAM instead of being inlined.

Accessing the address of an expression when the expression has multiple tunable/rolled variables in it will result in an error.

See `LibBlockParameterBaseAddr` in `paramlib.tlc`.

**LibBlockParameterDataTypeId**

`LibBlockParameterDataTypeId(param)` returns the numeric ID corresponding to the data type of the specified block parameter.

See `LibBlockParameterDataTypeId` in `paramlib.tlc`.

**LibBlockParameterDataTypeName**

`LibBlockParameterDataTypeName(param, reim)` returns the name of the data type corresponding to the specified block parameter.

See `LibBlockParameterDataTypeName` in `paramlib.tlc`.

**LibBlockParameterDimensions**

`LibBlockParameterDimensions(param)` returns a row vector of length `N` (where `N >= 1`) giving the dimensions of the parameter data.

For example,

```
%assign dims = LibBlockParameterDimensions("paramName")
%assign nDims = SIZE(dims,1)
%foreach i=nDims
 /* Dimension %<i+1> = %<dims[i]> */
%endforeach
```

`LibBlockParameterDimensions` differs from `LibBlockParameterSize` in that it returns the dimensions of the parameter data prior to collapsing the `Matrix` parameter to a column-major vector. The collapsing occurs for run-time parameters that have specified their `outputAsMatrix` field as `False`.

See `LibBlockParameterDimensions` in `paramlib.tlc`.

## LibBlockParameterIsComplex

`LibBlockParameterIsComplex(param)` returns 1 if the specified block parameter is complex, 0 otherwise.

See `LibBlockParameterIsComplex` in `paramlib.tlc`.

## LibBlockParameterSize

`LibBlockParameterSize(param)` returns a vector of size 2 in the format `[nRows, nCols]` where `nRows` is the number of rows and `nCols` is the number of columns.

See `LibBlockParameterSize` in `paramlib.tlc`.

## LibBlockParameterString

Based on the block parameter reference (`param`), `LibBlockParameterString(param)` returns the specified block parameter interpreted as a string, for example, this function returns:

- `STRINGOF(param.Value[0])` if the parameter is a row matrix
- `STRINGOF(param.Value)` otherwise

---

**Note** It is an error to invoke this function with a matrix-valued parameter with more than one row.

---

If you are accessing only a parameter value by using `LibBlockParameterValue` or `LibBlockParameterString`, consider converting the parameter from `Tunable` to `Nontunable`. Then, use `ssWriteRTWParamSettings` to write the value of the parameter to the `model.rtw` file. Inlining parameters reduces RAM usage because the code generator uses the numeric values of parameters, instead of their symbolic names, in the generated code.

See `LibBlockParameterString` in `paramlib.tlc`.

## LibBlockParameterValue

Based on the block parameter reference (`param`) and the index element of the array (`eIdx`), `LibBlockParameterValue(param, eIdx)` returns the numeric value of a parameter. You can use

the `LibBlockParameterWidth(param)` function to get the width of the array, and then use `elidx` (valid values of 0 to width-1) to get a particular element of the array.

If you are accessing only a parameter value by using `LibBlockParameterValue` or `LibBlockParameterString`, consider converting the parameter from Tunable to Nontunable. Then, use `ssWriteRTWParamSettings` to write the value of the parameter to the `model.rtw` file. Inlining parameters reduces RAM usage because the code generator uses the numeric values of parameters, instead of their symbolic names, in the generated code.

### Example

If you want to generate code for a different integrator depending on a parameter for a block, use:

```
%assign mode = LibBlockParameterValue(Integrator, 0)
%switch (mode)
 %case 1
 %<CodeForIntegrator1>
 %break
 %case 2
 %<CodeForIntegrator2>
 %break
 %default
 Error: Unrecognized integrator value.
 %break
%endswitch
```

See `LibBlockParameterValue` in `paramlib.tlc`.

### LibBlockParameterWidth

`LibBlockParameterWidth(param)` returns the number of elements (width) of a parameter.

See `LibBlockParameterWidth` in `paramlib.tlc`.

### LibGetParameterValue

`LibGetParameterValue` returns the data vector of the model parameter written to the `ModelParameters` record in the `model.rtw`. For example, you can use:

```
%assign numRowsValues = SIZE(LibGetParameterValue(RowIndex), 1)
```

For records that are not model parameters, the code generator returns the `record.Value`. Use the `LibGetParameterValue` function to access the data vector of the model parameter instead of fetching the `record.Value`.

If the data vector of the model parameter that the function `LibGetParameterValue` returns is a numeric scalar and results in an error for a numeric expression, append a `[0]` to it. For example, if

```
%assign sum = LibGetParameterValue(RowIndex) + 10
```

returns this error:

```
"The + operator only works on numeric arguments"
```

Then modify the expression as:

```
%assign sum = LibGetParameterValue(RowIndex)[0] + 10
```

See `LibGetParameterValue` in `paramlib.tlc`.

## Block State and Work Vector Functions

### **LibBlockAssignDWork(dwork, ucv, lcv, sigIdx, rhs)**

Based on the block's dwork index or record (`dwork`), the user control variable (`ucv`), the loop control variable (`lcv`), and the signal index (`sigIdx`), `LibBlockAssignDWork` assigns a block's dwork to a specified right hand side value (`rhs`).

See `LibBlockAssignDWork` in `customstoragelib.tlc`.

### **LibBlockContinuousState(ucv, lcv, idx)**

Returns a string corresponding to the specified block continuous state (CSTATE) element.

See `LibBlockContinuousState` in `blocklib.tlc`.

### **LibBlockContinuousStateDerivative(ucv, lcv, idx)**

Returns a string corresponding to the specified block continuous state (CSTATE) element.

See also `LibBlockDiscreteState`.

See `LibBlockContinuousStateDerivative` in `blocklib.tlc`.

### **LibBlockContStateDisabled(ucv, lcv, idx)**

Returns a string corresponding to the specified block continuous state (CSTATE) element.

See also `LibBlockDiscreteState`.

See `LibBlockContStateDisabled` in `blocklib.tlc`.

### **LibBlockDWork(dwork, ucv, lcv, idx)**

Returns a string corresponding to the specified block dwork element. The last input argument is overloaded to handle complex dworks.

`idx = "re3"` — Returns the real part of element 3 if `dwork` is complex, otherwise returns element 3.

`idx = "im3"` — Returns the imaginary part of element 3 if `dwork` is complex, otherwise returns "".

`idx = "3"` — Returns the complex container of element 3 if `dwork` is complex, otherwise returns element 3.

If either `ucv` or `lcv` is specified (i.e., it is not equal to "") then the index part of the last input argument (`sigIdx`) is ignored.

See `LibBlockDWork` in `blocklib.tlc`.

**LibBlockDWorkAddr(dwork, ucv, lcv, idx)**

Returns a string corresponding to the address of the specified block dwork element.

See LibBlockDWorkAddr in blocklib.tlc.

**LibBlockDWorkDataTypeId(dwork)**

Returns the data type ID of the specified block dwork.

See LibBlockDWorkDataTypeId in blocklib.tlc.

**LibBlockDWorkDataTypeName(dwork, reim)**

Returns the data type name of the specified block dwork.

See LibBlockDWorkDataTypeName in blocklib.tlc.

**LibBlockDWorkIsComplex(dwork)**

Returns 1 if the specified block dwork is complex. Returns 0 otherwise.

See LibBlockDWorkIsComplex in blocklib.tlc.

**LibBlockDWorkName(dwork)**

Returns the name of the specified block dwork.

See LibBlockDWorkName in blocklib.tlc.

**LibBlockDWorkStorageClass(dwork)**

Returns the storage class of the specified block dwork.

See LibBlockDWorkStorageClass in blocklib.tlc.

**LibBlockDWorkStorageTypeQualifier(dwork)**

Returns the storage type qualifier of the specified block dwork.

See LibBlockDWorkStorageTypeQualifier in blocklib.tlc.

**LibBlockDWorkUsedAsDiscreteState(dwork)**

Returns 1 if the specified block dwork is used as a discrete state, returns 0 otherwise.

See LibBlockDWorkUsedAsDiscreteState in blocklib.tlc.

**LibBlockDWorkWidth(dwork)**

Returns the width of the specified block dwork.

See LibBlockDWorkWidth in blocklib.tlc.

**LibBlockDiscreteState(ucv, lcv, idx)**

Returns a string corresponding to the specified block discrete state (DSTATE) element.

See LibBlockDiscreteState in blocklib.tlc.

**LibBlockIWork(definediwork, ucv, lcv, idx)**

Returns a string corresponding to the specified block IWORK element. See LibBlockRWork.

See LibBlockIWork in blocklib.tlc.

**LibBlockMode(ucv, lcv, idx)**

Returns a string corresponding to the specified block MODE element.

See LibBlockMode in blocklib.tlc.

**LibBlockNonSampledZC(ucv, lcv, NSZCIdx)**

Returns a string corresponding to the specified block NSZC.

LibBlockNonSampledZC returns an element for the nonsampled zero-crossing state based on ucv, lcv, and NSZCIdx.

**Arguments**

ucv — User control variable string

lcv — Loop control variable string

NSZCIdx — Nonsampled zero-crossing index

See LibBlockNonSampledZC in blocklib.tlc.

**LibBlockPWork(definedpwork, ucv, lcv, idx)**

Returns a string corresponding to the specified block PWORK element. See LibBlockRWork.

See LibBlockPWork in blocklib.tlc.

**LibBlockRWork(definedrwork, ucv, lcv, idx)**

Returns a string corresponding to the specified block RWORK element. The first argument, definedrwork, is a symbol defined in the mdlRTW routine of the C MEX file with code like:

```
ssWriteRTWorkVect([...], "RWork", [...], "MyRWorkName", [...])
```

Alternatively, if `RWork` defines have not been made, `definedrwork` is ignored and the raw `RWork` vector is accessed. In this case, uses in a loop rolling context are disallowed.

See `LibBlockRWork` in `blocklib.tlc`.

## **LibBlockZCSignalValue(ucv, lcv, zcsIdx, zcElIdx)**

### **Purpose**

Returns a string corresponding to the specified block `ZCSignalValue`

### **Arguments**

`ucv`

User control variable string.

`lcv`

Loop control variable string.

`zcsIdx`

zc signal Idx

`zcElIdx`

Idx of zc signal element in the zc signal

### **Description**

`LibBlockZCSignalValue` returns an element for the zero crossing state based on `ucv`, `lcv`, and `zcsIdx`.

See `LibBlockZCSignalValue` in `blocklib.tlc`.

## Block Path and Error Reporting Functions

### **LibBlockReportError(block, errorstring)**

Use `LibBlockReportError` when reporting errors for a block. `LibBlockReportError` is designed to be used from block target files (e.g., the TLC file for an inlined S-function).

`LibBlockReportError` can be called with or without the block record scoped. To call the function without a block record scoped, pass the block record. To call the function when the block is scoped, pass `block = []`.

```
LibBlockReportError([], "error string")
-- If block is scoped
LibBlockReportError(blockrecord, "error string")
-- If block record is available
```

See `LibBlockReportError` in `utllib.tlc`.

### **LibBlockReportFatalError(block, errorstring)**

Use `LibBlockReportFatalError` when reporting fatal (assert) errors for a block. Use `LibBlockReportFatalError` for defensive programming. Refer to “Generating Errors from TLC Files” on page A-2.

See `LibBlockReportFatalError` in `utllib.tlc`.

### **LibBlockReportWarning(block, warnstring)**

Use `LibBlockReportWarning` when reporting warnings for a block. `LibBlockReportWarning` is designed to be used from block target files (e.g., the TLC file for an inlined S-function).

`LibBlockReportWarning` can be called with or without the block record scoped. To call this function without a block record scoped, pass the block record. To call this function when the block is scoped, pass `block = []`.

```
LibBlockReportWarning([], "warn string")
-- If block is scoped
LibBlockReportWarning(blockrecord, "warn string")
-- If block record is available
```

See `LibBlockReportWarning` in `utllib.tlc`.

### **LibGetBlockName(block)**

`LibGetBlockName` returns the short block path name string for a block record, excluding carriage returns and other special characters that can be present in the name.

See `LibGetBlockName` in `utllib.tlc`.

## **LibGetBlockPath(block)**

`LibGetBlockPath` returns the full block path name string for a block record, including carriage returns and other special characters that can be present in the name. Currently, the only other special string sequences defined are `'/*'` and `'*/'`.

The full block path name string is useful when you are accessing blocks from MATLAB. For example, you can use the full block name with `hilite_system` via `FEVAL` to match the Simulink path name exactly.

Use `LibGetFormattedBlockPath` to get a block path suitable for placing in a comment or error message.

See `LibGetBlockPath` in `utllib.tlc`.

## **LibGetFormattedBlockPath(block)**

`LibGetFormattedBlockPath` returns the full path name string of a block without special characters. The string returned from `LibGetFormattedBlockPath` is suitable for placing the block name, in comments or generated code, on a single line.

Currently, the special characters are carriage returns, `'/*'`, and `'*/'`. A carriage return is converted to a space, `'/*'` is converted to `'/+'`, and `'*/'` is converted to `'+/'`. Note that a `'/'` in the name is automatically converted to a `'//'` to distinguish it from a path separator.

Use `LibGetBlockPath` to get the block path for MATLAB functions used in reference blocks in your model.

See `LibGetFormattedBlockPath` in `utllib.tlc`.

## Code Configuration Functions

### LibAddSourceFileCustomSection(file, builtInSection, newSection)

Adds a custom section to a source file. You must associate a custom section with one of the built-in sections: Includes, Defines, Types, Enums, Definitions, Declarations, Functions, or Documentation. Nothing happens if the section already exists, except to report an error if a inconsistent built-in section association is attempted. `LibAddSourceFileCustomSection` is available only with the Embedded Coder product.

#### Arguments

`file` — Source file reference

`builtInSection` — Name of the associated built-in section

`newSection` — Name of the new (custom) section

See `LibAddSourceFileCustomSection` in `codetemplatelib.tlc`.

### LibAddToCommonIncludes(incFileName)

Adds items to a list of `#include /package` specification items. Each member of the list is unique. Attempting to add a duplicate member does nothing.

`LibAddToCommonIncludes` should be called from block TLC methods to specify generation of `#include` statements in `model.h`. Specify the names of files on the include path inside angle brackets, e.g., `<sysinclude.h>`. Specify the names of local files without angle brackets, e.g., `myinclude.h`. Each call to `LibAddToCommonIncludes` adds the specified file to the list only if it is not already there. Filenames with and without angle brackets (e.g., `<math.h>` and `math.h`) are considered different. The `#include` statements are placed inside `model.h`.

#### Example

```
LibAddToCommonIncludes("tpu332lib.h")
```

See `LibAddToCommonIncludes` in `cachelib.tlc`.

### LibAddToModelSources(newFile)

`LibAddToModelSources` serves two purposes:

- To notify the build process that it must build with the specified source file
- To update the `SOURCES: file1.c file2.c ... comment` in the generated code.

For inlined S-functions, `LibAddToModelSources` is generally called from `BlockTypeSetup`. `LibAddToModelSources` adds a filename to the list of sources for building this model.

`LibAddToModelSources` returns 1 if the filename passed in was a duplicate (i.e., it was already in the sources list) and 0 if it was not a duplicate.

You can use the `LibAddToModelSources` function for other purposes in TLC aside from writing S-functions. If you write your own S-functions, use the `SFunctionModules` block parameter instead of `LibAddToModelSources`. See `LibAddToModelSources` in `utillib.tlc`.

## LibCacheDefine(buffer)

Each call to LibCacheDefine appends your buffer to the existing cache buffer. For blocks, LibCacheDefine is generally called from BlockTypeSetup.

LibCacheDefine caches #define statements for inclusion in *model\_private.h* or *model.c*. Call LibCacheDefine from inside BlockTypeSetup to cache a #define statement. Each call to LibCacheDefine appends your buffer to the existing cache buffer. The #define statements are placed inside *model\_private.h* or *model.c*.

### Example

```
%openfile buffer
#define INTERP(x,x1,x2,y1,y2) (y1+((y2 - y1)/(x2 - x1))*(x-x1))
#define this that
%closefile buffer
%<LibCacheDefine(buffer)>
```

See LibCacheDefine in *cachelib.tlc*.

## LibCacheExtern(buffer)

LibCacheExtern should be called from inside BlockTypeSetup to cache an extern statement. Each call to LibCacheExtern appends your buffer to the existing cache buffer. The extern statements are placed in *model\_private.h*.

### Example

```
%openfile buffer
extern real_T mydata;
%closefile buffer
%<LibCacheExtern(buffer)>
```

See LibCacheExtern in *cachelib.tlc*.

## LibCacheFunctionPrototype(buffer)

LibCacheFunctionPrototype should be called from inside BlockTypeSetup to cache a function prototype. Each call to LibCacheFunctionPrototype appends your buffer to the existing cache buffer. The prototypes are placed inside *model\_private.h*.

### Example

```
%openfile buffer
extern int_T fun1(real_T x);
extern real_T fun2(real_T y, int_T i);
%closefile buffer
%<LibCacheFunctionPrototype(buffer)>
```

See LibCacheFunctionPrototype in *cachelib.tlc*.

## LibCacheTypedefs(buffer)

`LibCacheTypedefs` should be called from inside `BlockTypeSetup` to cache typedef declarations. Each call to `LibCacheTypedefs` appends your buffer to the existing cache buffer. The typedef statements are placed inside `model.h` (or `model_common.h`).

### Example

```
%openfile buffer
typedef foo bar;
%closefile buffer
%<LibCacheTypedefs(buffer)>
```

See `LibCacheTypedefs` in `cachelib.tlc`.

## LibCallModelInitialize()

Returns code for calling the model's initialize function (valid for ERT only).

See `LibCallModelInitialize` in `codetemplatelib.tlc`.

## LibCallModelStep(tid)

Returns code for calling the model's step function (valid for ERT only).

See `LibCallModelStep` in `codetemplatelib.tlc`.

## LibCallModelTerminate()

Returns code for calling the model's terminate function (valid for ERT only).

See `LibCallModelTerminate` in `codetemplatelib.tlc`.

## LibCallSetEventForThisBaseStep(buffername)

Returns code for calling the model's set events function (valid for ERT only).

### Argument

`buffername` — Name of the variable used to buffer the events. For the example `ert_main.c`, this is `eventFlags`.

See `LibCallSetEventForThisBaseStep` in `codetemplatelib.tlc`.

## LibClearFileSectionContents(fileIdx, attrib)

Before writing file to disk, clear file sections with custom values.

### Arguments

`fileIdx` (scope or number) — File index

`attrib` (string) — Name of model attribute

See `LibGetSourceFileAttribute` in `codetemplatelib.tlc`.

## **LibCreateSourceFile(type, creator, name)**

Creates a new C or C++ file and returns its reference. If the file already exists, `LibCreateSourceFile` returns the existing file's reference.

### **Syntax**

```
%assign fileH = LibCreateSourceFile
 ("Source", "Custom", "foofile")
```

### **Arguments**

`type` (string) — Valid values are "Source" and "Header" for .c and .h files, respectively.

`creator` (string) — Who is creating the file? An error is reported if different creators attempt to create the same file.

`name` (string) — Base name of the file (i.e., without the extension). Note that files are not written to disk if they are empty.

### **Returns**

Reference to the model file (scope).

See `LibCreateSourceFile` in `codetemplatelib.tlc`.

## **LibGetFileRecordName (file)**

Returns model file name (including the path) without the file extension. To retrieve the file name (including the path) with the file extension, use `LibGetSourceFileSection`.

### **Arguments**

`file` — Source file reference

See `LibGetFileRecordName` in `codetemplatelib.tlc`.

## **LibGetMdlPrvHdrBaseName()**

Returns the base name of the model's private header file, for example, `model_private.h`.

See `LibGetMdlPrvHdrBaseName` in `codetemplatelib.tlc`.

## **LibGetMdlPubHdrBaseName()**

Returns the base name of the model's public header file, for example, `model.h`.

See `LibGetMdlPubHdrBaseName` in `codetemplatelib.tlc`.

### **LibGetMdlSrcBaseName()**

Returns the base name of the model's main source file, for example, *model.c*.

See `LibGetMdlSrcBaseName` in `codetemplatelib.tlc`.

### **LibGetMdlDataSrcBaseName()**

Returns the base name of the model's data file, for example, *model\_data.c*.

See `LibGetMdlDataSrcBaseName` in `codetemplatelib.tlc`.

### **LibGetMdlTypesHdrBaseName()**

Returns the base name of the model types file, for example, *model\_types.h*.

See `LibGetMdlTypesHdrBaseName` in `codetemplatelib.tlc`.

### **LibGetMdlCapiHdrBaseName()**

Returns the base name of the model capi header file, for example, *model\_capi.h*.

See `LibGetMdlCapiHdrBaseName` in `codetemplatelib.tlc`.

### **LibGetMdlCapiSrcBaseName()**

Returns the base name of the model capi source file, for example, *model\_capi.c*.

See `LibGetMdlCapiSrcBaseName` in `codetemplatelib.tlc`.

### **LibGetMdlCapiHostHdrBaseName()**

Returns the base name of the model capi host header file, for example, *model\_host\_capi.h*.

See `LibGetMdlCapiHostHdrBaseName` in `codetemplatelib.tlc`.

### **LibGetMdlTestIfHdrBaseName()**

Returns the base name of the model testinterface header file, for example, *model\_testinterface.h*.

See `LibGetMdlTestIfHdrBaseName` in `codetemplatelib.tlc`.

### **LibGetMdlTestIfSrcBaseName()**

Returns the base name of the model testinterface source file, for example, *model\_testinterface.c*.

See `LibGetMdlTestIfSrcBaseName` in `codetemplatelib.tlc`.

## LibGetDataTypeTransHdrBaseName()

Returns the base name of the data type transition file, for example, *model\_dt.h* for code generation's Real-Time and Embedded-C code formats.

See `LibGetDataTypeTransHdrBaseName` in `codetemplatelib.tlc`.

## LibGetModelDotCFile()

Returns a reference to the *model.c* or *.cpp* source file. You can then cache additional code using `LibSetSourceFileSection`.

### Syntax

```
%assign srcFile = LibGetModelDotCFile()
%<LibSetSourceFileSection(srcFile, "Functions", mybuf)>
```

### Returns

Returns a reference to the *model.c* or *.cpp* source file.

See `LibGetModelDotCFile` in `codetemplatelib.tlc`.

## LibGetModelDotHFile()

Returns a reference to the *model.h* source file. You can then cache additional code using `LibSetSourceFileSection`.

### Syntax

```
%assign hdrFile = LibGetModelDotHFile()
%<LibSetSourceFileSection(hdrFile, "Functions", mybuf)>
```

### Returns

Returns a reference to the *model.h* source file.

See `LibGetModelDotHFile` in `codetemplatelib.tlc`.

## LibGetModelName()

Returns the name of the model (without an extension).

See `LibGetModelName` in `codetemplatelib.tlc`.

## LibGetNumSourceFiles()

Returns the number of source files (*.c* or *.cpp* and *.h*) that have been created.

### Syntax

```
%assign numFiles = LibGetNumSourceFiles()
```

**Returns**

Returns the number of files (number).

See `LibGetNumSourceFiles` in `codetemplatelib.tlc`.

**LibGetRTModelErrorStatus()**

Returns the code required to get the model error status.

**Syntax**

```
%<LibGetRTModelErrorStatus(>);
```

See `LibGetRTModelErrorStatus` in `codetemplatelib.tlc`.

**LibGetSourceFileAttribute(fileIdx, attrib)**

Returns the specified attribute of a file. The table lists the valid attributes.

Attribute			
Name (with file extension)	SystemsInFile	IsEmpty	SharedType
BaseName	RequiredIncludes	Indent	CodeTemplate
Type	UtilityIncludes	WrittenToDisk	OutputDirectory
Creator	Filter	Shared	Group

**Arguments**

`fileIdx` (scope or number) — File index

`attrib` (string) — Name of model attribute

See `LibGetSourceFileAttribute` in `codetemplatelib.tlc`.

**LibGetSourceFileFromIdx(fileIdx)**

Returns a model file reference based on its index. This reference can be useful for a common operation on all files, for example, to set the leading file banner of all files.

**Syntax**

```
%assign fileH = LibGetSourceFileFromIdx(fileIdx)
```

**Argument**

`fileIdx` (number) — Index of model file

**Returns**

Reference (scope) to the model file.

See `LibGetSourceFileFromIdx` in `codetemplatelib.tlc`.

## LibGetSourceFileSection(fileIdx, section)

Returns the contents of a file. See “LibSetSourceFileSection(fileH, section, value)” on page 21-45 for a list of valid sections.

### Arguments

`fileIdx` (scope or number) — File index

`section` (string) — File section of interest

See `LibGetSourceFileSection` in `codetemplatelib.tlc`.

## LibGetSourceFileTag(fileIdx)

Returns `fileName_h` and `fileName_c` for header and source files, respectively, where `fileName` is the name of the model file.

### Syntax

```
%assign tag = LibGetSourceFileTag(fileIdx)
```

### Argument

`fileIndex` (number) — File index

### Returns

Returns the tag (string).

See `LibGetSourceFileTag` in `codetemplatelib.tlc`.

## LibMdlRegCustomCode(buffer, location)

Places declaration statements and executable code inside the `model_initialize` function.

### Arguments

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- "header" — Place buffer at top of function
- "declaration" — Place buffer at top of function
- "execution" — Place buffer at top of function, but after header
- "trailer" — Place buffer at bottom of function

### Returns

Nothing

See `LibMdlRegCustomCode` in `hookslib.tlc`.

## LibMdlStartCustomCode(buffer, location)

Places declaration statements and executable code inside the start function. Start code is executed once, during the model initialization phase.

### Syntax

```
LibMdlStartCustomCode(buffer, location)
```

### Arguments

**buffer** — String buffer containing text to append to the internal cache buffer.

**location** — String specifying where to place the buffer's contents. Possible values are

- "header" — Place buffer at top of function
- "declaration" — Place buffer at top of function
- "execution" — Place buffer at top of function, but after header
- "trailer" — Place buffer at bottom of function

### Returns

Nothing

### Description

`LibMdlStartCustomCode` places declaration statements and executable code inside the start function. This code is output into the following functions, depending on the current value for the `CodeFormat` TLC variable:

Function Name	Value of CodeFormat TLC variable
<code>model_initialize</code>	Embedded-C (if not <code>ModelReferenceCoderTarget</code> )
<code>mdlStart</code>	Embedded-C (if <code>ModelReferenceCoderTarget</code> )
<code>mdlStart</code>	S-Function
<code>MdlStart</code>	RealTime

Each call to `LibMdlStartCustomCode` appends your buffer to the internal cache buffer.

See `LibMdlStartCustomCode` in `hookslib.tlc`.

## LibMdlTerminateCustomCode(buffer, location)

### Purpose

Places declaration statements and executable code inside the terminate function.

### Syntax

```
LibMdlTerminateCustomCode(buffer, location)
```

### Arguments

**buffer** — String buffer containing text to append to the internal cache buffer.

location — String specifying where to place the buffer's contents. Possible values are

- "header" — Place buffer at top of function
- "declaration" — Place buffer at top of function
- "execution" — Place buffer at top of function, but after header
- "trailer" — Place buffer at bottom of function

### Returns

Nothing

### Description

LibMdlTerminateCustomCode places declaration statements and executable code inside the terminate function. This code is output into the following functions, depending on the current value of the CodeFormat TLC variable:

Function Name	Value of CodeFormat TLC variable
<i>model_terminate</i>	Embedded-C
<i>mdlTerminate</i>	S-Function
<i>MdlTerminate</i>	RealTime

Each call to LibMdlTerminateCustomCode appends your buffer to the internal cache buffer.

See LibMdlTerminateCustomCode in hookslib.tlc.

## LibSetRTModelErrorStatus(str)

Returns the code required to set the model error status.

### Syntax

```
LibSetRTModelErrorStatus("\0verrun\0")
```

### Argument

str (string) — char \* to a C string

See LibSetRTModelErrorStatus in codetemplatelib.tlc.

## LibSetSourceFileCodeTemplate(opFile, name)

By default, \*.c and \*.h files are generated with the code templates specified in the **Code Generation > Templates** pane of the Configuration Parameters dialog box.

LibSetSourceFileCodeTemplate allows you to change the template for a file.

---

**Note** Custom templates are a feature of the Embedded Coder product.

---

### Syntax

```
%assign tag = LibSetSourceFileCodeTemplate(opFile,name)
```

**Arguments**

`opFile` (scope) — Reference to file

`name` (string) — Name of the desired template

**Returns**

Nothing

See `LibSetSourceFileCodeTemplate` in `codetemplatelib.tlc`.

**LibSetSourceFileCustomSection(file, attrib, value)**

Adds to the contents of a custom section previously created with `LibAddSourceFileCustomSection`. Available only with Embedded Coder software.

**Arguments**

`file` (scope or number) — Source file reference or index

`attrib` (string) — Name of custom section

`value` (string) — Value to be appended to section

See `LibSetSourceFileCustomSection` in `codetemplatelib.tlc`.

**LibSetSourceFileOutputDirectory(opFile, name)**

By default, \*.c and \*.h files are generated into a build folder at the current location. `LibSetSourceFileOutputDirectory` allows you to change the folder into which a specified source file is to be generated. Note that the caller is responsible for specifying a valid folder.

**Syntax**

```
%assign tag = LibSetSourceFileOutputDirectory(opFile,dirName)
```

**Arguments**

`opFile` (scope) — Reference to file

`dirName` (string) — Name of the desired output folder

**Returns**

Nothing

See `LibSetSourceFileOutputDirectory` in `codetemplatelib.tlc`.

**LibSetSourceFileSection(fileH, section, value)**

Adds to the contents of a specified section within a specified file. Valid file sections include

File Section	Description
Banner	Set the file banner (comment) at the top of the file.
Includes	Append to the <code>#include</code> section.
Defines	Append to the <code>#define</code> section.
IntrinsicTypes	Append to the intrinsic <code>typedef</code> section. Intrinsic types are those that depend only on intrinsic C types.
PrimitiveTypedefs	Append to the primitive <code>typedef</code> section. Primitive typedefs are those that depend only on intrinsic C types and <code>typedefs</code> previously defined in the <code>IntrinsicTypes</code> section.
UserTop	Append to the User Top section.
Typedefs	Append to the <code>typedef</code> section. The <code>typedefs</code> can depend on a previously defined type.
Enums	Append to the enumerated types section.
Definitions	Append to the data definition section.
ExternData	(Reserved) Code generator extern data.
ExternFcns	(Reserved) Code generator extern functions.
FcnPrototypes	(Reserved) Code generator function prototypes.
Declarations	Append to the data declaration section.
Functions	Append to the C functions section.
CompilerErrors	Append to the <code>#error</code> section.
CompilerWarnings	Append to the <code>#warning</code> section.
Documentation	Append to the documentation (comment) section.
UserBottom	Append to the User Bottom section.

The code generator orders the code as listed above.

### Syntax

Example (iterating over the files):

```
%openfile tmpBuf
 whatever
%closefile tmpBuf

%foreach fileIdx = LibGetNumSourceFiles()
 %assign fileH = LibGetSourceFileFromIdx(fileIdx)
 %<LibSetSourceFileSection(fileH,"SectionOfInterest",tmpBuf)>
%endforeach

%assign fileH = LibCreateSourceFile("Header","Custom","foofile")
%<LibSetSourceFileSection(fileH,"Defines", "#define F00 5.0\n")>
```

### Arguments

`fileH` (scope or number) — Reference or index to a file

`section` (string) — File section of interest

value (string) — Value

See `LibSetSourceFileSection` in `codetemplatelib.tlc`.

## **LibSystemDerivativeCustomCode(system, buffer, location)**

### **Purpose**

Places declaration statements and executable code inside a subsystem's derivative function.

### **Syntax**

```
LibSystemDerivativeCustomCode(system, buffer, location)
```

### **Arguments**

`system` — Reference to the subsystem whose derivative function is to be modified.

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- "header" — Place buffer at top of function
- "declaration" — Place buffer at top of function
- "execution" — Place buffer at top of function, but after header
- "trailer" — Place buffer at bottom of function

### **Returns**

Nothing

### **Description**

`LibSystemDerivativeCustomCode` places declaration statements and executable code inside the derivative function for the subsystem specified by `system`. This code is output into the following functions, depending on the current value of the `CodeFormat` TLC variable:

Function Name	Value of CodeFormat TLC variable
<code>mdlDerivatives</code>	S-Function
<code>model_derivatives</code>	RealTime

`LibSystemDerivativeCustomCode` is not relevant when the value of the `CodeFormat` TLC variable is `Embedded-C`, because blocks with continuous states cannot be used.

Each call to `LibSystemDerivativeCustomCode` appends your buffer to the internal cache buffer. An error is generated if you attempt to add code to a subsystem that does not have continuous states.

See `LibSystemDerivativeCustomCode` in `hookslib.tlc`.

---

**Note** To avoid a potential mismatch between simulation and code generation results, do not use `LibSystemDerivativeCustomCode` to read from and write to global Simulink data (signals, states, and block parameters). Instead, use the proper modeling pattern (for example, Data Store Read, Data Store Write, State Reader, and State Writer blocks.)

---

## **LibSystemDisableCustomCode(system, buffer, location)**

### **Purpose**

Places declaration statements and executable code inside a subsystem's disable function.

### **Syntax**

```
LibSystemDisableCustomCode(system, buffer, location)
```

### **Arguments**

`system` — Reference to the subsystem whose disable function is to be modified.

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- "header" — Place buffer at top of function
- "declaration" — Place buffer at top of function
- "execution" — Place buffer at top of function, but after header
- "trailer" — Place buffer at bottom of function

### **Returns**

Nothing

### **Description**

`LibSystemDisableCustomCode` places declaration statements and executable code inside the disable function for the subsystem specified by `system`. Each call to `LibSystemDisableCustomCode` appends your buffer to the internal cache buffer.

An error is generated if you attempt to add code to a subsystem that does not have a disable function.

See `LibSystemDisableCustomCode` in `hookslib.tlc`.

---

**Note** To avoid a potential mismatch between simulation and code generation results, do not use `LibSystemDisableCustomCode` to read from and write to global Simulink data (signals, states, and block parameters). Instead, use the proper modeling pattern (for example, Data Store Read, Data Store Write, State Reader, and State Writer blocks.)

---

## **LibSystemEnableCustomCode(system, buffer, location)**

### **Purpose**

Places declaration statements and executable code inside a subsystem's enable function.

### **Syntax**

```
LibSystemEnableCustomCode(system, buffer, location)
```

**Arguments**

`system` — Reference to the subsystem whose enable function is to be modified.

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- "header" — Place buffer at top of function
- "declaration" — Place buffer at top of function
- "execution" — Place buffer at top of function, but after header
- "trailer" — Place buffer at bottom of function

**Returns**

Nothing

**Description**

`LibSystemEnableCustomCode` places declaration statements and executable code inside the enable function for the subsystem specified by `system`. Each call to `LibSystemEnableCustomCode` appends your buffer to the internal cache buffer.

An error is generated if you attempt to add code to a subsystem that does not have an enable function.

See `LibSystemEnableCustomCode` in `hookslib.tlc`.

---

**Note** To avoid a potential mismatch between simulation and code generation results, do not use `LibSystemEnableCustomCode` to read from and write to global Simulink data (signals, states, and block parameters). Instead, use the proper modeling pattern (for example, Data Store Read, Data Store Write, State Reader, and State Writer blocks.)

---

**LibSystemInitializeCustomCode(system, buffer, location)****Purpose**

Places declaration statements and executable code inside a subsystem's initialize function.

**Syntax**

```
LibSystemInitializeCustomCode(system, buffer, location)
```

**Arguments**

`system` — Reference to the subsystem whose initialize function is to be modified.

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- "header" — Place buffer at top of function

- "declaration" — Place buffer at top of function
- "execution" — Place buffer at top of function, but after header
- "trailer" — Place buffer at bottom of function

### Returns

Nothing

### Description

`LibSystemInitializeCustomCode` places declaration statements and executable code inside the initialize function for the subsystem specified by `system`. This code is output into the following functions, depending on the current value of the `CodeFormat` TLC variable:

Function Name	Value of CodeFormat TLC variable
<code>model_initialize</code>	Embedded-C
<code>mdlInitializeConditions</code>	S-Function
<code>MdlStart</code>	RealTime

Code for a subsystem is output into the subsystem's initialization function. Each call to `LibSystemInitializeCustomCode` appends your buffer to the internal cache buffer.

---

**Note** Enable systems that are not configured to reset on enable are inlined into `MdlStart`. For this case, the subsystem's custom code is found in `MdlStart` above and below the enable subsystem's initialization code.

---

See `LibSystemInitializeCustomCode` in `hookslib.tlc`.

---

**Note** To avoid a potential mismatch between simulation and code generation results, do not use `LibSystemInitializeCustomCode` to read from and write to global Simulink data (signals, states, and block parameters). Instead, use the proper modeling pattern (for example, Data Store Read, Data Store Write, State Reader, and State Writer blocks.)

---

## LibSystemOutputCustomCode(system, buffer, location)

### Purpose

Places declaration statements and executable code inside a subsystem's output function.

### Syntax

```
LibSystemOutputCustomCode(system, buffer, location)
```

### Arguments

`system` — Reference to the subsystem whose output function is to be modified.

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- "header" — Place buffer at top of function
- "declaration" — Place buffer at top of function
- "execution" — Place buffer at top of function, but after header
- "trailer" — Place buffer at bottom of function

### Returns

Nothing

### Description

`LibSystemOutputCustomCode` places declaration statements and executable code inside the output function for the subsystem specified by `system`. This code is output into the following functions, depending on the current value of the `CodeFormat` TLC variable:

Function Name	Value of CodeFormat TLC variable
<code>model_step</code>	Embedded-C (CombineOutputUpdateFcns is 1)
<code>model_output</code>	Embedded-C (CombineOutputUpdateFcns is 0)
<code>mdlOutputs</code>	S-Function
<code>MdlOutputs</code>	RealTime

Each call to `LibSystemOutputCustomCode` appends your buffer to the internal cache buffer.

See `LibSystemOutputCustomCode` in `hookslib.tlc`.

---

**Note** To avoid a potential mismatch between simulation and code generation results, do not use `LibSystemOutputCustomCode` to read from and write to global Simulink data (signals, states, and block parameters). Instead, use the proper modeling pattern (for example, Data Store Read, Data Store Write, State Reader, and State Writer blocks.)

---

## LibSystemUpdateCustomCode(system, buffer, location)

### Purpose

Places code inside a subsystem's update function.

### Syntax

```
LibSystemUpdateCustomCode(system, buffer, location)
```

### Arguments

`system` — Reference to the subsystem whose update function is to be modified.

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- "header" — Place buffer at top of function
- "declaration" — Place buffer at top of function

- "execution" — Place buffer at top of function, but after header
- "trailer" — Place buffer at bottom of function

### Returns

Nothing

### Description

`LibSystemUpdateCustomCode` places declaration statements and executable code inside the update function for the subsystem specified by `system`. This code is output into the following functions, depending on the current value of the `CodeFormat` TLC variable:

Function Name	Value of CodeFormat TLC variable
<code>model_step</code>	Embedded-C (CombineOutputUpdateFcns is 1)
<code>model_update</code>	Embedded-C (CombineOutputUpdateFcns is 0)
<code>mdlUpdate</code>	S-Function
<code>MdlUpdate</code>	RealTime

Each call to `LibSystemUpdateCustomCode` appends your buffer to the internal cache buffer.

See `LibSystemUpdateCustomCode` in `hookslib.tlc`.

---

**Note** To avoid a potential mismatch between simulation and code generation results, do not use `LibSystemUpdateCustomCode` to read from and write to global Simulink data (signals, states, and block parameters). Instead, use the proper modeling pattern (for example, Data Store Read, Data Store Write, State Reader, and State Writer blocks.)

---

### LibWriteModelData()

Returns data for the model (valid for ERT only).

See `LibWriteModelData` in `codetemplatelib.tlc`.

### LibWriteModelInput(tid, rollThreshold)

Returns the code for writing to a specified root input (that is, a model inport block). This function is valid for ERT only, and not valid for referenced models.

#### Arguments

`tid` (number) — Task identifier (0 is fastest rate and `n` is the slowest)

`rollThreshold` — Width of signal before wrapping in a for loop.

See `LibWriteModelInput` in `codetemplatelib.tlc`.

## **LibWriteModelInputs()**

Returns code that writes to all root inputs (that is, the model inport blocks). This function is valid for ERT only, and is not valid for referenced models.

See `LibWriteModelInputs` in `codetemplatelib.tlc`.

## **LibWriteModelOutput(tid, rollThreshold)**

Returns code that writes to a specified root output (that is, a model outport block). This function is valid for ERT only, and not valid for referenced models.

### **Arguments**

`tid` (number) — Task identifier (0 is fastest rate and `n` is the slowest)

`rollThreshold` — Width of signal before wrapping in a `for` loop.

See `LibWriteModelOutput` in `codetemplatelib.tlc`.

## **LibWriteModelOutputs()**

Returns code that writes to all root outputs (that is, the model outport blocks). This function is valid for ERT only, and not valid for referenced models.

See `LibWriteModelOutputs` in `codetemplatelib.tlc`.

## **See Also**

### **Related Examples**

- “Target Language Compiler Library Functions Overview” on page 21-2
- “Target Language Compiler Function Conventions” on page 21-3

## Sample Time Functions

### **LibAsynchronousTriggeredTID(tid)**

Returns whether this TID corresponds to a asynchronous triggered rate.

See LibAsynchronousTriggeredTID in `utllib.tlc`.

### **LibAsyncTaskAccessTimeInFcn(tid, fcnType)**

Returns 1 if the specified asynchronous task identifier (TID) is given function type.

See LibAsyncTaskAccessTimeInFcn in `utllib.tlc`.

### **LibBlockSampleTime(block)**

Returns the block's sample time. The returned value depends on the sample time classification of the block, as shown in the following table.

Block Classification	Returned Value
Discrete	The actual sample time of a block (real > 0)
Continuous	0.0
Triggered	-1.0
Constant	-2.0

See LibBlockSampleTime in `blocklib.tlc`.

### **LibGetClockTick(tid)**

Returns integer task time (current clock tick of the task timer). The resolution of the timer can be obtained from LibGetClockTickStepSize(tid). The data type ID of the timer can be obtained from LibGetClockTickDataTypeId(tid).

See LibGetClockTick in `utllib.tlc`.

### **LibGetClockTickDataTypeId(tid)**

Returns clock tick data type ID.

See LibGetClockTickDataTypeId in `utllib.tlc`.

### **LibGetClockTickHigh(tid)**

Returns high-order word of the integer task time. LibGetClockTickHigh is used when uint32 pairs are used to store absolute time. The resolution of a clock tick can be obtained from LibGetClockTickStepSize(tid).

See LibGetClockTickHigh in `utllib.tlc`.

## **LibGetClockTickStepSize(tid)**

Returns clock tick step size, which is the resolution of the integer task time. `LibGetClockTickStepSize` cannot be used if the task does not have a timer.

See `LibGetClockTickStepSize` in `utllib.tlc`.

## **LibGetElapseTime(system)**

Returns time elapsed since the last time the subsystem started to execute.

See `LibGetElapseTime` in `utllib.tlc`.

## **LibGetElapseTimeCounter(system)**

Returns an integer elapsed time. This is the number of clock ticks elapsed since the last time the system started. To get real-world elapsed time, this integer elapsed time must be multiplied by the applicable resolution.

You can obtain the resolution by calling `LibGetElapseTimeResolution(system)`. You can obtain the data type ID of the integer elapsed time counter by calling `LibGetElapseTimeCounterDTypeId(system)`.

See `LibGetElapseTimeCounter` in `utllib.tlc`.

## **LibGetElapseTimeCounterDTypeId(system)**

Returns the data type ID of the integer elapsed time returned by `LibGetElapseTimeCounter`.

See `LibGetElapseTimeCounterDTypeId` in `utllib.tlc`.

## **LibGetElapseTimeResolution(system)**

Returns the resolution of the elapsed time returned by `LibGetElapseTimeCounter`.

See `LibGetElapseTimeResolution` in `utllib.tlc`.

## **LibGetGlobalTIDFromLocalSFcnTID(sfcnTID)**

Returns the model task identifier (sample time index) corresponding to the specified local S-function task identifier or port sample time. `LibGetGlobalTIDFromLocalSFcnTID` allows you to use one function to determine a global TID, independent of port- or block-based sample times.

The input argument to `LibGetGlobalTIDFromLocalSFcnTID` should be one of the following:

- For block-based sample times (e.g., in S-function `mdlInitializeSizes`, `ssSetNumSampleTimes(S, N)` with  $N > 1$  was specified), `sfcnTID` is a nonnegative integer giving the corresponding local S-function sample time.
- For port-based sample times (e.g., in S-function `mdlInitializeSizes`, `ssSetNumSampleTimes(S, PORT_BASED_SAMPLE_TIMES)` was specified), `sfcnTID` is a string

of the form "InputPortIdxI" or "OutputPortIdxI", where *I* is an integer ranging from 0 to the number of ports (e.g., "InputPortIdx0").

## Examples

### Multirate block

```
%assign globalTID = LibGetGlobalTIDFromLocalSFcnTID(2)
```

or

```
%assign globalTID =
LibGetGlobalTIDFromLocalSFcnTID("InputPortIdx4")
%assign period =
CompiledModel.SampleTime[globalTID].PeriodAndOffset[0]
%assign offset =
CompiledModel.SampleTime[globalTID].PeriodAndOffset[1]
```

### Inherited sample time block

```
%switch (LibGetSFcnTIDType(0))
 %case "discrete"
 %case "continuous"
 %assign globalTID = LibGetGlobalTIDFromLocalSFcnTID(2)
 %assign period = ...
 CompiledModel.SampleTime[globalTID].PeriodAndOffset[0]
 %assign offset = ...
 CompiledModel.SampleTime[globalTID].PeriodAndOffset[1]
 %break
 %case "triggered"
 %assign period = -1
 %assign offset = -1
 %break
 %case "constant"
 %assign period = rtInf
 %assign offset = 0
 %break
 %default
 %<LibBlockReportFatalError([], "Unknown tid type")>
%endswitch
```

See LibGetGlobalTIDFromLocalSFcnTID in `utllib.tlc`.

## LibGetNumAsyncTasks()

Return the number of asynchronous tasks in generated code.

See LibGetNumAsyncTasks in `utllib.tlc`.

## LibGetNumSFcnSampleTimes(block)

Returns the number of S-function sample times for a block.

See LibGetNumSFcnSampleTimes in `utllib.tlc`.

## LibGetNumSyncPeriodicTasks()

Return the number of periodic tasks in generated code.

See `LibGetNumSyncPeriodicTasks` in `utllib.tlc`.

## LibGetNumTasks()

Return the number of tasks in generated code.

See `LibGetNumTasks` in `utllib.tlc`.

## LibGetSampleTimePeriodAndOffset(tid, idx)

Returns the sample time period value or offset value for a specified task.

### Arguments

`tid` — Specify the identifier of the task for which to return information.

`idx` — Specify 0 to return the sample time period value or 1 to return the sample time offset value.

### Examples

```
%% Get sample time period and offset for task 0
%assign sampleTime = LibGetSampleTimePeriodAndOffset(0,0)
%assign offsetTime = LibGetSampleTimePeriodAndOffset(0,1)

%% Get sample time periods for tasks 0 and 1
%assign periodTID0 = LibGetSampleTimePeriodAndOffset(0,0)
%assign periodTID1 = LibGetSampleTimePeriodAndOffset(1,0)
```

See `LibGetSampleTimePeriodAndOffset` in `codetemplatelib.tlc`.

## LibGetSFcnTIDType(sfcnTID)

Returns the type of the specified S-function task identifier (`sfcnTID`). Possible values are:

- "continuous" — The specified `sfcnTID` is continuous.
- "discrete" — The specified `sfcnTID` is discrete.
- "triggered" — The specified `sfcnTID` is triggered.
- "constant" — The specified `sfcnTID` is constant.

The format of `sfcnTID` must be the same as for `LibIsSFcnSampleHit`.

---

**Note** This is useful primarily in the context of S-functions that specify an inherited sample time.

---

See `LibGetSFcnTIDType` in `utllib.tlc`.

## LibGetTaskTime(tid)

Returns a string to access the absolute time of the task, which is a floating-point number. However, if you have configured the model for integer-only code generation (by deselecting **Support floating-point numbers**), the string represents an integer equal to the number of base rate ticks (the absolute time divided by the base sample time) rather than the absolute time. In integer-only code, the task time is an integer time value whose resolution is the model fundamental step size.

LibGetTaskTime is the TLC version of the SimStruct macro: `"ssGetTaskTime(S,tid)"`.

See LibGetTaskTime in `utllib.tlc`.

## LibGetTaskTimeFromTID(block)

Returns a string to access the absolute time of the task associated with the block.

If the value of the CodeFormat TLC variable is not Embedded-C, LibGetTaskTimeFromTID returns the string `"RTMGet("T")"` if the block is constant or the system is single rate, and `"RTMGetTaskTimeForTID(tid)"` otherwise.

If the value for the CodeFormat TLC variable is Embedded-C, LibGetTaskTimeFromTID returns `"RTMGetTaskTimeForTID(tid)"`.

If the block is constant or the system is single rate, this is the TLC version of the SimStruct macro: `"ssGetT(S)"` and `"ssGetTaskTime(S, tid)"` otherwise.

In both cases, S is the name of the SimStruct.

See LibGetTaskTimeFromTID in `utllib.tlc`.

## LibGetTID01EQ()

Returns the value of the TID01EQ flag — true (1) if sampling rates of the continuous task and the first discrete task are equal and false (0) otherwise.

When a model has continuous time and the flag TID01EQ is true, both continuous time and the fastest discrete time are treated as one rate in generated code. The code associated with the fastest discrete rate is guarded by a major time step check. When the model has only two rates, and TID01EQ is true, the generated code has a single-rate call interface.

Use LibGetTID01EQ to detect and account for the case where continuous time and the fastest discrete time are treated as one rate.

See LibGetTID01EQ in `codetemplatelib.tlc`, `bareboard_mrmain.tlc`, and `ertmainlib.tlc`.

## LibIsContinuous(TID)

Returns 1 if the specified task identifier (TID) is continuous and 0 otherwise. Note that task identifiers equal to `"triggered"` or `"constant"` are not continuous.

See LibIsContinuous in `utllib.tlc`.

## LibIsDiscrete(TID)

Returns 1 if the specified task identifier (TID) is discrete and 0 otherwise. Note that task identifiers equal to "triggered" or "constant" are not discrete.

See `LibIsDiscrete` in `utllib.tlc`.

## LibSSFcnSampleHit(sfcnTID)

Returns 1 if a sample hit occurs for the specified local S-function task identifier (TID) and 0 otherwise.

The input argument to `LibSSFcnSampleHit` should be one of the following:

- `sfcnTID`: integer (e.g., 2)

For block-based sample times (e.g., in S-function `mdlInitializeSizes`, `ssSetNumSampleTimes(S,N)` with  $N > 1$  was specified), `sfcnTID` is an integer starting at 0 of the corresponding local S-function sample time.

- `sfcnTID`: "InputPortIdxI" or "OutputPortIdxI" (e.g., "InputPortIdx0").

For port-based sample times (e.g., in S-function `mdlInitializeSizes`, `ssSetNumSampleTimes(S,PORT_BASED_SAMPLE_TIMES)` was specified), `sfcnTID` is a string giving the input (or output) port index.

### Examples

- Consider a multirate S-function block with four block sample times. The call `LibSSFcnSampleHit(2)` returns the code to check for a sample hit on the third S-function block sample time.
- Consider a multirate S-function block with three input and eight output sample times. The call `LibSSFcnSampleHit("InputPortIdx0")` returns the code to check for a sample hit on the first input port. The call `LibSSFcnSampleHit("OutputPortIdx7")` returns the code to check for a sample hit on the eighth output port.

See `LibSSFcnSampleHit` in `utllib.tlc`.

## LibSSFcnSingleRate(block)

Returns a Boolean value (1 or 0) indicating whether the S-function is single rate (one sample time) or multirate (multiple sample times).

See `LibSSFcnSingleRate` in `utllib.tlc`.

## LibSSFcnSpecialSampleHit(sfcnSTI, sfcnTID)

Returns the Simulink macro to promote a slow task (`sfcnSTI`) into a faster task (`sfcnTID`).

This advanced function is specifically intended for use in rate transition blocks. `LibSSFcnSpecialSampleHit` determines the global TID from the S-function TID

The input arguments to `LibSSFcnSpecialSampleHit` are

- For multirate S-function blocks:

`sfcnSTI`: local S-function sample time index (`sti`) of the slow task that is to be promoted

`sfcnTID`: local S-function task ID (`tid`) of the fast task where the slow task is to run

- For single-rate S-function blocks using `SS_OPTION_RATE_TRANSITION`, `sfcnSTI` and `sfcnTID` are ignored and should be specified as "".

The format of `sfcnSTI` and `sfcnTID` must follow that of the argument to `LibIsSFcnSampleHit`.

### Examples

- A rate transition S-function (one sample time with `SS_OPTION_RATE_TRANSITION`)

```
if (%<LibIsSFcnSpecialSampleHit("", "")>) {
```

- A multirate S-function with port-based sample times where the output rate is slower than the input rate (e.g., a zero-order hold operation)

```
if (%<LibIsSFcnSpecialSampleHit("OutputPortIdx0", "InputPortIdx0")>) {
```

See `LibIsSFcnSpecialSampleHit` in `utllib.tlc`.

### **LibIsSingleRateModel()**

Returns `true` if model is single rate and `false` otherwise.

See `LibIsSingleRateModel` in `codetemplatelib.tlc`.

### **LibIsSingleTasking()**

Returns `true` if the model is configured for single-tasking execution and `false` if the model is configured for multitasking execution.

See `LibIsSingleTasking` in `codetemplatelib.tlc`.

### **LibIsZOHContinuous(TID)**

Returns 1 if the specified task identifier (TID) is zero order hold (ZOH) continuous and 0 otherwise. A TID equal to triggered or constant is not ZOH continuous.

See `LibIsZOHContinuous` in `utllib.tlc`.

### **LibNumAsynchronousSampleTimes()**

Returns the number of asynchronous sample times in the model.

See `LibNumAsynchronousSampleTimes` in `codetemplatelib.tlc`.

### **LibNumDiscreteSampleTimes()**

Returns the number of discrete sample times in the model.

See `LibNumDiscreteSampleTimes` in `codetemplatelib.tlc`.

**LibNumSynchronousSampleTimes()**

Returns the number of synchronous sample times in the model.

See `LibNumSynchronousSampleTimes` in `codetemplatelib.tlc`.

**LibPortBasedSampleTimeBlockIsTriggered(block)**

Determines whether the port-based S-function block is triggered.

See `LibPortBasedSampleTimeBlockIsTriggered` in `blocklib.tlc`.

**LibSetVarNextHitTime(block, tNext)**

Generates code to set the next variable hit time. Blocks with variable sample time must call `LibSetVarNextHitTime` in their output functions.

See `LibSetVarNextHitTime` in `blocklib.tlc`.

**LibTriggeredTID(tid)**

Returns whether this TID corresponds to a triggered rate.

See `LibTriggeredTID` in `utllib.tlc`.

- “Target Language Compiler Function Conventions” on page 21-3

## Miscellaneous Functions

### **LibAddtoSystemCustomIncludes(system, incFileName)**

For use by inlined S-functions within a subsystem. Adds `#include` file to the system header file.

Call this function from the “BlockInstanceSetup(block, system)” on page 20-21 method of the block so that different S-functions can include different header files. Specify your header file without any braces (for example, “myInclude.h”) and include the system header file in braces (for example, “<sysinclude.h>”).

Each call to this function adds the file to the list of included headers files only if it is not already included.

#### **Example**

```
%function BlockInstanceSetup(block, system) Output
 %assign incFileName = "sfun_custincl.h"
 %<LibAddToSystemCustomIncludes(system, incFileName)>
%endfunction
```

```
%function Outputs(block, system) Output
%endfunction
```

See LibAddToSystemCustomIncludes in commonhdrlib.tlc.

### **LibBlockExecuteFcnCall(block, callIdx)**

For use by inlined S-functions with function-call outputs. Returns a string to call the function-call subsystem with required arguments or generates the subsystem's code in place (inlined).

#### **Example**

```
%foreach callIdx = NumSFcnSysOutputCalls
 %if LibIsEqual(SFcnSystemOutputCall[callIdx].BlockToCall,...
 "unconnected")
 %continue
 %endif
 %% call the downstream system
 %<LibBlockExecuteFcnCall(block, callIdx)>\
%endforeach
```

See LibBlockExecuteFcnCall in syslib.tlc.

### **LibBlockExecuteFcnDisable(block, callIdx)**

For use by inlined S-Functions to call the function-call system disable function. Returns a string to either call the function-call subsystem disable function with required arguments or to call the generated subsystem disable code (inlined).

#### **Example**

```
%foreach callIdx = NumSFcnSysOutputCallDsts
 %if LibIsEqual(SFcnSystemOutputCall[callIdx].BlockToCall, "unconnected")
 %continue
 %endif
%endforeach
```

```

%endif
%% call the downstream system
%<LibBlockExecuteFcnDisable(block, callIdx)>\
%endforeach

```

See `LibBlockExecuteFcnDisable` in `syslib.tlc`.

## **LibBlockExecuteFcnEnable(block, callIdx)**

For use by inlined S-Functions to call the function-call system enable function. Returns a string to call the function-call subsystem enable function with required arguments or the generated subsystem enable code (inlined).

### **Example**

```

%foreach callIdx = NumSFcnSysOutputCallDsts
 %if LibIsEqual(SFcnSystemOutputCall[callIdx].BlockToCall, "unconnected")
 %continue
 %endif
 %% call the downstream system
 %<LibBlockExecuteFcnEnable(block, callIdx)>\
%endforeach

```

See `LibBlockExecuteFcnEnable` in `syslib.tlc`.

## **LibBlockInputSignalAliasedThruDataTypeId(idx)**

Return the data type ID the input signal is aliased thru to.

See `LibBlockInputSignalAliasedThruDataTypeId` in `dtypelib.tlc`.

## **LibBlockOutputSignalAliasedThruDataTypeId(idx)**

Return the data type ID the output signal is aliased thru to.

See `LibBlockOutputSignalAliasedThruDataTypeId` in `dtypelib.tlc`

## **LibGenConstVectWithInit(data, typeId, varId)**

Returns an initialized static constant variable string of form:

```
static const typeName varId[] = { data };
```

The `typeName` is generated from `typeId`, which can be one of

```
tSS_DOUBLE, tSS_SINGLE, tSS_BOOLEAN, tSS_INT8, tSS_UINT8,
tSS_INT16, tSS_UINT16, tSS_INT32, tSS_UINT32
```

The data input argument must be a numeric scalar or vector and must be finite (no `Inf`, `-Inf`, or `NaN` values).

See `LibGenConstVectWithInit` in `utllib.tlc`.

## **LibGetBlockAttribute(block, attr)**

Get a field value inside a block record.

**Syntax**

```
%if LibIsEqual(LibGetBlockAttribute(ssBlock, "MaskType"), ...
 "Task Block")
 %assign isTaskBlock = 1
%endif
```

**Returns**

Returns the value of the attribute (field) or an empty string if it does not exist.

See `LibGetBlockAttribute` in `asynclib.tlc`.

**LibGetCallerClockTickCounter(sfcnBlock)**

For use by asynchronous S-functions with function call outputs. Asynchronous tasks can manage their own time. `LibGetCallerClockTickCounter` is used to access an upstream asynchronous task's time counter. This is preferred when being driven by another asynchronous rate (e.g., an Interrupt block driving a Task block) because the time the interrupt occurred is used, rather than the time the task is allowed to run.

**Returns**

Returns a string for the counter variable for the upstream asynchronous task.

See `LibGetCallerClockTickCounter` in `asynclib.tlc`.

**LibGetCallerClockTickCounterHigh(sfcnBlock)**

For use by asynchronous S-functions with function-call outputs. Asynchronous tasks can manage their own time. `LibGetCallerClockTickCounterHigh` is used to access the high word of an upstream asynchronous task's time counter. This is preferred when being driven by another asynchronous rate (for example, an Interrupt block driving a Task block) because the time the interrupt occurred is used rather than the time the Task is allowed to run.

**Returns**

Returns a string for the high word of the counter variable for the upstream asynchronous task.

See `LibGetCallerClockTickCounterHigh` in `asynclib.tlc`.

**LibGetDataComplexNameFromId(id)**

Returns the name of the complex data type corresponding to a data type ID. For example, if `id==tSS_DOUBLE` then `LibGetDataComplexNameFromId` returns `"creal_T"`.

See `LibGetDataComplexNameFromId` in `dtypelib.tlc`.

**LibGetDataEnumFromId(id)**

Returns the data type enum corresponding to a data type ID. For example, if `id==tSS_DOUBLE`, then enum is "SS\_DOUBLE". If `id` does not correspond to a built-in data type, `LibGetDataTypeEnumFromId` returns "".

See `LibGetDataTypeEnumFromId` in `dtypeslib.tlc`.

### **LibGetDataTypeIdAliasedThruToFromId(id)**

Returns the data type `IdAliasedThruTo` that corresponds to a data type ID. For example, if `yourfloat` is an alias to `myfloat`, and `myfloat` is an alias to `double`, then the `IdAliasedThruTo` for both `yourfloat` and `myfloat` is 0 (because the ID for `double` is 0).

See `LibGetDataTypeIdAliasedThruToFromId` in `dtypeslib.tlc`.

### **LibGetDataTypeIdAliasedToFromId(id)**

Returns the data type `IdAliasedTo` that corresponds to a data type ID. For example, if `yourfloat` is an alias to `myfloat`, and `myfloat` is an alias to `double`, then the `IdAliasedTo` for `yourfloat` is the ID for `myfloat`, and the `IdAliasedTo` for `myfloat` is 0 (because the ID for `double` is 0).

See `LibGetDataTypeIdAliasedToFromId` in `dtypeslib.tlc`.

### **LibGetDataTypeIdResolvesToFromId(id)**

Returns the data type `IdResolvesTo` that corresponds to a data type ID.

See `LibGetDataTypeIdResolvesToFromId` in `dtypeslib.tlc`.

### **LibGetDataTypeNameFromId(id)**

Returns the data type name that corresponds to a data type ID.

See `LibGetDataTypeNameFromId` in `dtypeslib.tlc`.

### **LibGetDataTypeSLSizeFromId(id)**

Return the size (as Simulink knows it) corresponding to a data type ID.

See `LibGetDataTypeSLSizeFromId` in `dtypeslib.tlc`.

### **LibGetDataTypeStorageIdFromId(id)**

Returns the data type `StorageId` corresponding to a data type ID. For example, if the input ID is the ID for a 16-bit signed fixed-point data type, then the `StorageId` corresponds to `int16`.

See `LibGetDataTypeStorageIdFromId` in `dtypeslib.tlc`.

## LibGetFcnCallBlock(sfcnblock,callIdx)

Given an S-function block and call index, return the block record for the downstream function-call subsystem block.

### Syntax

```
%assign ssBlock = LibGetFcnCallBlock(block,0)
```

### Returns

The block record of the downstream function-call subsystem connected to that element (call index).

See LibGetFcnCallBlock in `asynclib.tlc`.

## LibGetRecordDataTypeId(rec)

Returns the data type identifier of the specified record as an integer.

See LibGetRecordDataTypeId in `dtypelib.tlc`.

## LibGetRecordDimensions(rec)

Returns the dimensions of the specified record as a vector of integers.

See LibGetRecordDimensions in `dtypelib.tlc`.

## LibGetRecordIsComplex(rec)

Returns the value 1 if the specified record is complex, and zero otherwise.

See LibGetRecordIsComplex in `dtypelib.tlc`.

## LibGetRecordWidth(rec)

Returns the width of the specified record as an integer.

See LibGetRecordWidth in `dtypelib.tlc`.

## LibGetT()

Returns a string to access the absolute time, which is a floating-point number. However, if you have configured the model for integer-only code generation (by deselecting **Support floating-point numbers**), the string represents an integer equal to the number of base rate ticks (the absolute time divided by the base sample time) rather than the absolute time.

You should use LibGetT to access time only.

LibGetT is the TLC version of the SimStruct macro `ssGetT`.

See LibGetT in `utllib.tlc`.

## LibIsComplex(arg)

Returns 1 if the argument passed in is complex, 0 otherwise.

See `LibIsComplex` in `utllib.tlc`.

## LibIsFirstInitCond()

`LibIsFirstInitCond` returns generated code intended for placement in the initialization function. This code determines, during run-time, whether the initialization function is being called for the first time.

`LibIsFirstInitCond` also sets a flag that tells the code generator if it needs to declare and maintain the `first-initialize-condition` flag.

`LibIsFirstInitCond` is the TLC version of the SimStruct macro `ssIsFirstInitCond`.

See `LibIsFirstInitCond` in `syslib.tlc`.

## LibIsMajorTimeStep()

Returns a string to access whether the current simulation step is a major time step.

`LibIsMajorTimeStep` is the TLC version of the SimStruct macro `ssIsMajorTimeStep`.

See `LibIsMajorTimeStep` in `utllib.tlc`.

## LibIsMinorTimeStep()

Returns a string to access whether the current simulation step is a minor time step.

`LibIsMinorTimeStep` is the TLC version of the SimStruct macro `ssIsMinorTimeStep`.

See `LibIsMinorTimeStep` in `utllib.tlc`.

## LibManageAsyncCounter(sfcnBlock, callIdx)

For use by asynchronous S-Functions with function-call outputs. Asynchronous tasks can manage their own time, and use `LibManageAsyncCounter` to determine whether a need exists for an asynchronous counter to manage its own timer.

### Example

```
%if LibManageAsyncCounter(block, callIdx)
 %% %<LibSetAsyncCounter(block, callIdx), CodeGetCounter>
```

where `CodeGetCounter` is target specific code reading hardware timer.

### Returns

Returns `TLC_TRUE` if an asynchronous counter is required to manage its own counter, otherwise `TLC_FALSE`.

See `LibManageAsyncCounter` in `asynclib.tlc`.

### **LibMaxIntValue(dtype)**

For a built-in integer data type, `LibMaxIntValue` returns the formatted maximum value of that data type.

See `LibMaxIntValue` in `dtypelib.tlc`.

### **LibMinIntValue(dtype)**

For a built-in integer data type, `LibMinIntValue` returns the formatted minimum value of that data type.

See `LibMinIntValue` in `dtypelib.tlc`.

### **LibNeedAsyncCounter(sfcnBlock, callIdx)**

For use by asynchronous S-functions with function-call outputs. Asynchronous tasks use `LibNeedAsyncCounter` to determine whether a need exists for an asynchronous counter.

#### **Example**

```
%if LibNeedAsyncCounter(block,0)
 %<LibSetAsyncCounter(block,0), "tickGet(">
```

#### **Returns**

Returns `TLC_TRUE` if an asynchronous counter is required, otherwise `TLC_FALSE`.

See `LibNeedAsyncCounter` in `asynclib.tlc`.

### **LibSetAsyncClockTicks(sfcnBlock, callIdx, buf1, buf2)**

For use by asynchronous S-functions with function-call outputs. Asynchronous tasks can manage their own time. Use `LibSetAsyncClockTicks` to return code that sets `clockTick` counters that are to be maintained by the asynchronous task. If the data type of a `clockTick` counter maintained by the asynchronous task is `tSS_TIMER_UINT32_PAIR`, the low and high word of the `clockTick` counter are set.

#### **Arguments**

`buf1` — Code that reads the low word of the hardware counter

`buf2` — Code that reads the high word of the hardware counter. Leave `buf2` empty if hardware counter length is less than 32 bits.

#### **Returns**

Returns code that sets `clockTick` counters that are to be maintained by the asynchronous task.

**Example**

```
%if LibNeedAsyncCounter(block, callIdx)
%<LibSetAsyncCounter(block, 0, buf1, buf2)>
%endif
```

See `LibSetAsyncClockTicks` in `asynclib.tlc`.

**LibSetAsyncCounter(sfcnBlock, callIdx, buf)**

For use by asynchronous S-functions with function-call outputs. Asynchronous tasks can manage their own time. Use `LibSetAsyncCounter` to return code that sets a counter variable that is to be maintained by the asynchronous task.

**Returns**

Returns code that sets the counter variable that is to be maintained by the asynchronous task.

**Example**

```
%if LibNeedAsyncCounter(block,0)
 %<LibSetAsyncCounter(block,0, "tickGet()")>
%endif
```

See `LibSetAsyncCounter` in `asynclib.tlc`.

**LibSetAsyncCounterHigh(sfcnBlock, callIdx, buf)**

For use by asynchronous S-functions with function-call outputs. Asynchronous tasks can manage their own time. Use `LibSetAsyncCounterHigh` to return code that sets the higher word of the counter variable that is to be maintained by the asynchronous task.

**Returns**

Returns code that sets the higher word of the counter variable that is to be maintained by the asynchronous task.

**Example**

```
%if LibNeedAsyncCounter(block,0)
%<LibSetAsyncCounterHigh(block,0, "hightTickGet()")>
%endif
```

See `LibSetAsyncCounterHigh` in `asynclib.tlc`.

**LibTIDInSystem(system, fcnType)****Purpose**

Returns a task identifier (TID) if it is in the scope of a subsystem function and can be called before or during TLC generating code.

**Syntax**

```
LibTIDInSystem(system, fcnType)
```

**Arguments**

*system*

A record within the global CompiledModel record.

*fcnType*

One of the following: 'Output', 'Update', 'Outputupdate'.

**Description**

This function returns a TID if it is in the scope of a subsystem function and can be called before or during TLC generating code. It returns the TID argument name, if a TID is passed as argument in the system function scope. If TID is not passed as argument in the scope, this function returns:

- '0' if model is single tasking.
- The TID value of the subsystem if the subsystem is single rate.
- A local TID variable name, if the subsystem is multirate. A local TID variable is added to the subsystem code.

---

**Note** This function issue an error message if it is called for a reusable subsystem whose instances run at different rates.

---

See LibTIDInSystem in syslib.tlc.

**LibIsRowMajor**

Returns true when the current model uses the row-major array layout.

See LibIsRowMajor in dtypelib.tlc.

**Obsolete Functions**

The following table shows obsolete functions and the functions that have replaced them.

Obsolete Function	Equivalent Replacement Function
LibBlockOutputLocation	LibBlockDstSignalLocation
LibCacheGlobalPrmData	Use the block function Start
LibCacheIncludes	LibAddToCommonIncludes
LibContinuousState	LibBlockContinuousState
LibControlPortInputSignal	LibBlockSrcSignalLocation
LibConvertZCDirection	Function is not used in code generation.
LibDataInputPortWidth	LibBlockInputSignalWidth
LibDataOutputPortWidth	LibBlockOutputSignalWidth
LibDefineIWork LibDefinePWork LibDefineRWork	IWork, PWork, and RWork names are now specified via the mdlRTW function in your C MEX S-function.

<b>Obsolete Function</b>	<b>Equivalent Replacement Function</b>
LibDiscreteState	LibBlockDiscreteState
LibExportFileCustomCode	LibSetSourceFileSection
LibExternalResetSignal	LibBlockInputSignal
LibHeaderFileCustomCode	LibSetSourceFileSection
LibIsEqual	Use built-in function ISEQUAL
LibMapSignalSource	FcnMapDataTypedSignalSource
LibMaxBlockIOWidth	Function is not used in Simulink Coder code generation.
LibMaxDataInputPortWidth	Function is not used in Simulink Coder code generation.
LibMaxDataOutputPortWidth	Function is not used in Simulink Coder code generation.
LibPathName	LibGetBlockPath, LibGetFormattedBlockPath
LibPrevZCState	LibBlockPrevZCState
LibPrmFileCustomCode	LibSetSourceFileSection
LibRegFileCustomCode	LibSetSourceFileSection
LibRegisterGNUMathFcnPrototypes	Function is not used in Simulink Coder code generation.
LibRegisterISOCMathFcnPrototypes	Function is not used in Simulink Coder code generation.
LibRegisterMathFcnPrototype	Function is not used in Simulink Coder code generation.
LibRenameParameter	Specifying parameter names is now supported via the mdlRTW function in your C MEX S-function.

## See Also

### Related Examples

- “Target Language Compiler Function Conventions” on page 21-3

## Advanced Functions

### LibAppendToModelReferenceUserData(data)

Appends the given data object to the user data in the binfo file for the model currently being built. This function is only called during builds for model reference targets.

---

**Note** The data argument cannot be a vector or matrix. To work around this limitation, create a record with a field containing the vector or matrix data and pass this record into the function.

---

See LibAppendToModelReferenceUserData in modelrefutil.tlc.

### LibBlockInputSignalBufferDstPort(portIdx)

Returns the output port corresponding to input port (portIdx) that share the same memory, otherwise (-1) is returned. You will need to use LibBlockInputSignalBufferDstPort when you specify ssSetInputPortOverWritable(S, portIdx, TRUE) in your S-function.

If an input port and some output port of a block are

- Not test points, and
- The input port is overwritable

then the output port might reuse the same buffer as the input port. In this case, LibBlockInputSignalBufferDstPort returns the index of the output port that reuses the specified input port's buffer. If none of the block's output ports reuse the specified input port buffer, then LibBlockInputSignalBufferDstPort returns -1.

LibBlockInputSignalBufferDstPort is the TLC version of the Simulink macro ssGetInputPortBufferDstPort.

#### Example

Assume you have a block that has two input ports, both of which receive a complex number in 2-wide vectors. The block outputs the product of the two complex numbers.

```
%assign u1r = LibBlockInputSignal (0, "", "", 0)
%assign u1i = LibBlockInputSignal (0, "", "", 1)
%assign u2r = LibBlockInputSignal (1, "", "", 0)
%assign u2i = LibBlockInputSignal (1, "", "", 1)
%assign yr = LibBlockOutputSignal (0, "", "", 0)
%assign yi = LibBlockOutputSignal (0, "", "", 1)
%if (LibBlockInputSignalBufferDstPort(0) != -1)
 %% The first input is going to be overwritten by yr so
 %% we need to save the real part in a temporary variable.
 {
 real_T tmpRe = %<u1r>;
%assign u1r = "tmpRe";
 }
%endif
%<yr> = %<u1r> * %<u2r> - %<u1i> * %<u2i>;
%<yi> = %<u1r> * %<u2i> + %<u1i> * %<u2r>;
%if (LibBlockInputSignalBufferDstPort(0) != -1)
```

```

 }
%endif

```

Note that, because only one output port exists, this example could have used `(LibBlockInputSignalBufferDstPort(0) == 0)` as the Boolean condition for the `%if` statements.

See `LibBlockInputSignalBufferDstPort` in `blkio.lib.tlc`.

### **LibBlockInputSignalStorageClass(portIdx, sigIdx)**

Returns the storage class of the specified block input port signal. The storage class can be "Auto", "ExportedSignal", "ImportedExtern", or "ImportedExternPointer".

See `LibBlockInputSignalStorageClass` in `blkio.lib.tlc`.

### **LibBlockInputSignalStorageTypeQualifier(portIdx, sigIdx)**

Returns the storage type qualifier of the specified block input port signal. The type qualifier can be anything entered by the user, such as `const`. The default type qualifier is "Auto", which means do the default action.

See `LibBlockInputSignalStorageTypeQualifier` in `blkio.lib.tlc`.

### **LibBlockOutputSignalIsGlobal(portIdx)**

Returns 1 if the specified block output port signal is declared in the global scope, otherwise returns 0.

If `LibBlockOutputSignalIsGlobal` returns 1, then the variable holding this signal is accessible from anywhere in generated code. For example, `LibBlockOutputSignalIsGlobal` returns 1 for signals that are test points, external, or invariant.

See `LibBlockOutputSignalIsGlobal` in `blkio.lib.tlc`.

### **LibBlockOutputSignalIsInBlockIO(portIdx)**

Returns 1 if the specified block output port exists in the global block I/O data structure. You might need to use this if you specify `ssSetOutputPortReusable(S, portIdx, TRUE)` in your S-function.

See `sfun_multiport.tlc`.

See `LibBlockOutputSignalIsInBlockIO` in `blkio.lib.tlc`.

### **LibBlockOutputSignalIsValidLValue(portIdx)**

Returns 1 if the specified block output port signal can be used as a valid left-side argument (lvalue) in an assignment expression, otherwise returns 0. For example, `LibBlockOutputSignalIsValidLValue` returns 1 if the block output port signal is in read/write memory.

See `LibBlockOutputSignalIsValidLValue` in `blkio.lib.tlc`.

### **LibBlockOutputSignalStorageClass(portIdx)**

Returns the storage class of the block's specified output signal. The storage class can be "Auto", "ExportedSignal", "ImportedExtern", or "ImportedExternPointer".

See `LibBlockOutputSignalStorageClass` in `blkio.lib.tlc`.

### **LibBlockOutputSignalStorageTypeQualifier(portIdx)**

Returns the storage type qualifier of the block's specified output signal. The type qualifier can be anything entered by the user, such as `const`. The default type qualifier is `Auto`, which means do the default action.

See `LibBlockOutputSignalStorageType` in `blkio.lib.tlc`.

### **LibBlockSrcSignalBlock(portIdx, sigIdx)**

Returns a reference to the block that is the source of the specified block input port element. The return argument is one of the following:

<code>[systemIdx, blockIdx]</code>	If the block output or state is unique
<code>"ExternalInput"</code>	If external input (root inport)
<code>"Ground"</code>	If unconnected or connected to ground
<code>"FcnCall"</code>	If function-call output
<code>0</code>	If not unique (i.e., source for a Merge block or a signal reused because of block I/O optimization)

#### **Example**

The following code fragment finds the block that drives the second input on the first port of the current block, then assigns the input signal of this source block to the variable `y`:

```
%assign srcBlock = LibBlockSrcSignalBlock(0, 1)
%% Make sure that the source is a block
%if TYPE(srcBlock) == "Vector"
 %assign sys = srcBlock[0]
 %assign blk = srcBlock[1]
 %assign block = CompiledModel.System[sys].Block[blk]
 %with block
 %assign u = LibBlockInputSignal(0, "", "", 0)
 y = %<u>;
 %endwith
%endif
```

See `LibBlockSrcSignalBlock` in `blkio.lib.tlc`.

## **LibBlockSrcSignalIsDiscrete(portIdx, sigIdx)**

Returns 1 if the source signal corresponding to the specified block input port element is discrete, otherwise returns 0.

Note that `LibBlockSrcSignalIsDiscrete` also returns 0 if the driving block cannot be uniquely determined to be a merged or reused signal (i.e., the source is a Merge block or the signal has been reused because of optimization).

See `LibBlockSrcSignalIsDiscrete` in `blkio.lib.tlc`.

## **LibBlockSrcSignalIsGlobalAndModifiable(portIdx, sigIdx)**

`LibBlockSrcSignalIsGlobalAndModifiable` returns 1 if the source signal corresponding to the specified block input port element satisfies the following three conditions:

- It is readable everywhere in the generated code.
- It can be referenced by its address.
- Its value can change (i.e., it is not declared as a `const`).

Otherwise, `LibBlockSrcSignalIsGlobalAndModifiable` returns 0.

See `LibBlockSrcSignalIsGlobalAndModifiable` in `blkio.lib.tlc`.

## **LibBlockSrcSignalIsInvariant(portIdx, sigIdx)**

Returns 1 if the source signal corresponding to the specified block input port element is invariant (i.e., the signal does not change).

For example, a source block with a constant TID (or equivalently, an infinite sample time) would output an invariant signal.

See `LibBlockSrcSignalIsInvariant` in `blkio.lib.tlc`.

## **LibGetModelReferenceUserData(modelName)**

Gets the user data for the given model. This returns a vector with one element for each time `LibAppendToUserData` is called in the given model. This function cannot be called during builds where the target type is SIM.

See `LibGetModelReferenceUserData` in `modelrefutil.tlc`.

## **LibGetReferencedModelNames()**

Gets the names of the models referenced by the model that is currently being built. Returns the data as a structure with two fields:

- `NumReferencedModels`: an integer with the number of model names

- `ReferencedModel`: an array of structures, where each structure has a field `-Name-` containing the name of a referenced model

See `LibGetReferencedModelNames` in `modelrefutil.tlc`.

### **LibIsModelReferenceRTWTarget()**

Returns true if the build process is generating code for model reference target.

See `LibIsModelReferenceRTWTarget` in `utllib.tlc`.

### **LibIsModelReferenceSimTarget()**

Return true if we are generating code for model reference Simulation target.

See `LibIsModelReferenceSimTarget` in `utllib.tlc`.

### **LibIsModelReferenceTarget()**

Return true if we are generating code for model reference target.

See `LibIsModelReferenceTarget` in `utllib.tlc`.

## **See Also**

### **Related Examples**

- “Target Language Compiler Library Functions Overview” on page 21-2
- “Target Language Compiler Function Conventions” on page 21-3

## Block Compatibility Functions

### **LibBlockSetIsExpressionCompliant(block)**

Specify that a block's TLC file is compliant with expression folding. Call this function from within the `BlockInstanceSetup` function. The input to this function is the block record.

See `LibBlockSetIsExpressionCompliant(block)` in `block_api.tlc`.

### **LibBlockSetIntegerDowncastUnnecessary(block)**

Specify that this block does not need to enforce integer downcasts for its output expression. The input to this function is the block record.

See `LibBlockSetIntegerDowncastUnnecessary(block)` in `block_api.tlc`.

### **LibBlockSetCustomStorageComplianceLevel (block, level)**

Set the custom storage compliance level of a block.

The inputs to this function are the block record and the custom storage class compliance level. The possible levels are as follows:

- 0—The block does not support custom storage classes.
- 1— The block supports level 1 custom storage classes. Level 1 custom storage classes do not support the `set` method.
- 2—The block supports level 1 and 2 custom storage classes. Level 2 custom storage classes include level 1 custom storage classes and those that implement a `set` method.

See `LibBlockSetCustomStorageComplianceLevel(block, level)` in `block_api.tlc`.

# TLC Error Handling

## TLC Error Handling

### Error Reporting

You might need to detect and report error conditions in your TLC code. Error detection and reporting are used most often in library functions. While rare, it is also possible to encounter error conditions in block target file code if the S-function `mdlCheckParameters` function does not detect an unforeseen condition.

To report an error condition detected in your TLC code, use the `LibBlockReportError` or `LibBlockReportFatalError` utility functions. Here is an example of using `LibBlockReportError` in the `paramlib.tlc` function `LibBlockParameter` to report the condition of an improper use of that function:

```
%if TYPE(param.Value) == "Matrix"
 %% exit if the parameter is a true matrix,
 %% i.e., has more than one row or columns.
 %if nRows > 1
 %assign errTxt = "Must access parameter %<param.Name> using "...
 "LibBlockMatrixParameter."
 %<LibBlockReportError([], errTxt)>
 %endif
%endif
```

Browse through the files in the folder `matlabroot/rtw/c/tlc` (open) for more examples of the use of `LibBlockReportError`.

### Generating Errors from TLC Files

#### TLC Error Generation Overview

To generate errors from TLC files, you can use the `%exit` directive. Alternatively, you can use one of the library functions described below that calls `%exit` for you. The two types of errors are

Usage errors	These can be caused by incorrect models.
Fatal (internal) TLC coding errors	These <i>cannot</i> be caused by incorrect models.

#### Usage Errors

Usage errors are errors resulting from incorrect models or attributes defined on a model. For example, suppose you have an S-Function block and an inline TLC file for a specific D/A device. If a model can contain only one copy of this S-function, then an error needs to be generated for a model that contains two copies of this S-Function block.

#### Using Library Functions

To generate usage errors related to a specific block, use the library function

```
LibBlockReportError(block,"error string")
```

The `block` argument is the block record if it isn't scoped. If the block is currently scoped, then you can specify `block` as `[]`.

To generate general usage errors that are not related to a specific block, use

```
LibReportError("error string")
```

These library functions prefix the string `Simulink Coder Error:` to the message you provide when reporting the error.

For a usage example of these functions, refer to `gensfun.tlc` for block errors and `commonsetup.tlc` for common errors. There are other files that use these functions in the TLC source folders within `matlabroot/rtw/c/tlc` (open).

### Fatal (Internal) TLC Coding Errors

Suppose you have an S-function that has a local function that can accept only numerical numbers. You might want to add an assert requiring that the inputs be only numerical numbers. These asserts can indicate fatal coding errors for which the user does not have a way of building a model or specifying attributes that can cause the error to occur.

#### Using Library Functions

The two available library functions are

```
LibBlockReportFatalError(block,"fatal coding error message")
```

where `block` is the offending block record (or `[]` if the block is already scoped), and

```
LibReportFatalError("fatal coding error message")
```

for error messages that are not block specific. For example, to add assert code you could use

```
%if TYPE(argument) != "Number"
 %<LibBlockReportFatalError(block,"unexpected argument type")>
%endif
```

These library functions prefix the string `Simulink Coder Fatal:` to the message you provide and display the call stack when reporting the error.

For a usage example of these functions, refer to `gensfun.tlc` for block errors and `commonsetup.tlc` for common errors. There are other files that use these functions in the folder `matlabroot/rtw/c/tlc` (open).

#### Using %exit

You can call `%exit` to generate fatal error messages. However, MathWorks suggests that you use one of the library functions described above.

When generating fatal error messages directly with `%exit`, it is good practice to give a stack trace with the error message. This lets you see the call chain of functions that caused the error. To generate a stack trace, generate the message using the format:

```
%setcommandswitch "-v1"
%exit Simulink Coder Fatal: error string
```

#### Formatting Error Messages

If you want to display a formatted, multiple-line error message, create a local variable that contains the message text. For example:

```
%openfile message
My message text
with newlines
%closefile message
```

After formatting your error message, use one of the error reporting library functions described above, such as `LibReportError`, to report your error when it occurs. For example:

```
%<LibReportError(message)>
```

The error reporting library functions provide an error message prefix, such as `Simulink Coder Error:`.

### Testing Error Messages

It is strongly suggested that you test your error messages before releasing your new TLC code. To test your error messages, copy the relevant code into a `test.tlc` file and run

```
tlc test.tlc
```

at the MATLAB prompt.

## Using TLC Error Messages to Troubleshoot

This section lists and describes error messages generated by the Target Language Compiler. Use this reference to

- Confirm that an error has been reported
- Determine possible causes for an error
- Determine possible ways to fix an error

### **%closefile or %selectfile or %flushfile argument must be a valid open file**

In `%closefile` or `%selectfile` or `%flushfile`, the argument must be a valid file variable opened with `%openfile`.

### **%define no longer supported, use %function instead**

Macros are not supported. You must rewrite macros as functions or inline them in your code.

### **%error directive: text**

Code containing the `%error` directive generates this message. It normally indicates some condition that the code was unable to handle and displays the text following the `%error` directive.

### **%exit directive: text**

Code containing the `%exit` directive causes this message. It typically indicates some condition that the code was unable to handle and displays the text following the `%exit` directive. Note that this directive causes the Target Language Compiler to terminate regardless of the `-mnumber` command-line option.

### **%filescope has already been used in this file**

The user attempted to use the `%filescope` directive more than once in a file.

**%trace directive: text**

The `%trace` directive produces this error message and displays the text following the `%trace` directive. Trace directives are reported only when the `-v` option (verbose mode) appears on the command line. Note that `%trace` directives are not considered errors and do not cause the Target Language Compiler to stop processing.

**%warning directive: text**

The `%warning` directive produces this error message and displays the text following the `%warning` directive. Note that `%warning` directives are not considered errors and do not cause the Target Language Compiler to stop processing.

**A %implements directive must appear within a block template file and must match the %language and type specified**

A block template file was found, but it did not contain an `%implements` directive. An `%implements` directive is required so that the expected language and type are implemented by this block template file. See “Object-Oriented Facility for Generating Target Code” on page 18-23 for more information.

**A %switch statement can only have one %default**

The user has written a `%switch` statement with multiple `%default` cases, as in the following example:

```
%switch expr
 %case 1
 code...
 %break
 %default

more code...
 %break
 %default %% error
 even more code...
 %break
%endswitch
```

**A language choice must be made using the %language directive prior to using GENERATE or GENERATE\_TYPE**

To use the `GENERATE` or `GENERATE_TYPE` built-in functions, the Target Language Compiler requires that you first specify the language being generated. This causes the block-level target file to implement the same language and type as specified in the `%language` directive.

**A non-homogeneous vector was passed to GENERATE\_FORMATTED\_VALUE**

The built-in `GENERATE_FORMATTED_VALUE` can process only vectors that have homogeneous elements (that is, vectors in which all the elements have the same type).

## Ambiguous reference to identifier — must use array index to refer to one of multiple scopes

In a repeated scope identifier from a database file, you must specify an index to disambiguate the reference. For example

```
Database file:
block
{
 Name "Abc2"
 Parameter {
 Name "foo"
 Value 2
 }
}
block
{
 Name "Abc3"
 Parameter {
 Name "foo"
 Value 3
 }
}
TLC file:
%<GETFIELD(block, "Name")>
```

In the preceding example, the reference to `block` is ambiguous because multiple repeated scopes named `block` appear in the database file. Use an index to disambiguate the references, as in:

```
%<GETFIELD(block[0], "Name")>
```

## An %if statement can only have one %else

The user has written an `%if` statement with multiple `%else` blocks, as in the following example:

```
%if expr
 code...
%else
 more code...
%else %% error
 even mode code...
%endif
```

## Argument to identifier must be a string

The following built-in functions expect a string and report this error if the argument passed is not a string.

---

CAST	GENERATE_FILENAME
EXISTS	GENERATE_FUNCTION_EXISTS
FEVAL	GENERATE_TYPE
FILE_EXISTS	GET_COMMAND_SWITCH
FORMAT	IDNUM

GENERATE

SYSNAME

---

## Arguments to directive must be records

Arguments to `%mergerecord` and `%copyrecord` must be records. Also, the first argument to the following built-in functions must be a record:

- ISALIAS
- REMOVEFIELD
- FIELDNAMES
- ISFIELD
- GETFIELD
- SETFIELD

## Arguments to TLC from the MATLAB command line must be strings

An attempt was made to invoke the Target Language Compiler from MATLAB, but some of the arguments that were passed were not strings.

## Assertion failed

An expression in an `%assert` statement evaluated to false.

## Assignment to scope identifier is only allowed when using the + operator to add members

Scope assignment must be `scope = scope + variable`.

## Attempt to define a function identifier on top of an existing variable or function

A function cannot be defined twice. Make sure that you don't have the same function defined in separate TLC files.

## Attempt to divide by zero

The Target Language Compiler does not allow division by zero.

## Bad cast - unable to cast this expression to type

The Target Language Compiler cannot cast this expression from its current type to the specified type. For example, the Target Language Compiler cannot cast a string to a number, as in

```
%assign x = "1234"
%assign y = CAST("Number", x);
```

### **Bad directory (dirname) in O: filename**

The -O option did not specify a valid folder.

### **builtin was expecting expression of type type, got one of type type**

A built-in was passed an expression of incorrect type.

### **Cannot %undef any builtin functions or variables**

User is not allowed to undefine a TLC built-in or variable. For example

```
%undef FORMAT %% error
```

### **Cannot convert string your\_string to a number**

Cannot convert the string to a number.

### **Changing value of identifier from the RTW file**

You have overwritten the value that appeared in the .rtw file.

### **Error opening filename**

The Target Language Compiler could not open the file specified on the command line.

### **Error writing to file error**

There was an error while writing to the current output stream; error contains the system specific error message.

### **Errors occurred — aborting**

This error message is the last error to be reported. It occurs when either

- The number of error messages exceeds the error message threshold (5 by default).
- Processing completes and errors have occurred.

### **Expansion directives %<> cannot be nested**

It is illegal to nest expansion directives. For example,

```
%<foo(%<expr>)>
```

Instead, do the following:

```
%assign tmp = %<expr>
%<foo(tmp)>
```

## Expansion directives %<> cannot span multiple lines; use \ at end of line

An expansion directive cannot span multiple lines. To work around this restriction, use the \ line continuation character. The following is incorrect:

```
%<CompiledModel.System[Sysidx].Block[BlkIdx].Name +
"Hello">
```

Instead, use:

```
%<CompiledModel.System[Sysidx].Block[BlkIdx].Name + \
"Hello">
```

## Extra arguments to the function-name built-in function were ignored (Warning)

The following built-in functions report this warning when too many arguments are passed to them:

---

CAST	NUMTLCFILES
EXISTS	OUTPUT_LINES
FILE_EXISTS	SIZE
FORMAT	STRING
GENERATE_FILENAME	STRINGOF
GENERATE_FUNCTION_EXISTS	SYSNAME
IDNUM	TLCFILES
ISFINITE	TYPE
ISINF	WHITE_SPACE
ISNAN	WILL_ROLL

---

## File name too long (directory =dirname, name =filename)

The specified *filename* was too long. The default limits are 256 characters for *filename* and 1024 characters for *dirname*, but the limits can be larger, depending on the platform.

## format is not a legal format value

The specified format was not legal for the %realformat directive. Valid format strings are "EXPONENTIAL" and "CONCISE".

## Function argument mismatch; function function\_name expects number arguments

When calling a function, too many or too few arguments were passed to it.

## Function reached the end and did not return a value

Functions that are not declared as `void` or `Output` must return a value. If a return value is not desired, declare the function as `void`, otherwise make it return a value.

## Function values are not allowed

Attempt to use a TLC function as a variable.

## Identifier identifier multiply defined. Second and succeeding definitions ignored.

The user is attempting to add the same field to a record more than once, as in the following code.

```
%createrecord err { foo 1; rec { val 2 } }
%addtorecord err foo 2 %% error
```

## Identifier identifier used on a %foreach statement was already in scope (Warning)

The argument to a `%foreach` statement cannot be defined prior to entering the `%foreach`.

## Illegal use of eval (i.e., %<...>)

It is illegal to use evals in `.rtw` files. There are also some places where evals are not allowed in directives. For example:

```
%function %<foo>(a, b, c) void %% error
%endfunction
```

## Indices may not be negative

An index used in a `[ ]` expression must be a nonnegative integer.

## Indices must be constant integral numbers

An index used in a `[ ]` expression must be an integer number.

## Invalid handle

An invalid handle was passed to the Target Language Compiler server mode.

## Invalid identifier range, the leading strings string1 and string2 must match

In a range of signals, for example, `u1:u10`, the identifier in the first argument did not match the identifier in the second.

## Invalid identifier range, the lower bound (bound) must be less than the upper bound (bound)

In a range of signals, for example, `u1:u10`, the lower bound was higher than the upper bound.

## Invalid type for unary operator

Unary operators – and + require numeric types. Unary operator – requires an integral type. Unary operator ! requires a numeric type.

## Invalid type type

An invalid type was passed to a built-in function.

## It is illegal to return a function from a function

A function value cannot be returned from a function call.

## Named value identifier already exists within this scope-identifier; use %assign to change the value

You cannot use the block addition operator + to add a value that is already a member of the indicated block. Use %assign to change the value of an existing value. This example produces this error:

```
%assign x = BLK { a 1; b 2 }
%assign a = 3
%assign x = x + a
```

Use this instead:

```
%assign x.a = 3
```

## No %case statement(s) seen yet, statement ignored

Statements that appear inside a %switch statement but precede %case statements are ignored, as in the following code:

```
%switch expr
%assign x = 2 %% this statement will be ignored
 %case 1
 code
 %break
%endswitch
```

## Only double and character arrays can be converted from MATLAB to TLC. This can occur if the MATLAB function does not return a value (see %matlab)

Only double and character arrays can be converted from MATLAB to the Target Language Compiler. This error can occur if the MATLAB function does not return a value (see %matlab). For example,

```
%assign a = FEVAL("int8",3)
%matlab disp(a)
```

### **Only one output is allowed from the TLC**

An attempt was made to receive multiple outputs from the MATLAB version of the Target Language Compiler.

### **Only strings of length 1 can be assigned using the [ ] notation**

The right-hand side of a string assignment using the [ ] operator must be a string of length 1. You can replace only a single character using this notation.

### **Only strings or cells of strings may be used as the argument to Query and ExecString**

A cell containing nonstring data was passed as the third argument to Query or ExecString in server mode.

### **Only vectors of the same length as the existing vector value can be assigned using the [ ] notation**

In the [ ] notation to replace a row of a matrix, the row must be a vector of the same length as the existing rows.

### **Output file identifier opened with %openfile was not closed**

Output files opened with %openfile must be closed with %closefile. The *identifier* is the name of the variable specified in the %openfile directive.

---

**Note** This might also occur a syntax error is present in a code section between an `openfile` and `closefile`, or if you try to assign the output of a function of type `void` or `Output` to a variable.

---

### **Ranges, identifier ranges, and repeat values cannot be repeated**

You cannot repeat a range, identifier range, or repeat value. This prevents things like [1@2@3].

### **String cannot modify the setting for the command line switch '-switch'**

%setcommandswitch does not recognize the specified switch, or cannot modify it (e.g., -r cannot be modified).

### **string is not a recognized user defined property of this handle**

The query performed on a TLC server mode handle is looking for an undefined property.

## Syntax error

The indicated line contains a syntax error, for more information on syntax, see “Target Language Compiler Directives” on page 18-2.

### **The %break directive can only appear within a %foreach, %for, %roll, or %switch statement**

The %break directive can be used only in a %foreach, %for, %roll, or %switch statement.

### **The %case and %default directives can only be used within the %switch statement**

A %case or %default directive can appear only within a %switch statement.

### **The %continue directive can only appear within a %foreach, %for, or %roll statement**

The %continue directive can be used only in a %foreach, %for, or %roll statement.

### **The %foreach statement expects a constant numeric argument**

The argument of a %foreach must be a numeric type. For example:

```
%foreach Index = [1 2 3 4]
...
%endforeach
```

%foreach cannot accept a vector as input.

### **The %if statement expects a constant numeric argument**

The argument of an %if statement must be a numeric type. For example,

```
%if [1 2 3]
...
%endif
```

%if cannot accept a vector as input.

### **The %implements directive expects a string or string vector as the list of languages**

You can use the %implements directive to specify a string for the language being implemented, or to indicate that it implements multiple languages by using a vector of strings. You cannot specify any other argument type to the %implements directive.

## The %implements directive specifies type as the type where type was expected

The type specified in the %implements directive must exactly match the type specified in the block or on the GENERATE\_TYPE directive. If you want to specify that the block accept multiple input types, use the %implements \* directive, as in

```
%implements * "C" %% I accept any type and generate C code
```

## The %implements language does not match the language currently being generated (language)

The language or languages specified in the %implements directive must exactly match the %language directive.

## The %return statement can only appear within the body of a function

A %return statement can be only in the body of a function.

## The == and != operators can only be used to compare values of the same type

The == and != operator arguments must be the same type. You can use the CAST() built-in function to change them into the same type.

## The argument for %openfile must be a valid string

When you open an output file, the name specified for the file must be a valid string.

## The argument for %with must be a valid scope

The argument to %with must be a valid scope identifier. For example,

```
%assign x = 1
%with x
...
%endwith
```

In this code, the %with statement argument is a number and produces this error message.

## The argument for an [ ] operation must be a repeated scope symbol, a vector, or a matrix

When you use the [ ] operator to index, the expression on the left of the brackets must be a vector, matrix, string, numeric constant, or a repeated scope identifier. When you use array indexing on a scalar, the constant is automatically scalar expanded and the value of the scalar is returned. For example,

```
%openfile x
%assign y = x[0]
```

This example causes this error because `x` is a file and is not valid for indexing.

### The argument to `%addincludepath` must be a valid string

The argument to `%addincludepath` must be a string.

### The argument to `%include` must be a valid string

The argument to the input file control directive must be a valid string with the filename given in double quotation marks.

### The begin directive must be in the same file as the corresponding end directive.

These Target Language Compiler begin directives must appear in the same file as their corresponding end directives: `%function`, `%switch`, `%foreach`, `%roll`, and `%for`. Place the construct entirely within one Target Language Compiler source file.

### The begin directive on this line has no matching end directive

For block-scoped directives, this error is produced if a matching end directive is missing. This error can occur for the following block-scoped Target Language Compiler directives.

Begin Directive	End Directive	Description
<code>%if</code>	<code>%endif</code>	Conditional inclusion
<code>%for</code>	<code>%endfor</code>	Looping
<code>%foreach</code>	<code>%endforeach</code>	Looping
<code>%roll</code>	<code>%endroll</code>	Loop rolling
<code>%with</code>	<code>%endwith</code>	Scoping directive
<code>%switch</code>	<code>%endswitch</code>	Switch directive
<code>%function</code>	<code>%endfunction</code>	Function declaration directive
<code>{</code>	<code>}</code>	Record creation

The error is reported on the line that opens the scope and does not have matching end scope.

---

**Note** Nested scopes must be closed before their parent scopes. Failure to include an end for a nested scope often causes this error, as in

```
%if Block.Name == "Sin 3"
 %foreach idx = Block.Width %endif
%% Error reported here that the %foreach was not terminated
```

---

### The construct `%matlab function_name(...)` construct is illegal in standalone tlc

You cannot call MATLAB from stand-alone TLC.

### **The FEVAL() function can accept only 2-dimensional arrays from MATLAB, not number dimensions**

Return values from MATLAB can have at most two dimensions.

### **The FEVAL() function can accept vectors of numbers or strings only when calling MATLAB**

Vectors passed to MATLAB can be numbers or strings. See “FEVAL Function” on page 18-32.

### **The FEVAL() function requires the name of a function to call**

FEVAL requires a function to call. This error appears only inside MATLAB.

### **The final argument to %roll must be a valid block scope**

When you use %roll, the final argument (prior to extra user-specified arguments) must be a valid block scope. See “%roll” on page 18-22 for a description of this command.

### **The first argument of a ? : operator must be a Boolean expression**

The ? : operator must have a Boolean expression as its first operand.

### **The first argument to GENERATE or GENERATE\_TYPE must be a valid scope**

When you call GENERATE or GENERATE\_TYPE, the first argument must be a valid scope. See the “GENERATE and GENERATE\_TYPE Functions” on page 18-24 for more information and examples.

### **The function name requires at least number arguments**

User is passing too few arguments to a function, as in the following code:

```
%function foo(a, b, c)
 %return a + b + c
%endfunction

%<foo(1, 2)> %% error
```

### **The GENERATE function requires at least 2 arguments**

When you call the GENERATE built-in function, the first two arguments must be the block and the name of the function to call.

### **The GENERATE\_TYPE function requires at least 3 arguments**

When you call the GENERATE\_TYPE built-in function, the first three arguments must be the block, the name of the function to call, and the type.

## **The ISINF(), ISNAN(), ISFINITE(), REAL(), and IMAG() functions expect a real or complex valued argument**

These functions expect a Real or complex value as the input argument.

## **The language being implemented cannot be changed within a block template file**

You cannot change the language using the %language directive within a block template file.

## **The language being implemented has changed from old-language to new-language (Warning)**

The language being implemented should not be changed in midstream because GENERATE function calls that appear prior to the %language directive can cause generate functions to load for the prior language. Only one language directive should appear in a given file.

## **The left-hand side of a . operator must be a valid scope identifier**

When you use the . operator, the left-hand side of the . operator must be a valid in-scope identifier. For example:

```
%assign x = 1
%assign y = x.y
```

In this code, the reference to x.y produces this error message because x is not defined as a scope.

## **The left-hand side of an assignment must be a simple expression comprised of ., [ ], and identifiers**

Illegal left-hand side of assignment.

## **The number of columns specified (specified-columns) did not match the actual number of columns in the rows (actual-columns)**

When you specify a Target Language Compiler matrix, the number of columns specified must match the actual number of columns in the matrix. For example,

```
%assign mat = Matrix(2,1) [[1,2];[2,3]]
```

In this case, the number of columns in the declaration of the matrix (1) did not match the number of columns seen in the matrix (2). Either change the number of columns in the matrix, or change the matrix declaration.

## **The number of rows specified (specified-rows) did not match the actual number of rows seen in the matrix (actual-rows)**

When you specify a Target Language Compiler matrix, the number of rows must match the actual number of rows in the matrix. For example,

```
%assign mat = Matrix(1,2) [[1,2];[2,3]]
```

In this case, the number of rows in the declaration of the matrix (1) did not match the number of rows seen in the matrix (2). Either change the number of rows in the matrix or change the matrix declaration.

### **The operator\_name operator only works on Boolean arguments**

The && and || operators work only on Boolean values.

### **The operator\_name operator only works on integral arguments**

The &, ^, |, <<, >> and % operators work on numbers only.

### **The operator\_name operator only works on numeric arguments**

The arguments to the following operators both must be either numeric or real: <, <=, >, >=, -, \*, /. This error can also occur when you use + as a unary operator. In addition, the FORMAT built-in function expects either a numeric or real argument.

### **The return value from the RollHeader function must be a string**

When you use %roll, the RollHeader() function specified in Roller.tlc must return a string value. See “%roll” on page 18-22 for a complete discussion of the %roll construct.

### **The roll argument to %roll must be a nonempty vector of numbers or ranges**

When you use %roll, the roll vector cannot be empty and must contain numbers or ranges of numbers. See “%roll” on page 18-22 for a complete discussion of the %roll construct.

### **The second value in a Range must be greater than the first value**

In a range, for example, 1:10, the lower bound was higher than the upper bound.

### **The specified index (index) was out of the range 0 - number-of-elements - 1**

This error occurs when you index into a nonscalar beyond the end of the variable. For example:

```
%assign x = [1 2 3]
%assign y = x[3]
```

This example would cause this error. Remember, in the Target Language Compiler, array indices start at 0 and go to the number of elements minus 1.

## **The STRINGOF built-in function expects a vector of numbers as its argument**

The STRINGOF function expects a vector of numbers. The function treats each number as the ASCII value of a valid character.

## **The SYSNAME built-in function expects an input string of the form xxx/yyy**

The SYSNAME function takes a single string of the form xxx/yyy as it appears in the .rtw file and returns a vector of two strings, xxx and yyy. If the input argument does not match this format, SYSNAME returns this error.

## **The threshold on a %roll statement must be a single number**

When you use %roll, the roll threshold specified must be a single number. See “%roll” on page 18-22 for a complete discussion of the %roll construct.

## **The use of feature is being deprecated and will not be supported in future versions of TLC. See the TLC manual for alternatives.**

The %define and %generate directives are not recommended, as they are being replaced.

## **The WILL\_ROLL built in function expects a range vector and an integer threshold**

The WILL\_ROLL function requires both arguments cited in the message.

## **There are no more free contexts. Use tlc('close', HANDLE) to free up a context**

The global context table has filled up while the TLC server mode is in use.

## **There was no type associated with the given block for GENERATE**

The scope specified to GENERATE must include a Type parameter that indicates which template file should be used to generate code for the specified scope. For example:

```
%assign scope = block { Name "foo" }
%<GENERATE(scope, "Output")>
```

This example produces the error message because the scope does not include the parameter Type. See the “GENERATE and GENERATE\_TYPE Functions” on page 18-24 for more information and examples.

**This assignment would overwrite an identifier-value pair from the RTW file. To avoid this error either qualify the left-hand side, or choose another identifier.**

The user is trying to modify a field of a record in a `%with` block without qualifying the left-hand side, as in this example:

```
%createrecord foo { field 1 }
%with foo
 %assign field = 2 %% error
%endwith
```

Instead, use

```
%createrecord foo { field 1 }
%with foo
 %assign foo.field = 2
%endwith
```

**TLC has leaked number symbols. You may have created a cyclic record. If this not the case then please report this leak to The MathWorks.**

There has been a memory leak while running TLC. The most common cause of this is having cyclic records.

**Unable to find identifier within the scope-identifier scope**

The given identifier was not found in the scope specified. For example,

```
%assign scope = ascope { x 5 }
%assign y = scope.y
```

In this code, the reference to `scope.y` produces this error message.

**Unable to open %include file filename**

The file included in an `%include` directive was not found on the path. Either move the file to a location on the current path, or use the `-I` command-line option or the `%addincludepath` directive to specify the folder that contains the file.

**Unable to open block template file filename from GENERATE or GENERATE\_TYPE**

You specified `GENERATE` but the given filename was not found on the Target Language Compiler path. You can

- Add the file to a folder on the path.
- Use the `%generatefile` directive to specify an alternative filename for this block type that is on the path.

- Add the folder in which this file appears to the search path using the `-I` command-line option or the `%addincluderpath` directive.

## Unable to open output file filename

The specified output file could not be opened. Either an invalid filename was specified or the file was read only.

## Undefined identifier identifier\_name

The identifier specified in this expression was undefined.

## Unknown type type in CAST expression

When you call the CAST built-in function, the type must be a valid type from the “Target Language Value Types” on page 18-13 table.

## Unrecognized command line switch passed to string: switch

You queried the current state of a switch, but the switch specified was not recognized.

## Unrecognized directive directive-name seen

An illegal `%` directive was encountered. The valid directives are shown below.

---

<code>%addincluderpath</code>	<code>%addtorecord</code>
<code>%assert</code>	<code>%assign</code>
<code>%break=</code>	<code>%case</code>
<code>%closefile</code>	<code>%continue</code>
<code>%copyrecord</code>	<code>%createrecord</code>
<code>%default</code>	<code>%define</code>
<code>%else</code>	<code>%elseif</code>
<code>%endbody</code>	<code>%endfor</code>
<code>%endforeach</code>	<code>%endfunction</code>
<code>%endif</code>	<code>%endroll</code>
<code>%endswitch</code>	<code>%endwith</code>
<code>%error</code>	<code>%exit</code>
<code>%filescope</code>	<code>%for</code>
<code>%foreach</code>	<code>%function</code>
<code>%generate</code>	<code>%generatefile</code>
<code>%if</code>	<code>%implements</code>
<code>%include</code>	<code>%language</code>
<code>%matlab</code>	<code>%mergerecord</code>

<code>%openfile</code>	<code>%realformat</code>
<code>%return</code>	<code>%roll</code>
<code>%selectfile</code>	<code>%setcommandswitch</code>
<code>%switch</code>	<code>%trace</code>
<code>%undef</code>	<code>%warning</code>
<code>%with</code>	

---

## Unrecognized type output-type for function

The function type modifier was not `Output` or `void`. For functions that do not produce output, the default without a type modifier indicates that the function should not produce output.

## Unterminated multiline comment.

A multiline comment (i.e., `/% %/`) does not have a terminator, as in the following code:

```
/% my comment

%assign x = 2
%assign y = x * 7
```

## Unterminated string

A string must be closed prior to the end of an expansion directive or the end of a line.

## Usage: tlc [options] file

A command-line problem has occurred. The error message contains a list of the available options.

## Use of feature incurs a performance hit, please see TLC manual for possible workarounds.

The `%undef` and expansion (i.e., `%<expr>`) features can degrade performance.

## Value of type type cannot be compared

Values of the specified *type* cannot be compared.

## Values of specified\_type type cannot be expanded

The specified type cannot be used on an expansion directive. Files and scopes cannot be expanded. This error can also occur when you expand a function without any arguments. If you use

```
%<Function>
```

call it with the required arguments.

## Values of type Special, Macro Expansion, Function, File, Full Identifier, and Index cannot be converted to MATLAB variables

Values of the types listed in the message cannot be converted to MATLAB variables.

## When appending to a buffer stream, the variable must be a string

You can specify the append option for a buffer stream only if the variable currently exists as a string. Do not use the append option if the variable does not exist or is not a string. This example produces this error.

```
%assign x = 1
%openfile x , "a"
%closefile x
```

## TLC Function Library Error Messages

The functions in the TLC function library can generate many error messages that are not documented. These messages are sufficiently self-descriptive so that they do not need additional explanation. However, if you encounter an error message that does not provide enough description to resolve your problem, contact our technical support staff.

## Modeling Guidelines for Generated Code

Use modeling guidelines when you develop models and generate code for embedded systems using Model-Based Design with MathWorks products. The guidelines provide model setting, block usage, and parameter considerations that impact code generation.

### Code Generation Modeling Guidelines

You can use code generation guidelines when developing models and generating code for embedded systems. The guidelines provide guidance on modeling patterns, block usage, and configuration parameter settings that impact code generation.

Code generation guidelines for blocks include:

- “cgsl\_0101: Zero-based indexing”
- “cgsl\_0102: Evenly spaced breakpoints in lookup tables”
- “cgsl\_0103: Precalculated signals and parameters”
- “cgsl\_0104: Modeling global shared memory using data stores”
- “cgsl\_0105: Modeling local shared memory using data stores”
- “cgsl\_0201: Redundant Unit Delay and Memory blocks”

Code generation guidelines for modeling patterns include:

- “cgsl\_0202: Usage of For, While, and For Each subsystems with vector signals”
- “cgsl\_0204: Vector and bus signals crossing into atomic subsystems or Model blocks”
- “cgsl\_0205: Signal handling for multirate models”
- “cgsl\_0206: Data integrity and determinism in multitasking models”

Code generation guidelines for configuration parameters include:

- “cgsl\_0301: Prioritization of code generation objectives for code efficiency”
- “cgsl\_0302: Diagnostic settings for multirate and multitasking models”

For information about verifying the readiness of your model for code generation, see “Check Model and Configuration for Code Generation” on page 46-8.

## Industry Standards

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined safety standards, including:

- “IEC 61508: 2010” on page 22-5
- “ISO 26262: 2018” on page 22-5
- “AUTOSAR Standard” on page 22-7
- “IEC 62304: 2015” on page 22-5
- “EN 50128 / EN 50128: 2011” on page 22-6
- “ISO 25119 Standard” on page 22-6

If you have a Simulink Check™ product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with the industry standard. For more information, see “Modeling Guidelines and Model Advisor Checks for Verifying Compliance with Industry Standards” on page 22-8.

### IEC 61508: 2010

Development of high-integrity systems within the automotive industry is characterized by demonstrating compliance with IEC 61508: 2010, *Functional safety of electrical/electronic/programmable electronic safety related systems*. This standard addresses E/E systems<sup>2</sup> in commercial vehicles – especially off-highway vehicles. IEC 61508: 2010 was published when most software was coded by hand, therefore the standard needs to be mapped to Model-Based Design technologies. For further information about MathWorks support for IEC 61508, see IEC 61508 Support in MATLAB and Simulink.

### ISO 26262: 2018

Development of high-integrity systems within the automotive industry is characterized by demonstrating compliance with ISO 26262. ISO 26262: 2018 *Road vehicles — Functional safety*. This standard, which is an adaptation of IEC 61508, addresses *E/E systems* in passenger road vehicles.

For additional information about MathWorks support for ISO 26262, see ISO 26262 Support in MATLAB and Simulink.

### IEC 62304: 2015

IEC 62304: 2015, *Medical device software - Software life cycle processes* is an international standard that defines the requirements of the software life-cycle processes for medical device software development. The standard specifies a set of processes, activities, and tasks that establish a common framework for designing safe and tested software for medical devices. For more information about MathWorks support for IEC 62304, see MATLAB and Simulink for Medical Devices.

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the IEC 62304 standard. For

<sup>2</sup> Systems that consists of electrical and electronic elements, including: programmable electronic elements, power supplies, input devices, communication paths, and output devices.

more information, see “Model Checks for IEC 61508, IEC 62304, ISO 26262, ISO 25119, and EN 50128/EN 50657 Standard Compliance” (Simulink Check).

## **EN 50128 / EN 50128: 2011**

High-integrity systems developed within the railway industry need to demonstrate compliance with:

- EN 50128: 2011, *Railway applications — Software for railway control and protection systems*
- EN 50657:2017, *Railways Applications - Rolling stock applications - Software on Board Rolling Stock*

These European standards specify procedures and technical requirements for the development of programmable electronic systems for use in railway control and protection applications. For more information about MathWorks support for EN 50128, see EN 50128/EN 50657.

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the EN 50128 standard. For more information, see “Model Checks for IEC 61508, IEC 62304, ISO 26262, ISO 25119, and EN 50128/EN 50657 Standard Compliance” (Simulink Check).

## **ISO 25119 Standard**

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined functional safety standards. ISO 25119, *Tractors and machinery for agriculture and forestry — Safety-related parts of control systems*, is such a standard.

MathWorks provides an IEC Certification Kit product that you can use to qualify MathWorks code generation and verification tools for projects based on the ISO 25119 standard. For more information, see “Qualification of Embedded Coder and AUTOSAR Blockset for use in processes that must comply with industry standards” on page 22-9.

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the ISO 25119 standard. For more information, see “Model Checks for IEC 61508, IEC 62304, ISO 26262, ISO 25119, and EN 50128/EN 50657 Standard Compliance” (Simulink Check).

## **DO-178C Standard**

Applying Model-Based Design to a high-integrity system requires extra consideration and rigor so that the system adheres to defined safety standards. DO-178C, *Software Considerations in Airborne Systems and Equipment Certification*, is such a standard. A supplement to DO-178C, DO-331, provides guidance on the use of Model-Based Design technologies. MathWorks provides a DO Qualification Kit product that you can use to qualify MathWorks verification tools for projects based on the DO-178C, DO-331, and related standards. For more information, see <https://www.mathworks.com/products/do-178/>.

For information about Model-Based Design and MathWorks support of aerospace and defense industry standards, see DO Qualification Kit.

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the DO-178C standard. For more information, see “Model Checks for DO-178C/DO-331 Standard Compliance” (Simulink Check).

## AUTOSAR Standard

Simulink software supports *AUTomotive Open System ARchitecture* (AUTOSAR), an open and standardized automotive software architecture. Automobile manufacturers, suppliers, and tool developers jointly develop AUTOSAR components.

The AUTOSAR standard addresses:

- Architecture - Application, run-time environment, and service layers, which serve to decouple AUTOSAR software components from the execution platform. Standard interfaces between software components and the run-time environment allow reuse or relocation of components within the Electronic Control Unit (ECU) topology of a vehicle.

The standard defines two AUTOSAR platforms:

- Classic Platform (CP), with Application, Runtime Environment (RTE), and Basic Software (BSW) layers
- Adaptive Platform (AP), with Application, AUTOSAR Runtime for Adaptive Applications (ARA), Services, and Basis layers
- Methodology - Specification of code formats and description file templates, for example.
- Foundation - Requirements and specifications shared between AUTOSAR platforms, supporting platform interoperability.
- Application Interfaces - Specification of interfaces for typical automotive applications.

For more information, see:

- [www.autosar.org](http://www.autosar.org) for details on the AUTOSAR standard.
- “AUTOSAR Blockset” for information on modeling and simulating AUTOSAR software, from which Embedded Coder can generate code.
- MATLAB and Simulink for AUTOSAR to learn about using MathWorks products and third-party tools for AUTOSAR.

If you have an AUTOSAR Blockset product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the AUTOSAR standard. For more information, see “AUTOSAR Blockset Checks” (AUTOSAR Blockset).

## Modeling Guidelines and Model Advisor Checks for Verifying Compliance with Industry Standards

Use modeling guidelines when you develop models and generate code for embedded systems that are intended for use in projects that must comply with industry standards.

### High-Integrity System Modeling Guidelines

“High-Integrity System Modeling” guidelines provide model setting, block usage, and block parameter considerations for creating models that are complete, unambiguous, robust, and verifiable. Use these guidelines when you develop models and generate code for safety-critical systems, such as in projects that need to comply with the DO-178C / DO-331, IEC 61508, IEC 62304, ISO 26262, or EN 50128 industry standards.

If you have a Simulink Check product license, you can use the Model Advisor to check for compliance with the high-integrity modeling guidelines. To check your model or subsystem:

- 1 Open the Model Advisor.
- 2 Navigate to **By Product > Simulink Check > Modeling Standards > <Standard> Checks**.
- 3 Run the checks in the folder.

To review the High-Integrity System Modeling guidelines and their corresponding Model Advisor checks, see “Model Checks for High Integrity Systems Modeling” (Simulink Check).

### MAB Guidelines

MathWorks Advisory Board (MAB) guidelines stipulate important basic rules for modeling in Simulink and Stateflow. The overall purpose of these modeling guidelines is to allow for a simple, common understanding by modelers and consumers of control system models. The main objectives of these guidelines are readability, simulation and verification, and code generation.

If you have a Simulink Check license, you can check that your Simulink model or subsystem, and the code that you generate from it, complies with MAB guidelines. To check your model or subsystem:

- 1 Open the Model Advisor.
- 2 Navigate to **By Product > Simulink Check > Modeling Standards > MAB Checks**.
- 3 Run the checks in the folder.

To review the MAB guidelines and their corresponding Model Advisor checks, see “Modeling Guidelines and Model Advisor Checks for MAB and JMAAB” .

### See Also

## Qualification of Embedded Coder and AUTOSAR Blockset for use in processes that must comply with industry standards

You can use the IEC Certification Kit to qualify Embedded Coder for use in development processes that must comply with IEC 61508, ISO 26262, EN 50128, EN 50657, ISO 25119, ISO 21434, and related functional-safety standards such as IEC 62304. Qualification covers the code generator that is used to transform an executable model (model used for production code generation) into production C/C++ code for application software components.

You can qualify AUTOSAR Blockset when using the Embedded Coder code generator to generate code that is suitable for AUTOSAR platforms, including:

- Transformation of an executable model into production quality C/C++ code and files for AUTOSAR application software components.
- Creation of an AUTOSAR configuration for a model, model AUTOSAR elements, and generate AUTOSAR XML and AUTOSAR-compatible C/C++ code from a model.

To streamline the certification of your embedded systems, the IEC Certification Kit provides:

- Tool qualification artifacts, which provide software development and verification workflows, tool use cases, and error mitigation methods.

Test suites, which you can use to validate tool usage and generated code.

- Functionality to generate bidirectional traceability matrices between the model and generated code. For more information, see “Validate Traceability” on page 22-9.

For more information about the IEC Certification Kit, see “IEC Certification Kit (for ISO 26262 and IEC 61508)”.

### Validate Traceability

Typically, applications that require certification require some level of traceability between requirements, models, and corresponding code.

To...	Use...
Associate requirements documents with objects in Simulink models	The “Requirements Management Interface Setup” (Requirements Toolbox) that is available if you have a Requirements Toolbox™ license.
Trace model blocks and subsystems to generated code	The “Model-to-Code Traceability” on page 79-10 option when generating an HTML report during the code generation or build process.
Trace generated code to model blocks and subsystems	The “Code-to-Model Traceability” on page 79-8 option when generating an HTML report during the code generation or build process.

## Coding Standards

Software coding standards play an important role in preventing unreliable programming constructs in software development processes. For embedded systems, important coding standards include:

- “MISRA C” on page 22-10
- “Secure Coding” on page 22-10

The ability to check whether your model and code complies with coding standards can help to prevent security vulnerabilities. Embedded Coder and Simulink offer capabilities to minimize issues that affect compliance with MISRA C:2012 and secure coding standards. Capabilities include:

- Code Generation Advisor, which helps you configure a model or subsystem so that the code generator is most likely to produce MISRA C:2012 compliant code. For more information, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 46-2.
- Model Advisor checks, which you can use as you developed your model or subsystem to increase the likelihood of generating code that complies with MISRA C:2012 and secure coding standards. For more information, see:
  - “Model Advisor Checks for Verifying Compliance with Secure Coding Standards” on page 22-12
  - “Modeling Guidelines and Model Advisor Checks for Verifying Compliance with MISRA C:2012” on page 23-20

## MISRA C

The MISRA C and MISRA C++ standards are a set of coding guidelines for the C and C++ programming languages that promote safety, security, and reliability in embedded system software. These guidelines, published by the Motor Industry Software Reliability Association (MISRA) define a “safe-subset” of the C language to protect against language aspects that can compromise the safety and security of embedded systems. For more information, see [What is MISRA C?](#)

When using MISRA C:2012 coding guidelines to evaluate the quality of your generated C code, you are required per section 5.3 of the *MISRA C:2012 Guidelines for the Use of C Language in Critical Systems* document to prepare a compliance statement for the project being evaluated. To assist you in the development of this compliance statement, MathWorks evaluates the MISRA C:2012 guidelines against C code generated by using Embedded Coder. The results of the evaluation are published as:

- Compliance Summary Tables on page 23-6, which identify the method used to obtain compliance for each rule and directive.
- Deviations on page 23-27, which identify rules or directives that are not compliant.

For more information, see “Developing a MISRA C:2012 Compliance Statement” on page 23-2.

## Secure Coding

CERT C, ISO/IEC 17961, and CWE are coding rule guidelines developed specifically to address the growing number of cyber security concerns within embedded systems. These coding standards are for software developers to use in the development of code in the C language:

- CERT C — Provides secure coding practices for the C languages. Security vulnerabilities in embedded software increase chances of attacks from malicious actors. These guidelines help eliminate constructs with undefined behavior that can lead to unexpected results at runtime and expose security weaknesses. For more information, see [What is CERT C?](#)
- Common Weakness Enumeration (CWE™) — Identifies common software weakness types that can occur in software architecture, design, code, or implementation. These weaknesses can lead to security vulnerabilities.
- ISO/IEC TS 19761:2013 *Information Technology — Programming Languages, Their Environments And System Software Interfaces — C Secure Coding Rules* — The formal ISO® standard for secure coding in C. This standard is designed to be enforced by using static analysis tools without excessive false positives.

## Model Advisor Checks for Verifying Compliance with Secure Coding Standards

If you have Embedded Coder or Simulink Check, you can check that your Simulink model, and the compiled code, conforms to the secure coding standards. To check your model:

- 1 Open the Model Advisor.
- 2 Navigate to **By Task > Modeling Guidelines for Secure Coding (CERT C, CWE, ISO/IEC TS 17961)** .
- 3 Run the checks in the folder.

To review the Model Advisor checks, see “Secure Coding Checks for CERT C, CWE, and ISO/IEC TS 17961 Standards” (Simulink Check).

If you have a Polyspace® Bug Finder™ product license, you can evaluate your code against these secure coding standards. For more information, see:

- “CWE Coding Standard and Polyspace Results” (Polyspace Bug Finder)
- “Check for Coding Standard Violations” (Polyspace Bug Finder)

### See Also

“Modeling Guidelines and Model Advisor Checks for Verifying Compliance with MISRA C:2012” on page 23-20 | “Coding Standards” on page 22-10

## Develop a Model That Complies with the AUTOSAR Standard

Generate AUTOSAR-compliant C code and export AUTOSAR XML (ARXML) descriptions from a Simulink® model.

AUTOSAR Blockset software supports AUTomotive Open System ARchitecture (AUTOSAR), an open and standardized automotive software architecture. Automobile manufacturers, suppliers, and tool developers jointly develop AUTOSAR components. To develop AUTOSAR components in Simulink, follow this general workflow:

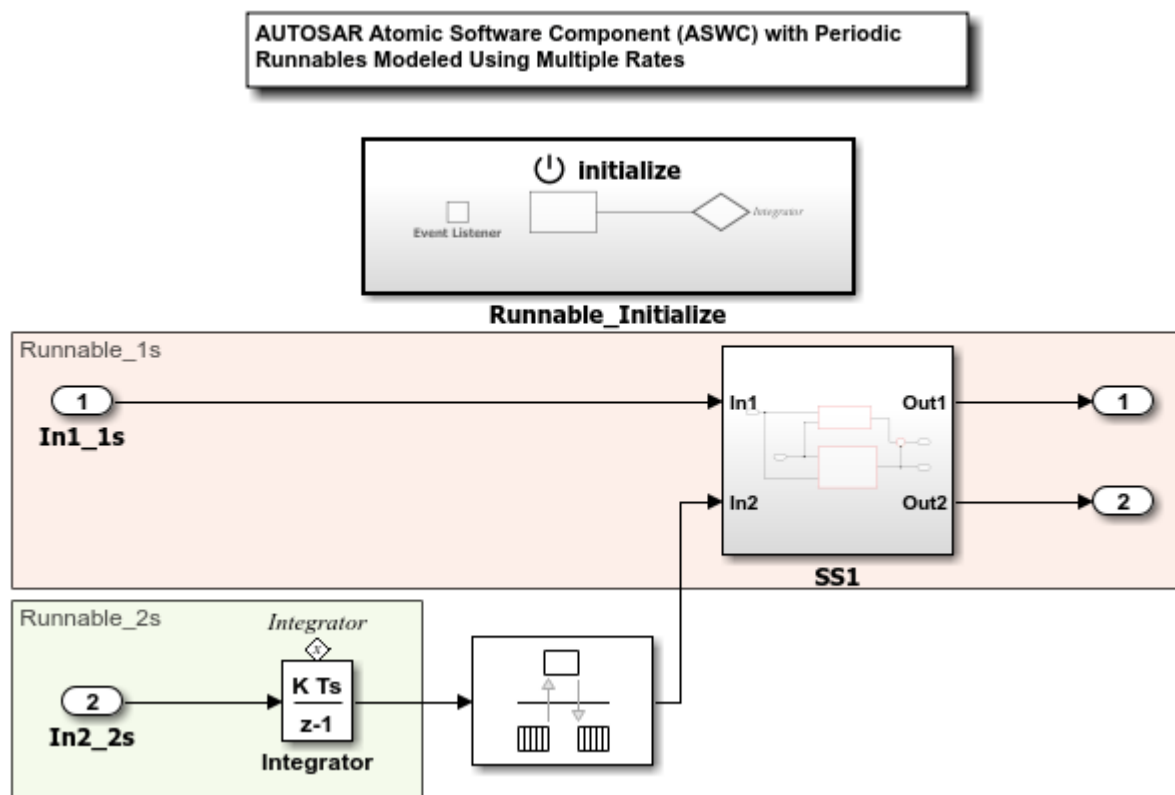

- 1 Create a Simulink representation of an AUTOSAR component.
- 2 Develop the component by refining the AUTOSAR configuration and creating algorithmic model content.
- 3 Generate ARXML descriptions and algorithmic C or C++ code for testing in Simulink or integration into an AUTOSAR run-time environment. (AUTOSAR code generation requires Simulink Coder™ and Embedded Coder®.)

### Prepare Model for AUTOSAR Code Generation

To see the steps for generating AUTOSAR-compliant C code and exporting ARXML descriptions from an AUTOSAR model, open a model and prepare the model for AUTOSAR code generation.

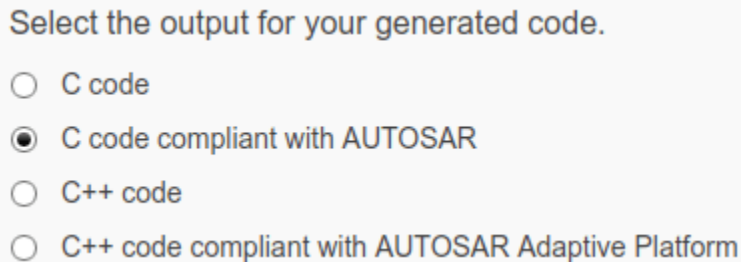

Open a model from which you want to generate AUTOSAR code and descriptions. The model can be unconfigured or only partially configured for code generation. This example uses AUTOSAR example model `autosar_sw_c`.

```
open_system(fullfile(matlabroot, 'examples', 'autosarblockset', 'main', 'autosar_sw_c'));
```

To prepare the model for AUTOSAR code generation, use the Embedded Coder Quick Start. From the **Apps** tab, open the AUTOSAR Component Designer app. On the **AUTOSAR** tab, click **Quick Start**.

Work through the quick-start procedure. In the Output window, select output option **C code compliant with AUTOSAR**.

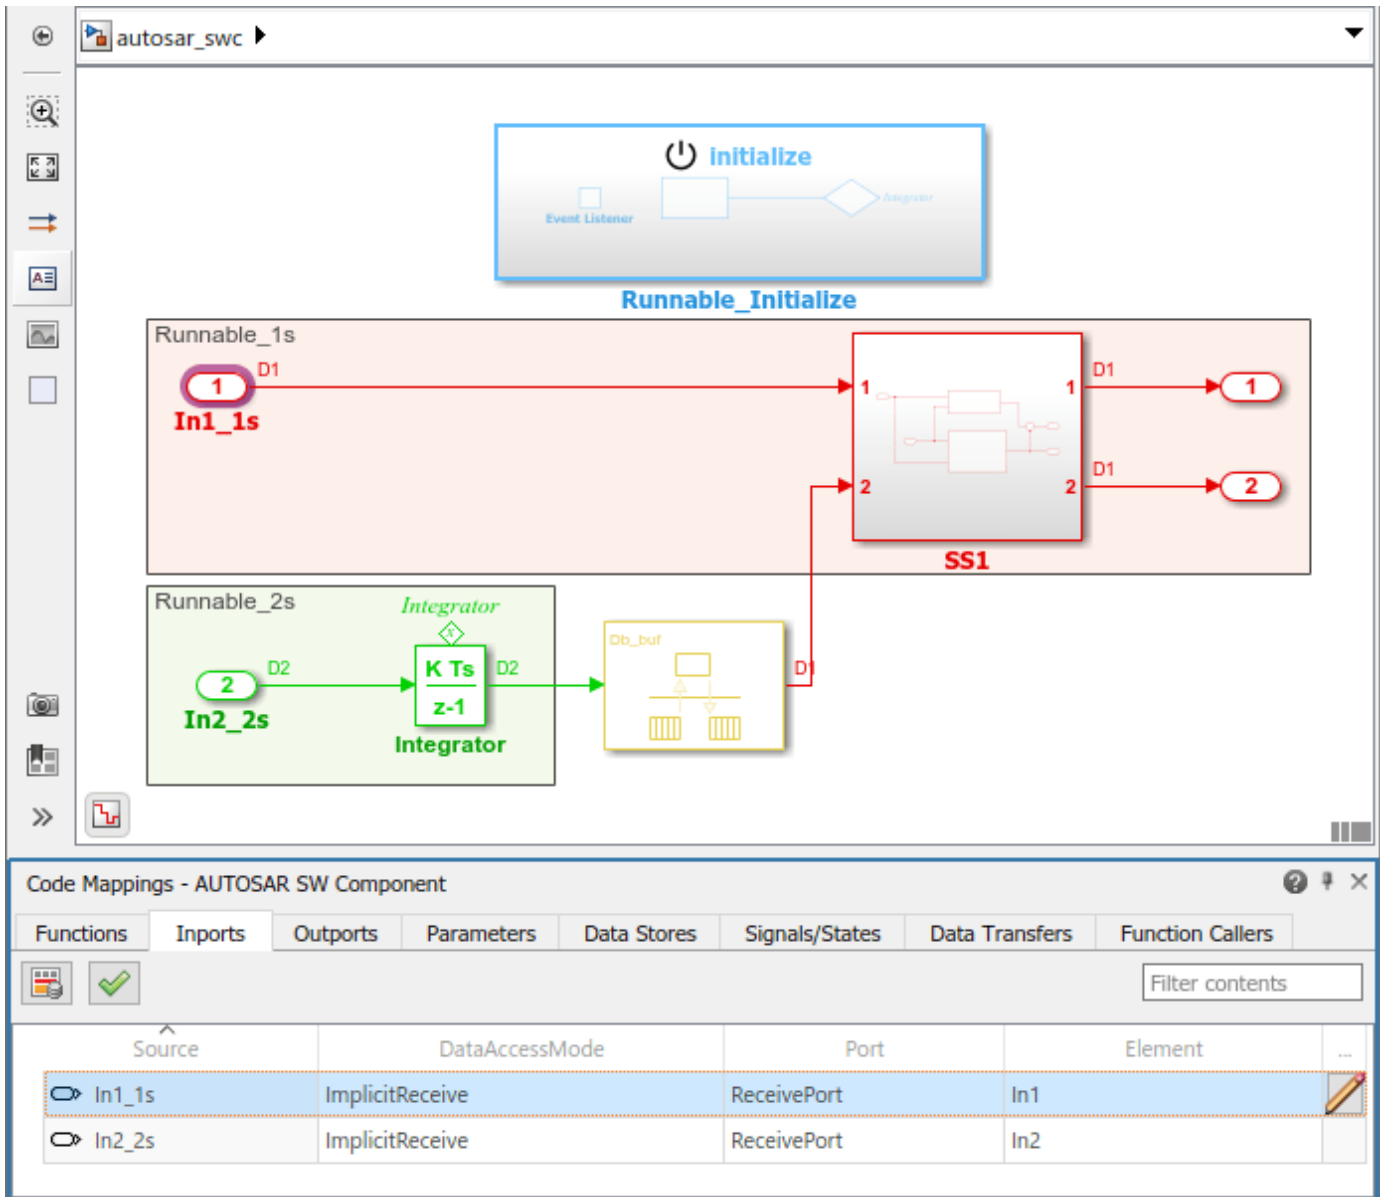

The quick-start software takes the following steps to configure an AUTOSAR software component model:

- 1** Configures code generation settings for the model. If the AUTOSAR target is not already selected, the software sets model configuration parameter **System target file** to `autosar.tlc` and **Generate XML for schema version** to a default schema value.
- 2** If no AUTOSAR mapping exists, creates a mapped AUTOSAR software component for the model.
- 3** Performs a model build.

In the last window, when you click **Finish**, your model opens in the AUTOSAR Code perspective. The Code perspective displays your model, and directly below the model, the Code Mappings editor.

### Develop Simulink Representation of AUTOSAR Software Component

After you create an AUTOSAR software component model in Simulink, use the Code Mappings editor and the AUTOSAR Dictionary to further develop the AUTOSAR component. For more information, see “AUTOSAR Component Configuration” (AUTOSAR Blockset).

In a tabbed table format, the Code Mappings editor displays Simulink model elements, such as entry-point functions, inports, outputs, and data transfers. Use the editor to map Simulink model elements to AUTOSAR component elements from a Simulink model perspective. AUTOSAR component elements are defined in the AUTOSAR standard, and include runnable entities, ports, and inter-runnable variables (IRVs).

In the Code Mappings editor, when you select a model element, it is highlighted in the model and an edit icon  is displayed. To view additional AUTOSAR properties for the element, click the icon. Here is the AUTOSAR properties display for a model inport.

**Communication attributes**

AliveTimeout

HandleNeverReceived

InitValue

[Open in Property Inspector](#)

In each Code Mappings editor tab, you can select model elements and modify their AUTOSAR mapping and attributes. Your modifications are reflected in the generated ARXML descriptions and C code. If you are using AUTOSAR example model `autosar_sw` with this example, modify the communication attributes for the mapped Simulink inport `In1_1s`. In the AUTOSAR properties display, change the `AliveTimeout` attribute from 60 to 30, change `HandleNeverReceived` from cleared to selected, and change `InitValue` from 0 to 1.

To configure the AUTOSAR properties of the mapped AUTOSAR software component, open the AUTOSAR Dictionary. In the Code Mappings editor, click the AUTOSAR Dictionary button, which is the leftmost button. The AUTOSAR Dictionary opens in the AUTOSAR view that corresponds to the Simulink element that you last selected and mapped in the Code Mappings editor. If you selected and mapped a Simulink inport, the dictionary opens in ReceiverPorts view and displays the AUTOSAR port to which you mapped the inport.

In a tree format, the AUTOSAR Dictionary displays the mapped AUTOSAR component and its elements, communication interfaces, computation methods, software address methods, and XML options. Use the dictionary to configure AUTOSAR elements and properties from an AUTOSAR component perspective.

In the ReceiverPorts view, select the AUTOSAR receiver port to which the Simulink inport was mapped in the Code Mappings editor. If an AUTOSAR element has additional undisplayed attributes, selecting the element displays them. In each AUTOSAR element view, you can add or rename AUTOSAR elements and modify their displayed properties. Your modifications are reflected in the generated ARXML descriptions and C code.

If you are using AUTOSAR example model `autosar_swk` with this example, rename the AUTOSAR receiver port from `ReceivePort` to `RequirePort`. To initiate the edit, click in the **Name** value field.

### Generate C Code and ARXML Descriptions

If you have Simulink Coder and Embedded Coder software, you can build the AUTOSAR model. Building the AUTOSAR model generates AUTOSAR-compliant C code and exports ARXML descriptions. In the model window, press **Ctrl+B**.

When the build completes, a code generation report opens. Examine the report. Verify that your Code Mappings editor and AUTOSAR Dictionary changes are reflected in the C code and ARXML descriptions. For example, use the **Find** field to search for the name of the AUTOSAR receiver port that you modified and renamed.

The generated C code encodes the AUTOSAR receiver port name in AUTOSAR run-time environment API read calls.

```

26 /* Model step function for TID0 */
27 void Runnable_1s(void) /* Sample time: [1.0s, 0.0s] */
28 {
29 float64 rtb_RateTransition;
30 float64 rtb_Sum_n;
31
32 /* RateTransition: '<Root>/RateTransition' */
33 rtb_RateTransition = Rte_IrVIRead_Runnable_1s_IRV1();
34
35 /* Outputs for Atomic SubSystem: '<S2>/SS2' */
36 /* Sum: '<S4>/Sum' incorporates:
37 * Gain: '<S4>/Gain'
38 * Inport: '<Root>/In1_1s'
39 */
40 rtb_Sum_n = 2.0 * rtb_RateTransition + Rte_IRead_Runnable_1s_RequirePort_In1();
41
42 /* End of Outputs for SubSystem: '<S2>/SS2' */
43
44 /* Outputs for Atomic SubSystem: '<S2>/SS1' */
45 /* Output: '<Root>/Out1' incorporates:
46 * Gain: '<S3>/Gain1'
47 * Gain: '<S3>/Gain2'
48 * Inport: '<Root>/In1_1s'
49 * Sum: '<S2>/Sum'
50 * Sum: '<S3>/Sum'
51 */
52 Rte_IWrite_Runnable_1s_SenderPort_Out1(5.0 *
53 (Rte_IRead_Runnable_1s_RequirePort_In1() + 3.0 * rtb_RateTransition) +
54 rtb_Sum_n);
55
56 /* End of Outputs for SubSystem: '<S2>/SS1' */
57
58 /* Output: '<Root>/Out2' */
59 Rte_IWrite_Runnable_1s_SenderPort_Out2(rtb_Sum_n);
60 }

```

The generated ARXML description of the AUTOSAR receiver port uses the modified port name and the modified values for port communication attributes AliveTimeout, HandleNeverReceived, and InitValue.

## Develop a Model That Complies with the IEC 61508 Standard

This example shows how to use the Model Advisor to check that a model complies with the IEC 61508 safety standard.

The IEC 61508 Model Advisor checks identify issues with a model that impede deployment in safety-related applications or limit traceability.

### Understanding the Model

Model `rtwdemo_iec61508` check whether the 1-norm distance between points  $(x_1, x_2)$  and  $(y_1, y_2)$  is less than or equal to a given threshold `thr`. For two points  $(x_1, x_2)$  and  $(y_1, y_2)$ , the 1-norm distance is given as:

$$\sum_{i=1}^2 |x_i - y_i|$$

Open and review the model.

```
model='rtwdemo_iec61508';
open_system(model)
```

### Run the IEC 61508 Modeling Standard Checks

To deploy the model in a safety-related software component that must comply with the IEC 61508 safety standard, check the model for issues that might impede deployment in such an environment or limit traceability between the model and generated source code.

- 1 To open the Model Advisor, in the Simulink® editor, click the **Modeling** tab and select Model Advisor. A **System Selector - Model Advisor** dialog box opens. Select the model or system that you want to review and click **OK**. Or enter `modeladvisor('rtwdemo_IEC61508')` at the MATLAB® command line.
- 2 In the left pane of the Model Advisor, expand **By Task > Modeling Standards for IEC 61508**. If the **By Task** folder is not displayed in the Model Advisor window, open **Settings > Preferences** and select **Show By Task Folder**.
- 3 Select the checks that you want to include in your model analysis.
- 4 Click on the folder that contains the checks and, on the right pane of the Model Advisor, select **Show report after run** to automatically generate and display the report in HTML format.
- 5 Click **Run Selected Checks** to execute the analysis.

### Review Check Results

The Model Advisor processes the IEC 61508 checks and displays the results.

- 1 After the analysis is complete, review the aggregate results in the right pane of the Model Advisor. You can see the total number of checks that passed, failed, were flagged as warnings, and did not execute.
- 2 To review the results for a specific check, in the **By Task > Modeling Standards for IEC 61508** folder, select a check. For more information about the check and how to resolve reported issues, click **Help**.
- 3 Address the reported issues and rerun the checks.

- 4 To review the generated HTML report of the results, select the **By Task > Modeling Standards for IEC 61508** folder and click the link in the **Report** box.
- 5 Print the generated HTML report. You can use the report as evidence in the IEC 61508 compliance process.
- 6 If desired, click the **Generate Code Using Embedded Coder** button in the model to inspect the generated code and the traceability report.

# MISRA C:2012 Compliance and Deviations for Code Generated by Using Embedded Coder

---

- “Developing a MISRA C:2012 Compliance Statement” on page 23-2
- “Evaluate Your Generated Code for MISRA C:2012 Compliance” on page 23-4
- “MISRA C:2012 Compliance Information Summary Tables” on page 23-6
- “Modeling Guidelines and Model Advisor Checks for Verifying Compliance with MISRA C:2012” on page 23-20
- “Deviations Rationale for MISRA C:2012 Compliance” on page 23-27

## Developing a MISRA C:2012 Compliance Statement

As part of the model development process, it is important that C code generated by Embedded Coder from Simulink and Stateflow complies with industry coding standards.

When using MISRA C:2012 coding guidelines to evaluate the quality of your generated C code, you are required per section 5.3 of the *MISRA C:2012 Guidelines for the Use of C Language in Critical Systems* document to prepare a compliance statement for the project being evaluated. To assist you in the development of this compliance statement, MathWorks evaluates the MISRA C:2012 guidelines against C code generated by using Embedded Coder and provides the following information:

- Compliance Summary Tables on page 23-6, which identify the method used to obtain compliance for each rule and directive.
- Deviations on page 23-27, which identify rules or directives that are not compliant.

For information about the process MathWorks uses to evaluate generated C code against MISRA C:2012 guidelines, see “MathWorks Process for Identifying Violations of MISRA C:2012 Guidelines in Generated C Code” on page 23-2.

For additional information about the MISRA organization, their coding guidelines, and the MISRA publication timeline, see [www.misra.org.uk](http://www.misra.org.uk).

---

**Disclaimer** While adhering to the recommendations in the MISRA C:2012 Compliance and Deviations for Code Generated using Embedded Coder documentation will reduce the risk that an error is introduced during development and not be detected, it is not a guarantee that the system being developed will be safe. Conversely, if some of the recommendations are not followed, it does not mean that the system being developed will be unsafe.

---

### MathWorks Process for Identifying Violations of MISRA C:2012 Guidelines in Generated C Code

To determine any potential violations in the generated code, MathWorks maintains an extensive set of test models that cover the standard usage of compliant blocks. For each release, MathWorks uses these test models with the following products to evaluate the modeling, code generation, and analysis of generated code.

Product	Purpose
Simulink	Create/maintain models.
Stateflow	Create/maintain models.
Fixed-Point Designer™	Create/maintain models.
Embedded Coder	Generate C code.
Simulink Check	Execute MISRA C:2012 Model Advisor checks. <sup>a</sup>

Product	Purpose
Polyspace Bug Finder	Identify bug/coding defects.  Use the checkers for “MISRA C:2012 Directives and Rules” (Polyspace Bug Finder) to analyze the generated code and provide information about violations.

a MISRA C:2012 checks are available only when you have a Simulink Check or Embedded Coder license.

---

**Note** The compliance analysis performed by the Polyspace MISRA C:2012 Checker assesses C code generated by Embedded Coder. No assessment is made of the Embedded Coder tool chain. Handwritten C code and third-party libraries that are used with code generated by Embedded Coder are not considered. Other MISRA C code analysis tools can yield different results.

---

## Evaluate Your Generated Code for MISRA C:2012 Compliance

It is important to check that C code generated by Embedded Coder from Simulink and Stateflow complies with MISRA C:2012 coding standards. This workflow illustrates the process of evaluating your generated code for compliance to MISRA C:2012 guidelines.

- 1 Design your model in Simulink or Stateflow.
- 2 Open the Model Advisor and run the MISRA C:2012 checks (Simulink Check), which are available in **By Task > Modeling Standards for MISRA C:2012**.
- 3 If necessary, modify the model to adhere to the “Modeling Guidelines and Model Advisor Checks for Verifying Compliance with MISRA C:2012” on page 23-20.
- 4 After the MISRA C:2012 checks pass, generate code by using Embedded Coder.

To avoid possible name clashes, multiple functions definitions, and multiple data definitions, use one of these code generation approaches:

- Single model: Generate code from a single model, including submodels, by using Model blocks.
  - Multiple models: Generate code from multiple models, including:
    - A shared utility folder to synchronize functions
    - Data ownership to control data definitions
    - Hand integration to manage code generated from various models
- 5 Run the checkers for “MISRA C:2012 Directives and Rules” (Polyspace Bug Finder).

For more information about running a Polyspace analysis on your generated code, including analysis options and results, see:

- “Bug Finder Analysis in Simulink” (Polyspace Bug Finder)
  - “Code Prover Analysis in Simulink” (Polyspace Code Prover)
- 6 Justify violations to the MISRA C:2012 coding standards using Polyspace annotations (Polyspace Bug Finder).

## MISRA C:2012 Compliance Information Summary Tables

In this section...
"MISRA C:2012 Main Document" on page 23-6
"MISRA C:2012 Amendment 1" on page 23-15
"MISRA C:2012 Amendment 2" on page 23-16
"Explanatory Notes" on page 23-16

MathWorks evaluates C code generated by Embedded Coder from Simulink and Stateflow against the MISRA C:2012 coding standards. The results from this effort are available in these compliance summary tables. These tables identify:

- Methods used to obtain compliance:
  - Compliant: Compliance to the rule/directive is achieved through adherence to the code generation process, modeling guidelines, or Model Advisor checks. When applicable, there are explanatory notes that provide information relevant to compliance methods or actions that you can perform to satisfy the directive or rule.
  - Deviation: The rule or directive is not compliant.
- Whether the Polyspace MISRA C:2012 Checker supports the rule or directive.

You can use these tables when preparing the MISRA C:2012 compliance statement for your project as required per section 5.3 of the *MISRA C:2012 Guidelines for the Use of C Language in Critical Systems* document. These tables align with the published MISRA C:2012 rule and directives tables. The categories in the table are based on Appendix E of the MISRA guidelines identified for automatically generated code. They can be used for Mandatory and Required categories only (not for Advisory and Readability categories).

### MISRA C:2012 Main Document

#### "Implementation" MISRA C:2012 Directives

Directive	Category	Compliance	Polyspace Support?
1.1	Required	Compliant: <ul style="list-style-type: none"> <li>• hisl_0060</li> <li>• hisl_0016: Usage of blocks that compute relational operators</li> <li>• "Explanatory Note for Directive 1.1" on page 23-17</li> </ul>	Yes, partially supported

#### "Compilation and Build" MISRA C:2012 Directives

Directive	Category	Compliance	Polyspace Support?
2.1	Required	Compliant	Yes

**"Requirements Traceability" MISRA C:2012 Directives**

8.6	Required	Compliant	Yes
8.8	Required	Compliant	Yes
8.10	Required	Compliant	Yes
8.12	Required	Compliant: • "Explanatory Note for Rule 8.12" on page 23-18	Yes
8.14	Advisory	Compliant	Yes

<sup>a</sup> Guideline suggests Rule 8.14 as Required for manually generated code.

**"Initialization" MISRA C:2012 Rules**

Rule	Category <sup>a</sup>	Compliance	Polyspace Support?
9.1	Mandatory	Compliant: • hisl_0029 • Check usage of Assignment blocks	Yes
9.4	Required	Compliant	Yes
9.5	Readability	Compliant	Yes

<sup>a</sup> Guideline suggests Rule 9.5 as Required for manually generated code.

**"The Essential Type Model" MISRA C:2012 Rules**

Rule	Category <sup>a</sup>	Compliance	Polyspace Support?
10.2	Advisory	Compliant	Yes
10.3	Advisory	Compliant	Yes

a Guideline suggests Rule 10.2 and 10.3 as Required for manually generated code.

**"Pointer Type Conversion" MISRA C:2012 Rules**

Rule	Category	Compliance	Polyspace Support?
11.1	Required	Compliant	Yes
11.2	Required	Compliant	Yes
11.3	Required	Compliant: • hisl_0020	Yes
11.6	Required	Compliant	Yes
11.7	Required	Compliant	Yes
11.8	Required	Compliant: • hisl_0020	Yes

**"Expressions" MISRA C:2012 Rules**

Rule	Category	Compliance	Polyspace Support?
12.2	Required	Compliant	Yes

**"Side Effects" MISRA C:2012 Rules**

Rule	Category	Compliance	Polyspace Support?
13.1	Required	Compliant	Yes
13.2	Required	Compliant: • hisl_0062	Yes
13.5	Required	Compliant: • hisl_0062  Deviation: • "MISRA C:2012 Rule 13.5 Deviation Rationale" on page 23-30	Yes
13.6	Mandatory	Compliant	Yes

**"Control Statement Expressions" MISRA C:2012 Rules**

Rule	Category <sup>a</sup>	Compliance	Polyspace Support?
14.2	Readability	Compliant: <ul style="list-style-type: none"> <li>• hisl_0006</li> <li>• hisl_0007</li> <li>• hisl_0008</li> <li>• hisl_0010</li> <li>• hisl_0011</li> <li>• hisl_0101</li> </ul>	Yes
14.3	Required	Compliant: <ul style="list-style-type: none"> <li>• hisl_0101</li> <li>• hisl_0060</li> </ul>	Yes

a Guideline suggests Rule 14.2 as Required for manually generated code.

**"Control Flow" MISRA C:2012 Rules**

Rule	Category <sup>a</sup>	Compliance	Polyspace Support?
15.2	Advisory	Compliant	Yes
15.3	Advisory	Compliant	Yes
15.6	Required	Compliant	Yes
15.7	Readability	Compliant	Yes

a Guideline suggests Rule 15.2, 15.3 and 15.7 as Required for manually generated code.

**"Switch statements" MISRA C:2012 Rules**

Rule	Category <sup>a</sup>	Compliance	Polyspace Support?
16.2	Advisory	Compliant	Yes
16.3	Advisory	Compliant	Yes
16.4	Advisory	Compliant: <ul style="list-style-type: none"> <li>• hisl_0006</li> <li>• hisl_0007</li> <li>• hisl_0008</li> <li>• hisl_0010</li> <li>• hisl_0011</li> </ul>	Yes
16.5	Advisory	Compliant	Yes
16.6	Advisory	Compliant	Yes
16.7	Advisory	Compliant	Yes

a Guideline suggests Rule 16.2, 16.3, 16.4, 16.5, 16.6 and 16.7 as Required for manually generated code.

**Explanatory Notes**

These explanatory notes are referenced from the "MISRA C:2012 Compliance Information Summary Tables" on page 23-6.

### Explanatory Note for Directive 1.1

Information about the implementation-defined behavior for Embedded Coder is available in “Configure Run-Time Environment Options” on page 9-2 . Compiler documentation is out of scope.

Character set encoding is managed by using the `SavedCharacterEncoding` model parameter. For additional information, see `slCharacterEncoding`.

Configure the integer division method in the Model Configuration Parameters dialog box, on the **Hardware Implementation** pane. For additional information, see “Configure Run-Time Environment Options” on page 9-2

Embedded Coder generates `#pragma` when the user:

- Selects the use of memory sections
- Creates a custom storage class with memory sections on page 37-14

In both instances, you are responsible for documenting the intended use of the `#pragma`. For more information, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2.

To enable the generation of bitfields:

- 1 Select at least one of these model configuration parameters:
  - **Pack Boolean data into bitfields.** This parameter is available only for ERT-based system target files on page 47-2.
  - **Use bitsets for storing state configuration.**
  - **Use bitsets for storing Boolean data.**
- 2 Create a custom storage class with defined bitfields. See “Create Storage Classes by Using the Custom Storage Class Designer” on page 37-14 for more information.

If your model uses conversion of one datatype to another, Polyspace Checker shows violation of Dir 1.1 from the generated code of the model. In this case, the violation coming from the model is not an issue if you document this explicit conversion according to the MISRA guidelines.

### Explanatory Note for MISRA Directive 3.1

You can link requirements model elements. These links are included in the generated C code to provide traceability from a requirements document, to the model elements, and to the generated code. For additional information, see “View Requirements Toolbox Links Associated with Model Elements” and “Link Blocks and Requirements” (Requirements Toolbox).

### Explanatory Note for Directive 4.1

You can use Polyspace Bug Finder to identify run-time errors and Polyspace Code Prover™ to prove the absence of run-time errors. For information, see:

- “Configure and Run Analysis” (Polyspace Code Prover)
- “Configure and Run Analysis” (Polyspace Bug Finder)

Simulink Design Verifier can be used to detect design errors at the model level. For more information, see “Run a Design Error Detection Analysis” (Simulink Design Verifier).

To handle the overflow violations, see “Handle Overflows in Simulink Models” (Fixed-Point Designer).

### **Explanatory Note for Directive 4.3**

Embedded Coder does not directly call assembly language code. You can add calls to assembly language functions through S-functions, code replacement libraries, Stateflow, and in MATLAB blocks. These calls are documented as calls to “External C Functions” on page 25-48. In these cases, you are responsible for encapsulation.

For additional information, see:

- “External C Functions” on page 25-48
- “Code Replacement Customization”
- “Control Data and Function Placement in Memory by Inserting Pragmas” on page 42-2

### **Explanatory Note for Directive 4.6**

Embedded Coder replaces basic data types with typedefs types, which are compatible with Directive 4.6. A guideline is not required because this behavior is default behavior in Embedded Coder. For additional information, see “Replace and Rename Data Types to Conform to Coding Standards” on page 35-22 and Typedefs on page 25-57.

### **Explanatory Note for Directive 4.11**

The requirements of this directive are satisfied by:

*“Demonstrate statically that the input parameters can never take invalid values”.*

You can use Polyspace Code Prover to analyze parameter ranges and prove the absence of run-time errors caused by out-of-range values. For additional information, see “Run Polyspace Analysis on Code Generated with Embedded Coder” (Polyspace Code Prover).

### **Explanatory Note for Rule 2.1**

Embedded Coder does not check user defined code from the Stateflow. You must take care of the violations reported.

### **Explanatory Note for Rules 5.1, 5.2, 5.4, 5.5, 5.6, 5.7, and 5.8**

Embedded Coder is configurable to limit the number of characters imposed by the implementation. For additional information, see **Maximum identifier length**.

To ensure unique names for different types of variables (local scope variables, global scope variables, macros, and so on), implement a naming convention. For additional information, see **Model Configuration Parameters: Code Generation Symbols**.

In case of long identifiers, it is recommended to use shared utilities. For more information, see “Generate Shared Utility Code”

### **Explanatory Note for Rule 8.12**

Embedded Coder supports the use of enumerated data. The file used to define the enumeration can be either manually or automatically generated. Files defining enumerations generated by Embedded Coder are compliant with MISRA C:2012 Rule 8.12 by design. If you manually create the definition

file, you are responsible for ensuring compliance. For additional information, see “Use Enumerated Data in Simulink Models”.

**Explanatory Note for Rules 10.1 and 10.2**

Embedded Coder does not directly create data of type char. Data of char type can be introduced by user-defined S-functions, code replacement libraries, and custom storage classes. In this case, limit the usage of plain char to:

- Plain char type for character values
- Signed and unsigned char type for numeric values

## Modeling Guidelines and Model Advisor Checks for Verifying Compliance with MISRA C:2012

The “MISRA C:2012 Compliance Information Summary Tables” on page 23-6 identifies modeling guidelines that are relevant to the compliance of generated C code with MISRA C:2012 coding standards. For a list of these guidelines and their corresponding Model Advisor check, see “High-Integrity System Modeling Guidelines and Model Advisor Checks for Verifying Compliance with MISRA C:2012” on page 23-24. For mapping of MISRA C:2012 Model Advisor checks to the MISRA C:2012 rules or directives, see “MISRA C:2012 Model Advisor Checks Rationale” on page 23-20.

### MISRA C:2012 Model Advisor Checks Rationale

This table provides MISRA C:2012 rationale for the MISRA C:2012 Model Advisor checks.

Model Advisor Check	MISRA C:2012 Rule or Directive
“Check configuration parameters for MISRA C:2012” (Simulink Check)	
Set <b>Use division for fixed-point net slope computation</b> to On or Use division for reciprocals of integers only.	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
Set <b>Inf or NaN block output</b> to warning or error.	MISRA C:2012 Directive 4.1: Run-time failures shall be minimized
Set <b>Model Verification block enabling</b> to Disable All.	General recommendation for embedded systems.
Set <b>Undirected event broadcasts</b> to error.	MISRA C:2012 Rule 17.2: Functions shall not call themselves, either directly or indirectly
Set configuration parameter <b>Wrap on overflow</b> to warning or error.	MISRA C:2012 Directive 4.1: Run-time failures shall be minimized
Set <b>Production hardware signed integer division rounds to</b> to Zero or Floor.	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
Clear <b>Shift right on a signed integer as arithmetic shift</b> .	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
Set <b>Compile-time recursion limit for MATLAB functions</b> to 0 .	MISRA C:2012 Rule 17.2: Functions shall not call themselves, either directly or indirectly
Clear <b>Dynamic memory allocation in MATLAB functions</b> .	MISRA C:2012 Directive 4.12: Dynamic memory allocation shall not be used.  MISRA C:2012 Rule 21.3: The memory allocation and deallocation functions of <stdlib.h> shall not be used.
Clear <b>Enable run-time recursion for MATLAB functions</b> .	MISRA C:2012 Rule 17.2: Functions shall not call themselves, either directly or indirectly

Model Advisor Check	MISRA C:2012 Rule or Directive
Set <b>Bitfield declarator type specifier</b> to <code>uint_T</code> .	MISRA C:2012 Rule 6.1: Bit-fields shall only be declared with an appropriate type  MISRA C:2012 Rule 6.2: Single-bit named bit fields shall not be of a signed type
Set <b>Casting Modes</b> to Standards Compliant.	MISRA C:2012 Rules 10.x: The essential type model
Set <b>Code replacement library</b> to None or AUTOSAR 4.0	General recommendation for embedded systems.
Clear <b>External mode</b> .	General recommendation for embedded systems.  MISRA C:2012 Directive 4.12 Dynamic memory allocation shall not be used  MISRA C:2012 Rule 21.3 The memory allocation and deallocation functions of <code>&lt;stdlib.h&gt;</code> shall not be used  MISRA C:2012 Rule 21.6 The Standard Library input/output functions shall not be used
Clear <b>Generate shared constants</b> .	MISRA Rule 8.5: An external object or function shall be declared once in one and only one file
Clear <b>MAT-file logging</b>	General recommendation for embedded systems.
Set <b>Maximum identifier length</b> to the implementation-dependent limit. The default is 31.	MISRA C:2012 Rules 5.1-9: Identifiers
Set <b>Parentheses level</b> to Standards(Parentheses for Standards Compliance) or Maximum(Specify precedence with parentheses).	MISRA C:2012 Rule 12.1: The precedence of operators within expressions should be made explicit
Select <b>Preserve static keyword in function declarations</b> .	MISRA Rule 8.7: Functions and objects should not be defined with external linkage if they are referenced in only one translation unit  MISRA Rule 8.8: The static storage class specifier shall be used in all declarations of objects and functions that have internal linkage
Clear <b>Replace multiplications by powers of two with signed bitwise shifts</b> .	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type
Set <b>Shared code placement</b> to Shared location	Prerequisite of configuration parameter <b>Generate shared constants</b>
Clear <b>Support continuous time</b> .	General recommendation for embedded systems.
Clear <b>Support non-finite numbers</b>	MISRA C:2012 Directive 4.1: Run-time failures shall be minimized

Model Advisor Check	MISRA C:2012 Rule or Directive
Clear <b>Support non-inlined S-functions</b> .	General recommendation for embedded systems.
Set <b>System-generated identifiers</b> to Shortened.	<p>MISRA C:2012 5.1: External identifiers shall be distinct</p> <p>MISRA C:2012 5.2: Identifiers declared in the same scope and name space shall be distinct</p> <p>MISRA C:2012 5.4: Macro identifiers shall be distinct</p> <p>MISRA C:2012 5.5: Identifiers shall be distinct from macro names</p>
Set <b>System target file</b> to an ERT-based target.	General recommendation for embedded systems.
Clear <b>Use dynamic memory allocation for model initialization</b> .	MISRA C:2012 Directive 4.12: Dynamic memory allocation shall not be used.
Select only when <b>Code Interface Packaging</b> is set to Reusable Function.	MISRA C:2012 Rule 21.3: The memory allocation and deallocation functions of <stdlib.h> shall not be used.
EnableSignedLeftShifts - off	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type
"Check for blocks not recommended for C/C++ production code deployment"	General recommendation for embedded systems.
"Check for blocks not recommended for MISRA C:2012"	
<p>Lookup Table blocks using cubic spline interpolation or extrapolation methods.</p> <p>Specific blocks are:</p> <ul style="list-style-type: none"> <li>• 1-D Lookup Table</li> <li>• 2-D Lookup Table</li> <li>• n-D Lookup Table</li> </ul>	<p>MISRA C:2012 Rule 11.3: A cast shall not be performed between a pointer to object type and a pointer to a different object type.</p> <p>MISRA C:2012 Rule 11.5: A conversion should not be performed from pointer to void into pointer to object.</p> <p>MISRA C:2012 Rule 11.8: A cast shall not remove any const or volatile qualification from the type pointed to by a pointer.</p> <p>MISRA C:2012 Rule 11.9: The macro NULL shall be the only permitted form of integer null pointer constant.</p> <p>MISRA C:2012 Rule 12.1: The precedence of operators within expressions should be made explicit.</p>

Model Advisor Check	MISRA C:2012 Rule or Directive
<p>Deprecated Lookup Table blocks.</p> <p>Specific blocks are:</p> <ul style="list-style-type: none"> <li>• Lookup Table</li> <li>• Lookup Table (2-D)</li> </ul>	<p>MISRA C:2012 Rule 11.3: A cast shall not be performed between a pointer to object type and a pointer to a different object type.</p> <p>MISRA C:2012 Rule 11.5: A conversion should not be performed from pointer to void into pointer to object.</p> <p>MISRA C:2012 Rule 11.8: A cast shall not remove any const or volatile qualification from the type pointed to by a pointer.</p> <p>MISRA C:2012 Rule 11.9: The macro NULL shall be the only permitted form of integer null pointer constant.</p> <p>MISRA C:2012 Rule 12.1: The precedence of operators within expressions should be made explicit.</p> <p>MISRA C:2012 Rule 12.2: The right hand operand of a shift operator shall lie in the range zero to one less than the width in bits of the essential type of the left hand operand.</p>
<p>S-Function Builder blocks</p>	<p>MISRA C:2012 Rule 8.4: A compatible declaration shall be visible when an object or function with external linkage is defined.</p> <p>MISRA C:2012 Rule 8.5: An external object or function shall be declared once in one and only one file.</p>
<p>From Workspace blocks</p>	<p>MISRA C:2012 Rule 18.4: The +, -, += and -= operators should not be applied to an expression of pointer type.</p>
<p>String blocks were found in the model or subsystem.</p> <p>Specific blocks are:</p> <ul style="list-style-type: none"> <li>• Compose String</li> <li>• Scan String</li> <li>• String to Single</li> <li>• String to Double</li> <li>• To String</li> </ul>	<p>MISRA C:2012 Directive 4.7: If a function returns error information, then that error information shall be tested</p> <p>MISRA C:2012 Rule 17.7: The value returned by a function having non-void return type shall be used</p> <p>MISRA C:2012 Rule 21.6: The Standard Library input/output functions shall not be used</p>
<p>“Check for unsupported block names” (Simulink Check)</p>	<p>MISRA C:2012 Rule 3.1: The character sequences /* and // shall not be used within a comment.</p>

Model Advisor Check	MISRA C:2012 Rule or Directive
“Check usage of Assignment blocks” (Simulink Check)	MISRA C:2012 Rule 9.1: The value of an object with automatic storage duration shall not be read before it has been set.
“Check for switch case expressions without a default case” (Simulink Check)	MISRA C:2012 Rule 16.4: Every switch statement shall have a default label.
“Check for missing error ports for AUTOSAR receiver interfaces” (Simulink Check)	MISRA C:2012 Directive 4.7 If a function returns error information, then that error information shall be tested.  MISRA C:2012 Rule 17.7: The value returned by a function having non-void return type shall be used.
“Check for bitwise operations on signed integers” (Simulink Check)	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
“Check for recursive function calls” (Simulink Check)	MISRA C:2012 Rule 17.2: Functions shall not call themselves, either directly or indirectly.
“Check for equality and inequality operations on floating-point values” (Simulink Check)	MISRA C:2012 Directive 1.1: Any implementation-defined behaviour on which the output of the program depends shall be documented and understood.
“Check for missing const qualifiers in model functions” (Simulink Check)	MISRA C:2012 Rule 8.13: A pointer should point to a const-qualified type whenever possible.
“Check integer word length” (Simulink Check)	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
“Check bus object names that are used as bus element names” (Simulink Check)	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.  MISRA C:2012 Rule 5.6: A typedef name shall be a unique identifier.

## High-Integrity System Modeling Guidelines and Model Advisor Checks for Verifying Compliance with MISRA C:2012

To augment the modeling guidelines developed by the MathWorks Advisory Board (MAB), MathWorks has published a set of modeling guidelines that focus on high-integrity applications.

Many high-integrity modeling guidelines have Model Advisor checks that you can use to verify adherence of your model to the guideline. This table identifies the high-integrity modeling guidelines and provides the corresponding Model Advisor check. Not all modeling guidelines have a corresponding Model Advisor check.

High-Integrity Guideline	Model Advisor Check
“hisl_0001: Usage of Abs block”	“Check usage of Abs blocks” (Simulink Check)
“hisl_0002: Usage of remainder and reciprocal operations”	“Check usage of remainder and reciprocal operations” (Simulink Check)

High-Integrity Guideline	Model Advisor Check
"hisl_0005: Usage of Product blocks"	Not applicable
"hisl_0006: Usage of While Iterator blocks"	"Check usage of While Iterator blocks" (Simulink Check)
"hisl_0008: Usage of For Iterator Blocks"	"Check usage of For Iterator blocks" (Simulink Check)
"hisl_0010: Usage of If blocks and If Action Subsystem blocks"	"Check usage of If blocks and If Action Subsystem blocks" (Simulink Check)
"hisl_0011: Usage of Switch Case blocks and Action Subsystem blocks"	"Check usage of Switch Case blocks and Switch Case Action Subsystem blocks" (Simulink Check)
"hisl_0016: Usage of blocks that compute relational operators"	"Check relational comparisons on floating-point signals" (Simulink Check)
"hisl_0017: Usage of blocks that compute relational operators (2)"	"Check usage of Relational Operator blocks" (Simulink Check)
"hisl_0018: Usage of Logical Operator block"	"Check usage of Logical Operator blocks" (Simulink Check)
"hisl_0019: Usage of bitwise operations"	"Check usage of bit operation blocks" (Simulink Check)
"hisl_0020: Blocks not recommended for MISRA C:2012 compliance"	"Check for blocks not recommended for C/C++ production code deployment" (Simulink Check)  "Check for blocks not recommended for MISRA C:2012" (Simulink Check)
"hisl_0029: Usage of Assignment blocks"	"Check usage of Assignment blocks" (Simulink Check)
"hisl_0032: Model object names"	"Check model object names" (Simulink Check)
"hisl_0045: Configuration Parameters > Math and Data Types > Implement logic signals as Boolean data (vs. double)"	"Check safety-related optimization settings for logic signals" (Simulink Check)
"hisl_0053: Configuration Parameters > Code Generation > Optimization > Remove code from floating-point to integer conversions that wraps out-of-range values"	"Check safety-related optimization settings for data type conversions" (Simulink Check)
"hisl_0054: Configuration Parameters > Code Generation > Optimization > Remove code that protects against division arithmetic exceptions"	"Check safety-related optimization settings for division arithmetic exceptions" (Simulink Check)
"hisl_0060: Configuration parameters that improve MISRA C:2012 compliance"	"Check configuration parameters for MISRA C:2012" (Simulink Check)
"hisl_0061: Unique identifiers for clarity"	"Check Stateflow charts for uniquely defined data objects" (Simulink Check)
"hisl_0062: Global variables in graphical functions"	"Check global variables in graphical functions" (Simulink Check)

High-Integrity Guideline	Model Advisor Check
"hisl_0063: Length of user-defined object names to improve MISRA C:2012 compliance"	"Check for length of user-defined object names" (Simulink Check)
"hisl_0101: Avoid operations that result in dead logic to improve code compliance"	Not applicable
"hisl_0102: Data type of loop control variables to improve MISRA C:2012 compliance"	"Check data type of loop control variables" (Simulink Check)
"hisl_0314: Configuration Parameters > Diagnostics > Data Validity > Signals"	"Check safety-related diagnostic settings for signal data" (Simulink Check)
"hisf_0004: Protect against recursive function calls to improve code compliance"	Not applicable
"hisf_0065: Type cast operations in Stateflow to improve code compliance"	"Check assignment operations in Stateflow Charts" (Simulink Check)
"hisf_0211: Protect against use of unary operators in Stateflow Charts to improve code compliance"	"Check Stateflow charts for unary operators" (Simulink Check)

## Deviations Rationale for MISRA C:2012 Compliance

Instances in which the generated code does not comply with the MISRA C:2012 guidelines are marked as deviations in the “MISRA C:2012 Compliance Information Summary Tables” on page 23-6. In accordance with Section 5.4 of the MISRA C:2012 guidelines, information about the deviations includes:

- The guideline being deviated
- The circumstances in which the deviation is permitted
- Justification for the deviation, including a risk assessment
- Demonstration of how safety is assured
- Potential consequences of non-conformance

Deviations to the MISRA C:2012 directives and rules include:

- “MISRA C:2012 Directive 4.7 Deviation Rationale” on page 23-27
- “MISRA C:2012 Rule 13.5 Deviation Rationale” on page 23-30

### MISRA C:2012 Directive 4.7 Deviation Rationale

#### Directive Definition

If a function returns error information, then that error information shall be tested.

#### Rationale

---

**Note** This directive is violated only when an AUTOSAR-based code generation target is used.

---

When a function call provides information that indicates an unsuccessful operation, the calling program has to check for the indication of an error when the function is returned. The function calls are not limited to calls in the standard library.

#### Description

AUTOSAR sender interface function calls, such as `Rte_Write_...`, have return type `Std_ReturnType` that indicates if writing the value was successful. The matching Simulink pattern is a top-level output port that is configured as an AUTOSAR Sender Interface.

#### Model Example

AUTOSAR Configuration

### Generated Code Sample

In the sample code, note the use of AUTOSAR function call `Rte_Write_...` in **`Rte_Write_OUT_DE1_OUT_DE1(rtb_TmpSignalConversionAtIN_DE1);`**

```
void Runnable_Step(void)
{
 /* local block i/o variables */
 real_T rtb_TmpSignalConversionAtIN_DE1;
 ...
 rtb_TmpSignalConversionAtIN_D_l = Rte_Read_IN_DE1_IN_DE1
 (&rtb_TmpSignalConversionAtIN_DE1);
 ...
 if (rtb_TmpSignalConversionAtIN_D_l > 0) {
 ...
 }
}
```

```
 Rte_Write_OUT_DE1_OUT_DE1(rtb_TmpSignalConversionAtIN_DE1);
 }
 ...
}
```

### Justification

Failures of `Rte_Write_...` function calls are typically handled on the receiver side because function call returns do not always include all potential errors.

### Conditions Under Which the Deviation is Requested

The deviation is requested for all instances of AUTOSAR sender ports.

### Consequences of Noncompliance

The calling program cannot react when the sender operation is unsuccessful.

### Actions to Control Reporting

When a Polyspace analysis of your code finds known or acceptable coding rule violations, you can suppress the violations in subsequent analyses by adding code annotations (Polyspace Bug Finder) to the Outport block. In future analyses, Polyspace hides results justified through annotations in the **Results List** pane. To review the coding rule violations, see “Filter and Group Results in Polyspace Desktop User Interface” (Polyspace Bug Finder).

If you have already provided annotations for MISRA C:2004 violations, Polyspace imports these justifications when you check your code for MISRA C:2012 violations. For additional information, see “Import Existing MISRA C: 2004 Justifications to MISRA C: 2012 Results” (Polyspace Bug Finder).

For additional information, see:

- “Modeling Patterns for AUTOSAR Runnables” (AUTOSAR Blockset)
- “Develop a Model That Complies with the AUTOSAR Standard” on page 22-13
- “MISRA C:2012 Compliance Information Summary Tables” on page 23-6

## MISRA C:2012 Rule 13.5 Deviation Rationale

### Rule Definition

The right hand operand of a logical `&&` or `||` operator shall not contain persistent side effects.

### Rationale

Persistent side effects of the right hand side operand of the `&&` and `||` operators can occur depending on the left hand side operand, which is contrary to the expectations of the programmer.

---

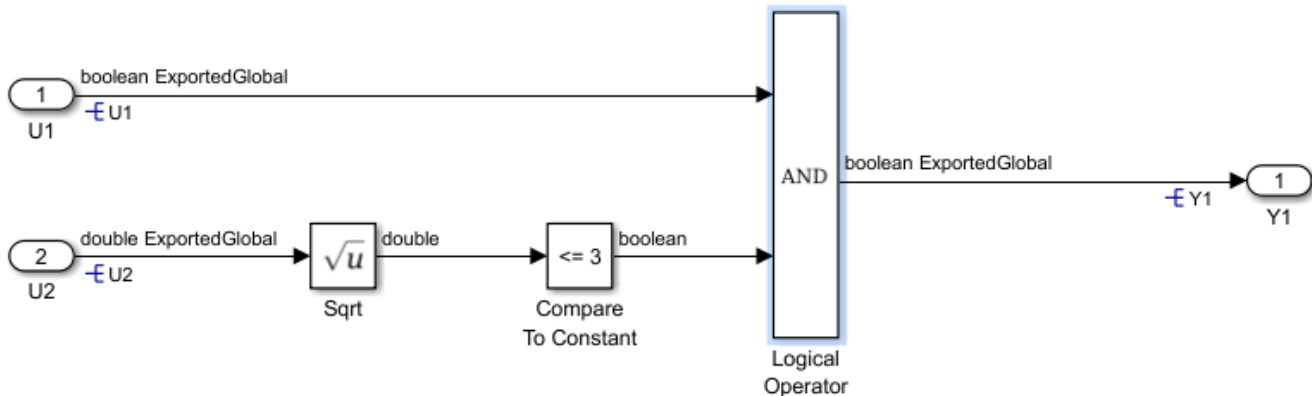

**Note** The term *persistent side effect* is defined in "Appendix J: Glossary" of the *MISRA C:2012 Guidelines for the Use of C Language in Critical Systems* document.

---

### Description

Using math operations as second input to Logical Operator blocks configured as AND or OR operation.

### Model Example

### Generated Code Sample

In the sample code, note the use of operand && in `Y1 = (U1 && (sqrt(U2) <= 3.0));`.

```

/* Exported block signals */
boolean_T U1; /* '<Root>/U1' */
real_T U2; /* '<Root>/U2' */
boolean_T Y1; /* '<Root>/Logical Operator' */

/* Model step function */
void DEV_R1305_01main_step(void)
{
 /* Logic: '<Root>/Logical Operator' incorporates:
 * Constant: '<S1>/Constant'
 * Inport: '<Root>/U1'
 * Inport: '<Root>/U2'
 * RelationalOperator: '<S1>/Compare'
 * Sqrt: '<Root>/Sqrt'
 */
 Y1 = (U1 && (sqrt(U2) <= 3.0));
}

```

### Justification

Some standard math functions have at least one persistent side effect of modifying the global `errno` variable, as defined in the C90 or C99 standard. Since the `errno` variable is not used by Embedded Coder, the second operand can be treated as not having persistent side effects.

---

**Note** Polyspace Bug Finder treats every function with no available source code as potentially having side effects.

---

### Conditions Under Which the Deviation is Requested

This deviation is requested for all calls to standard math functions used as right hand side argument of && and || operators.

### **Consequences of Noncompliance**

There are no consequences associated with noncompliance with MISRA C:2012 Rule 13.5 in the circumstances described in this deviation record. There are no additional verification and validation requirements resulting from this deviation.

### **Actions to Control Reporting**

When a Polyspace analysis of your code finds known or acceptable coding rule violations, you can suppress the violations in subsequent analyses by adding code annotations (Polyspace Bug Finder) to the Logical Operator block. In future analyses, Polyspace hides results justified through annotations in the **Results List** pane. To review the coding rule violations, see “Filter and Group Results in Polyspace Desktop User Interface” (Polyspace Bug Finder).

If you have already provided annotations for MISRA C:2004 violations, Polyspace imports these justifications when you check your code for MISRA C:2012 violations. For additional information, see “Import Existing MISRA C: 2004 Justifications to MISRA C: 2012 Results” (Polyspace Bug Finder).

For additional information, see “MISRA C:2012 Compliance Information Summary Tables” on page 23-6.

## Use Blocks and Products Supported for Code Generation

### In this section...

“Related Products” on page 24-2

“Simulink Built-In Blocks That Support Code Generation” on page 24-4

“Simulink Block Data Type Support Table” on page 24-20

“Block Set Support for Code Generation” on page 24-20

As you construct a model, to prevent issues later in the development process, determine whether the Simulink Coder and Embedded Coder code generators support the products and blocks that you want to use.

### Related Products

The following table summarizes MathWorks products that extend and complement Simulink Coder software. For information about these products and how code generation supports them, refer to their product documentation at [www.mathworks.com](http://www.mathworks.com).

Product	Extends Code Generation Capabilities for ...
Aerospace Blockset™	Aircraft, spacecraft, rocket, propulsion systems, and unmanned airborne vehicles
Audio Toolbox™	Audio processing systems
Automated Driving Toolbox™	Designing, simulating, and testing ADAS and autonomous driving systems
AUTOSAR Blockset	Modeling and simulation of AUTOSAR Classic and Adaptive ECU software
Communications Toolbox™	Physical layer of communication systems
Computer Vision Toolbox™	Video processing, image processing, and computer vision systems
Control System Toolbox™	Linear control systems
DSP System Toolbox™	Signal processing systems
Embedded Coder	Embedded systems, rapid prototyping boards, and microprocessors in mass production
Fixed-Point Designer	Fixed-point systems
Fuzzy Logic Toolbox™	System designs based on fuzzy logic
HDL Verifier™	Direct programming interface (DPI) component and transaction-level model (TLM) generation from Simulink
IEC Certification Kit	ISO 26262 and IEC 61508 certification
Model-Based Calibration Toolbox™	Developing processes for systematically identifying optimal balance of engine performance, emissions, and fuel economy, and reusing statistical models for control design, hardware-in-the-loop (HIL) testing, or powertrain simulation

<b>Product</b>	<b>Extends Code Generation Capabilities for ...</b>
Model Predictive Control Toolbox™	Model predictive controllers
Deep Learning Toolbox™	Neural networks
Parallel Computing Toolbox™	Parallel builds for large Simulink models
Phased Array System Toolbox™	Sensor array systems in radar, sonar, wireless communications, and medical imaging applications
Polyspace Bug Finder	MISRA-C compliance and static analysis of generated code
Polyspace Code Prover	Formal analysis of generated code
Powertrain Blockset™	Real-time testing of powertrain applications
Robotics System Toolbox™	Design, simulate, and test robotics applications
ROS Toolbox	Design, simulate, and deploy ROS-based applications
Simscape™	Systems spanning mechanical, electrical, hydraulic, and other physical domains as physical networks
Simscape Driveline™	Driveline (drivetrain) systems
Simscape Electrical™	Electronic, electromechanical, and electrical power systems
Simscape Fluids™	Hydraulic power and control systems
Simscape Multibody™	Three-dimensional mechanical systems
Simulink 3D Animation™	Systems with 3D visualizations
Simulink Check	Model standards compliance checking and metrics
Simulink Code Inspector™	Automated reviews of generated code
Simulink Control Design™	Autotuning of PID controllers and online frequency response estimation
Simulink Coverage	Model and code structural coverage analysis
Simulink Design Optimization™	Tuning adaptive lookup tables and checking signal characteristics
Simulink Desktop Real-Time™	Rapid prototyping or hardware-in-the-loop (HIL) simulation of control system and signal processing algorithms
Simulink Real-Time™	Rapid control prototyping, hardware-in-the-loop (HIL) simulation, and other real-time testing applications
Simulink Report Generator™	Automatically generating project documentation in a standard format
Requirements Toolbox	Authoring and tracing requirements to design and code
Simulink Test	Software-in-the-loop (SIL), processor-in-the-loop (PIL), and real-time hardware-in-the-loop (HIL) testing of generated code
SoC Blockset™	Designing, evaluating, and implementing SoC hardware and software architectures

Product	Extends Code Generation Capabilities for ...
Stateflow	State machines and flow charts
System Identification Toolbox™	Systems identified from measured input-output data
Vehicle Dynamics Blockset™	Modeling and simulation of vehicle dynamics in 3D environment
Vehicle Network Toolbox™	CAN blocks for Accelerator and Rapid Accelerator simulations and code deployment on Windows

## Simulink Built-In Blocks That Support Code Generation

The following tables summarize code generator support for Simulink blocks. There is a table for each block library. For more detail, including data types each block supports, in the MATLAB Command Window, type `showblockdatatypetable`, or consult the block reference pages. For some blocks, the generated code might rely on `memcpy` or `memset` (`string.h`).

### Additional Math and Discrete: Additional Discrete

Block	Support Notes
Fixed-Point State-Space	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting block parameter <b>Treat as atomic unit</b> .
Transfer Fcn Direct Form II	
Transfer Fcn Direct Form II Time Varying	

**Additional Math and Discrete: Increment/Decrement**

Block	Support Notes
Decrement Real World	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting block parameter <b>Treat as atomic unit</b> .
Decrement Stored Integer	
Decrement Time To Zero	Supports code generation.
Decrement To Zero	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting block parameter <b>Treat as atomic unit</b> .
Increment Real World	
Increment Stored Integer	

**Continuous**

Block	Support Notes
Derivative	Not recommended for production-quality code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. The code generated can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code.  In general, consider using the Simulink Model Discretizer to map continuous blocks into discrete equivalents that support production code generation. Use the <b>Model Discretizer</b> app. One exception is the Second-Order Integrator block because, for this block, the Model Discretizer produces an approximate discretization.
Integrator	
Integrator	
PID Controller	
PID Controller (2DOF)	
Second-Order Integrator	
State-Space	
Transfer Fcn	
Transport Delay	
Variable Transport Delay	
Zero-Pole	

**Discontinuities**

<b>Block</b>	<b>Support Notes</b>
Backlash	Supports code generation.
Coulomb and Viscous Friction	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting block parameter <b>Treat as atomic unit</b> .
Dead Zone	Supports code generation.
Dead Zone Dynamic	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting block parameter <b>Treat as atomic unit</b> .
Hit Crossing	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Quantizer	Supports code generation.
Rate Limiter	Cannot use inside a triggered subsystem hierarchy.
Rate Limiter Dynamic	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting block parameter <b>Treat as atomic unit</b> .
Relay	Support code generation.
Saturation	
Saturation Dynamic	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting block parameter <b>Treat as atomic unit</b> .
Wrap To Zero	

**Discrete**

<b>Block</b>	<b>Support Notes</b>
Delay	Supports code generation.
Difference	<ul style="list-style-type: none"> <li>The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. Logical Operator	
Relational Operator	
Shift Arithmetic	

**Lookup Tables**

<b>Block</b>	<b>Support Notes</b>
Sine, Cosine	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the <b>Treat as atomic unit</b> check box.
Direct Lookup Table (n-D)	Support code generation.
Interpolation Using Prelookup	
1-D Lookup Table	
2-D Lookup Table	
n-D Lookup Table	
Lookup Table Dynamic	
Prelookup	
Sine	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting block parameter <b>Treat as atomic unit</b> .

**Math Operations**

Block	Support Notes
Abs	Support code generation.
Add	
Algebraic Constraint	Ignored during code generation.
Assignment	Support code generation.
Bias	
Complex to Magnitude-Angle	
Complex to Real-Imag	
Divide	
Dot Product	
Find Nonzero Elements	
Gain	
Magnitude-Angle to Complex	
Math Function (10 <sup>u</sup> )	
Math Function (conj)	
Math Function (exp)	
Math Function (hermitian)	
Math Function (hypot)	
Math Function (log)	
Math Function (log10)	
Math Function (magnitude <sup>2</sup> )	
Math Function (mod)	
Math Function (pow)	
Math Function (reciprocal)	
Math Function (rem)	
Math Function (square)	
Math Function (transpose)	
Vector Concatenate, Matrix Concatenate	
MinMax	
MinMax Running Resettable	
Permute Dimensions	
Polynomial	
Product, Matrix Multiply	
Product of Elements	
Real-Imag to Complex	
Sqrt	

Block	Support Notes
Reshape	
Rounding Function	
Sign	
Sqrt	
Sine Wave Function	<ul style="list-style-type: none"> <li>Does not refer to absolute time when configured for sample-based operation. Depends on absolute time when in time-based operation.</li> <li>Depends on absolute time when used inside a triggered subsystem hierarchy.</li> </ul>
Slider Gain	Support code generation.
Sqrt	
Squeeze	
Add	
Trigonometric Function	Functions <code>asinh</code> , <code>acosh</code> , and <code>atanh</code> are not supported by all compilers. If you use a compiler that does not support those functions, the software issues a warning for the block and the generated code fails to link.
Unary Minus	Supports code generation.
Vector Concatenate, Matrix Concatenate	
Weighted Sample Time Math	

### Messages & Events

Block	Support Notes
Hit Crossing	Not recommended for production code. Does not support non-floating data type for ert targets.
Queue	Code generation is not supported for event actions and statistics.
Receive	Supports code generation.
Send	Supports code generation.
Sequence Viewer	This block can be used for visualizing message transitions during simulation, but is not included in the generated code.

**Model Verification**

Block	Support Notes
Assertion	Supports code generation.
Check Discrete Gradient	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Check Dynamic Gap	Support code generation.
Check Dynamic Lower Bound	
Check Dynamic Range	
Check Dynamic Upper Bound	
Check Input Resolution	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Check Static Gap	
Check Static Lower Bound	
Check Static Range	
Check Static Upper Bound	

**Model-Wide Utilities**

Block	Support Notes
Block Support Table	Ignored during code generation.
DocBlock	Uses the template symbol you specify for the <b>Embedded Coder Flag</b> block parameter to add comments to generated code. Requires an Embedded Coder license. For more information, see “Use a Simulink DocBlock to Add a Comment” on page 52-5.
Model Info	Ignored during code generation.
Timed-Based Linearization	
Trigger-Based Linearization	

**Ports & Subsystems**

<b>Block</b>	<b>Support Notes</b>
Subsystem	Support code generation.
Configurable Subsystem	
Enable	
Enabled Subsystem	
Enabled and Triggered Subsystem	
For Each Subsystem	
For Iterator Subsystem	
Function-Call Feedback Latch	
Function-Call Generator	
Function-Call Split	
Function-Call Subsystem	
If	
If Action Subsystem	
Inport (In1)	
Model	
Outport (Out1)	
Resettable Subsystem	
Subsystem	
Switch Case	
Switch Case Action Subsystem	
Trigger	
Triggered Subsystem	
Unit System Configuration	
Variant Subsystem, Variant Model	
While Iterator Subsystem	

**Signal Attributes**

<b>Block</b>	<b>Support Notes</b>
Bus to Vector	Support code generation.
Data Type Conversion	
Data Type Conversion Inherited	
Data Type Duplicate	
Data Type Propagation	
Data Type Scaling Strip	
IC	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Probe	Supports code generation.
Rate Transition	<ul style="list-style-type: none"> <li>• Supports code generation.</li> <li>• Cannot use inside a triggered subsystem hierarchy.</li> </ul>
Signal Conversion	Support code generation.
Signal Specification	
Unit Conversion	
Weighted Sample Time	
Width	

**Signal Routing**

<b>Block</b>	<b>Support Notes</b>
Bus Assignment	Support code generation.
Bus Creator	
Bus Selector	
Data Store Memory	
Data Store Read	
Data Store Write	
Demux	
Environment Controller	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
From	Support code generation.
Goto	
Goto Tag Visibility	
Index Vector	
Manual Switch	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Manual Variant Sink	Support code generation.
Manual Variant Source	
Merge	When multiple signals connected to a Merge block have a non- <code>Auto</code> storage class, all non- <code>Auto</code> signals connected to that block must <i>be identically labeled</i> and <i>have the same storage class</i> . When Merge blocks connect directly to one another, these rules apply to all signals connected to Merge blocks in the group.
Multiport Switch	Support code generation.
Mux	
Selector	
State Reader	
State Writer	
Switch	

Block	Support Notes
Variant Sink	
Variant Source	
Vector Concatenate, Matrix Concatenate	

### Sinks

Block	Support Notes
Display	Ignored for code generation.
Floating Scope and Scope Viewer	
Output (Out1)	Supports code generation.
Scope	Ignored for code generation.
Stop Simulation	<ul style="list-style-type: none"> <li>Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.</li> <li>Generated code stops executing when the stop condition is true.</li> </ul>
Terminator	Supports code generation.
To File	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
To Workspace	Ignored for code generation.
Record, XY Graph	

## Sources

Block	Support Notes
Band-Limited White Noise	Cannot use inside a triggered subsystem hierarchy.
Chirp Signal	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Clock	
Constant	Supports code generation.
Counter Free-Running	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Counter Limited	<ul style="list-style-type: none"> <li>The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. Digital Clock	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Enumerated Constant	Supports code generation.
From File	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times.

Block	Support Notes
From Spreadsheet	While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
From Workspace	Supports code generation.
Ground	Supports code generation.
Inport (In1)	Supports code generation.
Pulse Generator	Cannot use inside a triggered subsystem hierarchy. Does not refer to absolute time when configured for sample-based operation. Depends on absolute time when in time-based operation.
Ramp	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Random Number	Supports code generation.
Repeating Sequence	<ul style="list-style-type: none"> <li>• Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.</li> <li>• Consider using the Repeating Sequence Stair or Repeating Sequence Interpolated block instead.</li> </ul>
Repeating Sequence Interpolated	<ul style="list-style-type: none"> <li>• The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. Signal Builder	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times.

Block	Support Notes
Signal Generator	While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Sine Wave	<ul style="list-style-type: none"> <li>• Depends on absolute time when used inside a triggered subsystem hierarchy.</li> <li>• Does not refer to absolute time when configured for sample-based operation. Depends on absolute time when in time-based operation.</li> </ul>
Step	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Uniform Random Number	Supports code generation.
Waveform Generator	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

### User-Defined

Block	Support Notes
Simulink Function	Support code generation.
Initialize Function	
Interpreted MATLAB Function	Consider using the MATLAB Function block instead.
Level-2 MATLAB S-Function	If a corresponding TLC file is available, the Level-2 MATLAB S-Function block uses the TLC file to generate code, otherwise code generation throws an error.
MATLAB Function	Support code generation.
MATLAB System	
S-Function	S-functions that call into MATLAB are not supported for code generation.
S-Function Builder	
Simulink Function	Support code generation.
Terminate Function	

## **Simulink Block Data Type Support Table**

The Simulink Block Data Type Support table summarizes characteristics of blocks in the Simulink and Fixed-Point Designer block libraries, including whether or not they are recommended for use in production code generation. To view this table, in the MATLAB Command Window, type `showblockdatatypetable`, or consult the block reference pages.

## **Block Set Support for Code Generation**

Several products that include blocks are available for you to consider for code generation. However, before using the blocks for one of these products, consult the documentation for that product to confirm which blocks support code generation.

## Consider Modeling Semantic when Generating Code

In this section...
"Data Propagation" on page 24-21
"Sample Time Propagation" on page 24-22
"Latches for Subsystem Blocks" on page 24-23
"Block Execution Order" on page 24-24
"Algebraic Loops" on page 24-25

### Data Propagation

The first stage of code generation is compilation of the block diagram. This stage is analogous to that of a C or C++ program. The compiler carries out type checking and preprocessing. Similarly, the Simulink engine verifies that input/output data types of block ports are consistent, line widths between blocks are of expected thickness, and the sample times of connecting blocks are consistent.

The Simulink engine propagates data from one block to the next along signal lines. The data propagated consists of

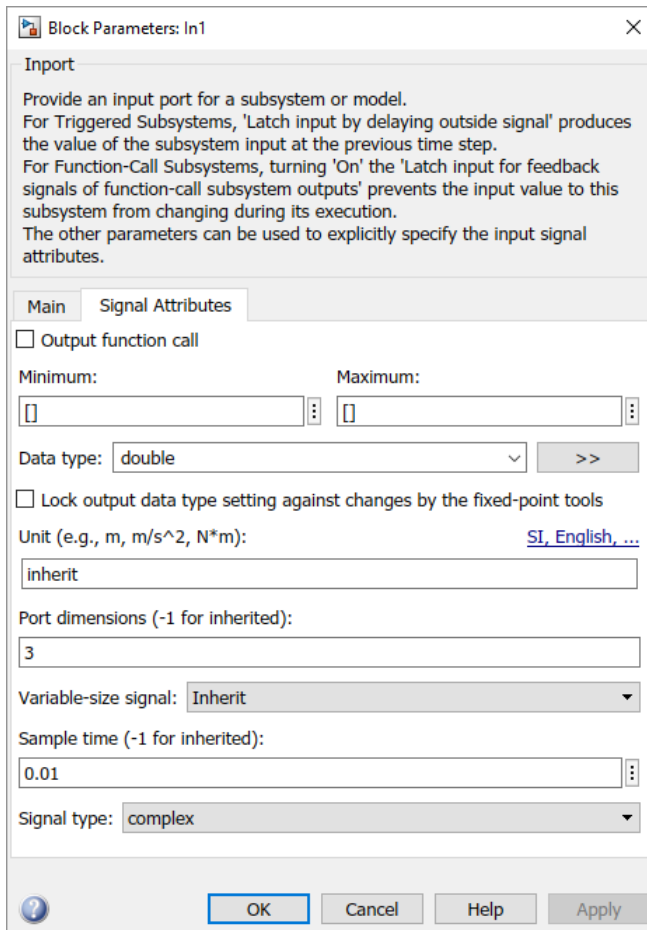

- Data type
- Line widths
- Sample times

You can verify what data types a Simulink block supports by typing

```
showblockdatatypetable
```

at the MATLAB prompt, or (from the Help browser) clicking the command above.

The Simulink engine typically derives signal attributes from a source block. For example, the Inport block's parameters dialog box specifies the signal attributes for the block.

In this example, the Inport block has a port width of 3, a sample time of .01 seconds, the data type is double, and the signal is complex.

This figure shows the propagation of the signal attributes associated with the Inport block through a simple block diagram.

In this example, the Gain and Outport blocks inherit the attributes specified for the Inport block.

## Sample Time Propagation

Inherited sample times in source blocks (for example, a root inport) can sometimes lead to unexpected and unintended sample time assignments. Since a block may specify an inherited sample time, information available at the outset is often insufficient to compile a block diagram completely.

In such cases, the Simulink engine propagates the known or assigned sample times to those blocks that have inherited sample times but that have not yet been assigned a sample time. Thus, the engine continues to fill in the blanks (the unknown sample times) until sample times have been assigned to

as many blocks as possible. Blocks that still do not have a sample time are assigned a default sample time.

For a completely deterministic model (one where no sample times are set using the above rules), you should explicitly specify the sample times of your source blocks. Source blocks include root inport blocks and blocks without input ports. You do not have to set subsystem input port sample times. You might want to do so, however, when creating modular systems.

An unconnected input implicitly connects to ground. For ground blocks and ground connections, the sample time is always constant (`inf`).

All blocks have an inherited sample time ( $T_s = -1$ ). They are assigned a sample time of  $(T_f - T_i)/50$ .

### Blocks Whose Outputs Have Constant Values

When you display sample time colors, by default, Constant blocks appear magenta in color to indicate that the block outputs have constant values during simulation. Downstream blocks whose output values are also constant during simulation, such as Gain blocks, similarly appear magenta if they use an inherited sample time. The code generated for these blocks depends in part on the tunability of the block parameters.

If you set model configuration parameter **Default parameter behavior** to `Inlined`, the block parameters are not tunable in the generated code. Because the block outputs are constant, the code generator eliminates the block code due to constant folding. If the code generator cannot fold the code, or if you select settings to disable constant folding, the block code appears in the model initialization function. The generated code is more efficient because it does not compute the outputs of these blocks during execution.

However, if you configure a block or model so that the block parameters appear in the generated code as tunable variables, the code generator represents the blocks in a different way. Block parameters are tunable if, for example:

- You set parameter **Default parameter behavior** to `Tunable`. By default, numeric block parameters appear as tunable fields of a global parameter structure.
- You use a tunable parameter, such as a `Simulink.Parameter` object that uses a storage class other than `Auto`, as the value of one or more numeric block parameters. These block parameters are tunable regardless of the setting that you choose for model configuration parameter **Default parameter behavior**.

If a block parameter is tunable, the generated code must compute the block outputs during execution. Therefore, the block code appears in the model `step` function. If the model uses multiple discrete rates, the block code appears in the output function for the fastest downstream rate that uses the block outputs.

### Latches for Subsystem Blocks

When an Inport block is the signal source for a triggered or function-call subsystem, you can use latch options to preserve input values while the subsystem executes. The Inport block latch options include:

For	Use
Triggered subsystems	<b>Latch input by delaying outside signal</b>

For	Use
Function-call subsystems	<b>Latch input for feedback signals of function-call subsystem outputs</b>

When you select subsystem block parameter **Latch input for feedback signals of function-call subsystem outputs** for a function-call subsystem, the code generator

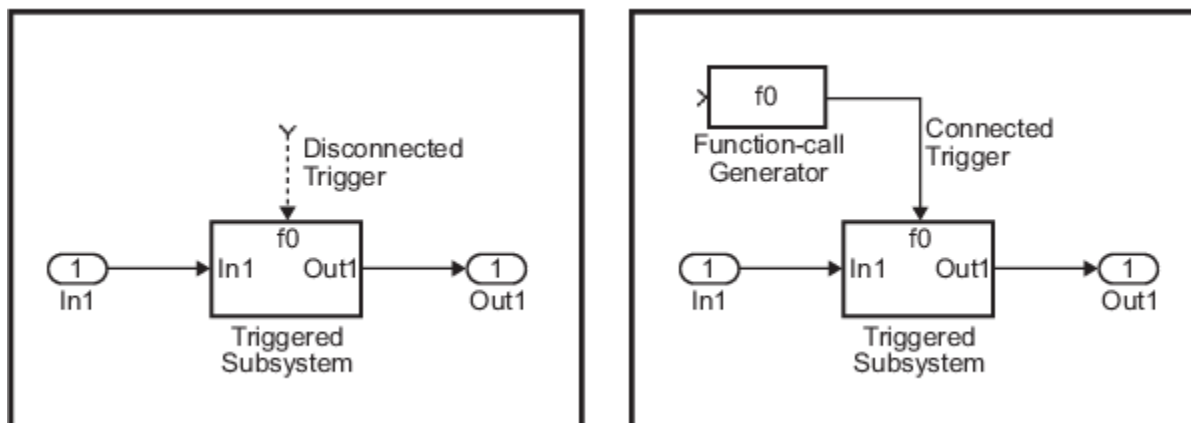

- Preserves latches in generated code regardless of optimizations that might be set
- Places the code for latches at the start of a subsystem's output/update function

For more information on these options, see the block description of Inport.

## Block Execution Order

Once the Simulink engine compiles the block diagram, it creates a *model*.rtw file (analogous to an object file generated from a C or C++ file). The *model*.rtw file contains the connection information of the model, as well as the signal attributes. Thus, the timing engine in can determine when blocks with different rates should be executed.

You cannot override this execution order by directly calling a block (in handwritten code) in a model. For example, in the next figure the `disconnected_trigger` model on the left has its trigger port connected to ground, which can lead to the blocks inheriting a constant sample time. Calling the trigger function, `f()`, directly from user code does not work. Instead, you should use a function-call generator to specify the rate at which `f()` should be executed, as shown in the `connected_trigger` model on the right.

Instead of the function-call generator, you could use another block that can drive the trigger port. Then, you should call the model's main entry point to execute the trigger function.

For multirate models, a common use of the code generator is to generate code for individual models separately and then manually code the I/O between the generated code modules. This approach places the burden of data consistency between models on the developer of the models. Another approach is to let Simulink and the code generator maintain data consistency between rates and generate multirate code for use in a multitasking environment. The Rate Transition block is able to interface periodic and asynchronous signals. For a description of the Simulink Coder block libraries, see "Asynchronous Events". For more information on multirate code generation, see "Modeling for Multitasking Execution".

## Algebraic Loops

Algebraic loops are circular dependencies between variables. This prevents the straightforward direct computation of their values. For example, in the case of a system of equations

- $x = y + 2$
- $y = -x$

the values of  $x$  and  $y$  cannot be directly computed.

To solve this, either repeatedly try potential solutions for  $x$  and  $y$  (in an intelligent manner, for example, using gradient based search) or “solve” the system of equations. In the previous example, solving the system into an explicit form leads to

- $2x = 2$
- $y = -x$
- $x = 1$
- $y = -1$

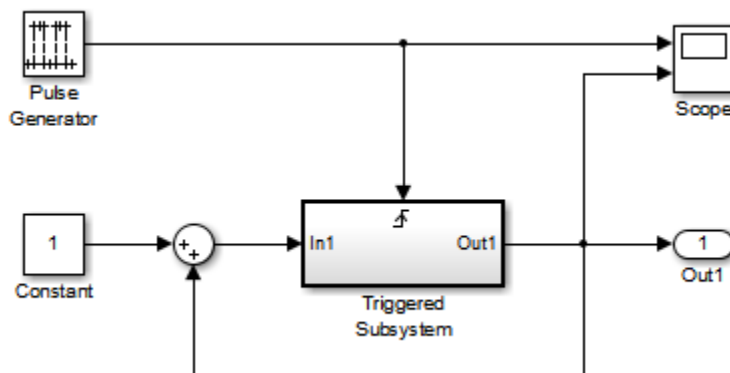

An algebraic loop exists whenever the output of a block having direct feedthrough (such as Gain, Sum, Product, and Transfer Fcn) is fed back as an input to the same block. The Simulink engine is often able to solve models that contain algebraic loops, such as the next diagram.

The code generator does not produce code that solves algebraic loops. This restriction includes models that use Algebraic Constraint blocks in feedback paths. However, the Simulink engine can often eliminate algebraic loops that arise, by grouping equations in certain ways in models that contain them. It does this by separating the update and output functions to avoid circular dependencies. For details, see “Algebraic Loop Concepts”.

### Algebraic Loops in Triggered Subsystems

While the Simulink engine can minimize algebraic loops involving atomic and enabled subsystems, a special consideration applies to some triggered subsystems. An example for which code can be generated is shown in the following model and triggered subsystem.

The default Simulink behavior is to combine output and update methods for the subsystem, which creates an apparent algebraic loop, even though the Unit Delay block in the subsystem has no direct feedthrough.

You can allow the Simulink engine to solve the problem by splitting the output and update methods of triggered and enabled-triggered subsystems when feasible. If you want the code generator to take advantage of this feature, select subsystem block parameter **Minimize algebraic loop occurrences**. Select this parameter to avoid algebraic loop warnings in triggered subsystems involved in loops.

---

**Note** If you check this box, the generated code for the subsystem might contain split output and update methods, even if the subsystem is not actually involved in a loop. Also, if a direct feedthrough block (such as a Gain block) is connected to the inport in the above triggered subsystem, the Simulink engine cannot solve the problem, and the code generator is unable to generate code.

---

A model configuration parameter **Minimize algebraic loop occurrences** is available also. Selecting it enables the code generator to produce code for models containing Model blocks that are involved in algebraic loops.

## Modeling Guidelines for Blocks

Code generation modeling guidelines include recommended model settings, block usage, and block parameters. When you develop models for code generation, use these guidelines.

Code Generation Modeling Guidelines	<p>"cgsl_0101: Zero-based indexing"</p> <p>"cgsl_0102: Evenly spaced breakpoints in lookup tables"</p> <p>"cgsl_0103: Precalculated signals and parameters"</p> <p>"cgsl_0104: Modeling global shared memory using data stores"</p> <p>"cgsl_0105: Modeling local shared memory using data stores"</p> <p>"cgsl_0201: Redundant Unit Delay and Memory blocks"</p>
-------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

## Prepare a Model for Code Generation

Several standard methods are available for setting up a model to generate specific C constructs in your code. For preparing your model for code generation, some of these methods include: configuring signals and ports, initializing states, and setting up configuration parameters for code generation. Depending on the components of your model, some of these methods are optional. Methods for configuring a model to generate specific C constructs are organized by category, for example, the Control Flow category includes constructs `if-else`, `switch`, `for`, and `while`. Refer to the name of a construct to see how you should configure blocks and parameters in your model. Different modeling methodologies are available, such as Simulink blocks, Stateflow charts, and MATLAB Function blocks, to implement a C construct.

Model examples in “Modeling Patterns for C Code Constructs” have the following naming conventions:

Model Components	Naming Convention
Inputs	u1, u2, u3, and so on
Outputs	y1, y2, y3, and so on
Parameters	p1, p2, p3, and so on
States	x1, x2, x3, and so on

Input ports are named to reflect the signal names that they propagate.

### Configure Input Ports, Output Ports, and Arbitrary Signals

- 1 Create a model in Simulink. For more information, see “Interactive Model Editing”.
- 2 On the **Modeling** tab, click **Model Data Editor**. You can also use the keyboard shortcut **Ctrl + Shift + E**.
- 3 Set the **Change view** drop-down list to **Design**.
- 4 Use the **Storage Class** column to apply a storage class to the signal.

For example, apply the storage class `ExportedGlobal`, which makes the signal appear in the generated code as a separate global variable. The variable has the same name as the signal in the model.

### Initialize and Configure States

- 1 In the Model Data Editor, on the **States** tab, use the **Initial Value** column to specify initial values for a block state (such as the state of a Unit Delay block).
- 2 Set the **Change view** drop-down list to **Code**.
- 3 Use the **Name** column to give the state a name.
- 4 Use the **Storage Class** column to apply a storage class to the state.

### Set Up Configuration Parameters for Code Generation

- 1 On the **C Code** tab, click **Settings** to open the Configuration Parameters dialog box. You can also use the keyboard shortcut **Ctrl + E**.

Open the Configuration Parameter dialog box by selecting **Simulation > Model Configuration parameters**.

- 2 Open the **Solver** pane and select
  - **Solver type:** Fixed-Step
  - **Solver:** discrete (no continuous states)
- 3 Open the **Optimization** pane, and set **Default parameter behavior** to Inlined.
- 4 Open the **Code Generation** pane, and specify `ert.tlc` as the **System Target File**.
- 5 Clear **Generate makefile**.
- 6 Select **Generate code only**.
- 7 Enable the HTML report generation by opening the **Code Generation > Report** pane and selecting **Create code generation report** and **Open report automatically**. Click the horizontal ellipsis and, under **Advanced parameters**, select **Code-to-model**. Enabling the HTML report generation is optional.
- 8 Click **Apply** and then **OK** to exit.

## Set Up an Example Model With a Stateflow Chart

Follow this general procedure to create a simple model containing a Stateflow chart.

- 1 From the **Stateflow > Chart** library, add a Stateflow chart to your model .
- 2 Add Inport blocks and Outport blocks according to the example model.
- 3 Open the **Stateflow Editor** by performing one of the following:
  - Double-click the Stateflow chart.
  - Press **Ctrl+R**.
- 4 Add inputs to you chart as described in “Add Stateflow Data” (Stateflow).
- 5 Specify the **Name** (`u1`, `u2`, ...) and the **Type** (Inherit: Same as Simulink) for each input, unless specified differently in the example.
- 6 Add outputs to you chart as described in “Add Stateflow Data” (Stateflow).
- 7 Specify the **Name** (`y1`, `y2`, ...) and **Type** (Inherit: Same as Simulink) for each output, unless specified differently in the example.
- 8 In the **Stateflow Editor**, create the Stateflow diagram specific to the example.
- 9 The inputs and outputs appear on the chart in your model.
- 10 Connect the Inport and Outport blocks to the Stateflow Chart.

- 11 Configure the input and output signals; see “Configure Input Ports, Output Ports, and Arbitrary Signals” on page 25-2.

## Set Up an Example Model With a MATLAB Function Block

- 1 Add the number of Inport and Outport blocks according to a C construct example included in this chapter.
- 2 From the Simulink User-defined Functions library drag a MATLAB Function block into the model.
- 3 Double-click the block. The MATLAB Function Block Editor opens. Edit the function to implement your application.
- 4 On the **Editor** tab, click **Save** and close the MATLAB Function Block Editor.
- 5 Connect the Inport and Outport blocks to the MATLAB Function block. See “Configure Input Ports, Output Ports, and Arbitrary Signals” on page 25-2.
- 6 Save your model.

## Definition, Initialization, and Declaration of Parameter Data

This example shows how to export the definition, initialization, and declaration of a global variable that the generated code uses as a parameter.

### C Construct

```
int32 myParam = 3;
extern int32 myParam;
```

### Procedure

1. Open the example model `ex_defn_decl`.

2. In the model, select the Gain block. In the Property Inspector, set the value of the **Gain** parameter to `myParam`.
3. Next to the parameter value, click the action button (the button with three vertical dots) and select **Create**.
4. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(3)`. Click **Create**. A `Simulink.Parameter` object, `myParam`, appears in the base workspace. The Gain block uses the object to set the value of the Gain parameter, in this case, 3.
5. In the `Simulink.Parameter` property dialog box, set **Data type** to `int32`.
6. Set **Storage class** to `ExportToFile`.
7. Set **Header File** to `myDecls.h`.
8. Set **Definition File** to `myDefns.c`. Click **OK**.
9. To build the model and generate code, press **Ctrl+B**.

### Results

The generated header file `myDecls.h` declares the global variable `myParam` by using the `extern` keyword.

```
/* Declaration for custom storage class: ExportToFile */
extern int32_T myParam; /* Referenced by: '<Root>/Gain' */
```

The generated source file `myDefns.c` defines and initializes `myParam`.

```
/* Definition for custom storage class: ExportToFile */
int32_T myParam = 3; /* Referenced by: '<Root>/Gain' */
```

## Definition and Declaration of Signal Data

This example shows how to export the definition and declaration of a global variable that the generated code uses as a signal.

### C Construct

```
float mySig;
extern float mySig;
```

### Procedure

1. Open the example model `ex_defn_decl`.

```
open_system('ex_defn_decl');
```

2. In the Model Data Editor, open the **Inports/Outports** tab.
3. In the Model Data Editor, for the Inport block, set **Data Type** to single.

```
set_param('ex_defn_decl/In1', 'OutDataTypeStr', 'single');
```

4. Open the **Embedded Coder** app.
5. In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
6. In the Code Mappings editor, on the **Inports** tab, set **Storage class** for the Inport block to `ExportToFile`.
7. In the Property Inspector, set **Identifier** to `mySig`, **Header File** to `myDecls.h`, and **Definition File** to `myDefns.c`.

```
cm = coder.mapping.api.get('ex_defn_decl');
setInport(cm, 'In1', 'StorageClass', 'ExportToFile', 'Identifier', 'mySig', 'HeaderFile', 'myDecls.h', 'D
```

8. Generate code from the model.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
evalc('slbuild(''ex_defn_decl'')');
```

### Results

The generated header file `myDecls.h` declares the global variable `mySig` by using the `extern` keyword.

```
file = fullfile('ex_defn_decl_ert_rtw', 'myDecls.h');
rtwdemodbtype(file, '/* Declaration for', ...
 'extern real32_T mySig', 1, 1);
```

```
/* Declaration for custom storage class: ExportToFile */
extern real32_T mySig; /* '<Root>/In1' */
```

The generated source file `myDefns.c` defines and initializes `mySig`.

```
file = fullfile('ex_defn_decl_ert_rtw','myDefns.c');
rtwdemodbtype(file,'/* Definition for', ...
 'real32_T mySig;',1,1);
```

```
/* Definition for custom storage class: ExportToFile */
real32_T mySig; /* '<Root>/In1' */
```

## Data Type Conversion

This example shows how to create a data type conversion by using a Data Type Conversion block, Stateflow Chart, or MATLAB Function block.

### C Construct

```
y1 = (double)u1;
```

### Modeling Pattern for Data Type Conversion — Simulink Block

To create a data type conversion, use a Data Type Conversion block from the **Simulink > Commonly Used Blocks library**.

1. Open example model `ex_data_type_SL`.

2. Click the Inport block. In the Property Inspector, under **Signal Attributes**, specify **Data type** as `int32`.
3. Click the Data Type Conversion block. In the Property Inspector, specify the **Output data type** parameter as `double`.
4. In the Configuration Parameters dialog box, set the **Casting modes** parameter to `Explicit`. By default, Simulink® sets the **Casting modes** parameter to `Nominal` that generates minimal casting. For more details, see “Control Cast Expressions in Generated Code” on page 52-41.
5. To build the model and generate code, press **Ctrl+B**.

The generated code appears in `ex_data_type_SL.c`:

```
int32_T u1; /* '<Root>/u1' */
real_T y1; /* '<Root>/y1' */

/* Model step function */
void ex_data_type_SL_step(void)
{
 /* Output: '<Root>/y1' incorporates:
 * DataTypeConversion: '<Root>/Data Type Conversion'
 * Inport: '<Root>/u1'
 */
 y1 = (real_T)u1;
}
```

The code generator type definition for `double` is `real_T`.

### Modeling Pattern for Data Type Conversion — Stateflow Chart

You can use a Stateflow® chart in place of a Data Type Conversion block, to create a data type conversion.

1. Open example model `ex_data_type_SF`.

2. Click the Inport block. In the Property Inspector, under **Signal Attributes**, specify **Data type** as `int32`.
3. In the Configuration Parameters dialog box, set the **Casting modes** parameter to `Explicit`.
4. To build the model and generate code, press **Ctrl+B**.

The generated code appears in `ex_data_type_SF.c`:

```
int32_T u1; /* '<Root>/u1' */
real_T y1; /* '<Root>/Type_Conversion' */

/* Model step function */
void ex_data_type_SF_step(void)
{
 /* Chart: '<Root>/Type_Conversion' incorporates:
 * Inport: '<Root>/u1'
 */
 y1 = (real_T)u1;
}
```

### Modeling Pattern for Data Type Conversion — MATLAB Function Block

1. Open example model `ex_data_type_ML`.

2. The MATLAB Function Block contains this function:

```
function y1 = typeconv(u1)
y1 = double(u1);
end
```

3. Click the Inport block. In the Property Inspector, under **Signal Attributes**, specify **Data type** as `int32`.

4. In the Configuration Parameters dialog box, set the **Casting modes** parameter to Explicit.
5. To build the model and generate code, press **Ctrl+B**.

The generated code appears in `ex_data_type_ML.c`:

```
int32_T u1; /* '<Root>/u1' */
real_T y1; /* '<Root>/MATLAB Function' */

/* Model step function */
void ex_data_type_ML_step(void)
{
 /* MATLAB Function: '<Root>/MATLAB Function' incorporates:
 * Inport: '<Root>/u1'
 */
 y1 = (real_T)u1;
}
```

### Other Type Conversions in Modeling

Type conversions can also occur on the output of blocks where the output variable is specified as a different data type. For example, in the Gain block, you can set the **Parameter data type** as `Inherit via internal rule` to control the output signal data type. Another example of type conversion can occur at the boundary of a Stateflow chart. You can specify the output variable as a different data type.

Data Type Conversion

### Related Examples

- “Parameter Data Types in the Generated Code” on page 33-129

## Type Qualifiers

This example shows how to apply the `const` and `volatile` keywords to a global variable that represents parameter data.

### C Construct

```
const volatile double myParam = 9.8;
```

### Procedure

1. Open the example model `ex_const_volatile`.

```
open_system('ex_const_volatile');
```

2. In the model, select the Gain block. In the Property Inspector, set the value of the **Gain** parameter to `myParam`.

3. Next to the parameter value, click the action button (the button with three vertical dots) and select **Create**.

```
myParam = Simulink.Parameter(9.8);
set_param('ex_const_volatile/Gain', 'Gain', 'myParam');
```

4. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(9.8)`. Click **Create**. A `Simulink.Parameter` object, `myParam`, appears in the base workspace. The Gain block uses the object to set the value of the Gain parameter, in this case, 9.8.

5. On the **Code Generation** tab, click the **Configure in Coder App** button. In the Code Mappings editor, set **Storage Class** to `ConstVolatile`. Alternatively, to apply only one of the keywords, use the storage classes `Const` or `Volatile`.

```
myParam.StorageClass = 'ConstVolatile';
```

6. To build the model and generate code, press **Ctrl+B**.

```
currentDir = pwd;
[~,cgDir] = rtdemodir();
evalc('slbuild(''ex_const_volatile'')');
```

### Results

The generated source file `ex_const_volatile.c` defines `myParam` by using the `const` and `volatile` keywords.

```
file = fullfile('ex_const_volatile_ert_rtw', 'ex_const_volatile.c');
rtdemodbtype(file, '/* Definition for custom', ...
 'const volatile real_T myParam = 9.8;', 1, 1);
```

```
/* Definition for custom storage class: ConstVolatile */
const volatile real_T myParam = 9.8; /* Referenced by: '<Root>/Gain' */
```

## Relational and Logical Operators

This example shows how to implement relational and logical operators by using Simulink blocks, Stateflow Charts, and MATLAB Function blocks.

### Modeling Pattern for Relational or Logical Operators – Simulink Blocks

To include a logical operation in your model, use the Logical Operator block from the **Logic and Bit Operations** library.

1. Open example model `ex_data_type_SL`.

The Logical Operator block performs an OR operation in the model. To change the operation, double-click the block and set the **Operator** field to any of the operations in the menu.

You can implement relational operators by replacing the Logical Operator block with a Relational Operator block.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the logical operator OR is in the `ex_logical_SL_step` function in `ex_logical_SL.c`.

```
/* Exported block signals */
boolean_T u1; /* '<Root>/u1' */
boolean_T u2; /* '<Root>/u2' */
boolean_T y1; /* '<Root>/y1' */

/* Model step function */
void ex_logical_SL_step(void)
{
 /* Output: '<Root>/y1' incorporates:
 * Inport: '<Root>/u1'
 * Inport: '<Root>/u2'
 * Logic: '<Root>/Logical Operator'
 */
 y1 = (u1 || u2);
}
```

### Modeling Pattern for Relational and Logical Operators – Stateflow Chart

1. Open example model `ex_data_type_SF`.

In the Stateflow chart, the relational or logical operation actions are on the transition from one junction to another. Relational statements specify conditions to conditionally allow a transition. In that case, the statements are within square brackets.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the logical operator OR is in the `ex_logical_SF_step` function in `ex_logical_SF.c`.

```
/* Exported block signals */
boolean_T u1; /* '<Root>/u1' */
boolean_T u2; /* '<Root>/u2' */
boolean_T y1; /* '<Root>/Logical Operator' */

/* Model step function */
void ex_logical_SF_step(void)
{
 /* Chart: '<Root>/Logical Operator' incorporates:
 * Inport: '<Root>/u1'
 * Inport: '<Root>/u2'
 */
 y1 = (u1 || u2);
}
```

### Modeling Pattern for Relational and Logical Operators – MATLAB Function Block

This example shows the MATLAB Function block method for incorporating operators into the generated code by using a relational operator.

1. Open example model `ex_logical_ML`.

2. The MATLAB Function Block contains this function:

```
function y1 = fcn(u1, u2)
```

```
y1 = u1 > u2;
end
```

3. To build the model and generate code, press **Ctrl+B**.

The generated code appears in `ex_data_type_ML.c`:

```
/* Exported block signals */
real_T u1; /* '<Root>/u1' */
real_T u2; /* '<Root>/u2' */
boolean_T y; /* '<Root>/MATLAB Function' */

/* Model step function */
void ex_logical_ML_step(void)
{
 /* MATLAB Function: '<Root>/MATLAB Function' incorporates:
 * Inport: '<Root>/u1'
 * Inport: '<Root>/u2'
 */
 y = (u1 > u2);
}
```

Logical Operator

## Bitwise Operations

This example shows how to implement bitwise operations by using Simulink blocks, Stateflow Charts, and MATLAB Function blocks.

### Simulink Bitwise-Operator Block

To include a logical operation in your model, use the Bitwise Operator block from the **Logic and Bit Operations** library.

1. Open example model `ex_bit_logic_SL`.

The Logical Operator blocks perform an AND operation in the model. To change the operation, double-click the block and set the **Operator** field to any of the operations in the menu.

2. Double-click the block to open the Block Parameters dialog box.
3. To perform bitwise operations with a bit-mask, select **Use bit mask**.

If another input uses bitwise operations, clear the **Use bit mask** parameter and enter the number of input ports.

4. In the **Bit Mask** field, enter a decimal number. Use `bin2dec` or `hex2dec` to convert the input from binary or hexadecimal. In this example, enter `hex2dec('D9')`.

5. To build the model and generate code, press **Ctrl+B**.

The code implementing the bitwise operator AND is in the `ex_bit_logic_SL_step` function in `ex_bit_logic_SL.c`:

```
/* Exported block signals */
uint8_T u1; /* '<Root>/u1' */
uint8_T y1; /* '<Root>/Bitwise Operator' */

/* Model step function */
void ex_bit_logic_SL_step(void)
{
 /* S-Function (sfix_bitop): '<Root>/Bitwise Operator' incorporates:
 * Inport: '<Root>/u1'
 */
 y1 = (uint8_T)(u1 & 217);
}
```

### Stateflow Chart

1. Open example model `ex_bit_logic_SF`.

2. Right-click the Stateflow chart to open the chart **Properties**.
3. Verify that the **Enable C-bit operations** check box is selected. For more information, see “Enable C-bit operations” (Stateflow).
4. To build the model and generate code, press **Ctrl+B**.

The code implementing the bitwise operator AND is in the `ex_bit_logic_SF_step` function in `ex_bit_logic_SF.c`:

```
/* Exported block signals */
uint8_T u1; /* '<Root>/u1' */
uint8_T y1; /* '<Root>/Bit_Logic' */

/* Model step function */
void ex_bit_logic_SF_step(void)
{
 /* Chart: '<Root>/Bit_Logic' incorporates:
 * Inport: '<Root>/u1'
 */
 y1 = (uint8_T)(u1 & 0xD9);
}
```

### MATLAB Function Block

In this example, to show the MATLAB Function block method for implementing bitwise logic into the generated code, use the bitwise OR, '|'.

1. Open example model `ex_bit_logic_ML`.

2. The MATLAB Function Block contains this function:

```
function y1 = fcn(u1, u2)
%#eml
```

```
y1 = bitor(u1, u2);
end
```

3. To build the model and generate code, press **Ctrl+B**.

The code implementing the bitwise operator OR is in the `ex_bit_logic_ML_step` function in `ex_bit_logic_ML.c`:

```
/* Exported block signals */
uint8_T u1; /* '<Root>/u1' */
uint8_T u2; /* '<Root>/u2' */
uint8_T y1; /* '<Root>/Bitwise OR' */

/* Model step function */
void ex_bit_logic_ML_step(void)
{
 /* MATLAB Function: '<Root>/Bitwise OR' incorporates:
 * Inport: '<Root>/u1'
 * Inport: '<Root>/u2'
 */
 y1 = (uint8_T)(u1 | u2);
}
```

Bitwise Operator

## Enumeration

To generate an enumerated data type, define an enumeration class in a MATLAB® file. Then, use the enumeration class as the data type of signals, block parameters, and states in your model.

### C Construct

```
typedef enum {
 Choice1 = 0,
 Choice2
} myEnumType;
```

### Procedure

In your current folder, create the MATLAB file `ex_myEnumType.m`. The file defines an enumeration class `ex_myEnumType`.

```
classdef ex_myEnumType < Simulink.IntEnumType

 enumeration
 Choice1(0)
 Choice2(1)
 end %enumeration

 methods (Static)
 function retVal = getHeaderFile()
 retVal = 'myEnumHdr.h';
 end %function

 function retVal = getDataScope()
 retVal = 'Exported';
 end %function
 end %methods

end %classdef
```

1. Open the model `ex_pattern_enum` that has an Enumerated Constant block and a Multiport Switch block.

2. In the Model Data Editor, select the **Parameters** tab.
3. In the model, click the Enumerated Constant block.

4. In the Model Data Editor, use the **Value** column to set the constant value to `myChoice`. Next to `myChoice`, click the action button (with three vertical dots) and select **Create**.
5. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(ex_myEnumType.Choice1)` and click **Create**. A `Simulink.Parameter` object named `myChoice` appears in the base workspace. The object stores the enumerated value `Choice1` of the type `ex_myEnumType`.
6. On the **Code Generation** tab, set **Storage Class** to `ExportedGlobal`. With this setting, the object appears in the generated code as a global variable.
7. In the Model Data Editor, select the **Signals** tab.
8. In the model, select the output signal of the Enumerated Constant block.
9. In the Model Data Editor, use the **Data Type** column to set the signal data type to `Enum: ex_myEnumType`.
10. Select the Multiport Switch block.
11. In the Property Inspector, set:
  - **Data port order** to `Specify indices`.
  - **Data port indices** to `enumeration('ex_myEnumType')`. This expression returns all of the enumeration members of `ex_myEnumType`.
12. Set the model configuration parameter **File packaging format** to `Modular`. With this setting, in the generated code, the definition of `ex_myEnumType` can appear in the specified header file, `myEnumHdr.h`.
13. To build the model and generate code, press **Ctrl+B**.

## Results

View the generated header file `myEnumHdr.h`. The file defines the enumerated data type.

```
typedef enum {
 Choice1 = 0, /* Default value */
 Choice2
} ex_myEnumType;
```

View the source file `ex_pattern_enum.c`. The file defines the variable `myChoice`. The algorithm in the `step` function uses `myChoice` to route one of the input signals to the output signal.

```
ex_myEnumType myChoice = Choice1; /* Variable: myChoice

/* Model step function */
void ex_pattern_enum_step(void)
{
 /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
 * Constant: '<S1>/Constant'
 */
 if (myChoice == Choice1) {
 /* Outport: '<Root>/Data Out' incorporates:
```

```
 * Inport: '<Root>/Data In 1'
 */
 rtY.DataOut = rtU.DataIn1;
} else {
 /* Outport: '<Root>/Data Out' incorporates:
 * Inport: '<Root>/Data In 2'
 */
 rtY.DataOut = rtU.DataIn2;
}

/* End of MultiPortSwitch: '<Root>/Multiport Switch' */
}
```

## If-Else

This example shows how to implement an if-else construct by using Simulink blocks, Stateflow Charts, and MATLAB Function block.

### C Construct

```
if (u1 > u2)
{
 y1 = u1;
}
else
{
 y1 = u2;
}
```

### Modeling Pattern for If-Else: Switch block

One method to create an if-else statement is to use a Switch block from the **Simulink > Signal Routing** library.

1. Open example model ex\_if\_else\_SL.

The model contains the Switch block with the block parameter **Criteria for passing first input** of  $u2 \neq 0$ . The software selects  $u1$  if  $u2$  is TRUE, otherwise  $u2$  passes.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the if-else construct is in the ex\_if\_else\_SL\_step function in ex\_if\_else\_SL.c:

```
/* External inputs (root inport signals with default storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with default storage) */
ExternalOutputs Y;

/* Model step function */
void ex_if_else_SL_step(void)
```

```

{
 /* Switch: '<Root>/Switch' incorporates:
 * Inport: '<Root>/u1'
 * Inport: '<Root>/u2'
 * RelationalOperator: '<Root>/Relational Operator'
 */
 if (U.u1 > U.u2) {
 /* Outport: '<Root>/y1' */
 Y.y1 = U.u1;
 } else {
 /* Outport: '<Root>/y1' */
 Y.y1 = U.u2;
 }

 /* End of Switch: '<Root>/Switch' */
}

```

### Modeling Pattern for If-Else: Stateflow Chart

1. Open example model `ex_if_else_SF`.

The model contains an If-Else decision pattern that you add by right clicking inside the chart > **Add Pattern in Chart > Decision > If-Else**.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the if-else construct is in the `ex_if_else_SF_step` function in `ex_if_else_SF.c`:

```

/* External inputs (root inport signals with default storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with default storage) */
ExternalOutputs Y;

/* Model step function */
void ex_if_else_SF_step(void)
{
 /* Chart: '<Root>/Chart' incorporates:
 * Inport: '<Root>/u1'
 * Inport: '<Root>/u2'

```

```

*/
/* If-Else */
if (U.u1 >= U.u2) {
 /* Output: '<Root>/y1' */
 Y.y1 = U.u1;
} else {
 /* Output: '<Root>/y1' */
 Y.y1 = U.u2;
}

/* End of Chart: '<Root>/Chart' */
}

```

### Modeling Pattern for If-Else: MATLAB Function Block

1. Open example model ex\_if\_else\_ML.

2. The MATLAB Function Block contains this function:

```

function y1 = fcn(u1, u2)
if u1 > u2;
 y1 = u1;
else y1 = u2;
end

```

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the if-else construct is in the ex\_if\_else\_ML\_step function in ex\_if\_else\_ML.c:

```

/* External inputs (root inport signals with default storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with default storage) */
ExternalOutputs Y;

/* Model step function */
void ex_if_else_ML_step(void)
{
 /* MATLAB Function: '<Root>/MATLAB Function' incorporates:
 * Inport: '<Root>/u1'
 * Inport: '<Root>/u2'
 */
 if (U.u1 >= U.u2) {

```

```
 /* Output: '<Root>/y1' */
 Y.y1 = U.u1;
} else {
 /* Output: '<Root>/y1' */
 Y.y1 = U.u2;
}

/* End of MATLAB Function: '<Root>/MATLAB Function' */
}
```

# Switch

This example shows how to implement a `switch` construct by using Simulink blocks, Stateflow Charts, and MATLAB Function block.

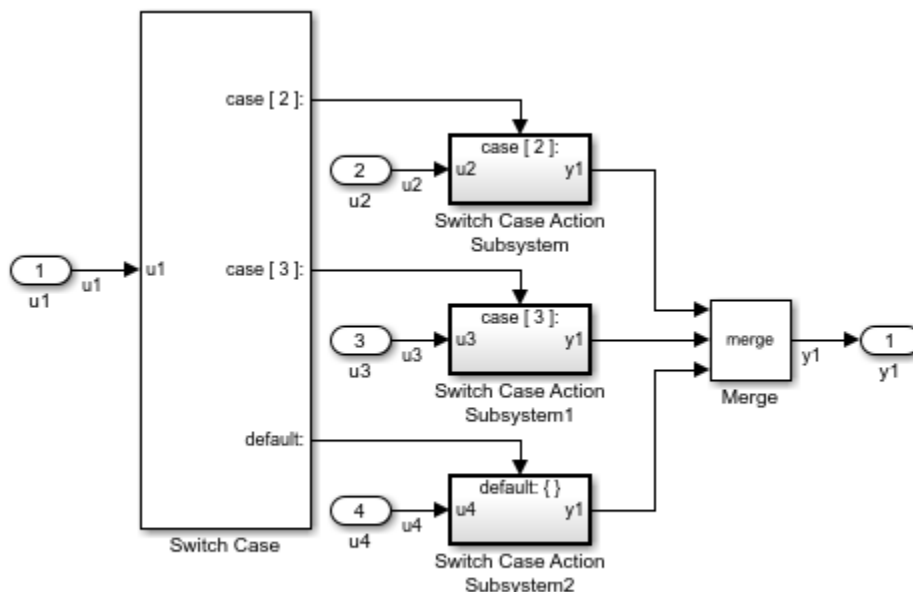

## C Construct

```
switch (u1)
{
 case 2:
 y1 = u2;
 break;
 case 3:
 u3;
 break;
 default:
 y1 = u4;
 break;
}
```

## Modeling Pattern for Switch: Switch Case block

One method to create a `switch` statement is to use a Switch Case block from the **Simulink > Signal Routing** library.

1. Open example model `ex_switch_SL`.

Copyright 2021 The MathWorks, Inc.

The model contains a Switch Case Action Subsystem. The Switch Case block takes an integer input, therefore, the input signal `u1` is type cast to `int32`.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the switch construct is in the `ex_switch_SL_step` function in `ex_switch_SL.c`:

```

/* Exported block signals */
int32_T u1; /* '<Root>/u1' */

/* External inputs (root inport signals with default storage) */
ExternalInputs rtU;

/* External outputs (root outports fed by signals with default storage) */
ExternalOutputs rtY;

/* Model step function */
void ex_switch_SL_step(void)
{
 /* SwitchCase: '<Root>/Switch Case' incorporates:
 * Inport: '<Root>/u1'
 */
 switch (u1) {
 case 2:
 /* Outputs for IfAction SubSystem: '<Root>/Switch Case Action Subsystem' incorporates:
 * ActionPort: '<S1>/Action Port'
 */
 /* Outport: '<Root>/y1' incorporates:
 * Inport: '<Root>/u2'
 * SignalConversion generated from: '<S1>/u2'
 */
 rtY.y1 = rtU.u2;

 /* End of Outputs for SubSystem: '<Root>/Switch Case Action Subsystem' */
 break;

 case 3:
 /* Outputs for IfAction SubSystem: '<Root>/Switch Case Action Subsystem1' incorporates:
 * ActionPort: '<S2>/Action Port'
 */
 /* Outport: '<Root>/y1' incorporates:
 * Inport: '<Root>/u3'
 * SignalConversion generated from: '<S2>/u3'
 */
 rtY.y1 = rtU.u3;

 /* End of Outputs for SubSystem: '<Root>/Switch Case Action Subsystem1' */
 break;

 default:
 /* Outputs for IfAction SubSystem: '<Root>/Switch Case Action Subsystem2' incorporates:
 * ActionPort: '<S3>/Action Port'
 */
 /* Outport: '<Root>/y1' incorporates:
 * Inport: '<Root>/u4'
 * SignalConversion generated from: '<S3>/u4'
 */
 rtY.y1 = rtU.u4;

 /* End of Outputs for SubSystem: '<Root>/Switch Case Action Subsystem2' */
 break;
 }
}

```

```

}

/* End of SwitchCase: '<Root>/Switch Case' */
}

```

### Modeling Pattern for Switch: MATLAB Function Block

1. Open example model ex\_switch\_ML.

Copyright 2021 The MathWorks, Inc.

The MATLAB Function Block contains this function:

```

function y1 = fcn(u1, u2, u3, u4)

switch u1
 case 2
 y1 = u2;
 case 3
 y1 = u3;
 otherwise
 y1 = u4;
end

```

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the switch construct is in the ex\_switch\_ML\_step function in ex\_switch\_ML.c:

```

/* External inputs (root inport signals with default storage) */
ExternalInputs rtU;

/* External outputs (root outports fed by signals with default storage) */
ExternalOutputs rtY;

```

```

/* Model step function */
void ex_switch_ML_step(void)
{
 /* MATLAB Function: '<Root>/MATLAB Function' incorporates:
 * Inport: '<Root>/u1'
 */
 switch (rtU.u1) {
 case 2:
 /* Outport: '<Root>/y1' incorporates:
 * Inport: '<Root>/u2'
 */
 rtY.y1 = rtU.u2;
 break;

 case 3:
 /* Outport: '<Root>/y1' incorporates:
 * Inport: '<Root>/u3'
 */
 rtY.y1 = rtU.u3;
 break;

 default:
 /* Outport: '<Root>/y1' incorporates:
 * Inport: '<Root>/u4'
 */
 rtY.y1 = rtU.u4;
 break;
 }

 /* End of MATLAB Function: '<Root>/MATLAB Function' */
}

```

### Convert If-Elseif-Else to Switch statement

If a MATLAB Function block or a Stateflow chart uses `if-elseif-else` decision logic, you can convert the block or chart to a `switch` statement by using a configuration parameter. Select the **Configuration Parameters > Code Generation > Code Style > “Convert if-elseif-else patterns to switch-case statements”** parameter. For more information, see “Converting If-Elseif-Else Code to Switch-Case Statements” on page 52-104. For more information on this conversion by using a Stateflow chart, see “Enhance Readability of Code for Flow Charts” on page 52-94.

## For Loop

This example shows how to implement a for loop construct by using Simulink blocks, Stateflow Charts, and MATLAB Function blocks.

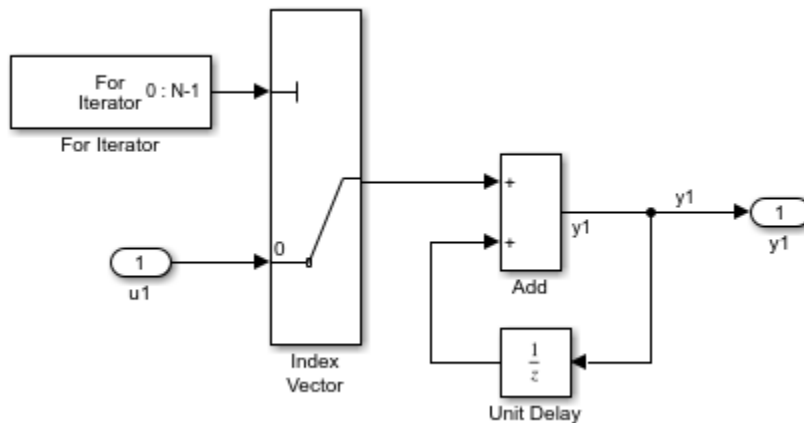

### C Construct

```
y1 = 0;
for(inx = 0; inx <10; inx++)
{
 y1 = u1[inx] + y1;
}
```

### Modeling Pattern for For Loop: For-Iterator Subsystem block

One method for creating a for loop is to use a For Iterator Subsystem block from the **Simulink > Ports and Subsystems** library.

1. Open example model ex\_for\_loop\_SL.

The model contains a For Iterator Subsystem block that repeats execution of the contents of the subsystem during a simulation time step.

Observe the following settings in the model:

- Open the For Iterator block. In the Block Parameters dialog box, the **Index-mode** parameter is Zero-based and the **Iteration limit** parameter is 10.
- Open the Unit Delay block. In the Block Parameters dialog box, the **Initial Conditions** parameter is 0. This parameter initializes the state to zero.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the for loop is in the ex\_for\_loop\_SL\_step function in ex\_for\_loop\_SL.c:

```
/* External inputs (root inport signals with default storage) */
ExternalInputs U;
```

```

/* External outputs (root outports fed by signals with default storage) */
ExternalOutputs Y;

/* Model step function */
void ex_for_loop_SL_step(void)
{
 int32_T rtb_y1;
 int32_T s1_iter;

 /* Outputs for Iterator SubSystem: '<Root>/For Iterator Subsystem' incorporates:
 * ForIterator: '<S1>/For Iterator'
 */
 for (s1_iter = 0; s1_iter < 10; s1_iter++) {
 /* Sum: '<S1>/Add' incorporates:
 * Inport: '<Root>/u1'
 * MultiPortSwitch: '<S1>/Index Vector'
 * UnitDelay: '<S1>/Unit Delay'
 */
 rtb_y1 = U.u1[s1_iter] + DWork.UnitDelay_DSTATE;

 /* Update for UnitDelay: '<S1>/Unit Delay' */
 DWork.UnitDelay_DSTATE = rtb_y1;
 }

 /* End of Outputs for SubSystem: '<Root>/For Iterator Subsystem' */

 /* Output: '<Root>/y1' */
 Y.y1 = rtb_y1;
}

```

### Modeling Pattern for For Loop: Stateflow Chart

1. Open example model ex\_for\_loop\_SF.

The chart contains a For loop decision pattern that you add by right clicking inside the chart > **Add Pattern in Chart > Loop > For**.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the for loop is in the ex\_for\_loop\_SF\_step function in ex\_for\_loop\_SF.c:

```

/* External inputs (root inport signals with default storage) */
ExternalInputs U;

```

```

/* External outputs (root outputs fed by signals with default storage) */
ExternalOutputs Y;

/* Model step function */
void ex_for_loop_SF_step(void)
{
 int32_T inx;

 /* Chart: '<Root>/Chart' */
 for (inx = 0; inx < 10; inx++) {
 /* Outport: '<Root>/y1' incorporates:
 * Inport: '<Root>/u1'
 */
 Y.y1 += U.u1[inx];
 }

 /* End of Chart: '<Root>/Chart' */
}

```

### Modeling Pattern for For Loop: MATLAB Function block

1. Open example model ex\_for\_loop\_ML.

The MATLAB Function Block contains this function:

```

function y1 = fcn(u1)

y1 = 0;

for inx=1:10
 y1 = u1(inx) + y1 ;
end

```

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the for loop is in the ex\_for\_loop\_ML\_step function in ex\_for\_loop\_ML.c:

```

/* Exported block signals */
real_T u1[10];
real_T y1;

/* '<Root>/u1' */
/* '<Root>/MATLAB Function' */

/* Model step function */
void ex_for_loop_ML_step(void)

```

```
{
 int32_T inx;

 /* MATLAB Function: '<Root>/MATLAB Function' incorporates:
 * Inport: '<Root>/u1'
 */
 y1 = 0.0;
 for (inx = 0; inx < 10; inx++) {
 y1 += u1[inx];
 }

 /* End of MATLAB Function: '<Root>/MATLAB Function' */
}
```

## While Loop

This example shows how to implement a while loop construct by using Simulink blocks, Stateflow Charts, and MATLAB Function blocks.

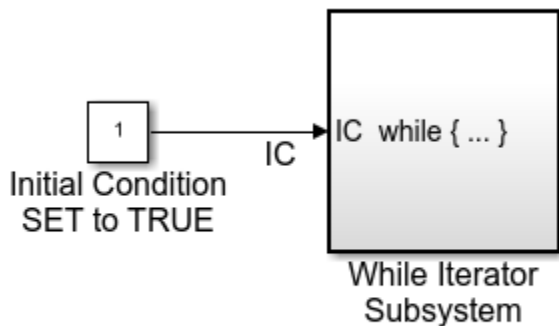

### C Construct

```
while(flag && (num_iter <= 100))
{
 flag = func ();
 num_iter ++;
}
```

### Modeling Pattern for While Loop: While Iterator Subsystem block

One method for creating a while loop is to use a While Iterator Subsystem block from the **Simulink > Ports and Subsystems** library.

1. Open example model ex\_while\_loop\_SL.

Copyright 2021 The MathWorks, Inc.

The model contains a While Iterator Subsystem block that repeats execution of the contents of the subsystem during a simulation time step.

Observe the following settings in the model:

- The Constant block provides an initial condition to the While Iterator Subsystem. For the Constant block, the **Constant value** is 1 and the **Output data type** is boolean. The initial condition can be dependent on the input to the block.
- In the While Iterator Subsystem, the func subsystem block has an output flag of 0 or 1 depending on the result of the algorithm in func( ). func() is the **Function name** in func subsystem.
- In the While Iterator Subsystem, for the While Iterator block, the **Maximum number of iterations** is 100.
- For the While Iterator block, the **While loop type** is while.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the while loop is in the ex\_while\_loop\_SL\_step function in ex\_while\_loop\_SL.c:

```

/* Model step function */
void ex_while_loop_SL_step(void)
{
 int32_T s1_iter;
 boolean_T loopCond;

 /* Outputs for Iterator SubSystem: '<Root>/While Iterator Subsystem' incorporates:
 * WhileIterator: '<S1>/While Iterator'
 */
 s1_iter = 1;

 /* SystemReset for Atomic SubSystem: '<S1>/func' */
 func_Reset();

 /* End of SystemReset for SubSystem: '<S1>/func' */
 loopCond = true;
 while (loopCond && (s1_iter <= 100)) {
 /* Outputs for Atomic SubSystem: '<S1>/func' */
 func();

 /* End of Outputs for SubSystem: '<S1>/func' */
 loopCond = flag;
 s1_iter++;
 }

 /* End of Outputs for SubSystem: '<Root>/While Iterator Subsystem' */
}

```

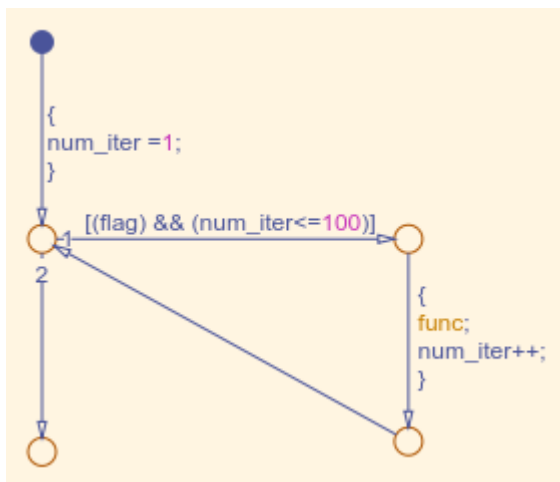

### Modeling Pattern for While Loop: Stateflow Chart

1. Open example model ex\_while\_loop\_SF.

Copyright 2021 The MathWorks, Inc.

In the model, the ex\_while\_loop\_SF/Chart executes the while loop.

The chart contains a While loop decision pattern that you add by right clicking inside the chart > **Add Pattern in Chart > Loop > While**.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the while loop is in the ex\_while\_loop\_SF\_step function in ex\_while\_loop\_SF.c:

```
/* Model step function */
void ex_while_loop_SF_step(void)
{
 /* Chart: '<Root>/Chart' */
 num_iter = 1;
 while (flag && (num_iter <= 100)) {
 /* Outputs for Function Call SubSystem: '<Root>/func' */
```

```

 func();

 /* End of Outputs for SubSystem: '<Root>/func' */
 num_iter++;
}

/* End of Chart: '<Root>/Chart' */
}

```

### Modeling Pattern for For Loop: MATLAB Function block

1. Open example model ex\_while\_loop\_ML.

Copyright 2021 The MathWorks, Inc.

The MATLAB Function Block contains this function:

```

function fcn(func_flag)

flag = true;
num_iter = 1;

while(flag && (num_iter<=100))
 func;
 flag = func_flag;
 num_iter = num_iter + 1;
end

```

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the while loop is in the ex\_while\_loop\_ML\_step function in ex\_while\_loop\_ML.c:

```

/* Model step function */
void ex_while_loop_ML_step(void)
{
 int32_T num_iter;

```

```
boolean_T flag;
boolean_T func_flag_0;

/* MATLAB Function: '<Root>/MATLAB Function' */
func_flag_0 = func_flag;
flag = true;
num_iter = 1;
while (flag && (num_iter <= 100)) {
 /* Outputs for Function Call SubSystem: '<Root>/func' */
 func();

 /* End of Outputs for SubSystem: '<Root>/func' */
 flag = func_flag_0;
 num_iter++;
}

/* End of MATLAB Function: '<Root>/MATLAB Function' */
}
```

- “Create Flow Charts by Using Pattern Wizard” (Stateflow)

## More About

- “Implement MATLAB Functions in Simulink with MATLAB Function Blocks”

## Do While Loop

This example shows how to implement a do while loop construct by using Simulink blocks and Stateflow Charts.

### C Construct

```
num_iter = 1;
do {
 flag = func();
 num_iter++;
}
while (flag && num_iter <= 100)
```

### Modeling Pattern for Do While Loop: While Iterator Subsystem block

One method for creating a do while loop is to use a While Iterator Subsystem block from the **Simulink > Ports and Subsystems** library.

1. Open example model ex\_do\_while\_loop\_SL.

The model contains a While Iterator Subsystem block that repeats execution of the contents of the subsystem during a simulation time step.

Observe the following settings in the While Iterator Subsystem:

- The func subsystem block has an output flag of 0 or 1 depending on the result of the algorithm in func( ). func( ) is the **FUNCTION NAME** in func subsystem.
- For the While Iterator block, the **Maximum number of iterations** is 100.
- For the While Iterator block, the **While loop type** is do-while.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the do while loop is in the ex\_do\_while\_loop\_SL\_step function in ex\_do\_while\_loop\_SL.c:

```
/* Model step function */
void ex_do_while_loop_SL_step(void)
{
 int32_T s1_iter;

 /* Outputs for Iterator SubSystem: '<Root>/While Iterator Subsystem' incorporates:
```

```

* WhileIterator: '<S1>/While Iterator'
*/
sl_iter = 1;

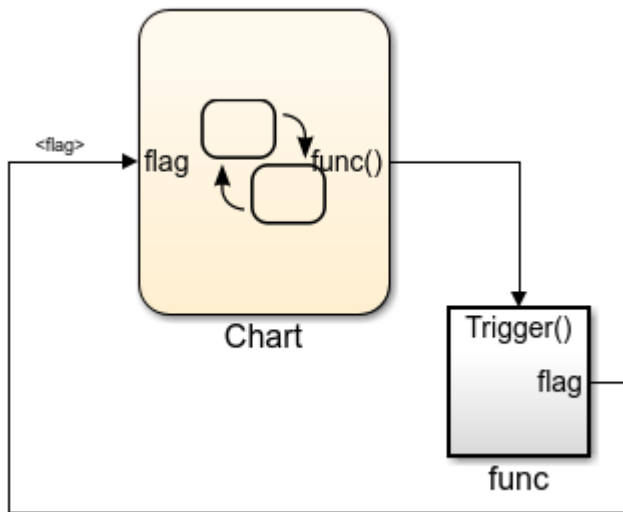

/* SystemReset for Atomic SubSystem: '<S1>/func' */
func_Reset();

/* End of SystemReset for SubSystem: '<S1>/func' */
/* End of Outputs for SubSystem: '<Root>/While Iterator Subsystem' */
do {
 func();
 sl_iter++;
} while (flag && (sl_iter <= 100));
}

```

### Modeling Pattern for Do While Loop: Stateflow Chart

1. Open example model ex\_do\_while\_loop\_SF.

In the model, the ex\_do\_while\_loop\_SF/Chart executes the do while loop.

The chart contains a `While` loop decision pattern that you add by selecting **Chart > Add Pattern in Chart > Loop > While**.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the `do while` loop is in the `ex_do_while_loop_SF_step` function in `ex_do_while_loop_SF.c`:

```
/* Model step function */
void ex_do_while_loop_SF_step(void)
{
 int32_T num_iter;

 /* Chart: '<Root>/Chart' */
 num_iter = 1;
 do {
 func();
 num_iter++;
 } while (flag && (num_iter <= 100));
}
```

## See Also

While Iterator Subsystem

## Related Examples

- “While Loop” on page 25-35
- “Create Flow Charts by Using Pattern Wizard” (Stateflow)

## Function Call

This example shows how to generate a function call by adding a subsystem, which implements the operations that you want.

### C Construct

```
void add_function(void)
{
 y1 = u1 + u2;
}
```

### Procedure

1. Open example model `ex_function_call`.

The subsystem has two inputs and returns one output.

Selecting the **Treat as atomic unit** parameter enables parameters on the **Code Generation** tab. The **Code Generation** tab provides these customizations:

- **Function packaging** set to Nonreusable function
- **Function name options** set to User specified
- **Function name** specified as `add_function`
- **File name options** set to Use function name

2. To build the model and generate code, press **Ctrl+B**.

### Results

In `ex_function_call.c`, the function is called from `ex_function_call_step`:

```
/* Model step function */
void ex_function_call_step(void)
{
```

```
/* Outputs for Atomic SubSystem: '<Root>/Add_Subsystem' */
add_function();

/* End of Outputs for SubSystem: '<Root>/Add_Subsystem' */
}
```

The function prototype is externally declared through the subsystem file, `add_function.h`:

```
extern void add_function(void);
```

The function definition is in the subsystem file `add_function.c`:

```
void add_function(void)
{
 /* Output: '<Root>/y1' incorporates:
 * Inport: '<Root>/u1'
 * Inport: '<Root>/u2'
 * Sum: '<S1>/Sum'
 */
 rtY.y1 = u1 + u2;
}
```

## See Also

Function-Call Subsystem

## Related Examples

## Function Prototyping

This example shows how to create and customize your function prototype.

### C Construct

```
double add_function(double u1, double u2)
{
 return u1 + u2;
}
```

### Function Call by Using Graphical Functions

1. Open example model ex\_func\_SF. This example model contains two Inport blocks and one Output block.

The Stateflow chart contains a graphical function that you create by clicking the **fx** button and placing a graphical function into the Stateflow chart.

The graphical function contains this signature:

```
output = add_function(u1, u2)
```

In the Stateflow chart, there is an example of a simple transition that calls `add_function`.

2. Open the Model Explorer. From the Model Hierarchy tree, select **ex\_func\_SF > Chart > add\_function**. On the right pane, make sure that the **Function Inline Option** is set as Function.
3. From the Model Hierarchy tree, click **Chart**. On the right pane make sure that the **Export Chart Level Functions** parameter is selected.
4. To build the model and generate code, press **Ctrl+B**.

ex\_func\_SF.c contains the generated code:

```
/* Function for Chart: '<Root>/Chart' */
void add_function(real_T in1, real_T in2, real_T *output)
{
 *output = in1 + in2;
}

/* Model step function */
void ex_func_SF_step(void)
{
 /* Chart: '<Root>/Chart' incorporates:
 * Inport: '<Root>/u1'
 * Inport: '<Root>/u2'
 */
 add_function(u1, u2, &y1);

 /* Output: '<Root>/y1' */
 rtY.y1_e = y1;
}
```

### Control Function Prototype of the *model\_step* Function

1. Open example model ex\_control\_step\_function.

2. Open the Code perspective. In the Code Mappings editor, select the **Entry-Point Functions** tab.
3. In the step function row, under the **Function Preview** column, click the prototype hyperlink. The configuration dialog box used for customization opens. The first field in the dialog box, **C function prototype**, automatically updates to preview the changes to the step function as you make them.
4. Change the function name. If you do not specify a name, the code generator names the function based on a default naming rule. For this example, rename the function by setting **C Step Function Name** to **ex\_control\_run**. The function preview changes to reflect the new step function name.
5. Configure step function arguments. If an application requires a **void-void** interface, clear **Configure arguments for Step function prototype**. For this example, select that option.
6. Display current default settings for the entry-point function arguments by clicking **Get default**. An updated diagram appears.

7. Configure the function return argument by setting **C return argument** to `void` or one of the listed output arguments. For this example, select `void`. Check your change in the preview.

8. Configure the function input and output arguments. For each root inport and outport, you can change the C type qualifier and argument name. For details, see “Configure Name and Arguments for Individual Step Functions” on page 32-119.

For this example:

- For `u1`, set **C Type Qualifier** to `Value` and **C Identifier Name** to `arg_u1`.
- For `u2`, set **C Type Qualifier** to `Pointer to const` and **C Identifier Name** to `arg_u2`.
- For the outport, set **C Identifier Name** to `arg_y1`.

Review your changes in the preview.

9. To validate your changes, click **Validate**.

10. Apply your changes. Click **Apply**. Then, click **OK**.

11. To build the model and generate code, press **Ctrl+B**.

`ex_control_step_function.c` contains the generated code:

```
void ex_control_run(real_T arg_u1, const real_T *arg_u2, real_T *arg_y1)
```

## See Also

### Related Examples

## External C Functions

This example shows several methods for integrating legacy C functions into generated code. These methods create an S-function or make a call to an external C function. For more information on S-functions, see “S-Functions and Code Generation” on page 12-2.

### C Construct

```
extern double add(double, double);

#include "add.h"
double add(double u1, double u2)
{
 double y1;
 y1 = u1 + u2;
 return (y1);
}
```

### Create S-Functions by Using Legacy Code Tool

Use the Legacy Code Tool to create an S-function and generate a TLC file. The code generation software uses the TLC file to generate code from this S-function. The advantage to using the Legacy Code Tool is that the generated code is fully inlined and does not need wrapper functions to access the custom code.

1. Create a C header file named `add.h` that contains the function signature:

```
extern double add(double, double);
```

2. Create a C source file named `add.c` that contains the function body:

```
double add(double u1, double u2)
{
 double y1;
 y1 = u1 + u2;
 return (y1);
}
```

3. To build an S-function for use in simulation and code generation, run the following script or execute each of these commands at the MATLAB® command line:

```
%% Initialize legacy code tool data structure
def = legacy_code('initialize');

%% Specify Source File
def.SourceFiles = {'add.c'};

%% Specify Header File
def.HeaderFiles = {'add.h'};

%% Specify the Name of the generated S-function
def.SFunctionName = 'add_function';
```

```

%% Create a c-mex file for S-function
legacy_code('sfcn_cmex_generate', def);

%% Define function signature and target the Output method
def.OutputFcnSpec = ['double y1 = add(double u1, double u2)'];

%% Compile/Mex and generate a block that can be used in simulation
legacy_code('generate_for_sim', def);

%% Create a TLC file for Code Generation
legacy_code('sfcn_tlc_generate', def);

%% Create a Masked S-function Block
legacy_code('slblock_generate', def);

Start Compiling add_function
 mex('-IC:\TEMP\Bdoc22a_1891349_13144\ibC86E06\31\tp2ef22d7b\ex61094511', '-c', '-outdir', 'C
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
 mex('add_function.c', '-IC:\TEMP\Bdoc22a_1891349_13144\ibC86E06\31\tp2ef22d7b\ex61094511', 'C
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling add_function
Exit

```

The output of this script produces:

- A new model containing the S-function block.
- A TLC file named `add_function.tlc`.
- A C source file named `add_function.c`.
- A mexw32 dll file named `add_function.mexw32`.

4. Add import blocks and an output block and make the connections, as shown in the model.

5. Name and save your model. In this example, the model is named `ex_function_call_lct`.

6. To build the model and generate code, press **Ctrl+B**.

This code is generated in `ex_function_call_lct.c`:

```

/* Exported block signals */

```

```

real_T u1; /* '<Root>/u1' */
real_T u2; /* '<Root>/u2' */

/* External outputs (root outputs fed by signals with default storage) */
ExternalOutputs rtY;

/* Model step function */
void ex_function_call_lct_step(void)
{
 /* Output: '<Root>/y1' incorporates:
 * Inport: '<Root>/u1'
 * Inport: '<Root>/u2'
 * S-Function (add_function): '<Root>/add_function'
 */
 rtY.y1 = add(u1, u2);
}

```

The user-specified header file `add.h` is included in `ex_function_call_lct.h`:

```
#include "add.h"
```

### Call C Functions by Using a Stateflow Chart

1. Create a C header file named `add.h` that contains the example function signature. Refer to the preceding example.
2. Create a C source file named `add.c` that contains the function body. Refer to the preceding example.
3. Add inport blocks and an output block and make the connections, as shown in the model. In this example, the model is named `ex_function_call_SF`.

4. Double-click the Stateflow® chart and edit the chart as shown. Place the call to the `add` function within a transition action.

5. Select the **Configuration Parameters > Code Generation > Custom Code** pane. On the **Code information** tab, select **Include headers**. In the **Include headers** field, enter the `#include` statement:

```
#include "add.h"
```

6. Select **Source files**. In the **Source files** field, enter:

```
add.c
```

7. Select the **Configuration Parameters > Code Generation > Custom Code > Use the same custom code settings as Simulation Target** parameter.

8. To build the model and generate code, press **Ctrl+B**.

`ex_exfunction_call_SF.c` contains the following code in the step function:

```
/* Definition for custom storage class: Global */
real_T u1; /* '<Root>/u1' */
real_T u2; /* '<Root>/u2' */
real_T y1; /* '<Root>/Chart' */

/* Model step function */
void ex_function_call_SF_step(void)
{
 /* Chart: '<Root>/Chart' incorporates:
 * Inport: '<Root>/u1'
 * Inport: '<Root>/u2'
 */
 y1 = (real_T)add(u1, u2);
}
```

`ex_exfunction_call_SF.h` contains the include statement for `add.h`:

```
#include "add.h"
```

### Use MATLAB Function Block to Call C Functions

1. Create a C header file named `add.h` that contains the example function signature. Refer to the preceding example.

2. Create a C source file named `add.c` that contains the function body. Refer to the preceding example.

3. In the Simulink Library Browser, click **Simulink > User Defined Functions**. Drag a MATLAB Function block into your model.

4. Double-click the MATLAB Function block. Edit the function to include:

```
function y1 = add_function(u1, u2)

% Set the class and size of output
y1 = u1;

% Call external C function
y1 = coder.ceval('add',u1,u2);

end
```

5. Select the **Configuration Parameters > Code Generation > Custom Code** pane. On the **Code information** tab, select **Include headers**. In the **Include headers** field, enter the `#include` statement:

```
#include "add.h"
```

6. In the **Code information** tab, select **Source files**. In the **Source files** field, enter:

```
add.c
```

7. Add two Inport blocks and one Outport block to the model and connect it to the MATLAB Function block.

8. Save the model as `ex_function_call_ML`.

9. To build the model and generate code, press **Ctrl+B**.

`ex_exfunction_call_ML.c` contains the following code in the step function:

```
/* Definition for custom storage class: Global */
real_T u1; /* '<Root>/u1' */
real_T u2; /* '<Root>/u2' */
real_T y1; /* '<Root>/MATLAB Function' */

/* Model step function */
void ex_function_call_ML_step(void)
```

```
{
 /* MATLAB Function: '<Root>/MATLAB Function' incorporates:
 * Inport: '<Root>/u1'
 * Inport: '<Root>/u2'
 */
 y1 = add(u1, u2);
}
```

ex\_exfunction\_call\_ML.h contains the include statement for add.h:

```
#include "add.h"
```

## Macro Definitions (#define)

### C Construct

```
#define myParam 9.8;
```

### Export Generated Macro Definition

1. Open example model ex\_param\_macro.

2. In the model, select the Gain block. In the Property Inspector, set the value of the **Gain** parameter to myParam.
3. Next to the parameter value, click the action button (the button with three vertical dots) and select **Create**.
4. In the Create New Data dialog box, set **Value** to Simulink.Parameter(9.8). Click **Create**. A Simulink.Parameter object, myParam, appears in the base workspace. The Gain block uses the object to set the value of the Gain parameter, in this case, 9.8.
5. On the **Code Generation** tab, click the **Configure in Coder App** button. In the Code Mappings editor, set **Storage Class** to Define. Click **OK**.
6. To build the model and generate code, press **Ctrl+B**.

The generated header file ex\_param\_macro.h defines myParam as a macro.

```
/* Definition for custom storage class: Define */
#define myParam 9.8 /* Referenced by: '<Root>/Gain'
```

### Reuse Macro from Handwritten Code

1. In the Code Mappings editor, on the **Parameters** tab, click the **Update Code Mappings** button.
2. Change **Storage Class** of myParam from Define to ImportedDefine.
3. In the Property Inspector, under **Code** section, set **Header File** to external\_params.h. The generated code imports the macro definition from a custom header file named external\_params.h.
4. In your current folder, create the C header file external\_params.h, which contains the #define statement.

```
#ifndef _EXTERNAL_PARAMS
#define _EXTERNAL_PARAMS

#define myParam 9.8

#endif
```

```
/* EOF */
```

5. To build the model and generate code, press **Ctrl+B** .

The generated header file `ex_param_macro.h` does not define the macro. Instead, the file includes (`#include`) the custom header file `external_params.h`.

```
/* Includes for objects with custom storage classes */
#include "external_params.h"
```

The source file `ex_param_macro.c` contains a guard to check that a definition for `myParam` exists.

```
#include "rtwtypes.h"
#include "external_params.h"

/*
 * Check that imported macros with storage class "ImportedDefine" are defined
 */
#ifndef myParam
#error The variable for the parameter "myParam" is not defined
#endif
```

## **Conditional Inclusions (#if / #endif)**

You can generate preprocessor conditional directives in your code by implementing Variant Subsystem blocks in your model. In the generated code, preprocessor conditional directives select a section of code to execute at compile time. To implement variants in your model, see “Create a Simple Variant Model”. To generate code for variants, see “Generate Preprocessor Conditionals for Variant Systems” on page 26-32.

## Typedef

Create data type aliases by generating typedef statements.

### C Construct

```
typedef float float_32;
```

### Procedure

To create a data type alias in Simulink®, use a `Simulink.AliasType`. The code generator creates a typedef statement in the generated code.

The built-in Simulink data type `single` corresponds to the C data type `float`.

1. At the command prompt, create a `Simulink.AliasType` object named `float_32` that represents an alias of `single`.

```
float_32 = Simulink.AliasType('single');
```

2. Open the example model `ex_typedef`.

Copyright 2022 The MathWorks, Inc.

3. In the Model Data Editor, open the **Inports/Outports** tab.
4. From the **Change View** menu, select Design.
5. In the model, select the Inport block.
6. In the Model Data Editor, for the Inport block, set **Data Type** to `float_32`. Click Refresh data type if `float_32` is not available in the drop down options.
7. Open the **Embedded Coder** app.
8. In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
9. In the Code Mappings editor, on the **Inports** tab, set **Storage Class** for the Inport block to `ExportedGlobal`. The Inport block appears in the generated code as a separate global variable.
10. In the Property Inspector, for the Inport block, set the **Code > Identifier** property to `mySig`.
11. To build the model and generate code, press **Ctrl+B**.

### Results

The generated header file `ex_typedef.h` defines the data type alias `float_32`.

```
#ifndef DEFINED_TYPEDEF_FOR_float_32_
#define DEFINED_TYPEDEF_FOR_float_32_
```

```
typedef real32_T float_32;
#endif
```

By default, the code generator also creates the alias `real32_T`, which corresponds to the C data type `float`. You can see the `typedef` statement in the generated header file `rtwtypes.h`.

```
typedef float real32_T;
```

The generated source file `ex_typedef.c` uses `float_32` to define the global variable `mySig`.

```
/* Exported block signals */
float_32 mySig; /* '<Root>/In1' */
```

## See Also

`Simulink.AliasType`

## Related Examples

- “Control Data Type Names in Generated Code” on page 35-2
- “Structures of Signals” on page 25-62

## Structures of Parameters

Create a structure in the generated code. The structure stores parameter data.

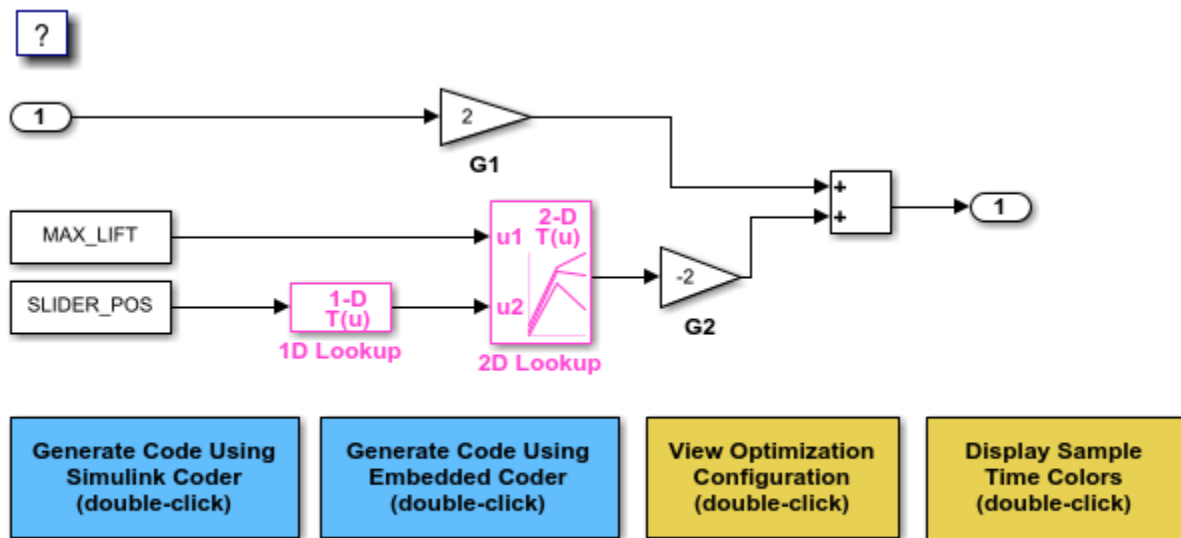

### C Construct

```
typedef struct {
 double G1;
 double G2;
} myStructType;

myStructType myStruct = {
 2.0,
 -2.0
};
```

### Procedure

1. Open the example model `rtwdemo_paraminline`.

Copyright 1994-2020 The MathWorks, Inc.

2. On the **Modeling** tab, click **Model Data Editor**. In the Model Data Editor, select the **Parameters** tab.
3. In the model, click the Gain block labeled G1. In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to `myStruct.G1`.
4. Set the value of the **Gain** parameter in the G2 block to `myStruct.G2`.
5. Next to `myStruct.G2`, click the action button (with three vertical dots) and select **Create**.
6. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(struct)` and click **Create**. A `Simulink.Parameter` object named `myStruct` appears in the base workspace.

7. In the Simulink.Parameter property dialog box, next to the **Value** property, click the action button and select **Open Variable Editor**.
8. Right-click the white space under the **Field** column and select **New**. Name the new structure field G1. Use the **Value** column to set the value of the field to 2.
9. Add a field G2 whose value is -2, and then close the Variable Editor.
10. In the Simulink.Parameter property dialog box, on the **Code Generation** tab, set **Storage class** to **ExportedGlobal**. The structure myStruct appears in the generated code as a global variable.
11. Generate code from the model.

## Results

The generated header file `rtwdemo_paraminline_types.h` defines a structure type that has a random name.

```
typedef struct {
 real_T G1;
 real_T G2;
} struct_6h72eH5WfuEIyQr5YrdGuB;
```

The source file `rtwdemo_paraminline.c` defines and initializes the structure variable myStruct.

```
/* Exported block parameters */
struct_6h72eH5WfuEIyQr5YrdGuB myStruct = {
 2.0,
 -2.0
};

/* Variable: myStruct
 * Referenced by:
 * '<Root>/G1'
 * '<Root>/G2'
 */
```

## Specify Name of Structure Type

1. Optionally, specify a name to use for the structure type definition (`struct`). At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object that represents the structure type.
2. The default name of the object is `slBus1`. Change the name by copying the object into a new MATLAB variable.
3. In the Model Data Editor, click the **Show/refresh additional information** button.
4. In the data table, find the row that corresponds to `myStruct`. Use the **Data Type** column to set the data type of `myStruct` to `Bus: myStructType`.
5. Generate code from the model.

The code generates the definition of the structure type `myStructType` and uses this type to define the global variable `myStruct`.

```
myStructType myStruct = {
 2.0,
 -2.0
} ; /* Variable: myStruct
```

## See Also

## Structures of Signals

This example shows how to create a structure of signal data in the generated code.

### C Construct

```
typedef struct {
 double signal1;
 double signal2;
 double signal3;
} my_signals_type;
```

### Procedure

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of buses in your model.

1. Create the `ex_signal_struct` model by using Gain blocks, a Bus Creator block, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

Copyright 2021 The MathWorks, Inc.

2. To configure the Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.
3. In the toolbar, on the **Modeling** tab, under **Design**, click **Bus Editor**.
4. In the Bus Editor toolbar, in the **Add** gallery, click **Bus** to create a `Simulink.Bus` object. Then, name it `my_signals_type`. With `my_signals_type` selected, in the **Add** gallery, click **Bus Element** three times to add three elements. Name them `signal1`, `signal2`, and `signal3`. For more information, see Bus Editor.

5. Save the bus objects in your current folder as `ex_signal_struct_data.mat`.

This bus object represents the structure type that you want the generated code to use.

6. In the Bus Creator block dialog box, set **Output data type** to `Bus: my_signals_type`.

7. Select **Output as nonvirtual bus**. Click **OK**. A nonvirtual bus appears in the generated code as a structure.

8. Open the **Simulink Coder** app. In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.

9. Open the **Signals/States** tab. In the model, select the output signal of the Bus Creator block and click the **Add selected signals to code mappings** button in the Code Mappings editor.

11. For the added signal, set **Storage Class** to `ExportedGlobal`.

12. In the Property Inspector, set the **Code > Identifier** property to `sig_struct_var`. The output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

13. Generate code from the model.

## Results

The generated header file `ex_signal_struct_types.h` defines the structure type `my_signals_type`.

```
typedef struct {
 real_T signal1;
 real_T signal2;
 real_T signal3;
} my_signals_type;
```

The source file `ex_signal_struct.c` allocates memory for the global variable `sig_struct_var`, which represents the output of the Bus Creator block.

```
/* Exported block signals */
my_signals_type sig_struct_var; /* '<Root>/Bus Creator' */
```

In the same file, in the model step function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

## Nested Structures of Signals

You can create nested structures of signal data in the generated code.

### C Construct

```
typedef struct {
 double signal1;
 double signal2;
 double signal3;
} B_struct_type;

typedef struct {
 double signal1;
 double signal2;
} C_struct_type;

typedef struct {
 B_struct_type subStruct_B;
 C_struct_type subStruct_C;
} A_struct_type;
```

### Procedure

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of buses in your model.

To nest a structure inside another structure, use a bus object as the data type of an element in another bus object.

1. Create the `ex_signal_nested_struct` model with Gain blocks, Bus Creator blocks, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

Copyright 2021 The MathWorks, Inc.

2. To configure a Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.

3. In the toolstrip, on the **Modeling** tab, under **Design**, click **Bus Editor**.

In the Bus Editor toolstrip, in the **Add** gallery, click **Bus** to create a Simulink.Bus object. Then, name it `A_struct_type`. With `A_struct_type` selected, in the **Add** gallery, click **Bus Element** twice to add two elements. Name the elements `subStruct_B` and `subStruct_C`. For more information, see Bus Editor. This bus object represents the top-level structure type that you want the generated code to use.

4. Similarly, create Simulink.Bus objects `B_struct_type` (with three elements) and `C_struct_type` (with two elements).

5. In the `A_struct_type` object, for the `subStruct_B` element, set **Data Type** to `Bus: B_struct_type`. Similarly, for the `subStruct_C` element, set **Data Type** to `Bus: C_struct_type`.

The screenshot shows the 'Contents of Base Workspace' window with a table of bus structures and the 'Property Inspector' window.

Name	DataType	Complexity	Dimensions
▼ A_struct_type			
▼ subStruct_B	Bus: B_struct_type	real	1
— signal1	double	real	1
— signal2	double	real	1
— signal3	double	real	1
▼ subStruct_C	Bus: C_struct_type	real	1
— signal1	double	real	1
— signal2	double	real	1
▼ B_struct_type			
— signal1	double	real	1
— signal2	double	real	1
— signal3	double	real	1
▼ C_struct_type			
— signal1	double	real	1
— signal2	double	real	1

The Property Inspector window shows the selected object: Simulink.Bus: A\_struct\_type. It has a 'Name' field containing 'A\_struct\_type' and a 'Description' field. The 'Code Generation' section is also visible.

Each element in `A_struct_type` uses another bus object as a data type. These elements represent substructures.

6. In the dialog box of the Bus Creator block that collects the three Gain signals, set **Output data type** to Bus: `B_struct_type`. Click **Apply**.

7. Select **Output as nonvirtual bus** and click **OK**.

8. In the dialog box of the other subordinate Bus Creator block, set **Output data type** to Bus: `C_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

9. In the last Bus Creator block dialog box, set **Output data type** to Bus: `A_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

10. Open the **Simulink Coder** app. In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.

11. Open the **Signals/States** tab. In the model, select the output signal of the `A_struct_type` Bus Creator block, which feeds the Unit Delay block. Click the **Add selected signals to code mappings** button in the Code Mappings editor.

12. For the added signal, set **Storage Class** to `ExportedGlobal`.

13. In the Property Inspector, set the **Code > Identifier** property to `sig_struct_var`. The output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

14. Generate code from the model.

### Results

The generated header file `ex_signal_nested_struct_types.h` defines the structure types. Each structure type corresponds to a `Simulink.Bus` object.

```
typedef struct {
 real_T signal1;
 real_T signal2;
 real_T signal3;
} B_struct_type;

typedef struct {
 real_T signal1;
 real_T signal2;
} C_struct_type;

typedef struct {
 B_struct_type subStruct_B;
 C_struct_type subStruct_C;
} A_struct_type;
```

The generated source file `ex_signal_nested_struct.c` allocates memory for the global structure variable `sig_struct_var`. By default, the name of the `A_struct_type` Bus Creator block is `Bus Creator2`.

```
/* Exported block signals */
A_struct_type sig_struct_var; /* '<Root>/Bus Creator2' */
```

In the same file, in the model `step` function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

## Bitfields

### C Construct

```
typedef struct {
 unsigned int p1 : 1;
 unsigned int p2 : 1;
 unsigned int p3 : 1;
} my_struct_type
```

### Procedure

1. Open example model `ex_struct_bitfield_CSC`. The model contains three Constant blocks and three Output blocks.

Copyright 2021 The MathWorks, Inc.

2. Open the Model Data Editor. On the **Modeling** tab, click **Model Data Editor**.
3. In the Model Data Editor, on the **Parameters** tab, in the **Value** column, observe that the value of the first Constant block is `p1`. Next to the parameter value, click the action button (the button with three vertical dots) and select **Create**.
4. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(false)`. Click **Create**. A `Simulink.Parameter` object, `p1`, appears in the base workspace. The object stores a Boolean value, `false`, and uses the data type `boolean`.
5. In the `Simulink.Parameter` property dialog box, click **OK**.
6. Use the Model Data Editor to configure the other Constant blocks to refer to new parameter objects named `p2` and `p3`.
7. Open the **Embedded Coder** app.
8. In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
9. In the Code Mappings editor, on the **Parameters** tab, click the **Update Code Mappings** button.
10. Use the **Storage Class** column to apply the storage class `BitField` to all parameter objects.
10. In the Property Inspector, use the **Struct Name** column to configure each object to use the same structure type, `my_struct`.

11. Generate code from the model.

### Results

The generated header file `ex_struct_bitfield_CSC.h` defines the structure type `my_struct_type`.

```
/* Type definition for custom storage class: BitField */
typedef struct myStruct_tag {
 uint_T p1 : 1; /* Referenced by: '<Root>/Constant1' */
 uint_T p2 : 1; /* Referenced by: '<Root>/Constant2' */
 uint_T p3 : 1; /* Referenced by: '<Root>/Constant3' */
} myStruct_type;
```

The generated source file `ex_struct_bitfield_CSC.c` defines and initializes the structure variable `my_struct`.

```
/* Definition for custom storage class: BitField */
myStruct_type myStruct = {
 /* p1 */
 false,

 /* p2 */
 false,

 /* p3 */
 false
};
```

## Arrays for Parameters

### C Construct

```
float myParams[5]= {1.0F,2.0F,3.0F,4.0F,5.0F};
```

### Procedure

1. Create the `ex_param_array` model by using a Gain block.

2. In the model, select the Gain block. In the Property Inspector, set the value of the **Gain** parameter to `myParam`.
3. Next to the parameter value, click the action button (the button with three vertical dots) and select **Create**.
4. In the Create New Data dialog box, set **Value** to `Simulink.Parameter ([1 2 3 4 5])`. Click **Create**. A `Simulink.Parameter` object, `myParam`, appears in the base workspace. The Gain block uses the object to set the value of the Gain parameter.
5. In the `Simulink.Parameter` property dialog box, set **Storage class** to `ExportedGlobal`. Click **OK**.

With this setting, `myParams` appears in the generated code as a separate global variable.

6. Set **Data type** to `single`. Click **OK**.
7. To build the model and generate code, press **Ctrl+B**.

### Results

The generated source file `ex_param_array.c` defines and initializes the global variable `myParams`.

```

/* Exported block parameters */
real32_T myParam[5] = { 1.0F, 2.0F, 3.0F, 4.0F, 5.0F } ;/* Variable: myParam
* Referenced by: '<Root>/Gain'
*/

```

## Arrays for Signals

### C Construct

```
double myIn[5];
double myOut[5];
```

### Procedure

1. Open example model `ex_signal_array`.

2. In the Model Data Editor, select the **Inports/Outports** tab.
3. From the **Change View** drop-down list, select Design.

Observe these settings:

- For the Inport block, the **Signal Name** is `myIn` and Dimensions is `[5 1]`.
- For the Outport block, the **Signal Name** is `myOut`.

4. Open the **Embedded Coder** app.
5. In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
6. In the Code Mappings editor, on the **Inports** tab, for the Inport block and the Outport block, the **Storage Class** is `ExportedGlobal`. With this setting, the blocks appear in the generated code as separate global variables.
7. To build the model and generate code, press **Ctrl+B**.

### Results

The generated source file `ex_signal_array.c` defines the global variables `myIn` and `myOut` as arrays with 5 elements each.

```
/* Exported block signals */
real32_T myIn[5]; /* '<Root>/In1' */
real32_T myOut[5]; /* '<Root>/Out1' */
```

## Pointers

When your handwritten code allocates memory for signal, state, or parameter data, you can generate code that accesses that data through a pointer. Apply a storage class such as `ImportedExternPointer` to a data item in the model. Your handwritten code provides the pointer definition.

### C Construct

```
extern double *myIn;
```

### Procedure

1. Open example model `ex_pointer`.

2. Open the **Embedded Coder** app.
3. In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
4. In the Code Mappings editor, on the **Inports** tab, set **Storage Class** for the Inport block to `ImportedExternPointer`.
5. Generate code from the model.

### Results

The generated header file `ex_pointer.h` declares the pointer.

```
/* Imported (extern) pointer block signals */
extern real_T *In1; /* '<Root>/In1' */
```

In the generated source file `ex_pointer.c`, in the model step function, the algorithm dereferences the pointer, `In1`.

```
/* Model step function */
void ex_pointer_step(void)
{
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 */
 rtY.Out1 = *In1;
}
```

## Implement Dimension Variants for Array Sizes in Generated Code

### Dimension Variants

Use symbolic dimensions to simulate various sets of dimension choices without regenerating code for every set. Set up your model with dimensions that you specify as symbols in blocks and data objects. These symbols propagate throughout the model during simulation, and then go into the generated code. Modeling constraints for symbols during simulation (for example,  $C=A+B$ ) are output as preprocessor conditionals in either the `model.h` or the `model_types.h` file.

You can directly specify dimension information as a symbol or a numeric constant for these blocks and data objects:

- Inport
- Outport
- Signal Specification
- Data Store Memory
- Interpreted MATLAB Function
- `Simulink.Signal`
- `Simulink.Parameter`
- `Simulink.BusElement`
- `AUTOSAR.Parameter`

The Data Store Memory and Interpreted MATLAB Function blocks also support variable dimension signals. For these blocks, the symbolic dimensions control the maximum allowed size.

You must provide the initialization code for `Simulink.Parameter` objects that contain symbolic dimensions. To prevent the generated code from initializing these parameters, you must either:

- Configure the parameters to use a storage class with the **Data scope** property set to `Imported`, such as the `ImportedExtern` or `ImportedExternPointer` built-in storage classes.
- Configure the parameters to use a storage class with the **Data initialization** property set to `None`.

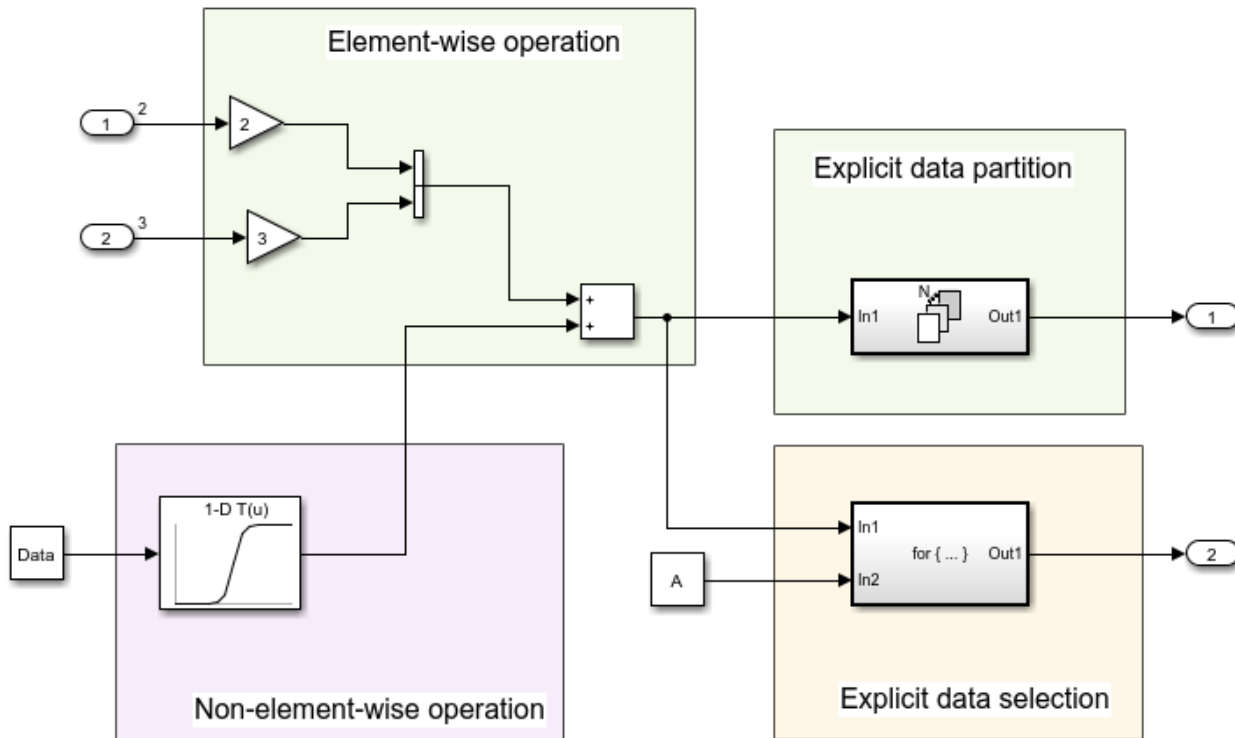

You use `Simulink.Parameter` objects to specify dimension information as symbols. For more information on signal dimensions, see “Determine Signal Dimensions”.

You must fix symbolic dimension values at compile-time. You can not resolve a symbolic dimension to another variable and then vary it during run-time because you define the behavior during simulation.

**Note:** The dimension variants feature is on by default. You can turn off this feature by clearing the “Allow symbolic dimension specification” parameter in the Configuration Parameters dialog box.

### Define Symbolic Dimensions

This example uses the model `rtwdemo_dimension_variants` to show how to implement symbolic dimensions. This model has four modeling patterns involving vectors and matrices.

- 1 To show block names, on the **Debug** tab, on the **Information Overlays** menu, clear the **Hide Automatic Block Names** parameter.
- 2 Open the **Embedded Coder** app. In the **C Code** tab, select **Code Interface > Individual Element Code Mappings**.
- 3 In the Code Mappings editor, on the **Parameters** tab, click the refresh button. Seven `Simulink.Parameter` objects appear. Four of these objects are for specifying symbolic dimensions. These `Simulink.Parameter` objects have the names A, B, C, and D. Notice that these parameters have a storage class of `CompilerFlag`.

To use a `Simulink.Parameter` object for dimension specification, it must be defined in the base workspace and have one of these storage classes:

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- User-defined custom storage class that defines data as a macro in a specified header file

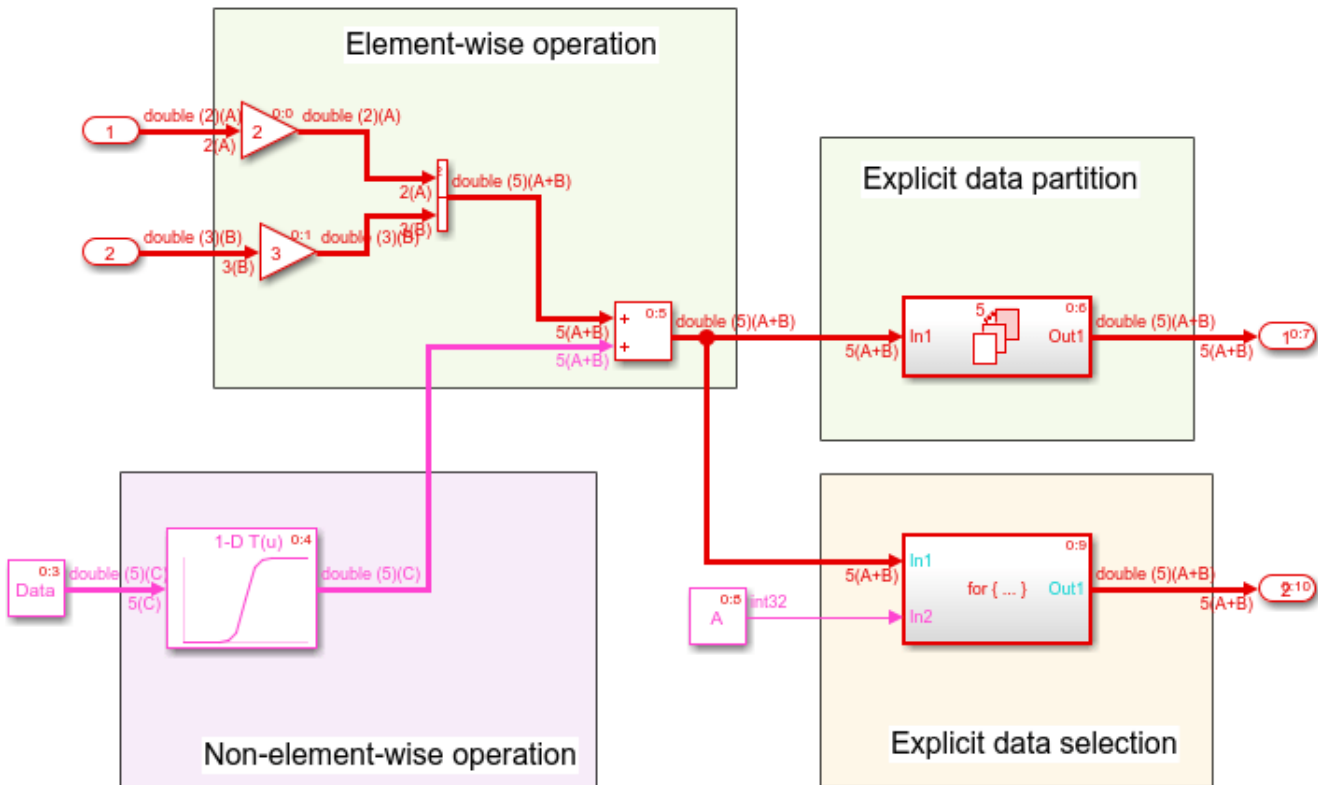

For `Simulink.Parameter` objects with an `ImportedDefine` custom storage class, provide a header file on the MATLAB path. Insert the name of the header file in the **HeaderFile** field in the `Simulink.Parameter` dialog box.

You can use MATLAB expressions to specify symbolic dimensions. For a list of supported MATLAB expressions, see the section **Operators and Operands in Variant Condition Expressions** in “Introduction to Variant Controls”.

### Specify Symbolic Dimensions for Blocks and Data Objects

- 1 Click Inport Block In2. On the Property Inspector, on the **Parameters** tab, the **Port Dimensions** field contains the `Simulink.Parameter` object A. For Inport blocks, you specify symbolic dimensions in the **Port Dimensions** field.
- 2 Click Inport block In3. The **Port Dimensions** field contains the `Simulink.Parameter` object B.
- 3 Click the Constant block. The **Constant value** parameter has a value of Data. In the Code Mappings editor, on the **Parameters** tab, click the `Simulink.Parameter` object Data. On the Property Inspector, the **Dimension** field has the character vector `'[1,C]'`, which is equivalent to `'[1,5]'` because C has a value of 5. The **Value** field contains an array with 5 values, which is consistent with its dimensions. The dimensions of the data object must be consistent with the value of the `Simulink.Parameter` object that is in the **Dimensions** field. Notice that Data has a **Storage class** of `ImportedExtern`.
- 4 Open the 1-D Lookup Table1 block parameters dialog box. The **Table data** field contains the `Simulink.Parameter`, PT. The **Breakpoints 1** field contains the `Simulink.Parameter`, PB.
- 5 In the Code Mappings editor, click PB and PT and view their properties. These parameters contain the character vector `'[1,D]'` in their **Dimensions** field and are arrays consisting of 15 values. The value of D is consistent with the dimension of the PB and PT parameters because D has a value of 15.
- 6 Simulate the model. Simulink propagates the dimensions symbolically in the diagram. During propagation, Simulink establishes modeling constraints among symbols. Simulink then checks for consistency with these constraints based on current numerical assignments. One modeling constraint for `rtwdemo_dimension_variants` is that  $C=A+B$ . The **Diagnostic Viewer** produces a warning for any violations of constraints.
- 7 Change the dimension specification to a different configuration and simulate the model again.

Though not shown in this example, you can specify an n-D dimension expression with one or more of the dimensions being a symbol (for example, ' [A,B,C] ' or ' [1,A,3] '). To preserve multi-dimensional information, you must specify an n-D dimension expression with each dimension that you want to preserve being a symbol.

### Generate Code for a Model with Dimension Variants

Once you have verified dimension specifications through model simulation, generate code for `rtwdemo_dimension_variants`.

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
model='rtwdemo_dimension_variants';
slbuild(model)
```

```
Starting build procedure for: rtwdemo_dimension_variants
Successful completion of build procedure for: rtwdemo_dimension_variants
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_dimension_variants	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 50.894s

View the generated code. In the `rtwdemo_dimension_variants.h` file, symbolic dimensions are in data declarations.

```
hfile = fullfile(cgDir,'rtwdemo_dimension_variants_ert_rtw',...
 'rtwdemo_dimension_variants.h');
rtwdemodbtype(hfile,'/* External inputs', '/* Real-time', 1, 0);

/* External inputs (root inport signals with default storage) */
typedef struct {
 real_T In2[A]; /* '<Root>/In2' */
 real_T In3[B]; /* '<Root>/In3' */
} ExtU;

/* External outputs (root outports fed by signals with default storage) */
typedef struct {
 real_T Out1[(A + B)]; /* '<Root>/Out1' */
 real_T Out2[(A + B)]; /* '<Root>/Out2' */
} ExtY;
```

The `rtwdemo_dimension_variants.h` file contains data definitions and preprocessor conditionals that define constraints established among the symbols during simulation. One of these constraints is that the value of a symbolic dimension must be greater than 1. This file also includes the user-provided header file for any Simulink.Parameter objects with an ImportedDefine custom storage class.

```
hfile = fullfile(cgDir,'rtwdemo_dimension_variants_ert_rtw',...
 'rtwdemo_dimension_variants.h');
rtwdemodbtype(hfile,'#ifndef A', '/* Macros for accessing', 1, 0);

#ifndef A
#error The variable for the parameter "A" is not defined
#endif

#ifndef B
#error The variable for the parameter "B" is not defined
#endif

#ifndef C
#error The variable for the parameter "C" is not defined
#endif

#ifndef D
#error The variable for the parameter "D" is not defined
#endif

/*

/* Constraint 'C < 11' registered by:
 * '<S2>/Assignment'
 */
#if C >= 11
error "The preprocessor definition 'C' must be less than '11'"
#endif
```

In the `rtwdemo_dimension_variants.c` file, symbolic dimensions participate in loop bound calculations, array size and index offset calculations, and a parameterized utility function (for example, Lookup Table block) calculation.

```

cfile = fullfile(cgDir, 'rtwdemo_dimension_variants_ert_rtw', ...
 'rtwdemo_dimension_variants.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_dimension_variants_step(void)
{
 real_T rtb_VectorConcatenate[A + B];

```

## Set Parameter Value Based on Variant Choice

When you specify the dimensions of a parameter in a model by using a symbol, you must make sure that the parameter value is consistent with the dimension value. To simulate different choices for the dimension value, you must manually correct the parameter value.

For example, in the `rtwdemo_dimension_variants` model, the `Simulink.Parameter` object `Data` stores a vector value, `[1 2 3 4 5]`, and uses a symbolic dimension `C` with initial value 5. If you change the value of `C`, to simulate the model, you must make sure the number of elements in the vector value matches the new value of `C`.

To reduce the effort of maintenance when you change the value of `C`, you can set the value of `Data` to an expression involving `C`.

- 1 Open the model.

```

rtwdemo_dimension_variants

```

- 2 At the command prompt, inspect the initial values of `Data` and `C`. The value of `Data` is a vector of integers from 1 to `C`.

```
Data.Value
```

```
ans =
```

```
 1 2 3 4 5
```

```
C.Value
```

```
ans =
```

```
 5
```

- 3 In MATLAB code syntax, the value of `Data` is `1:C`. To preserve this relationship between the parameter objects, set the value of `Data` by using the `slexpr` function.

```
Data.Value = slexpr('1:C');
```

- 4 To prevent data type propagation errors, set the data type of `Data` explicitly to `double`, which is the data type that the parameter acquired before you set the parameter value to an expression.

```
Data.DataType = 'double';
```

- 5 Set the value of `C` to a different number, such as 6. Due to dimension constraints in the model, you must set the value of another dimension symbol, `A`, to 3.

```
C.Value = 6;
```

```
A.Value = 3;
```

- 6 Simulate the model. The block diagram shows that the value of `Data` now has six elements.

For more complicated applications, you can write your own MATLAB function that returns parameter values based on dimension symbols. Set the value of the parameter `data` to an expression that calls your function.

For general information about using an expression to set the value of a `Simulink.Parameter` object, see “Set Variable Value by Using a Mathematical Expression”.

## Code Generation Optimization Considerations

When you create a model with symbolic dimensions, be aware of the following optimization considerations:

- The code generator reuses buffers only if dimension propagation establishes equivalence among buffers.
- Two loops with symbolic loop bound calculations are fused together only if they share equivalent symbolic expression.
- Optimizations do not eliminate a symbolic expression or condition check based on the current value of a symbolic dimension.

## Backward Compatibility

If an existing model uses `Simulink.Parameter` objects to specify dimensions, it can be incompatible with dimension variants. Here are two common scenarios:

- Only a subset of blocks accepts symbolic dimension specifications. If a block is not compatible with symbolic dimensions, it causes an update diagram error.
- `Simulink.Parameter` objects that you use to define symbolic dimensions or have symbolic dimensions must have one of the storage classes described in this example. If these specifications are not met, the build procedure for the model fails during code generation.

You can address these backward compatibility issues by doing the following:

- Turn off dimension variants feature by clearing the **Allow symbolic dimension specification** parameter in the Configuration Parameters dialog box.
- Update `Simulink.Parameter` objects that define symbolic dimensions or have symbolic dimension specifications.
- Update the model so that only supported blocks have symbolic dimensions or propagate symbolic dimensions.

## Supported Blocks

For a list of supported blocks, see the Block Support Table. To access the information in this table, enter `showblockdatatype` at the MATLAB command prompt. Unsupported blocks (for example, MATLAB Function) can still work in a model containing symbolic dimensions as long as these blocks do not directly interact with symbolic dimensions.

In the following cases, supported blocks do not propagate symbolic dimensions.

- For Assignment and Selector blocks, you set the **Block Parameters > Index Option** parameter to `Index vector (dialog)`. For Selector and Assignment blocks, if you specify a symbolic dimension for the Index parameter, the code generator does not honor the symbolic dimension in the generated code.
- For the Product block, you specify a value of 1 for the **Block Parameters > Number of inputs** parameter, and you set the **Multiply over** parameter to `Specified dimensions`.
- For the ForEach block, you specify a symbolic dimension for the **Partition Width** parameter.

Note that the following modeling patterns are among those modeling patterns that can cause Simulink to error out:

- For Switch blocks, an input signal or the **Threshold** parameter has symbolic dimensions, and you select **Allow different data input sizes (Results in variable-size output signal)**.
- A Data Store Read block selects elements of a `Simulink.Bus` signal that has symbolic dimensions.

- For Lookup Table blocks, on the **Block Parameters > Algorithm** tab, you select the parameter **Use one input port for all input data**.

## Limitations

The following products and software capabilities support dimension variants in that they act on the numeric value of a symbolic dimension. These features do not support the propagation of symbolic dimensions during model simulation and the preservation of symbolic dimensions in the generated code.

- Code Replacement for Lookup Tables
- Software-in-the-Loop (SIL) and Processor-in-the-Loop (PIL) simulations
- Accelerator and rapid accelerator simulation modes
- Scope and simulation observation (for example, logging, SDI, and so on)
- Model coverage
- Simulink Design Verifier
- Fixed-Point Designer
- Data Dictionary
- Simulink PLC Coder
- HDL Coder

The following do not support dimension variants:

- System Object
- Stateflow charts that use MATLAB as the action language
- Physical modeling
- Discrete-event simulation
- Frame data
- MATLAB functions

The following limitations also apply to models that utilize symbolic dimensions.

- For simulation, the size of a symbolic dimension can equal 1. For code generation, the size of a symbolic dimension must be greater than 1.
- If a symbolic dimension is a MATLAB expression that contains an arithmetic expression and either a relational or logical expression, you must add `+0` after the relational or logical part of the MATLAB expression. If you do not add `+0`, the model errors out during simulation because you cannot mix a boolean data type with integer or double data types. Adding `+0` converts the data type of the relational or logical part of the expression from a `boolean` to a `double`.

For example, suppose in the Inport block parameters dialog box, the **Port dimensions** parameter has the expression `[(C==8)*D+E, 3]`. The **Data type** parameter is set to `double`. Since `C==8` is a relational expression, you must change the expression to `[((C==8)+0)*D+E, 3]` to prevent the model from producing an error during simulation.

- Simulink propagates symbolic dimensions for an entire structure or matrix, but not for a part of a structure or matrix. For example, the `Simulink.Parameter P` is a 2x3 matrix with symbolic dimensions `[Dim, Dim1]`.

```

p=Simulink.Parameter(struct('A',[1 2 3;4 5 6]))
p.DataType='Bus:bo'
bo=Simulink.Bus
bo.Elements(1).Name='A'
bo.Elements(1).Dimensions='[Dim,Dim1]'
Dim=Simulink.Parameter(2)
Dim1=Simulink.Parameter(3)
p.CoderInfo.StorageClass='Custom'
p.CoderInfo.CustomStorageClass='Define'
Dim.CoderInfo.StorageClass='Custom'
Dim.CoderInfo.CustomStorageClass='Define'
Dim1.CoderInfo.StorageClass='Custom'
Dim1.CoderInfo.CustomStorageClass='Define'

```

If you specify `p.A` for a dimensions parameter, Simulink propagates the symbolic dimensions `[Dim,Dim1]`. If you specify `p.A(1,:)`, Simulink propagates the numeric dimension 3 but not the symbolic dimension, `Dim1`.

- The MATLAB expression `A(:)` does not maintain symbolic dimension information. Use `A` instead.
- The MATLAB expression `P(2:A)` does not maintain symbolic dimension information. Use the Selector block instead.
- The MATLAB expression `P(2,:)` is not a tunable expression, so it does not maintain symbolic dimension information.
- Suppose that you set the value of a mask parameter, `myMaskParam`, by using a field of a structure or by using a subset of the structures in an array of structures. You store the structure or array of structures in a `Simulink.Parameter` object so that you can use a `Simulink.Bus` object to apply symbolic dimensions to the structure fields. Under the mask, you configure a block parameter to use one of the fields that have symbolic dimensions. The table shows some example cases.

Description	Value of mask parameter (myMaskParam)	Value of block parameter
myStruct is a structure with field <code>gains</code> , which uses symbolic dimensions.	<code>myStruct.gains</code>	<code>myMaskParam</code>
myStruct is a structure with field hierarchy <code>myStruct.subStruct.gains</code> . The field <code>gains</code> uses symbolic dimensions.	<code>myStruct.subStruct</code>	<code>myMaskParam.gains</code>
myStructs is an array of structures. Each structure has a field <code>gains</code> , which uses symbolic dimensions.	<code>myStructs(2)</code>	<code>myMaskParam.gains</code>

In these cases, you cannot generate code from the model. As a workaround, choose one of these techniques:

- Use the entire structure (`myStruct`) or array of structures (`myStructs`) as the value of the mask parameter. Under the mask, configure the block parameter to dereference the target field from the mask parameter by using an expression such as `myMaskParam.subStruct.gains`.

- Use literal dimensions instead of symbolic dimensions for the target field (gains).

This limitation also applies when you use a field of a structure or a subset of the structures in an array of structures as the value of a model argument in a Model block.

## Code Generation for Variant Blocks

The code generator produces code from a Simulink model containing one or more Variant Subsystem, Variant Model, Variant Source, and Variant Sink blocks. To learn how to create a model containing variant blocks, see “Create a Simple Variant Model”. To learn how to create a custom Model Advisor check that evaluates the generated code from active and inactive variant paths in a variant system model, see “Create Custom Check to Evaluate Active and Inactive Variant Paths from a Model” (Simulink Check).

---

**Note** During code generation, a warning related to 'Code generation function packaging' for the Variant block might be displayed. In the block parameters dialog of the Variant block, click **Code Generation** and then select **Reusable** function from the **Function packaging** drop-down list to solve this issue.

---

Code is generated for different variant choices, the active variant, and the default variant. To generate code for variants, set the following conditions in the Variant Subsystem, Variant Source, or Variant Sink block:

- Select Expression as **Variant control mode**.
- Select code compile as **Variant activation time**.

Code generated for Variant Subsystem blocks is surrounded by C preprocessor conditionals `#if`, `#else`, `#elif`, and `#endif`. Code generated for Variant Source and Variant Sink blocks is surrounded by C preprocessor conditionals `#if` and `#endif`. Therefore, the active variant is selected at compile time and the preprocessor conditionals determine which sections of the code to execute.

To construct variant models and generate preprocessor directives in the generated code, see the example “Use Variant Models to Generate Code That Uses C Preprocessor Conditionals” on page 26-73.

To construct variant subsystems and generate preprocessor directives in the generated code, see the example “Use Variant Subsystem To Generate Code That Uses C Preprocessor Conditionals” on page 26-68.

To construct models with variant sources and sinks and generate preprocessor directives in the generated code, see the example “Represent Variant Source and Sink Blocks in Generated Code” on page 26-37.

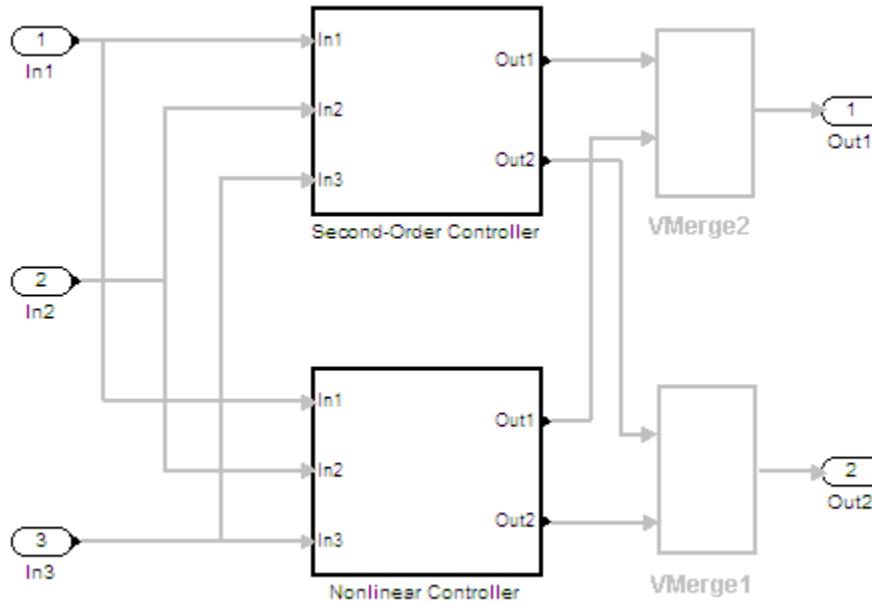

### Restrictions on Variant Subsystem Code Generation

To generate preprocessor conditionals, the types of blocks that you can place within the child subsystems of a Variant Subsystem block are limited. Connections are not allowed in the Variant Subsystem block diagram. However, during the code generation process, one `VariantMerge` block is placed at the input of each Output block within the Variant Subsystem block diagram. All of the child subsystems connect to each of the `VariantMerge` blocks.

In the figure below, the code generation process makes the following connections and adds `VariantMerge` blocks to the `sldemo_variant_subsystems` model.

When compared to a generic Merge block the `VariantMerge` block can have only one parameter which is the number of Inputs. The `VariantMerge` block is used for code generation in variant

subsystems internally, and is not available externally to be used in models. The number of inputs for `VariantMerge` is determined and wired as shown in the figure below.

The child subsystems of the Variant Subsystem block must be atomic subsystems. Select **Treat as atomic unit** parameter in the Subsystem block parameters dialog, to make the subsystems atomic. The `VariantMerge` blocks are inserted at the output of the subsystems if more than one child subsystems are present. If the source block of a `VariantMerge` block input is nonvirtual, an error message will be displayed during code generation. You must make the source block contiguous, by inserting Signal Conversion blocks inside the variant choices. The signals that enter a Variant Subsystem block must have the same signal properties (for example, signal dimensions, port width, and storage class). The `VariantMerge` block does not support different signal properties because the input ports and output ports share the same memory. You can use symbolic dimensions to generate code for a variant subsystem with child subsystems of different output signal dimensions.

## Generated Code Components Not Compiled Conditionally

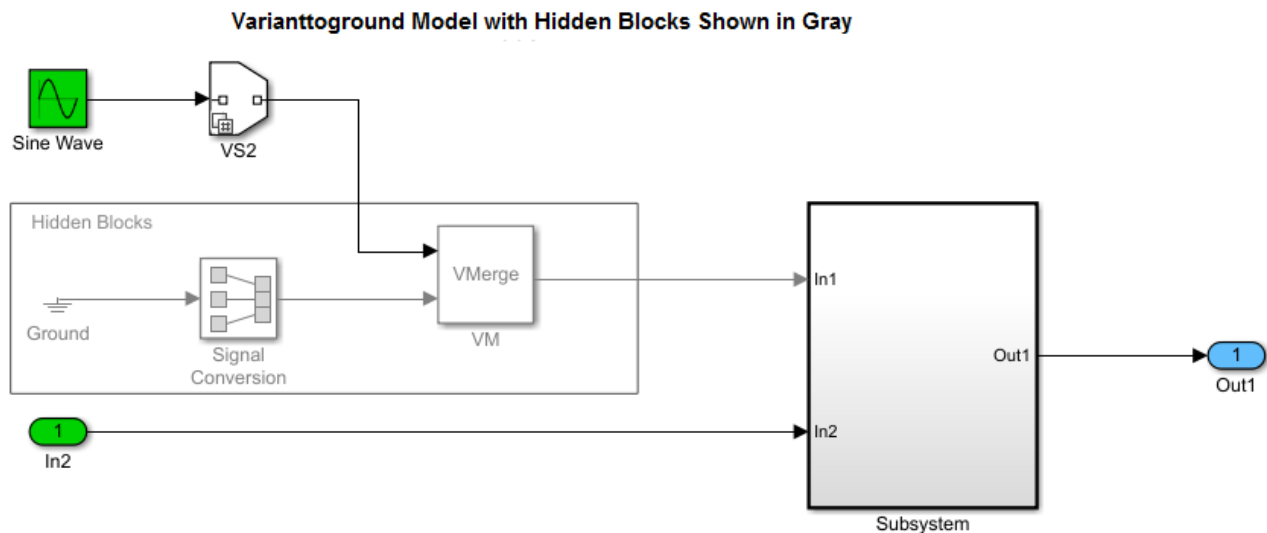

The following components are not conditionally compiled even if only code for variant subsystems or models that are conditionally compiled reference them.

- `rtModel` data structure fields
- `#include`'s of utility files
- Global constant parameter structure fields that are referenced by multiple subsystems activated by different variants
- Parameters that are configured to use an imported, exported, or custom code generation storage class, and are referenced by multiple subsystems that are activated by different variants
- Parameters that are configured to use an imported, exported, or custom code generation storage class, and are used by variant model blocks

## Code Generation for Variant Blocks with One Variant Choice

For modeling patterns in which a Root Inport block connects to a Variant block with one variant choice, Simulink inserts a hidden block combination of a Ground block, Signal Conversion block, and a Variant Merge block. If the variant choice evaluates to false, this block combination produces an output of 0.0.

For example, the model `Varianttground` contains a Variant Source block with one variant choice. When the Variant Control `SYSCONST_A==6` evaluates to true, the input to `Subsystem` is a sine wave. When `SYSCONST_A==6` evaluates to false, the input to `Subsystem` is 0.0.

The `varianttground.c` file contains this code:

```
* Sin: '<Root>/Sine Wave' incorporates:
 * SignalConversion generated from: '<Root>/Subsystem'
 */
#if SYSCONST_A == 6

 Varianttground_B.VM_Conditional_Signal_Subsystem_0 = sin
 (Varianttground_M->Timing.t[0]);

#else

 /* SignalConversion generated from: '<Root>/Subsystem' */
 Varianttground_B.VM_Conditional_Signal_Subsystem_0 = 0.0;

#endif

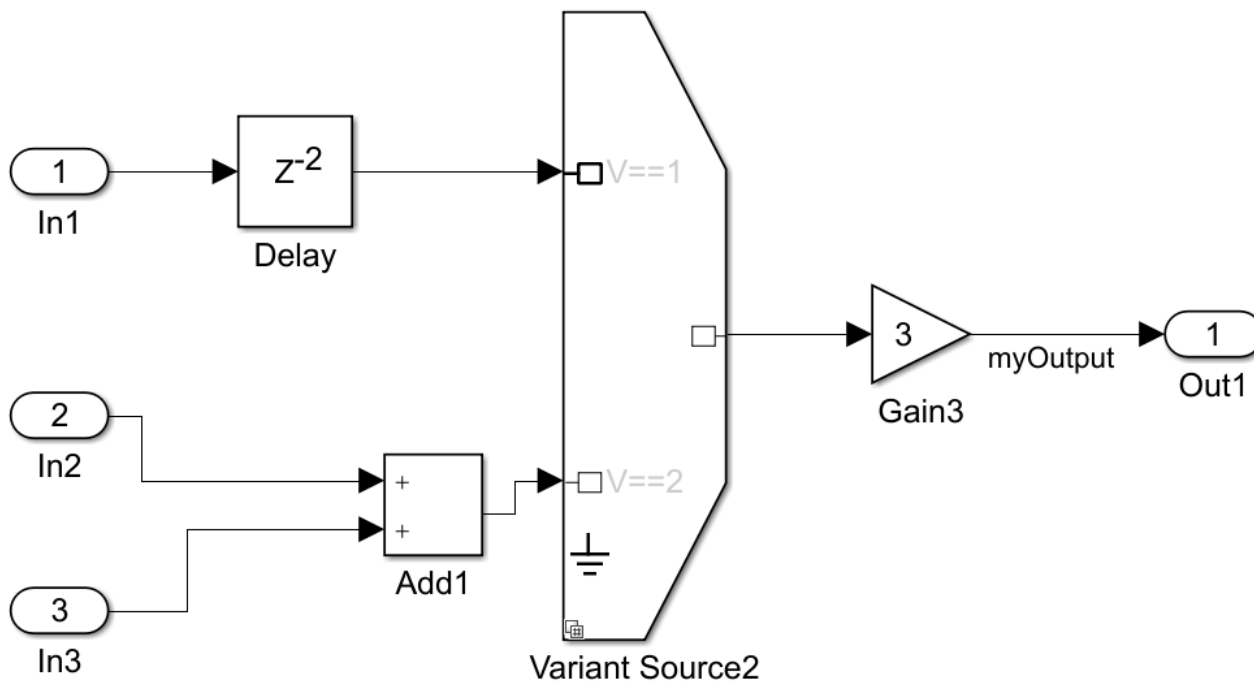

/* End of Sin: '<Root>/Sine Wave' */
```

The comments in the generated code indicate the presence of the hidden signal conversion block. In the hyperlinked comments, you can trace to the original block in the model that triggered the insertion of the hidden block. The code does not contain a comment for the Variant Merge block because this block does not have associated generated code. The Variant Merge block is used internally and is not in the Simulink library.

## Global Data Guarding: Signals and States

When a model has variant blocks, the global signals and states are guarded in the generated code with their corresponding variant condition.

Consider a model containing a Variant Source block. The Variant Source block has conditions  $V==1$  and  $V==2$ .

In the generated code, global signals are guarded in declaration, model initialization, and definition of data as shown below.

Signals guarding:

Declaration:

```
/* Exported block signals */
#if V == 1 || V == 2

real_T myOutput; /* '<Root>/Gain3' */

#endif
```

Model initialization:

```
/* exported global signals */
#if V == 1 || V == 2

myOutput = 0.0;

#endif
```

Definition of data:

```

* Exported Global Signals
*
* Note: Exported global signals are block signals with an exported global
* storage class designation. Code generation will declare the memory for
* these signals and export their symbols.
*/
#if V == 1 || V == 2

extern real_T myOutput; /* '<Root>/Gain3' */

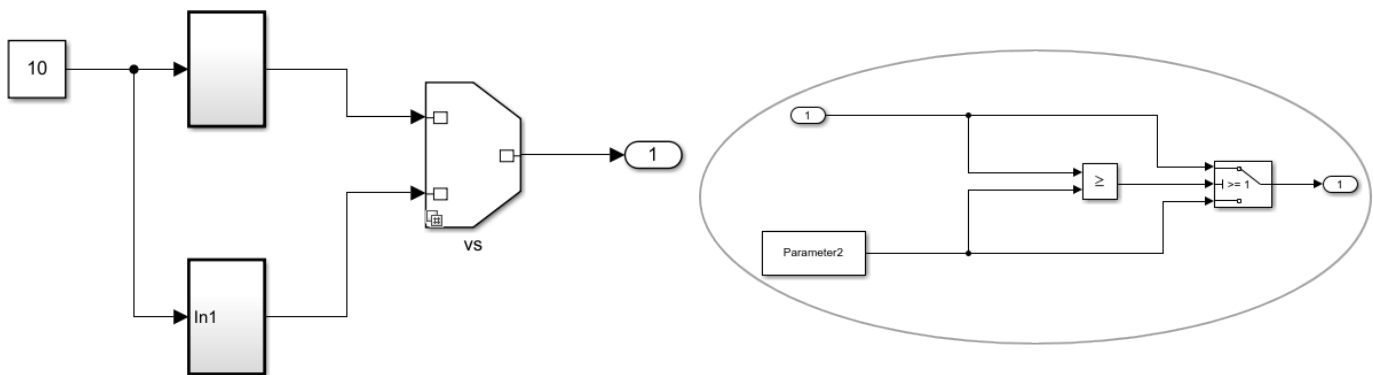

#endif

```

## Global Data Guarding: Parameters

When you generate code for a model containing variant blocks, the parameters are guarded in the generated code.

Consider a model with Constant block attached to a Variant Source block.

In the generated code, the parameter of the Constant block is guarded in header file as shown below.

```

/* Exported data definition */
/* Const memory section */
/* Definition for custom storage class: Const */
#if V == 2

const int32_T Parameter2 = 1;

#endif

```

## Guarding Reference Model Headers

When a model has Model Reference blocks that are conditional due to inline variants, the header file and the instances referring to the Model Reference blocks are guarded.

Consider this model with two Model References blocks that are conditional due to inline variants.

When you generate code for this model, the header file and instances referring to the Model Reference blocks are guarded as shown in the code below.

```
#include "mWithTwoModelBlocks_Top_types.h"
#include "multiword_types.h"

#if (A == 1) //Guarding
#define mWithTwoModelBlocks_Ref2_MDLREF_HIDE_CHILD_
#include "mWithTwoModelBlocks_Ref2.h"
#endif

#if (B == 1) //Guarding
#include "mWithTwoModelBlocks_Ref1.h"
#endif
```

## Guarding S-Function Block Headers

When a model has an S-Function block that is conditional due to any connected variant blocks, Simulink guards the header files associated with the S-Function block with the corresponding variant condition in the generated code.

Consider a model with an S-Function block connected to a Variant Source block. In the generated code, the header file is guarded with the variant condition.

```
#ifndef mSFunctionInclude_COMMON_INCLUDES_
#define mSFunctionInclude_COMMON_INCLUDES_
#include "rtwtypes.h"
#include "rt_logging.h"
#if V == 1 //Guarding
#include "myHeader.h"
```

```
#endif
#endif
```

```
/* mSFunctionInclude_COMMON_INCLUDES_ */
```

## Represent Subsystem and Variant Models in Generated Code

### In this section...

“Step 1: Represent Variant Choices in Simulink” on page 26-22

“Step 2: Specify Conditions That Control Variant Choice Selection” on page 26-25

“Step 3: Configure Model for Generating Preprocessor Conditionals” on page 26-27

“Step 4: Review Generated Code” on page 26-28

“Limitations” on page 26-31

**Required products:** Simulink, Embedded Coder, Simulink Coder

Using Simulink, you can create models that are based on a modular design platform that comprises a fixed common structure with a finite set of variable components. The variability helps you develop a single, fixed master design with variable components. For more information, see “What Are Variants and When to Use Them”. When you implement variants in the generated code, you can:

- Reuse generated code from a set of application models that share functionality with minor variations.
- Share generated code with a third party that activates one of the variants in the code.
- Validate the supported variants for a model and then choose to activate one variant for a particular application, without regenerating and re-validating the code.
- Generate code for the default variant that is selected when an active variant does not exist.

Using Embedded Coder, you can generate code from Simulink models containing one or more variant choices. The generated code contains preprocessor conditionals that control the activation of each variant choice.

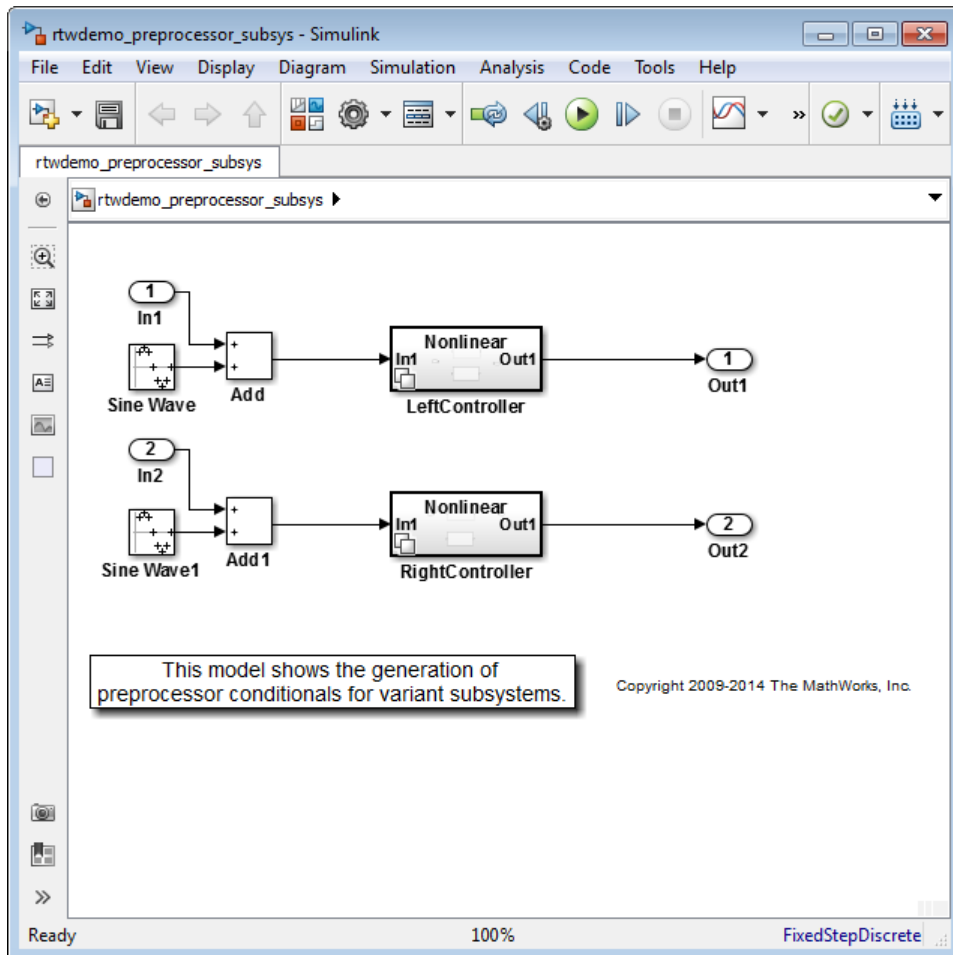

This example shows how to represent variant choices in a Simulink model and then prepare the model so that those variant choices are represented in generated code.

### Step 1: Represent Variant Choices in Simulink

Variant choices are two or more configurations of a component in your model. This example uses the model `rtwdemo_preprocessor_subsys` to illustrate how to represent variant choices inside Variant Subsystem blocks. For other ways to represent variant choices, see “Compare Variant Blocks”.

- 1 Open the model `rtwdemo_preprocessor_subsys`.

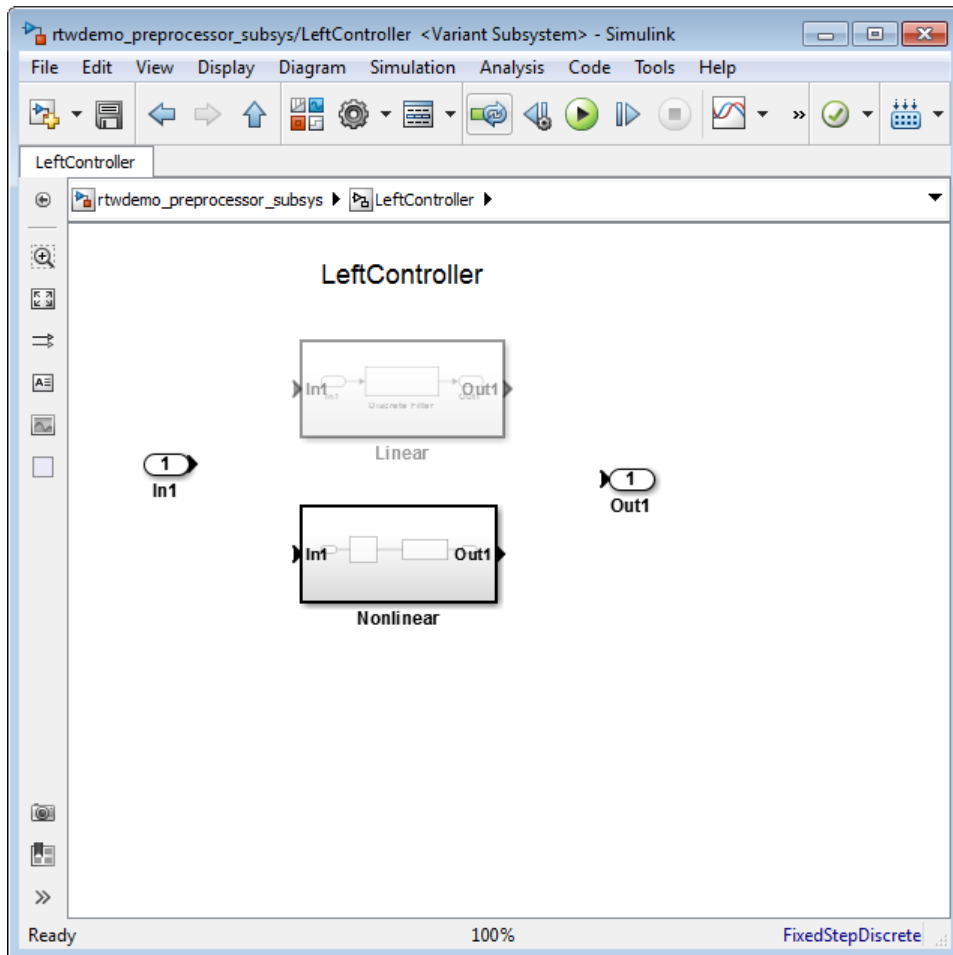

```
open_system('rtwdemo_preprocessor_subsys')
```

The model contains two Variant Subsystem blocks: **LeftController** and **RightController**.

**Note** You can only add Inport, Outport, Subsystem, and Model blocks inside a Variant Subsystem block.

- 2 Open the **LeftController** block.

The **LeftController** block serves as the container for the variant choices. It contains two variant choices represented using Subsystem blocks **Nonlinear** and **Linear**. The nonlinear controller subsystems implement hysteresis, whereas the linear controller subsystems act as simple low-pass filters.

The Subsystem blocks have the same number of inports and outports as the containing Variant Subsystem block.

Variant choices can have different numbers of inports and outports. See “Map Inports and Outports of Variant Choices in Variant Subsystem”.

- 3 Open the **Nonlinear** block.

The **Nonlinear** block represents one variant choice that Simulink activates when a condition is satisfied. The **Linear** block represents another variant choice.

**Tip** When you are prototyping variant choices, you can create empty Subsystem blocks with no inputs or outputs inside a Variant Subsystem block. The empty subsystem recreates the situation in which that subsystem is inactive without the need for completely modeling the variant choice.

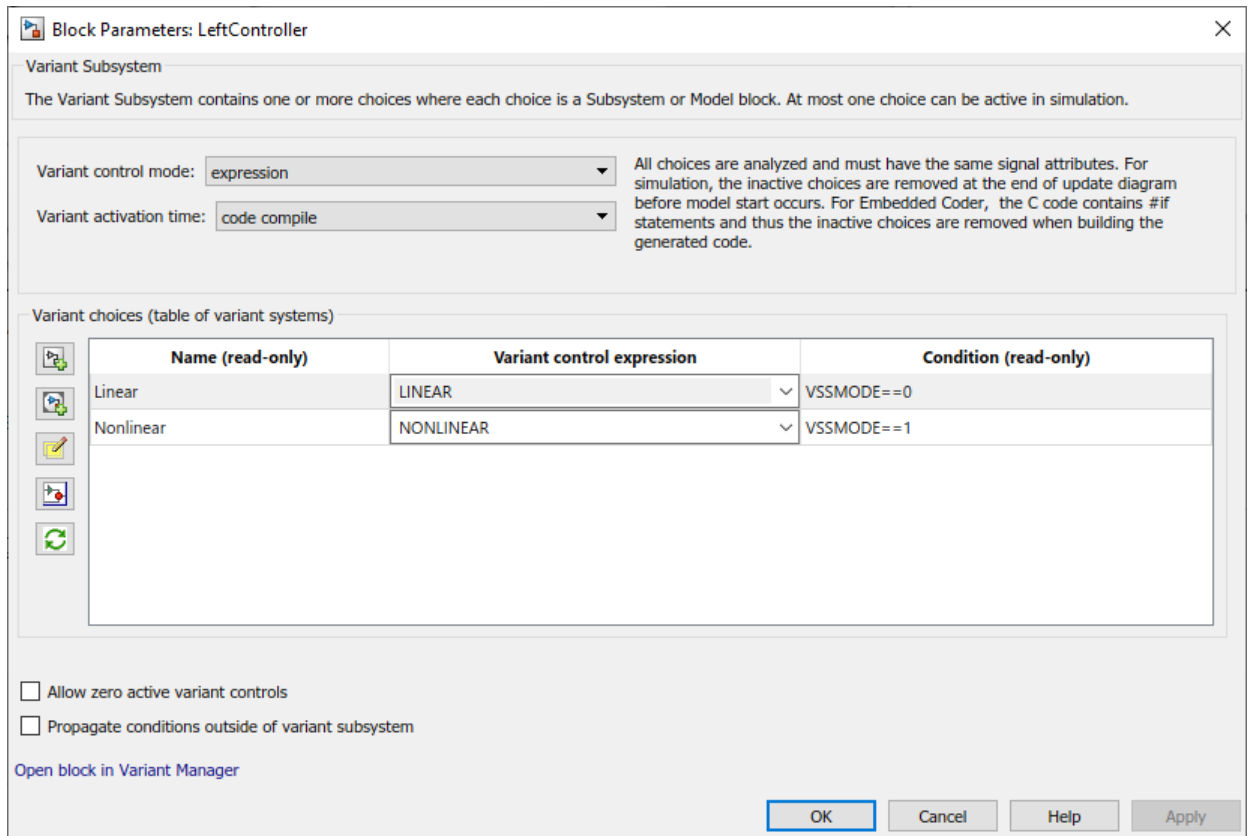

## Step 2: Specify Conditions That Control Variant Choice Selection

You can switch between variant choices by constructing conditional expressions called variant controls for each variant choice represented in a Variant Subsystem block. Variant controls determine which variant choice is active, and changing the value of a variant control causes the active variant choice to switch.

A variant control is a Boolean expression that activates a specific variant choice when it evaluates to `true`.

For more information, see “Introduction to Variant Controls”.

- 1 Right-click the **LeftController** block and select **Block Parameters (Subsystem)**.

The **Condition** column displays the Boolean expression that when true activates each variant choice. In this example, these conditions are specified using Simulink.Variant objects LINEAR and NONLINEAR.

- Use these commands to specify a variant control using a Simulink.Variant object.

```
LINEAR = Simulink.Variant;
LINEAR.Condition = 'VSSMODE==0';
NONLINEAR = Simulink.Variant;
NONLINEAR.Condition = 'VSSMODE==1';
```

Here, VSSMODE is called a variant control variable that can be specified in one of the ways listed in “Types of Variant Control Variables (Operands) in Variant Blocks”.

- Define the variant control variable VSSMODE.

You can define VSSMODE as a scalar variable or as a Simulink.Parameter object. In addition to enabling the specification of parameter value, Simulink.Parameter objects allow you to specify other attributes such as data type that are required for generating code.

```
VSSMODE = Simulink.Parameter;
VSSMODE.Value = 1;
VSSMODE.DataType = 'int32';
VSSMODE.CoderInfo.StorageClass = 'Custom';
VSSMODE.CoderInfo.StorageClass = 'ImportedDefine';
VSSMODE.CoderInfo.CustomAttributes.HeaderFile = 'rtwdemo_importedmacros.h';
```

Variant control variables defined as Simulink.Parameter objects can have one of these storage classes.

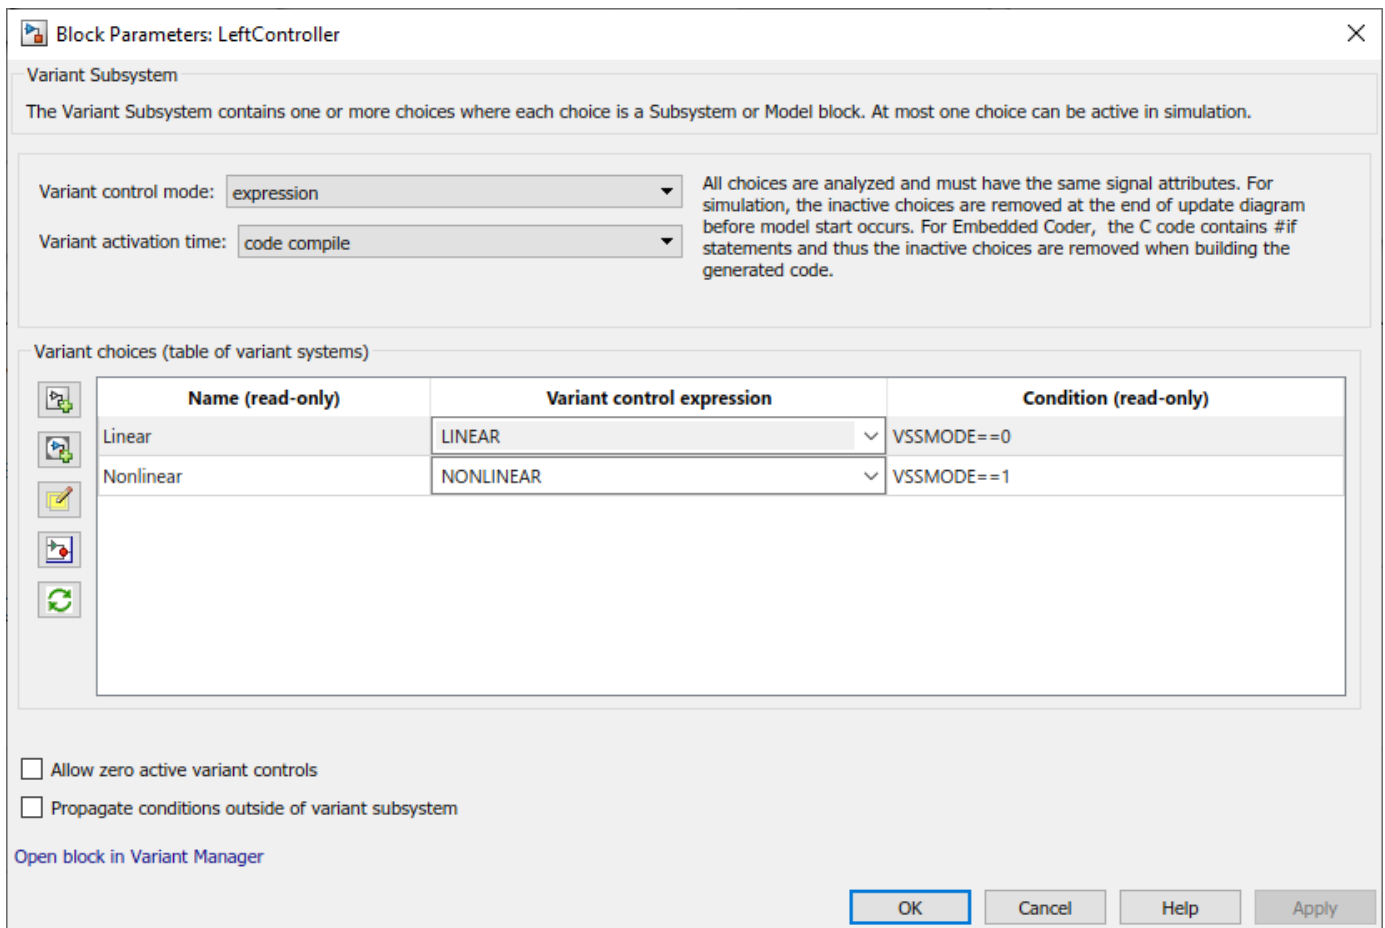

- Define or ImportedDefine with header file specified
- CompilerFlag
- SystemConstant (AUTOSAR)
- Your own custom storage class that defines data as a macro

You can also convert a scalar variant control variable into a Simulink.Parameter object. See “Convert Variant Control Variables into Simulink.Parameter Objects”.

### Step 3: Configure Model for Generating Preprocessor Conditionals

Code generated for each variant choice is enclosed within C preprocessor conditionals `#if`, `#else`, `#elif`, and `#endif`. Therefore, the active variant is selected at compile time and the preprocessor conditionals determine which sections of the code to execute.

- 1 In the **Modeling** tab of the Simulink toolstrip, click **Model Settings**.
- 2 Select the **Code Generation** pane, and set **System target file** to `ert.tlc`.
- 3 In the **Report** pane, select **Create code generation report**.
- 4 In the Configuration Parameters dialog box, clear **Ignore custom storage classes** and click **Apply**.
- 5 In your model, right-click the **LeftController** block and select **Block Parameters (Subsystem)**.
- 6 Set the **Variant activation time** parameter to `code compile`.

When you select this option, Simulink analyzes all variant choices during an update diagram or simulation. This analysis provides early validation of the code generation readiness of all variant choices.

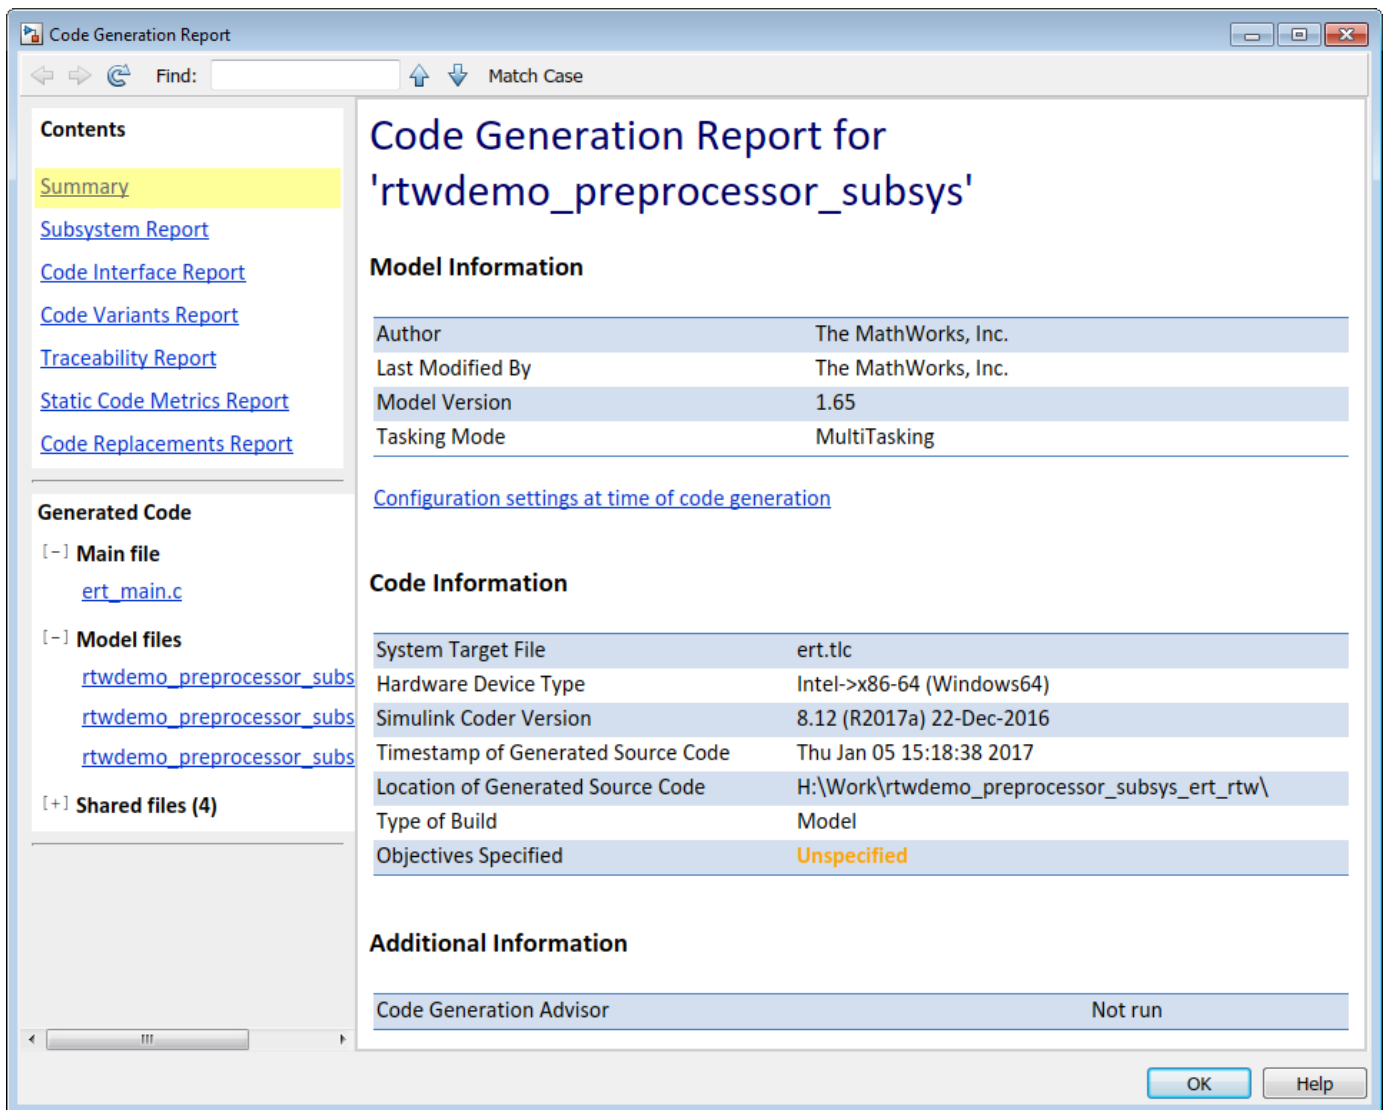

- 7 Build the model.

## Step 4: Review Generated Code

The code generation report contains a section dedicated to the subsystems that have variants controlled by preprocessor conditionals.

- 1 In the **C Code** tab of the toolstrip, select **Open Report**.

- 2 Select the **Code Variant Report** from the left.

In this example, the generated code includes references to the Simulink.Variant objects LINEAR and NONLINEAR. The code also includes the definitions of macros corresponding to those variants. The definitions depend on the value of VSSMODE, which is supplied in an external header file rtwdemo\_importedmacros.h. The active variant is determined by using preprocessor conditionals (#if) on the macros (#define) LINEAR and NONLINEAR.

- 3 Select the rtwdemo\_preprocessor\_subsys\_types.h file from the left.

This file contains the definitions of macros LINEAR and NONLINEAR.

```
#ifndef LINEAR
 #define LINEAR (VSSMODE == 0)
#endif

#ifndef NONLINEAR
```

```

 #define NONLINEAR (VSSMODE == 1)
#endif

```

- 4 Select the `rtwdemo_preprocessor_subsys.c` file from the left.

In this file, calls to the step and initialization functions of each variant are conditionally compiled.

```

 /* Outputs for Atomic SubSystem: '<Root>/LeftController' */
#if LINEAR
 /* Output and update for atomic system: '<S1>/Linear' */
 ...
#elif NONLINEAR
 /* Output and update for atomic system: '<S1>/Nonlinear' */
 ...
#endif

```

## Limitations

- When you are generating code for Variant Subsystem blocks, the blocks cannot have:
  - Mass matrices
  - Function call ports
  - Outports with constant sample time
  - Simscape blocks
- The port numbers and names for each active child subsystem must belong to a subset of the port numbers and names of the parent Variant Subsystem block.

## Generate Preprocessor Conditionals for Variant Systems

### In this section...

“Define Variant Controls” on page 26-32

“Configure Model for Generating Preprocessor Conditional Directives” on page 26-33

“Special Considerations for Generating Preprocessor Conditionals” on page 26-33

“Generate Variant Control Macros in Same Header File” on page 26-34

### Define Variant Controls

For variant systems, variant controls determine which variant choice is active. You can specify a variant control as a condition expression, a `Simulink.Variant` object specifying a condition expression, a MATLAB variable, or a `Simulink.Parameter` object. This example shows how to define variant controls as `Simulink.Parameter` objects.

- 1 Open the Model Explorer. Select the **base workspace**. Alternatively, you can create a `Simulink.Parameter` in data dictionary.
- 2 In the Model Explorer, select **Add > Simulink Parameter**. Specify a name for the new parameter.
- 3 Use the function `Simulink.VariantManager.findVariantControlVars` to find and convert MATLAB variables used in variant control expressions into `Simulink.Parameter` objects. For an example, see “Convert Variant Control Variables into Simulink.Parameter Objects”.
- 4 On the `Simulink.Parameter` property dialog box, specify the **Value** and **Data type**.
- 5 Select one of these **Storage class** values.
  - Define
  - `ImportedDefine(Custom)`
  - `CompilerFlag(Custom)`
  - A storage class created using the Custom Storage Class Designer. Your storage class must have the **Data initialization** parameter set to `Macro` and the **Data scope** parameter set to `Imported`. See “Control Data Representation by Configuring Storage Class Properties” on page 37-17 for more information.
- 6 Specify the value of the variant control. If the storage class is `ImportedDefine(Custom)`, do the following:
  - a Specify the **Header File** parameter as an external header file in the Custom Attributes section of the `Simulink.Parameter` property dialog box.
  - b Enter the values of the variant controls in the external header file.

**Note** The generated code refers to a variant control as a user-defined macro. The generated code does not contain the value of the macro. The value of the variant control determines the active variant in the compiled code.

If the variant control is a `CompilerFlag` custom storage class, the value of the variant control is set at compile time. Use the **Configuration Parameters > Code Generation > Custom Code > Code information > Defines** parameter to add a list of variant controls

(macro definitions) to the compiler command line. For example, for variant control `VSSMODE`, in the text field for the **Defines** parameter, enter:

```
-DVSSMODE=1
```

If you want to modify the value of the variant control after generating a makefile, use a makefile option when compiling your code. For example, at a command line outside of MATLAB, enter:

```
makecommand -f model.mk DEFINES_CUSTOM="-DVSSMODE=1"
```

---

**Note** You can define the variant controls using `Simulink.Parameter` object of enumerated type. This approach provides meaningful names and improves the readability of the conditions. The generated code includes preprocessor conditionals to check that the variant condition contains valid values of the enumerated type.

---

## Configure Model for Generating Preprocessor Conditional Directives

- 1 Open the Configuration Parameters dialog box.
- 2 Select the **Code Generation** pane, and set **System target file** as `ert.tlc`.
- 3 In the **Report** pane, select **Create code generation report**.
- 4 In the Configuration Parameters dialog box, clear the “Ignore custom storage classes” parameter. In order to generate preprocessor conditionals, you must use custom storage classes.
- 5 In the Variant Subsystem, Variant Source, or Variant Sink block parameter dialog boxes, set the **Variant activation time** parameter to `code compile`.
- 6 Generate code.

## Special Considerations for Generating Preprocessor Conditionals

- The port numbers and names for each child variant subsystem must belong to a subset of the port numbers and names of the parent Variant Subsystem block.
- The code generation process checks that there is at least one active variant by using the variant control values stored in the base workspace. The variant control that evaluates to `true` becomes the active variant. If none of the variant controls evaluates to `true`, the default variant, if specified, becomes the active variant. The code generation process issues an error if an active variant does not exist.
- Implement the condition expressions of the variant controls such that only one variant control evaluates to `true`. The generated code includes a test of the variant controls to determine that there is only one active variant. If this test fails, your code will not compile.
- If you comment out child subsystems listed in the **Variant Choices** table in the Variant Subsystem block parameter dialog box, the code generator does not generate code for the commented out subsystems.
- For Variant Subsystems, the `model_private.h` file contains conditional parameter definitions. For example, if the value of a Constant block is a `Simulink.Parameter` with an `ImportedDefine` custom storage class, and the Constant block is in a Variant Subsystem, the conditional definition of the `Simulink.Parameter` is in the `model_private.h` file.

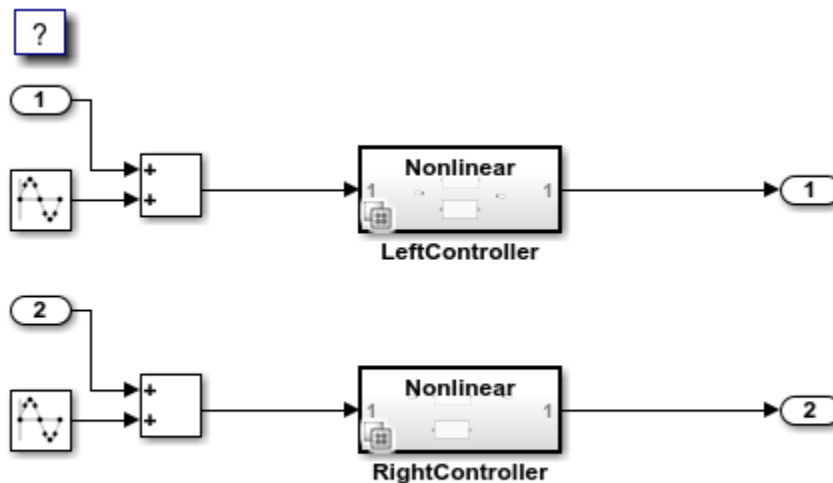

## Generate Variant Control Macros in Same Header File

This example shows how to aggregate multiple variant control macros (`#define`) into the same generated header file. This aggregation makes it easier for you to manage the complexities inherent in a system with multiple interacting variant conditions.

### Explore Example Model

Run the script `prepare_rtwdemo_preproc_subsys`, which opens the model `rtwdemo_preprocessor_subsys` and prepares it for this example.

```
run(fullfile(matlabroot, 'examples', 'ecoder', 'main', 'prepare_rtwdemo_preproc_subsys'));
```

Copyright 2009-2020 The MathWorks, Inc.

The model contains two Variant Subsystem blocks.

Navigate inside the variant subsystems. The subsystems each have a linear and a nonlinear algorithm variant.

At the root level of the model, open the block dialog box of the variant subsystem labeled `LeftController`. The algorithm variants in the subsystem activate based on the states of two Simulink.Variant objects, `LINEAR` and `NONLINEAR`, in the base workspace.

The state of each object depends on the value of the variant control variable, `VSSMODE`, which is a Simulink.Parameter object in the base workspace. The parameter object uses the custom storage class `Define` and is configured to appear in the generated code as a C-code macro in `macros.h`.

### Change Name of Generated Header File Through Model Explorer

In this example, change the name of the generated header file from `macros.h` to `variant_controls.h`.

On the **Modeling** tab, select **Model Explorer**.

In the **Model Hierarchy** pane, expand `Simulink Root` and select `Base Workspace`. The **Contents** pane displays all the objects in the base workspace.

Select VSSMODE and then in the **Simulink.Parameter:VSSMODE** pane, click the **Code Generation** tab.

In the **HeaderFile** parameter, specify the name of the file as `variant_controls.h`.

Alternatively, you can change the file name programmatically, by using this command. For more information on `Simulink.CoderInfo`, see `Simulink.CoderInfo`.

```
Simulink.CoderInfo.CustomAttributes.HeaderFile = 'variant_controls.h';
```

### Reduce Maintenance Effort by Creating Custom Storage Class

To change the name of the header file, you must change the configuration of each parameter object. You can use the Model Data Editor to perform batch editing, but when you add a new variant control variable (parameter object), you must remember to specify the name of the header file for that object. Also, the Model Data Editor shows the parameter objects used by only one model at a time.

Instead, you can create a custom storage class and specify the name of the header file only once: In the definition of the custom storage class.

Set your current folder to a writable location.

At the command prompt, copy the built-in `SimulinkDemos` package into your current folder as `myPackage`.

```
copyfile(fullfile(matlabroot,...
 'toolbox','simulink','simdemos','dataclasses','+SimulinkDemos'),...
 '+myPackage','f')
```

Navigate inside the `+myPackage` folder to the file `Parameter.m` and open the file.

Uncomment the methods section that defines the method `setupCoderInfo`. In the call to the function `useLocalCustomStorageClasses`, replace `'packageName'` with `'myPackage'`. When you finish, the section appears as follows:

```
methods
 function setupCoderInfo(h)
 % Use custom storage classes from this package
 useLocalCustomStorageClasses(h, 'myPackage');
 end
end % methods
```

Save and close the file.

Set your current folder to the folder that contains the package `myPackage`.

Open the Custom Storage Class Designer.

```
cscdesigner('myPackage')
```

Select the custom storage class `Define`.

Click **Copy**. A new custom storage class, `Define_1`, appears. Select this new custom storage class.

Set **Name** to `VariantControlVar`.

Set **Header file** to Specify. In the text box, enter `variant_controls.h`.

Click **Apply**, **Save**, and **OK**.

At the command prompt, replace the `Simulink.Parameter` object `VSSMODE` with `myPackage.Parameter` object. Apply the new custom storage class `VariantControlVar`.

```
MODE_A = myPackage.Parameter;
MODE_A.Value = 1;
MODE_A.DataType = 'int32';
MODE_A.CoderInfo.StorageClass = 'Custom';
MODE_A.CoderInfo.CustomStorageClass = 'VariantControlVar';

MODE_B = myPackage.Parameter;
MODE_B.Value = 1;
MODE_B.DataType = 'int32';
MODE_B.CoderInfo.StorageClass = 'Custom';
MODE_B.CoderInfo.CustomStorageClass = 'VariantControlVar';
```

Now, to indicate that a parameter object represents a variant control variable, you can apply the custom storage class `VariantControlVar`. To change the name of the header file, use the Custom Storage Class Designer.

## Represent Variant Source and Sink Blocks in Generated Code

### In this section...

“Represent Variant Source and Variant Sink Blocks in Simulink” on page 26-37

“Specify Conditions That Control Variant Choice Selection” on page 26-40

“Review the Generated Code” on page 26-41

“Generate Code with Zero Active Variant Controls” on page 26-43

You can use Variant Source and Variant Sink blocks to perceive multiple implementations of a model in a single, unified block diagram. Each implementation depends on conditions that you set for Variant Source and Variant Sink blocks. Simulink propagates these conditions to upstream and downstream blocks including root input and root output ports.

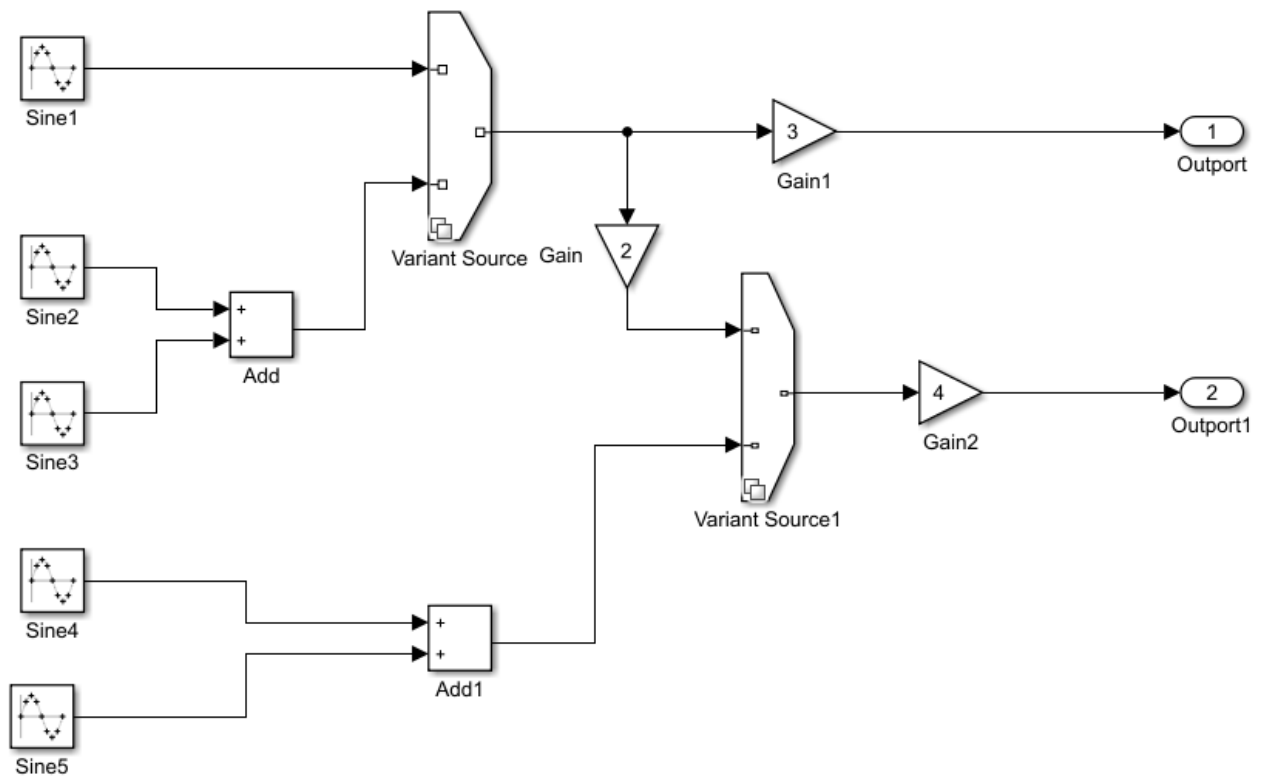

You can generate:

- Code from a Simulink model containing Variant Sink and Variant Source blocks.
- Code that contains preprocessor conditionals that control the activation of each variant choice.
- Preprocessor conditionals that allow for no active variant choice.

### Represent Variant Source and Variant Sink Blocks in Simulink

This example shows how Variant Source blocks make model elements conditional.

- 1 From the Simulink Block Library, add 1 Sine Wave Function block, two Add blocks, three Gain blocks, two Outports, and two Variant Source blocks into a new model.
- 2 Open the Sine Wave Function block. For the **Sine type** parameter, select `Sample based`. For the **Time (t)** parameter, select `Use simulation time`. For the **Sample time** parameter, insert a value of `0.2`.
- 3 Make four copies of the Sine Wave Function block.
- 4 Connect and name the blocks as shown.

- 5 Insert values of 2, 3, and 4 in the Gain2, Gain3, and Gain4 blocks, respectively.
- 6 Give the model the name `inline_variants_example`.
- 7 Open the Block Parameters dialog box for `Variant Source`.

- 8 In the **Variant control** column, for Port 1, replace Choice\_1 with V==1. For Port 2, replace Choice\_2 with V==2.
- 9 Open the Block Parameters dialog box for Variant Source1.
- 10 In the **Variant control** column, replace Choice\_1 with W==1. For Port 2, replace Choice\_2 with W==2.
- 11 In the MATLAB Command Window, use these commands to define V and W as Simulink.Parameter objects.

```
V = Simulink.Parameter;
V.Value = 1;
V.DataType='int32';
V.CoderInfo.StorageClass = 'custom';
V.CoderInfo.CustomStorageClass = 'Define';
V.CoderInfo.CustomAttributes.HeaderFile='inline_importedmacro.h'
```

```
W = Simulink.Parameter;
W.Value = 2;
W.DataType='int32';
W.CoderInfo.StorageClass = 'custom';
W.CoderInfo.CustomStorageClass = 'Define';
W.CoderInfo.CustomAttributes.HeaderFile='inline_importedmacro.h'
```

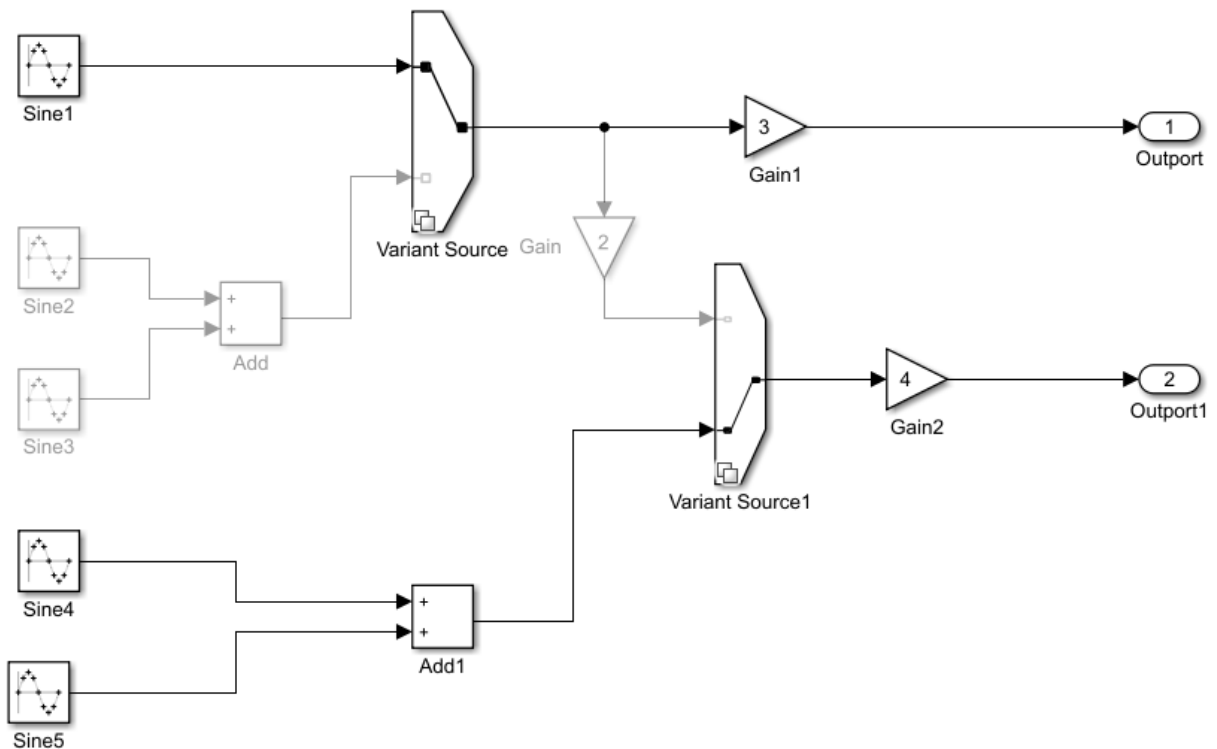

In this example, the variant control variables are Simulink.Parameter objects. For code generation, if you use Simulink.Variant objects to specify variant controls, use Simulink.Parameter objects or MATLAB variables to specify their conditions. .

Variant control variables defined as `Simulink.Parameter` objects can have one of these storage classes:

- Define with header file specified
- ImportedDefine with header file specified
- CompilerFlag
- SystemConstant (AUTOSAR)
- User-defined custom storage class that defines data as a macro in a specified header file

If you use scalar variant control variables to simulate the model, you can convert those variables into `Simulink.Parameter` objects. See “Convert Variant Control Variables into `Simulink.Parameter` Objects”.

## 12 Simulate the model.

Input port 1 is the active choice for `Variant Source` because the value of variant control variable `V` is 1. Input port 2 is the active choice for `Variant Source1` because the value of variant control variable `W` is 2. The inactive choices are removed from execution, and their paths are grayed-out in the diagram.

## Specify Conditions That Control Variant Choice Selection

You can generate code in which each variant choice is enclosed within C preprocessor conditionals `#if` and `#endif`. The compiler chooses the active variant at compile time and the preprocessor conditionals determine which sections of the code to execute.

- 1 In the **Modeling** tab of the Simulink toolstrip, click **Model Settings**.

- 2 On the **Code Generation** pane, and set **System target file** to `ert.tlc`.
- 3 On the **Solver** pane, set the **Type** parameter to **Fixed-step**.
- 4 In your model, open the block parameters dialog box for **Variant Source**.
- 5 Set the **Variant activation time** parameter to `code compile`. During an update diagram or simulation, when you set this parameter value, Simulink analyzes all variant choices. This analysis provides early validation of the code generation readiness of variant choices. During code generation, when you set this parameter value, the code generator generates preprocessor conditionals that control the activation of each variant choice.
- 6 Clear the **Allow zero active variant controls** parameter.
- 7 Open the Block Parameters dialog box for **Variant Source 1**. Repeat steps 5 through 7.
- 8 Build the model. When code generation is complete, the generated code is displayed in the Code view.

## Review the Generated Code

- 1 In the Code view, select the `inline_variants_example.c` file.
- 2 In the `inline_variants_example.c` file, the call to the `inline_variants_example_step` function is conditionally compiled as shown:

```

/* Model step function */
void inline_variants_example_step(void)
{
 real_T rtb_VariantMerge_For_Variant_So;
 real_T rtb_VariantMerge_For_Variant__e;

 /* Sin: '<Root>/Sine2' incorporates:
 * Sin: '<Root>/Sine3'
 * Sum: '<Root>/Add'
 */
 #if V == 2

 rtb_VariantMerge_For_Variant_So = sin((real_T)
 inline_variants_example_DW.counter * 2.0 * 3.1415926535897931 / 10.0) + sin
 ((real_T)inline_variants_example_DW.counter_g * 2.0 * 3.1415926535897931 /
 10.0);

 #endif

 /* End of Sin: '<Root>/Sine2' */

 /* Sin: '<Root>/Sine4' incorporates:
 * Sin: '<Root>/Sine5'
 * Sum: '<Root>/Add1'
 */
 #if W == 2

 rtb_VariantMerge_For_Variant__e = sin((real_T)
 inline_variants_example_DW.counter_c * 2.0 * 3.1415926535897931 / 10.0) +
 sin((real_T)inline_variants_example_DW.counter_i * 2.0 * 3.1415926535897931 /
 10.0);

 #endif

```

```

 /* End of Sin: '<Root>/Sine4' */

 /* Sin: '<Root>/Sine1' */
 #if V == 1

 rtb_VariantMerge_For_Variant_So = sin((real_T)
 inline_variants_example_DW.counter_m * 2.0 * 3.1415926535897931 / 10.0);

 #endif

 /* End of Sin: '<Root>/Sine1' */

 /* Output: '<Root>/Outputport' incorporates:
 * Gain: '<Root>/Gain1'
 */
 inline_variants_example_Y.Outputport = 3.0 * rtb_VariantMerge_For_Variant_So;

 /* Gain: '<Root>/Gain' */
 #if W == 1

 rtb_VariantMerge_For_Variant__e = 2.0 * rtb_VariantMerge_For_Variant_So;

 #endif

 /* End of Gain: '<Root>/Gain' */

 /* Output: '<Root>/Outputport1' incorporates:
 * Gain: '<Root>/Gain2'
 */
 inline_variants_example_Y.Outputport1 = 4.0 * rtb_VariantMerge_For_Variant__e;

 /* Update for Sin: '<Root>/Sine2' incorporates:
 * Sin: '<Root>/Sine3'
 */
 #if V == 2

 inline_variants_example_DW.counter++;
 if (inline_variants_example_DW.counter == 10) {
 inline_variants_example_DW.counter = 0;
 }

 inline_variants_example_DW.counter_g++;
 if (inline_variants_example_DW.counter_g == 10) {
 inline_variants_example_DW.counter_g = 0;
 }

 #endif

 /* End of Update for Sin: '<Root>/Sine2' */

 /* Update for Sin: '<Root>/Sine4' incorporates:
 * Sin: '<Root>/Sine5'
 */
 #if W == 2

 inline_variants_example_DW.counter_c++;
 if (inline_variants_example_DW.counter_c == 10) {
 inline_variants_example_DW.counter_c = 0;
 }
 #endif

```

```

 }

 inline_variants_example_DW.counter_i++;
 if (inline_variants_example_DW.counter_i == 10) {
 inline_variants_example_DW.counter_i = 0;
 }

#endif

 /* End of Update for Sin: '<Root>/Sine4' */

 /* Update for Sin: '<Root>/Sine1' */
 #if V == 1

 inline_variants_example_DW.counter_m++;
 if (inline_variants_example_DW.counter_m == 10) {
 inline_variants_example_DW.counter_m = 0;
 }

 #endif

 /* End of Update for Sin: '<Root>/Sine1' */
}

```

The variables `rtb_VariantMerge_For_Variant_So` and `rtb_VariantMerge_For_Variant_e` hold the input values to the Variant Source blocks. Notice that the code for these variables is conditional. The variables `inline_variants_example_Y.Outputport` and `inline_variants_example_Y.Outputport1` hold the output values of the Variant Source blocks. Notice that the code for these variables is not conditional.

## Generate Code with Zero Active Variant Controls

You can generate code in which blocks connected to the input and the output of a Variant Source block are conditional.

- 1 For Variant Source, open the Block Parameters dialog box. Select the parameter **Allow zero active variant controls**.
- 2 For Variant Source 1, open the Block Parameters dialog box. Select the parameter **Allow zero active variant controls**.

When you select the **Allow zero active variant controls** parameter, you can generate code for a model containing Variant Source and Variant Sink blocks even when you specify a value for a variant control variable that does not allow for an active variant. Choosing a value for a variant control variable that does not allow for an active variant and not selecting the **Allow zero active variant controls** parameter, produces an error.

Generate code for `inline_variants_example`. Notice in the `inline_variants_example.c` file, that the code for the variables `inline_variants_example_Y.Outputport1` and `inline_variants_example_Y.Outputport2` is conditional.

```

/* Model step function */
void inline_variants_example_step(void)
{
 ...
 #if V == 1 || V == 2

```

```
 inline_variants_example_Y.Outport = 3.0 * rtb_VariantMerge_For_Variant_So;
#endif

...
#if (V == 1 && W == 1) || (V == 2 && W == 1) || W == 2
 inline_variants_example_Y.Outport1 = 4.0 * rtb_VariantMerge_For_Variant__e;
#endif

...
```

## Configure Dimension Variants for S-Function Blocks

To configure symbolic dimensions for S-function blocks, you can use the following C/C++ functions. You can configure S-functions to support forward propagation, backward propagation, or forward and backward propagation of symbolic dimensions during simulation.

Many of these functions return the variable `SymbDimsId`. A `SymbDimsId` is a unique integer value. This value corresponds to each symbolic dimension specification that you create or is the result of a mathematical operation that you perform with symbolic dimensions.

C/C++ S-Functions	Purpose
<code>ssSetSymbolicDimsSupport</code>	Specify whether or not an S-function supports symbolic dimensions.
<code>mdlSetInputPortSymbolicDimensions</code>	Specify the symbolic dimensions of an input port and how those dimensions propagate forward.
<code>mdlSetOutputPortSymbolicDimensions</code>	Specify the symbolic dimensions of an output port and how those dimensions propagate backward.
<code>ssRegisterSymbolicDimsExpr</code>	Create a <code>SymbDimsId</code> from an expression string ( <code>aExpr</code> ). The expression string must form a valid syntax in C.
<code>ssRegisterSymbolicDims</code>	Create a <code>SymbDimsId</code> from a vector of <code>SymbDimsIds</code> .
<code>ssRegisterSymbolicDimsString</code>	Create a <code>SymbDimsId</code> from an identifier string ( <code>aString</code> ).
<code>ssRegisterSymbolicDimsIntValue</code>	Create a <code>SymbDimsId</code> from an integer value ( <code>aIntValue</code> ).
<code>ssRegisterSymbolicDimsPlus</code>	Create a <code>SymbDimsId</code> by adding two symbolic dimensions.
<code>ssRegisterSymbolicDimsMinus</code>	Create a <code>SymbDimsId</code> by subtracting two symbolic dimensions.
<code>ssRegisterSymbolicDimsMultiply</code>	Create a <code>SymbDimsId</code> by multiplying two symbolic dimensions.
<code>ssRegisterSymbolicDimsDivide</code>	Create a <code>SymbDimsId</code> by dividing two symbolic dimensions.
<code>ssGetNumSymbolicDims</code>	Get the number of dimensions for a <code>SymbDimsId</code> .
<code>ssGetSymbolicDim</code>	Get a <code>SymbDimsId</code> from a vector of <code>SymbDimsIds</code> .
<code>ssSetInputPortSymbolicDimsId</code>	Set the precompiled <code>SymbDimsId</code> of an input port. You can call this function from inside the <code>mdlInitializeSizes</code> function.
<code>ssGetCompInputPortSymbolicDimsId</code>	Get the compiled <code>SymbDimsId</code> of an input port.

C/C++ S-Functions	Purpose
ssSetCompInputPortSymbolicDimsId	Set the compiled SymbDimsId of an input port.
ssSetOutputPortSymbolicDimsId	Set the precompiled SymbDimsId of an output port. You can call this function from inside the mdlInitializeSizes function.
ssGetCompOutputPortSymbolicDimsId	Get the compiled SymbDimsId of an output port.
ssSetCompOutputPortSymbolicDimsId	Set the compiled SymbDimsId of an output port.
ssSetCompDWorkSymbolicDimsId	Set the compiled SymbDimsId of an index of a block's data type work (DWork) vector.

## Generate Code from an S-Function Block with Dimension Variants

The model `ex_msymbdims_sfcn_one` contains an S-function that subtracts the symbolic dimension B from a symbolic input dimension,  $A - B$ . The model supports forward propagation because the symbolic dimensions of the output ports are set. The model does not support backward propagation of symbolic dimensions because the compiled symbolic dimensions of the input ports are not set.

```
model='ex_msymbdims_sfcn_one';
open_system(model);
```

## S-Function That Supports Forward and Backward Propagation of Symbolic Dimensions

This S-function transposes two symbolic dimensions. It supports forward and backward propagation of symbolic dimensions because the compiled symbolic dimension of both the input and output ports are set.

```

static void mdlInitializeSizes(SimStruct *S)
{
 // Enable symbolic dimensions for the s-function.
 ssSetSymbolicDimsSupport(S, true);
}

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_INPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetInputPortSymbolicDimensions(SimStruct* S,
 int_T portIndex, SymbDimsId symbDimsId)
{
 assert(0 == portIndex);

 ssSetCompInputPortSymbolicDimsId(S, portIndex, symbDimsId);

 assert(2U == ssGetNumSymbolicDims(S, symbDimsId));

 if (SL_INHERIT ==
 ssGetCompOutputPortSymbolicDimsId(S, portIndex)) {
 const SymbDimsId idVec[] = {
 ssGetSymbolicDim(S, symbDimsId, 1),
 ssGetSymbolicDim(S, symbDimsId, 0)};
 }
}

```

```
 // Register the transposed dimensions.
 // Set the output symbolic dimension to the resulting id.
const SymbDimsId outputDimsId =
 ssRegisterSymbolicDims(S, idVec, 2U);

 ssSetCompOutputPortSymbolicDimsId(S, portIndex,

## Represent Variant Condition Values of Enumerated Type in Generated Code

You can generate C code from a Simulink model with variant condition variables or values of Simulink-supported enumeration types. Enumerated types improve code readability because the condition values and variables in control expressions are represented as meaningful names instead of integers. In this section, you will learn:

- How to generate C code from a model with variant condition values of enumerated types.
- How the variant condition values are represented in the generated code.

### Use Enumerated Type Derived From Built-In Integer

This example shows how to generate C code from a Simulink model with variant condition values of enumerated type derived from the built-in integer `int32`.

Open the `slexVariantSetupUsingIntEnums` model. This model runs the `PostLoadFcn` defined in the **File > ModelProperties > Callbacks** dialog. This function populates the base workspace with the control variables for the variant blocks.

In this model, the Variant Sink and the Variant Source blocks specify two potential variants for the Linear controller and Nonlinear controller subsystems. The control expression for the Linear controller subsystem is `V == ControllerChoice.Linear`. The control expression for the Nonlinear controller subsystem is `V == ControllerChoice.NonLinear`. Here, `ControllerChoice` is an integer-based enumeration class derived from the built-in data type, `int32`. The class is defined in the `ControllerChoice.m` file. The class has two enumeration values, `Linear` and `NonLinear`. These enumerated values have underlying integer values `0` and `1`.

#### Switch Between Variant Choices

- 1 Click **Simulation > Run** and see the variant conditions being propagated to the blocks. By default, the model simulates for the Linear controller subsystem.

- 2 To modify the active choice, set the value of **V** to `ControllerChoice.Nonlinear`, then simulate the model again. The model simulates for the Nonlinear controller subsystem.

### Generate Code from Model

Before you generate code from the model, you must have write permission in your current folder.

- 1 To generate code, in the Apps gallery of the model toolstrip, click **Embedded Coder**. The **C Code** tab appears.
- 2 Click the **Generate Code > Build** icon. (  ).

### Review Generated Code

- 1 In the **C Code** tab of the toolstrip, select **Open Report**.

The screenshot shows the 'Code Generation Report' window. The title bar reads 'Code Generation Report'. The main content area is titled 'Code Generation Report for 'slexVariantSetupUsingIntEnums''. It is divided into several sections:

- Contents:** A list of report sections including Summary (highlighted), Subsystem Report, Code Interface Report, Traceability Report, Static Code Metrics Report, Code Replacements Report, and Coder Assumptions.
- Generated Code:** A tree view showing the main file 'ert\_main.c' and model files 'slexVariantSetupUsingIntEnums\_ert.c' (repeated four times), data files 'slexVariantSetupUsingIntEnums\_ert\_data.c', and utility files (2).
- Model Information:** A table with the following data:
 

Author	The MathWorks, Inc.
Last Modified By	
Model Version	7.15
Tasking Mode	MultiTasking
- Configuration settings at time of code generation:** A link to view settings.
- Code Information:** A table with the following data:
 

System Target File	ert.tlc
Hardware Device Type	32-bit Generic
Simulink Coder Version	9.4 (R2020b) 19-May-2020
Timestamp of Generated Source Code	Mon Jun 29 10:48:28 2020
Location of Generated Source Code	L:\R2020b_docs\Enum Codegen support\slexVariantSetupUsingIntEnums_ert_rtw\
Type of Build	Model
Objectives Specified	Unspecified

At the bottom right, there are 'OK' and 'Help' buttons.

In the generated code, the variant control values `ControllerChoice.Linear` and `ControllerChoice.Nonlinear` are converted to `ControllerChoice_Linear` and `ControllerChoice_Nonlinear`, respectively. A valid C processor recognizes this format. The code also includes the definitions of macros corresponding to these variants. The active variant is determined by using preprocessor conditionals (`#if`) on the macros (`#define`) `ControllerChoice_Linear` and `ControllerChoice_Nonlinear`.

```
#if V == ControllerChoice_Linear

slexVariantSetupUsingIntEnums_B.VariantMerge_For_Variant_Source =
slexVariantSetupUsingIntEnums_P.DiscreteTransferFcn_NumCoef_a *
slexVariantSetupUsingIntEnum_DW.DiscreteTransferFcn_states_o;

#endif

#if V == ControllerChoice_Nonlinear

slexVariantSetupUsingIntEnums_B.VariantMerge_For_Variant_Source =
look1_binlpxw(slexVariantSetupUsingIntEnums_P.DiscreteTransferFcn_NumCoef_l *
slexVariantSetupUsingIntEnum_DW.DiscreteTransferFcn_states_n,
slexVariantSetupUsingIntEnums_P.uDLookupTable_bp01Data,
slexVariantSetupUsingIntEnums_P.uDLookupTable_tableData, 10U);

#endif
```

- 2 To view the definitions of macros, `ControllerChoice_Linear` and `ControllerChoice_Nonlinear`, click the `Controller.h` file in the **Generated Code** pane of the report.

```
#define ControllerChoice_Linear (0) /* Default value */
#define ControllerChoice_Nonlinear (1)
#endif /* RTW_HEADER_Controller_h_ */
```

- 3 To view the definition of the variant control variable, `V`, click the `slexVariantSetupUsingIntEnums_types.h` file.

```
#ifndef V
#define V ControllerChoice_Linear
#endif
```

## Use In-Memory Enumerated Type Derived From Simulink.IntEnumType

The Simulink model in this example shows how to generate C code from a model having variant control variables of enumerated type derived from `Simulink.IntEnumType`.

- 1 Open the `slexVariantSetupUsingInMemoryEnums` model. The model runs the `PreLoadFcn` defined in the **File > ModelProperties > Callbacks** dialog. This populates the base workspace with the control variables for the variant blocks.
- 2 Generate C code. The variant control variables `Controller.Linear` and `Controller.Nonlinear` are represented as `Controller_Linear` and `Controller_Nonlinear` in the generated code, as the above example also shows.

The macros `Controller_Linear` and `Controller_Nonlinear` are defined in the `Controller.h` file.

```
#define Controller_Linear (0) /* Default value */
#define Controller_Nonlinear (1)
#endif /* RTW_HEADER_Controller_h_ */
```

The variant control variable is defined in the `slexVariantSetupUsingInMemoryEnums_types.h` file.

```
#ifndef V
#define V Controller_Linear
#endif
```

## Options to Represent Variant Parameters in Generated Code

You can generate the code only for active values or for both active and inactive values of variant parameters in Simulink. You can also represent the values of variant parameters as inline variables or as tunable variables in the generated code.

---

**Note** For variant parameters associated with the `startup` activation time, you can generate code for both active and inactive choices by installing Simulink Coder or Embedded Coder.

For variant parameters associated with the `code compile` activation time:

- You must install Simulink Coder to generate code for only active values of variant parameters. Generating code using Simulink Coder is supported only if values of a variant parameter have same dimension.
  - You must install Embedded Coder to generate code for both active and inactive values of variant parameters. Generating code using Embedded Coder is supported for variant parameters values having same and different dimensions.
- 

### Limitations

Variant parameters do not support generating code for AUTOSAR targets.

### Overview of Variant Parameters

Variant parameters can have multiple values. Each value of the variant parameter is associated with a variant condition expression. During simulation, the value of a variant parameter associated with the condition that evaluates to `true` is the active value of the variant parameter. The value associated with the condition that evaluates to `false` is the inactive value of the variant parameter. When you generate code, you can choose to include only the active value or both the active and inactive values in the generated code. You can also choose to represent the values as inline or as tunable variables in the generated code. For more information on variant parameters, see “Use Variant Parameters to Reuse Block Parameters with Different Values”.

### Choice of Values in Generated Code

Simulink supports generating code only for active values or for both active and inactive values of variant parameters. Values included in the code are based on the variant activation time you specify for the variant parameters. For more information, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow”.

When you specify the variant activation time as:

- `'update diagram'` -- Simulink does not analyze the values of variant parameters for incompatibilities in signal attributes. It generates code only for the active values of variant parameters.
- `'update diagram analyze all choices'` -- Simulink analyzes both active and inactive values of variant parameters for incompatibilities in signal attributes, however it generates code only for the active values of variant parameters.

- 'code compile' -- Simulink analyzes both active and inactive values of variant parameters for incompatibilities in signal attributes and it also generates code for both active and inactive values of the variant parameters. The values are enclosed in C preprocessor conditional statements `#if` and `#endif` that are conditionally compiled when you compile the generated code.
- 'startup' -- Simulink analyzes both active and inactive values of variant parameters for incompatibilities in signal attributes and it also generates code for both active and inactive values of the variant parameters. The values are enclosed in regular `if` conditions inside the `model_initialize` function of the generated code that are conditionally evaluated when you run the executable that is built from the code.

## Types of Variables in Generated Code

Simulink supports representing the values of variant parameters as inline variables or as tunable variables in the generated code. The representation of values in the code are based on the storage class you specify for the variant parameters.

- **Inline variable:** If you specify the storage class of a variant parameter as "Auto", which is a default storage class, and the activation time as `update diagram` or `update diagram analyze all choices`, then the variant parameter is inlined to the literal numeric value of the parameter in the generated code. If you specify the storage class of a variant parameter as `Auto` and the activation time as `code compile`, then the variant parameter is inlined as macros in the generated code. Inlined variables reduce global RAM usage and increase efficiency of the generated code. The code does not allocate memory to represent numeric block parameters, such as the **Gain** parameter of a Gain block. Instead, the code is inlined to the literal numeric value of the parameter.
- **Tunable:** If you specify the storage class of a variant parameter as anything other than `Auto`, then the variant parameter is represented using symbolic names in the generated code. For a list of built-in storage classes supported for different activation times see "Storage Classes for Different Variant Activation Times" on page 26-58.

## Storage Classes for Different Variant Activation Times

When you specify a condition expression to determine the active choice, each variant control variable of the expression has a storage class associated with it. Use storage classes to control the appearance and placement of the variant control variables in the generated code. Storage classes also prevent the optimizations such as elimination of the storage for variant control variables in the generated code. For more information, see "Choose Storage Class for Controlling Data Representation in Generated Code".

The variables used in the variant condition expressions must satisfy these criteria to generate code with Simulink Coder or Embedded Coder.

- The variant control variables in variant condition expressions must have these storage classes.
  - This table lists the built-in storage classes supported for different activation times to generate code using Simulink Coder and Embedded Coder.

Built-in Storage Class	Variant activation time	
	code compile	startup
"ExportedGlobal"	x	✓

Built-in Storage Class	Variant activation time	
"Model Default"	x	✓
"ImportedExtern, ImportedExternPointer"	x	✓
"Auto"	x	x

- This table lists the custom storage classes supported for different activation times to generate code using Embedded Coder.

Custom Storage Class	Variant activation time	
	code compile	startup
"GetSet" on page 33-81	x	✓
"Define, ImportedDefine" on page 33-80	✓	x
"CompilerFlag" on page 33-79	✓	x
Const and ConstVolatile. See, "Const, Volatile, and ConstVolatile" on page 33-79	x	x
"Bitfield" on page 33-79	x	✓
"Struct" on page 33-83	x	✓
"ExportToFile" on page 33-80	x	✓
"ImportFromFile" on page 33-82	x	✓
Volatile. See, "Const, Volatile, and ConstVolatile" on page 33-79	x	✓

- If the activation time of a variant control variable is set to `startup`, then specifying its storage class to any of these is not supported:
  - Storage classes such as `Define` that generates macros in the code.
  - Storage classes such as `Const` that generates constant qualified variables in the code.
- If the activation time of a variant control variable is set to `code compile` and if the values have different dimensions, then specifying its storage class such as `Define` that generates macros in the code is not supported.

## Symbolic Dimensions in Generated Code

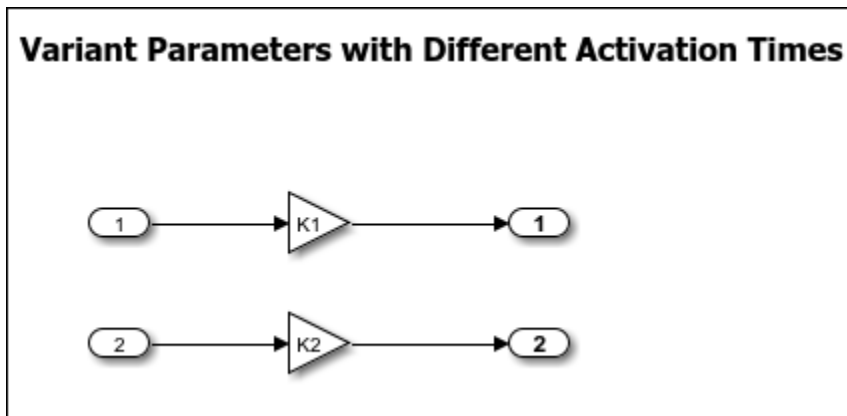

If a variant parameter has values with multiple dimensions, Simulink generates symbols to represent dimensions in the generated code. Representing dimensions as symbols enable the code to flexibly switch between dimension values for the given active choice without regenerating code every time you change the value of the variant control variable. For more information on symbolic dimensions in variant parameters, see "Compile Code Conditionally for all Values of Variant Parameters with Same and Different Dimensions".

## Generate C Code for Variant Parameters

This example shows how to generate C code for variant parameters.

### Explore the Model

Consider the `slexVariantParameters.slx` model.

The **Gain** parameters of the Gain1 and the Gain2 blocks are variant parameters with their values set to K1 and K2, respectively. The variable K1 has two values: 3.5 and 8.5. The variable K2 has two values: 4.5 and 9.5.

Simulink chooses active values of K1 and K2 based on the value of the variant control variable V. If `V==1` evaluates to `true`, then the value of K1 is set to 3.5, and the value of K2 is set to 8.5. If `V==2` evaluates to `true`, then the value of K1 is set to 4.5, and the value of K2 is set to 9.5.

In this example, the variant activation time is set to `update diagram`, and the storage class is set as `Auto`. When you generate a code from this model, the code is generated only for the active values of K1 and K2. In the generated code, the values are inlined to the literal value of the parameters.

### Generate Inline and Tunable Code for Variant Parameters using Embedded Coder

Before you generate code from the model, you must have write permission in your current folder.

- 1 Prepare the model for code generation by specifying code generation settings in the Configuration Parameters dialog box. Choose the solver and code generation target, and check the model configuration for execution efficiency. For more details on each of these steps, see "Generate Code Using Embedded Coder" on page 50-2.
- 2 In the **Apps** gallery of the model toolstrip, click **Simulink Coder**.
- 3 On the **C Code** tab, click **Build**.

The code generator creates the folder `slexVariantParameters_ert_rtw` in your current working folder and places source code files in that folder. The generated code is in two primary files: `slexVariantParameters.c` and `slexParameters.h`. The file `slexVariantParameters.h` contains the value of the variant control variable, and the file `slexVariantParameters.c` contains the values of the variant parameters.

- 4 In the **C Code** tab, select **Open Report**.

- 5 Select the `slexVariantParameters.c` file from the **Generated Code** pane of the report. The code is generated only for the active values of the K1 and K2. In the generated code, the values are inlined to the literal value of the parameters.

```
slexVariantParameters_Y.Out1 = 3.5 * slexVariantParameters_U.In1;
slexVariantParameters_Y.Out2 = 4.5 * slexVariantParameters_U.In2;
```

- 6 In the model, change the activation time to `code compile` and the storage class to `ExportedGlobal`, then generate the code again. Observe the change in the style of the generated code.

The code is generated only for all the active and inactive values of K1 and K2. In the generated code, the values are represented using symbolic names.

This table shows the difference in the style of the generated code for storage classes `Auto` and `ExportedGlobal` with different activation times.

Activation time	Storage class	
	Auto (default)	ExportedGlobal

## Generate Code for Variant Subsystem with Child Subsystems of Different Output Signal Dimensions

### In this section...

“Example Model” on page 26-65

“Simulate Model” on page 26-65

“Generate Code” on page 26-66

This example shows how to use symbolic dimensions to generate code with preprocessor conditionals for a variant subsystem consisting of child subsystems of different output signal dimensions. The value of the variant control variable determines the active variant choice and the output signal dimensions. By changing the value of the variant control variable, you change the active variant and the output signal dimensions in the generated code.

### Example Model

The model `slxVariantSymbolicDims` contains a Variant Subsystem consisting of the child subsystems `Subsystem` and `Subsystem1`. When the variant control variable `Var` has a value of 1, `Subsystem` is the active variant. When `Var` has a value of 2, `Subsystem1` is the active variant.

### Simulate Model

To generate code with preprocessor conditionals, the output signal dimensions of the child subsystems must be the same during simulation. In this example, double-clicking the subsystem `Activate Variant Choice` changes the active variant and the output signal dimension. When `Var`

equals 1, the output signal dimension of each child subsystem is 5. When Var equals 2, the output signal dimension of each child subsystem is 6.

- 1 Open the example model `slexVariantSymbolicDims`.
- 2 On the **Debug** tab, select **Information Overlays > Signal Dimensions**.
- 3 Open the Variant Subsystem Block Parameters dialog box. The **Variant activation time** parameter is set to `code compile`.
- 4 Open `Subsystem`. In the Constant Block Parameters dialog box, the **Constant value** parameter is P1.
- 5 Open `Subsystem1`. In the Constant Block Parameters dialog box, the **Constant value** parameter is P2.
- 6 Open the base workspace. The `Simulink.Parameters` P1 and P2 are arrays with dimensions `'[1,A]'`. The `Simulink.Parameter` A has a value of 5. Var has a value of 1.
- 7 Simulate the model. `Subsystem` is the active variant with an output signal dimension of 5.
- 8 Double-click the masked subsystem `ActivateVariant`.
- 9 In the base workspace, Var has a value of 2. P1 and P2 have a dimension of 6. A has a value of 6.
- 10 Simulate the model. `Subsystem1` is the active variant with an output signal dimension of 6.

In the base workspace, A has a **Storage class** of `ImportedDefine(Custom)`. To use a `Simulink.Parameter` object for dimension specification, it must have one of these storage classes:

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- User-defined custom storage class that defines data as a macro in a specified header file

In the base workspace, P1 and P2 have a storage class of `ImportedExtern`. A `Simulink.Parameter` object that uses a `Simulink.Parameter` for symbolic dimension specification must have a storage class of either `ImportedExtern` or `ImportedExternPointer`, or a storage class with the **Data initialization** property set to `None`.

## Generate Code

- 1 Open the header file `slexVariantSymbolicDims_variant_defines.h`. The definition of A is conditional upon the value of Var.

```
/* Copyright 2016 The MathWorks, Inc. */
// To select variant choice during compile, define Var at compile time,

#ifndef Var
#define Var 1
#endif

#if Var == 1
#define A 5
#elif Var == 2
#define A 6
#else
#error "Variant control variable, Var, must be defined as 1 or 2"
#endif
```

- 2 Generate code.

- 3 Open the `slexVariantSymbolicDims.h` file. The output dimension size is A.

```
/* External outputs (root outputs fed by signals with auto storage) */
typedef struct {
 int32_T Out1[A]; /* '<Root>/Out1' */
} ExternalOutputs_slexVariantSymb;
```

- 4 Open the `slexVariantSymbolicDims.c` file. If `Var` equals 1, P1 has five values. If `Var` equals 2, P2 has six values. In the Configuration Parameters dialog box, on the **Code Generation** > **Custom Code** pane, the **Additional code** parameter contains this code.

```
/* user code (top of source file) */
#if Var == 1

int32_T P1[] = { 5, 5, 5, 5, 5 };

#elif Var == 2

int32_T P2[] = { 6, 6, 6, 6, 6, 6 };

#endif
```

Preprocessor conditionals control the size of A and which array, P1 or P2, is active in the generated code. By changing the value of `Var`, you can change the size of A and the active array.

## Use Variant Subsystem To Generate Code That Uses C Preprocessor Conditionals

This example shows how to use Simulink® variant subsystems to generate C preprocessor conditionals that control which child subsystem of the variant subsystem is active in the generated code produced by the Simulink® Coder™.

### Overview of Variant Subsystems

A Variant Subsystem block contains two or more child subsystems where one child is active during model execution. The active child subsystem is referred to as the *active variant*. You can programmatically switch the active variant of the Variant Subsystem block by changing values of variables in the base workspace, or by manually overriding variant selection using the Variant Subsystem block dialog. The *active variant* is programmatically wired to the Inport and Outport blocks of the Variant Subsystem by Simulink® during model compilation.

To programmatically control variant selection, a `Simulink.Variant` object is associated with each child subsystem in the Variant Subsystem block dialog. `Simulink.Variant` objects are created in the MATLAB® base workspace. These objects have a property named `Condition`, an expression, which evaluates to a Boolean value and is used to determine the active variant child subsystem.

By default the generated code contains only the active variant. Alternatively, you can parameterize the selection of the active variant, and make it dependent on the values of variables and objects in the base MATLAB® workspace. When you generate code, you can generate code for all variants and defer the choice of active variant until it is time to compile that code.

### Specifying Variants for a Subsystem Block

Opening the example model `rtwdemo_preprocessor_subsys` will run the **PostLoadFcn** defined in the "File: ModelProperties: Callbacks" dialog. This will populate the base workspace with the variables for the Variant Subsystem blocks.

```
open_system('rtwdemo_preprocessor_subsys')
```

Copyright 2009-2020 The MathWorks, Inc.

The LeftController variant subsystem contains two child subsystems: Linear and Nonlinear. The LeftController/Linear child subsystem executes when the Simulink.Variant object LINEAR evaluates to true, and the LeftController/Nonlinear child subsystem executes when the Simulink.Variant object NONLINEAR evaluates to true.

Simulink.Variant objects are specified for the LeftController subsystem by right-clicking the LeftController subsystem and selecting **Subsystem Parameters**, which will open the LeftController subsystem block dialog.

```
open_system('rtwdemo_preprocessor_subsys/LeftController');
```

The LeftController subsystem block dialog creates an association between the Linear and Nonlinear subsystems with the two Simulink.Variant objects, LINEAR and NONLINEAR, that exist in the base workspace. These objects have a property named Condition, an expression, which evaluates to a Boolean value and determines the active variant child subsystem (Linear or Nonlinear). The condition is also shown in the subsystem block dialog. In this example, the conditions of LINEAR and NONLINEAR are 'VSSMODE == 0' and 'VSSMODE == 1', respectively.

In this example, the Simulink.Variant objects are created in the base workspace.

```
LINEAR = Simulink.Variant;
LINEAR.Condition = 'VSSMODE==0';
NONLINEAR = Simulink.Variant;
NONLINEAR.Condition = 'VSSMODE==1';
```

### Specifying a Variant Control Variable

Variant objects allow you to reuse arbitrarily complex conditions throughout a model. Multiple Variant Subsystem blocks can use the same Simulink.Variant objects, allowing you to toggle the activation of choices as a set. You can toggle the set prior to simulation by changing the value of VSSMODE in the MATLAB environment or when compiling the generated code, as explained in the next section. In this example, LeftController and RightController reference the same variant objects, so that you can toggle them simultaneously.

The nonlinear controller subsystems implement hysteresis, while the linear controller subsystems act as simple low-pass filters. Open the subsystem for the left channel. The subsystems for the right channel are similar.

The generated code accesses the variant control variable `VSSMODE` as a user-defined macro. In this example, `rtwdemo_importedmacros.h` supplies `VSSMODE`. Within the MATLAB environment, you specify `VSSMODE` using a `Simulink.Parameter` object. Its value will be ignored when generating code including preprocessor conditionals. However, the value is used for simulation. The legacy header file specifies the value of the macro to be used when compiling the generated code, which ultimately activates one of the two specified variants in the embedded executable.

Variant control variables can be defined as `Simulink.Parameter` objects with one of these storage classes:

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- `SystemConstant` (`AUTOSAR`)
- User-defined custom storage class that defines data as a macro in a specified header file

```
VSSMODE = Simulink.Parameter;
VSSMODE.Value = 1;
VSSMODE.DataType = 'int32';
VSSMODE.CoderInfo.StorageClass = 'Custom';
VSSMODE.CoderInfo.CustomStorageClass = 'ImportedDefine';
VSSMODE.CoderInfo.CustomAttributes.HeaderFile = 'rtwdemo_importedmacros.h';
```

### Simulating the Model with Different Variants

Because you set the value of `VSSMODE` to 1, the model uses the nonlinear controllers during simulation.

```
sim('rtwdemo_preprocessor_subsys')
youtnl = yout;
```

If you change the value of `VSSMODE` to 0, the model uses the linear controllers during simulation.

```
VSSMODE.Value = int32(0);
sim('rtwdemo_preprocessor_subsys')
youtl = yout;
```

You can plot and compare the response of the linear and nonlinear controllers:

```
figure('Tag','CloseMe');
plot(tout, youtnl.signals(1).values, 'r-', tout, youtl.signals(1).values, 'b-')
title('Response of Left Channel Linear and Nonlinear Controllers');
ylabel('Response');
xlabel('Time (seconds)');
legend('nonlinear','linear')
axis([0 100 -0.8 0.8]);
```

### Using C Preprocessor Conditionals

This example model has been configured to generate C preprocessor conditionals. To generate code for the model, in **C Code** tab of the toolstrip select **Build**.

To activate code generation of preprocessor conditionals, check whether the following conditions are true:

- Select an Embedded Coder® target in **Code Generation > System target file** in the Configuration Parameters dialog box
- In the Variant Subsystem block parameter dialog box, set the **Variant activation time** parameter to code compile.

In this example, the generated code includes references to the Simulink.Variant objects **LINEAR** and **NONLINEAR**, as well as the definitions of macros corresponding to those variants. Those definitions depend on the value of **VSSMODE**, which is supplied in an external header file `rtwdemo_importedmacros.h`. The active variant is determined by using preprocessor conditionals (`#if`) on the macros (`#define`) **LINEAR** and **NONLINEAR**.

The macros **LINEAR** and **NONLINEAR** are defined in the generated `rtwdemo_preprocessor_subsys_types.h`, header file:

```
#ifndef LINEAR
#define LINEAR (VSSMODE == 0)
#endif
```

```
#ifndef NONLINEAR
#define NONLINEAR (VSSMODE == 1)
#endif
```

In the generated code, the code related to the variants is guarded by C preprocessor conditionals. For example, in `rtwdemo_preprocessor_subsys.c`, the calls to the step and initialization functions of each variant are conditionally compiled:

```
/* Outputs for atomic SubSystem: '<Root>/LeftController' */
#if LINEAR
 /* Output and update for atomic system: '<S1>/Linear' */
#elseif NONLINEAR
 /* Output and update for atomic system: '<S1>/Nonlinear' */
#endif
```

Close the model, figure, and workspace variables from the example.

```
bdclose('rtwdemo_preprocessor_subsys')
close(findobj(0,'Tag','CloseMe'));
clear LINEAR NONLINEAR VSSMODE
clear tout yout youtl youtnl
```

## Use Variant Models to Generate Code That Uses C Preprocessor Conditionals

This example shows you how to use variant models to generate code that uses preprocessor conditionals to control which code is linked into the embedded executable.

### Overview of Variant Models

You can use a Model block to reference one Simulink® model (the *child model*) from another Simulink® model (the *parent model*). A Variant Subsystem block can have different *variants*. The variants can include a set of Model blocks, from which the Variant Subsystem block selects one. The figure below is a conceptual depiction of variant models. In this example the Right Controller model block can potentially select from two Model blocks. The models referenced by the Model blocks provide variations upon a nominal, prescribed functionality.

A Variant Subsystem block has only one variant active at a time. You can use the Variant Subsystem block dialog to select the active variant. Alternatively, you can parameterize the selection of the active variant, and make it dependent on the values of variables and objects in the base MATLAB® workspace. When you generate code, you can generate code for all variants and defer the choice of active variant until it is time to compile that code.

### Specifying Variant Models

Opening the example model `rtwdemo_preprocessor` runs the **PostLoadFcn** defined in the "File: ModelProperties: Callbacks" dialog. This populates the base workspace with the control variables for the Variant Subsystem blocks.

```
open_system('rtwdemo_preprocessor')
```

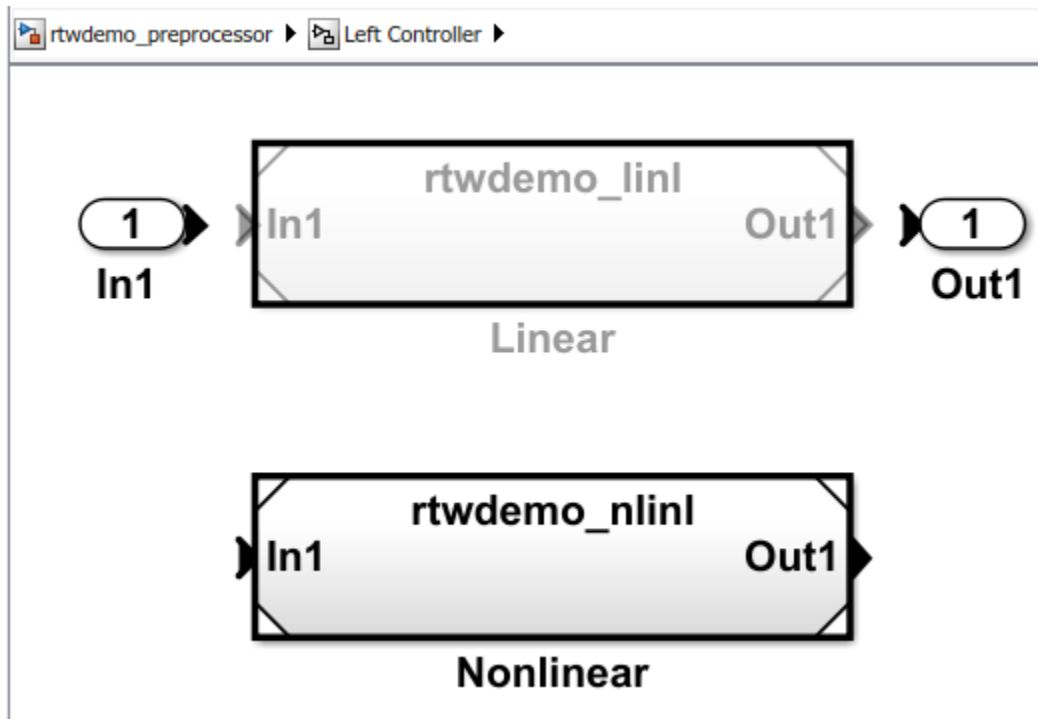

Copyright 2009-2020 The MathWorks, Inc.

The Left Controller variant subsystem contains two child Model blocks: Linear and Nonlinear. The Left Controller/Linear child model executes when the Simulink.Variant object LINEAR evaluates to true, and the Left Controller/Nonlinear child model executes when the Simulink.Variant object NONLINEAR evaluates to true.

Simulink.Variant objects are specified for the Left Controller subsystem by right-clicking the Left Controller subsystem and selecting Subsystem Parameters, which opens the Left Controller Variant Subsystem block dialog box.

Variant choices (list of child subsystems or model blocks)			
	Name (read-only)	Variant control	Condition (read-only)
	Linear	LINEAR	VSSMODE==0
	Nonlinear	NONLINEAR	VSSMODE==1

The Left Controller subsystem block dialog creates an association between the Linear and Nonlinear Model blocks with the two Simulink.Variant objects from the base workspace, LINEAR and NONLINEAR. These objects have a property named Condition, which is an expression that evaluates to a Boolean value and determines the active variant model (Linear or Nonlinear). The condition is also shown in the subsystem block dialog. In this example, the conditions of LINEAR and NONLINEAR are 'VSSMODE == 0' and 'VSSMODE == 1', respectively.

In this example, `Simulink.Variant` objects are created in the base workspace.

```
LINEAR = Simulink.Variant;
LINEAR.Condition = 'VSSMODE==0';
NONLINEAR = Simulink.Variant;
NONLINEAR.Condition = 'VSSMODE==1';
```

### Specifying a Variant Control Variable

Variant objects allow you to reuse arbitrarily complex conditions throughout a model. Multiple Variant Subsystem blocks can use the same `Simulink.Variant` objects, allowing you to toggle the activation of variant models as a set. You can toggle the set prior to simulation by changing the value of `VSSMODE` in the MATLAB environment or when compiling the generated code, as explained in the next section. In this example, `Left Controller` and `Right Controller` reference the same variant objects, so that you can toggle them simultaneously.

The nonlinear controller models implement hysteresis, while the linear controller models act as simple low-pass filters. Open the subsystem for the left channel. The models for the right channel are similar.

The generated code accesses the variant control variable `VSSMODE` as a user-defined macro. In this example, `rtwdemo_importedmacros.h` supplies `VSSMODE`. Within the MATLAB environment, you specify `VSSMODE` using a `Simulink.Parameter` object. Its value will be ignored when generating code including preprocessor conditionals. However, the value is used for simulation. The legacy header file specifies the value of the macro to be used when compiling the generated code, which ultimately activates one of the two specified variants in the embedded executable.

Variant control variables can be defined as `Simulink.Parameter` objects with one of these storage classes:

- Define or ImportedDefine with header file specified
- CompilerFlag
- SystemConstant (AUTOSAR)
- User-defined custom storage class that defines data as a macro in a specified header file

```
VSSMODE = Simulink.Parameter;
VSSMODE.Value = 1;
VSSMODE.DataType = 'int32';
VSSMODE.CoderInfo.StorageClass = 'Custom';
VSSMODE.CoderInfo.CustomStorageClass = 'ImportedDefine';
VSSMODE.CoderInfo.CustomAttributes.HeaderFile = 'rtwdemo_importedmacros.h';
```

### Simulating the Model with Different Variants

Because you set the value of VSSMODE to 1, the model uses the nonlinear controllers during simulation.

```
sim('rtwdemo_preprocessor')
youtnl = yout;
```

If you change the value of VSSMODE to 0, the model uses the linear controllers during simulation.

```
VSSMODE.Value = int32(0);
sim('rtwdemo_preprocessor')
youtl = yout;
```

You can plot and compare the response of the linear and nonlinear controllers:

```
figure('Tag','CloseMe');
plot(tout, youtnl.signals(1).values, 'r-', tout, youtl.signals(1).values, 'b-')
title('Response of Left Channel Linear and Nonlinear Controllers');
ylabel('Response');
xlabel('Time (seconds)');
legend('nonlinear','linear')
axis([0 100 -0.8 0.8]);
```

### Using C Preprocessor Conditionals

This example model has been configured to generate C preprocessor conditionals. To generate code for the model, in **C Code** tab of the toolstrip select **Build**.

To activate code generation of preprocessor conditionals, check whether the following conditions are true:

- Select an Embedded Coder® target in **Code Generation > System target file** in the Configuration Parameters dialog box
- In the Variant Subsystem block parameter dialog box, set the **Variant activation time** parameter to code compile.

In this example, the generated code includes references to the `Simulink.Variant` objects `LINEAR` and `NONLINEAR`, as well as the definitions of macros corresponding to those variants. Those definitions depend on the value of `VSSMODE`, which is supplied in an external header file `rtwdemo_importedmacros.h`. The active variant is determined by using preprocessor conditionals (`#if`) on the macros (`#define`) `LINEAR` and `NONLINEAR`.

The macros `LINEAR` and `NONLINEAR` are defined in the generated `rtwdemo_preprocessor_types.h` header file:

```
#ifndef LINEAR|
#define LINEAR (VSSMODE == 0)|
#endif|
```

```

|ifndef NONLINEAR|
|define NONLINEAR (VSSMODE == 1)|
|endif|

```

In the generated code, the code related to the variants is guarded by C preprocessor conditionals. For example, in `rtwdemo_preprocessor.c`, the calls to the step and initialization functions of each variant are conditionally compiled:

```

/* Outputs for Atomic SubSystem: '<Root>/Left Controller' */

/* ModelReference: '<S1>/Linear' incorporates:
 * ModelReference: '<S1>/NonLinear'
 */
#if LINEAR

 rtwdemo_linl(&rtb_Add, &rtb_VariantMergeForOutportOut_h,
 &(rtwdemo_preprocessor_DWork.Linear_InstanceData_c.rtdw));

#elif NONLINEAR

 /* ModelReference: '<S1>/NonLinear' */
 rtwdemo_nlinl(&rtb_Add, &rtb_VariantMergeForOutportOut_h,
 &(rtwdemo_preprocessor_DWork.Nonlinear_InstanceData_e.rtdw));

#endif /* LINEAR */

```

Close the model, figure, and workspace variables from the example.

```

bdclose('rtwdemo_preprocessor')
close(findobj(0, 'Tag', 'CloseMe'));
clear LINEAR NONLINEAR VSSMODE
clear tout yout youtl youtnl

```

# Timers in Simulink Coder

## Absolute and Elapsed Time Computation

### In this section...

“About Timers” on page 27-2

“Timers for Periodic and Asynchronous Tasks” on page 27-2

“Allocation of Timers” on page 27-2

“Integer Timers in Generated Code” on page 27-3

“Elapsed Time Counters in Triggered Subsystems” on page 27-3

### About Timers

Certain blocks require the value of either *absolute* time (that is, the time from the start of program execution to the present time) or *elapsed* time (for example, the time elapsed between two trigger events). Targets that support the real-time model (`rtModel`) data structure provide efficient time computation services to blocks that request absolute or elapsed time. Absolute and elapsed timer features include

- Timers are implemented as unsigned integers in generated code.
- In multirate models, at most one timer is allocated per rate. If no blocks executing at a given rate require a timer, a timer is not allocated to that rate. This minimizes memory allocated for timers and significantly reduces overhead involved in maintaining timers.
- Allocation of elapsed time counters for use of blocks within triggered subsystems is minimized, further reducing memory usage and overhead.
- S-function and TLC APIs let your S-functions access timers, in simulation and code generation.
- The word size of the timers is determined by a user-specified maximum counter value that you set with model configuration parameter **Application lifespan (days)**. If you specify this value, timers do not overflow. For more information, see “Control Memory Allocation for Time Counters”.

See “Absolute Time Limitations” for more information about absolute time and the restrictions that it imposes.

### Timers for Periodic and Asynchronous Tasks

Timing services provided for blocks execute within *periodic* tasks (that is, tasks running at the model base rate or subrates).

The code generator also provides timer support for blocks whose execution is *asynchronous* with respect to the periodic timing source of the model. See the following topics:

- “Timers in Asynchronous Tasks” on page 29-39
- “Create a Customized Asynchronous Library” on page 29-41

### Allocation of Timers

If you create or maintain an S-Function block that requires absolute or elapsed time data, it must register the requirement (see “Access Timers Programmatically” on page 27-4). In multirate models, timers are allocated on a per-rate basis. For example, consider a model structured as follows:

- There are three rates, A, B, and C, in the model.
- No blocks running at rate B require absolute or elapsed time.
- Two blocks running at rate C register a requirement for absolute time.
- One block running at rate A registers a requirement for absolute time.

In this case, two timers are generated, running at rates A and C respectively. The timing engine updates the timers as the tasks associated with rates A and C execute. Blocks executing at rates A and C obtain time data from the timers associated with rates A and C.

## Integer Timers in Generated Code

In the generated code, timers for absolute and elapsed time are implemented as unsigned integers. The default size is 64 bits. This is the amount of memory allocated for a timer if you set model configuration parameter **Application lifespan (days)** to `inf`. For an application with a sample rate of 1000 MHz, a 64-bit counter will not overflow for more than 500 years. See “Timers in Asynchronous Tasks” on page 29-39 and “Control Memory Allocation for Time Counters” on page 71-10 for more information.

## Elapsed Time Counters in Triggered Subsystems

Some blocks, such as the Discrete-Time Integrator block, perform computations requiring the elapsed time ( $\Delta T$ ) since the previous block execution. Blocks requiring elapsed time data must register the requirement (see “Access Timers Programmatically” on page 27-4). A triggered subsystem then allocates and maintains a single elapsed time counter if required. This timer functions at the subsystem level, not at the individual block level. The timer is generated if the triggered subsystem (or a unconditionally executed subsystem within the triggered subsystem) contains one or more blocks requiring elapsed time data.

---

**Note** If you are using simplified initialization mode, elapsed time is reset on first execution after becoming enabled, whether or not the subsystem is configured to reset on enable. For more information, see “Underspecified initialization detection”.

## Access Timers Programmatically

### In this section...

“About Timer APIs” on page 27-4

“C API for S-Functions” on page 27-4

“TLC API for Code Generation” on page 27-6

### About Timer APIs

This topic describes APIs that let your S-functions take advantage of the efficiencies offered by absolute and elapsed timers. SimStruct macros are provided for use in simulation, and TLC functions are provided for inlined code generation. Note that

- To generate and use the new timers as described above, your S-functions must register the need to use an absolute or elapsed timer by calling `ssSetNeedAbsoluteTime` or `ssSetNeedElapseTime` in `mdlInitializeSampleTime`.
- Existing S-functions that read absolute time but do not register by using these macros continue to operate as expected, but generate less efficient code.

### C API for S-Functions

The SimStruct macros described in this topic provide access to absolute and elapsed timers for S-functions during simulation.

In the functions below, the SimStruct `*S` argument is a pointer to the `simstruct` of the calling S-function.

- `void ssSetNeedAbsoluteTime(SimStruct *S, boolean b)`: if `b` is `TRUE`, registers that the calling S-function requires absolute time data, and allocates an absolute time counter for the rate at which the S-function executes (if such a counter has not already been allocated).
- `int ssGetNeedAbsoluteTime(SimStruct *S)`: returns 1 if the S-function has registered that it requires absolute time.
- `double ssGetTaskTime(SimStruct *S, tid)`: read absolute time for a given task with task identifier `tid`. `ssGetTaskTime` operates transparently, regardless of whether or not you use the new timer features. `ssGetTaskTime` is documented in the SimStruct Functions chapter of the Simulink documentation.
- `void ssSetNeedElapseTime(SimStruct *S, boolean b)`: if `b` is `TRUE`, registers that the calling S-function requires elapsed time data, and allocates an elapsed time counter for the triggered subsystem in which the S-function executes (if such a counter has not already been allocated). See also “Elapsed Time Counters in Triggered Subsystems” on page 27-3.
- `int ssGetNeedElapseTime(SimStruct *S)`: returns 1 if the S-function has registered that it requires elapsed time.
- `void ssGetElapseTime(SimStruct *S, (double *)elapseTime)`: returns, to the location pointed to by `elapseTime`, the value (as a double) of the elapsed time counter associated with the S-function.
- `void ssGetElapseTimeCounterDtype(SimStruct *S, (int *)dtype)`: returns the data type of the elapsed time counter associated with the S-function to the location pointed to by

`dtype`. This function is intended for use with the `ssGetElapseTimeCounter` function (see below).

- `void ssGetElapseResolution(SimStruct *S, (double *)resolution)`: returns the resolution (that is, the sample time) of the elapsed time counter associated with the S-function to the location pointed to by `resolution`. This function is intended for use with the `ssGetElapseTimeCounter` function (see below).
- `void ssGetElapseTimeCounter(SimStruct *S, (void *)elapseTime)`: This function is provided for the use of blocks that require the elapsed time values for fixed-point computations. `ssGetElapseTimeCounter` returns, to the location pointed to by `elapseTime`, the integer value of the elapsed time counter associated with the S-function. If the counter size is 64 bits, the value is returned as an array of two 32-bit words, with the low-order word stored at the lower address.

To determine how to access the returned counter value, obtain the data type of the counter by calling `ssGetElapseTimeCounterDtype`, as in the following code:

```
int *y_dtype;
ssGetElapseTimeCounterDtype(S, y_dtype);

switch(*y_dtype) {
 case SS_DOUBLE_UINT32:
 {
 uint32_T dataPtr[2];
 ssGetElapseTimeCounter(S, dataPtr);
 }
 break;
 case SS_UINT32:
 {
 uint32_T dataPtr[1];
 ssGetElapseTimeCounter(S, dataPtr);
 }
 break;
 case SS_UINT16:
 {
 uint16_T dataPtr[1];
 ssGetElapseTimeCounter(S, dataPtr);
 }
 break;
 case SS_UINT8:
 {
 uint8_T dataPtr[1];
 ssGetElapseTimeCounter(S, dataPtr);
 }
 break;
 case SS_DOUBLE:
 {
 real_T dataPtr[1];
 ssGetElapseTimeCounter(S, dataPtr);
 }
 break;
 default:
 ssSetErrorStatus(S, "Invalid data type for elapse time
 counter");
 break;
}
```

If you want to use the actual elapsed time, issue a call to the `ssGetElapseTime` function to access the elapsed time directly. You do not need to get the counter value and then calculate the elapsed time.

```
double *y_elapseTime;
.
.
.
ssGetElapseTime(S, elapseTime)
```

## TLC API for Code Generation

The following TLC functions support elapsed time counters in generated code when you inline S-functions by writing TLC scripts for them.

- `LibGetTaskTimeFromTID(block)`: Generates code to read the absolute time for the task in which `block` executes.

`LibGetTaskTimeFromTID` is documented with other sample time functions in the TLC Function Library Reference pages of the Target Language Compiler documentation.

---

**Note** Do not use `LibGetT` for this purpose. `LibGetT` always reads the base rate (`tid 0`) timer. If `LibGetT` is called for a block executing at a subrate, the wrong timer is read, causing serious errors.

---

- `LibGetElapseTime(system)`: Generates code to read the elapsed time counter for `system`. (`system` is the parent system of the calling block.) See “Generate Code for an Elapsed Time Counter” on page 27-7 for an example of code generated by this function.
- `LibGetElapseTimeCounter(system)`: Generates code to read the integer value of the elapsed time counter for `system`. (`system` is the parent system of the calling block.) This function should be used in conjunction with `LibGetElapseTimeCounterDtypeId` and `LibGetElapseTimeResolution`. (See the discussion of `ssGetElapseTimeCounter` above.)
- `LibGetElapseTimeCounterDtypeId(system)`: Generates code that returns the data type of the elapsed time counter for `system`. (`system` is the parent system of the calling block.)
- `LibGetElapseTimeResolution(system)`: Generates code that returns the resolution of the elapsed time counter for `system`. (`system` is the parent system of the calling block.)

## Generate Code for an Elapsed Time Counter

This example shows a model that includes a triggered subsystem, `Amplifier`, consisting of a Discrete-Time Integrator block that uses an elapsed time counter. The model `ex_elapseTime` is in the folder `matlab/help/toolbox/rtw/examples`.

### ex\_elapseTime Model

### Amplifier Subsystem

Code in the generated header file `ex_elapseTime.h` for the model uses 64 bits to implement the timer for the base rate (`clockTick0` and `clockTickH0`).

```

/*
 * Timing:
 * The following substructure contains information regarding
 * the timing information for the model.
 */
struct {
 time_T taskTime0;
 uint32_T clockTick0;
 uint32_T clockTickH0;
 time_T stepSize0;
 time_T tFinal;
 boolean_T stopRequestedFlag;
} Timing;

```

The code generator allocates storage for the previous-time value and elapsed-time value of the `Amplifier` subsystem (`Amplifier_PREV_T`) in the `D_Work(states)` structure in `ex_elapsedTime.h`.

```

/* Block states (auto storage) for system '<Root>' */
typedef struct {
 real_T DiscreteTimeIntegrator_DSTATE;

```

```

 /* '<S1>/Discrete-Time Integrator' */
 int32_T clockTickCounter;
 /* '<Root>/Pulse Generator' */
 uint32_T Amplifier_ELAPS_T[2];
 /* '<Root>/Amplifier' */
 uint32_T Amplifier_PREV_T[2];
 /* '<Root>/Amplifier' */
 } DW_ex_elapseTime_T;

```

The elapsed time computation is performed as follows within the `ex_elapseTime_step` function:

```

/* ---
 Outputs for Triggered SubSystem:
 '<Root>/Amplifier' incorporates:
 TriggerPort: '<S1>/Trigger'
--- */
zcEvent = rt_ZCFcn(RISING_ZERO_CROSSING,
 &ex_elapseTime_PrevZCX.Amplifier_Trig_ZCE,
 ((real_T)rtb_PulseGenerator));
if (zcEvent != NO_ZCEVENT) {
 elapseT_H = ex_elapseTime_M->Timing.clockTickH0 -
 ex_elapseTime_DW.Amplifier_PREV_T[1];
 if (ex_elapseTime_DW.Amplifier_PREV_T[0] >
 ex_elapseTime_M->Timing.clockTick0) {
 elapseT_H--;
 }

 ex_elapseTime_DW.Amplifier_ELAPS_T[0] =
 ex_elapseTime_M->Timing.clockTick0
 - ex_elapseTime_DW.Amplifier_PREV_T[0];
 ex_elapseTime_DW.Amplifier_PREV_T[0] =
 ex_elapseTime_M->Timing.clockTick0;
 ex_elapseTime_DW.Amplifier_ELAPS_T[1] =
 elapseT_H;
 ex_elapseTime_DW.Amplifier_PREV_T[1] =
 ex_elapseTime_M->Timing.clockTickH0;

```

As shown above, the elapsed time is maintained as a state of the triggered subsystem. The Discrete-Time Integrator block finally performs its output and update computations using the elapsed time.

```

/* ---
DiscreteIntegrator: '<S1>/Discrete-Time Integrator'
--- */
OUTPUT = ex_elapseTime_DW.DiscreteTimeIntegrator_DSTATE;

/* ---
Update for DiscreteIntegrator:
 '<S1>/Discrete-Time Integrator' incorporates:
 Constant: '<Root>/Constant'
--- */
ex_elapseTime_DW.DiscreteTimeIntegrator_DSTATE += 0.3 * (real_T)
 ex_elapseTime_DW.Amplifier_ELAPS_T[0] * 1.5;

```

### **More About**

- [“Absolute and Elapsed Time Computation”](#)
- [“Absolute Time Limitations”](#)

## Absolute Time Limitations

*Absolute time* is the time that has elapsed from the beginning of program execution to the present time, as distinct from *elapsed time*, the interval between two events. See “Absolute and Elapsed Time Computation” on page 27-2 for more information.

When you design an application that is intended to run indefinitely, you must take care when logging time values, or using charts or blocks that depend on absolute time. If the value of time reaches the largest value that can be represented by the data type used by the timer to store time, the timer overflows and the logged time or block output is incorrect.

If your target uses `rtModel`, you can avoid timer overflow by specifying a value for model configuration parameter **Application lifespan**. See “Integer Timers in Generated Code” on page 27-3 for more information.

The following limitations apply to absolute time:

- If you log time values by selecting model configuration parameter **Time**, your model uses absolute time.
- Every Stateflow chart that uses time is dependent on absolute time. The only way to eliminate the dependency is to change the Stateflow chart to not use time.
- The following Simulink blocks depend on absolute time:
  - Backlash
  - Chirp Signal
  - Clock
  - Derivative
  - Digital Clock
  - Discrete-Time Integrator (only when used in triggered subsystems)
  - From File
  - From Workspace
  - Pulse Generator
  - Ramp
  - Rate Limiter
  - Repeating Sequence
  - Signal Generator
  - Sine Wave (only when the **Sine type** parameter is set to Time-based)
  - Step
  - To File
  - To Workspace (only when logging to `StructureWithTime` format)
  - Transport Delay
  - Variable Transport Delay

In addition to the Simulink blocks above, blocks in other blocksets may depend on absolute time. See the documentation for the blocksets that you use.

“Single-Tasking Versus Multitasking Operation” on page 28-4

### Sample Time Considerations

Simulink models run at one or more sample times. The Simulink product provides considerable flexibility in building multirate systems, that is, systems with more than one sample time. However, this same flexibility also allows you to construct models for which the code generator cannot generate real-time code for execution in a multitasking environment. To make multirate models operate as expected in real time (that is, to give the right answers), you sometimes must modify your model or instruct the Simulink engine to modify the model for you. In general, the modifications involve placing Rate Transition blocks between blocks that have unequal sample times. The following sections discuss issues you must address to use a multirate model in a multitasking environment. For a comprehensive discussion of sample times, including rate transitions, see “What Is Sample Time?”, “Sample Times in Subsystems”, “Sample Times in Systems”, “Resolve Rate Transitions”, and associated topics.

### Tasking Modes

There are two execution modes for a fixed-step model: single-tasking and multitasking. These modes are available only for fixed-step solvers. To select an execution mode, select model configuration parameter **Treat each discrete rate as a separate task**. When you select this parameter, multitasking execution is applied for a multirate model. When you clear this parameter, single-tasking execution is applied.

---

**Note** A model that is multirate and uses multitasking cannot reference a multirate model that uses single-tasking.

---

Execution of models in a real-time system can be done with the aid of a real-time operating system, or it can be done on *bare-metal* target hardware, where the model runs in the context of an interrupt service routine (ISR).

The fact that a system (such as The Open Group UNIX or Microsoft Windows systems) is multitasking does not imply that your program can execute in real time. This is because the program might not preempt other processes when required.

In operating systems (such as PC-DOS) where only one process can exist at a given time, an interrupt service routine (ISR) must perform the steps of saving the processor context, executing the model code, collecting data, and restoring the processor context.

Other operating systems, such as POSIX-compliant ones, provide automatic context switching and task scheduling. This simplifies the operations performed by the ISR. In this case, the ISR simply enables the model execution task, which is normally blocked. The next figure illustrates this difference.

## Model Execution and Rate Transitions

To generate code that executes as expected in real time, you (or the Simulink engine) might need to identify and handle sample rate transitions within the model. In multitasking mode, by default the Simulink engine flags errors during simulation if the model contains invalid rate transitions. You can use the model configuration parameter **Multitask data transfer** to alter this behavior. Parameter **Single task data transfer** is available for the same purpose for single-tasking mode.

To avoid raising rate transition errors, insert Rate Transition blocks between tasks. You can request that the Simulink engine handle rate transitions automatically by inserting hidden Rate Transition blocks. See “Automatic Rate Transition” on page 28-19 for an explanation of this option.

To understand such problems, first consider how Simulink simulations differ from real-time programs.

## Execution During Simulink Model Simulation

Before the Simulink engine simulates a model, it orders the blocks based upon their topological dependencies. This includes expanding virtual subsystems into the individual blocks they contain and flattening the entire model into a single list. Once this step is complete, each block is executed in order.

The key to this process is the ordering of blocks. A block whose output is directly dependent on its input (that is, a block with direct feedthrough) cannot execute until the block driving its input executes.

Some blocks set their outputs based on values acquired in a previous time step or from initial conditions specified as a block parameter. The output of such a block is determined by a value stored in memory, which can be updated independently of its input. During simulation, computations are performed prior to advancing the variable corresponding to time. This results in computations occurring instantaneously (that is, no computational delay).

## Model Execution in Real Time

A real-time program differs from a Simulink simulation in that the program must execute the model code synchronously with real time. Every calculation results in some computational delay. This means the sample intervals cannot be shortened or lengthened (as they can be in a Simulink simulation), which leads to less efficient execution.

Consider the following timing figure.

Note the processing inefficiency in the sample interval  $t1$ . That interval cannot be compressed to increase execution speed because, by definition, sample times are clocked in real time.

You can circumvent this potential inefficiency by using the multitasking mode. The multitasking mode defines tasks with different priorities to execute parts of the model code that have different sample rates.

See “Multitasking and Pseudomultitasking Modes” on page 28-9 for a description of how this works. It is important to understand that section before proceeding here.

## Single-Tasking Versus Multitasking Operation

Single-tasking programs require longer sample intervals, because all computations must be executed within each clock period. This can result in inefficient use of available CPU time, as shown in the previous figure.

Multitasking mode can improve the efficiency of your program if the model is large and has many blocks executing at each rate.

However, if your model is dominated by a single rate, and only a few blocks execute at a slower rate, multitasking can actually degrade performance. In such a model, the overhead incurred in task switching can be greater than the time required to execute the slower blocks. In this case, it is more efficient to execute all blocks at the dominant rate.

If you have a model that can benefit from multitasking execution, you might need to modify your model by adding Rate Transition blocks (or instruct the Simulink engine to do so) to generate expected results.

For more information about the two modes of execution and examples, see “Modeling for Single-Tasking Execution” on page 28-6 and “Modeling for Multitasking Execution” on page 28-9.

## Modeling for Single-Tasking Execution

### Single-Tasking Mode

You can execute model code in a strictly single-tasking manner. While this mode is less efficient with regard to execution speed, in certain situations, it can simplify your model.

In single-tasking mode, the base sample rate must define a time interval that is long enough to allow the execution of all blocks within that interval.

The next figure illustrates the inefficiency inherent in single-tasking execution.

Single-tasking system execution requires a base sample rate that is long enough to execute one step through the entire model.

### Build a Program for Single-Tasking Execution

To use single-tasking execution, clear model configuration parameter **Treat each discrete rate as a separate task**. If you select the parameter, single-tasking mode is used in the following cases:

- If your model contains one sample time
- If your model contains a continuous and a discrete sample time and the fixed step size is equal to the discrete sample time

### Single-Tasking Execution

This example examines how a simple multirate model executes in both real time and simulation, using a fixed-step solver. It considers operation in both single-tasking and multitasking modes, as determined by setting model configuration parameter **Treat each discrete rate as a separate task**.

The example model is shown in the next figure. The discussion refers to the six blocks of the model as A through F, as labeled in the block diagram.

The execution order of the blocks (indicated in the upper right of each block) has been forced into the order shown by assigning higher priorities to blocks F, E, and D. The ordering shown is one possible valid execution ordering for this model. For more information, see “Simulation Phases in Dynamic Systems”.

The execution order is determined by data dependencies between blocks. In a real-time system, the execution order determines the order in which blocks execute within a given time interval or task. This discussion treats the model's execution order as a given, because it is concerned with the allocation of block computations to tasks, and the scheduling of task execution.

**Note** The discussion and timing diagrams in this section are based on the assumption that the Rate Transition blocks are used in the default (protected) mode, with block parameters **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** selected

This example considers the execution of the above model when model configuration parameter **Treat each discrete rate as a separate task** is cleared, which indicates the single-tasking mode.

In a single-tasking system, if you select model configuration parameter **Block reduction**, fast-to-slow Rate Transition blocks are optimized out of the model. The default case is shown (parameter **Block reduction** selected), so block B does not appear in the timing diagrams in this section. For more information, see “Block reduction”.

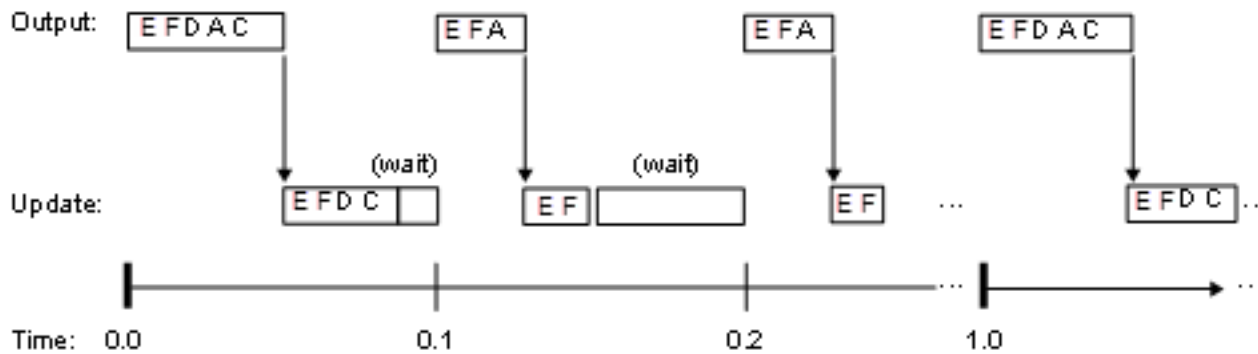

The following table shows, for each block in the model, the execution order, sample time, and whether the block has an output or update computation. Block A does not have discrete states, and accordingly does not have an update computation.

#### Execution Order and Sample Times (Single-Tasking)

Blocks (in Execution Order)	Sample Time (in Seconds)	Output	Update
E	0.1	Y	Y
F	0.1	Y	Y
D	1	Y	Y
A	0.1	Y	N
C	1	Y	Y

#### Real-Time Single-Tasking Execution

The next figure shows the scheduling of computations when the generated code is deployed in a real-time system. The generated program is shown running in real time, under control of interrupts from a 10 Hz timer.

At time 0.0, 1.0, and every second thereafter, both the slow and fast blocks execute their output computations; this is followed by update computations for blocks that have states. Within a given time interval, output and update computations are sequenced in block execution order.

The fast blocks execute on every tick, at intervals of 0.1 second. Output computations are followed by update computations.

The system spends some portion of each time interval (labeled “wait”) idling. During the intervals when only the fast blocks execute, a larger portion of the interval is spent idling. This illustrates an inherent inefficiency of single-tasking mode.

**Simulated Single-Tasking Execution**

The next figure shows the execution of the model during the Simulink simulation loop.

Because time is simulated, the placement of ticks represents the iterations of the simulation loop. Blocks execute in exactly the same order as in the previous figure, but without the constraint of a real-time clock. Therefore there is no idle time between simulated sample periods.

# Modeling for Multitasking Execution

## Multitasking and Pseudomultitasking Modes

When periodic tasks execute in a multitasking mode, by default the blocks with the fastest sample rates are executed by the task with the highest priority, the next fastest blocks are executed by a task with the next higher priority, and so on. Time available in between the processing of high-priority tasks is used for processing lower priority tasks. This results in efficient program execution.

Where tasks are asynchronous rather than periodic, there may not necessarily be a relationship between sample rates and task priorities; the task with the highest priority need not have the fastest sample rate. You specify asynchronous task priorities using Async Interrupt and Task Sync blocks. You can switch the sense of what priority numbers mean by selecting or clearing model configuration parameter **Higher priority value indicates higher task priority**.

In multitasking environments (that is, under a real-time operating system), you can define separate tasks and assign them priorities. For bare-metal target hardware (that is, no real-time operating system present), you cannot create separate tasks. However, generated application modules implement what is effectively a multitasking execution scheme using overlapped interrupts, accompanied by programmatic context switching.

This means an interrupt can occur while another interrupt is currently in progress. When this happens, the current interrupt is preempted, the floating-point unit (FPU) context is saved, and the higher priority interrupt executes its higher priority (that is, faster sample rate) code. Once complete, control is returned to the preempted ISR.

The next figures illustrate how timing of tasks in multirate systems are handled by the code generator in multitasking, pseudomultitasking, and single-tasking environments.

- ↑ Vertical arrows indicate sample time hits.
- ⋮ Dotted lines with downward pointing arrows indicate the release of control to a lower priority task.
- ⋮ Dotted lines with upward pointing arrows indicate preemption by a higher priority task.
- Dark gray areas indicate task execution.
- ▨ Hashed areas indicate task preemption by a higher priority task.
- Light gray areas indicate task execution is pending.

The next figure shows how overlapped interrupts are used to implement pseudomultitasking. In this case, Interrupt 0 does not return until after Interrupts 1, 2, and 3.

## Build a Program for Multitasking Execution

To use multitasking execution, select model configuration parameter **Treat each discrete rate as a separate task**. This parameter is active only if you set **Solver type** to Fixed-step. Auto mode results in a multitasking environment if your model has two or more different sample times. A model with a continuous and a discrete sample time runs in single-tasking mode if the fixed-step size is equal to the discrete sample time.

## Execute Multitasking Models

In cases where the continuous part of a model executes at a rate that is different from the discrete part, or a model has blocks with different sample rates, the Simulink engine assigns each block a *task identifier* (*tid*) to associate the block with the task that executes at the block's sample rate.

You set sample rates and their constraints on the **Solver** pane of the Model Configuration Parameters dialog box. To generate code, select Fixed-step for the solver type. Certain restrictions apply to the sample rates that you can use:

- The sample rate of a block must be an integer multiple of the base (that is, the fastest) sample period.
- When you set model configuration parameter **Periodic sample time constraint** to unconstrained, the base sample period is determined by the setting of parameter **Fixed step size**.
- When you set parameter **Periodic sample time constraint** to Specified, the base rate fixed-step size is the first element of the sample time matrix that you specify for parameter **Sample time properties**. The **Solver** pane from the example model `rtwdemo_mrmtbb` shows an example.

Higher priority value indicates higher task priority

- Continuous blocks execute by using an integration algorithm that runs at the base sample rate. The base sample period is the greatest common denominator of rates in the model only when you set model configuration parameter **Periodic sample time constraint** to Unconstrained and parameter **Fixed step size** to Auto.
- The continuous and discrete parts of the model can execute at different rates only if the discrete part is executed at the same or a slower rate than the continuous part and is an integer multiple of the base sample rate.

## Multitasking Execution

This example examines how a simple multirate model executes in both real time and simulation, using a fixed-step solver. It considers operation in both single-tasking and multitasking modes, as determined by setting model configuration parameter **Treat each discrete rate as a separate task**.

The example model is shown in the next figure. The discussion refers to the six blocks of the model as A through F, as labeled in the block diagram.

The execution order of the blocks (indicated in the upper right of each block) has been forced into the order shown by assigning higher priorities to blocks F, E, and D. The ordering shown is one possible valid execution ordering for this model. For more information, see “Simulation Phases in Dynamic Systems”.

The execution order is determined by data dependencies between blocks. In a real-time system, the execution order determines the order in which blocks execute within a given time interval or task. This discussion treats the model's execution order as a given, because it is concerned with the allocation of block computations to tasks, and the scheduling of task execution.

---

**Note** The discussion and timing diagrams in this section are based on the assumption that the Rate Transition blocks are used in the default (protected) mode, with block parameters **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** selected

---

This example considers the execution of the preceding model when model configuration parameter **Tasking mode** is set to **MultiTasking**. Block computations are executed under two tasks, prioritized by rate:

- The slower task, which gets the lower priority, is scheduled to run every second. This is called the *1 second task*.
- The faster task, which gets higher priority, is scheduled to run 10 times per second. This is called the *0.1 second task*. The 0.1 second task can preempt the 1 second task.

The following table shows, for each block in the model, the execution order, the task under which the block runs, and whether the block has an output or update computation. Blocks A and B do not have discrete states, and accordingly do not have an update computation.

**Task Allocation of Blocks in Multitasking Execution**

Blocks (in Execution Order)	Task	Output	Update
E	0.1 second task	Y	Y
F	0.1 second task	Y	Y
D	The Rate Transition block uses port-based sample times. Output runs at the output port sample time under 0.1 second task. Update runs at input port sample time under 1 second task. For more information on port-based sample times, see "Referenced Model Sample Times".	Y	Y
A	0.1 second task	Y	N
B	The Rate Transition block uses port-based sample times. Output runs at the output port sample time under 0.1 second task. For more information on port-based sample times, see "Referenced Model Sample Times".	Y	N
C	1 second task	Y	Y

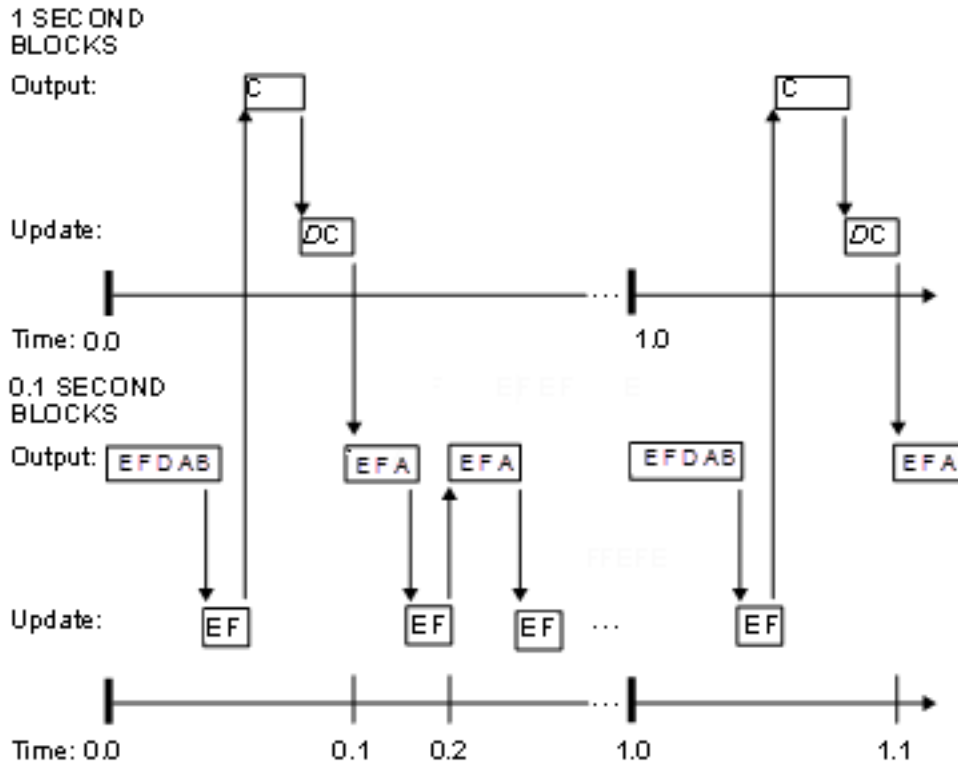

**Real-Time Multitasking Execution**

The next figure shows the scheduling of computations in MultiTasking solver mode when the generated code is deployed in a real-time system. The generated program is shown running in real time, as two tasks under control of interrupts from a 10 Hz timer.

## Simulated Multitasking Execution

The next figure shows the Simulink execution of the same model, in `MultiTasking` solver mode. In this case, the Simulink engine runs the blocks in one thread of execution, simulating multitasking. No preemption occurs.

## Handle Rate Transitions

### Rate Transitions

Two periodic sample rate transitions can exist within a model:

- A faster block driving a slower block
- A slower block driving a faster block

The following sections concern models with periodic sample times with zero offset only. Other considerations apply to multirate models that involve asynchronous tasks. For details on how to generate code for asynchronous multitasking, see “Asynchronous Support”.

In multitasking and pseudomultitasking systems, differing sample rates can cause blocks to be executed in the wrong order. To prevent possible errors in calculated data, you must control model execution at these transitions. When connecting faster and slower blocks, you or the Simulink engine must add Rate Transition blocks between them. Fast-to-slow transitions are illustrated in the next figure.

Slow-to-fast transitions are illustrated in the next figure.

---

**Note** Although the Rate Transition block offers a superset of the capabilities of the Unit Delay block (for slow-to-fast transitions) and the Zero-Order Hold block (for fast-to-slow transitions), you should use the Rate Transition block instead of these blocks.

---

## Data Transfer Problems

Rate Transition blocks deal with issues of data integrity and determinism associated with data transfer between blocks running at different rates.

- *Data integrity*: A problem of data integrity exists when the input to a block changes during the execution of that block. Data integrity problems can be caused by preemption.

Consider the following scenario:

- A faster block supplies the input to a slower block.
- The slower block reads an input value  $V_1$  from the faster block and begins computations using that value.
- The computations are preempted by another execution of the faster block, which computes a new output value  $V_2$ .
- A data integrity problem now arises: when the slower block resumes execution, it continues its computations, now using the “new” input value  $V_2$ .

Such a data transfer is called *unprotected*. “Faster to Slower Transitions in Real Time” on page 28-22 shows an unprotected data transfer.

In a *protected* data transfer, the output  $V_1$  of the faster block is held until the slower block finishes executing.

- *Deterministic* versus *nondeterministic* data transfer: In a *deterministic* data transfer, the timing of the data transfer is completely predictable, as determined by the sample rates of the blocks.

The timing of a *nondeterministic* data transfer depends on the availability of data, the sample rates of the blocks, and the time at which the receiving block begins to execute relative to the driving block.

You can use the Rate Transition block to protect data transfers in your application and make them deterministic. These characteristics are considered desirable in most applications. However, the Rate Transition block supports flexible options that allow you to compromise data integrity and determinism in favor of lower latency. The next section summarizes these options.

## Data Transfer Assumptions

When processing data transfers between tasks, the code generator makes these assumptions:

- Data transitions occur between a single reading task and a single writing task.
- A read or write of a byte-sized variable is atomic.
- When two tasks interact through a data transition, only one of them can preempt the other.
- For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task preempts the slower rate task.
- All tasks run on a single processor. Time slicing is not allowed.

- Processes do not crash or restart (especially while data is transferred between tasks).

## Rate Transition Block Options

Several parameters of the Rate Transition block are relevant to its use in code generation for real-time execution, as discussed below. For a complete block description, see Rate Transition.

The Rate Transition block handles periodic (fast to slow and slow to fast) and asynchronous transitions. When inserted between two blocks of differing sample rates, the Rate Transition block automatically configures its input and output sample rates for the type of transition; you do not need to specify whether a transition is slow-to-fast or fast-to-slow (low-to-high or high-to-low priorities for asynchronous tasks).

The critical decision you must make in configuring a Rate Transition block is the choice of data transfer mechanism to be used between the two rates. Your choice is dictated by considerations of safety, memory usage, and performance. As the Rate Transition block parameter dialog box in the next figure shows, the data transfer mechanism is controlled by two options.

- **Ensure data integrity during data transfer:** When you select this parameter, data transferred between rates maintains its integrity (the data transfer is protected). When you clear this parameter, data might not maintain its integrity (the data transfer is unprotected). By default, parameter **Ensure data integrity during data transfer** is selected.
- **Ensure deterministic data transfer (maximum delay):** This parameter is supported for periodic tasks with an offset of zero and fast and slow rates that are multiples of each other. When this parameter is selected, the Rate Transition block behaves like a Zero-Order Hold block (for fast to slow transitions) or a Unit Delay block (for slow to fast transitions). The Rate Transition

block controls the timing of data transfer in a completely predictable way. When this parameter is cleared, the data transfer is nondeterministic. By default, **Ensure deterministic data transfer (maximum delay)** is selected for transitions between periodic rates with an offset of zero; for asynchronous transitions, it cannot be selected.

The Rate Transition block offers three modes of operation with respect to data transfer. In order of level of safety:

- **Protected/Deterministic (default):** This is the safest mode. The drawback of this mode is that it introduces deterministic latency into the system for the case of slow-to-fast periodic rate transitions. For that case, the latency introduced by the Rate Transition block is one sample period of the slower task. For the case of fast-to-slow periodic rate transitions, the Rate Transition block does not introduce additional latency.
- **Protected/NonDeterministic:** In this mode, for slow-to-fast periodic rate transitions, data integrity is protected by double-buffering data transferred between rates. For fast-to-slow periodic rate transitions, a semaphore flag is used. The blocks downstream from the Rate Transition block use the latest available data from the block that drives the Rate Transition block. Maximum latency is less than or equal to one sample period of the faster task.

The drawbacks of this mode are its nondeterministic timing. The advantage of this mode is its low latency.

- **Unprotected/NonDeterministic:** This mode is not recommended for mission-critical applications. The latency of this mode is the same as for Protected/NonDeterministic mode, but memory requirements are reduced since neither double-buffering nor semaphores are required. That is, the Rate Transition block does nothing in this mode other than to pass signals through; it simply exists to notify you that a rate transition exists (and can cause generated code to compute incorrect answers). Selecting this mode, however, generates the least amount of code.

---

**Note** In unprotected mode (**Ensure data integrity during data transfer** is selected), the Rate Transition block does nothing other than allow the rate transition to exist in the model.

---

### Rate Transition Blocks and Continuous Time

The sample time at the output port of a Rate Transition block can only be discrete or fixed in minor time step. This means that when a Rate Transition block inherits continuous sample time from its destination block, it treats the inherited sample time as Fixed in Minor Time Step. Therefore, the output function of the Rate Transition block runs only at major time steps. If the destination block sample time is continuous, Rate Transition block output sample time is the base rate sample time (if solver is fixed-step), or zero-order-hold-continuous sample time (if solver is variable-step).

### Automatic Rate Transition

The Simulink engine can detect mismatched rate transitions in a multitasking model during an update diagram and automatically insert Rate Transition blocks to handle them. To enable this, select model configuration parameter **Automatically handle rate transition for data transfer**. By default, this parameter is cleared. When you select this parameter:

- Simulink handles transitions between periodic sample times and asynchronous tasks.
- Simulink inserts hidden Rate Transition blocks in the block diagram.

- The code generator produces code for the Rate Transition blocks that were automatically inserted. This code is identical to the code generated for Rate Transition blocks that were inserted manually.
- Automatically inserted Rate Transition blocks operate in protected mode for periodic tasks and asynchronous tasks. You cannot alter this behavior. For periodic tasks, automatically inserted Rate Transition blocks operate with the level of determinism specified by model configuration parameter **Deterministic data transfer**. The default setting is *Whenever possible*, which enables determinism for data transfers between periodic sample-times that are related by an integer multiple. For more information, see “Deterministic data transfer”. To use other modes, you must insert Rate Transition blocks and set their modes manually.

For example, in this model, SineWave2 has a sample time of 2, and SineWave3 has a sample time of 3.

When you select model configuration parameter **Automatically handle rate transition for data transfer**, Simulink inserts a Rate Transition block between each Sine Wave block and the Product block. The inserted blocks have the parameter values to reconcile the Sine Wave block sample times.

If the input port and output port data sample rates in a model are not multiples of each other, Simulink inserts a Rate Transition block whose sample rate is the greatest common divisor (GCD) of the two rates. If no other block in the model contains this new rate, an error occurs during simulation. In this case, you must insert a Rate Transition block manually.

## Visualize Inserted Rate Transition Blocks

When you select model configuration parameter **Automatically handle rate transition for data transfer**, Simulink inserts Rate Transition blocks in the paths that have mismatched transition rates. These blocks are hidden by default. To visualize the inserted blocks, update the diagram. Badge labels appear in the model and indicate where Simulink inserted Rate Transition blocks during the compilation phase. For example, in this model, three Rate Transition blocks were inserted between the two Sine Wave blocks and the Multiplexer and Integrator when the model compiled. The ZOH and DbBuf badge labels indicate these blocks.

You can show or hide badge labels. Open the **Debug** tab. In the **Diagnostics** section of the **Information Overlays/Sample Time** gallery select or clear **Automatic Rate Transitions**.

To configure the hidden Rate Transition blocks so that the blocks are visible, right-click a badge label and click **Insert rate transition block**.

When you make hidden Rate Transition blocks visible:

- You can see the type of Rate Transition block inserted and the location of the block in the model.
- You can set the block parameter **Initial Conditions**.
- You can change block parameter settings for rate transfer.

Validate the changes to your model by updating your diagram.

Displaying inserted Rate Transition blocks is not compatible with export-function models. To learn more about the types of Rate Transition blocks, see Rate Transition.

## Periodic Sample Rate Transitions

These sections describe cases in which Rate Transition blocks are required for periodic sample rate transitions. The discussion and timing diagrams in these sections are based on the assumption that the Rate Transition block is used in its default (protected/deterministic) mode. Model configuration parameters **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** are selected. These are the settings used for automatically inserted Rate Transition blocks.

### Faster to Slower Transitions in a Simulink Model

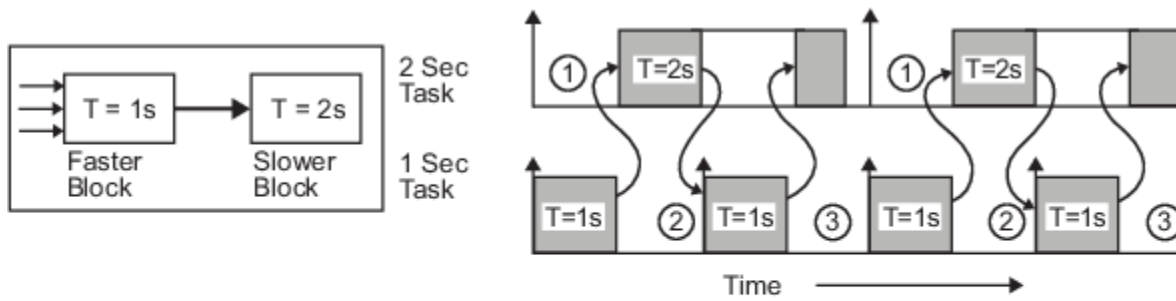

In a model where a faster block drives a slower block having direct feedthrough, the outputs of the faster block are computed first. In simulation intervals where the slower block does not execute, the simulation progresses more rapidly because there are fewer blocks to execute. The next figure illustrates this situation.

A Simulink simulation does not execute in real time, which means that it is not bound by real-time constraints. The simulation waits for, or moves ahead to, whatever tasks are required to complete simulation flow. The actual time interval between sample time steps can vary.

### Faster to Slower Transitions in Real Time

In models where a faster block drives a slower block, you must compensate for the fact that execution of the slower block might span more than one execution period of the faster block. This means that the outputs of the faster block can change before the slower block has finished computing its outputs. The next figure shows a situation in which this problem arises ( $T = \text{sample time}$ ). Note that lower priority tasks are preempted by higher priority tasks before completion.

- ① The faster task (T=1s) completes.
- ② Higher priority preemption occurs.
- ③ The slower task (T=2s) resumes and its inputs have changed. This leads to unpredictable results.

In the above figure, the faster block executes a second time before the slower block has completed execution. This can cause unpredictable results because the input data to the slow task is changing. Data might not maintain its integrity in this situation.

To avoid this situation, the Simulink engine must hold the outputs of the 1 second (faster) block until the 2 second (slower) block finishes executing. The way to accomplish this is by inserting a Rate Transition block between the 1 second and 2 second blocks. The input to the slower block does not change during its execution, maintaining data integrity.

It is assumed that the Rate Transition block is used in its default (protected/deterministic) mode.

The Rate Transition block executes at the sample rate of the slower block, but with the priority of the faster block.

When you add a Rate Transition block, the block executes before the 2 second block (its priority is higher) and its output value is held constant while the 2 second block executes (it executes at the slower sample rate).

### Slower to Faster Transitions in a Simulink Model

In a model where a slower block drives a faster block, the Simulink engine again computes the output of the driving block first. During sample intervals where only the faster block executes, the simulation progresses more rapidly.

The next figure shows the execution sequence.

As you can see from the preceding figures, the Simulink engine can simulate models with multiple sample rates in an efficient manner. However, a Simulink simulation does not operate in real time.

### Slower to Faster Transitions in Real Time

In models where a slower block drives a faster block, the generated code assigns the faster block a higher priority than the slower block. This means the faster block is executed before the slower block, which requires special care to avoid incorrect results.

- ① The faster block executes a second time prior to the completion of the slower block.
- ② The faster block executes before the slower block.

This timing diagram illustrates two problems:

- Execution of the slower block is split over more than one faster block interval. In this case the faster task executes a second time before the slower task has completed execution. This means the inputs to the faster task can have incorrect values some of the time.
- The faster block executes before the slower block (which is backward from the way a Simulink simulation operates). In this case, the 1 second block executes first; but the inputs to the faster task have not been computed. This can cause unpredictable results.

To eliminate these problems, you must insert a Rate Transition block between the slower and faster blocks.

It is assumed that the Rate Transition block is used in its default (protected/deterministic) mode.

The next figure shows the timing sequence that results with the added Rate Transition block.

Three key points about transitions in this diagram (refer to circled numbers):

- 1 The Rate Transition block output runs in the 1 second task, but at a slower rate (2 seconds). The output of the Rate Transition block feeds the 1 second task blocks.
- 2 The Rate Transition update uses the output of the 2 second task to update its internal state.
- 3 The Rate Transition output in the 1 second task uses the state of the Rate Transition that was updated in the 2 second task.

The first problem is alleviated because the Rate Transition block is updating at a slower rate and at the priority of the slower block. The input to the Rate Transition block (which is the output of the slower block) is read after the slower block completes executing.

The second problem is alleviated because the Rate Transition block executes at a slower rate and its output does not change during the computation of the faster block it is driving. The output portion of a Rate Transition block is executed at the sample rate of the slower block, but with the priority of the faster block. Since the Rate Transition block drives the faster block and has effectively the same priority, it is executed before the faster block.

**Note** This use of the Rate Transition block changes the model. The output of the slower block is now delayed by one time step compared to the output without a Rate Transition block.

## Protect Data Integrity with volatile Keyword

When you select model configuration parameter **Ensure data integrity during data transfer**, the code generated for a Rate Transition block defines global buffers and semaphores and uses them to protect the integrity of the transferred data.

Particularly for a multitasking application, the tasks (rates) involved in a data transfer can write to the transferred data, buffers, and semaphores at times that your compiler cannot anticipate. To prevent your compiler from optimizing the assembly code in a manner that compromises the integrity of the transferred data, the code generator applies the keyword `volatile` to the buffers and semaphores. The code generator does not apply `volatile` to the global variable that represents the transferred data because the `volatile` buffers and semaphores typically offer enough protection.

With Embedded Coder, you can explicitly apply `volatile` to the transferred data by applying the built-in custom storage class `Volatile` to the input of the Rate Transition block. For example, you can use this technique to help protect the integrity of data that your external code shares with the generated code.

Alternatively, to protect data that your external code shares with the generated code, you can write your own C functions that read and write the data in a protected manner. Then, you can apply the custom storage class `GetSet` to the data in the model, which causes the generated code to call your functions instead of directly accessing the data.

For more information about applying `volatile`, see “Protect Global Data with `const` and `volatile` Type Qualifiers” on page 42-13. For more information about `GetSet`, see “Access Data Through Functions with Storage Class `GetSet`” on page 37-25.

## Separate Rate Transition Block Code and Data from Algorithm Code and Data

You can specify whether the code generator inlines code and data it produces for Rate Transition blocks with model code or places the code and data in separate functions that the model code calls. You control this by selecting the **Rate Transition block code** parameter. Separating Rate Transition block code and data from algorithm code and data enables you to independently analyze, optimize, and test Rate Transition block and algorithm code. By default, Rate Transition block code is set inline with algorithm code and data. You can separate the code and data so that the generated code contains separate `get` and `set` functions that the `model_step` functions call and a dedicated structure for state data. The generated code also contains separate `start` and `initialize` functions that the `model_initialize` function calls.

### Example Model

Open the example model `rtwdemo_ratetrans`. This multirate, multitasking model contains several Rate Transition blocks operating at different modes.

```
open_system('rtwdemo_ratetrans');
set_param('rtwdemo_ratetrans','SystemTargetFile','ert.tlc');
set_param('rtwdemo_ratetrans','GenerateComments','Off');
```

### Separate Code for Rate Transition blocks

In the Configuration Parameters dialog box, the **Rate Transition block code** parameter is set to `Function`. Generate code for the model. The code is in the files `rtwdemo_ratetrans.c` and `rtwdemo_ratetrans.h`.

```

currentDir = pwd;
[~,cgDir] = rtwdemodir();
slbuild('rtwdemo_ratetrans');

Starting build procedure for: rtwdemo_ratetrans
Successful completion of build procedure for: rtwdemo_ratetrans

rtM->Timing.clockTick1++;
}

void rtwdemo_ratetrans_initialize(void)
{
 rtDW.bitsForTID1.Algorithm_RESET_ELAPS_T = true;
 rtDW.Integrator1_SYSTEM_ENABLE = 1U;
 rtDW.Integrator2_SYSTEM_ENABLE = 1U;
 rtDW.Integrator3_SYSTEM_ENABLE = 1U;
}

```

The code is inlined in functions `rtwdemo_ratetrans_step0` and `rtwdemo_ratetrans_step1`.

### Limitation

The code generator does not separate the code and data for Rate Transition blocks that have variable-size signals or are inside of a For Each Subsystem block.

## Configure Time-Based Scheduling

For details about solver options, see “Solver Pane”.

### Configure Start and Stop Times

The value of model configuration parameter **Stop time** must be greater than or equal to the value of parameter **Start time**. If the stop time is zero, or if the total simulation time (Stop minus Start) is less than zero, the generated program runs for one step. If the stop time is set to `inf`, the generated program runs indefinitely.

When using the GRT or ERT targets, you can override the stop time when running a generated program from the Microsoft Windows command prompt or UNIX<sup>3</sup> command line. To override the stop time that was set during code generation, use the `-tf` switch.

```
model -tf n
```

The program runs for `n` seconds. If `n = inf`, the program runs indefinitely.

Certain blocks have a dependency on absolute time. If you are designing a program that is intended to run indefinitely (model configuration parameter **Stop time** = `inf`), and your generated code does not use the `rtModel` data structure (that is, it uses `simstructs` instead), you must not use these blocks. See “Absolute Time Limitations” on page 27-10 for a list of blocks that can potentially overflow timers.

If you know how long an application that depends on absolute time needs to run, you can prevent the timers from overflowing and force the use of optimal word sizes by selecting model configuration parameter **Application lifespan (days)**. See “Control Memory Allocation for Time Counters” on page 71-10 for details.

### Configure the Solver Type

For code generation, you must configure a model to use a fixed-step solver for system target files except for S-function and RSim system target files. You can configure the S-function and RSim targets with a fixed-step or variable-step solver.

### Configure the Tasking Mode

The code generator supports both single-tasking and multitasking modes for periodic sample times. See “Time-Based Scheduling and Code Generation” on page 28-2 for details.

## Time-Based Scheduling Example Models

### Optimize Memory Usage for Time Counters

This example shows how to optimize the amount of memory that the code generator allocates for time counters. The example optimizes the memory that stores elapsed time, the interval of time between two events.

The code generator represents time counters as unsigned integers. The word size of time counters is based on the setting of the model configuration parameter **Application lifespan (days)**, which specifies the expected maximum duration of time the application runs. You can use this parameter to prevent time counter overflows. The default size is 64 bits.

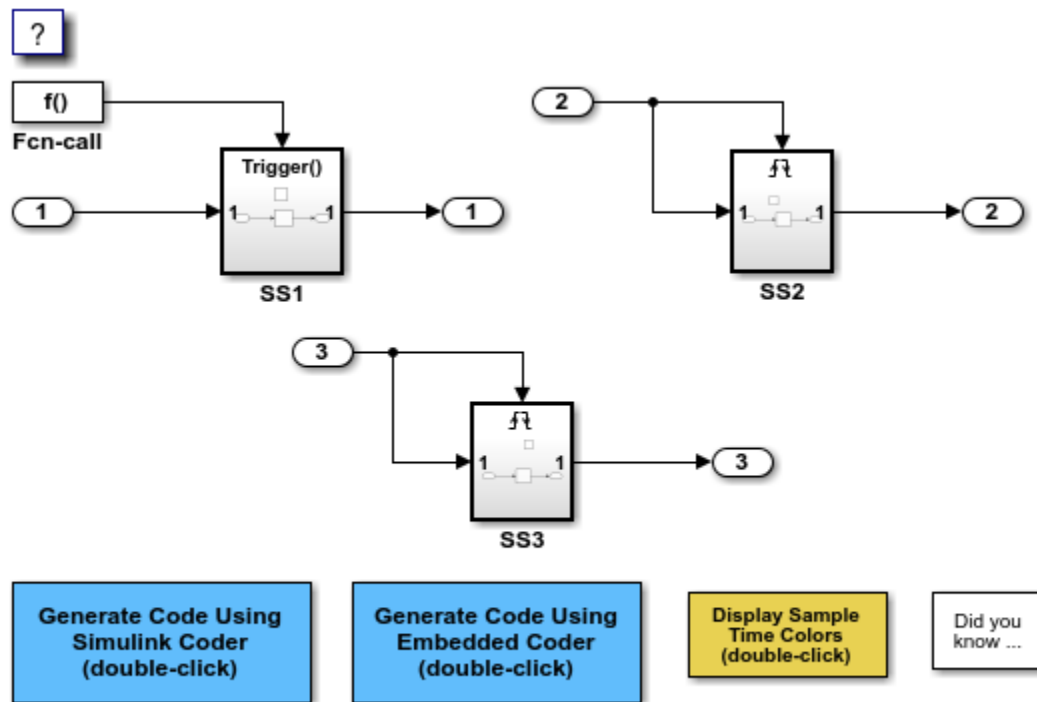

The number of bits that a time counter uses depends on the setting of the **Application lifespan (days)** parameter. For example, if a time counter increments at a rate of 1 kHz, to avoid an overflow, the counter has the following number of bits:

- Lifespan < 0.25 sec: 8 bits
- Lifespan < 1 min: 16 bits
- Lifespan < 49 days: 32 bits
- Lifespan > 50 days: 64 bits

A 64-bit time counter does not overflow for 590 million years.

#### Open Example Model

Open the example model `rtwdemo_abstime`.

Copyright 1994-2020 The MathWorks, Inc.

The model consists of three subsystems SS1, SS2, and SS3. Open the Model Configuration Parameters dialog box. On the **Math and Data Types** pane, the **Application lifespan (days)** parameter is set to the default, which is `inf`.

The three subsystems contain a discrete-time integrator that requires elapsed time as input to compute its output value. The subsystems vary as follows:

- SS1 - Clocked at 1 kHz. Does not require a time counter. **Sample time type** parameter for trigger port is set to `periodic`. Elapsed time is inlined as 0.001.
- SS2 - Clocked at 100 Hz. Requires a time counter. Based on a lifespan of 1 day, a 32-bit counter stores the elapsed time.
- SS3 - Clocked at 0.5 Hz. Requires a time counter. Based on a lifespan of 1 day, a 16-bit counter stores the elapsed time.

### Simulate the Model

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for the three subsystems appear red, green, and blue. Triggered subsystems are blue-green.

### Generate Code and Report

1. Create a temporary folder for the build and inspection process.
2. Configure the model for the code generator to use the GRT system target file and a lifespan of `inf` days.

### 3. Build the model.

```
Starting build procedure for: rtwdemo_abstime
Successful completion of build procedure for: rtwdemo_abstime
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason

1 of 1 models built (0 models already up to date)

Build duration: 0h 0m 22.027s

#### Review Generated Code

Open the generated source file `rtwdemo_abstime.h`.

```
struct tag_RTM_rtwdemo_abstime_T {
 const char_T *errorStatus;

 /*
 * Timing:
 * The following substructure contains information regarding
 * the timing information for the model.
 */
 struct {
 uint32_T clockTick1;
 uint32_T clockTickH1;
 uint32_T clockTick2;
 uint32_T clockTickH2;
 struct {
 uint16_T TID[3];
 uint16_T cLimit[3];
 } TaskCounters;
 } Timing;
};

/* Block states (default storage) */
extern DW_rtwdemo_abstime_T rtwdemo_abstime_DW;

/* Zero-crossing (trigger) state */
extern PrevZCX_rtwdemo_abstime_T rtwdemo_abstime_PrevZCX;

/* External inputs (root inport signals with default storage) */
extern ExtU_rtwdemo_abstime_T rtwdemo_abstime_U;

/* External outputs (root outports fed by signals with default storage) */
extern ExtY_rtwdemo_abstime_T rtwdemo_abstime_Y;

/* Model entry point functions */
extern void rtwdemo_abstime_initialize(void);
extern void rtwdemo_abstime_step0(void);
extern void rtwdemo_abstime_step1(void);
extern void rtwdemo_abstime_step2(void);
```

```

extern void rtwdemo_abstime_terminate(void);

/* Real-time Model object */
extern RT_MODEL_rtwdemo_abstime_T *const rtwdemo_abstime_M;

/*-
 * The generated code includes comments that allow you to trace directly
 * back to the appropriate location in the model. The basic format
 * is <system>/block_name, where system is the system number (uniquely
 * assigned by Simulink) and block_name is the name of the block.
 *
 * Use the MATLAB hilite_system command to trace the generated code back
 * to the model. For example,
 *
 * hilite_system('<S3>') - opens system 3
 * hilite_system('<S3>/Kp') - opens and selects block Kp which resides in S3
 *
 * Here is the system hierarchy for this model
 *
 * '<Root>' : 'rtwdemo_abstime'
 * '<S1>' : 'rtwdemo_abstime/SS1'
 * '<S2>' : 'rtwdemo_abstime/SS2'
 * '<S3>' : 'rtwdemo_abstime/SS3'
 */
#endif
/* RTW_HEADER_rtwdemo_abstime_h_ */

```

Four 32-bit unsigned integers, `clockTick1`, `clockTickH1`, `clockTick2`, and `clockTickH2` are counters for storing the elapsed time of subsystems SS2 and SS3.

### Enable Optimization and Regenerate Code

1. Reconfigure the model to set the lifespan to 1 day.
2. Build the model.

```

Starting build procedure for: rtwdemo_abstime
Successful completion of build procedure for: rtwdemo_abstime

```

Build Summary

/* Model entry point functions */
extern void rtdemo_abstime_initialize(void);
extern void rtdemo_abstime_step0(void);
extern void rtdemo_abstime_step1(void);
extern void rtdemo_abstime_step2(void);
extern void rtdemo_abstime_terminate(void);

/* Real-time Model object */
extern RT_MODEL_rtdemo_abstime_T *const rtdemo_abstime_M;

/*-
 * The generated code includes comments that allow you to trace directly
 * back to the appropriate location in the model. The basic format
 * is <system>/block_name, where system is the system number (uniquely
 * assigned by Simulink) and block_name is the name of the block.
 *
 * Use the MATLAB hilite_system command to trace the generated code back
 * to the model. For example,
 *
 * hilite_system('<S3>') - opens system 3
 * hilite_system('<S3>/Kp') - opens and selects block Kp which resides in S3
 *
 * Here is the system hierarchy for this model
 *
 * '<Root>' : 'rtdemo_abstime'
 * '<S1>' : 'rtdemo_abstime/SS1'
 * '<S2>' : 'rtdemo_abstime/SS2'
 * '<S3>' : 'rtdemo_abstime/SS3'
 */
#endif
/* RTW_HEADER_rtdemo_abstime_h_ */

```

The new setting for the **Application lifespan (days)** parameter instructs the code generator to set aside less memory for the time counters. The regenerated code includes:

- 32-bit unsigned integer, `clockTick1`, for storing the elapsed time of the task for SS2
- 16-bit unsigned integer, `clockTick2`, for storing the elapsed time of the task for SS3

## Single-Rate Modeling (Bare Board, No OS)

This model shows code generation for a single-rate discrete-time model configured for a bare-board target (one with no operating system).

### Open Example Model

Open the example model `rtwdemo_srb`.

```
open_system('rtwdemo_srb')
```

Copyright 1994-2020 The MathWorks, Inc.

The model uses one sample time and is configured to display sample-time colors when an update diagram occurs. Inport blocks `In1_1s` and `In2_1s` specify a 1-second sample time, which is enforced by the setting of model configuration parameter **Periodic sample time constraint**.

The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.

Because the model is configured with one sample time, the model appears red, which is the color that represents the fastest discrete sample time in the model.

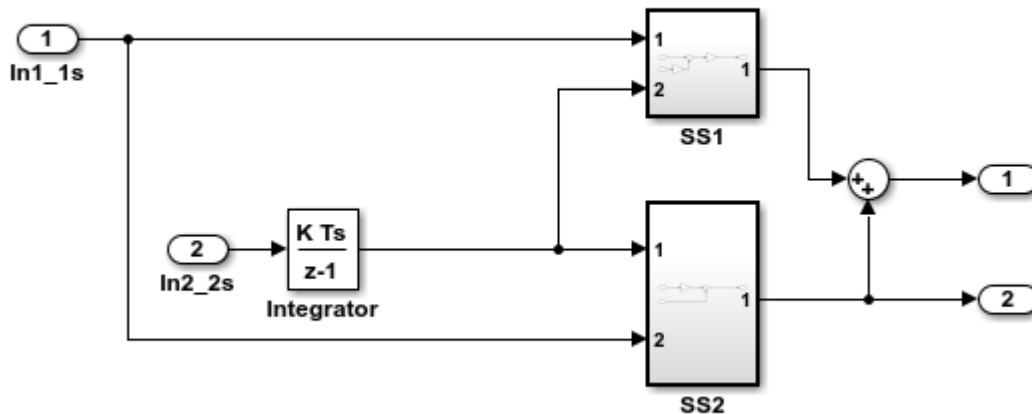

## Multirate Modeling in Single-Tasking Mode (Bare Board, no OS)

This model shows the code generated for a multirate discrete-time model configured for single-tasking on a bare-board target (one with no operating system).

### Open Example Model

Open the example model `rtwdemo_mrstbb`.

```
open_system('rtwdemo_mrstbb')
```

Copyright 1994-2020 The MathWorks, Inc.

The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the setting of model configuration parameter **Periodic sample time constraint**. The solver is set for single-tasking operation. Rate transition blocks are, therefore, not included between blocks executing at different sample times because preemption will not occur.

The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times.

## Multirate Modeling in Multitasking Mode (Bare Board, no OS)

This model shows the code generated for a multirate discrete-time model configured for a multitasking bare-board target (one with no operating system).

### Open Example Model

Open the example model `rtwdemo_mrmtbb`.

```
open_system('rtwdemo_mrmtbb')
```

Copyright 1994-2020 The MathWorks, Inc.

### Explore Example Model

The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the setting of model configuration parameter **Periodic sample time constraint**. The solver is set for multitasking operation, which means a rate transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Proper rate transitions are always enforced by Simulink and Simulink Coder. This model specifies an explicit rate transition block. Alternatively, this block could be automatically inserted by Simulink setting model configuration parameter **Automatically handle rate transition for data transfer**.

The model is configured to display sample-time colors upon diagram update. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times.

### Data Transfer Assumptions

Basis of operation for data transfers between tasks:

- Data transitions occur between a single reading task and a single writing task.
- A read or write of a byte sized variable is atomic.
- When two tasks interact through a data transition, only one of them can preempt the other.
- For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task always preempts the slower rate task.
- Tasks run on a single processor. Time slicing is not allowed.

- Processes do not crash and restart (especially while data is being transferred between tasks)

## Multirate Modeling in Multitasking Mode (VxWorks® OS)

This example generates code for a multirate discrete-time model configured for a multitasking operating system target (VxWorks®). The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the setting of model configuration parameter **Periodic sample time constraint**. The solver is set for multitasking operation, which means a Rate Transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Simulink® and the code generator enforce proper rate transitions. This model specifies an explicit Rate Transition block. Alternatively, you can instruct Simulink® to insert this block for you by setting model configuration parameter **Automatically handle rate transition for data transfer**.

The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing Ctrl+D. To display the legend, press Ctrl+J. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times.

## Trade Determinism and Data Integrity to Improve System Performance

This model shows the differences in the operation modes of the Rate Transition block when used in a multirate, multitasking model. The flexible options for the Rate Transition block allow you to select the mode that is best suited for your application. You can trade levels of determinism and data integrity to improve system performance.

### Rate Transition Block Modes of Operation

**Ensure data integrity and determinism (DetAndInteg)** : Data is transferred such that all data bytes for the signal (including all elements of a wide signal) are from the same time step. Additionally,

it is ensured that the relative sample time (delay) from which the data is transferred from one rate to another is always the same. Only ANSI-C code is used, no target specific 'critical section' protection is needed.

**Ensure integrity (IntegOnly)** : Data is transferred such that all data bytes for the signal (including all elements of a wide signal) are from the same time step. However, from one transfer of data to the next, the relative sample time (delay) for which the data is transferred can vary. In this mode, the code to read/write the data is run more often than in the DetandInt mode. In the worst case, the delay is equivalent to the DetandInt mode, but the delay can be less which is important in some applications. Also, this mode supports data transfers to/from asynchronous rates which the DetandInt mode cannot support. Only ANSI-C code is used, no target specific 'critical section' protection is needed.

**No data consistency operations are performed (None)** : For this case, the Rate Transition block does not generate code. This mode is acceptable in some applications where atomic access of scalar data types is guaranteed and when the relative temporal values of the data is not important. This mode does not introduce any delay.

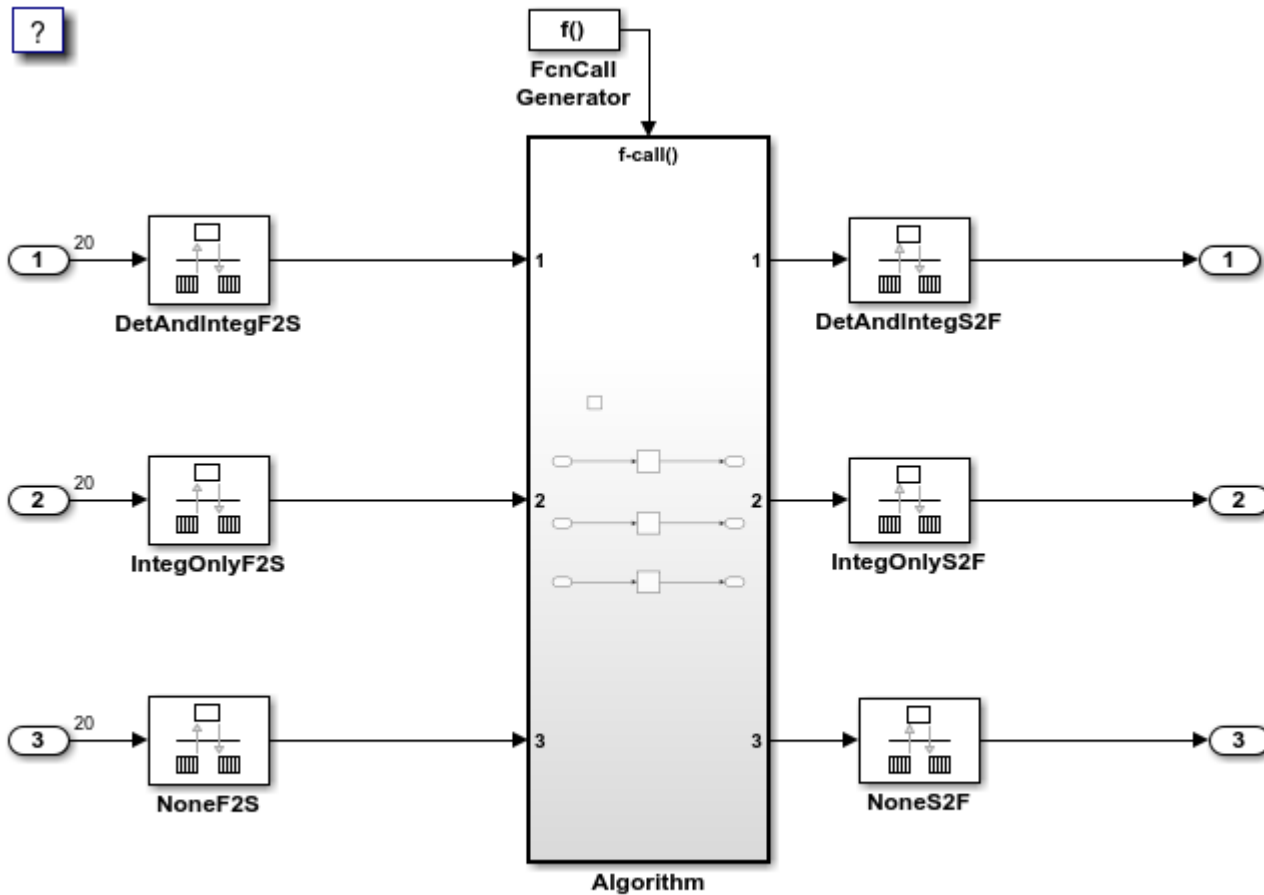

### Data Transfer Assumptions

Basis of operation for data transfers between tasks:

- Data transitions occur between a single reading task and a single writing task.
- A read or write of a byte sized variable is atomic.
- When two tasks interact through a data transition, only one of them can preempt the other.
- For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task always preempts the slower rate task.
- All tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash/restart (especially while data is being transferred between tasks)

### Model `rtwdemo_ratetrans`

```
open_system('rtwdemo_ratetrans')
```

Copyright 1994-2020 The MathWorks, Inc.

Model `rtwdemo_ratetrans` shows the differences in the operation modes of the following Rate Transition blocks.

### Rate Transition block `DetAndIntegF2S`

Determinism and data integrity (fast to slow transition):

- The block output is used as a persistent data buffer.
- Data is written to output at slower rate but done during the faster rate context
- Data as seen by the slower rate is always the value when both the faster and slower rate last executed. Any subsequent steps by the faster rate (and associated data updates) while the slower rate is running are not seen by the slower rate.

### Rate Transition block `DetAndIntegS2F`

Determinism and data integrity (slow to fast transition):

- Uses two persistent data buffers, an internal buffer and the blocks output.
- The internal buffer is copied to the output at the slower rate but done during the faster rate context.

- The internal buffer is written at the slower rate and during the slower rate context.
- The data that Fast rate sees is always delayed, i.e. data is from the previous step of the slow rate code.

### **Rate Transition block IntegOnlyF2S**

Data integrity only (fast to slow transition):

- The block output is used as a persistent data buffer.
- Data is written to buffer during the faster rate context if a flag indicates it not in the process of being read.
- The flag is set and data is copied from the buffer to output at the slow rate, the flag is then cleared. This is an additional copy as compared to the deterministic case.
- Data as seen by the slower rate can be from a more recent step of the faster rate than from when the slower rate and faster rate both executed.

### **Rate Transition block IntegOnlyS2F**

Data integrity only (slow to fast transition):

- Uses two persistent data buffers, both are internal buffers.
- One of the 2 buffers is always copied to the output at faster rate.
- One of the 2 buffers is written at the slower rate and during the slower rate context, then the active buffer is switched.
- The data as seen by the faster rate can be more recent than for the deterministic case. Specifically, when both the slower and faster rate have their hits, the faster rate will see a previous value from the slower rate. But, subsequent steps for the faster rate may see an updated value (when the slower rate updates the non-active buffer and switches the active buffer flag).

### **Rate Transition block NoneF2S**

No code is generated for the Rate Transition block when determinism and data integrity is waived.

### **Rate Transition block NoneS2F**

No code is generated for the Rate Transition block when determinism and data integrity is waived.

```
bdclose('rtwdemo_ratetrans');
```

## Asynchronous Events

### Asynchronous Support

Normally, you time models from which you plan to generate code from a *periodic* interrupt source (for example, a hardware timer). Blocks in a periodically clocked single-rate model run at a timer interrupt rate (the base rate of the model). Blocks in a periodically clocked multirate model run at the base rate or at multiples of that rate.

Many systems must also support execution of blocks in response to events that are *asynchronous* with respect to the periodic timing source of the system. For example, a peripheral device might signal completion of an input operation by generating an interrupt. The system must service such interrupts, for example, by acquiring data from the interrupting device.

This topic explains how to use blocks to model and generate code for asynchronous event handling, including servicing of hardware-generated interrupts, maintenance of timers, asynchronous read and write operations, and spawning of asynchronous tasks under a real-time operating system (RTOS). This block library demonstrates integration with an example RTOS (VxWorks). Although the blocks target an example RTOS, this chapter provides source code analysis and other information you can use to develop blocks that support asynchronous event handling for an alternative target RTOS.<sup>4</sup>

### Block Library for Calls to an Example Real-Time Operating System

The next figure shows the blocks in the vxLib1 block library.

The key blocks in the library are the Async Interrupt and Task Sync blocks. These blocks are targeted for an example RTOS (VxWorks). You can use them, with modification, to support your RTOS applications.

---

**Note** Use the blocks in the Interrupt Templates block library (Async Interrupt and Task Sync) for simulation and code generation. These blocks provide starting point examples to help you develop custom blocks for a target environment.

---

To implement asynchronous support for an RTOS other than the example RTOS, use these guidelines and the example code in “Create a Customized Asynchronous Library” on page 29-41 to adapt the Interrupt Template library blocks for your RTOS.

<sup>4</sup> VxWorks is a registered trademark of Wind River Systems, Inc.

The Interrupt Template library includes blocks that you can use to:

- Generate interrupt-level code — Async Interrupt block
- Spawn an RTOS task that calls a function call subsystem — Task Sync block

The use of protected and unprotected Rate Transition blocks in asynchronous contexts is discussed in “Rate Transitions and Asynchronous Blocks” on page 29-35. For general information on rate transitions, see “Time-Based Scheduling and Code Generation” on page 28-2.

## Examples and Additional Information

- Example model `rtwdemo_async` uses the `tornado.tlc` system target file and Interrupt Template block library. To open the model, type `rtwdemo_async` at the MATLAB command prompt.
- Example model `rtwdemo_async_mdltreftop` uses the `tornado.tlc` system target file and Interrupt Template block library. To open the model, type `rtwdemo_async_mdltreftop` at the MATLAB command prompt.
- “Time-Based Scheduling and Code Generation” discusses general multitasking and rate transition issues for periodic models.
- The Embedded Coder documentation discusses the `ert.tlc` system target file, including task execution and scheduling.
- For information about the system calls to the example RTOS (VxWorks) mentioned in this topic, see VxWorks system documentation on the Wind River website.

## Generate Interrupt Service Routines

To generate an interrupt service routine (ISR) associated with a specific VME interrupt level for an example RTOS (for example, VxWorks), use the Async Interrupt block. The Async Interrupt block enables the specified interrupt level and installs an ISR that calls a connected function call subsystem.

You can also use the Async Interrupt block in a simulation. It provides an input port that you can enable and connect to a simulated interrupt source.

---

**Note** The operating system integration techniques that are demonstrated in this section use blocks that are in the Interrupt Templates block library. The blocks in that library provide starting point examples to help you develop custom blocks for a target environment.

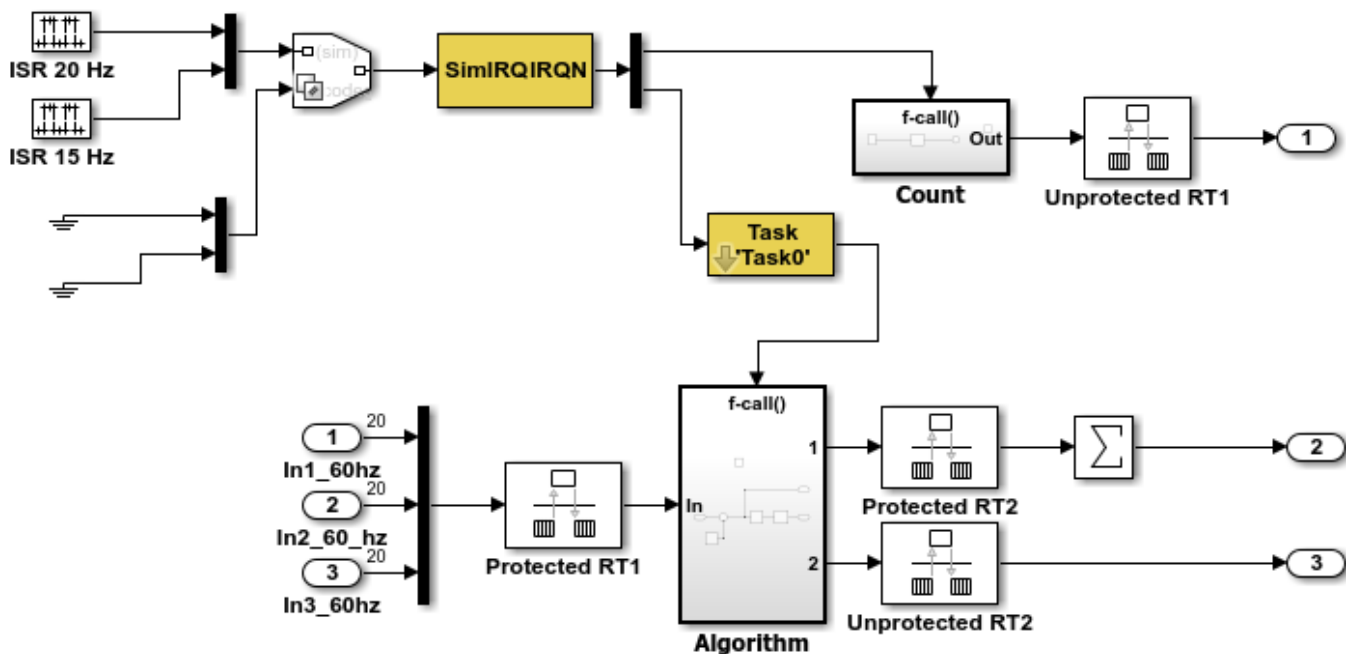

---

### Connecting the Async Interrupt Block

To generate an ISR, connect an output of the Async Interrupt block to the control input of:

- A function call subsystem
- The input of a Task Sync block
- The input to a Stateflow chart configured for a function call input event

Example model `rtwdemo_async` shows an Async Interrupt block that is configured to service two interrupt sources. Each of the two output signals is connected to a function call subsystem.

### Requirements and Restrictions

- The Async Interrupt block supports VME interrupts 1 through 7.

- The Async Interrupt block uses these system calls to the example RTOS (VxWorks):
  - `sysIntEnable`
  - `sysIntDisable`
  - `intConnect`
  - `intLock`
  - `intUnlock`
  - `tickGet`

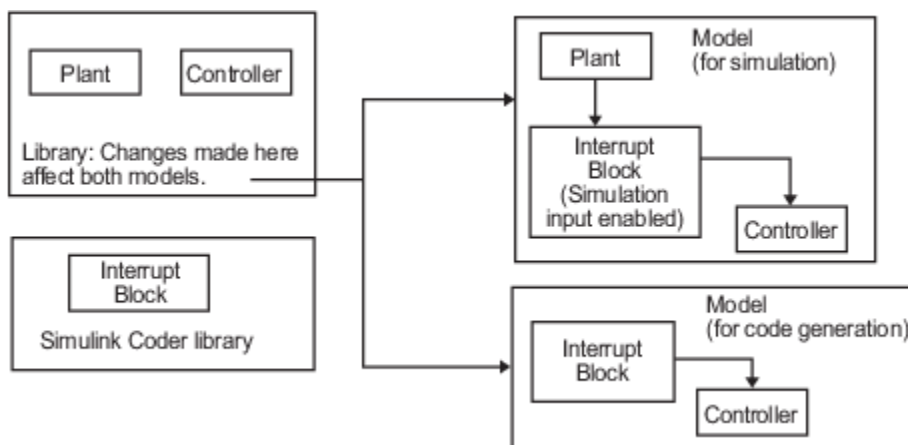

## Performance Considerations

Execution of large subsystems at interrupt level can have a significant impact on interrupt response time for interrupts of equal and lower priority in the system. It is best to keep ISRs as short as possible. Connect only function call subsystems that contain a small number of blocks to an Async Interrupt block.

A better solution for large subsystems is to use the Task Sync block to synchronize the execution of the function call subsystem to a RTOS task. Place the Task Sync block between the Async Interrupt block and the function call subsystem. The Async Interrupt block installs the Task Sync block as the ISR. The ISR releases a synchronization semaphore (performs a `semGive`) to the task, and returns immediately from interrupt level. The task is then scheduled and run by the RTOS (VxWorks). See “Spawn and Synchronize Execution of RTOS Task” on page 29-11 for more information.

## Dual-Model Approach for Developing Real-Time Systems that Include ISRs

When developing a real-time system that includes ISRs, consider using a *dual-model* approach. Develop one model that includes a plant and a controller for simulation, and another model that includes only the controller for code generation. By using a Simulink library, you can implement changes to both models simultaneously. This figure shows how changes made to the plant or controller, both of which are in a library, are propagated to the models.

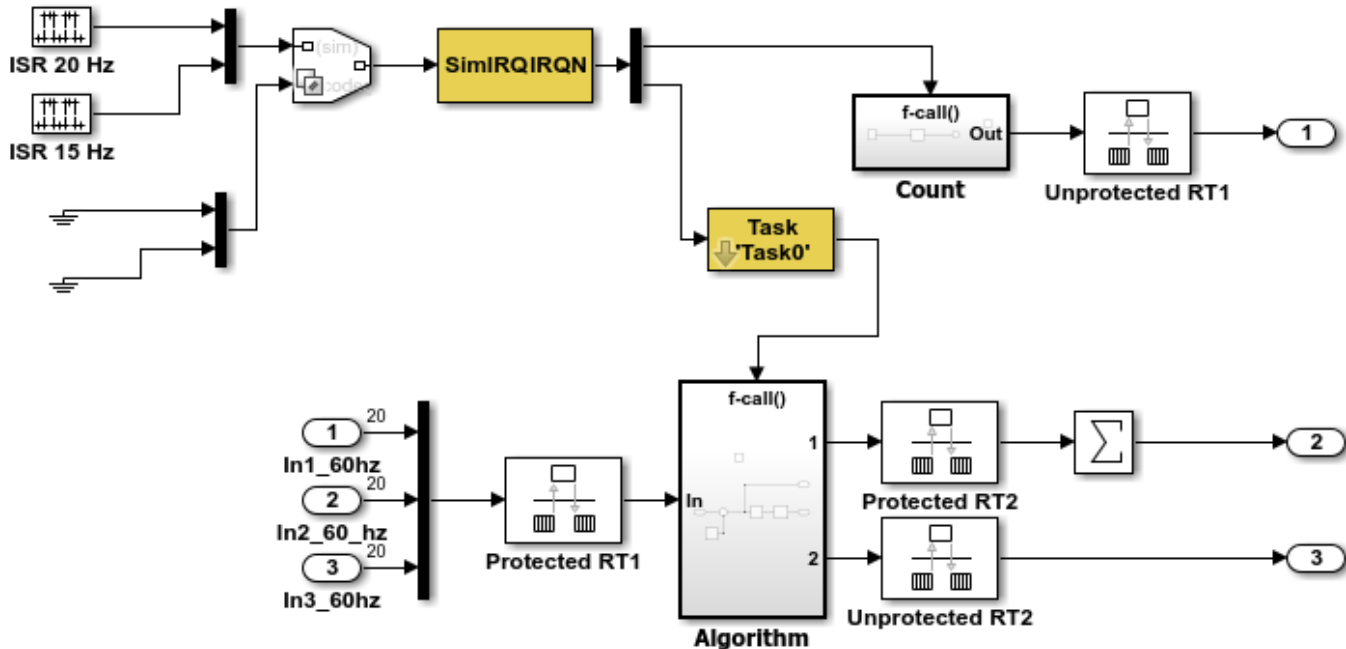

### Dual-Model Use of Async Interrupt Block for Simulation and Code Generation

A *single-model* approach is also possible. The Plant component of the model is active only during simulation. For code generation, you switch out the Plant components out of the system and you generate code only for the interrupt block and controller parts of the model.

## Dual-Model Approach: Simulation

Example model `rtwdemo_async` shows the dual-model approach to modeling. During simulation, the Pulse Generator blocks provide simulated interrupt signals.

During simulation:

- When the value of the input port is nonzero, Simulink imitates the behavior of each interrupt by calling the destination function unconditionally where the interrupt occurs.
- Subsystems connected to Async Interrupt block output ports execute in order of their priority in the RTOS (in this example, VxWorks). If two or more interrupt signals occur simultaneously, the Async Interrupt block executes the downstream systems in the order specified by their interrupt levels (level 7 gets the highest priority). The first input element maps to the first output element.

You can use the Async Interrupt block in a simulation without enabling the simulation input. The Async Interrupt block inherits the base rate of the model and calls the connected subsystems in order of their priorities in the RTOS. (In this case, the Async Interrupt block behaves as if inputs receive a 1 simultaneously.)

## Dual-Model Approach: Code Generation

In the generated code for the example model:

- Ground blocks provide input signals to the Variant Source block
- The Async Interrupt block does not use its simulation input

The Ground blocks drive control input of the Variant Source block, so the code generator does not produce code for that signal path. The code generator does not produce code for blocks that drive the simulation control input to the Variant Source block because that path is not selected during code generation. However, the sample times of driving blocks for the simulation input to the Variant Source block contribute to the sample times supported in the generated code. To avoid including unnecessary sample times in the generated code, use the sample times of the blocks driving the simulation input in the model where generated code is intended.

The code generator produces standalone functions for the ISRs and the interrupt vector table is as follows:

#### Offset

```
192 &isr_num1_vec192()
193 &isr_num2_vec193()
```

Consider the code generated from this model, assuming that the Async Interrupt block parameters are configured as shown in this figure.

### Initialization Code

During code generation, the Async Interrupt block installs interrupt code in the code generated for subsystem blocks as interrupt service routines. The interrupt vectors for IRQ1 and IRQ2 are stored at locations 192 and 193, relative to the base of the interrupt vector table, as specified by the **VME interrupt vector offset(s)** parameter.

Installing an ISR requires two RTOS (VxWorks) calls, `int_connect` and `sysInt_Enable`. The Async Interrupt block inserts these calls in the `mdl_initialize` function, as shown in this code fragment.

```

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num1_vec192 */
if(intConnect(INUM_TO_IVEC(192), isr_num1_vec192, 0) != OK) {
 printf("intConnect failed for ISR 1.\n");
}
sysIntEnable(1);

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num2_vec193 */
if(intConnect(INUM_TO_IVEC(193), isr_num2_vec193, 0) != OK)
{
 printf("intConnect failed for ISR 2.\n");
}
sysIntEnable(2);

```

The Async Interrupt block does not configure the hardware that generates the interrupt. Typically, the interrupt source is a VME I/O board, which generates interrupts for specific events (for example, at the end of an analog-to-digital conversion). You set up the VME interrupt level and vector in registers or by using jumpers on the board. You can use the `mdlStart` routine of a user-written device driver (S-function) to set up the registers and enable interrupt generation on the board. You

must match the interrupt level and vector specified in the Async Interrupt block parameter dialog box to the level and vector set up on the I/O board.

### Generated ISR Code

The actual ISR generated for IRQ1 in the RTOS (VxWorks) is listed below.

```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */

void isr_num1_vec192(void)
{
 int_T lock;
 FP_CONTEXT context;

 /* Use tickGet() as a portable tick counter example.
 A much higher resolution can be achieved with a
 hardware counter */
 Async_Code_M->Timing.clockTick2 = tickGet();

 /* disable interrupts (system is configured as non-ive) */
 lock = intLock();

 /* save floating point context */
 fppSave(&context);

 /* Call the system: <Root>/Subsystem A */
 Count(0, 0);

 /* restore floating point context */
 fppRestore(&context);

 /* re-enable interrupts */
 intUnlock(lock);
}
```

Note these features of the ISR:

- Because of the setting of the **Preemption Flag(s)** parameter, the ISR is locked; that is, it cannot be preempted by a higher priority interrupt. The ISR is locked and unlocked in the example RTOS (VxWorks) by calls to the functions `int_lock` and `int_unlock`.
- The connected subsystem, `Count`, is called from within the ISR.
- The `Count` function executes algorithmic (model) code. Therefore, the floating-point context is saved and restored across the call to `Count`.
- The ISR maintains its own absolute time counter, which is distinct from other periodic base rate or subrate counters in the system. Timing data is maintained for use by code generated for blocks executed within the ISR that require absolute or elapsed time.

See “Timers in Asynchronous Tasks” on page 29-39 for details.

### Model Termination Code

The model termination function disables the interrupts in the RTOS (VxWorks):

```
/* Model terminate function */
void Async_Code_terminate(void)
{
```

```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Disable interrupt for ISR system: isr_num1_vec192 */
sysIntDisable(1);

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Disable interrupt for ISR system: isr_num2_vec193 */
sysIntDisable(2);
}
```

## Spawn and Synchronize Execution of RTOS Task

This example shows how to simulate and generate code for asynchronous events on a real-time multitasking system. The model contains an Async Interrupt block, a Task Sync block, asynchronously executed subsystems Count and Algorithm, and Rate Transition blocks. The Async Interrupt block creates two Versa Module Eurocard (VME) interrupt service routines (ISRs) that pass interrupt signals to subsystem Count and the Task Sync block. Count executes at interrupt level. Algorithm executes as an asynchronous task. The code that the code generator produces for subsystems is tailored for the VxWorks® operating system.

### About the Example Model

Open the example model rtwdemo\_async.

Copyright 1994-2020 The MathWorks, Inc.

You can place an Async Interrupt block between a simulated interrupt source and one of these model elements:

- Function call subsystem
- Task Sync block
- A Stateflow® chart configured for a function call input event

- A referenced model with an Inport block that connects to one of the preceding model elements

The Async Interrupt and Task Sync blocks enable the subsystems to execute asynchronously. Reconfigure the Async Interrupt and Task Sync blocks to generate code for an alternative run-time environment.

Count represents a simple interrupt service routine (ISR) that executes at interrupt level. It is best to keep ISRs as simple as possible. This subsystem includes only a Discrete-Time Integrator block.

Algorithm includes more substance. It includes multiple blocks and produces two output values. Execution of larger subsystems at interrupt level can significantly impact response time for interrupts of equal and lower priority in the system. A better solution for larger subsystems is to use the Task Sync block to represent the ISR for the function-call subsystem.

The Async Interrupt block generates calls to ISRs. Place the block between a simulated interrupt source and one of the following:

- Function call subsystem
- Task Sync block
- A Stateflow® chart configured for a function call input event

For each specified interrupt level, the block generates a Versa Module Eurocard (VME) ISR that executes the connected subsystem, Task Sync block, or chart.

In the example model, the Async Interrupt block is configured for VME interrupts 1 and 2, by using interrupt vector offsets 192 and 193. Interrupt 1 connects directly to subsystem Count. Interrupt 2 connects to a Task Sync block, which serves as the ISR for Algorithm. Place a Task Sync block in one of the following locations:

- Between an Async Interrupt block and a function-call subsystem or Stateflow® chart.
- At the output port of a Stateflow® chart that has an event, Output to Simulink, that you configure as a function call.

In the example model, the Task Sync block is between the Async Interrupt block and function-call subsystem Algorithm. The Task Sync block is configured with the task name Task(), a priority of 50, a stack size of 8192, and data transfers of the task synchronized with the caller task. The spawned task uses a semaphore to synchronize task execution. The Async Interrupt block triggers a release of the task semaphore.

Four Rate Transition blocks handle data transfers between ports that operate at different rates. In two instances, Protected Rate Transition blocks protect data transfers (prevent them from being preempted and corrupted). In the other two instances, Unprotected Rate Transition blocks introduce no special behavior. Their presence informs Simulink® of a rate transition.

The code generated for the Async Interrupt and Task Sync blocks is tailored for the example RTOS (VxWorks®). However, you can modify the blocks to generate code specific to your run-time environment.

### Data Transfer Assumptions

- Data transfers occur between one reading task and one writing task.
- A read or write operation on a byte-size variable is atomic.
- When two tasks interact, only one can preempt the other.

- For periodic tasks, the task with the faster rate has higher priority than the task with the slower rate. The task with the faster rate preempts the tasks with slower rates.
- Tasks run on a single processor. Time slicing is not allowed.
- Processes do not stop and restart, especially while data is being transferred between tasks.

### Simulate the Model

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for input and output appear red and green, respectively. Constants are reddish-blue. Asynchronous interrupts and tasks are purple. The Rate Transition Blocks, which are a hybrid rate (their input and output sample times can differ), are yellow.

### Generate Code and Report

Generate code and a code generation report for the model. Generated code for the Async Interrupt and Task Sync blocks is for the example RTOS (VxWorks®). However, you can modify the blocks to generate code for another run-time environment.

1. Create a temporary folder for the build and inspection process.
2. Build the model.

```
Starting build procedure for: rtwdemo_async
Warning: Simulink Coder: The tornado.tlc target will be removed in a future
release.
Successful completion of code generation for: rtwdemo_async
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
rtwdemo_async	Code generated	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 36.229s

### Review Initialization Code

Open the generated source file `rtwdemo_async.c`. The initialization code:

1. Creates and initializes the synchronization semaphore `Task0_semaphore`.

```
*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID = semBCreate(SEM_Q_PRIORITY,
SEM_EMPTY);
if (rtwdemo_async_DW.SFunction_PWORK.SemID == NULL) {
 printf("semBCreate call failed for block Task0.\n");
}
```

2. Spawns task `task0` and assigns the task priority 50.

```
rtwdemo_async_DW.SFunction_IWORK.TaskID = taskSpawn("Task0",
50.0,
VX_FP_TASK,
```

```

 8192.0,
 (FUNCPTR)Task0,
 0, 0, 0, 0, 0, 0, 0, 0, 0, 0);
if (rtwdemo_async_DW.SFunction_IWORK.TaskID == ERROR) {
 printf("taskSpawn call failed for block Task0.\n");
}

/* End of Start for S-Function (vxtask1): '<S4>/S-Function' */
;

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num1_vec192 */
if (intConnect(INUM_TO_IVEC(192), isr_num1_vec192, 0) != OK) {
 printf("intConnect failed for ISR 1.\n");
}

sysIntEnable(1);

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num2_vec193 */
if (intConnect(INUM_TO_IVEC(193), isr_num2_vec193, 0) != OK) {
 printf("intConnect failed for ISR 2.\n");
}

sysIntEnable(2);

```

3. Connects and enables ISR `isr_num1_vec192` for interrupt 1 and ISR `isr_num2_vec193` for interrupt 2.

```

The order of these operations is important. Before the code generator enables the interrupt that activates the task, it must spawn the task.

## Review Task and Task Synchronization Code

In the generated source file `rtwdemo_async.c`, review the task and task synchronization code.

The code generator produces the code for function `Task0` from the Task Sync block. That function includes a small amount of interrupt-level code and runs as an RTOS task.

The task waits in an infinite `for` loop until the system releases a synchronization semaphore. If the system releases the semaphore, the function updates its task timer and calls the code generated for the `Algorithm` subsystem.

In the example model, the **Synchronize the data transfer of this task with the caller task** parameter for the Task Sync block is set. This parameter setting updates the timer associated with the Task Sync block (`rtM->Timing.clockTick2`) with the value of the timer that the Async Interrupt block (`rtM->Timing.clockTick3`) maintains. As a result, code for blocks within the `Algorithm` subsystem use timer values that are based on the time of the most recent interrupt, rather than the most recent activation of `Task0`.

```
{
 /* Wait for semaphore to be released by system: rtwdemo_async/Task Sync */
 for (;;) {
 if (semTake(*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID,NO_WAIT) !=

The code generator produces code for ISRs `isr_num1_vec192` and `isr_num2_vec293`. ISR `isr_num2_vec192`:

- Disables interrupts.
- Saves floating-point context.
- Calls the code generated for the subsystem that connects to the referenced model Inport block, which receives the interrupt.
- Restores floating-point context.
- Reenables interrupts.

```

void isr_num1_vec192(void)
{
 int_T lock;
 FP_CONTEXT context;

 /* Use tickGet() as a portable tick
 counter example. A much higher resolution can
 be achieved with a hardware counter */
 rtwdemo_async_M->Timing.clockTick3 = tickGet();

```

```

/* disable interrupts (system is configured as non-preemptive) */

### Review Task Termination Code

The Task Sync block generates the following termination code.

```
static void rtwdemo_async_terminate(void)
```

```

{
 /* Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

 /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
 /* Disable interrupt for ISR system: isr_num1_vec192 */
 sysIntDisable(1);

 /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
 /* Disable interrupt for ISR system: isr_num2_vec193 */
 sysIntDisable(2);

 /* End of Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

 /* Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' incorporates:
 * SubSystem: '<S3>/Subsystem'
 */

 /* Termination for function-call system: '<S3>/Subsystem' */

 /* Terminate for S-Function (vxtask1): '<S4>/S-Function' */

 /* VxWorks Task Block: '<S4>/S-Function' (vxtask1) */
 /* Destroy task: Task0 */
 taskDelete(rtwdemo_async_DW.SFunction_IWORK.TaskID);

 /* End of Terminate for S-Function (vxtask1): '<S4>/S-Function' */
 ;

 /* End of Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
}

```

## Pass Asynchronous Events in RTOS as Input to a Referenced Model

This example shows how to simulate and generate code for asynchronous events on a real-time multitasking system.

### About the Example Model

Open the example model `rtwdemo_async_md1reftop`.

```
open_system('rtwdemo_async_md1reftop');
```

The model simulates an interrupt source and includes an `Async Interrupt` block and referenced model. The `Async Interrupt` block creates two Versa Module Eurocard (VME) interrupt service routines (ISRs) that pass interrupt signals to Inport blocks 1 and 2 of the referenced model.

You can place an `Async Interrupt` block between a simulated interrupt source and one of these model elements:

- Function call subsystem
- Task Sync block
- A Stateflow chart configured for a function call input event
- A referenced model with an Inport block that connects to one of the preceding model elements

In this example model, the `Async Interrupt` block passes asynchronous events (function-call trigger signals), `Interrupt1` and `Interrupt2`, to the referenced model through Inport blocks 1 and 2.

The code generator produces code that is tailored for the VxWorks operating system. Reconfigure the `Async Interrupt` block to generate code for an alternative application run-time environment.

Open the referenced model. The referenced model includes the two `Inport` blocks that receive the interrupts, each connected to an `Asynchronous Task Specification` block, function-call subsystems `Count` and `Algorithm`, and `Rate Transition` blocks. The `Asynchronous Task Specification` block, in combination with a root-level `Inport` block, allows a reference model to receive asynchronous function-call input. To use the block:

- 1 Connect the `Asynchronous Task Specification` block to the output port of the root-level `Inport` block that outputs a function-call trigger.
- 2 Select the **Output function call** parameter of the `Inport` block to specify that it accepts function-call signals.
- 3 On the parameters dialog box for the `Asynchronous Task Specification` block, set the task priority for the asynchronous task associated with an `Inport` block. Specify an integer or []. If you specify an integer, it must match the priority of the interrupt initiated by the `Async Interrupt` block in the parent model. If you specify [], the priorities do not have to match.

The `Asynchronous Task Specification` block for the higher priority interrupt, `interrupt1`, connect to function-call subsystem `Count`. `Count` represents a simple interrupt service routine (ISR). The second `Asynchronous Task Specification` block connect to the subsystem `Algorithm`, which includes more substance. It includes multiple blocks and produces two output values. Both subsystems execute at interrupt level.

For each interrupt level specified for the `Async Interrupt` block in the parent model, the block generates a VME ISR that executes the connected subsystem, `Task Sync` block, or chart.

In the example top model, the `Async Interrupt` block is configured for VME interrupts 1 and 2, using interrupt vector offsets 192 and 193. Interrupt 1 is wired to trigger subsystem `Count`. Interrupt 2 is wired to trigger subsystem `Algorithm`.

The `Rate Transition` blocks handle data transfers between ports that operate at different rates. In two instances, the blocks protect data transfers (prevent them from being preempted and corrupted). In the other instance, no special behavior occurs.

### Data Transfer Assumptions

- Data transfers occur between one reading task and one writing task.
- A read or write operation on a byte-sized variable is atomic.
- When two tasks interact, only one can preempt the other.
- For periodic tasks, the task with the faster rate has higher priority than the task with the slower rate. The task with the faster rate preempts the tasks with slower rates.
- Tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash and restart, especially while data is being transferred between tasks.

### Simulate the Model

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for input and output appear red and green, respectively. Constants are magenta. Asynchronous interrupts are purple. The `Rate Transition` blocks, which are hybrid (input and output sample times can differ), appear yellow.

## Generate Code and Report

Generate code and a code generation report for the model. Async Interrupt block and Task Sync block generated code is for the example RTOS (VxWorks). However, you can modify the blocks to generate code for another run-time environment.

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

2. Build the model.

```
slbuild('rtwdemo_async_mdltreftop');
Starting serial model reference code generation build
Warning: Simulink Coder: The tornado.tlc target will be removed in a future release.
Successfully updated the model reference code generation target for: rtwdemo_async_mdltreftop
Starting build procedure for: rtwdemo_async_mdltreftop
Warning: Simulink Coder: The tornado.tlc target will be removed in a future release.
Successful completion of code generation for: rtwdemo_async_mdltreftop

Build Summary

```

## Review Initialization Code

Open the generated source file `rtwdemo_async_mdltreftop.c`. The initialization code connects and enables ISR `isr_num1_vec192` for interrupt 1 and ISR `isr_num2_vec193` for interrupt 2.

```
cfile = fullfile(cgDir, 'rtwdemo_async_mdltreftop_tornado_rtw', 'rtwdemo_async_mdltreftop.c');
rtwdemodbtype(cfile, ...
 'static void rtwdemo_async_mdltreftop_initialize(void)', ...
 '/* Model terminate function */', ...
 1, 0);

static void rtwdemo_async_mdltreftop_initialize(void)
{
 /* Start for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

 /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
```

```

/* Connect and enable ISR function: isr_num1_vec192 */
if (intConnect(INUM_TO_IVEC(192), isr_num1_vec192, 0) != OK) {
 printf("intConnect failed for ISR 1.\n");
}

sysIntEnable(1);

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num2_vec193 */
if (intConnect(INUM_TO_IVEC(193), isr_num2_vec193, 0) != OK) {
 printf("intConnect failed for ISR 2.\n");
}

sysIntEnable(2);

/* End of Start for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

/* SystemInitialize for ModelReference: '<Root>/Model' incorporates:
 * Inport: '<Root>/In1_60hz'
 * Inport: '<Root>/In2_60_hz'
 * Inport: '<Root>/In3_60hz'
 * Outport: '<Root>/Out1'
 * Outport: '<Root>/Out2'
 * Outport: '<Root>/Out3'
 */
rtwdemo_async_mdrefbot_Init(&rtwdemo_async_mdleftop_Y.Out1);
rtwdemo_async_mdrefbot_Enable();
}

```

## Review ISR Code

In the generated source file `rtwdemo_async_mdleftop.c`, review the code for ISRs `isr_num1_vec192` and `isr_num2_vec293`. Each ISR:

- Disables interrupts.
- Saves floating-point context.
- Calls the code generated for the subsystem connected to the referenced model Inport block that receives the interrupt.
- Restores floating-point context.
- Reenables interrupts.

```

cfile = fullfile(cgDir, 'rtwdemo_async_mdleftop_tornado_rtw', 'rtwdemo_async_mdleftop.c');
rtwdemodbtype(cfile, ...
 'void isr_num1_vec192(void)', ...
 'time_T rt_SimUpdateDiscreteEvents', ...
 1, 0);

void isr_num1_vec192(void)
{
 int_T lock;
 FP_CONTEXT context;

 /* disable interrupts (system is configured as non-preemptive) */
 lock = intLock();

 /* save floating point context */

```

```

fppSave(&context);

/* Call the system: '<Root>/Model' */
{
 /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

 /* ModelReference: '<Root>/Model' incorporates:
 * Inport: '<Root>/In1_60hz'
 * Inport: '<Root>/In2_60_hz'
 * Inport: '<Root>/In3_60hz'
 * Outport: '<Root>/Out1'
 * Outport: '<Root>/Out2'
 * Outport: '<Root>/Out3'
 */
 rtwdemo_async_mdrefbot_Interrupt1(&rtwdemo_async_mdleftop_Y.Out1);

 /* End of Outputs for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
}

/* restore floating point context */
fppRestore(&context);

/* re-enable interrupts */
intUnlock(lock);
}

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
void isr_num2_vec193(void)
{
 FP_CONTEXT context;

 /* save floating point context */
 fppSave(&context);

 /* Call the system: '<Root>/Model' */
 {
 /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

 /* ModelReference: '<Root>/Model' incorporates:
 * Inport: '<Root>/In1_60hz'
 * Inport: '<Root>/In2_60_hz'
 * Inport: '<Root>/In3_60hz'
 * Outport: '<Root>/Out1'
 * Outport: '<Root>/Out2'
 * Outport: '<Root>/Out3'
 */
 rtwdemo_async_mdrefbot_Interrupt2();

 /* End of Outputs for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
 }

 /* restore floating point context */
 fppRestore(&context);
}

```

### Review Task Termination Code

The Task Sync block generates the following termination code.

```

cfile = fullfile(cgDir, 'rtwdemo_async_mdltreftop_tornado_rtw', 'rtwdemo_async_mdltreftop.c');
rtwdemodbtype(cfile, ...
 'static void rtwdemo_async_mdltreftop_terminate(void)', ...
 '/*=====*/', ...
 1, 0);

static void rtwdemo_async_mdltreftop_terminate(void)
{
 /* Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

 /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
 /* Disable interrupt for ISR system: isr_num1_vec192 */
 sysIntDisable(1);

 /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
 /* Disable interrupt for ISR system: isr_num2_vec193 */
 sysIntDisable(2);

 /* End of Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
}

```

## Rate Transitions and Asynchronous Blocks

Because an asynchronous function call subsystem can preempt or be preempted by other model code, an inconsistency arises when more than one signal element is connected to an asynchronous block. The issue is that signals passed to and from the function call subsystem can be in the process of being written to or read from when the preemption occurs. Thus, some old and some new data is used. This situation can also occur with scalar signals in some cases. For example, if a signal is a double (8 bytes), the read or write operation might require two machine instructions.

---

**Note** The operating system integration techniques that are demonstrated in this section use blocks that are in the Interrupt Templates block library. The blocks in that library provide starting point examples to help you develop custom blocks for a target environment.

---

### About Rate Transitions and Asynchronous Blocks

The Simulink Rate Transition block is designed to deal with preemption problems that occur in data transfer between blocks running at different rates. These issues are discussed in “Time-Based Scheduling and Code Generation”.

You can handle rate transition issues automatically by selecting model configuration parameter **Automatically handle rate transition for data transfer**. This saves you from having to manually insert Rate Transition blocks to avoid invalid rate transitions, including invalid *asynchronous-to-periodic* and *asynchronous-to-asynchronous* rate transitions, in multirate models. For asynchronous tasks, the Simulink engine configures inserted blocks for data integrity but not determinism during data transfers.

For asynchronous rate transitions, the Rate Transition block provides data integrity, but cannot provide determinism. Therefore, when you insert Rate Transition blocks explicitly, you must clear the block parameter **Ensure deterministic data transfer (maximum delay)**.

When you insert a Rate Transition block between two blocks to maintain data integrity and priorities are assigned to the tasks associated with the blocks, the code generator assumes that the higher priority task can preempt the lower priority task and the lower priority task cannot preempt the higher priority task. If the priority associated with task for either block is not assigned or the priorities of the tasks for both blocks are the same, the code generator assumes that either task can preempt the other task.

Priorities of periodic tasks are assigned by the Simulink engine, in accordance with the parameters specified in the **Solver selection** section of the **Solver** pane of the Configuration Parameters dialog box. When the **Periodic sample time constraint** parameter is set to Unconstrained, the model base rate priority is set to 40. Priorities for subrates then increment or decrement by 1 from the base rate priority, depending on the setting of parameter **Higher priority value indicates higher task priority**.

You can assign priorities manually by using parameter **Periodic sample time properties**. The Simulink engine does not assign a priority to asynchronous blocks. For example, the priority of a function call subsystem that connects back to an Async Interrupt block is assigned by the Async Interrupt block.

Block parameter **Simulink task priority** of the Async Interrupt block specifies a priority level (required) for every interrupt number entered for parameter **VME interrupt number(s)**. The priority array sets the priorities of the subsystems connected to each interrupt.

For the Task Sync block, if the example RTOS (VxWorks) is the target, clear block parameter **Higher priority value indicates higher task priority**. Parameter **Simulink task priority** specifies the block priority relative to connected blocks (in addition to assigning an RTOS priority to the generated task code).

The `vxlib1` library provides two types of rate transition blocks as a convenience. These are simply preconfigured instances of the Rate Transition block:

- Protected Rate Transition block: Rate Transition block that is configured with block parameter **Ensure data integrity during data transfers** selected and **Ensure deterministic data transfer** cleared.
- Unprotected Rate Transition block: Rate Transition block that is configured with the **Ensure data integrity during data transfers** cleared.

## Handle Rate Transitions for Asynchronous Tasks

For rate transitions that involve asynchronous tasks, you can maintain data integrity. However, you cannot achieve determinism. You have the option of using the Rate Transition block or target-specific rate transition blocks.

Consider the following model, which includes a Rate Transition block.

You can use the Rate Transition block in either of the following modes:

- Maintain data integrity, no determinism
- Unprotected

Alternatively, you can use target-specific rate transition blocks. The following blocks are available for the example RTOS (VxWorks):

- Protected Rate Transition block (reader)
- Protected Rate Transition block (writer)
- Unprotected Rate Transition block

## Handle Multiple Asynchronous Interrupts

Consider the following model, in which two functions trigger the same subsystem.

The two tasks must have equal priorities. When priorities are the same, the outcome depends on whether they are firing periodically or asynchronously, and also on a diagnostic setting. The following table and notes describe these outcomes:

### Supported Sample Time and Priority for Function Call Subsystem with Multiple Triggers

	Async Priority = 1	Async Priority = 2	Async Priority Unspecified	Periodic Priority = 1	Periodic Priority = 2
Async Priority = 1	Supported (1)				
Async Priority = 2		Supported (1)			
Async Priority Unspecified			Supported (2)		
Periodic Priority = 1				Supported	
Periodic Priority = 2					Supported

- 1 Control these outcomes by using model configuratoin parameter **Tasks with equal priority** ; set this diagnostic to **none** if tasks of equal priority cannot preempt each other in the target system.
- 2 For this case, the following warning message is issued unconditionally:

The function call subsystem <name> has multiple asynchronous triggers that do not specify priority. Data integrity will not be maintained if these triggers can preempt one another.

Empty cells in the above table represent multiple triggers with differing priorities, which are unsupported.

The code generator provides absolute time management for a function call subsystem connected to multiple interrupts in the case where timer settings for TriggerA and TriggerB (time source, resolution) are the same.

Assume that all of the following conditions are true for the model shown above:

- A function call subsystem is triggered by two asynchronous triggers (TriggerA and TriggerB) having identical priority settings.
- Each trigger sets the source of time and timer attributes by calling the functions `ssSetTimeSource` and `ssSetAsyncTimerAttributes`.

- The triggered subsystem contains a block that needs elapsed or absolute time (for example, a Discrete Time Integrator).

The asynchronous function call subsystem has one global variable, `clockTick#` (where `#` is the task ID associated with the subsystem). This variable stores absolute time for the asynchronous task. There are two ways timing can be handled:

- If the time source is set to `SS_TIMESOURCE_BASERATE`, the code generator produces timer code in the function call subsystem, updating the clock tick variable from the base rate clock tick. Data integrity is maintained if the same priority is assigned to `TriggerA` and `TriggerB`.
- If the time source is `SS_TIMESOURCE_SELF`, generated code for both `TriggerA` and `TriggerB` updates the same clock tick variable from the hardware clock.

The word size of the clock tick variable can be set directly or be established according to setting of model configuration parameter **Application lifespan (days)** and the timer resolution set by the `TriggerA` and `TriggerB` S-functions (which must be the same). See “Timers in Asynchronous Tasks” on page 29-39 and “Control Memory Allocation for Time Counters” on page 71-10 for more information.

## Protect Data Integrity with volatile Keyword

When you select block parameter **Ensure data integrity during data transfer**, the code generated for a Rate Transition block defines `volatile` global buffers and semaphores and uses them to protect the integrity of the transferred data. For additional protection, or for protection without a Rate Transition block, you can explicitly apply `volatile` to the transferred data. For more information, see “Protect Global Data with `const` and `volatile` Type Qualifiers” on page 42-13.

## Timers in Asynchronous Tasks

An ISR can set a source for absolute time. This is done with the function `ssSetTimeSource`. The function `ssSetTimeSource` cannot be called before `ssSetOutputPortWidth` is called. If this occurs, the program will come to a halt and generate an error message. `ssSetTimeSource` has the following three options:

- `SS_TIMESOURCE_SELF`: Each generated ISR maintains its own absolute time counter, which is distinct from a periodic base rate or subrate counters in the system. The counter value and the timer resolution value (specified with the block parameter **Timer resolution (seconds)** of the Async Interrupt block) are used by downstream blocks to determine absolute time values required by block computations.
- `SS_TIMESOURCE_CALLER`: The ISR reads time from a counter maintained by its caller. Time resolution is thus the same as its caller's resolution.
- `SS_TIMESOURCE_BASERATE`: The ISR can read absolute time from the model's periodic base rate. Time resolution is thus the same as its base rate resolution.

---

**Note** The operating system integration techniques that are demonstrated in this section use blocks that are in the Interrupt Templates block library. The blocks in that library provide starting point examples to help you develop custom blocks for a target environment.

---

By default, the counter is implemented as a 32-bit unsigned integer member of the `Timing` substructure of the real-time model structure. For a target that supports the `rtModel` data structure, when the time data type is not set by using `ssSetAsyncTimeDataType`, the counter word size is determined by the setting for model configuration parameter **Application lifespan (days)**. As an example (from ERT target code),

```
/* Real-time Model Data Structure */
struct _RT_MODEL_elapseTime_exp_Tag {
 const char *errorStatus;

 /*
 * Timing:
 * The following substructure contains information regarding
 * the timing information for the model.
 */
 struct {
 uint32_T clockTick1;
 uint32_T clockTick2;
 } Timing;
};
```

The example omits unused fields in the `Timing` data structure (a feature of ERT target code not found in GRT). For a target that supports the `rtModel` data structure, the counter word size is determined by the setting of model configuration parameter **Application lifespan (days)**.

By default, the `vxlib1` library blocks for the example RTOS (VxWorks) set the timer source to `SS_TIMESOURCE_SELF` and update their counters by using the system call `tickGet`. `tickGet` returns a timer value maintained by the RTOS kernel. The maximum word size for the timer is `UINT32`. The following example shows a generated call to `tickGet`.

```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
void isr_num2_vec193(void)
```

```
{

 /* Use tickGet() as a portable tick counter example. A much
 higher resolution can be achieved with a hardware counter */
 rtM->Timing.clockTick2 = tickGet();
 . . .
```

The `tickGet` call is supplied only as an example. It can (and in many instances should) be replaced by a timing source that has better resolution. If you are implementing a custom asynchronous block for an RTOS other than the example RTOS (VxWorks), you should either generate an equivalent call to the target RTOS, or generate code to read a timer register on the target hardware.

Change the setting for the block parameter **Timer resolution (seconds)** for your Async Interrupt block to match the resolution of timing source for you target computer.

The counter is updated at interrupt level. Its value represents the tick value of the timing source at the most recent execution of the ISR. The rate of this timing source is unrelated to sample rates in the model. In fact, typically it is faster than the model's base rate. Select the timer source and set its rate and resolution based on the expected rate of interrupts to be serviced by the Async Interrupt block.

For an example of timer code generation, see “Async Interrupt Block Implementation” on page 29-41.

## Create a Customized Asynchronous Library

This topic describes how to implement asynchronous blocks for use with your target RTOS, using the Async Interrupt and Task Sync blocks as a starting point. Rate Transition blocks are target-independent, so you do not need to develop customized rate transition blocks.

---

**Note** The operating system integration techniques that are demonstrated in this section use blocks that are in the Interrupt Templates block library. The blocks in that library provide starting point examples to help you develop custom blocks for a target environment.

---

### About Implementing Asynchronous Blocks

You can customize the asynchronous library blocks by modifying the block implementation. These files are

- The block's underlying S-function MEX-file
- The TLC files that control code generation of the block

In addition, you need to modify the block masks to remove references specific to the example RTOS (VxWorks) and to incorporate parameters required by your target RTOS.

Custom block implementation is an advanced topic, requiring familiarity with the Simulink MEX S-function format and API, and with the Target Language Compiler (TLC). These topics are covered in the following documents:

- Simulink topics “What Is an S-Function?”, “Use S-Functions in Models”, “How S-Functions Work”, and “Implementing S-Functions” describe MEX S-functions and the S-function API in general.
- The “Inlining S-Functions”, “Inline C MEX S-Functions”, and “S-Functions and Code Generation” describe how to create a TLC block implementation for use in code generation.

The following sections discuss the C/C++ and TLC implementations of the asynchronous library blocks, including required `SimStruct` macros and functions in the TLC asynchronous support library (`asynclib.tlc`).

### Async Interrupt Block Implementation

The source files for the Async Interrupt block are located in `matlabroot/rtw/c/tornado/devices` (open):

- `vxinterrupt1.c`: C MEX-file source code, for use in configuration and simulation
- `vxinterrupt1.tlc`: TLC implementation, for use in code generation
- `asynclib.tlc`: library of TLC support functions, called by the TLC implementation of the block. The library calls are summarized in “`asynclib.tlc` Support Library” on page 29-46.

### C MEX Block Implementation

Most of the code in `vxinterrupt1.c` performs ordinary functions that are not related to asynchronous support (for example, obtaining and validating parameters from the block mask, marking parameters nontunable, and passing parameter data to the `model.rtw` file).

The `mdlInitializeSizes` function uses special `SimStruct` macros and `SS_OPTIONS` settings that are required for asynchronous blocks, as described below.

Note that the following macros cannot be called before `ssSetOutputPortWidth` is called:

- `ssSetTimeSource`
- `ssSetAsyncTimerAttributes`
- `ssSetAsyncTimerResolutionEl`
- `ssSetAsyncTimerDataType`
- `ssSetAsyncTimerDataTypeEl`
- `ssSetAsyncTaskPriorities`
- `ssSetAsyncTaskPrioritiesEl`

If one of the above macros is called before `ssSetOutputPortWidth`, the following error message appears:

```
SL_SfcnMustSpecifyPortWidthBfCallSomeMacro {
S-function '%s' in '%<BLOCKFULLPATH>'
must set output port %d width using
ssSetOutputPortWidth before calling macro %s
}
```

#### **ssSetAsyncTimerAttributes**

`ssSetAsyncTimerAttributes` declares that the block requires a timer, and sets the resolution of the timer as specified for block parameter **Timer resolution (seconds)**.

The function prototype is

```
ssSetAsyncTimerAttributes(SimStruct *S, double res)
```

where

- `S` is a `SimStruct` pointer.
- Parameter **Timer resolution (seconds)** is set to `res`.

The following code excerpt shows the call to `ssSetAsyncTimerAttributes`.

```
/* Setup Async Timer attributes */
ssSetAsyncTimerAttributes(S,mxGetPr(TICK_RES)[0]);
```

#### **ssSetAsyncTaskPriorities**

`ssSetAsyncTaskPriorities` sets the Simulink task priority for blocks executing at each interrupt level, as specified for block parameter **Simulink task priority**.

The function prototype is

```
ssSetAsyncTaskPriorities(SimStruct *S, int numISRs,
 int *priorityArray)
```

where

- `S` is a `SimStruct` pointer.

- `numISRs` is the number of interrupts specified for block parameter **VME interrupt number(s)** .
- `priorityarray` is an integer array containing the interrupt numbers specified for block parameter **VME interrupt number(s)**.

The following code excerpt shows the call to `ssSetAsyncTaskPriorities`:

```
/* Setup Async Task Priorities */
priorityArray = malloc(numISRs*sizeof(int_T));
for (i=0; i<numISRs; i++) {
 priorityArray[i] = (int_T)(mxGetPr(ISR_PRIORITIES)[i]);
}
ssSetAsyncTaskPriorities(S, numISRs, priorityArray);
free(priorityArray);
priorityArray = NULL;
}
```

### SS\_OPTION Settings

The code excerpt below shows the `SS_OPTION` settings for `vxinterrupt1.c`. `SS_OPTION_ASYNCCHRONOUS_INTERRUPT` should be used when a function call subsystem is attached to an interrupt. For more information, see the documentation for `SS_OPTION` and `SS_OPTION_ASYNCCHRONOUS` in `matlabroot/simulink/include/simstruc.h`.

```
ssSetOptions(S, (SS_OPTION_EXCEPTION_FREE_CODE |
 SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME |
 SS_OPTION_ASYNCCHRONOUS_INTERRUPT |
```

If an S-function specifies the `SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME` option and inherits a sample time of `Inf`, the code generator determines how to produce code for the block based on whether the block is invariant. A block is invariant if its port signals are invariant. A signal is invariant if it has a constant value during the entire simulation. If you specify a Constant block sample time, do not assume that the port signals are invariant. For more information, see “Inline Invariant Signals”. If the block is not invariant, the code generator produces code only in the initialize entry-point function. If the block is invariant, the code generator does not produce code for the block.

### TLC Implementation

This section discusses each function of `vxinterrupt1.tlc`, with an emphasis on target-specific features that you will need to change to generate code for your target RTOS.

#### Generate #include Directives

`vxinterrupt1.tlc` begins with the statement

```
%include "vxlib.tlc"
```

`vxlib.tlc` is a target-specific file that generates directives to include header files for the example RTOS (VxWorks). You should replace this with a file that generates includes for your target RTOS.

#### BlockInstanceSetup Function

For each connected output of the Async Interrupt block, `BlockInstanceSetup` defines a function name for the corresponding ISR in the generated code. The functions names are of the form

```
isr_num_vec_offset
```

where *num* is the ISR number defined for block parameter **VME interrupt number(s)**, and *offset* is an interrupt table offset defined by block parameter **VME interrupt vector offset(s)**.

In a custom implementation, this naming convention is optional.

The function names are cached for use by the `Outputs` function, which generates the actual ISR code.

### Outputs Function

`Outputs` iterates over the connected outputs of the Async Interrupt block. An ISR is generated for each such output.

The ISR code is cached in the "Functions" section of the generated code. Before generating the ISR, `Outputs` does the following:

- Generates a call to the downstream block (cached in a temporary buffer).
- Determines whether the ISR should be locked or not (as specified by block parameter **Preemption Flag(s)**).
- Determines whether the block connected to the Async Interrupt block is a Task Sync block. (This information is obtained by using the `asynclib` calls `LibGetFcnCallBlock` and `LibGetBlockAttribute`.) If so,
  - The preemption flag for the ISR must be set to 1. An error results otherwise.
  - The RTOS (VxWorks) calls to save and restore floating-point context are generated, unless the user has configured the model for integer-only code generation.

When generating the ISR code, `Outputs` calls the `asynclib` function `LibNeedAsyncCounter` to determine whether a timer is required by the connected subsystem. If so, and if the time source is set to be `SS_TIMESOURCE_SELF` by `ssSetTimeSource`, `LibSetAsyncCounter` is called to generate an RTOS (VxWorks) `tickGet` function call and update the counter. In your implementation, you should generate either an equivalent call to the target RTOS, or generate code to read the a timer register on the target hardware.

### Start Function

The `Start` function generates the required RTOS (VxWorks) calls (`int_connect` and `sysInt_Enable`) to connect and enable each ISR. You should replace this with calls to your target RTOS.

### Terminate Function

The `Terminate` function generates the call `sysIntDisable` to disable each ISR. You should replace this with calls to your target RTOS.

## Task Sync Block Implementation

The source files for the Task Sync block are located in `matlabroot/rtw/c/tornado/devices` (open). They are

- `vxtask1.cpp`: MEX-file source code, for use in configuration and simulation.
- `vxtask1.tlc`: TLC implementation, for use in code generation.
- `asynclib.tlc`: library of TLC support functions, called by the TLC implementation of the block. The library calls are summarized in "asynclib.tlc Support Library" on page 29-46.

## C MEX Block Implementation

Like the Async Interrupt block, the Task Sync block sets up a timer, in this case with a fixed resolution. The priority of the task associated with the block is obtained from block parameter **Simulink task priority**. The SS\_OPTION settings are the same as those used for the Async Interrupt block.

```
ssSetAsyncTimerAttributes(S, 0.01);

priority = (int_T) (*(mxGetPr(PRIORITY)));
ssSetAsyncTaskPriorities(S,1,&priority);

ssSetOptions(S, (SS_OPTION_EXCEPTION_FREE_CODE |
 SS_OPTION_ASYNCHRONOUS |
 SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME |
)
}

```

## TLC Implementation

### Generate #include Directives

`vxtask1.tlc` begins with the statement

```
%include "vxlib.tlc"
```

`vxlib.tlc` is a target-specific file that generates directives to include header files for the example RTOS (VxWorks). You should replace this with a file that generates includes for your target RTOS.

### BlockInstanceSetup Function

The `BlockInstanceSetup` function derives the task name, block name, and other identifiers used later in code generation. It also checks for and warns about unconnected block conditions, and generates a storage declaration for a semaphore (`stopSem`) that is used in case of interrupt overflow conditions.

### Start Function

The `Start` function generates the required RTOS (VxWorks) calls to define storage for the semaphore that is used in management of the task spawned by the Task Sync block. Depending on the value of the `CodeFormat` TLC variable of the target, either a static storage declaration or a dynamic memory allocation call is generated. This function also creates a semaphore (`semBCreate`) and spawns an RTOS task (`taskSpawn`). You should replace these with calls to your target RTOS.

### Outputs Function

The `Outputs` function generates an example RTOS (VxWorks) task that waits for a semaphore. When it obtains the semaphore, it updates the block's tick timer and calls the downstream subsystem code, as described in "Spawn and Synchronize Execution of RTOS Task" on page 29-11. `Outputs` also generates code (called from interrupt level) that grants the semaphore.

### Terminate Function

The `Terminate` function generates the example RTOS (VxWorks) call `taskDelete` to end execution of the task spawned by the block. You should replace this with calls to your target RTOS.

Note also that if the target RTOS has dynamically allocated memory associated with the task, the `Terminate` function should deallocate the memory.

## asynclib.tlc Support Library

`asynclib.tlc` is a library of TLC functions that support the implementation of asynchronous blocks. Some functions are specifically designed for use in asynchronous blocks. For example, `LibSetAsyncCounter` generates a call to update a timer for an asynchronous block. Other functions are utilities that return information required by asynchronous blocks (for example, information about connected function call subsystems).

The following table summarizes the public calls in the library. For details, see the library source code and the `vxinterrupt1.tlc` and `vxtask1.tlc` files, which call the library functions.

### Summary of asynclib.tlc Library Functions

Function	Description
<code>LibBlockExecuteFcnCall</code>	For use by inlined S-functions with function call outputs. Generates code to execute a function call subsystem.
<code>LibGetBlockAttribute</code>	Returns a field value from a block record.
<code>LibGetFcnCallBlock</code>	Given an S-Function block and call index, returns the block record for the downstream function call subsystem block.
<code>LibGetCallerClockTickCounter</code>	Provides access to the time counter of an upstream asynchronous task.
<code>LibGetCallerClockTickCounter-HighWord</code>	Provides access to the high word of the time counter of an upstream asynchronous task.
<code>LibManageAsyncCounter</code>	Determines whether an asynchronous task needs a counter and manages its own timer.
<code>LibNeedAsyncCounter</code>	If the calling block requires an asynchronous counter, returns <code>TLC_TRUE</code> , otherwise returns <code>TLC_FALSE</code> .
<code>LibSetAsyncClockTicks</code>	Returns code that sets <code>clockTick</code> counters that are to be maintained by the asynchronous task.
<code>LibSetAsyncCounter</code>	Generates code to set the tick value of the block's asynchronous counter.
<code>LibSetAsyncCounterHighWord</code>	Generates code to set the tick value of the high word of the block's asynchronous counter

## Import Asynchronous Event Data for Simulation

### Capabilities

You can import asynchronous event data into a function-call subsystem via an Inport block. For standalone fixed-step simulations, you can specify:

- The time points at which each asynchronous event occurs
- The number of asynchronous events at each time point

### Input Data Format

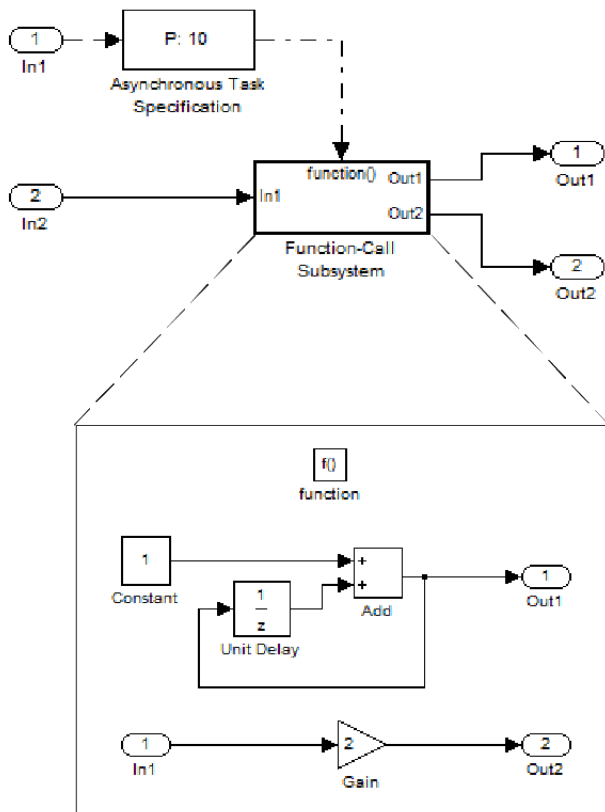

You can enter your asynchronous data at the MATLAB command line or on the **Data Import/Export** pane of the Configuration Parameters dialog box. In either case, a number of restrictions apply to the data format.

- The expression for parameter model configuration parameter **Input** must be a comma-separated list of tables.
- The table corresponding to the input port outputting asynchronous events must be a column vector containing time values for the asynchronous events.
  - The time vector of the asynchronous events must be of double data type and monotonically increasing.
  - Time data must be integer multiples of the model step size.
  - To specify multiple function calls at a given time step, you must repeat the time value accordingly. In other words, if you wish to specify three asynchronous events at  $t = 1$  and two events at  $t = 9$ , then you must list 1 three times and 9 twice in your time vector. (`t = [1 1 1 9 9]'`)
- The table corresponding to normal data input port can be of another supported format.

See “Load Data to Root-Level Input Ports” for more information.

### Example

In this model, a function-call subsystem is used to track the total number of asynchronous events and to multiply a set of input values by 2.

- 1 To input data by using the Model Configuration Parameters dialog box,
  - a Select **Input**.
  - b For this example, enter the following command in the MATLAB window:

```
>> t = [1 1 5 9 9 9]', tu = [[0:10]' [0:10]']
```

Alternatively, you can enter the data as  $t$ ,  $tu$  in the Data Import/Export pane:

The screenshot shows the 'Data Import/Export' configuration window. On the left, a 'Select:' pane lists various options, with 'Data Import/Export' highlighted. The main area is divided into two sections: 'Load from workspace' and 'Save to workspace'. In the 'Load from workspace' section, the 'Input:' checkbox is checked and set to 't, tu'. In the 'Save to workspace' section, the 'Time, State, Output' group is expanded. 'Time:' is checked and set to 'tout', with a 'Format:' dropdown set to 'Array'. 'Output:' is checked and set to 'yout'. 'Limit data points to last:' is checked and set to '1000'. Other options like 'States:', 'Final states:', and 'Save complete SimState in final state' are unchecked.

Here,  $t$  is a column vector containing the times of asynchronous events for Inport block In1 while  $tu$  is a table of input values versus time for Inport block In2.

- 2 By default, the **Time** and **Output** parameters are selected and the output variables are named *tout* and *yout*.
- 3 Simulate the model.
- 4 Display the output by entering [tout yout] at the MATLAB command line and obtain:

```
ans =

 0 0 -1
 1 2 2
 2 2 2
 3 2 2
 4 2 2
 5 3 10
 6 3 10
 7 3 10
 8 3 10
 9 6 18
 10 6 18
```

Here the first column contains the simulation times.

The second column represents the output of Out1 — the total number of asynchronous events. Since the function-call subsystem is triggered twice at  $t = 1$ , the output is 2. It is not called again until  $t = 5$ , and so does not increase to 3 until then. Finally, it is called three times at 9, so it increases to 6.

The third column contains the output of Out2 obtained by multiplying the input value at each asynchronous event time by 2. At any other time, the output is held at its previous value

## Asynchronous Support Limitations

### In this section...

“Asynchronous Task Priority” on page 29-51

“Convert an Asynchronous Subsystem into a Model Reference” on page 29-51

### Asynchronous Task Priority

The Simulink product does not simulate asynchronous task behavior. Although you can specify a task priority for an asynchronous task represented in a model with the Task Sync block, the priority setting is for code generation purposes only and is not honored during simulation.

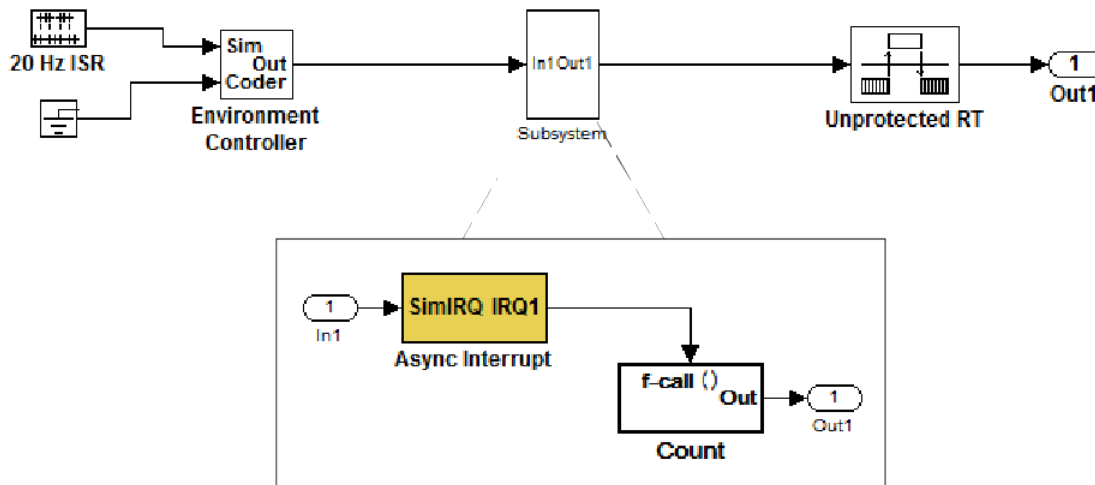

### Convert an Asynchronous Subsystem into a Model Reference

You can use the Asynchronous Task Specification block to specify an asynchronous function-call input to a referenced model. However, you must convert the Async Interrupt and Function-Call blocks into a subsystem and then convert the subsystem into a referenced model.

This example shows how to complete a conversion.

- 1 Convert the Async Interrupt and Count blocks into a subsystem. Select both blocks and right-click Count. From the menu, select **Subsystem & Model Reference > Create Subsystem from Selection**.

- 2 To prepare for converting the new subsystem to a Model block, set these model configuration parameters in the top model.
  - Set **Multitask data transfer** to error.
  - Set **Multitask conditionally executed subsystem** to error.
  - Set **Bus signal treated as vector** to error.
  - Set **Context-dependent inputs** to error.
  - Set **Multitask data store** to error.
  - Set **Underspecified initialization detection** to Simplified.
  - If your model is large or complex, run the Model Advisor checks in the folder “Migrating to Simplified Initialization Mode Overview” and make the suggested changes.
- 3 Convert the subsystem to an atomic subsystem. Select the subsystem block parameter **Treat as atomic unit**.

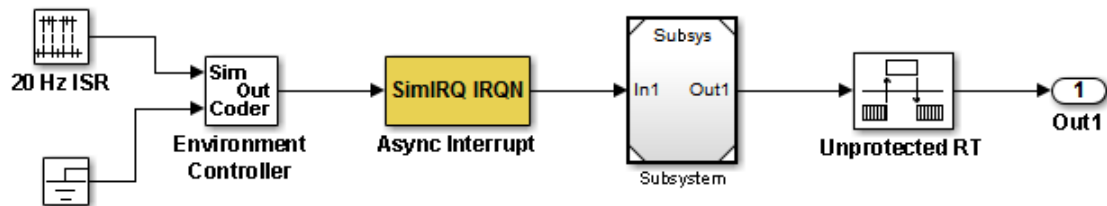

- 4 Convert the subsystem to a Model block. Right-click the subsystem and select **Subsystem & Model Reference > Convert Subsystem to > Referenced Model**. The Model Reference Conversion Advisor opens.
- 5 Replace the subsystem in the top model with the new Model block.

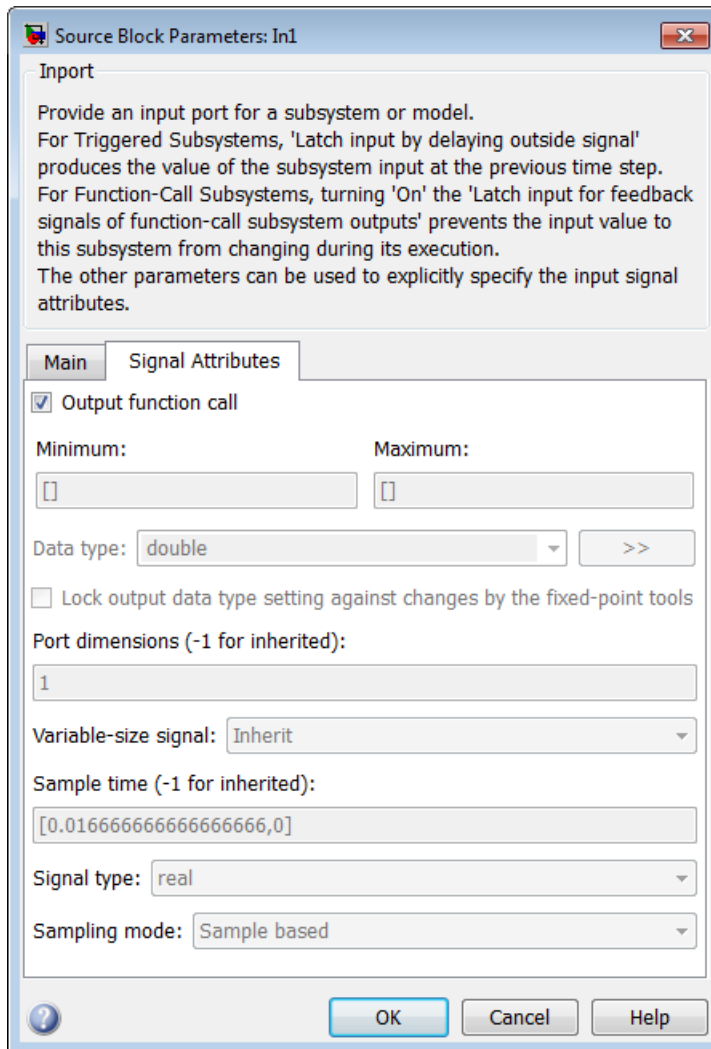

- 6 Move the Async Interrupt block from the referenced model to the top model, before the Model block.

- 7 Insert an Asynchronous Task Specification block in the referenced model. Set the priority of the Asynchronous Task Specification block. (For more information on setting the priority, see Asynchronous Task Specification.)

- 8 In the referenced model, double-click the input port to open its Source Block Parameters dialog box. In the **Signal Attributes** tab, select the **Output function call** parameter. Click **OK**.

- 9 Save your model and then update the diagram to verify your settings.

## Use Discrete and Continuous Time

### In this section...

“Support for Discrete and Continuous Time Blocks” on page 30-2

“Support for Continuous Solvers” on page 30-2

“Support for Stop Time” on page 30-2

### Support for Discrete and Continuous Time Blocks

The ERT system target file supports code generation for discrete and continuous time blocks. If you select model configuration parameter **Support: continuous time**, you can use these blocks in your models, without restriction.

Note that use of certain blocks is not recommended for production code generation for embedded systems. The Simulink Block Data Type Support table summarizes characteristics of blocks in the Simulink and Fixed-Point Designer block libraries, including whether or not they are recommended for use in production code generation. To view this table, execute the following command and see the “Code Generation Support” column of the table that appears:

```
showblockdatatypetable
```

### Support for Continuous Solvers

The ERT target supports continuous solvers. In the **Solver** options dialog, you can select an available solver in the **Solver** menu. (Note that the solver **Type** must be **fixed-step** for use with the ERT target.)

---

**Note** Custom targets must be modified to support continuous time. The required modifications are described in “Customize System Target Files”.

---

### Support for Stop Time

The ERT target supports the stop time for a model. When generating host-based executables, the stop time value is honored if one of these model configuration parameters is selected:

- **External mode**
- **MAT-file logging**
- **Classic call interface**

Otherwise, the executable runs indefinitely.

The ERT system target file provides generated and static examples of the `ert_main.c` file. The `ert_main.c` file controls the overall model code execution by calling the `model_step` function and optionally checking the `ErrorStatus/StopRequested` flags to terminate execution. For a custom target, if you provide your own custom static `main.c`, consider including support for checking these flags.

## Optimize Multirate Multitasking Execution for RTOS Run-Time Environments

Using the `rtmStepTask` macro, run-time environments that employ task management mechanisms of an real-time operating system (RTOS)—for example, VxWorks—can improve performance of generated code by eliminating redundant scheduling calls during the execution of tasks in a multirate, multitasking model. The following sections describe implementation details.

### Use `rtmStepTask`

The `rtmStepTask` macro is defined in `model.h` and its syntax is as follows:

```
boolean task_ready = rtmStepTask(rtm, idx);
```

The arguments are:

- `rtm`: pointer to the real-time model structure (`rtM`)
- `idx`: task identifier (`tid`) of the task whose scheduling counter is to be tested

`rtmStepTask` returns `TRUE` if the task's scheduling counter equals zero, indicating that the task should be scheduled for execution on the current time step. Otherwise, it returns `FALSE`.

If your system target file supports model configuration parameter **Generate an example main program**, you can generate calls to `rtmStepTask` by using the TLC function `RTMTaskRunsThisBaseStep`.

### Schedule Code for Real-time Model without an RTOS

To understand the optimization that is available for an RTOS target, consider how the ERT target schedules tasks for bareboard targets (where RTOS is not present). The ERT target maintains scheduling counters and event flags for each subrate task. The scheduling counters are implemented within the real-time model (`rtM`) data structure as arrays, indexed on task identifier (`tid`).

The scheduling counters are updated by the base-rate task. The counters are clock rate dividers that count up the sample period associated with each subrate task. When a given subrate counter reaches a value that indicates it has a hit, the sample period for that rate has elapsed and the counter is reset to zero. When this occurs, the subrate task must be scheduled for execution.

The event flags indicate whether or not a given task is scheduled for execution. For a multirate, multitasking model, the event flags are maintained by code in the main program for the model. For each task, the code maintains a task counter. When the counter reaches 0, indicating that the task's sample period has elapsed, the event flag for that task is set.

On each time step, the counters and event flags are updated and the base-rate task executes. Then, the scheduling flags are checked in `tid` order, and tasks whose event flag is set is executed. Therefore, tasks are executed in order of priority.

For bareboard targets that cannot rely on an external RTOS, the event flags are mandatory to allow overlapping task preemption. However, an RTOS target uses the operating system itself to manage overlapping task preemption, making the maintenance of the event flags redundant.

## Schedule Code for Multirate Multitasking on an RTOS

The following task scheduling code, from `ertmainlib.tlc`, is designed for multirate multitasking operation on an example RTOS (VxWorks) target. The example uses the TLC function `RTMTaskRunsThisBaseStep` to generate calls to the `rtmStepTask` macro. A loop iterates over each subrate task, and `rtmStepTask` is called for each task. If `rtmStepTask` returns `TRUE`, the RTOS `semGive` function is called, and the RTOS schedules the task to run.

```
%assign ifarg = RTMTaskRunsThisBaseStep("i")
for (i = 1; i < %<FcnNumST>; i++) {
 if (%<ifarg>) {
 semGive(taskSemList[i]);
 if (semTake(taskSemList[i],NO_WAIT) != ERROR) {
 logMsg("Rate for SubRate task %d is too fast.\n",i,0,0,0,0);
 semGive(taskSemList[i]);
 }
 }
}
```

## Suppress Redundant Scheduling Calls

Redundant scheduling calls are still generated by default for backward compatibility. To change this setting and suppress them, add the following TLC variable definition to your system target file before the `%include "codegenentry.tlc"` statement:

```
%assign SuppressSetEventsForThisBaseRateFcn = 1
```

## Define Storage Classes, Memory Sections, and Function Templates for Software Architecture

In a team or large organization, to enable multiple users to generate code that conforms to a standard architecture, you can create and share code generation definitions, such as storage classes, with those users. When configuring code generation settings for different models, the users can apply the definitions to data and function elements in the models, generating standardized code.

### Create Code Definitions for Use in the Code Mappings Editor

To control the appearance of model elements in the generated code, you apply code definitions to the elements by using the Code Mappings editor. Configure the default code generation behavior for a category of model elements by selecting a code definition in the default mapping for the category. Configure individual data elements by mapping them to code definitions in the Code Mappings editor.

To create code definitions that you and other users can use in the Code Mappings editor, use an Embedded Coder Dictionary.

When you create definitions in an Embedded Coder Dictionary, decide where to store the definitions by considering how you intend to use them. This table lists where to store the code definitions and how to use Simulink data dictionaries.

Usage of Definitions	Location for Code Definitions	Data Dictionary Use
Multiple models — sharing a set of code definitions to standardize code	Simulink data dictionary that all of the models are configured to use for the coder dictionary	Link each model to a data dictionary that defines the code definitions, either directly or through an intermediate dictionary reference.
One model — prototyping generated code by using one model	Local Embedded Coder Dictionary of the model.	You can optionally link the model to a data dictionary that contains other data. If you link the model to a dictionary that contains other code definitions, the model can also use those code definitions.

To use an Embedded Coder Dictionary and for its limitations with respect to code generation definitions, see Embedded Coder Dictionary.

### Create Code Definitions for External Data Objects
