Use **bm** to simulate any vector-valued BM process of the form:

$$dX_t = \mu(t)dt + V(t)dW_t$$

where:

- $X_t$  is an **NVars**-by-1 state vector of process variables.
- $\mu$  is an **NVars**-by-1 drift-rate vector.
- $V$  is an **NVars**-by-**NBrowns** instantaneous volatility rate matrix.
- $dW_t$  is an **NBrowns**-by-1 vector of (possibly) correlated zero-drift/unit-variance rate Brownian components.

### Creation

#### Syntax

```
BM = bm(Mu,Sigma)
BM = bm(___,Name,Value)
```

#### Description

**BM = bm(Mu,Sigma)** creates a default **BM** object.

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

---

**Note** You can specify combinations of array and function input parameters as needed.

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time  $t$  as its only input argument. Otherwise, a parameter is assumed to be a function of time  $t$  and state  $X(t)$  and is invoked with both input arguments.

---

`BM = bm( ___, Name, Value)` creates a `bm` object with additional options specified by one or more `Name, Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`

The `BM` object has the following “Properties” on page 19-4:

- `StartTime` — Initial observation time
- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `Simulation` — A simulation function or method

## Input Arguments

### **Mu — Mu represents the parameter $\mu$**

array or deterministic function of time | deterministic function of time and state

`Mu` represents the parameter  $\mu$ , specified as an array or deterministic function of time.

If you specify `Mu` as an array, it must be an `NVars`-by-1 column vector representing the drift rate (the expected instantaneous rate of drift, or time trend).

As a deterministic function of time, when `Mu` is called with a real-valued scalar time  $t$  as its only input, `Mu` must produce an `NVars`-by-`NVars` matrix. If you specify `Mu` as a function of time and state, it calculates the expected instantaneous rate of drift. This function must generate an `NVars`-by-1 column vector when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An `NVars`-by-1 state vector  $X_t$ .

Data Types: `double` | `function_handle`

### **Sigma — Sigma represents the parameter $V$**

array or deterministic function of time | deterministic function of time and state

`Sigma` represents the parameter  $V$ , specified as an array or deterministic function of time.

If you specify `Sigma` as an array, it must be an `NVars`-by-`NBrowns` matrix of instantaneous volatility rates or as a deterministic function of time. In this case, each row of `Sigma` corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when `Sigma` is called with a real-valued scalar time  $t$  as its only input, `Sigma` must produce an `NVars`-by-`NBrowns` matrix. If you specify `Sigma` as a function of time and state, it must return an `NVars`-by-`NBrowns` matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An `NVars`-by-1 state vector  $X_t$ .

Although the `gbm` constructor enforces no restrictions on the sign of `Sigma` volatilities, they are specified as positive values.

Data Types: double | function\_handle

## Properties

### **StartTime — Starting time of first observation, applied to all state variables**

0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a numeric.

Data Types: double

### **StartState — Initial values of state variables**

1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If `StartState` is a scalar, `bm` applies the same initial value to all state variables on all trials.

If `StartState` is a column vector, `bm` applies a unique initial value to each state variable on all trials.

If `StartState` is a matrix, `bm` applies a unique initial value to each state variable on each trial.

Data Types: double

### **Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)**

`NBrowns`-by-`NBrowns` identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an `NBrowns`-by-`NBrowns` positive semidefinite matrix, or as a deterministic function  $C(t)$  that accepts the current time  $t$  and returns an `NBrowns`-by-`NBrowns` positive semidefinite correlation matrix. If `Correlation` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

A `Correlation` matrix represents a static condition.

As a deterministic function of time, `Correlation` allows you to specify a dynamic correlation structure.

Data Types: double

### **Simulation — User-defined simulation function or SDE simulation method**

`simulation` by Euler approximation (`simByEuler`) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: `function_handle`

**Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)**  
value stored from drift-rate function (default) | drift object or function accessible by  $(t, X_t)$

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The drift rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `drift` class allows you to create drift-rate objects using `drift` of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- `A` is an `NVars`-by-1 vector-valued function accessible using the  $(t, X_t)$  interface.
- `B` is an `NVars`-by-`NVars` matrix-valued function accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `drift` object are:

- `Rate`: The drift-rate function,  $F(t, X_t)$
- `A`: The intercept term,  $A(t, X_t)$ , of  $F(t, X_t)$
- `B`: The first order term,  $B(t, X_t)$ , of  $F(t, X_t)$

`A` and `B` enable you to query the original inputs. The function stored in `Rate` fully encapsulates the combined effect of `A` and `B`.

When specified as MATLAB double arrays, the inputs `A` and `B` are clearly associated with a linear drift rate parametric form. However, specifying either `A` or `B` as a function allows you to customize virtually any drift rate specification.

---

**Note** You can express `drift` and `diffusion` classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components `A` and `B` as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `F = drift(0, 0.1)` % Drift rate function  $F(t, X)$

Data Types: `object`

**Diffusion — Diffusion rate component of continuous-time stochastic differential equations (SDEs)**

value stored from diffusion-rate function (default) | diffusion object or functions accessible by  $(t, X_t)$

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The diffusion rate specification supports the simulation of sample paths of **NVars** state variables driven by **NBrowns** Brownian motion sources of risk over **NPeriods** consecutive observation periods, approximating continuous-time stochastic processes.

The **diffusion** class allows you to create diffusion-rate objects using **diffusion**:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- **D** is an **NVars**-by-**NVars** diagonal matrix-valued function.
- Each diagonal element of **D** is the corresponding element of the state vector raised to the corresponding element of an exponent **Alpha**, which is an **NVars**-by-1 vector-valued function.
- **V** is an **NVars**-by-**NBrowns** matrix-valued volatility rate function **Sigma**.
- **Alpha** and **Sigma** are also accessible using the  $(t, X_t)$  interface.

The displayed parameters for a **diffusion** object are:

- **Rate**: The diffusion-rate function,  $G(t, X_t)$ .
- **Alpha**: The state vector exponent, which determines the format of  $D(t, X_t)$  of  $G(t, X_t)$ .
- **Sigma**: The volatility rate,  $V(t, X_t)$ , of  $G(t, X_t)$ .

**Alpha** and **Sigma** enable you to query the original inputs. (The combined effect of the individual **Alpha** and **Sigma** parameters is fully encapsulated by the function stored in **Rate**.) The **Rate** functions are the calculation engines for the **drift** and **diffusion** objects, and are the only parameters required for simulation.

---

**Note** You can express **drift** and **diffusion** classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components **A** and **B** as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: object

## Object Functions

|             |                                                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| interpolate | Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models            |
| simulate    | Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models |
| simByEuler  | Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models                  |

## Examples

## Create a bm Object

Create a univariate Brownian motion (`bm`) object to represent the model:  $dX_t = 0.3dW_t$ .

```
obj = bm(0, 0.3) % (A = Mu, Sigma)

obj =
  Class BM: Brownian Motion
  -----
    Dimensions: State = 1, Brownian = 1
  -----
    StartTime: 0
    StartState: 0
    Correlation: 1
      Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
      Simulation: simulation method/function simByEuler
      Mu: 0
      Sigma: 0.3
```

`bm` objects display the parameter `A` as the more familiar `Mu`.

The `bm` class also provides an overloaded Euler simulation method that improves run-time performance in certain common situations. This specialized method is invoked automatically only if *all* the following conditions are met:

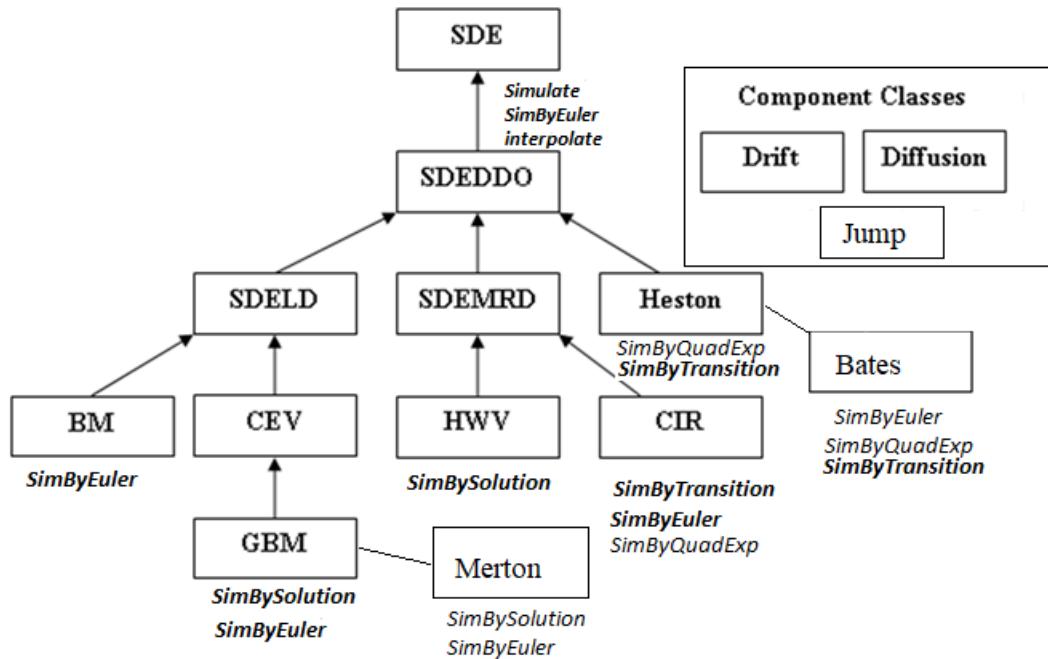

- The expected drift, or trend, rate `Mu` is a column vector.
- The volatility rate, `Sigma`, is a matrix.
- No end-of-period adjustments and/or processes are made.
- If specified, the random noise process `Z` is a three-dimensional array.
- If `Z` is unspecified, the assumed Gaussian correlation structure is a double matrix.

## More About

### Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.

For more information, see “SDE Class Hierarchy” on page 18-5.

## Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time  $t$  and a state vector  $X_t$ , and return an array of appropriate dimension. Even if you originally specified an input as an array, **bm** treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

## Introduced in R2008a

## cev

Constant Elasticity of Variance (CEV) model

### Description

Creates and displays `cev` objects, which derive from the `sdeLD` (SDE with drift rate expressed in linear form) class.

Use `cev` objects to simulate sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

This model allows you to simulate any vector-valued CEV of the form:

$$dX_t = \mu(t)X_t dt + D(t, X_t^{\alpha(t)})V(t)dW_t$$

where:

- $X_t$  is an `NVars`-by-1 state vector of process variables.
- $\mu$  is an `NVars`-by-`NVars` (generalized) expected instantaneous rate of return matrix.
- $D$  is an `NVars`-by-`NVars` diagonal matrix, where each element along the main diagonal is the corresponding element of the state vector raised to the corresponding power of  $\alpha$ .
- $V$  is an `NVars`-by-`NBrowns` instantaneous volatility rate matrix.
- $dW_t$  is an `NBrowns`-by-1 Brownian motion vector.

### Creation

#### Syntax

```
CEV = cev(Return,Alpha,Sigma)
CEV = cev( ___,Name,Value)
```

#### Description

`CEV = cev(Return,Alpha,Sigma)` creates a default CEV object.

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

---

**Note** You can specify combinations of array and function input parameters as needed.

---

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time  $t$  as its only input argument. Otherwise, a parameter is assumed to be a function of time  $t$  and state  $X(t)$  and is invoked with both input arguments.

`CEV = cev( ___, Name, Value)` creates a CEV object with additional options specified by one or more `Name, Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`

The CEV object has the following “Properties” on page 19-12:

- `StartTime` — Initial observation time
- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `Simulation` — A simulation function or method
- `Return` — Access function for the input argument `Return`, callable as a function of time and state
- `Alpha` — Access function for the input argument `Alpha`, callable as a function of time and state
- `Sigma` — Access function for the input argument `Sigma`, callable as a function of time and state

## Input Arguments

### **Return — Return represents the parameter $\mu$**

array or deterministic function of time or deterministic function of time and state

`Return` represents the parameter  $\mu$ , specified as an array or deterministic function of time.

If you specify `Return` as an array, it must be an `NVars`-by-`NVars` matrix representing the expected (mean) instantaneous rate of return.

As a deterministic function of time, when `Return` is called with a real-valued scalar time  $t$  as its only input, `Return` must produce an `NVars`-by-`NVars` matrix. If you specify `Return` as a function of time and state, it must return an `NVars`-by-`NVars` matrix when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An `NVars`-by-1 state vector  $X_t$ .

Data Types: `double` | `function_handle`

### **Alpha — Return represents the parameter $D$**

array or deterministic function of time or deterministic function of time and state

`Alpha` represents the parameter  $D$ , specified as an array or deterministic function of time.

If you specify `Alpha` as an array, it represents an `NVars`-by-1 column vector of exponents.

As a deterministic function of time, when `Alpha` is called with a real-valued scalar time  $t$  as its only input, `Alpha` must produce an `NVars`-by-1 matrix.

If you specify it as a function of time and state, **Alpha** must return an **NVars**-by-1 column vector of exponents when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An **NVars**-by-1 state vector  $X_t$ .

Data Types: double | function\_handle

### **Sigma — Sigma represents the parameter V**

array or deterministic function of time or deterministic function of time and state

**Sigma** represents the parameter  $V$ , specified as an array or a deterministic function of time.

If you specify **Sigma** as an array, it must be an **NVars**-by-**NBrowns** matrix of instantaneous volatility rates. In this case, each row of **Sigma** corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when **Sigma** is called with a real-valued scalar time  $t$  as its only input, **Sigma** must produce an **NVars**-by-**NBrowns** matrix. If you specify **Sigma** as a function of time and state, it must return an **NVars**-by-**NBrowns** matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An **NVars**-by-1 state vector  $X_t$ .

Data Types: double | function\_handle

---

**Note** Although **cev** does not enforce restrictions on the signs of these input arguments, each argument is specified as a positive value.

---

## Properties

### **StartTime — Starting time of first observation, applied to all state variables**

0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

### **StartState — Initial values of state variables**

1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If **StartState** is a scalar, **cev** applies the same initial value to all state variables on all trials.

If **StartState** is a column vector, **cev** applies a unique initial value to each state variable on all trials.

If **StartState** is a matrix, **cev** applies a unique initial value to each state variable on each trial.

Data Types: double

**Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)**

NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function  $C(t)$  that accepts the current time  $t$  and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

As a deterministic function of time, Correlation allows you to specify a dynamic correlation structure.

Data Types: double

**Simulation — User-defined simulation function or SDE simulation method**

simulation by Euler approximation (`simByEuler`) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function\_handle

**Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)**

value stored from drift-rate function (default) | drift object or function accessible by  $(t, X_t)$

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The drift rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The `drift` class allows you to create drift-rate objects using `drift` of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- A is an NVars-by-1 vector-valued function accessible using the  $(t, X_t)$  interface.
- B is an NVars-by-NVars matrix-valued function accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `drift` object are:

- Rate: The drift-rate function,  $F(t, X_t)$
- A: The intercept term,  $A(t, X_t)$ , of  $F(t, X_t)$
- B: The first order term,  $B(t, X_t)$ , of  $F(t, X_t)$

A and B enable you to query the original inputs. The function stored in Rate fully encapsulates the combined effect of A and B.

When specified as MATLAB double arrays, the inputs A and B are clearly associated with a linear drift rate parametric form. However, specifying either A or B as a function allows you to customize virtually any drift rate specification.

---

**Note** You can express `drift` and `diffusion` classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components A and B as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: `struct | double`

**Diffusion — Diffusion rate component of continuous-time stochastic differential equations (SDEs)**

value stored from diffusion-rate function (default) | diffusion object or functions accessible by  $(t, X_t)$

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as an object or function accessible by  $(t, X_t)$ .

The diffusion rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `diffusion` class allows you to create diffusion-rate objects using `diffusion`:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- D is an `NVars`-by-`NVars` diagonal matrix-valued function.
- Each diagonal element of D is the corresponding element of the state vector raised to the corresponding element of an exponent `Alpha`, which is an `NVars`-by-1 vector-valued function.
- V is an `NVars`-by-`NBrowns` matrix-valued volatility rate function `Sigma`.
- `Alpha` and `Sigma` are also accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `diffusion` object are:

- `Rate`: The diffusion-rate function,  $G(t, X_t)$ .
- `Alpha`: The state vector exponent, which determines the format of  $D(t, X_t)$  of  $G(t, X_t)$ .
- `Sigma`: The volatility rate,  $V(t, X_t)$ , of  $G(t, X_t)$ .

`Alpha` and `Sigma` enable you to query the original inputs. (The combined effect of the individual `Alpha` and `Sigma` parameters is fully encapsulated by the function stored in `Rate`.) The `Rate` functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

---

**Note** You can express `drift` and `diffusion` classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components A and B as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

---

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: struct | double

## Object Functions

|                          |                                                                                                                                                        |

| <code>simByEuler</code>  | Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models                  |

## Examples

### Create a cev Object

Create a univariate cev object to represent the model:  $dX_t = 0.25X_t + 0.3X_t^{\frac{1}{2}}dW_t$ .

```
obj = cev(0.25, 0.5, 0.3) % (B = Return, Alpha, Sigma)

obj =
  Class CEV: Constant Elasticity of Variance
  -----
  Dimensions: State = 1, Brownian = 1
  -----
  StartTime: 0
  StartState: 1
  Correlation: 1
  Drift: drift rate function F(t,X(t))
  Diffusion: diffusion rate function G(t,X(t))
  Simulation: simulation method/function simByEuler
  Return: 0.25
  Alpha: 0.5
  Sigma: 0.3
```

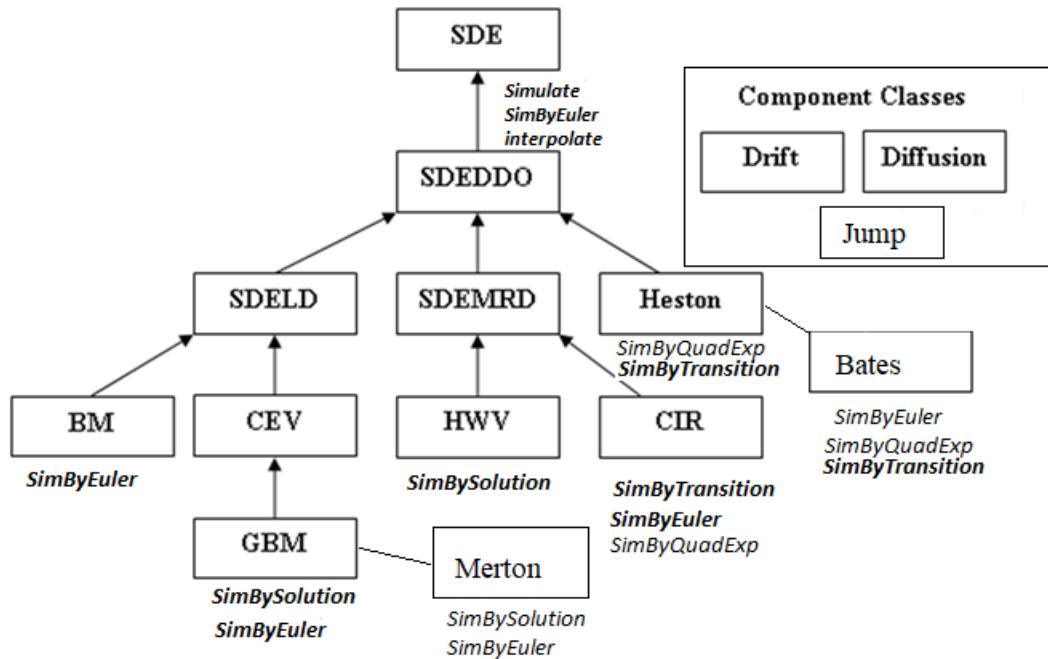

cev objects display the parameter `B` as the more familiar `Return`

## More About

### Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.

For more information, see “SDE Class Hierarchy” on page 18-5.

## Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time  $t$  and a state vector  $X_t$ , and return an array of appropriate dimension. Even if you originally specified an input as an array, **cev** treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

## Introduced in R2008a

## cir

Cox-Ingersoll-Ross (CIR) mean-reverting square root diffusion model

### Description

Creates and displays `cir` objects, which derive from the `sdemr` (SDE with drift rate expressed in mean-reverting form) class.

Use `cir` objects to simulate sample paths of `NVars` state variables expressed in mean-reverting drift-rate form. These state variables are driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time CIR stochastic processes with square root diffusions.

You can simulate any vector-valued CIR process of the form:

$$dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW_t$$

where:

- $X_t$  is an `NVars`-by-1 state vector of process variables.
- $S$  is an `NVars`-by-`NVars` matrix of mean reversion speeds (the rate of mean reversion).
- $L$  is an `NVars`-by-1 vector of mean reversion levels (long-run mean or level).
- $D$  is an `NVars`-by-`NVars` diagonal matrix, where each element along the main diagonal is the square root of the corresponding element of the state vector.
- $V$  is an `NVars`-by-`NBrowns` instantaneous volatility rate matrix.
- $dW_t$  is an `NBrowns`-by-1 Brownian motion vector.

### Creation

#### Syntax

```
CIR = cir(Speed,Level,Sigma)
CIR = cir(___,Name,Value)
```

#### Description

`CIR = cir(Speed,Level,Sigma)` creates a default CIR object.

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.

- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

---

**Note** You can specify combinations of array and function input parameters as needed.

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time  $t$  as its only input argument. Otherwise, a parameter is assumed to be a function of time  $t$  and state  $X(t)$  and is invoked with both input arguments.

---

`CIR = cir(___,Name,Value)` creates a CIR object with additional options specified by one or more `Name,Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1, ..., NameN,ValueN`

The CIR object has the following “Properties” on page 19-20:

- `StartTime` — Initial observation time
- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `Simulation` — A simulation function or method
- `Speed` — Access function for the input argument `Speed`, callable as a function of time and state
- `Level` — Access function for the input argument `Level`, callable as a function of time and state
- `Sigma` — Access function for the input argument `Sigma`, callable as a function of time and state

## Input Arguments

### Speed — Speed represents the parameter $S$

array or deterministic function of time or deterministic function of time and state

`Speed` represents the parameter  $S$ , specified as an array or deterministic function of time.

If you specify `Speed` as an array, it must be an `NVars`-by-`NVars` matrix of mean-reversion speeds (the rate at which the state vector reverts to its long-run average `Level`).

As a deterministic function of time, when `Speed` is called with a real-valued scalar time  $t$  as its only input, `Speed` must produce an `NVars`-by-`NVars` matrix. If you specify `Speed` as a function of time and state, it calculates the speed of mean reversion. This function must generate an `NVars`-by-`NVars` matrix of reversion rates when called with two inputs:

- A real-valued scalar observation time  $t$ .
- An `NVars`-by-1 state vector  $X_t$ .

Data Types: `double` | `function_handle`

**Level — Level represents the parameter  $L$** 

array or deterministic function of time or deterministic function of time and state

Level represents the parameter  $L$ , specified as an array or deterministic function of time.

If you specify Level as an array, it must be an NVars-by-1 column vector of reversion levels.

As a deterministic function of time, when Level is called with a real-valued scalar time  $t$  as its only input, Level must produce an NVars-by-1 column vector. If you specify Level as a function of time and state, it must generate an NVars-by-1 column vector of reversion levels when called with two inputs:

- A real-valued scalar observation time  $t$ .
- An NVars-by-1 state vector  $X_t$ .

Data Types: double | function\_handle

**Sigma — Sigma represents the parameter  $V$** 

array or deterministic function of time or deterministic function of time and state

Sigma represents the parameter  $V$ , specified as an array or a deterministic function of time.

If you specify Sigma as an array, it must be an NVars-by-NBrowns matrix of instantaneous volatility rates or as a deterministic function of time. In this case, each row of Sigma corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when Sigma is called with a real-valued scalar time  $t$  as its only input, Sigma must produce an NVars-by-NBrowns matrix. If you specify Sigma as a function of time and state, it must return an NVars-by-NBrowns matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An NVars-by-1 state vector  $X_t$ .

Data Types: double | function\_handle

---

**Note** Although cir does not enforce restrictions on the signs of these input arguments, each argument is specified as a positive value.

---

## Properties

**StartTime — Starting time of first observation, applied to all state variables**

0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

**StartState — Initial values of state variables**

1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If `StartState` is a scalar, `cir` applies the same initial value to all state variables on all trials.

If `StartState` is a column vector, `cir` applies a unique initial value to each state variable on all trials.

If `StartState` is a matrix, `cir` applies a unique initial value to each state variable on each trial.

Data Types: double

**Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)**

NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function  $C(t)$  that accepts the current time  $t$  and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If `Correlation` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

A `Correlation` matrix represents a static condition.

As a deterministic function of time, `Correlation` allows you to specify a dynamic correlation structure.

Data Types: double

**Simulation — User-defined simulation function or SDE simulation method**

simulation by Euler approximation (`simByEuler`) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function\_handle

**Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)**

value stored from drift-rate function (default) | drift object or function accessible by  $(t, X_t)$

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The drift rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The `drift` class allows you to create drift-rate objects using `drift` of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- A is an NVars-by-1 vector-valued function accessible using the  $(t, X_t)$  interface.
- B is an NVars-by-NVars matrix-valued function accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `drift` object are:

- **Rate**: The drift-rate function,  $F(t, X_t)$
- **A**: The intercept term,  $A(t, X_t)$ , of  $F(t, X_t)$
- **B**: The first order term,  $B(t, X_t)$ , of  $F(t, X_t)$

A and B enable you to query the original inputs. The function stored in Rate fully encapsulates the combined effect of A and B.

When specified as MATLAB double arrays, the inputs A and B are clearly associated with a linear drift rate parametric form. However, specifying either A or B as a function allows you to customize virtually any drift rate specification.

---

**Note** You can express drift and diffusion classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components A and B as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: struct | double

**Diffusion – Diffusion rate component of continuous-time stochastic differential equations (SDEs)**

value stored from diffusion-rate function (default) | diffusion object or functions accessible by  $(t, X_t)$

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The diffusion rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The diffusion class allows you to create diffusion-rate objects using diffusion:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- D is an NVars-by-NVars diagonal matrix-valued function.
- Each diagonal element of D is the corresponding element of the state vector raised to the corresponding element of an exponent Alpha, which is an NVars-by-1 vector-valued function.
- V is an NVars-by-NBrowns matrix-valued volatility rate function Sigma.
- Alpha and Sigma are also accessible using the  $(t, X_t)$  interface.

The displayed parameters for a diffusion object are:

- **Rate**: The diffusion-rate function,  $G(t, X_t)$ .
- **Alpha**: The state vector exponent, which determines the format of  $D(t, X_t)$  of  $G(t, X_t)$ .
- **Sigma**: The volatility rate,  $V(t, X_t)$ , of  $G(t, X_t)$ .

Alpha and Sigma enable you to query the original inputs. (The combined effect of the individual Alpha and Sigma parameters is fully encapsulated by the function stored in Rate.) The Rate

functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

---

**Note** You can express `drift` and `diffusion` classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components A and B as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: `struct | double`

## Object Functions

|                              |                                                                                                                                                        |

| <code>simulate</code>        | Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models |
| <code>simByEuler</code>      | Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models                  |
| <code>simByTransition</code> | Simulate CIR sample paths with transition density                                                                                                      |
| <code>simByQuadExp</code>    | Simulate Bates, Heston, and CIR sample paths by quadratic-exponential discretization scheme                                                            |

## Examples

### Create a `cir` Object

The Cox-Ingersoll-Ross (CIR) short rate class derives directly from SDE with mean-reverting drift

$$(\text{SDEMRD}): dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW$$

where  $D$  is a diagonal matrix whose elements are the square root of the corresponding element of the state vector.

Create a `cir` object to represent the model:  $dX_t = 0.2(0.1 - X_t)dt + 0.05X_t^{\frac{1}{2}}dW$ .

```
obj = cir(0.2, 0.1, 0.05) % (Speed, Level, Sigma)
obj =
  Class CIR: Cox-Ingessoll-Ross
  -----
  Dimensions: State = 1, Brownian = 1
  -----
  StartTime: 0
  StartState: 1
  Correlation: 1
  Drift: drift rate function F(t,X(t))
  Diffusion: diffusion rate function G(t,X(t))
  Simulation: simulation method/function simByEuler
  Sigma: 0.05
```

Level: 0.1  
Speed: 0.2

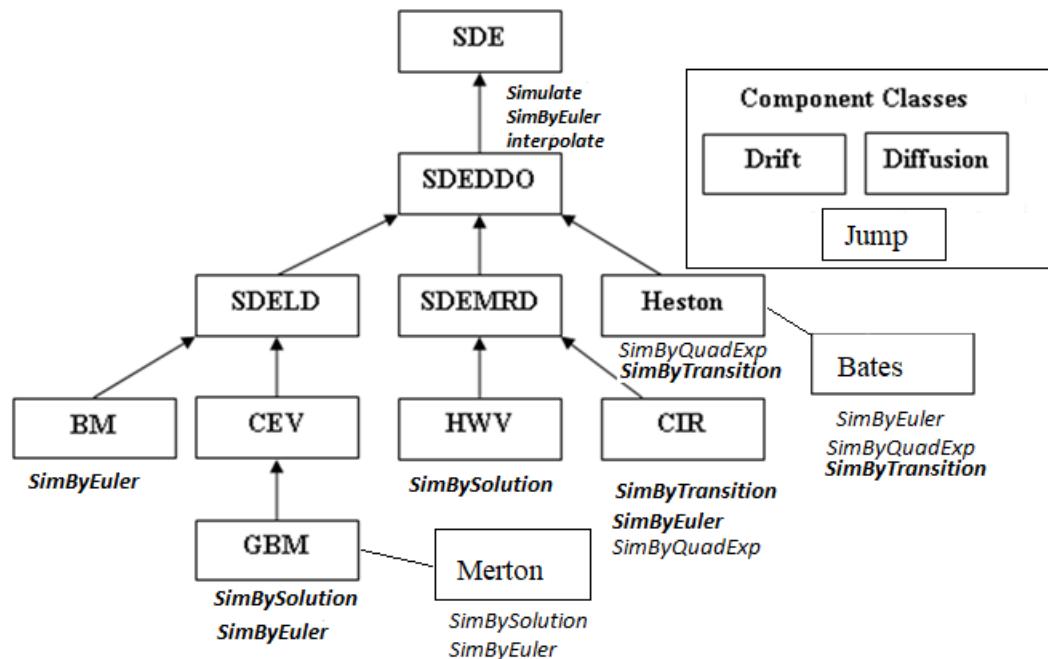

Although the last two objects are of different classes, they represent the same mathematical model. They differ in that you create the `cir` object by specifying only three input arguments. This distinction is reinforced by the fact that the `Alpha` parameter does not display – it is defined to be `1/2`.

## More About

### Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.

For more information, see “SDE Class Hierarchy” on page 18-5.

## Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time  $t$  and a state vector  $X_t$ , and return an array of appropriate dimension. Even if you originally specified an input as an array, `cir` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

## Introduced in R2008a

# diffusion

Diffusion-rate model component

## Description

The **diffusion** object specifies the diffusion-rate component of continuous-time stochastic differential equations (SDEs).

The diffusion-rate specification supports the simulation of sample paths of **NVars** state variables driven by **NBrowns** Brownian motion sources of risk over **NPeriods** consecutive observation periods, approximating continuous-time stochastic processes.

The diffusion-rate specification can be any **NVars**-by-**NBrowns** matrix-valued function **G** of the general form:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t) \quad (19-1)$$

where:

- **D** is an **NVars**-by-**NVars** diagonal matrix-valued function.
- Each diagonal element of **D** is the corresponding element of the state vector raised to the corresponding element of an exponent **Alpha**, which is an **NVars**-by-1 vector-valued function.
- **V** is an **NVars**-by-**NBrowns** matrix-valued volatility rate function **Sigma**.
- **Alpha** and **Sigma** are also accessible using the  $(t, X_t)$  interface.

And a diffusion-rate specification is associated with a vector-valued SDE of the form:

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t$$

where:

- $X_t$  is an **NVars**-by-1 state vector of process variables.
- $dW_t$  is an **NBrowns**-by-1 Brownian motion vector.
- **D** is an **NVars**-by-**NVars** diagonal matrix, in which each element along the main diagonal is the corresponding element of the state vector raised to the corresponding power of  $\alpha$ .
- **V** is an **NVars**-by-**NBrowns** matrix-valued volatility rate function **Sigma**.

The diffusion-rate specification is flexible, and provides direct parametric support for static volatilities and state vector exponents. It is also extensible, and provides indirect support for dynamic/nonlinear models via an interface. This enables you to specify virtually any diffusion-rate specification.

# Creation

## Syntax

```
DiffusionRate = diffusion(Alpha,Sigma)
```

## Description

`DiffusionRate = diffusion(Alpha,Sigma)` creates default `DiffusionRate` model component.

Specify required input parameters `A` and `B` as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

---

**Note** You can specify combinations of array and function input parameters as needed.

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time `t` as its only input argument. Otherwise, a parameter is assumed to be a function of time `t` and state `X(t)` and is invoked with both input arguments.

---

The `diffusion` object that you create encapsulates the composite drift-rate specification and returns the following displayed parameters:

- `Rate` — The diffusion-rate function,  $G$ . `Rate` is the diffusion-rate calculation engine. It accepts the current time  $t$  and an `NVars`-by-1 state vector  $X_t$  as inputs, and returns an `NVars`-by-1 diffusion-rate vector.
- `Alpha` — Access function for the input argument `Alpha`.
- `Sigma` — Access function for the input argument `Sigma`.

## Input Arguments

### **Alpha — Return represents the parameter $D$**

array or deterministic function of time

`Alpha` represents the parameter  $D$ , specified as an array or deterministic function of time.

If you specify `Alpha` as an array, it represents an `NVars`-by-1 column vector of exponents.

As a deterministic function of time, when `Alpha` is called with a real-valued scalar time `t` as its only input, `Alpha` must produce an `NVars`-by-1 matrix.

If you specify it as a function of time and state, `Alpha` must return an `NVars`-by-1 column vector of exponents when invoked with two inputs:

- A real-valued scalar observation time  $t$ .

- An NVars-by-1 state vector  $X_t$ .

Data Types: double | function\_handle

#### Sigma — Sigma represents the parameter V

array or deterministic function of time

Sigma represents the parameter  $V$ , specified as an array or a deterministic function of time.

If you specify Sigma as an array, it must be an NVars-by-NBrowns two-dimensional matrix of instantaneous volatility rates. In this case, each row of Sigma corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when Sigma is called with a real-valued scalar time  $t$  as its only input, Sigma must produce an NVars-by-NBrowns matrix. If you specify Sigma as a function of time and state, it must return an NVars-by-NBrowns matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An NVars-by-1 state vector  $X_t$ .

Data Types: double | function\_handle

---

**Note** Although diffusion enforces no restrictions on the signs of these volatility parameters, each parameter is specified as a positive value.

---

## Properties

### Rate — Composite diffusion-rate function

value stored from diffusion-rate function (default) | function accessible by  $(t, X_t)$

This property is read-only.

Composite diffusion-rate function, specified as:  $G(t, X_t)$ . The function stored in Rate fully encapsulates the combined effect of Alpha and Sigma where:

- Alpha is the state vector exponent, which determines the format of  $D(t, X_t)$  of  $G(t, X_t)$ .
- Sigma is the volatility rate,  $V(t, X_t)$ , of  $G(t, X_t)$ .

Data Types: struct | double

## Examples

### Create a diffusion Object

Create a diffusion-rate function G:

```
G = diffusion(1, 0.3) % Diffusion rate function G(t,X)
```

```
G =
Class DIFFUSION: Diffusion Rate Specification
```

```

-----
Rate: diffusion rate function G(t,X(t))
Alpha: 1
Sigma: 0.3

```

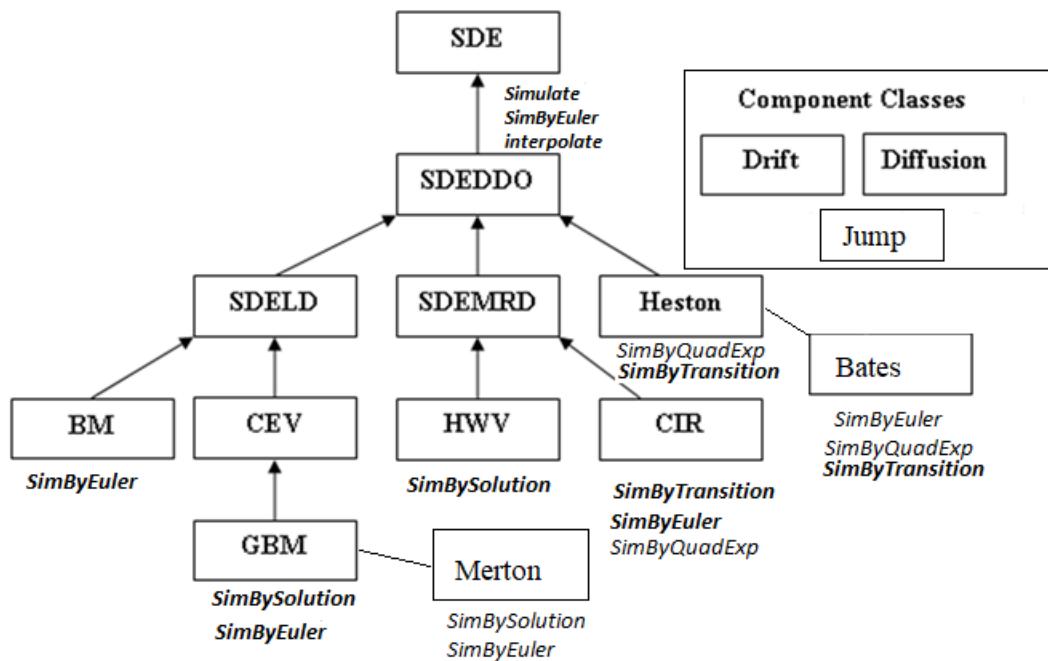

The `diffusion` object displays like a MATLAB® structure and contains supplemental information, namely, the object's class and a brief description. However, in contrast to the SDE representation, a summary of the dimensionality of the model does not appear, because the `diffusion` class creates a model component rather than a model. `G` does not contain enough information to characterize the dimensionality of a problem.

## More About

### Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.

For more information, see “SDE Class Hierarchy” on page 18-5.

## Algorithms

When you specify the input arguments `Alpha` and `Sigma` as MATLAB arrays, they are associated with a specific parametric form. By contrast, when you specify either `Alpha` or `Sigma` as a function, you can customize virtually any diffusion-rate specification.

Accessing the output diffusion-rate parameters `Alpha` and `Sigma` with no inputs simply returns the original input specification. Thus, when you invoke diffusion-rate parameters with no inputs, they

behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke diffusion-rate parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters `Alpha` and `Sigma` accept the observation time  $t$  and a state vector  $X_t$ , and return an array of appropriate dimension. Specifically, parameters `Alpha` and `Sigma` evaluate the corresponding diffusion-rate component. Even if you originally specified an input as an array, `diffusion` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

# drift

Drift-rate model component

## Description

The `drift` object specifies the drift-rate component of continuous-time stochastic differential equations (SDEs).

The drift-rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The drift-rate specification can be any `NVars`-by-1 vector-valued function  $F$  of the general form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- $A$  is an `NVars`-by-1 vector-valued function accessible using the  $(t, X_t)$  interface.
- $B$  is an `NVars`-by-`NVars` matrix-valued function accessible using the  $(t, X_t)$  interface.

And a drift-rate specification is associated with a vector-valued SDE of the form

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t$$

where:

- $X_t$  is an `NVars`-by-1 state vector of process variables.
- $dW_t$  is an `NBrowns`-by-1 Brownian motion vector.
- $A$  and  $B$  are model parameters.

The drift-rate specification is flexible, and provides direct parametric support for static/linear drift models. It is also extensible, and provides indirect support for dynamic/nonlinear models via an interface. This enables you to specify virtually any drift-rate specification.

## Creation

### Syntax

```
DriftRate = drift(A,B)
```

### Description

`DriftRate = drift(A,B)` creates a default `DriftRate` model component.

Specify required input parameters  $A$  and  $B$  as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

---

**Note** You can specify combinations of array and function input parameters as needed.

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time  $t$  as its only input argument. Otherwise, a parameter is assumed to be a function of time  $t$  and state  $X(t)$  and is invoked with both input arguments.

---

The `drift` object that you create encapsulates the composite drift-rate specification and returns the following displayed parameters:

- `Rate` — The drift-rate function,  $F$ . `Rate` is the drift-rate calculation engine. It accepts the current time  $t$  and an NVars-by-1 state vector  $X_t$  as inputs, and returns an NVars-by-1 drift-rate vector.
- `A` — Access function for the input argument `A`.
- `B` — Access function for the input argument `B`.

### Input Arguments

#### **A — A represents the parameter A**

array or deterministic function of time

`A` represents the parameter  $A$ , specified as an array or deterministic function of time.

If you specify `A` as an array, it must be an NVars-by-1 column vector of intercepts.

As a deterministic function of time, when `A` is called with a real-valued scalar time  $t$  as its only input, `A` must produce an NVars-by-1 column vector. If you specify `A` as a function of time and state, it must generate an NVars-by-1 column vector of intercepts when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An NVars-by-1 state vector  $X_t$ .

Data Types: `double` | `function_handle`

#### **B — B represents the parameter B**

array or deterministic function of time

`B` represents the parameter  $B$ , specified as an array or deterministic function of time.

If you specify `B` as an array, it must be an NVars-by-NVars two-dimensional matrix of state vector coefficients.

As a deterministic function of time, when `B` is called with a real-valued scalar time  $t$  as its only input, `B` must produce an NVars-by-NVars matrix. If you specify `B` as a function of time and state, it must generate an NVars-by-NVars matrix of state vector coefficients when invoked with two inputs:

- A real-valued scalar observation time  $t$ .

- An NVars-by-1 state vector  $X_t$ .

Data Types: double | function\_handle

## Properties

### Rate — Composite drift-rate function

value stored from drift-rate function (default) | function accessible by  $F(t,X_t)$

This property is read-only.

Composite drift-rate function, specified as  $F(t,X_t)$ . The function stored in Rate fully encapsulates the combined effect of A and B, where A and B are:

- A: The intercept term,  $A(t,X_t)$ , of  $F(t,X_t)$
- B: The first order term,  $B(t,X_t)$ , of  $F(t,X_t)$

Data Types: struct | double

## Examples

### Create a drift Object

Create a drift-rate function F:

```
F = drift(0, 0.1) % Drift rate function F(t,X)
F =
  Class DRIFT: Drift Rate Specification
  -----
  Rate: drift rate function F(t,X(t))
  A: 0
  B: 0.1
```

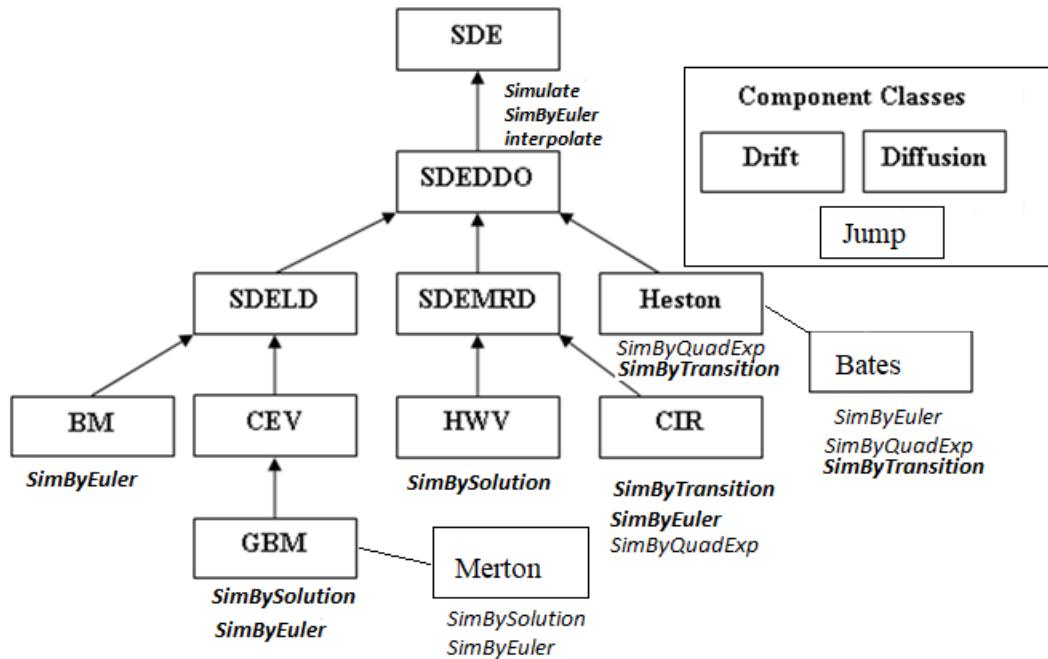

The `drift` object displays like a MATLAB® structure and contains supplemental information, namely, the object's class and a brief description. However, in contrast to the SDE representation, a summary of the dimensionality of the model does not appear, because the `drift` class creates a model component rather than a model. F does not contain enough information to characterize the dimensionality of a problem.

## More About

### Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.

For more information, see “SDE Class Hierarchy” on page 18-5.

## Algorithms

When you specify the input arguments A and B as MATLAB arrays, they are associated with a linear drift parametric form. By contrast, when you specify either A or B as a function, you can customize virtually any drift-rate specification.

Accessing the output drift-rate parameters A and B with no inputs simply returns the original input specification. Thus, when you invoke drift-rate parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke drift-rate parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters A and B accept the observation time  $t$  and a state vector  $X_t$ , and return an array of appropriate dimension. Specifically, parameters A and B evaluate the corresponding drift-rate component. Even if you originally specified an input as an array, **drift** treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

# Financial Time Series

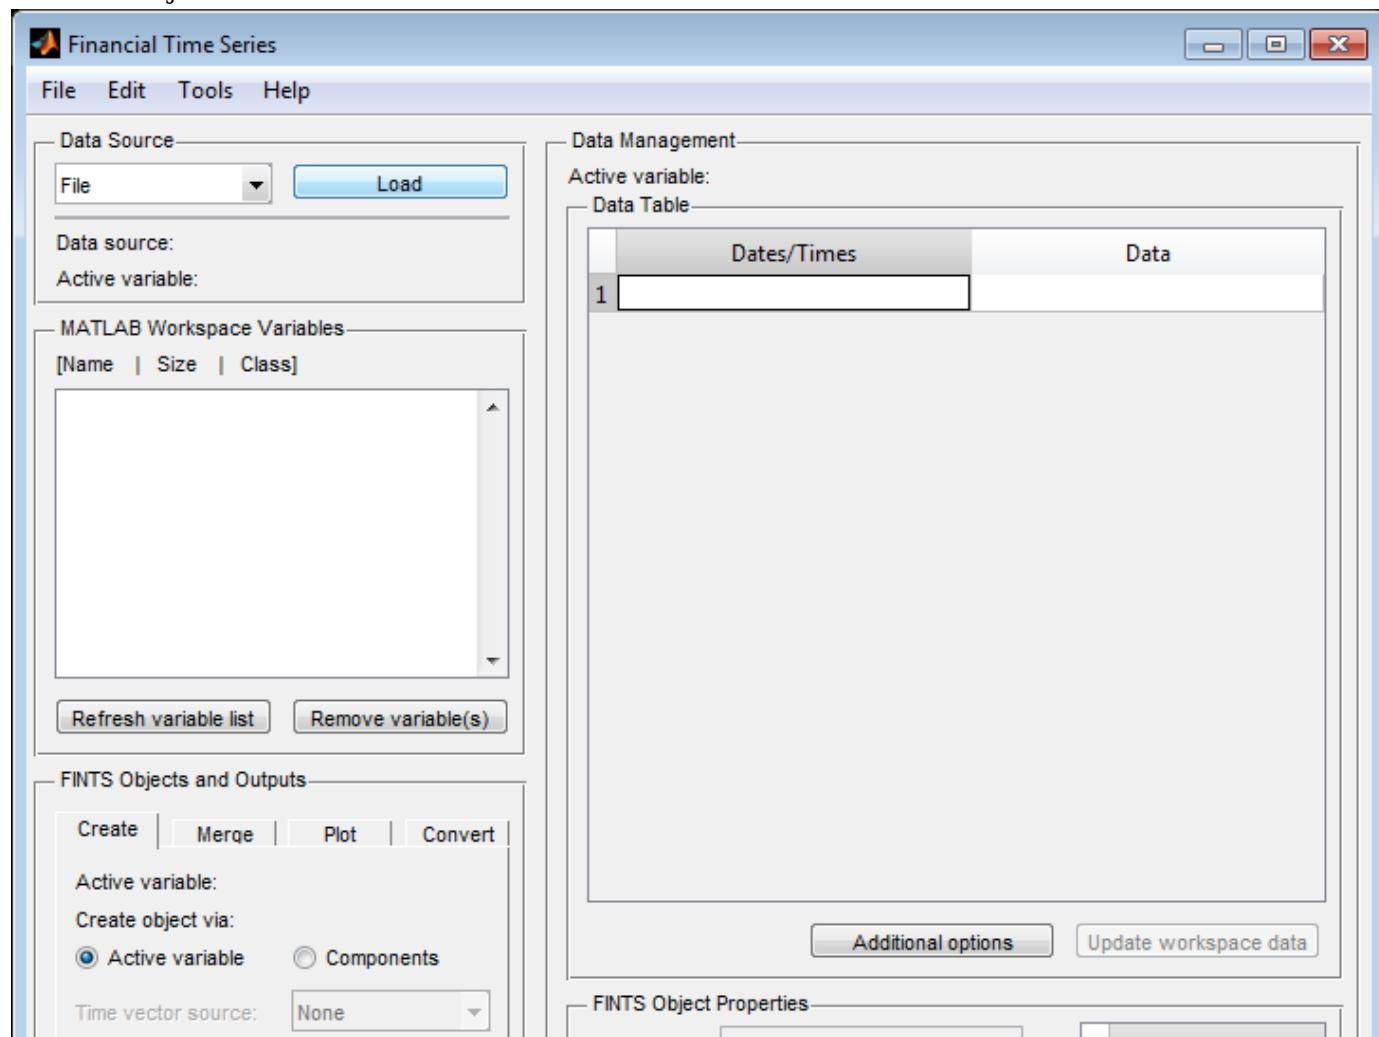

Create and manage Financial Time Series

**Note** The **Financial Time Series** app will be removed in a future release and will no longer accept a `fints` object.

Use `fts2timetable` to convert a `fints` object to a `timetable` object. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

## Description

The **Financial Time Series** app enables you to create and manage Financial Time Series (`fints`) objects.

## Open the Financial Time Series App

From the MATLAB command prompt: Enter `ftstool`.

## gbm

Geometric Brownian motion (GBM) model

### Description

Creates and displays geometric Brownian motion models, which derive from the `cev` (constant elasticity of variance) class.

Geometric Brownian motion (GBM) models allow you to simulate sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time GBM stochastic processes. Specifically, this model allows the simulation of vector-valued GBM processes of the form

$$dX_t = \mu(t)X_t dt + D(t, X_t)V(t)dW_t$$

where:

- $X_t$  is an `NVars`-by-1 state vector of process variables.
- $\mu$  is an `NVars`-by-`NVars` generalized expected instantaneous rate of return matrix.
- $D$  is an `NVars`-by-`NVars` diagonal matrix, where each element along the main diagonal is the corresponding element of the state vector  $X_t$ .
- $V$  is an `NVars`-by-`NBrowns` instantaneous volatility rate matrix.
- $dW_t$  is an `NBrowns`-by-1 Brownian motion vector.

### Creation

#### Syntax

```
GBM = gbm(Return,Sigma)
GBM = gbm(___,Name,Value)
```

#### Description

`GBM = gbm(Return,Sigma)` creates a default GBM object.

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

---

**Note** You can specify combinations of array and function input parameters as needed.

---

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time  $t$  as its only input argument. Otherwise, a parameter is assumed to be a function of time  $t$  and state  $X(t)$  and is invoked with both input arguments.

`GBM = gbm(____, Name, Value)` creates a GBM object with additional options specified by one or more `Name, Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`

The GBM object has the following “Properties” on page 19-40:

- `StartTime` — Initial observation time
- `StartState` — Initial state at `StartTime`
- `Correlation` — Access function for the `Correlation` input, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `Simulation` — A simulation function or method
- `Return` — Access function for the input argument `Return`, callable as a function of time and state
- `Sigma` — Access function for the input argument `Sigma`, callable as a function of time and state

## Input Arguments

### **Return — Return represents the parameter $\mu$**

array or deterministic function of time or deterministic function of time and state

`Return` represents the parameter  $\mu$ , specified as an array or deterministic function of time.

If you specify `Return` as an array, it must be an `NVars`-by-`NVars` matrix representing the expected (mean) instantaneous rate of return.

As a deterministic function of time, when `Return` is called with a real-valued scalar time  $t$  as its only input, `Return` must produce an `NVars`-by-`NVars` matrix. If you specify `Return` as a function of time and state, it must return an `NVars`-by-`NVars` matrix when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An `NVars`-by-1 state vector  $X_t$ .

Data Types: `double` | `function_handle`

### **Sigma — Sigma represents the parameter $V$**

array or deterministic function of time or deterministic function of time and state

`Sigma` represents the parameter  $V$ , specified as an array or a deterministic function of time.

If you specify `Sigma` as an array, it must be an `NVars`-by-`NBrowns` matrix of instantaneous volatility rates or as a deterministic function of time. In this case, each row of `Sigma` corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when `Sigma` is called with a real-valued scalar time  $t$  as its only input, `Sigma` must produce an `NVars`-by-`NBrowns` matrix. If you specify `Sigma` as a function of time and state, it must return an `NVars`-by-`NBrowns` matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An `NVars`-by-1 state vector  $X_t$ .

Although the `gbm` object enforces no restrictions on the sign of `Sigma` volatilities, they are specified as positive values.

Data Types: double | function\_handle

## Properties

### **StartTime — Starting time of first observation, applied to all state variables**

0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

### **StartState — Initial values of state variables**

1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If `StartState` is a scalar, the `gbm` object applies the same initial value to all state variables on all trials.

If `StartState` is a column vector, the `gbm` object applies a unique initial value to each state variable on all trials.

If `StartState` is a matrix, the `gbm` object applies a unique initial value to each state variable on each trial.

Data Types: double

### **Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)**

`NBrowns`-by-`NBrowns` identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an `NBrowns`-by-`NBrowns` positive semidefinite matrix, or as a deterministic function  $C(t)$  that accepts the current time  $t$  and returns an `NBrowns`-by-`NBrowns` positive semidefinite correlation matrix. If `Correlation` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

A `Correlation` matrix represents a static condition.

As a deterministic function of time, `Correlation` allows you to specify a dynamic correlation structure.

Data Types: double

**Simulation — User-defined simulation function or SDE simulation method**simulation by Euler approximation (`simByEuler`) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: `function_handle`**Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)**value stored from drift-rate function (default) | drift object or function accessible by  $(t, X_t)$ 

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .The drift rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.The `drift` class allows you to create drift-rate objects (using `drift`) of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- `A` is an `NVars`-by-1 vector-valued function accessible using the  $(t, X_t)$  interface.
- `B` is an `NVars`-by-`NVars` matrix-valued function accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `drift` object are:

- `Rate`: The drift-rate function,  $F(t, X_t)$
- `A`: The intercept term,  $A(t, X_t)$ , of  $F(t, X_t)$
- `B`: The first order term,  $B(t, X_t)$ , of  $F(t, X_t)$

A and B enable you to query the original inputs. The function stored in `Rate` fully encapsulates the combined effect of A and B.

When specified as MATLAB double arrays, the inputs A and B are clearly associated with a linear drift rate parametric form. However, specifying either A or B as a function allows you to customize virtually any drift rate specification.

---

**Note** You can express `drift` and `diffusion` classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components A and B as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `F = drift(0, 0.1)` % Drift rate function  $F(t, X)$ Data Types: `struct` | `double`**Diffusion — Diffusion rate component of continuous-time stochastic differential equations (SDEs)**value stored from diffusion-rate function (default) | diffusion object or functions accessible by  $(t, X_t)$

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The diffusion rate specification supports the simulation of sample paths of **NVars** state variables driven by **NBrowns** Brownian motion sources of risk over **NPeriods** consecutive observation periods, approximating continuous-time stochastic processes.

The **diffusion** class allows you to create diffusion-rate objects (using **diffusion**):

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- **D** is an **NVars**-by-**NVars** diagonal matrix-valued function.
- Each diagonal element of **D** is the corresponding element of the state vector raised to the corresponding element of an exponent **Alpha**, which is an **NVars**-by-1 vector-valued function.
- **V** is an **NVars**-by-**NBrowns** matrix-valued volatility rate function **Sigma**.
- **Alpha** and **Sigma** are also accessible using the  $(t, X_t)$  interface.

The **diffusion** object's displayed parameters are:

- **Rate**: The diffusion-rate function,  $G(t, X_t)$ .
- **Alpha**: The state vector exponent, which determines the format of  $D(t, X_t)$  of  $G(t, X_t)$ .
- **Sigma**: The volatility rate,  $V(t, X_t)$ , of  $G(t, X_t)$ .

**Alpha** and **Sigma** enable you to query the original inputs. (The combined effect of the individual **Alpha** and **Sigma** parameters is fully encapsulated by the function stored in **Rate**.) The **Rate** functions are the calculation engines for the **drift** and **diffusion** objects, and are the only parameters required for simulation.

---

**Note** You can express **drift** and **diffusion** classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components **A** and **B** as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: struct | double

## Object Functions

## Examples

## Create a gbm Object

Create a univariate gbm object to represent the model:  $dX_t = 0.25X_tdt + 0.3X_tdW_t$ .

```
obj = gbm(0.25, 0.3) % (B = Return, Sigma)

obj =
Class GBM: Generalized Geometric Brownian Motion
-----
Dimensions: State = 1, Brownian = 1
-----
StartTime: 0
StartState: 1
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Return: 0.25
Sigma: 0.3
```

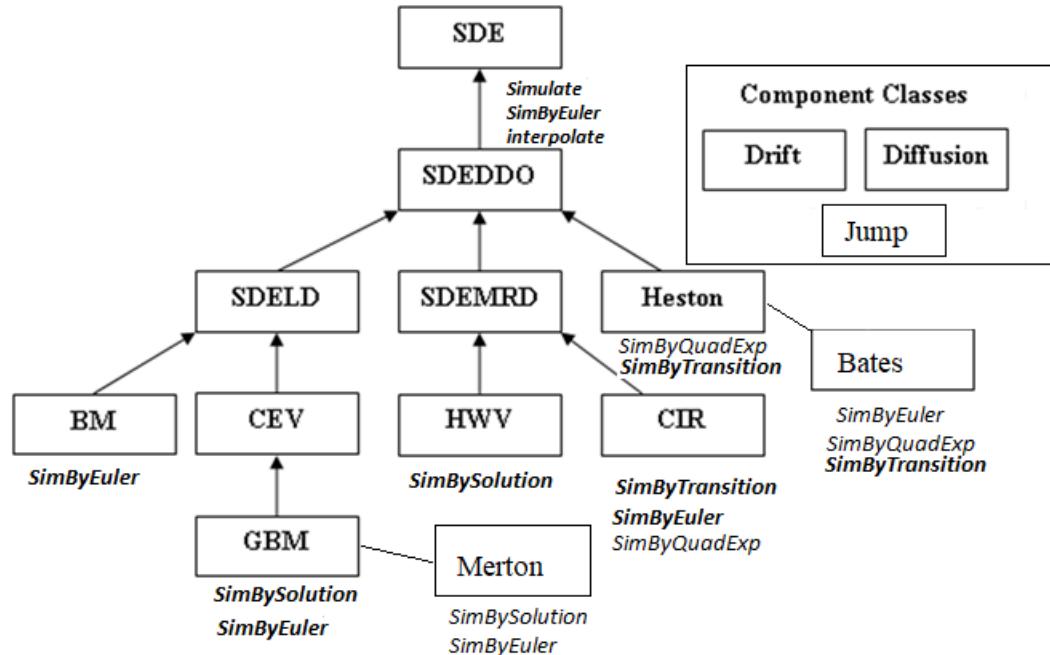

gbm objects display the parameter B as the more familiar Return

## More About

### Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.

For more information, see “SDE Class Hierarchy” on page 18-5.

## Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time  $t$  and a state vector  $X_t$ , and return an array of appropriate dimension. Even if you originally specified an input as an array, `gbm` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

# simBySolution

Simulate approximate solution of diagonal-drift GBM processes

## Syntax

```
[Paths,Times,Z] = simBySolution(MDL,NPeriods)
[Paths,Times,Z] = simBySolution(___,Name,Value)
```

## Description

[Paths,Times,Z] = simBySolution(MDL,NPeriods) simulates approximate solution of diagonal-drift for geometric Brownian motion (GBM) processes.

[Paths,Times,Z] = simBySolution(\_\_\_,Name,Value) adds optional name-value pair arguments.

You can perform quasi-Monte Carlo simulations using the name-value arguments for MonteCarloMethod and QuasiSequence. For more information, see “Quasi-Monte Carlo Simulation” on page 18-62.

## Examples

### Simulating Equity Markets Using GBM Simulation Functions

Use GBM simulation functions. Separable GBM models have two specific simulation functions:

- An overloaded Euler simulation function (`simulate`), designed for optimal performance.
- A `simBySolution` function that provides an approximate solution of the underlying stochastic differential equation, designed for accuracy.

Load the `Data_GlobalIdx2` data set and specify the SDE model as in “Representing Market Models Using SDE Objects” on page 18-28, and the GBM model as in “Representing Market Models Using SDELDD, CEV, and GBM Objects” on page 18-30.

```
load Data_GlobalIdx2
prices = [Dataset.TSX Dataset.CAC Dataset.DAX ...
          Dataset.NIK Dataset.FTSE Dataset.SP];

returns = tick2ret(prices);

nVariables = size(returns,2);
expReturn = mean(returns);
sigma = std(returns);
correlation = corrcoef(returns);
t = 0;
X = 100;
X = X(ones(nVariables,1));

F = @(t,X) diag(expReturn)* X;
G = @(t,X) diag(X) * diag(sigma);
```

```
SDE = sde(F, G, 'Correlation', ...
    correlation, 'StartState', X);

GBM = gbm(diag(expReturn), diag(sigma), 'Correlation', ...
    correlation, 'StartState', X);
```

To illustrate the performance benefit of the overloaded Euler approximation function (`simulate`), increase the number of trials to 10000.

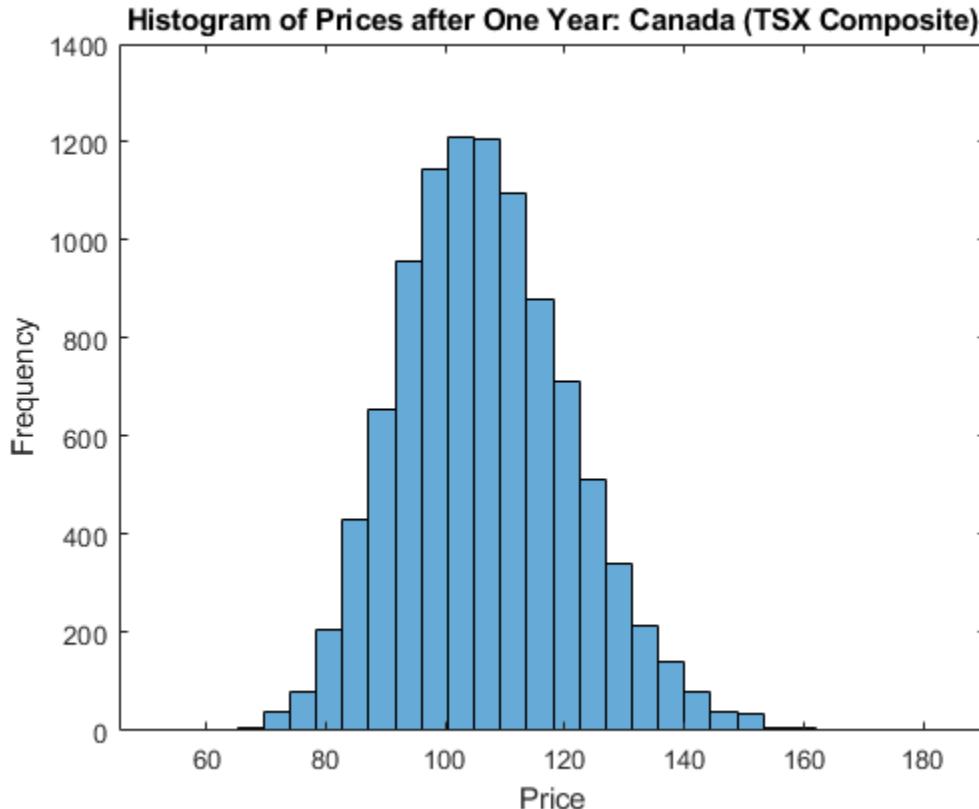

```
nPeriods = 249;      % # of simulated observations
dt       = 1;        % time increment = 1 day
rng(142857, 'twister')
[X,T] = simulate(GBM, nPeriods, 'DeltaTime', dt, ...
    'nTrials', 10000);
```

`whos X`

| Name | Size        | Bytes      | Class  | Attributes |
|------|-------------|------------|--------|------------|
| X    | 250x6x10000 | 1200000000 | double |            |

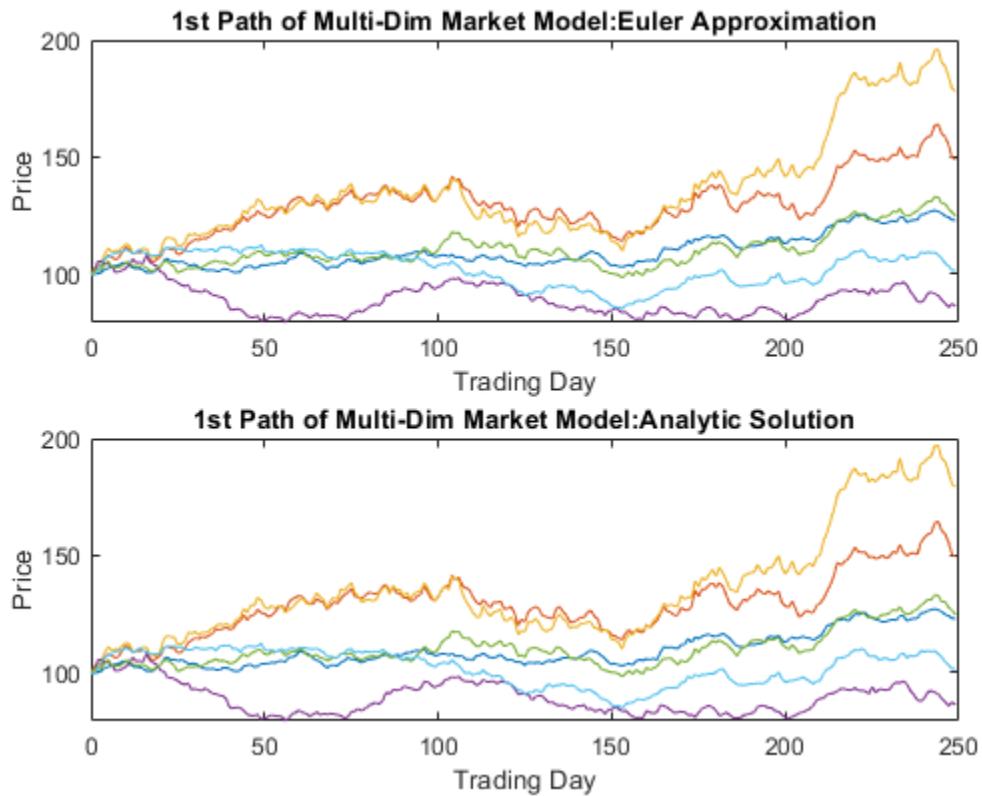

Using this sample size, examine the terminal distribution of Canada's TSX Composite to verify qualitatively the lognormal character of the data.

```
histogram(squeeze(X(end,1,:)), 30), xlabel('Price'), ylabel('Frequency')
title('Histogram of Prices after One Year: Canada (TSX Composite)')
```

Simulate 10 trials of the solution and plot the first trial:

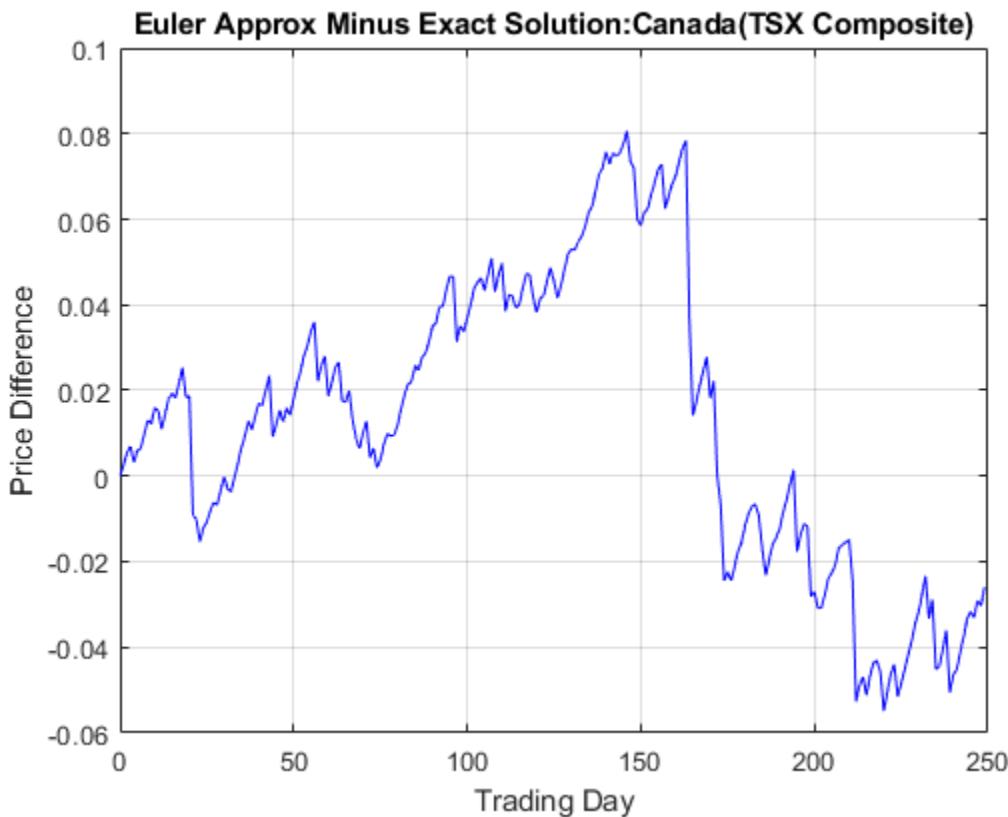

```
rng('default')
[S,T] = simulate(SDE, nPeriods, 'DeltaTime', dt, 'nTrials', 10);
rng('default')
[X,T] = simBySolution(GBM, nPeriods, ...
    'DeltaTime', dt, 'nTrials', 10);
subplot(2,1,1)
plot(T, S(:,:,1)), xlabel('Trading Day'), ylabel('Price')
title('1st Path of Multi-Dim Market Model:Euler Approximation')
subplot(2,1,2)
plot(T, X(:,:,1)), xlabel('Trading Day'), ylabel('Price')
title('1st Path of Multi-Dim Market Model:Analytic Solution')
```

In this example, all parameters are constants, and `simBySolution` does indeed sample the exact solution. The details of a single index for any given trial show that the price paths of the Euler approximation and the exact solution are close, but not identical.

The following plot illustrates the difference between the two functions:

```
subplot(1,1,1)
plot(T, S(:,1,1) - X(:,1,1), 'blue'), grid('on')
xlabel('Trading Day'), ylabel('Price Difference')
title('Euler Approx Minus Exact Solution:Canada(TSX Composite)')
```

The `simByEuler` Euler approximation literally evaluates the stochastic differential equation directly from the equation of motion, for some suitable value of the  $dt$  time increment. This simple approximation suffers from discretization error. This error can be attributed to the discrepancy between the choice of the  $dt$  time increment and what in theory is a continuous-time parameter.

The discrete-time approximation improves as `DeltaTime` approaches zero. The Euler function is often the least accurate and most general method available. All models shipped in the simulation suite have the `simByEuler` function.

In contrast, the `simBySolution` function provides a more accurate description of the underlying model. This function simulates the price paths by an approximation of the closed-form solution of separable models. Specifically, it applies a Euler approach to a transformed process, which in general is not the exact solution to this GBM model. This is because the probability distributions of the simulated and true state vectors are identical only for piecewise constant parameters.

When all model parameters are piecewise constant over each observation period, the simulated process is exact for the observation times at which the state vector is sampled. Since all parameters are constants in this example, `simBySolution` does indeed sample the exact solution.

For an example of how to use `simBySolution` to optimize the accuracy of solutions, see “Optimizing Accuracy: About Solution Precision and Error” on page 18-65.

## Simulating Equity Markets Using GBM Model with Quasi-Monte Carlo Simulation

This example shows how to use `simBySolution` with a GBM model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead pseudo random numbers.

Load the `Data_GlobalIdx2` data set and specify the GBM model as in “Representing Market Models Using SDELD, CEV, and GBM Objects” on page 18-30.

```
load Data_GlobalIdx2
prices = [Dataset.TSX Dataset.CAC Dataset.DAX ...
          Dataset.NIK Dataset.FTSE Dataset.SP];

returns = tick2ret(prices);
nVariables = size(returns,2);
expReturn = mean(returns);
sigma = std(returns);
correlation = corrcoef(returns);
X = 100;
X = X(ones(nVariables,1));

GBM = gbm(diag(expReturn),diag(sigma), 'Correlation', ...
           correlation, 'StartState', X);
```

Perform a quasi-Monte Carlo simulation by using `simBySolution` with the optional name-value arguments for 'MonteCarloMethod' and 'QuasiSequence'.

```
[paths,time,z] = simBySolution(GBM, 10,'ntrials',4096,'MonteCarloMethod','quasi','QuasiSequence')
```

## Input Arguments

### MDL — Geometric Brownian motion (GBM) model

`gbm` object

Geometric Brownian motion (GBM) model, specified as a `gbm` object that is created using `gbm`.

Data Types: `object`

### NPeriods — Number of simulation periods

positive integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1`, ..., `NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[Paths,Times,Z] = simBySolution(GBM,NPeriods,'DeltaTime',dt,'NTrials',10)`

---

**NTrials — Simulated trials (sample paths) of NPERIODS observations each**  
1 (single path of correlated state variables) (default) | positive integer

Simulated trials (sample paths) of NPERIODS observations each, specified as the comma-separated pair consisting of 'NTrials' and a positive scalar integer.

Data Types: double

**DeltaTimes — Positive time increments between observations**  
1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of 'DeltaTimes' and a scalar or a NPERIODS-by-1 column vector.

DeltaTime represents the familiar  $dt$  found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: double

**NSteps — Number of intermediate time steps within each time increment dt (specified as DeltaTime)**

1 (indicating no intermediate evaluation) (default) | positive integer

Number of intermediate time steps within each time increment  $dt$  (specified as DeltaTime), specified as the comma-separated pair consisting of 'NSteps' and a positive scalar integer.

The `simBySolution` function partitions each time increment  $dt$  into NSteps subintervals of length  $dt/NSteps$ , and refines the simulation by evaluating the simulated state vector at  $NSteps - 1$  intermediate points. Although `simBySolution` does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: double

**Antithetic — Flag to indicate whether simBySolution uses antithetic sampling to generate the Gaussian random variates**

False (no antithetic sampling) (default) | logical with values True or False

Flag to indicate whether `simBySolution` uses antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as the comma-separated pair consisting of 'Antithetic' and a scalar logical flag with a value of True or False.

When you specify True, `simBySolution` performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials (1, 3, 5, ...) correspond to the primary Gaussian paths.
- Even trials (2, 4, 6, ...) are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

---

**Note** If you specify an input noise process (see Z), `simBySolution` ignores the value of Antithetic.

Data Types: logical

**MonteCarloMethod — Monte Carlo method to simulate stochastic processes**

"standard" (default) | string with values "standard", "quasi", or "randomized-quasi" | character vector with values 'standard', 'quasi', or 'randomized-quasi'

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of 'MonteCarloMethod' and a string or character vector with one of the following values:

- "standard" — Monte Carlo using pseudo random numbers.
- "quasi" — Quasi-Monte Carlo using low-discrepancy sequences.
- "randomized-quasi" — Randomized quasi-Monte Carlo.

---

**Note** If you specify an input noise process (see Z), `simBySolution` ignores the value of `MonteCarloMethod`.

---

Data Types: string | char

**QuasiSequence — Low discrepancy sequence to drive the stochastic processes**

"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of 'QuasiSequence' and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

---

**Note**

- If `MonteCarloMethod` option is not specified or specified as "standard", `QuasiSequence` is ignored.
  - If you specify an input noise process (see Z), `simBySolution` ignores the value of `QuasiSequence`.
- 

Data Types: string | char

**Z — Direct specification of the dependent random noise process used to generate the Brownian motion vector**

generates correlated Gaussian variates based on the `Correlation` member of the `SDE` object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process used to generate the Brownian motion vector (Wiener process) that drives the simulation, specified as the comma-separated pair consisting of 'Z' and a function or as an (`NPERIODS * NSTEPS`)-by-`NBROWNS`-by-`NTRIALS` three-dimensional array of dependent random variates.

The input argument Z allows you to directly specify the noise generation process. This process takes precedence over the `Correlation` parameter of the input `gbm` object and the value of the `Antithetic` input flag.

---

**Note** If you specify `Z` as a function, it must return an `NBROWNS`-by-1 column vector, and you must call it with two inputs:

- A real-valued scalar observation time  $t$ .
  - An `NVARS`-by-1 state vector  $X_t$ .
- 

Data Types: double | function

**StorePaths — Flag that indicates how the output array Paths is stored and returned**

True (default) | logical with values True or False

Flag that indicates how the output array `Paths` is stored and returned, specified as the comma-separated pair consisting of '`StorePaths`' and a scalar logical flag with a value of `True` or `False`.

If `StorePaths` is `True` (the default value) or is unspecified, `simBySolution` returns `Paths` as a three-dimensional time series array.

If `StorePaths` is `False` (logical 0), `simBySolution` returns the `Paths` output array as an empty matrix.

Data Types: logical

**Processes — Sequence of end-of-period processes or state vector adjustments of the form**

`simBySolution` makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments of the form, specified as the comma-separated pair consisting of '`Processes`' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The `simBySolution` function runs processing functions at each interpolation time. They must accept the current interpolation time  $t$ , and the current state vector  $X_t$ , and return a state vector that may be an adjustment to the input state.

`simBySolution` applies processing functions at the end of each observation period. These functions must accept the current observation time  $t$  and the current state vector  $X_t$ , and return a state vector that may be an adjustment to the input state.

The end-of-period `Processes` argument allows you to terminate a given trial early. At the end of each time step, `simBySolution` tests the state vector  $X_t$  for an all-NaN condition. Thus, to signal an early termination of a given trial, all elements of the state vector  $X_t$  must be NaN. This test enables a user-defined `Processes` function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

If you specify more than one processing function, `simBySolution` invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

Data Types: cell | function

## Output Arguments

### Paths — Simulated paths of correlated state variables

array

Simulated paths of correlated state variables, returned as a (NPERIODS + 1)-by-NVARS-by-NTRIALS three-dimensional time series array.

For a given trial, each row of Paths is the transpose of the state vector  $X_t$  at time  $t$ . When the input flag `StorePaths = False`, `simBySolution` returns Paths as an empty matrix.

### Times — Observation times associated with the simulated paths

column vector

Observation times associated with the simulated paths, returned as a (NPERIODS + 1)-by-1 column vector. Each element of Times is associated with the corresponding row of Paths.

### Z — Dependent random variates used to generate the Brownian motion vector

array

Dependent random variates used to generate the Brownian motion vector (Wiener processes) that drive the simulation, returned as a (NPERIODS \* NSTEPS)-by-NBROWNS-by-NTRIALS three-dimensional time series array.

## More About

### Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another of the same expected value, but smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent of any other pair, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

## Algorithms

The `simBySolution` function simulates NTRIALS sample paths of NVARS correlated state variables, driven by NBROWNS Brownian motion sources of risk over NPERIODS consecutive observation periods, approximating continuous-time GBM short-rate models by an approximation of the closed-form solution.

Consider a separable, vector-valued GBM model of the form:

$$dX_t = \mu(t)X_t dt + D(t, X_t)V(t)dW_t$$

where:

- $X_t$  is an NVARS-by-1 state vector of process variables.
- $\mu$  is an NVARS-by-NVARS generalized expected instantaneous rate of return matrix.
- $V$  is an NVARS-by-NBROWNS instantaneous volatility rate matrix.
- $dW_t$  is an NBROWNS-by-1 Brownian motion vector.

The `simBySolution` function simulates the state vector  $X_t$  using an approximation of the closed-form solution of diagonal-drift models.

When evaluating the expressions, `simBySolution` assumes that all model parameters are piecewise-constant over each simulation period.

In general, this is *not* the exact solution to the models, because the probability distributions of the simulated and true state vectors are identical *only* for piecewise-constant parameters.

When parameters are piecewise-constant over each observation period, the simulated process is exact for the observation times at which  $X_t$  is sampled.

Gaussian diffusion models, such as `hwv`, allow negative states. By default, `simBySolution` does nothing to prevent negative states, nor does it guarantee that the model be strictly mean-reverting. Thus, the model may exhibit erratic or explosive growth.

# simBySolution

Simulate approximate solution of diagonal-drift HWV processes

## Syntax

```
[Paths,Times,Z] = simBySolution(MDL,NPeriods)
[Paths,Times,Z] = simBySolution(___,Name,Value)
```

## Description

`[Paths,Times,Z] = simBySolution(MDL,NPeriods)` simulates approximate solution of diagonal-drift for Hull-White/Vasicek Gaussian Diffusion (HWV) processes.

`[Paths,Times,Z] = simBySolution(___,Name,Value)` adds optional name-value pair arguments.

You can perform quasi-Monte Carlo simulations using the name-value arguments for `MonteCarloMethod` and `QuasiSequence`. For more information, see “Quasi-Monte Carlo Simulation” on page 18-62.

## Examples

### Use simBySolution with an hwv Object

Create an `hwv` object to represent the model:

$$dX_t = 0.2(0.1 - X_t)dt + 0.05dW_t.$$

```
hwv = hwv(0.2, 0.1, 0.05) % (Speed, Level, Sigma)
```

```
hwv =
```

```
Class HWV: Hull-White/Vasicek
-----
Dimensions: State = 1, Brownian = 1
-----
StartTime: 0
StartState: 1
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Sigma: 0.05
Level: 0.1
Speed: 0.2
```

The `simBySolution` function simulates the state vector  $X_t$  using an approximation of the closed-form solution of diagonal drift HWV models. Each element of the state vector  $X_t$  is expressed as the sum of `NBrowns` correlated Gaussian random draws added to a deterministic time-variable drift.

```
NPeriods = 100  
[Paths,Times,Z] = simBySolution(hwv, NPeriods,'NTrials', 10);
```

## Quasi-Monte Carlo Simulation Using HWV Model

This example shows how to use `simBySolution` with a HWV model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead pseudo random numbers.

```
HWV = hwv(1.5,100,10,'startstate',100);
```

Perform a quasi-Monte Carlo simulation by using `simBySolution` with the optional name-value arguments for 'MonteCarloMethod' and 'QuasiSequence'.

```
[paths,time,z] = simBySolution(HWV, 10,'ntrials',4096,'MonteCarloMethod','quasi','QuasiSequence')
```

## Input Arguments

### MDL — Hull-White/Vasicek (HWV) model

hwv object

Hull-White/Vasicek (HWV) mode, specified as a `hwv` object that is created using `hwv`.

Data Types: object

### NPeriods — Number of simulation periods

positive integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: double

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[Paths,Times,Z] = simBySolution(HWV,NPeriods,'DeltaTime',dt,'NTrials',10)`

### NTrials — Simulated trials (sample paths) of NPeriods observations each

1 (single path of correlated state variables) (default) | positive integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as the comma-separated pair consisting of '`NTrials`' and a positive scalar integer.

Data Types: double

### DeltaTime — Positive time increments between observations

1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of 'DeltaTimes' and a scalar or a NPeriods-by-1 column vector.

**DeltaTime** represents the familiar  $dt$  found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: double

**NSteps — Number of intermediate time steps within each time increment  $dt$  (specified as **DeltaTime**)**

1 (indicating no intermediate evaluation) (default) | positive integer

Number of intermediate time steps within each time increment  $dt$  (specified as **DeltaTime**), specified as the comma-separated pair consisting of 'NSteps' and a positive scalar integer.

The **simBySolution** function partitions each time increment  $dt$  into **NSteps** subintervals of length  $dt/NSteps$ , and refines the simulation by evaluating the simulated state vector at **NSteps** – 1 intermediate points. Although **simBySolution** does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: double

**Antithetic — Flag to indicate whether **simBySolution** uses antithetic sampling to generate the Gaussian random variates**

False (no antithetic sampling) (default) | logical with values True or False

Flag to indicate whether **simBySolution** uses antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as the comma-separated pair consisting of 'Antithetic' and a scalar logical flag with a value of True or False.

When you specify True, **simBySolution** performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials (1, 3, 5, ...) correspond to the primary Gaussian paths.
- Even trials (2, 4, 6, ...) are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

---

**Note** If you specify an input noise process (see **Z**), **simBySolution** ignores the value of **Antithetic**.

---

Data Types: logical

**MonteCarloMethod — Monte Carlo method to simulate stochastic processes**

"standard" (default) | string with values "standard", "quasi", or "randomized-quasi" | character vector with values 'standard', 'quasi', or 'randomized-quasi'

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of 'MonteCarloMethod' and a string or character vector with one of the following values:

- "standard" — Monte Carlo using pseudo random numbers.
- "quasi" — Quasi-Monte Carlo using low-discrepancy sequences.

- "randomized-quasi" — Randomized quasi-Monte Carlo.

---

**Note** If you specify an input noise process (see Z), `simBySolution` ignores the value of `MonteCarloMethod`.

---

Data Types: string | char

**QuasiSequence — Low discrepancy sequence to drive the stochastic processes**

"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of 'QuasiSequence' and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

---

**Note**

- If `MonteCarloMethod` option is not specified or specified as "standard", `QuasiSequence` is ignored.
  - If you specify an input noise process (see Z), `simBySolution` ignores the value of `QuasiSequence`.
- 

Data Types: string | char

**Z — Direct specification of the dependent random noise process used to generate the Brownian motion vector**

generates correlated Gaussian variates based on the `Correlation` member of the `SDE` object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process used to generate the Brownian motion vector (Wiener process) that drives the simulation, specified as the comma-separated pair consisting of 'Z' and a function or as an (`NPeriods` \* `NSteps`)-by-`NBrowns`-by-`NTrials` three-dimensional array of dependent random variates.

The input argument Z allows you to directly specify the noise generation process. This process takes precedence over the `Correlation` parameter of the input `gbm` object and the value of the `Antithetic` input flag.

---

**Note** If you specify Z as a function, it must return an `NBrowns`-by-1 column vector, and you must call it with two inputs:

- A real-valued scalar observation time  $t$ .
  - An `NVars`-by-1 state vector  $X_t$ .
- 

Data Types: double | function

**StorePaths — Flag that indicates how the output array Paths is stored and returned**  
 True (default) | logical with values True or False

Flag that indicates how the output array `Paths` is stored and returned, specified as the comma-separated pair consisting of '`StorePaths`' and a scalar logical flag with a value of `True` or `False`.

If `StorePaths` is `True` (the default value) or is unspecified, `simBySolution` returns `Paths` as a three-dimensional time series array.

If `StorePaths` is `False` (logical 0), `simBySolution` returns the `Paths` output array as an empty matrix.

Data Types: logical

**Processes — Sequence of end-of-period processes or state vector adjustments of the form**  
`simBySolution` makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments of the form, specified as the comma-separated pair consisting of '`Processes`' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The `simBySolution` function runs processing functions at each interpolation time. They must accept the current interpolation time  $t$ , and the current state vector  $X_t$ , and return a state vector that may be an adjustment to the input state.

`simBySolution` applies processing functions at the end of each observation period. These functions must accept the current observation time  $t$  and the current state vector  $X_t$ , and return a state vector that may be an adjustment to the input state.

The end-of-period `Processes` argument allows you to terminate a given trial early. At the end of each time step, `simBySolution` tests the state vector  $X_t$  for an all-NaN condition. Thus, to signal an early termination of a given trial, all elements of the state vector  $X_t$  must be NaN. This test enables a user-defined `Processes` function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

If you specify more than one processing function, `simBySolution` invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

Data Types: cell | function

## Output Arguments

**Paths — Simulated paths of correlated state variables**  
 array

Simulated paths of correlated state variables, returned as a (`NPeriods + 1`)-by-`NVars`-by-`NTrials` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector  $X_t$  at time  $t$ . When the input flag `StorePaths` = `False`, `simBySolution` returns `Paths` as an empty matrix.

**Times — Observation times associated with the simulated paths**  
column vector

Observation times associated with the simulated paths, returned as a (`NPeriods + 1`)-by-1 column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

**Z — Dependent random variates used to generate the Brownian motion vector**  
array

Dependent random variates used to generate the Brownian motion vector (Wiener processes) that drive the simulation, returned as a (`NPeriods * NSteps`)-by-`NBrowns`-by-`NTrials` three-dimensional time series array.

## More About

### Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another of the same expected value, but smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent of any other pair, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

## Algorithms

The `simBySolution` method simulates `NTrials` sample paths of `NVars` correlated state variables, driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time Hull-White/Vasicek (HWV) by an approximation of the closed-form solution.

Consider a separable, vector-valued HWV model of the form:

$$dX_t = S(t)[L(t) - X_t]dt + V(t)dW_t$$

where:

- $X$  is an  $NVars$ -by-1 state vector of process variables.
- $S$  is an  $NVars$ -by- $NVars$  matrix of mean reversion speeds (the rate of mean reversion).
- $L$  is an  $NVars$ -by-1 vector of mean reversion levels (long-run mean or level).
- $V$  is an  $NVars$ -by- $NBrowns$  instantaneous volatility rate matrix.
- $W$  is an  $NBrowns$ -by-1 Brownian motion vector.

The `simBySolution` method simulates the state vector  $X_t$  using an approximation of the closed-form solution of diagonal-drift models.

When evaluating the expressions, `simBySolution` assumes that all model parameters are piecewise-constant over each simulation period.

In general, this is *not* the exact solution to the models, because the probability distributions of the simulated and true state vectors are identical *only* for piecewise-constant parameters.

When parameters are piecewise-constant over each observation period, the simulated process is exact for the observation times at which  $X_t$  is sampled.

Gaussian diffusion models, such as `hwv`, allow negative states. By default, `simBySolution` does nothing to prevent negative states, nor does it guarantee that the model be strictly mean-reverting. Thus, the model may exhibit erratic or explosive growth.

# heston

Heston model

## Description

Creates and displays **heston** objects, which derive from the **sdeddo** (SDE from drift and diffusion objects).

Use **heston** objects to simulate sample paths of two state variables. Each state variable is driven by a single Brownian motion source of risk over **NPeriods** consecutive observation periods, approximating continuous-time stochastic volatility processes.

Heston models are bivariate composite models. Each Heston model consists of two coupled univariate models:

- A geometric Brownian motion (**gbm**) model with a stochastic volatility function.

$$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t}$$

This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.

- A Cox-Ingersoll-Ross (**cir**) square root diffusion model.

$$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

This model describes the evolution of the variance rate of the coupled GBM price process.

## Creation

### Syntax

```
heston = heston(Return,Level,Speed,Volatility)
heston = heston(___,Name,Value)
```

### Description

**heston** = **heston**(**Return**,**Level**,**Speed**,**Volatility**) creates a default **heston** object.

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

**Note** You can specify combinations of array and function input parameters as needed.

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time  $t$  as its only input argument. Otherwise, a parameter is assumed to be a function of time  $t$  and state  $X(t)$  and is invoked with both input arguments.

---

`heston = heston( ___,Name,Value)` constructs a `heston` object with additional options specified by one or more `Name,Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`

The `heston` object has the following “Properties” on page 19-68:

- `StartTime` — Initial observation time
- `StartState` — Initial state at `StartTime`
- `Correlation` — Access function for the `Correlation` input, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `Simulation` — A simulation function or method
- `Return` — Access function for the input argument `Return`, callable as a function of time and state
- `Speed` — Access function for the input argument `Speed`, callable as a function of time and state
- `Level` — Access function for the input argument `Level`, callable as a function of time and state
- `Volatility` — Access function for the input argument `Volatility`, callable as a function of time and state

### Input Arguments

#### **Return — Return represents the parameter $\mu$**

array or deterministic function of time or deterministic function of time and state

`Return` represents the parameter  $\mu$ , specified as an array or deterministic function of time.

If you specify `Return` as an array, it must be an `NVars`-by-`NVars` matrix representing the expected (mean) instantaneous rate of return.

As a deterministic function of time, when `Return` is called with a real-valued scalar time  $t$  as its only input, `Return` must produce an `NVars`-by-`NVars` matrix. If you specify `Return` as a function of time and state, it must return an `NVars`-by-`NVars` matrix when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An `NVars`-by-1 state vector  $X_t$ .

Data Types: `double` | `function_handle`

#### **Level — Level represents the parameter $L$**

array or deterministic function of time or deterministic function of time and state

`Level` represents the parameter  $L$ , specified as an array or deterministic function of time.

If you specify `Level` as an array, it must be an `NVars`-by-1 column vector of reversion levels.

As a deterministic function of time, when `Level` is called with a real-valued scalar time  $t$  as its only input, `Level` must produce an `NVars`-by-1 column vector. If you specify `Level` as a function of time and state, it must generate an `NVars`-by-1 column vector of reversion levels when called with two inputs:

- A real-valued scalar observation time  $t$ .
- An `NVars`-by-1 state vector  $X_t$ .

Data Types: `double` | `function_handle`

### **Speed — Return represents the parameter $S$**

array or deterministic function of time or deterministic function of time and state

`Speed` represents the parameter  $S$ , specified as an array or deterministic function of time.

If you specify `Speed` as an array, it must be an `NVars`-by-`NVars` matrix of mean-reversion speeds (the rate at which the state vector reverts to its long-run average `Level`).

As a deterministic function of time, when `Speed` is called with a real-valued scalar time  $t$  as its only input, `Speed` must produce an `NVars`-by-`NVars` matrix. If you specify `Speed` as a function of time and state, it calculates the speed of mean reversion. This function must generate an `NVars`-by-`NVars` matrix of reversion rates when called with two inputs:

- A real-valued scalar observation time  $t$ .
- An `NVars`-by-1 state vector  $X_t$ .

Data Types: `double` | `function_handle`

### **Volatility — Volatility represents the instantaneous volatility of the CIR stochastic variance model**

scalar or deterministic function of time or deterministic function of time and state

`Volatility` (often called the *volatility of volatility* or *volatility of variance*) represents the instantaneous volatility of the CIR stochastic variance model, specified as a scalar, or deterministic function of time.

If you specify `Volatility` as a scalar, it represents the instantaneous volatility of the CIR stochastic variance model.

As a deterministic function of time, when `Volatility` is called with a real-valued scalar time  $t$  as its only input, `Volatility` must produce a scalar. If you specify it as a function time and state, `Volatility` generates a scalar when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- A 2-by-1 state vector  $X_t$ .

Data Types: `double` | `function_handle`

---

**Note** Although `heston` does not enforce restrictions on the signs of any of these input arguments, each argument is specified as a positive value.

## Properties

### **StartTime — Starting time of first observation, applied to all state variables**

0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

### **StartState — Initial values of state variables**

1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If StartState is a scalar, heston applies the same initial value to all state variables on all trials.

If StartState is a column vector, heston applies a unique initial value to each state variable on all trials.

If StartState is a matrix, heston applies a unique initial value to each state variable on each trial.

Data Types: double

### **Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)**

NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function  $C(t)$  that accepts the current time  $t$  and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

As a deterministic function of time, Correlation allows you to specify a dynamic correlation structure.

Data Types: double

### **Simulation — User-defined simulation function or SDE simulation method**

simulation by Euler approximation (`simByEuler`) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function\_handle

### **Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)**

value stored from drift-rate function (default) | drift object or function accessible by  $(t, X_t)$

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The drift rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `drift` class allows you to create drift-rate objects using `drift` of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- `A` is an `NVars`-by-1 vector-valued function accessible using the  $(t, X_t)$  interface.
- `B` is an `NVars`-by-`NVars` matrix-valued function accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `drift` object are:

- `Rate`: The drift-rate function,  $F(t, X_t)$
- `A`: The intercept term,  $A(t, X_t)$ , of  $F(t, X_t)$
- `B`: The first order term,  $B(t, X_t)$ , of  $F(t, X_t)$

`A` and `B` enable you to query the original inputs. The function stored in `Rate` fully encapsulates the combined effect of `A` and `B`.

When specified as MATLAB double arrays, the inputs `A` and `B` are clearly associated with a linear drift rate parametric form. However, specifying either `A` or `B` as a function allows you to customize virtually any drift rate specification.

---

**Note** You can express `drift` and `diffusion` classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components `A` and `B` as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `F = drift(0, 0.1)` % Drift rate function  $F(t, X)$

Data Types: `struct` | `double`

### **Diffusion — Diffusion rate component of continuous-time stochastic differential equations (SDEs)**

value stored from diffusion-rate function (default) | diffusion object or functions accessible by  $(t, X_t)$

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The diffusion rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `diffusion` class allows you to create diffusion-rate objects using `diffusion`:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- $D$  is an NVars-by-NVars diagonal matrix-valued function.
- Each diagonal element of  $D$  is the corresponding element of the state vector raised to the corresponding element of an exponent  $\text{Alpha}$ , which is an NVars-by-1 vector-valued function.
- $V$  is an NVars-by-NBrowns matrix-valued volatility rate function  $\text{Sigma}$ .
- $\text{Alpha}$  and  $\text{Sigma}$  are also accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `diffusion` object are:

- **Rate**: The diffusion-rate function,  $G(t, X_t)$ .
- **Alpha**: The state vector exponent, which determines the format of  $D(t, X_t)$  of  $G(t, X_t)$ .
- **Sigma**: The volatility rate,  $V(t, X_t)$ , of  $G(t, X_t)$ .

$\text{Alpha}$  and  $\text{Sigma}$  enable you to query the original inputs. (The combined effect of the individual  $\text{Alpha}$  and  $\text{Sigma}$  parameters is fully encapsulated by the function stored in **Rate**.) The **Rate** functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

---

**Note** You can express `drift` and `diffusion` classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components **A** and **B** as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t, X)`

Data Types: `struct | double`

## Object Functions

## Examples

### Create a `heston` Object

The Heston (`heston`) class derives directly from SDE from Drift and Diffusion (`sdeddo`). Each Heston model is a bivariate composite model, consisting of two coupled univariate models:

$$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t}$$

$$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

Create a `heston` object to represent the model:

$$dX_{1t} = 0.1X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t}$$

$$dX_{2t} = 0.2[0.1 - X_{2t}]dt + 0.05\sqrt{X_{2t}}dW_{2t}$$

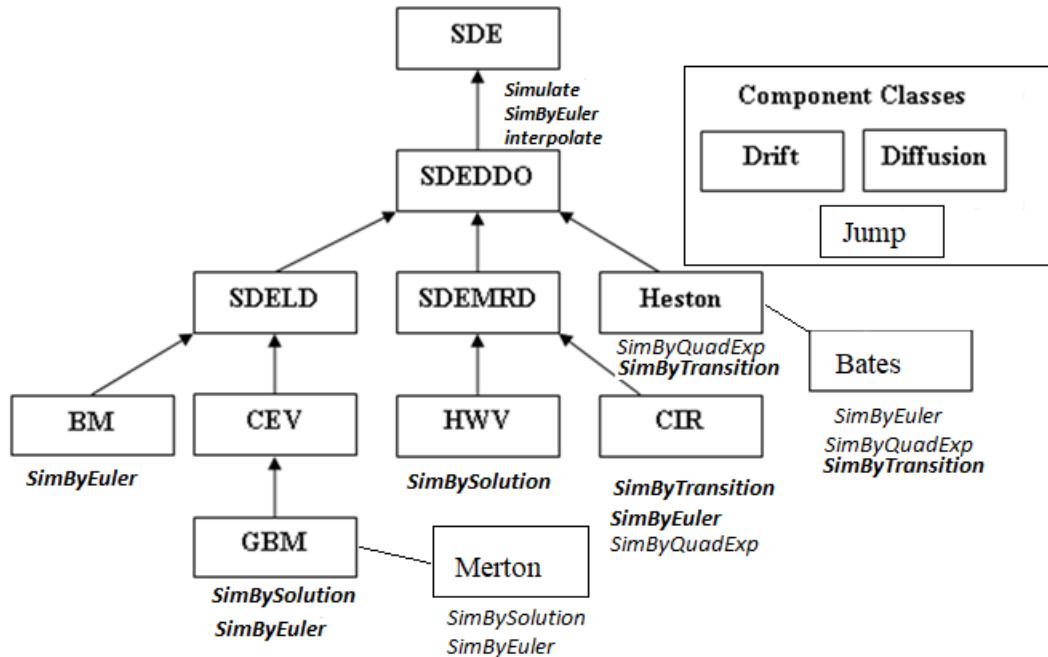

```
obj = heston (0.1, 0.2, 0.1, 0.05) % (Return, Speed, Level, Volatility)
obj =
  Class HESTON: Heston Bivariate Stochastic Volatility
  -----
  Dimensions: State = 2, Brownian = 2
  -----
  StartTime: 0
  StartState: 1 (2x1 double array)
  Correlation: 2x2 diagonal double array
  Drift: drift rate function F(t,X(t))
  Diffusion: diffusion rate function G(t,X(t))
  Simulation: simulation method/function simByEuler
  Return: 0.1
  Speed: 0.2
  Level: 0.1
  Volatility: 0.05
```

## More About

### Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.

For more information, see “SDE Class Hierarchy” on page 18-5.

## Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time  $t$  and a state vector  $X_t$ , and return an array of appropriate dimension. Even if you originally specified an input as an array, `heston` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

## hwv

Hull-White/Vasicek (HWV) Gaussian Diffusion model

### Description

Create and displays `hwv` objects, which derive from the `sdemrd` (SDE with drift rate expressed in mean-reverting form) class.

Use `hwv` objects to simulate sample paths of `NVars` state variables expressed in mean-reverting drift-rate form. These state variables are driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time Hull-White/Vasicek stochastic processes with Gaussian diffusions.

This model allows you to simulate vector-valued Hull-White/Vasicek processes of the form:

$$dX_t = S(t)[L(t) - X_t]dt + V(t)dW_t \quad (19-2)$$

where:

- $X_t$  is an `NVars`-by-1 state vector of process variables.
- $S$  is an `NVars`-by-`NVars` of mean reversion speeds (the rate of mean reversion).
- $L$  is an `NVars`-by-1 vector of mean reversion levels (long-run mean or level).
- $V$  is an `NVars`-by-`NBrowns` instantaneous volatility rate matrix.
- $dW_t$  is an `NBrowns`-by-1 Brownian motion vector.

### Creation

#### Syntax

```
HWV = hwv(Speed,Level,Sigma)
HWV = hwv( ___,Name,Value)
```

#### Description

`HWV = hwv(Speed,Level,Sigma)` creates a default `HWV` object.

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

---

**Note** You can specify combinations of array and function input parameters as needed.

---

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time  $t$  as its only input argument. Otherwise, a parameter is assumed to be a function of time  $t$  and state  $X(t)$  and is invoked with both input arguments.

`HWV = hwv( ___, Name, Value)` creates a `HWV` object with additional options specified by one or more `Name, Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`

The `HWV` object has the following “Properties” on page 19-76:

- `StartTime` — Initial observation time
- `StartState` — Initial state at `StartTime`
- `Correlation` — Access function for the `Correlation` input, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `Simulation` — A simulation function or method
- `Speed` — Access function for the input argument `Speed`, callable as a function of time and state
- `Level` — Access function for the input argument `Level`, callable as a function of time and state
- `Sigma` — Access function for the input argument `Sigma`, callable as a function of time and state

## Input Arguments

### **Speed — Speed represents the parameter S**

array or deterministic function of time or deterministic function of time and state

`Speed` represents the parameter  $S$ , specified as an array or deterministic function of time.

If you specify `Speed` as an array, it must be an `NVars`-by-`NVars` matrix of mean-reversion speeds (the rate at which the state vector reverts to its long-run average `Level`).

As a deterministic function of time, when `Speed` is called with a real-valued scalar time  $t$  as its only input, `Speed` must produce an `NVars`-by-`NVars` matrix. If you specify `Speed` as a function of time and state, it calculates the speed of mean reversion. This function must generate an `NVars`-by-`NVars` matrix of reversion rates when called with two inputs:

- A real-valued scalar observation time  $t$ .
- An `NVars`-by-1 state vector  $X_t$ .

Data Types: `double` | `function_handle`

### **Level — Level represents the parameter L**

array or deterministic function of time or deterministic function of time and state

`Level` represents the parameter  $L$ , specified as an array or deterministic function of time.

If you specify `Level` as an array, it must be an `NVars`-by-1 column vector of reversion levels.

As a deterministic function of time, when `Level` is called with a real-valued scalar time  $t$  as its only input, `Level` must produce an `NVars`-by-1 column vector. If you specify `Level` as a function of time

and state, it must generate an NVars-by-1 column vector of reversion levels when called with two inputs:

- A real-valued scalar observation time  $t$ .
- An NVars-by-1 state vector  $X_t$ .

Data Types: double | function\_handle

**Sigma — Sigma represents the parameter V**

array or deterministic function of time or deterministic function of time and state

Sigma represents the parameter  $V$ , specified as an array or a deterministic function of time.

If you specify Sigma as an array, it must be an NVars-by-NBrowns matrix of instantaneous volatility rates or as a deterministic function of time. In this case, each row of Sigma corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when Sigma is called with a real-valued scalar time  $t$  as its only input, Sigma must produce an NVars-by-NBrowns matrix. If you specify Sigma as a function of time and state, it must return an NVars-by-NBrowns matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An NVars-by-1 state vector  $X_t$ .

Data Types: double | function\_handle

---

**Note** Although the hwv object does not enforce restrictions on the signs of any of these input arguments, each argument is specified as a positive value.

---

## Properties

**StartTime — Starting time of first observation, applied to all state variables**  
0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

**StartState — Initial values of state variables**  
1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If StartState is a scalar, the hwv object applies the same initial value to all state variables on all trials.

If StartState is a column vector, the hwv object applies a unique initial value to each state variable on all trials.

If StartState is a matrix, the hwv object applies a unique initial value to each state variable on each trial.

Data Types: double

**Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)**

NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function  $C(t)$  that accepts the current time  $t$  and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

As a deterministic function of time, Correlation allows you to specify a dynamic correlation structure.

Data Types: double

**Simulation — User-defined simulation function or SDE simulation method**

simulation by Euler approximation (`simByEuler`) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function\_handle

**Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)**

value stored from drift-rate function (default) | drift object or function accessible by  $(t, X_t)$

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The drift rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The `drift` class allows you to create drift-rate objects using `drift` of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- A is an NVars-by-1 vector-valued function accessible using the  $(t, X_t)$  interface.
- B is an NVars-by-NVars matrix-valued function accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `drift` object are:

- Rate: The drift-rate function,  $F(t, X_t)$
- A: The intercept term,  $A(t, X_t)$ , of  $F(t, X_t)$
- B: The first order term,  $B(t, X_t)$ , of  $F(t, X_t)$

A and B enable you to query the original inputs. The function stored in Rate fully encapsulates the combined effect of A and B.

When specified as MATLAB double arrays, the inputs A and B are clearly associated with a linear drift rate parametric form. However, specifying either A or B as a function allows you to customize virtually any drift rate specification.

**Note** You can express drift and diffusion classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components A and B as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: struct | double

**Diffusion — Diffusion rate component of continuous-time stochastic differential equations (SDEs)**

value stored from diffusion-rate function (default) | diffusion object or functions accessible by  $(t, X_t)$

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The diffusion rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The diffusion class allows you to create diffusion-rate objects using diffusion:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- D is an NVars-by-NVars diagonal matrix-valued function.
- Each diagonal element of D is the corresponding element of the state vector raised to the corresponding element of an exponent Alpha, which is an NVars-by-1 vector-valued function.
- V is an NVars-by-NBrowns matrix-valued volatility rate function Sigma.
- Alpha and Sigma are also accessible using the  $(t, X_t)$  interface.

The displayed parameters for a diffusion object are:

- Rate: The diffusion-rate function,  $G(t, X_t)$ .
- Alpha: The state vector exponent, which determines the format of  $D(t, X_t)$  of  $G(t, X_t)$ .
- Sigma: The volatility rate,  $V(t, X_t)$ , of  $G(t, X_t)$ .

Alpha and Sigma enable you to query the original inputs. (The combined effect of the individual Alpha and Sigma parameters is fully encapsulated by the function stored in Rate.) The Rate functions are the calculation engines for the drift and diffusion objects, and are the only parameters required for simulation.

---

**Note** You can express drift and diffusion classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components A and B as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: struct | double

## Object Functions

|               |                                                                                                                                                        |

## Examples

### Create a hwv Object

The Hull-White/Vasicek (HWV) short rate class derives directly from SDE with mean-reverting drift (that is, `sdemrd`):  $dX_t = S(t)[L(t) - X_t]dt + V(t)dW_t$ .

Create an `hwv` object to represent the model:  $dX_t = 0.2(0.1 - X_t)dt + 0.05dW_t$ .

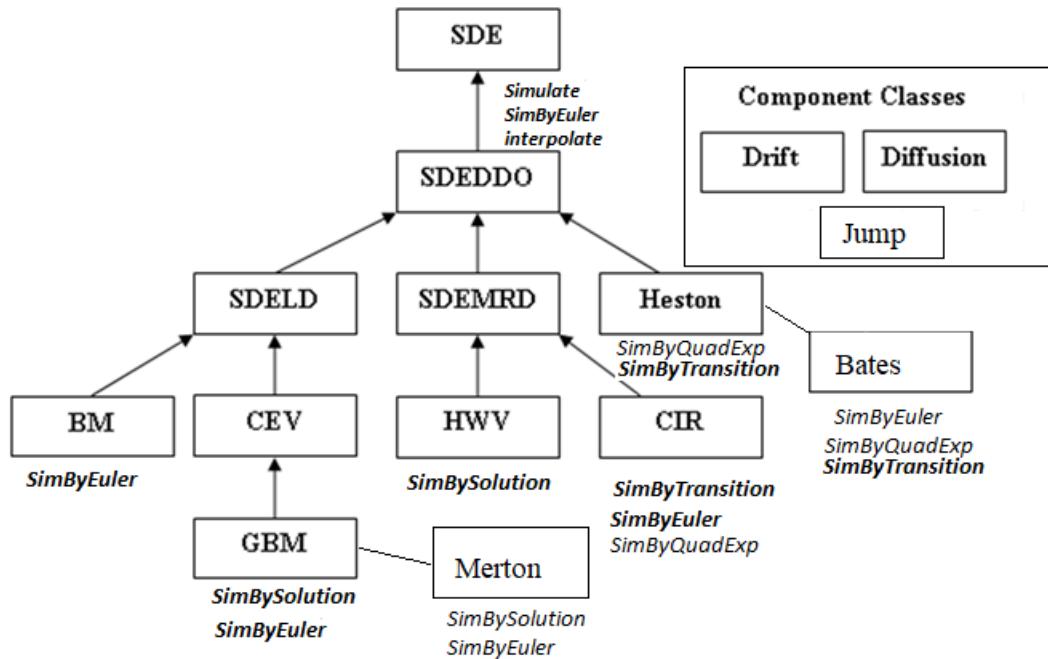

```
obj = hwv(0.2, 0.1, 0.05) % (Speed, Level, Sigma)
obj =
  Class HWV: Hull-White/Vasicek
  -----
  Dimensions: State = 1, Brownian = 1
  -----
  StartTime: 0
  StartState: 1
  Correlation: 1
  Drift: drift rate function F(t,X(t))
  Diffusion: diffusion rate function G(t,X(t))
  Simulation: simulation method/function simByEuler
  Sigma: 0.05
  Level: 0.1
  Speed: 0.2
```

## More About

### Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.

For more information, see “SDE Class Hierarchy” on page 18-5.

## Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time  $t$  and a state vector  $X_t$ , and return an array of appropriate dimension. Even if you originally specified an input as an array, **hwv** treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

## Introduced in R2008a

# interpolate

Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models

## Syntax

```
[XT,T] = interpolate(MDL,Times,Paths)  
[XT,T] = interpolate(___,Name,Value)
```

## Description

`[XT,T] = interpolate(MDL,Times,Paths)` performs a Brownian interpolation into a user-specified time series array, based on a piecewise-constant Euler sampling approach.

`[XT,T] = interpolate(___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Stochastic Interpolation Without Refinement

Many applications require knowledge of the state vector at intermediate sample times that are initially unavailable. One way to approximate these intermediate states is to perform a deterministic interpolation. However, deterministic interpolation techniques fail to capture the correct probability distribution at these intermediate times. Brownian (or stochastic) interpolation captures the correct joint distribution by sampling from a conditional Gaussian distribution. This sampling technique is sometimes referred to as a *Brownian Bridge*.

The default stochastic interpolation technique is designed to interpolate into an existing time series and ignore new interpolated states as additional information becomes available. This technique is the usual notion of interpolation, which is called *Interpolation without refinement*.

Alternatively, the interpolation technique may insert new interpolated states into the existing time series upon which subsequent interpolation is based, by that means refining information available at subsequent interpolation times. This technique is called *interpolation with refinement*.

Interpolation without refinement is a more traditional technique, and is most useful when the input series is closely spaced in time. In this situation, interpolation without refinement is a good technique for inferring data in the presence of missing information, but is inappropriate for extrapolation. Interpolation with refinement is more suitable when the input series is widely spaced in time, and is useful for extrapolation.

The stochastic interpolation method is available to any model. It is best illustrated, however, by way of a constant-parameter Brownian motion process. Consider a correlated, bivariate Brownian motion (BM) model of the form:

$$\begin{aligned} dX_{1t} &= 0.3dt + 0.2dW_{1t} - 0.1dW_{2t} \\ dX_{2t} &= 0.4dt + 0.1dW_{1t} - 0.2dW_{2t} \\ E[dW_{1t}dW_{2t}] &= \rho dt = 0.5dt \end{aligned}$$

- 1** Create a `bm` object to represent the bivariate model:

```
mu      = [0.3; 0.4];
sigma  = [0.2 -0.1; 0.1 -0.2];
rho    = [1 0.5; 0.5 1];
obj    = bm(mu,sigma,'Correlation',rho);
```

- 2** Assuming that the drift (`Mu`) and diffusion (`Sigma`) parameters are annualized, simulate a single Monte Carlo trial of daily observations for one calendar year (250 trading days):

```
rng default % make output reproducible
dt     = 1/250; % 1 trading day = 1/250 years
[X,T] = simulate(obj,250,'DeltaTime',dt);
```

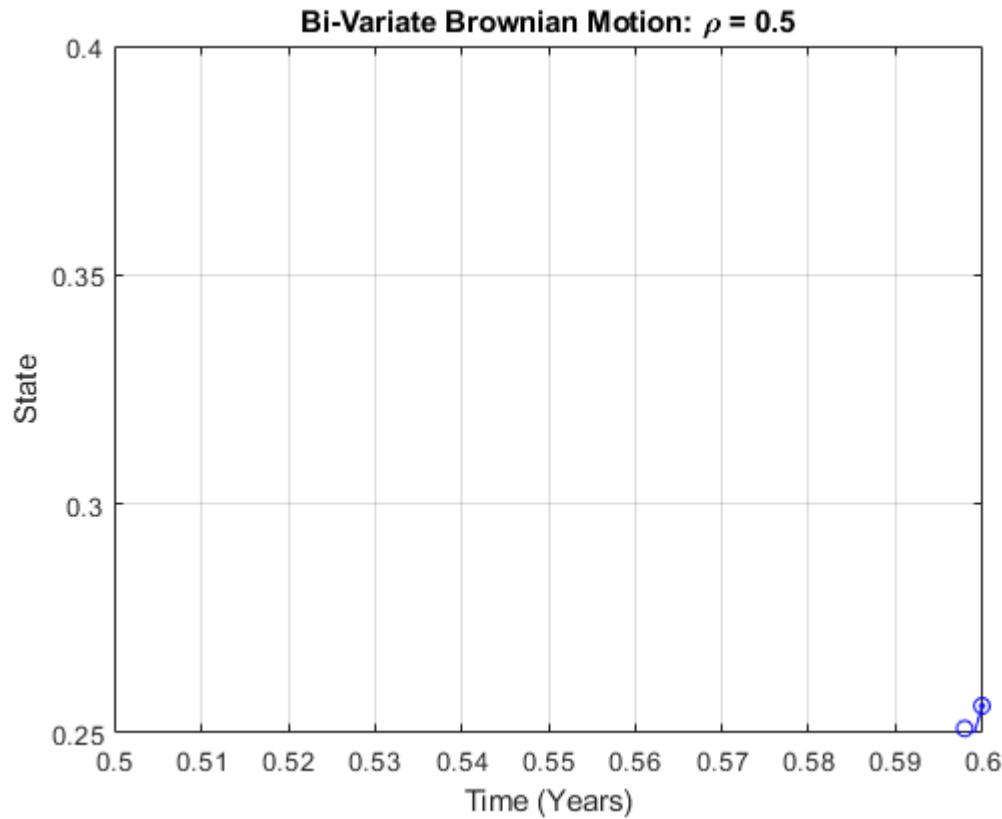

- 3** It is helpful to examine a small interval in detail.

- a** Interpolate into the simulated time series with a Brownian bridge:

```
t = ((T(1) + dt/2):(dt/2):(T(end) - dt/2));
x = interpolate(obj,t,X,'Times',T);
```

- b** Plot both the simulated and interpolated values:

```
plot(T,X(:,1),'.-r',T,X(:,2),'.-b')
grid on;
hold on;
plot(t,x(:,1),'or',t,x(:,2),'ob')
hold off;
xlabel('Time (Years)')
ylabel('State')
title('Bi-Variate Brownian Motion: \rho = 0.5')
axis([0.4999 0.6001 0.25 0.4])
```

In this plot:

- The solid red and blue dots indicate the simulated states of the bivariate model.
- The straight lines that connect the solid dots indicate intermediate states that would be obtained from a deterministic linear interpolation.
- Open circles indicate interpolated states.
- Open circles associated with every other interpolated state encircle solid dots associated with the corresponding simulated state. However, interpolated states at the midpoint of each time increment typically deviate from the straight line connecting each solid dot.

### Simulation of Conditional Gaussian Distributions

You can gain additional insight into the behavior of stochastic interpolation by regarding a Brownian bridge as a Monte Carlo simulation of a conditional Gaussian distribution.

This example examines the behavior of a Brownian bridge over a single time increment.

- 1 Divide a single time increment of length  $dt$  into 10 subintervals:

```

mu      = [0.3; 0.4];
sigma  = [0.2 -0.1; 0.1 -0.2];
rho    = [1 0.5; 0.5 1];
obj    = bm(mu,sigma,'Correlation',rho);

rng default; % make output reproducible
dt     = 1/250; % 1 trading day = 1/250 years

```

```
[X,T] = simulate(obj,250,'DeltaTime',dt);

n      = 125;    % index of simulated state near middle
times = (T(n):(dt/10):T(n+1));
nTrials = 25000; % # of Trials at each time
```

- 2** In each subinterval, take 25000 independent draws from a Gaussian distribution, conditioned on the simulated states to the left, and right:

```
average = zeros(length(times),1);
variance = zeros(length(times),1);
for i = 1:length(times)
    t = times(i);
    x = interpolate(obj,t(ones(nTrials,1)),...
        X,'Times',T);
    average(i) = mean(x(:,1));
    variance(i) = var(x(:,1));
end
```

- 3** Plot the sample mean and variance of each state variable:

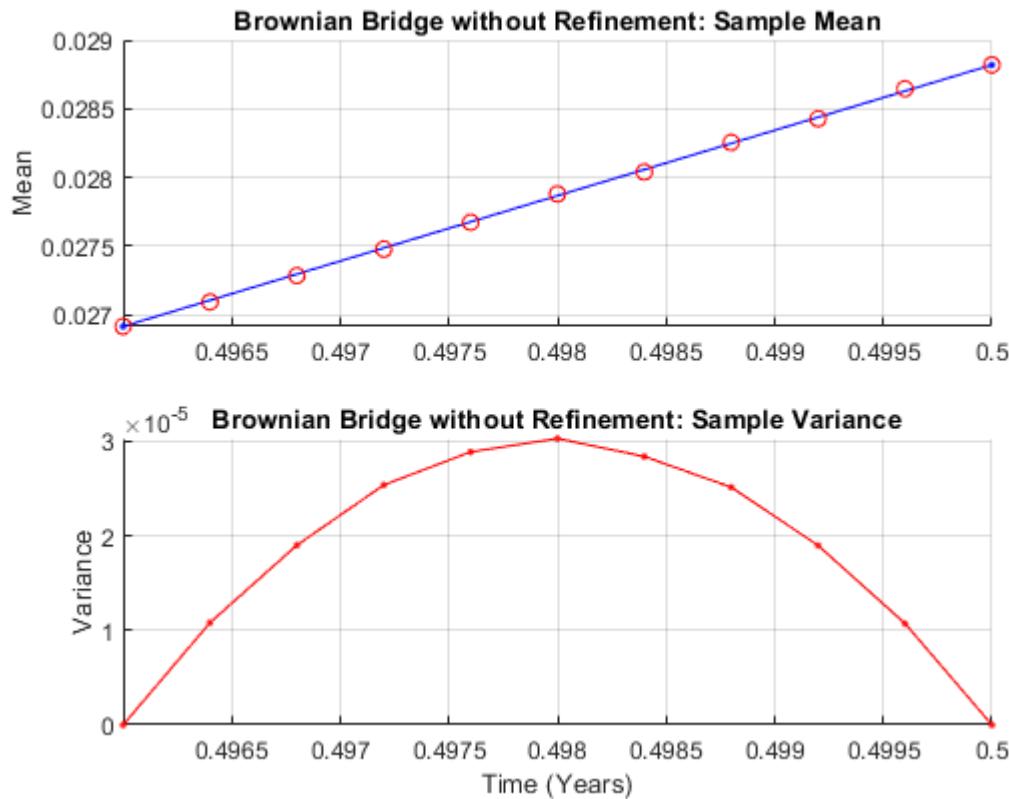

---

**Note** The following graph plots the sample statistics of the first state variable only, but similar results hold for any state variable.

---

```
subplot(2,1,1);
hold on;
grid on;
plot([T(n) T(n+1)], [X(n,1) X(n+1,1)], '.-b')
plot(times, average, 'or')
hold off;
title('Brownian Bridge without Refinement: Sample Mean')
ylabel('Mean')
limits = axis;
axis([T(n) T(n+1) limits(3:4)]);

subplot(2,1,2)
hold on;
grid on;
plot(T(n), 0, '.-b', T(n+1), 0, '.-b')
plot(times, variance, '.-r')
hold('off');
title('Brownian Bridge without Refinement: Sample Variance')
xlabel('Time (Years)')
ylabel('Variance')
limits = axis;
axis([T(n) T(n+1) limits(3:4)]);
```

The Brownian interpolation within the chosen interval,  $dt$ , illustrates the following:

- The conditional mean of each state variable lies on a straight-line segment between the original simulated states at each endpoint.
- The conditional variance of each state variable is a quadratic function. This function attains its maximum midway between the interval endpoints, and is zero at each endpoint.
- The maximum variance, although dependent upon the actual model diffusion-rate function  $G(t,X)$ , is the variance of the sum of NBrowns correlated Gaussian variates scaled by the factor  $dt/4$ .

The previous plot highlights interpolation without refinement, in that none of the interpolated states take into account new information as it becomes available. If you had performed interpolation with refinement, new interpolated states would have been inserted into the time series and made available to subsequent interpolations on a trial-by-trial basis. In this case, all random draws for any given interpolation time would be identical. Also, the plot of the sample mean would exhibit greater variability, but would still cluster around the straight-line segment between the original simulated states at each endpoint. The plot of the sample variance, however, would be zero for all interpolation times, exhibiting no variability.

## Input Arguments

**MDL — Stochastic differential equation model object**

Stochastic differential equation model, specified as an `sde`, `bm`, `gbm`, `cev`, `cir`, `hwv`, `heston`, `sdeddo`, `sdeld`, or `sdemrd` object.

All MDL parameters are assumed piecewise constant, evaluated from the most recent observation time in `Times` that precedes a specified interpolation time in `T`. This is consistent with the Euler approach of Monte Carlo simulation.

Data Types: object

### **Times — Interpolation times**

vector

Interpolation times, specified as a `NTimes` element vector. The length of this vector determines the number of rows in the interpolated output time series `XT`.

Data Types: double

### **Paths — Sample paths of correlated state variables**

time series array

Sample paths of correlated state variables, specified as a `NPeriods`-by-`NVars`-by-`NTrials` time series array.

For a given trial, each row of this array is the transpose of the state vector  $X_t$  at time  $t$ . `Paths` is the initial time series array into which the `interpolate` function performs the Brownian interpolation.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1`, ..., `NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[XT,T] = interpolate(MDL,T,Paths,'Times',t)`

### **Times — Observation times associated with the time series input Paths**

zero-based, unit-increment column vector of length `NPeriods` (default) | column vector

Observation times associated with the time series input `Paths`, specified as the comma-separated pair consisting of '`Times`' and a column vector.

Data Types: double

### **Refine — Flag that indicates whether `interpolate` uses the interpolation times you request**

`False` (`interpolate` bases the interpolation only on the state information specified in `Paths`) (default) | logical with values `True` or `False`

Flag that indicates whether `interpolate` uses the interpolation times you request (see `T`) to refine the interpolation as new information becomes available, specified as the comma-separated pair consisting of '`Refine`' and a logical with a value of `True` or `False`.

Data Types: logical

**Processes — Sequence of background processes or state vector adjustments**

interpolate makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of background processes or state vector adjustments, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The `interpolate` function runs processing functions at each interpolation time. They must accept the current interpolation time  $t$ , and the current state vector  $X_t$ , and return a state vector that may be an adjustment to the input state.

If you specify more than one processing function, `interpolate` invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and so on.

Data Types: `cell` | `function`

## Output Arguments

**XT — Interpolated state variables**

array

Interpolated state variables, returned as a `NTimes`-by-`NVars`-by-`NTrials` time series array.

For a given trial, each row of this array is the transpose of the interpolated state vector  $X_t$  at time  $t$ . `XT` is the interpolated time series formed by interpolating into the input `Paths` time series array.

**T — Interpolation times associated with the output time series XT**

column vector

Interpolation times associated with the output time series `XT`, returned as a `NTimes`-by-1 column vector.

If the input interpolation time vector `Times` contains no missing observations (`Nans`), the output of `T` is the same time vector as `Times`, but with the `Nans` removed. This reduces the length of `T` and the number of rows of `XT`.

## Algorithms

This function performs a Brownian interpolation into a user-specified time series array, based on a piecewise-constant Euler sampling approach.

Consider a vector-valued SDE of the form:

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t$$

where:

- $X$  is an `NVars`-by-1 state vector.
- $F$  is an `NVars`-by-1 drift-rate vector-valued function.
- $G$  is an `NVars`-by-`NBrowns` diffusion-rate matrix-valued function.

- $W$  is an  $N$ Browns-by-1 Brownian motion vector.

Given a user-specified time series array associated with this equation, this function performs a Brownian (stochastic) interpolation by sampling from a conditional Gaussian distribution. This sampling technique is sometimes called a *Brownian bridge*.

---

**Note** Unlike simulation methods, the `interpolate` function does not support user-specified noise processes.

---

- The `interpolate` function assumes that all model parameters are piecewise-constant, and evaluates them from the most recent observation time in `Times` that precedes a specified interpolation time in `T`. This is consistent with the Euler approach of Monte Carlo simulation.
- When an interpolation time falls outside the interval specified by `Times`, a Euler simulation extrapolates the time series by using the nearest available observation.
- The user-defined time series `Paths` and corresponding observation `Times` must be fully observed (no missing observations denoted by NaNs).
- The `interpolate` function assumes that the user-specified time series array `Paths` is associated with the `sde` object. For example, the `Times` and `Paths` input pair are the result of an initial course-grained simulation. However, the interpolation ignores the initial conditions of the `sde` object (`StartTime` and `StartState`), allowing the user-specified `Times` and `Paths` input series to take precedence.

**Introduced in R2008a**

# sde

Stochastic Differential Equation (SDE) model

## Description

Creates and displays general stochastic differential equation (SDE) models from user-defined drift and diffusion rate functions.

Use `sde` objects to simulate sample paths of `NVars` state variables driven by `NBROWNS` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

An `sde` object enables you to simulate any vector-valued SDE of the form:

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t$$

where:

- $X_t$  is an `NVars`-by-1 state vector of process variables.
- $dW_t$  is an `NBROWNS`-by-1 Brownian motion vector.
- $F$  is an `NVars`-by-1 vector-valued drift-rate function.
- $G$  is an `NVars`-by-`NBROWNS` matrix-valued diffusion-rate function.

## Creation

### Syntax

```
SDE = sde(DriftRate,DiffusionRate)
SDE = sde(____,Name,Value)
```

#### Description

`SDE = sde(DriftRate,DiffusionRate)` creates a default SDE object.

`SDE = sde(____,Name,Value)` creates a SDE object with additional options specified by one or more `Name`,`Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1, ..., NameN,ValueN`.

The SDE object has the following “Properties” on page 19-92:

- `StartTime` — Initial observation time
- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument, callable as a function of time

- Drift — Composite drift-rate function, callable as a function of time and state
- Diffusion — Composite diffusion-rate function, callable as a function of time and state
- Simulation — A simulation function or method

### Input Arguments

**DriftRate** — DriftRate is a user-defined drift-rate function and represents the parameter  $F$

vector or object of class drift

DriftRate is a user-defined drift-rate function and represents the parameter  $F$ , specified as a vector or object of class drift.

DriftRate is a function that returns an NVars-by-1 drift-rate vector when called with two inputs:

- A real-valued scalar observation time  $t$ .
- An NVars-by-1 state vector  $X_t$ .

Alternatively, DriftRate can also be an object of class drift that encapsulates the drift-rate specification. In this case, however, sde uses only the Rate parameter of the object. For more information on the drift object, see drift.

Data Types: double | object

**DiffusionRate** — DiffusionRate is a user-defined drift-rate function and represents the parameter  $G$

matrix or object of class diffusion

DiffusionRate is a user-defined drift-rate function and represents the parameter  $G$ , specified as a matrix or object of class diffusion.

DiffusionRate is a function that returns an NVars-by-NBROWSNS diffusion-rate matrix when called with two inputs:

- A real-valued scalar observation time  $t$ .
- An NVars-by-1 state vector  $X_t$ .

Alternatively, DiffusionRate can also be an object of class diffusion that encapsulates the diffusion-rate specification. In this case, however, sde uses only the Rate parameter of the object. For more information on the diffusion object, see diffusion.

Data Types: double | object

### Properties

**StartTime** — Starting time of first observation, applied to all state variables

0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

**StartState** — Initial values of state variables

1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If `StartState` is a scalar, `sde` applies the same initial value to all state variables on all trials.

If `StartState` is a column vector, `sde` applies a unique initial value to each state variable on all trials.

If `StartState` is a matrix, `sde` applies a unique initial value to each state variable on each trial.

Data Types: double

**Correlation – Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)**

NBROWNS-by-NBROWNS identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBROWNS-by-NBROWNS positive semidefinite matrix, or as a deterministic function  $C(t)$  that accepts the current time  $t$  and returns an NBROWNS-by-NBROWNS positive semidefinite correlation matrix. If `Correlation` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

A `Correlation` matrix represents a static condition.

As a deterministic function of time, `Correlation` allows you to specify a dynamic correlation structure.

Data Types: double

**Simulation – User-defined simulation function or SDE simulation method**

simulation by Euler approximation (`simByEuler`) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function\_handle

**Drift – Drift rate component of continuous-time stochastic differential equations (SDEs)**

value stored from drift-rate function (default) | drift object or function accessible by  $(t, X_t)$

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The drift rate specification supports the simulation of sample paths of `NVars` state variables driven by NBROWNS Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `drift` class allows you to create drift-rate objects (using `drift`) of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- $A$  is an `NVars`-by-1 vector-valued function accessible using the  $(t, X_t)$  interface.

- B is an NVars-by-NVars matrix-valued function accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `drift` object are:

- **Rate:** The drift-rate function,  $F(t, X_t)$
- **A:** The intercept term,  $A(t, X_t)$ , of  $F(t, X_t)$
- **B:** The first order term,  $B(t, X_t)$ , of  $F(t, X_t)$

A and B enable you to query the original inputs. The function stored in Rate fully encapsulates the combined effect of A and B.

When specified as MATLAB double arrays, the inputs A and B are clearly associated with a linear drift rate parametric form. However, specifying either A or B as a function allows you to customize virtually any drift rate specification.

---

**Note** You can express `drift` and `diffusion` classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components A and B as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: object

### **Diffusion — Diffusion rate component of continuous-time stochastic differential equations (SDEs)**

value stored from diffusion-rate function (default) | diffusion object or functions accessible by  $(t, X_t)$

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The diffusion rate specification supports the simulation of sample paths of NVars state variables driven by NBROWNS Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The `diffusion` class allows you to create diffusion-rate objects (using `diffusion`):

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- D is an NVars-by-NVars diagonal matrix-valued function.
- Each diagonal element of D is the corresponding element of the state vector raised to the corresponding element of an exponent Alpha, which is an NVars-by-1 vector-valued function.
- V is an NVars-by-NBROWNS matrix-valued volatility rate function Sigma.
- Alpha and Sigma are also accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `diffusion` object are:

- **Rate:** The diffusion-rate function,  $G(t, X_t)$ .

- **Alpha:** The state vector exponent, which determines the format of  $D(t,X_t)$  of  $G(t,X_t)$ .
- **Sigma:** The volatility rate,  $V(t,X_t)$ , of  $G(t,X_t)$ .

**Alpha** and **Sigma** enable you to query the original inputs. (The combined effect of the individual **Alpha** and **Sigma** parameters is fully encapsulated by the function stored in **Rate**.) The **Rate** functions are the calculation engines for the **drift** and **diffusion** objects, and are the only parameters required for simulation.

---

**Note** You can express **drift** and **diffusion** classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components A and B as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: object

## Object Functions

|             |                                                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| interpolate | Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models            |
| simulate    | Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models |
| simByEuler  | Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models                  |

## Examples

### Create an SDE Object

Construct an SDE object `obj` to represent a univariate geometric Brownian Motion model of the form:  $dX_t = 0.1X_t dt + 0.3X_t dW_t$ .

Create drift and diffusion functions that are accessible by the common  $(t, X_t)$  interface:

```
F = @(t,X) 0.1 * X;
G = @(t,X) 0.3 * X;
```

Pass the functions to `sde` to create an object (`obj`) of class `sde`:

```
obj = sde(F, G)      % dX = F(t,X)dt + G(t,X)dW
obj =
  Class SDE: Stochastic Differential Equation
  -----
  Dimensions: State = 1, Brownian = 1
  -----
  StartTime: 0
  StartState: 1
  Correlation: 1
  Drift: drift rate function F(t,X(t))
  Diffusion: diffusion rate function G(t,X(t))
  Simulation: simulation method/function simByEuler
```

`obj` displays like a MATLAB® structure, with the following information:

- The object's class
- A brief description of the object
- A summary of the dimensionality of the model

The object's displayed parameters are as follows:

- `StartTime`: The initial observation time (real-valued scalar)
- `StartState`: The initial state vector (NVARS-by-1 column vector)
- `Correlation`: The correlation structure between Brownian process
- `Drift`: The drift-rate function  $F(t, X_t)$
- `Diffusion`: The diffusion-rate function  $G(t, X_t)$
- `Simulation`: The simulation method or function.

Of these displayed parameters, only `Drift` and `Diffusion` are required inputs.

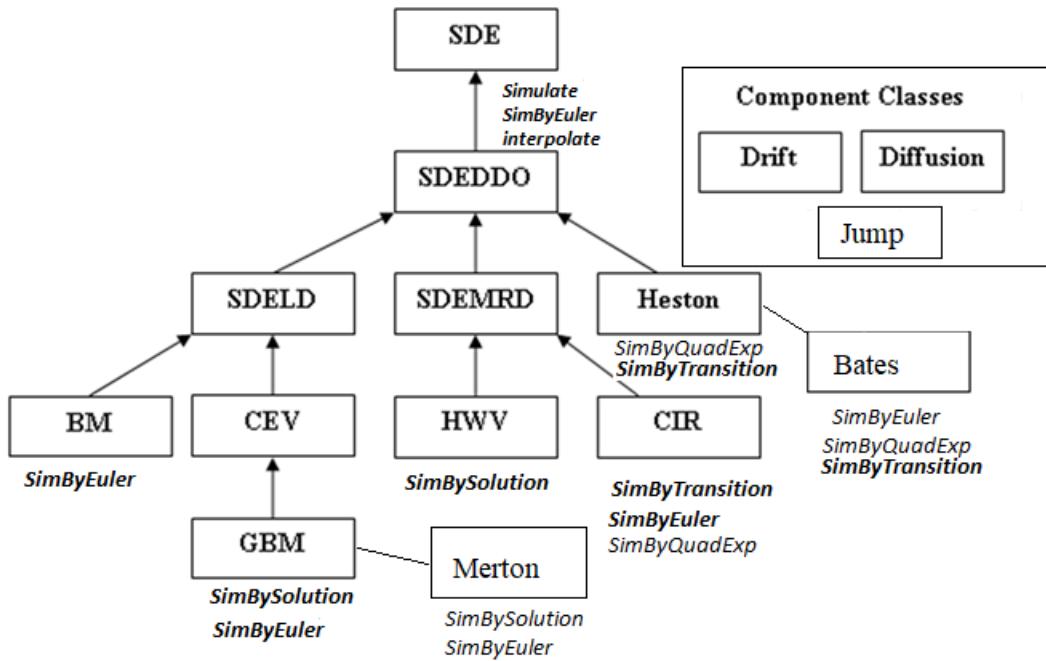

The only exception to the  $(t, X_t)$  evaluation interface is `Correlation`. Specifically, when you enter `Correlation` as a function, the SDE engine assumes that it is a deterministic function of time,  $C(t)$ . This restriction on `Correlation` as a deterministic function of time allows Cholesky factors to be computed and stored before the formal simulation. This inconsistency dramatically improves run-time performance for dynamic correlation structures. If `Correlation` is stochastic, you can also include it within the simulation architecture as part of a more general random number generation function.

## More About

### Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.

For more information, see “SDE Class Hierarchy” on page 18-5.

## Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time  $t$  and a state vector  $X_t$ , and return an array of appropriate dimension. Even if you originally specified an input as an array, **sde** treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

## Introduced in R2008a

# sdedo

Stochastic Differential Equation (SDEDDO) model from Drift and Diffusion components

## Description

Creates and displays `sdedo` objects, instantiated with objects of class `drift` and `diffusion`. These restricted `sdedo` objects contain the input `drift` and `diffusion` objects; therefore, you can directly access their displayed parameters.

This abstraction also generalizes the notion of drift and diffusion-rate objects as functions that `sdedo` evaluates for specific values of time  $t$  and state  $X_t$ . Like `sde` objects, `sdedo` objects allow you to simulate sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

This method enables you to simulate any vector-valued SDEDDO of the form:

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t \quad (19-3)$$

where:

- $X_t$  is an `NVars`-by-1 state vector of process variables.
- $dW_t$  is an `NBrowns`-by-1 Brownian motion vector.
- $F$  is an `NVars`-by-1 vector-valued drift-rate function.
- $G$  is an `NVars`-by-`NBrowns` matrix-valued diffusion-rate function.

## Creation

### Syntax

```
SDEDDO = sdedo(DriftRate,DiffusionRate)
SDEDDO = sdedo(___,Name,Value)
```

#### Description

`SDEDDO = sdedo(DriftRate,DiffusionRate)` creates a default `SDEDDO` object.

`SDEDDO = sdedo(___,Name,Value)` creates a `SDEDDO` object with additional options specified by one or more `Name,Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1, ..., NameN,ValueN`.

The `SDEDDO` object has the following displayed “Properties” on page 19-101:

- `StartTime` — Initial observation time

- **StartState** — Initial state at time **StartTime**
- **Correlation** — Access function for the **Correlation** input argument, callable as a function of time
- **Drift** — Composite drift-rate function, callable as a function of time and state
- **Diffusion** — Composite diffusion-rate function, callable as a function of time and state
- **A** — Access function for the drift-rate property **A**, callable as a function of time and state
- **B** — Access function for the drift-rate property **B**, callable as a function of time and state
- **Alpha** — Access function for the diffusion-rate property **Alpha**, callable as a function of time and state
- **Sigma** — Access function for the diffusion-rate property **Sigma**, callable as a function of time and state
- **Simulation** — A simulation function or method

### **Input Arguments**

**DriftRate** — **DriftRate** is a user-defined drift-rate function and represents the parameter **F**

vector or object of class **Drift**

**DriftRate** is a user-defined drift-rate function and represents the parameter  $F$ , specified as a vector or object of class **drift**.

**DriftRate** is a function that returns an **NVars**-by-1 drift-rate vector when called with two inputs:

- A real-valued scalar observation time  $t$ .
- An **NVars**-by-1 state vector  $X_t$ .

Alternatively, **DriftRate** can also be an object of class **drift** that encapsulates the drift-rate specification. In this case, however, **sde** uses only the **Rate** parameter of the object. For more information on the **drift** object, see **drift**.

Data Types: **double**

**DiffusionRate** — **DiffusionRate** is a user-defined drift-rate function and represents the parameter **G**

matrix or object of class **Diffusion**

**DiffusionRate** is a user-defined drift-rate function and represents the parameter  $G$ , specified as a matrix or object of class **diffusion**.

**DiffusionRate** is a function that returns an **NVars**-by-**NBrowns** diffusion-rate matrix when called with two inputs:

- A real-valued scalar observation time  $t$ .
- An **NVars**-by-1 state vector  $X_t$ .

Alternatively, **DiffusionRate** can also be an object of class **diffusion** that encapsulates the diffusion-rate specification. In this case, however, **sde** uses only the **Rate** parameter of the object. For more information on the **diffusion** object, see **diffusion**.

Data Types: **double**

## Properties

### **StartTime — Starting time of first observation, applied to all state variables**

0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

### **StartState — Initial values of state variables**

1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If StartState is a scalar, `sdedo` applies the same initial value to all state variables on all trials.

If StartState is a column vector, `sdedo` applies a unique initial value to each state variable on all trials.

If StartState is a matrix, `sdedo` applies a unique initial value to each state variable on each trial.

Data Types: double

### **Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)**

NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function  $C(t)$  that accepts the current time  $t$  and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

As a deterministic function of time, Correlation allows you to specify a dynamic correlation structure.

Data Types: double

### **Simulation — User-defined simulation function or SDE simulation method**

simulation by Euler approximation (`simByEuler`) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function\_handle

### **Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)**

value stored from drift-rate function (default) | drift object or function accessible by  $(t, X_t)$

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The drift rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `drift` class allows you to create drift-rate objects using `drift` of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- `A` is an `NVars`-by-1 vector-valued function accessible using the  $(t, X_t)$  interface.
- `B` is an `NVars`-by-`NVars` matrix-valued function accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `drift` object are:

- `Rate`: The drift-rate function,  $F(t, X_t)$
- `A`: The intercept term,  $A(t, X_t)$ , of  $F(t, X_t)$
- `B`: The first order term,  $B(t, X_t)$ , of  $F(t, X_t)$

`A` and `B` enable you to query the original inputs. The function stored in `Rate` fully encapsulates the combined effect of `A` and `B`.

When specified as MATLAB double arrays, the inputs `A` and `B` are clearly associated with a linear drift rate parametric form. However, specifying either `A` or `B` as a function allows you to customize virtually any drift rate specification.

---

**Note** You can express `drift` and `diffusion` classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components `A` and `B` as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `F = drift(0, 0.1)` % Drift rate function  $F(t, X)$

Data Types: `struct` | `double`

### **Diffusion — Diffusion rate component of continuous-time stochastic differential equations (SDEs)**

value stored from diffusion-rate function (default) | diffusion object or functions accessible by  $(t, X_t)$

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The diffusion rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `diffusion` class allows you to create diffusion-rate objects using `diffusion`:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- $D$  is an  $N_{\text{Vars}}$ -by- $N_{\text{Vars}}$  diagonal matrix-valued function.
- Each diagonal element of  $D$  is the corresponding element of the state vector raised to the corresponding element of an exponent  $\text{Alpha}$ , which is an  $N_{\text{Vars}}$ -by-1 vector-valued function.
- $V$  is an  $N_{\text{Vars}}$ -by- $N_{\text{Browns}}$  matrix-valued volatility rate function  $\text{Sigma}$ .
- $\text{Alpha}$  and  $\text{Sigma}$  are also accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `diffusion` object are:

- **Rate**: The diffusion-rate function,  $G(t, X_t)$ .
- **Alpha**: The state vector exponent, which determines the format of  $D(t, X_t)$  of  $G(t, X_t)$ .
- **Sigma**: The volatility rate,  $V(t, X_t)$ , of  $G(t, X_t)$ .

**Alpha** and **Sigma** enable you to query the original inputs. (The combined effect of the individual **Alpha** and **Sigma** parameters is fully encapsulated by the function stored in **Rate**.) The **Rate** functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

---

**Note** You can express `drift` and `diffusion` classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components **A** and **B** as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `G = diffusion(1, 0.3)` % Diffusion rate function  $G(t, X)$

Data Types: `struct` | `double`

## Object Functions

|                          |                                                                                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>interpolate</code> | Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models            |
| <code>simulate</code>    | Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models |
| <code>simByEuler</code>  | Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models                  |

## Examples

### Create a `sdeddo` Object

The `sdeddo` class derives from the base `sde` class. To use this class, you must pass drift and diffusion-rate objects to the `sdeddo` function.

Create `drift` and `diffusion` rate objects:

```
F = drift(0, 0.1);      % Drift rate function F(t, X)
G = diffusion(1, 0.3); % Diffusion rate function G(t, X)
```

Pass the functions to the `sdeddo` function to create an object `obj` of class `sdeddo`:

```
obj = sdeddo(F, G)      % dX = F(t, X)dt + G(t, X)dW
obj =
  Class SDEDDO: SDE from Drift and Diffusion Objects
```

```
-----
Dimensions: State = 1, Brownian = 1
-----
StartTime: 0
StartState: 1
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
A: 0
B: 0.1
Alpha: 1
Sigma: 0.3
```

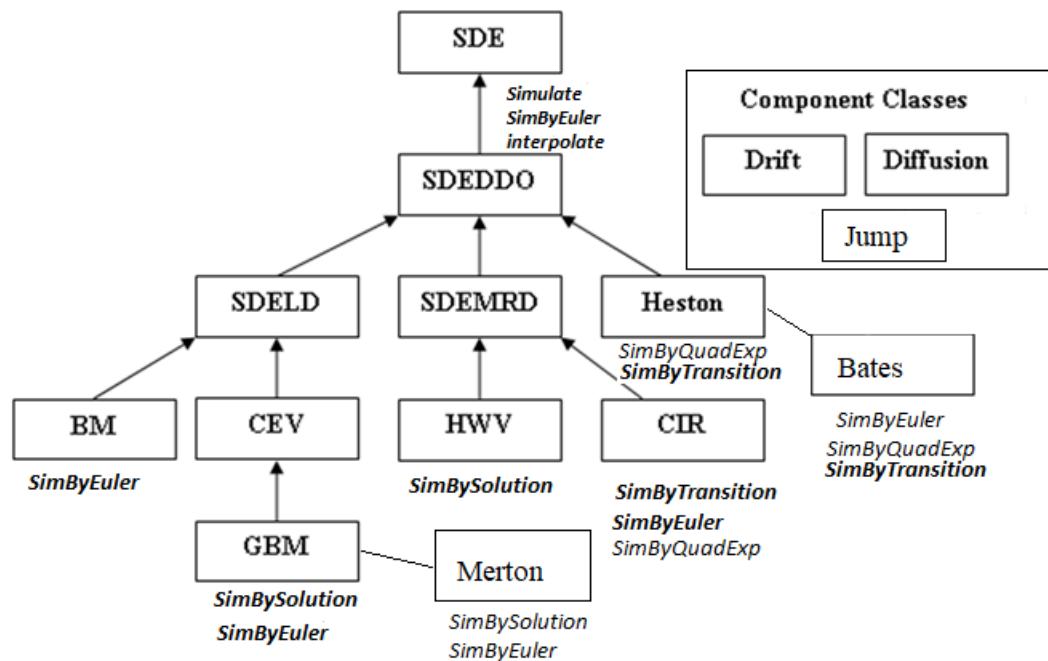

In this example, the object displays the additional parameters associated with input `drift` and `diffusion` objects.

## More About

### Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.

For more information, see “SDE Class Hierarchy” on page 18-5.

## Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time  $t$  and a state vector  $X_t$ , and return an array of appropriate dimension. Even if you originally specified an input as an array, `sdeddo` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

# sdeld

SDE with Linear Drift (SDELD) model

## Description

Creates and displays SDE objects whose drift rate is expressed in linear drift-rate form and that derive from the `sdeddo` (SDE from drift and diffusion objects class).

Use `sdeld` objects to simulate sample paths of `NVars` state variables expressed in linear drift-rate form. They provide a parametric alternative to the mean-reverting drift form (see `sdemrd`).

These state variables are driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes with linear drift-rate functions.

The `sdeld` object allows you to simulate any vector-valued SDELD of the form:

$$dX_t = (A(t) + B(t)X_t)dt + D(t, X_t^{\alpha(t)})V(t)dW_t$$

where:

- $X_t$  is an `NVars`-by-1 state vector of process variables.
- $A$  is an `NVars`-by-1 vector.
- $B$  is an `NVars`-by-`NVars` matrix.
- $D$  is an `NVars`-by-`NVars` diagonal matrix, where each element along the main diagonal is the corresponding element of the state vector raised to the corresponding power of  $\alpha$ .
- $V$  is an `NVars`-by-`NBrowns` instantaneous volatility rate matrix.
- $dW_t$  is an `NBrowns`-by-1 Brownian motion vector.

## Creation

### Syntax

```
SDELD = sdeld(A,B,Alpha,Sigma)
SDELD = sdeld(_____,Name,Value)
```

### Description

`SDELD = sdeld(A,B,Alpha,Sigma)` creates a default SDELD object.

`SDELD = sdeld(_____,Name,Value)` creates a SDELD object with additional options specified by one or more `Name`,`Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1, ..., NameN,ValueN`.

The SDELD object has the following displayed “Properties” on page 19-109:

- `StartTime` — Initial observation time
- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `A` — Access function for the input argument `A`, callable as a function of time and state
- `B` — Access function for the input argument `B`, callable as a function of time and state
- `Alpha` — Access function for the input argument `Alpha`, callable as a function of time and state
- `Sigma` — Access function for the input argument `Sigma`, callable as a function of time and state
- `Simulation` — A simulation function or method

### **Input Arguments**

#### **A — A represents the parameter A**

array or deterministic function of time or deterministic function of time and state

`A` represents the parameter  $A$ , specified as an array or deterministic function of time.

If you specify `A` as an array, it must be an `NVars`-by-1 column vector of intercepts.

As a deterministic function of time, when `A` is called with a real-valued scalar time  $t$  as its only input, `A` must produce an `NVars`-by-1 column vector. If you specify `A` as a function of time and state, it must generate an `NVars`-by-1 column vector of intercepts when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An `NVars`-by-1 state vector  $X_t$ .

Data Types: `double` | `function_handle`

#### **B — B represents the parameter B**

array or deterministic function of time or deterministic function of time and state

`B` represents the parameter  $B$ , specified as an array or deterministic function of time.

If you specify `B` as an array, it must be an `NVars`-by-`NVars` matrix of state vector coefficients.

As a deterministic function of time, when `B` is called with a real-valued scalar time  $t$  as its only input, `B` must produce an `NVars`-by-`NVars` matrix. If you specify `B` as a function of time and state, it must generate an `NVars`-by-`NVars` matrix of state vector coefficients when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An `NVars`-by-1 state vector  $X_t$ .

Data Types: `double` | `function_handle`

#### **Alpha — Alpha represents the parameter D**

array or deterministic function of time or deterministic function of time and state

`Alpha` represents the parameter  $D$ , specified as an array or deterministic function of time.

If you specify **Alpha** as an array, it represents an **NVars**-by-1 column vector of exponents.

As a deterministic function of time, when **Alpha** is called with a real-valued scalar time  $t$  as its only input, **Alpha** must produce an **NVars**-by-1 matrix.

If you specify it as a function of time and state, **Alpha** must return an **NVars**-by-1 column vector of exponents when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An **NVars**-by-1 state vector  $X_t$ .

Data Types: double | function\_handle

### **Sigma — Sigma represents the parameter V**

array or deterministic function of time or deterministic function of time and state

**Sigma** represents the parameter  $V$ , specified as an array or a deterministic function of time.

If you specify **Sigma** as an array, it must be an **NVars**-by-**NBrowns** matrix of instantaneous volatility rates or as a deterministic function of time. In this case, each row of **Sigma** corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when **Sigma** is called with a real-valued scalar time  $t$  as its only input, **Sigma** must produce an **NVars**-by-**NBrowns** matrix. If you specify **Sigma** as a function of time and state, it must return an **NVars**-by-**NBrowns** matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An **NVars**-by-1 state vector  $X_t$ .

Although thegbm constructor enforces no restrictions on the sign of **Sigma** volatilities, they are specified as positive values.

Data Types: double | function\_handle

---

**Note** Although **sdeld** does not enforce restrictions on the signs of **Alpha** or **Sigma**, each parameter is specified as a positive value.

---

## Properties

### **StartTime — Starting time of first observation, applied to all state variables**

0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

### **StartState — Initial values of state variables**

1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If **StartState** is a scalar, **sdeld** applies the same initial value to all state variables on all trials.

If `StartState` is a column vector, `sdeld` applies a unique initial value to each state variable on all trials.

If `StartState` is a matrix, `sdeld` applies a unique initial value to each state variable on each trial.

Data Types: double

**Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)**

NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function  $C(t)$  that accepts the current time  $t$  and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If `Correlation` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

A `Correlation` matrix represents a static condition.

As a deterministic function of time, `Correlation` allows you to specify a dynamic correlation structure.

Data Types: double

**Simulation — User-defined simulation function or SDE simulation method**

simulation by Euler approximation (`simByEuler`) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function\_handle

**Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)**

value stored from drift-rate function (default) | drift object or function accessible by  $(t, X_t)$

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The drift rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The `drift` class allows you to create drift-rate objects using `drift` of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- A is an NVars-by-1 vector-valued function accessible using the  $(t, X_t)$  interface.
- B is an NVars-by-NVars matrix-valued function accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `drift` object are:

- **Rate:** The drift-rate function,  $F(t, X_t)$
- **A:** The intercept term,  $A(t, X_t)$ , of  $F(t, X_t)$
- **B:** The first order term,  $B(t, X_t)$ , of  $F(t, X_t)$

A and B enable you to query the original inputs. The function stored in Rate fully encapsulates the combined effect of A and B.

When specified as MATLAB double arrays, the inputs A and B are clearly associated with a linear drift rate parametric form. However, specifying either A or B as a function allows you to customize virtually any drift rate specification.

---

**Note** You can express drift and diffusion classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components A and B as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: struct | double

### **Diffusion — Diffusion rate component of continuous-time stochastic differential equations (SDEs)**

value stored from diffusion-rate function (default) | diffusion object or functions accessible by  $(t, X_t)$

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The diffusion rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The diffusion class allows you to create diffusion-rate objects using diffusion:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- D is an NVars-by-NVars diagonal matrix-valued function.
- Each diagonal element of D is the corresponding element of the state vector raised to the corresponding element of an exponent Alpha, which is an NVars-by-1 vector-valued function.
- V is an NVars-by-NBrowns matrix-valued volatility rate function Sigma.
- Alpha and Sigma are also accessible using the  $(t, X_t)$  interface.

The displayed parameters for a diffusion object are:

- **Rate:** The diffusion-rate function,  $G(t, X_t)$ .
- **Alpha:** The state vector exponent, which determines the format of  $D(t, X_t)$  of  $G(t, X_t)$ .
- **Sigma:** The volatility rate,  $V(t, X_t)$ , of  $G(t, X_t)$ .

Alpha and Sigma enable you to query the original inputs. (The combined effect of the individual Alpha and Sigma parameters is fully encapsulated by the function stored in Rate.) The Rate

functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

**Note** You can express `drift` and `diffusion` classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components A and B as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: `struct | double`

## Object Functions

|                          |                                                                                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>interpolate</code> | Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models            |
| <code>simulate</code>    | Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models |
| <code>simByEuler</code>  | Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models                  |

## Examples

### Create a `sdeLD` Object

The `sdeLD` class derives from the `sdeddo` class. These objects allow you to simulate correlated paths of NVARS state variables expressed in linear drift-rate form:

$$dX_t = (A(t) + B(t)X_t)dt + D(t, X_t^{\alpha(t)})V(t)dW_t.$$

```
obj = sdeLD(0, 0.1, 1, 0.3) % (A, B, Alpha, Sigma)

obj =
  Class SDELD: SDE with Linear Drift
  -----
  Dimensions: State = 1, Brownian = 1
  -----
  StartTime: 0
  StartState: 1
  Correlation: 1
    Drift: drift rate function F(t,X(t))
    Diffusion: diffusion rate function G(t,X(t))
    Simulation: simulation method/function simByEuler
      A: 0
      B: 0.1
      Alpha: 1
      Sigma: 0.3
```

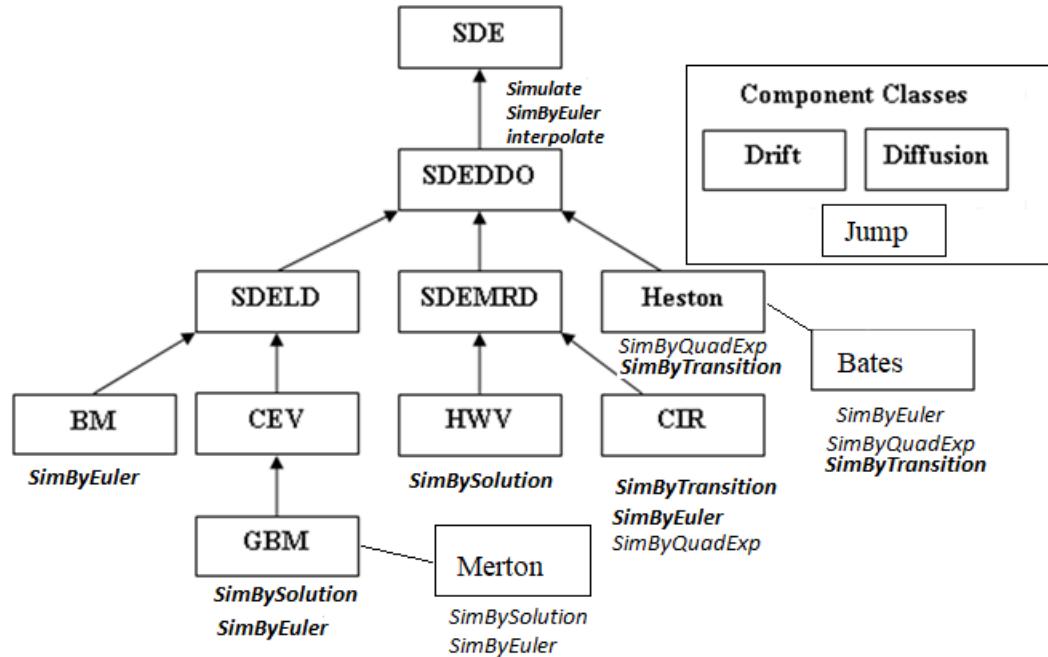

`sdeLD` objects provide a parametric alternative to the mean-reverting drift form and also provide an alternative interface to the `sdeddo` parent class, because you can create an object without first having to create its drift and diffusion-rate components.

## More About

### Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.

For more information, see “SDE Class Hierarchy” on page 18-5.

## Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time  $t$  and a state vector  $X_t$ , and return an array of appropriate dimension. Even if you originally specified an input as an array, `sdeld` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

## Introduced in R2008a

# sdemrd

SDE with Mean-Reverting Drift (SDEMRD) model

## Description

Creates and displays SDE objects whose drift rate is expressed in mean-reverting drift-rate form and which derive from the `sdeddo` class (SDE from drift and diffusion objects).

Use `sdemrd` objects to simulate of sample paths of `NVars` state variables expressed in mean-reverting drift-rate form, and provide a parametric alternative to the linear drift form (see `sdeld`). These state variables are driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes with mean-reverting drift-rate functions.

The `sdemrd` object allows you to simulate any vector-valued SDEMRD of the form:

$$dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\alpha(t)})V(t)dW_t$$

where:

- $X_t$  is an `NVars`-by-1 state vector of process variables.
- $S$  is an `NVars`-by-`NVars` matrix of mean reversion speeds.
- $L$  is an `NVars`-by-1 vector of mean reversion levels.
- $D$  is an `NVars`-by-`NVars` diagonal matrix, where each element along the main diagonal is the corresponding element of the state vector raised to the corresponding power of  $\alpha$ .
- $V$  is an `NVars`-by-`NBrowns` instantaneous volatility rate matrix.
- $dW_t$  is an `NBrowns`-by-1 Brownian motion vector.

## Creation

### Syntax

```
SDEMRD = sdemrd(Speed,Level,Alpha,Sigma)
SDEMRD = sdemrd(____,Name,Value)
```

### Description

`SDEMRD = sdemrd(Speed,Level,Alpha,Sigma)` creates a default SDEMRD object.

`SDEMRD = sdemrd(____,Name,Value)` creates a SDEMRD object with additional options specified by one or more `Name`,`Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1, ..., NameN,ValueN`.

The SDELD object has the following displayed “Properties” on page 19-117:

- `StartTime` — Initial observation time
- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `Speed` — Access function for the input argument `Speed`, callable as a function of time and state
- `Level` — Access function for the input argument `Level`, callable as a function of time and state
- `Alpha` — Access function for the input argument `Alpha`, callable as a function of time and state
- `Sigma` — Access function for the input argument `Sigma`, callable as a function of time and state
- `Simulation` — A simulation function or method

### **Input Arguments**

#### **Speed — Speed represents the parameter S**

array or deterministic function of time or deterministic function of time and state

`Speed` represents the parameter  $S$ , specified as an array or deterministic function of time.

If you specify `Speed` as an array, it must be an `NVars`-by-`NVars` matrix of mean-reversion speeds (the rate at which the state vector reverts to its long-run average `Level`).

As a deterministic function of time, when `Speed` is called with a real-valued scalar time  $t$  as its only input, `Speed` must produce an `NVars`-by-`NVars` matrix. If you specify `Speed` as a function of time and state, it calculates the speed of mean reversion. This function must generate an `NVars`-by-`NVars` matrix of reversion rates when called with two inputs:

- A real-valued scalar observation time  $t$ .
- An `NVars`-by-1 state vector  $X_t$ .

Data Types: `double` | `function_handle`

#### **Level — Level represents the parameter L**

array or deterministic function of time or deterministic function of time and state

`Level` represents the parameter  $L$ , specified as an array or deterministic function of time.

If you specify `Level` as an array, it must be an `NVars`-by-1 column vector of reversion levels.

As a deterministic function of time, when `Level` is called with a real-valued scalar time  $t$  as its only input, `Level` must produce an `NVars`-by-1 column vector. If you specify `Level` as a function of time and state, it must generate an `NVars`-by-1 column vector of reversion levels when called with two inputs:

- A real-valued scalar observation time  $t$ .
- An `NVars`-by-1 state vector  $X_t$ .

Data Types: `double` | `function_handle`

#### **Alpha — Alpha represents the parameter D**

array or deterministic function of time or deterministic function of time and state

**Alpha** represents the parameter  $D$ , specified as an array or deterministic function of time.

If you specify **Alpha** as an array, it represents an **NVars**-by-1 column vector of exponents.

As a deterministic function of time, when **Alpha** is called with a real-valued scalar time  $t$  as its only input, **Alpha** must produce an **NVars**-by-1 matrix.

If you specify it as a function of time and state, **Alpha** must return an **NVars**-by-1 column vector of exponents when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An **NVars**-by-1 state vector  $X_t$ .

Data Types: double | function\_handle

### **Sigma — Sigma represents the parameter V**

array or deterministic function of time or deterministic function of time and state

**Sigma** represents the parameter  $V$ , specified as an array or a deterministic function of time.

If you specify **Sigma** as an array, it must be an **NVars**-by-**NBrowns** matrix of instantaneous volatility rates or as a deterministic function of time. In this case, each row of **Sigma** corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when **Sigma** is called with a real-valued scalar time  $t$  as its only input, **Sigma** must produce an **NVars**-by-**NBrowns** matrix. If you specify **Sigma** as a function of time and state, it must return an **NVars**-by-**NBrowns** matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time  $t$ .
- An **NVars**-by-1 state vector  $X_t$ .

Data Types: double | function\_handle

---

**Note** Although **sdemrd** does not enforce restrictions on the signs of **Alpha** or **Sigma**, each parameter is specified as a positive value.

---

## Properties

### **StartTime — Starting time of first observation, applied to all state variables**

0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

### **StartState — Initial values of state variables**

1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If **StartState** is a scalar, **sdemrd** applies the same initial value to all state variables on all trials.

If `StartState` is a column vector, `sdemrd` applies a unique initial value to each state variable on all trials.

If `StartState` is a matrix, `sdemrd` applies a unique initial value to each state variable on each trial.

Data Types: double

**Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)**

`NBrowns`-by-`NBrowns` identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an `NBrowns`-by-`NBrowns` positive semidefinite matrix, or as a deterministic function  $C(t)$  that accepts the current time  $t$  and returns an `NBrowns`-by-`NBrowns` positive semidefinite correlation matrix. If `Correlation` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

A `Correlation` matrix represents a static condition.

As a deterministic function of time, `Correlation` allows you to specify a dynamic correlation structure.

Data Types: double

**Simulation — User-defined simulation function or SDE simulation method**

`simulation` by Euler approximation (`simByEuler`) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function\_handle

**Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)**

value stored from drift-rate function (default) | drift object or function accessible by  $(t, X_t)$

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The drift rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `drift` class allows you to create drift-rate objects using `drift` of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- `A` is an `NVars`-by-1 vector-valued function accessible using the  $(t, X_t)$  interface.
- `B` is an `NVars`-by-`NVars` matrix-valued function accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `drift` object are:

- **Rate:** The drift-rate function,  $F(t, X_t)$
- **A:** The intercept term,  $A(t, X_t)$ , of  $F(t, X_t)$
- **B:** The first order term,  $B(t, X_t)$ , of  $F(t, X_t)$

A and B enable you to query the original inputs. The function stored in Rate fully encapsulates the combined effect of A and B.

When specified as MATLAB double arrays, the inputs A and B are clearly associated with a linear drift rate parametric form. However, specifying either A or B as a function allows you to customize virtually any drift rate specification.

---

**Note** You can express drift and diffusion classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components A and B as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: struct | double

### **Diffusion — Diffusion rate component of continuous-time stochastic differential equations (SDEs)**

value stored from diffusion-rate function (default) | diffusion object or functions accessible by  $(t, X_t)$

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The diffusion rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The diffusion class allows you to create diffusion-rate objects using diffusion:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- D is an NVars-by-NVars diagonal matrix-valued function.
- Each diagonal element of D is the corresponding element of the state vector raised to the corresponding element of an exponent Alpha, which is an NVars-by-1 vector-valued function.
- V is an NVars-by-NBrowns matrix-valued volatility rate function Sigma.
- Alpha and Sigma are also accessible using the  $(t, X_t)$  interface.

The displayed parameters for a diffusion object are:

- **Rate:** The diffusion-rate function,  $G(t, X_t)$ .
- **Alpha:** The state vector exponent, which determines the format of  $D(t, X_t)$  of  $G(t, X_t)$ .
- **Sigma:** The volatility rate,  $V(t, X_t)$ , of  $G(t, X_t)$ .

Alpha and Sigma enable you to query the original inputs. (The combined effect of the individual Alpha and Sigma parameters is fully encapsulated by the function stored in Rate.) The Rate

functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

**Note** You can express `drift` and `diffusion` classes in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components A and B as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: `struct | double`

## Object Functions

|                          |                                                                                                                                                        |

## Examples

### Create a `sdemrd` Object

The `sdemrd` class derives directly from the `sdeddo` class. It provides an interface in which the drift-rate function is expressed in mean-reverting drift form:  $dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\alpha(t)})V(t)dW_t$ .

`sdemrd` objects provide a parametric alternative to the linear drift form by reparameterizing the general linear drift such that:  $A(t) = S(t)L(t)$ ,  $B(t) = -S(t)$ .

Create an `sdemrd` object `obj` with a square root exponent to represent the model:

$$dX_t = 0.2(0.1 - X_t)dt + 0.05X_t^{\frac{1}{2}}dW_t.$$

```
obj = sdemrd(0.2, 0.1, 0.5, 0.05) % (Speed, Level, Alpha, Sigma)
obj =
  Class SDEMRD: SDE with Mean-Reverting Drift
  -----
  Dimensions: State = 1, Brownian = 1
  -----
  StartTime: 0
  StartState: 1
  Correlation: 1
  Drift: drift rate function F(t,X(t))
  Diffusion: diffusion rate function G(t,X(t))
  Simulation: simulation method/function simByEuler
  Alpha: 0.5
  Sigma: 0.05
  Level: 0.1
  Speed: 0.2
```

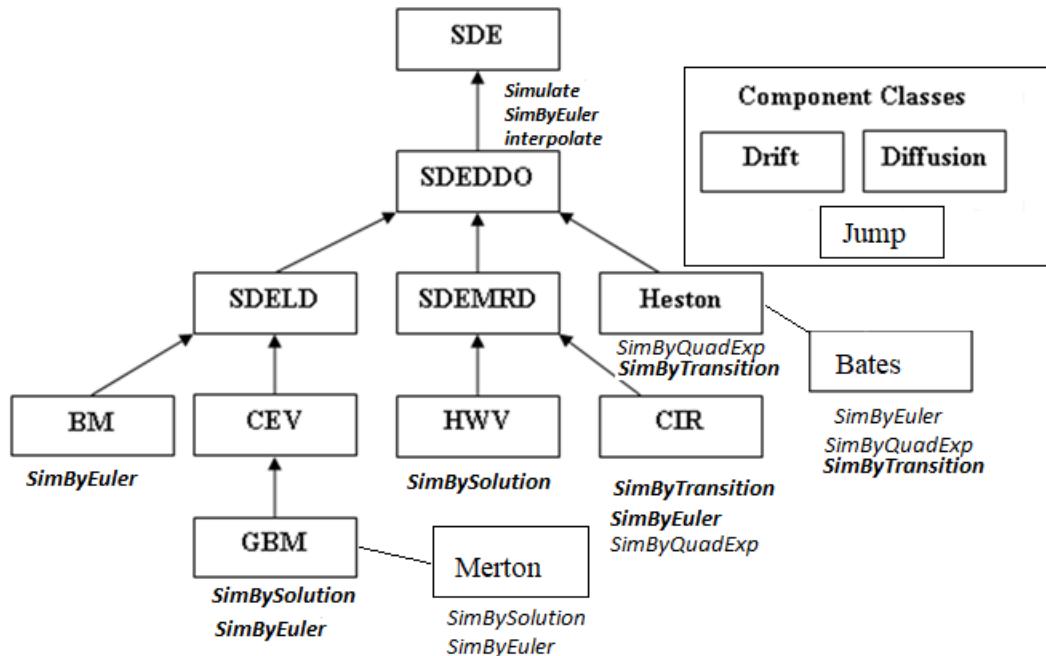

`sdemrd` objects display the familiar `Speed` and `Level` parameters instead of A and B.

## More About

### Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.

For more information, see “SDE Class Hierarchy” on page 18-5.

## Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time  $t$  and a state vector  $X_t$ , and return an array of appropriate dimension. Even if you originally specified an input as an array, **sdemrd** treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

## Introduced in R2008a

# bates

Bates stochastic volatility model

## Description

The `bates` function creates a `bates` object, which represents a Bates model.

The Bates model is a bivariate composite model that derives from the `heston` object. The Bates model is composed of two coupled and dissimilar univariate models, each driven by a single Brownian motion source of risk and a single compound Poisson process representing the arrivals of important events over `NPeriods` consecutive observation periods. The Bates model approximates continuous-time Bates stochastic volatility processes.

The first univariate model is a GBM model with a stochastic volatility function and a stochastic jump process, and usually corresponds to a price process whose variance rate is governed by the second univariate model. The second model is a Cox-Ingersoll-Ross (CIR) square root diffusion model that describes the evolution of the variance rate of the coupled GBM price process.

Bates models are bivariate composite models. Each Bates model consists of two coupled univariate models:

- A geometric Brownian motion (`gbm`) model with a stochastic volatility function and jumps.

$$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t} + Y(t)X_{1t}dN_t$$

This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.

- A Cox-Ingersoll-Ross (`cir`) square root diffusion model.

$$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

This model describes the evolution of the variance rate of the coupled Bates price process.

## Creation

### Syntax

```
Bates = bates(Return, Speed, Level, Volatility, JumpFreq, JumpMean, JumpVol)
Bates = bates(___, Name, Value)
```

### Description

`Bates = bates(Return, Speed, Level, Volatility, JumpFreq, JumpMean, JumpVol)` create a `bates` object with the default options.

Since Bates models are bivariate models composed of coupled univariate models, all required inputs correspond to scalar parameters. Specify required inputs as one of two types:

- MATLAB array. Specify an array to indicate a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- MATLAB function. Specify a function to provide indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported by an interface because all implementation details are hidden and fully encapsulated by the function.

**Note** You can specify combinations of array and function input parameters as needed. Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time  $t$  as its only input argument. Otherwise, a parameter is assumed to be a function of time  $t$  and state  $X_t$  and is invoked with both input arguments.

---

`Bates = bates( ___,Name,Value)` sets “Properties” on page 19-127 using name-value pair arguments in addition to the input arguments in the preceding syntax. Enclose each property name in quotes.

The `bates` object has the following “Properties” on page 19-127:

- `StartTime` — Initial observation time
- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument
- `Drift` — Composite drift-rate function
- `Diffusion` — Composite diffusion-rate function
- `Simulation` — A simulation function or method

### Input Arguments

**Return — Expected mean instantaneous rate of return of GBM price process**  
array | deterministic function of time | deterministic function of time and state

Expected mean instantaneous rate of return of the GBM price process, specified as an array, or a deterministic function of time.

If you specify `Return` as an array, it must be scalar.

If you specify `Return` as a deterministic function of time, you call `Return` with a real-valued scalar time  $t$  as its only input, it must return a scalar.

If you specify `Return` as a deterministic function of time and state, it must return a scalar when you call it with two inputs:

- A real-valued scalar observation time  $t$
- A 2-by-1 bivariate state vector  $X_t$

Data Types: `double` | `function_handle`

**Speed — Mean-reversion speed of CIR stochastic variance process**  
array | deterministic function of time | deterministic function of time and state

Mean-reversion speed of the CIR stochastic variance process, specified as an array or deterministic function of time.

If you specify `Speed` as an array, it must be a scalar.

If you specify `Speed` as a deterministic function of time, you call `Speed` with a real-valued scalar time  $t$  as its only input, it must return a scalar.

If you specify `Speed` as a function of time and state, the function calculates the speed of mean reversion. This function must return a scalar of reversion rates when you call it with two inputs:

- A real-valued scalar observation time  $t$
- A 2-by-1 bivariate state vector  $X_t$

---

**Note** Although `bates` enforces no restrictions on `Speed`, the mean-reversion speed is nonnegative such that the underlying process reverts to some stable level.

---

Data Types: `double` | `function_handle`

**Level — Reversion level or long-run average of CIR stochastic variance process**  
`array` | deterministic function of time | deterministic function of time and state

Reversion level or long-run average of the CIR stochastic variance process, specified as an array, or deterministic function of time.

If you specify `Level` as an array, it must be a scalar.

If you specify `Level` as a deterministic function of time, you call `Level` with a real-valued scalar time  $t$  as its only input, it must return a scalar.

If you specify `Level` as a deterministic function of time and state, it must return a scalar of reversion levels when you call it with two inputs:

- A real-valued scalar observation time  $t$
- A 2-by-1 bivariate state vector  $X_t$

Data Types: `double` | `function_handle`

**Volatility — Instantaneous volatility CIR stochastic variance process**  
`scalar` | deterministic function of time | deterministic function of time and state

Instantaneous volatility of the CIR stochastic variance process (often called the *volatility of volatility* or *volatility of variance*), specified as a scalar, a deterministic function of time, or a deterministic function of time and state.

If you specify `Volatility` as a scalar, it represents the instantaneous volatility of the CIR stochastic variance model.

If you specify `Volatility` as a deterministic function of time, you call `Volatility` with a real-valued scalar time  $t$  as its only input, it must return a scalar.

If you specify `Volatility` as a deterministic function of time and state, `Volatility` must return a scalar when you call it with two inputs:

- A real-valued scalar observation time  $t$

- A 2-by-1 bivariate state vector  $X_t$

**Note** Although `bates` enforces no restrictions on **Volatility**, the volatility is usually nonnegative.

---

Data Types: `double` | `function_handle`

**JumpFreq — Instantaneous jump frequencies representing intensities of Poisson processes**  
array | deterministic function of time | deterministic function of time and state

Instantaneous jump frequencies representing the intensities (the mean number of jumps per unit time) of Poisson processes ( $N_t$ ) that drive the jump simulation, specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify `JumpFreq` as an array, it must be a scalar.

If you specify `JumpFreq` as a deterministic function of time, you call `JumpFreq` with a real-valued scalar time  $t$  as its only input, it must return a scalar.

If you specify `JumpFreq` as a function of time and state, `JumpFreq` must return a scalar when you call it with two inputs:

- A real-valued scalar observation time  $t$
- A 2-by-1 bivariate state vector  $X_t$

Data Types: `double` | `function_handle`

**JumpMean — Instantaneous mean of random percentage jump sizes**  
array | deterministic function of time | deterministic function of time and state

Instantaneous mean of random percentage jump sizes  $J$ , where  $\log(1+J)$  is normally distributed with mean  $(\log(1+JumpMean) - 0.5 \times JumpVol^2)$  and standard deviation `JumpVol`, specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify `JumpMean` as an array, it must be a scalar.

If you specify `JumpMean` as a deterministic function of time, you call `JumpMean` with a real-valued scalar time  $t$  as its only input, it must return a scalar.

If you specify `JumpMean` as a function of time and state, `JumpMean` must return a scalar when you call it with two inputs:

- A real-valued scalar observation time  $t$
- A 2-by-1 bivariate state vector  $X_t$

Data Types: `double` | `function_handle`

**JumpVol — Instantaneous standard deviation**  
array | deterministic function of time | deterministic function of time and state

Instantaneous standard deviation of  $\log(1+J)$ , specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify `JumpVol` as an array, it must be a scalar.

If you specify `JumpVol` as a deterministic function of time, you call `JumpVol` with a real-valued scalar time  $t$  as its only input, it must return a scalar.

If you specify `JumpVol` as a function of time and state, `JumpVol` must return a scalar when you call it with two inputs:

- A real-valued scalar observation time  $t$
- A 2-by-1 bivariate state vector  $X_t$

Data Types: double | function\_handle

## Properties

### **StartTime — Starting time of first observation, applied to all state variables**

0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar.

Data Types: double

### **StartState — Initial values of state variables**

1 (default) | scalar | column vector | matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If `StartState` is a scalar, `bates` applies the same initial value to all state variables on all trials.

If `StartState` is a bivariate column vector, `bates` applies a unique initial value to each state variable on all trials.

If `StartState` is a matrix, `bates` applies a unique initial value to each state variable on each trial.

Data Types: double

### **Correlation — Correlation between Gaussian random variates drawn to generate Brownian motion vector (Wiener processes)**

2-by-2 identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as a scalar, a 2-by-2 positive semidefinite matrix, or as a deterministic function  $C_t$  that accepts the current time  $t$  and returns an 2-by-2 positive semidefinite correlation matrix. If `Correlation` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

A `Correlation` matrix represents a static condition.

If you specify `Correlation` as a deterministic function of time, `Correlation` allows you to specify a dynamic correlation structure.

Data Types: double

### **Drift — Drift-rate component of continuous-time stochastic differential equations (SDEs)**

value stored from drift-rate function (default) | drift object or function accessible by  $(t, X_t)$

This property is read-only.

Drift-rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The drift rate specification supports the simulation of sample paths of **NVars** state variables driven by **NBrowns** Brownian motion sources of risk over **NPeriods** consecutive observation periods, approximating continuous-time stochastic processes.

Use the **drift** function to create **drift** objects of the form

$$F(t, X_t) = A(t) + B(t)X_t$$

Here:

- **A** is an **NVars**-by-1 vector-valued function accessible by the  $(t, X_t)$  interface.
- **B** is an **NVars**-by-**NVars** matrix-valued function accessible by the  $(t, X_t)$  interface.

The displayed parameters for a **drift** object follow.

- **Rate** — Drift-rate function,  $F(t, X_t)$
- **A** — Intercept term,  $A(t, X_t)$ , of  $F(t, X_t)$
- **B** — First-order term,  $B(t, X_t)$ , of  $F(t, X_t)$

**A** and **B** enable you to query the original inputs. The function stored in **Rate** fully encapsulates the combined effect of **A** and **B**.

Specifying **AB** as MATLAB double arrays clearly associates them with a linear drift rate parametric form. However, specifying either **A** or **B** as a function allows you to customize virtually any drift-rate specification.

---

**Note** You can express **drift** and **diffusion** objects in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components **A** and **B** as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `F = drift(0, 0.1) % Drift-rate function F(t, X)`

Data Types: **object**

**Diffusion — Diffusion-rate component of continuous-time stochastic differential equations (SDEs)**

value stored from diffusion-rate function (default) | diffusion object or functions accessible by  $(t, X_t)$

This property is read-only.

Diffusion-rate component of continuous-time stochastic differential equations (SDEs), specified as a **drift** object or function accessible by  $(t, X_t)$ .

The diffusion-rate specification supports the simulation of sample paths of **NVars** state variables driven by **NBrowns** Brownian motion sources of risk over **NPeriods** consecutive observation periods for approximating continuous-time stochastic processes.

Use the **diffusion** function to create **diffusion** objects of the form

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

Here:

- $D$  is an NVars-by-NVars diagonal matrix-valued function.
- Each diagonal element of  $D$  is the corresponding element of the state vector raised to the corresponding element of an exponent  $\text{Alpha}$ , which is an NVars-by-1 vector-valued function.
- $V$  is an NVars-by-NBrowns matrix-valued volatility rate function  $\text{Sigma}$ .
- $\text{Alpha}$  and  $\text{Sigma}$  are also accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `diffusion` object are:

- **Rate** — Diffusion-rate function,  $G(t, X_t)$
- **Alpha** — State vector exponent, which determines the format of  $D(t, X_t)$  of  $G(t, X_t)$
- **Sigma** — Volatility rate,  $V(t, X_t)$ , of  $G(t, X_t)$

**Alpha** and **Sigma** enable you to query the original inputs. (The combined effect of the individual **Alpha** and **Sigma** parameters is fully encapsulated by the function stored in **Rate**.) The **Rate** functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

---

**Note** You can express `drift` and `diffusion` objects in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components **A** and **B** as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `G = diffusion(1, 0.3) % Diffusion-rate function G(t, X)`

Data Types: object

#### Simulation — User-defined simulation function or SDE simulation method

`simulation` by Euler approximation (`simByEuler`) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function\_handle

## Object Functions

|                              |                                                                                                                                                        |

    Correlation: 2x2 double array
        Drift: drift rate function F(t,X(t))
        Diffusion: diffusion rate function G(t,X(t))
        Simulation: simulation method/function simByEuler
    Return: 0.03
    Speed: 1
    Level: 0.05
    Volatility: 0.2
    JumpFreq: 0.1
    JumpMean: 0.02
    JumpVol: 0.08
```

## More About

### Instance Hierarchy

There are inheritance relationships among the SDE classes, as follows.

For more information, see “SDE Class Hierarchy” on page 18-5.

## Algorithms

The Bates model (Bates 1996) is an extension of the Heston model and adds not only stochastic volatility, but also the jump diffusion parameters as in Merton (1976) were also added to model sudden asset price movements.

Under the risk-neutral measure the model is expressed as follows

$$\begin{aligned}
 dS_t &= (\gamma - q - \lambda_p \mu_j) S_t dt + \sqrt{v_t} S_t dW_t + JS_t dP_t \\
 dv_t &= \kappa(\theta - v_t) dt + \sigma_v \sqrt{v_t} dW_t^v \\
 E[dW_t dW_t^v] &= pdt \\
 \text{prob}(dP_t = 1) &= \lambda_p dt
 \end{aligned}$$

Here:

$\gamma$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$J$  is the random percentage jump size conditional on the jump occurring, where

$$\ln(1 + J) \sim N(\ln(1 + u_j) - \frac{\delta^2}{2}, \delta^2)$$

$(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{ \frac{-\left[\ln(1+J) - (\ln(1+\mu_j) - \frac{\delta^2}{2})\right]^2}{2\delta^2} \right\}$$

Here:

$\mu_j$  is the mean of  $J$  ( $\mu_j > -1$ ).

$\lambda_p$  is the annual frequency (intensity) of the Poisson process  $P_t$  ( $\lambda_p \geq 0$ ).

$v$  is the initial variance of the underlying asset ( $v_0 > 0$ ).

$\theta$  is the long-term variance level ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for the variance ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of volatility ( $\sigma_v > 0$ ).

$p$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  ( $-1 \leq p \leq 1$ ).

The "Feller condition" ensures positive variance: ( $2\kappa\theta > \sigma_v^2$ ).

The stochastic volatility along with the jump help better model the asymmetric leptokurtic features, the volatility smile, and the large random fluctuations such as crashes and rallies.

## merton

Merton jump diffusion model

### Description

The `merton` function creates a `merton` object, which derives from the `gbm` object.

The `merton` model, based on the Merton76 model, allows you to simulate sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk and `NJumps` compound Poisson processes representing the arrivals of important events over `NPeriods` consecutive observation periods. The simulation approximates continuous-time `merton` stochastic processes.

You can simulate any vector-valued `merton` process of the form

$$dX_t = B(t, X_t)X_t dt + D(t, X_t)V(t, x_t)dW_t + Y(t, X_t, N_t)X_t dN_t$$

Here:

- $X_t$  is an `NVars`-by-1 state vector of process variables.
- $B(t, X_t)$  is an `NVars`-by-`NVars` matrix of generalized expected instantaneous rates of return.
- $D(t, X_t)$  is an `NVars`-by-`NVars` diagonal matrix in which each element along the main diagonal is the corresponding element of the state vector.
- $V(t, X_t)$  is an `NVars`-by-`NVars` matrix of instantaneous volatility rates.
- $dW_t$  is an `NBrowns`-by-1 Brownian motion vector.
- $Y(t, X_t, N_t)$  is an `NVars`-by-`NJumps` matrix-valued jump size function.
- $dN_t$  is an `NJumps`-by-1 counting process vector.

## Creation

### Syntax

```
Merton = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol)
Merton = merton(___,Name,Value)
```

### Description

`Merton = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol)` creates a default `merton` object. Specify required inputs as one of two types:

- MATLAB array. Specify an array to indicate a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- MATLAB function. Specify a function to provide indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported by an interface because all implementation details are hidden and fully encapsulated by the function.

---

**Note** You can specify combinations of array and function input parameters as needed. Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time  $t$  as its only input argument. Otherwise, a parameter is assumed to be a function of time  $t$  and state  $X_t$  and is invoked with both input arguments.

`Merton = merton( ___,Name,Value)` sets “Properties” on page 19-137 using name-value pair arguments in addition to the input arguments in the preceding syntax. Enclose each property name in quotes.

The `merton` object has the following “Properties” on page 19-137:

- `StartTime` — Initial observation time
- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument
- `Drift` — Composite drift-rate function
- `Diffusion` — Composite diffusion-rate function
- `Simulation` — A simulation function or method

### Input Arguments

#### **Return — Expected mean instantaneous rates of asset return**

array | deterministic function of time | deterministic function of time and state

Expected mean instantaneous rates of asset return, denoted as  $B(t, X_t)$ , specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify `Return` as an array, it must be an `NVars`-by-`NVars` matrix representing the expected (mean) instantaneous rate of return.

If you specify `Return` as a deterministic function of time, when you call `Return` with a real-valued scalar time  $t$  as its only input, it must return an `NVars`-by-`NVars` matrix.

If you specify `Return` as a deterministic function of time and state, it must return an `NVars`-by-`NVars` matrix when you call it with two inputs:

- A real-valued scalar observation time  $t$
- An `NVars`-by-1 state vector  $X_t$

Data Types: `double` | `function_handle`

#### **Sigma — Instantaneous volatility rates**

array | deterministic function of time | deterministic function of time and state

Instantaneous volatility rates, denoted as  $V(t, X_t)$ , specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify `Sigma` as an array, it must be an `NVars`-by-`NBrowns` matrix of instantaneous volatility rates or a deterministic function of time. In this case, each row of `Sigma` corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

If you specify `Sigma` as a deterministic function of time, when you call `Sigma` with a real-valued scalar time  $t$  as its only input, it must return an `NVars`-by-`NBrowns` matrix.

If you specify `Sigma` as a deterministic function of time and state, it must return an `NVars`-by-`NBrowns` matrix when you call it with two inputs:

- A real-valued scalar observation time  $t$
- An `NVars`-by-1 state vector  $X_t$

---

**Note** Although `merton` enforces no restrictions for `Sigma`, volatilities are usually nonnegative.

---

Data Types: `double` | `function_handle`

**JumpFreq — Instantaneous jump frequencies representing intensities of Poisson processes**  
array | deterministic function of time | deterministic function of time and state

Instantaneous jump frequencies representing the intensities (the mean number of jumps per unit time) of the Poisson processes  $N_t$  that drive the jump simulation, specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify `JumpFreq` as an array, it must be an `NJumps`-by-1 vector.

If you specify `JumpFreq` as a deterministic function of time, when you call `JumpFreq` with a real-valued scalar time  $t$  as its only input, `JumpFreq` must produce an `NJumps`-by-1 vector.

If you specify `JumpFreq` as a deterministic function of time and state, it must return an `NVars`-by-`NBrowns` matrix when you call it with two inputs:

- A real-valued scalar observation time  $t$
- An `NVars`-by-1 state vector  $X_t$

Data Types: `double` | `function_handle`

**JumpMean — Instantaneous mean of random percentage jump sizes**  
array | deterministic function of time | deterministic function of time and state

Instantaneous mean of random percentage jump sizes  $J$ , where  $\log(1+J)$  is normally distributed with mean  $(\log(1+JumpMean) - 0.5 \times JumpVol^2)$  and standard deviation `JumpVol`, specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify `JumpMean` as an array, it must be an `NVars`-by-`NJumps` matrix.

If you specify `JumpMean` as a deterministic function of time, when you call `JumpMean` with a real-valued scalar time  $t$  as its only input, it must return an `NVars`-by-`NJumps` matrix.

If you specify `JumpMean` as a deterministic function of time and state, it must return an `NVars`-by-`NJumps` matrix when you call it with two inputs:

- A real-valued scalar observation time  $t$
- An `NVars`-by-1 state vector  $X_t$

Data Types: `double` | `function_handle`

**JumpVol — Instantaneous standard deviation**  
array | deterministic function of time | deterministic function of time and state

Instantaneous standard deviation of  $\log(1+J)$ , specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify `JumpVol` as an array, it must be an `NVars`-by-`NJumps` matrix.

If you specify `JumpVol` as a deterministic function of time, when you call `JumpVol` with a real-valued scalar time  $t$  as its only input, it must return an `NVars`-by-`NJumps` matrix.

If you specify `JumpVol` as a deterministic function of time and state, it must return an `NVars`-by-`NJumps` matrix when you call it with two inputs:

- A real-valued scalar observation time  $t$
- An `NVars`-by-1 state vector  $X_t$

Data Types: `double` | `function_handle`

## Properties

### **StartTime — Starting time of first observation, applied to all state variables**

`0` (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar.

Data Types: `double`

### **StartState — Initial values of state variables**

`1` (default) | scalar | column vector | matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If `StartState` is a scalar, `merton` applies the same initial value to all state variables on all trials.

If `StartState` is a column vector, `merton` applies a unique initial value to each state variable on all trials.

If `StartState` is a matrix, `merton` applies a unique initial value to each state variable on each trial.

Data Types: `double`

### **Correlation — Correlation between Gaussian random variates drawn to generate Brownian motion vector (Wiener processes)**

`NBrowns`-by-`NBrowns` identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an `NBrowns`-by-`NBrowns` positive semidefinite matrix, or as a deterministic function  $C_t$  that accepts the current time  $t$  and returns an `NBrowns`-by-`NBrowns` positive semidefinite correlation matrix. If `Correlation` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

A `Correlation` matrix represents a static condition.

If you specify `Correlation` as a deterministic function of time, you can specify a dynamic correlation structure.

Data Types: `double`

**Drift — Drift-rate component of continuous-time stochastic differential equations (SDEs)**  
value stored from drift-rate function (default) | drift object or function accessible by  $(t, X_t)$

This property is read-only.

Drift-rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The drift-rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

Use the `drift` function to create `drift` objects of the form

$$F(t, X_t) = A(t) + B(t)X_t$$

Here:

- A is an NVars-by-1 vector-valued function accessible using the  $(t, X_t)$  interface.
- B is an NVars-by-NVars matrix-valued function accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `drift` object are:

- Rate — Drift-rate function,  $F(t, X_t)$
- A — Intercept term,  $A(t, X_t)$ , of  $F(t, X_t)$
- B — First-order term,  $B(t, X_t)$ , of  $F(t, X_t)$

A and B enable you to query the original inputs. The function stored in Rate fully encapsulates the combined effect of A and B.

Specifying AB as MATLAB double arrays clearly associates them with a linear drift rate parametric form. However, specifying either A or B as a function allows you to customize virtually any drift-rate specification.

---

**Note** You can express `drift` and `diffusion` objects in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components A and B as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `F = drift(0, 0.1)` % Drift-rate function F(t,X)

Data Types: object

**Diffusion — Diffusion-rate component of continuous-time stochastic differential equations (SDEs)**

value stored from diffusion-rate function (default) | diffusion object or functions accessible by  $(t, X_t)$

This property is read-only.

Diffusion-rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by  $(t, X_t)$ .

The diffusion-rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods for approximating continuous-time stochastic processes.

Use the `diffusion` function to create `diffusion` objects of the form

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

Here:

- `D` is an `NVars`-by-`NVars` diagonal matrix-valued function.
- Each diagonal element of `D` is the corresponding element of the state vector raised to the corresponding element of an exponent `Alpha`, which is an `NVars`-by-1 vector-valued function.
- `V` is an `NVars`-by-`NBrowns` matrix-valued volatility rate function `Sigma`.
- `Alpha` and `Sigma` are also accessible using the  $(t, X_t)$  interface.

The displayed parameters for a `diffusion` object are:

- `Rate` — Diffusion-rate function,  $G(t, X_t)$
- `Alpha` — State vector exponent, which determines the format of  $D(t, X_t)$  of  $G(t, X_t)$
- `Sigma` — Volatility rate,  $V(t, X_t)$ , of  $G(t, X_t)$

`Alpha` and `Sigma` enable you to query the original inputs. (The combined effect of the individual `Alpha` and `Sigma` parameters is fully encapsulated by the function stored in `Rate`.) The `Rate` functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

---

**Note** You can express `drift` and `diffusion` objects in the most general form to emphasize the functional  $(t, X_t)$  interface. However, you can specify the components `A` and `B` as functions that adhere to the common  $(t, X_t)$  interface, or as MATLAB arrays of appropriate dimension.

---

Example: `G = diffusion(1, 0.3)` % Diffusion-rate function  $G(t, X)$

Data Types: `object`

#### **Simulation — User-defined simulation function or SDE simulation method**

`simulation` by Euler approximation (`simByEuler`) (default) | `function` | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: `function_handle`

## **Object Functions**

|                            |                                                                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>simByEuler</code>    | Simulate Merton jump diffusion sample paths by Euler approximation                                                                                     |
| <code>simBySolution</code> | Simulate approximate solution of diagonal-drift Merton jump diffusion process                                                                          |
| <code>simulate</code>      | Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models |

## **Examples**

### Create merton Object

Merton jump diffusion models allow you to simulate sample paths of NVARS state variables driven by NBROWNS Brownian motion sources of risk and NJumps compound Poisson processes representing the arrivals of important events over NPeriods consecutive observation periods. The simulation approximates continuous-time merton stochastic processes.

Create a `merton` object.

```
AssetPrice = 80;
    Return = 0.03;
    Sigma = 0.16;
    JumpMean = 0.02;
    JumpVol = 0.08;
    JumpFreq = 2;

    mertonObj = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol, ...
        'startstat',AssetPrice)

mertonObj =
    Class MERTON: Merton Jump Diffusion
-----
    Dimensions: State = 1, Brownian = 1
-----
    StartTime: 0
    StartState: 80
    Correlation: 1
        Drift: drift rate function F(t,X(t))
        Diffusion: diffusion rate function G(t,X(t))
        Simulation: simulation method/function simByEuler
            Sigma: 0.16
            Return: 0.03
            JumpFreq: 2
            JumpMean: 0.02
            JumpVol: 0.08
```

## More About

### Instance Hierarchy

There are inheritance relationships among the SDE classes, as follows.

For more information, see “SDE Class Hierarchy” on page 18-5.

## Algorithms

The Merton jump diffusion model (Merton 1976) is an extension of the Black-Scholes model, and models sudden asset price movements (both up and down) by adding the jump diffusion parameters with the Poisson process  $P_t$ .

Under the risk-neutral measure the model is expressed as follows

$$\begin{aligned} dS_t &= (\gamma - q - \lambda_p \mu_j) S_t dt + \sigma_M S_t dW_t + JS_t dP_t \\ \text{prob}(dP_t = 1) &= \lambda_p dt \end{aligned}$$

Here:

$\gamma$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$J$  is the random percentage jump size conditional on the jump occurring, where

$$\ln(1 + J) \sim N(\ln(1 + \mu_j) - \frac{\delta^2}{2}, \delta^2)$$

$(1+J)$  has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}} \exp\left\{ \frac{-\left[\ln(1 + J) - (\ln(1 + \mu_j) - \frac{\delta^2}{2})\right]^2}{2\delta^2} \right\}$$

Here:

$\mu_j$  is the mean of  $J(\mu_j > -1)$ .

$\lambda_p$  is the annual frequency (intensity) of the Poisson process  $P_t$  ( $\lambda_p \geq 0$ ).

$\sigma_M$  is the volatility of the asset price ( $\sigma_M > 0$ ).

Under this formulation, extreme events are explicitly included in the stochastic differential equation as randomly occurring discontinuous jumps in the diffusion trajectory. Therefore, the disparity between observed tail behavior of log returns and that of Brownian motion is mitigated by the inclusion of a jump mechanism.

## Introduced in R2020a

# backtestStrategy

Create backtestStrategy object to define portfolio allocation strategy

## Description

Create a backtestStrategy object which defines a portfolio allocation strategy.

Use this workflow to develop and run a backtest:

- 1 Define the strategy logic using a backtestStrategy object to specify how the strategy rebalances a portfolio of assets.
- 2 Use backtestEngine to create a backtestEngine object that specifies the parameters of the backtest.
- 3 Use runBacktest to run the backtest against historical asset price data and, optionally, trading signal data.
- 4 Use equityCurve to plot the equity curves of each strategy.
- 5 Use summary to summarize the backtest results in a table format.

For more detailed information on this workflow, see “Backtest Investment Strategies” on page 4-220.

## Creation

### Syntax

```
strategy = backtestStrategy(name,rebalanceFcn)
strategy = backtestStrategy(____,Name,Value)
```

### Description

`strategy = backtestStrategy(name,rebalanceFcn)` creates a backtestStrategy object.

`strategy = backtestStrategy(____,Name,Value)` sets properties on page 19-147 using name-value pair arguments and any of the arguments in the previous syntax. You can specify multiple name-value pair arguments. For example, `strat = backtestStrategy('MyStrategy',@myRebalFcn,'TransactionCost',0.005,'LookbackWindow',20).`

### Input Arguments

**name — Strategy name**  
string

Strategy name, specified as a string.

Data Types: string

**rebalanceFcn — Rebalance function**  
function handle

Rebalance function, specified as a function handle. A function handle computes new portfolio weights during the backtest. The `rebalanceFcn` argument implements the core logic of the trading strategy and must have one of the following signatures:

- `new_weights = rebalanceFcn(weights,assetPrices)`
- `new_weights = rebalanceFcn(weights,assetPrices,signalData)`

The rebalance function is called by the `backtestEngine` object each time the strategy must be rebalanced. The `backtestEngine` object calls the rebalance function with the following arguments:

- `weights` — The current portfolio weights before rebalancing, specified as decimal percentages.
- `assetPrices` — A timetable containing a rolling window of adjusted asset prices. NaNs are allowed in the `assetPrices` timetable.

---

**Note** If the backtest engine encounters a `NaN` return for an asset with a non-zero position, an error is generated. To correct this, either remove missing asset prices from the `assetPrices` timetable or have the rebalance functions avoid investing in assets that encounter invalid returns.

- `signalData` — A timetable containing a rolling window of signal data. NaNs or `<missing>` are allowed in the `signalData` timetable.

If you provide signal data to the `backtestEngine` object, then the engine object passes it to the strategy rebalance function using the three input argument syntax. If do not provide signal data the `backtestEngine` object, then the engine object calls the rebalance function with the two input argument syntax.

The rebalance function must return a single output argument for `new_weights` which is a vector of asset weights specified as decimal percentages.

- If the `new_weights` sum to 1, then the portfolio is fully invested.
- If the `new_weights` sum to less than 1, then the portfolio will has the remainder in cash, earning the `RiskFreeRate` specified in the `backtestEngine` object.
- If the `new_weights` sum to more than 1, then there is a negative cash position (margin) and the cash borrowed accrues interest at the cash borrowing rate specified in the `CashBorrowRate` property of the `backtestEngine` object.

For more information on developing a `rebalanceFcn` function handle, see “Backtest Investment Strategies” on page 4-220.

Data Types: `function_handle`

#### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `strat = backtestStrategy('MyStrategy', @myRebalFcn, 'TransactionCost', 0.005, 'LookbackWindow', 20)`

**RebalanceFrequency — Rebalance frequency during backtest**

1 (default) | integer | duration object | calendarDuration object | vector of datetime objects

Rebalance frequency during the backtest, specified as the comma-separated pair consisting of 'RebalanceFrequency' and a scalar integer, duration object, calendarDuration object, or a vector of datetime objects.

If using an integer, the integer represents the number of time steps between rebalancing. For example, if you provide the `backtestEngine` object with daily price data, then the `RebalanceFrequency` specifies the number of days between rebalancing. The default is 1, meaning the strategy rebalances with each time step.

If using a `duration` object or `calendarDuration`, the backtest engine creates a rebalance schedule of times, starting at the backtest start time, with rebalance times occurring after each step of the specified duration.

If using a vector of `datetime` objects, the `RebalanceFrequency` defines an explicit schedule of rebalance times. The backtest engine will rebalance at each datetime in the provided schedule.

---

**Note** For both the duration and datetime syntaxes, if a rebalance time is not found in the backtest dataset, the engine will rebalance at the nearest time prior to the scheduled time. For example, if the rebalance schedule contains a weekend, the rebalance will occur on the Friday before.

---

Data Types: double | object

**TransactionCosts — Transaction costs for trades**

0 (not computed) (default) | numeric | vector | function handle

Transaction costs for trades, specified as the comma-separated pair consisting of 'TransactionCosts' and a scalar numeric, vector, or function handle. You can specify transaction costs in three ways:

- `rate` — A scalar decimal percentage charge to both purchases and sales of assets. For example ,if you set `TransactionCosts` to `0.001`, then each transaction (buys and sells) would pay 0.1% in transaction fees.
- `[buyRate, sellRate]` — A 1-by-2 vector of decimal percentage rates that specifies separate rates for buying and selling of assets.
- `computeTransactionCostsFcn` — A function handle to compute customized transaction fees. If you specify a function handle, the `backtestEngine` object calls the `TransactionCosts` function to compute the fees for each rebalance. The user-defined function handle must have the following signature:

```
[buyCosts,sellCosts] = computeCostsFcn(deltaPositions)
```

The user-defined function handle takes a single input argument `deltaPositions`, which is a vector of changes in asset positions for all assets (in currency units) as a result of a rebalance. Positive elements in the `deltaPositions` vector indicate purchases while negative entries represent sales. The user-defined function handle must return two output arguments `buyCosts` and `sellCosts`, which contain the total costs (in currency) for the entire rebalance for each type of transaction.

Data Types: double | function\_handle

**LookbackWindow — Lookback window**

[0 Inf] (default) | 1-by-2 vector using integers | duration object | calendarDuration object

Lookback window, specified as the comma-separated pair consisting of 'LookbackWindow' and a 1-by-2 vector of integers, a duration object, or calendarDuration object.

When using a 1-by-2 vector with integers that defines the minimum and maximum size of the rolling window of data (asset prices and signal data) that you provide to the `rebalanceFcn` argument. You specify these limits in terms of the number of time steps. When specified as integers, the lookback window is defined in terms of rows of data from the asset (`pricesTT`) and signal (`signalTT`) timetables used in the backtest. The lookback minimum sets the minimum number of rows of asset price data that must be available to the rebalance function before a strategy rebalance can occur. The lookback maximum sets the maximum size for the rolling window of price data that is passed to the `rebalance` function.

For example, if the `backtestEngine` object is provided with daily price data, then `LookbackWindow` specifies the size bounds of the rolling window in days. The default is [0 Inf], meaning that all available past data is given to the rebalance function. If you specify a non-zero minimum, then the software does not call `rebalanceFcn` until enough time steps process to meet the minimum size.

If you specify `LookbackWindow` as a single scalar value, then the value is both the minimum and maximum of the `LookbackWindow` (that is, a fixed-sized window).

If using a `duration` object or `calendarDuration`, the lookback window minimum and maximum are defined in terms of timespans relative to the time at a rebalance. For example if the lookback minimum was set to five days (that is, `days(5)`), the rebalance will only occur if the backtest start time is at least five days prior to the rebalance time. Similarly, if the lookback maximum was set to six months (that is, `calmonths(6)`), the lookback window would contain only data that occurred at six months prior to the rebalance time or later.

---

**Note** Alternatively, the `LookbackWindow` can be set to a single scalar value indicating that the rolling window should be exactly that size (either in terms of rows or a time duration). The minimum and maximum size will both be set to the provided value.

---

Data Types: double | object

**InitialWeights — Initial portfolio weights**

[ ] (default) | vector

Initial portfolio weights, specified as the comma-separated pair consisting of 'InitialWeights' and a vector. The `InitialWeights` vector sets the portfolio weights before the `backtestEngine` object begins the backtest. The size of the initial weights vector must match the number of assets used in the backtest.

Alternatively, you can set the `InitialWeights` name-value pair argument to empty ([ ]) to indicate the strategy will begin with no investments and in a 100% cash position. The default for `InitialWeights` is empty ([ ]).

Data Types: double

## Properties

### **Name — Strategy name**

string

Strategy name, specified as a string.

Data Types: string

### **RebalanceFcn — Rebalance function**

function handle

Rebalance function, specified as a function handle.

Data Types: function\_handle

### **RebalanceFrequency — Rebalance frequency during backtest**

1 (default) | numeric

Rebalance frequency during the backtest, specified as a scalar numeric.

Data Types: double

### **TransactionCosts — Transaction costs**

0 (default) | numeric | vector | function handle

Transaction costs, specified as a scalar numeric, vector, or function handle.

Data Types: double | function\_handle

### **LookbackWindow — Lookback window**

[0 Inf] (default) | numeric | vector

Lookback window, specified as a scalar numeric or vector.

Data Types: double

### **InitialWeights — Initial weights**

[ ] (default) | vector

Initial weights, specified as a vector.

Data Types: double

## Examples

### Create Backtesting Strategies

Define a backtest strategy by using a `backtestStrategy` object. `backtestStrategy` objects contain properties specific to a trading strategy, such as the rebalance frequency, transaction costs, and a rebalance function. The rebalance function implements the core logic of the strategy and is used by the backtesting engine during the backtest to allow the strategy to change its asset allocation and to make trades. In this example, to illustrate how to create and use backtest strategies in MATLAB®, you prepare two simple strategies for backtesting:

- 1 An equal weighted strategy
- 2 A strategy that attempts to "chase returns"

The strategy logic for these two strategies is defined in the rebalance functions on page 19-0 .

## Set Strategy Properties

A `backtestStrategy` object has several properties that you set using parameters for the `backtestStrategy` function.

### Initial Weights

The `InitialWeights` property contains the asset allocation weights at the start of the backtest. The default value for `InitialWeights` is empty ([ ]), which indicates that the strategy begins the backtest uninvested, meaning that 100% of the capital is in cash earning the risk-free rate.

Set the `InitialWeights` to a specific asset allocation. The size of the initial weights vector must match the number of assets in the backtest.

```
% Initialize the strategies with 30 weights, since the backtest
% data comes from a year of the 30 DJIA stocks.
numAssets = 30;

% Give the initial weights for both strategies equal weighting. Weights
% must sum to 1 to be fully invested.
initialWeights = ones(1,numAssets);
initialWeights = initialWeights / sum(initialWeights);
```

### Transaction Costs

The `TransactionCosts` property allows you to set the fees that the strategy pays for trading assets. Transaction costs are paid as a percentage of the total change in position for each asset. Specify costs in decimal percentages. For example, if `TransactionCosts` is set to 1% (0.01) and the strategy buys \$100 worth of a stock, then the transaction costs incurred are \$1.

Transaction costs are set using a 1-by-2 vector that sets separate fee rates for purchases and sales of assets. In this example, both strategies pay the same transaction costs — 25 basis points for asset purchases and 50 basis points for sales.

```
% Define the Transaction costs as [buyCosts sellCost] and specify the costs
% as decimal percentages.
tradingCosts = [0.0025 0.005];
```

You can also set the `TransactionCosts` property to a function handle if you need to implement arbitrarily complex transaction cost structures. For more information on creating transaction cost functions, see `backtestStrategy`.

### Rebalance Frequency

The `RebalanceFrequency` property determines how often the backtesting engine rebalances and reallocates the portfolio of a strategy using the `rebalance` function. Set the `RebalanceFrequency` in terms of time steps in the backtest. For example, if the backtesting engine is testing a strategy with a set of daily price data, then set the `rebalance` function in days. Essentially, `RebalanceFrequency` represents the number of rows of price data to process between each call to the strategy `rebalance` function.

```
% Both strategies rebalance every 4 weeks (20 days).
rebalFreq = 20;
```

## Lookback Window

Each time the backtesting engine calls a strategy rebalance function, a window of asset price data (and possibly signal data) is passed to the rebalance function. The rebalance function can then make trading and allocation decisions based on a rolling window of market data. The `LookbackWindow` property sets the size of these rolling windows. Set the window in terms of time steps. The window determines the number of rows of data from the asset price timetable that are passed to the rebalance function.

The `LookbackWindow` property can be set in two ways. For a fixed-sized rolling window of data (for example, "50 days of price history"), the `LookbackWindow` property is set to a single scalar value ( $N = 50$ ). The software then calls the rebalance function with a price timetable containing exactly  $N$  rows of rolling price data.

Alternatively, you can define the `LookbackWindow` property by using a 1-by-2 vector `[min max]` that specifies the minimum and maximum size for an expanding window of data. In this way, you can set flexible window sizes. For example:

- `[10 Inf]` — At least 10 rows of data
- `[0 50]` — No more than 50 rows of data
- `[0 Inf]` — All available data (that is, no minimum, no maximum); this is the default value
- `[20 20]` — Exactly 20 rows of data; this is equivalent to setting `LookbackWindow` to the scalar value 20

The software does not call the rebalance function if the data is insufficient to create a valid rolling window, regardless of the value of the `RebalanceFrequency` property.

If the strategy does not require any price or signal data history, then you can indicate that the rebalance function requires no data by setting the `LookbackWindow` property to 0.

```
% The equal weight strategy does not require any price history data.
ewLookback = 0;

% The "chase returns" strategy bases its decisions on the trailing
% 10-day asset returns. The lookback window is set to 11 since computing 10 days
% of returns requires the close price from day 0.
chaseLookback = 11;
```

## Rebalance Function

The rebalance function (`rebalanceFcn`) is the user-authored function that contains the logic of the strategy. The backtesting engine calls the strategy rebalance function with a fixed set of parameters and expects it to return a vector of asset weights representing the new, desired portfolio allocation after a rebalance. For more information, see the rebalance functions on page 19-0 .

## Create Strategies

Using the prepared strategy properties, you can create the two strategy objects.

```
% Create the equal weighted strategy. The rebalance function @equalWeights
% is defined in the Rebalance Functions section at the end of this example.
equalWeightStrategy = backtestStrategy("EqualWeight",@equalWeight,...
```

```
'RebalanceFrequency',rebalFreq, ...
'TradingCosts',tradingCosts, ...
'LookbackWindow',ewLookback, ...
'InitialWeights',initialWeights)

equalWeightStrategy =
    backtestStrategy with properties:

        Name: "EqualWeight"
        RebalanceFcn: @equalWeight
        RebalanceFrequency: 20
        TransactionCosts: [0.0025 0.0050]
        LookbackWindow: 0
        InitialWeights: [0.0333 0.0333 0.0333 0.0333 0.0333 0.0333 ... ]

% Create the "chase returns" strategy. The rebalance function
% @chaseReturns is defined in the Rebalance Functions section at the end of this example.
chaseReturnsStrategy = backtestStrategy("ChaseReturns",@chaseReturns, ...
    'RebalanceFrequency',rebalFreq, ...
    'TransactionCosts',tradingCosts, ...
    'LookbackWindow',chaseLookback, ...
    'InitialWeights',initialWeights)

chaseReturnsStrategy =
    backtestStrategy with properties:

        Name: "ChaseReturns"
        RebalanceFcn: @chaseReturns
        RebalanceFrequency: 20
        TransactionCosts: [0.0025 0.0050]
        LookbackWindow: 11
        InitialWeights: [0.0333 0.0333 0.0333 0.0333 0.0333 0.0333 ... ]
```

## Set Up Backtesting Engine

To backtest the two strategies, use the `backtestEngine` object. The backtesting engine sets parameters of the backtest that apply to all strategies, such as the risk-free rate and initial portfolio value. For more information, see `backtestEngine`.

```
% Create an array of strategies for the backtestEngine.
strategies = [equalWeightStrategy chaseReturnsStrategy];

% Create backtesting engine to test both strategies.
backtester = backtestEngine(strategies);
```

## Rebalance Functions

Strategy rebalance functions defined using the `rebalanceFcn` argument for `backtestStrategy` must adhere to a fixed API that the backtest engine expects when interacting with each strategy. Rebalance functions must implement one of the following two syntaxes:

```
function new_weights = exampleRebalanceFcn(current_weights,assetPriceTimeTable)

function new_weights = exampleRebalanceFcn(current_weights,assetPriceTimeTable,signalDataTableTab)
```

All rebalance functions take as their first input argument the current allocation weights of the portfolio. `current_weights` represents the asset allocation just before the rebalance occurs. During

a rebalance, you can use `current_weights` in a variety of ways. For example, you can use `current_weights` to determine how far the portfolio allocation has drifted from the target allocation or to size trades during the rebalance to limit turnover.

The second and third arguments of the rebalance function syntax are the rolling windows of asset prices and optional signal data. The two tables contain the trailing N rows of the asset and signal timetables that are passed to the `runBacktest` function, where N is set using the `LookbackWindow` property of each strategy.

If optional signal data is provided to the `runBacktest` function, then the backtest engine passes the rolling window of signal data to each strategy that supports it.

The `equalWeight` strategy simply invests equally across all assets.

```
function new_weights = equalWeight(current_weights,assetPrices) %#ok<INUSD>

% Invest equally across all assets.
num_assets = numel(current_weights);
new_weights = ones(1,num_assets) / num_assets;

end
```

The `chaseReturns` strategy invests only in the top X stocks based on their rolling returns in the lookback window. This naive strategy is used simply as an illustrative example.

```
function new_weights = chaseReturns(current_weights,assetPrices)

% Set number of stocks to invest in.
numStocks = 15;

% Compute rolling returns from lookback window.
rollingReturns = assetPrices{end,:} ./ assetPrices{1,:};

% Select the X best performing stocks over the lookback window
 [~,idx] = sort(rollingReturns,'descend');
 bestStocksIndex = idx(1:numStocks);

% Initialize new weights to all zeros.
new_weights = zeros(size(current_weights));

% Invest equally across the top performing stocks.
new_weights(bestStocksIndex) = 1;
new_weights = new_weights / sum(new_weights);

end
```

Backtesting Strategy Framework in Financial Toolbox (2 min 17 sec)

**Introduced in R2020b**

# backtestEngine

Create backtestEngine object to backtest strategies and analyze results

## Description

Create a backtestEngine to run a backtest of portfolio investment strategies on historical data.

Use this workflow to develop and run a backtest:

- 1** Define the strategy logic using a backtestStrategy object to specify how a strategy rebalances a portfolio of assets.
- 2** Use backtestEngine to create a backtestEngine object that specifies parameters of the backtest.
- 3** Use runBacktest to run the backtest against historical asset price data and, optionally, trading signal data.
- 4** Use equityCurve to plot the equity curves of each strategy.
- 5** Use summary to summarize the backtest results in a table format.

For more detailed information on this workflow, see “Backtest Investment Strategies” on page 4-220.

## Creation

### Syntax

```
backtester = backtestEngine(strategies)
backtester = backtestEngine(___,Name,Value)
```

### Description

`backtester = backtestEngine(strategies)` creates a backtestEngine object. Use the backtestEngine object to backtest the portfolio trading strategies defined in the backtestStrategy objects.

`backtester = backtestEngine(___,Name,Value)` sets properties on page 19-156 using name-value pair arguments and any of the arguments in the previous syntax. You can specify multiple name-value pair arguments. For example, `backtester = backtestEngine(strategies,'RiskFreeRate',0.02,'InitialPortfolioValue',1000,'RatesConvention','Annualized','Basis',2)`.

### Input Arguments

**strategies — Backtest strategies**  
vector of backtestStrategy objects

Backtest strategies, specified as a vector of backtestStrategy objects. Each backtestStrategy object defines a portfolio trading strategy.

Data Types: object

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `backtester = backtestEngine(strategies, 'RiskFreeRate', 0.02, 'InitialPortfolioValue', 1000, 'RatesConvention', "Annualized", 'Basis', 2)`

#### RiskFreeRate — Risk free rate

0 (default) | numeric | timetable

Risk free rate, specified as the comma-separated pair consisting of '`RiskFreeRate`' and a scalar numeric or a one-column timetable.

---

**Note** If you specify a timetable:

- The dates in the specified timetable must include the start and end dates of the backtest.
  - The series of dates in the specified timetable between the start and end dates (inclusive) must correspond exactly to the corresponding series of dates in the `assetPrices` timetable.
- 

If `RatesConvention` is "Annualized", then `RiskFreeRate` specifies an annualized rate.

If `RatesConvention` is "PerStep", then the `RiskFreeRate` is a decimal percentage and represents the risk free rate for one time step in the backtest. For example, if the backtest uses daily asset price data, then the `RiskFreeRate` value must be the daily rate of return for cash.

Data Types: double | timetable

#### CashBorrowRate — Cash borrowing rate

0 (default) | numeric | timetable

Cash borrowing rate, specified as the comma-separated pair consisting of '`CashBorrowRate`' and a scalar numeric or a one-column timetable.

---

**Note** If you specify a timetable:

- The dates in the specified timetable must include the start and end dates of the backtest.
  - The series of dates in the specified timetable between the start and end dates (inclusive) must correspond exactly to the corresponding series of dates in the `assetPrices` timetable.
- 

The `CashBorrowRate` specifies the rate of interest accrual on negative cash balances (margin) during the backtest.

If `RatesConvention` is "Annualized", then `CashBorrowRate` specifies an annualized rate.

If `RatesConvention` is "PerStep", then the `CashBorrowRate` value is a decimal percentage and represents the interest accrual rate for one time step in the backtest. For example, if the backtest is using daily asset price data, then the `CashBorrowRate` value must be the daily interest rate for negative cash balances.

Data Types: double | timetable

**InitialPortfolioValue — Initial portfolio value**

10000 (default) | numeric

Initial portfolio value, specified as the comma-separated pair consisting of '`InitialPortfolioValue`' and a scalar numeric.

Data Types: double

**RatesConvention — Defines how backtest engine uses RiskFreeRate and CashBorrowRate to compute interest**

"Annualized" (default) | character vector with value 'Annualized' or 'PerStep' | string with value "Annualized" or "PerStep"

Defines how backtest engine uses `RiskFreeRate` and `CashBorrowRate` to compute interest, specified as the comma-separated pair consisting of '`RatesConvention`' and a character vector or string.

- 'Annualized' — The rates are treated as annualized rates and the backtest engine computes incremental interest based on the day count convention specified in the `Basis` property. This is the default.
- 'PerStep' — The rates are treated as per-step rates and the backtest engine computes interest at the provided rates at each step of the backtest.

Data Types: char | string

**DateAdjustment — Date handling behavior for rebalance dates that are missing from asset prices timetable**

"Previous" (default) | character vector with value 'Previous', 'Next', or 'None' | string with value "Previous", "Next", or "None"

Date handling behavior for rebalance dates that are missing from asset prices timetable, specified as the comma-separated pair consisting of '`DateAdjustment`' and a character vector or string.

- 'Previous' — For each rebalance date in the rebalance schedule, the rebalance occurs on the nearest date in the asset timetable that occurs on or before the requested rebalance date. This is the default.
- 'Next' — Move to the next date.
- 'None' — Dates are not adjusted and the backtest engine errors when encountering a rebalance date that does not appear in the asset prices timetable.

Data Types: char | string

**Basis — Defines day-count convention when computing interest at RiskFreeRate or CashBorrowRate**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Defines the day-count convention when computing interest at the `RiskFreeRate` or `CashBorrowRate`, specified as the comma-separated pair consisting of 'Basis' and a scalar integer using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

---

**Note** `Basis` is only used when the `RatesConvention` property is set to "Annualized". If the `RatesConvention` is "PerStep", and `Basis` is set, `backtestEngine` ignores the `Basis` value.

---

Data Types: double

## Properties

### Strategies — Backtest strategies

vector of `backtestStrategy` objects

Backtest strategies, specified as a vector of `backtestStrategy` objects.

Data Types: object

### RiskFreeRate — Risk free rate

0 (default) | numeric | timetable

Risk free rate, specified as a scalar numeric or timetable.

Data Types: double

### CashBorrowRate — Cash borrowing rate

0 (default) | numeric | timetable

Cash borrowing rate, specified as a scalar numeric or timetable.

Data Types: double

**InitialPortfolioValue — Initial portfolio value**

10000 (default) | numeric

Initial portfolio value, specified as a scalar numeric.

Data Types: double

**AnnualizedRates — Use annualized rates for RiskFreeRate and CashBorrowRate**

true (default) | logical with value true or false

Use annualized rates for RiskFreeRate and CashBorrowRate, specified as a scalar logical.

Data Types: logical

**DateAdjustment — Date handling behavior for rebalance dates that are missing from asset prices timetable**

"Previous" (default) | string with value "Previous", "Next", or "None"

Date handling behavior for rebalance dates that are missing from asset prices timetable, specified as a string.

Data Types: char | string

**Basis — Day-count basis of annualized rates for RiskFreeRate and CashBorrowRate**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of annualized rates for RiskFreeRate and CashBorrowRate, specified a scalar integer.

Data Types: double

**NumAssets — Number of assets in portfolio universe**

[ ] (default) | numeric

This property is read-only.

Number of assets in the portfolio universe, a numeric. NumAssets is derived from the timetable of adjusted prices passed to runBacktest. NumAssets is empty until you run the backtest using the runBacktest function.

Data Types: double

**Returns — Strategy returns**

[ ] (default) | timetable

This property is read-only.

Strategy returns, a NumTimeSteps-by-NumStrategies timetable of strategy returns. Returns are per time step. For example, if you use daily prices with runBacktest, then Returns is the daily strategy returns. Returns is empty until you run the backtest using the runBacktest function.

Data Types: timetable

**Positions — Asset positions for each strategy**

[ ] (default) | structure

This property is read-only.

Asset positions for each strategy, a structure containing a NumTimeSteps-by-NumAssets timetable of asset positions for each strategy. For example, if you use daily prices in the runBacktest, then the

**Positions** structure holds timetables containing the daily asset positions. **Positions** is empty until you run the backtest using the `runBacktest` function.

Data Types: `struct`

#### **Turnover — Strategy turnover**

[ ] (default) | timetable

This property is read-only.

Strategy turnover, a NumTimeSteps-by-NumStrategies timetable. **Turnover** is empty until you run the backtest using the `runBacktest` function.

Data Types: `timetable`

#### **BuyCost — Transaction costs for asset purchases of each strategy**

[ ] (default) | timetable

This property is read-only.

Transaction costs for the asset purchases of each strategy, a NumTimeSteps-by-NumStrategies timetable. **BuyCost** is empty until you run the backtest using the `runBacktest` function.

Data Types: `timetable`

#### **SellCost — Transaction costs for asset sales of each strategy**

[ ] (default) | timetable

This property is read-only.

Transaction costs for the asset sales of each strategy, a NumTimeSteps-by-NumStrategies timetable. **SellCost** is empty until you run the backtest using the `runBacktest` function.

Data Types: `timetable`

## **Object Functions**

`runBacktest` Run backtest on one or more strategies  
`summary` Generate summary table of backtest results  
`equityCurve` Plot equity curves of strategies

## **Examples**

### **Backtest Strategy Using `backtestEngine`**

Use a backtesting engine in MATLAB® to run a backtest on an investment strategy over a time series of market data. You can define a backtesting engine by using `backtestEngine` object. A `backtestEngine` object sets properties of the backtesting environment, such as the risk-free rate, and holds the results of the backtest. In this example, you can create a backtesting engine to run a simple backtest and examine the results.

#### **Create Strategy**

Define an investment strategy by using the `backtestStrategy` function. This example builds a simple equal-weighted investment strategy that invests equally across all assets. For more information on creating backtest strategies, see `backtestStrategy`.

```
% The rebalance function is simple enough that you can use an anonymous function
equalWeightRebalanceFcn = @(current_weights,~) ones(size(current_weights)) / numel(current_weights);

% Create the strategy
strategy = backtestStrategy("EqualWeighted",equalWeightRebalanceFcn, ...
    'RebalanceFrequency',20, ...
    'TransactionCosts',[0.0025 0.005], ...
    'LookbackWindow',0)

strategy =
backtestStrategy with properties:

    Name: "EqualWeighted"
    RebalanceFcn: [function_handle]
    RebalanceFrequency: 20
    TransactionCosts: [0.0025 0.0050]
    LookbackWindow: 0
    InitialWeights: [1x0 double]
```

## Set Backtesting Engine Properties

The backtesting engine has several properties that you set by using parameters to the `backtestEngine` function.

### Risk-Free Rate

The `RiskFreeRate` property holds the interest rate earned for uninvested capital (that is, cash). When the sum of portfolio weights is below 1, the remaining capital is invested in cash and earns the risk-free rate. The risk-free rate and the cash-borrow rate can be defined in annualized terms or as explicit "per-time-step" interest rates. The `RatesConvention` property is used to specify how the `backtestEngine` interprets the two rates (the default interpretation is "Annualized"). For this example, set the risk-free rate to 2% annualized.

```
% 2% annualized risk-free rate
riskFreeRate = 0.02;
```

### Cash Borrow Rate

The `CashBorrowRate` property sets the interest accrual rate applied to negative cash balances. If at any time the portfolio weights sum to a value greater than 1, then the cash position is negative by the amount in excess of 1. This behavior of portfolio weights is analogous to borrowing capital on margin to invest with leverage. Like the `RiskFreeRate` property, the `CashBorrowRate` property can either be annualized or per-time-step depending on the value of the `RatesConvention` property.

```
% 6% annualized margin interest rate
cashBorrowRate = 0.06;
```

### Initial Portfolio Value

The `InitialPortfolioValue` property sets the value of the portfolio at the start of the backtest for all strategies. The default is \$10,000.

```
% Start backtest with $1M
initPortfolioValue = 1000000;
```

## Create Backtest Engine

Using the prepared properties, create the backtesting engine using the `backtestEngine` function.

```
% The backtesting engine takes an array of backtestStrategy objects as the first argument
backtester = backtestEngine(strategy, ...
    'RiskFreeRate',riskFreeRate, ...
    'CashBorrowRate',cashBorrowRate, ...
    'InitialPortfolioValue',initPortfolioValue)

backtester =
  backtestEngine with properties:

    Strategies: [1x1 backtestStrategy]
    RiskFreeRate: 0.0200
    CashBorrowRate: 0.0600
    RatesConvention: "Annualized"
    Basis: 0
    InitialPortfolioValue: 1000000
    DateAdjustment: "Previous"
    NumAssets: []
    Returns: []
    Positions: []
    Turnover: []
    BuyCost: []
    SellCost: []
```

Several additional properties of the backtesting engine are initialized to empty. The backtesting engine populates these properties, which contain the results of the backtest, upon completion of the backtest.

## Load Data and Run Backtest

Run the backtest over daily price data from the 30 component stocks of the DJIA.

```
% Read table of daily adjusted close prices for 2006 DJIA stocks
T = readtable('dowPortfolio.xlsx');

% Remove the DJI index column and convert to timetable
pricesTT = table2timetable(T(:,[1 3:end]),'RowTimes','Dates');
```

Run the backtest using the `runBacktest` function.

```
backtester = runBacktest(backtester,pricesTT)

backtester =
  backtestEngine with properties:

    Strategies: [1x1 backtestStrategy]
    RiskFreeRate: 0.0200
    CashBorrowRate: 0.0600
    RatesConvention: "Annualized"
    Basis: 0
    InitialPortfolioValue: 1000000
    DateAdjustment: "Previous"
    NumAssets: 30
    Returns: [250x1 timetable]
```

```

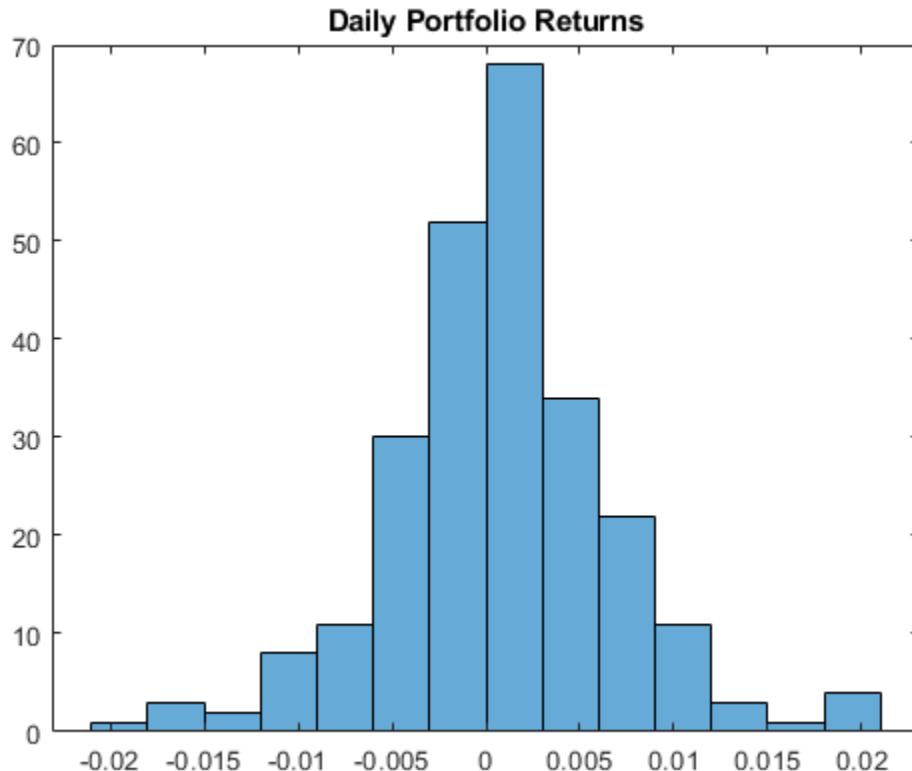

Positions: [1x1 struct]
Turnover: [250x1 timetable]
BuyCost: [250x1 timetable]
SellCost: [250x1 timetable]

```

## Examine Results

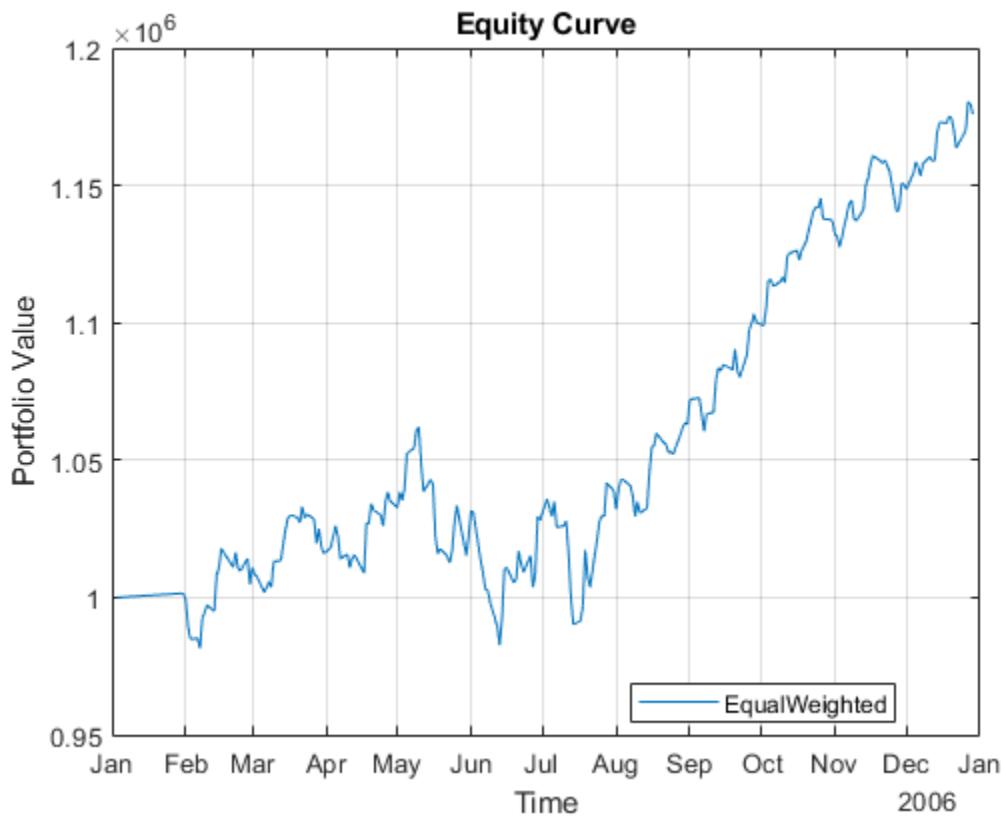

The backtesting engine populates the read-only properties of the `backtestEngine` object with the backtest results. Daily values for portfolio returns, asset positions, turnover, and transaction costs are available to examine.

```
% Generate a histogram of daily portfolio returns
histogram(backtester.Returns{:,1})
title('Daily Portfolio Returns')
```

Use `equityCurve` to plot the equity curve for the simple equal-weighted investment strategy.

```
equityCurve(backtester)
```

## External Websites

Backtesting Strategy Framework in Financial Toolbox (2 min 17 sec)

## Introduced in R2020b

# runBacktest

Run backtest on one or more strategies

## Syntax

```
backtester = runBacktest(backtester,pricesTT)
backtester = runBacktest(backtester,pricesTT,signalTT)
backtester = runBacktest(___,Name,Value)
```

## Description

`backtester = runBacktest(backtester,pricesTT)` runs the backtest over the timetable of adjusted asset price data.

`runBacktest` initializes each strategy previously defined using `backtestStrategy` to the `InitialPortfolioValue` and then begins processing the timetable of price data (`pricesTT`) as follows:

- 1 At each time step, the `runBacktest` function applies the asset returns to the strategy portfolio positions.
- 2 The `runBacktest` function determines which strategies to rebalance based on the `RebalanceFrequency` property of the `backtestStrategy` objects.
- 3 For strategies that need rebalancing, the `runBacktest` function calls their rebalance functions with a rolling window of asset price data based on the `LookbackWindow` property of each `backtestStrategy`.
- 4 Transaction costs are calculated and charged based on the changes in asset positions and the `TransactionCosts` property of each `backtestStrategy` object.
- 5 After the backtest is complete, the results are stored in several properties of the `backtestEngine` object.

`backtester = runBacktest(backtester,pricesTT,signalTT)` run the backtest using the adjusted asset price data and signal data. When you specify the signal data timetable (`signalTT`), then the `runBacktest` function runs the backtest and additionally passes a rolling window of signal data to the rebalance function of each strategy during the rebalance step.

`backtester = runBacktest(___,Name,Value)` specifies options using one or more optional name-value pair arguments in addition to the input arguments in the previous syntax. For example, `backtester = runBacktest(backtester,assetPrices,'Start',50,'End',100)`.

## Examples

### Run Backtests

The MATLAB® backtesting engine runs backtests of portfolio investment strategies over timeseries of asset price data. After creating a set of backtest strategies using `backtestStrategy` and the backtest engine using `backtestEngine`, the `runBacktest` function executes the backtest. This example illustrates how to use the `runBacktest` function to test investment strategies.

## Load Data

Load one year of stock price data. For readability, this example only uses a subset of the DJIA stocks.

```
% Read table of daily adjusted close prices for 2006 DJIA stocks
T = readtable('dowPortfolio.xlsx');

% Prune the table to only hold the dates and selected stocks
timeColumn = "Dates";
assetSymbols = ["BA", "CAT", "DIS", "GE", "IBM", "MCD", "MSFT"];
T = T(:,[timeColumn assetSymbols]);

% Convert to timetable
pricesTT = table2timetable(T, 'RowTimes', 'Dates');

% View the final asset price timetable
head(pricesTT)
```

| Dates       | BA    | CAT   | DIS   | GE    | IBM   | MCD   | MSFT  |
|-------------|-------|-------|-------|-------|-------|-------|-------|
| 03-Jan-2006 | 68.63 | 55.86 | 24.18 | 33.6  | 80.13 | 32.72 | 26.19 |
| 04-Jan-2006 | 69.34 | 57.29 | 23.77 | 33.56 | 80.03 | 33.01 | 26.32 |
| 05-Jan-2006 | 68.53 | 57.29 | 24.19 | 33.47 | 80.56 | 33.05 | 26.34 |
| 06-Jan-2006 | 67.57 | 58.43 | 24.52 | 33.7  | 82.96 | 33.25 | 26.26 |
| 09-Jan-2006 | 67.01 | 59.49 | 24.78 | 33.61 | 81.76 | 33.88 | 26.21 |
| 10-Jan-2006 | 67.33 | 59.25 | 25.09 | 33.43 | 82.1  | 33.91 | 26.35 |
| 11-Jan-2006 | 68.3  | 59.28 | 25.33 | 33.66 | 82.19 | 34.5  | 26.63 |
| 12-Jan-2006 | 67.9  | 60.13 | 25.41 | 33.25 | 81.61 | 33.96 | 26.48 |

## Create Strategy

In this introductory example, test an equal weighted investment strategy. This strategy invests an equal portion of the available capital into each asset. This example does describe the details about how create backtest strategies. For more information on creating backtest strategies, see [backtestStrategy](#).

Set the `RebalanceFrequency` to rebalance the portfolio every 60 days. This example does not use a lookback window to rebalance.

```
% Create the strategy
numAssets = size(pricesTT,2);
equalWeightsVector = ones(1,numAssets) / numAssets;
equalWeightsRebalanceFcn = @(~,~) equalWeightsVector;

ewStrategy = backtestStrategy("EqualWeighted",equalWeightsRebalanceFcn, ...
    'RebalanceFrequency',60,...)
    'LookbackWindow',0,...)
    'TransactionCosts',0.005,...)
    'InitialWeights',equalWeightsVector)

ewStrategy =
    backtestStrategy with properties:
        Name: "EqualWeighted"
        RebalanceFcn: @(~,~)equalWeightsVector
```

```
RebalanceFrequency: 60
TransactionCosts: 0.0050
LookbackWindow: 0
InitialWeights: [0.1429 0.1429 0.1429 0.1429 0.1429 0.1429 0.1429]
```

## Run Backtest

Create a backtesting engine and run a backtest over a year of stock data. For more information on creating backtest engines, see [backtestEngine](#).

```
% Create the backtest engine. The backtest engine properties that hold the
% results are initialized to empty.
backtester = backtestEngine(ewStrategy)

backtester =
    backtestEngine with properties:

        Strategies: [1x1 backtestStrategy]
        RiskFreeRate: 0
        CashBorrowRate: 0
        RatesConvention: "Annualized"
        Basis: 0
    InitialPortfolioValue: 10000
    DateAdjustment: "Previous"
        NumAssets: []
        Returns: []
        Positions: []
        Turnover: []
        BuyCost: []
        SellCost: []

% Run the backtest. The empty properties are now populated with
% timetables of detailed backtest results.
backtester = runBacktest(backtester,pricesTT)

backtester =
    backtestEngine with properties:

        Strategies: [1x1 backtestStrategy]
        RiskFreeRate: 0
        CashBorrowRate: 0
        RatesConvention: "Annualized"
        Basis: 0
    InitialPortfolioValue: 10000
    DateAdjustment: "Previous"
        NumAssets: 7
            Returns: [250x1 timetable]
            Positions: [1x1 struct]
            Turnover: [250x1 timetable]
            BuyCost: [250x1 timetable]
            SellCost: [250x1 timetable]
```

## Backtest Summary

Use the `summary` function to generate a summary table of backtest results.

```
% Examining results. The summary table shows several performance metrics.
summary(backtester)

ans=9×1 table
    EqualWeighted
```

---

|                 | EqualWeighted |
|-----------------|---------------|
| TotalReturn     | 0.22943       |
| SharpeRatio     | 0.11415       |
| Volatility      | 0.0075013     |
| AverageTurnover | 0.00054232    |
| MaxTurnover     | 0.038694      |
| AverageReturn   | 0.00085456    |
| MaxDrawdown     | 0.098905      |
| AverageBuyCost  | 0.030193      |
| AverageSellCost | 0.030193      |

## Warm Starting Backtests

When running a backtest in MATLAB®, you need to understand what the initial conditions are when the backtest begins. The initial weights for each strategy, the size of the strategy lookback window, and any potential split of the dataset into training and testing partitions affects the results of the backtest. This example shows how to use the `runBacktest` function with the `'Start'` and `'End'` name-value pair arguments that interact with the `'LookbackWindow'` and `'RebalanceFrequency'` properties of the `backtestStrategy` object to "warm start" a backtest.

### Load Data

Load one year of stock price data. For readability, this example uses only a subset of the DJIA stocks.

```
% Read table of daily adjusted close prices for 2006 DJIA stocks.
T = readtable('dowPortfolio.xlsx');

% Prune the table to include only the dates and selected stocks.
timeColumn = "Dates";
assetSymbols = ["BA", "CAT", "DIS", "GE", "IBM", "MCD", "MSFT"];
T = T(:,[timeColumn assetSymbols]);

% Convert to timetable.
pricesTT = table2timetable(T, 'RowTimes', 'Dates');

% View the final asset price timetable.
head(pricesTT)
```

```
ans=8×7 timetable
    Dates       BA      CAT      DIS      GE      IBM      MCD      MSFT
    _____    ____    ____    ____    ____    ____    ____    ____    ____  
03-Jan-2006   68.63   55.86   24.18   33.6    80.13   32.72   26.19  
04-Jan-2006   69.34   57.29   23.77   33.56   80.03   33.01   26.32

```

|             |      |       |       |       |       |       |       |
|-------------|------|-------|-------|-------|-------|-------|-------|
| 12-Jan-2006 | 67.9 | 60.13 | 25.41 | 33.25 | 81.61 | 33.96 | 26.48 |
|-------------|------|-------|-------|-------|-------|-------|-------|

## Create Strategy

This example backtests an "inverse variance" strategy. The inverse variance rebalance function is implemented in the Local Functions on page 19-0 section. For more information on creating backtest strategies, see `backtestStrategy`. The inverse variance strategy uses the covariance of asset returns to make decisions about asset allocation. The `LookbackWindow` for this strategy must contain at least 30 days of trailing data (about 6 weeks), and at most, 60 days (about 12 weeks).

Set `RebalanceFrequency` for `backtestStrategy` to rebalance the portfolio every 25 days.

```
% Create the strategy
minLookback = 30;
maxLookback = 60;
ivStrategy = backtestStrategy("InverseVariance",@inverseVarianceFcn, ...
    'RebalanceFrequency',25, ...
    'LookbackWindow',[minLookback maxLookback], ...
    'TransactionCosts',[0.0025 0.005])

ivStrategy =
  backtestStrategy with properties:

    Name: "InverseVariance"
    RebalanceFcn: @inverseVarianceFcn
    RebalanceFrequency: 25
    TransactionCosts: [0.0025 0.0050]
    LookbackWindow: [30 60]
    InitialWeights: [1x0 double]
```

## Run Backtest and Examine Results

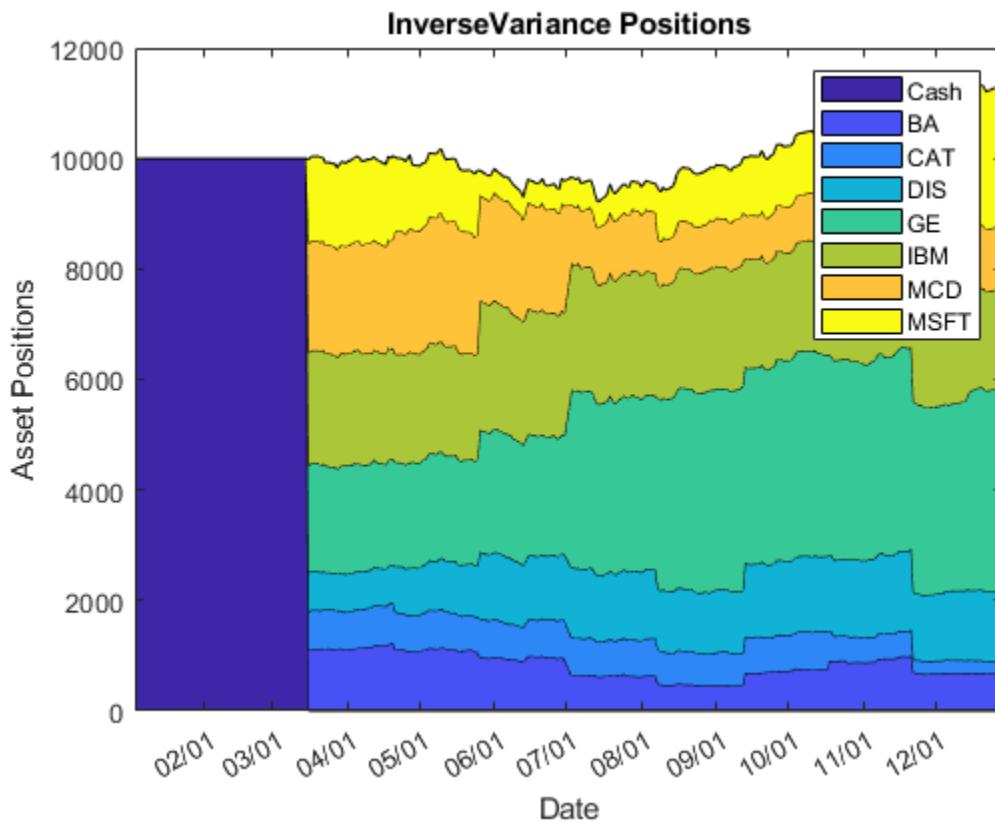

Create a backtesting engine and run a backtest over a year of stock data. For more information on creating backtest engines, see `backtestEngine`.

```
% Create the backtest engine.
backtester = backtestEngine(ivStrategy);

% Run the backtest.
backtester = runBacktest(backtester,pricesTT);
```

Use the `assetAreaPlot` helper function, defined in the Local Functions on page 19-0 section of this example, to display the change in the asset allocation over the course of the backtest.

```
assetAreaPlot(backtester,"InverseVariance")
```

Notice that the inverse variance strategy begins all in cash and remains in that state for about 2.5 months. This is because the `backtestStrategy` object does not have a specified set of initial weights, which you specify using the `InitialPortfolioValue` name-value pair argument. The inverse variance strategy requires 30 days of trailing asset price history before rebalancing. You can use the `printRebalanceTable` helper function, defined in the Local Functions on page 19-0 section, to display the rebalance schedule.

```
printRebalanceTable(ivStrategy,pricesTT,minLookback);
```

| First Day of Data | Backtest Start Date | Minimum Days to Rebalance |
|-------------------|---------------------|---------------------------|
| 03-Jan-2006       | 03-Jan-2006         | 30                        |

| Rebalance Dates | Days of Available Price History | Enough Data to Rebalance |
|-----------------|---------------------------------|--------------------------|
| 08-Feb-2006     | 26                              | "No"                     |
| 16-Mar-2006     | 51                              | "Yes"                    |
| 21-Apr-2006     | 76                              | "Yes"                    |
| 26-May-2006     | 101                             | "Yes"                    |
| 03-Jul-2006     | 126                             | "Yes"                    |
| 08-Aug-2006     | 151                             | "Yes"                    |
| 13-Sep-2006     | 176                             | "Yes"                    |
| 18-Oct-2006     | 201                             | "Yes"                    |

|             |     |       |
|-------------|-----|-------|
| 22-Nov-2006 | 226 | "Yes" |
| 29-Dec-2006 | 251 | "Yes" |

The first rebalance date comes on February 8 but the strategy does not have enough price history to fill out a valid lookback window (minimum is 30 days), so no rebalance occurs. The next rebalance date is on March 16, a full 50 days into the backtest.

This situation is not ideal as these 50 days sitting in an all-cash position represent approximately 20% of the total backtest. Consequently, when the backtesting engine reports on the performance of the strategy (that is, the total return, Sharpe ratio, volatility, and so on), the results do not reflect the "true" strategy performance because the strategy only began to make asset allocation decisions only about 20% into the backtest.

### Warm Start Backtest

It is possible to "warm start" the backtest. A warm start means that the backtest results reflect the strategy performance in the market conditions reflected in the price timetable. To start, set the initial weights of the strategy to avoid starting all in cash.

The inverse variance strategy requires 30 days of price history to fill out a valid lookback window, so you can partition the price data set into two sections, a "warm-up" set and a "test" set.

```
warmupRange = 1:30;
% The 30th row is included in both ranges since the day 30 price is used
% to compute the day 31 returns.
testRange = 30:height(pricesTT);
```

Use the warm-up partition to set the initial weights of the inverse variance strategy. By doing so, you can begin the backtest with the strategy already "running" and avoid the initial weeks spent in the cash position.

```
% Use the rebalance function to set the initial weights. This might
% or might not be possible for other strategies depending on the details of
% the strategy logic.
initWeights = inverseVarianceFcn([],pricesTT(warmupRange,:));
```

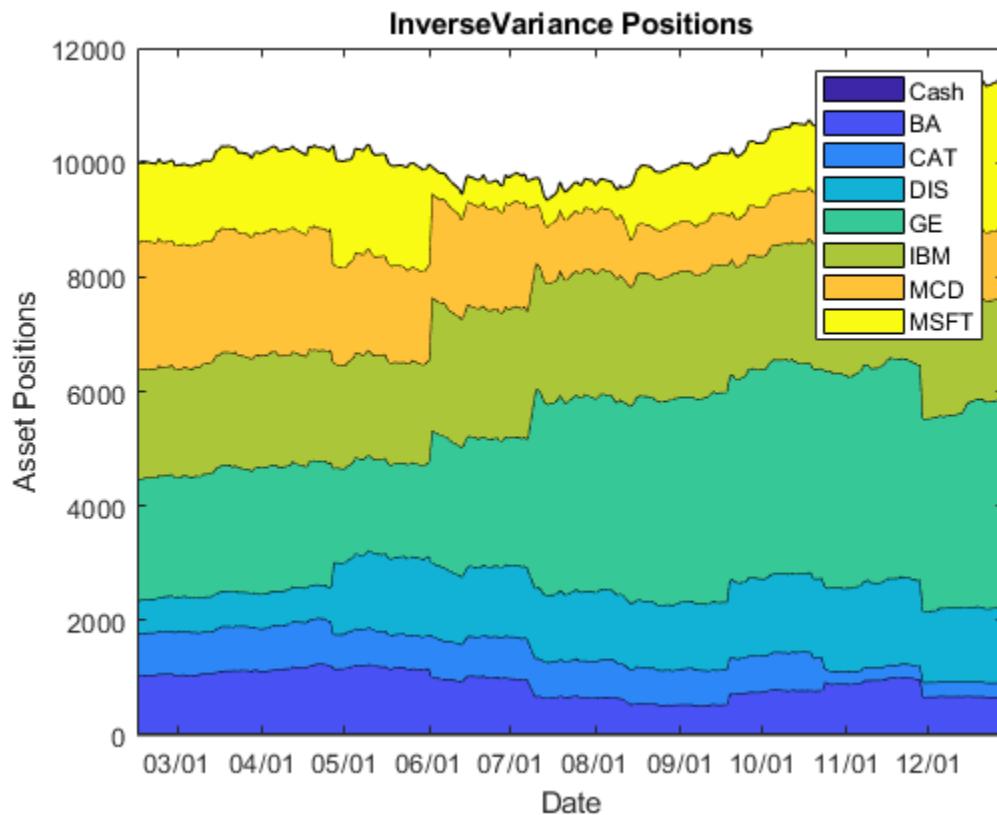

Update the strategy and rerun the backtest. Since the warm-up range is used to initialize the inverse variance strategy, you must omit this data from the backtest to avoid a look-ahead bias, or "seeing the future," and to backtest only over the "test range."

```
% Set the initial weights on the strategy in the backtester. You can do this when you
% create the strategy as well, using the 'InitialWeights' parameter.
backtester.Strategies(1).InitialWeights = initWeights;

% Rerun the backtest over the "test" range.
backtester = runBacktest(backtester,pricesTT(testRange,:));
```

When you generate the area plot, you can see that the issue where the strategy is in cash for the first portion of the backtest is avoided.

```
assetAreaPlot(backtester,"InverseVariance")
```

However, if you look at the rebalance table, you can see that the strategy still "missed" the first rebalance date. When you run the backtest over the test range of the data set, the first rebalance date is on March 22. This is because the warm-up range is omitted from the price history and the strategy had only 26 days of history available on that date (less than the minimum 30 days required for the lookback window). Therefore, the March 22 rebalance is skipped.

To avoid backtesting over the warm-up range, the range was removed it from the data set. This means the new backtest start date and all subsequent rebalance dates are 30 days later. The price history data contained in the warm-up range was completely removed, so when the backtest engine hit the first rebalance date the price history was insufficient to rebalance.

```
printRebalanceTable(ivStrategy,pricesTT(testRange,:),minLookback);
```

| First Day of Data | Backtest Start Date | Minimum Days to Rebalance |
|-------------------|---------------------|---------------------------|
| 14-Feb-2006       | 14-Feb-2006         | 30                        |

| Rebalance Dates | Days of Available Price History | Enough Data to Rebalance |
|-----------------|---------------------------------|--------------------------|
| 22-Mar-2006     | 26                              | "No"                     |
| 27-Apr-2006     | 51                              | "Yes"                    |
| 02-Jun-2006     | 76                              | "Yes"                    |
| 10-Jul-2006     | 101                             | "Yes"                    |

|             |     |       |
|-------------|-----|-------|
| 14-Aug-2006 | 126 | "Yes" |
| 19-Sep-2006 | 151 | "Yes" |
| 24-Oct-2006 | 176 | "Yes" |
| 29-Nov-2006 | 201 | "Yes" |

This scenario is also not correct since the original price timetable (warm-up and test partitions together) does have enough price history by March 22 to fill out a valid lookback window. However, the earlier data is not available to the backtest engine because the backtest was run using only the test partition.

### Use Start and End Parameters for runBacktest

The ideal workflow in this situation is to both *omit* the warm-up data range from the backtest to avoid the look-ahead bias but *include* the warm-up data in the price history to be able to fill out the lookback window of the strategy with all available price history data. You can do so by using the 'Start' parameter for the `runBacktest` function.

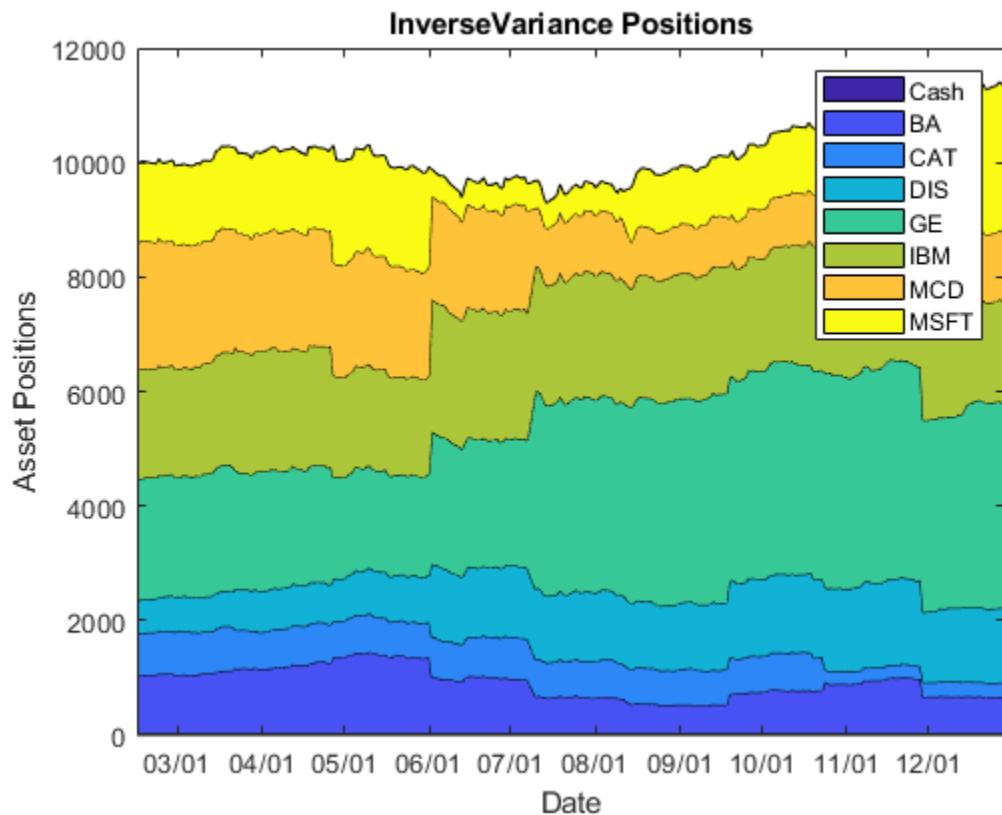

The 'Start' and 'End' name-value pair arguments for `runBacktest` enable you to start and end the backtest on specific dates. You can specify 'Start' and 'End' as rows of the prices timetable or as datetime values (see the documentation for the `runBacktest` function for details). The 'Start' argument lets the backtest begin on a particular date while giving the backtest engine access to the full data set.

Rerun the backtest using the 'Start' name-value pair argument rather than only running on a partition of the original data set.

```
% Rerun the backtest starting on the last day of the warmup range.
startRow = warmupRange(end);
backtester = runBacktest(backtester,pricesTT,'Start',startRow);
```

Plot the new asset area plot.

```
assetAreaPlot(backtester,"InverseVariance")
```

View the new rebalance table with the new 'Start' parameter.

```
printRebalanceTable(ivStrategy,pricesTT,minLookback,startRow);
```

| First Day of Data | Backtest Start Date             | Minimum Days to Rebalance |
|-------------------|---------------------------------|---------------------------|
| 03-Jan-2006       | 14-Feb-2006                     | 30                        |
| Rebalance Dates   | Days of Available Price History | Enough Data to Rebalance  |
| 22-Mar-2006       | 55                              | "Yes"                     |
| 27-Apr-2006       | 80                              | "Yes"                     |
| 02-Jun-2006       | 105                             | "Yes"                     |
| 10-Jul-2006       | 130                             | "Yes"                     |
| 14-Aug-2006       | 155                             | "Yes"                     |
| 19-Sep-2006       | 180                             | "Yes"                     |
| 24-Oct-2006       | 205                             | "Yes"                     |
| 29-Nov-2006       | 230                             | "Yes"                     |

The inverse variance strategy now has enough data to rebalance on the first rebalance date (March 22) and the backtest is "warm started." By using the original data set, the first day of data remains January 3, and the 'Start' parameter allows you to move the backtest start date forward to avoid the warm-up range.

Even though the results are not dramatically different, this example illustrates the interaction between the `LookbackWindow` and `RebalanceFrequency` name-value pair arguments for a `backtestStrategy` object and the range of data used in the `runBacktest` when you evaluate the performance of a strategy in a backtest.

## Local Functions

The strategy rebalance function is implemented as follows. For more information on creating strategies and writing rebalance functions, see `backtestStrategy`.

```
function new_weights = inverseVarianceFcn(current_weights, pricesTT)
    % Inverse-variance portfolio allocation.

    assetReturns = tick2ret(pricesTT);
    assetCov = cov(assetReturns{:, :});
    new_weights = 1 ./ diag(assetCov);
    new_weights = new_weights / sum(new_weights);

end
```

This helper function plots the asset allocation as an area plot.

```
function assetAreaPlot(backtester,strategyName)

t = backtester.Positions.(strategyName).Time;
positions = backtester.Positions.(strategyName).Variables;
h = area(t,positions);
title(sprintf('%s Positions',strategyName));
xlabel('Date');
ylabel('Asset Positions');
datetick('x','mm/dd','keepticks');
xlim([t(1) t(end)])
oldylim = ylim;
ylim([0 oldylim(2)]);
cm = parula(numel(h));
for i = 1:numel(h)
    set(h(i),'FaceColor',cm(i,:));
end
legend(backtester.Positions.(strategyName).Properties.VariableNames)

end
```

This helper function generates a table of rebalance dates along with the available price history at each date.

```
function printRebalanceTable(strategy,pricesTT,minLookback,startRow)

if nargin < 4
    startRow = 1;
end

allDates = pricesTT.Properties.DimensionNames{1};
rebalanceDates = allDates(startRow:strategy.RebalanceFrequency:end);
[~,rebalanceIndices] = ismember(rebalanceDates,pricesTT.Dates);

disp(table(allDates(1),rebalanceDates(1),minLookback,'VariableNames',{'First Day of Data','Backt
fprintf('\n\n');
numHistory = rebalanceIndices(2:end);
```

```
sufficient = repmat("No",size(numHistory));
sufficient(numHistory > minLookback) = "Yes";
disp(table(rebalanceDates(2:end),rebalanceIndices(2:end),sufficient,'VariableNames',{'Rebalance Dates','Rebalance Indices','Sufficient'}));
end
```

## Input Arguments

### backtester — Backtesting engine

backtestEngine object

Backtesting engine, specified as a backtestEngine object. Use backtestEngine to create the backtester object.

Data Types: object

### pricesTT — Asset prices

timetable

Asset prices, specified as a timetable of asset prices that the backtestEngine uses to backtest the strategies. Each column of the prices timetable must contain a timeseries of prices for an asset. Historical asset prices must be adjusted for splits and dividends.

Data Types: timetable

### signaLTT — Signal data

timetable

(Optional) Signal data, specified as a timetable of trading signals that the strategies use to make trading decisions. signaLTT is optional. If provided, the backtestEngine calls the strategy rebalance functions with both asset price data and signal data. The signaLTT timetable must have the same time dimension as the pricesTT timetable.

Data Types: timetable

## Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, ..., NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: backtester = runBacktest(backtester,assetPrices,'Start',50,'End',100)

### Start — Time step to start backtest

1 (default) | integer | datetime

Time step to start the backtest, specified as the comma-separated pair consisting of 'Start' and a scalar integer or datetime.

If an integer, the Start time refers to the row in the pricesTT timetable where the backtest begins.

If a datetime object, the backtest will begin at the first time in the prices timetable that occurs on or after the 'Start' parameter. The backtest will end on the last time in the prices timetable that occurs on or before the 'End' parameter. The 'Start' and 'End' parameters set the boundary of the data that is included in the backtest.

Data Types: double | datetime

#### **End — Time step to end backtest**

Last row in `pricesTT` timetable (default) | integer | datetime

Time step to end the backtest, specified as the comma-separated pair consisting of 'End' and a scalar integer or datetime.

If an integer, the End time refers to the row in the `pricesTT` timetable where the backtest ends.

If a `datetime` object, TBD

Data Types: double | datetime

## **Output Arguments**

### **backtester — Backtesting engine**

`backtestEngine` object

Backtesting engine, returned as an updated `backtestEngine` object. After backtesting is complete, `runBacktest` populates several properties in the `backtestEngine` object with the results of the backtest. You can summarize the results by using the `summary` function.

## **Introduced in R2020b**

## summary

Generate summary table of backtest results

### Syntax

```
summaryTable = summary(backtester)
```

### Description

`summaryTable = summary(backtester)` generates a table of metrics to summarize the backtest. Each row of the table is a calculated metric and each column represents a strategy. You must run the `summary` function only after running the `runBacktest` function.

## Examples

### Examining Backtest Results

The MATLAB® backtesting engine runs backtests of portfolio investment strategies over time series of asset price data. You can use `summary` to compare multiple strategies over the same market scenario. This example shows how to examine the results of a backtest with two strategies.

#### Load Data

Load one year of stock price data. For readability, this example uses a subset of the DJIA stocks.

```
% Read table of daily adjusted close prices for 2006 DJIA stocks
T = readtable('dowPortfolio.xlsx');

% Prune the table to include only the dates and selected stocks
timeColumn = "Dates";
assetSymbols = ["BA", "CAT", "DIS", "GE", "IBM", "MCD", "MSFT"];
T = T(:,[timeColumn assetSymbols]);

% Convert to timetable
pricesTT = table2timetable(T, 'RowTimes', 'Dates');

% View the final asset price timetable
head(pricesTT)
```

ans=8x7 timetable

| Dates       | BA    | CAT   | DIS   | GE    | IBM   | MCD   | MSFT  |
|-------------|-------|-------|-------|-------|-------|-------|-------|
| 03-Jan-2006 | 68.63 | 55.86 | 24.18 | 33.6  | 80.13 | 32.72 | 26.19 |
| 04-Jan-2006 | 69.34 | 57.29 | 23.77 | 33.56 | 80.03 | 33.01 | 26.32 |
| 05-Jan-2006 | 68.53 | 57.29 | 24.19 | 33.47 | 80.56 | 33.05 | 26.34 |
| 06-Jan-2006 | 67.57 | 58.43 | 24.52 | 33.7  | 82.96 | 33.25 | 26.26 |
| 09-Jan-2006 | 67.01 | 59.49 | 24.78 | 33.61 | 81.76 | 33.88 | 26.21 |
| 10-Jan-2006 | 67.33 | 59.25 | 25.09 | 33.43 | 82.1  | 33.91 | 26.35 |
| 11-Jan-2006 | 68.3  | 59.28 | 25.33 | 33.66 | 82.19 | 34.5  | 26.63 |

|             |      |       |       |       |       |       |       |
|-------------|------|-------|-------|-------|-------|-------|-------|
| 12-Jan-2006 | 67.9 | 60.13 | 25.41 | 33.25 | 81.61 | 33.96 | 26.48 |
|-------------|------|-------|-------|-------|-------|-------|-------|

The inverse variance strategy requires some price history to initialize, so you can allocate a portion of the data to use for setting initial weights. By doing this, you can "warm start" the backtest.

```
warmupRange = 1:20;
testRange = 21:height(pricesTT);
```

## Create Strategies

Define an investment strategy by using the `backtestStrategy` function. This example builds two strategies:

- Equal weighted
- Inverse variance

This example does not provide details on how to build the strategies. For more information on creating strategies, see `backtestStrategy`. The strategy rebalance functions are implemented in the Rebalance Functions on page 19-0 section.

```
% Create the strategies
ewInitialWeights = equalWeightFcn([],pricesTT(warmupRange,:));
ewStrategy = backtestStrategy("EqualWeighted",@equalWeightFcn, ...
    'RebalanceFrequency',20,... ...
    'TransactionCosts',[0.0025 0.005],...
    'LookbackWindow',0,... ...
    'InitialWeights',ewInitialWeights);

ivInitialWeights = inverseVarianceFcn([],pricesTT(warmupRange,:));
ivStrategy = backtestStrategy("InverseVariance",@inverseVarianceFcn, ...
    'RebalanceFrequency',20,... ...
    'TransactionCosts',[0.0025 0.005],...
    'InitialWeights',ivInitialWeights);

% Aggregate the strategies into an array
strategies = [ewStrategy ivStrategy];
```

## Run Backtest

Create a backtesting engine and run a backtest over a year of stock data. For more information on creating backtesting engines, see `backtestEngine`. The software initializes several properties of the `backtestEngine` object to empty. These read-only properties are populated by the engine after you run the backtest.

```
% Create the backtesting engine using the default settings
backtester = backtestEngine(strategies)

backtester =
  backtestEngine with properties:
    Strategies: [1x2 backtestStrategy]
    RiskFreeRate: 0
    CashBorrowRate: 0
    RatesConvention: "Annualized"
    Basis: 0
    InitialPortfolioValue: 10000
```

```
DateAdjustment: "Previous"
    NumAssets: []
        Returns: []
    Positions: []
    Turnover: []
    BuyCost: []
    SellCost: []
```

Run the backtest using `runBacktest`.

```
% Run the backtest
backtester = runBacktest(backtester,pricesTT(testRange,:));
```

### Examine Summary Results

The `summary` function uses the results of the backtest and returns a table of high-level results from the backtest.

```
s1 = summary(backtester)
```

```
s1=9x2 table
```

|                 | EqualWeighted | InverseVariance |
|-----------------|---------------|-----------------|
| TotalReturn     | 0.17567       | 0.17155         |
| SharpeRatio     | 0.097946      | 0.10213         |
| Volatility      | 0.0074876     | 0.0069961       |
| AverageTurnover | 0.0007014     | 0.0024246       |
| MaxTurnover     | 0.021107      | 0.097472        |
| AverageReturn   | 0.00073178    | 0.00071296      |
| MaxDrawdown     | 0.097647      | 0.096299        |
| AverageBuyCost  | 0.018532      | 0.061913        |
| AverageSellCost | 0.037064      | 0.12383         |

Each row of the table output is a measurement of the performance of a strategy. Each strategy occupies a column. The `summary` function reports on the following metrics:

- **TotalReturn** — The nonannualized total return of the strategy, inclusive of fees, over the full backtest period.
- **SharpeRatio** — The nonannualized Sharpe ratio of each strategy over the backtest. For more information, see `sharpe`.
- **Volatility** — The nonannualized standard deviation of per-time-step strategy returns.
- **AverageTurnover** — The average per-time-step portfolio turnover, expressed as a decimal percentage.
- **MaxTurnover** — The maximum portfolio turnover in a single rebalance, expressed as a decimal percentage.
- **AverageReturn** — The arithmetic mean of the per-time step portfolio returns.
- **MaxDrawdown** — The maximum drawdown of the portfolio, expressed as a decimal percentage. For more information, see `maxdrawdown`.
- **AverageBuyCost** — The average per-time-step transaction costs the portfolio incurred for asset purchases.

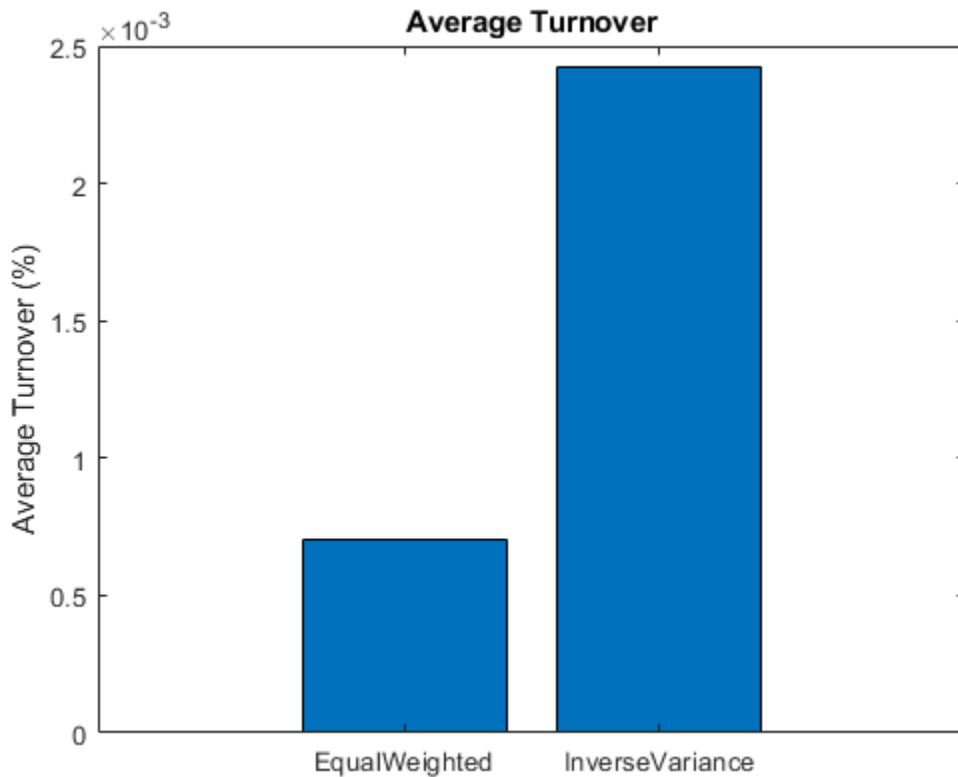

- **AverageSellCost** — The average per-time-step transaction costs the portfolio incurred for asset sales.

Sometimes it is useful to transpose the **summary** table when plotting the metrics of different strategies.

```
s2 = rows2vars(s1);
s2.Properties.VariableNames{1} = 'StrategyName'
```

| StrategyName        | TotalReturn | SharpeRatio | Volatility | AverageTurnover | MaxTurnover |
|---------------------|-------------|-------------|------------|-----------------|-------------|
| {'EqualWeighted'}   | 0.17567     | 0.097946    | 0.0074876  | 0.0007014       | 0.0211      |
| {'InverseVariance'} | 0.17155     | 0.10213     | 0.0069961  | 0.0024246       | 0.0974      |

```
bar(s2.AverageTurnover)
title('Average Turnover')
ylabel('Average Turnover (%)')
set(gca,'xticklabel',s2.StrategyName)
```

## Examine Detailed Results

After you run the backtest, the **backtestEngine** object updates the read-only fields with the detailed results of the backtest. The **Returns**, **Positions**, **Turnover**, **BuyCost**, and **SellCost** properties each contain a timetable of results. Since this example uses daily price data in the backtest, these timetables hold daily results.

```
backtester

backtester =
  backtestEngine with properties:

    Strategies: [1x2 backtestStrategy]
    RiskFreeRate: 0
    CashBorrowRate: 0
    RatesConvention: "Annualized"
    Basis: 0
    InitialPortfolioValue: 10000
    DateAdjustment: "Previous"
    NumAssets: 7
    Returns: [230x2 timetable]
    Positions: [1x1 struct]
    Turnover: [230x2 timetable]
    BuyCost: [230x2 timetable]
    SellCost: [230x2 timetable]
```

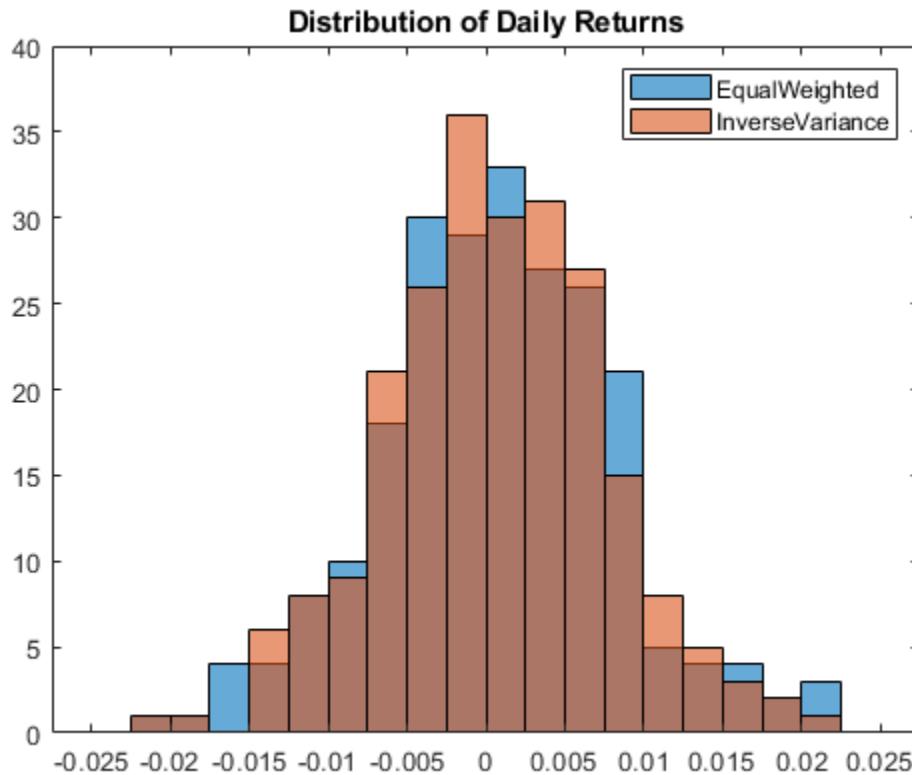

## Returns

The `Returns` property holds a timetable of strategy (simple) returns for each time step. These returns are inclusive of all transaction fees.

```
head(backtester.Returns)
```

```
ans=8×2 timetable
Time           EqualWeighted      InverseVariance
_____
02-Feb-2006   -0.007553       -0.0070957
03-Feb-2006   -0.0037771     -0.003327
06-Feb-2006   -0.0010094     -0.0014312
07-Feb-2006   0.0053284      0.0020578
08-Feb-2006   0.0099755      0.0095781
09-Feb-2006   -0.0026871     -0.0014999
10-Feb-2006   0.0048374      0.0059589
13-Feb-2006   -0.0056868     -0.0051232
```

```
binedges = -0.025:0.0025:0.025;
h1 = histogram(backtester.Returns.EqualWeighted,'BinEdges',binedges);
hold on
histogram(backtester.Returns.InverseVariance,'BinEdges',binedges);
hold off
title('Distribution of Daily Returns')
legend([strategies.Name]);
```

## Positions

The **Positions** property holds a structure of timetables, one per strategy.

`backtester.Positions`

```
ans = struct with fields:
    EqualWeighted: [231x8 timetable]
    InverseVariance: [231x8 timetable]
```

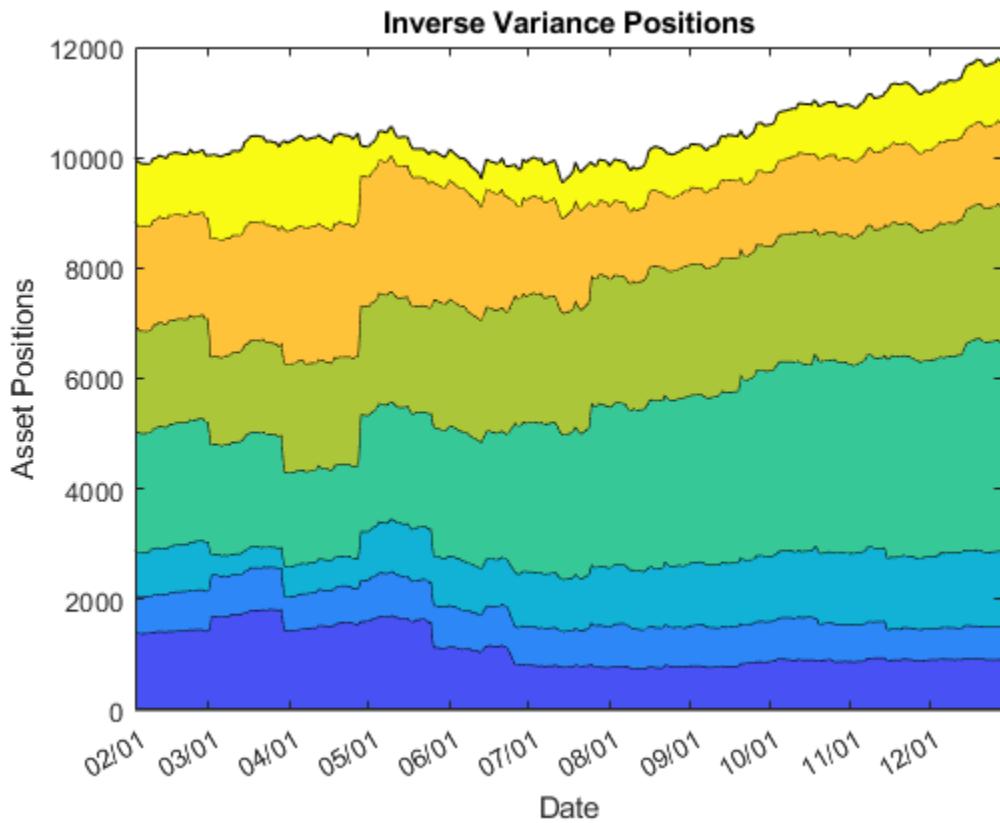

The **Positions** timetable of each strategy holds the per-time-step positions for each asset as well as the **Cash** asset (which earns the risk-free rate). The **Positions** timetables contain one more row than the other results timetables because the **Positions** timetables include initial positions of the strategy as their first row. You can consider the initial positions as the **Time = 0** portfolio positions. In this example, the **Positions** timetables start with February 1, while the others start on February 2.

`head(backtester.Positions.InverseVariance)`

| Time        | Cash       | BA     | CAT    | DIS    | GE     | IBM    | MCD    | MSFT   |
|-------------|------------|--------|--------|--------|--------|--------|--------|--------|
| 01-Feb-2006 | 0          | 1401.2 | 682.17 | 795.14 | 2186.8 | 1900.1 | 1874.9 | 1111.1 |
| 02-Feb-2006 | 0          | 1402.8 | 673.74 | 789.74 | 2170.8 | 1883.5 | 1863.6 | 1111.1 |
| 03-Feb-2006 | 1.0987e-12 | 1386.5 | 671.2  | 787.2  | 2167.3 | 1854.3 | 1890.5 | 1111.1 |
| 06-Feb-2006 | 0          | 1391.9 | 676.78 | 785.62 | 2161.1 | 1843.6 | 1899.1 | 1111.1 |
| 07-Feb-2006 | 0          | 1400   | 661.66 | 840.23 | 2131.9 | 1851.6 | 1902.3 | 1111.1 |

|             |             |        |        |        |        |        |        |    |
|-------------|-------------|--------|--------|--------|--------|--------|--------|----|
| 08-Feb-2006 | -2.2198e-12 | 1409.8 | 677.9  | 846.58 | 2160.4 | 1878.2 | 1911   | 11 |
| 09-Feb-2006 | -2.2165e-12 | 1414.8 | 674.35 | 840.87 | 2172.2 | 1869   | 1908.3 | 11 |
| 10-Feb-2006 | -2.2297e-12 | 1425.1 | 677.29 | 839.6  | 2195.8 | 1890.6 | 1909.3 | 11 |

```
% Plot the change of asset allocation over time
t = backtester.Positions.InverseVariance.Time;
positions = backtester.Positions.InverseVariance.Variables;
h = area(t,positions);
title('Inverse Variance Positions');
xlabel('Date');
ylabel('Asset Positions');
datetick('x','mm/dd','keepticks');
ylim([0 12000])
xlim([t(1) t(end)])
cm = parula(numel(h));
for i = 1:numel(h)
    set(h(i), 'FaceColor', cm(i,:));
end
```

### Turnover

The **Turnover** timetable holds the per-time-step portfolio turnover.

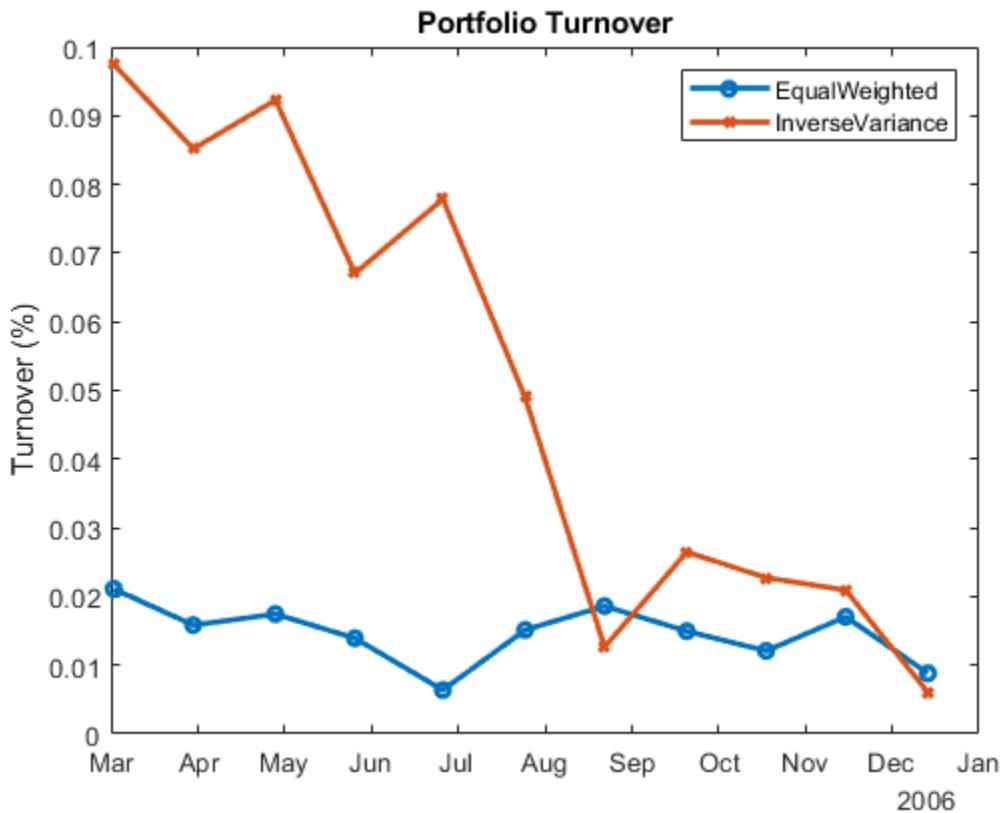

```
head(backtester.Turnover)
```

```
ans=8×2 timetable
Time      EqualWeighted      InverseVariance
```

|             |   |   |
|-------------|---|---|
| 02-Feb-2006 | 0 | 0 |
| 03-Feb-2006 | 0 | 0 |
| 06-Feb-2006 | 0 | 0 |
| 07-Feb-2006 | 0 | 0 |
| 08-Feb-2006 | 0 | 0 |
| 09-Feb-2006 | 0 | 0 |
| 10-Feb-2006 | 0 | 0 |
| 13-Feb-2006 | 0 | 0 |

Depending on your rebalance frequency, the Turnover table can contain mostly zeros. Removing these zeros when you visualize the portfolio turnover is useful.

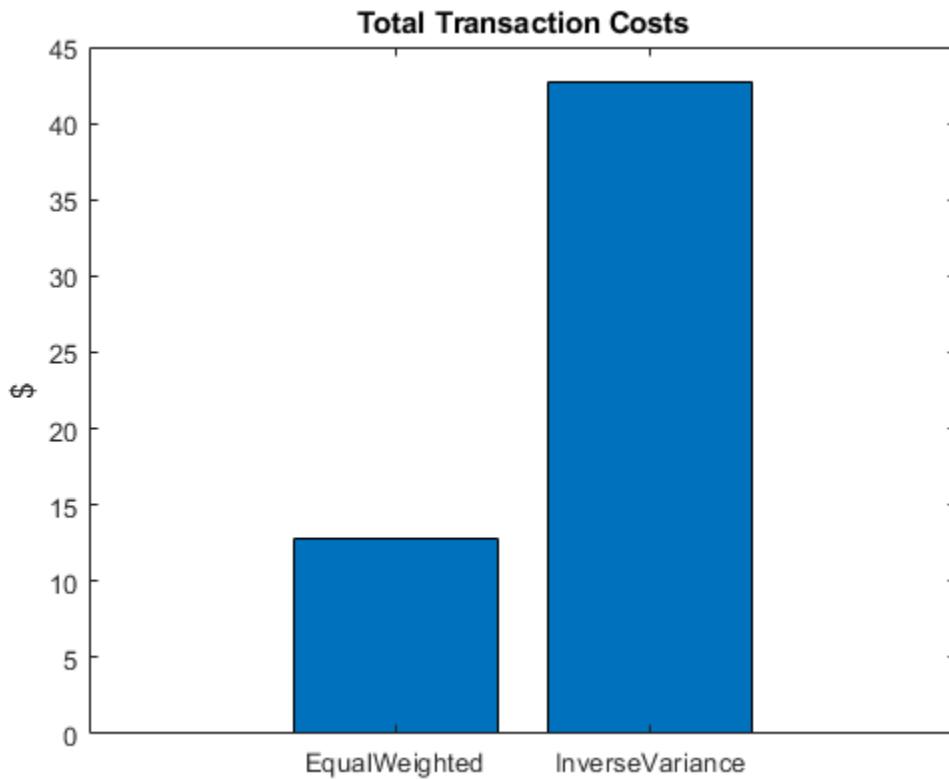

```
nonZeroIdx = sum(backtester.Turnover.Variables,2) > 0;
to = backtester.Turnover(nonZeroIdx,:);
plot(to.Time,to.EqualWeighted,'-o',to.Time,to.InverseVariance,'-x',...
    'LineWidth',2,'MarkerSize',5);
legend([strategies.Name]);
title('Portfolio Turnover');
ylabel('Turnover (%)');
```

### BuyCost and SellCost

The **BuyCost** and **SellCost** timetables hold the per-time-step transaction fees for each type of transaction, purchases, and sales.

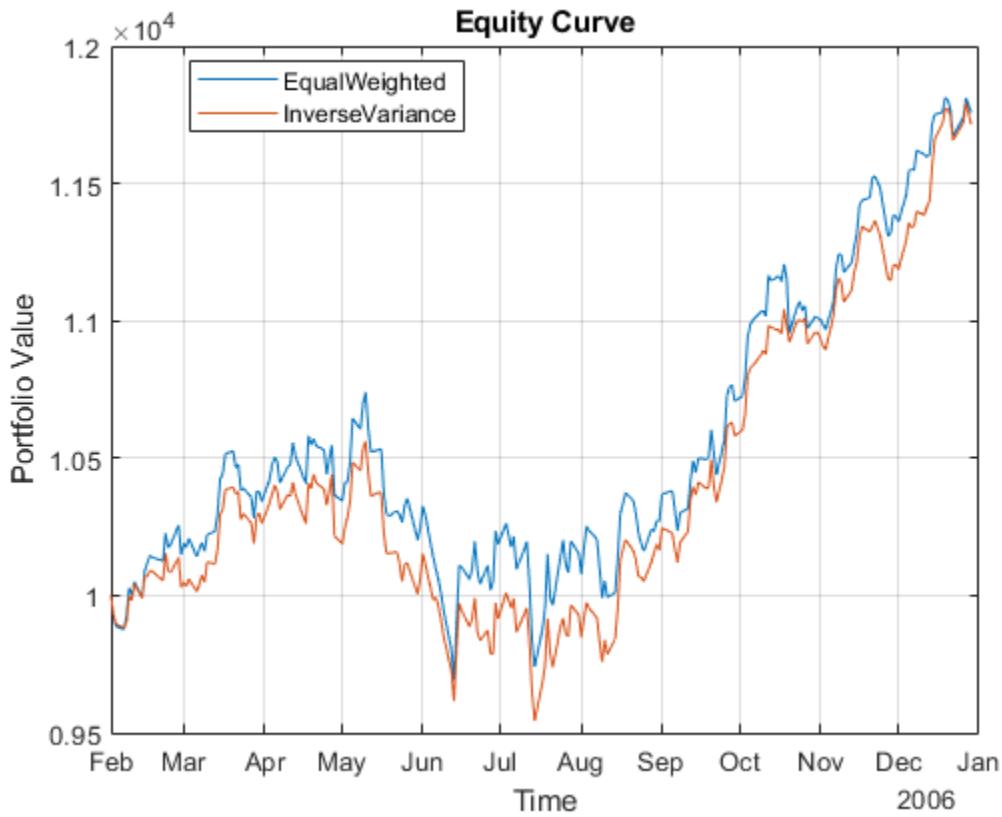

```
totalCost = sum(backtester.BuyCost{::,:}) + sum(backtester.SellCost{::,:});
bar(totalCost);
title('Total Transaction Costs');
ylabel('$')
set(gca,'xticklabel',[strategies.Name])
```

### Generate Equity Curve

Use `equityCurve` to plot the equity curve for the equal weighted and inverse variance strategies.

```
equityCurve(backtester)
```

## Rebalance Functions

This section contains the implementation of the strategy rebalance functions. For more information on creating strategies and writing rebalance functions, see `backtestStrategy`.

```
function new_weights = equalWeightFcn(current_weights, pricesTT) %#ok<INUSL>
% Equal weighted portfolio allocation

nAssets = size(pricesTT, 2);
new_weights = ones(1,nAssets);
new_weights = new_weights / sum(new_weights);

end

function new_weights = inverseVarianceFcn(current_weights, pricesTT) %#ok<INUSL>
% Inverse-variance portfolio allocation

assetReturns = tick2ret(pricesTT);
assetCov = cov(assetReturns{:, :});
new_weights = 1 ./ diag(assetCov);
new_weights = new_weights / sum(new_weights);
```

end

## Input Arguments

### backtester — Backtesting engine

backtestEngine object

Backtesting engine, specified as a backtestEngine object. Use `backtestEngine` to create the backtesting engine and then use `runBacktest` to run a backtest.

Data Types: object

## Output Arguments

### summaryTable — Metrics summarizing backtest

table

Metrics summarizing the backtest, returned as a table where each row of the table is a calculated metric and each column represents a strategy. The reported metrics are as follows:

- `TotalReturn` — The total return of the strategy over the entire backtest
- `SharpeRatio` — The Sharpe ratio for each strategy
- `Volatility` — The volatility of each strategy over the backtest
- `AverageTurnover` — Average turnover per-time-step as a decimal percent
- `MaxTurnover` — Maximum turnover in a single time step
- `AverageReturn` — Average return per-time-step
- `MaxDrawdown` — Maximum portfolio drawdown as a decimal percent
- `AverageBuyCost` — Average per-time-step transaction costs for asset purchases
- `AverageSellCost` — Average per-time-step transaction costs for asset sales

## Introduced in R2020b

# equityCurve

Plot equity curves of strategies

## Syntax

```
equityCurve(backtester)
h = equityCurve(ax,backtester)
```

## Description

`equityCurve(backtester)` plots the equity curves of each strategy that you create using `backtestStrategy`. After creating the backtesting engine using `backtestEngine` and running the backtest with `runBacktest`, use `equityCurve` to plot the strategies and compare their performance.

`h = equityCurve(ax,backtester)` additionally returns the figure handle `h`.

## Examples

### Generate Equity Curve for Backtest

The MATLAB® backtesting engine runs backtests of portfolio investment strategies over time series of asset price data. After creating a set of backtest strategies using `backtestStrategy` and the backtesting engine using `backtestEngine`, the `runBacktest` function executes the backtest. After using the `runBacktest` function to test investment strategies, you can run the `equityCurve` function to plot the equity curves of strategies.

#### Load Data

Load one year of stock price data. For readability, this example uses only a subset of the DJIA stocks.

```
% Read a table of daily adjusted close prices for 2006 DJIA stocks
T = readtable('dowPortfolio.xlsx');

% Prune the table to hold only the dates and selected stocks
timeColumn = "Dates";
assetSymbols = ["BA", "CAT", "DIS", "GE", "IBM", "MCD", "MSFT"];
T = T(:,[timeColumn assetSymbols]);

% Convert to timetable
pricesTT = table2timetable(T,'RowTimes','Dates');

% View the final asset price timetable
head(pricesTT)
```

| Dates       | BA    | CAT   | DIS   | GE   | IBM   | MCD   | MSFT  |
|-------------|-------|-------|-------|------|-------|-------|-------|
| 03-Jan-2006 | 68.63 | 55.86 | 24.18 | 33.6 | 80.13 | 32.72 | 26.19 |

|             |       |       |       |       |       |       |       |
|-------------|-------|-------|-------|-------|-------|-------|-------|
| 04-Jan-2006 | 69.34 | 57.29 | 23.77 | 33.56 | 80.03 | 33.01 | 26.32 |
| 05-Jan-2006 | 68.53 | 57.29 | 24.19 | 33.47 | 80.56 | 33.05 | 26.34 |
| 06-Jan-2006 | 67.57 | 58.43 | 24.52 | 33.7  | 82.96 | 33.25 | 26.26 |
| 09-Jan-2006 | 67.01 | 59.49 | 24.78 | 33.61 | 81.76 | 33.88 | 26.21 |
| 10-Jan-2006 | 67.33 | 59.25 | 25.09 | 33.43 | 82.1  | 33.91 | 26.35 |
| 11-Jan-2006 | 68.3  | 59.28 | 25.33 | 33.66 | 82.19 | 34.5  | 26.63 |
| 12-Jan-2006 | 67.9  | 60.13 | 25.41 | 33.25 | 81.61 | 33.96 | 26.48 |

## Create Strategy

Test an equal-weighted investment strategy. This strategy invests an equal portion of the available capital into each asset. This example does not describe how to create backtesting strategies. For more information on creating backtesting strategies, see `backtestStrategy`.

Set `'RebalanceFrequency'` to rebalance the portfolio every 60 days. This example does not use a lookback window to rebalance.

```
% Create the strategy
numAssets = size(pricesTT,2);
equalWeightsVector = ones(1,numAssets) / numAssets;
equalWeightsRebalanceFcn = @(~,~) equalWeightsVector;

ewStrategy = backtestStrategy("EqualWeighted",equalWeightsRebalanceFcn, ...
    'RebalanceFrequency',60,... ...
    'LookbackWindow',0,... ...
    'TransactionCosts',0.005,... ...
    'InitialWeights',equalWeightsVector)

ewStrategy =
    backtestStrategy with properties:

        Name: "EqualWeighted"
        RebalanceFcn: @(~,~)equalWeightsVector
        RebalanceFrequency: 60
        TransactionCosts: 0.0050
        LookbackWindow: 0
        InitialWeights: [0.1429 0.1429 0.1429 0.1429 0.1429 0.1429 0.1429]
```

## Run Backtest

Create a backtesting engine and run a backtest over a year of stock data. For more information on creating backtest engines, see `backtestEngine`.

```
% Create the backtesting engine. The backtesting engine properties that hold the
% results are initialized to empty.
backtester = backtestEngine(ewStrategy)

backtester =
    backtestEngine with properties:

        Strategies: [1x1 backtestStrategy]
        RiskFreeRate: 0
        CashBorrowRate: 0
        RatesConvention: "Annualized"
        Basis: 0
        InitialPortfolioValue: 10000
```

```
DateAdjustment: "Previous"
    NumAssets: []
        Returns: []
        Positions: []
        Turnover: []
        BuyCost: []
        SellCost: []

% Run the backtest. The empty properties are now populated with
% timetables of detailed backtest results.
backtester = runBacktest(backtester,pricesTT)

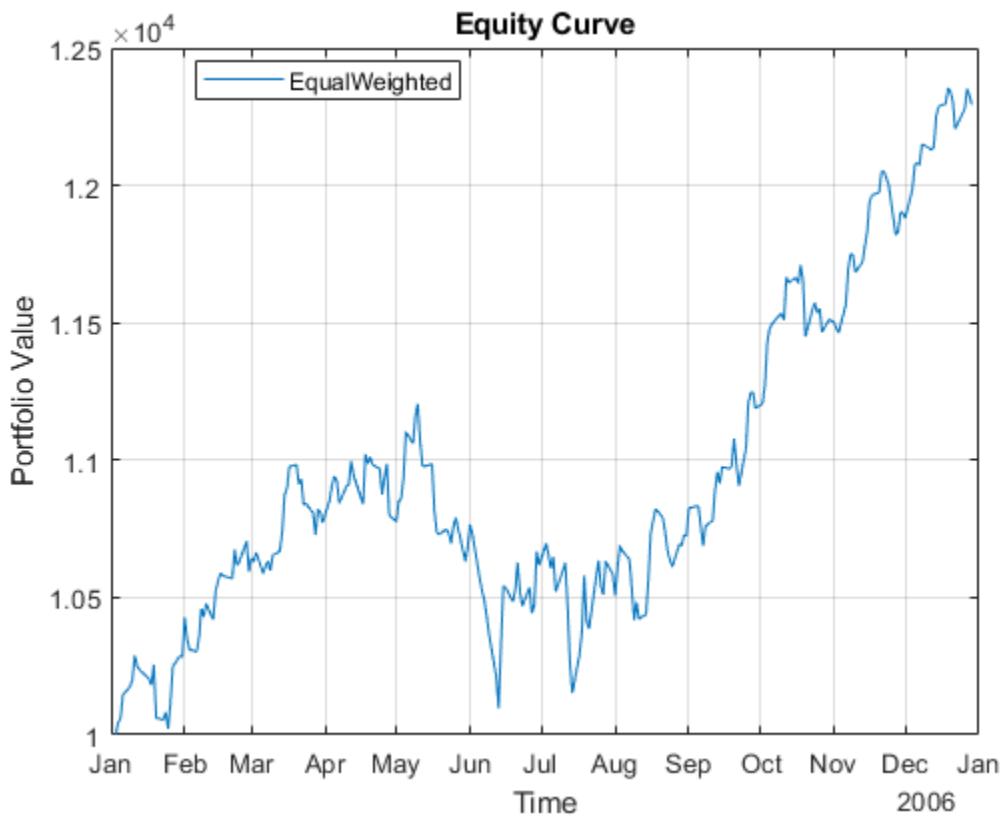

backtester =
    backtestEngine with properties:

        Strategies: [1x1 backtestStrategy]
        RiskFreeRate: 0
        CashBorrowRate: 0
        RatesConvention: "Annualized"

```

## Generate Equity Curve

Use the `equityCurve` to plot the equity curve for the equal-weight strategy.

```
equityCurve(backtester)
```

## Input Arguments

### **backtester — Backtesting engine**

backtestEngine object

Backtesting engine, specified as a backtestEngine object. Use backtestEngine to create the backtester object.

---

**Note** The backtester argument must use a backtestEngine object that has been run using runBacktest.

---

Data Types: object

### **ax — Valid axis object**

object

(Optional) Valid axis object, specified as an ax object that you create using axes. The plot is created on the axes specified by the optional ax argument instead of on the current axes (gca). The optional argument ax can precede any of the input argument combinations.

Data Types: object

## Output Arguments

### **h — Figure handle**

handle object

Figure handle for the equity curve plot, returned as handle object.

## simByEuler

Simulate Bates sample paths by Euler approximation

### Syntax

```
[Paths,Times,Z,N] = simByEuler(MDL,NPeriods)
[Paths,Times,Z,N] = simByEuler(___,Name,Value)
```

### Description

[Paths,Times,Z,N] = simByEuler(MDL,NPeriods) simulates NTrials sample paths of Bates bivariate models driven by NBrowns Brownian motion sources of risk and NJumps compound Poisson processes representing the arrivals of important events over NPeriods consecutive observation periods. The simulation approximates continuous-time stochastic processes by the Euler approach.

[Paths,Times,Z,N] = simByEuler(\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for MonteCarloMethod and QuasiSequence. For more information, see “Quasi-Monte Carlo Simulation” on page 18-62.

### Examples

#### Simulate Bates Sample Paths by Euler Approximation

Create a bates object.

```
AssetPrice = 80;
    Return = 0.03;
    JumpMean = 0.02;
    JumpVol = 0.08;
    JumpFreq = 0.1;

    V0 = 0.04;
    Level = 0.05;
    Speed = 1.0;
    Volatility = 0.2;
    Rho = -0.7;
    StartState = [AssetPrice;V0];
    Correlation = [1 Rho;Rho 1];

batesObj = bates(Return, Speed, Level, Volatility, ...
    JumpFreq, JumpMean, JumpVol, 'startstate', StartState, ...
    'correlation', Correlation)

batesObj =
    Class BATES: Bates Bivariate Stochastic Volatility
-----
Dimensions: State = 2, Brownian = 2
```

```
-----
StartTime: 0
StartState: 2x1 double array
Correlation: 2x2 double array
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Return: 0.03
Speed: 1
Level: 0.05
Volatility: 0.2
JumpFreq: 0.1
JumpMean: 0.02
JumpVol: 0.08
```

Use `simByEuler` to simulate `NTrials` sample paths of this Bates bivariate model driven by `NBrowns` Brownian motion sources of risk and `NJumps` compound Poisson processes representing the arrivals of important events over `NPeriods` consecutive observation periods. This function approximates continuous-time stochastic processes by the Euler approach.

```
NPeriods = 2;
[Paths,Times,Z,N] = simByEuler(batesObj,NPeriods)
```

Paths = 3×2

|         |        |
|---------|--------|
| 80.0000 | 0.0400 |
| 90.8427 | 0.0873 |
| 32.7458 | 0.1798 |

Times = 3×1

|   |
|---|
| 0 |
| 1 |
| 2 |

Z = 2×2

|         |        |
|---------|--------|
| 0.5377  | 0.9333 |
| -2.2588 | 2.1969 |

N = 2×1

|   |
|---|
| 0 |
| 0 |

The output `Paths` is 3 × 2 dimension. Row number 3 is from `NPeriods + 1`. The first row is defined by the `bates` name-value pair argument `StartState`. The remaining rows are simulated data. `Paths` always has two columns because the Bates model is a bivariate model. In this case, the first column is the simulated asset price and the second column is the simulated volatilities.

### Quasi-Monte Carlo Simulation with simByEuler Using a Bates Model

Create a `bates` object.

```
AssetPrice = 80;
    Return = 0.03;
    JumpMean = 0.02;
    JumpVol = 0.08;
    JumpFreq = 0.1;

    V0 = 0.04;
    Level = 0.05;
    Speed = 1.0;
    Volatility = 0.2;
    Rho = -0.7;
    StartState = [AssetPrice;V0];
    Correlation = [1 Rho;Rho 1];

batesObj = bates(Return, Speed, Level, Volatility, ...
    JumpFreq, JumpMean, JumpVol, 'startstate', StartState, ...
    'correlation', Correlation)

batesObj =
    Class BATES: Bates Bivariate Stochastic Volatility
    -----
        Dimensions: State = 2, Brownian = 2
    -----
        StartTime: 0
        StartState: 2x1 double array
        Correlation: 2x2 double array
            Drift: drift rate function F(t,X(t))
            Diffusion: diffusion rate function G(t,X(t))
            Simulation: simulation method/function simByEuler
        Return: 0.03
        Speed: 1
        Level: 0.05
        Volatility: 0.2
        JumpFreq: 0.1
        JumpMean: 0.02
        JumpVol: 0.08
```

Define the quasi-Monte Carlo simulation using the optional name-value arguments for `'MonteCarloMethod'` and `'QuasiSequence'`.

```
%[paths,time,z] = simByEuler(batesObj,10,'ntrials',4096,'method','basic','montecarlomethod','qua
```

## Input Arguments

**MDL — Stochastic differential equation model object**

Stochastic differential equation model, specified as a `bates` object. You can create a `bates` object using `bates`.

Data Types: object

**NPeriods — Number of simulation periods**

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of **NPeriods** determines the number of rows of the simulated output series.

Data Types: double

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[Paths,Times,Z,N] = simByEuler(bates,NPeriods,'DeltaTimes',dt)`

**NTrials — Simulated trials (sample paths)**

1 (single path of correlated state variables) (default) | positive scalar integer

Simulated trials (sample paths) of **NPeriods** observations each, specified as the comma-separated pair consisting of '**NTrials**' and a positive scalar integer.

Data Types: double

**DeltaTimes — Positive time increments between observations**

1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of '**DeltaTimes**' and a scalar or an **NPeriods**-by-1 column vector.

**DeltaTimes** represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: double

**NSteps — Number of intermediate time steps within each time increment *dt***

1 (indicating no intermediate evaluation) (default) | positive scalar integer

Number of intermediate time steps within each time increment *dt* (specified as **DeltaTimes**), specified as the comma-separated pair consisting of '**NSteps**' and a positive scalar integer.

The **simByEuler** function partitions each time increment *dt* into **NSteps** subintervals of length *dt*/**NSteps**, and refines the simulation by evaluating the simulated state vector at **NSteps** – 1 intermediate points. Although **simByEuler** does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: double

**Antithetic — Flag to use antithetic sampling to generate the Gaussian random variates**

false (no antithetic sampling) (default) | logical with values true or false

Flag to use antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as the comma-separated pair consisting of '**Antithetic**' and a scalar numeric or logical 1 (true) or 0 (false).

When you specify `true`, `simByEuler` performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials ( $1, 3, 5, \dots$ ) correspond to the primary Gaussian paths.
- Even trials ( $2, 4, 6, \dots$ ) are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

**Note** If you specify an input noise process (see `Z`), `simByEuler` ignores the value of `Antithetic`.

---

Data Types: `logical`

**Z — Direct specification of the dependent random noise process for generating Brownian motion vector**

generates correlated Gaussian variates based on the `Correlation` member of the `SDE` object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process for generating the Brownian motion vector (Wiener process) that drives the simulation, specified as the comma-separated pair consisting of '`Z`' and a function or as an (`NPeriods`  $\square$  `NSteps`) -by-`NBrowns`-by-`NTrials` three-dimensional array of dependent random variates.

**Note** If you specify `Z` as a function, it must return an `NBrowns`-by-1 column vector, and you must call it with two inputs:

- A real-valued scalar observation time  $t$
  - An `NVars`-by-1 state vector  $X_t$
- 

Data Types: `double` | function

**N — Dependent random counting process for generating number of jumps**

random numbers from Poisson distribution with parameter `JumpFreq` from a `bates` object (default) | three-dimensional array | function

Dependent random counting process for generating the number of jumps, specified as the comma-separated pair consisting of '`N`' and a function or an (`NPeriods`  $\square$  `NSteps`) -by-`NJumps`-by-`NTrials` three-dimensional array of dependent random variates.

**Note** If you specify a function, `N` must return an `NJumps`-by-1 column vector, and you must call it with two inputs: a real-valued scalar observation time  $t$  followed by an `NVars`-by-1 state vector  $X_t$ .

---

Data Types: `double` | function

**StorePaths — Flag that indicates how Paths is stored and returned**

`true` (default) | logical with values `true` or `false`

Flag that indicates how the output array `Paths` is stored and returned, specified as the comma-separated pair consisting of '`StorePaths`' and a scalar numeric or logical 1 (`true`) or 0 (`false`).

If `StorePaths` is `true` (the default value) or is unspecified, `simByEuler` returns `Paths` as a three-dimensional time-series array.

If `StorePaths` is `false` (logical 0), `simByEuler` returns `Paths` as an empty matrix.

Data Types: logical

#### **MonteCarloMethod — Monte Carlo method to simulate stochastic processes**

"standard" (default) | string with values "standard", "quasi", or "randomized-quasi" | character vector with values 'standard', 'quasi', or 'randomized-quasi'

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of 'MonteCarloMethod' and a string or character vector with one of the following values:

- "standard" — Monte Carlo using pseudo random numbers.
- "quasi" — Quasi-Monte Carlo using low-discrepancy sequences.
- "randomized-quasi" — Randomized quasi-Monte Carlo.

---

**Note** If you specify an input noise process (see `Z` and `N`), `simByEuler` ignores the value of `MonteCarloMethod`.

---

Data Types: string | char

#### **QuasiSequence — Low discrepancy sequence to drive the stochastic processes**

"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of 'QuasiSequence' and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

---

**Note** If `MonteCarloMethod` option is not specified or specified as "standard", `QuasiSequence` is ignored.

---

Data Types: string | char

#### **Processes — Sequence of end-of-period processes or state vector adjustments**

`simByEuler` makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The `simByEuler` function runs processing functions at each interpolation time. The functions must accept the current interpolation time  $t$ , and the current state vector  $X_t$  and return a state vector that can be an adjustment to the input state.

If you specify more than one processing function, `simByEuler` invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

The end-of-period `Processes` argument allows you to terminate a given trial early. At the end of each time step, `simByEuler` tests the state vector  $X_t$  for an all-NaN condition. Thus, to signal an early termination of a given trial, all elements of the state vector  $X_t$  must be NaN. This test enables you to define a `Processes` function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

Data Types: `cell` | `function`

## Output Arguments

**Paths — Simulated paths of correlated state variables**  
array

Simulated paths of correlated state variables, returned as a `(NPeriods + 1)-by-NVars-by-NTrials` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector  $X_t$  at time  $t$ . When `StorePaths` is set to `false`, `simByEuler` returns `Paths` as an empty matrix.

**Times — Observation times associated with simulated paths**  
column vector

Observation times associated with the simulated paths, returned as an `(NPeriods + 1)-by-1` column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

**Z — Dependent random variates for generating Brownian motion vector**  
array

Dependent random variates for generating the Brownian motion vector (Wiener processes) that drive the simulation, returned as an `(NPeriods  $\square$  NSteps)-by-NBrowns-by-NTrials` three-dimensional time-series array.

**N — Dependent random variates for generating jump counting process vector**  
array

Dependent random variates used to generate the jump counting process vector, returned as an `(NPeriods  $\square$  NSteps)-by-NJumps-by-NTrials` three-dimensional time series array.

## More About

### Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another that has the same expected value but a smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent other pairs, but the two paths within each pair are

highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

## Algorithms

Bates models are bivariate composite models. Each Bates model consists of two coupled univariate models.

- One model is a geometric Brownian motion (`gbm`) model with a stochastic volatility function and jumps.

$$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t} + Y(t)X_{1t}dN_t$$

This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.

- The other model is a Cox-Ingersoll-Ross (`cir`) square root diffusion model.

$$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

This model describes the evolution of the variance rate of the coupled Bates price process.

This simulation engine provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion. Thus, the discrete-time process approaches the true continuous-time process only as `DeltaTimes` approaches zero.

# simByEuler

Simulate Merton jump diffusion sample paths by Euler approximation

## Syntax

```
[Paths,Times,Z,N] = simByEuler(MDL,NPeriods)
[Paths,Times,Z,N] = simByEuler(___,Name,Value)
```

## Description

`[Paths,Times,Z,N] = simByEuler(MDL,NPeriods)` simulates `N` trials sample paths of `NVars` correlated state variables driven by `NBrowns` Brownian motion sources of risk and `NJumps` compound Poisson processes representing the arrivals of important events over `NPeriods` consecutive observation periods. The simulation approximates the continuous-time Merton jump diffusion process by the Euler approach.

`[Paths,Times,Z,N] = simByEuler(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for `MonteCarloMethod` and `QuasiSequence`. For more information, see “Quasi-Monte Carlo Simulation” on page 18-62.

## Examples

### Simulate Merton Jump Diffusion Sample Paths by Euler Approximation

Create a `merton` object.

```
AssetPrice = 80;
    Return = 0.03;
    Sigma = 0.16;
    JumpMean = 0.02;
    JumpVol = 0.08;
    JumpFreq = 2;

    mertonObj = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol, ...
        'startstat',AssetPrice)

mertonObj =
    Class MERTON: Merton Jump Diffusion
    -----
        Dimensions: State = 1, Brownian = 1
    -----
        StartTime: 0
        StartState: 80
        Correlation: 1
            Drift: drift rate function F(t,X(t))
            Diffusion: diffusion rate function G(t,X(t))
            Simulation: simulation method/function simByEuler
```

```
Sigma: 0.16
Return: 0.03
JumpFreq: 2
JumpMean: 0.02
JumpVol: 0.08
```

Use **simByEuler** to simulate **NTrials** sample paths of **NVars** correlated state variables driven by **NBrowns** Brownian motion sources of risk and **NJumps** compound Poisson processes representing the arrivals of important events over **NPeriods** consecutive observation periods. The function **simByEuler** approximates a continuous-time Merton jump diffusion process by the Euler approach.

```
NPeriods = 2;
[Paths,Times,Z,N] = simByEuler(mertonObj,NPeriods)
```

Paths = 3×1

```
80.0000
266.5590
306.2600
```

Times = 3×1

```
0
1
2
```

Z = 2×1

```
1.8339
-2.2588
```

N = 2×1

```
1
2
```

Paths is a 3-by-1 matrix. The only column is the path of the simulated **AssetPrice**. The output Z is a series of matrices used to generate the Brownian motion vector. The output N is a series of matrices used to generate jump vectors.

### Quasi-Monte Carlo Simulation with **simByEuler** Using a Merton Model

Create a **merton** object.

```
AssetPrice = 80;
    Return = 0.03;
    Sigma = 0.16;
    JumpMean = 0.02;
    JumpVol = 0.08;
    JumpFreq = 2;
```

```
mertonObj = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol,...  
    'startstat',AssetPrice)

mertonObj =  
    Class MERTON: Merton Jump Diffusion  
    -----  
        Dimensions: State = 1, Brownian = 1  
    -----  
        StartTime: 0  
        StartState: 80  
        Correlation: 1  
            Drift: drift rate function F(t,X(t))  
            Diffusion: diffusion rate function G(t,X(t))  
            Simulation: simulation method/function simByEuler  
                Sigma: 0.16  
                Return: 0.03  
                JumpFreq: 2  
                JumpMean: 0.02  
                JumpVol: 0.08
```

Define the quasi-Monte Carlo simulation using the optional name-value arguments for 'MonteCarloMethod' and 'QuasiSequence'.

```
%[paths,time,z] = simByEuler(mertonObj,10,'ntrials',4096,'method','basic','montecarlomethod','qua
```

## Input Arguments

**MDL — Stochastic differential equation model**  
object

Stochastic differential equation model, specified as a `merton` object. You can create a `merton` object using `merton`.

Data Types: object

**NPeriods — Number of simulation periods**  
positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: double

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1`, ..., `NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[Paths,Times,Z,N] = simByEuler(merton,NPeriods,'DeltaTimes',dt)`

**NTrials — Simulated trials (sample paths)**

1 (single path of correlated state variables) (default) | positive scalar integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as the comma-separated pair consisting of '`NTrials`' and a positive scalar integer.

Data Types: double

**DeltaTimes — Positive time increments between observations**

1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of '`DeltaTimes`' and a scalar or a `NPeriods`-by-1 column vector.

`DeltaTimes` represents the familiar  $dt$  found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: double

**NSteps — Number of intermediate time steps within each time increment**

1 (indicating no intermediate evaluation) (default) | positive scalar integer

Number of intermediate time steps within each time increment  $dt$  (specified as `DeltaTimes`), specified as the comma-separated pair consisting of '`NSteps`' and a positive scalar integer.

The `simByEuler` function partitions each time increment  $dt$  into `NSteps` subintervals of length  $dt/NSteps$ , and refines the simulation by evaluating the simulated state vector at `NSteps - 1` intermediate points. Although `simByEuler` does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: double

**Antithetic — Flag to use antithetic sampling to generate the Gaussian random variates**

false (no antithetic sampling) (default) | logical with values true or false

Flag to use antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as the comma-separated pair consisting of '`Antithetic`' and a scalar numeric or logical 1 (`true`) or 0 (`false`).

When you specify `true`, `simByEuler` performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials (1, 3, 5, ...) correspond to the primary Gaussian paths.
- Even trials (2, 4, 6, ...) are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

---

**Note** If you specify an input noise process (see `Z`), `simByEuler` ignores the value of `Antithetic`.

---

Data Types: logical

**Z — Direct specification of the dependent random noise process for generating Brownian motion vector**

generates correlated Gaussian variates based on the `Correlation` member of the `SDE` object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process for generating the Brownian motion vector (Wiener process) that drives the simulation, specified as the comma-separated pair consisting

of 'Z' and a function or as an (`NPeriods`  $\square$  `NSteps`) -by-`NBrowns`-by-`NTrials` three-dimensional array of dependent random variates.

---

**Note** If you specify `Z` as a function, it must return an `NBrowns`-by-1 column vector, and you must call it with two inputs:

- A real-valued scalar observation time  $t$
  - An `NVars`-by-1 state vector  $X_t$
- 

Data Types: double | function

**N — Dependent random counting process for generating number of jumps**

random numbers from Poisson distribution with parameter `JumpFreq` from `merton` object (default) | three-dimensional array | function

Dependent random counting process for generating the number of jumps, specified as the comma-separated pair consisting of 'N' and a function or an (`NPeriods`  $\square$  `NSteps`) -by-`NJumps`-by-`NTrials` three-dimensional array of dependent random variates.

If you specify a function, `N` must return an `NJumps`-by-1 column vector, and you must call it with two inputs: a real-valued scalar observation time  $t$  followed by an `NVars`-by-1 state vector  $X_t$ .

Data Types: double | function

**StorePaths — Flag that indicates how Paths is stored and returned**

true (default) | logical with values true or false

Flag that indicates how the output array `Paths` is stored and returned, specified as the comma-separated pair consisting of 'StorePaths' and a scalar numeric or logical 1 (true) or 0 (false).

If `StorePaths` is true (the default value) or is unspecified, `simByEuler` returns `Paths` as a three-dimensional time series array.

If `StorePaths` is false (logical 0), `simByEuler` returns `Paths` as an empty matrix.

Data Types: logical

**MonteCarloMethod — Monte Carlo method to simulate stochastic processes**

"standard" (default) | string with values "standard", "quasi", or "randomized-quasi" | character vector with values 'standard', 'quasi', or 'randomized-quasi'

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of 'MonteCarloMethod' and a string or character vector with one of the following values:

- "standard" — Monte Carlo using pseudo random numbers.
- "quasi" — Quasi-Monte Carlo using low-discrepancy sequences.
- "randomized-quasi" — Randomized quasi-Monte Carlo.

---

**Note** If you specify an input noise process (see `Z` and `N`), `simByEuler` ignores the value of `MonteCarloMethod`.

---

Data Types: string | char

**QuasiSequence — Low discrepancy sequence to drive the stochastic processes**

"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of 'QuasiSequence' and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

---

**Note** If MonteCarloMethod option is not specified or specified as "standard", QuasiSequence is ignored.

---

Data Types: string | char

**Processes — Sequence of end-of-period processes or state vector adjustments**

simByEuler makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The simByEuler function runs processing functions at each interpolation time. The functions must accept the current interpolation time  $t$ , and the current state vector  $X_t$  and return a state vector that can be an adjustment to the input state.

If you specify more than one processing function, simByEuler invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

The end-of-period Processes argument allows you to terminate a given trial early. At the end of each time step, simByEuler tests the state vector  $X_t$  for an all-NaN condition. Thus, to signal an early termination of a given trial, all elements of the state vector  $X_t$  must be NaN. This test enables you to define a Processes function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

Data Types: cell | function

## Output Arguments

**Paths — Simulated paths of correlated state variables**

array

Simulated paths of correlated state variables, returned as an (NPeriods + 1)-by-NVars-by-NTrials three-dimensional time series array.

For a given trial, each row of Paths is the transpose of the state vector  $X_t$  at time  $t$ . When StorePaths is set to false, simByEuler returns Paths as an empty matrix.

**Times — Observation times associated with simulated paths**

column vector

Observation times associated with the simulated paths, returned as an (`NPeriods + 1`)-by-1 column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

**Z — Dependent random variates for generating Brownian motion vector**

array

Dependent random variates used to generate the Brownian motion vector (Wiener processes) that drive the simulation, returned as an (`NPeriods`  $\square$  `NSteps`)-by-`NBrowns`-by-`NTrials` three-dimensional time-series array.

**N — Dependent random variates used for generating jump counting process vector**

array

Dependent random variates for generating the jump counting process vector, returned as an (`NPeriods`  $\square$  `NSteps`)-by-`NJumps`-by-`NTrials` three-dimensional time-series array.

## More About

### Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another that has the same expected value but a smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent other pairs, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

## Algorithms

This function simulates any vector-valued SDE of the following form:

$$dX_t = B(t, X_t)X_t dt + D(t, X_t)V(t, x_t)dW_t + Y(t, X_t, N_t)X_t dN_t$$

Here:

- $X_t$  is an `NVars`-by-1 state vector of process variables.
- $B(t, X_t)$  is an `NVars`-by-`NVars` matrix of generalized expected instantaneous rates of return.
- $D(t, X_t)$  is an `NVars`-by-`NVars` diagonal matrix in which each element along the main diagonal is the corresponding element of the state vector.
- $V(t, X_t)$  is an `NVars`-by-`NVars` matrix of instantaneous volatility rates.

- $dW_t$  is an **NBrowns**-by-1 Brownian motion vector.
- $Y(t, X_t, N_t)$  is an **NVars**-by-**NJumps** matrix-valued jump size function.
- $dN_t$  is an **NJumps**-by-1 counting process vector.

`simByEuler` simulates **NTrials** sample paths of **NVars** correlated state variables driven by **NBrowns** Brownian motion sources of risk over **NPeriods** consecutive observation periods, using the Euler approach to approximate continuous-time stochastic processes.

This simulation engine provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion. Thus, the discrete-time process approaches the true continuous-time process only as **DeltaTimes** approaches zero.

### Introduced in R2020a

# simBySolution

Simulate approximate solution of diagonal-drift Merton jump diffusion process

## Syntax

```
[Paths,Times,Z,N] = simBySolution(MDL,NPeriods)
[Paths,Times,Z,N] = simBySolution(___,Name,Value)
```

## Description

`[Paths,Times,Z,N] = simBySolution(MDL,NPeriods)` simulates `NNTrials` sample paths of `NVars` correlated state variables driven by `NBrowns` Brownian motion sources of risk and `NJumps` compound Poisson processes representing the arrivals of important events over `NPeriods` consecutive observation periods. The simulation approximates continuous-time Merton jump diffusion process by an approximation of the closed-form solution.

`[Paths,Times,Z,N] = simBySolution(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for `MonteCarloMethod` and `QuasiSequence`. For more information, see “Quasi-Monte Carlo Simulation” on page 18-62.

## Examples

### Use simBySolution with merton Object

Simulate the approximate solution of diagonal-drift Merton process.

Create a `merton` object.

```
AssetPrice = 80;
    Return = 0.03;
    Sigma = 0.16;
    JumpMean = 0.02;
    JumpVol = 0.08;
    JumpFreq = 2;

    mertonObj = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol, ...
        'startstat',AssetPrice)

mertonObj =
Class MERTON: Merton Jump Diffusion
-----
Dimensions: State = 1, Brownian = 1
-----
StartTime: 0
StartState: 80
Correlation: 1
Drift: drift rate function F(t,X(t))
```

```
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
    Sigma: 0.16
    Return: 0.03
    JumpFreq: 2
    JumpMean: 0.02
    JumpVol: 0.08
```

Use `simBySolution` to simulate `NTrials` sample paths of `NVARS` correlated state variables driven by `NBrowns` Brownian motion sources of risk and `NJumps` compound Poisson processes representing the arrivals of important events over `NPeriods` consecutive observation periods. The function approximates continuous-time Merton jump diffusion process by an approximation of the closed-form solution.

```
nPeriods = 100;
[Paths,Times,Z,N] = simBySolution(mertonObj, nPeriods, 'nTrials', 3)

### Quasi-Monte Carlo Simulation Using Merton Model

This example shows how to use `simBySolution` with a Merton model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead pseudo random numbers.

Create a `merton` object.

```
AssetPrice = 80;
Return = 0.03;
Sigma = 0.16;
JumpMean = 0.02;
JumpVol = 0.08;
JumpFreq = 2;

Merton = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol,'startstat',AssetPrice)

Merton =
  Class MERTON: Merton Jump Diffusion
  -----
    Dimensions: State = 1, Brownian = 1
  -----
    StartTime: 0
    StartState: 80
    Correlation: 1
      Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
      Simulation: simulation method/function simByEuler
      Sigma: 0.16
      Return: 0.03
      JumpFreq: 2
      JumpMean: 0.02
      JumpVol: 0.08
```

Perform a quasi-Monte Carlo simulation by using `simBySolution` with the optional name-value arguments for 'MonteCarloMethod' and 'QuasiSequence'.

```
[paths,time,z,n] = simBySolution(Merton, 10,'ntrials',4096,'montecarlomethod','quasi','QuasiSeque
```

## Input Arguments

### MDL — Merton model

`merton` object

Merton model, specified as a `merton` object. You can create a `merton` object using `merton`.

Data Types: `object`

### NPeriods — Number of simulation periods

positive integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1`, ..., `NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: [Paths,Times,Z,N] =  
simBySolution(merton,NPeriods,'DeltaTimes',dt,'NNTrials',10)

**NNTrials — Simulated NTrials (sample paths)**

1 (single path of correlated state variables) (default) | positive integer

Simulated NTrials (sample paths) of NPeriods observations each, specified as the comma-separated pair consisting of 'NNTrials' and a positive scalar integer.

Data Types: double

**DeltaTimes — Positive time increments between observations**

1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of 'DeltaTimes' and a scalar or an NPeriods-by-1 column vector.

DeltaTimes represents the familiar  $dt$  found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: double

**NSteps — Number of intermediate time steps within each time increment**

1 (indicating no intermediate evaluation) (default) | positive integer

Number of intermediate time steps within each time increment  $dt$  (specified as DeltaTimes), specified as the comma-separated pair consisting of 'NSteps' and a positive scalar integer.

The simBySolution function partitions each time increment  $dt$  into NSteps subintervals of length  $dt/NSteps$ , and refines the simulation by evaluating the simulated state vector at NSteps – 1 intermediate points. Although simBySolution does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: double

**Antithetic — Flag to use antithetic sampling to generate the Gaussian random variates**  
false (no antithetic sampling) (default) | logical with values true or false

Flag to use antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as the comma-separated pair consisting of 'Antithetic' and a scalar numeric or logical 1 (true) or 0 (false).

When you specify true, simBySolution performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd NTrials (1, 3, 5, ...) correspond to the primary Gaussian paths.
- Even NTrials (2, 4, 6, ...) are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

---

**Note** If you specify an input noise process (see Z), simBySolution ignores the value of Antithetic.

---

Data Types: logical

**MonteCarloMethod — Monte Carlo method to simulate stochastic processes**

"standard" (default) | string with values "standard", "quasi", or "randomized-quasi" | character vector with values 'standard', 'quasi', or 'randomized-quasi'

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of 'MonteCarloMethod' and a string or character vector with one of the following values:

- "standard" — Monte Carlo using pseudo random numbers.
- "quasi" — Quasi-Monte Carlo using low-discrepancy sequences.
- "randomized-quasi" — Randomized quasi-Monte Carlo.

---

**Note** If you specify an input noise process (see Z and N), simBySolution ignores the value of MonteCarloMethod.

---

Data Types: string | char

**QuasiSequence — Low discrepancy sequence to drive the stochastic processes**

"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of 'QuasiSequence' and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

---

**Note**

- If MonteCarloMethod option is not specified or specified as "standard", QuasiSequence is ignored.
  - If you specify an input noise process (see Z), simBySolution ignores the value of QuasiSequence.
- 

Data Types: string | char

**Z — Direct specification of the dependent random noise process for generating Brownian motion vector**

generates correlated Gaussian variates based on the Correlation member of the SDE object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process for generating the Brownian motion vector (Wiener process) that drives the simulation, specified as the comma-separated pair consisting of 'Z' and a function or an (NPeriods \* NSteps)-by-NBrowns-by-NNTrials three-dimensional array of dependent random variates.

The input argument Z allows you to directly specify the noise generation process. This process takes precedence over the Correlation parameter of the input merton object and the value of the Antithetic input flag.

Specifically, when Z is specified, Correlation is not explicitly used to generate the Gaussian variates that drive the Brownian motion. However, Correlation is still used in the expression that

appears in the exponential term of the  $\log[X_t]$  Euler scheme. Thus, you must specify  $Z$  as a correlated Gaussian noise process whose correlation structure is consistently captured by **Correlation**.

**Note** If you specify  $Z$  as a function, it must return an  $N_{\text{Browns}}$ -by-1 column vector, and you must call it with two inputs:

- A real-valued scalar observation time  $t$
  - An  $N_{\text{Vars}}$ -by-1 state vector  $X_t$
- 

Data Types: double | function

**N — Dependent random counting process for generating number of jumps**

random numbers from Poisson distribution with `merton` object parameter `JumpFreq` (default) | three-dimensional array | function

Dependent random counting process for generating the number of jumps, specified as the comma-separated pair consisting of 'N' and a function or an  $(N_{\text{Periods}} \times N_{\text{Steps}})$ -by- $N_{\text{Jumps}}$ -by- $N_{\text{Trials}}$  three-dimensional array of dependent random variates. If you specify a function,  $N$  must return an  $N_{\text{Jumps}}$ -by-1 column vector, and you must call it with two inputs: a real-valued scalar observation time  $t$  followed by an  $N_{\text{Vars}}$ -by-1 state vector  $X_t$ .

Data Types: double | function

**StorePaths — Flag that indicates how Paths is stored and returned**

true (default) | logical with values true or false

Flag that indicates how the output array `Paths` is stored and returned, specified as the comma-separated pair consisting of 'StorePaths' and a scalar numeric or logical 1 (true) or 0 (false).

If `StorePaths` is true (the default value) or is unspecified, `simBySolution` returns `Paths` as a three-dimensional time series array.

If `StorePaths` is false (logical 0), `simBySolution` returns `Paths` as an empty matrix.

Data Types: logical

**Processes — Sequence of end-of-period processes or state vector adjustments of the form**

`simBySolution` makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

`simBySolution` applies processing functions at the end of each observation period. These functions must accept the current observation time  $t$  and the current state vector  $X_t$ , and return a state vector that can be an adjustment to the input state.

The end-of-period `Processes` argument allows you to terminate a given trial early. At the end of each time step, `simBySolution` tests the state vector  $X_t$  for an all-NaN condition. Thus, to signal an early termination of a given trial, all elements of the state vector  $X_t$  must be NaN. This test enables a user-

defined `Processes` function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

If you specify more than one processing function, `simBySolution` invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

Data Types: `cell` | `function`

## Output Arguments

### **Paths — Simulated paths of correlated state variables**

array

Simulated paths of correlated state variables, returned as an  $(N\text{Periods} + 1)$ -by- $N\text{Vars}$ -by- $N\text{NTrials}$  three-dimensional time-series array.

For a given trial, each row of `Paths` is the transpose of the state vector  $X_t$  at time  $t$ . When `StorePaths` is set to `false`, `simBySolution` returns `Paths` as an empty matrix.

### **Times — Observation times associated with simulated paths**

column vector

Observation times associated with the simulated paths, returned as an  $(N\text{Periods} + 1)$ -by-1 column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

### **Z — Dependent random variates for generating the Brownian motion vector**

array

Dependent random variates for generating the Brownian motion vector (Wiener processes) that drive the simulation, returned as a  $(N\text{Periods} * N\text{Steps})$ -by- $N\text{Browns}$ -by- $N\text{NTrials}$  three-dimensional time-series array.

### **N — Dependent random variates for generating the jump counting process vector**

array

Dependent random variates for generating the jump counting process vector, returned as an  $(N\text{Periods} \square N\text{Steps})$ -by- $N\text{Jumps}$ -by- $N\text{NTrials}$  three-dimensional time-series array.

## More About

### Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another that has the same expected value but a smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent other pairs, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo `NTrials`.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

## Algorithms

The `simBySolution` function simulates the state vector  $X_t$  by an approximation of the closed-form solution of diagonal drift Merton jump diffusion models. Specifically, it applies a Euler approach to the transformed  $\log[X_t]$  process (using Ito's formula). In general, this is not the exact solution to the Merton jump diffusion model because the probability distributions of the simulated and true state vectors are identical only for piecewise constant parameters.

This function simulates any vector-valued `merton` process of the form

$$dX_t = B(t, X_t)X_t dt + D(t, X_t)V(t, x_t)dW_t + Y(t, X_t, N_t)X_t dN_t$$

Here:

- $X_t$  is an NVars-by-1 state vector of process variables.
- $B(t, X_t)$  is an NVars-by-NVars matrix of generalized expected instantaneous rates of return.
- $D(t, X_t)$  is an NVars-by-NVars diagonal matrix in which each element along the main diagonal is the corresponding element of the state vector.
- $V(t, X_t)$  is an NVars-by-NVars matrix of instantaneous volatility rates.
- $dW_t$  is an NBrowns-by-1 Brownian motion vector.
- $Y(t, X_t, N_t)$  is an NVars-by-NJumps matrix-valued jump size function.
- $dN_t$  is an NJumps-by-1 counting process vector.

## simByQuadExp

Simulate Bates, Heston, and CIR sample paths by quadratic-exponential discretization scheme

### Syntax

```
[Paths,Times,Z] = simByQuadExp(MDL,NPeriods)
[Paths,Times,Z] = simByQuadExp(___,Name,Value)

[Paths,Times,Z,N] = simByQuadExp(MDL,NPeriods)
[Paths,Times,Z,N] = simByQuadExp(___,Name,Value)
```

### Description

`[Paths,Times,Z] = simByQuadExp(MDL,NPeriods)` simulates `NTrials` sample paths of a Heston model driven by two Brownian motion sources of risk, or a CIR model driven by one Brownian motion source of risk. Both Heston and Bates models approximate continuous-time stochastic processes by a quadratic-exponential discretization scheme. The `simByQuadExp` simulation derives directly from the stochastic differential equation of motion; the discrete-time process approaches the true continuous-time process only in the limit as `DeltaTimes` approaches zero.

`[Paths,Times,Z] = simByQuadExp(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

`[Paths,Times,Z,N] = simByQuadExp(MDL,NPeriods)` simulates `NTrials` sample paths of a Bates model driven by two Brownian motion sources of risk, approximating continuous-time stochastic processes by a quadratic-exponential discretization scheme. The `simByQuadExp` simulation derives directly from the stochastic differential equation of motion; the discrete-time process approaches the true continuous-time process only in the limit as `DeltaTimes` approaches zero.

`[Paths,Times,Z,N] = simByQuadExp(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for `MonteCarloMethod` and `QuasiSequence`. For more information, see “Quasi-Monte Carlo Simulation” on page 18-62.

### Examples

#### Simulate Bates Sample Paths by Quadratic-Exponential Discretization Scheme

Create a `bates` object.

```
AssetPrice = 80;
    Return = 0.03;
    JumpMean = 0.02;
    JumpVol = 0.08;
    JumpFreq = 0.1;
```

```

V0 = 0.04;
Level = 0.05;
Speed = 1.0;
Volatility = 0.2;
Rho = -0.7;
StartState = [AssetPrice;V0];
Correlation = [1 Rho;Rho 1];

batesObj = bates(Return, Speed, Level, Volatility, ...
    JumpFreq, JumpMean, JumpVol, 'startstate', StartState, ...
    'correlation', Correlation)

batesObj =
    Class BATES: Bates Bivariate Stochastic Volatility
    -----
        Dimensions: State = 2, Brownian = 2
    -----
        StartTime: 0
        StartState: 2x1 double array
        Correlation: 2x2 double array
        Drift: drift rate function F(t,X(t))
        Diffusion: diffusion rate function G(t,X(t))
        Simulation: simulation method/function simByEuler
        Return: 0.03
        Speed: 1
        Level: 0.05
        Volatility: 0.2
        JumpFreq: 0.1
        JumpMean: 0.02
        JumpVol: 0.08

```

Use `simByQuadExp` to simulate `NTrials` sample paths directly from the stochastic differential equation of motion; the discrete-time process approaches the true continuous-time process only in the limit as `DeltaTimes` approaches zero.

```
NPeriods = 2;
[Paths,Times,Z,N] = simByQuadExp(batesObj,NPeriods)
```

Paths = 3x2

|         |        |
|---------|--------|
| 80.0000 | 0.0400 |
| 64.3377 | 0.1063 |
| 31.5703 | 0.1009 |

Times = 3x1

|   |
|---|
| 0 |
| 1 |
| 2 |

Z = 2x2

|         |        |
|---------|--------|
| 0.5377  | 1.8339 |
| -2.2588 | 0.8622 |

```
N = 2x1
```

```
0  
0
```

The output `Paths` is returned as a (`NPeriods + 1`)-by-`NVars`-by-`NTrials` three-dimensional time-series array.

### Quasi-Monte Carlo Simulation Using Bates Model

This example shows how to use `simByQuadExp` with a Bates model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead pseudo random numbers.

Define the parameters for the `bates` object.

```
AssetPrice = 80;  
Return = 0.03;  
JumpMean = 0.02;  
JumpVol = 0.08;  
JumpFreq = 0.1;  
  
V0 = 0.04;  
Level = 0.05;  
Speed = 1.0;  
Volatility = 0.2;  
Rho = -0.7;  
StartState = [AssetPrice;V0];  
Correlation = [1 Rho;Rho 1];
```

Create a `bates` object.

```
Bates = bates(Return, Speed, Level, Volatility, ...  
    JumpFreq, JumpMean, JumpVol, 'startstate', StartState, ...  
    'correlation', Correlation)  
  
Bates =  
    Class BATES: Bates Bivariate Stochastic Volatility  
    -----  
    Dimensions: State = 2, Brownian = 2  
    -----  
    StartTime: 0  
    StartState: 2x1 double array  
    Correlation: 2x2 double array  
        Drift: drift rate function F(t,X(t))  
        Diffusion: diffusion rate function G(t,X(t))  
        Simulation: simulation method/function simByEuler  
        Return: 0.03  
        Speed: 1  
        Level: 0.05  
    Volatility: 0.2  
    JumpFreq: 0.1  
    JumpMean: 0.02  
    JumpVol: 0.08
```

Perform a quasi-Monte Carlo simulation by using `simByQuadExp` with the optional name-value arguments for 'MonteCarloMethod' and 'QuasiSequence'.

```
[paths,time,z] = simByQuadExp(Bates,10,'ntrials',4096,'montecarlomethod','quasi','quasisequence')
```

## Input Arguments

### **MDL — Stochastic differential equation model**

bates object | heston object | cir object

Stochastic differential equation model, specified as a `bates`, `heston`, or `cir` object. You can create these objects using `bates`, `heston`, or `cir`.

Data Types: object

### **NPeriods — Number of simulation periods**

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: double

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1`, ..., `NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[Paths,Times,Z,N] = simByQuadExp(bates_obj,NPeriods,'DeltaTime',dt)`

### **NTrials — Simulated trials (sample paths) of NPeriods observations each**

1 (single path of correlated state variables) (default) | positive scalar integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as the comma-separated pair consisting of 'NTrials' and a positive scalar integer.

Data Types: double

### **DeltaTime — Positive time increments between observations**

1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of 'DeltaTime' and a scalar or a `NPeriods`-by-1 column vector.

`DeltaTime` represents the familiar  $dt$  found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: double

### **NSteps — Number of intermediate time steps within each time increment $dt$ (specified as `DeltaTime`)**

1 (indicating no intermediate evaluation) (default) | positive scalar integer

Number of intermediate time steps within each time increment  $dt$  (specified as `DeltaTimes`), specified as the comma-separated pair consisting of '`NSteps`' and a positive scalar integer.

The `simByQuadExp` function partitions each time increment  $dt$  into `NSteps` subintervals of length  $dt/NSteps$ , and refines the simulation by evaluating the simulated state vector at `NSteps - 1` intermediate points. Although `simByQuadExp` does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: double

**MonteCarloMethod — Monte Carlo method to simulate stochastic processes**

"standard" (default) | string with values "standard", "quasi", or "randomized-quasi" | character vector with values 'standard', 'quasi', or 'randomized-quasi'

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of '`MonteCarloMethod`' and a string or character vector with one of the following values:

- "standard" — Monte Carlo using pseudo random numbers.
- "quasi" — Quasi-Monte Carlo using low-discrepancy sequences.
- "randomized-quasi" — Randomized quasi-Monte Carlo.

---

**Note** If you specify an input noise process (see `Z` and `N`), `simByQuadExp` ignores the value of `MonteCarloMethod`.

---

Data Types: string | char

**QuasiSequence — Low discrepancy sequence to drive the stochastic processes**

"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of '`QuasiSequence`' and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

---

**Note** If `MonteCarloMethod` option is not specified or specified as "standard", `QuasiSequence` is ignored.

---

Data Types: string | char

**Antithetic — Flag to use antithetic sampling to generate the Gaussian random variates**  
false (no antithetic sampling) (default) | logical with values true or false

Flag to use antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as the comma-separated pair consisting of '`Antithetic`' and a scalar numeric or logical 1 (true) or 0 (false).

When you specify `true`, `simByQuadExp` performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials ( $1, 3, 5, \dots$ ) correspond to the primary Gaussian paths.
- Even trials ( $2, 4, 6, \dots$ ) are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

---

**Note** If you specify an input noise process (see Z), `simByEuler` ignores the value of `Antithetic`.

---

Data Types: logical

### Z — Direct specification of dependent random noise process for generating Brownian motion vector

generates correlated Gaussian variates based on the `Correlation` member of the `heston`, `bates`, or `cir` object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process for generating the Brownian motion vector (Wiener process) that drives the simulation, specified as the comma-separated pair consisting of 'Z' and a function or an (`NPeriods`  $\square$  `NSteps`) -by-`NBrowns`-by-`NTrials` three-dimensional array of dependent random variates.

If you specify Z as a function, it must return an `NBrowns`-by-1 column vector, and you must call it with two inputs:

- A real-valued scalar observation time  $t$
- An `NVars`-by-1 state vector  $X_t$

Data Types: double | function

### N — Dependent random counting process for generating number of jumps

random numbers from Poisson distribution with parameter `JumpFreq` from a `bates` object (default) | three-dimensional array | function

Dependent random counting process for generating the number of jumps, specified as the comma-separated pair consisting of 'N' and a function or an (`NPeriods`  $\square$  `NSteps`) -by-`NJumps`-by-`NTrials` three-dimensional array of dependent random variates. If you specify a function, N must return an `NJumps`-by-1 column vector, and you must call it with two inputs: a real-valued scalar observation time  $t$  followed by an `NVars`-by-1 state vector  $X_t$ .

---

**Note** The N name-value pair argument is supported only when you use a `bates` object for the `MDL` input argument.

---

Data Types: double | function

### StorePaths — Flag that indicates how Paths is stored and returned

true (default) | logical with values true or false

Flag that indicates how the output array `Paths` is stored and returned, specified as the comma-separated pair consisting of 'StorePaths' and a scalar numeric or logical 1 (true) or 0 (false).

If `StorePaths` is true (the default value) or is unspecified, `simByQuadExp` returns `Paths` as a three-dimensional time-series array.

If `StorePaths` is false (logical 0), `simByQuadExp` returns `Paths` as an empty matrix.

Data Types: logical

**Processes — Sequence of end-of-period processes or state vector adjustments**

`simByQuadExp` makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The `simByQuadExp` function runs processing functions at each interpolation time. The functions must accept the current interpolation time  $t$ , and the current state vector  $X_t$  and return a state vector that can be an adjustment to the input state.

If you specify more than one processing function, `simByQuadExp` invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

The end-of-period Processes argument allows you to terminate a given trial early. At the end of each time step, `simByQuadExp` tests the state vector  $X_t$  for an all-NaN condition. Thus, to signal an early termination of a given trial, all elements of the state vector  $X_t$  must be NaN. This test enables you to define a Processes function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

Data Types: cell | function

## Output Arguments

**Paths — Simulated paths of correlated state variables**

array

Simulated paths of correlated state variables for a heston, bates, or cir model, returned as a `(NPeriods + 1)-by-NVars-by-NTrials` three-dimensional time series array.

For a given trial, each row of Paths is the transpose of the state vector  $X_t$  at time  $t$ . When `StorePaths` is set to `false`, `simByQuadExp` returns Paths as an empty matrix.

**Times — Observation times associated with simulated paths**

column vector

Observation times for a heston, bates, or cir model associated with the simulated paths, returned as a `(NPeriods + 1)-by-1` column vector. Each element of Times is associated with the corresponding row of Paths.

**Z — Dependent random variates for generating Brownian motion vector**

array

Dependent random variates for a heston, bates, or cir model for generating the Brownian motion vector (Wiener processes) that drive the simulation, returned as an `(NPeriods ∘ NSteps)-by-NBrowns-by-NTrials` three-dimensional time-series array.

**N — Dependent random variates for generating jump counting process vector**

array

Dependent random variates for a bates model for generating the jump counting process vector, returned as a `(NPeriods × NSteps)-by-NJumps-by-NTrials` three-dimensional time-series array.

## More About

### Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another of the same expected value, but smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent of any other pair, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

## Algorithms

### Heston

In the Heston stochastic volatility model, the asset value process and volatility process are defined as

$$\begin{aligned} dS(t) &= \gamma(t)S(t)dt + \sqrt{V(t)}S(t)dW_S(t) \\ dV(t) &= \kappa(\theta - V(t))dt + \sigma\sqrt{V(t)}dW_V(t) \end{aligned}$$

Here:

- $\gamma$  is the continuous risk-free rate.
- $\theta$  is a long-term variance level.
- $\kappa$  is the mean reversion speed for the variance.
- $\sigma$  is the volatility of volatility.

### CIR

You can simulate any vector-valued CIR process of the form

$$dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW_t$$

Here:

- $X_t$  is an NVars-by-1 state vector of process variables.
- $S$  is an NVars-by-NVars matrix of mean reversion speeds (the rate of mean reversion).
- $L$  is an NVars-by-1 vector of mean reversion levels (long-run mean or level).

- $D$  is an NVars-by-NVars diagonal matrix, where each element along the main diagonal is the square root of the corresponding element of the state vector.
- $V$  is an NVars-by-NBrowns instantaneous volatility rate matrix.
- $dW_t$  is an NBrowns-by-1 Brownian motion vector.

## Bates

Bates models are bivariate composite models. Each Bates model consists of two coupled univariate models.

- A geometric Brownian motion (`gbm`) model with a stochastic volatility function and jumps that is expressed as follows.

$$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t} + Y(t)X_{1t}dN_t$$

This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.

- A Cox-Ingersoll-Ross (`cir`) square root diffusion model that is expressed as follows.

$$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

This model describes the evolution of the variance rate of the coupled Bates price process.

## simByEuler

Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models

### Syntax

```
[Paths,Times,Z] = simByEuler(MDL,NPeriods)
[Paths,Times,Z] = simByEuler(___,Name,Value)
```

### Description

[Paths,Times,Z] = simByEuler(MDL,NPeriods) simulates NTrials sample paths of NVars correlated state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods. simByEuler uses the Euler approach to approximate continuous-time stochastic processes.

[Paths,Times,Z] = simByEuler(\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for MonteCarloMethod and QuasiSequence. For more information, see “Quasi-Monte Carlo Simulation” on page 18-62.

### Examples

#### Simulate Equity Markets Using simByEuler

##### Load the Data and Specify the SDE Model

```
load Data_GlobalIdx2
prices = [Dataset.TSX Dataset.CAC Dataset.DAX ...
          Dataset.NIK Dataset.FTSE Dataset.SP];

returns = tick2ret(prices);

nVariables = size(returns,2);
expReturn = mean(returns);
sigma = std(returns);
correlation = corrcoef(returns);
t = 0;
X = 100;
X = X(ones(nVariables,1));

F = @(t,X) diag(expReturn)* X;
G = @(t,X) diag(X) * diag(sigma);

SDE = sde(F, G, 'Correlation', ...
           correlation, 'StartState', X);
```

### Simulate a Single Path Over a Year

```
nPeriods = 249; % # of simulated observations
dt = 1; % time increment = 1 day
rng(142857,'twister')
[S,T] = simByEuler(SDE, nPeriods, 'DeltaTime', dt);
```

### Simulate 10 trials and examine the SDE model

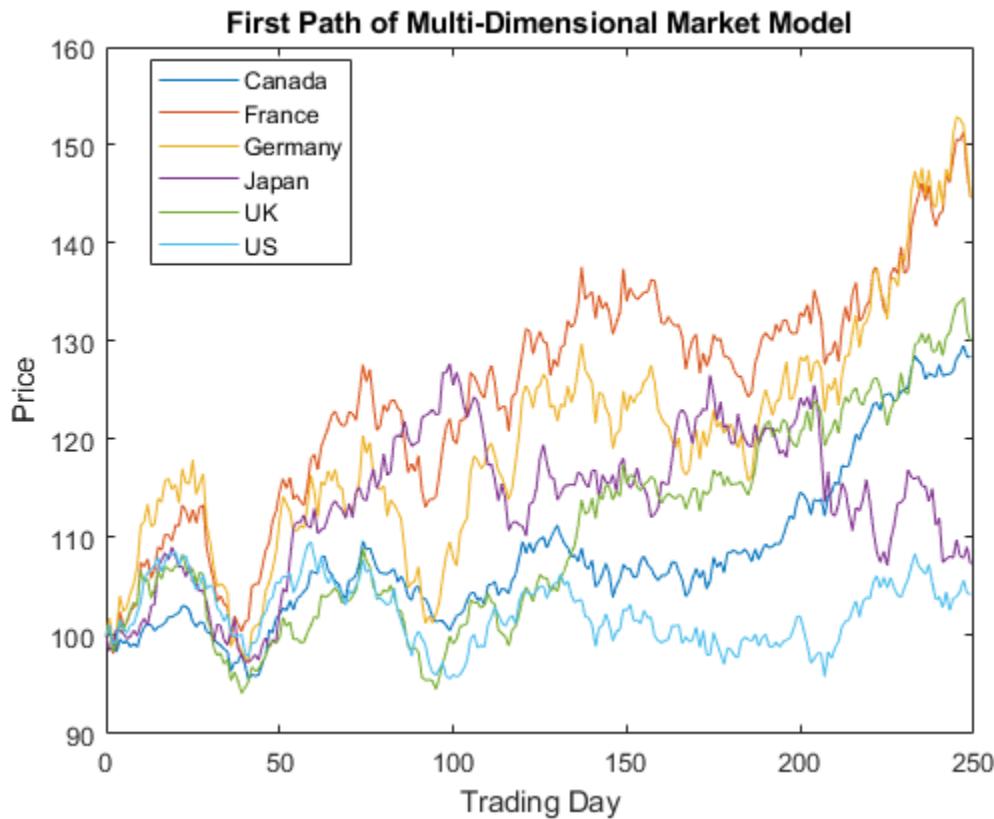

```
rng(142857,'twister')
[S,T] = simulate(SDE, nPeriods, 'DeltaTime', dt, 'nTrials', 10);
```

whos S

| Name | Size     | Bytes  | Class  | Attributes |
|------|----------|--------|--------|------------|
| S    | 250x6x10 | 120000 | double |            |

### Plot the paths

```
plot(T, S(:,:,1)), xlabel('Trading Day'), ylabel('Price')
title('First Path of Multi-Dimensional Market Model')
legend({'Canada' 'France' 'Germany' 'Japan' 'UK' 'US'},...
'Location', 'Best')
```

### Euler Simulation for a CIR Object

The Cox-Ingersoll-Ross (CIR) short rate class derives directly from SDE with mean-reverting drift

$$(SDEMRD): dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW$$

where  $D$  is a diagonal matrix whose elements are the square root of the corresponding element of the state vector.

Create a `cir` object to represent the model:  $dX_t = 0.2(0.1 - X_t)dt + 0.05X_t^{\frac{1}{2}}dW$ .

```
CIR = cir(0.2, 0.1, 0.05) % (Speed, Level, Sigma)
```

```
CIR =
Class CIR: Cox-Ingersoll-Ross
-----
Dimensions: State = 1, Brownian = 1
-----
StartTime: 0
StartState: 1
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Sigma: 0.05
Level: 0.1
Speed: 0.2
```

Simulate a single path over a year using `simByEuler`.

```
nPeriods = 249;      % # of simulated observations
dt       = 1;        % time increment = 1 day
rng(142857, 'twister')
[Paths,Times] = simByEuler(CIR,nPeriods, 'Method', 'higham-mao', 'DeltaTime', dt)
```

```
Paths = 250x1
```

### Quasi-Monte Carlo Simulation with simByEuler Using a CIR Model

The Cox-Ingersoll-Ross (CIR) short rate class derives directly from SDE with mean-reverting drift

$$(SDEM RD): dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW$$

where  $D$  is a diagonal matrix whose elements are the square root of the corresponding element of the state vector.

Create a `cir` object to represent the model:  $dX_t = 0.2(0.1 - X_t)dt + 0.05X_t^{\frac{1}{2}}dW$ .

```

cir_obj = cir(0.2, 0.1, 0.05) % (Speed, Level, Sigma)
cir_obj =
  Class CIR: Cox-Ingersoll-Ross
  -----
  Dimensions: State = 1, Brownian = 1
  -----
  StartTime: 0
  StartState: 1
  Correlation: 1
    Drift: drift rate function F(t,X(t))
    Diffusion: diffusion rate function G(t,X(t))
    Simulation: simulation method/function simByEuler
    Sigma: 0.05
    Level: 0.1
    Speed: 0.2
```

Define the quasi-Monte Carlo simulation using the optional name-value arguments for '`MonteCarloMethod`' and '`QuasiSequence`'.

```
[paths,time,z] = simByEuler(cir_obj,10,'ntrials',4096,'method','basic','montecarlomethod','quasi
```

### Quasi-Monte Carlo Simulation with simByEuler Using a Heston Model

The Heston (`heston`) class derives directly from SDE from Drift and Diffusion (`sdeddo`). Each Heston model is a bivariate composite model, consisting of two coupled univariate models:

$$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t}$$

$$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

Create a `heston` object.

```
heston_obj = heston (0.1, 0.2, 0.1, 0.05) % (Return, Speed, Level, Volatility)

heston_obj =
  Class HESTON: Heston Bivariate Stochastic Volatility
  -----
  Dimensions: State = 2, Brownian = 2
  -----
  StartTime: 0
  StartState: 1 (2x1 double array)
  Correlation: 2x2 diagonal double array
    Drift: drift rate function F(t,X(t))
    Diffusion: diffusion rate function G(t,X(t))
  Simulation: simulation method/function simByEuler
    Return: 0.1
    Speed: 0.2
    Level: 0.1
  Volatility: 0.05
```

Define the quasi-Monte Carlo simulation using the optional name-value arguments for '`MonteCarloMethod`' and '`QuasiSequence`'.

```
[paths,time,z] = simByEuler(heston_obj,10,'ntrials',4096,'montecarlomethod','quasi','quasisequence')
```

### Quasi-Monte Carlo Simulation with `simByEuler` Using GBM Model

Create a univariate `gbm` object to represent the model:  $dX_t = 0.25X_t dt + 0.3X_t dW_t$ .

```
gbm_obj = gbm(0.25, 0.3) % (B = Return, Sigma)

gbm_obj =
  Class GBM: Generalized Geometric Brownian Motion
  -----
  Dimensions: State = 1, Brownian = 1
  -----
  StartTime: 0
  StartState: 1
  Correlation: 1
    Drift: drift rate function F(t,X(t))
    Diffusion: diffusion rate function G(t,X(t))
  Simulation: simulation method/function simByEuler
    Return: 0.25
    Sigma: 0.3
```

`gbm` objects display the parameter `B` as the more familiar `Return`.

Define the quasi-Monte Carlo simulation using the optional name-value arguments for '`MonteCarloMethod`' and '`QuasiSequence`'.

```
[paths,time,z] = simByEuler(gbm_obj,10,'ntrials',4096,'montecarlomethod','quasi','quasisequence')
```

## Input Arguments

### MDL — Stochastic differential equation model

object

Stochastic differential equation model, specified as an `sde`, `bm`, `gbm`, `cev`, `cir`, `hwv`, `heston`, `sdeddo`, `sdeld`, or `sdemrd` object.

Data Types: object

### NPeriods — Number of simulation periods

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: double

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1`, ..., `NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[Paths,Times,Z] = simByEuler(SDE,NPeriods,'DeltaTime',dt)`

### Method — Method to handle negative values

'basic' (default) | character vector with values 'basic', 'absorption', 'reflection', 'partial-truncation', 'full-truncation', or 'higham-mao' | string with values "basic", "absorption", "reflection", "partial-truncation", "full-truncation", or "higham-mao"

Method to handle negative values, specified as the comma-separated pair consisting of '`Method`' and a character vector or string with a supported value.

---

**Note** The `Method` argument is only supported when using a CIR object. For more information on creating a CIR object, see `cir`.

---

Data Types: char | string

### NTrials — Simulated trials (sample paths) of NPeriods observations each

1 (single path of correlated state variables) (default) | positive scalar integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as the comma-separated pair consisting of '`NTrials`' and a positive scalar integer.

Data Types: double

### DeltaTimes — Positive time increments between observations

1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of '`DeltaTimes`' and a scalar or a `NPeriods`-by-1 column vector.

**DeltaTime** represents the familiar  $dt$  found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: double

**NSteps — Number of intermediate time steps within each time increment  $dt$  (specified as **DeltaTime**)**

1 (indicating no intermediate evaluation) (default) | positive scalar integer

Number of intermediate time steps within each time increment  $dt$  (specified as **DeltaTime**), specified as the comma-separated pair consisting of 'NSteps' and a positive scalar integer.

The **simByEuler** function partitions each time increment  $dt$  into NSteps subintervals of length  $dt/NSteps$ , and refines the simulation by evaluating the simulated state vector at NSteps – 1 intermediate points. Although **simByEuler** does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: double

**Antithetic — Flag to indicate whether **simByEuler** uses antithetic sampling to generate the Gaussian random variates**

False (no antithetic sampling) (default) | logical with values True or False

Flag indicates whether **simByEuler** uses antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes). This argument is specified as the comma-separated pair consisting of 'Antithetic' and a scalar logical flag with a value of True or False.

When you specify True, **simByEuler** performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials (1, 3, 5, ...) correspond to the primary Gaussian paths.
- Even trials (2, 4, 6, ...) are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

---

**Note** If you specify an input noise process (see Z), **simByEuler** ignores the value of Antithetic.

---

Data Types: logical

**Z — Direct specification of the dependent random noise process used to generate the Brownian motion vector**

generates correlated Gaussian variates based on the Correlation member of the SDE object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process used to generate the Brownian motion vector (Wiener process) that drives the simulation. This argument is specified as the comma-separated pair consisting of 'Z' and a function or as an (NPeriods  $\square$  NSteps)-by-NBrowns-by-NTrials three-dimensional array of dependent random variates.

---

**Note** If you specify Z as a function, it must return an NBrowns-by-1 column vector, and you must call it with two inputs:

- A real-valued scalar observation time  $t$ .
  - An NVars-by-1 state vector  $X_t$ .
- 

Data Types: double | function

**StorePaths — Flag that indicates how the output array Paths is stored and returned**

True (default) | logical with values True or False

Flag that indicates how the output array Paths is stored and returned, specified as the comma-separated pair consisting of 'StorePaths' and a scalar logical flag with a value of True or False.

If StorePaths is True (the default value) or is unspecified, simByEuler returns Paths as a three-dimensional time series array.

If StorePaths is False (logical 0), simByEuler returns the Paths output array as an empty matrix.

Data Types: logical

**MonteCarloMethod — Monte Carlo method to simulate stochastic processes**

"standard" (default) | string with values "standard", "quasi", or "randomized-quasi" | character vector with values 'standard', 'quasi', or 'randomized-quasi'

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of 'MonteCarloMethod' and a string or character vector with one of the following values:

- "standard" — Monte Carlo using pseudo random numbers.
- "quasi" — Quasi-Monte Carlo using low-discrepancy sequences.
- "randomized-quasi" — Randomized quasi-Monte Carlo.

---

**Note** If you specify an input noise process (see Z), simByEuler ignores the value of MonteCarloMethod.

---

Data Types: string | char

**QuasiSequence — Low discrepancy sequence to drive the stochastic processes**

"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of 'QuasiSequence' and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

---

**Note** If MonteCarloMethod option is not specified or specified as "standard", QuasiSequence is ignored.

---

Data Types: string | char

**Processes — Sequence of end-of-period processes or state vector adjustments**

`simByEuler` makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments of the form, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The `simByEuler` function runs processing functions at each interpolation time. They must accept the current interpolation time  $t$ , and the current state vector  $X_t$ , and return a state vector that may be an adjustment to the input state.

If you specify more than one processing function, `simByEuler` invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

Data Types: cell | function

## Output Arguments

**Paths — Simulated paths of correlated state variables**

array

Simulated paths of correlated state variables, returned as a (`NPeriods + 1`)-by-`NVars`-by-`NTrials` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector  $X_t$  at time  $t$ . When the input flag `StorePaths = False`, `simByEuler` returns `Paths` as an empty matrix.

**Times — Observation times associated with the simulated paths**

column vector

Observation times associated with the simulated paths, returned as a (`NPeriods + 1`)-by-1 column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

**Z — Dependent random variates used to generate the Brownian motion vector**

array

Dependent random variates used to generate the Brownian motion vector (Wiener processes) that drive the simulation, returned as a (`NPeriods ⌊ NSteps`)-by-`NBrowns`-by-`NTrials` three-dimensional time series array.

## More About

**Antithetic Sampling**

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another of the same expected value, but smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the

*antithetic path.* Any given pair is independent of any other pair, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

## Algorithms

This function simulates any vector-valued SDE of the form

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t$$

where:

- $X$  is an  $N\text{Vars}$ -by-1 state vector of process variables (for example, short rates or equity prices) to simulate.
- $W$  is an  $N\text{Browns}$ -by-1 Brownian motion vector.
- $F$  is an  $N\text{Vars}$ -by-1 vector-valued drift-rate function.
- $G$  is an  $N\text{Vars}$ -by- $N\text{Browns}$  matrix-valued diffusion-rate function.

`simByEuler` simulates `NTrials` sample paths of `NVars` correlated state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, using the Euler approach to approximate continuous-time stochastic processes.

- This simulation engine provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion. Thus, the discrete-time process approaches the true continuous-time process only as `DeltaTime` approaches zero.
- The input argument `Z` allows you to directly specify the noise-generation process. This process takes precedence over the `Correlation` parameter of the `sde` object and the value of the `Antithetic` input flag. If you do not specify a value for `Z`, `simByEuler` generates correlated Gaussian variates, with or without antithetic sampling as requested.
- The end-of-period `Processes` argument allows you to terminate a given trial early. At the end of each time step, `simByEuler` tests the state vector  $X_t$  for an all-NaN condition. Thus, to signal an early termination of a given trial, all elements of the state vector  $X_t$  must be NaN. This test enables a user-defined `Processes` function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

# simByTransition

Simulate CIR sample paths with transition density

## Syntax

```
[Paths,Times] = simByTransition(MDL,NPeriods)
[Paths,Times] = simByTransition(___,Name,Value)
```

## Description

`[Paths,Times] = simByTransition(MDL,NPeriods)` simulates `NTrials` sample paths of `NVars` independent state variables driven by the Cox-Ingersoll-Ross (CIR) process sources of risk over `NPeriods` consecutive observation periods. `simByTransition` approximates a continuous-time CIR model using an approximation of the transition density function.

`[Paths,Times] = simByTransition(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for `MonteCarloMethod` and `QuasiSequence`. For more information, see “Quasi-Monte Carlo Simulation” on page 18-62.

## Examples

### Simulate Future Term Structures Using a CIR Model

Using the short rate, simulate the rate dynamics and term structures in the future using a CIR model. The CIR model is expressed as

$$dr(t) = \alpha(b - r(t))dt + \sigma\sqrt{r(t)}dW(t)$$

The exponential affine form of the bond price is

$$B(t, T) = e^{-A(t, T)r(t) + C(t, T)}$$

where

$$A(t, T) = \frac{2(e^{\gamma(T-t)} - 1)}{(\gamma + \alpha)(e^{\gamma(T-t)} - 1) + 2\gamma}$$

$$B(t, T) = \frac{2ab}{\sigma^2} \log \left( \frac{2\gamma e^{(\alpha + \gamma)(T-t)/2}}{(\gamma + \alpha)(e^{\gamma(T-t)} - 1) + 2\gamma} \right)$$

and

$$\gamma = \sqrt{\alpha^2 + 2\sigma^2}$$

Define the parameters for the `cir` object.

```
alpha = .1;
b = .05;
sigma = .05;
r0 = .04;
```

Define the function for bond prices.

```
gamma = sqrt(alpha^2 + 2*sigma^2);
A_func = @(t, T) ...
    2*(exp(gamma*(T-t))-1)/((alpha+gamma)*(exp(gamma*(T-t))-1)+2*gamma);
C_func = @(t, T) ...
    (2*alpha*b/sigma^2)*log(2*gamma*exp((alpha+gamma)*(T-t)/2))/((alpha+gamma)*(exp(gamma*(T-t))-1));
P_func = @(t,T,r_t) exp(-A_func(t,T)*r_t+C_func(t,T));
```

Create a `cir` object.

```
obj = cir(alpha,b,sigma,'StartState',r0)

obj =
Class CIR: Cox-Ingersoll-Ross
-----
Dimensions: State = 1, Brownian = 1
-----
StartTime: 0
StartState: 0.04
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Sigma: 0.05
Level: 0.05
Speed: 0.1
```

Define the simulation parameters.

```
nTrials = 100;
nPeriods = 5; % Simulate future short over the next five years
nSteps = 12; % Set intermediate steps to improve the accuracy
```

Simulate the short rates. The returning path is a (`NPeriods` + 1)-by-`NVars`-by-`NTrials` three-dimensional time-series array. For this example, the size of the output is 6-by-1-by-100.

```
rng('default'); % Reproduce the same result
rPaths = simByTransition(obj,nPeriods,'nTrials',nTrials,'nSteps',nSteps);
size(rPaths)
```

```
ans = 1x3
```

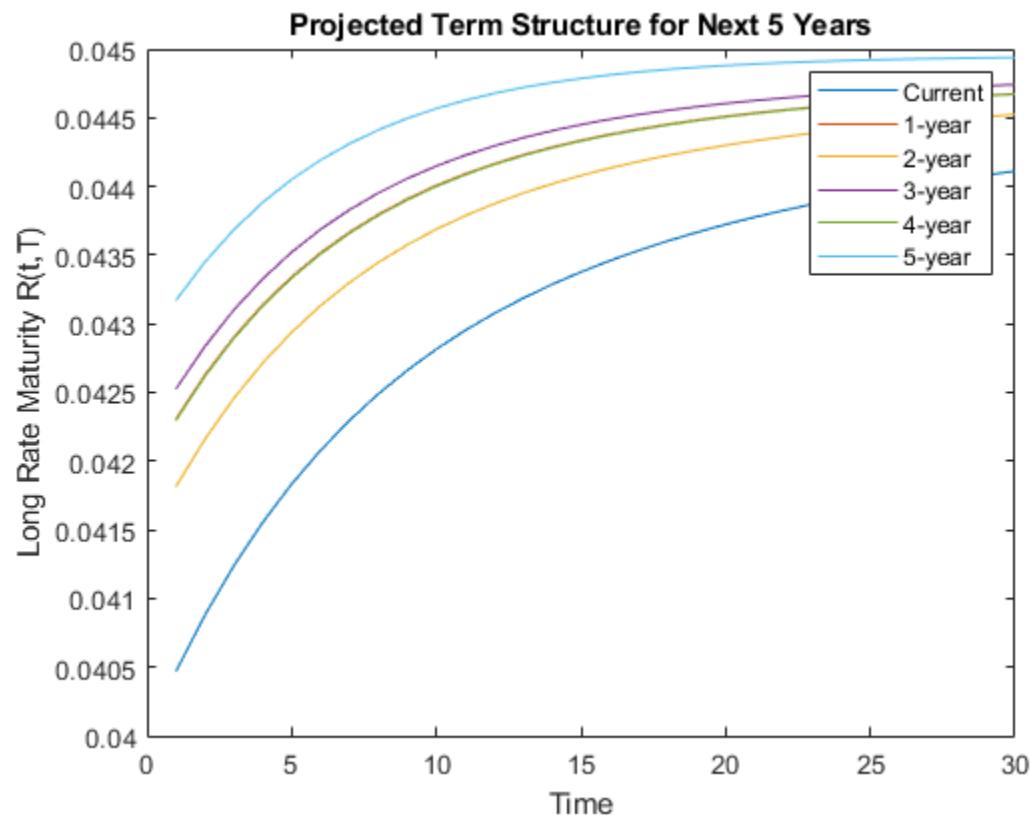

```
6     1     100
```

```
rPathsExp = mean(rPaths,3);
```

Determine the term structure over the next 30 years.

```
maturity = 30;
T = 1:maturity;
futuresTimes = 1:nPeriods+1;
```

```
% Preallocate simTermStruct
simTermStructure = zeros(nPeriods+1,30);
for i = futuresTimes
    for t = T
        bondPrice = P_func(i,i+t,rPathsExp(i));
        simTermStructure(i,t) = -log(bondPrice)/t;
    end
end
plot(simTermStructure')
legend('Current','1-year','2-year','3-year','4-year','5-year')
title('Projected Term Structure for Next 5 Years')
ylabel('Long Rate Maturity R(t,T)')
xlabel('Time')
```

### Quasi-Monte Carlo Simulation Using a CIR Model

The Cox-Ingersoll-Ross (CIR) short rate class derives directly from SDE with mean-reverting drift

$$(SDEMRD): dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW$$

where  $D$  is a diagonal matrix whose elements are the square root of the corresponding element of the state vector.

Create a `cir` object to represent the model:  $dX_t = 0.2(0.1 - X_t)dt + 0.05X_t^{\frac{1}{2}}dW$ .

```
cir_obj = cir(0.2, 0.1, 0.05) % (Speed, Level, Sigma)  
  
cir_obj =  
  Class CIR: Cox-Inggersoll-Ross  
  -----  
  Dimensions: State = 1, Brownian = 1  
  -----  
  StartTime: 0  
  StartState: 1  
  Correlation: 1  
    Drift: drift rate function F(t,X(t))  
    Diffusion: diffusion rate function G(t,X(t))  
    Simulation: simulation method/function simByEuler  
      Sigma: 0.05  
      Level: 0.1  
      Speed: 0.2
```

Define the quasi-Monte Carlo simulation using the optional name-value arguments for 'MonteCarloMethod' and 'QuasiSequence'.

```
[paths,time] = simByTransition(cir_obj,10,'ntrials',4096,'montecarlomethod','quasi','quasisequence')
```

## Input Arguments

**MDL — Stochastic differential equation model**  
object

Stochastic differential equation model, specified as a `cir` object. For more information on creating a CIR object, see `cir`.

Data Types: object

**NPeriods — Number of simulation periods**  
positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: double

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[Paths,Times] = simByTransition(CIR,NPeriods,'DeltaTimes',dt)`

**NTrials — Simulated trials (sample paths)**

1 (single path of correlated state variables) (default) | positive integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as the comma-separated pair consisting of '`NTrials`' and a positive scalar integer.

Data Types: double

#### **DeltaTimes — Positive time increments between observations**

1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of '`DeltaTimes`' and a scalar or a `NPeriods`-by-1 column vector.

`DeltaTime` represents the familiar  $dt$  found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: double

#### **NSteps — Number of intermediate time steps**

1 (indicating no intermediate evaluation) (default) | positive integer

Number of intermediate time steps within each time increment  $dt$  (defined as `DeltaTimes`), specified as the comma-separated pair consisting of '`NSteps`' and a positive scalar integer.

The `simByTransition` function partitions each time increment  $dt$  into `NSteps` subintervals of length  $dt/NSteps$ , and refines the simulation by evaluating the simulated state vector at `NSteps` – 1 intermediate points. Although `simByTransition` does not report the output state vector at these intermediate points, the refinement improves accuracy by enabling the simulation to more closely approximate the underlying continuous-time process.

Data Types: double

#### **StorePaths — Flag for storage and return method**

True (default) | logical with values True or False

Flag for storage and return method that indicates how the output array `Paths` is stored and returned, specified as the comma-separated pair consisting of '`StorePaths`' and a scalar logical flag with a value of True or False.

- If `StorePaths` is True (the default value) or is unspecified, then `simByTransition` returns `Paths` as a three-dimensional time series array.
- If `StorePaths` is False (logical 0), then `simByTransition` returns the `Paths` output array as an empty matrix.

Data Types: logical

#### **MonteCarloMethod — Monte Carlo method to simulate stochastic processes**

"standard" (default) | string with values "standard", "quasi", or "randomized-quasi" | character vector with values 'standard', 'quasi', or 'randomized-quasi'

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of '`MonteCarloMethod`' and a string or character vector with one of the following values:

- "standard" — Monte Carlo using pseudo random numbers that has a convergence rate of  $O(N^{\frac{1}{2}})$ .
- "quasi" — Quasi-Monte Carlo rate of convergence is faster than standard Monte Carlo with errors approaching size of  $O(N^{-1})$ .

- "randomized-quasi" — Quasi-random sequences, also called low-discrepancy sequences, are deterministic uniformly distributed sequences which are specifically designed to place sample points as uniformly as possible.

Data Types: string | char

**QuasiSequence — Low discrepancy sequence to drive the stochastic processes**

"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of 'QuasiSequence' and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

---

**Note** If MonteCarloMethod option is not specified or specified as "standard", QuasiSequence is ignored.

---

Data Types: string | char

**Processes — Sequence of end-of-period processes or state vector adjustments**

simByEuler makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

simByTransition applies processing functions at the end of each observation period. The processing functions accept the current observation time  $t$  and the current state vector  $X_t$ , and return a state vector that may adjust the input state.

If you specify more than one processing function, simByTransition invokes the functions in the order in which they appear in the cell array.

Data Types: cell | function

## Output Arguments

**Paths — Simulated paths of correlated state variables**

array

Simulated paths of correlated state variables, returned as an (NPeriods + 1)-by-NVars-by-NTrials three-dimensional time series array.

For a given trial, each row of Paths is the transpose of the state vector  $X_t$  at time  $t$ . When the input flag StorePaths = False, simByTransition returns Paths as an empty matrix.

**Times — Observation times associated with the simulated paths**

column vector

Observation times associated with the simulated paths, returned as an (NPeriods + 1)-by-1 column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

## More About

### Transition Density Simulation

The SDE has no solution such that  $r(t) = f(r(0), \dots)$ .

In other words, the equation is not explicitly solvable. However, the transition density for the process is known.

The exact simulation for the distribution of  $r(t_1), \dots, r(t_n)$  is that of the process at times  $t_1, \dots, t_n$  for the same value of  $r(0)$ . The transition density for this process is known and is expressed as

$$r(t) = \frac{\sigma^2(1 - e^{-\alpha(t-u)})}{4\alpha} x_d^2 \left( \frac{4\alpha e^{-\alpha(t-u)}}{\sigma^2(1 - e^{-\alpha(t-u)})} r(u) \right), t > u$$

where

$$d \equiv \frac{4b\alpha}{\sigma^2}$$

## Algorithms

Use the `simByTransition` function to simulate any vector-valued CIR process of the form

$$dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW_t$$

where

- $X_t$  is an NVars-by-1 state vector of process variables.
- $S$  is an NVars-by-NVars matrix of mean reversion speeds (the rate of mean reversion).
- $L$  is an NVars-by-1 vector of mean reversion levels (long-run mean or level).
- $D$  is an NVars-by-NVars diagonal matrix, where each element along the main diagonal is the square root of the corresponding element of the state vector.
- $V$  is an NVars-by-NBrowns instantaneous volatility rate matrix.
- $dW_t$  is an NBrowns-by-1 Brownian motion vector.

**Introduced in R2018b**

# simulate

Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models

## Syntax

```
[Paths,Times,Z] = simulate(MDL)
[Paths,Times,Z] = simulate(___,Optional)
```

## Description

`[Paths,Times,Z] = simulate(MDL)` simulates `NTrials` sample paths of `NVars` correlated state variables, driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

`simulate` accepts any variable-length list of input arguments that the simulation method or function referenced by the `SDE.Simulation` parameter requires or accepts. It passes this input list directly to the appropriate SDE simulation method or user-defined simulation function.

`[Paths,Times,Z] = simulate(___,Optional)` adds optional input arguments.

## Examples

### Antithetic Sampling to a Path-Dependent Barrier Option

Consider a European up-and-in call option on a single underlying stock. The evolution of this stock's price is governed by a Geometric Brownian Motion (GBM) model with constant parameters:

$$dX_t = 0.05X_t dt + 0.3X_t dW_t$$

Assume the following characteristics:

- The stock currently trades at 105.
- The stock pays no dividends.
- The stock volatility is 30% per annum.
- The option strike price is 100.
- The option expires in three months.
- The option barrier is 120.
- The risk-free rate is constant at 5% per annum.

The goal is to simulate various paths of daily stock prices, and calculate the price of the barrier option as the risk-neutral sample average of the discounted terminal option payoff. Since this is a barrier option, you must also determine if and when the barrier is crossed.

This example performs antithetic sampling by explicitly setting the `Antithetic` flag to `true`, and then specifies an end-of-period processing function to record the maximum and terminal stock prices on a path-by-path basis.

Create a GBM model using `gbm`.

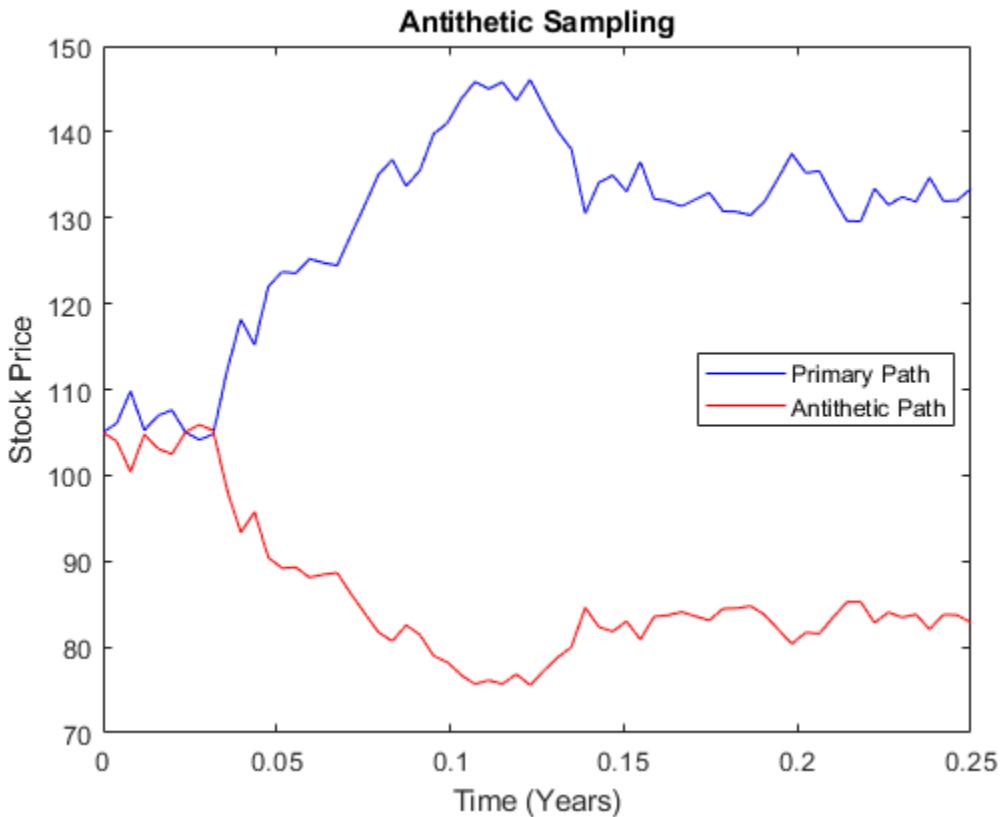

```
barrier      = 120;          % barrier
strike       = 100;          % exercise price
rate         = 0.05;         % annualized risk-free rate
sigma        = 0.3;          % annualized volatility
nPeriods     = 63;           % 63 trading days
dt           = 1 / 252;       % time increment = 252 days
T            = nPeriods * dt; % expiration time = 0.25 years
obj          = gbm(rate, sigma, 'StartState', 105);
```

Perform a small-scale simulation that explicitly returns two simulated paths.

```
rng('default')           % make output reproducible
[X, T] = obj.simBySolution(nPeriods, 'DeltaTime', dt, ...
    'nTrials', 2, 'Antithetic', true);
```

Perform antithetic sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs. Odd paths (1,3,5,...) correspond to the primary Gaussian paths. Even paths (2,4,6,...) are the matching antithetic paths of each pair, derived by negating the Gaussian draws of the corresponding primary (odd) path. Verify this by examining the matching paths of the primary/antithetic pair.

```
plot(T, X(:,:,1), 'blue', T, X(:,:,2), 'red')
xlabel('Time (Years)'), ylabel('Stock Price'), ...
    title('Antithetic Sampling')
legend({'Primary Path' 'Antithetic Path'}, ...
    'Location', 'Best')
```

To price the European barrier option, specify an end-of-period processing function to record the maximum and terminal stock prices. This processing function is accessible by time and state, and is implemented as a nested function with access to shared information that allows the option price and corresponding standard error to be calculated. For more information on using an end-of-period processing function, see "Pricing Equity Options" on page 18-45.

Simulate 200 paths using the processing function method.

```

rng('default')          % make output reproducible
barrier = 120;          % barrier
strike = 100;           % exercise price
rate = 0.05;            % annualized risk-free rate
sigma = 0.3;             % annualized volatility
nPeriods = 63;          % 63 trading days
dt = 1 / 252;           % time increment = 252 days
T = nPeriods * dt;      % expiration time = 0.25 years
obj = gbm(rate, sigma, 'StartState', 105);
nPaths = 200;            % # of paths = 100 sets of pairs
f = Example_BARRIERoption(nPeriods, nPaths);
simulate(obj, nPeriods, 'DeltaTime', dt, ...
    'nTrials', nPaths, 'Antithetic', true, ...
    'Processes', f.SaveMaxLast);

```

Approximate the option price with a 95% confidence interval.

```

optionPrice = f.OptionPrice(strike, rate, barrier);
standardError = f.StandardError(strike, rate, barrier, ...

```

```
        true);
lowerBound = optionPrice - 1.96 * standardError;
upperBound = optionPrice + 1.96 * standardError;

displaySummary(optionPrice, standardError, lowerBound, upperBound);

Up-and-In Barrier Option Price: 6.6572
    Standard Error of Price: 0.7292
Confidence Interval Lower Bound: 5.2280
Confidence Interval Upper Bound: 8.0864
```

## Utility Function

```
function displaySummary(optionPrice, standardError, lowerBound, upperBound)
fprintf(' Up-and-In Barrier Option Price: %8.4f\n', ...
        optionPrice);
fprintf('     Standard Error of Price: %8.4f\n', ...
        standardError);
fprintf(' Confidence Interval Lower Bound: %8.4f\n', ...
        lowerBound);
fprintf(' Confidence Interval Upper Bound: %8.4f\n', ...
        upperBound);
end
```

## Input Arguments

**MDL — Stochastic differential equation model**  
object

Stochastic differential equation model, specified as an `sde`, `batesbm`, `gbm`, `cev`, `cir`, `hwv`, `heston`, `merton`, `sdeddo`, `sdeld`, or `sdemrd` object.

Data Types: object

**Optional — (Optional) Any variable-length list of input arguments that the simulation method or function referenced by the SDE.Simulation parameter requires or accepts**  
input arguments

Any variable-length list of input arguments that the simulation method or function referenced by the `SDE.Simulation` parameter requires or accepts, specified as a variable-length list of input arguments. This input list is passed directly to the appropriate SDE simulation method or user-defined simulation function.

Data Types: double

## Output Arguments

**Paths — Three-dimensional time series array, consisting of simulated paths of correlated state variables**  
array

Three-dimensional time series array, consisting of simulated paths of correlated state variables, returned as an `(NPeriods + 1)-by-NVars-by-NTrials` array.

For a given trial, each row of `Paths` is the transpose of the state vector  $X_t$  at time  $t$ .

**Times — Observation times associated with the simulated paths**  
column vector

Observation times associated with the simulated paths, returned as a (NPeriods + 1)-by-1 column vector.

**Z — Three-dimensional time series array of dependent random variates used to generate the Brownian motion vector (Wiener processes)**  
array | matrix | table | timetable

Three-dimensional time series array of dependent random variates used to generate the Brownian motion vector (Wiener processes) that drove the simulated results found in Paths, returned as a NTimes-by-NBrowns-by-NTrials array.

NTimes is the number of time steps at which the simulate function samples the state vector. NTimes includes intermediate times designed to improve accuracy, which simulate does not necessarily report in the Paths output time series.

## More About

### Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another of the same expected value, but smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent of any other pair, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

## Algorithms

This function simulates any vector-valued SDE of the form:

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t \quad (19-4)$$

where:

- $X$  is an NVars-by-1 state vector of process variables (for example, short rates or equity prices) to simulate.
- $W$  is an NBrowns-by-1 Brownian motion vector.
- $F$  is an NVars-by-1 vector-valued drift-rate function.
- $G$  is an NVars-by-NBrowns matrix-valued diffusion-rate function.

## Introduced in R2008a

# ts2func

Convert time series arrays to functions of time and state

## Syntax

```
F = ts2func(Array)
F = ts2func(___,Name,Value)
```

## Description

`F = ts2func(Array)` encapsulates a time series array associated with a vector of real-valued observation times within a MATLAB function suitable for Monte Carlo simulation of an `NVars`-by-1 state vector  $X_t$ .

$n$  periods.

`F = ts2func(___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Illustrate the Dynamic Behavior of Market Parameters

Load the data.

```
load Data_GlobalIdx2
```

Simulate risk-neutral sample paths.

```
dt      = 1/250;
returns = tick2ret(Dataset.CAC);
sigma   = std(returns)*sqrt(250);
yields  = Dataset.EB3M;
yields  = 360*log(1 + yields);
```

Simulate paths using a constant, risk-free return

```
nPeriods = length(yields); % Simulated observations
rng(5713,'twister')
obj      = gbm(mean(yields),diag(sigma),'StartState',100)

obj =
    Class GBM: Generalized Geometric Brownian Motion
    -----
        Dimensions: State = 1, Brownian = 1
    -----
        StartTime: 0
        StartState: 100
        Correlation: 1
        Drift: drift rate function F(t,X(t))
        Diffusion: diffusion rate function G(t,X(t))
        Simulation: simulation method/function simByEuler
```

```
Return: 0.0278117
Sigma: 0.231906

[X1,T] = simulate(obj,nPeriods,'DeltaTime',dt);
```

**Simulate paths using a dynamic, deterministic rate of return (get r)**

```
r = ts2func(yields,'Times',(0:nPeriods - 1));
```

**Simulate paths using a dynamic, deterministic rate of return (r output 1)**

```
r(0,100)
```

```
ans = 0.0470
```

**Simulate paths using a dynamic, deterministic rate of return (r output 2)**

```
r(7.5,200)
```

```
ans = 0.0472
```

**Simulate paths using a dynamic, deterministic rate of return (r output 3)**

```
r(7.5)
```

```
ans = 0.0472
```

**Simulate paths using a dynamic, deterministic rate of return**

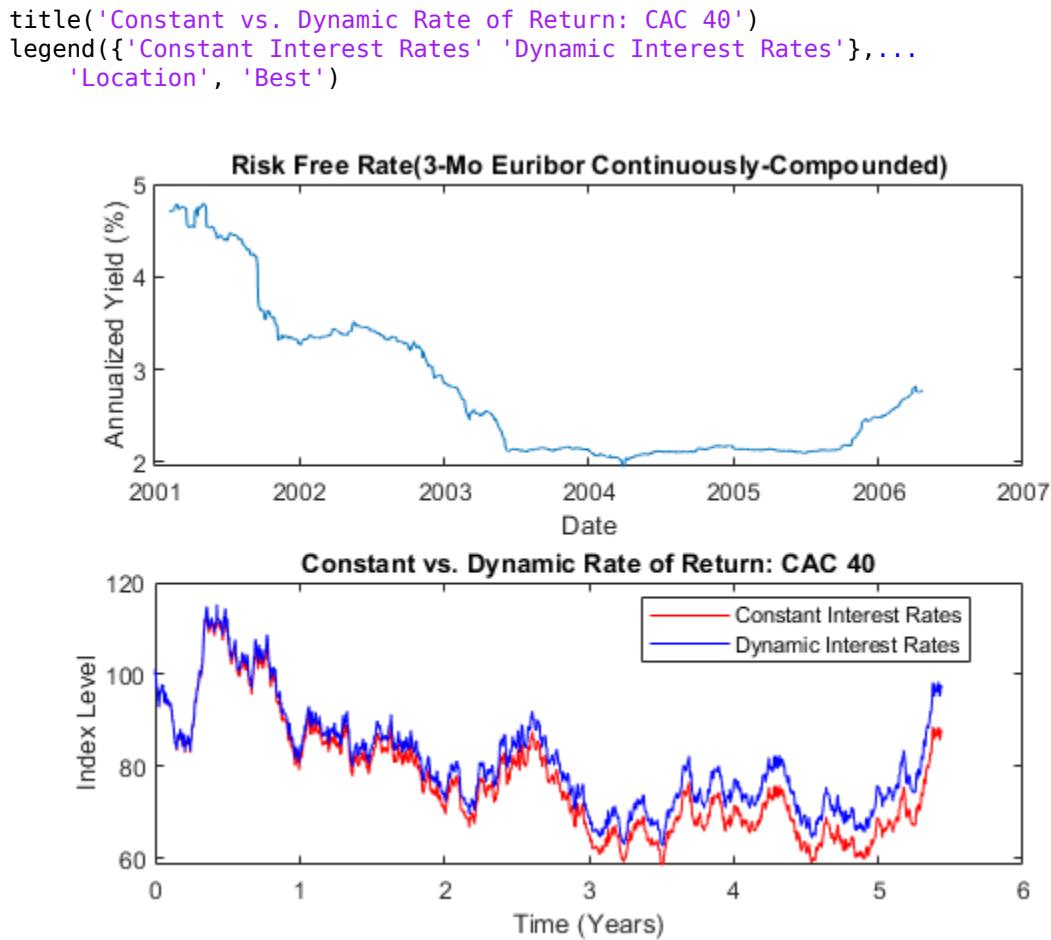

```
rng(5713,'twister')
obj = gbm(r, diag(sigma), 'StartState',100)

obj =
Class GBM: Generalized Geometric Brownian Motion
-----
Dimensions: State = 1, Brownian = 1
-----
StartTime: 0
StartState: 100
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Return: function ts2func/vector2Function
Sigma: 0.231906
```

```
X2 = simulate(obj,nPeriods,'DeltaTime',dt);
```

**Compare the two simulation trials.**

```
subplot(2,1,1)
plot(dates,100*yields)
datetick('x')
xlabel('Date')
ylabel('Annualized Yield (%)')
title('Risk Free Rate(3-Mo Euribor Continuously-Compounded)')
subplot(2,1,2)
plot(T,X1,'red',T,X2,'blue')
xlabel('Time (Years)')
ylabel('Index Level')
```

## Input Arguments

**Array — Time series array to encapsulate within a callable function of time and state**  
vector | 2-dimensional matrix | three-dimensional array

Time series array to encapsulate within a callable function of time and state, specified as a vector, two-dimensional matrix, or three-dimensional array

Data Types: double

## Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, ..., NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: F = ts2func(yields, 'Times', (0:nPeriods - 1)')

**Times — Monotonically increasing observation times associated with the time series input array Array**

zero-based, unit-increment vector of the same length as that of the dimension of Array (default) | vector

Monotonically increasing observation times associated with the time series input array (Array), specified as the comma-separated pair consisting of 'Times' and a vector.

Data Types: double

**TimeDimension — Specifies which dimension of the input time series array Array is associated with time**

1 (indicates that time is associated with the rows of Array) (default) | scalar integer

Specifies which dimension of the input time series array (Array) is associated with time, specified as the comma-separated pair consisting of 'TimeDimension' and a scalar integer.

Data Types: double

**StateDimension — Specifies which dimension of the input time series array Array is associated with the NVars state variables**

first dimension of Array not already associated with time is associated with first available dimension of Array not already assigned to TimeDimension (default) | positive scalar integer

Specifies which dimension of the input time series array (Array) is associated with the NVars state variables, specified as the comma-separated pair consisting of 'StateDimension' and a positive scalar integer.

Data Types: double

**Deterministic — Flag to indicate whether the output function is a deterministic function of time alone**

false (meaning F is a callable function of time and state,  $F(t,X)$ ) (default) | scalar logical

Flag to indicate whether the output function is a deterministic function of time alone, specified as the comma-separated pair consisting of 'Deterministic' and a scalar integer flag.

If Deterministic is true, the output function F is a deterministic function of time,  $F(t)$ , and the only input it accepts is a scalar, real-valued time t. If Deterministic is false, the output function F accepts two inputs, a scalar, real-valued time t followed by an NVars-by-1 state vector  $X(t)$ .

Data Types: logical

## Output Arguments

**F — Callable function  $F(t)$  of a real-valued scalar observation time t**

vector | matrix | table | timetable

Callable function  $F(t)$  of a real-valued scalar observation time t, returned as a function.

If the optional input argument Deterministic is true, F is a deterministic function of time,  $F(t)$ , and the only input it accepts is a scalar, real-valued time t. Otherwise, if Deterministic is false (the default), F accepts a scalar, real-valued time t followed by an NVars-by-1 state vector  $X(t)$ .

---

**Note** You can invoke `F` with a second input (such as an `NVars`-by-1 state vector `X`), which is a placeholder that `ts2func` ignores. For example, while `F(t)` and `F(t,X)` produce identical results, the latter directly supports SDE simulation methods.

---

## Algorithms

- When you specify `Array` as a scalar or a vector (row or column), `ts2func` assumes that it represents a univariate time series.
- `F` returns an array with one less dimension than the input time series array `Array` with which `F` is associated. Thus, when `Array` is a vector, a 2-dimensional matrix, or a three-dimensional array, `F` returns a scalar, vector, or 2-dimensional matrix, respectively.
- When the scalar time `t` at which `ts2func` evaluates the function `F` does not coincide with an observation time in `Times`, `F` performs a zero-order-hold interpolation. The only exception is if `t` precedes the first element of `Times`, in which case  $F(t) = F(Times(1))$ .
- To support Monte Carlo simulation methods, the output function `F` returns an `NVars`-by-1 column vector or a two-dimensional matrix with `NVars` rows.
- The output function `F` is always a deterministic function of time,  $F(t)$ , and may always be called with a single input regardless of the `Deterministic` flag. The distinction is that when `Deterministic` is false, the function `F` may also be called with a second input, an `NVars`-by-1 state vector `X(t)`, which is a placeholder and ignored. While `F(t)` and `F(t,X)` produce identical results, the former specifically indicates that the function is a deterministic function of time, and may offer significant performance benefits in some situations.

**Introduced in R2008a**

# abs2active

Convert constraints from absolute to active format

## Syntax

```
ActiveConSet = abs2active(AbsConSet, Index)
```

## Description

`ActiveConSet = abs2active(AbsConSet, Index)` transforms a constraint matrix to an equivalent matrix expressed in active weight format (relative to the index).

## Examples

### Convert Constraints in Terms of Absolute Weights Into Constraints in Terms of Active Portfolio Weights

Set up constraints for a portfolio optimization for portfolio  $w_0$  with constraints in the form  $A^*w \leq b$ , where  $w$  is absolute portfolio weights. (Absolute weights do not depend on the tracking portfolio.) Use `abs2active` to convert constraints in terms of absolute weights into constraints in terms of active portfolio weights, defined relative to the tracking portfolio  $w_0$ . Assume three assets with the following mean and covariance of asset returns:

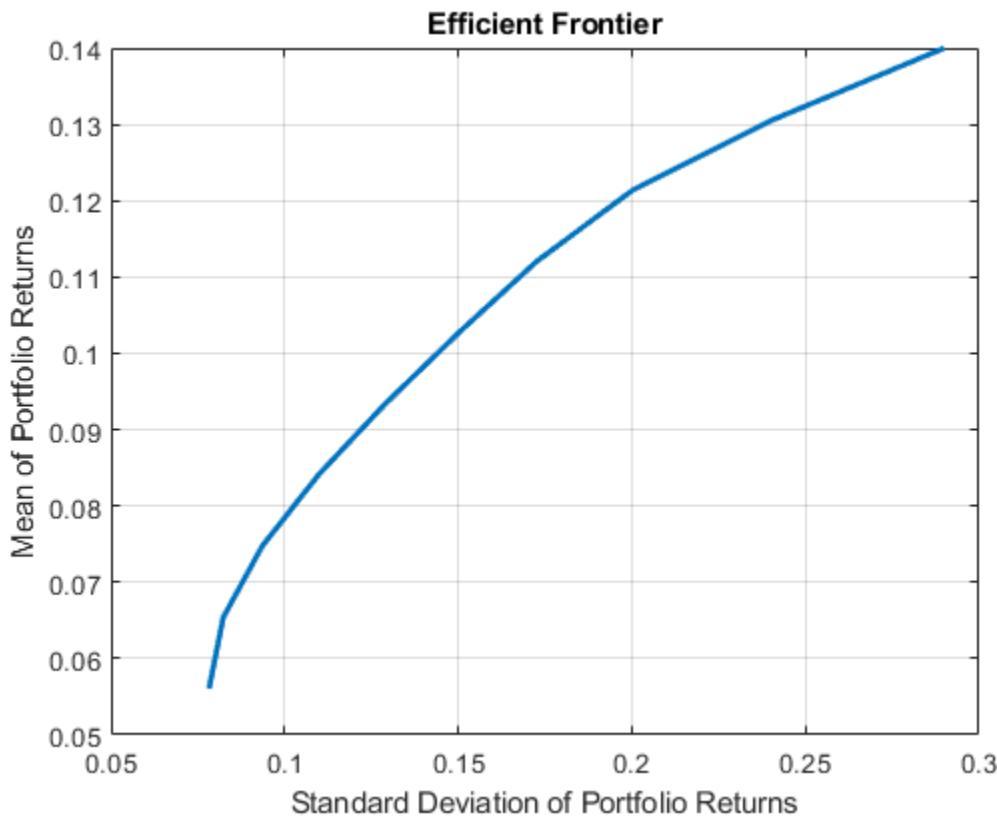

```
m = [ 0.14; 0.10; 0.05 ];
C = [ 0.29^2 0.4*0.29*0.17 0.1*0.29*0.08; 0.4*0.29*0.17 0.17^2 0.3*0.17*0.08; ...
0.1*0.29*0.08 0.3*0.17*0.08 0.08^2 ];
```

Absolute portfolio constraints are the typical ones (weights sum to 1 and fall from 0 through 1), create the  $A$  and  $b$  matrices using `portcons`.

```
AbsCons = portcons('PortValue', 1, 3, 'AssetLims', [0; 0; 0], [1; 1; 1]);
```

Use the `Portfolio` object to determine the efficient frontier.

```
p = Portfolio('AssetMean', m, 'AssetCovar', C);
p = p.setInequality(AbsCons(:, 1:end-1), AbsCons(:, end));
p.plotFrontier;
```

The tracking portfolio  $w_0$  is:

$$w_0 = [0.1; 0.55; 0.35];$$

Use `abs2active` to compute the constraints for active portfolio weights.

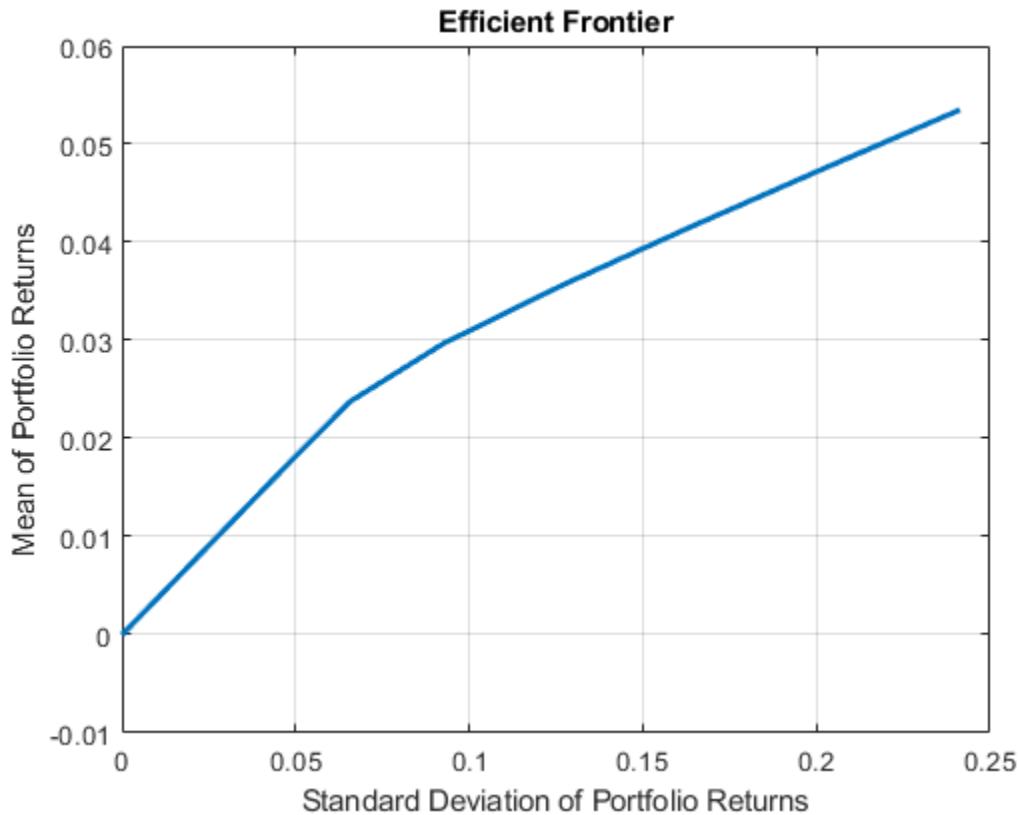

```
ActCons = abs2active(AbsCons, w0)
```

ActCons = 8×4

|         |         |         |        |
|---------|---------|---------|--------|
| 1.0000  | 1.0000  | 1.0000  | 0      |
| -1.0000 | -1.0000 | -1.0000 | 0      |
| 1.0000  | 0       | 0       | 0.9000 |
| 0       | 1.0000  | 0       | 0.4500 |
| 0       | 0       | 1.0000  | 0.6500 |
| -1.0000 | 0       | 0       | 0.1000 |
| 0       | -1.0000 | 0       | 0.5500 |
| 0       | 0       | -1.0000 | 0.3500 |

Use the `Portfolio` object  $p$  and its efficient frontier to demonstrate expected returns and risk relative to the tracking portfolio  $w_0$ .

```
p = p.setInequality(ActCons(:,1:end-1), ActCons(:,end));  
p.plotFrontier;
```

Note, when using `abs2active` to compute “active constraints” for use with a `Portfolio` object, don't use the `Portfolio` object's default constraints because the relative weights can be positive or negative (the `setDefaultConstraints` function for a `Portfolio` object specifies weights to be nonnegative).

## Input Arguments

### **AbsConSet — Portfolio linear inequality constraint matrix expressed in absolute weight format**

matrix

Portfolio linear inequality constraint matrix expressed in absolute weight format, specified as  $[A \ b]$  such that  $A^*w \leq b$ , where  $A$  is a number of constraints (`NCONSTRAINTS`) by number of assets (`NASSETS`) weight coefficient matrix, and  $b$  and  $w$  are column vectors of length `NASSETS`. The value  $w$  represents a vector of absolute asset weights whose elements sum to the total portfolio value. See the output `ConSet` from `portcons` for additional details about constraint matrices.

Data Types: double

### **Index — Index portfolio weights**

vector

Index portfolio weights, specified as a `NASSETS`-by-1 vector. The sum of the index weights must equal the total portfolio value (for example, a standard portfolio optimization imposes a sum-to-1 budget constraint).

Data Types: double

## Output Arguments

**ActiveConSet — Transformed portfolio linear inequality constraint matrix expressed in active weight format**

matrix

Transformed portfolio linear inequality constraint matrix expressed in active weight format, returned in the form [A b] such that  $A^*w \leq b$ . The value w represents a vector of active asset weights (relative to the index portfolio) whose elements sum to zero.

## Algorithms

`abs2active` transforms a constraint matrix to an equivalent matrix expressed in active weight format (relative to the index). The transformation equation is

$$Aw_{absolute} = A(w_{active} + w_{index}) \leq b_{absolute}.$$

Therefore

$$Aw_{active} \leq b_{absolute} - Aw_{index} = b_{active}.$$

The initial constraint matrix consists of `NCONSTRAINTS` portfolio linear inequality constraints expressed in absolute weight format. The index portfolio vector contains `NASSETS` assets.

## Introduced before R2006a

# accrfrac

Fraction of coupon period before settlement

## Syntax

```
Fraction = accrfrac(Settle,Maturity)
Fraction = accrfrac(____,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,
LastCouponDate)
```

## Description

`Fraction = accrfrac(Settle,Maturity)` returns the fraction of the coupon period before settlement.

Use `accrfrac` for computing accrued interest. `accrfrac` calculates accrued interest for bonds with regular or odd first or last coupon periods.

Required input arguments must be number of bonds, `NUMBONDS`-by-1 or 1-by-`NUMBONDS`, conforming vectors or scalars.

`Fraction = accrfrac(____,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,
LastCouponDate)` returns the fraction of the coupon period before settlement with optional inputs.

Optional input arguments must be either `NUMBONDS`-by-1 or 1-by-`NUMBONDS` conforming vectors, scalars, or empty matrices.

## Examples

### Find Accrued Interest for a Bond

This example shows how to find the accrued interest for given bond data.

```
Settle = '14-Mar-1997';
Maturity = [ '30-Nov-2000'
            '31-Dec-2000'
            '31-Jan-2001'];
Period = 2;
Basis = 0;
EndMonthRule = 1;

Fraction = accrfrac(Settle, Maturity, Period, Basis, ...
EndMonthRule)

Fraction = 3×1

    0.5714
    0.4033
    0.2320
```

## Find Accrued Interest for a Bond Using a datetime Array

This example shows how to find the accrued interest for a given bond's data using a datetime array.

```
Fraction = accrfrac(datetime('14-Mar-1997', 'Locale', 'en_US'), ['30-Nov-2000'; '31-Dec-2000'; '31-Jan-2001'])
```

Fraction = 3×1

0.5714  
0.4033  
0.2320

## Input Arguments

### Settle — Settlement date

serial date numbers | date character vector | datetime object

Settlement date, specified as a scalar or an NUMBONDS-by-1 vector of serial date numbers, date character vectors, or a datetime array. Settle must be earlier than Maturity.

Data Types: double | char | datetime

### Maturity — Maturity date

serial date number | date character vector | datetime array

Maturity date, specified as a scalar or an NUMBONDS-by-1 vector of serial date numbers, date character vectors, or a datetime array.

Data Types: double | char | datetime

### Period — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Coupons per year of the bond, specified as a scalar or an NUMBONDS-by-1 vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: single | double

### Basis — Day-count basis of the instrument

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as a scalar integer with a value of 0 through 13 or a NUMBONDS-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)

- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: `single` | `double`

#### **EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag for month having 30 or fewer days, specified as a scalar nonnegative integer or an `NUMBONDS`-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: `logical`

#### **IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a scalar or an `NUMBONDS`-by-1 vector of serial date numbers, date character vectors, or a datetime array.

Data Types: `double` | `char` | `datetime`

#### **FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a scalar or an `NUMBONDS`-by-1 vector of serial date numbers, date character vectors, or a datetime array.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

#### **LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a scalar or an `NUMBONDS`-by-1 vector of serial date numbers, date character vectors, or a datetime array.

`LastCouponDate` is used when a bond has an irregular last coupon period. In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

## Output Arguments

### Fraction — Fraction of coupon period before settlement

vector

Fraction of the coupon period before settlement, returned as an `NUMBONDS`-by-1 vector.

# acrubond

Accrued interest of security with periodic interest payments

## Syntax

```
AccruInterest = acrubbond(IssueDate, Settle, FirstCouponDate, Face, CouponRate)
AccruInterest = acrubbond(_____, Period, Basis)
```

## Description

`AccruInterest = acrubbond(IssueDate, Settle, FirstCouponDate, Face, CouponRate)`  
 returns the accrued interest for a security with periodic interest payments. `acrubbond` computes the accrued interest for securities with standard, short, and long first coupon periods.

---

**Note** `cfaamounts` or `accrfrac` is recommended when calculating accrued interest beyond the first period.

---

`AccruInterest = acrubbond(_____, Period, Basis)` adds optional arguments for `Period` and `Basis`.

## Examples

### Find Accrued Interest of a Bond with Periodic Interest Payments

This example shows how to find the accrued interest for a bond with semiannual interest payments.

```
AccruInterest = acrubbond('31-jan-1983', '1-mar-1993', ...
                           '31-jul-1983', 100, 0.1, 2, 0)
AccruInterest = 0.8011
```

### Find Accrued Interest of a Bond with Periodic Interest Payments Using datetime Inputs

This example shows how to use `datetime` inputs to find the accrued interest for a bond with semiannual interest payments.

```
AccruInterest = acrubbond(datetime('31-jan-1983', 'Locale', 'en_US'), datetime('1-mar-1993', 'Locale')
                           100, 0.1, 2, 0)
AccruInterest = 0.8011
```

## Input Arguments

### IssueDate — Issue date of security

serial date number | date character vector | `datetime`

Issue date of the security, specified as a scalar or a NINST-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**Settle — Settlement date of security**

serial date number | date character vector | datetime

Settlement date of the security, specified as a scalar or a NINST-by-1 vector of serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

**FirstCouponDate — First coupon date of security**

serial date number | date character vector | datetime

First coupon date of the security, specified as a scalar or a NINST-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**Face — Redemption value of security**

numeric

Redemption value (par value) of the security, specified as a scalar or a NINST-by-1 vector.

Data Types: double

**CouponRate — Coupon rate of security**

decimal fraction

Coupon rate of the security, specified as a scalar or a NINST-by-1 vector of decimal fraction values.

Data Types: double

**Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

(Optional) Number of coupon payments per year for the security, specified as scalar or a NINST-by-1 vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis**

0 (actual/actual) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

(Optional) Day-count basis for the security, specified as a scalar or a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)

- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

## Output Arguments

### **AccruInterest — Accrued interest**

numeric

Accrued interest for the security, returned as a scalar or a `NINST`-by-1 vector.

## See Also

## acrudisc

Accrued interest of discount security paying at maturity

### Syntax

```
AccruInterest = acrudisc(Settle,Maturity,Face,Discount)
AccruInterest = acrudisc(_____,Period,Basis)
```

### Description

`AccruInterest = acrudisc(Settle,Maturity,Face,Discount)` returns the accrued interest of a discount security paid at maturity.

`AccruInterest = acrudisc(_____,Period,Basis)` adds optional arguments for `Period` and `Basis`.

### Examples

#### Find Accrued Interest of a Discount Security Paid at Maturity

This example shows how to find the accrued interest of a discount security paid at maturity.

```
AccruInterest = acrudisc('05/01/1992', '07/15/1992', ...
    100, 0.1, 2, 0)
```

```
AccruInterest = 2.0604
```

#### Find Accrued Interest of a Discount Security Paid at Maturity Using datetime Inputs

This example shows how to use `datetime` inputs to find the accrued interest of a discount security paid at maturity.

```
AccruInterest = acrudisc(datetime('1-May-1992','Locale','en_US'),datetime('15-Jul-1992','Locale',...
    100, 0.1, 2, 0))
```

```
AccruInterest = 2.0604
```

### Input Arguments

#### Settle — Settlement date of security

serial date number | date character vector | `datetime`

Settlement date of the security, specified as a scalar or a NINST-by-1 vector of serial date numbers, date character vectors, or `datetime` arrays. The `Settle` date must be before the `Maturity` date.

Data Types: `double` | `char` | `datetime`

**Maturity — Maturity date of security**

serial date number | date character vector | datetime

Maturity date of the security, specified as a scalar or a NINST-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**Face — Redemption value of security**

numeric

Redemption value (par value) of the security, specified as a scalar or a NINST-by-1 vector.

Data Types: double

**Discount — Discount rate of security**

decimal fraction

Discount rate of the security, specified as a scalar or a NINST-by-1 vector of decimal fraction values.

Data Types: double

**Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

(Optional) Number of coupon payments per year for security, specified as scalar or a NINST-by-1 vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis**

0 (actual/actual) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

(Optional) Day-count basis for security, specified as a scalar or a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

## Output Arguments

### **AccruInterest — Accrued interest**

numeric

Accrued interest, returned as a scalar or a NINST-by-1 vector.

# active2abs

Convert constraints from active to absolute format

## Syntax

```
AbsConSet = active2abs(ActiveConSet, Index)
```

## Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ActiveConSet | <p>Portfolio linear inequality constraint matrix expressed in active weight format. ActiveConSet is formatted as [A b] such that <math>A^*w \leq b</math>, where A is a number of constraints (NCONSTRAINTS) by number of assets (NASSETS) weight coefficient matrix, and b and w are column vectors of length NASSETS. The value w represents a vector of active asset weights (relative to the index portfolio) whose elements sum to 0.</p> <p>See the output ConSet from portcons for additional details about constraint matrices.</p> |
| Index        | NASSETS-by-1 vector of index portfolio weights. The sum of the index weights must equal the total portfolio value (for example, a standard portfolio optimization imposes a sum-to-one budget constraint).                                                                                                                                                                                                                                                                                                                                  |

## Description

`AbsConSet = active2abs(ActiveConSet, Index)` transforms a constraint matrix to an equivalent matrix expressed in absolute weight format. The transformation equation is

$$Aw_{\text{active}} = A(w_{\text{absolute}} - w_{\text{index}}) \leq b_{\text{active}}.$$

Therefore

$$Aw_{\text{absolute}} \leq b_{\text{active}} + Aw_{\text{index}} = b_{\text{absolute}}.$$

The initial constraint matrix consists of NCONSTRAINTS portfolio linear inequality constraints expressed in active weight format (relative to the index portfolio). The index portfolio vector contains NASSETS assets.

`AbsConSet` is the transformed portfolio linear inequality constraint matrix expressed in absolute weight format, also of the form [A b] such that  $A^*w \leq b$ . The value w represents a vector of active asset weights (relative to the index portfolio) whose elements sum to the total portfolio value.

# addEquality

Add linear equality constraints for portfolio weights to existing constraints

## Syntax

```
obj = addEquality(obj,AEquality,bEquality)
```

## Description

`obj = addEquality(obj,AEquality,bEquality)` adds linear equality constraints for portfolio weights to existing constraints for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “`Portfolio Object Workflow`” on page 4-17, “`PortfolioCVaR Object Workflow`” on page 5-15, and “`PortfolioMAD Object Workflow`” on page 6-15.

Given a linear equality constraint matrix `AEquality` and vector `bEquality`, every weight in a portfolio `Port` must satisfy the following:

$$AEquality * Port = bEquality$$

This function “stacks” additional linear equality constraints onto any existing linear equality constraints that exist in the input portfolio object. If no constraints exist, this method is the same as `setEquality`.

## Examples

### Add a Linear Equality Constraint for a Portfolio Object

Use the `addEquality` method to create linear equality constraints. Add another linear equality constraint to ensure that the last three assets constitute 50% of a portfolio.

```
p = Portfolio;
A = [ 1 1 1 0 0 ]; % First equality constraint
b = 0.5;
p = setEquality(p, A, b);

A = [ 0 0 1 1 1 ]; % Second equality constraint
b = 0.5;
p = addEquality(p, A, b);

disp(p.NumAssets);
5

disp(p.AEquality);

1     1     1     0     0
0     0     1     1     1

disp(p.bEquality);
```

```
0.5000  
0.5000
```

### Add a Linear Equality Constraint for a PortfolioCVaR Object

Use the `addEquality` method to create linear equality constraints. Add another linear equality constraint to ensure that the last three assets constitute 50% of a portfolio.

```
p = PortfolioCVaR;  
A = [ 1 1 1 0 0 ]; % First equality constraint  
b = 0.5;  
p = setEquality(p, A, b);  
  
A = [ 0 0 1 1 1 ]; % Second equality constraint  
b = 0.5;  
p = addEquality(p, A, b);  
  
disp(p.NumAssets);  
5  
  
disp(p.AEquality);  
  
1 1 1 0 0  
0 0 1 1 1  
  
disp(p.bEquality);  
  
0.5000  
0.5000
```

### Add a Linear Equality Constraint for a PortfolioMAD Object

Use the `addEquality` method to create linear equality constraints. Add another linear equality constraint to ensure that the last three assets constitute 50% of a portfolio.

```
p = PortfolioMAD;  
A = [ 1 1 1 0 0 ]; % First equality constraint  
b = 0.5;  
p = setEquality(p, A, b);  
  
A = [ 0 0 1 1 1 ]; % Second equality constraint  
b = 0.5;  
p = addEquality(p, A, b);  
  
disp(p.NumAssets);  
5  
  
disp(p.AEquality);  
  
1 1 1 0 0  
0 0 1 1 1
```

---

```
disp(p.bEquality);
```

```
0.5000
0.5000
```

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

**AEquality — Linear equality constraints formed from matrix**  
matrix

Linear equality constraints, specified as a matrix.

---

**Note** An error results if `AEquality` is empty and `bEquality` is nonempty.

Data Types: double

**bEquality — Linear equality constraints formed from vector**  
vector

Linear equality constraints, specified as a vector.

---

**Note** An error results if `bEquality` is empty and `AEquality` is nonempty.

Data Types: double

## Output Arguments

**obj — Updated portfolio object**  
object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

## Tips

- You can also use dot notation to add the linear equality constraints for portfolio weights.

```
obj = obj.addEquality(AEquality, bEquality)
```

- You can also remove linear equality constraints from a portfolio object using dot notation.

```
obj = obj.setEquality([ ], [ ])
```

## Introduced in R2011a

# addGroupRatio

Add group ratio constraints for portfolio weights to existing group ratio constraints

## Syntax

```
obj = addGroupRatio(obj, GroupA, GroupB, LowerRatio)
obj = addGroupRatio(obj, GroupA, GroupB, LowerRatio, UpperRatio)
```

## Description

`obj = addGroupRatio(obj, GroupA, GroupB, LowerRatio)` adds group ratio constraints for portfolio weights to existing group ratio constraints for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “`Portfolio` Object Workflow” on page 4-17, “`PortfolioCVaR` Object Workflow” on page 5-15, and “`PortfolioMAD` Object Workflow” on page 6-15.

Given base and comparison group matrices `GroupA` and `GroupB` and, either `LowerRatio`, or `UpperRatio` bounds, group ratio constraints require any portfolio in `Port` to satisfy the following:

```
(GroupB * Port) .* LowerRatio <= GroupA * Port <= (GroupB * Port) .* UpperRatio
```

---

**Note** This collection of constraints usually requires that portfolio weights be nonnegative and that the products `GroupA * Port` and `GroupB * Port` are always nonnegative. Although negative portfolio weights and non-Boolean group ratio matrices are supported, use with caution.

---

`obj = addGroupRatio(obj, GroupA, GroupB, LowerRatio, UpperRatio)` adds group ratio constraints for portfolio weights to existing group ratio constraints with an additional option for `UpperRatio`.

Given base and comparison group matrices `GroupA` and `GroupB` and, either `LowerRatio`, or `UpperRatio` bounds, group ratio constraints require any portfolio in `Port` to satisfy the following:

```
(GroupB * Port) .* LowerRatio <= GroupA * Port <= (GroupB * Port) .* UpperRatio
```

---

**Note** This collection of constraints usually requires that portfolio weights be nonnegative and that the products `GroupA * Port` and `GroupB * Port` are always nonnegative. Although negative portfolio weights and non-Boolean group ratio matrices are supported, use with caution.

---

## Examples

### Add Group Ratio Constraints to a Portfolio Object

Set a group ratio constraint to ensure that the weight in financial assets does not exceed 50% of the weight in nonfinancial assets. Then add another group ratio constraint to ensure that the weight in financial assets constitute at least 20% of the weight in nonfinancial assets of the portfolio.

```
p = Portfolio;
GA = [ true true true false false false ]; % financial companies
```

```
GB = [ false false false true true true ]; % nonfinancial companies
p = setGroupRatio(p, GA, GB, [], 0.5);

GA = [ true false true false true false ]; % odd-numbered companies
GB = [ false false false true true true ]; % nonfinancial companies
p = addGroupRatio(p, GA, GB, 0.2);

disp(p.NumAssets);
```

### Input Arguments

**obj — Object for portfolio object**

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

**GroupA — Base groups for comparison**

matrix of logical or numerical arrays

Base groups for comparison, specified as a matrix of logical or numerical arrays.

---

**Note** The group matrices `GroupA` and `GroupB` are usually indicators of membership in groups, which means that their elements are usually either 0 or 1. Because of this interpretation, the `GroupA` and `GroupB` matrices can be logical or numerical arrays.

---

Data Types: `double`

**GroupB — Comparison group**

matrix of logical or numerical arrays

Comparison group, specified as a matrix of logical or numerical arrays.

---

**Note** The group matrices `GroupA` and `GroupB` are usually indicators of membership in groups, which means that their elements are usually either 0 or 1. Because of this interpretation, the `GroupA` and `GroupB` matrices can be logical or numerical arrays.

---

Data Types: `double`

**LowerRatio — Lower-bound for ratio of GroupB groups to GroupA groups**

vector

Lower-bound for ratio of GroupB groups to GroupA groups, specified as a vector.

---

**Note** If input is scalar, `LowerRatio` undergoes scalar expansion to be conformable with the group matrices.

---

Data Types: `double`

**UpperRatio — Upper-bound for ratio of GroupB groups to GroupA groups**

vector

Upper-bound for ratio of GroupB groups to GroupA groups, specified as a vector.

---

**Note** If input is scalar, `UpperRatio` undergoes scalar expansion to be conformable with the group matrices.

---

Data Types: double

## Output Arguments

### **obj — Updated portfolio object**

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

## Tips

- You can also use dot notation to add group ratio constraints for the portfolio weights to existing group ratio constraints.  
`obj = obj.addGroupRatio(GroupA, GroupB, LowerRatio, UpperRatio)`
- To remove group ratio constraints from any of the portfolio objects using dot notation, enter empty arrays for the corresponding arrays.

## See Also

`setGroupRatio`

## Introduced in R2011a

## addGroups

Add group constraints for portfolio weights to existing group constraints

### Syntax

```
obj = addGroups(obj, GroupMatrix, LowerGroup)
obj = addGroups(obj, GroupMatrix, LowerGroup, UpperGroup)
```

### Description

`obj = addGroups(obj, GroupMatrix, LowerGroup)` adds group constraints for portfolio weights to existing group constraints for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “`Portfolio` Object Workflow” on page 4-17, “`PortfolioCVaR` Object Workflow” on page 5-15, and “`PortfolioMAD` Object Workflow” on page 6-15.

Given `GroupMatrix` and either `LowerGroup` or `UpperGroup`, a portfolio `Port` must satisfy the following:

```
LowerGroup <= GroupMatrix * Port <= UpperGroup
```

`obj = addGroups(obj, GroupMatrix, LowerGroup, UpperGroup)` adds group constraints for portfolio weights to existing group constraints with an additional option for `UpperGroup`.

Given `GroupMatrix` and either `LowerGroup` or `UpperGroup`, a portfolio `Port` must satisfy the following:

```
LowerGroup <= GroupMatrix * Port <= UpperGroup
```

### Examples

#### Add Group Constraints to a Portfolio Object

Set a group constraint to ensure that the first three assets constitute at most 30% of a portfolio. Then add another group constraint to ensure that the odd-numbered assets constitute at least 20% of a portfolio.

```
p = Portfolio;
G = [ true true true false false false ]; % group matrix for first group constraint
p = setGroups(p, G, [], 0.3);
G = [ true false true false true true ]; % group matrix for second group constraint
p = addGroups(p, G, 0.2);
disp(p.NumAssets);
```

5

```
disp(p.GroupMatrix);
```

|   |   |   |   |   |
|---|---|---|---|---|
| 1 | 1 | 1 | 0 | 0 |
| 1 | 0 | 1 | 0 | 1 |

```

disp(p.LowerGroup);
    -Inf
    0.2000

disp(p.UpperGroup);
    0.3000
    Inf

```

### Add Group Constraints to a PortfolioCVaR Object

Set a group constraint to ensure that the first three assets constitute at most 30% of a portfolio. Then add another group constraint to ensure that the odd-numbered assets constitute at least 20% of a portfolio.

```

p = PortfolioCVaR;
G = [ true true true false false ];      % group matrix for first group constraint
p = setGroups(p, G, [], 0.3);
G = [ true false true false true ];      % group matrix for second group constraint
p = addGroups(p, G, 0.2);
disp(p.NumAssets);

    5

disp(p.GroupMatrix);
    1     1     1     0     0
    1     0     1     0     1

disp(p.LowerGroup);
    -Inf
    0.2000

disp(p.UpperGroup);
    0.3000
    Inf

```

### Add Group Constraints to a PortfolioMAD Object

Set a group constraint to ensure that the first three assets constitute at most 30% of a portfolio. Then add another group constraint to ensure that the odd-numbered assets constitute at least 20% of a portfolio.

```

p = PortfolioMAD;
G = [ true true true false false ];      % group matrix for first group constraint
p = setGroups(p, G, [], 0.3);
G = [ true false true false true ];      % group matrix for second group constraint
p = addGroups(p, G, 0.2);
disp(p.NumAssets);

```

```
disp(p.GroupMatrix);  
1 1 1 0 0  
1 0 1 0 1  
  
disp(p.LowerGroup);  
-Inf  
0.2000  
  
disp(p.UpperGroup);  
0.3000  
Inf
```

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using **Portfolio**, **PortfolioCVaR**, or **PortfolioMAD** object. For more information on creating a portfolio object, see

- **Portfolio**
- **PortfolioCVaR**
- **PortfolioMAD**

Data Types: object

**GroupMatrix — Group constraint matrix**  
matrix

Group constraint matrix, specified as a matrix.

---

**Note** The group matrix **GroupMatrix** often indicates membership in groups, which means that its elements are usually either 0 or 1. Because of this interpretation, **GroupMatrix** can be a logical or numerical matrix.

---

Data Types: double

**LowerGroup — Lower bound for group constraints**  
vector

Lower bound for group constraints, specified as a vector.

---

**Note** If input is scalar, **LowerGroup** undergoes scalar expansion to be conformable with **GroupMatrix**.

---

Data Types: double

**UpperGroup — Upper bound for group constraints**  
vector

Upper bound for group constraints, specified as a vector.

---

**Note** If input is scalar, `UpperGroup` undergoes scalar expansion to be conformable with `GroupMatrix`.

---

Data Types: double

## Output Arguments

### **obj — Updated portfolio object**

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

## Tips

- You can also use dot notation to add group constraints for portfolio weights.  
`obj = obj.addGroups(GroupMatrix, LowerGroup, UpperGroup)`
- To remove group constraints from any of the portfolio objects using dot notation, enter empty arrays for the corresponding arrays.

### Introduced in R2011a

## addInequality

Add linear inequality constraints for portfolio weights to existing constraints

### Syntax

```
obj = addInequality(obj,AInequality,bInequality)
```

### Description

`obj = addInequality(obj,AInequality,bInequality)` adds linear inequality constraints for portfolio weights to existing constraints for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “`Portfolio Object Workflow`” on page 4-17, “`PortfolioCVaR Object Workflow`” on page 5-15, and “`PortfolioMAD Object Workflow`” on page 6-15.

Given a linear inequality constraint matrix `AInequality` and vector `bInequality`, every weight in a portfolio `Port` must satisfy the following:

```
AInequality * Port <= bInequality
```

This function “stacks” additional linear inequality constraints onto any existing linear inequality constraints that exist in the input portfolio object. If no constraints exist, this function is the same as `setInequality`.

### Examples

#### Add Linear Inequality Constraint to a Portfolio Object

Set a linear inequality constraint to ensure that the first three assets constitute at most 50% of a portfolio. Then add another linear inequality constraint to ensure that the last three assets constitute at least 50% of a portfolio.

```
p = Portfolio;
A = [ 1 1 1 0 0 ]; % first inequality constraint
b = 0.5;
p = setInequality(p, A, b);

A = [ 0 0 -1 -1 -1 ]; % second inequality constraint
b = -0.5;
p = addInequality(p, A, b);

disp(p.NumAssets);
5

disp(p.AInequality);
1     1     1     0     0
0     0    -1    -1    -1

disp(p.bInequality);
```

```
0.5000
-0.5000
```

### Add Linear Inequality Constraint to a PortfolioCVaR Object

Set a linear inequality constraint to ensure that the first three assets constitute at most 50% of a portfolio. Then add another linear inequality constraint to ensure that the last three assets constitute at least 50% of a portfolio.

```
p = PortfolioCVaR;
A = [ 1 1 1 0 0 ]; % first inequality constraint
b = 0.5;
p = setInequality(p, A, b);

A = [ 0 0 -1 -1 -1 ]; % second inequality constraint
b = -0.5;
p = addInequality(p, A, b);

disp(p.NumAssets);

5

disp(p.AInequality);

1      1      1      0      0
0      0     -1     -1     -1

disp(p.bInequality);

0.5000
-0.5000
```

### Add Linear Inequality Constraint to a PortfolioMAD Object

Set a linear inequality constraint to ensure that the first three assets constitute at most 50% of a portfolio. Then add another linear inequality constraint to ensure that the last three assets constitute at least 50% of a portfolio.

```
p = PortfolioMAD;
A = [ 1 1 1 0 0 ]; % first inequality constraint
b = 0.5;
p = setInequality(p, A, b);

A = [ 0 0 -1 -1 -1 ]; % second inequality constraint
b = -0.5;
p = addInequality(p, A, b);

disp(p.NumAssets);

5

disp(p.AInequality);
```

```
1      1      1      0      0  
0      0     -1     -1     -1  
  
disp(p.bInequality);  
  
0.5000  
-0.5000
```

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

**AInequality — Linear inequality constraints formed from matrix**  
matrix

Linear inequality constraints, specified as a matrix.

---

**Note** An error results if `AInequality` is empty and `bInequality` is nonempty.

---

Data Types: double

**bInequality — Linear inequality constraints formed from vector**  
vector

Linear inequality constraints, specified as a vector.

---

**Note** An error results if `bInequality` is empty and `AInequality` is nonempty.

---

Data Types: double

## Output Arguments

**obj — Updated portfolio object**  
object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`

- PortfolioCVaR
- PortfolioMAD

## Tips

- You can also use dot notation to add the linear inequality constraints for portfolio weights.  
`obj = obj.addInequality(AInequality, bInequality)`
- You can also remove linear inequality constraints from any of the portfolio objects using dot notation.  
`obj = obj.setInequality([ ], [ ])`

## Introduced in R2011a

## adline

Accumulation/Distribution line

**Note** Using a `fints` object for the `Data` argument of `adline` is not recommended. Use a matrix, timetable, or table instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
ADLine = adline(Data)
```

### Description

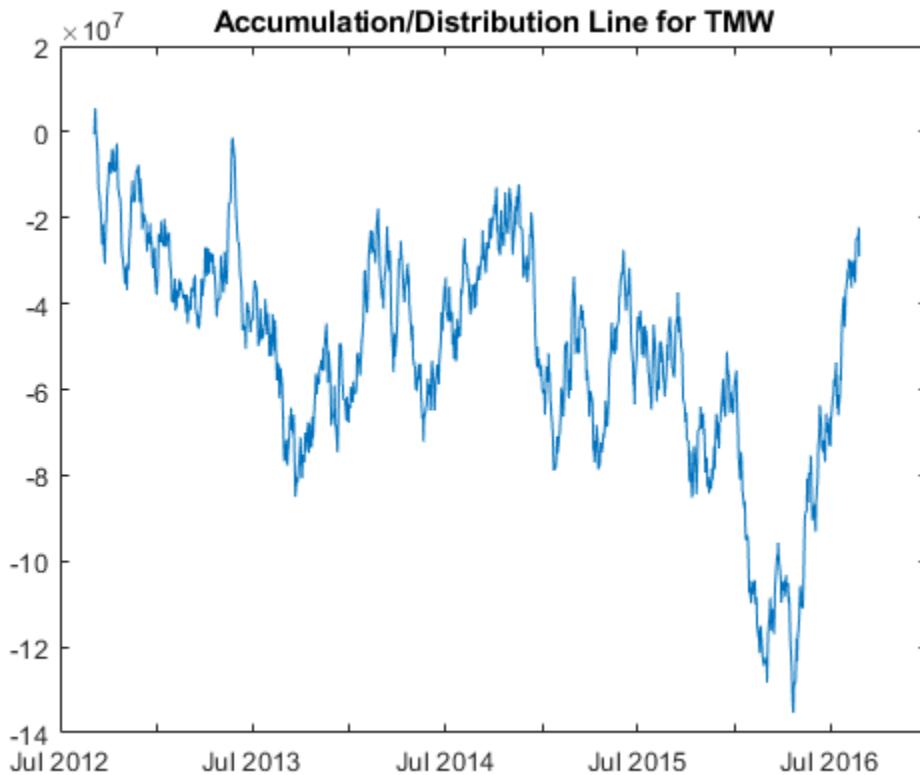

`ADLine = adline(Data)` calculates the Accumulation/Distribution Line from a set of high, low, closing prices, and volume traded of a security.

### Examples

#### Calculate the Accumulation/Distribution Line for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
line = adline(TMW);
plot(line.Time,line.ADLine)
title('Accumulation/Distribution Line for TMW')
```

## Input Arguments

**Data — Data with high, low, closing prices, and volume traded**  
matrix | table | timetable

Data with high, low, closing prices and volume traded, specified as a matrix, table, or timetable. For matrix input, Data is M-by-4 with high, low, closing prices, and volume traded. Timetables and tables with M rows must contain a variable named 'High', 'Low', 'Close', and 'Volume' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

**ADLINE — Accumulation/Distribution line**  
matrix | table | timetable

Accumulation/Distribution line, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

# adosc

Accumulation/Distribution oscillator

**Note** Using a `fints` object for the `Data` argument of `adosc` is not recommended. Use a matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

## Syntax

```
ado = adosc(Data)
```

## Description

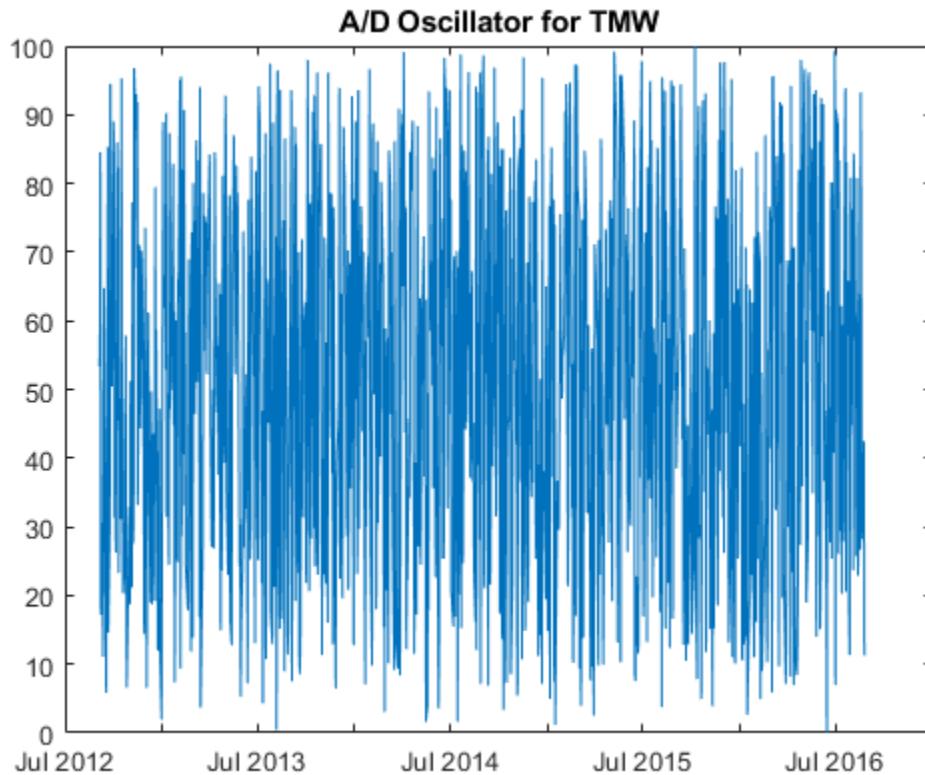

`ado = adosc(Data)` calculates the Accumulation/Distribution (A/D) oscillator.

## Examples

### Calculate the Accumulation/Distribution Oscillator for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
AD0sc = adosc(TMW);
plot(AD0sc.dates, AD0sc.AD0scillator)
title('A/D Oscillator for TMW')
```

## Input Arguments

### Data — Data with open, high, low, close information

matrix | table | timetable

Data with open, high, low, close information, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-4 matrix of open, high, low, and closing prices. Timetables and tables with M rows must contain variables named 'Open', 'High', 'Low', and 'Close' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### ado — Accumulation/Distribution oscillator

matrix | table | timetable

Accumulation/Distribution oscillator, returned with the same number of rows (M) and type (matrix, table, or timetable) as the input **Data**.

## amortize

Amortization schedule

### Syntax

```
[Principal,Interest,Balance,Payment] = amortize(Rate,NumPeriods,PresentValue)
[Principal,Interest,Balance,Payment] = amortize(_____,FutureValue,Due)
```

### Description

[Principal,Interest,Balance,Payment] = amortize(Rate,NumPeriods,PresentValue) returns the principal and interest payments of a loan, the remaining balance of the original loan amount, and the periodic payment.

[Principal,Interest,Balance,Payment] = amortize(\_\_\_\_\_,FutureValue,Due) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute an Amortization Schedule for a Conventional 30-Year, Fixed-Rate Mortgage With Fixed Monthly Payments

Compute an amortization schedule for a conventional 30-year, fixed-rate mortgage with fixed monthly payments and assume a fixed rate of 12% APR and an initial loan amount of \$100,000.

```
Rate      = 0.12/12;    % 12 percent APR = 1 percent per month
NumPeriods = 30*12;    % 30 years = 360 months
PresentValue = 100000;
```

```
[Principal, Interest, Balance, Payment] = amortize(Rate, ...
NumPeriods, PresentValue);
```

The output argument `Payment` contains the fixed monthly payment.

```
format bank
Payment
Payment =
1028.61
```

Summarize the amortization schedule graphically by plotting the current outstanding loan balance, the cumulative principal, and the interest payments over the life of the mortgage. In particular, note that total interest paid over the life of the mortgage exceeds \$270,000, far in excess of the original loan amount.

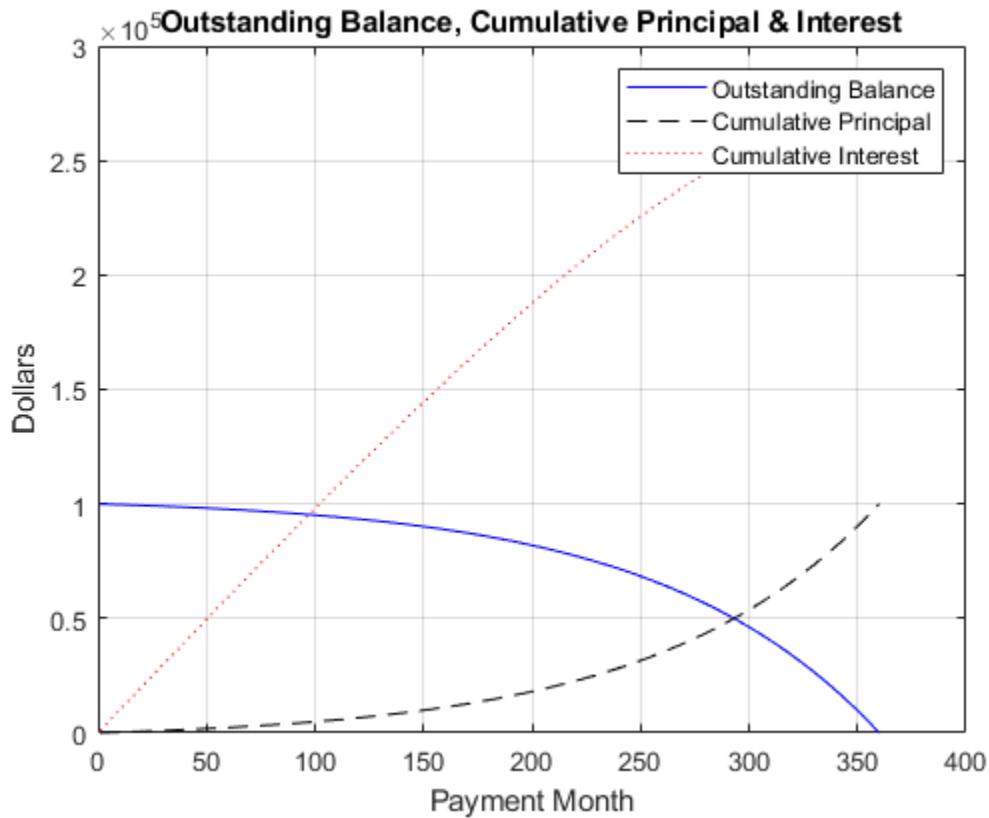

```
plot(Balance, 'b'), hold('on')
plot(cumsum(Principal), '--k')
```

```

plot(cumsum(Interest), ':r')

xlabel('Payment Month')
ylabel('Dollars')
grid('on')
title('Outstanding Balance, Cumulative Principal & Interest')
legend('Outstanding Balance', 'Cumulative Principal', ...
'Cumulative Interest')

```

The solid blue line represents the declining principal over the 30-year period. The dotted red line indicates the increasing cumulative interest payments. Finally, the dashed black line represents the cumulative principal payments, reaching \$100,000 after 30 years.

## Input Arguments

### Rate — Interest-rate per period

scalar numeric decimal

Interest-rate per period, specified as a scalar numeric decimal.

Data Types: double

### NumPeriods — Number of payment periods

scalar numeric

Number of payment periods, specified as a scalar numeric.

Data Types: double

**PresentValue — Present value of the loan**

scalar numeric

Present value of the loan, specified as a scalar numeric.

Data Types: double

**FutureValue — Future value of the loan**

0 (default) | scalar numeric

(Optional) Future value of the loan, specified as a scalar numeric.

Data Types: double

**Due — When payments are due**

0 (end of period) (default) | scalar integer with value of 0 or 1

(Optional) When payments are due, specified as a scalar integer with value of 0 (end of period) or 1 (beginning of period).

Data Types: double

## Output Arguments

**Principal — Principal paid in each period**

vector

Principal paid in each period, returned as a 1-by-NumPeriods vector.

**Interest — Interest paid in each period**

vector

Interest paid in each period, returned as a 1-by-NumPeriods vector.

**Balance — Remaining balance of the loan in each payment period**

vector

Remaining balance of the loan in each payment period, returned as a 1-by-NumPeriods vector.

**Payment — Payment per period**

scalar numeric

Payment per period, returned as a scalar numeric.

## See Also

## Topics

[“Analyzing and Computing Cash Flows” on page 2-14](#)

## Introduced before R2006a

# annurate

Periodic interest rate of annuity

## Syntax

```
Rate = annurate(NumPeriods,Payment,PresentValue)
Rate = annurate(___,FutureValue,Due)
```

## Description

`Rate = annurate(NumPeriods,Payment,PresentValue)` returns the periodic interest rate paid on a loan or annuity.

`Rate = annurate(___,FutureValue,Due)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Calculate the Periodic Interest Rate Paid on a Loan or Annuity

This example shows how to find the periodic interest rate of a four-year, \$5000 loan with a \$130 monthly payment made at the end of each month.

```
Rate = annurate(4*12, 130, 5000, 0, 0)
```

```
Rate = 0.0094
```

Rate multiplied by 12 gives an annual interest rate of 11.32% on the loan.

## Input Arguments

### NumPeriods — Number of payment periods

scalar numeric

Number of payment periods, specified as a scalar numeric.

Data Types: double

### Payment — Payment per period

scalar numeric

Payment per period, specified as a scalar numeric.

Data Types: double

### PresentValue — Present value of the loan

scalar numeric

Present value of the loan, specified as a scalar numeric.

Data Types: double

**FutureValue — Future value of the loan**

0 (default) | scalar numeric

(Optional) Future value of the loan, specified as a scalar numeric.

Data Types: double

**Due — When payments are due**

0 (end of period) (default) | scalar integer with value of 0 or 1

(Optional) When payments are due, specified as a scalar integer with value of 0 (end of period) or 1 (beginning of period).

Data Types: double

## Output Arguments

**Rate — Periodic interest-rate paid of a loan or annuity**

scalar numeric decimal

Periodic interest-rate paid of a loan or annuity, returned as a scalar numeric decimal.

## See Also

## Topics

"Analyzing and Computing Cash Flows" on page 2-14

## Introduced before R2006a

# annuterm

Number of periods to obtain value

## Syntax

```
NumPeriods = annuterm(Rate,Payment,PresentValue)
NumPeriods = annuterm(____,FutureValue,Due)
```

## Description

`NumPeriods = annuterm(Rate,Payment,PresentValue)` calculates the number of periods needed to obtain a future value. To calculate the number of periods needed to pay off a loan, enter the payment or the present value as a negative value.

`NumPeriods = annuterm(____,FutureValue,Due)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Calculate the Number of Periods Needed to Obtain a Future Value

This example shows a savings account with a starting balance of \$1500. \$200 is added at the end of each month and the account pays 9% interest, compounded monthly. How many months will it take to save \$5,000?

```
NumPeriods = annuterm(0.09/12, 200, 1500, 5000, 0)
```

```
NumPeriods = 15.6752
```

## Input Arguments

### Rate — Interest-rate per period

scalar numeric decimal

Interest-rate per period, specified as a scalar numeric decimal.

Data Types: double

### Payment — Payment per period

scalar numeric

Payment per period, specified as a scalar numeric.

Data Types: double

### PresentValue — Present value of the loan

scalar numeric

Present value of the loan, specified as a scalar numeric.

Data Types: double

**FutureValue — Future value of the loan**

0 (default) | scalar numeric

(Optional) Future value of the loan, specified as a scalar numeric.

Data Types: double

**Due — When payments are due**

0 (end of period) (default) | scalar integer with value of 0 or 1

(Optional) When payments are due, specified as a scalar integer with value of 0 (end of period) or 1 (beginning of period).

Data Types: double

## Output Arguments

**NumPeriods — Number of payment periods**

scalar numeric

Number of payment periods, returned as a scalar numeric.

## Introduced before R2006a

# arith2geom

Arithmetic to geometric moments of asset returns

## Syntax

```
[mg,Cg = arith2geom(ma,Ca)
[mg,Cg = arith2geom(____,t)
```

## Description

[ $mg, Cg = \text{arith2geom}(ma, Ca)$ ] transforms moments associated with a simple Brownian motion into equivalent continuously compounded moments associated with a geometric Brownian motion with a possible change in periodicity.

[ $mg, Cg = \text{arith2geom}(____, t)$ ] adds an optional argument  $t$ .

## Examples

### Obtain Arithmetic to Geometric Moments of Asset Returns

This example shows several variations of using `arith2geom`.

Given arithmetic mean  $m$  and covariance  $C$  of monthly total returns, obtain annual geometric mean  $mg$  and covariance  $Cg$ . In this case, the output period (1 year) is 12 times the input period (1 month) so that the optional input  $t = 12$ .

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
[mg, Cg] = arith2geom(m, C, 12)
```

$mg = 4 \times 1$

```
0.8934
2.9488
4.9632
17.0835
```

$Cg = 4 \times 4$   
 $10^3 \times$

Given annual arithmetic mean  $\mathbf{m}$  and covariance  $\mathbf{C}$  of asset returns, obtain monthly geometric mean  $\mathbf{mg}$  and covariance  $\mathbf{Cg}$ . In this case, the output period (1 month) is 1/12 times the input period (1 year) so that the optional input  $t = 1/12$ .

```
[mg, Cg] = arith2geom(m, C, 1/12)
```

mg = 4×1

```
0.0044  
0.0096  
0.0125  
0.0203
```

Cg = 4×4

```
0.0005    0.0003    0.0002      0  
0.0003    0.0025    0.0017    0.0010

0        0.0010    0.0029    0.0107
```

Given arithmetic mean  $\mathbf{m}$  and covariance  $\mathbf{C}$  of monthly total returns, obtain quarterly continuously compounded return moments. In this case, the output is 3 of the input periods so that the optional input  $t = 3$ .

```
[mg, Cg] = arith2geom(m, C, 3)
```

mg = 4×1

```
0.1730  
0.4097  
0.5627  
1.0622
```

Cg = 4×4

```
0.0267    0.0204    0.0106      0  
0.0204    0.1800    0.1390    0.1057

0        0.1057    0.3418    1.8886
```

## Input Arguments

**ma — Arithmetic mean of asset-return data**  
vector

Arithmetic mean of asset-return data, specified as an  $n$ -vector.

Data Types: double

**Ca — Arithmetic covariance of asset-return data**  
matrix

Arithmetic covariance of asset-return data, specified as an n-by-n symmetric, positive semidefinite matrix. If  $C_A$  is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

Data Types: double

**t — Target period of geometric moments in terms of periodicity of arithmetic moments**  
1 (default) | scalar positive numeric

(Optional) Target period of geometric moments in terms of periodicity of arithmetic moments, specified as a scalar positive numeric.

Data Types: double

## Output Arguments

**mg — Continuously compounded or "geometric" mean of asset returns over the target period**  
vector

Continuously compounded or "geometric" mean of asset returns over the target period ( $t$ ), returned as an  $n$ -vector.

**Cg — Continuously compounded or "geometric" covariance of asset returns over the target period**  
matrix

Continuously compounded or "geometric" covariance of asset returns over the target period ( $t$ ), returned as an n-by-n matrix.

## Algorithms

Arithmetic returns over period  $t_A$  are modeled as multivariate normal random variables with moments

$$E[X] = m_A$$

and

$$\text{cov}(X) = C_A$$

Geometric returns over period  $t_G$  are modeled as multivariate lognormal random variables with moments

$$E[Y] = 1 + m_G$$

$$\text{cov}(Y) = C_G$$

Given  $t = t_G / t_A$ , the transformation from geometric to arithmetic moments is

$$1 + m_{G_i} = \exp(tm_{A_i} + \frac{1}{2}tC_{A_{ii}})$$

$$C_{G_{ij}} = (1 + m_{G_i})(1 + m_{G_j})(\exp(tC_{A_{ij}}) - 1)$$

For  $i, j = 1, \dots, n$ .

**Note** If  $t = 1$ , then  $\mathbf{Y} = \exp(\mathbf{X})$ .

---

The `arith2geom` function has no restriction on the input mean `ma` but requires the input covariance `Ca` to be a symmetric positive-semidefinite matrix.

The functions `arith2geom` and `geom2arith` are complementary so that, given `m`, `C`, and `t`, the sequence

```
[mg,Cg] = arith2geom(m,C,t);  
[ma,Ca] = geom2arith(mg,Cg,1/t);
```

yields `ma = m` and `Ca = C`.

# ascii2fts

Create financial time series object from ASCII file

---

**Note** `ascii2fts` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
FTS = ascii2fts(filename,descrow,colheadrow,skiprows)
FTS = ascii2fts(___,timedata)
```

## Description

`FTS = ascii2fts(filename,descrow,colheadrow,skiprows)` creates a financial time series object `FTS` from the ASCII file named `filename`. This form of the function can only read a data file without time-of-day information and create a financial time series object without time information. If time information is present in the ASCII file, an error message appears.

The general format of the text data file is

- Can contain header text lines.
- Can contain column header information. The column header information must immediately precede the data series columns unless `skiprows` is specified.
- Leftmost column must be the date column.
- Dates must be in a valid character vector date format:
  - 'ddmmmyy' or 'ddmmmyyyy'
  - 'mm/dd/yy' or 'mm/dd/yyyy'
  - 'dd-mmm-yy' or 'dd-mmm-yyyy'
  - 'mmm.dd,yy' or 'mmm.dd,yyyy'
- Time information must be in 'hh:mm' format.
- Each column must be separated either by spaces or a tab.

`FTS = ascii2fts(___,timedata)` creates an `FTS` object with time information.

## Examples

### Create Financial Time Series Object From ASCII File With No Description

- If your data file contains no description or column header rows:

|        |       |         |         |         |         |     |
|--------|-------|---------|---------|---------|---------|-----|
| 1/3/95 | 36.75 | 36.9063 | 36.6563 | 36.875  | 1167900 |     |
| 1/4/95 | 37    | 37.2813 | 36.625  | 37.1563 | 1994700 | ... |

You can create a financial time series object from it with the simplest form of the `ascii2fts` function:

```
myinc = ascii2fts('my_inc.dat')

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In ascii2fts (line 64)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)

myinc =

desc: my_inc.dat
freq: Unknown (0)

'dates: (2)'  'series1: (2)'  'series2: (2)'  'series3: (2)'...
'03-Jan-1995'  [ 36.7500]  [ 36.9063]  [ 36.6563]
'04-Jan-1995'  [      37]  [ 37.2813]  [ 36.6250]
```

### Create Financial Time Series Object From ASCII File Containing Description and Column Headers

- If your data file contains description and column header information with the data series immediately following the column header row:

```
International Business Machines Corporation (IBM)
Daily prices (1/3/95 to 4/5/99)
DATE      OPEN      HIGH      LOW      CLOSE      VOLUME
1/3/95    36.75    36.9063   36.6563   36.875    1167900
1/4/95    37       37.2813   36.625    37.1563   1994700 ...
```

You must specify the row numbers containing the description and column headers:

```
ibm = ascii2fts('ibm9599.dat', 1, 3)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In ascii2fts (line 64)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)

ibm =

desc: International Business Machines Corporation (IBM)
freq: Unknown (0)
'dates: (2)'  'OPEN: (2)'  'HIGH: (2)'  'LOW: (2)' ...
'03-Jan-1995'  [ 36.7500]  [ 36.9063]  [ 36.6563]
'04-Jan-1995'  [      37]  [ 37.2813]  [ 36.6250]
```

### Create Financial Time Series Object From ASCII File Containing Rows Between Column Headers

- If your data file contains rows between the column headers and the data series:

```
Staples, Inc. (SPLS)
Daily prices
DATE      OPEN      HIGH      LOW      CLOSE      VOLUME
Starting date: 04/08/1996
Ending date: 04/07/1999
```

```
4/8/96 19.50 19.75 19.25 19.375 548500
4/9/96 19.75 20.125 19.375 20 1135900 ...
```

You need to indicate to `ascii2fts` the rows in the file that must be skipped. Assume that you have called the data file containing the Staples data (`staples.dat`).

```
spls = ascii2fts('staples.dat', 1, 3, [4 5])
```

The command above indicates that the fourth and fifth rows in the file should be skipped in creating the financial time series object:

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In ascii2fts (line 64)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
spls =
```

```
desc: Staples, Inc. (SPLS)
freq: Unknown (0)
```

```
'dates: (2)'  'OPEN: (2)'    'HIGH: (2)'    'LOW: (2)'
'08-Apr-1996'  [ 19.5000]  [ 19.7500]  [19.2500]
'09-Apr-1996'  [ 19.7500]  [ 20.1250]  [19.3750]
```

## Create Financial Time Series Object From ASCII File Containing Time-of-Day Information

- Create a financial time series object containing time-of-day information.

Create a data file with time information:

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
serial_dates_times = [datenum(dates), datenum(times)];
data = round(10*rand(6,2));
stat = fts2ascii('myfts_file2.txt', serial_dates_times, data, ...
{'dates'; 'times'; 'Data1'; 'Data2'}, 'My FTS with Time')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fts2ascii (line 60)
```

```
stat =
```

```
1
```

Read the data file back and create a financial time series object:

```
MyFts = ascii2fts('myfts_file2.txt', 't', 1, 2, 1)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
```

```
> In ascii2fts (line 64)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
```

```
> In fints/display (line 66)
```

```
MyFts =
```

```
desc: My FTS with Time
freq: Unknown (0)
```

```
'dates: (6)'    'times: (6)'    'Data1: (6)'    'Data2: (6)'  
'01-Jan-2001'  '11:00'        [      9]  [      4]  
'          '     '12:00'        [      7]  [      9]  
'02-Jan-2001'  '11:00'        [      2]  [      1]  
'          '     '12:00'        [      4]  [      4]  
'03-Jan-2001'  '11:00'        [      9]  [      8]  
'          '     '12:00'        [      9]  [      0]
```

## Input Arguments

**filename — Name of ascii data file**

character vector

Name of ascii data file, specified as a character vector.

Data Types: char

**descrow — Row number in the data file containing description**

numeric

Row number in the data file that contains the description used for the description field of the financial time series object, specified as a numeric.

Data Types: double

**colheadrow — Row number that has the column header names**

numeric

Row number that has the column header names, specified as a numeric.

Data Types: double

**skiprows — Row numbers to skip in data file**

scalar numeric | vector

Row numbers to skip in the data file, specified as a scalar numeric or vector.

Data Types: double

**timedata — Time data indicator**

character vector with values 'T' or 'NT'

Time data indicator, specified as a character vector. Set to 'T' if time-of-day data is present in the ASCII data file or to 'NT' if no time-of-day data is present.

Data Types: char

## Output Arguments

**FTS — Financial time series object**

fints object

Financial time series object, returned as a fints object.

Data Types: object

**See Also**

## bar, barh

Bar chart

---

**Note** bar, barh is not recommended. Use bar or barh instead.

---

### Syntax

```
bar(tsobj)
bar(tsobj, width)
bar(__ style)
hbar = bar(__)
barh(tsobj)
barh(tsobj, width)
barh(__ style)
hbar = barh(__)
```

### Description

bar(tsobj) draws the columns of data series of the object tsobj. The number of data series dictates the number of vertical bars per group. Each group is the data for one particular date.

---

**Note** Use the MATLAB command shading faceted to put edges on the bars. Use shading flat to turn edges off.

---

bar(tsobj, width) specifies the width of the bars.

bar(\_\_ style) changes the style of the bar chart.

hbar = bar(\_\_) returns a vector of bar handles.

barh(tsobj) draws the columns of data series of the object tsobj. The number of data series dictates the number of horizontal bars per group. Each group is the data for one particular date.

barh(tsobj, width) specifies the width of the bars.

barh(\_\_ style) changes the style of the bar chart.

hbar = barh(\_\_) returns a vector of bar handles.

### Examples

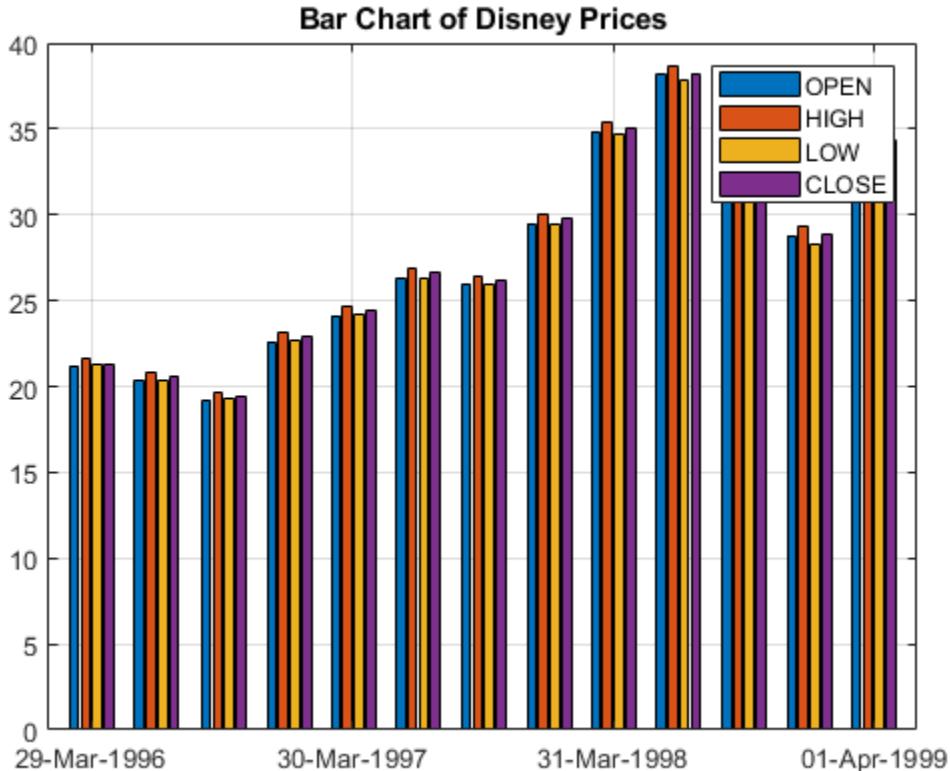

#### Create a Bar Chart for a Stock

This example shows how to create a bar chart for Disney stock showing high, low, opening, and closing prices.

```
load disney
bar(q_dis)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="matlab:help/fints">fints</a>

```
title('Bar Chart of Disney Prices')
```

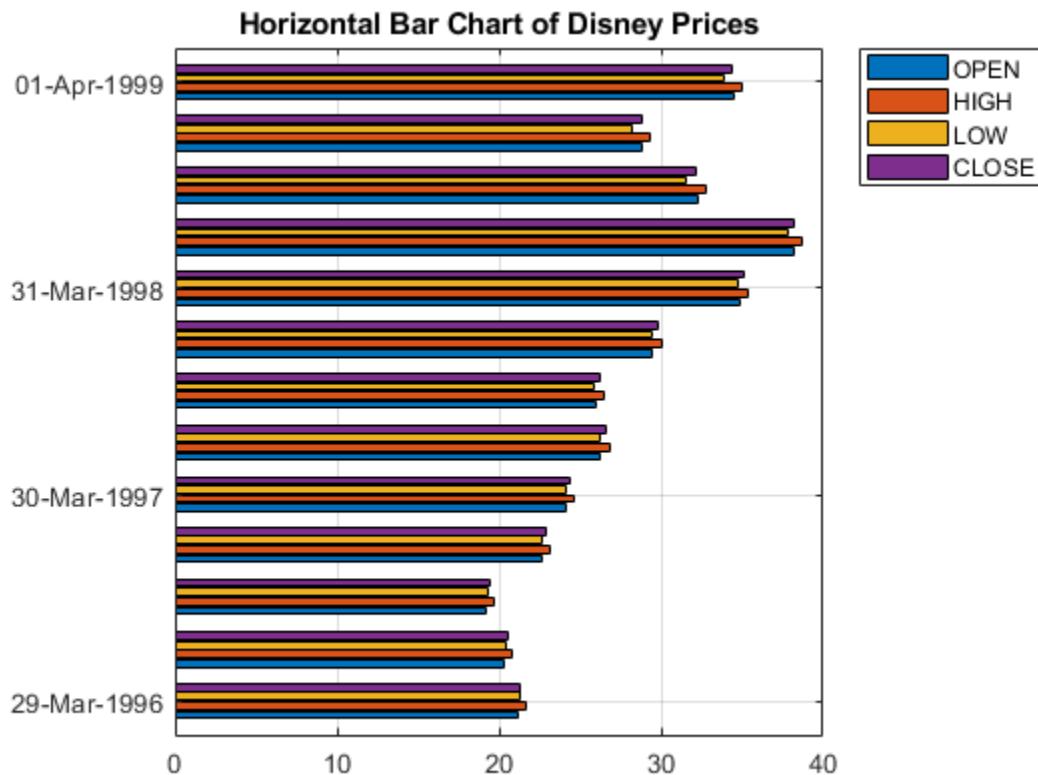

### Create a Horizontal Bar Chart for a Stock

This example shows how to create a horizontal bar chart for Disney stock showing high, low, opening, and closing prices.

```
load disney
barh(q_dis)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="matlab:help/fints">fints</a>

```
title('Horizontal Bar Chart of Disney Prices')
```

## Input Arguments

**tsobj — Financial time series object**  
fints object

Financial time series object, specified as a `fints` object.

Data Types: object

**width — Width of the bars and separation of bars within a group**  
0.8 (default) | positive numeric

(Optional) Width of the bars and separation of bars within a group, specified as a positive numeric. If `width` is 1, the bars within a group touch one another. Values > 1 produce overlapping bars.

Data Types: double

**style — Type of grouping**  
'grouped' (default) | character vector with values of 'grouped' or 'stacked'

(Optional) Type of grouping, specified as a character vector.

Data Types: double

## Output Arguments

### **hbar — Bar handles**

vector

Bar handles, returned as a vector.

### **See Also**

[bar3](#), [bar3h](#) | [candle](#) | [highlow](#)

**Introduced before R2006a**

## bar3, bar3h

3-D bar chart

---

**Note** bar3, bar3h is not recommended. Use bar3 or bar3h instead.

---

### Syntax

```
bar3(tsobj)
bar3(tsobj,width)
bar3(__ style)
hbar3 = bar3(__ )
bar3h(tsobj)
bar3h(tsobj,width)
bar3h(__ style)
hbar3 = bar3h(__ )
```

### Description

bar3(tsobj) draws the columns of data series of the object tsobj. The number of data series dictates the number of vertical bars per group. Each group is the data for one particular date.

---

**Note** Use the MATLAB command shading faceted to put edges on the bars. Use shading flat to turn edges off.

---

bar3(tsobj,width) specifies the width of the bars.

bar3(\_\_ style) changes the style of the bar chart.

hbar3 = bar3(\_\_ ) returns a vector of bar handles.

bar3h(tsobj) draws the columns of data series of the object tsobj. The number of data series dictates the number of horizontal bars per group. Each group is the data for one particular date.

bar3h(tsobj,width) specifies the width of the bars.

bar3h(\_\_ style) changes the style of the bar chart.

hbar3 = bar3h(\_\_ ) returns a vector of bar handles.

### Examples

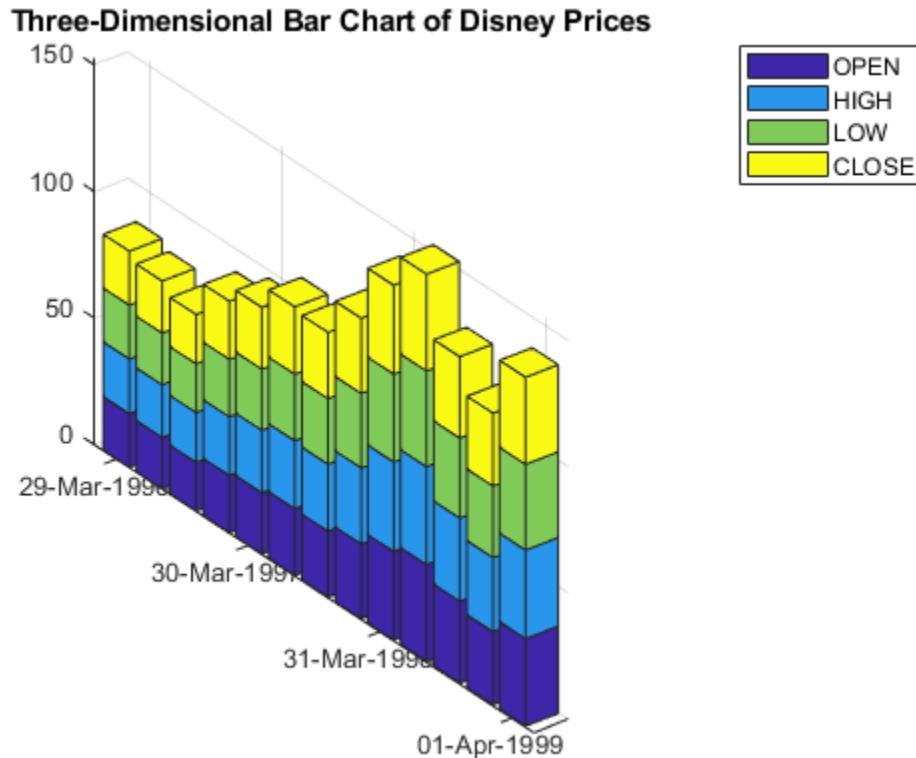

#### Create a Three-Dimensional Bar Chart

This example shows how to create a three-dimensional bar chart for Disney stock showing high, low, opening, and closing prices.

```
load disney
bar3(q_dis, 'stacked')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [matlab.lang.FINTS](#)

```
title('Three-Dimensional Bar Chart of Disney Prices')
```

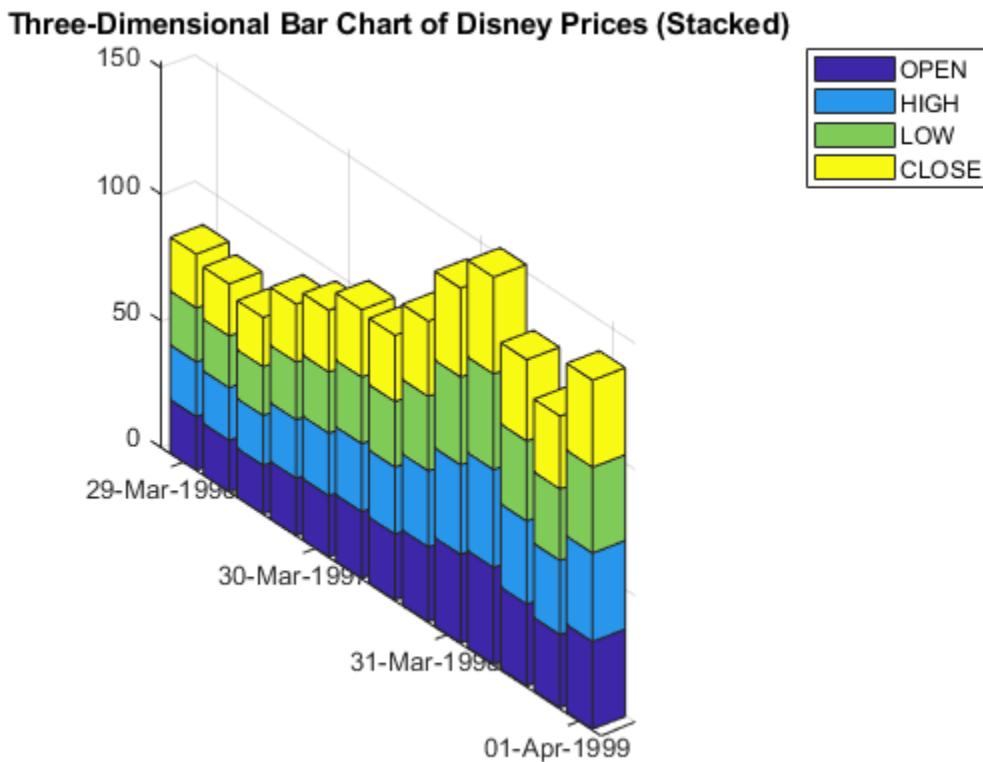

### Create a Three-Dimensional (Stacked) Bar Chart

This example shows how to create a three-dimensional, stacked bar chart for Disney stock showing high, low, opening, and closing prices.

```
load disney
bar3(q_dis, 'stacked')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [matlab.lang.FINTS](#)

```
title('Three-Dimensional Bar Chart of Disney Prices (Stacked)')
```

## Input Arguments

**tsobj — Financial time series object**  
fints object

Financial time series object, specified as a `fints` object.

Data Types: object

**width — Width of the bars and separation of bars within a group**  
0.8 (default) | positive numeric

(Optional) Width of the bars and separation of bars within a group, specified as a positive numeric. If `width` is 1, the bars within a group touch one another. Values > 1 produce overlapping bars.

Data Types: double

**style — Type of grouping**  
'detached' (default) | character vector with values of 'grouped', 'stacked', or 'detached'

(Optional) Type of grouping, specified as a character vector.

Data Types: double

## Output Arguments

### **hbar3 — Bar handles**

vector

Bar handles, returned as a vector.

### **See Also**

`bar`, `barh` | `candle` | `highlow`

**Introduced before R2006a**

## beytbill

Bond equivalent yield for Treasury bill

### Syntax

```
Yield = beytbill(Settle,Maturity,Discount)
```

### Description

`Yield = beytbill(Settle,Maturity,Discount)` returns the bond equivalent yield for a Treasury bill.

### Examples

#### Find the Bond Equivalent Yield for a Treasury Bill

This example shows how to find the bond equivalent yield for a Treasury bill that has a settlement date of February 11, 2000, a maturity date of August 7, 2000, and a discount rate is 5.77.

```
Yield = beytbill('2/11/2000', '8/7/2000', 0.0577)
```

```
Yield = 0.0602
```

#### Find the Bond Equivalent Yield for a Treasury Bill Using datetime Inputs

This example shows how to use `datetime` inputs to find the bond equivalent yield for a Treasury bill that has a settlement date of February 11, 2000, a maturity date of August 7, 2000, and the discount rate is 5.77.

```
Yield = beytbill(datetime('11-Feb-2000','Locale','en_US'), datetime('7-Aug-2000','Locale','en_US'))
```

```
Yield = 0.0602
```

### Input Arguments

#### Settle — Settlement date of Treasury bill

serial date number | date character vector | `datetime`

Settlement date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-1 vector of serial date numbers, date character vectors, or `datetime` arrays. `Settle` must be earlier than `Maturity`.

Data Types: double | char | `datetime`

#### Maturity — Maturity date of Treasury bill

serial date number | date character vector | `datetime`

Maturity date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

#### **Discount — Discount rate of Treasury bill**

decimal

Discount rate of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of decimal fraction values.

Data Types: double

## **Output Arguments**

#### **Yield — Treasury bill yield**

decimal

Treasury bill yield, returned as a scalar or NTBILLS-by-1 vector.

---

**Note** The number of days to maturity is typically quoted as: md - sd - 1. A NaN is returned for all cases in which negative prices are implied by the discount rate, *Discount*, and the number of days between *Settle* and *Maturity*.

---

## **See Also**

`datenum` | `prtbill` | `yldtbill` | `datetime`

## binprice

Binomial put and call American option pricing using Cox-Ross-Rubinstein model

### Syntax

```
[AssetPrice,OptionValue] = binprice(Price,Strike,Rate,Time,Increment,  
Volatility,Flag)  
[AssetPrice,OptionValue] = binprice( ___,DividendRate,Dividend,ExDiv)
```

### Description

[AssetPrice,OptionValue] = binprice(Price,Strike,Rate,Time,Increment, Volatility,Flag) prices an American option using the Cox-Ross-Rubinstein binomial pricing model. An American option can be exercised any time until its expiration date.

[AssetPrice,OptionValue] = binprice( \_\_\_,DividendRate,Dividend,ExDiv) adds optional arguments for DividendRate,Dividend, and ExDiv.

### Examples

#### Price an American Option Using the Cox-Ross-Rubinstein Binomial Pricing Model

This example shows how to price an American put option with an exercise price of \$50 that matures in 5 months. The current asset price is \$52, the risk-free interest rate is 10%, and the volatility is 40%. There is one dividend payment of \$2.06 in 3-1/2 months. When specifying the input argument ExDiv in terms of number of periods, divide the ex-dividend date, specified in years, by the time Increment.

$$\text{ExDiv} = (3.5/12) / (1/12) = 3.5$$

```
[Price, Option] = binprice(52, 50, 0.1, 5/12, 1/12, 0.4, 0, 0, 2.06, 3.5)
```

Price = 6×6

|         |         |         |         |         |         |
|---------|---------|---------|---------|---------|---------|
| 52.0000 | 58.1367 | 65.0226 | 72.7494 | 79.3515 | 89.0642 |
| 0       | 46.5642 | 52.0336 | 58.1706 | 62.9882 | 70.6980 |
| 0       | 0       | 41.7231 | 46.5981 | 49.9992 | 56.1192 |
| 0       | 0       | 0       | 37.4120 | 39.6887 | 44.5467 |
| 0       | 0       | 0       | 0       | 31.5044 | 35.3606 |
| 0       | 0       | 0       | 0       | 0       | 28.0688 |

Option = 6×6

|        |        |         |         |         |         |

| 0      | 0      | 0       | 14.2245 | 10.3113 | 5.4533  |
| 0      | 0      | 0       | 0       | 18.4956 | 14.6394 |
| 0      | 0      | 0       | 0       | 0       | 21.9312 |

The output returned is the asset price and American option value at each node of the binary tree.

## Input Arguments

### **Price — Current price of underlying asset**

numeric

Current price of underlying asset, specified as a scalar numeric value.

Data Types: double

### **Strike — Exercise price of the option**

numeric

Exercise price of the option, specified as a scalar numeric value.

Data Types: double

### **Rate — Risk-free interest rate**

decimal

Risk-free interest rate, specified as scalar decimal fraction.

Data Types: double

### **Time — Option time until maturity**

numeric

Option time until maturity, specified as a scalar for the number of years.

Data Types: double

### **Increment — Time increment**

numeric

Time increment, specified as a scalar numeric. **Increment** is adjusted so that the length of each interval is consistent with the maturity time of the option. (**Increment** is adjusted so that **Time** divided by **Increment** equals an integer number of increments.)

Data Types: double

### **Volatility — Asset volatility**

numeric

Asset volatility, specified as a scalar numeric.

Data Types: double

### **Flag — Flag indicating whether option is a call or put**

integer with values 0 or 1

Flag indicating whether option is a call or put, specified as a scalar **Flag** = 1 for a call option, or **Flag** = 0 for a put option.

Data Types: logical

**DividendRate — Dividend rate**

0 (default) | decimal

(Optional) Dividend rate, specified as a scalar decimal. If you enter a value for `DividendRate`, set `Dividend` and `ExDiv` = 0 or do not enter them. If you enter values for `Dividend` and `ExDiv`, set `DividendRate` = 0.

Data Types: double

**Dividend — Dividend payment**

0 (default) | numeric

(Optional) Dividend payment at an ex-dividend date (`ExDiv`), specified as a 1-by-N row vector. For each dividend payment, there must be a corresponding ex-dividend date. If you enter values for `Dividend` and `ExDiv`, set `DividendRate` = 0.

Data Types: double

**ExDiv — Ex-dividend date**

0 (default) | numeric

(Optional) Ex-dividend date, specified as a 1-by-N vector row vector for the number of periods.

Data Types: double

## Output Arguments

**AssetPrice — Asset price**

vector

Asset price, returned as a vector that represents each node of the Cox-Ross-Rubinstein (CRR) binary tree.

**OptionValue — Option value**

vector

Option value, returned as a vector that represents each node of the Cox-Ross-Rubinstein (CRR) binary tree.

## blkimpv

Implied volatility for futures options from Black model

### Syntax

```
Volatility = blkimpv(Price,Strike,Rate,Time,Value)
Volatility = blkimpv(_____,Name,Value)
```

### Description

`Volatility = blkimpv(Price,Strike,Rate,Time,Value)` computes the implied volatility of a futures price from the market value of European futures options using Black's model. If the `Class` name-value argument is empty or unspecified, the default is a call option

---

**Note** Any input argument can be a scalar, vector, or matrix. When a value is a scalar, that value is used to compute the implied volatility of all the options. If more than one input is a vector or matrix, the dimensions of all nonscalar inputs must be identical.

Ensure that `Rate` and `Time` are expressed in consistent units of time.

---

`Volatility = blkimpv(_____,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Find Implied Volatility for Futures Options from Black's Model

This example shows how to find the implied volatility for a European call futures option that expires in four months, trades at \$1.1166, and has an exercise price of \$20. Assume that the current underlying futures price is also \$20 and that the risk-free rate is 9% per annum. Furthermore, assume that you are interested in implied volatilities no greater than 0.5 (50% per annum). Under these conditions, the following commands all return an implied volatility of 0.25, or 25% per annum.

```
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 'Limit',0.5);
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 'Limit',0.5,'Class',{'Call'});
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 'Limit',0.5,'Class',true);
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 'Limit',0.5,'Class',true,'Method','jackel2016')
```

Volatility = 0.2500

### Input Arguments

#### Price — Current price of underlying asset

scalar numeric

Current price of the underlying asset (that is, a futures contract), specified as a scalar numeric.

Data Types: double

**Strike — Exercise price of the futures option**

scalar numeric

Exercise price of the futures option, specified as a scalar numeric.

Data Types: double

**Rate — Annualized continuously compounded risk-free rate of return over life of the option**

scalar positive decimal

Annualized continuously compounded risk-free rate of return over the life of the option, specified as a scalar positive decimal.

Data Types: double

**Time — Time to expiration of the futures option**

scalar numeric

Time to expiration of the futures option, specified as the number of years using a scalar numeric.

Data Types: double

**Value — Price of a European option from which implied volatility of underlying asset is derived**

scalar numeric

Price of a European futures option from which the implied volatility of the underlying asset is derived, specified as a scalar numeric.

Data Types: double

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `Volatility = blkimpv(Yield,CouponRate,Settle,Maturity,'Method','jackel2016')`

**Limit — Upper bound of implied volatility search interval**

10 (1000% per annum) (default) | positive scalar numeric

Upper bound of the implied volatility search interval, specified as the comma-separated pair consisting of 'Limit' and a positive scalar numeric. If `Limit` is empty or unspecified, the default is 10, or 1000% per annum.

---

**Note** If you are using `Method` with a value of 'jackel2016', the `Limit` argument is ignored.

Data Types: double

**Tolerance — Implied volatility termination tolerance**

1e-6 (default) | positive scalar numeric

Implied volatility termination tolerance, specified as the comma-separated pair consisting of 'Tolerance' and a positive scalar numeric. If empty or missing, the default is 1e-6.

**Note** If you are using Method with a value of 'jackel2016', the Tolerance argument is ignored.

Data Types: double

**Class — Option class from which implied volatility is derived**

true (call option) (default) | logical | cell array of character vectors | string array

Option class indicating option type (call or put) from which implied volatility is derived, specified as the comma-separated pair consisting of 'Class' and a logical indicator, cell array of character vectors, or string array.

To specify call options, set Class = true or Class = {'call'}. To specify put options, set Class = false or Class = {'put'} or Class = ["put"]. If Class is empty or unspecified, the default is a call option.

Data Types: logical | cell | string

**Method — Method for computing implied volatility**

'jackel2016' (default) | character vector with values 'search' or 'jackel2016' | string with values "search" or "jackel2016"

Method for computing implied volatility, specified as the comma-separated pair consisting of 'Method' and a character vector with a value of 'search' or 'jackel2016' or a string with a value of "search" or "jackel2016".

Data Types: char | string

## Output Arguments

**Volatility — Implied volatility of underlying asset derived from European futures option prices**

decimal

Implied volatility of the underlying asset derived from European futures option prices, returned as a decimal. If no solution is found, blkimpv returns NaN.

## blkprice

Black model for pricing futures options

### Syntax

```
[Call,Put] = blkprice(Price,Strike,Rate,Time,Volatility)
```

### Description

[Call,Put] = blkprice(Price,Strike,Rate,Time,Volatility) computes European put and call futures option prices using Black's model.

**Note** Any input argument can be a scalar, vector, or matrix. If a scalar, then that value is used to price all options. If more than one input is a vector or matrix, then the dimensions of those non-scalar inputs must be the same.

Ensure that Rate, Time, and Volatility are expressed in consistent units of time.

---

### Examples

#### Compute European Put and Call Futures Option Prices Using Black's Model

This example shows how to price European futures options with exercise prices of \$20 that expire in four months. Assume that the current underlying futures price is also \$20 with a volatility of 25% per annum. The risk-free rate is 9% per annum.

```
[Call, Put] = blkprice(20, 20, 0.09, 4/12, 0.25)
```

```
Call = 1.1166
```

```
Put = 1.1166
```

### Input Arguments

#### Price — Current price of underlying asset

numeric

Current price of the underlying asset (that is, a futures contract), specified as a numeric value.

Data Types: double

#### Strike — Exercise price of the futures option

numeric

Exercise price of the futures option, specified as a numeric value.

Data Types: double

---

**Rate — Annualized continuously compounded risk-free rate of return over life of the option**  
positive decimal

Annualized continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal number.

Data Types: double

**Time — Time to expiration of option**  
numeric

Time to expiration of the option, specified as the number of years. Time must be greater than 0.

Data Types: double

**Volatility — Annualized asset price volatility**  
positive decimal

Annualized futures price volatility, specified as a positive decimal number.

Data Types: double

## Output Arguments

**Call — Price of a European call futures option**  
matrix

Price of a European call futures option, returned as a matrix.

**Put — Price of a European put futures option**  
matrix

Price of a European put futures option, returned as a matrix.

## Introduced before R2006a

## blsdelta

Black-Scholes sensitivity to underlying price change

### Syntax

```
[CallDelta,PutDelta] = blsdelta(Price,Strike,Rate,Time,Volatility)
[CallDelta,PutDelta] = blsdelta(___,Yield)
```

### Description

[CallDelta,PutDelta] = blsdelta(Price,Strike,Rate,Time,Volatility) returns delta, the sensitivity in option value to change in the underlying asset price. Delta is also known as the hedge ratio. blsdelta uses normcdf, the normal cumulative distribution function in the Statistics and Machine Learning Toolbox.

---

**Note** blsdelta can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

Yield = Rate

When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

Yield = ForeignRate

where ForeignRate is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

[CallDelta,PutDelta] = blsdelta(\_\_\_,Yield) adds an optional argument for Yield.

### Examples

#### Find the Sensitivity in Option Value to Change in the Underlying Asset Price

This example shows how to find the Black-Scholes delta sensitivity for an underlying asset price change.

```
[CallDelta, PutDelta] = blsdelta(50, 50, 0.1, 0.25, 0.3, 0)
CallDelta = 0.5955
PutDelta = -0.4045
```

### Input Arguments

#### Price — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: double

**Strike — Exercise price of option**

numeric

Exercise price of the option, specified as a numeric value.

Data Types: double

**Rate — Annualized, continuously compounded risk-free rate of return over life of option**

positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: double

**Time — Time (in years) to expiration of the option**

numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: double

**Volatility — Annualized asset price volatility**

positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: double

**Yield — Annualized, continuously compounded yield of the underlying asset over life of option**

0 (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Data Types: double

## Output Arguments

**CallDelta — Delta of call option**

numeric

Delta of the call option, returned as a numeric value.

**PutDelta — Delta of put option**

numeric

Delta of the put option, returned as a numeric.

# blsgamma

Black-Scholes sensitivity to underlying delta change

## Syntax

```
Gamma = blsgamma(Price,Strike,Rate,Time,Volatility)
Gamma = blsgamma(___,Yield)
```

## Description

`Gamma = blsgamma(Price,Strike,Rate,Time,Volatility)` returns gamma, the sensitivity of delta to change in the underlying asset price. `blsgamma` uses `normpdf`, the probability density function in the Statistics and Machine Learning Toolbox.

---

**Note** `blsgamma` can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument `Yield` as:

`Yield = Rate`

When pricing currencies (Garman-Kohlhagen model), enter the input argument `Yield` as:

`Yield = ForeignRate`

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

`Gamma = blsgamma(___,Yield)` adds an optional argument for `Yield`.

## Examples

### Find Gamma for a Change in the Underlying Asset Price

This example shows how to find the gamma, the sensitivity of delta to a change in the underlying asset price.

```
Gamma = blsgamma(50, 50, 0.12, 0.25, 0.3, 0)
```

```
Gamma = 0.0512
```

## Input Arguments

### Price — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: `double`

**Strike — Exercise price of option**

numeric

Exercise price of the option, specified as a numeric value.

Data Types: double

**Rate — Annualized, continuously compounded risk-free rate of return over life of option**

positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: double

**Time — Time (in years) to expiration of the option**

numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: double

**Volatility — Annualized asset price volatility**

positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: double

**Yield — Annualized, continuously compounded yield of the underlying asset over life of option**

0 (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Data Types: double

## Output Arguments

**Gamma — Delta to change in underlying security price**

numeric

Delta to change in underlying security price, returned as a numeric value.

## blsimpv

Black-Scholes implied volatility

### Syntax

```
Volatility = blsimpv(Price,Strike,Rate,Time,Value)
Volatility = blsimpv(____,Name,Value)
```

### Description

`Volatility = blsimpv(Price,Strike,Rate,Time,Value)` using a Black-Scholes model computes the implied volatility of an underlying asset from the market value of European options. If the `Class` name-value argument is empty or unspecified, the default is a call option

---

**Note** The input arguments `Price`, `Strike`, `Rate`, `Time`, `Value`, `Yield`, and `Class` can be scalars, vectors, or matrices. If scalars, then that value is used to compute the implied volatility from all options. If more than one of these inputs is a vector or matrix, then the dimensions of all non-scalar inputs must be the same.

Also, ensure that `Rate`, `Time`, and `Yield` are expressed in consistent units of time.

---

`Volatility = blsimpv(____,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute the Implied Volatility of an Underlying Asset Using a Black-Scholes Model

This example shows how to compute the implied volatility for a European call option trading at \$10 with an exercise price of \$95 and three months until expiration. Assume that the underlying stock pays no dividend and trades at \$100. The risk-free rate is 7.5% per annum. Furthermore, assume that you are interested in implied volatilities no greater than 0.5 (50% per annum). Under these conditions, the following statements all compute an implied volatility of 0.3130, or 31.30% per annum.

```
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 'Limit', 0.5);
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 'Limit', 0.5, 'Yield', 0, 'Class', {'Call'});
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 'Limit', 0.5, 'Yield', 0, 'Class', true);
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 'Limit', 0.5, 'Yield', 0, 'Class', true, 'Method', 'jac')
```

Volatility = 0.3130

### Input Arguments

#### Price — Current price of underlying asset

scalar numeric

Current price of the underlying asset, specified as a scalar numeric.

Data Types: double

#### **Strike — Exercise price of the option**

scalar numeric

Exercise price of the option, specified as a scalar numeric.

Data Types: double

#### **Rate — Annualized continuously compounded risk-free rate of return over life of the option**

scalar positive decimal

Annualized continuously compounded risk-free rate of return over the life of the option, specified as a scalar positive decimal.

Data Types: double

#### **Time — Time to expiration of option**

scalar numeric

Time to expiration of the option, specified as the number of years using a scalar numeric.

Data Types: double

#### **Value — Price of a European option from which implied volatility of underlying asset is derived**

scalar numeric

Price of a European option from which the implied volatility of the underlying asset is derived, specified as a scalar numeric.

Data Types: double

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: Volatility =

```
blsimpv(Yield,CouponRate,Settle,Maturity,'Method','jackel2016')
```

#### **Limit — Upper bound of implied volatility search interval**

10 (1000% per annum) (default) | positive scalar numeric

Upper bound of the implied volatility search interval, specified as the comma-separated pair consisting of 'Limit' and a positive scalar numeric. If Limit is empty or unspecified, the default is 10, or 1000% per annum.

---

**Note** If you are using Method with a value of 'jackel2016', the Limit argument is ignored.

---

Data Types: double

**Yield — Annualized continuously compounded yield of underlying asset over life of the option**

0 (default) | decimal

Annualized continuously compounded yield of the underlying asset over the life of the option, specified as the comma-separated pair consisting of 'Yield' and a decimal number. If Yield is empty or missing, the default value is 0.

For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

---

**Note** `blsimpv` can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

`Yield = Rate`

When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

`Yield = ForeignRate`

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

Data Types: double

**Tolerance — Implied volatility termination tolerance**

1e-6 (default) | positive scalar numeric

Implied volatility termination tolerance, specified as the comma-separated pair consisting of 'Tolerance' and a positive scalar numeric. If empty or missing, the default is 1e-6.

---

**Note** If you are using Method with a value of 'jackel2016', the Tolerance argument is ignored.

---

Data Types: double

**Class — Option class from which implied volatility is derived**

true (call option) (default) | logical | cell array of character vectors | string array

Option class indicating option type (call or put) from which implied volatility is derived, specified as the comma-separated pair consisting of 'Class' and a logical indicator, cell array of character vectors, or string array.

To specify call options, set `Class = true` or `Class = {'call'}`. To specify put options, set `Class = false` or `Class = {'put'}` or `Class = ["put"]`. If Class is empty or unspecified, the default is a call option.

Data Types: logical | cell | string

**Method — Method for computing implied volatility**

'jackel2016' (default) | character vector with values 'search' or 'jackel2016' | string with values "search" or "jackel2016"

Method for computing implied volatility, specified as the comma-separated pair consisting of 'Method' and a character vector with a value of 'search' or 'jackel2016' or a string with a value of "search" or "jackel2016".

Data Types: char | string

## Output Arguments

**Volatility – Implied volatility of underlying asset derived from European option prices**  
decimal

Implied volatility of the underlying asset derived from European option prices, returned as a decimal. If no solution is found, `blsimpv` returns NaN.

### Introduced before R2006a

## blslambda

Black-Scholes elasticity

### Syntax

```
[CallEl,PutEl] = blslambda(Price,Strike,Rate,Time,Volatility)
[CallEl,PutEl] = blslambda(___,Yield)
```

### Description

[CallEl,PutEl] = blslambda(Price,Strike,Rate,Time,Volatility) returns the elasticity of an option. CallEl is the call option elasticity or leverage factor, and PutEl is the put option elasticity or leverage factor. Elasticity (the leverage of an option position) measures the percent change in an option price per 1 percent change in the underlying asset price. blslambda uses normcdf, the normal cumulative distribution function in the Statistics and Machine Learning Toolbox.

---

**Note** blslambda can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

Yield = Rate

When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

Yield = ForeignRate

where ForeignRate is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

[CallEl,PutEl] = blslambda(\_\_\_,Yield) adds an optional argument for Yield.

### Examples

#### Find the Black-Scholes Elasticity (Lambda) for an Option

This example shows how to find the Black-Scholes elasticity, or leverage, of an option position.

```
[CallEl, PutEl] = blslambda(50, 50, 0.12, 0.25, 0.3)
```

CallEl = 8.1274

PutEl = -8.6466

### Input Arguments

#### Price — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: double

#### **Strike — Exercise price of option**

numeric

Exercise price of the option, specified as a numeric value.

Data Types: double

#### **Rate — Annualized, continuously compounded risk-free rate of return over life of option**

positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: double

#### **Time — Time (in years) to expiration of the option**

numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: double

#### **Volatility — Annualized asset price volatility**

positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: double

#### **Yield — Annualized, continuously compounded yield of the underlying asset over life of option**

0 (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Data Types: double

## **Output Arguments**

#### **CallEl — Call option elasticity**

numeric

Call option elasticity or leverage factor, returned as a numeric value.

#### **PutEl — Put option elasticity**

numeric

Put option elasticity or leverage factor, returned as a numeric value.

## Introduced before R2006a

# blsprice

Black-Scholes put and call option pricing

## Syntax

```
[Call,Put] = blsprice(Price,Strike,Rate,Time,Volatility)
[Call,Put] = blsprice(____,Yield)
```

## Description

`[Call,Put] = blsprice(Price,Strike,Rate,Time,Volatility)` computes European put and call option prices using a Black-Scholes model.

---

**Note** Any input argument can be a scalar, vector, or matrix. If a scalar, then that value is used to price all options. If more than one input is a vector or matrix, then the dimensions of those non-scalar inputs must be the same.

Ensure that `Rate`, `Time`, `Volatility`, and `Yield` are expressed in consistent units of time.

---

`[Call,Put] = blsprice(____,Yield)` adds an optional argument for `Yield`.

## Examples

### Compute European Put and Call Option Prices Using a Black-Scholes Model

This example shows how to price European stock options that expire in three months with an exercise price of \$95. Assume that the underlying stock pays no dividend, trades at \$100, and has a volatility of 50% per annum. The risk-free rate is 10% per annum.

```
[Call, Put] = blsprice(100, 95, 0.1, 0.25, 0.5)
```

Call = 13.6953

Put = 6.3497

### Compute European Put and Call Option Prices on a Stock Index Using a Black-Scholes Model

The S&P 100 index is at 910 and has a volatility of 25% per annum. The risk-free rate of interest is 2% per annum and the index provides a dividend yield of 2.5% per annum. Calculate the value of a three-month European call and put with a strike price of 980.

```
[Call,Put] = blsprice(910,980,.02,.25,.25,.025)
```

Call = 19.6863

Put = 90.4683

## Price a European Call Option with the Garman-Kohlhagen Model

Price an FX option on buying GBP with USD.

```
S = 1.6; % spot exchange rate
X = 1.6; % strike
T = .3333;
r_d = .08; % USD interest rate
r_f = .11; % GBP interest rate
sigma = .2;

Price = blsprice(S,X,r_d,T,sigma,r_f)
Price = 0.0639
```

## Input Arguments

### Price — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: double

### Strike — Exercise price of the option

numeric

Exercise price of the option, specified as a numeric value.

Data Types: double

### Rate — Annualized continuously compounded risk-free rate of return over life of the option

positive decimal

Annualized continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal number.

Data Types: double

### Time — Time to expiration of option

numeric

Time to expiration of the option, specified as the number of years.

Data Types: double

### Volatility — Annualized asset price volatility

positive decimal

Annualized asset price volatility (that is, annualized standard deviation of the continuously compounded asset return), specified as a positive decimal number.

Data Types: double

**Yield — Annualized continuously compounded yield of underlying asset over life of the option**

0 (default) | decimal

(Optional) Annualized continuously compounded yield of the underlying asset over the life of the option, specified as a decimal number. If **Yield** is empty or missing, the default value is 0.

For example, **Yield** could represent the dividend yield (annual dividend rate expressed as a percentage of the price of the security) or foreign risk-free interest rate for options written on stock indices and currencies.

---

**Note** `blsprice` can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument **Yield** as:

**Yield = Rate**

When pricing currencies (Garman-Kohlhagen model), enter the input argument **Yield** as:

**Yield = ForeignRate**

where **ForeignRate** is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

Data Types: double

## Output Arguments

**Call — Price of a European call option**

matrix

Price of a European call option, returned as a matrix.

**Put — Price of a European put option**

matrix

Price of a European put option, returned as a matrix.

# blsrho

Black-Scholes sensitivity to interest-rate change

## Syntax

```
[CallRho,PutRho] = blsrho(Price,Strike,Rate,Time,Volatility)
[CallRho,PutRho] = blsrho(_____,Yield)
```

## Description

`[CallRho,PutRho] = blsrho(Price,Strike,Rate,Time,Volatility)` returns the call option rho `CallRho`, and the put option rho `PutRho`. Rho is the rate of change in value of derivative securities with respect to interest rates. `blsrho` uses `normcdf`, the normal cumulative distribution function in the Statistics and Machine Learning Toolbox.

---

**Note** `blsrho` can also handle an underlying asset such as currencies. When pricing currencies (Garman-Kohlhagen model), enter the input argument `Yield` as:

`Yield = ForeignRate`

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

`[CallRho,PutRho] = blsrho(_____,Yield)` adds an optional argument for `Yield`.

## Examples

### Find the Black-Scholes Sensitivity (Rho) to Interest-Rate Change

This example shows how to find the Black-Scholes sensitivity, rho, to interest-rate change.

```
[CallRho, PutRho] = blsrho(50, 50, 0.12, 0.25, 0.3, 0)
```

`CallRho = 6.6686`

`PutRho = -5.4619`

## Input Arguments

**Price — Current price of underlying asset**  
numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: double

**Strike — Exercise price of option**  
numeric

Exercise price of the option, specified as a numeric value.

Data Types: double

**Rate — Annualized, continuously compounded risk-free rate of return over life of option**  
positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: double

**Time — Time (in years) to expiration of the option**  
numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: double

**Volatility — Annualized asset price volatility**  
positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: double

**Yield — Annualized, continuously compounded yield of the underlying asset over life of option**  
0 (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Data Types: double

## Output Arguments

**CallRho — Call option rho**  
numeric

Call option rho, returned as a numeric value.

**PutRho — Put option rho**  
numeric

Put option rho, returned as a numeric value.

## blstheta

Black-Scholes sensitivity to time-until-maturity change

### Syntax

```
[CallTheta,PutTheta] = blstheta(Price,Strike,Rate,Time,Volatility)
[CallTheta,PutTheta] = blstheta(_____,Yield)
```

### Description

`[CallTheta,PutTheta] = blstheta(Price,Strike,Rate,Time,Volatility)` returns the call option theta `CallTheta`, and the put option theta `PutTheta`.

Theta is the sensitivity in option value with respect to time and is measured in years. `CallTheta` or `PutTheta` can be divided by 365 to get Theta per calendar day or by 252 to get Theta by trading day.

`blstheta` uses `normcdf`, the normal cumulative distribution function, and `normpdf`, the normal probability density function, in the Statistics and Machine Learning Toolbox.

---

**Note** `blstheta` can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument `Yield` as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument `Yield` as:

```
Yield = ForeignRate
```

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

`[CallTheta,PutTheta] = blstheta(_____,Yield)` adds an optional argument for `Yield`.

### Examples

#### Compute the Black-Scholes Sensitivity to Time-Until-Maturity Change (Theta)

This example shows how to compute theta, the sensitivity in option value with respect to time.

```
[CallTheta, PutTheta] = blstheta(50, 50, 0.12, 0.25, 0.3, 0)
```

```
CallTheta = -8.9630
```

```
PutTheta = -3.1404
```

## Input Arguments

### **Price — Current price of underlying asset**

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: double

### **Strike — Exercise price of option**

numeric

Exercise price of the option, specified as a numeric value.

Data Types: double

### **Rate — Annualized, continuously compounded risk-free rate of return over life of option**

positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: double

### **Time — Time (in years) to expiration of the option**

numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: double

### **Volatility — Annualized asset price volatility**

positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: double

### **Yield — Annualized, continuously compounded yield of the underlying asset over life of option**

0 (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Data Types: double

## Output Arguments

### **CallTheta — Call option theta**

numeric

Call option theta, returned as a numeric value.

**PutTheta — Put option theta**

numeric

Put option theta, returned as a numeric value.

# blsvega

Black-Scholes sensitivity to underlying price volatility

## Syntax

```
Vega = blsvega(Price,Strike,Rate,Time,Volatility)
Vega = blsvega(_____,Yield)
```

## Description

`Vega = blsvega(Price,Strike,Rate,Time,Volatility)` rate of change of the option value with respect to the volatility of the underlying asset. `blsvega` uses `normpdf`, the normal probability density function in the Statistics and Machine Learning Toolbox.

---

**Note** `blsvega` can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument `Yield` as:

`Yield = Rate`

When pricing currencies (Garman-Kohlhagen model), enter the input argument `Yield` as:

`Yield = ForeignRate`

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

---

`Vega = blsvega(_____,Yield)` adds an optional argument for `Yield`.

## Examples

### Compute Black-Scholes Sensitivity to Underlying Price Volatility (Vega)

This example shows how to compute vega, the rate of change of the option value with respect to the volatility of the underlying asset.

```
Vega = blsvega(50, 50, 0.12, 0.25, 0.3, 0)
```

```
Vega = 9.6035
```

## Input Arguments

**Price — Current price of underlying asset**  
numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: `double`

**Strike — Exercise price of option**

numeric

Exercise price of the option, specified as a numeric value.

Data Types: double

**Rate — Annualized, continuously compounded risk-free rate of return over life of option**

positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: double

**Time — Time (in years) to expiration of the option**

numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: double

**Volatility — Annualized asset price volatility**

positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: double

**Yield — Annualized, continuously compounded yield of the underlying asset over life of option**

0 (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Data Types: double

## Output Arguments

**Vega — Rate of change of option value with respect to volatility of underlying asset**

numeric

Rate of change of the option value with respect to the volatility of the underlying asset, returned as a numeric value.

# bondDefaultBootstrap

Bootstrap default probability curve from bond prices

## Syntax

```
[ProbabilityData,HazardData] = bondDefaultBootstrap(ZeroData,MarketData,  
Settle)  
[ProbabilityData,HazardData] = bondDefaultBootstrap(____,Name,Value)
```

## Description

[ProbabilityData,HazardData] = bondDefaultBootstrap(ZeroData,MarketData, Settle) bootstraps the default probability curve from bond prices.

Using bondDefaultBootstrap, you can:

- Extract discrete default probabilities for a certain period from market bond data.
- Interpolate these default probabilities to get the default probability curve for pricing and risk management purposes.

[ProbabilityData,HazardData] = bondDefaultBootstrap(\_\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Determine the Default Probability and Hazard Rate Values for Treasury Bonds

Use the following bond data.

```
Settle = datenum('08-Jul-2016');  
MarketDate = datenum({'06/15/2018', '01/08/2019', '02/01/2021', '03/18/2021', '08/04/2025'}, 'mmddyy');  
CouponRate = [2.240 2.943 5.750 3.336 4.134]'/100;  
MarketPrice = [101.300 103.020 115.423 104.683 108.642]';  
MarketData = [MarketDate,MarketPrice,CouponRate];
```

Calculate the ProbabilityData and HazardData.

```
TreasuryParYield = [0.26 0.28 0.36 0.48 0.61 0.71 0.95 1.19 1.37 1.69 2.11]'/100;  
TreasuryDates = datemnth(Settle, [[1 3 6], 12 * [1 2 3 5 7 10 20 30]]');  
[ZeroRates, CurveDates] = pyld2zero(TreasuryParYield, TreasuryDates, Settle);  
ZeroData = [CurveDates, ZeroRates];  
format longg  
[ProbabilityData,HazardData]=bondDefaultBootstrap(ZeroData,MarketData,Settle)
```

ProbabilityData = 5×2

|        |                    |
|--------|--------------------|
| 737226 | 0.0299675399937611 |
| 737433 | 0.0418832295824674 |
| 738188 | 0.090518332884262  |
| 738233 | 0.101248065083713  |

```

739833          0.233002708031915

HazardData = 5x2

    737226      0.0157077745460244
    737433      0.0217939816590403
    738188      0.025184912824721
    738233      0.0962608718640789
    739833      0.0361632398787917

```

In `bondDefaultBootstrap`, the first column of the `ProbabilityData` output and the first column of the `HazardData` output contain the respective ending dates for the corresponding default probabilities and hazard rates. However, the starting dates used for the computation of the time ranges for default probabilities can be different from those of hazard rates. For default probabilities, the time ranges are all computed from the `Settle` date to the respective end dates shown in the first column of `ProbabilityData`. In contrast, the time ranges for the hazard rates are computed using the `Settle` date and the first column of `HazardData`, so that the first hazard rate applies from the `Settle` date to the first market date, the second hazard rate from the first to the second market date, and so on, and the last hazard rate applies from the second-to-last market date onwards.

```

datestr(Settle)

ans =
'08-Jul-2016'

datestr(ProbabilityData(:,1))

ans = 5x11 char array
    '15-Jun-2018'
    '08-Jan-2019'
    '01-Feb-2021'
    '18-Mar-2021'
    '04-Aug-2025'

datestr(HazardData(:,1))

ans = 5x11 char array
    '15-Jun-2018'
    '08-Jan-2019'
    '01-Feb-2021'
    '18-Mar-2021'
    '04-Aug-2025'

```

The time ranges for the default probabilities all start on '`08-Jul-2016`' and they end on '`15-Jun-2018`', '`08-Jan-2019`', '`01-Feb-2021`', '`18-Mar-2021`', and '`04-Aug-2025`', respectively. As for the hazard rates, the first hazard rate starts on '`08-Jul-2016`' and ends on '`15-Jun-2018`', the second hazard rate starts on '`15-Jun-2018`' and ends on '`08-Jan-2019`', the third hazard rate starts on '`08-Jan-2019`' and ends on '`01-Feb-2021`', and so forth.

### Reprice a Bond Listed on the Default Probability Curve

Reprice one of the bonds from bonds list based on the default probability curve. The expected result of this repricing is a perfect match with the market quote.

Use the following Treasury data from US Department of the Treasury.

```
Settle = datetime('08-Jul-2016','Locale','en_US');
TreasuryParYield = [0.26 0.28 0.36 0.48 0.61 0.71 0.95 1.19 1.37 1.69 2.11]'/100;
TreasuryDates = datemnth(Settle, [[1 3 6], 12 * [1 2 3 5 7 10 20 30]]');
```

Preview the bond date using semiannual coupon bonds with market quotes, coupon rates, and a settle date of July-08-2016.

```
MarketDate = datenum({'06/01/2017','06/01/2019','06/01/2020','06/01/2022'}','mm/dd/yyyy');
CouponRate = [7 8 9 10]'/100;
MarketPrice = [101.300 109.020 114.42 118.62]';
MarketData = [MarketDate, MarketPrice, CouponRate];

BondList = array2table(MarketData, 'VariableNames', {'Maturity', 'Price', 'Coupon'});
BondList.Maturity = datetime(BondList.Maturity,'Locale','en_US','ConvertFrom','datenum');
BondList.Maturity.Format = 'MMM-dd-yyyy'
```

BondList=4×3 table

| Maturity    | Price  | Coupon |
|-------------|--------|--------|
| Jun-01-2017 | 101.3  | 0.07   |
| Jun-01-2019 | 109.02 | 0.08   |
| Jun-01-2020 | 114.42 | 0.09   |
| Jun-01-2022 | 118.62 | 0.1    |

Choose the second coupon bond as the one to be priced.

```
number = 2;
TestCase = BondList(number, :);
```

Preview the risk-free rate data provided here that is based on a continuous compound rate.

```
[ZeroRates, CurveDates] = pyld2zero(TreasuryParYield, TreasuryDates, Settle);
ZeroData = [datenum(CurveDates), ZeroRates];
RiskFreeRate = array2table(ZeroData, 'VariableNames', {'Date', 'Rate'});
RiskFreeRate.Date = datetime(RiskFreeRate.Date,'Locale','en_US','ConvertFrom','datenum');
RiskFreeRate.Date.Format = 'MMM-dd-yyyy'
```

RiskFreeRate=11×2 table

| Date        | Rate      |
|-------------|-----------|
| Aug-08-2016 | 0.0026057 |
| Oct-08-2016 | 0.0027914 |

Preview the selected bond to reprice based on the PD curve.

```
TestCase
```

```
TestCase=1x3 table
```

| Maturity    | Price  | Coupon |
|-------------|--------|--------|
| Jun-01-2019 | 109.02 | 0.08   |

To reprice the bond, first generate cash flows and payment dates.

```
[Payments, PaymentDates] = cfamounts(TestCase.Coupon, Settle, TestCase.Maturity);
AccInt=-Payments(1);
```

```
% Truncate the payments as well as payment dates for calculation  
% PaymentDates(1) is the settle date, no need for following calculations  
PaymentDates = PaymentDates(2:end)
```

```
PaymentDates = 1x6 datetime  
Columns 1 through 5
```

```
01-Dec-2016 01-Jun-2017 01-Dec-2017 01-Jun-2018 01-Dec-2018

Column 6
```

```
01-Jun-2019
```

```
Payments = Payments(2:end)
```

```
Payments = 1x6
```

```
4 4 4 4 4 104
```

Calculate the discount factors on the payment dates.

```
DF = zero2disc(interp1(RiskFreeRate.Date, RiskFreeRate.Rate, PaymentDates, 'linear', 'extrap'))  
DF = 1x6
```

```
0.9987 0.9959 0.9926 0.9887 0.9845 0.9799
```

Assume that the recovery amount is a fixed proportion of bond's face value. The bond's face value is 100, and the recovery ratio is set to 40% as assumed in bondDefaultBootstrap.

```
Num = length(Payments);  
RecoveryAmount = repmat(100*0.4, 1, Num)
```

```
RecoveryAmount = 1x6
```

```
40 40 40 40 40 40
```

Calculate the probability of default based on the default curve.

```
DefaultProb1 = bondDefaultBootstrap(ZeroData, MarketData, Settle, 'ZeroCompounding', -1, 'Probability')  
SurvivalProb = 1 - DefaultProb1(:,2)
```

```
SurvivalProb = 6x1
```

## Input Arguments

### **ZeroData — Zero rate data**

matrix | IRDataCurve object

Zero rate data, specified as an M-by-2 matrix of dates and zero rates or an IRDataCurve object of zero rates. For array input, the dates must be entered as serial date numbers, and discount rate must be in decimal form.

When ZeroData is an IRDataCurve object, ZeroCompounding and ZeroBasis are implicit in ZeroData and are redundant inside this function. In this case, specify these optional parameters when constructing the IRDataCurve object before using this bondDefaultBootstrap function.

For more information on an IRDataCurve object, see “Creating an IRDataCurve Object” (Financial Instruments Toolbox).

Data Types: double

### **MarketData — Bond market data**

matrix

Bond market data, specified as an N-by-3 matrix of maturity dates, market prices, and coupon rates for bonds. The dates must be entered as serial date numbers, market prices must be numeric values, and coupon rate must be in decimal form.

---

**Note** A warning is displayed when MarketData is not sorted in ascending order by time.

---

Data Types: double

### **Settle — Settlement date**

serial date number | date character vector | datetime object | date string object

Settlement date, specified as a serial date number, a date character vector, a datetime object, or a date string object. Settle must be earlier than or equal to the maturity dates in MarketData.

Data Types: double | char | datetime | string

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

---

**Note** Any optional input of size `N`-by-1 is also acceptable as an array of size 1-by-`N`, or as a single value applicable to all contracts.

---

Example: `[ProbabilityData,HazardData] = bondDefaultBootstrap(ZeroData,MarketData,Settle,'RecoveryRate',Recovery,'Zero Compounding',-1)`

### **RecoveryRate — Recovery rate**

`0.4` (default) | decimal

Recovery rate, specified as the comma-separated pair consisting of `'RecoveryRate'` and a `N`-by-1 vector of recovery rates, expressed as a decimal from 0 through 1.

Data Types: double

### **ProbabilityDates — Dates for output of default probability data**

column of dates in `MarketData` (default) | serial date number | date character vector | datetime object | date string object

Dates for the output of default probability data, specified as the comma-separated pair consisting of `'ProbabilityDates'` and a `P`-by-1 vector, given as serial date numbers, datetime objects, date character vectors, or date string objects.

Data Types: double | char | datetime | string

### **ZeroCompounding — Compounding frequency of the zero curve**

`2` (semiannual) (default) | integer with value of 1,2,3,4,6,12, or -1

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of `'ZeroCompounding'` and a `N`-by-1 vector. Values are:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

Data Types: double

### **ZeroBasis — Basis of the zero curve**

`0` (actual/actual) (default) | integer with value of 0 to 13

Basis of the zero curve, specified as the comma-separated pair consisting of 'ZeroBasis' and the same values listed for Basis.

Data Types: double

#### **RecoveryMethod — Recovery method**

'facevalue' (default) | character vector with value of 'presentvalue' or 'facevalue' | string object with value of 'presentvalue' or 'facevalue'

Recovery method, specified as the comma-separated pair consisting of 'RecoveryMethod' and a character vector or a string with a value of 'presentvalue' or 'facevalue'.

- 'presentvalue' assumes that upon default, a bond is valued at a given fraction to the hypothetical present value of its remaining cash flows, discounted at risk-free rate.
- 'facevalue' assumes that a bond recovers a given fraction of its face value upon recovery.

Data Types: char | string

#### **Face — Face or par value**

100 (default) | numeric

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector of bonds.

Data Types: double

#### **Period — Payment frequency**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Payment frequency, specified as the comma-separated pair consisting of 'Period' and a N-by-1 vector with values of 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

#### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)

- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer, 0 or 1, using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

**IssueDate — Bond issue date**

if IssueDate not specified, cash flow payment dates determined from other inputs (default) | serial date number | date character vector | datetime object | date string object

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a N-by-1 vector, given as serial date numbers, datetime objects, date character vectors, or date string objects.

Data Types: double | char | datetime | string

**FirstCouponDate — First actual coupon date**

if you do not specify a FirstCouponDate, cash flow payment dates are determined from other inputs (default) | serial date number

First actual coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a serial date number. FirstCouponDate is used when a bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Data Types: double

**LastCouponDate — Last actual coupon date**

if you do not specify a LastCouponDate, cash flow payment dates are determined from other inputs (default) | scalar for serial date number

Last actual coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a serial date number. LastCouponDate is used when a bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Data Types: double

**StartDate — Forward starting date of payments**

if you do not specify StartDate, effective start date is Settle date (default) | serial date number

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a serial date number. `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

Data Types: double

#### **BusinessDayConvention — Business day conventions**

'actual' (default) | character vector or string object with values 'actual', 'follow', 'modifiedfollow', 'previous' or 'modifiedprevious'

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector or a string object. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- 'actual' — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- 'follow' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- 'modifiedfollow' — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- 'previous' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- 'modifiedprevious' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell | string

## **Output Arguments**

#### **ProbabilityData — Default probability values**

matrix

Default probability values, returned as a P-by-2 matrix with dates and corresponding cumulative default probability values. The dates match those in `MarketData`, unless the optional input parameter `ProbabilityDates` is provided.

#### **HazardData — Hazard rate values**

matrix

Hazard rate values, returned as an N-by-2 matrix with dates and corresponding hazard rate values for the survival probability model. The dates match those in `MarketData`.

---

**Note** A warning is displayed when nonmonotone default probabilities (that is, negative hazard rates) are found.

## More About

### Bootstrap Default Probability

A default probability curve can be bootstrapped from a collection of bond market quotes.

Extracting discrete default probabilities for a certain period from market bond data is represented by the formula

$$\text{Price} = \text{Disc}(t_N) \times FV \times Q(t_N) + \frac{C}{f} \times \sum_{i=1}^N \text{Disc}(t_i) \times Q(t_i) + \sum_{(i=1)}^N \text{Disc}(t_i) \times R(t_i) \times (Q(t_i - 1) - Q(t_i))$$

where:

$FV$  — Face value

$Q$  — Survival probability

$C$  — Coupon

$R$  — Recovery amount

$f$  — Payment frequency (for example, 2 for semiannual coupon bonds)

The default probability is:

`DefaultProbability = 1 - SurvivalProbability`

## Introduced in R2017a

# bndconvp

Bond convexity given price

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

---

## Syntax

```
[YearConvexity,PerConvexity] = bndconvp(Price,CouponRate,Settle,Maturity)
[YearConvexity,PerConvexity] = bndconvp(____,Name,Value)
```

## Description

`[YearConvexity,PerConvexity] = bndconvp(Price,CouponRate,Settle,Maturity)` computes the convexity of NUMBONDS fixed income securities given a clean price for each bond. The clean price of a bond excludes any interest that has accrued since issue or the most recent coupon payment.

`bndconvp` determines the convexity for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). `bndconvp` also determines the convexity of a zero coupon bond. Convexity is a measure of the rate of change in duration; measured in time. The greater the rate of change, the more the duration changes as yield changes.

`[YearConvexity,PerConvexity] = bndconvp(____,Name,Value)` adds optional name-value pair arguments.

## Examples

### Find Bond Convexity Given Price

This example shows how to compute the convexity of three bonds given their prices.

```
Price = [106; 100; 98];
CouponRate = 0.055;
Settle = '02-Aug-1999';
Maturity = '15-Jun-2004';
Period = 2;
Basis = 0;

[YearConvexity, PerConvexity] = bndconvp(Price, ...
CouponRate, Settle, Maturity, Period, Basis)

YearConvexity = 3x1
```

```
21.4447  
21.0363  
20.8951
```

PerConvexity = 3×1

```
85.7788  
84.1454  
83.5803
```

### Find Bond Convexity Given Price Using datetime Inputs

This example shows how to compute the convexity of three bonds given their prices using datetime inputs.

```
Price = [106; 100; 98];  
CouponRate = 0.055;  
Period = 2;  
Basis = 0;  
Settle = datetime('02-Aug-1999','Locale','en_US');  
Maturity = datetime('15-Jun-2004','Locale','en_US');  
[YearConvexity, PerConvexity] = bndconvp(Price,...  
CouponRate, Settle, Maturity, Period, Basis)
```

YearConvexity = 3×1

```
21.4447  
21.0363  
20.8951
```

PerConvexity = 3×1

```
85.7788  
84.1454  
83.5803
```

## Input Arguments

**Price — Clean price (excludes accrued interest)**  
numeric

Clean price (excludes accrued interest), specified as numeric value using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

**CouponRate — Annual percentage rate used to determine coupons payable on a bond**  
decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

#### **Settle — Settlement date for certificate of deposit**

serial date number | date character vector | datetime

Settlement date for the certificate of deposit, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

#### **Maturity — Maturity date for certificate of deposit**

serial date number | date character vector | datetime

Maturity date for the certificate of deposit, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

#### **Name-Value Pair Arguments**

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: [YearConvexity,PerConvexity] = bndconvp(Price,CouponRate,Settle,Maturity,'Period',4,'Basis',7)

#### **Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

#### **Basis — Day-count basis of instrument**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)

- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an **IssueDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **FirstCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

Data Types: double | char | datetime

**Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

**CompoundingFrequency — Compounding frequency for yield calculation**

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

Data Types: double

**DiscountBasis — Basis used to compute the discount factors for computing the yield**

SIA uses 0 (default) | integers of the set [0 . . 13] | vector of integers of the set [0 . . 13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

---

**Note** If a SIA day-count basis is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

---

If an ICMA day-count basis or BUS/252 is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the specified bases from the **Basis** input argument are used.

---

Data Types: double

**LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period**

compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. **LastCouponInterest** is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

## Output Arguments

**YearConvexity — Yearly (annualized) convexity**

numeric

Yearly (annualized) convexity, returned as a NUMBONDS-by-1 vector.

**PerConvexity — Periodic convexity reported on semiannual bond basis**  
numeric

Periodic convexity reported on a semiannual bond basis (in accordance with SIA convention), returned as a NUMBONDS-by-1 vector.

## Introduced before R2006a

## bndconvy

Bond convexity given yield

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

---

### Syntax

```
[YearConvexity,PerConvexity] = bndconvy(Yield,CouponRate,Settle,Maturity)
[YearConvexity,PerConvexity] = bndconvy(____,Name,Value)
```

### Description

`[YearConvexity,PerConvexity] = bndconvy(Yield,CouponRate,Settle,Maturity)` computes the convexity of NUMBONDS fixed income securities given a clean price for each bond.

`bndconvy` determines the convexity for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). `bndconvy` also determines the convexity of a zero coupon bond.

`[YearConvexity,PerConvexity] = bndconvy(____,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Find Bond Convexity Given Yield

This example shows how to compute the convexity of a bond at three different yield values.

```
Yield = [0.04; 0.055; 0.06];
CouponRate = 0.055;
Settle = '02-Aug-1999';
Maturity = '15-Jun-2004';
Period = 2;
Basis = 0;

[YearConvexity, PerConvexity]=bndconvy(Yield, CouponRate, ...
Settle, Maturity, Period, Basis)

YearConvexity = 3x1
21.4825
21.0358
20.8885
```

```
PerConvexity = 3×1
```

```
85.9298
84.1434
83.5541
```

### Find Bond Convexity Given Yield Using datetime Inputs

This example shows how to use `datetime` inputs to compute the convexity of a bond at three different yield values.

```
Yield = [0.04; 0.055; 0.06];
CouponRate = 0.055;
Settle = datetime('02-Aug-1999','Locale','en_US');
Maturity = datetime('15-Jun-2004','Locale','en_US');
Period = 2;
Basis = 0;
[YearConvexity, PerConvexity]=bndconvy(Yield, CouponRate, ...
Settle, Maturity, Period, Basis)
```

```
YearConvexity = 3×1
```

```
21.4825
21.0358
20.8885
```

```
PerConvexity = 3×1
```

```
85.9298
84.1434
83.5541
```

## Input Arguments

### **Yield — Yield to maturity on semiannual basis**

numeric

Yield to maturity on a semiannual basis, specified as numeric value using a scalar or a `NUMBONDS`-by-1 or 1-by-`NUMBONDS` vector.

Data Types: `double`

### **CouponRate — Annual percentage rate used to determine coupons payable on a bond**

decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a `NUMBONDS`-by-1 or 1-by-`NUMBONDS` vector.

Data Types: `double`

**Settle — Settlement date for certificate of deposit**

serial date number | date character vector | datetime

Settlement date for the certificate of deposit, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

**Maturity — Maturity date for certificate of deposit**

serial date number | date character vector | datetime

Maturity date for the certificate of deposit, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**Name-Value Pair Arguments**

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: [YearConvexity,PerConvexity] = bndconv(Yield,CouponRate,Settle, Maturity,'Period',4,'Basis',7)

**Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0,1,2,3,4,6,7,8,9,10,11,12,13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)

- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an **IssueDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **FirstCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **LastCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The StartDate is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a StartDate, the effective start date is the Settle date.

Data Types: double | char | datetime

**Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

**CompoundingFrequency — Compounding frequency for yield calculation**

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**DiscountBasis — Basis used to compute the discount factors for computing the yield**

SIA uses 0 (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

---

**Note** If a SIA day-count basis is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

---

If an ICMA day-count basis or BUS/252 is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the specified bases from the `Basis` input argument are used.

---

Data Types: double

**LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period**

compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. `LastCouponInterest` is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

## Output Arguments

**YearConvexity — Yearly (annualized) convexity**

numeric

Yearly (annualized) convexity, returned as a NUMBONDS-by-1 vector.

**PerConvexity — Periodic convexity reported on semiannual bond basis**

numeric

Periodic convexity reported on a semiannual bond basis (in accordance with SIA convention), returned as a NUMBONDS-by-1 vector.

## Introduced before R2006a

# bnndurp

Bond duration given price

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

---

## Syntax

```
[ModDuration,YearDuration,PerDuration] = bnndurp(Price,CouponRate,Settle,  
Maturity)  
[ModDuration,YearDuration,PerDuration] = bnndurp(____,Name,Value)
```

## Description

`[ModDuration,YearDuration,PerDuration] = bnndurp(Price,CouponRate,Settle,Maturity)` computes the Macaulay and modified duration of NUMBONDS fixed-income securities given a clean price for each bond.

`bnndurp` determines the Macaulay and modified duration for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). `bnndurp` also determines the Macaulay and modified duration for a zero coupon bond.

`[ModDuration,YearDuration,PerDuration] = bnndurp(____,Name,Value)` adds optional name-value pair arguments.

## Examples

### Find Bond Duration Given Price

This example shows how to compute the duration of three bonds given their prices.

```
Price = [106; 100; 98];  
CouponRate = 0.055;  
Settle = '02-Aug-1999';  
Maturity = '15-Jun-2004';  
Period = 2;  
Basis = 0;  
  
[ModDuration, YearDuration, PerDuration] = bnndurp(Price,...  
CouponRate, Settle, Maturity, Period, Basis)  
  
ModDuration = 3x1  
4.2400
```

```
4.1925  
4.1759
```

```
YearDuration = 3x1
```

```
4.3275  
4.3077  
4.3007
```

```
PerDuration = 3x1
```

```
8.6549  
8.6154  
8.6014
```

### Find Bond Duration Given Price Using datetime Inputs

This example shows how to use `datetime` inputs to compute the duration of three bonds given their prices.

```
Price = [106; 100; 98];  
CouponRate = 0.055;  
Settle = datetime('02-Aug-1999','Locale','en_US');  
Maturity = datetime('15-Jun-2004','Locale','en_US');  
Period = 2;  
Basis = 0;  
[ModDuration, YearDuration, PerDuration] = bnddurp(Price,...  
CouponRate, Settle, Maturity, Period, Basis)
```

```
ModDuration = 3x1
```

```
4.2400  
4.1925  
4.1759
```

```
YearDuration = 3x1
```

```
4.3275  
4.3077  
4.3007
```

```
PerDuration = 3x1
```

```
8.6549  
8.6154  
8.6014
```

## Input Arguments

### **Price — Clean price (excludes accrued interest)**

numeric

Clean price (excludes accrued interest), specified as numeric value using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

### **CouponRate — Annual percentage rate used to determine coupons payable on a bond**

decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

### **Settle — Settlement date for certificate of deposit**

serial date number | date character vector | datetime

Settlement date for the certificate of deposit, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

### **Maturity — Maturity date for certificate of deposit**

serial date number | date character vector | datetime

Maturity date for the certificate of deposit, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: [ModDuration, YearDuration, PerDuration] =  
bnddurp(Price, CouponRate, Settle, Maturity, 'Period', 4, 'Basis', 7)

### **Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### **Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an **IssueDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

Data Types: double | char | datetime

**Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

**CompoundingFrequency — Compounding frequency for yield calculation**

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**DiscountBasis — Basis used to compute the discount factors for computing the yield**

SIA uses 0 (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

**Note** If a SIA day-count basis is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the specified bases from the **Basis** input argument are used.

---

Data Types: double

**LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period**

compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. **LastCouponInterest** is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

## Output Arguments

### **ModDuration — Modified duration in years**

numeric

Modified duration in years reported on a semiannual bond basis (in accordance with SIA convention), returned as a NUMBONDS-by-1 vector.

### **YearDuration — Macaulay duration in years**

numeric

Macaulay duration in years, returned as a NUMBONDS-by-1 vector.

### **PerDuration — Periodic Macaulay duration**

numeric

Periodic Macaulay duration reported on a semiannual bond basis (in accordance with SIA convention), returned as a NUMBONDS-by-1 vector.

## bnndury

Bond duration given yield

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

---

### Syntax

```
[ModDuration,YearDuration,PerDuration] = bnndury(Yield,CouponRate,Settle,  
Maturity)  
[ModDuration,YearDuration,PerDuration] = bnndury(____,Name,Value)
```

### Description

`[ModDuration,YearDuration,PerDuration] = bnndury(Yield,CouponRate,Settle,Maturity)` computes the Macaulay and modified duration of NUMBONDS fixed income securities given yield to maturity for each bond.

`bnndury` determines the Macaulay and modified duration for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). `bnndury` also determines the Macaulay and modified duration for a zero coupon bond.

`[ModDuration,YearDuration,PerDuration] = bnndury(____,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Find Bond Duration Given Yield

This example shows how to compute the duration of a bond at three different yield values.

```
Yield = [0.04; 0.055; 0.06];  
CouponRate = 0.055;  
Settle = '02-Aug-1999';  
Maturity = '15-Jun-2004';  
Period = 2;  
Basis = 0;  
  
[ModDuration,YearDuration,PerDuration]=bnndury(Yield,...  
CouponRate, Settle, Maturity, Period, Basis)  
  
ModDuration = 3x1
```

4.2444

```
4.1924
4.1751
```

YearDuration = 3×1

```
4.3292
4.3077
4.3004
```

PerDuration = 3×1

```
8.6585
8.6154
8.6007
```

### **Find Bond Duration Given Yield Using datetime Inputs**

This example shows how to use datetime inputs to compute the duration of a bond at three different yield values.

```
Yield = [0.04; 0.055; 0.06];
CouponRate = 0.055;
Settle = datetime('02-Aug-1999','Locale','en_US');
Maturity = datetime('15-Jun-2004','Locale','en_US');
Period = 2;
Basis = 0;
[ModDuration,YearDuration,PerDuration]=bnddury(Yield, ...
CouponRate, Settle, Maturity, Period, Basis)
```

ModDuration = 3×1

```
4.2444
4.1924
4.1751
```

YearDuration = 3×1

```
4.3292
4.3077
4.3004
```

PerDuration = 3×1

```
8.6585
8.6154
8.6007
```

## Input Arguments

### **Yield — Yield to maturity on a semiannual basis**

decimal

Yield to maturity on a semiannual basis, specified as a decimal value using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

### **CouponRate — Annual percentage rate used to determine coupons payable on a bond**

decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

### **Settle — Settlement date for certificate of deposit**

serial date number | date character vector | datetime

Settlement date for the certificate of deposit, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

### **Maturity — Maturity date for certificate of deposit**

serial date number | date character vector | datetime

Maturity date for the certificate of deposit, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: [ModDuration, YearDuration, PerDuration] =  
bnddury(Yield, CouponRate, Settle, Maturity, 'Period', 4, 'Basis', 7)

### **Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### **Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an **IssueDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The StartDate is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a StartDate, the effective start date is the Settle date.

Data Types: double | char | datetime

**Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

**CompoundingFrequency — Compounding frequency for yield calculation**

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**DiscountBasis — Basis used to compute the discount factors for computing the yield**

SIA uses 0 (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

---

**Note** If a SIA day-count basis is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

---

If an ICMA day-count basis or BUS/252 is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the specified bases from the **Basis** input argument are used.

---

Data Types: double

**LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period**

compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. **LastCouponInterest** is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

## Output Arguments

### ModDuration — Modified duration in years

numeric

Modified duration in years reported on a semiannual bond basis (in accordance with SIA convention), returned as a NUMBONDS-by-1 vector.

### YearDuration — Macaulay duration in years

numeric

Macaulay duration in years, returned as a NUMBONDS-by-1 vector.

### PerDuration — Periodic Macaulay duration

numeric

Periodic Macaulay duration reported on a semiannual bond basis (in accordance with SIA convention), returned as a NUMBONDS-by-1 vector.

# bndkrdur

Bond key rate duration given zero curve

## Syntax

```
KeyRateDuration = bndkrdur(ZeroData,CouponRate,Settle,Maturity)
KeyRateDuration = bndkrdur(____,Name,Value)
```

## Description

`KeyRateDuration = bndkrdur(ZeroData,CouponRate,Settle,Maturity)` computes the key rate durations for one or more bonds given a zero curve and a set of key rates.

`KeyRateDuration = bndkrdur(____,Name,Value)` adds optional name-value pair arguments.

## Examples

### Find the Bond Key Rate Duration Given the Zero Curve

This example shows how to compute the key rate duration of a bond for key rate times of 2, 5, 10, and 30 years.

```
ZeroRates = [0.0476 0.0466 0.0465 0.0468 0.0473 0.0478 ...
0.0493 0.0539 0.0572 0.0553 0.0530]';

ZeroDates = daysadd('31-Dec-1998',[30 360 360*2 360*3 360*5 ...
360*7 360*10 360*15 360*20 360*25 360*30],1);

ZeroData = [ZeroDates ZeroRates];

krdur = bndkrdur(ZeroData,.0525,'12/31/1998',...
'11/15/2028','KeyRates',[2 5 10 30])

krdur = 1×4

    0.2986    0.8791    4.1353    9.5814
```

### Find the Bond Key Rate Duration Given the Zero Curve Using datetime Inputs

This example shows how to use `datetime` inputs for `Settle` and `Maturity` and also use a table for `ZeroData` to compute the key rate duration of a bond for key rate times of 2, 5, 10, and 30 years.

```
ZeroRates = [0.0476 0.0466 0.0465 0.0468 0.0473 0.0478 ...
0.0493 0.0539 0.0572 0.0553 0.0530]';

ZeroDates = daysadd('31-Dec-1998',[30 360 360*2 360*3 360*5 ...
360*7 360*10 360*15 360*20 360*25 360*30],1);
```

```
ZeroData = table(datetime(ZeroDates,'ConvertFrom','datenum','Locale','en_US'), ZeroRates);

krdur = bndkrdur(ZeroData,.0525,datetime('12/31/1998','Locale','en_US'),...
datetime('11/15/2028','Locale','en_US'),'KeyRates',[2 5 10 30])

krdur = 1x4

    0.2986    0.8791    4.1353    9.5814
```

## Input Arguments

### ZeroData — Zero curve

matrix | table

Zero Curve, specified as a numRates-by-2 matrix or a numRates-by-2 table.

If **ZeroData** is represented as a numRates-by-2 matrix, the first column is a MATLAB serial date number and the second column is the accompanying zero rates.

If **ZeroData** is a table, the first column can be serial date numbers, date character vectors, or datetime arrays. The second column must be numeric data corresponding to the zero rates.

Data Types: double | table

### CouponRate — Annual percentage rate used to determine coupons payable on a bond

decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a NUMBONDS-by-1 vector.

Data Types: double

### Settle — Settlement date for all bonds and zero curve

serial date number | date character vector | datetime

Settlement date for all bonds and zero curve, specified as a scalar using a serial date number, date character vector, or datetime array. **Settle** must be the same settlement date for all the bonds and the zero curve.

Data Types: double | char | datetime

### Maturity — Maturity date for bonds

serial date number | date character vector | datetime

Maturity date for bonds, specified as a scalar or a NUMBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Name-Value Pair Arguments

Specify optional pairs of arguments as **Name1=Value1**, ..., **NameN=ValueN**, where **Name** is the argument name and **Value** is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `KeyRateDuration = bndkrdrur(ZeroData,.0525,'12/31/1998','11/15/2028','KeyRates',[2 5 10 30])`

**InterpMethod — Interpolation method used to obtain points from zero curve**

'linear' (default) | 'cubic', 'pchip'

Interpolation method used to obtain points from the zero curve, specified as the comma-separated pair consisting of 'InterpMethod' and a character vector using one of the following values:

- 'linear' (default)
- 'cubic'
- 'pchip'

Data Types: char

**ShiftValue — Value that zero curve is shifted up and down to compute duration**

.01 (100 basis points) (default) | numeric

Value that zero curve is shifted up and down to compute duration, specified as the comma-separated pair consisting of 'ShiftValue' and a scalar numeric value.

Data Types: double

**KeyRates — Rates to perform the duration calculation**

set to each of the zero dates (default) | numeric

Rates to perform the duration calculation, specified as the comma-separated pair consisting of 'KeyRates' and a time to maturity using a scalar or a NUMBONDS-by-1 vector.

Data Types: double

**CurveCompounding — Compounding frequency of curve**

2 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency of the curve, specified as the comma-separated pair consisting of 'CurveCompounding' and a scalar using one of the following values:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

Data Types: double

**CurveBasis — Basis of the curve**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Basis of the curve, specified as the comma-separated pair consisting of 'CurveBasis' and a scalar using one of the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

**Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 vector. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an **IssueDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **FirstCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **LastCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays. The `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

Data Types: double | char | datetime

#### Face – Face value of bond

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 vector.

Data Types: double

## Output Arguments

#### KeyRateDuration – Key rate durations

matrix

Key rate durations, returned as a numBonds-by-numRates matrix.

## Algorithms

`bndkrdr` computes the key rate durations for one or more bonds given a zero curve and a set of key rates. By default, the key rates are each of the zero curve rates. For each key rate, the duration is computed by shifting the zero curve up and down by a specified amount (`ShiftValue`) at that particular key rate, computing the present value of the bond in each case with the new zero curves, and then evaluating the following:

$$krdur_i = \frac{(PV_{down} - PV_{up})}{(PV \times ShiftValue \times 2)}$$

---

**Note** The shift to the curve is computed by shifting the particular key rate by the `ShiftValue` and then interpolating the values of the curve in the interval between the previous and next key rates. For the first key rate, any curve values before the date are equal to the `ShiftValue`; likewise, for the last key rate, any curve values after the date are equal to the `ShiftValue`.

---

“Yield Conventions” on page 2-24

**Introduced before R2006a**

## bndprice

Price fixed-income security from yield to maturity

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

---

### Syntax

```
[Price,AccruedInt] = bndprice(Yield,CouponRate,Settle,Maturity)
[Price,AccruedInt] = bndprice(____,Name,Value)
```

### Description

`[Price,AccruedInt] = bndprice(Yield,CouponRate,Settle,Maturity)` given bonds with SIA date parameters and yields to maturity, returns the clean prices and accrued interest due.

`[Price,AccruedInt] = bndprice(____,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Price a Treasury Bond from Yield to Maturity

This example shows how to price a treasury bond at three different yield values.

```
Yield = [0.04; 0.05; 0.06];
CouponRate = 0.05;
Settle = '20-Jan-1997';
Maturity = '15-Jun-2002';
Period = 2;
Basis = 0;

[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle, ...
Maturity, Period, Basis)
```

Price = 3×1

```
104.8106
99.9951
95.4384
```

AccruedInt = 3×1

```
0.4945
0.4945
```

---

0.4945

### Price a Treasury Bond from Yield to Maturity Using datetime Inputs

This example shows how to use `datetime` inputs to price a treasury bond at three different yield values.

```

Yield = [0.04; 0.05; 0.06];
CouponRate = 0.05;
Settle = datetime('20-Jan-1997','Locale','en_US');
Maturity = datetime('15-Jun-2002','Locale','en_US');
Period = 2;
Basis = 0;
[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle, ...
Maturity, Period, Basis)

```

Price = 3×1

```

104.8106
99.9951
95.4384

```

AccruedInt = 3×1

```

0.4945
0.4945
0.4945

```

### Price a Treasury Bond with Different Yield Values

This example shows how to price a Treasury bond at two different yield values that include parameter/value pairs for `CompoundingFrequency`, `DiscountBasis`, and `LastCouponPeriodInterest`.

```
bndprice(.04,0.08,'5/25/2004','4/21/2005','Period',1,'Basis',8, ...
'LastCouponInterest','simple')
```

ans = 103.4743

## Input Arguments

**Yield — Bond yield to maturity**  
numeric

Bond yield to maturity is specified as a scalar or a `NUMBONDS`-by-1 or 1-by-`NUMBONDS` vector. `Yield` is on a semiannual basis for `Basis` values 0 through 7 and 13 and an annual basis for `Basis` values 8 through 12.

Data Types: double

**CouponRate — Annual percentage rate used to determine coupons payable on a bond**  
decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

**Settle — Settlement date of bond**

serial date number | date character vector | datetime

Settlement date of the bond, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

**Maturity — Maturity date of bond**

serial date number | date character vector | datetime

Maturity date of the bond, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**Name-Value Pair Arguments**

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: [Price, AccruedInt] = bndprice(Yield, CouponRate, Settle, Maturity, 'Period', 4, 'Basis', 9)

**Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

#### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

#### **IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an **IssueDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

#### **FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **FirstCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **LastCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **StartDate**, the effective start date is the **Settle** date.

Data Types: double | char | datetime

**Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

**CompoundingFrequency — Compounding frequency for yield calculation**

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**DiscountBasis — Basis used to compute the discount factors for computing the yield**

SIA bases uses 0 (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

---

**Note** If a SIA day-count basis is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

---

If an ICMA day-count basis or BUS/252 is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the specified bases from the **Basis** input argument are used.

---

Data Types: double

**LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period**

compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. **LastCouponInterest** is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

## Output Arguments

**Price — Clean price of bond**

numeric

Clean price of bond, returned as a NUMBONDS-by-1 vector. The dirty price of the bond is the clean price plus the accrued interest. It equals the present value of the bond cash flows of the yield to maturity with semiannual compounding.

### **AccruedInt — Accrued interest payable at settlement**

numeric

accrued interest payable at settlement, returned as a NUMBONDS-by-1 vector.

## **More About**

### **Price and Yield Conventions**

The Price and Yield are related to different formulae for SIA and ICMA conventions.

For SIA conventions, Price and Yield are related by the formula:

$$\text{Price} + \text{Accrued Interest} = \text{sum}(\text{Cash_Flow} * (1+\text{Yield}/2)^{(-\text{Time})})$$

where the sum is over the bond's cash flows and corresponding times in units of semiannual coupon periods.

For ICMA conventions, the Price and Yield are related by the formula:

$$\text{Price} + \text{Accrued Interest} = \text{sum}(\text{Cash_Flow} * (1+\text{Yield})^{(-\text{Time})})$$

## **Algorithms**

For SIA conventions, the following formula defines bond price and yield:

$$PV = \sum_{i=1}^n \left( \frac{CF}{(1 + \frac{z}{f})^{TF}} \right)$$

where:

|        |                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $PV =$ | Present value of a cash flow.                                                                                                                                                                                                                                                                                                                                                                |
| $CF =$ | Cash flow amount.                                                                                                                                                                                                                                                                                                                                                                            |
| $z =$  | Risk-adjusted annualized rate or yield corresponding to a given cash flow. The yield is quoted on a semiannual basis.                                                                                                                                                                                                                                                                        |
| $f =$  | Frequency of quotes for the yield. Default is 2 for Basis values 0 to 7 and 13 and 1 for Basis values 8 to 12. The default can be overridden by specifying the CompoundingFrequency name-value pair.                                                                                                                                                                                         |
| $TF =$ | Time factor for a given cash flow. The time factor is computed using the compounding frequency and the discount basis. If these values are not specified, then the defaults are as follows: CompoundingFrequency default is 2 for Basis values 0 to 7 and 13 and 1 for Basis values 8 to 12. DiscountBasis is 0 for Basis values 0 to 7 and 13 and the input Basis for Basis values 8 to 12. |

---

**Note** The Basis is always used to compute accrued interest.

---

For ICMA conventions, the frequency of annual coupon payments determines bond price and yield.

## Introduced before R2006a

## bndspread

Static spread over spot curve

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

---

### Syntax

```
Spread = bndspread(SpotInfo,Price,Coupon,Settle,Maturity)
Spread = bndspread(___,Name,Value)
```

### Description

`Spread = bndspread(SpotInfo,Price,Coupon,Settle,Maturity)` computes the static spread (Z-spread) to benchmark in basis points.

`Spread = bndspread(___,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Compute the Static Spread Over a Spot Curve

This example shows how to compute a Federal National Mortgage Association (FNMA) 4 3/8 spread over a Treasury spot curve and plot the results.

```
RefMaturity = [datenum('02/27/2003');
               datenum('05/29/2003');
               datenum('10/31/2004');
               datenum('11/15/2007');
               datenum('11/15/2012');
               datenum('02/15/2031')];

RefCpn = [0;
          0;
          2.125;
          3;
          4;
          5.375] / 100;

RefPrices = [99.6964;
             99.3572;
             100.3662;
             99.4511;
             99.4299;
             106.5756];
```

```

RefBonds = [RefPrices, RefMaturity, RefCpn];
Settle   = datenum('26-Nov-2002');
[ZeroRates, CurveDates] = zbtprice(RefBonds(:, 2:end), ...
RefPrices, Settle)

ZeroRates = 6×1

### Compute the Static Spread Over a Spot Curve Using `datetime` Inputs

This example shows how to compute a Federal National Mortgage Association (FNMA) 4 3/8 spread over a Treasury spot curve using `datetime` inputs for Settle and Maturity and a table for `SpotInfo` and plot the results.

```
RefMaturity = [datenum('02/27/2003');
               datenum('05/29/2003');
               datenum('10/31/2004');
               datenum('11/15/2007');
               datenum('11/15/2012');
               datenum('02/15/2031')];

RefCpn = [0;
          0;
          2.125;
          3;
          4;
          5.375] / 100;

RefPrices = [99.6964;
             99.3572;
             100.3662;
             99.4511;
             99.4299];
```

```

106.5756];

RefBonds = [RefPrices, RefMaturity, RefCpn];
Settle   = datetime('26-Nov-2002','Locale','en_US');
[ZeroRates, CurveDates] = zbtprice(RefBonds(:, 2:end), ...
RefPrices, Settle)

ZeroRates = 6x1

plot(CurveDates, ZeroRates*100, 'b', CurveDates, ...
ZeroRates*100+SpreadInBP/100, 'r--')
legend({'Treasury'; 'FNMA 4 3/8'})
xlabel('Curve Dates')
ylabel('Spot Rate [%]')
grid;

```

## Input Arguments

### SpotInfo — Spot-rates information

matrix | table | term structure

Spot-rates information, specified as matrix of two columns, an annualized term structure created by `intenvset`, or a table.

- Matrix of two columns— The first column is the `SpotDate`, and the second column, `ZeroRates`, is the zero-rate corresponding to maturities on the `SpotDate`. It is recommended that the spot-rates are spaced as evenly apart as possible, perhaps one that is built from 3-months deposit rates. For example, using the 3-month deposit rates:

```
SpotInfo = ...
[datenum('2-Jan-2004') , 0.03840;
 datenum('2-Jan-2005') , 0.04512;
 datenum('2-Jan-2006') , 0.05086];
```

- Annualized term structure — Refer to `intenvset` to create an annualized term structure. For example:

```
Settle = datenum('1-Jan-2004');
Rates = [0.03840; 0.04512; 0.05086];
EndDates = [datenum('2-Jan-2004'); datenum('2-Jan-2005');...
            datenum('2-Jan-2006')];
SpotInfo = intenvset('StartDates' , Settle , ...)
```

```
'Rates'      , Rates    ,...
'EndDates'   , EndDates, ...
'Compounding', 2       , ...
'Basis'      , 0);
```

- **Table** — If **SpotInfo** is a table, the first column can be either a serial date number, date character vector, or datetime array. The second column is numerical data representing zero rates. For example:

```
ZeroRates = [0.012067955808764;0.012730933424479;0.019360902068703;0.031704525214251;0.042306085224510;0.054987415342936];
CurveDates = [731639;731730;732251;733361;735188;741854];
Settle    = datenum('26-Nov-2002');
Price     = 105.484;
Coupon    = 0.04375;
Maturity  = datenum('15-Oct-2006');
Period    = 2;
Basis     = 1;
SpotInfo  = table(datestr(CurveDates), ZeroRates);
```

Data Types: double | table | struct

**Price — Price for every \$100 notional amount of bonds whose spreads are computed**  
numeric

Price for every \$100 notional amount of bonds whose spreads are computed, specified as numeric value using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

**Coupon — Annual coupon rate of bonds whose spreads are computed**  
decimal

Annual coupon rate of bonds whose spreads are computed, specified as decimal value using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

**Settle — Settlement date of bond**

serial date number | date character vector | datetime

Settlement date of the bond, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The **Settle** date must be before the **Maturity** date.

Data Types: double | char | datetime

**Maturity — Maturity date of bond**

serial date number | date character vector | datetime

Maturity date of the bond, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**Name-Value Pair Arguments**

Specify optional pairs of arguments as **Name1=Value1**, ..., **NameN=ValueN**, where **Name** is the argument name and **Value** is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `Spread = bndspread(SpotInfo, Price, Coupon, Settle, Maturity, 'Period', 4, 'Basis', 7)`

**Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an **IssueDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **FirstCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **LastCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The **StartDate** is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a **StartDate**, the effective start date is the **Settle** date.

Data Types: double | char | datetime

**Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

**CompoundingFrequency — Compounding frequency for yield calculation**

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**DiscountBasis — Basis used to compute the discount factors for computing the yield**

SIA uses 0 (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.  
Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

---

**Note** If a SIA day-count basis is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

---

If an ICMA day-count basis or BUS/252 is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the specified bases from the **Basis** input argument are used.

---

Data Types: double

#### **LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period**

compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. LastCouponInterest is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

## **Output Arguments**

#### **Spread — Static spread to benchmark in basis points**

numeric

Static spread to benchmark, returned in basis points as a scalar or a NUMBONDS-by-1 vector.

## **Introduced before R2006a**

## bndtotalreturn

Total return of fixed-coupon bond

### Syntax

```
[BondEquiv,EffectiveRate] = bndtotalreturn(Price,CouponRate,Settle,Maturity,  
ReinvestRate)  
[BondEquiv,EffectiveRate] = bndtotalreturn(____,Name,Value)
```

### Description

[BondEquiv,EffectiveRate] = bndtotalreturn(Price,CouponRate,Settle,Maturity, ReinvestRate) calculates the total return for fixed-coupon bonds to maturity or to a specific investment horizon.

[BondEquiv,EffectiveRate] = bndtotalreturn(\_\_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Compute the Total Return of a Fixed-Coupon Bond

Use bndtotalreturn to compute the total return for a fixed-coupon bond, given an investment horizon date.

Define fixed-coupon bond.

```
Price = 101;  
CouponRate = 0.05;  
Settle = '15-Nov-2011';  
Maturity = '15-Nov-2031';  
ReinvestRate = 0.04;
```

Calculate the total return to maturity.

```
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ...  
Settle, Maturity, ReinvestRate)
```

```
BondEquiv = 0.0460
```

```
EffectiveRate = 0.0466
```

Specify an investment horizon.

```
HorizonDate = '15-Nov-2021';  
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ...  
Settle, Maturity, ReinvestRate, 'HorizonDate', HorizonDate)
```

```
BondEquiv = 0.0521
```

```
EffectiveRate = 0.0528
```

Perform scenario analysis on the reinvestment rate.

```
ReinvestRate = [0.03; 0.035; 0.04; 0.045; 0.05];
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ...
Settle, Maturity, ReinvestRate, 'HorizonDate', HorizonDate)
```

BondEquiv = 5×1

```
0.0557
0.0538
0.0521
0.0505
0.0490
```

EffectiveRate = 5×1

```
0.0565
0.0546
0.0528
0.0511
0.0496
```

## Compute the Total Return of a Fixed-Coupon Bond Using datetime Inputs

Use `bndtotalreturn` with `datetime` inputs to compute the total return for a fixed-coupon bond, given an investment horizon date.

```
Price = 101;
CouponRate = 0.05;
Settle = datetime('15-Nov-2011','Locale','en_US');
Maturity = datetime('15-Nov-2031','Locale','en_US');
HorizonDate = datetime('15-Nov-2021','Locale','en_US');
ReinvestRate = 0.04;
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ...
Settle, Maturity, ReinvestRate, 'HorizonDate', HorizonDate)

BondEquiv = 0.0521
EffectiveRate = 0.0528
```

## Input Arguments

**Price — Clean price at settlement date**  
matrix

Clean price at the settlement date, specified as a scalar or a `NINST`-by-1 vector.

Data Types: `double`

**CouponRate — Coupon rate**  
decimal

Coupon rate, specified as a scalar or a `NINST`-by-1 vector of decimal values.

Data Types: double

**Settle — Settlement date of fixed-coupon bond**

serial date number | date character vector | datetime

Settlement date of the fixed-coupon bond, specified as scalar or a NINST-by-1 vector of serial date numbers, date character vectors, or datetime arrays. If supplied as a NINST-by-1 vector of dates, settlement dates can be different, as long as they are before the Maturity date and HorizonDate.

Data Types: double | char | datetime

**Maturity — Maturity date of fixed-coupon bond**

serial date number | date character vector | datetime

Maturity date of the fixed-coupon bond, specified as scalar or a NINST-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**ReinvestRate — Reinvestment rate**

decimal

Reinvestment rate (the rate earned by reinvesting the coupons), specified as scalar or a NINST-by-2 vector of decimal values.

Data Types: double

**Name-Value Pair Arguments**

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: [BondEquiv,EffectiveRate] =  
bndtotalreturn(Price,CouponRate,Settle,Maturity,ReinvestRate,'HorizonDate','1  
5-Nov-2021')

**HorizonDate — Investment horizon date**

Maturity date (default) | serial date number | date character vector | datetime

Investment horizon date, specified as the comma-separated pair consisting of 'HorizonDate' and a scalar or a NINST-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If HorizonDate is unspecified, the total return is calculated to Maturity.

Data Types: double | char | datetime

**HorizonPrice — Price at investment horizon date**

calculated based on ReinvestRate (default) | numeric

Price at investment horizon date, specified as the comma-separated pair consisting of 'HorizonPrice' and a scalar or a NINST-by-1 vector.

If HorizonPrice is unspecified, the price at the HorizonDate is calculated based on the ReinvestRate. If the HorizonDate equals the Maturity date, the HorizonPrice is ignored and the total return to maturity is calculated based on the Face value.

Data Types: double

**Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NINST-by-1 vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis**

0 (actual/actual) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NINST-by-1 vector. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NINST-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an **IssueDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NINST-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **FirstCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NINST-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **LastCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NINST-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **StartDate**, the effective start date is the Settle date.

Data Types: double | char | datetime

**Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NINST-by-1 vector.

Data Types: double

**CompoundingFrequency — Compounding frequency for yield calculation**

integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NINST-by-1 vector.

- 1 — Annual compounding

- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**DiscountBasis — Basis used to compute the discount factors for computing the yield**  
integers of the set [0...13] | vector of integers of the set [0...13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

---

**Note** The default behavior is for SIA bases (0-7) to use the actual/actual day count to compute discount factors, and for ICMA day counts (8 - 12) and BUS/252 to use the specified **DiscountBasis**.

---

Data Types: double

## Output Arguments

**BondEquiv — Total return in bond equivalent basis**  
numeric

Total return in bond equivalent basis, returned as a NUMBONDS-by-1 vector.

**EffectiveRate — Total return in effective rate basis**

numeric

Total return in effective rate basis, returned as a NUMBONDS-by-1 vector.

## Introduced in R2012b

# bndyield

Yield to maturity for fixed-income security

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

---

## Syntax

```
Yield = bndyield(Price,CouponRate,Settle,Maturity)
Yield = bndyield(_____,Name,Value)
```

## Description

`Yield = bndyield(Price,CouponRate,Settle,Maturity)` given NUMBONDS bonds with SIA date parameters and clean prices (excludes accrued interest), returns the bond equivalent yields to maturity.

`Yield = bndyield(_____,Name,Value)` adds optional name-value arguments.

## Examples

### Compute Yield to Maturity for a Treasury Bond

This example shows how to compute the yield of a Treasury bond at three different price values.

```
Price = [95; 100; 105];
CouponRate = 0.05;
Settle = '20-Jan-1997';
Maturity = '15-Jun-2002';
Period = 2;
Basis = 0;

Yield = bndyield(Price, CouponRate, Settle, ...
Maturity, Period, Basis)

Yield = 3x1
    0.0610
    0.0500
    0.0396
```

### Compute Yield to Maturity for a Treasury Bond Using datetime Inputs

This example shows how to use `datetime` inputs to compute the yield of a Treasury bond at three different price values.

```
Price = [95; 100; 105];
CouponRate = 0.05;
Settle = datetime('20-Jan-1997','Locale','en_US');
Maturity = datetime('15-Jun-2002','Locale','en_US');
Period = 2;
Basis = 0;
Yield = bndyield(Price, CouponRate, Settle, ...
Maturity, Period, Basis)

Yield = 3x1

0.0610
0.0500
0.0396
```

### Compute the Yield of a Treasury Bond Using the Same Basis for Discounting and Generating the Cash Flows

Compute the yield of a Treasury bond.

```
Price = [95; 100; 105];
CouponRate = 0.0345;
Settle = '15-May-2016';
Maturity = '02-Feb-2026';
Period = 2;
Basis = 1;
format long

Yield = bndyield(Price,CouponRate,Settle,Maturity,Period,Basis)

Yield = 3x1

0.040764403932618
0.034482347625316
0.028554719853118
```

Using the same data, compute the yield of a Treasury bond using the same basis for discounting and generating the cash flows.

```
DiscountBasis = 1;

Yield = bndyield(Price,CouponRate,Settle,Maturity,'Period',Period,'Basis',Basis, ...
'DiscountBasis',DiscountBasis)

Yield = 3x1

0.040780176658036
0.034495592361619
```

---

0.028565614029497

## Input Arguments

### **Price — Clean price of the bond**

numeric

Clean price of the bond (current price without accrued interest), specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

### **CouponRate — Annual percentage rate used to determine coupons payable on a bond**

decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

### **Settle — Settlement date of bond**

serial date number | date character vector | datetime

Settlement date of the bond, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

### **Maturity — Maturity date of bond**

serial date number | date character vector | datetime

Maturity date of the bond, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: Yield =

```
bndyield(Price,CouponRate,Settle,Maturity,'Period',4,'Basis',9)
```

### **Period — Number of coupon payments per year**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an **IssueDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **FirstCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **LastCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **StartDate**, the effective start date is the **Settle** date.

Data Types: double | char | datetime

**Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

**CompoundingFrequency — Compounding frequency for yield calculation**

SIA uses 2, ICMA uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. Values are:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding

- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**DiscountBasis — Basis used to compute the discount factors for computing the yield**  
SIA uses 0 (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.  
Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

---

**Note** If a SIA day-count basis is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the default behavior is for SIA bases to use the **actual/actual** day count to compute discount factors.

---

If an ICMA day-count basis or BUS/252 is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the specified bases from the **Basis** input argument are used.

---

Data Types: double

**LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period**  
compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-

by-NUMBONDS vector. This is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

## Output Arguments

### **Yield — Yield to maturity with semiannual compounding**

numeric

Yield to maturity with semiannual compounding, returned as a NUMBONDS-by-1 vector.

## More About

### Price and Yield Conventions

The Price and Yield are related to different formulae for SIA and ICMA conventions.

For SIA conventions, Price and Yield are related by the formula:

$$\text{Price} + \text{Accrued Interest} = \text{sum}(\text{Cash_Flow} * (1 + \text{Yield}/2)^{(-\text{Time})})$$

where the sum is over the bond's cash flows and corresponding times in units of semiannual coupon periods.

For ICMA conventions, the Price and Yield are related by the formula:

$$\text{Price} + \text{Accrued Interest} = \text{sum}(\text{Cash_Flow} * (1 + \text{Yield})^{(-\text{Time})})$$

## Algorithms

For SIA conventions, the following formula defines bond price and yield:

$$PV = \frac{CF}{(1 + \frac{z}{f})^{TF}},$$

where:

|        |                                                                                                                                                                                                                                    |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $PV =$ | Present value of a cash flow.                                                                                                                                                                                                      |
| $CF =$ | The cash flow amount.                                                                                                                                                                                                              |
| $z =$  | The risk-adjusted annualized rate or yield corresponding to a given cash flow. The yield is quoted on a semiannual basis.                                                                                                          |
| $f =$  | The frequency of quotes for the yield.                                                                                                                                                                                             |
| $TF =$ | Time factor for a given cash flow. Time is measured in semiannual periods from the settlement date to the cash flow date. In computing time factors, use SIA actual/actual day count conventions for all time factor calculations. |

For ICMA conventions, the frequency of annual coupon payments determines bond price and yield.

# bolling

Bollinger band chart

---

**Note** bolling is not recommended. Use bollinger instead.

---

## Syntax

```
bolling(Asset,Samples,Alpha,Width)
```

```
[Movavgv,UpperBand,LowerBand] = bolling(Asset,Samples,Alpha,Width)
```

## Arguments

|         |                                                                                                                                                                                      |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Asset   | Vector of asset data.                                                                                                                                                                |
| Samples | Number of samples to use in computing the moving average.                                                                                                                            |
| Alpha   | (Optional) Exponent used to compute the element weights of the moving average. Default = 0 (simple moving average).                                                                  |
| Width   | (Optional) Number of standard deviations to include in the envelope. A multiplicative factor specifying how tight the bands should be around the simple moving average. Default = 2. |

## Description

`bolling(Asset,Samples,Alpha,Width)` plots Bollinger bands for given Asset data. This form of the function does not return any data.

`[Movavgv,UpperBand,LowerBand] = bolling(Asset,Samples,Alpha,Width)` returns Movavgv with the moving average of the Asset data, UpperBand with the upper band data, and LowerBand with the lower band data. This form of the function does not plot any data.

---

**Note** The standard deviations are normalized by N-1, where N = the sequence length.

---

## Examples

If Asset is a column vector of closing stock prices

```
bolling(Asset, 20, 1)
```

plots linear 20-day moving average Bollinger bands based on the stock prices.

```
[Movavgv, UpperBand, LowerBand] = bolling(Asset, 20, 1)
```

returns Movavgv, UpperBand, and LowerBand as vectors containing the moving average, upper band, and lower band data, without plotting the data.

# bollinger

Time series Bollinger band

**Note** Using a `fints` object for the `Data` argument of `bollinger` is not recommended. Use a matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

## Syntax

```
[middle,upper,lower] = bollinger(Data)
[middle,upper,lower] = bollinger(___,Name,Value)
```

## Description

`[middle,upper,lower] = bollinger(Data)` calculates the middle, upper, and lower bands that make up the Bollinger bands from a series of data. A Bollinger band chart plots actual asset data along with three other bands of data: the upper band that is two standard deviations above a user-specified moving average; the lower band that is two standard deviations below that moving average; and the middle band that is the moving average itself.

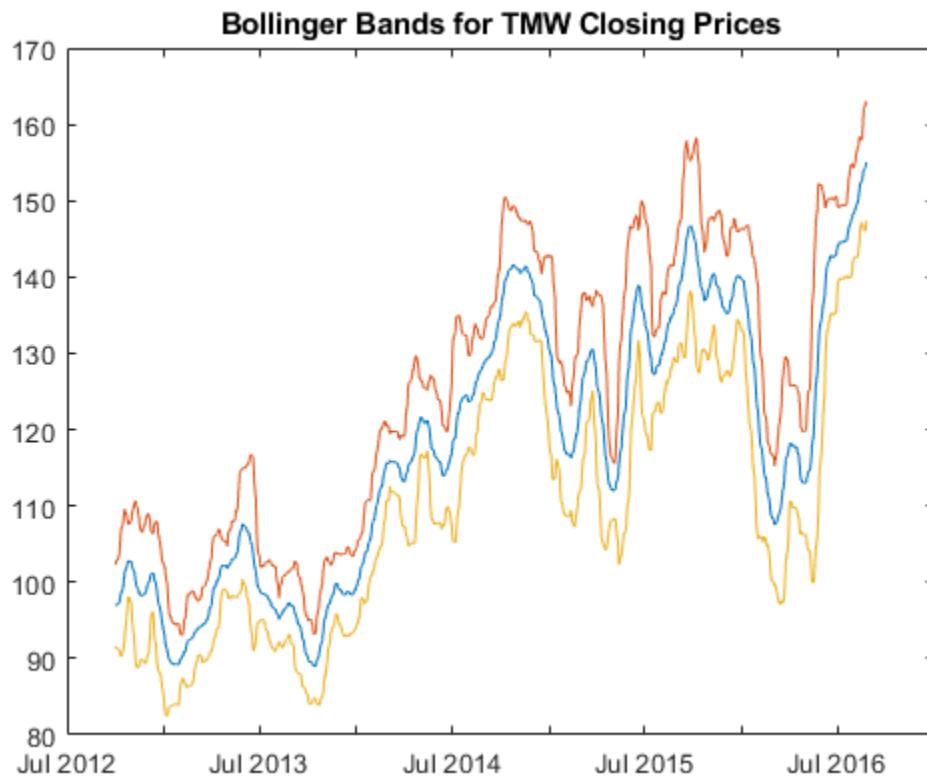

`[middle,upper,lower] = bollinger(___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Calculate the Bollinger Bands for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
[middle,upper,lower]= bollinger(TMW);
CloseBolling = [middle.Close, upper.Close,... 
lower.Close];
plot(middle.Time,CloseBolling)
title('Bollinger Bands for TMW Closing Prices')
```

## Input Arguments

### Data — Data for market prices

matrix | table | timetable

Data for market prices, specified as a matrix, table, or timetable. For matrix input, Data must be column-oriented.

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, ..., NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: [middle,upper,lower] = bollinger(TMW\_CLOSE,'WindowSize',10,'Type',1)

### WindowSize — Number of observations of input series to include in moving average in periods

10 (default) | positive integer

Number of observations of the input series to include in the moving average in periods, specified as the comma-separated pair consisting of 'WindowSize' and a scalar positive integer.

Data Types: double

**Type — Type of moving average to compute**

0 (simple) (default) | integer with value 0 or 1

Type of moving average to compute, specified as the comma-separated pair consisting of 'Type' and a scalar integer with a value of 0 (simple) or 1 (linear).

Data Types: double

**NumStd — Number of standard deviations for the upper and lower bounds**

2 (default) | positive integer

Number of standard deviations for the upper and lower bounds, specified as the comma-separated pair consisting of 'NumStd' and a scalar positive integer.

Data Types: double

## Output Arguments

**middle — Moving average series representing the middle band**

matrix | table | timetable

Moving average series representing the middle band, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

**upper — Moving average series representing the upper band**

matrix | table | timetable

Moving average series representing the upper band, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

**lower — Moving average series representing the lower band**

matrix | table | timetable

Moving average series representing the lower band, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## Topics

"Using Timetables in Finance" on page 12-7

"Convert Financial Time Series Objects fints to Timetables" on page 12-2

## Introduced before R2006a

## boxcox

Box-Cox transformation

**Note** Using a `fints` object for the `tsobj` argument of `boxcox` is not recommended. Use `fts2timetable` to convert a `fints` object to a `timetable` object and then use `timetable2table` and `table2array`.

---

### Syntax

```
[transdat,lambda] = boxcox(data)
[transfts,lambda] = boxcox(tsobj)
transdat = boxcox(lambda,data)
transdat = boxcox(lambda,tsobj)
```

### Description

`[transdat,lambda] = boxcox(data)` transforms the data vector `data` using the Box-Cox transformation method into `transdat`. It also estimates the transformation parameter  $\lambda$ .

`[transfts,lambda] = boxcox(tsobj)` transforms the financial time series object `tsobj` using the Box-Cox transformation method into `transfts`. It also estimates the transformation parameter  $\lambda$ .

`transdat = boxcox(lambda,data)` transform the `data` using a certain specified  $\lambda$  for the Box-Cox transformation. This syntax does not find the optimum  $\lambda$  that maximizes the LLF.

`transdat = boxcox(lambda,tsobj)` transform the `tsobj` using a certain specified  $\lambda$  for the Box-Cox transformation. This syntax does not find the optimum  $\lambda$  that maximizes the LLF.

### Examples

#### Transform a Data Series Contained in a Financial Times Series Object

Use `boxcox` to transform the data series contained in a financial time series object into another set of data series with relatively normal distributions.

Create a financial time series object from the supplied `whirlpool.dat` data file.

```
whrl = ascii2fts('whirlpool.dat', 1, 2, []);
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see ["mat"](#)

Fill any missing values denoted with `NaN`'s in `whrl` with values calculated using the linear method.

```
f_whrl = fillts(whrl);
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see ["mat"](#)

Transform the nonnormally distributed filled data series `f_whrl` into a normally distributed one using Box-Cox transformation.

```
bc_whrl = boxcox(f_whrl);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

Compare the result of the Close data series with a normal (Gaussian) probability distribution function and the nonnormally distributed f\_whrl.

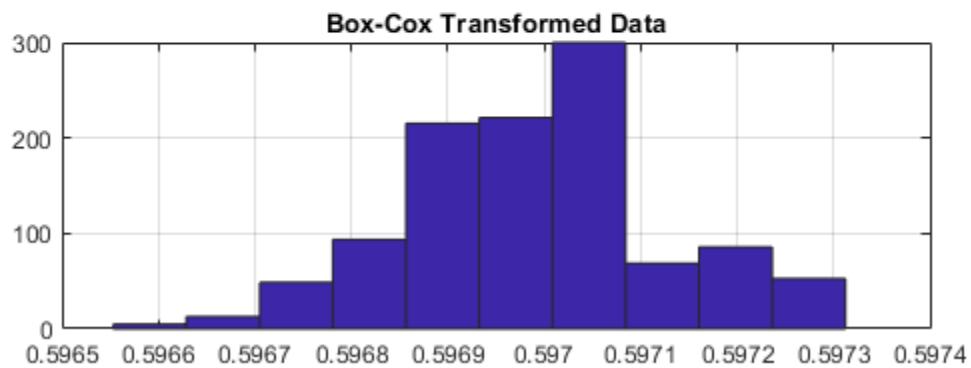

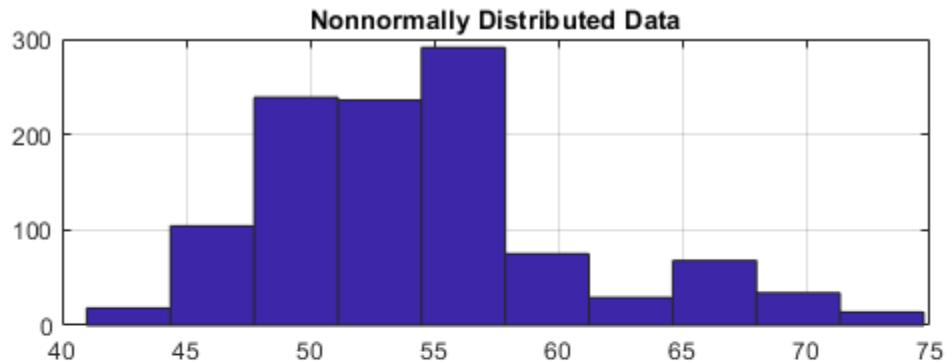

```
subplot(2, 1, 1);
hist(f_whrl.Close);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
grid; title('Nonnormally Distributed Data');
subplot(2, 1, 2);
hist(bc_whrl.Close);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
grid; title('Box-Cox Transformed Data');
```

The bar chart on the top represents the probability distribution function of the filled data series, f\_whrl, which is the original data series whrl with the missing values interpolated using the linear method. The distribution is skewed toward the left (not normally distributed). The bar chart on the bottom is less skewed to the left. If you plot a Gaussian probability distribution function (PDF) with similar mean and standard deviation, the distribution of the transformed data is very close to normal (Gaussian). When you examine the contents of the resulting object bc\_whrl, you find an identical object to the original object whrl but the contents are the transformed data series.

## Input Arguments

**data — Data**

positive column vector

Data, specified as a positive column vector.

Data Types: double

**tsobj — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

**lambda — Lambda**

numeric | structure

Lambda, specified as a scalar numeric or structure.

If the input `data` is a vector, `lambda` is a scalar. If the input is a financial time series object (`tsobj`), `lambda` is a structure with fields similar to the components of the object. For example, if `tsobj` contains series names `Open` and `Close`, `lambda` has fields `lambda.Open` and `lambda.Close`.

Data Types: double | struct

## Output Arguments

**transdat — Data Box-Cox transformation**

vector

Data Box-Cox transformation, returned as a vector.

**transfts — Financial time series Box-Cox transformation**

vector

Financial time series Box-Cox transformation, returned as a vector.

**lambda — Lambda transformation parameter**

numeric

Lambda transformation parameter, returned as a numeric.

## More About

**Box Cox Transformation**

`boxcox` transforms nonnormally distributed data to a set of data that has approximately normal distribution. The Box-Cox transformation is a family of power transformations.

If  $\lambda$  is not = 0, then

$$\text{data}(\lambda) = \frac{\text{data}^\lambda - 1}{\lambda}$$

If  $\lambda$  is = 0, then

$$data(\lambda) = \log(data)$$

The logarithm is the natural logarithm (log base e). The algorithm calls for finding the  $\lambda$  value that maximizes the Log-Likelihood Function (LLF). The search is conducted using `fminsearch`.

## Introduced before R2006a

## busdate

Next or previous business day

### Syntax

```
Busday = busdate(Date)
Busday = busdate(___,DirFlag,Holiday,Weekend)
```

### Description

`Busday = busdate(Date)` returns the scalar, vector, or matrix of the next or previous business days, depending on the definition for `Holiday`.

`Busday = busdate(___,DirFlag,Holiday,Weekend)` returns the scalar, vector, or matrix of the next or previous business days, depending on the optional input arguments, including `Holiday`.

If both `Date` and `Holiday` are either serial date numbers or date character vectors, `Busday` is returned as a serial date number.

However, if either `Date` or `Holiday` are datetime arrays, `Busday` is returned as a datetime array.

Use the function `datestr` to convert serial date numbers to formatted date character vectors.

### Examples

#### Determine Business Days

Determine the next business day when `Date` is a character vector.

```
Busday = busdate('3-Jul-2001', 1)
Busday = 731037
datestr(Busday)

ans =
'05-Jul-2001'
```

Indicate that Saturday is a business day by appropriately setting the `Weekend` argument. July 4, 2003 falls on a Friday. Use `busdate` to verify that Saturday, July 5, is actually a business day.

```
Weekend = [1 0 0 0 0 0];
Date = datestr(busdate('3-Jul-2003', 1, [], Weekend))

Date =
'05-Jul-2003'
```

If either `Date` or `Holiday` are datetime arrays, `Busday` is returned as a datetime array.

```
Busday = busdate(datetime('3-Jul-2001','Locale','en_US'), 1)
```

---

```
Busday = datetime
05-Jul-2001
```

## Input Arguments

### Date — Reference business date

serial date number | date character vector | datetime object

Reference business date, specified as a scalar, vector, or matrix using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### DirFlag — Business day convention

follow (default) | date character vector with values of follow, modifiedfollow, previous, or modifiedprevious | cell array of date character vectors with values of follow, modifiedfollow, previous, or modifiedprevious

Business day convention, specified date character vector or cell array of date character vectors with values of follow, modifiedfollow, previous, or modifiedprevious.

Also, DirFlag can be a scalar, vector, or matrix of search directions, where Next is DIREC = 1 (default) or Previous is DIREC = -1.

Data Types: double | char | datetime

### Holiday — Holidays and nontrading-day dates

non-trading day vector is determined by the routine holidays (default) | serial date number | date character vector | datetime object

Holidays and nontrading-day dates, specified as vector.

All dates in Holiday must be the same format: either serial date numbers, or date character vectors, or datetime arrays. (Using serial date numbers improves performance.)

Data Types: double | char | datetime

### Weekend — Weekend days

[1 0 0 0 0 0 1] (Saturday and Sunday form the weekend) (default) | vector of length 7, containing 0 and 1, where 1 indicates weekend days

Weekend days, specified as a vector of length 7, containing 0 and 1, where 1 indicates weekend days and the first element of this vector corresponds to Sunday.

Data Types: double

## Output Arguments

### Busday — Next or previous business day

scalar | vector | matrix

Next or previous business day, returned as a scalar, vector, or matrix depending on the definition for Holiday. If Date is a datetime array, Busday returns a datetime array. Otherwise, Busday returns a serial date numbers.

# busdays

Business days for given period

## Syntax

```
bdates = busdays(sdate,edate)
bdates = busdays(___,bdmode,Holiday)
```

## Description

`bdates = busdays(sdate,edate)` generates a vector of business days between the last business date of the period that contains the start date (`sdate`), and the last business date of period that contains the end date (`edate`).

`bdates = busdays(___,bdmode,Holiday)` generates a vector of business days between the last business date of the period that contains the start date (`sdate`), and the last business date of period that contains the end date (`edate`) using optional input arguments. If `Holiday` is not supplied, the dates are generated based on United States holidays. If you do not supply `bdmode`, `bdates` generates a daily vector.

## Examples

### Determine Business Days for a Given Period

Determine the business days for a weekly period.

```
bdates = datestr(busdays('1/2/01','1/9/01','weekly'))
bdates = 2x11 char array
    '05-Jan-2001'
    '12-Jan-2001'
```

The end of the week is considered to be a Friday. Between 1/2/01 (Monday) and 1/9/01 (Tuesday), there is only one end-of-week day, 1/5/01 (Friday). Because 1/9/01 is part of the following week, the following Friday (1/12/01) is also reported.

Determine the business days for a weekly period using a datetime input for `sdate`.

```
bdates = busdays(datetime('2-Jan-2001','Locale','en_US'),'9-Jan-2001','weekly')
bdates = 2x1 datetime
    05-Jan-2001
    12-Jan-2001
```

Determine the business days for a monthly period.

```
vec = datestr(busdays('1/8/16','3/1/16','monthly'))
vec = 3x11 char array
    '29-Jan-2016'
```

```
'29-Feb-2016'  
'31-Mar-2016'
```

The start date (1/8/16) is in the month of January, 2016. The last business day for the month of January is 1/29/16 (Friday). The end date (3/1/16) is in the month of March, 2016. The last business day for the month of March is 3/31/16 (Thursday). The month of February, 2016 lies between the start date and the end date. The last business day for the month of February is 2/29/16 (Monday).

## Input Arguments

### sdate — Start date

serial date number | date character vector | datetime object

Start date, specified as a serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### edate — End date

serial date number | date character vector | datetime object

End date, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### bdmode — Frequency of business days

DAILY (1) (default) | nonnegative numeric with values 1 through 5 | date character vector with values DAILY, WEEKLY, MONTHLY, QUARTERLY, SEMIANNUAL or ANNUAL

Frequency of business days, specified as a nonnegative numeric with values 1 through 5 or date character vector with values of DAILY, WEEKLY, MONTHLY, QUARTERLY, SEMIANNUAL, or ANNUAL

Valid periodicities include:

- DAILY, Daily, daily, D, d, 1 (default)
- WEEKLY, Weekly, weekly, W, w, 2
- MONTHLY, Monthly, monthly, M, m, 3
- QUARTERLY, Quarterly, quarterly, Q, q, 4
- SEMIANNUAL, Semiannual, semiannual, S, s, 5
- ANNUAL, Annual, annual, A, a, 6

Character vectors must be enclosed in single quotation marks.

For example, if bdmode is set to monthly, busdays returns end-of-month business dates for all full or partial months between the start date and end date inclusive.

Data Types: double | char

### Holiday — Holiday and nontrading-day dates

if Holiday is [ ] holiday dates are based on United States holidays specified by holidays (default) | serial date number | date character vector | datetime object

---

Holiday and nontrading-day dates, specified as a vector in date character vector, serial date, or datetime array format. If you specify `Holiday`, you must also supply the frequency `bdmode`. Using a `Holiday` value of `NaN` uses a holiday list that has no dates.

Data Types: `double` | `char` | `datetime`

## Output Arguments

### **bdates — Business days**

column vector

Business days, returned as a column vector of business dates, in serial date format (default) or datetime format (if `sdate`, `edate`, or `Holiday` are in datetime format). Business dates can exist before and/or after the specified `sdate` and `edate`.

## See Also

`isbusday` | `holidays` | `datetime`

## Introduced before R2006a

## candle

Candlestick chart

---

**Note** `candle` is updated to accept data input as a matrix, `timetable`, or `table`.

---

### Syntax

```
candle(Data)
candle(Data,Color)
h = candle(ax ____)
```

### Description

`candle(Data)` plots a candlestick chart from a series of opening, high, low, and closing prices of a security. If the closing price is greater than the opening price, the body (the region between the open and close price) is unfilled; otherwise the body is filled.

`candle(Data,Color)` adds an optional argument for `Color`.

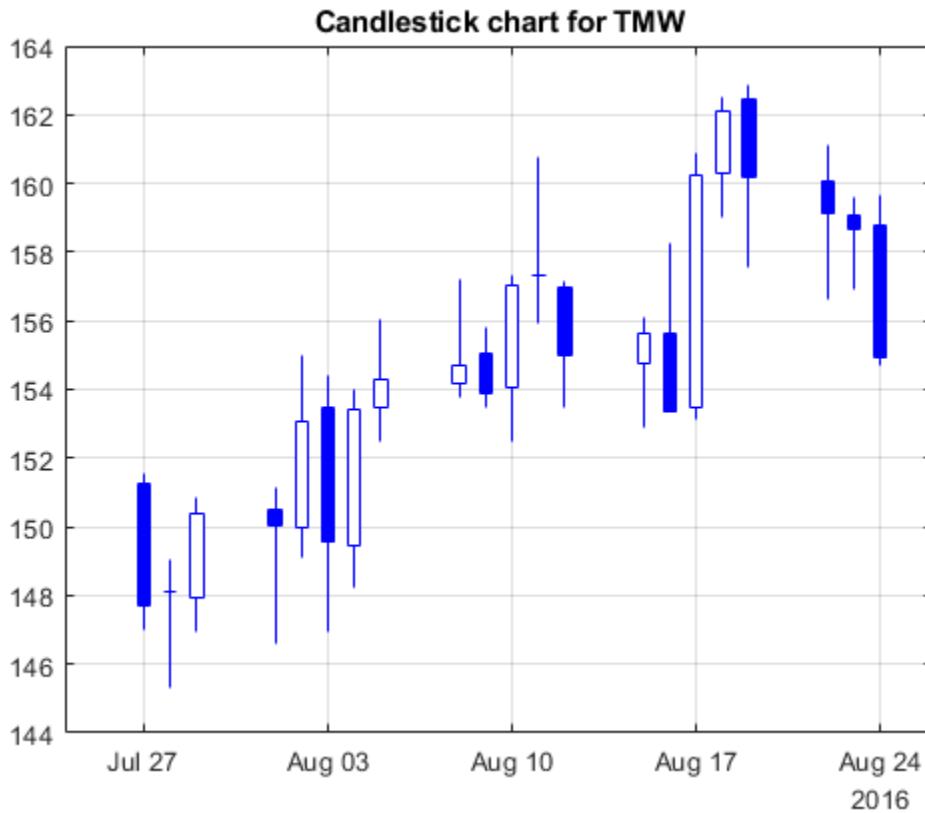

`h = candle(ax ____)` adds an optional argument for `ax`.

### Examples

#### Generate a Candlestick Chart for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock. This is a candlestick chart with blue candles, for the most recent 21 days in `SimulatedStock.mat`.

```
load SimulatedStock.mat;
candle(TMW(end-20:end,:),'b');
title('Candlestick chart for TMW')
```

## Input Arguments

### Data — Data for opening, high, low, and closing prices

matrix | table | timetable

Data for opening, high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-4 matrix of opening, high, low, and closing prices stored in the corresponding columns. Timetables and tables with M rows must contain variables named 'Open', 'High', 'Low', and 'Close' (case insensitive).

Data Types: double | table | timetable

### Color — (Optional) Three element color vector

background color of figure window (default) | color vector [R G B] | string

Three element color vector, specified as a [R G B] color vector or a string specifying the color name. The default color differs depending on the background color of the figure window.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1]; for example, [0.4 0.6 0.7].

- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

| Color Name | Short Name | RGB Triplet | Hexadecimal Color Code | Appearance |
|------------|------------|-------------|------------------------|------------|
| 'red'      | 'r'        | [1 0 0]     | '#FF0000'              |            |
| 'green'    | 'g'        | [0 1 0]     | '#00FF00'              |            |
| 'blue'     | 'b'        | [0 0 1]     | '#0000FF'              |            |
| 'cyan'     | 'c'        | [0 1 1]     | '#00FFFF'              |            |
| 'magenta'  | 'm'        | [1 0 1]     | '#FF00FF'              |            |
| 'yellow'   | 'y'        | [1 1 0]     | '#FFFF00'              |            |
| 'black'    | 'k'        | [0 0 0]     | '#000000'              |            |
| 'white'    | 'w'        | [1 1 1]     | '#FFFFFF'              |            |

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

| RGB Triplet            | Hexadecimal Color Code | Appearance |
|------------------------|------------------------|------------|
| [0 0.4470 0.7410]      | '#0072BD'              |            |
| [0.8500 0.3250 0.0980] | '#D95319'              |            |
| [0.9290 0.6940 0.1250] | '#EDB120'              |            |
| [0.4940 0.1840 0.5560] | '#7E2F8E'              |            |
| [0.4660 0.6740 0.1880] | '#77AC30'              |            |
| [0.3010 0.7450 0.9330] | '#4DBEEE'              |            |
| [0.6350 0.0780 0.1840] | '#A2142F'              |            |

Data Types: double | string

#### ax — Valid axis object

current axes (ax = gca) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The candle plot is created in the axes specified by ax instead of in the current axes (ax = gca). The option ax can precede any of the input argument combinations.

Data Types: object

## Output Arguments

#### h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

**See Also**

“Convert Financial Time Series Objects fints to Timetables” on page 12-2

**Introduced before R2006a**

## candle (fts)

Time series candle plot

---

**Note** `candle (fts)` is not recommended. Use `candle` instead.

---

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

### Syntax

```
candle(tsobj)
candle(tsobj,color)
candle(tsobj,color,dateform)
candle(___,Name,Value)
hcdl = candle(___,Name,Value)
```

### Description

`candle(tsobj)` generates a candle plot of the data in the financial time series object. `tsobj` must contain at least four data series representing the high, low, open, and closing prices. These series must have the names `High`, `Low`, `Open`, and `Close` (case-insensitive).

`candle(tsobj,color)` additionally specifies the color of the candle box.

`candle(tsobj,color,dateform)` additionally specifies the date character vector format used as the X-axis tick labels. See `datestr` for a list of date character vector formats.

`candle(___,Name,Value)` indicates the actual names of the required data series if the data series do not have the default names.

`hcdl = candle(___,Name,Value)` returns the handle to the patch objects and the line object that make up the candle plot.

### Examples

#### Create a Candle Plot for a Financial Time Series Object

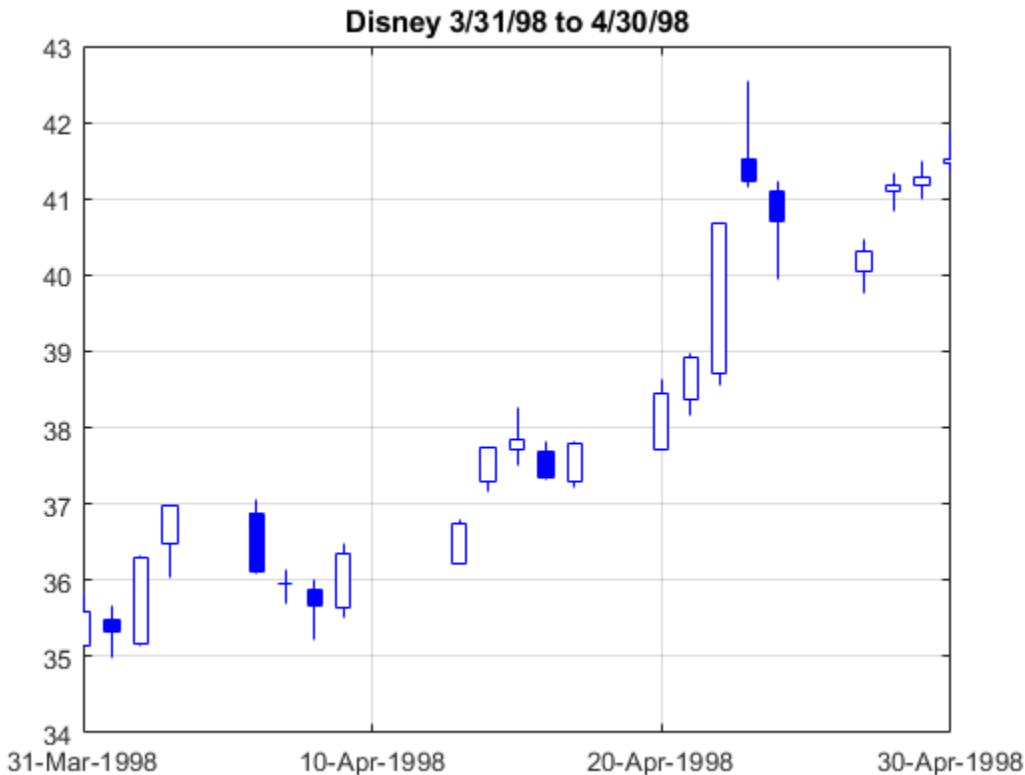

This example shows how to create a candle plot for Disney stock for the dates March 31, 1998 through April 30, 1998.

```
load disney.mat
candle(dis('3/31/98::4/30/98'))
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see <a href="mat

Warning: Low prices must be less than or equal to the corresponding opening prices.

```
title('Disney 3/31/98 to 4/30/98')
```

## Input Arguments

## **tsobj – Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

## Data Types: object

**color** – Three-element row vector representing RGB or a color identifier.

background color of figure window (default) | color vector [R G B] | character vector

(Optional) A three-element row vector representing RGB color vector or a character vector specifying the color name. The default color differs depending on the background color of the figure window. For more information, see [plot](#).

## Data Types: double | char

## dateform – Date format

'dd-mm-yyyy HH:MM' (default) | character vector

(Optional) Date format, specified as a date character vector format used as the x-axis tick labels. (See `datetick`.) You can specify a `dateform` only when `tsobj` does not contain time-of-day data. If `tsobj` contains time-of-day data, `dateform` is restricted to '`dd-mmm-yyyy HH:MM`'.

## Data Types: char

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `candle(dis('28-May-1998::18-Jun-1998'), 'HighName', 'SeriesHigh')`

### **HighName — High name**

'' (default) | character vector

High name, specified as the comma-separated pair consisting of 'HighName' and a character vector with a value for the high prices series name.

Data Types: char

### **LowName — High name**

'' (default) | character vector

Low name, specified as the comma-separated pair consisting of 'LowName' and a character vector with a value for the low prices series name.

Data Types: char

### **OpenName — Open name**

'' (default) | character vector

Open name, specified as the comma-separated pair consisting of 'OpenName' and a character vector with a value for the open prices series name.

Data Types: char

### **CloseName — High name**

'' (default) | character vector

Close name, specified as the comma-separated pair consisting of 'CloseName' and a character vector with a value for the closing prices series name.

Data Types: char

## Output Arguments

### **hcdl — Candle handles**

vector

Candle handles, returned as a three-element column vector representing the handles to the two patches and one line that forms the candle plot.

## cdai

Accrued interest on certificate of deposit

### Syntax

```
AccrInt = cdai(CouponRate, Settle, Maturity, IssueDate)
AccrInt = cdai(____, Basis)
```

### Description

`AccrInt = cdai(CouponRate, Settle, Maturity, IssueDate)` computes the accrued interest on a certificate of deposit.

`cdai` assumes that the certificates of deposit pay interest at maturity. Because of the simple interest treatment of these securities, this function is best used for short-term maturities (less than 1 year). The default simple interest calculation uses the `Basis` for the actual/360 convention (2).

`AccrInt = cdai(____, Basis)` adds an optional argument for `Basis`.

### Examples

#### Find the Accrued Interest on a Certificate of Deposit

This example shows how to compute the accrued interest due, given a certificate of deposit with the following characteristics.

```
CouponRate      = 0.05;
Settle          = '02-Jan-02';
Maturity        = '31-Mar-02';
IssueDate       = '1-Oct-01';

AccrInt = cdai(CouponRate, Settle, Maturity, IssueDate)
AccrInt = 1.2917
```

#### Find the Accrued Interest on a Certificate of Deposit Using datetime Inputs

This example shows how to use `datetime` inputs to compute the accrued interest due, given a certificate of deposit with the following characteristics.

```
CouponRate = 0.05;
Settle = datetime('02-Jan-02','Locale','en_US');
Maturity = datetime('31-Mar-02','Locale','en_US');
IssueDate = datetime('1-Oct-01','Locale','en_US');
AccrInt = cdai(CouponRate, Settle, Maturity, IssueDate)

AccrInt = 1.2917
```

## Input Arguments

### CouponRate — Annual interest rate

decimal

Annual interest rate, specified as decimal using a scalar or a NCDS-by-1 or 1-by-NCDS vector.

Data Types: double

### Settle — Settlement date for certificate of deposit

serial date number | date character vector | datetime

Settlement date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

### Maturity — Maturity date for certificate of deposit

serial date number | date character vector | datetime

Maturity date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### IssueDate — Issue date for certificate of deposit

serial date number | date character vector | datetime

Issue date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Basis — Day-count basis for certificate of deposit

2 (actual/360) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

(Optional) Day-count basis for the certificate of deposit, specified as a scalar or a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

## Output Arguments

### **AccrInt — Accrued interest per \$100 of face value**

numeric

Accrued interest per \$100 of face value, returned as a NCDS-by-1 or 1-by-NCDS vector.

## cdprice

Price of certificate of deposit

### Syntax

```
[Price,AccrInt] = cdprice(Yield,CouponRate,Settle,Maturity,IssueDate)
[PriceAccrInt] = cdprice(____,Basis)
```

### Description

[Price,AccrInt] = cdprice(Yield,CouponRate,Settle,Maturity,IssueDate) computes the price of a certificate of deposit given its yield.

cdprice assumes that the certificates of deposit pay interest at maturity. Because of the simple interest treatment of these securities, this function is best used for short-term maturities (less than 1 year). The default simple interest calculation uses the Basis for the actual/360 convention (2).

[PriceAccrInt] = cdprice(\_\_\_\_,Basis) adds an optional argument for Basis.

### Examples

#### Compute the Price and Accrued Interest for a Certificate of Deposit

This example shows how to compute the price and the accrued interest due on the settlement date, given a certificate of deposit with the following characteristics.

```
Yield      = 0.0525;
CouponRate = 0.05;
Settle     = '02-Jan-02';
Maturity   = '31-Mar-02';
IssueDate  = '1-Oct-01';

[Price, AccruedInt] = cdprice(Yield, CouponRate, Settle, ...
Maturity, IssueDate)

Price = 99.9233
AccruedInt = 1.2917
```

#### Compute the Price and Accrued Interest for a Certificate of Deposit Using datetime Inputs

This example shows how to use datetime inputs to compute the price and the accrued interest due on the settlement date, given a certificate of deposit with the following characteristics.

```
Yield = 0.0525;
CouponRate = 0.05;
Settle = datetime('02-Jan-02','Locale','en_US');
Maturity = datetime('31-Mar-02','Locale','en_US');
```

```

IssueDate = datetime('1-Oct-01','Locale','en_US');

[Price, AccruedInt] = cdprice(Yield, CouponRate, Settle, ...
Maturity, IssueDate)

Price = 99.9233

AccruedInt = 1.2917

```

## Input Arguments

**Yield — Simple yield to maturity over basis denominator**  
numeric

Simple yield to maturity over the basis denominator, specified as a numeric value using a scalar or a NCDS-by-1 or 1-by-NCDS vector.

Data Types: double

**CouponRate — Coupon annual interest rate**  
decimal

Coupon annual interest rate, specified as decimal using a scalar or a NCDS-by-1 or 1-by-NCDS vector.

Data Types: double

**Settle — Settlement date for certificate of deposit**  
serial date number | date character vector | datetime

Settlement date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the **Maturity** date.

Data Types: double | char | datetime

**Maturity — Maturity date for certificate of deposit**  
serial date number | date character vector | datetime

Maturity date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**IssueDate — Issue date for certificate of deposit**  
serial date number | date character vector | datetime

Issue date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**Basis — Day-count basis for certificate of deposit**  
2 (actual/360) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

(Optional) Day-count basis for the certificate of deposit, specified as a scalar or a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

## Output Arguments

**Price** — Clean price of certificate of deposit per \$100  
numeric

Clean price of the certificate of deposit per \$100, returned as a NCDS-by-1 or 1-by-NCDS vector.

**AccrInt** — Accrued interest payable at settlement per unit of face value  
numeric

Accrued interest payable at settlement per unit of face value, returned as a NCDS-by-1 or 1-by-NCDS vector.

## Introduced before R2006a

# cdsbootstrap

Bootstrap default probability curve from credit default swap market quotes

## Syntax

```
[ProbData,HazData] = cdsbootstrap(ZeroData,MarketData,Settle)
[ProbData,HazData] = cdsbootstrap(___,Name,Value)
```

## Description

[ProbData,HazData] = cdsbootstrap(ZeroData,MarketData,Settle) bootstraps the default probability curve using credit default swap (CDS) market quotes. The market quotes can be expressed as a list of maturity dates and corresponding CDS market spreads, or as a list of maturities and corresponding up-fronts and standard spreads for standard CDS contracts. The estimation uses the standard model of the survival probability.

[ProbData,HazData] = cdsbootstrap(\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Bootstrap Default Probability Curve from Credit Default Swap Market Quotes

This example shows how to use `cdsbootstrap` with market quotes for CDS contracts to generate `ProbData` and `HazData` values.

```
Settle = '17-Jul-2009'; % valuation date for the CDS
Spread_Time = [1 2 3 5 7]';
Spread = [140 175 210 265 310]';
Market_Dates = daysadd(datenum(Settle),360*Spread_Time,1);
MarketData = [Market_Dates Spread];
Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [1.35 1.43 1.9 2.47 2.936 3.311]'/100;
Zero_Dates = daysadd(datenum(Settle),360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate];

format long
[ProbData,HazData] = cdsbootstrap(ZeroData,MarketData,Settle)

ProbData = 5×2

## Input Arguments

### ZeroData — Zero rate data

vector | IRDataCurve object

Zero rate data, specified as a M-by-2 vector of dates and zero rates or an IRDataCurve object of zero rates.

When ZeroData is an IRDataCurve object, ZeroCompounding and ZeroBasis are implicit in ZeroData and are redundant inside this function. In this case, specify these optional parameters when constructing the IRDataCurve object before using the cdsbootstrap function.

For more information on an IRDataCurve object, see “Creating an IRDataCurve Object” (Financial Instruments Toolbox).

Data Types: double

### MarketData — Bond market data

matrix

Bond market data, specified as a N-by-2 matrix of dates and corresponding market spreads or N-by-3 matrix of dates, upfronts, and standard spreads of CDS contracts. The dates must be entered as serial date numbers, upfronts must be numeric values between 0 and 1, and spreads must be in basis points.

Data Types: double

### Settle — Settlement date

serial date number | date character vector

Settlement date, specified as a serial date number or a date character vector. The Settle date must be earlier than or equal to the dates in MarketData

Data Types: double | char

## Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, ..., NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

---

**Note** Any optional input of size N-by-1 is also acceptable as an array of size 1-by-N, or as a single value applicable to all contracts. Single values are internally expanded to an array of size N-by-1.

---

Example: [ProbData, HazData] =  
cdsbootstrap(ZeroData, MarketData, Settle, 'RecoveryRate', Recovery, 'ZeroCompounding', -1)

**RecoveryRate — Recovery rate**

0.4 (default) | decimal

Recovery rate, specified as the comma-separated pair consisting of 'RecoveryRate' and a N-by-1 vector of recovery rates, specified as a decimal from 0 to 1.

Data Types: double

**Period — Premium payment frequency**

4 (default) | numeric with values 1, 2, 3, 4, 6 or 12

Premium payment frequency, specified as the comma-separated pair consisting of 'Period' and a N-by-1 vector with values of 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis of contract**

2 (actual/360) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Day-count basis of the contract, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

Data Types: double

**BusinessDayConvention — Business day conventions**

'actual' (default) | character vector

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- 'actual' — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- 'follow' — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- 'modifiedfollow' — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- 'previous' — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- 'modifiedprevious' — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char

**PayAccruedPremium — Flag for accrued premiums paid upon default**

true (default) | integer with value 1 or 0

Flag for accrued premiums paid upon default, specified as the comma-separated pair consisting of 'PayAccruedPremium' and a N-by-1 vector of Boolean flags that is true (default) if accrued premiums are paid upon default, false otherwise.

Data Types: logical

**TimeStep — Number of days as time step for numerical integration**

10 (days) (default) | nonnegative integer

Number of days to take as time step for the numerical integration, specified as the comma-separated pair consisting of 'TimeStep' and a nonnegative integer.

Data Types: double

**ZeroCompounding — Compounding frequency of the zero curve**

2 (semianual) (default) | integer with value of 1,2,3,4,6,12, or -1

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of 'ZeroCompounding' and an integer with values:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

Data Types: double

**ZeroBasis — Basis of the zero curve**

0 (actual/actual) (default) | integer with value of 0 to 13

Basis of the zero curve, specified as the comma-separated pair consisting of 'ZeroBasis' and an integer with values that are identical to **Basis**.

Data Types: double

#### **ProbDates — Dates for probability data**

column of dates in **MarketData** (default) | serial date number | date character vector

Dates for probability data, specified as the comma-separated pair consisting of 'ProbDates' and a P-by-1 vector of dates, given as serial date numbers or date character vectors.

Data Types: double | char

## Output Arguments

#### **ProbData — Default probability values**

matrix

Default probability values, returned as a P-by-2 matrix with dates and corresponding cumulative default probability values. The dates match those in **MarketData**, unless the optional input parameter **ProbDates** is provided.

#### **HazData — Hazard rate values**

matrix

Hazard rate values, returned as a N-by-2 matrix with dates and corresponding hazard rate values for the survival probability model. The dates match those in **MarketData**.

---

**Note** A warning is displayed when non-monotone default probabilities (that is, negative hazard rates) are found.

## Algorithms

If the time to default is denoted by  $\tau$ , the default probability curve, or function,  $PD(t)$ , and its complement, the survival function  $Q(t)$ , are given by:

$$PD(t) = P[\tau \leq t] = 1 - P[\tau > t] = 1 - Q(t)$$

In the standard model, the survival probability is defined in terms of a piecewise constant hazard rate  $h(t)$ . For example, if  $h(t) =$

$\lambda_1$ , for  $0 \leq t \leq t_1$

$\lambda_2$ , for  $t_1 < t \leq t_2$

$\lambda_3$ , for  $t_2 < t$

then the survival function is given by  $Q(t) =$

$$e^{-\lambda_1 t}, \text{ for } 0 \leq t \leq t_1$$

$$e^{-\lambda_1 t - \lambda_2(t - t_1)}, \text{ for } t_1 < t \leq t_2$$

$$e^{-\lambda_1 t_1 - \lambda_2(t_2 - t_1) - \lambda_3(t - t_2)}, \text{ for } t_2 < t$$

Given  $n$  market dates  $t_1, \dots, t_n$  and corresponding market CDS spreads  $S_1, \dots, S_n$ , `cdsbootstrap` calibrates the parameters  $\lambda_1, \dots, \lambda_n$  and evaluates  $PD(t)$  on the market dates, or an optional user-defined set of dates.

## Introduced in R2010b

# cdsprice

Determine price for credit default swap

## Syntax

```
[Price,AccPrem,PaymentDates,PaymentTimes,PaymentCF] = cdsprice(ZeroData,
ProbData,Settle,Maturity,ContractSpread)
[Price,AccPrem,PaymentDates,PaymentTimes,PaymentCF] = cdsprice( __ ,
Name,Value)
```

## Description

[Price,AccPrem,PaymentDates,PaymentTimes,PaymentCF] = cdsprice(ZeroData, ProbData, Settle, Maturity, ContractSpread) computes the price, or the mark-to-market value for CDS instruments.

[Price,AccPrem,PaymentDates,PaymentTimes,PaymentCF] = cdsprice( \_\_ , Name,Value) adds optional name-value pair arguments.

## Examples

### Determine the Price for a Credit Default Swap

This example shows how to use `cdsprice` to compute the clean price for a CDS contract using the following data.

```
Settle = '17-Jul-2009'; % valuation date for the CDS
Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [1.35 1.43 1.9 2.47 2.936 3.311]'/100;
Zero_Dates = daysadd(Settle,360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate];

ProbData = [daysadd(datenum(Settle),360,1), 0.0247];
Maturity = '20-Sep-2010';
ContractSpread = 135;

[Price,AccPrem] = cdsprice(ZeroData,ProbData,Settle,Maturity,ContractSpread)

Price = 1.5461e+04
AccPrem = 10500
```

## Input Arguments

### ZeroData — Zero rate data

vector | `IRDataCurve` object

Zero rate data, specified as a M-by-2 vector of dates and zero rates or an `IRDataCurve` object of zero rates.

When `ZeroData` is an `IRDataCurve` object, `ZeroCompounding` and `ZeroBasis` are implicit in `ZeroData` and are redundant inside this function. In this case, specify these optional parameters when constructing the `IRDataCurve` object before using the `cdsprice` function.

For more information on an `IRDataCurve` object, see “Creating an `IRDataCurve` Object” (Financial Instruments Toolbox).

Data Types: `double` | `struct`

**ProbData — Default probability values**

matrix

Default probability values, specified as a  $P$ -by-2 matrix with dates and corresponding cumulative default probability values.

Data Types: `double` | `char`

**Settle — Settlement date**

serial date number | date character vector

Settlement date, specified as a scalar serial date number or date character vector. The `Settle` date must be earlier than or equal to the dates in `Maturity`.

Data Types: `double` | `char`

**Maturity — Maturity date**

serial date number | date character vector

Maturity date, specified as a  $N$ -by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char`

**ContractSpread — Contract spreads**

numeric

Contract spreads, specified as a  $N$ -by-1 vector of spreads, expressed in basis points.

Data Types: `double`

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1`, ..., `NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

---

**Note** Any optional input of size  $N$ -by-1 is also acceptable as an array of size 1-by- $N$ , or as a single value applicable to all contracts. Single values are internally expanded to an array of size  $N$ -by-1.

---

Example: `[Price,AccPrem] = cdsprice(ZeroData,ProbData,Settle,Maturity,ContractSpread,'Basis',7,'BusinessDayConvention','previous')`

**RecoveryRate — Recovery rate**

0.4 (default) | decimal

Recovery rate, specified as the comma-separated pair consisting of 'RecoveryRate' and a N-by-1 vector of recovery rates, specified as a decimal from 0 to 1.

Data Types: double

#### **Period — Premium payment frequency**

4 (default) | numeric with values 1, 2, 3, 4, 6 or 12

Premium payment frequency, specified as the comma-separated pair consisting of 'Period' and a N-by-1 vector with values of 1, 2, 3, 4, 6, or 12.

Data Types: double

#### **Basis — Day-count basis of contract**

2 (actual/360) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis of the contract, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

Data Types: double

#### **BusinessDayConvention — Business day conventions**

actual (default) | character vector

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- **actual** — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- **follow** — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.

- **modifiedfollow** — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- **previous** — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- **modifiedprevious** — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char

**PayAccruedPremium — Flag for accrued premiums paid upon default**

true (default) | integer with value 1 or 0

Flag for accrued premiums paid upon default, specified as the comma-separated pair consisting of 'PayAccruedPremium' and a N-by-1 vector of Boolean flags that is true (default) if accrued premiums are paid upon default, false otherwise.

Data Types: logical

**Notional — Contract notional values**

10MM (default) | positive or negative integer

Contract notional values, specified as the comma-separated pair consisting of 'Notional' and a N-by-1vector of integers. Use positive integer values for long positions and negative integer values for short positions.

Data Types: double

**TimeStep — Number of days as time step for numerical integration**

10 (days) (default) | nonnegative integer

Number of days to take as time step for the numerical integration, specified as the comma-separated pair consisting of 'TimeStep' and a nonnegative integer.

Data Types: double

**ZeroCompounding — Compounding frequency of the zero curve**

2 (semiannual) (default) | integer with value of 1,2,3,4,6,12, or -1

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of 'ZeroCmpounding' and an integer with values:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

Data Types: double

**ZeroBasis — Basis of the zero curve**

0 (actual/actual) (default) | integer with value of 0 to 13

Basis of the zero curve, specified as the comma-separated pair consisting of 'ZeroBasis' and an integer with values that are identical to Basis.

Data Types: double

## Output Arguments

**Price — CDS clean prices**

vector

CDS clean prices, returned as a N-by-1 vector.

**AccPrem — Accrued premiums**

vector

Accrued premiums, returned as a N-by-1 vector.

**PaymentDates — Payment dates**

matrix

Payment dates, returned as a N-by-numCF matrix.

**PaymentTimes — Payment times**

matrix

Payment times, returned as a N-by-numCF matrix of accrual fractions.

**PaymentCF — Payments**

matrix

Payments, returned as a N-by-numCF matrix.

## More About

**CDS Price**

The price or mark-to-market (MtM) value of an existing CDS contract.

The CDS price is computed using the following formula:

$$\text{CDS price} = \text{Notional} * (\text{Current Spread} - \text{Contract Spread}) * \text{RPV01}$$

Current Spread is the current breakeven spread for a similar contract, according to current market conditions. RPV01 is the 'risky present value of a basis point,' the present value of the premium payments, considering the default probability. This formula assumes a long position, and the right side is multiplied by -1 for short positions.

## Algorithms

The premium leg is computed as the product of a spread  $S$  and the risky present value of a basis point (RPV01). The RPV01 is given by:

$$RPV01 = \sum_{j=1}^N Z(tj) \Delta(tj - 1, tj, B) Q(tj)$$

when no accrued premiums are paid upon default, and it can be approximated by

$$RPV01 \approx \frac{1}{2} \sum_{j=1}^N Z(tj) \Delta(tj - 1, tj, B) (Q(tj - 1) + Q(tj))$$

when accrued premiums are paid upon default. Here,  $t_0 = 0$  is the valuation date, and  $t_1, \dots, t_n = T$  are the premium payment dates over the life of the contract,  $T$  is the maturity of the contract,  $Z(t)$  is the discount factor for a payment received at time  $t$ , and  $\Delta(t_{j-1}, t_j, B)$  is a day count between dates  $t_{j-1}$  and  $t_j$  corresponding to a basis  $B$ .

The protection leg of a CDS contract is given by the following formula:

$$\begin{aligned} ProtectionLeg &= \int_0^T Z(\tau)(1 - R)dPD(\tau) \\ &\approx (1 - R) \sum_{i=1}^M Z(\tau i)(PD(\tau i) - PD(\tau i - 1)) \\ &= (1 - R) \sum_{i=1}^M Z(\tau i)(Q(\tau i - 1) - Q(\tau i)) \end{aligned}$$

where the integral is approximated with a finite sum over the discretization  $\tau_0 = 0, \tau_1, \dots, \tau_M = T$ .

If the spread of an existing CDS contract is  $S_C$ , and the current breakeven spread for a comparable contract is  $S_0$ , the current price, or mark-to-market value of the contract is given by:

$$MtM = \text{Notional} (S_0 - S_C) RPV01$$

This assumes a long position from the protection standpoint (protection was bought). For short positions, the sign is reversed.

## cdsspread

Determine spread of credit default swap

### Syntax

```
[Spread,PaymentDates,PaymentTimes,] = cdsspread(ZeroData,ProbData,Settle,  
Maturity,)  
[Spread,PaymentDates,PaymentTimes,] = cdsspread( ___,Name,Value)
```

### Description

[Spread,PaymentDates,PaymentTimes,] = cdsspread(ZeroData,ProbData,Settle,Maturity,) computes the spread of the CDS.

[Spread,PaymentDates,PaymentTimes,] = cdsspread( \_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Determine the Spread of a Credit Default Swap

This example shows how to use cdsspread to compute the spread (in basis points) for a CDS contract with the following data.

```
Settle = '17-Jul-2009'; % valuation date for the CDS  
Zero_Time = [.5 1 2 3 4 5]';  
Zero_Rate = [1.35 1.43 1.9 2.47 2.936 3.311]'/100;  
Zero_Dates = daysadd(Settle,360*Zero_Time,1);  
ZeroData = [Zero_Dates Zero_Rate];  
ProbData = [daysadd(datenum(Settle),360,1), 0.0247];  
Maturity = '20-Sep-2010';  
  
Spread = cdsspread(ZeroData,ProbData,Settle,Maturity)  
Spread = 148.2705
```

### Input Arguments

#### ZeroData — Zero rate data

vector | IRDataCurve object

Zero rate data, specified as a M-by-2 vector of dates and zero rates or an IRDataCurve object of zero rates.

When ZeroData is an IRDataCurve object, ZeroCompounding and ZeroBasis are implicit in ZeroData and are redundant inside this function. In this case, specify these optional parameters when constructing the IRDataCurve object before using the cdsspread function.

For more information on an `IRDataCurve` object, see “Creating an `IRDataCurve` Object” (Financial Instruments Toolbox).

Data Types: double | struct

#### **ProbData — Default probability values**

matrix

Default probability values, specified as a P-by-2 matrix with dates and corresponding cumulative default probability values.

Data Types: double | char

#### **Settle — Settlement date**

serial date number | date character vector

Settlement date, specified as a scalar serial date number or date character vector. The `Settle` date must be earlier than or equal to the dates in `Maturity`.

Data Types: double | char

#### **Maturity — Maturity date**

serial date number | date character vector

Maturity date, specified as a N-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char

#### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1`, ..., `NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

---

**Note** Any optional input of size N-by-1 is also acceptable as an array of size 1-by-N, or as a single value applicable to all contracts. Single values are internally expanded to an array of size N-by-1.

---

Example: `Spread = cdsspread(ZeroData, ProbData, Settle, Maturity, 'Basis', 7, 'BusinessDayConvention', 'previous')`

#### **RecoveryRate — Recovery rate**

0 .4 (default) | decimal

Recovery rate, specified as the comma-separated pair consisting of 'RecoveryRate' and a N-by-1 vector of recovery rates, specified as a decimal from 0 to 1.

Data Types: double

#### **Period — Premium payment frequency**

4 (default) | numeric with values 1, 2, 3, 4, 6 or 12

Premium payment frequency, specified as the comma-separated pair consisting of 'Period' and a N-by-1 vector with values of 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis of contract**

2 (actual/360) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis of the contract, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

Data Types: double

**BusinessDayConvention — Business day conventions**

actual (default) | character vector

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- **actual** — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- **follow** — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- **modifiedfollow** — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- **previous** — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- **modifiedprevious** — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char

**PayAccruedPremium — Flag for accrued premiums paid upon default**

true (default) | integer with value 1 or 0

Flag for accrued premiums paid upon default, specified as the comma-separated pair consisting of 'PayAccruedPremium' and a N-by-1 vector of Boolean flags that is true (default) if accrued premiums are paid upon default, false otherwise.

Data Types: logical

**TimeStep — Number of days as time step for numerical integration**

10 (days) (default) | nonnegative integer

Number of days to take as time step for the numerical integration, specified as the comma-separated pair consisting of 'TimeStep' and a nonnegative integer.

Data Types: double

**ZeroCompounding — Compounding frequency of the zero curve**

2 (semiannual) (default) | integer with value of 1,2,3,4,6,12, or -1

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of 'ZeroCompounding' and an integer with values:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

Data Types: double

**ZeroBasis — Basis of the zero curve**

0 (actual/actual) (default) | integer with value of 0 to 13

Basis of the zero curve, specified as the comma-separated pair consisting of 'ZeroBasis' and a positive integer with values that are identical to Basis.

Data Types: double

## Output Arguments

**Spread — Spreads (in basis points)**

vector

Spreads (in basis points), returned as a N-by-1 vector.

**PaymentDates — Payment dates**

matrix

Payment dates, returned as a N-by-numCF matrix.

### PaymentTimes — Payment times

matrix

Payment times, returned as a N-by-numCF matrix of accrual fractions.

## More About

### CDS Spread

The market, or breakeven, spread value of a CDS.

The CDS spread can be computed by equating the value of the protection leg with the value of the premium leg:

$$\text{Market Spread} * \text{RPV01} = \text{Value of Protection Leg}$$

The left side corresponds to the value of the premium leg, and this has been decomposed as the product of the market or breakeven spread times the RPV01 or 'risky present value of a basis point' of the contract. The latter is the present value of the premium payments, considering the default probability. The Market Spread can be computed as the ratio of the value of the protection leg, to the RPV01 of the contract. `cdsspread` returns the resulting spread in basis points.

## Algorithms

The premium leg is computed as the product of a spread  $S$  and the risky present value of a basis point (RPV01). The RPV01 is given by:

$$\text{RPV01} = \sum_{j=1}^N Z(tj) \Delta(tj - 1, tj, B) Q(tj)$$

when no accrued premiums are paid upon default, and it can be approximated by

$$\text{RPV01} \approx \frac{1}{2} \sum_{j=1}^N Z(tj) \Delta(tj - 1, tj, B) (Q(tj - 1) + Q(tj))$$

when accrued premiums are paid upon default. Here,  $t_0 = 0$  is the valuation date, and  $t_1, \dots, t_n = T$  are the premium payment dates over the life of the contract,  $T$  is the maturity of the contract,  $Z(t)$  is the discount factor for a payment received at time  $t$ , and  $\Delta(t_{j-1}, t_j, B)$  is a day count between dates  $t_{j-1}$  and  $t_j$  corresponding to a basis  $B$ .

The protection leg of a CDS contract is given by the following formula:

$$\text{ProtectionLeg} = \int_0^T Z(\tau)(1 - R)dPD(\tau)$$

$$\approx (1 - R) \sum_{i=1}^M Z(\tau i) (PD(\tau i) - PD(\tau i - 1))$$

$$= (1 - R) \sum_{i=1}^M Z(\tau i) (Q(\tau i - 1) - Q(\tau i))$$

where the integral is approximated with a finite sum over the discretization  $\tau_0 = 0, \tau_1, \dots, \tau_M = T$ .

A breakeven spread  $S_0$  makes the value of the premium and protection legs equal. It follows that:

$$S_0 = \frac{\text{ProtectionLeg}}{\text{RPV01}}$$

### Introduced in R2010b

## cdsrpv01

Compute risky present value of a basis point for credit default swap

### Syntax

```
RPV01 = cdspv01(ZeroData,ProbData,Settle,Maturity)
RPV01 = cdspv01(_____,Name,Value)

[RPV01,PaymentDates,PaymentTimes] = cdspv01(ZeroData,ProbData,Settle,
Maturity)
[RPV01,PaymentDates,PaymentTimes] = cdspv01(_____,Name,Value)
```

### Description

RPV01 = cdspv01(ZeroData,ProbData,Settle,Maturity) computes the risky present value of a basis point (RPV01) for a credit default swap (CDS).

RPV01 = cdspv01(\_\_\_\_\_,Name,Value) adds optional name-value arguments.

[RPV01,PaymentDates,PaymentTimes] = cdspv01(ZeroData,ProbData,Settle, Maturity) computes the risky present value of a basis point (RPV01), PaymentDates, and PaymentTimes for a credit default swap (CDS).

[RPV01,PaymentDates,PaymentTimes] = cdspv01(\_\_\_\_\_,Name,Value) computes the risky present value of a basis point (RPV01), PaymentDates, and PaymentTimes for a credit default swap (CDS) using optional name-value pair arguments.

### Examples

#### Calculate the RPV01 Value for a CDS

Calculate the RPV01 value, given the following specification for a CDS.

```
Settle = '17-Jul-2009'; % valuation date for the CDS
Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [1.35 1.43 1.9 2.47 2.936 3.311]'/100;
Zero_Dates = daysadd(Settle,360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate];
ProbData = [daysadd(datenum(Settle),360,1), 0.0247];
Maturity = '20-Sep-2010';

RPV01 = cdspv01(ZeroData,ProbData,Settle,Maturity)
RPV01 = 1.1651
```

### Input Arguments

#### ZeroData — Dates and zero rates

object from IRDataCurve or vector of dates and zero rates

Dates and zero rates, specified by an M-by-2 vector of dates and zero rates or the object `IRDataCurve` for zero rates. For more information on an `IRDataCurve` object, see “Creating an `IRDataCurve` Object” (Financial Instruments Toolbox).

Data Types: `struct` | `double`

#### **ProbData — Dates and default probabilities**

vector of dates and default probabilities

Dates and default probabilities, specified by a P-by-2 array.

Data Types: `double`

#### **Settle — Settlement date**

serial date number | character vector | cell array of character vectors

Settlement date, specified by a serial date number or date character vector. This must be earlier than or equal to the dates in `Maturity`.

Data Types: `char` | `cell` | `double`

#### **Maturity — CDS maturity date**

serial date number | character vector | cell array of character vectors

CDS maturity date, specified by an N-by-1 vector of serial date numbers or date character vectors containing the maturity dates. The CDS premium payment dates occur at regular intervals, and the last payment occurs on these maturity dates.

Data Types: `char` | `cell` | `double`

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1`, ..., `NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

```
Example: RPV01 =
cdsrpv01(ZeroData,ProbData,Settle,Maturity,'Period',1,'StartDate','20-
Sep-2010','Basis',1,
'BusinessDayConvention',actual,'CleanRPV01',true,'PayAccruedPremium',true,'Ze
roCompounding',1,'ZeroBasis',1)
```

#### **Period — Number of premium payments per year**

4 (default) | positive integer from the set [1,2,3,4,6,12] | vector of positive integers from the set [1,2,3,4,6,12]

Number of premium payments per year, specified as the comma-separated pair consisting of '`Period`' and an N-by-1 vector. Values are 1, 2, 3, 4, 6, and 12.

Data Types: `double`

#### **StartDate — Dates the CDS premium leg starts**

Settle date (default) | serial date number | character vector | cell array of character vectors

Dates when the CDS premium leg actually starts, specified as the comma-separated pair consisting of '`StartDate`' and an N-by-1 vector of serial date numbers or date character vectors. Must be on or

between the Settle and Maturity dates. For a forward-starting CDS, specify this date as a future date after Settle.

Data Types: double | char | cell

#### Basis — Day-count basis of contract

2 (actual/360) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis of the contract, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

Data Types: double

#### BusinessDayConvention — Business day conventions

actual (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector or N-by-1 cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- **actual** — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- **follow** — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- **modifiedfollow** — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- **previous** — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.

- **modifiedprevious** — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

#### **CleanRPV01 — Flag for premium accrual**

true (default) | boolean flag with value true or false

Flag for premium accrual, specified as the comma-separated pair consisting of 'CleanRPV01' and a N-by-1 vector of Boolean flags, which is **true** if the premium accrued at **StartDate** is excluded in the **RPV01**, and **false** otherwise.

Data Types: logical

#### **PayAccruedPremium — Flag for accrued premium payment**

true (default) | boolean flag with value true or false

Flag for accrued premium payment, specified as the comma-separated pair consisting of 'PayAccruedPremium' and a N-by-1 vector of Boolean flags, **true** if accrued premiums are paid upon default, **false** otherwise.

Data Types: logical

#### **ZeroCompounding — Compounding frequency of zero curve**

2 semiannual compounding (default) | integer with acceptable value [1, 2, 3, 4, 6, 12, -1]

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of 'ZeroCompounding' and an integer with values:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

---

**Note** When **ZeroData** is an **IRDataCurve** object, the arguments **ZeroCompounding** and **ZeroBasis** are implicit in **ZeroData** and are redundant inside this function. In that case, specify these optional arguments when constructing the **IRDataCurve** object before calling this function.

---

Data Types: double

#### **ZeroBasis — Basis of zero curve**

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Basis of the zero curve, specified as the comma-separated pair consisting of 'ZeroBasis' and a positive integer using a **NINST**-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

## Output Arguments

### RPV01 — RPV01 value

scalar | vector

RPV01 value, returned as an N-by-1 vector.

### PaymentDates — Payment dates

scalar | vector

Payment dates, returned as an N-by-numCF matrix of dates.

### PaymentTimes — Payment times

scalar | vector

Payment times, returned as an N-by-numCF matrix of accrual fractions.

## More About

### RPV01

RPV01, associated with a CDS, is the value of a stream of 1-basis-point premiums according to the payment structure of the CDS contract, and considering the default probability over time.

For more information, see [3] and [4] for details.

# creditexposures

Compute credit exposures from contract values

## Syntax

```
[exposures,exposurecpty] = creditexposures(values,counterparties)
[exposures,exposurecpty] = creditexposures(___,Name,Value)

[exposures,exposurecpty,collateral] = creditexposures(___,Name,Value)
```

## Description

[exposures,exposurecpty] = creditexposures(values,counterparties) computes the counterparty credit exposures from an array of mark-to-market OTC contract values. These exposures are used when calculating the CVA (credit value adjustment) for a portfolio.

[exposures,exposurecpty] = creditexposures(\_\_\_,Name,Value) adds optional name-value arguments.

[exposures,exposurecpty,collateral] = creditexposures(\_\_\_,Name,Value) computes the counterparty credit exposures from an array of mark-to-market OTC contract values using optional name-value pair arguments for CollateralTable and Dates, the collateral output is returned for the simulated collateral amounts available to counterparties at each simulation date and over each scenario.

## Examples

### View Contract Values and Exposures Over Time for a Particular Counterparty

After computing the mark-to-market contract values for a portfolio of swaps over many scenarios, compute the credit exposure for a particular counterparty. View the contract values and credit exposure over time.

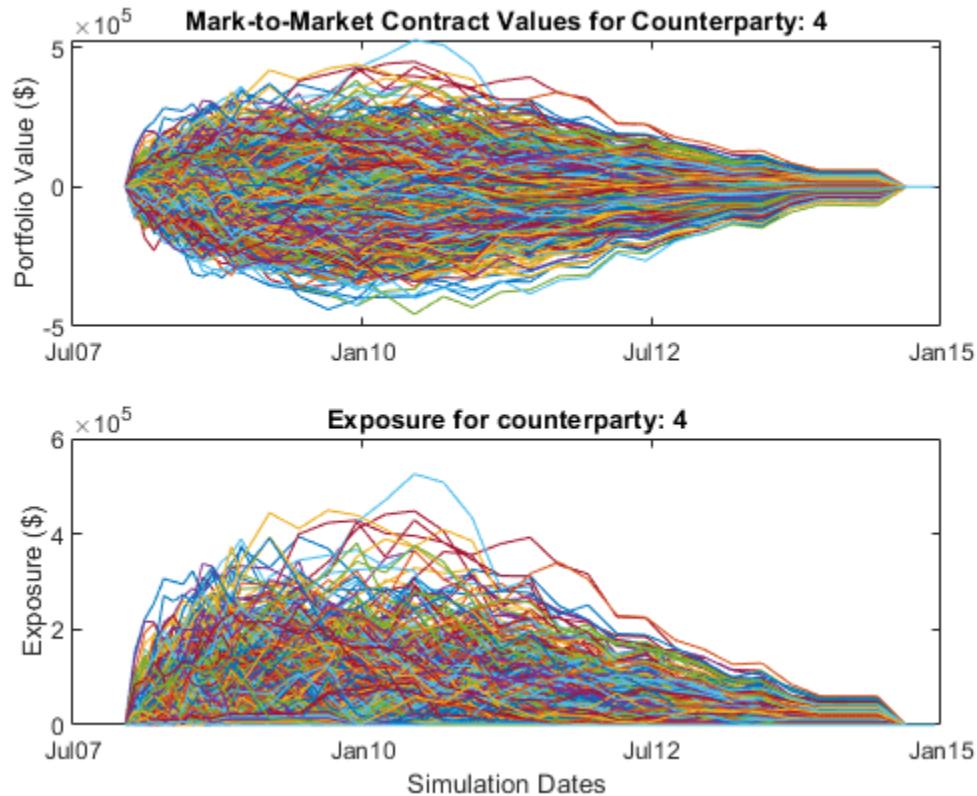

First, load data (`ccr.mat`) containing the mark-to-market contract values for a portfolio of swaps over many scenarios.

```
load ccr.mat
% Look at one counterparty.
cpID = 4;
cpValues = squeeze(sum(values(:,swaps.Counterparty == cpID,:),2));
subplot(2,1,1)
plot(simulationDates,cpValues);
title(sprintf('Mark-to-Market Contract Values for Counterparty: %d',cpID));
datetick('x','mmyy')
ylabel('Portfolio Value ($)')
% Compute the exposure by counterparty.
[exposures, expcpty] = creditexposures(values,swaps.Counterparty, ...
'NettingID',swaps.NettingID);
% View the credit exposure over time for the counterparty.
subplot(2,1,2)
```

```

cpIdx = find(expcpty == cpID);
plot(simulationDates,squeeze(exposures(:,cpIdx,:)));
title(sprintf('Exposure for counterparty: %d',cpIdx));
datetick('x','mmmyy')
ylabel('Exposure ($)')
xlabel('Simulation Dates')

```

### Compute the Credit Exposure and Determine the Incremental Exposure for a New Trade

Load the data (`ccr.mat`) containing the mark-to-market contract values for a portfolio of swaps over many scenarios.

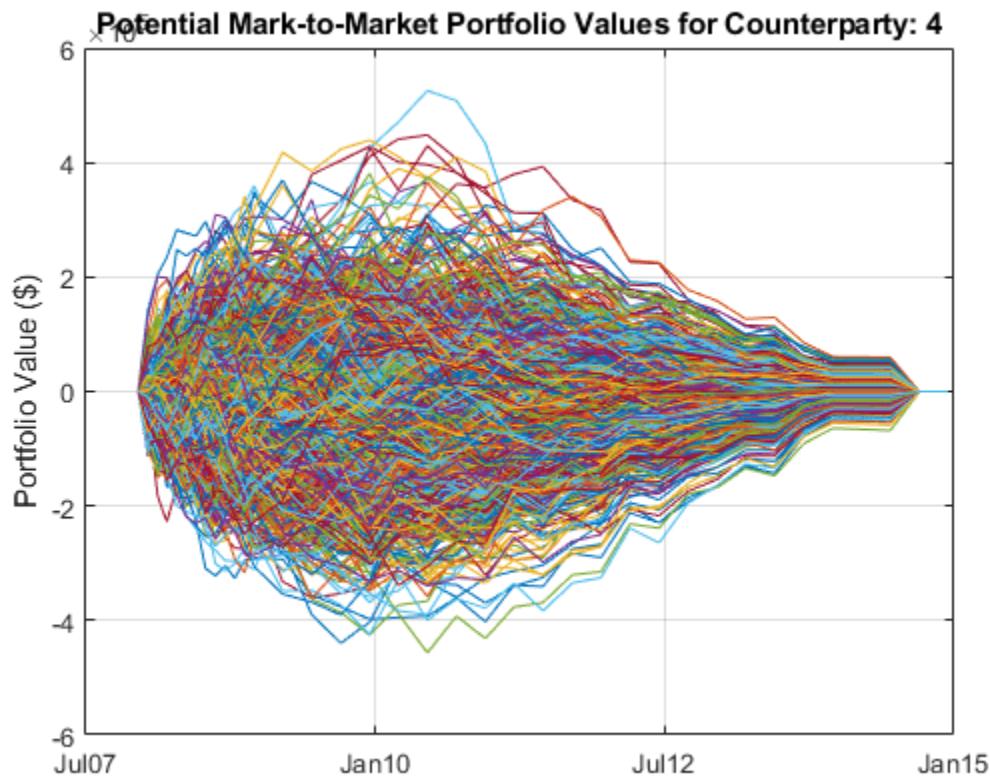

```
load ccr.mat
```

Look at one counterparty.

```

cpID = 4;
cpIdx = swaps.Counterparty == cpID;
cpValues = values(:,cpIdx,:);
plot(simulationDates,squeeze(sum(cpValues,2)));
grid on;
title(sprintf('Potential Mark-to-Market Portfolio Values for Counterparty: %d',cpID));
datetick('x','mmmyy')
ylabel('Portfolio Value ($)')

```

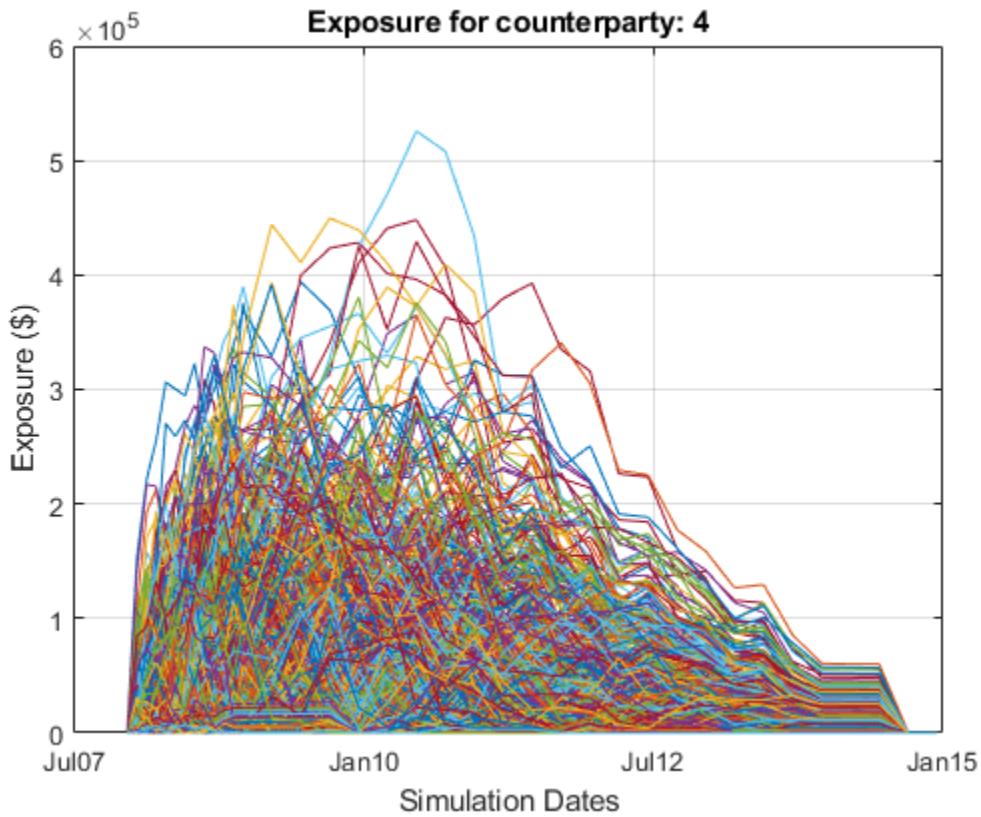

Compute the exposures.

```
netting = swaps.NettingID(cpIdx);
exposures = creditexposures(cpValues,cpID,'NettingID',netting);
```

View the credit exposure over time for the counterparty.

```
figure;
plot(simulationDates,squeeze(exposures));
grid on
title(sprintf('Exposure for counterparty: %d',cpID));
datetick('x','mmyy')
ylabel('Exposure ($)')
xlabel('Simulation Dates')
```

Compute the credit exposure profiles.

```
profilesBefore = exposureprofiles(simulationDates,exposures)
profilesBefore = struct with fields:
    Dates: [37x1 double]
    EE: [37x1 double]
    PFE: [37x1 double]
    MPFE: 2.1580e+05
    EffEE: [37x1 double]
    EPE: 2.8602e+04
    EffEPE: 4.9579e+04
```

Consider a new trade with a counterparty. For this example, take another trade from the original swap portfolio and "copy" it for a new counterparty. This example is only for illustrative purposes.

```
newTradeIdx = 3;
newTradeValues = values(:,newTradeIdx,:);

% Append a new trade to your existing portfolio.
cpValues = [cpValues newTradeValues];
netting = [netting; cpID];
exposures = creditexposures(cpValues,cpID,'NettingID',netting);
```

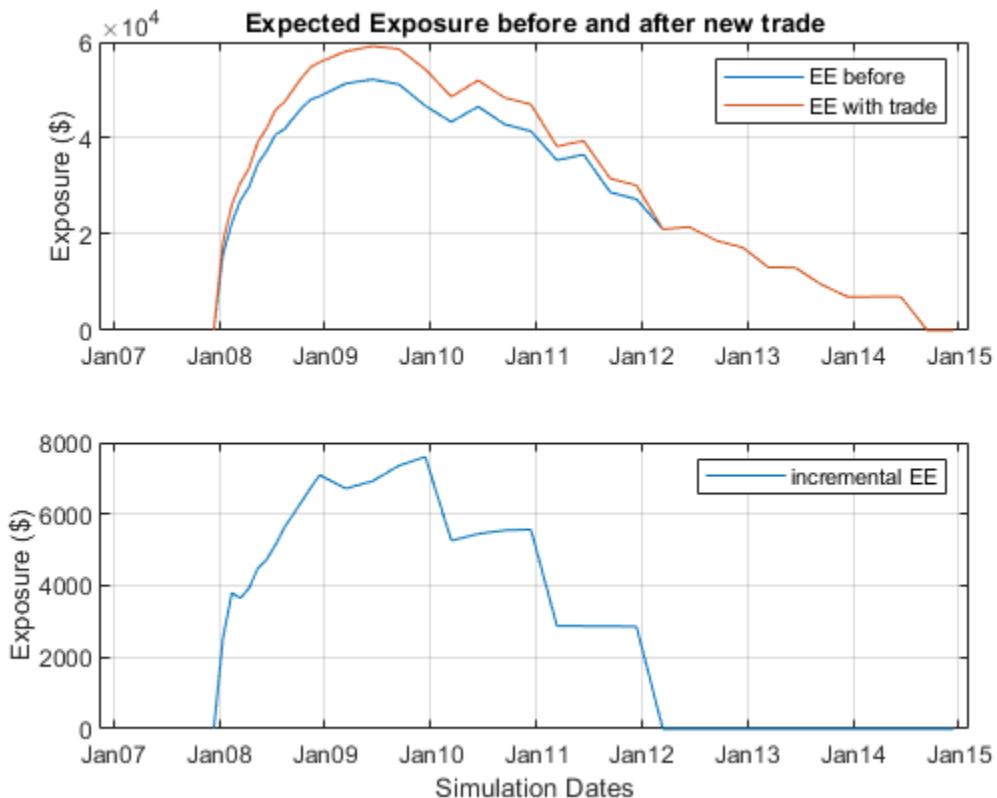

Compute the new credit exposure profiles.

```
profilesAfter = exposureprofiles(simulationDates,exposures)
```

```
profilesAfter = struct with fields:  
    Dates: [37x1 double]  
        EE: [37x1 double]  
        PFE: [37x1 double]  
        MPFE: 2.4689e+05  
        EffEE: [37x1 double]  
        EPE: 3.1609e+04  
        EffEPE: 5.6178e+04
```

Visualize the expected exposures and the new trade's incremental exposure. Use the incremental exposure to compute the incremental credit value adjustment (CVA) charge.

```
figure;  
subplot(2,1,1)  
plot(simulationDates,profilesBefore.EE,...  
     simulationDates,profilesAfter.EE);  
grid on;  
legend({'EE before','EE with trade'})  
datetick('x','mmyy','keeplimits')  
title('Expected Exposure before and after new trade');  
ylabel('Exposure ($)')  
  
subplot(2,1,2)  
incrementalEE = profilesAfter.EE - profilesBefore.EE;  
plot(simulationDates,incrementalEE);  
grid on;  
legend('incremental EE')  
datetick('x','mmyy','keeplimits')  
ylabel('Exposure ($)')  
xlabel('Simulation Dates')
```

### Compute Exposures for Counterparties Under Collateral Agreement

Load the data (`ccr.mat`) containing the mark-to-market contract values for a portfolio of swaps over many scenarios.

```
load ccr.mat
```

Only look at a single counterparty for this example.

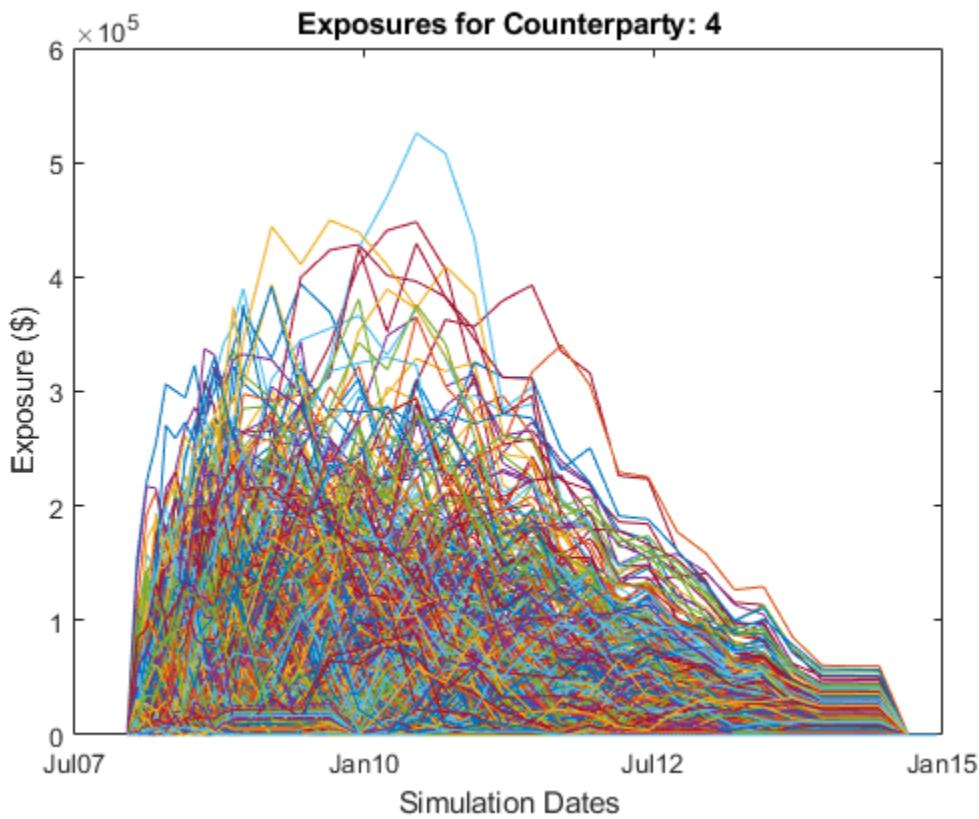

```
cpID = 4;
cpIdx = swaps.Counterparty == cpID;
cpValues = values(:,cpIdx,:);
```

Compute the uncollateralized exposures.

```
exposures = creditexposures(cpValues,swaps.Counterparty(cpIdx),...
    'NettingID',swaps.NettingID(cpIdx));
```

View the credit exposure over time for the counterparty.

```
plot(simulationDates,squeeze(exposures));
expYLim = get(gca,'YLim');
title(sprintf('Exposures for Counterparty: %d',cpID));
datetick('x','mmmyy')
ylabel('Exposure ($)')
xlabel('Simulation Dates')
```

Add a collateral agreement for the counterparty. The 'CollateralTable' parameter is a MATLAB® table. You can create tables from spreadsheets or other data sources, in addition to building them inline as seen here. For more information, see [table](#).

```
collateralVariables = {'Counterparty'; 'PeriodOfRisk'; 'Threshold'; 'MinimumTransfer'};
periodOfRisk = 14;
threshold = 100000;
minTransfer = 10000;
collateralTable = table(cpID, periodOfRisk, threshold, minTransfer, ...
'VariableNames', collateralVariables)

collateralTable=1×4 table
  Counterparty      PeriodOfRisk      Threshold      MinimumTransfer
    _____        _____        _____        _____
        4                  14          1e+05          10000
```

Compute the collateralized exposures.

```
[collatExp, collatCpty, collateral] = creditexposures(cpValues, ...
swaps.Counterparty(cpIdx), 'NettingID', swaps.NettingID(cpIdx), ...
'CollateralTable', collateralTable, 'Dates', simulationDates);
```

Plot the collateral levels and collateralized exposures.

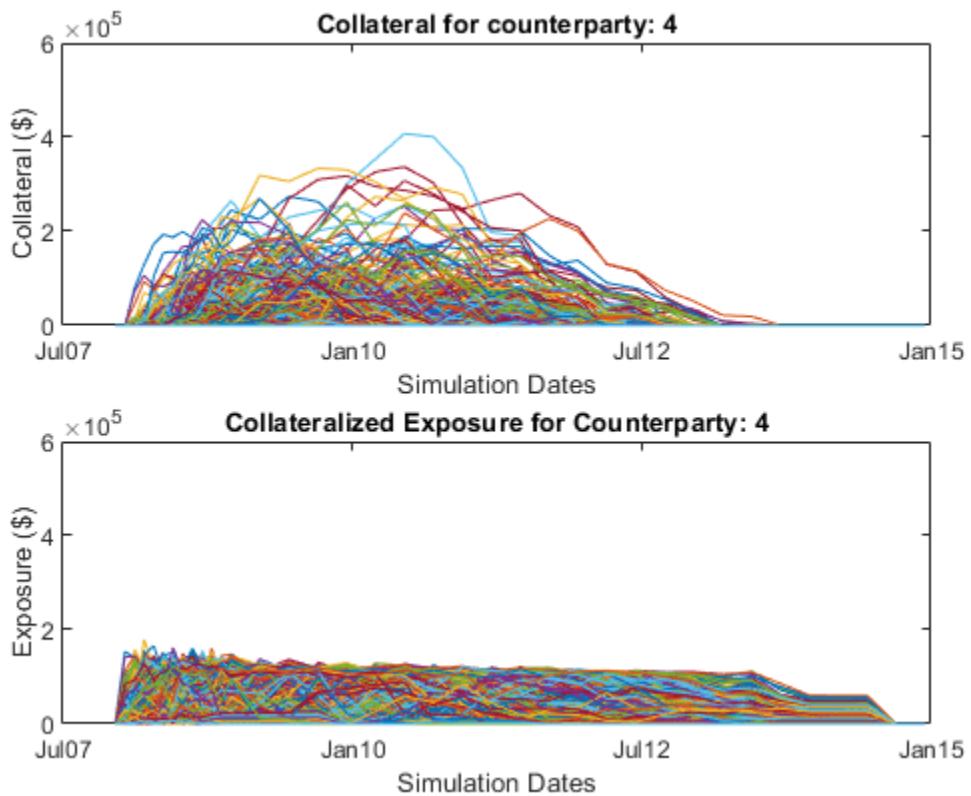

```
figure;
subplot(2,1,1)
```

```

plot(simulationDates,squeeze(collateral));
set(gca,'YLim',expYLim);
title(sprintf('Collateral for counterparty: %d',cpID));
datetick('x','mmmyy')
ylabel('Collateral ($)')
xlabel('Simulation Dates')

subplot(2,1,2)
plot(simulationDates,squeeze(collatExp));
set(gca,'YLim',expYLim);
title(sprintf('Collateralized Exposure for Counterparty: %d',cpID));
datetick('x','mmmyy')
ylabel('Exposure ($)')
xlabel('Simulation Dates');

```

## Input Arguments

**values — 3-D array of simulated mark-to-market values of portfolio of contracts**  
array

3-D array of simulated mark-to-market values of a portfolio of contracts simulated over a series of simulation dates and across many scenarios, specified as a NumDates-by-NumContracts-by-NumScenarios “cube” of contract values. Each row represents a different simulation date, each column a different contract, and each “page” is a different scenario from a Monte-Carlo simulation.

Data Types: double

**counterparties — Counterparties corresponding to each contract**

vector | cell array

Counterparties corresponding to each contract in `values`, specified as a `NumContracts`-element vector of counterparties. Counterparties can be a vector of numeric IDs or a cell array of counterparty names. By default, each counterparty is assumed to have one netting set that covers all of its contracts. If counterparties are covered by multiple netting sets, then use the `NettingID` parameter. A value of `NaN` (or '' in a cell array) indicates that a contract is not included in any netting set unless otherwise specified by `NettingID`. `counterparties` is case insensitive and leading or trailing white spaces are removed.

Data Types: double | cell

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[exposures,exposurecpty] = creditexposures(values,counterparties,'NettingID','10','ExposureType','Additive')`

**NettingID — Netting set IDs indicate which netting set each contract belongs**

vector | cell array

Netting set IDs to indicate to which netting set each contract in `values` belongs, specified by a `NumContracts`-element vector of netting set IDs. `NettingID` can be a vector of numeric IDs or else a cell array of character vector identifiers. The `creditexposures` function uses `counterparties` and `NettingID` to define each unique netting set (all contracts in a netting set must be with the same counterparty). By default, each counterparty has a single netting set which covers all of their contracts. A value of `NaN` (or '' in a cell array) indicates that a contract is not included in any netting set. `NettingID` is case insensitive and leading or trailing white spaces are removed.

Data Types: double | cell

**ExposureType — Calculation method for exposures**

'Counterparty' (default) | character vector with value of 'Counterparty' or 'Additive'

Calculation method for exposures, specified with values:

- 'Counterparty' — Compute exposures per counterparty.
- 'Additive' — Compute additive exposures at the contract level. Exposures are computed per contract and sum to the total counterparty exposure.

Data Types: char

**CollateralTable — Table containing information on collateral agreements of counterparties**

MATLAB table

Table containing information on collateral agreements of counterparties, specified as a MATLAB table. The table consists of one entry (row) per collateralized counterparty and must have the following variables (columns):

- 'Counterparty' — Counterparty name or ID. The Counterparty name or ID should match the parameter 'Counterparty' for the `ExposureType` argument.
- 'PeriodOfRisk' — Margin period of risk in days. The number of days from a margin call until the posted collateral is available from the counterparty.
- 'Threshold' — Collateral threshold. When counterparty exposures exceed this amount, the counterparty must post collateral.
- 'MinimumTransfer' — Minimum transfer amount. The minimum amount over/under the threshold required to trigger transfer of collateral.

---

**Note** When computing collateralized exposures, both the `CollateralTable` parameter and the `Dates` parameter must be specified.

---

Data Types: `table`

**Dates — Simulation dates corresponding to each row of the values array**

vector of date numbers | cell array of character vectors

Simulation dates corresponding to each row of the `values` array, specified as a `NUMDATES`-by-1 vector of simulation dates. `Dates` is either a vector of MATLAB date numbers or else a cell array of character vectors in a known date format. See `datenum` for known date formats.

---

**Note** When computing collateralized exposures, both the `CollateralTable` parameter and the `Dates` parameter must be specified.

---

Data Types: `double` | `cell`

## Output Arguments

**exposures — 3-D array of credit exposures**

array

3-D array of credit exposures representing the potential losses from each counterparty or contract at each date and over all scenarios. The size of `exposures` depends on the `ExposureType` input argument:

- When `ExposureType` is 'Counterparty', `exposures` returns a `NumDates`-by-`NumCounterparties`-by-`NumScenarios` "cube" of credit exposures representing potential losses that could be incurred over all dates, counterparties, and scenarios, if a counterparty defaulted (ignoring any post-default recovery).
- When `ExposureType` is 'Additive', `exposures` returns a `NumDates`-by-`NumContracts`-by-`NumScenarios` "cube," where each element is the additive exposure of each contract (over all dates and scenarios). Additive exposures sum to the counterparty-level exposure.

**exposurecpty — Counterparties that correspond to columns of exposures array**

vector

Counterparties that correspond to columns of the `exposures` array, returned as `NumCounterparties` or `NumContracts` elements depending on the `ExposureType`.

**collateral — Simulated collateral amounts available to counterparties at each simulation date and over each scenario**

3D array

Simulated collateral amounts available to counterparties at each simulation date and over each scenario, returned as a NumDates-by-NumCounterparties-by-NumScenarios 3D array. Collateral amounts are calculated using a Brownian bridge to estimate contract values between simulation dates. For more information, see “Brownian Bridge” on page 19-518. If the **CollateralTable** was not specified, this output is empty.

## More About

### Brownian Bridge

A Brownian bridge is used to simulate portfolio values at intermediate dates to compute collateral available at the subsequent simulation dates.

For example, to estimate collateral available at a particular simulation date,  $t_i$ , you need to know the state of the portfolio at time  $t_i - dt$ , where  $dt$  is the margin period of risk. Portfolio values are simulated at these intermediate dates by drawing from a distribution defined by the Brownian bridge between  $t_i$  and the previous simulation date,  $t_{i-1}$ .

If the contract values at time  $t_{i-1}$  and  $t_i$  are known and you want to estimate the contract value at time  $t_c$  (where  $t_c$  is  $t_i - dt$ ), then a sample from a normal distribution is used with variance:

$$\frac{(t_i - t_c)(t_c - t_{i-1})}{(t_i - t_{i-1})^2}$$

and with mean that is simply the linear interpolation of the contract values between the two simulation dates at time  $t_c$ . For more details, see References.

# exposureprofiles

Compute exposure profiles from credit exposures

## Syntax

```
profilestructs = exposureprofiles(dates,exposures)
profilestructs = exposureprofiles(___,Name,Value)
```

## Description

`profilestructs = exposureprofiles(dates,exposures)` computes common counterparty credit exposures profiles from an array of exposures.

`profilestructs = exposureprofiles(___,Name,Value)` adds optional name-value arguments.

## Examples

### View Exposure Profiles of a Particular Counterparty

After computing the mark-to-market contract values for a portfolio of swaps over many scenarios, view the exposure profiles of a particular counterparty.

Load the data (`ccr.mat`) that contains the mark-to-market contract values for a portfolio of swaps over many scenarios.

```
load ccr.mat
```

Compute the exposure by counterparty.

```
[exposures, expcpty] = creditexposures(values,swaps.Counterparty, ...
'NettingID',swaps.NettingID);
```

Compute the credit exposure profiles for all counterparties.

```
cpProfiles = exposureprofiles(simulationDates,exposures)

cpProfiles=5x1 struct array with fields:
    Dates
    EE
    PFE
    MPFE
    EffEE
    EPE
    EffEPE
```

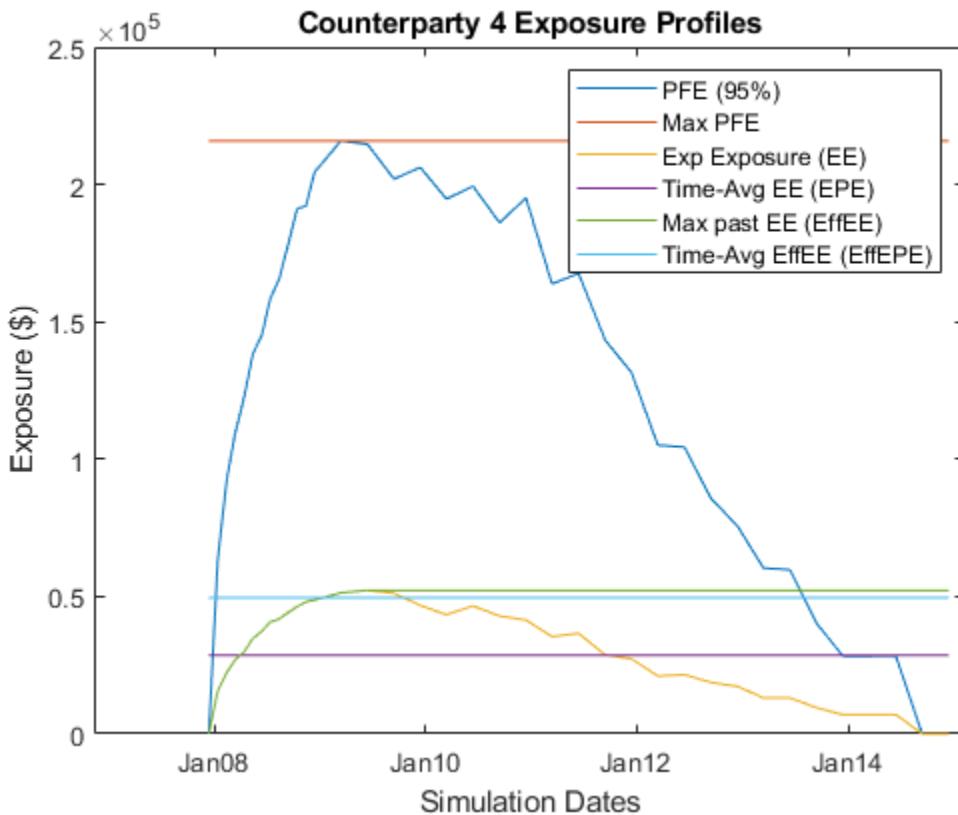

Visualize the exposure profiles for a particular counterparty.

```
cpIdx = find(expcpty == 4);
numDates = numel(simulationDates);
```

```

plot(simulationDates,cpProfiles(cpIdx).PFE, ...
    simulationDates,cpProfiles(cpIdx).MPFE * ones(numDates,1), ...
    simulationDates,cpProfiles(cpIdx).EE, ...
    simulationDates,cpProfiles(cpIdx).EPE * ones(numDates,1), ...
    simulationDates,cpProfiles(cpIdx).EffEE, ...
    simulationDates,cpProfiles(cpIdx).EffEPE * ones(numDates,1));
legend({'PFE (95%)','Max PFE','Exp Exposure (EE)',...
    'Time-Avg EE (EPE)','Max past EE (EffEE)',...
    'Time-Avg EffEE (EffEPE)'})
datetick('x','mmmyy','keeplimits')
title(sprintf('Counterparty %d Exposure Profiles',cpIdx));
ylabel('Exposure ($)')
xlabel('Simulation Dates')

```

## Input Arguments

### **dates — Simulation dates**

vector of date numbers | cell array of character vectors

Simulation dates, specified as vector of date numbers or a cell array of character vectors in a known date format. For more information for known date formats, see the function `datenum`.

Data Types: double | char | cell

### **exposures — 3-D array of potential losses due to counterparty default array**

3-D array of potential losses due to counterparty default on a set of instruments simulated over a series of simulation dates and across many scenarios, specified as a NumDates-by-NumCounterParties-by-NumScenarios “cube” of credit exposures. Each row represents a different simulation date, each column a different counterparty, and each “page” is a different scenario from a Monte-Carlo simulation.

Data Types: double

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: profilestructs =  
exposureprofiles(dates,exposures,'ProfileSpec','PFE','PFEProbabilityLevel',.9)  
)

#### ProfileSpec — Exposure profiles

All (generate all profiles) (default) | character vector with possible values EE, PFE, MPE, EffEE, EPE, EffEPE, All | cell array of character vectors with possible values EE, PFE, MPE, EffEE, EPE, EffEPE

Exposure profiles, specified as a character vector or cell array of character vectors with the following possible values:

- EE — Expected Exposure. The mean of the distribution of exposures at each date. A [NumDates-by-1] vector.
- PFE — Potential Future Exposure. A high percentile (default 95%) of the distribution of possible exposures at each date. This is sometimes referred to as “Peak Exposure.” A [NumDates-by-1] vector.
- MPFE — Maximum Potential Future Exposure. The maximum potential future exposure (PFE) over all dates
- EffEE — Effective Expected Exposure. The maximum expected exposure (at a specific date) that occurs at that date or any prior date. This is the expected exposure, but constrained to be nondecreasing over time. A [NumDates-by-1] vector.
- EPE — Expected Positive Exposure. The weighted average over time of expected exposures. A scalar.
- EffEPE — Effective Expected Positive Exposure. The weighted average over time of the effective expected exposure (EffEE). A scalar.
- All — Generate all the previous profiles.

---

**Note** Exposure profiles are computed on a per-counterparty basis.

---

Data Types: char | cell

#### PFEProbabilityLevel — Level for potential future exposure (PFE) and maximum potential future exposure (MPFE)

.95 (the 95th percentile) (default) | scalar with value [0 . . 1]

Level for potential future exposure (PFE) and maximum potential future exposure (MPFE), specified as a scalar with value [0..1].

Data Types: double

## Output Arguments

### **profilestructs — Structure of credit exposure profiles**

array of structs holding credit exposure profiles for each counterparty

Structure of credit exposure profiles, returned as an array of structs holding credit exposure profiles for each counterparty, returned as a struct, with the fields of the struct as the (abbreviated) names of every exposure profile. Profiles listed in the **ProfileSpec** (and their related profiles) are populated, while those not requested contain empty ([ ]). **profilestructs** contains the **dates** information as a vector of MATLAB date numbers requested in the **ProfileSpec** argument.

## cdyield

Yield on certificate of deposit (CD)

### Syntax

```
Yield = cdyield(Price,CouponRate,Settle,Maturity,IssueDate)
Yield = cdyield(___,Basis)
```

### Description

`Yield = cdyield(Price,CouponRate,Settle,Maturity,IssueDate)` computes the yield to maturity of a certificate of deposit given its clean price.

`cdyield` assumes that the certificates of deposit pay interest at maturity. Because of the simple interest treatment of these securities, this function is best used for short-term maturities (less than 1 year). The default simple interest calculation uses the `Basis` for the actual/360 convention (2).

`Yield = cdyield(___,Basis)` adds an optional argument for `Basis`.

### Examples

#### Compute the Yield to Maturity of a Certificate of Deposit

This example shows how to compute the yield on the certificate of deposit (CD), given a CD with the following characteristics.

```
Price      = 101.125;
CouponRate = 0.05;
Settle     = '02-Jan-02';
Maturity   = '31-Mar-02';
IssueDate  = '1-Oct-01';

Yield = cdyield(Price, CouponRate, Settle, Maturity, IssueDate)
Yield = 0.0039
```

#### Compute the Yield to Maturity of a Certificate of Deposit Using datetime Inputs

This example shows how to use `datetime` inputs to compute the yield on the certificate of deposit (CD), given a CD with the following characteristics.

```
Price      = 101.125;
CouponRate = 0.05;
Settle     = datetime('02-Jan-02','Locale','en_US');
Maturity   = datetime('31-Mar-02','Locale','en_US');
IssueDate  = datetime('1-Oct-01','Locale','en_US');

Yield = cdyield(Price, CouponRate, Settle, Maturity, IssueDate)
```

---

```
Yield = 0.0039
```

## Input Arguments

**Price — Clean price of certificate of deposit per \$100 face**  
numeric

Clean price of the certificate of deposit per \$100 face, specified as a numeric value using a scalar or a NCDS-by-1 or 1-by-NCDS vector.

Data Types: double

**CouponRate — Coupon annual interest rate**  
decimal

Coupon annual interest rate, specified as decimal using a scalar or a NCDS-by-1 or 1-by-NCDS vector.

Data Types: double

**Settle — Settlement date of certificate of deposit**  
serial date number | date character vector | datetime

Settlement date of the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

**Maturity — Maturity date of certificate of deposit**  
serial date number | date character vector | datetime

Maturity date of the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**IssueDate — Issue date for certificate of deposit**  
serial date number | date character vector | datetime

Issue date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**Basis — Day-count basis for certificate of deposit**  
2 (actual/360) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

(Optional) Day-count basis for the certificate of deposit, specified as a scalar or a NINST-by-1 vector.  
Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

## Output Arguments

### **Yield — Simple yield to maturity of certificate of deposit**

numeric

Simple yield to maturity of the certificate of deposit, returned as a NCDS-by-1 or 1-by-NCDS vector.

## Introduced before R2006a

# cfamounts

Cash flow and time mapping for bond portfolio

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, `StartDate`, `Face`, `AdjustCashFlowsBasis`, `BusinessDayConvention`, `CompoundingFrequency`, `DiscountBasis`, `Holidays`, and `PrincipalType`.

---

## Syntax

```
[CFlowAmounts,CFlowDates,TFactors,CFlowFlags,CFPrincipal] = cfamounts(
    CouponRate,Settle,Maturity)
[CFlowAmounts,CFlowDates,TFactors,CFlowFlags,CFPrincipal] = cfamounts( __ ,
    Name,Value)
```

## Description

`[CFlowAmounts,CFlowDates,TFactors,CFlowFlags,CFPrincipal] = cfamounts( CouponRate,Settle,Maturity)` returns matrices of cash flow amounts, cash flow dates, time factors, and cash flow flags for a portfolio of `NUMBONDS` fixed-income securities.

The elements contained in the `cfamounts` outputs for the cash flow matrix, time factor matrix, and cash flow flag matrix correspond to the cash flow dates for each security. The first element of each row in the cash flow matrix is the accrued interest payable on each bond. This accrued interest is zero in the case of all zero coupon bonds. `cfamounts` determines all cash flows and time mappings for a bond whether or not the coupon structure contains odd first or last periods. All output matrices are padded with NaNs as necessary to ensure that all rows have the same number of elements.

`[CFlowAmounts,CFlowDates,TFactors,CFlowFlags,CFPrincipal] = cfamounts( __ , Name,Value)` adds optional name-value arguments.

## Examples

### Compute the Cash Flow Structure and Time Factors for a Bond Portfolio

This example shows how to compute the cash flow structure and time factors for a bond portfolio that contains a corporate bond paying interest quarterly and a Treasury bond paying interest semiannually.

```
Settle = '01-Nov-1993';
Maturity = [ '15-Dec-1994' ; '15-Jun-1995' ];
CouponRate= [0.06; 0.05];
Period = [4; 2];
Basis = [1; 0];
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = ...
cfamounts(CouponRate,Settle, Maturity, Period, Basis)
```

```
CFlowAmounts = 2x6
```

|         |        |        |        |          |          |
|---------|--------|--------|--------|----------|----------|
| -0.7667 | 1.5000 | 1.5000 | 1.5000 | 1.5000   | 101.5000 |
| -1.8989 | 2.5000 | 2.5000 | 2.5000 | 102.5000 | NaN      |

```
CFlowDates = 2x6
```

|        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|
| 728234 | 728278 | 728368 | 728460 | 728552 | 728643 |
| 728234 | 728278 | 728460 | 728643 | 728825 | NaN    |

```
TFactors = 2x6
```

|   |        |        |        |        |        |
|---|--------|--------|--------|--------|--------|
| 0 | 0.2404 | 0.7403 | 1.2404 | 1.7403 | 2.2404 |
| 0 | 0.2404 | 1.2404 | 2.2404 | 3.2404 | NaN    |

```
CFlowFlags = 2x6
```

|   |   |   |   |   |     |
|---|---|---|---|---|-----|
| 0 | 3 | 3 | 3 | 3 | 4   |
| 0 | 3 | 3 | 3 | 4 | NaN |

### Compute the Cash Flow Structure and Time Factors for a Bond Portfolio and Return a datetime array for CFlowDates

This example shows how to compute the cash flow structure and time factors for a bond portfolio that contains a corporate bond paying interest quarterly and a Treasury bond paying interest semiannually and CFlowDates is returned as a datetime array.

```
Settle = datetime('01-Nov-1993','Locale','en_US');
Maturity = ['15-Dec-1994';'15-Jun-1995'];
CouponRate= [0.06; 0.05];
Period = [4; 2];
Basis = [1; 0];
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = cfamounts(CouponRate, ...
Settle, Maturity, Period, Basis)
```

```
CFlowAmounts = 2x6
```

|         |        |        |        |          |          |
|---------|--------|--------|--------|----------|----------|
| -0.7667 | 1.5000 | 1.5000 | 1.5000 | 1.5000   | 101.5000 |
| -1.8989 | 2.5000 | 2.5000 | 2.5000 | 102.5000 | NaN      |

```
CFlowDates = 2x6 datetime
Columns 1 through 5
```

|             |             |             |             |             |
|-------------|-------------|-------------|-------------|-------------|
| 01-Nov-1993 | 15-Dec-1993 | 15-Mar-1994 | 15-Jun-1994 | 15-Sep-1994 |

| 0 | 3 | 3 | 3 | 4 | NaN |

### Compute the Cash Flow Structure and Time Factors for a Bond Portfolio Using Optional Name-Value Pairs

This example shows how to compute the cash flow structure and time factors for a bond portfolio that contains a corporate bond paying interest quarterly and a Treasury bond paying interest semiannually. This example uses the following Name-Value pairs for `Period`, `Basis`, `BusinessDayConvention`, and `AdjustCashFlowsBasis`.

```
Settle = '01-Jun-2010';
Maturity = ['15-Dec-2011'; '15-Jun-2012'];
CouponRate= [0.06; 0.05];
Period = [4; 2];
Basis = [1; 0];

[CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = ...
cfamounts(CouponRate, Settle, Maturity, 'Period', Period, ...
'Basis', Basis, 'AdjustCashFlowsBasis', true, ...
'BusinessDayConvention', 'modifiedfollow')
```

```
CFlowAmounts = 2×8
```

|         |        |        |        |        |          |        |        |          |
|---------|--------|--------|--------|--------|----------|--------|--------|----------|
| -1.2667 | 1.5000 | 1.5000 | 1.5000 | 1.5000 | 1.5000   | 1.5000 | 1.5000 | 101.5000 |
| -2.3077 | 2.4932 | 2.5068 | 2.4932 | 2.5000 | 102.5000 | NaN    | NaN    |          |

```
CFlowDates = 2×8
```

|        |        |        |        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| 734290 | 734304 | 734396 | 734487 | 734577 | 734669 | 734761 | 734852 | 734851 |
| 734290 | 734304 | 734487 | 734669 | 734852 | 735035 | NaN    | NaN    | NaN    |

```
TFactors = 2×8
```

|   |        |        |        |        |        |        |        |  |
|---|--------|--------|--------|--------|--------|--------|--------|--|
| 0 | 0.0778 | 0.5778 | 1.0778 | 1.5778 | 2.0778 | 2.5778 | 3.0778 |  |
| 0 | 0.0769 | 1.0769 | 2.0769 | 3.0769 | 4.0769 | NaN    | NaN    |  |

```
CFlowFlags = 2×8
```

|   |   |   |   |   |   |     |     |
|---|---|---|---|---|---|-----|-----|
| 0 | 3 | 3 | 3 | 3 | 3 | 3   | 4   |
| 0 | 3 | 3 | 3 | 3 | 4 | NaN | NaN |

### Use cfamounts With a CouponRate Schedule

This example shows how to use `cfamounts` with a `CouponRate` schedule. For `CouponRate` and `Face` that change over the life of the bond, schedules for `CouponRate` and `Face` can be specified with an `NINST`-by-1 cell array, where each element is a `NumDates`-by-2 matrix where the first column is dates and the second column is associated rates.

```
CouponSchedule = {[datenum('15-Mar-2012') .04;datenum('15- Mar -2013') .05;...
datenum('15- Mar -2015') .06]}

CouponSchedule = 1x1 cell array
{3x2 double}

cfamounts(CouponSchedule,'01-Mar-2011','15-Mar-2015' )

ans = 1x10
-1.8453    2.0000    2.0000    2.0000    2.5000    2.5000    3.0000    3.0000    3.0000    103.0000
```

### Use cfamounts With a Face Schedule

This example shows how to use `cfamounts` with a `Face` schedule. For `CouponRate` and `Face` that change over the life of the bond, schedules for `CouponRate` and `Face` can be specified with an `NINST`-by-1 cell array, where each element is a `NumDates`-by-2 matrix where the first column is dates and the second column is associated rates.

```
FaceSchedule = {[datenum('15-Mar-2012') 100;datenum('15- Mar -2013') 90;...
datenum('15- Mar -2015') 80]}

FaceSchedule = 1x1 cell array
{3x2 double}

cfamounts(.05,'01-Mar-2011','15-Mar-2015','Face',FaceSchedule)

ans = 1x10
-2.3066    2.5000    2.5000   12.5000    2.2500   12.2500    2.0000    2.0000    2.0000    82.0000
```

### Use cfamounts to Generate the Cash Flows for a Sinking Bond

This example shows how to use `cfamounts` to generate the cash flows for a sinking bond.

```
[CFlowAmounts,CFDates,TFactors,CFFlags,CFPrincipal] = cfamounts(.05,'04-Nov-2010',...
{'15-Jul-2014';'15-Jul-2015'},'Face',{[datenum('15-Jul-2013') 100;datenum('15-Jul-2014')...
90;datenum('15-Jul-2015') 80]})

CFlowAmounts = 2x11
```

```
-1.5217    2.5000    2.5000    2.5000    2.5000    2.5000    12.5000    2.2500    92.2500
-1.5217    2.5000    2.5000    2.5000    2.5000    2.5000    12.5000    2.2500    12.2500
2.0
```

CFDates = 2×11

|        |        |        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|--------|--------|
| 734446 | 734518 | 734699 | 734883 | 735065 | 735249 | 735430 | 735614 |
| 734446 | 734518 | 734699 | 734883 | 735065 | 735249 | 735430 | 735614 |

TFactors = 2×11

|   |        |        |        |        |        |        |        |        |        |

## Input Arguments

**CouponRate — Annual percentage rate used to determine coupons payable on a bond**  
decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal using a scalar or a NBONDS-by-1 vector.

CouponRate is 0 for zero coupon bonds.

---

**Note** CouponRate and Face can change over the life of the bond. Schedules for CouponRate and Face can be specified with an NBONDS-by-1 cell array, where each element is a NumDates-by-2 matrix or cell array, where the first column is dates (serial date numbers or character vectors) and the second column is associated rates. The date indicates the last day that the coupon rate or face value is valid. This means that the corresponding CouponRate and Face value applies "on or before" the specified ending date.

---

Data Types: double | cell | char

**Settle — Settlement date of bond**

serial date number | date character vector | datetime

Settlement date of the bond, specified as a scalar or a NBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

**Maturity — Maturity date of bond**

serial date number | date character vector | datetime

Maturity date of the bond, specified as a scalar or a `NBONDS`-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = ...  
cfamounts(CouponRate, Settle,  
Maturity, 'Period', 4, 'Basis', 3, 'AdjustCashFlowsBasis', true, 'BusinessDayConvent  
ion', 'modifiedfollow')`

**Period — Number of coupon payments per year for bond**

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year for the bond, specified as the comma-separated pair consisting of 'Period' and a scalar or a `NBONDS`-by-1 vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**Basis — Day-count basis of bond**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis of the bond, specified as the comma-separated pair consisting of 'Basis' and a scalar or a `NBONDS`-by-1 vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NBONDS-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond issue date (the date the bond begins to accrue interest), specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays. The IssueDate cannot be after the Settle date.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

---

**Note** When FirstCouponDate and LastCouponDate

are both specified, the FirstCouponDate takes precedence in determining the coupon payment structure. If FirstCouponDate is not specified, then LastCouponDate determines the coupon structure of the bond.

---

Data Types: double | char | datetime

**LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

**Note** When `FirstCouponDate` and `LastCouponDate` are both specified, the `FirstCouponDate` takes precedence in determining the coupon payment structure. If `FirstCouponDate` is not specified, then `LastCouponDate` determines the coupon structure of the bond.

---

Data Types: double | char | datetime

**StartDate — Forward starting date of coupon payments**

serial date number | date character vector | datetime

Forward starting date of coupon payments after the `Settle` date, specified as the comma-separated pair consisting of '`StartDate`' and a scalar or a `NBONDS`-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

---

**Note** To make an instrument forward starting, specify `StartDate` as a future date.

---

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

Data Types: double | char | datetime

**Face — Face value of bond**

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of '`Face`' and a scalar or a `NBONDS`-by-1 vector.

---

**Note** `CouponRate` and `Face` can change over the life of the bond. Schedules for `CouponRate` and `Face` can be specified with an `NBONDS`-by-1 cell array where each element is a `NumDates`-by-2 matrix or cell array, where the first column is dates (serial date numbers or character vectors) and the second column is associated rates. The date indicates the last day that the coupon rate or face value is valid. This means that the corresponding `CouponRate` and `Face` value applies "on or before" the specified ending date.

When the corresponding `Face` value is used to compute the coupon cashflow on the specified ending date. Three things happen on the specified ending date:

- 1 The last coupon corresponding to the current `Face` value is paid.
  - 2 The principal differential (between the current and the next `Face` value) is paid.
  - 3 The date marks the beginning of the period with the next `Face` value, for which the cashflow does not occur until later.
- 

Data Types: double | cell | char

**AdjustCashFlowsBasis — Adjusts cash flows according to accrual amount based on actual period day count**

false (default) | logical with a value of true or false

Adjusts cash flows according to the accrual amount based on the actual period day count, specified as the comma-separated pair consisting of '`AdjustCashFlowsBasis`' and a scalar or a `NBONDS`-by-1 vector.

Data Types: logical

#### **BusinessDayConvention — Business day conventions**

'actual' (default) | character vector with values 'actual', 'follow', 'modifiedfollow', 'previous' or 'modifiedprevious'

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar or NBONDS-by-1 cell array of character vectors of business day conventions to be used in computing payment dates. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- 'actual' — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- 'follow' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- 'modifiedfollow' — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- 'previous' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- 'modifiedprevious' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

#### **CompoundingFrequency — Compounding frequency for yield calculation**

SIA uses 2, ICMA uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NBONDS-by-1 vector. Values are:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

#### **DiscountBasis — Basis used to compute the discount factors for computing the yield**

SIA uses 0 (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NBONDS-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

---

**Note** If a SIA day-count basis is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the default behavior is for SIA bases to use the `actual/actual` day count to compute discount factors.

---

If an ICMA day-count basis or BUS/252 is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the specified bases from the `Basis` input argument are used.

---

Data Types: double

**Holidays — Dates for holidays**

`holidays.m` used (default)

Dates for holidays, specified as the comma-separated pair consisting of '`Holidays`' and a `NHOLIDAYS`-by-1 vector of MATLAB dates using serial date numbers, date character vectors, or datetime arrays. Holidays are used in computing business days.

Data Types: double | char | datetime

**PrincipalType — Type of principal when a Face schedule is specified**

`sinking` (default) | character vector with values '`sinking`' or '`bullet`'

Type of principal when a Face schedule, specified as the comma-separated pair consisting of '`PrincipalType`' and a value of '`sinking`' or '`bullet`' using a scalar or a `NBONDS`-by-1 vector.

If '`sinking`', principal cash flows are returned throughout the life of the bond.

If '`bullet`', principal cash flow is only returned at maturity.

Data Types: char | cell

## Output Arguments

### **CFlowAmounts — Cash flow amounts**

matrix

Cash flow amounts, returned as a NBONDS-by-NCFS (number of cash flows) matrix. The first entry in each row vector is the accrued interest due at settlement. This amount could be zero, positive or negative. If no accrued interest is due, the first column is zero. If the bond is trading ex-coupon then the accrued interest is negative.

### **CFlowDates — Cash flow dates for a portfolio of bonds**

matrix

Cash flow dates for a portfolio of bonds, returned as a NBONDS-by-NCFS matrix. Each row represents a single bond in the portfolio. Each element in a column represents a cash flow date of that bond.

If all the above inputs (`Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, `LastCouponDate`, and `StartDate`) are either serial date numbers or date character vectors, then `CFlowDates` is returned as a serial date number. If any of these inputs are datetime arrays, then `CFlowDates` is returned as a datetime array.

### **TFactors — Matrix of time factors for a portfolio of bonds**

matrix

Matrix of time factors for a portfolio of bonds, returned as a NBONDS-by-NCFS matrix. Each row corresponds to the vector of time factors for each bond. Each element in a column corresponds to the specific time factor associated with each cash flow of a bond.

Time factors are for price/yield conversion and time factors are in units of whole semiannual coupon periods plus any fractional period using an actual day count. For more information on time factors, see "Time Factors" on page 19-538.

### **CFlowFlags — Cash flow flags for a portfolio of bonds**

matrix

Cash flow flags for a portfolio of bonds, returned as a NBONDS-by-NCFS matrix. Each row corresponds to the vector of cash flow flags for each bond. Each element in a column corresponds to the specific flag associated with each cash flow of a bond. Flags identify the type of each cash flow (for example, nominal coupon cash flow, front, or end partial, or "stub" coupon, maturity cash flow).

| Flag | Cash Flow Type                                                                                                                                                                  |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | Accrued interest due on a bond at settlement.                                                                                                                                   |
| 1    | Initial cash flow amount smaller than normal due to a "stub" coupon period. A stub period is created when the time from issue date to first coupon date is shorter than normal. |
| 2    | Larger than normal initial cash flow amount because the first coupon period is longer than normal.                                                                              |
| 3    | Nominal coupon cash flow amount.                                                                                                                                                |
| 4    | Normal maturity cash flow amount (face value plus the nominal coupon amount).                                                                                                   |
| 5    | End "stub" coupon amount (last coupon period is abnormally short and actual maturity cash flow is smaller than normal).                                                         |

| Flag | Cash Flow Type                                                                                                                                                                                        |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6    | Larger than normal maturity cash flow because the last coupon period longer than normal.                                                                                                              |
| 7    | Maturity cash flow on a coupon bond when the bond has less than one coupon period to maturity.                                                                                                        |
| 8    | Smaller than normal maturity cash flow when the bond has less than one coupon period to maturity.                                                                                                     |
| 9    | Larger than normal maturity cash flow when the bond has less than one coupon period to maturity.                                                                                                      |
| 10   | Maturity cash flow on a zero coupon bond.                                                                                                                                                             |
| 11   | Sinking principal and initial cash flow amount smaller than normal due to a "stub" coupon period. A stub period is created when the time from issue date to first coupon date is shorter than normal. |
| 12   | Sinking principal and larger than normal initial cash flow amount because the first coupon period is longer than normal.                                                                              |
| 13   | Sinking principal and nominal coupon cash flow amount.                                                                                                                                                |

**CFPrincipal – Principal cash flows**

matrix

Principal cash flows, returned as a NBONDS-by-NCFS matrix.

If `PrincipalType` is 'sinking', `CFPrincipal` output indicates when the principal is returned.

If `PrincipalType` is 'bullet', `CFPrincipal` is all zeros and, at `Maturity`, the appropriate `Face` value.

**More About****Time Factors**

Time factors help determine the present value of a stream of cash flows.

The term time factors refer to the exponent *TF* in the discounting equation

$$PV = \sum_{i=1}^n \left( \frac{CF}{\left(1 + \frac{z}{f}\right)^{TF}} \right),$$

where:

|        |                                                                                                                                                                                                                                             |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $PV =$ | Present value of a cash flow.                                                                                                                                                                                                               |
| $CF =$ | Cash flow amount.                                                                                                                                                                                                                           |
| $z =$  | Risk-adjusted annualized rate or yield corresponding to a given cash flow. The yield is quoted on a semiannual basis.                                                                                                                       |
| $f =$  | Frequency of quotes for the yield. Default is 2 for <code>Basis</code> values 0 to 7 and 13 and 1 for <code>Basis</code> values 8 to 12. The default can be overridden by specifying the <code>CompoundingFrequency</code> name-value pair. |

|        |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $TF =$ | Time factor for a given cash flow. The time factor is computed using the compounding frequency and the discount basis. If these values are not specified, then the defaults are as follows: CompoundingFrequency default is 2 for Basis values 0 to 7 and 13 and 1 for Basis values 8 to 12.<br><br>DiscountBasis is 0 for Basis values 0 to 7 and 13 and the value of the input Basis for Basis values 8 to 12. |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Note** The Basis is always used to compute accrued interest.

## cfconv

Cash flow convexity

### Syntax

```
CFlowConvexity = cfconv(CashFlow,Yield)
```

### Description

`CFlowConvexity = cfconv(CashFlow,Yield)` returns the convexity of a cash flow in periods.

### Examples

#### Compute the Convexity of a Cash Flow

This example shows how to return the convexity of a cash flow, given a cash flow of nine payments of \$2.50 and a final payment \$102.50, with a periodic yield of 2.5%.

```
CashFlow = [2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 102.5];  
Convex = cfconv(CashFlow, 0.025)  
Convex = 90.4493
```

### Input Arguments

#### CashFlow — Cash flow

vector of real numbers

Cash flow, specified as a vector of real numbers.

Data Types: double

#### Yield — Periodic yield

scalar decimal

Periodic yield, specified as a scalar decimal.

Data Types: double

### Output Arguments

#### CFlowConvexity — Convexity

scalar

Convexity returned as a scalar.

## cfdates

Cash flow dates for fixed-income security

### Syntax

```
CFlowDates = cfdates(Settle,Maturity)
CFlowDates = cfdates(___,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,
LastCouponDate)
```

### Description

`CFlowDates = cfdates(Settle,Maturity)` generates a matrix of actual cash flow payment dates for NUMBONDS fixed income securities. All cash flow dates are determined regardless of whether the first and last coupon periods are normal, long or short.

`CFlowDates = cfdates(___,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Obtain Cash Flow Dates for Fixed-Income Security

Compute the cash flow dates given the Settle and Maturity dates.

```
CFlowDates = cfdates('14 Mar 1997', '30 Nov 1998', 2, 0, 1)
```

```
CFlowDates = 1x4
```

```
729541      729724      729906      730089
```

```
datestr(CFlowDates)
```

```
ans = 4x11 char array
'31-May-1997'
'30-Nov-1997'
'31-May-1998'
'30-Nov-1998'
```

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, or `LastCouponDate` are datetime arrays, then `CFlowDates` is returned as a datetime array. For example:

```
CFlowDates = cfdates('14-Mar-1997', datetime('30-Nov-1998','Locale','en_US'), 2, 0, 1)
```

```
CFlowDates = 1x4 datetime
31-May-1997 30-Nov-1997 31-May-1998 30-Nov-1998
```

Given three securities with different maturity dates and the same default arguments:

```
Maturity = ['30-Sep-1997'; '31-Oct-1998'; '30-Nov-1998'];
CFlowDates = cfdates('14-Mar-1997', Maturity)

CFlowDates = 3x4

    729480      729663      NaN      NaN
    729510      729694      729875      730059
    729541      729724      729906      730089
```

To look at the cash-flow dates for the last security:

```
datestr(CFlowDates(3,:))

ans = 4x11 char array
'31-May-1997'
'30-Nov-1997'
'31-May-1998'
'30-Nov-1998'
```

## Input Arguments

### **Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers | datetime array

Settlement date, specified as an **NINST**-by-1 vector using serial date numbers, cell array of date character vectors, or a datetime array. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell | datetime

### **Maturity — Maturity date**

cell array of date character vectors | vector of serial date numbers | datetime array

Maturity date, specified as an **NINST**-by-1 vector using serial date numbers, cell array of date character vectors, or a datetime array.

Data Types: double | char | cell | datetime

### **Period — Coupons per year of the bond**

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

(Optional) Coupons per year of the bond, specified as a vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: double

### **Basis — Day-count basis**

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

(Optional) Day-count basis, specified as positive integers using a **NINST**-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)

- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

(Optional) End-of-month rule flag, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

cash flow payment dates are determined from other inputs (default) | serial date number | date character vector | datetime

(Optional) Bond Issue date, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an **IssueDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**FirstCouponDate — Irregular or normal first coupon date**

cash flow payment dates are determined from other inputs (default) | serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **FirstCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Irregular or normal last coupon date**

cash flow payment dates are determined from other inputs (default) | serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **LastCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**Output Arguments****CFlowDates — Actual cash flow payment dates**

matrix

Actual cash flow payment dates, returned as a N-row matrix of dates in serial date format or datetime format (if any inputs are in datetime format). CFlowDates has NUMBONDS rows and the number of columns is determined by the maximum number of cash flow payment dates required to hold the bond portfolio. NaNs are padded for bonds which have less than the maximum number of cash flow payment dates. Use the function `datestr` to convert serial date numbers to formatted date character vectors.

If all of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, or `LastCouponDate` are either serial date numbers or date character vectors, then CFlowDates is returned as a serial date number.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, or `LastCouponDate` are datetime arrays, then CFlowDates is returned as a datetime array.

---

**Note** The cash flow flags for a portfolio of bonds were formerly available as the `cfdates` second output argument, `CFlowFlags`. You can now use `cfamounts` to get these flags. If you specify a `CFlowFlags` argument, `cfdates` displays a message directing you to use `cfamounts`.

## cfdatesq

Quasi-coupon dates for fixed-income security

### Syntax

```
QuasiCouponDates = cfdatesq(Settle,Maturity)
QuasiCouponDates = cfdatesq(___,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate,PeriodsBeforeSettle,PeriodsAfterMaturity)
```

### Description

`QuasiCouponDates = cfdatesq(Settle,Maturity)` returns a matrix of quasi-coupon dates expressed in serial date format (default) or datetime format (if any inputs are in datetime format).

Successive quasi-coupon dates determine the length of the standard coupon period for the fixed-income security of interest, and do not necessarily coincide with actual coupon payment dates. Quasi-coupon dates are determined regardless of whether the first or last coupon periods are normal, long, or short.

`QuasiCouponDates` has `NUMBONDS` rows and the number of columns is determined by the maximum number of quasi-coupon dates required to hold the bond portfolio. `NANs` are padded for bonds which have less than the maximum number quasi-coupon dates. By default, quasi-coupon dates after settlement and on or preceding maturity are returned. If settlement occurs on maturity, and maturity is a quasi-coupon date, then the maturity date is returned.

`QuasiCouponDates = cfdatesq(___,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate,PeriodsBeforeSettle,PeriodsAfterMaturity)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Obtain Quasi-Coupon Dates for Fixed-Income Security

Compute the quasi-coupon dates given the `Settle` and `Maturity` dates.

```
QuasiCouponDates = cfdatesq('14-Mar-1997', '30-Nov-1998', 2, 0, 1)
```

```
QuasiCouponDates = 1x4
```

```
729541      729724      729906      730089
```

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, or `LastCouponDate` are datetime arrays, then `QuasiCouponDates` is returned as a datetime array. For example:

```
QuasiCouponDates = cfdatesq('14-Mar-1997', datetime('30-Nov-1998','Locale','en_US'), 2, 0, 1)
```

---

```
QuasiCouponDates = 1x4 datetime
    31-May-1997    30-Nov-1997    31-May-1998    30-Nov-1998
```

## Input Arguments

### **Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers | datetime array

Settlement date, specified as an `NINST`-by-1 vector using serial date numbers, cell array of date character vectors, or a datetime array. `Settle` must be earlier than `Maturity`.

Data Types: `double` | `char` | `cell` | `datetime`

### **Maturity — Maturity date**

cell array of date character vectors | vector of serial date numbers | datetime array

Maturity date, specified as an `NINST`-by-1 vector using serial date numbers, cell array of date character vectors, or a datetime array.

Data Types: `double` | `char` | `cell` | `datetime`

### **Period — Coupons per year of the bond**

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

(Optional) Coupons per year of the bond, specified as a vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: `double`

### **Basis — Day-count basis**

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

(Optional) Day-count basis, specified as positive integers using a `NINST`-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

(Optional) End-of-month rule flag, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

cash flow payment dates are determined from other inputs (default) | serial date number | date character vector | datetime

(Optional) Bond Issue date, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an **IssueDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**FirstCouponDate — Irregular or normal first coupon date**

cash flow payment dates are determined from other inputs (default) | serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **FirstCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Irregular or normal last coupon date**

cash flow payment dates are determined from other inputs (default) | serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **LastCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**PeriodsBeforeSettle — Number of quasi-coupon dates on or before settlement to include**

0 (default) | nonnegative integer

(Optional) Number of quasi-coupon dates on or before settlement to include, specified as a nonnegative integer.

Data Types: double

**PeriodsAfterMaturity — Number of quasi-coupon dates after maturity to include**

0 (default) | nonnegative integer

(Optional) Number of quasi-coupon dates after maturity to include, specified as a nonnegative integer.

Data Types: double

## Output Arguments

**QuasiCouponDates — Quasi-coupon dates**

matrix

Quasi-coupon dates, returned as a N-row matrix of dates in serial date format or datetime format (if any inputs are in datetime format). QuasiCouponDates has NUMBONDS rows and the number of columns is determined by the maximum number of quasi-coupon dates required to hold the bond portfolio. NaNs are padded for bonds which have less than the maximum number quasi-coupon dates. By default, quasi-coupon dates after settlement and on or preceding maturity are returned. If settlement occurs on maturity, and maturity is a quasi-coupon date, then the maturity date is returned.

If all of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, or LastCouponDate are either serial date numbers or date character vectors, then QuasiCouponDates is returned as a serial date number.

If any of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, or LastCouponDate are datetime arrays, then QuasiCouponDates is returned as a datetime array.

## Introduced before R2006a

## cfdur

Cash-flow duration and modified duration

### Syntax

```
[Duration,ModDuration] = cfdur(CashFlow,Yield)
```

### Description

[Duration,ModDuration] = cfdur(CashFlow,Yield) calculates the duration and modified duration of a cash flow in periods.

### Examples

#### Compute the Duration and Modified Duration of a Cash Flow

This example shows how to calculate the duration and modified duration of a cash flow, given a cash flow of nine payments of \$2.50 and a final payment \$102.50, with a periodic yield of 2.5%.

```
CashFlow=[2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 102.5];  
[Duration, ModDuration] = cfdur(CashFlow, 0.025)  
Duration = 8.9709  
ModDuration = 8.7521
```

### Input Arguments

#### CashFlow — Cash flow

vector of real numbers | matrix of real numbers

Cash flow, specified as a vector or matrix of real numbers. When using a matrix, each column of the matrix is a separate CashFlow.

Data Types: double

#### Yield — Periodic yield

scalar decimal | vector of decimals

Periodic yield, specified as a scalar decimal or a vector of decimals.

Data Types: double

### Output Arguments

#### Duration — Duration

vector

Duration returned as a scalar or vector.

**ModDuration — Modified duration**

vector

Modified duration, returned as a scalar or vector.

## cfplot

Visualize cash flows of financial instruments

### Syntax

```
cfplot(CFlowDates,CFlowAmounts)
cfplot(___,Name,Value)

h = cfplot(___,Name,Value)
[h,axes_handle] = cfplot(___,Name,Value)
```

### Description

`cfplot(CFlowDates,CFlowAmounts)` plots a cash flow diagram for the specified cash flow amounts (`CFlowAmounts`) and dates (`CFlowDates`). The length and orientation of each arrow correspond to the cash flow amount.

`cfplot(___,Name,Value)` plots a cash flow diagram for the specified cash flow amounts (`CFlowAmounts`), dates (`CFlowDates`), and optional name-value pair arguments.

`h = cfplot(___,Name,Value)` returns the handle to the line objects used in the cash flow diagram.

`[h,axes_handle] = cfplot(___,Name,Value)` returns the handles to the line objects and the axes using optional name-value pair arguments.

### Examples

#### Plot Cash Flows

Define `CFlowAmounts` and `CFlowDates` using the `cfamounts` function.

```
CouponRate = [0.06; 0.05; 0.03];
Settle = '03-Jun-1999';
Maturity = ['15-Aug-2000'; '15-Dec-2000'; '15-Jun-2000'];
Period = [1; 2; 2]; Basis = [1; 0; 0];
[CFlowAmounts, CFlowDates] = cfamounts(...  
CouponRate, Settle, Maturity, Period, Basis)
```

`CFlowAmounts` = 3×5

```
-4.8000    6.0000   106.0000      NaN      NaN
-2.3352    2.5000    2.5000    2.5000   102.5000
-1.4011    1.5000    1.5000   101.5000      NaN
```

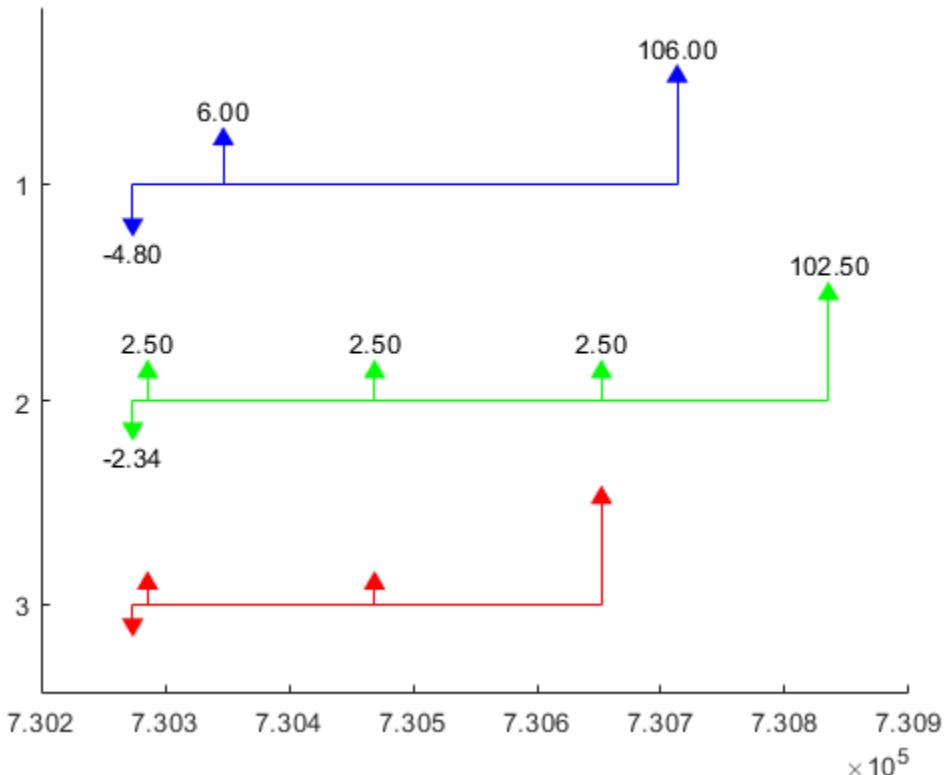

`CFlowDates` = 3×5

```
730274        730347        730713        NaN        NaN
730274        730286        730469        730652        730835
```

```
730274      730286      730469      730652      NaN
```

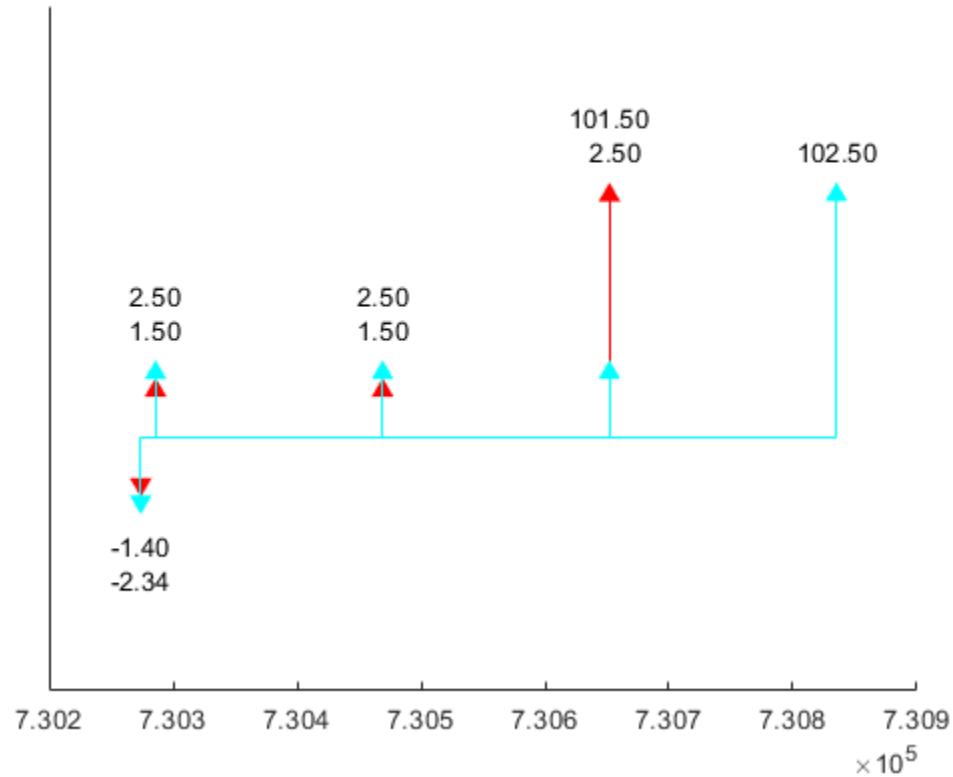

Plot all cash flows on the same axes, and label the first two.

```
cfplot(CFlowDates, CFlowAmounts, 'ShowAmnt', [1 2])
```

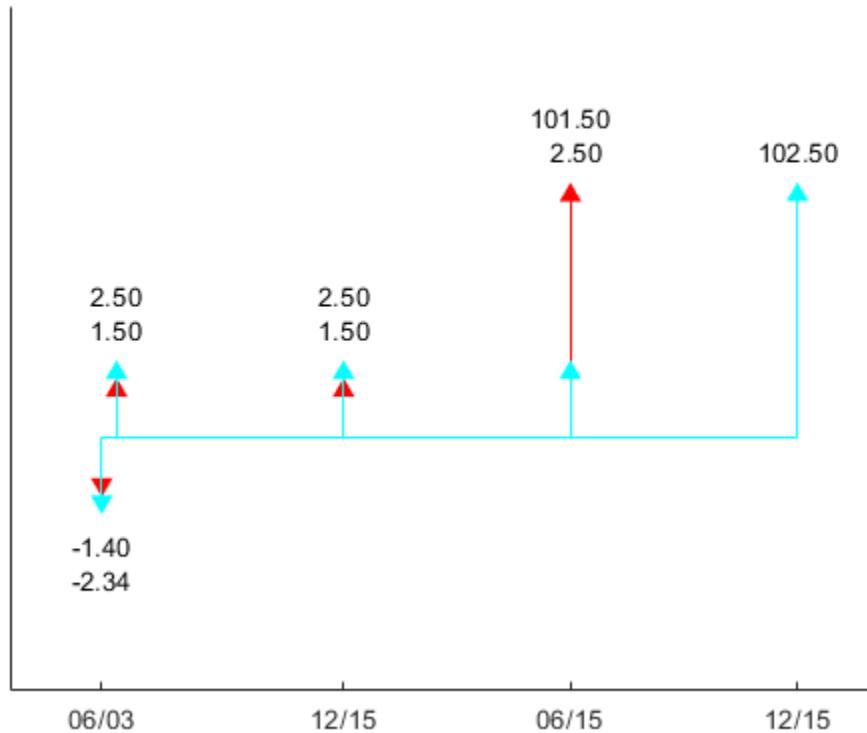

Group the second and third cash flows.

```
figure;
cfplot(CFlowDates, CFlowAmounts, 'Groups', {[2 3]}, 'ShowAmnt', 1);
```

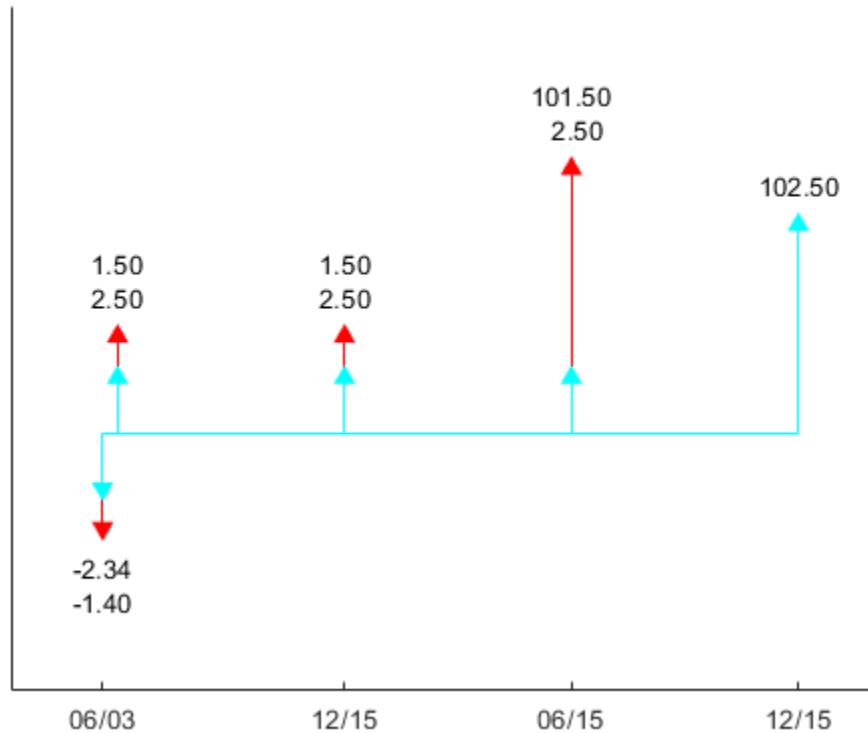

Format the date axis and place ticks on actual cash flow dates.

```
figure;
cfplot(CFlowDates, CFlowAmounts, 'Groups', {[2 3]}, 'ShowAmnt', 1, ...
'DateFormat', 6, 'DateSpacing', 100);
```

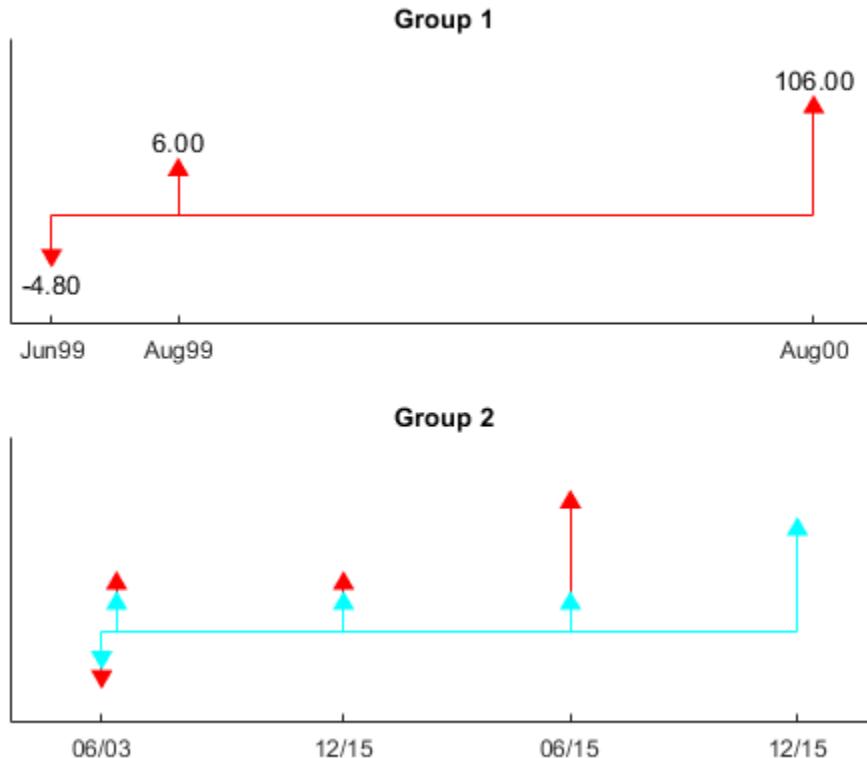

Stack the cash flow arrows occurring on the same dates.

```
figure;
cfplot(CFlowDates, CFlowAmounts, 'Groups', {[2 3]}, 'ShowAmnt', 1, ...
'DateFormat', 6, 'DateSpacing', 100, 'Stacked', 1);
```

Form subplots of multiple groups and add titles using axes handles.

```
figure;
[h, axes_handle] = cfplot(CFlowDates, CFlowAmounts, ...
'Groups', {[1] [2 3]}, 'ShowAmnt', 1, 'Stacked', 2, ...
'DateSpacing', [1 60 2 100], 'DateFormat', [1 12 2 6]);
title(axes_handle(1), 'Group 1', 'FontWeight', 'bold');
title(axes_handle(2), 'Group 2', 'FontWeight', 'bold');
```

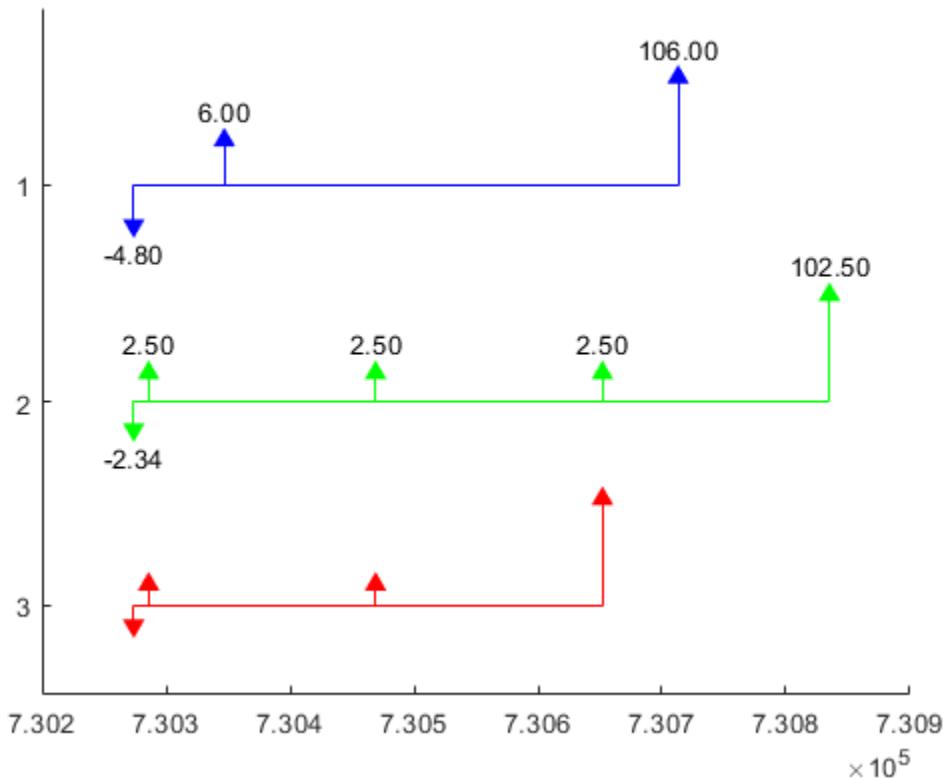

### Plot Cash Flows Using datetime Input for CFlowDates

Define CFlowDates using datetime input and plot the cash flow.

```

CouponRate = [0.06; 0.05; 0.03];
Settle = '03-Jun-1999';
Maturity = ['15-Aug-2000'; '15-Dec-2000'; '15-Jun-2000'];
Period = [1; 2; 2]; Basis = [1; 0; 0];
[CFlowAmounts, CFlowDates] = cfamounts(...%
CouponRate, Settle, Maturity, Period, Basis);
cfplot(datetime(CFlowDates,'ConvertFrom','datenum','Locale','en_US'), CFlowAmounts, 'ShowAmnt',
```

### Plot Cash Flows for Swap

Define the swap using the `swapbyzero` function.

```
Settle = datenum('08-Jun-2010');
RateSpec = intenvset('Rates', [.005 .0075 .01 .014 .02 .025 .03], ...
    'StartDates', Settle, 'EndDates', {'08-Dec-2010', '08-Jun-2011', ...
    '08-Jun-2012', '08-Jun-2013', '08-Jun-2015', '08-Jun-2017', ...
    '08-Jun-2020'});
Maturity = datenum('15-Sep-2020');
LegRate = [.025 50];
LegType = [1 0]; % fixed/floating
LatestFloatingRate = .005;
[Price, SwapRate, AI, RecCF, RecCFDates, PayCF, PayCFDates] = ...
    swapbyzero(RateSpec, LegRate, Settle, Maturity, 'LegType', LegType, ...
    'LatestFloatingRate', LatestFloatingRate)

Price = -6.7258
SwapRate = NaN
AI = 1.4575
RecCF = 1x12
```

```
-1.8219    2.5000    2.5000    2.5000    2.5000    2.5000    2.5000    2.5000    2.5000    2.5000    2.5000    2.5000
```

RecCFDates = 1×12

|        |        |        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|--------|--------|
| 734297 | 734396 | 734761 | 735127 | 735492 | 735857 | 736222 | 736588 |
|--------|--------|--------|--------|--------|--------|--------|--------|

PayCF = 1×12

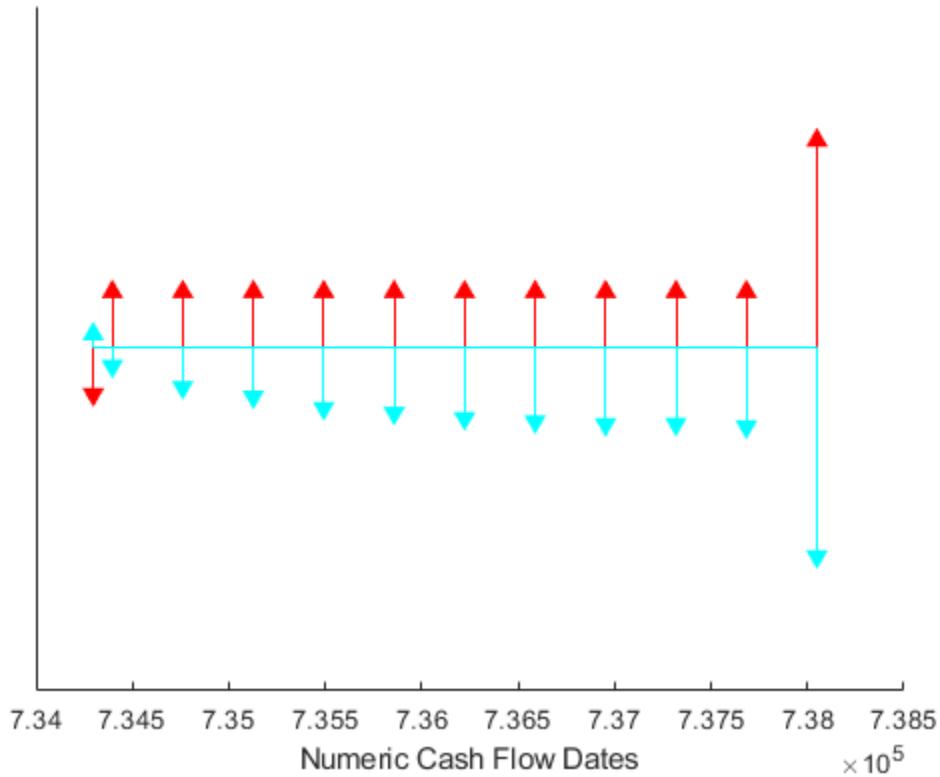

```
-0.3644    0.5000    1.4048    1.9823    2.8436    3.2842    3.8218    4.1733    4.5164    4.4
```

PayCFDates = 1×12

|        |        |        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|--------|--------|
| 734297 | 734396 | 734761 | 735127 | 735492 | 735857 | 736222 | 736588 |
|--------|--------|--------|--------|--------|--------|--------|--------|

Define CFlowDates and CFlowAmounts for the swap and generate a cash flow plot using cfplot.

```
CFlowDates = [PayCFDates;RecCFDates];
CFlowAmounts = [-PayCF;RecCF];
cfplot(CFlowDates, CFlowAmounts, 'Groups', {[1 2]} );
xlabel('Numeric Cash Flow Dates');
```

## Input Arguments

### CFlowDates — Matrix of serial date numbers for cash flows

vector

Matrix of serial date numbers or datetime arrays for cash flows, specified as a NINST-by-(Number of cash flows) matrix of cash flow dates in date numbers, with empty entries padded with NaNs.

Each row of the CFlowDates matrix represents an instrument so that CFlowDates(k,:) is the vector of cash flow dates for the kth instrument. Rows are padded with trailing NaNs if the number of cash flows is not the same for all instruments.

cfamounts can be used to generate CFlowDates.

Data Types: double

### CFlowAmounts — Matrix of cash flow amounts

vector

Matrix of cash flow amounts, specified as a NINST-by-(Number of cash flows) matrix of cash flow amounts, with empty entries padded with NaNs. The CFlowAmounts matrix must be the same size as CFlowDates.

cfamounts can be used to generate CFlowAmounts.

Data Types: double

## Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, ..., NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: cfplot(CFlowDates,CFlowAmounts,'Groups',[2 3],'ShowAmnt',1,'DateFormat',6,'DateSpacing',100)

### Groups — Group cash flows

'off' (default) | character vector with value 'off' or 'individual' | cell array of character vectors

Group cash flows, specified as the comma-separated pair consisting of 'Groups' and the following values:

- 'off' — Show all instruments in one set of axes, arranged from top to bottom.
- 'individual' — Generate subplots and plot each instrument in its own axis.
- GRP — Cell array of instrument groups, {Group1, Group2, ...}. This generates subplots and plots each group in each axis. When specifying {Group1, Group2, ...}, each Group must be mutually exclusive vectors of INSTIndex. Unspecified instruments are not shown in the grouped plot.

Data Types: char | cell

**Stacked — Stack arrows if cash flows are in same direction on same day**

ignored when 'Groups' is 'off', otherwise 'off' (default) | character vector with values 'off', 'all', or 'GRPIIndex'

Stack arrows if the cash flows are in the same direction on the same day, specified as the comma-separated pair consisting of 'Stacked' and the following values:

- 'off' — For all groups, all arrows originate from the horizontal line.
- 'all' — For all groups, arrows are stacked if the cash flows are in the same direction on the same day.
- 'GRPIIndex' — For specified groups, arrows are stacked if the cash flows are in the same direction on the same day.

Data Types: char

**ShowAmnt — Show amount on arrows**

'off' (default) | character vector with values 'off' or 'individual' | cell array of character vectors

Show amount on the arrows, specified as the comma-separated pair consisting of 'ShowAmnt' and the following values:

- 'off' — Hide cash flow amounts on arrows.
- 'all' — Show cash flow amounts on arrows.
- [INSTIndex or GRPIIndex] — Show cash flow amounts for the specified vector of instruments (when 'Groups' is 'off') or groups.

Data Types: char | cell

**DateSpacing — Control for date axis tick spacing**

'off' (default) | character vector with values 'off' or TickDateSpace | numeric value for TickDateSpace

Control for data spacing, specified as the comma-separated pair consisting of 'DateSpacing' and the following values:

- 'off' — The date axis ticks are spaced regularly.
- TickDateSpace — The date axis ticks are placed on actual cash flow dates. The ticks skip some cash flows if they are less than TickDateSpace apart.

Data Types: char | double

**DateFormat — Date format**

'off' (default) | character vector with values 'off' or DateFormNum | numeric value for DateFormNum

Date format, specified as the comma-separated pair consisting of 'DateFormat' and the following values:

- 'off' — The date axis tick labels are in date numbers.
- DateFormNum — The date format number (2 = 'mm/dd/yy', 6 = 'mm/dd', and 10 = 'yyyy'). Additional values for DateFormNum are as follows:

| DateFormNum | Example    |
|-------------|------------|
| 2           | 03/01/00   |
| 3           | Mar        |
| 5           | 03         |
| 6           | 03/01      |
| 7           | 01         |
| 8           | Wed        |
| 9           | W          |
| 10          | 2000       |
| 11          | 00         |
| 12          | Mar00      |
| 17          | Q1-00      |
| 18          | Q1         |
| 19          | 01/03      |
| 20          | 01/03/00   |
| 27          | Q1-2000    |
| 28          | Mar2000    |
| 29          | 2000-03-01 |

Data Types: char | double

## Output Arguments

### **h — Handles to line objects**

vector

Handles to line objects, returned as a NINST-by-3 matrix of handles to line objects, containing [hLines, hUArrowHead, hDArrowHead] where:

- hLines — Horizontal and vertical lines used in the cash flow diagram
- hUArrowHead — "Up" arrowheads
- hDArrowHead — "Down" arrowheads

### **axes\_handle — Handles to axes for plot or subplots**

vector

Handles to axes for the plot or subplots, returned as a (Number of axes)-by-1 vector of handles to axes.

## Topics

"Analyzing and Computing Cash Flows" on page 2-14

---

**Introduced in R2013a**

## cfport

Portfolio form of cash flow amounts

### Syntax

```
[CFBondDate,AllDates,AllTF,IndByBond] = cfport(CFlowAmounts,CFlowDates)
[CFBondDate,AllDates,AllTF,IndByBond] = cfport(___,TFactors)
```

### Description

[CFBondDate,AllDates,AllTF,IndByBond] = cfport(CFlowAmounts,CFlowDates) computes a vector of all cash flow dates of a bond portfolio, and a matrix mapping the cash flows of each bond to those dates. Use the matrix for pricing the bonds against a curve of discount factors.

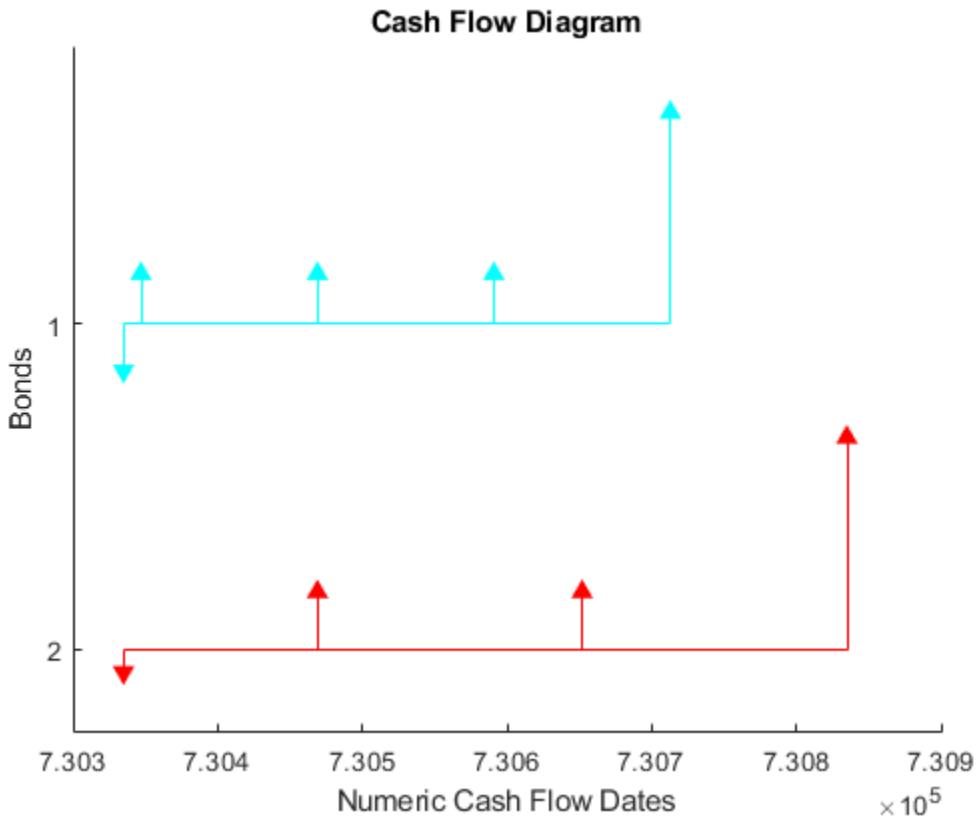

[CFBondDate,AllDates,AllTF,IndByBond] = cfport(\_\_\_,TFactors) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Calculate the Cash Flow Amounts, Cash Flow Dates, and Time Factors for Each of Two Bonds

Use the function `cfamounts` to calculate the cash flow amounts, cash flow dates, and time factors for each of two bonds. Then use the function `cfplot` to plot the cash flow diagram.

```
Settle = '03-Aug-1999';
Maturity = ['15-Aug-2000'; '15-Dec-2000'];
CouponRate= [0.06; 0.05];
Period = [3;2];
Basis = [1;0];
[CFlowAmounts, CFlowDates, TFactors] = cfamounts(CouponRate, ...
Settle, Maturity, Period, Basis);
cfplot(CFlowDates,CFlowAmounts)
xlabel('Numeric Cash Flow Dates')
ylabel('Bonds')
title('Cash Flow Diagram')
```

Call the function `cfport` to map the cash flow amounts to the cash flow dates. Each row in the resultant `CFBondDate` matrix represents a bond. Each column represents a date on which one or more of the bonds has a cash flow. A 0 means the bond did not have a cash flow on that date. The dates associated with the columns are listed in `AllDates`. For example, the first bond had a cash flow of 2.000 on 730347. The second bond had no cash flow on this date. For each bond, `IndByBond` indicates the columns of `CFBondDate`, or dates in `AllDates`, for which a bond has a cash flow.

```
[CFBondDate, AllDates, AllTF, IndByBond] = ...
cfport(CFlowAmounts, CFlowDates, TFactors)
```

`CFBondDate` = 2x7

|         |        |        |        |        |          |          |

### Calculate the Cash Flow Amounts, Cash Flow Dates Using a datetime Array, and Time Factors for Each of Two Bonds

Use the function `cfamounts` to calculate the cash flow amounts, cash flow dates, and time factors for each of two bonds.

```
Settle = datetime(1999,8,3);  
Maturity = ['15-Aug-2000'; '15-Dec-2000'];  
CouponRate= [0.06; 0.05];  
Period = [3;2];  
Basis = [1;0];  
[CFlowAmounts, CFlowDates, TFactors] = cfamounts(CouponRate, ...  
Settle, Maturity, Period, Basis);
```

Call the function `cfport` to map the cash flow amounts to the cash flow dates. Each row in the resultant `CFBondDate` matrix represents a bond. Each column represents a date on which one or more of the bonds has a cash flow. A 0 means the bond did not have a cash flow on that date. The dates associated with the columns are listed in `AllDates` returned as a datetime array.

```
[CFBondDate, AllDates, AllTF, IndByBond] = ...  
cfport(CFlowAmounts, CFlowDates, TFactors)
```

```
CFBondDate = 2x7
```

```
-1.8000    2.0000    2.0000    2.0000      0  102.0000      0  
-0.6694        0    2.5000        0    2.5000        0  102.5000
```

```
AllDates = 7x1 datetime
```

```
03-Aug-1999  
15-Aug-1999  
15-Dec-1999  
15-Apr-2000  
15-Jun-2000  
15-Aug-2000  
15-Dec-2000
```

```
AllTF = 7x1
```

```

0
0.0663
0.7322
1.3989
1.7322
2.0663
2.7322

```

IndByBond = 2×5

| 1 | 2 | 3 | 4 | 6   |
|---|---|---|---|-----|
| 1 | 3 | 5 | 7 | NaN |

## Input Arguments

### **CFlowAmounts — Cash flow amounts**

matrix

Cash flow amounts, specified as number of bonds (NUMBONDS) by number of cash flows (NUMCFS) matrix with entries listing cash flow amounts corresponding to each date in **CFlowDates**.

Data Types: double

### **CFlowDates — Cash flow dates**

serial date numbers | date character vector | datetime array

Cash flow dates, specified as an NUMBONDS-by-NUMCFS matrix with rows listing cash flow dates using a serial date number, date character vector, or datetime array, for each bond and padded with NaNs. If **CFlowDates** is a serial date number or a date character vector, **AllDates** is returned as an array of serial date numbers. If **CFlowDates** is a datetime array, then **AllDates** is returned as a datetime array.

Data Types: double

### **TFactors — Time between settlement and the cash flow date**

matrix

(Optional) Time between settlement and the cash flow date, specified as an NUMBONDS-by-NUMCFS matrix with entries listing the time between settlement and the cash flow date measured in semiannual coupon periods.

Data Types: double

## Output Arguments

### **CFBondDate — Cash flows indexed by bond and by date**

matrix

Cash flows indexed by bond and by date, returned as an NUMBONDS by number of dates (NUMDATES) matrix. Each row contains a bond's cash flow values at the indices corresponding to entries in **AllDates**. Other indices in the row contain zeros.

**AllDates — List of all dates that have any cash flow from the bond portfolio**  
matrix

List of all dates that have any cash flow from the bond portfolio, returned as an `NUMDATES`-by-1 matrix. The `AllDates` matrix is expressed in serial date format (default) or datetime format (if `CFlowDates` is in datetime format).

**AllTF — Time factors corresponding to the dates in AllDates**  
matrix

Time factors corresponding to the dates in `AllDates`, returned as an `NUMDATES`-by-1 matrix. If `TFactors` is not entered, `AllTF` contains the number of days from the first date in `AllDates`.

**IndByBond — Indices by bond**  
matrix

Indices by bond, returned as an `NUMBONDS`-by-`NUMCFS` matrix. The *i*th row contains a list of indices into `AllDates` where the *i*th bond has cash flows. Since some bonds have more cash flows than others, the matrix is padded with NaNs.

# cfprice

Compute price for cash flow given yield to maturity

## Syntax

```
Price = cfprice(CFlowAmounts,CFlowDates,Yield,Settle)
Price = cfprice(___,Name,Value)
```

## Description

`Price = cfprice(CFlowAmounts,CFlowDates,Yield,Settle)` computes a price given yield for a cash flow.

`Price = cfprice(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Price for a Cash Flow Given Yield to Maturity

Use `cfprice` to compute the price for a cash flow given yield to maturity.

Define data for the yield curve.

```
Settle = datenum('01-Jul-2003');
Yield = .05;
CFAmounts = [30;40;30];
CFDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'});
```

Compute the Price.

```
Price = cfprice(CFAmounts, CFDates, Yield, Settle)
```

```
Price = 3×1
```

```
28.4999
36.1689
25.8195
```

### Compute the Price for a Cash Flow Given Yield to Maturity Using datetime Inputs

Use `cfprice` to compute the price for a cash flow given yield to maturity using `datetime` inputs.

```
Settle = datenum('01-Jul-2003');
Yield = .05;
CFAmounts = [30;40;30];
CFDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'});
```

```
CFDates = datetime(CFDates,'ConvertFrom','datenum','Locale','en_US');
Settle = datetime(Settle,'ConvertFrom','datenum','Locale','en_US');
Price = cfprice(CFAmounts, CFDates, Yield, Settle)

Price = 3×1

28.4999
36.1689
25.8195
```

## Input Arguments

### **CFlowAmounts — Cash flow amounts**

vector

Cash flow amounts, specified as an `NINST`-by-`MOSTCFS` matrix. Each row is a list of cash flow values for one instrument. If an instrument has fewer than `MOSTCFS` cash flows, the end of the row is padded with `NaN`s.

Data Types: double

### **CFlowDates — Cash flow dates**

serial date number | date character vector | datetime array

Cash flow dates, specified as an `NINST`-by-`MOSTCFS` matrix. Each entry contains the date of the corresponding cash flow in `CFlowAmounts`.

Data Types: double | char | datetime

### **Yield — Yields**

vector

Yields specified as an `NINST`-by-1 vector.

Data Types: double

### **Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an `NMBS`-by-1 vector using serial date numbers or a cell array of date character vectors. The `Settle` date is the date on which the cash flows are priced.

Data Types: double | char | cell

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

---

**Note** An optional input of size `NINST`-by-1 is also acceptable as a single value applicable to all contracts. Single values are internally expanded to an array of size `NINST`-by-1.

---

---

Example: Price =  
 cfprice(CFlowAmounts,CFlowDates,Yield,Settle,'Basis',4,'CompoundingFrequency',4)

### Basis — Day-count basis

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a N-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

Data Types: double

### CompoundingFrequency — Compounding frequency

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

Data Types: double

## Output Arguments

### Price — Price of cash flows

vector

Price of cash flows, returned as an NINST-by-1 vector.

### Introduced in R2012a

# cfspread

Compute spread over yield curve for cash flow

## Syntax

```
Spread = cfspread(RateSpec, Price, CFlowAmounts, CFlowDates, Settle)
Spread = cfspread(____, Name, Value)
```

## Description

`Spread = cfspread(RateSpec, Price, CFlowAmounts, CFlowDates, Settle)` computes spread over a yield curve for a cash flow.

`Spread = cfspread(____, Name, Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute Spread Over a Yield Curve for a Cash Flow

Use `cfspread` to compute the spread over a yield curve for a cash flow.

Define data for the yield curve.

```
Settle = datenum('01-Jul-2003');
CurveDates = daysadd(Settle, 360*[.25 .5 1 2 3 5 7 10 20], 1);
ZeroRates = [.0089 .0096 .0107 .0130 .0166 .0248 .0306 .0356 .0454]';
```

Compute the `RateSpec`.

```
RateSpec = intenvset('StartDates', Settle, 'EndDates', CurveDates, ...
'Rates', ZeroRates)
```

```
RateSpec = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 2
        Disc: [9x1 double]
        Rates: [9x1 double]
        EndTimes: [9x1 double]
        StartTimes: [9x1 double]
        EndDates: [9x1 double]
    StartDates: 731763
    ValuationDate: 731763
        Basis: 0
    EndMonthRule: 1
```

Compute the spread.

```
Price = 98;
CFAmounts = [30;40;30];
```

```
CFDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'});  
Spread = cfspread(RateSpec, Price, CFAmounts, CFDates, Settle)  
Spread = 3×1  
103 ×  
-8.7956  
-4.0774  
-3.7073
```

### Compute Spread Over a Yield Curve for a Cash Flow Using `datetime` Inputs

Use `cfspread` to compute the spread over a yield curve for a cash flow using `datetime` inputs.

```
Settle = datenum('01-Jul-2003');  
CurveDates = daysadd(Settle,360*[.25 .5 1 2 3 5 7 10 20],1);  
ZeroRates = [.0089 .0096 .0107 .0130 .0166 .0248 .0306 .0356 .0454]';  
RateSpec = intenvset('StartDates', Settle, 'EndDates', CurveDates,...  
'Rates', ZeroRates);  
Price = 98;  
CFAmounts = [30;40;30];  
CFDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'});  
  
CFDates = datetime(CFDates,'ConvertFrom','datenum','Locale','en_US');  
Settle = datetime(Settle,'ConvertFrom','datenum','Locale','en_US');  
Spread = cfspread(RateSpec, Price, CFAmounts, CFDates, Settle)  
  
Spread = 3×1  
103 ×  
-8.7956  
-4.0774  
-3.7073
```

## Input Arguments

**RateSpec — Interest-rate specification for initial risk-free rate curve**  
structure

Interest-rate specification for initial risk-free rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

**Price — Price of cash flows**  
vector

Price of cash flows, specified as an `NINST`-by-1 vector.

Data Types: `double`

**CFlowAmounts — Cash flow amounts**

vector

Cash flow amounts, specified as an `NINST`-by-`MOSTCFS` matrix . Each row is a list of cash flow values for one instrument. If an instrument has fewer than `MOSTCFS` cash flows, the end of the row is padded with NaNs.

Data Types: double

**CFlowDates — Cash flow dates**

serial date number | date character vector | datetime array

Cash flow dates, specified as an `NINST`-by-`MOSTCFS` matrix . Each entry contains the date of the corresponding cash flow in `CFlowAmounts`.

Data Types: double | char | datetime

**Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an `NINST`-by-1 vector using serial date numbers or a cell array of date character vectors. The `Settle` date is the date on which the cash flows are priced.

Data Types: double | char | cell

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

---

**Note** An optional input of size `NINST`-by-1 is also acceptable as a single value applicable to all contracts. Single values are internally expanded to an array of size `NINST`-by-1.

---

Example: `Spread = cfsread(RateSpec, Price, CFlowAmounts, CFlowDates, Settle, 'Basis', 4)`

**Basis — Day-count basis**

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis, specified as the comma-separated pair consisting of '`Basis`' and a positive integer using a `NINST`-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)

- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

## Output Arguments

### **Spread — Spread of cash flows over a zero curve**

vector

Spread of cash flows over a zero curve, returned as an NINST-by-1 vector. The Spread is expressed in basis points.

## See Also

## Introduced in R2012a

# cfyield

Compute yield to maturity for cash flow given price

## Syntax

```
Yield = cfyield(CFlowAmounts,CFlowDates,Price,Settle)
Yield = cfyield(___,Name,Value)
```

## Description

`Yield = cfyield(CFlowAmounts,CFlowDates,Price,Settle)` computes yield to maturity for a cash flow given price.

`Yield = cfyield(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Yield to Maturity for a Cash Flow When Given a Price

Use `cfyield` to compute yield to maturity for a cash flow when given a price.

Define data for the yield curve and price.

```
Settle = datenum('01-Jul-2003');
Price = 98;
CFlowAmounts = [30 40 30];
CFlowDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'}');
```

Compute the Yield.

```
Yield = cfyield(CFlowAmounts, CFlowDates, Price, Settle)
Yield = 0.0099
```

### Compute the Yield to Maturity for a Cash Flow When Given a Price Using datetime Inputs

Use `cfyield` to compute yield to maturity for a cash flow, when given a price using `datetime` inputs.

```
Settle = datenum('01-Jul-2003');
Price = 98;
CFlowAmounts = [30 40 30];
CFlowDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'}');

CFlowDates = datetime(CFlowDates,'ConvertFrom','datenum','Locale','en_US');
Settle = datetime(Settle,'ConvertFrom','datenum','Locale','en_US');
Yield = cfyield(CFlowAmounts, CFlowDates, Price, Settle)
```

```
Yield = 0.0099
```

## Input Arguments

### CFlowAmounts — Cash flow amounts

vector

Cash flow amounts, specified as an `NINST`-by-`MOSTCFS` matrix. Each row is a list of cash flow values for one instrument. If an instrument has fewer than `MOSTCFS` cash flows, the end of the row is padded with NaNs.

Data Types: double

### CFlowDates — Cash flow dates

serial date number | date character vector | datetime array

Cash flow dates, specified as an `NINST`-by-`MOSTCFS` matrix. Each entry contains the date of the corresponding cash flow in `CFlowAmounts`.

Data Types: double | char | datetime

### Price — Prices

vector

Prices specified as an `NINST`-by-1 vector.

Data Types: double

### Settle — Settlement date

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an `NMBS`-by-1 vector using serial date numbers or a cell array of date character vectors. The `Settle` date is the date on which the cash flows are priced.

Data Types: double | char | cell

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1`, ..., `NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

---

**Note** An optional input of size `NINST`-by-1 is also acceptable as a single value applicable to all contracts. Single values are internally expanded to an array of size `NINST`-by-1.

---

Example: `Yield = cfyield(CFAmounts, CFDates, Yield, Settle, 'Basis', 4, 'CompoundingFrequency', 4)`

### Basis — Day-count basis

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a N-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

Data Types: double

#### **CompoundingFrequency — Compounding frequency**

2 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Compounding frequency, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a positive integer using a N-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

Data Types: double

**CompoundingFrequency — Compounding frequency**

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**Output Arguments****Yield — Yield for cash flows**

vector

Yield for cash flows, returned as an NINST-by-1 vector.

# cftimes

Time factors corresponding to bond cash flow dates

## Syntax

```
TFactors = cftimes(Settle,Maturity)
TFactors = cftimes(____,Name,Value)
```

## Description

`TFactors = cftimes(Settle,Maturity)` determines the time factors corresponding to the cash flows of a bond or set of bonds.

`cftimes` computes the time factor of a cash flow, which is the difference between the settlement date and the cash flow date, in units of semiannual coupon periods. In computing time factors, use SIA actual/actual day count conventions for all time factor calculations.

`TFactors = cftimes(____,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Time Factor of a Cash Flow

This example shows how to calculate a cash flow time factor.

```
Settle = '15-Mar-1997';
Maturity = '01-Sep-1999';
Period = 2;
TFactors = cftimes(Settle, Maturity, Period)

TFactors = 1×5
    0.9239    1.9239    2.9239    3.9239    4.9239
```

## Input Arguments

### Settle — Settlement date

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NINST-by-1 vector using serial date numbers or a cell array of date character vectors. `Settle` must be earlier than `Maturity`.

Data Types: double | char | cell

### Maturity — Maturity date

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an  $\text{NINST}$ -by-1 vector using serial date numbers or a cell array of date character vectors. The **Settle** date is the date on which the cash flows are priced.

Data Types: double | char | cell

### Name-Value Pair Arguments

Specify optional pairs of arguments as **Name1=Value1**, ..., **NameN=ValueN**, where **Name** is the argument name and **Value** is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `TFactors = cftimes(Settle,Maturity,'Period',4)`

#### Period — Number of coupon payments per year

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of '**Period**' and a scalar or a  $\text{NUMBONDS}$ -by-1 or 1-by- $\text{NUMBONDS}$  vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

#### Basis — Day-count basis

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis, specified as the comma-separated pair consisting of '**Basis**' and a positive integer using a  $\text{NINST}$ -by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

Data Types: double

#### EndMonthRule — End-of-month rule flag

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

#### **IssueDate — Bond issue date**

serial date number | date character vector | datetime

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify an **IssueDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

#### **FirstCouponDate — Irregular or normal first coupon date**

serial date number | date character vector | datetime

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **FirstCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

#### **LastCouponDate — Irregular or normal last coupon date**

serial date number | date character vector | datetime

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays.

If you do not specify a **LastCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

#### **StartDate — Forward starting date of payments**

serial date number | date character vector | datetime

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using serial date numbers, date character vectors, or datetime arrays. The **StartDate** is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a **StartDate**, the effective start date is the **Settle** date.

Data Types: double | char | datetime

**CompoundingFrequency — Compounding frequency for yield calculation**

SIA bases uses 2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

**Note** By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

---

Data Types: double

**DiscountBasis — Basis used to compute the discount factors for computing the yield**

SIA uses 0 (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-19.

---

**Note** If a SIA day-count basis is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

---

If an ICMA day-count basis or BUS/252 is defined in the **Basis** input argument and there is no value assigned for **DiscountBasis**, the specified bases from the **Basis** input argument are used.

---

Data Types: double

## Output Arguments

**TFactors — Time to cash flow**  
matrix

Time to cash flow, returned as an **NUMBONDS** rows. The number of columns is determined by the maximum number of cash flow payment dates required to hold the bond portfolio. NaNs are padded for bonds which have less than the maximum number of cash flow payment dates.

## Introduced before R2006a

## chaikosc

Chaikin oscillator

**Note** Using a `fints` object for the `Data` argument of `chaikosc` is not recommended. Use a matrix, timetable, or table instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
chosc = chaikocs(Data)
```

### Description

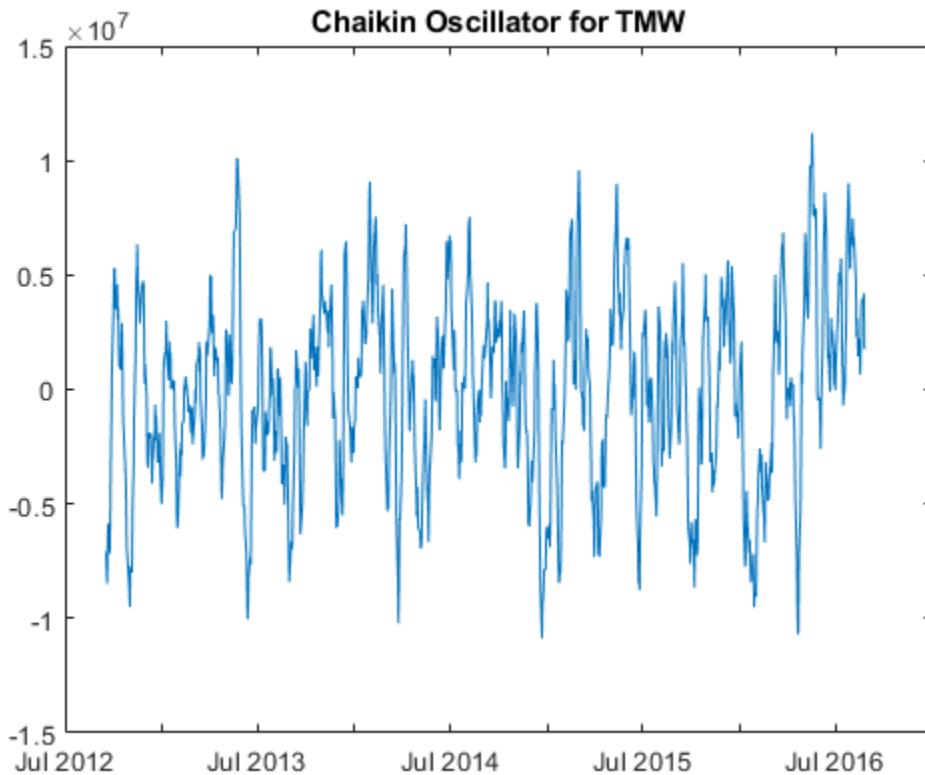

`chosc = chaikocs(Data)` calculates the Chaikin oscillator.

### Examples

#### Calculate the Chaikin Oscillator for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
oscillator = chaikosc(TMW);
plot(oscillator.Time, oscillator.ChaikinOscillator)
title('Chaikin Oscillator for TMW')
```

## Input Arguments

**Data — Data with high, low, open, close information**

matrix | table | timetable

Data with high, low, open, close information, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-4 matrix of high, low, opening, and closing prices. Timetables and tables with M rows must contain variables named 'High', 'Low', 'Open', and 'Close' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

**chosc — Chaikin oscillator**

matrix | table | timetable

Chaikin oscillator, returned with the same number of rows (M) and type (matrix, table, or timetable) as the input **Data**.

## References

# chaikvolat

Chaikin volatility

**Note** Using a `fints` object for the `Data` argument of `chaikvolat` is not recommended. Use a matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

## Syntax

```
volatility = chaikvolat(Data)
volatility = chaikvolat(___,Name,Value)
```

## Description

`volatility = chaikvolat(Data)` calculates the Chaikin volatility from a data series of high and low stock prices.

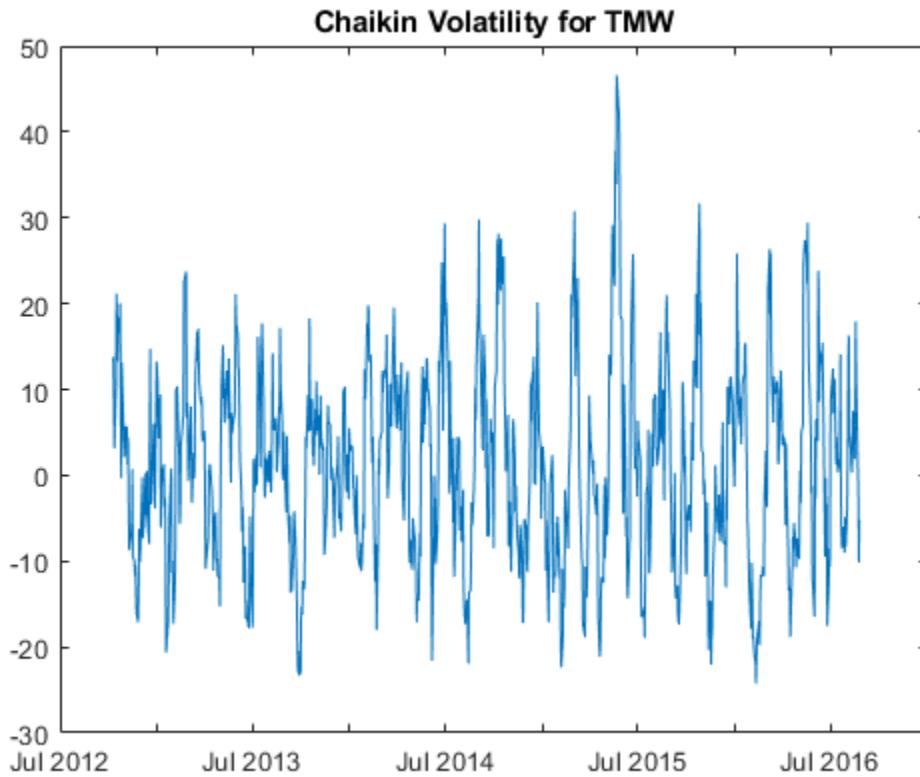

`volatility = chaikvolat(___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Calculate the Chaikin Volatility for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
volatility = chaikvolat(TMW,'NumPeriods',14,'WindowSize',14);
plot(volatility.Time,volatility.ChaikinVolatility)
title('Chaikin Volatility for TMW')
```

## Input Arguments

### Data — Data with high, low, open, close information

matrix | table | timetable

Data with high, low, open, close information, specified as a vector, matrix, table, or timetable. For matrix input, Data is an M-by-2 matrix of high and low prices stored in the first and second columns. Timetables and tables with M rows must contain variables named 'High' and 'Low' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, ..., NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `volatility = chaikvolat(TMW, 'NumPeriods', 10, 'WindowSize', 10)`

### NumPeriods — Period difference

10 (default) | positive integer

Period difference, specified as the comma-separated pair consisting of 'NumPeriods' and a scalar positive integer.

Data Types: double

#### **WindowSize — Length of the exponential moving average in periods**

10 (default) | positive integer

Length of the exponential moving average in periods, specified as the comma-separated pair consisting of 'WindowSize' and a scalar positive integer.

Data Types: double

## **Output Arguments**

### **volatility — Chaikin volatility**

matrix | table | timetable

Chaikin volatility, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## **More About**

### **Chaikin volatility**

Chaikin volatility calculates the Chaikin's volatility from the series of high and low stock prices.

By default, Chaikin's volatility values are based on a 10-period exponential moving average and 10-period difference.

## **References**

### **Introduced before R2006a**

## chartfts

Interactive display

---

**Note** `chartfts` will be removed in a future release and will no longer accept a `fints` object.

Use `fts2timetable` to convert a `fints` object to a `timetable` object. For more information, see “[Convert Financial Time Series Objects fints to Timetables](#)”.

---

### Syntax

```
chartfts(tsobj)
```

### Description

`chartfts(tsobj)` produces a figure window that contains one or more plots. You can use the mouse to observe the data at a particular time point of the plot.

---

**Note** Help menu item is not available for `chartfts` in MATLAB Online.

---

### Examples

Create a financial time series object from the supplied data file `ibm9599.dat`:

```
ibmfts = ascii2fts('ibm9599.dat', 1, 3, 2);
```

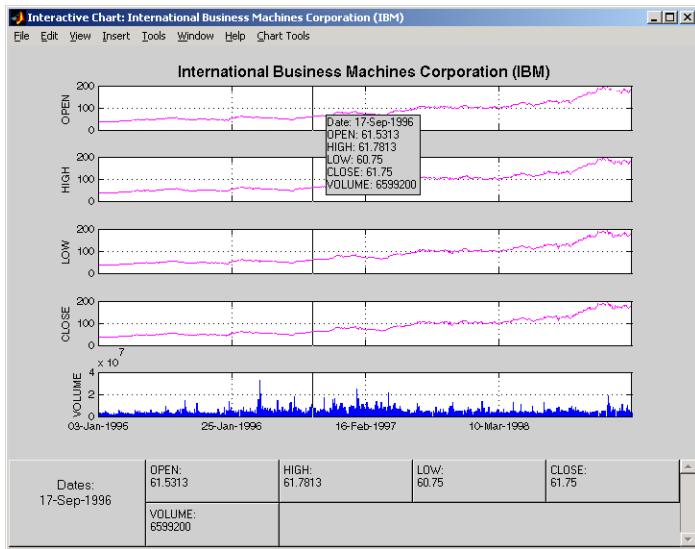

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
  > In `ascii2fts` (line 64)

Chart the financial time series object `ibmfts`:

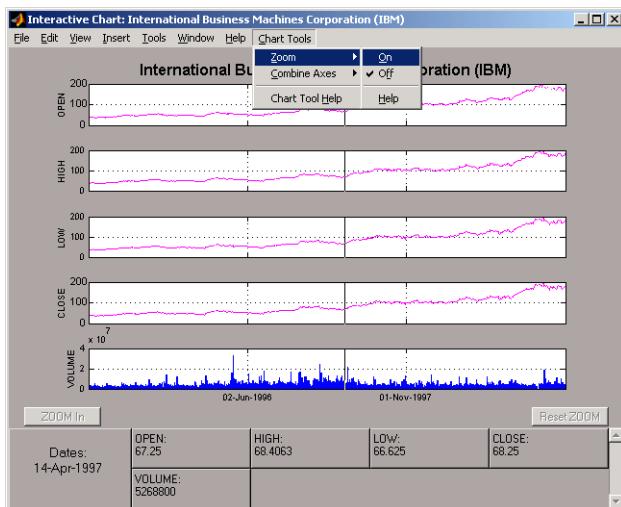

```
chartfts(ibmfts)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
  > In `fints/chartfts` (line 24)

With the **Zoom** feature set off, a mouse click on the indicator line displays object data in a pop-up box.

With the **Zoom** feature set on, mouse clicks indicate the area of the chart to zoom.

You can find a tutorial on using `chartfts` in “Visualizing Financial Time Series Objects” on page 11-24. See “Zoom Tool” on page 11-26 for details on performing the zoom. Also see “Combine Axes Tool” on page 11-29 for information about combining axes for specified plots.

## checkFeasibility

Check feasibility of input portfolios against portfolio object

### Syntax

```
status = checkFeasibility(obj,pwgt)
```

### Description

`status = checkFeasibility(obj,pwgt)` checks the feasibility of input portfolios against a portfolio object.

Use the `checkFeasibility` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to check the feasibility of input portfolios against a portfolio object. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-15, and “PortfolioMAD Object Workflow” on page 6-15.

### Examples

#### Determine if the Portfolio Is Feasible for a Portfolio Object

Given portfolio `p`, determine if `p` is feasible.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p);

checkFeasibility(p, pwgt)

ans = 1x10 logical array
```

1    1    1    1    1    1    1    1    1    1

#### Determine if the Portfolio Is Feasible for a PortfolioCVaR Object

Given portfolio `p`, determine if `p` is feasible.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
```

```

0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontier(p);

checkFeasibility(p, pwgt)

ans = 1x10 logical array

1 1 1 1 1 1 1 1 1 1

```

### Determine if the Portfolio Is Feasible for a PortfolioMAD Object

Given portfolio p, determine if p is feasible.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt = estimateFrontier(p);

checkFeasibility(p, pwgt)

ans = 1x10 logical array

1 1 1 1 1 1 1 1 1 1

```

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

**pwgt — Portfolios to check**

matrix

Portfolios to check, specified as a `NumAssets`-by-`NumPorts` matrix.

Data Types: double

## Output Arguments

**status — Indicator if portfolio is feasible**

row vector

Indicator if portfolio is feasible, returned as a row vector of `NumPorts` indicators that are `true` if portfolio is feasible and `false` otherwise.

---

**Note** By definition, any portfolio set must be nonempty and bounded. If the set is empty, no portfolios can be feasible. Use `estimateBounds` to test for nonempty and bounded sets.

---

Feasibility status is returned for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

## Tips

- You can also use dot notation to check the feasibility of input portfolios against a portfolio object.

```
status = obj.checkFeasibility(pwgt);
```
- The constraint tolerance to assess whether a constraint is satisfied is obtained from the hidden property `obj.defaultTolCon`.

## chfield

Change data series name

---

**Note** `chfield` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = chfield(olddf, oldname, newname)
```

### Description

`newfts = chfield(olddf, oldname, newname)` changes the name of the financial time series object component from `oldname` to `newname`.

Set `newfts = olddf` to change the name of an existing component without changing the name of the financial time series object.

To change the names of several components at once, specify the series of old and new component names in corresponding column cell arrays.

You cannot change the names of the object components `desc`, `freq`, and `dates`.

### Examples

#### Change Data Series Name

- 1 Create a `fints` object.

```
f = fints((today:today+1)', [4 -2 1; 9 5 7])  
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints (line 165)  
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/display (line 66)  
f =  
  
desc: (none)  
freq: Unknown (0)  
  
'dates: (2)'    'series1: (2)'    'series2: (2)'    'series3: (2)'  
'02-Oct-2017'   [           4]   [          -2]   [            1]  
'03-Oct-2017'   [           9]   [           5]   [            7]
```

- 2 Change a data series name using `chfield`.

```
newfts = chfield(f, 'series2', 'series2A')  
newfts =
```

```

desc: (none)
freq: Unknown (0)

{'dates: (2)'}    {'series1: (2)'}    {'series2A: (2)'}    {'series3: (2)'}
{'03-Sep-2021'}    {[        4]}    {[      -2]}    {[      1]}
{'04-Sep-2021'}    {[        9]}    {[      5]}    {[      7]}

```

## Input Arguments

### **oldfts — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

### **oldname — Name of the existing component in oldfts**

character vector | cell array of character vectors

Name of the existing component in `oldfts`, specified as a MATLAB character vector or column cell array.

Data Types: char | cell

### **newname — New name for the component in oldfts**

character vector | cell array of character vectors

New name for the component in `oldfts`, specified as a MATLAB character vector or column cell array.

Data Types: char | cell

## Output Arguments

### **newfts — Financial time series object**

fints object

Financial time series object, returned as a `fints` object.

## See Also

`fieldnames` | `isfield` | `rmfield`

## Introduced before R2006a

## convert2sur

Convert multivariate normal regression model to seemingly unrelated regression (SUR) model

### Syntax

```
DesignSUR = convert2sur(Design,Group)
```

### Description

DesignSUR = convert2sur(Design,Group) converts a multivariate normal regression model into a seemingly unrelated regression model with a specified grouping of the data series.

### Examples

#### Use convert2sur to Estimate Stock Alpha and Beta Values

This example shows a CAPM demonstration using 6 stocks and 60 months of simulated asset returns, where the model for each stock is `AssetReturn = Alpha * 1 + CashReturn + Beta * (MarketReturn - CashReturn) + Noise` and the parameters to estimate are `Alpha` and `Beta`.

Using simulated data, where the `Alpha` estimate(s) are displayed in the first row(s) and the `Beta` estimate(s) are display in the second row(s).

```
Market = (0.1 - 0.04) + 0.17*randn(60, 1);
Asset = (0.1 - 0.04) + 0.35*randn(60, 6);

Design = cell(60, 1);
for i = 1:60
    Design{i} = repmat([ 1, Market(i) ], 6, 1);
end
```

Obtain the aggregate estimates for all stocks.

```
[Param, Covar] = mvnrmle(Asset, Design);

disp({'All 6 Assets Combined'});
{'All 6 Assets Combined'}

disp(Param);

0.0233
0.1050
```

Estimate parameters for individual stocks using convert2sur

```
Group = 1:6;
DesignSUR = convert2sur(Design, Group);
[Param, Covar] = mvnrmle(Asset, DesignSUR);
Param = reshape(Param, 2, 6);

disp({ 'A', 'B', 'C', 'D', 'E', 'F' });
```

```

{'A'}    {'B'}    {'C'}    {'D'}    {'E'}    {'F'}
disp(Param);

0.0144    0.0270    0.0046    0.0419    0.0376    0.0291
0.3264   -0.1716    0.3248   -0.0630   -0.0001    0.0637

Estimate parameters for pairs of stocks by forming groups.

disp({'A & B', 'C & D', 'E & F'});
{'A & B'}    {'C & D'}    {'E & F'}

Group = { [1,2 ],[3,4],[5,6]};
DesignSUR = convert2sur(Design, Group);
[Param, Covar] = mvnrmle(Asset, DesignSUR);

Param = reshape(Param, 2, 3);

disp(Param);

0.0186    0.0190    0.0334
0.0988    0.1757    0.0293

```

## Input Arguments

### Design — Data series

matrix | cell array

Data series, specified as a matrix or a cell array that depends on the number of data series NUMSERIES.

- If NUMSERIES = 1, convert2sur returns the Design matrix.
- If NUMSERIES > 1, Design is a cell array with NUMSAMPLES cells, where each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.

Data Types: double | cell

### Group — Grouping for data series

vector | cell array

Grouping for data series, specified using separate parameters for each group. Specify groups either by series or by groups:

- To identify groups by series, construct an index vector that has NUMSERIES elements. Element  $i = 1, \dots, \text{NUMSERIES}$  in the vector, and has the index  $j = 1, \dots, \text{NUMGROUPS}$  of the group in which series  $i$  is a member.
- To identify groups by groups, construct a cell array with NUMGROUPS elements. Each cell contains a vector with the indexes of the series that populate a given group.

In either case, the number of series is NUMSERIES and the number of groups is NUMGROUPS, with  $1 \leq \text{NUMGROUPS} \leq \text{NUMSERIES}$ .

Data Types: double | cell

## Output Arguments

**DesignSUR — Seemingly unrelated regression model with a specified grouping of the data series**

matrix | cell array

Seemingly unrelated regression model with a specified grouping of the data series, returned as either a matrix or a cell array that depends on the value of `NUMSERIES`.

- If `NUMSERIES` = 1, `DesignSUR` = `Design`, which is a `NUMSAMPLES`-by-`NUMPARAMS` matrix.
- If `NUMSERIES` > 1 and `NUMGROUPS` groups are to be formed, `Design` is a cell array with `NUMSAMPLES` cells, where each cell contains a `NUMSERIES`-by-(`NUMGROUPS` \* `NUMPARAMS`) matrix of known values.

The original collection of parameters that are common to all series are replicated to form collections of parameters for each group.

**Introduced in R2006a**

# convertto

Convert to specified frequency

---

**Note** `convertto` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = convertto(olddf, newfreq)
```

## Description

`newfts = convertto(olddf, newfreq)` converts the object `olddf` to the new time series object `newfts` with the frequency `newfreq`.

## Examples

### Convert to Specified Frequency

- Create a `fints` object.

```
dates_and_times = (now:now+5)'
dates_and_times =
1.0e+05 *
7.3840
7.3840
7.3840
7.3841
7.3841
7.3841
```

```
f = fints(dates_and_times, randn(6,1))
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see Convert F

> In `fints` (line 169)

```
f =
desc: (none)
freq: Unknown (0)

{'dates: (6)'}    {'times: (6)'}    {'series1: (6)'}
{'03-Sep-2021'}  {'12:06'}        {[      -0.7697]}

```

## Input Arguments

### **oldfts — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

### **newfreq — New frequency indicator**

character vector | numeric

New frequency indicator, specified using one of the allowed values:

- 1, 'DAILY', 'Daily', 'daily', 'D', 'd'
- 2, 'WEEKLY', 'Weekly', 'weekly', 'W', 'w'
- 3, 'MONTHLY', 'Monthly', 'monthly', 'M', 'm'
- 4, 'QUARTERLY', 'Quarterly', 'quarterly', 'Q', 'q'
- 5, 'SEMIANNUAL', 'Semiannual', 'semiannual', 'S', 's'
- 6, 'ANNUAL', 'Annual', 'annual', 'A', 'a'

Data Types: char | double

## Output Arguments

### **newfts — Financial time series object**

fints object

Financial time series object, returned as a `fints` object.

## See Also

`toannual` | `todaily` | `tomonthly` | `toquarterly` | `tosemi` | `toweekly`

# corrcoef

Correlation coefficients for financial time series object

---

**Note** `corrcoef` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
r = corrcoef(X)
r = corrcoef(X,Y)
[r,p] = corrcoef(____)
[r,p,rlo,rup] = corrcoef(____)
[r,p,rlo,rup] = corrcoef(____,Name,Value)
```

## Description

`r = corrcoef(X)` calculates a matrix `r` of correlation coefficients for a financial times series object (`fints`) `X`, in which each row is an observation, and each column is a variable.

`corrcoef` is based on the MATLAB `corrcoef` function. See `corrcoef`.

`r = corrcoef(X,Y)` where `X` and `Y` are financial time series objects as column vectors, is the same as `r=corrcoef([X Y])`. `corrcoef` converts `X` and `Y` to column vectors if they are not; that is, `r = corrcoef(X,Y)` is equivalent to `r=corrcoef([X(:) Y(:)])` in that case.

If `c` is the covariance matrix, `c= cov(X)`, then `corrcoef(X)` is the matrix whose  $(i,j)$  'th element is  $c_{i,j}/\sqrt{c_{i,i}c_{j,j}}$ .

`[r,p] = corrcoef(____)` returns `p`, a matrix of p-values for testing the hypothesis of no correlation. Each p-value is the probability of getting a correlation as large as the observed value by random chance, when the true correlation is zero. If  $p(i,j)$  is less than 0.05, then the correlation  $r(i,j)$  is significant.

`[r,p,rlo,rup] = corrcoef(____)` returns matrices `rlo` and `rup`, of the same size as `r`, containing lower and upper bounds for a 95% confidence interval for each coefficient.

`[r,p,rlo,rup] = corrcoef(____,Name,Value)` specifies additional name-value arguments.

## Examples

### Compute Correlation Coefficients

This example shows how to generate random data having correlation between column 4 and the other columns.

```
x = randn(30,4);          % uncorrelated data
x(:,4) = sum(x,2);        % introduce correlation
f = fints((today:today+29)', x); % create a fints object using x
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat

[r,p] = corrcoef(x);      % compute sample correlation and p-values
[i,j] = find(p<0.05);   % find significant correlations
[i,j]                      % display their (row,col) indices

ans = 4x2

4     1
3     2
2     3
1     4
```

Class support for inputs X,Y: float: double and single.

## Input Arguments

### X — Financial time series object

fints object

Financial time series object, specified as a `fints` object where each row is an observation and each column is a variable.

Data Types: object

### Y — Financial time series object

fints object

Financial time series object, specified as a `fints` object where each row is an observation and each column is a variable.

Data Types: object

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[r,p] = corrcoef(x,y,'Alpha',0.5)`

### alpha — Confidence level

0.05 (95% confidence intervals) (default) | numeric from 0 to 1

Confidence level, specified as the comma-separated pair consisting of '`alpha`' and a numeric from 0 through 1 to specify a confidence level of  $100*(1-\text{ALPHA})\%$ .

Data Types: double

### rows — Define rows

'all' (default) | character vector with value of 'all', 'complete', or 'pairwise'

Define rows, specified as the comma-separated pair consisting of '`rows`' and a character vector with one of the following:

- 'all' — use all rows
- 'complete' — use rows with no NaN values
- 'pairwise' — compute  $r(i,j)$  using rows with no NaN values in column  $i$  or  $j$

Data Types: char

## Output Arguments

### **r — Correlation coefficients**

matrix

Correlation coefficients, returned as a matrix.

### **p — p-value**

matrix

p-value, returned as a matrix.

The  $p$ -value is computed by transforming the correlation to create a t-statistic having  $N - 2$  degrees of freedom, where  $N$  is the number of rows of  $X$ . The confidence bounds are based on an asymptotic normal distribution of  $0.5\log((1 + r)/(1 - r))$ , with an approximate variance equal to  $1/(N - 3)$ . These bounds are accurate for large samples when  $X$  has a multivariate normal distribution. The 'pairwise' option can produce an  $r$  matrix that is not positive definite.

### **rlo — Lower bounds for a 95% confidence interval for each coefficient**

matrix

Lower bounds for a 95% confidence interval for each coefficient, returned as a matrix.

### **rup — Upper bounds for a 95% confidence interval for each coefficient**

matrix

Upper bounds for a 95% confidence interval for each coefficient, returned as a matrix.

## corr2cov

Convert standard deviation and correlation to covariance

### Syntax

```
ExpCovariance = corr2cov(ExpSigma)
ExpCovariance = corr2cov(_____,ExpCorrC)
```

### Description

`ExpCovariance = corr2cov(ExpSigma)` converts standard deviation and correlation to covariance.

`ExpCovariance = corr2cov(_____,ExpCorrC)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Convert Standard Deviation and Correlation to Covariance

This example shows how to convert standard deviation and correlation to covariance.

```
ExpSigma = [0.5  2.0];
ExpCorrC = [1.0 -0.5
            -0.5  1.0];
ExpCovariance = corr2cov(ExpSigma, ExpCorrC)
ExpCovariance = 2×2
    0.2500    -0.5000
   -0.5000     4.0000
```

### Input Arguments

**ExpSigma — Standard deviations of each process**  
vector

Standard deviations of each process, specified as a vector of length  $n$  with the standard deviations of each process.  $n$  is the number of random processes.

Data Types: double

**ExpCorrC — Correlation matrix**  
matrix

(Optional) Correlation matrix, specified as an  $n$ -by- $n$  correlation coefficient matrix. A correlation coefficient is a statistic in which the covariance is scaled to a value between minus one (perfect negative correlation) and plus one (perfect positive correlation).

If `ExpCorrC` is not specified, the processes are assumed to be uncorrelated, and the identity matrix is used.

Data Types: `double`

## Output Arguments

### **ExpCovariance — Covariance matrix**

matrix

Covariance matrix, returned as an  $n$ -by- $n$  covariance matrix, where  $n$  is the number of processes.

The  $(i,j)$  entry is the expectation of the  $i$ 'th fluctuation from the mean times the  $j$ 'th fluctuation from the mean.

```
ExpCov(i,j) = ExpCorrC(i,j)*ExpSigma(i)*ExpSigma(j)
```

## COV

Covariance matrix for financial time series object

---

**Note** `cov` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

### Syntax

```
cov(X)  
cov(X)  
cov(X, 1)  
cov(X, Y)  
cov(X, Y, 1)
```

### Description

`cov(X)` returns a variance or covariance matrix.

If  $X$  is a financial time series object with one series, `cov(X)` returns the variance. For a financial time series object containing multiple series, where each row is an observation, and each series a variable, `cov(X)` is the covariance matrix.

`diag(cov(X))` is a vector of variances for each series and `sqrt(diag(cov(X)))` is a vector of standard deviations.

`cov(X)` normalizes by  $(N - 1)$  if  $N > 1$ , where  $N$  is the number of observations. This makes `cov(X)` the best unbiased estimate of the covariance matrix if the observations are from a normal distribution. For  $N = 1$ , `cov` normalizes by  $N$ .

`cov` for financial time series objects is based on the MATLAB `cov` function. See `cov`.

`cov(X, 1)` normalizes by  $N$  and produces the second moment matrix of the observations about their mean. `cov(X, Y, 0)` is the same as `cov(X, Y)` and `cov(X, 0)` is the same as `cov(X)`. The mean is removed from each column before calculating the result.

`cov(X, Y)` normalizes by  $N$  and produces the second moment of the sample about its mean. `var(X, 0)` is the same as `var(X)`.

`cov(X, Y)` normalizes by  $(N - 1)$  if  $N > 1$ , where  $N$  is the number of observations. This makes `cov(X, Y)` the best unbiased estimate of the covariance matrix if the observations are from a normal distribution. For  $N = 1$ , `cov` normalizes by  $N$ . `cov(X, Y)`, where  $X$  and  $Y$  are financial time series objects with the same number of elements, is equivalent to `cov([X(:) Y(:)])`.

`cov(X, Y, 1)` normalizes by  $N$  and produces the second moment matrix of the observations about their mean. `cov(X, Y, 0)` is the same as `cov(X, Y)` and `cov(X, 0)` is the same as `cov(X)`. The mean is removed from each column before calculating the result.

### Examples

## Create a Covariance Matrix

This example shows how to create a covariance matrix for the following dates.

```
dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
A = [-1 1 2 ; -2 3 1 ; 4 0 3];
f = fints(dates, A);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see ["matlab.finance.FINTS"](#).

```
c = cov(f)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see ["matlab.finance.FINTS"](#).

```
c = 3x3
```

|         |         |         |
|---------|---------|---------|
| 10.3333 | -4.1667 | 3.0000  |
| -4.1667 | 2.3333  | -1.5000 |
| 3.0000  | -1.5000 | 1.0000  |

## Input Arguments

### X — Financial time series object

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

### Y — Financial time series object

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

## cov2corr

Convert covariance to standard deviation and correlation coefficient

### Syntax

```
[ExpSigma,ExpCorrC] = cov2corr(ExpCovariance)
```

### Description

[ExpSigma,ExpCorrC] = cov2corr(ExpCovariance) converts covariance to standard deviations and correlation coefficients.

### Examples

#### Convert Covariance to Standard Deviations and Correlation Coefficients

This example shows how to convert a covariance matrix to standard deviations and correlation coefficients.

```
ExpCovariance = [0.25 -0.5  
                 -0.5    4.0];
```

```
[ExpSigma, ExpCorrC] = cov2corr(ExpCovariance)
```

```
ExpSigma = 1x2
```

```
0.5000    2.0000
```

```
ExpCorrC = 2x2
```

```
1.0000    -0.5000  
-0.5000    1.0000
```

### Input Arguments

**ExpCovariance — Covariance matrix**  
matrix

Covariance matrix, specified as an n-by-n covariance matrix, where n is the number of random processes. For an example, see cov or ewstats.

Data Types: double

### Output Arguments

**ExpSigma — Standard deviation of each process**  
vector

Standard deviation of each process, returned as an 1-by-n vector.

The entries of `ExpCorrC` range from 1 (completely correlated) to -1 (completely anti-correlated). A value of 0 in the  $(i,j)$  entry indicates that the  $i$ 'th and  $j$ 'th processes are uncorrelated.

```
ExpSigma(i) = sqrt( ExpCovariance(i,i) );
ExpCorrC(i,j) = ExpCovariance(i,j)/( ExpSigma(i)*ExpSigma(j) );
```

Data Types: double

### **ExpCorrC — Correlation coefficients**

matrix

Correlation coefficients, returned as an n-by-n matrix.

## cpncount

Coupon payments remaining until maturity

### Syntax

```
NumCouponsRemaining = cpncount(Settle,Maturity)
NumCouponsRemaining = cpncount(___,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

### Description

`NumCouponsRemaining = cpncount(Settle,Maturity)` returns the whole number of coupon payments between the `Settle` and `Maturity` dates for a coupon bond or set of bonds. Coupons falling on or before `Settle` are not counted, except for the `Maturity` payment which is always counted.

Required input arguments must be number of bonds, `NUMBONDS`-by-1 or 1-by-`NUMBONDS`, conforming vectors or scalars.

`NumCouponsRemaining = cpncount(___,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` returns the whole number of coupon payments between the `Settle` and `Maturity` dates for a coupon bond or set of bonds using optional input arguments.

Optional input arguments must be either `NUMBONDS`-by-1 or 1-by-`NUMBONDS` conforming vectors, scalars, or empty matrices.

### Examples

#### Find Coupon Payments Remaining Until Maturity

This example shows how to find the coupon payments remaining until maturity.

```
NumCouponsRemaining = cpncount('14 Mar 1997', '30 Nov 2000',...
2, 0, 0)
NumCouponsRemaining = 8
```

#### Find Coupon Payments Remaining Until Maturity for Different Maturity Dates

This example shows how to find the coupon payments remaining until maturity, given three coupon bonds with different maturity dates and the same default arguments.

```
Maturity = ['30 Sep 2000'; '31 Oct 2001'; '30 Nov 2002'];
NumCouponsRemaining = cpncount('14 Sep 1997', Maturity)
NumCouponsRemaining = 3×1
```

9  
11

## Input Arguments

### **Settle — Settlement date**

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array.  
**Settle** must be earlier than **Maturity**.

Data Types: double | char | datetime

### **Maturity — Maturity date**

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Period — Coupons per year of the bond**

2 (semiannual) (default) | vector of positive integers from the set [1,2,3,4,6,12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1,2,3,4,6,12].

Data Types: double

### **Basis — Day-count basis of the bond**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the bond, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

**EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag for month having 30 or fewer days, specified as scalar nonnegative integer [0, 1] or a using an N-by-1 vector of values. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

**FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

**FirstCouponDate** is used when a bond has an irregular first coupon period. When **FirstCouponDate** and **LastCouponDate** are both specified, **FirstCouponDate** takes precedence in determining the coupon payment structure. If you do not specify a **FirstCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

**LastCouponDate** is used when a bond has an irregular last coupon period. In the absence of a specified **FirstCouponDate**, a specified **LastCouponDate** determines the coupon structure of the bond. The coupon structure of a bond is truncated at the **LastCouponDate**, regardless of where it falls, and is followed only by the bond’s maturity cash flow date. If you do not specify a **LastCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

## Output Arguments

**NumCouponsRemaining — Whole number of coupon payments between the settlement and maturity dates for a coupon bond or set of bonds**  
vector

Whole number of coupon payments between the settlement and maturity dates for a coupon bond or set of bonds, returned as an NBONDS-by-1 vector.

Coupons falling on or before settlement are not counted, except for the maturity payment which is always counted.

## Topics

“Pricing and Computing Yields for Fixed-Income Securities” on page 2-18

## Introduced before R2006a

## cpndaten

Next coupon date for fixed-income security

### Syntax

```
NextCouponDate = cpndaten(Settle,Maturity)
NextCouponDate = cpndaten(_____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

### Description

`NextCouponDate = cpndaten(Settle,Maturity)` returns the next coupon date after the `Settle` date. This function finds the next coupon date whether or not the coupon structure is synchronized with the `Maturity` date.

Required input arguments must be number of bonds, `NUMBONDS`-by-1 or 1-by-`NUMBONDS`, conforming vectors or scalars.

`NextCouponDate = cpndaten(_____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)` returns the next coupon date after the `Settle` date using optional input arguments.

Optional input arguments must be either `NUMBONDS`-by-1 or 1-by-`NUMBONDS` conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NextCouponDate` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NextCouponDate` is returned as a datetime array.

### Examples

#### Calculate the Next Coupon Date After the Settlement Date

Determine the `NextCouponDate` when using character vectors for input arguments.

```
NextCouponDate = cpndaten('14-Mar-1997', '30-Nov-2000', 2, 0, 0);
datestr(NextCouponDate)

ans =
'30-May-1997'
```

Determine the `NextCouponDate` when using datetime arrays for input arguments.

```
NextCouponDate = cpndaten('14-Mar-1997', datetime('30-Nov-2000','Locale','en_US'),...
2, 0, 0)
```

```
NextCouponDate = datetime
30-May-1997
```

Determine the `NextCouponDate` when using character vectors for input arguments and the optional argument for `EndMonthRule`.

```
NextCouponDate = cpndaten('14-Mar-1997', '30-Nov-2000', 2, 0, 1);
datestr(NextCouponDate)

ans =
'31-May-1997'
```

Determine the `NextCouponDate` when using an input vector for `Maturity`.

```
Maturity = ['30-Sep-2000'; '31-Oct-2000'; '30-Nov-2000'];
NextCouponDate = cpndaten('14-Mar-1997', Maturity);
datestr(NextCouponDate)

ans = 3x11 char array
'31-Mar-1997'
'30-Apr-1997'
'31-May-1997'
```

## Input Arguments

### **Settle — Settlement date**

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array. `Settle` must be earlier than `Maturity`.

Data Types: double | char | datetime

### **Maturity — Maturity date**

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Period — Coupons per year of the bond**

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: single | double

### **Basis — Day-count basis of the bond**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the bond, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: `single` | `double`

**EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as scalar nonnegative integer [0, 1] or a using an N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: `logical`

**IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: `double` | `char` | `datetime`

**FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

LastCouponDate is used when a bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

## Output Arguments

**NextCouponDate — Next coupon date after the settlement date**

vector

Next coupon date after the settlement date, returned as an NUMBONDS-by-1 vector of next actual coupon dates after settlement. If settlement is a coupon date, this function never returns the settlement date. Instead, the actual coupon date strictly after settlement is returned, but not exceeding the maturity date. Thus, this function will always return the lesser of the actual maturity date and the next coupon payment date.

If all the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are either serial date numbers or date character vectors, then NextCouponDate is returned as a serial date number. The function datestr converts a serial date number to a formatted date character vector.

If any of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are datetime arrays, then NextCouponDate is returned as a datetime array.

## cpndatenq

Next quasi-coupon date for fixed-income security

### Syntax

```
NextQuasiCouponDate = cpndatenq(Settle,Maturity)
NextQuasiCouponDate = cpndatenq(____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

### Description

`NextQuasiCouponDate = cpndatenq(Settle,Maturity)` determines the next quasi coupon date for a portfolio of NUMBONDS fixed income securities whether or not the first or last coupon is normal, short, or long. For zero coupon bonds, `cpndatenq` returns quasi coupon dates as if the bond had a semiannual coupon structure. Successive quasi coupon dates determine the length of the standard coupon period for the fixed income security of interest and do not necessarily coincide with actual coupon payment dates.

Required input arguments must be number of bonds, NUMBONDS-by-1 or 1-by-NUMBONDS, conforming vectors or scalars.

`NextQuasiCouponDate = cpndatenq(____,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` determines the next quasi coupon date for a portfolio of NUMBONDS fixed income securities whether or not the first or last coupon is normal, short, or long using optional input arguments.

Optional input arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NextQuasiCouponDate` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NextQuasiCouponDate` is returned as a datetime array.

### Examples

#### Determine the Next Quasi Coupon Date for a Portfolio of Fixed-Income Securities

Given a pair of bonds with the following characteristics:

```
Settle = char('30-May-1997','10-Dec-1997');
Maturity = char('30-Nov-2002','10-Jun-2004');
```

Compute `NextCouponDate` for this pair of bonds.

```
NextCouponDate = cpndatenq(Settle, Maturity);
datestr(NextCouponDate)
```

```
ans = 2x11 char array
'31-May-1997'
'10-Jun-1998'
```

Compute the next quasi coupon dates for these two bonds.

```
NextQuasiCouponDate = cpndatenq(Settle, Maturity);
datestr(NextQuasiCouponDate)

ans = 2x11 char array
'31-May-1997'
'10-Jun-1998'
```

Because no `FirstCouponDate` has been specified, the results are identical.

Now supply an explicit `FirstCouponDate` for each bond.

```
FirstCouponDate = char('30-Nov-1997', '10-Dec-1998');
```

Compute the next coupon dates.

```
NextCouponDate = cpndaten(Settle, Maturity, 2, 0, 1, [], ...
FirstCouponDate);
datestr(NextCouponDate)

ans = 2x11 char array
'30-Nov-1997'
'10-Dec-1998'
```

The next coupon dates are identical to the specified first coupon dates.

Now recompute the next quasi coupon dates.

```
NextQuasiCouponDate = cpndatenq(Settle, Maturity, 2, 0, 1, [], ...
FirstCouponDate);
datestr(NextQuasiCouponDate)

ans = 2x11 char array
'31-May-1997'
'10-Jun-1998'
```

These results illustrate the distinction between actual coupon payment dates and quasi coupon dates. `FirstCouponDate` (and `LastCouponDate`, as well), when specified, is associated with an actual coupon payment and also serves as the synchronization date for determining all quasi coupon dates. Since each bond in this example pays semiannual coupons, and the first coupon date occurs more than six months after settlement, each will have an intermediate quasi coupon date before the actual first coupon payment occurs.

## Input Arguments

### **Settle — Settlement date**

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array.  
**Settle** must be earlier than **Maturity**.

Data Types: double | char | datetime

**Maturity — Maturity date**

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**Period — Coupons per year of the bond**

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: single | double

**Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: single | double

**EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond's coupon payment date is always the last actual day of the month.

Data Types: logical

#### **IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

#### **FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

**FirstCouponDate** is used when a bond has an irregular first coupon period. When **FirstCouponDate** and **LastCouponDate** are both specified, **FirstCouponDate** takes precedence in determining the coupon payment structure. If you do not specify a **FirstCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

#### **LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

**LastCouponDate** is used when a bond has an irregular last coupon period. In the absence of a specified **FirstCouponDate**, a specified **LastCouponDate** determines the coupon structure of the bond. The coupon structure of a bond is truncated at the **LastCouponDate**, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a **LastCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

## **Output Arguments**

#### **NextQuasiCouponDate — Next quasi coupon date for portfolio of NUMBONDS fixed income securities**

vector

Next quasi coupon date for a portfolio of NUMBONDS fixed income securities, whether or not the first or last coupon is normal, short, or long, returned as a NUMBONDS-by-1 vector.

For zero coupon bonds, **cpndatenq** returns quasi coupon dates as if the bond had a semiannual coupon structure. Successive quasi coupon dates determine the length of the standard coupon period

for the fixed income security of interest and do not necessarily coincide with actual coupon payment dates.

If all of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NextQuasiCouponDate` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NextQuasiCouponDate` is returned as a datetime array.

## Topics

“Pricing and Computing Yields for Fixed-Income Securities” on page 2-18

## Introduced before R2006a

# cpndatepq

Previous quasi-coupon date for fixed-income security

## Syntax

```
PreviousQuasiCouponDate = cpndatepq(Settle,Maturity)
PreviousQuasiCouponDate = cpndatepq(____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

## Description

`PreviousQuasiCouponDate = cpndatepq(Settle,Maturity)` determines the previous quasi-coupon date for a set of NUMBONDS fixed income securities. Prior quasi-coupon dates determine the length of the standard coupon period for the fixed income security of interest, and do not necessarily coincide with actual coupon payment dates. This function finds the previous quasi-coupon date for bonds with a coupon structure whose first or last period is either normal, short, or long.

Required input arguments must be number of bonds, NUMBONDS-by-1 or 1-by-NUMBONDS, conforming vectors or scalars.

`PreviousQuasiCouponDate = cpndatepq(____,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)`, using optional input arguments, determines the previous quasi-coupon date for a set of NUMBONDS fixed income securities.

Optional input arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `PreviousQuasiCouponDate` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `PreviousQuasiCouponDate` is returned as a datetime array.

## Examples

### Determine the Previous Quasi Coupon Date for a Portfolio of Fixed-Income Securities

Given a pair of bonds with the following characteristics:

```
Settle = char('30-May-1997','10-Dec-1997');
Maturity = char('30-Nov-2002','10-Jun-2004');
```

With no `FirstCouponDate` explicitly supplied, compute the `PreviousCouponDate` for this pair of bonds.

```
PreviousCouponDate = cpndatep(Settle, Maturity);
datestr(PreviousCouponDate)
```

```
ans = 2x11 char array
      '30-Nov-1996'
      '10-Dec-1997'
```

Note that since the settlement date for the second bond is also a coupon date, `cpndatep` returns this date as the previous coupon date.

Now establish a `FirstCouponDate` and `IssueDate` for this pair of bonds.

```
FirstCouponDate = char('30-Nov-1997', '10-Dec-1998');
IssueDate = char('30-May-1996', '10-Dec-1996');
```

Recompute the `PreviousCouponDate` for this pair of bonds.

```
PreviousCouponDate = cpndatep(Settle, Maturity, 2, 0, 1, ...
IssueDate, FirstCouponDate);
datestr(PreviousCouponDate)
```

```
ans = 2x11 char array
      '30-May-1996'
      '10-Dec-1996'
```

Since both of these bonds settled before the first coupon had been paid, `cpndatep` returns the `IssueDate` as the `PreviousCouponDate`.

Using the same data, compute `PreviousQuasiCouponDate`.

```
PreviousQuasiCouponDate = cpndatepq(Settle, Maturity, 2, 0, 1, ...
IssueDate, FirstCouponDate);
datestr(PreviousQuasiCouponDate)
```

```
ans = 2x11 char array
      '30-Nov-1996'
      '10-Dec-1997'
```

For the first bond the settlement date is not a normal coupon date. The `PreviousQuasiCouponDate` is the coupon date before or on the settlement date. Since the coupon structure is synchronized to `FirstCouponDate`, the previous quasi coupon date is `30-Nov-1996`. `PreviousQuasiCouponDate` disregards `IssueDate` and `FirstCouponDate` in this case. For the second bond the settlement date (`10-Dec-1997`) occurs on a date when a coupon would normally be paid in the absence of an explicit `FirstCouponDate`. `cpndatepq` returns this date as `PreviousQuasiCouponDate`.

## Input Arguments

### Settle — Settlement date

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array. `Settle` must be earlier than `Maturity`.

Data Types: double | char | datetime

### Maturity — Maturity date

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**Period — Coupons per year of the bond**

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: single | double

**Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: single | double

**EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

**FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

`LastCouponDate` is used when a bond has an irregular last coupon period. In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

## Output Arguments

**PreviousQuasiCouponDate — Previous quasi coupon date for portfolio of NUMBONDS fixed income securities**

vector

Previous quasi coupon date for a portfolio of `NUMBONDS` fixed income securities, whether or not the first or last coupon is normal, short, or long, returned as a `NUMBONDS`-by-1 vector of previous quasi-coupon dates before settlement. If settlement is a coupon date, this function returns the settlement date.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `PreviousQuasiCouponDate` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `PreviousQuasiCouponDate` is returned as a datetime array.

**Introduced before R2006a**

## cpndatep

Previous coupon date for fixed-income security

### Syntax

```
PreviousCouponDate = cpndatep(Settle,Maturity)
PreviousCouponDate = cpndatep(___,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

### Description

`PreviousCouponDate = cpndatep(Settle,Maturity)` returns the previous coupon date on or before settlement for a portfolio of bonds. This function finds the previous coupon date whether or not the coupon structure is synchronized with the maturity date. For zero coupon bonds the previous coupon date is the issue date, if available. However, if the issue date is not supplied, the previous coupon date for zero coupon bonds is the previous quasi coupon date calculated as if the frequency is semiannual.

Required input arguments must be number of bonds, `NUMBONDS`-by-1 or 1-by-`NUMBONDS`, conforming vectors or scalars.

`PreviousCouponDate = cpndatep(___,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` returns the previous coupon date on or before settlement for a portfolio of bonds.

Optional input arguments must be either `NUMBONDS`-by-1 or 1-by-`NUMBONDS` conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `PreviousCouponDate` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `PreviousCouponDate` is returned as a datetime array.

### Examples

#### Calculate the Previous Coupon Date on or Before Settlement

Determine the `PreviousCouponDate` when using character vectors for input arguments.

```
PreviousCouponDate = cpndatep('14-Mar-1997', '30-Jun-2000',...
2, 0, 0);
datestr(PreviousCouponDate)

ans =
'30-Dec-1996'
```

Determine the `PreviousCouponDate` when using datetime arrays for input arguments.

```
PreviousCouponDate = cpndatep(datetime('14-Mar-1997','Locale','en_US'), '30-Jun-2000',...
2, 0, 0)
```

```
PreviousCouponDate = datetime
30-Dec-1996
```

Determine the PreviousCouponDate when using character vectors for input arguments and the optional argument for EndMonthRule.

```
PreviousCouponDate = cpndatep('14-Mar-1997', '30-Jun-2000',...
2, 0, 1);
datestr(PreviousCouponDate)
```

```
ans =
'31-Dec-1996'
```

Determine the PreviousCouponDate when using an input vector for Maturity.

```
Maturity = ['30-Apr-2000'; '31-May-2000'; '30-Jun-2000'];
PreviousCouponDate = cpndatep('14-Mar-1997', Maturity);
datestr(PreviousCouponDate)
```

```
ans = 3x11 char array
'31-Oct-1996'
'30-Nov-1996'
'31-Dec-1996'
```

## Input Arguments

### Settle — Settlement date

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array. Settle must be earlier than Maturity.

Data Types: double | char | datetime

### Maturity — Maturity date

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### Period — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set [1,2,3,4,6,12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1,2,3,4,6,12].

Data Types: single | double

**Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: single | double

**EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond's coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

**FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

**FirstCouponDate** is used when a bond has an irregular first coupon period. When **FirstCouponDate** and **LastCouponDate** are both specified, **FirstCouponDate** takes precedence in determining the coupon payment structure. If you do not specify a **FirstCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

#### **LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

**LastCouponDate** is used when a bond has an irregular last coupon period. In the absence of a specified **FirstCouponDate**, a specified **LastCouponDate** determines the coupon structure of the bond. The coupon structure of a bond is truncated at the **LastCouponDate**, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a **LastCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

## Output Arguments

#### **PreviousCouponDate — Previous coupon date on or before settlement for portfolio of bonds**

vector

Previous coupon date on or before settlement for portfolio of bonds, returned as an NUMBONDS-by-1 vector. If settlement is a coupon date, this function returns the settlement date. The actual coupon date strictly on or before settlement is returned, but not exceeding the issue date, if available. Thus, this function always returns the lesser of the actual issue date and the previous coupon payment date with respect to the settlement date.

If all the inputs for **Settle**, **Maturity**, **IssueDate**, **FirstCouponDate**, and **LastCouponDate** are either serial date numbers or date character vectors, then **PreviousCouponDate** is returned as a serial date number. The function **datestr** converts a serial date number to a formatted date character vector.

If any of the inputs for **Settle**, **Maturity**, **IssueDate**, **FirstCouponDate**, and **LastCouponDate** are datetime arrays, then **PreviousCouponDate** is returned as a datetime array.

## cpndaysn

Number of days to next coupon date

### Syntax

```
NumDaysNext = cpndaysn(Settle,Maturity)
NumDaysNext = cpndaysn(___,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

### Description

`NumDaysNext = cpndaysn(Settle,Maturity)` returns the number of days from the settlement date to the next coupon date for a bond or set of bonds. For zero coupon bonds coupon dates are computed as if the bonds have a semiannual coupon structure. `NumDaysNext` returns a double for serial date number, date character vector, and datetime inputs.

Required input arguments must be number of bonds, `NUMBONDS`-by-1 or 1-by-`NUMBONDS`, conforming vectors or scalars.

`NumDaysNext = cpndaysn(___,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` returns the number of days from the settlement date to the next coupon date for a bond or set of bonds using optional input arguments.

Optional input arguments must be either `NUMBONDS`-by-1 or 1-by-`NUMBONDS` conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NumDaysNext` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NumDaysNext` is returned as a datetime array.

### Examples

#### Calculate the Number of Days From Settlement Date to Next Coupon Date

Determine the `NumDaysNext` when using character vectors for input arguments.

```
NumDaysNext = cpndaysn('14-Sep-2000', '30-Jun-2001', 2, 0, 0)
```

```
NumDaysNext = 107
```

Determine the `NumDaysNext` when using datetime arrays for input arguments.

```
NumDaysNext = cpndaysn(datetime('14-Sep-2000','Locale','en_US'), '30-Jun-2001', 2, 0, 0)
```

```
NumDaysNext = 107
```

Determine the `NumDaysNext` when using character vectors for input arguments and the optional argument for `EndMonthRule`.

```
NumDaysNext = cpndaysn('14-Sep-2000', '30-Jun-2001', 2, 0, 1)
```

```
NumDaysNext = 108
```

Determine the NumDaysNext when using an input vector for Maturity.

```
Maturity = ['30-Apr-2001'; '31-May-2001'; '30-Jun-2001'];
NumDaysNext = cpndaysn('14-Sep-2000', Maturity)
```

```
NumDaysNext = 3×1
```

```
47  
77  
108
```

## Input Arguments

### **Settle — Settlement date**

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array. Settle must be earlier than Maturity.

Data Types: double | char | datetime

### **Maturity — Maturity date**

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Period — Coupons per year of the bond**

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: single | double

### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)

- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: single | double

**EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: logical

**IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

**FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

**FirstCouponDate** is used when a bond has an irregular first coupon period. When **FirstCouponDate** and **LastCouponDate** are both specified, **FirstCouponDate** takes precedence in determining the coupon payment structure. If you do not specify a **FirstCouponDate**, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

**LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

`LastCouponDate` is used when a bond has an irregular last coupon period. In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

## Output Arguments

**NumDaysNext — Number of days from settlement date to next coupon date**  
vector

Number of days from settlement date to next coupon date, returned as an `NUMBONDS`-by-1 vector. For zero coupon bonds coupon dates are computed as if the bonds have a semiannual coupon structure. `NumDaysNext` returns a double for serial date number, date character vector, and datetime inputs.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NumDaysNext` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NumDaysNext` is returned as a datetime array.

## cpndaysp

Number of days since previous coupon date

### Syntax

```
NumDaysPrevious = cpndaysp(Settle,Maturity)
NumDaysPrevious = cpndaysp(_____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

### Description

`NumDaysPrevious = cpndaysp(Settle,Maturity)` returns the number of days between the previous coupon date and the settlement date for a bond or set of bonds. When the coupon frequency is 0 (a zero coupon bond), the previous coupon date is calculated as if the frequency were semiannual. `NumDaysPrevious` returns a double for serial date number, date character vector, and datetime inputs.

Required input arguments must be number of bonds, `NUMBONDS`-by-1 or 1-by-`NUMBONDS`, conforming vectors or scalars.

`NumDaysPrevious = cpndaysp(_____,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` returns the number of days between the previous coupon date and the settlement date for a bond or set of bonds using optional input arguments.

Optional input arguments must be either `NUMBONDS`-by-1 or 1-by-`NUMBONDS` conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NumDaysPrevious` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NumDaysPrevious` is returned as a datetime array.

### Examples

#### Calculate the Number of Days Between Previous Coupon Date and Settlement Date

Determine the `NumDaysPrevious` when using character vectors for input arguments.

```
NumDaysPrevious = cpndaysp('14-Mar-2000', '30-Jun-2001', 2, 0, 0)
```

```
NumDaysPrevious = 75
```

Determine the `NumDaysPrevious` when using a datetime array for an input argument.

```
NumDaysPrevious = cpndaysp(datetime('14-Mar-2000','Locale','en_US'), '30-Jun-2001', 2, 0, 0)
```

```
NumDaysPrevious = 75
```

Determine the NumDaysPrevious when using character vectors for input arguments and the optional argument for EndMonthRule.

```
NumDaysPrevious = cpndaysp('14-Mar-2000', '30-Jun-2001', 2, 0, 1)
```

```
NumDaysPrevious = 74
```

Determine the NumDaysPrevious when using an input vector for Maturity.

```
Maturity = ['30-Apr-2001'; '31-May-2001'; '30-Jun-2001'];
NumDaysPrevious = cpndaysp('14-Mar-2000', Maturity)
```

```
NumDaysPrevious = 3x1
```

```
135
105
74
```

## Input Arguments

### **Settle — Settlement date**

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array. Settle must be earlier than Maturity.

Data Types: double | char | datetime

### **Maturity — Maturity date**

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Period — Coupons per year of the bond**

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: single | double

### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value 0 through 13 or an N-by-1 vector of integers with values 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “[Basis](#)” on page 2-19.

Data Types: `single` | `double`

**EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: `logical`

**IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: `double` | `char` | `datetime`

**FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

**LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

`LastCouponDate` is used when a bond has an irregular last coupon period. In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

## Output Arguments

**NumDaysPrevious — Number of days between previous coupon date and settlement date vector**

Number of days between the previous coupon date and the settlement date, returned as an `NUMBONDS`-by-1 vector. If the settlement date is a coupon date, this function always returns the settlement date.

When the coupon frequency is 0 (a zero coupon bond), the previous coupon date is calculated as if the frequency were semiannual. `NumDaysPrevious` returns a double for serial date number, date character vector, and datetime inputs.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NumDaysPrevious` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NumDaysPrevious` is returned as a datetime array.

## cpnpersz

Number of days in coupon period

### Syntax

```
NumDaysPeriod = cpnpersz(Settle,Maturity)
NumDaysPeriod = cpnpersz(____,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

### Description

`NumDaysPeriod = cpnpersz(Settle,Maturity)` returns the number of days in the coupon period containing the settlement date. For zero coupon bonds, coupon dates are computed as if the bonds have a semiannual coupon structure. `NumDaysPeriod` returns a double for serial date number, date character vector, and datetime inputs.

Required input arguments must be number of bonds, `NUMBONDS`-by-1 or 1-by-`NUMBONDS`, conforming vectors or scalars.

`NumDaysPeriod = cpnpersz(____,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` returns the number of days in the coupon period containing the settlement date using optional input arguments.

Optional input arguments must be either `NUMBONDS`-by-1 or 1-by-`NUMBONDS` conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NumDaysPeriod` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NumDaysPeriod` is returned as a datetime array.

### Examples

#### Calculate the Number of Days in the Coupon Period Containing Settlement Date

Determine the `NumDaysPeriod` when using character vectors for input arguments.

```
NumDaysPeriod = cpnpersz('14-Sep-2000', '30-Jun-2001', 2, 0, 0)
```

```
NumDaysPeriod = 183
```

Determine the `NumDaysPeriod` when using a datetime array for an input argument.

```
NumDaysPeriod = cpnpersz(datetime('14-Sep-2000','Locale','en_US'), '30-Jun-2001', 2, 0, 0)
```

```
NumDaysPeriod = 183
```

Determine the NumDaysPeriod when using character vectors for input arguments and the optional argument for EndMonthRule.

```
NumDaysPeriod = cpnpersz('14-Sep-2000', '30-Jun-2001', 2, 0, 1)
```

```
NumDaysPeriod = 184
```

Determine the NumDaysPeriod when using an input vector for Maturity.

```
Maturity = ['30-Apr-2001'; '31-May-2001'; '30-Jun-2001'];
NumDaysPeriod = cpnpersz('14-Sep-2000', Maturity)
```

```
NumDaysPeriod = 3×1
```

```
184
183
184
```

## Input Arguments

### **Settle — Settlement date**

serial date numbers | date character vector | datetime object

Settlement date, specified as a vector of serial date number, date character vector, or datetime array. Settle must be earlier than Maturity.

Data Types: double | char | datetime

### **Maturity — Maturity date**

serial date number | date character vector | datetime array

Maturity date, specified as a vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Period — Coupons per year of the bond**

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1, 2, 3, 4, 6, 12].

Data Types: single | double

### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “[Basis](#)” on page 2-19.

Data Types: `single` | `double`

**EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: `logical`

**IssueDate — Bond issue date**

serial date number | date character vector | datetime array

Bond issue date, specified as a serial date number, date character vector, or datetime array.

Data Types: `double` | `char` | `datetime`

**FirstCouponDate — Date when bond makes first coupon payment**

serial date number | date character vector | datetime array

Date when a bond makes its first coupon payment, specified as a serial date number, date character vector, or datetime array.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: `double` | `char` | `datetime`

**LastCouponDate — Last coupon date of bond before maturity date**

serial date number | date character vector | datetime array

Last coupon date of a bond before maturity date, specified as a serial date number, date character vector, or datetime array.

`LastCouponDate` is used when a bond has an irregular last coupon period. In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

Data Types: double | char | datetime

## Output Arguments

**NumDaysPeriod — Number of days in coupon period containing settlement date vector**

Number of days in the coupon period containing the settlement date, returned as an `NUMBONDS`-by-1 vector. For zero coupon bonds, coupon dates are computed as if the bonds have a semiannual coupon structure.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either serial date numbers or date character vectors, then `NumDaysPeriod` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date character vector.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NumDaysPeriod` is returned as a datetime array.

# createholidays

Create trading calendars

## Syntax

```
createholidays(Filename,Codefile,InfoFile,TargetDir,IncludeWkds,Wprompt,  
NoGUI)
```

## Description

`createholidays(Filename,Codefile,InfoFile,TargetDir,IncludeWkds,Wprompt,  
NoGUI)` programmatically generates the market-specific `holidays.m` files (from  
`FinancialCalendar.com` financial center holiday data) without displaying the interface.

---

**Note** To use `createholidays`, you must obtain data, codes, and info files from <https://www.FinancialCalendar.com> trading calendars. The data files must be in the required MATLAB format.

---

## Examples

### Create `holidays.m` Files Using `createholidays`

Use `createholidays` to create `holidays*.m` files from `My_datafile.csv` in the folder `c:\work`. Weekends are included in the holidays list based on the input flag `INCLUDEWDKS = 1`

```
createholidays('FinancialCalendar\My_datafile.csv',...  
'FinancialCalendar\My_codesfile.csv',...  
'FinancialCalendar\My_infofile.csv','c:\work',1,1,1)
```

## Input Arguments

### **Filename — Data file name**

character vector

Data file name, specified using a character vector.

Data Types: `char`

### **Codefile — Code file name**

character vector

Code file name, specified using a character vector.

Data Types: `char`

### **InfoFile — Info file name**

character vector

Info file name, specified using a character vector.

Data Types: char

**TargetDir — Target folder where to write new `holidays.m` files**

character vector

Target folder where to write the new `holidays.m` files, specified using a character vector.

Data Types: char

**IncludeWkds — Option to include weekends in holiday list**

numeric with value 0 or 1

Option to include weekends in the holiday list, specified using a numeric with value 0 or 1. Values are:

- 0 – Do not include weekends in the holiday list.
- 1 – Include weekends in the holiday list.

Data Types: logical

**Wprompt — Option to prompt for file location for each `holiday.m` file that is created**

numeric with value 0 or 1

Option to prompt for the file location for each `holiday.m` file that is created, specified using a numeric with value 0 or 1. Values are:

- 0 – Do not prompt for the file location.
- 1 – Prompt for the file location.

Data Types: logical

**NoGUI — Run `createholidays` without displaying Trading Calendars user interface**

numeric with value 0 or 1

Run `createholidays` without displaying the Trading Calendars user interface, specified using a numeric with value 0 or 1. Values are:

- 0 – Display the GUI.
- 1 – Do not display the GUI.

Data Types: logical

## cumsum

Cumulative sum

**Note** `cumsum` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

### Syntax

```
newfts = cumsum(oldfits)
```

### Description

`newfts = cumsum(oldfits)` calculates the cumulative sum of each individual time series data series in the financial time series object `oldfits` and returns the result in another financial time series object `newfts`. `newfts` contains the same data series names as `oldfits`.

### Examples

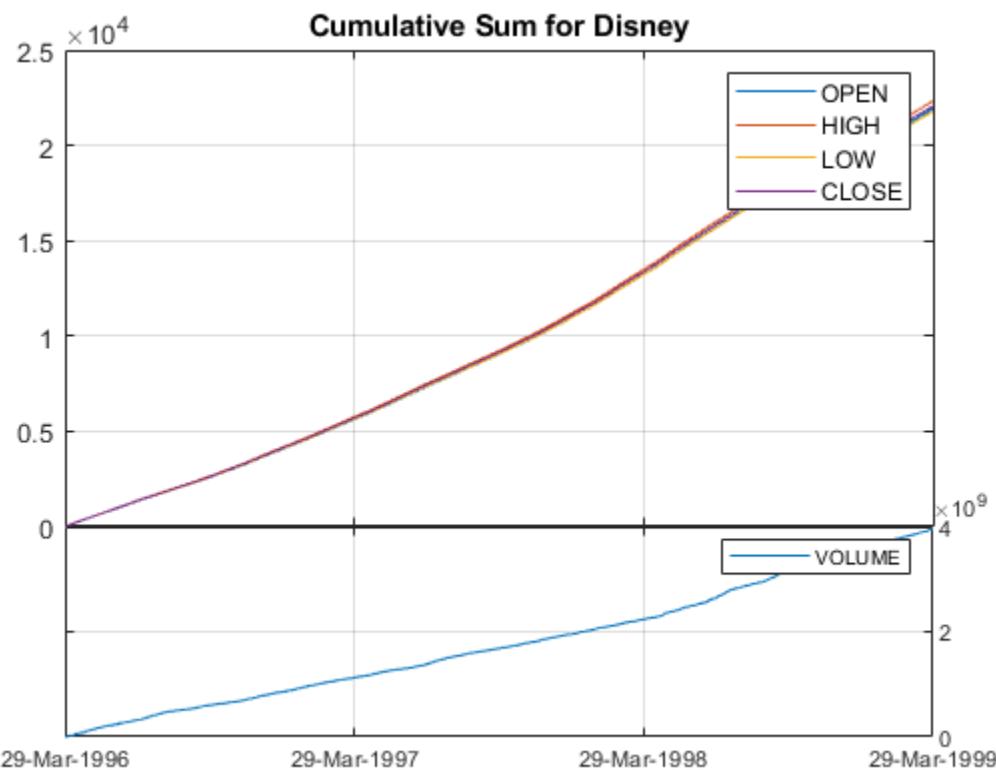

#### Compute the Cumulative Sum

This example shows how to compute the cumulative sum for Disney stock and plot the results.

```
load disney.mat
cs_dis = cumsum(fillts(dis));

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat
plot(cs_dis)

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat
title('Cumulative Sum for Disney')
```

## Input Arguments

**oldfts — Financial time series object**  
fints object

Financial time series object, specified as a `fints` object.

Data Types: object

## Output Arguments

**newfts — Financial time series object**  
fints object

Financial time series object, returned as a `fints` object.

## See Also

fints

## cur2frac

Decimal currency values to fractional values

### Syntax

```
Fraction = cur2frac(Decimal,Denominator)
```

### Description

`Fraction = cur2frac(Decimal,Denominator)` converts decimal currency values to fractional values. `Fraction` is returned as a character vector.

### Examples

#### Convert Decimal Currency Values to Fractional Values

This example shows how to convert decimal currency values to fractional values.

```
Fraction = cur2frac(12.125, 8)
```

```
Fraction =
'12.1'
```

### Input Arguments

#### Decimal — Decimal currency value

numeric decimal

Decimal currency value, specified as a scalar or vector using numeric decimal values.

Data Types: double

#### Denominator — Denominator of the fractions

numeric

Denominator of the fractions, specified as a scalar or vector using numeric values for the denominator.

Data Types: double

### Output Arguments

#### Fraction — Fractional values

character vector | cell array of character vectors

Fractional values, returned as a character vector or cell array of character vectors.

**See Also**

[cur2str](#) | [frac2cur](#)

**Introduced before R2006a**

## cur2str

Bank-formatted text

### Syntax

```
BankText = cur2str(Value,Digits)
```

### Description

`BankText = cur2str(Value,Digits)` returns the given value in bank format.

The output format for `BankText` is a numerical format with dollar sign prefix, two decimal places, and negative numbers in parentheses; for example, `($123.45)` and `$6789.01`. The standard MATLAB bank format uses two decimal places, no dollar sign, and a minus sign for negative numbers; for example, `-123.45` and `6789.01`.

### Examples

#### Return Bank Formatted Text

Return bank formatted text for a negative numeric value.

```
BankText = cur2str(-826444.4456,3)  
BankText =  
'($826444.446)'  
% Negative numbers are displayed in parentheses.
```

### Input Arguments

#### Value — Value to be formatted

numeric value

Value to be formatted, specified as a numeric value.

Data Types: `double`

#### Digits — Number of significant digits

2 (default) | integer

Number of significant digits, specified as an integer. A negative `Digits` rounds the value to the left of the decimal point.

Data Types: `double`

## Output Arguments

### **BankText — Bank-formatted text**

character vector

Bank-formatted text (BankText) is returned as a character vector with a leading dollar sign (\$). Negative numbers are displayed in parentheses.

### **See Also**

[frac2cur](#) | [cur2frac](#)

**Introduced before R2006a**

## date2time

Time and frequency from dates

### Syntax

```
[TFactors,F] = date2time(Settle,Maturity)  
[TFactors,F] = date2time(_____,Compounding,Basis,EndMonthRule)
```

### Description

[TFactors,F] = date2time(Settle,Maturity) computes time factors appropriate to compounded rate quotes between the Settle and Maturity dates. date2time is the inverse of time2date.

[TFactors,F] = date2time(\_\_\_\_\_,Compounding,Basis,EndMonthRule) computes time factors appropriate to compounded rate quotes between the Settle and Maturity dates using optional input arguments for Compounding, Basis, and EndMonthRule. date2time is the inverse of time2date.

### Examples

#### Compute date2time Using an actual/actual Basis

To get the date2time period between '31-Jul-2015' and '30-Sep-2015' using an actual/actual basis:

```
date2time('31-Jul-2015', '30-Sep-2015', 2, 0, 1)
```

```
ans = 0.3333
```

When using date2time quasi coupon, two quasi coupon dates are computed for a bond with a maturity corresponding to the Dates input. In this case, that would be "30-Sep-2015". Assuming that the compounding frequency is 2, the other quasi coupon date is six months prior to this date. Assuming the end of month rule is in place, then the other quasi coupon date is "31-Mar-2015". You can use these two dates to compute the total number of actual days in a period (which is 183). Given this, the fraction of time between the start and end date for the actual/actual basis is computed as follows.

(Actual Days between Start Date and End Date)/(Actual Number of Days between Quasi Coupon Dates)

There are 61 days between 31-Jul-2015 and 30-Sep-2015 and 183 days between the quasi coupon dates ("31-Mar-2015" and "30-Sep-2015") which leads to a final result of 61/183 or exactly 1/3.

### Input Arguments

#### Settle — Settlement date

serial date number | date character vector | datetime object

Settlement date, specified as a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

#### **Maturity — Maturity date**

serial date number | date character vector

Maturity date, specified as a scalar or N-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

#### **Compounding — Rate at which input zero rates are compounded when annualized**

2 (Semiannual compounding) (default) | scalar with numeric values of 0, 1, 2, 3, 4, 5, 6, 12, 365, -1

Rate at which input zero rates are compounded when annualized, specified as a scalar with numeric values of: 0, 1, 2, 3, 4, 5, 6, 12, 365, or -1. Allowed values are defined as:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

The optional **Compounding** argument determines the formula for the discount factors (**Disc**):

- **Compounding** = 0 for simple interest
  - **Disc** =  $1/(1 + Z * T)$ , where **T** is time in years and simple interest assumes annual times **F** = 1.
- **Compounding** = 1, 2, 3, 4, 6, 12
  - **Disc** =  $(1 + Z/F)^{(-T)}$ , where **F** is the compounding frequency, **Z** is the zero rate, and **T** is the time in periodic units, for example, **T** = **F** is one year.
- **Compounding** = 365
  - **Disc** =  $(1 + Z/F)^{(-T)}$ , where **F** is the number of days in the basis year and **T** is a number of days elapsed computed by basis.
- **Compounding** = -1
  - **Disc** =  $\exp(-T*Z)$ , where **T** is time in years.

#### **Basis — Day-count basis**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis, specified as an integer with a value 0 through 13 or a N-by-1 vector of integers with values 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: `single` | `double`

**EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as scalar nonnegative integer [0, 1] or a using a N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

## Output Arguments

**TFactors — Time factors**

vector

Time factors, appropriate to compounded rate quotes between `Settle` and `Maturity` dates, returned as a vector.

**F — Compounding frequencies**

scalar

Compounding frequencies, returned as a scalar.

## More About

### Difference Between `yearfrac` and `date2time`

The difference between `yearfrac` and `date2time` is that `date2time` counts full periods as a whole integer, even if the number of actual days in the periods are different. `yearfrac` does not count full periods.

For example,

```
yearfrac('1/1/2000', '1/1/2001', 9)
```

```
ans =
```

```
1.0167
```

`yearfrac` for Basis 9 (ACT/360 ICMA) calculates  $366/360 = 1.0167$ . So, even if the dates have the same month and date, with a difference of 1 in the year, the returned value may not be exactly 1. On the other hand, `date2time` calculates one full year period:

```
date2time('1/1/2000', '1/1/2001', 1, 9)
```

```
ans =
```

```
1
```

### Topics

“Handle and Convert Dates” on page 2-2

### Introduced before R2006a

## dateaxis

Convert serial-date axis labels to calendar-date axis labels

### Syntax

```
dateaxis(Tickaxis, DateForm, StartDate)
```

### Description

`dateaxis(Tickaxis, DateForm, StartDate)` replaces axis tick labels with date labels.

### Examples

#### Replace Axis Tick Labels with Date Labels

This example shows how to use `dateaxis` to replace axis tick labels with date labels on a graphic figure.

Convert the x-axis labels to an automatically determined date format.

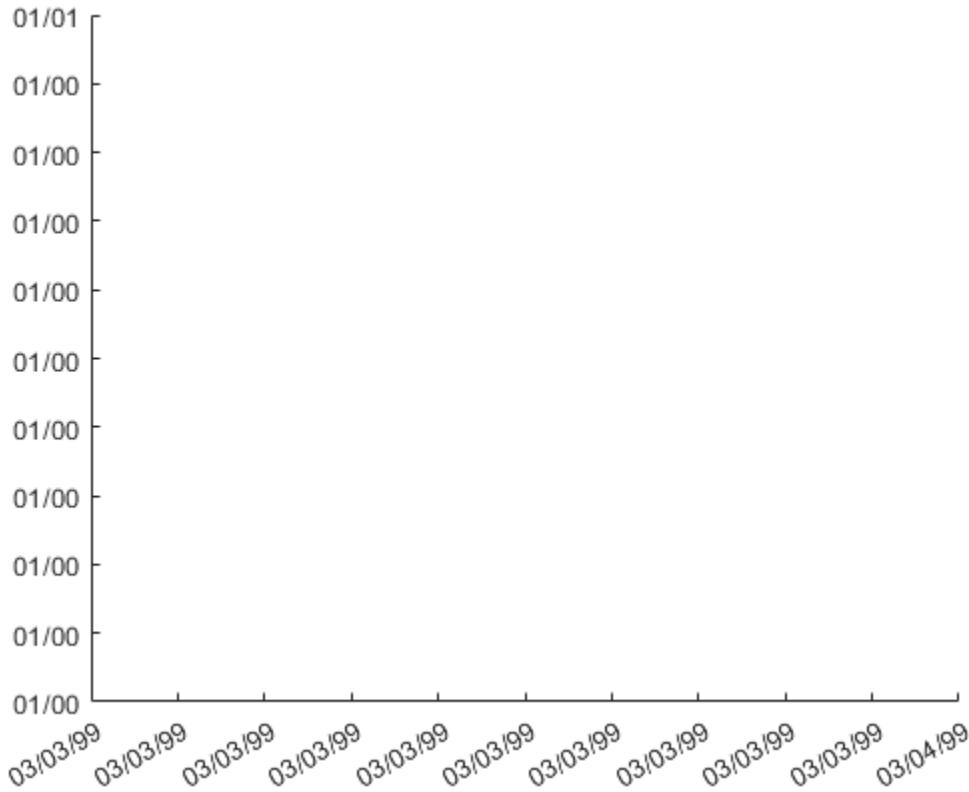

```
dateaxis('y', 6)
```

Convert the y-axis labels to the month/day format.

```
dateaxis('x', 2, datetime(1999,3,3))
```

Convert the x-axis labels to the month/day/year format. The minimum x-tick value is treated as March 3, 1999.

```
dateaxis('x', 2, datetime(1999,3,3))
```

## Input Arguments

### **Tickaxis — Determines which axis tick labels, x, y, z to replace**

'x' (default) | character vector with value 'x', 'y', or 'z'

(Optional) Determines which axis tick labels —x, y, or z— to replace, specified as a character vector.

Data Types: char

### **DateForm — Defines which date format to use**

date format based on the span of the axis limits (default) | integer from 0 to 17

(Optional) Defines which date format to use, specified as an integer from 0 to 17.

If no DateForm argument is entered, this function determines the date format based on the span of the axis limits. For example, if the difference between the axis minimum and maximum is less than 15, the tick labels are converted to three-letter day-of-the-week abbreviations (DateForm = 8).

| DateForm | Format               | Description                       |
|----------|----------------------|-----------------------------------|
| 0        | 01-Mar-1999 15:45:17 | day-month-year hour:minute:second |
| 1        | 01-mar-1999          | day-month-year                    |
| 2        | 03/01/99             | month/day/year                    |
| 3        | Mar                  | month, three letters              |

| DateForm | Format      | Description                 |
|----------|-------------|-----------------------------|
| 4        | M           | month, single letter        |
| 5        | 3           | month                       |
| 6        | 03/01       | month/day                   |
| 7        | 1           | day of month                |
| 8        | Wed         | day of week, three letters  |
| 9        | W           | day of week, single letter  |
| 10       | 1999        | year, four digits           |
| 11       | 99          | year, two digits            |
| 12       | Mar99       | month year                  |
| 13       | 15:45:17    | hour:minute:second          |
| 14       | 03:45:17 PM | hour:minute:second AM or PM |
| 15       | 15:45       | hour:minute                 |
| 16       | 03:45 PM    | hour:minute AM or PM        |
| 17       | 95/03/01    | year month day              |

Refer to the MATLAB `set` command for information on modifying the axis tick values and other axis parameters.

Data Types: double

#### **StartDate — Assigns the date to the first axis tick value**

lower axis limit converted to the appropriate date number (default) | date character vector | serial date number | datetime

(Optional) Assigns the date to the first axis tick value, specified as a serial date number, date character vector, or datetime. The tick values are treated as serial date numbers.

The default `StartDate` is the lower axis limit converted to the appropriate date number. For example, a tick value of 1 is converted to the date 01-Jan-0000. Entering `StartDate` as '`06-apr-1999`' assigns the date April 6, 1999 to the first tick value and the axis tick labels are set accordingly.

Data Types: char | double | datetime

# datedisp

Display date entries

## Syntax

```
datedisp(NumMat)
datedisp(_____,DateForm)
CharMat = datedisp(NumMat,DateForm)
```

## Description

`datedisp(NumMat)` displays a matrix with the serial dates formatted as date character vectors, using a matrix with mixed numeric entries and serial date number entries. Integers between `datenum('01-Jan-1900')` and `datenum('01-Jan-2200')` are assumed to be serial date numbers, while all other values are treated as numeric entries.

`datedisp(_____,DateForm)`, using the optional argument `DateForm`, displays a matrix with the serial dates formatted as date character vectors, using a matrix with mixed numeric entries and serial date number entries. Integers between `datenum('01-Jan-1900')` and `datenum('01-Jan-2200')` are assumed to be serial date numbers, while all other values are treated as numeric entries.

`CharMat = datedisp(NumMat,DateForm)` returns `CharMat`, character array representing `NumMat`. If no output variable is assigned, the function prints the array to the display.

## Examples

### Display a Matrix with the Serial Dates Formatted as Date Character Vectors

This example shows how to display a matrix with the serial dates formatted as date character vectors.

```
NumMat = [730730, 0.03, 1200 730100;
          730731, 0.05, 1000 NaN];

datedisp(NumMat)

01-Sep-2000    0.03    1200    11-Dec-1998
02-Sep-2000    0.05    1000        NaN
```

## Input Arguments

**NumMat — Numeric matrix to display**  
serial date numbers

Numeric matrix to display, specified as a serial date numbers.

Data Types: `double`

**DateForm — Date format**

scalar character vector to indicate format of text representing dates

Date format, specified as a scalar character vector to indicate the format of text representing dates. See `datestr` for available and default format flags.

Data Types: `char`

## Output Arguments

**CharMat — Character array representing NumMat**

array of date character vectors

Character array representing `NumMat`, returned as an array of date character vectors. If no output variable is assigned, the function prints the array to the display.

## Introduced before R2006a

# datefind

Indices of dates in matrix

## Syntax

```
Indices = datefind(Subset,Superset)
Indices = datefind(___,Tolerance)
```

## Description

`Indices = datefind(Subset,Superset)` returns a vector of indices to the date numbers in `Superset` that are present in `Subset`. If no date numbers match, `Indices = []`.

`Indices = datefind(___,Tolerance)` returns a vector of indices to the date numbers in `Superset` that are present in `Subset`, plus the optional argument for `Tolerance`. If no date numbers match, `Indices = []`.

## Examples

### Return a Vector of Indices to Date Numbers

This example shows how to return a vector of indices to date numbers.

```
Superset = datenum(1999, 7, 1:31);
Subset = [datenum(1999, 7, 10); datenum(1999, 7, 20)];
Indices = datefind(Subset, Superset, 1)

Indices = 6×1

9
10
11
19
20
21
```

## Input Arguments

### Subset — Subset of dates to find matching dates

matrix of nonnegative integers with values for serial date numbers or datetime arrays

Subset of dates to find matching dates in `Superset`, specified as a matrix of nonnegative integers with values for serial date numbers or datetime arrays.

`Subset` and `Superset` can be either serial date numbers or datetime arrays. These types do not have to match. `datefind` determines the underlying date to match dates of different data types.

**Note** The elements of `Subset` must be contained in `Superset`, without repetition. `datefind` works with non-repeating sequences of dates.

---

Example: `Subset = [datenum(1997,7,10); datenum(1997,7,20)];`

Data Types: `single | double`

#### **Superset — Superset of dates**

matrix of nonnegative integers with values for serial date numbers or datetime arrays

Superset of dates, specified as a matrix of serial date numbers or datetime arrays, whose elements are sought.

`Subset` and `Superset` can be either serial date numbers or datetime arrays. These types do not have to match. `datefind` determines the underlying date to match dates of different data types.

**Note** The elements of `Subset` must be contained in `Superset`, without repetition. `datefind` works with non-repeating sequences of dates.

---

Example: `Superset = datenum(1997,7,1:31);`

Data Types: `single | double`

#### **Tolerance — Tolerance for matching dates in Superset**

`0` (default) | positive integer or duration object

Tolerance for matching dates (+/-) in `Superset`, specified as a positive integer or duration object.

Data Types: `single | double`

## **Output Arguments**

### **Indices — Indices of dates in Superset that are present in Subset**

vector

Indices of dates in `Superset` that are present in `Subset` (plus or minus the tolerance if defined using the optional argument `Tolerance`), returned as a vector of indices to the date numbers or datetimes.

## **See Also**

`datenum` | `datetime`

# datemnth

Date of day in future or past month

## Syntax

```
TargetDate = datemnth(StartDate,NumberMonths)
TargetDate = datemnth(____,DayFlag,Basis,EndMonthRule)
```

## Description

`TargetDate = datemnth(StartDate,NumberMonths)` determines a date in a future or past month based on movement either forward or backward in time by a given number of months.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row character array of date character vectors, then `NumberMonths` must be an  $N$ -by-1 vector of integers or a single integer. `TargetDate` is then an  $N$ -by-1 vector of date numbers.

If `StartDate` is a serial date number or date character vector, `TargetDate` is returned as a serial date number. Use `datestr` to convert serial date numbers to formatted date character vectors.

If `StartDate` is a datetime array, then `TargetDate` is returned as a datetime array.

`TargetDate = datemnth(____,DayFlag,Basis,EndMonthRule)` determines a date in a future or past month based on movement either forward or backward in time by a given number of months, using optional input arguments for `DayFlag`, `Basis`, and `EndMonthRule`.

## Examples

### Determine the Dates of Days in a Future Month

Determine the `TargetDate` in a future month using a date character vector for `StartDate`.

```
StartDate = '03-Jun-1997';
NumberMonths = 6;
DayFlag = 0;
Basis = 0;
EndMonthRule = 1;

TargetDate = datemnth(StartDate, NumberMonths, DayFlag, ...
Basis, EndMonthRule)

TargetDate = 729727

datestr(TargetDate)

ans =
'03-Dec-1997'
```

Determine the `TargetDate` in a future month using a datetime array for `StartDate`.

```
Day = datemnth(datetime('3-jun-2001','Locale','en_US'), 6, 0, 0, 0)
```

```
Day = datetime  
03-Dec-2001
```

Determine the TargetDate in a future month using a vector for NumberMonths.

```
NumberMonths = [1; 3; 5; 7; 9];  
TargetDate = datemnth('31-jan-2001', NumberMonths);  
datestr(TargetDate)
```

```
ans = 5x11 char array  
'28-Feb-2001'  
'30-Apr-2001'  
'30-Jun-2001'  
'31-Aug-2001'  
'31-Oct-2001'
```

## Input Arguments

### **StartDate — Start date**

serial date number | date character vector | datetime object

Start date, specified as an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **NumberMonths — Number of months in future (positive) or past (negative)**

positive or negative integers

Number of months in future (positive) or past (negative), specified as an N-by-1 or 1-by-N vector containing positive or negative integers.

Data Types: double

### **DayFlag — Flag for how actual day number for target date in future or past month is determined**

0 (day number should be the day in the future or past month corresponding to the actual day number of the start date) (default) | numeric with values 0, 1, or 2

Flag for how the actual day number for the target date in future or past month is determined, specified as an N-by-1 or 1-by-N vector using a numeric with values 0, 1, or 2.

Possible values are:

- 0 (default) = day number should be the day in the future or past month corresponding to the actual day number of the start date.
- 1 = day number should be the first day of the future or past month.
- 2 = day number should be the last day of the future or past month.

This flag has no effect if EndMonthRule is set to 1.

Data Types: double

**Basis — Day-count basis of the instrument**

$0$  (actual/actual) (default) | numeric with value  $0$  through  $13$  | vector of numerics with values  $0$  through  $13$

Day-count basis to be used when determining the past or future date, specified as a scalar value with an integer with value of  $0$  through  $13$ , or an N-by-1 or 1-by-N vector of integers with values of  $0$  through  $13$ .

- $0 =$  actual/actual (default)
- $1 =$   $30/360$  (SIA)
- $2 =$  actual/ $360$
- $3 =$  actual/ $365$
- $4 =$   $30/360$  (BMA)
- $5 =$   $30/360$  (ISDA)
- $6 =$   $30/360$  (European)
- $7 =$  actual/ $365$  (Japanese)
- $8 =$  actual/actual (ICMA)
- $9 =$  actual/ $360$  (ICMA)
- $10 =$  actual/ $365$  (ICMA)
- $11 =$   $30/360E$  (ICMA)
- $12 =$  actual/ $365$  (ISDA)
- $13 =$  BUS/252

For more information, see “Basis” on page 2-19.

Data Types: single | double

**EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

$0$  (not in effect) (default) | nonnegative integer  $[0, 1]$

End-of-month rule flag for month having 30 or fewer days, specified as a scalar with a nonnegative integer  $0$  or  $1$ , or as an N-by-1 or 1-by-N vector of values  $0$  or  $1$ .

- $0 =$  Ignore rule, meaning that rule is not in effect.
- $1 =$  Set rule on, meaning that if you are beginning on the last day of a month, and the month has 30 or fewer days, you will end on the last actual day of the future or past month regardless of whether that month has 28, 29, 30 or 31 days.

Data Types: logical

## Output Arguments

**TargetDate — Target date in the future or past month**

vector

Target date in the future or past month, returned as an N-by-1 or 1-by-N vector containing the serial date number (default) or datetime (if `StartDate` is a datetime array) of the target date.

# datewrkdy

Date of future or past workday

## Syntax

```
EndDate = datewrkdy(StartDate, NumberWorkDays, NumberHolidays)
```

## Description

`EndDate = datewrkdy(StartDate, NumberWorkDays, NumberHolidays)` returns the serial number of the date a given number of workdays before or after the start date.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all.

For example, if `StartDate` is an  $n$ -row character array of date character vectors, then `NumberWorkDays` must be an  $N$ -by-1 vector of integers or a single integer. `EndDate` is then an  $N$ -by-1 vector of date numbers.

If `StartDate` is a serial date number or date character vector, `EndDate` is returned as a date number. Use `datestr` to convert serial date numbers to formatted date character vectors.

If `StartDate` is a datetime array, then `EndDate` is returned as a datetime array.

## Examples

### Determine the Date for a Future Workday

Determine the `EndDate` for a future workday using a date character vector for `StartDate`.

```
StartDate = '20-Dec-1994';
NumberWorkDays = 16;
NumberHolidays = 2;

EndDate = datewrkdy(StartDate, NumberWorkDays, NumberHolidays)

EndDate = 728671
datestr(EndDate)

ans =
'12-Jan-1995'
```

Determine the `EndDate` for a future workday using a datetime array for `StartDate`.

```
EndDate = datewrkdy(datetime('12-dec-2000','Locale','en_US'), 16, 2)

EndDate = datetime
04-Jan-2001
```

Determine the `EndDate` for future workdays using a vector for `NumberWorkDays`.

```
NumberWorkDays = [16; 20; 44];
EndDate = datewrkdy('12-dec-2000', NumberWorkDays, 2);
datestr(EndDate)

ans = 3x11 char array
    '04-Jan-2001'
    '10-Jan-2001'
    '13-Feb-2001'
```

## Input Arguments

### **StartDate — Start date**

serial date number | date character vector | datetime object

Start date, specified as an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **NumberWorkDays — Number of work or business days in future (positive) or past (negative)**

positive or negative integers

Number of work or business days in future (positive) or past (negative) that includes the starting date, specified as an N-by-1 or 1-by-N vector containing positive or negative integers.

NumberHolidays and NumberWorkDays must have the same sign.

Data Types: double

### **NumberHolidays — Number of holidays within NumberWorkDays**

positive or negative integers

Number of holidays within NumberWorkDays, specified as positive or negative integers using an N-by-1 or 1-by-N containing values for the number of days movement in terms of holidays into the future (if positive) or past (if negative).

NumberHolidays and NumberWorkDays must have the same sign.

Data Types: double

## Output Arguments

### **EndDate — Date of future or past workday**

vector

Date of future or past workday, returned as an N-by-1 or 1-by-N vector containing the serial date number (default) or the datetime (if **StartDate** is a datetime array) of the future or past date.

## days252bus

Number of business days between dates

### Syntax

```
NumberDays = days252bus(StartDate,EndDate)
NumberDays = days252bus(___HolidayVector)
```

### Description

`NumberDays = days252bus(StartDate,EndDate)` computes the number of business days (that is, non-holiday or non-weekend) between the two input dates.

`NumberDays = days252bus(___HolidayVector)` adds an optional argument for `HolidayVector`. If a holiday vector is not optionally specified, then the `holidays.m` file is used to determine the holidays.

### Examples

#### Computes the Number of Business Days Between Two Input Dates

This example shows how to compute the number of business days (i.e. non-holiday or non-weekend) between two dates using the `days252bus` convention.

```
NumberDays = days252bus('1/1/2009', '8/1/2009')
```

```
NumberDays = 146
```

#### Computes the Number of Business Days Between Two Input Dates Using a datetime Array

This example shows how to compute the number of business days (i.e. non-holiday or non-weekend) between two dates, specified as a datetime array, using the `days252bus` convention.

```
NumberDays = days252bus(datetime('1-Jan-2009','Locale','en_US'), '8/1/2009')
```

```
NumberDays = 146
```

### Input Arguments

#### StartDate — Start date

serial date number | date character vector | datetime

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, a cell array of date character vectors, or datetime array.

Data Types: double | char | datetime

**EndDate — End date**

serial date number | date character vector | datetime

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, a cell array of date character vectors, or datetime array.

Data Types: double | char | datetime

**HolidayVector — Holidays**

holidays.m (default) | serial date number | date character vector | datetime

Holidays, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, a cell array of date character vectors, or datetime array.

Data Types: double | char | datetime

## Output Arguments

**NumberDays — Number of days between two dates**

vector

Number of days between two dates, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

## See Also

days360psa | daysact | daysdif | days365 | datetime

## Topics

"Handle and Convert Dates" on page 2-2

## Introduced before R2006a

# days360

Days between dates based on 360-day year

## Syntax

```
NumDays = days360(StartDate,EndDate)
```

## Description

`NumDays = days360(StartDate,EndDate)` returns the number of days between `StartDate` and `EndDate` based on a 360-day year (that is, all months contain 30 days). If `EndDate` is earlier than `StartDate`, `NumDays` is negative.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an *n*-row character array of date character vectors, then `EndDate` must be an *N*-by-1 vector of integers or a single integer. `NumDays` is then an *N*-by-1 vector of date numbers.

## Examples

### Determine the Number of Days Between Two Dates Based on a 360-Day Year

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate`.

```
NumDays = days360('15-jan-2000', '15-mar-2000')
```

```
NumDays = 60
```

Determine the `NumDays` using a datetime array for `StartDate`.

```
NumDays = days360(datetime('15-jan-2000','Locale','en_US'), '15-mar-2000')
```

```
NumDays = 60
```

Determine the `NumDays` using a vector for `EndDate`.

```
MoreDays = ['15-mar-2000'; '15-apr-2000'; '15-jun-2000'];
NumDays = days360('15-jan-2000', MoreDays)
```

```
NumDays = 3×1
```

```
60
90
150
```

## Input Arguments

### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

#### **EndDate — End date**

serial date number | date character vector | datetime object

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## **Output Arguments**

### **NumDays — Number of days between two dates**

vector

Number of days between two dates, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

NumDays returns as a double for serial date number, date character vector, or datetime inputs for `StartDate` and `EndDate`.

## days360e

Days between dates based on 360-day year (European)

### Syntax

```
NumDays = days360e(StartDate,EndDate)
```

### Description

`NumDays = days360e(StartDate,EndDate)` returns the number of days between `StartDate` and `EndDate` based on a 360-day year (that is, all months contain 30 days). If `EndDate` is earlier than `StartDate`, `NumDays` is negative. This day count convention is used primarily in Europe. Under this convention, all months contain 30 days.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row character array of date character vectors, then `EndDate` must be an  $N$ -by-1 vector of integers or a single integer. “Determine the Number of Days Between Two Dates Given a Basis of 30/360 Based on European Convention” on page 19-678 `NumDays` is then an  $N$ -by-1 vector of date numbers.

### Examples

#### Determine the Number of Days Between Two Dates Given a Basis of 30/360 Based on European Convention

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate` for the month of January.

```
StartDate = '1-Jan-2002';
EndDate = '1-Feb-2002';
NumDays = days360e(StartDate, EndDate)

NumDays = 30
```

Determine the `NumDays` in the month of January using a datetime array for `StartDate`.

```
NumDays = days360e(datetime('1-Jan-2002','Locale','en_US'), '1-Feb-2002')

NumDays = 30
```

Determine the `NumDays` using a vector for `EndDate`.

```
MoreDays = ['15-mar-2000'; '15-apr-2000'; '15-jun-2000'];
NumDays = days360e('15-jan-2000', MoreDays)

NumDays = 3×1
```

```
60
90
150
```

## Input Arguments

### **StartDate — Start date**

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **EndDate — End date**

serial date number | date character vector | datetime object

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### **NumDays — Number of days between two dates given a basis of 30/360 based on European convention**

vector

Number of days between two dates given a basis of 30/360 based on European convention, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

NumDays returns as a double for serial date number, date character vector, or datetime inputs for StartDate and EndDate.

## days360isda

Days between dates based on 360-day year (International Swap Dealer Association (ISDA) compliant)

### Syntax

```
NumDays = days360isda(StartDate,EndDate)
```

### Description

NumDays = days360isda(StartDate,EndDate) returns the number of days between StartDate and EndDate based on a 360-day year (that is, all months contain 30 days) and is International Swap Dealer Association (ISDA) compliant. If EndDate is earlier than StartDate, NumDays is negative. Under this convention, all months contain 30 days.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if StartDate is an *n*-row character array of date character vectors, then EndDate must be an *N*-by-1 vector of integers or a single integer. NumDays is then an *N*-by-1 vector of date numbers.

### Examples

#### Determine the Number of Days Between Two Dates Given a Basis of 30/360 Based on ISDA Compliance

Determine the NumDays using date character vectors for StartDate and EndDate for the month of January.

```
StartDate = '1-Jan-2002';
EndDate = '1-Feb-2002';
NumDays = days360isda(StartDate, EndDate)

NumDays = 30
```

Determine the NumDays in the month of January using a datetime array for StartDate.

```
NumDays = days360isda(datetime('1-Jan-2002','Locale','en_US'), '1-Feb-2002')

NumDays = 30
```

Determine the NumDays using a vector for EndDate.

```
MoreDays = ['15-mar-2000'; '15-apr-2000'; '15-jun-2000'];
NumDays = days360isda('15-jan-2000', MoreDays)

NumDays = 3x1
```

```
60
90
150
```

## Input Arguments

### **StartDate — Start date**

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **EndDate — End date**

serial date number | date character vector | datetime object

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### **NumDays — Number of days between two dates given a basis of 30/360 based on European convention**

vector

Number of days between two dates given a basis of 30/360 based on International Swap Dealer Association (ISDA) compliance, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

NumDays returns as a double for serial date number, date character vector, or datetime inputs for StartDate and EndDate.

## days360psa

Days between dates based on 360-day year (Public Securities Association (PSA) compliant)

### Syntax

```
NumDays = days360psa(StartDate,EndDate)
```

### Description

NumDays = days360psa(StartDate,EndDate) returns the number of days between StartDate and EndDate based on a 360-day year (that is, all months contain 30 days) and is Public Securities Association (PSA) compliant. If EndDate is earlier than StartDate, NumDays is negative. Under this convention, all months contain 30 days.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if StartDate is an *n*-row character array of date character vectors, then EndDate must be an *N*-by-1 vector of integers or a single integer. NumDays is then an *N*-by-1 vector of date numbers.

### Examples

#### Determine the Number of Days Between Two Dates Given a Basis of 30/360 Based on PSA Compliance

Determine the NumDays using date character vectors for StartDate and EndDate for the month of January.

```
StartDate = '1-Jan-2002';
EndDate = '1-Feb-2002';
NumDays = days360psa(StartDate, EndDate)

NumDays = 30
```

Determine the NumDays in the month of January using a datetime array for StartDate.

```
NumDays = days360psa(datetime('1-Jan-2002','Locale','en_US'), '1-Feb-2002')

NumDays = 30
```

Determine the NumDays using a vector for EndDate.

```
MoreDays = ['15-mar-2000'; '15-apr-2000'; '15-jun-2000'];
NumDays = days360psa('15-jan-2000', MoreDays)

NumDays = 3x1
```

```
60
90
150
```

## Input Arguments

### **StartDate — Start date**

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **EndDate — End date**

serial date number | date character vector | datetime object

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### **NumDays — Number of days between two dates given a basis of 30/360 based on European convention**

vector

Number of days between two dates given a basis of 30/360 based on Public Securities Association (PSA) compliance, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

NumDays returns as a double for serial date number, date character vector, or datetime inputs for StartDate and EndDate.

## Introduced before R2006a

# days365

Days between dates based on 365-day year

## Syntax

```
NumDays = days365(StartDate,EndDate)
```

## Description

`NumDays = days365(StartDate,EndDate)` returns the number of days between `StartDate` and `EndDate` based on a 365-day year. All months contain their actual number of days. February always contains 28 days.

If `EndDate` is earlier than `StartDate`, `NumDays` is negative. Under this convention, all months contain 30 days.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row character array of date character vectors, then `EndDate` must be an  $N$ -by-1 vector of integers or a single integer. `NumDays` is then an  $N$ -by-1 vector of date numbers.

## Examples

### Determine the Number of Days Between Two Dates Based on a 365-Day Year

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate`.

```
NumDays = days365('15-jan-2000', '15-mar-2000')
```

```
NumDays = 59
```

Determine the `NumDays` using a datetime array for `StartDate`.

```
NumDays = days365(datetime('15-jan-2000','Locale','en_US'), '15-mar-2000')
```

```
NumDays = 59
```

Determine the `NumDays` using a vector for `EndDate`.

```
MoreDays = ['15-mar-2000'; '15-apr-2000'; '15-jun-2000'];
NumDays = days365('15-jan-2000', MoreDays)
```

```
NumDays = 3×1
```

```
59
90
151
```

## Input Arguments

### **StartDate — Start date**

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **EndDate — End date**

serial date number | date character vector | datetime object

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### **NumDays — Number of days between two dates based on 365-day year vector**

Number of days between two dates based on a 365-day year, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

NumDays returns as a double for serial date number, date character vector, or datetime inputs for StartDate and EndDate.

## References

- [1] Addendum to Securities Industry Association, *Standard Securities Calculation Methods: Fixed Income Securities Formulas for Analytic Measures*. Vol. 2, Spring 1995.

## Introduced before R2006a

## daysact

Actual number of days between dates

### Syntax

```
NumDays = daysact(StartDate)
NumDays = daysact(___,EndDate)
```

### Description

`NumDays = daysact(StartDate)` returns the actual number of days between the MATLAB base date and `StartDate`. In MATLAB, the base date 1 is 1-Jan-0000 A.D. See `datenum` for a similar function.

`NumDays = daysact(___,EndDate)` returns the actual number of days between `StartDate` and the optional argument `EndDate`.

If `EndDate` is earlier than `StartDate`, `NumDays` is negative. Under this convention, all months contain 30 days.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an *n*-row character array of date character vectors, then `EndDate` must be an *N*-by-1 vector of integers or a single integer. `NumDays` is then an *N*-by-1 vector of date numbers.

### Examples

#### Determine the Number of Days Between Two Dates Based the Actual Number of Days

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate`.

```
NumDays = daysact('7-sep-2002', '25-dec-2002')
NumDays = 109
```

Determine the `NumDays` using a datetime array for `StartDate`.

```
NumDays = daysact(datetime('7-sep-2002','Locale','en_US'), '25-dec-2002')
NumDays = 109
```

Determine the `NumDays` using a vector for `EndDate`.

```
MoreDays = ['09/07/2002'; '10/22/2002'; '11/05/2002'];
NumDays = daysact(MoreDays, '12/25/2002')

NumDays = 3x1
```

109  
64

---

50

## Input Arguments

### **StartDate — Start date**

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **EndDate — End date**

serial date number | date character vector | datetime object

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### **NumDays — Number of days between two dates based actual number of days**

vector

Number of days between two dates based on the actual number of days, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

NumDays returns as a double for serial date number, date character vector, or datetime inputs for `StartDate` and `EndDate`.

## daysadd

Date away from starting date for any day-count basis

### Syntax

```
NewDate = daysadd(StartDate,NumDays)
NewDate = daysadd(_____,Basis)
```

### Description

`NewDate = daysadd(StartDate,NumDays)` returns a date `NewDate` number of days away from `StartDate`.

If `StartDate` is a serial date number or date character vector, `NewDate` is returned as a date number.

If `StartDate` is a datetime array, then `NewDate` is returned as a datetime array.

`NewDate = daysadd(_____,Basis)` returns a date `NewDate` number of days away from `StartDate`, using the optional argument `Basis` for day-count.

If `StartDate` is a serial date number or date character vector, `NewDate` is returned as a date number.

If `StartDate` is a datetime array, then `NewDate` is returned as a datetime array.

### Examples

#### Determine the Date for Given Number of Days Away From StartDate

Determine the `NewDate` using a date character vector for `StartDate`.

```
NewDate = daysadd('01-Feb-2004', 31)
NewDate = 732009
datestr(NewDate)

ans =
'03-Mar-2004'
```

Determine the `NewDate` using a datetime array for `StartDate`.

```
NewDate = daysadd(datetime('01-Feb-2004','Locale','en_US'), 31)
NewDate = datetime
03-Mar-2004
```

Determine the `NewDate` using a vector for `StartDate`.

```
MoreDays = ['09/07/2002'; '10/22/2002'; '11/05/2002'];
NewDate = daysadd(MoreDays, 31, 2)
```

NewDate = 3×1

```
731497
731542
731556
```

```
datestr(NewDate)
```

```
ans = 3x11 char array
'08-Oct-2002'
'22-Nov-2002'
'06-Dec-2002'
```

## Input Arguments

### **StartDate — Start date**

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **NumDays — Number of days from StartDate**

positive or negative integer

Number of days from **StartDate**, specified an N-by-1 or 1-by-N vector using positive or negative integers. Enter a negative integer for dates before start date.

Data Types: double

### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or a N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)

- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

---

**Note** When using the 30/360 day-count basis, it is not always possible to find the exact date NewDate number of days away because of a known discontinuity in the method of counting days. A warning is displayed if this occurs.

---

Data Types: single | double

## Output Arguments

**NewDate — Date for given number of days away from StartDate**  
vector

Date for given number of days away from StartDate, returned as a scalar or an N-by-1 vector containing dates.

If StartDate is a serial date number or date character vector, NewDate is returned as a date number.

If StartDate is a datetime array, then NewDate is returned as a datetime array.

# daysdif

Days between dates for any for any day-count basis

## Syntax

```
NumDays = daysdif(StartDate,EndDate)
NumDays = daysdif(___,Basis)
```

## Description

`NumDays = daysdif(StartDate,EndDate)` returns the number of days between dates `StartDate` and `EndDate`. The first date for `StartDate` is not included when determining the number of days between first and last date.

Any input argument can contain multiple values, but if so, the other inputs must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row array of character vector dates, then `EndDate` must be an  $n$ -row array of character vector dates or a single date. `NumDays` is then an  $N$ -by-1 vector of numbers.

`NumDays = daysdif(___,Basis)` returns the number of days between dates `StartDate` and `EndDate` using the optional argument `Basis` for day-count. The first date for `StartDate` is not included when determining the number of days between first and last date.

Any input argument can contain multiple values, but if so, the other inputs must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an  $n$ -row array of character vector dates, then `EndDate` must be an  $n$ -row array of character vector dates or a single date. `NumDays` is then an  $N$ -by-1 vector of numbers.

## Examples

### Determine the Number of Days Between StartDate and EndDate

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate`.

```
NumDays = daysdif('3/1/99', '3/1/00', 1)
```

```
NumDays = 360
```

Determine the `NumDays` using a datetime array for `StartDate`.

```
NumDays = daysdif(datetime('1-Mar-1999','Locale','en_US'), '3/1/00', 1)
```

```
NumDays = 360
```

Determine the `NumDays` using a vector for `EndDate`.

```
MoreDays = ['3/1/2001'; '3/1/2002'; '3/1/2003'];
NumDays = daysdif('3/1/98', MoreDays)
```

```
NumDays = 3×1
```

1096  
1461  
1826

## Input Arguments

### **StartDate — Start date**

serial date number | date character vector | datetime object

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **EndDate — End date**

serial date number | date character vector | datetime object

End date, specified as a scalar or an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or a N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: single | double

## Output Arguments

**NumDays — Number of days between dates StartDate and EndDate**  
integer

Number of days between the StartDate and EndDate. NumDays returns as a double for serial date number, date character vector, and datetime inputs.

The first date for StartDate is not included when determining the number of days between first and last date.

## dec2thirtytwo

Decimal to thirty-second quotation

### Syntax

```
[OutNumber,Fractions] = dec2thirtytwo(InNumber,Accuracy)
```

### Description

[OutNumber,Fractions] = dec2thirtytwo(InNumber,Accuracy) changes a decimal price quotation for a bond or bond future to a fraction with a denominator of 32.

### Examples

#### Convert Decimal to Thirty-Second Quotation

This example shows two bonds that are quoted with decimal prices of 101.78 and 102.96. These prices are converted to fractions with a denominator of 32.

```
InNumber = [101.78; 102.96];
[OutNumber, Fractions] = dec2thirtytwo(InNumber)
```

OutNumber = 2×1

101  
102

Fractions = 2×1

25  
31

### Input Arguments

#### InNumber — Input number

numeric decimal fraction

Input number, specified as an N-by-1 vector of numeric decimal fractions.

Data Types: double

#### Accuracy — Rounding

1 (round down to nearest thirty second) (default) | numeric with values 1, 2, 4 or 10

Rounding, specified as an N-by-1 vector of accuracy desired with numeric values of 1, 2, 4 or 10. The values are: 1, round down to nearest thirty second, 2 (nearest half), 4 (nearest quarter), or 10 (nearest decile).

Data Types: double

## Output Arguments

**OutNumber — Output number which is InNumber rounded downward to closest integer**  
numeric

Output number which is InNumber rounded downward to closest integer, returned as a numeric value.

**Fractions — Fractional part in units of thirty-second**  
numeric

Fractional part in units of thirty-second, returned as a numeric value. The Fractions output conforms to accuracy as prescribed by the input Accuracy.

## depfixdb

Fixed declining-balance depreciation schedule

### Syntax

```
Depreciation = depfixdb(Cost,Salvage,Life,Period)
Depreciation = depfixdb(_____,Month)
```

### Description

`Depreciation = depfixdb(Cost,Salvage,Life,Period)` computes the fixed declining-balance depreciation for each `Period`.

`Depreciation = depfixdb(_____,Month)` adds an optional argument.

### Examples

#### Compute the Fixed Declining-Balance Depreciation

This example shows how to calculate the depreciation for the first five years for a car is purchased for \$11,000, with a salvage value of \$1500, and a lifetime of eight years.

```
Depreciation = depfixdb(11000, 1500, 8, 5)
Depreciation = 1x5
10^3 ×
2.4251    1.8904    1.4737    1.1488    0.8955
```

### Input Arguments

#### Cost — Initial value of the asset

numeric

initial value of the asset, specified as a scalar numeric.

Data Types: double

#### Salvage — Salvage value of the asset

numeric

Salvage value of the asset, specified as a scalar numeric.

Data Types: double

#### Life — Life of the asset in years

numeric

life of the asset in years, specified as scalar numeric.

Data Types: double

**Period — Number of years to calculate**

integer

Number of years to calculate, specified as scalar integer.

Data Types: double

**Month — Number of months in the first year of asset life**

12 (default) | numeric

(Optional) Number of months in the first year of asset life, specified as a scalar numeric.

Data Types: double

## Output Arguments

**Depreciation — Depreciation**

vector

Depreciation, returned as the fixed declining-balance depreciation for each Period.

## See Also

## Introduced before R2006a

## depgendb

General declining-balance depreciation schedule

### Syntax

```
Depreciation = depgendb(Cost,Salvage,Life,Factor)
```

### Description

Depreciation = depgendb(Cost,Salvage,Life,Factor) computes the declining-balance depreciation for each period.

### Examples

#### Calculate the Declining-Balance Depreciation

A car is purchased for \$10,000 and is to be depreciated over five years. The estimated salvage value is \$1000. Using the double-declining-balance method, the function calculates the depreciation for each year and returns the remaining depreciable value at the end of the life of the car.

Define the depreciation.

```
Life = 5;  
Salvage = 0;  
Cost = 10000;  
Factor=2;
```

Use depgendb to calculate the depreciation.

```
Depreciation = depgendb(10000, 1000, 5, 2)
```

```
Depreciation = 1x5  
103 ×
```

```
4.0000    2.4000    1.4400    0.8640    0.2960
```

The large value returned at the final year is the sum of the depreciation over the life time and is equal to the difference between the Cost and Salvage. The value of the asset in the final year is computed as (Cost - Salvage) = Sum\_Depreciation\_Upto\_Final\_Year.

### Input Arguments

#### Cost — Initial value of the asset

numeric

initial value of the asset, specified as a scalar numeric.

Data Types: double

**Salvage — Salvage value of the asset**

numeric

Salvage value of the asset, specified as a scalar numeric.

Data Types: double

**Life — Number of periods over which the asset is depreciated**

numeric

Number of periods over which the asset is depreciated, specified as a scalar numeric.

Data Types: double

**Factor — Depreciation factor**

numeric

Depreciation factor, specified as a scalar numeric. When Factor = 2, then the double-declining-balance method is used.

Data Types: double

## Output Arguments

**Depreciation — Depreciation**

vector

Depreciation, returned as the declining-balance depreciation for each period.

## deprdv

Remaining depreciable value

### Syntax

```
Depreciation = deprdv(Cost,Salvage,Accum)
```

### Description

Depreciation = deprdv(Cost,Salvage,Accum) computes the remaining depreciable value for an asset.

### Examples

#### Compute the Remaining Depreciable Value for an Asset

This example shows how to find the remaining depreciable value after six years for the cost of an asset for \$13,000 with a life of 10 years. The salvage value is \$1000.

```
Accum = depstln(13000, 1000, 10) * 6  
Accum = 7200  
Value = deprdv(13000, 1000, 7200)  
Value = 4800
```

### Input Arguments

#### Cost — Initial value of the asset

numeric

Initial value of the asset, specified as a scalar numeric.

Data Types: double

#### Salvage — Salvage value of the asset

numeric

Salvage value of the asset, specified as a scalar numeric.

Data Types: double

#### Accum — Accumulated depreciation of the asset for prior periods

numeric

Accumulated depreciation of the asset for prior periods, specified as a scalar numeric.

Data Types: double

## Output Arguments

### Depreciation – Depreciation

numeric

Depreciation, returned as the remaining depreciable value for an asset.

## depsoyd

Sum of years' digits depreciation

### Syntax

```
Sum = depsoyd(Cost,Salvage,Life)
```

### Description

Sum = depsoyd(Cost,Salvage,Life) computes the depreciation for an asset using the sum of years' digits method.

### Examples

#### Compute the Depreciation for an Asset Using the Sum of Years' Digits Method

This example shows how to calculate the depreciation for an asset using the sum of years' digits method where the asset is \$13,000 with a life of 10 years. The salvage value of the asset is \$1000.

```
Sum = depsoyd(13000, 1000, 10)'
```

```
Sum = 10×1  
103 ×
```

0.4364  
0.2182
```

### Input Arguments

#### Cost — Initial value of the asset

numeric

initial value of the asset, specified as a scalar numeric.

Data Types: double

#### Salvage — Salvage value of the asset

numeric

Salvage value of the asset, specified as a scalar numeric.

Data Types: double

**Life — Depreciable life of the asset in years**

numeric

Depreciable life of the asset in years, specified as a scalar numeric.

Data Types: double

## Output Arguments

**Sum — Depreciation values**

vector

Depreciation values, returned as a 1-by-Life vector of depreciation values with each element corresponding to a year of the asset's life.

## depstln

Straight-line depreciation schedule

### Syntax

```
Depreciation = depstln(Cost,Salvage,Life)
```

### Description

`Depreciation = depstln(Cost,Salvage,Life)` computes the straight-line depreciation for an asset.

### Examples

#### Compute the Straight-Line Depreciation for an Asset

This example shows how to calculate the straight-line depreciation for an asset that costs \$13,000 with a life of 10 years. The salvage value of the asset is \$1000.

```
Depreciation = depstln(13000, 1000, 10)
```

```
Depreciation = 1200
```

### Input Arguments

#### Cost — Initial value of the asset

numeric

Initial value of the asset, specified as a scalar numeric.

Data Types: double

#### Salvage — Salvage value of the asset

numeric

Salvage value of the asset, specified as a scalar numeric.

Data Types: double

#### Life — Depreciable life of the asset in years

numeric

Depreciable life of the asset in years, specified as a scalar numeric.

Data Types: double

## Output Arguments

### Depreciation – Depreciation

numeric

Depreciation, returned as a straight-line depreciation for an asset.

## diff

Differencing

**Note** `diff` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
newfts = diff(olddfsts)
```

### Description

`newfts = diff(olddfsts)` computes the difference of all the data in the data series of the object `olddfsts` and returns the result in the object `newfts`. `newfts` is a financial time series object containing the same data series (names) as the input `olddfsts`.

### Examples

#### Computes Difference of All the Data in the Data Series of the Object `olddfsts`

- 1 Create a `fints` object.

```
dates_and_times = (now:now+5)'
dates_and_times =
1.0e+05 *
7.3840
7.3840
7.3840
7.3841
7.3841
7.3841
```

```
olddfsts = fints(dates_and_times, randn(6,1))
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see Convert F

> In `fints` (line 169)

```
olddfsts =
desc: (none)
freq: Unknown (0)

{'dates: (6)'}    {'times: (6)'}    {'series1: (6)'}
{'03-Sep-2021'}    {'12:34'}        {[ -1.0616]}
{'04-Sep-2021'}    {'12:34'}        {[ 2.3505]}
{'05-Sep-2021'}    {'12:34'}        {[ -0.6156]}
{'06-Sep-2021'}    {'12:34'}        {[ 0.7481]}
```

```
{'07-Sep-2021'}    {'12:34'}      }    {[      -0.1924]}
{'08-Sep-2021'}    {'12:34'}      }    {[      0.8886]}
```

## 2 Convert the frequency using `convertto`.

```
newfts = diff(oldffts)
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see [Convert FINTS Objects to TIMETABLE](#)

```
> In fints/diff (line 21)
newfts =
```

```
desc: DIFF of
freq: Unknown (0)

{'dates: (5)'}    {'times: (5)'}    {'series1: (5)'}
{'04-Sep-2021'}    {'12:34'}      }    {[      3.4120]}
{'05-Sep-2021'}    {'12:34'}      }    {[      -2.9661]}
{'06-Sep-2021'}    {'12:34'}      }    {[      1.3637]}
{'07-Sep-2021'}    {'12:34'}      }    {[      -0.9405]}
{'08-Sep-2021'}    {'12:34'}      }    {[      1.0810]}
```

## Input Arguments

### **oldfts — Financial time series object**

`fints` object

Financial time series object, specified as a `fints` object.

Data Types: `object`

## Output Arguments

### **newfts — Financial time series object**

`fints` object

Financial time series object, returned as a `fints` object.

## disc2zero

Zero curve given discount curve

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: Compounding and Basis.

---

### Syntax

```
[ZeroRates,CurveDates] = disc2zero(DiscRates,CurveDates,Settle)
[ZeroRates,CurveDates] = disc2zero(____,Name,Value)
```

### Description

[ZeroRates,CurveDates] = disc2zero(DiscRates,CurveDates,Settle) returns a zero curve given a discount curve and its maturity dates. If either inputs for CurveDates or Settle are datetime arrays, the output CurveDates is returned as datetime arrays.

[ZeroRates,CurveDates] = disc2zero(\_\_\_\_,Name,Value) adds optional name-value pair arguments

### Examples

#### Determine the Zero Curve Given a Discount Curve and Maturity Dates

Given the following discount factors DiscRates over a set of maturity dates CurveDates, and a settlement date Settle:

```
DiscRates = [0.9996
             0.9947
             0.9896
             0.9866
             0.9826
             0.9786
             0.9745
             0.9665
             0.9552
             0.9466];

CurveDates = [datenum('06-Nov-2000')
              datenum('11-Dec-2000')
              datenum('15-Jan-2001')
              datenum('05-Feb-2001')
              datenum('04-Mar-2001')
              datenum('02-Apr-2001')
              datenum('30-Apr-2001')
              datenum('25-Jun-2001')
              datenum('04-Sep-2001')
              datenum('12-Nov-2001')];
```

```
Settle = datenum('03-Nov-2000');
```

Set daily compounding for the output zero curve, on an actual/365 basis.

```
Compounding = 365;
Basis = 3;
```

Execute the function `disc2zero` which returns the zero curve `ZeroRates` at the maturity dates `CurveDates`.

```
[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates, ...
Settle, Compounding, Basis)
```

`ZeroRates` = 10×1

```
0.0487
0.0510
0.0523
0.0524
0.0530
0.0526
0.0530
0.0532
0.0549
0.0536
```

`CurveDates` = 10×1

```
730796
730831
730866
730887
730914
730943
730971
731027
731098
731167
```

For readability, `DiscRates` and `ZeroRates` are shown here only to the basis point. However, MATLAB® software computed them at full precision. If you enter `DiscRates` as shown, `ZeroRates` may differ due to rounding.

### Determine the Zero Curve Given a Discount Curve and Maturity Dates Using `datetime` Inputs

Given the following discount factors, `DiscRates`, over a set of maturity dates, `CurveDates`, and a settlement date, `Settle`, use `datetime` inputs to return the zero curve, `ZeroRates`, at the maturity dates, `CurveDates`.

```
DiscRates = [0.9996
0.9947
```

```
0.9896
0.9866
0.9826
0.9786
0.9745
0.9665
0.9552
0.9466];

CurveDates = [datenum('06-Nov-2000')
              datenum('11-Dec-2000')
              datenum('15-Jan-2001')
              datenum('05-Feb-2001')
              datenum('04-Mar-2001')
              datenum('02-Apr-2001')
              datenum('30-Apr-2001')
              datenum('25-Jun-2001')
              datenum('04-Sep-2001')
              datenum('12-Nov-2001')];

Settle = datenum('03-Nov-2000');
Compounding = 365;
Basis = 3;

CurveDates = datetime(CurveDates,'ConvertFrom','datenum','Locale','en_US');
Settle = datetime(Settle,'ConvertFrom','datenum','Locale','en_US');

[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates, ...
Settle, Compounding, Basis)

ZeroRates = 10×1

```

## Input Arguments

### **DiscRates — Discount factors**

decimal fraction

Discount factors, specified as a column vector of decimal fractions. In aggregate, the factors in **DiscRates** constitute a discount curve for the investment horizon represented by **CurveDates**.

Data Types: double

### **CurveDates — Maturity dates**

serial date number | date character vector | datetime

Maturity dates that correspond to the discount factors in **DiscRates**, specified as a column vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | datetime | char

### **Settle — Common settlement date for discount rates in DiscRates**

serial date number | date character vector | datetime

Common settlement date for the discount rates in **DiscRates**, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | datetime | char

## Name-Value Pair Arguments

Specify optional pairs of arguments as **Name1=Value1**, ..., **NameN=ValueN**, where **Name** is the argument name and **Value** is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[ZeroRates,CurveDates] = disc2zero(DiscRates,CurveDates,Settle,'Compounding',6,'Basis',9)`

### **Compounding — Rate at which output zero rates are compounded when annualized**

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

Rate at which the output zero rates are compounded when annualized, specified as a numeric value. Allowed values are:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

Data Types: double

**Basis — Day-count basis used for annualizing output zero rates**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis used for annualizing the output zero rates, specified as a numeric value. Allowed values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

## Output Arguments

**ZeroRates — Zero curve for investment horizon represented by CurveDates**

numeric

Zero curve for the investment horizon represented by `CurveDates`, returned as a column vector of decimal fractions. The zero rates are the yields to maturity on theoretical zero-coupon bonds.

**CurveDates — Maturity dates that correspond to ZeroRates**

serial date number | date character vector | datetime

Maturity dates that correspond to the `ZeroRates`, returned as a column vector. This vector is the same as the input vector `CurveDates`, but the output is sorted by ascending maturity. If either inputs for `CurveDates` or `Settle` are datetime arrays, the output `CurveDates` is returned as datetime arrays.

Bank discount rate of security

### Syntax

```
DiscRate = discrete(Settle,Maturity,Face,Price)
DiscRate = discrete(____,Basis)
```

### Description

`DiscRate = discrete(Settle,Maturity,Face,Price)` computes the bank discount rate of a security. The bank discount rate normalizes by the face value of the security (for example, U. S. Treasury Bills) and understates the true yield earned by investors.

`DiscRate = discrete(____,Basis)` adds an optional argument for `Basis`.

### Examples

#### Compute the Bank Discount Rate of a Security

This example shows how to find the bank discount rate of a security.

```
DiscRate = discrete('12-jan-2000', '25-jun-2000', 100, 97.74, 0)
DiscRate = 0.0501
```

#### Compute the Bank Discount Rate of a Security Using datetime Inputs

This example shows how to use `datetime` inputs to find the bank discount rate of a security.

```
DiscRate = discrete(datetime('12-jan-2000','Locale','en_US'), datetime('25-jun-2000','Locale','en_US'), 100, 97.74, 0)
DiscRate = 0.0501
```

### Input Arguments

#### Settle — Settlement date

serial date number | date character vector | `datetime`

Settlement date, specified as serial date numbers, date character vectors, or `datetime` arrays.

Data Types: `double` | `datetime` | `char`

#### Maturity — Maturity date

serial date number | date character vector | `datetime`

Maturity date, specified as serial date number, date character vector, or `datetime` array.

Data Types: double | char | datetime

#### **Face — Redemption (par, face) value**

numeric

Redemption (par, face) value, specified as a numeric value.

Data Types: double

#### **Price — Security price**

numeric

Security price, specified as a numeric value.

Data Types: double

#### **Basis — Day-count basis of the instrument**

0 (actual/actual) (default) | integer with value of 0 to 13

(Optional) Day-count basis of the instrument, specified as a vector of integers.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

## **Output Arguments**

#### **DiscRate — Discount rate of security**

decimal

Discount rate of security, returned as a decimal.

# ecmlsrmlle

Least-squares regression with missing data

## Syntax

```
[Parameters,Covariance,Resid,Info] = ecmlsrmlle(Data,Design,MaxIterations,TolParam,TolObj,Param0,0)
```

## Arguments

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data          | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are represented as NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use mvnrmle.)                                                                                                                                                                                                                                                                                                                                                                                    |
| Design        | A matrix or a cell array that handles two model structures: <ul style="list-style-type: none"> <li>If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li> <li>If NUMSERIES ≥ 1, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample. |
| MaxIterations | (Optional) Maximum number of iterations for the estimation algorithm. Default value is 100.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| TolParam      | (Optional) Convergence tolerance for estimation algorithm based on changes in model parameter estimates. Default value is <code>sqrt(eps)</code> which is about 1.0e-8 for double precision. The convergence test for changes in model parameters is<br>$\ Param_k - Param_{k-1}\  < TolParam \times (1 + \ Param_k\ )$                                                                                                                                                                                                                                                                                                              |
|               | where Param represents the output Parameters, and iteration $k = 2, 3, \dots$ . Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam ≤ 0 and TolObj ≤ 0, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.                                                                                                                                                                                                                                                                                                                          |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TolObj      | (Optional) Convergence tolerance for estimation algorithm based on changes in the objective function. Default value is $\text{eps} \wedge 3/4$ which is about $1.0e-12$ for double precision. The convergence test for changes in the objective function is<br>$ Obj_k - Obj_{k-1}  < TolObj \times (1 +  Obj_k )$ for iteration $k = 2, 3, \dots$ . Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam $\leq 0$ and TolObj $\leq 0$ , do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests. |
| Param0      | (Optional) NUMPARAMS-by-1 column vector that contains a user-supplied initial estimate for the parameters of the regression model. Default is a zero vector.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Covar0      | (Optional) NUMSERIES-by-NUMSERIES matrix that contains a user-supplied initial or known estimate for the covariance matrix of the regression residuals. Default is an identity matrix.<br><br>For covariance-weighted least-squares calculations, this matrix corresponds with weights for each series in the regression. The matrix also serves as an initial guess for the residual covariance in the expectation conditional maximization (ECM) algorithm.                                                                                                                               |
| CovarFormat | (Optional) Character vector that specifies the format for the covariance matrix. The choices are: <ul style="list-style-type: none"><li>• 'full' — Default method. Compute the full covariance matrix.</li><li>• 'diagonal' — Force the covariance matrix to be a diagonal matrix.</li></ul>                                                                                                                                                                                                                                                                                                |

## Description

[Parameters, Covariance, Resid, Info] = ecmlsrmlle(Data, Design, MaxIterations, TolParam, TolObj, Param0, Covar0, CovarFormat) estimates a least-squares regression model with missing data. The model has the form

$$Data_k \sim N(Design_k \times Parameters, Covariance)$$

for samples  $k = 1, \dots, \text{NUMSAMPLES}$ .

ecmlsrmlle estimates a NUMPARAMS-by-1 column vector of model parameters called **Parameters**, and a NUMSERIES-by-NUMSERIES matrix of covariance parameters called **Covariance**.

ecmlsrmlle(Data, Design) with no output arguments plots the log-likelihood function for each iteration of the algorithm.

To summarize the outputs of ecmlsrmlle:

- **Parameters** is a NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model.
- **Covariance** is a NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression model's residuals. For least-squares models, this estimate may not be a maximum likelihood estimate except under special circumstances.

- **Resid** is a **NUMSAMPLES**-by-**NUMSERIES** matrix of residuals from the regression.

Another output, **Info**, is a structure that contains additional information from the regression. The structure has these fields:

- **Info.Obj** — A variable-extent column vector, with no more than **MaxIterations** elements, that contain each value of the objective function at each iteration of the estimation algorithm. The last value in this vector, **Obj(end)**, is the terminal estimate of the objective function. If you do least-squares, the objective function is the least-squares objective function.
- **Info.PrevParameters** — **NUMPARAMS**-by-1 column vector of estimates for the model parameters from the iteration just prior to the terminal iteration.
- **Info.PrevCovariance** — **NUMSERIES**-by-**NUMSERIES** matrix of estimates for the covariance parameters from the iteration just prior to the terminal iteration.

## Notes

If doing covariance-weighted least-squares, **Covar0** should usually be a diagonal matrix. Series with greater influence should have smaller diagonal elements in **Covar0** and series with lesser influence should have larger diagonal elements. Note that if doing CWLS, **Covar0** do not need to be a diagonal matrix even if **CovarFormat** = 'diagonal'.

You can configure **Design** as a matrix if **NUMSERIES** = 1 or as a cell array if **NUMSERIES**  $\geq$  1.

- If **Design** is a cell array and **NUMSERIES** = 1, each cell contains a **NUMPARAMS** row vector.
- If **Design** is a cell array and **NUMSERIES** > 1, each cell contains a **NUMSERIES**-by-**NUMPARAMS** matrix.

These points concern how **Design** handles missing data:

- Although **Design** should not have **Nan** values, ignored samples due to **Nan** values in **Data** are also ignored in the corresponding **Design** array.
- If **Design** is a 1-by-1 cell array, which has a single **Design** matrix for each sample, no **Nan** values are permitted in the array. A model with this structure must have **NUMSERIES**  $\geq$  **NUMPARAMS** with **rank(Design{1})** = **NUMPARAMS**.
- **ecmlsrmlle** is more strict than **mvnrmle** about the presence of **Nan** values in the **Design** array.

Use the estimates in the optional output structure **Info** for diagnostic purposes.

Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample. |
| Parameters | NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Covariance | (Optional) NUMSERIES-by-NUMSERIES matrix that contains a user-supplied estimate for the covariance matrix of the residuals of the regression. Default is an identity matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Description

Objective = ecmlsrobj(Data,Design,Parameters,Covariance) computes a least-squares objective function based on current parameter estimates with missing data. Objective is a scalar that contains the least-squares objective function.

## Notes

ecmlsrobj requires that Covariance be positive-definite.

Note that

```
ecmlsrobj(Data, Design, Parameters) = ecmmvnrobj(Data, ...
Design, Parameters, IdentityMatrix)
```

where IdentityMatrix is a NUMSERIES-by-NUMSERIES identity matrix.

You can configure **Design** as a matrix if **NUMSERIES** = 1 or as a cell array if **NUMSERIES**  $\geq$  1.

- If **Design** is a cell array and **NUMSERIES** = 1, each cell contains a **NUMPARAMS** row vector.
- If **Design** is a cell array and **NUMSERIES** > 1, each cell contains a **NUMSERIES**-by-**NUMPARAMS** matrix.

## Examples

## Introduced in R2006a

# ecmmvnrfish

Fisher information matrix for multivariate normal regression model

## Syntax

```
Fisher = ecmmvnrfish(Data,Design,Covariance,Method,MatrixFormat,CovarFormat)
```

## Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data         | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are represented as NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use mvnrfish.)                                                                                                                                                                                                                                                                                                                                                                                                   |
| Design       | A matrix or a cell array that handles two model structures: <ul style="list-style-type: none"> <li>If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li> <li>If NUMSERIES <math>\geq 1</math>, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample. |
| Covariance   | NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the residuals of the regression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Method       | (Optional) Character vector that identifies method of calculation for the information matrix: <ul style="list-style-type: none"> <li><b>hessian</b> — Default method. Use the expected Hessian matrix of the observed log-likelihood function. This method is recommended since the resultant standard errors incorporate the increased uncertainties due to missing data.</li> <li><b>fisher</b> — Use the Fisher information matrix.</li> </ul>                                                                                                                                                                                                    |
| MatrixFormat | (Optional) Character vector that identifies parameters to be included in the Fisher information matrix: <ul style="list-style-type: none"> <li><b>full</b> — Default format. Compute the full Fisher information matrix for both model and covariance parameter estimates.</li> <li><b>paramonly</b> — Compute only components of the Fisher information matrix associated with the model parameter estimates.</li> </ul>                                                                                                                                                                                                                            |

|             |                                                                                                                                                                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CovarFormat | (Optional) Character vector that specifies the format for the covariance matrix. The choices are: <ul style="list-style-type: none"><li>• 'full' — Default method. The covariance matrix is a full matrix.</li><li>• 'diagonal' — The covariance matrix is a diagonal matrix.</li></ul> |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Description

`Fisher = ecmmvnrfish(Data, Design, Covariance, Method, MatrixFormat, CovarFormat)` computes a Fisher information matrix based on current maximum likelihood or least-squares parameter estimates that account for missing data.

`Fisher` is a NUMPARAMS-by-NUMPARAMS Fisher information matrix or Hessian matrix. The size of NUMPARAMS depends on `MatrixFormat` and on current parameter estimates. If `MatrixFormat = 'full'`,

```
NUMPARAMS = NUMSERIES * (NUMSERIES + 3)/2
```

```
If MatrixFormat = 'paramonly',
```

```
NUMPARAMS = NUMSERIES
```

---

**Note** `ecmmvnrfish` operates slowly if you calculate the full Fisher information matrix.

---

## Examples

See “Multivariate Normal Regression” on page 9-13, “Least-Squares Regression” on page 9-14, “Covariance-Weighted Least Squares” on page 9-14, “Feasible Generalized Least Squares” on page 9-15, and “Seemingly Unrelated Regression” on page 9-16.

“Fisher Information” on page 9-4

“Multivariate Normal Linear Regression” on page 9-2

## Introduced in R2006a

# ecmmvnrmlle

Multivariate normal regression with missing data

## Syntax

```
[Param,Covar] = ecmmvnrmlle(Data,Design)
[Param,Covar,Resid,Info] = ecmmvnrmlle(___,MaxIterations,TolParam,TolObj,
Param0,Covar0,CovarFormat)
```

## Description

`[Param,Covar] = ecmmvnrmlle(Data,Design)` estimates a multivariate normal regression model with missing data. The model has the form

$$Data_k \sim N(Design_k \times Parameters, Covariance)$$

for samples  $k = 1, \dots, \text{NUMSAMPLES}$ .

`[Param,Covar,Resid,Info] = ecmmvnrmlle(___,MaxIterations,TolParam,TolObj,Param0,Covar0,CovarFormat)` adds an optional arguments for `MaxIterations`, `TolParam`, `TolObj`, `Param0`, `Covar0`, and `CovarFormat`.

## Examples

### Compute Multivariate Normal Regression With Missing Data

This example shows how to estimate a multivariate normal regression model with missing data.

First, load dates, total returns, and ticker symbols for the twelve stocks from the MAT-file.

```
load CAPMuniverse
whos Assets Data Dates
```

| Name   | Size    | Bytes  | Class  | Attributes |
|--------|---------|--------|--------|------------|
| Assets | 1x14    | 1568   | cell   |            |
| Data   | 1471x14 | 164752 | double |            |
| Dates  | 1471x1  | 11768  | double |            |

```
Dates = datetime(Dates,'ConvertFrom','datenum');
```

The assets in the model have the following symbols, where the last two series are proxies for the market and the riskless asset.

```
Assets(1:14)
```

```
ans = 1x14 cell
Columns 1 through 6
{'AAPL'}    {'AMZN'}    {'CSCO'}    {'DELL'}    {'EBAY'}    {'GOOG'}
```

```
Columns 7 through 12
{'HPQ'}    {'IBM'}    {'INTC'}    {'MSFT'}    {'ORCL'}    {'YHOO'}
Columns 13 through 14
{'MARKET'}    {'CASH'}
```

The data covers the period from January 1, 2000 to November 7, 2005 with daily total returns. Two stocks in this universe have missing values that are represented by NaNs. One of the two stocks had an IPO during this period and, consequently, has significantly less data than the other stocks.

Compute separate regressions for each stock, where the stocks with missing data have estimates that reflect their reduced observability.

```
[NumSamples, NumSeries] = size(Data);
NumAssets = NumSeries - 2;

StartDate = Dates(1);
EndDate = Dates(end);

Alpha = NaN(1, length(NumAssets));
Beta = NaN(1, length(NumAssets));
Sigma = NaN(1, length(NumAssets));
StdAlpha = NaN(1, length(NumAssets));
StdBeta = NaN(1, length(NumAssets));
StdSigma = NaN(1, length(NumAssets));
for i = 1:NumAssets
    % Set up separate asset data and design matrices
    TestData = zeros(NumSamples,1);
    TestDesign = zeros(NumSamples,2);

    TestData(:) = Data(:,i) - Data(:,14);
    TestDesign(:,1) = 1.0;
    TestDesign(:,2) = Data(:,13) - Data(:,14);

    % Estimate the multivariate normal regression for each asset separately.
    [Param, Covar] = ecmmvnrmlle(TestData, TestDesign)

end
Param = 2x1

## Input Arguments

### Data — Data

matrix

Data, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. Missing values are indicated by NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use `mvnrmlle`.)

Data Types: double

### Design — Design model

matrix | cell array

Design model, specified as a matrix or a cell array that handles two model structures:

- If `NUMSERIES` = 1, `Design` is a `NUMSAMPLES`-by-`NUMPARAMS` matrix with known values. This structure is the standard form for regression on a single series.
- If `NUMSERIES`  $\geq$  1, `Design` is a cell array. The cell array contains either one or `NUMSAMPLES` cells. Each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix of known values.

If `Design` has a single cell, it is assumed to have the same `Design` matrix for each sample. If `Design` has more than one cell, each cell contains a `Design` matrix for each sample.

Data Types: double | cell

### MaxIterations — Maximum number of iterations for the estimation algorithm

100 (default) | numeric

(Optional) Maximum number of iterations for the estimation algorithm, specified as a numeric.

Data Types: double

### TolParam — Convergence tolerance for estimation algorithm based on changes in model parameter estimates

1.0e-8 (default) | numeric

(Optional) Convergence tolerance for estimation algorithm based on changes in model parameter estimates, specified as a numeric. The convergence test for changes in model parameters is

$$\|Param_k - Param_{k-1}\| < TolParam \times (1 + \|Param_k\|)$$

where `Param` represents the output `Parameters`, and iteration  $k = 2, 3, \dots$ . Convergence is assumed when both the `TolParam` and `TolObj` conditions are satisfied. If both `TolParam`  $\leq 0$  and `TolObj`  $\leq 0$ , do the maximum number of iterations (`MaxIterations`), whatever the results of the convergence tests.

Data Types: double

**TolObj — Convergence tolerance for estimation algorithm based on changes in objective function**

`1.0e-12` (default) | numeric

(Optional) Convergence tolerance for estimation algorithm based on changes in the objective function, specified as a numeric. The convergence test for changes in the objective function is

$$|Obj_k - Obj_{k-1}| < TolObj \times (1 + |Obj_k|)$$

for iteration  $k = 2, 3, \dots$ . Convergence is assumed when both the `TolParam` and `TolObj` conditions are satisfied. If both `TolParam`  $\leq 0$  and `TolObj`  $\leq 0$ , do the maximum number of iterations (`MaxIterations`), whatever the results of the convergence tests.

Data Types: double

**Param0 — Estimate for the parameters of regression model**

`[]` (default) | vector

(Optional) Estimate for the parameters of the regression model, specified as an `NUMPARAMS`-by-1 column vector.

Data Types: double

**Covar0 — Estimate for the covariance matrix of regression residuals**

`[]` (default) | matrix

(Optional) Estimate for the covariance matrix of the regression residuals, specified as `NUMSERIES`-by-`NUMSERIES` matrix.

Data Types: double

**CovarFormat — Format for the covariance matrix**

`'full'` (default) | character vector

(Optional) Format for the covariance matrix, specified as a character vector. The choices are:

- `'full'` — Compute the full covariance matrix.
- `'diagonal'` — Force the covariance matrix to be a diagonal matrix.

Data Types: char

## Output Arguments

### Param — Estimates for parameters of the regression model

vector

Estimates for the parameters of the regression model, returned as a NUMPARAMS-by-1 column vector.

### Covar — Estimates for the covariance of regression model's residuals

matrix

Estimates for the covariance of the regression model's residuals, returned as a NUMSERIES-by-  
NUMSERIES matrix.

### Resid — Residuals from regression

matrix

Residuals from the regression, returned as a NUMSAMPLES-by-NUMSERIES matrix. For any missing  
values in Data, the corresponding residual is the difference between the conditionally imputed value  
for Data and the model, that is, the imputed residual.

---

**Note** The covariance estimate Covariance cannot be derived from the residuals.

---

### Info — Additional information from regression

structure

Additional information from the regression, returned as a structure. The structure has these fields:

- **Info.Obj** — A variable-extent column vector, with no more than MaxIterations elements, that contain each value of the objective function at each iteration of the estimation algorithm. The last value in this vector, Obj(end), is the terminal estimate of the objective function. If you do maximum likelihood estimation, the objective function is the log-likelihood function.
- **Info.PrevParameters** — NUMPARAMS-by-1 column vector of estimates for the model parameters from the iteration just prior to the terminal iteration.**Info.PrevCovariance** — NUMSERIES-by-  
NUMSERIES matrix of estimates for the covariance parameters from the iteration just prior to the terminal iteration.

## ecmmvnrobj

Log-likelihood function for multivariate normal regression with missing data

### Syntax

```
Objective = ecmmvnrobj(Data,Design,Parameters,Covariance,CovarFormat)
```

### Arguments

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data        | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are represented as NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use mvnrmle.)                                                                                                                                                                                                                                                                                                                                                                                                    |
| Design      | A matrix or a cell array that handles two model structures: <ul style="list-style-type: none"> <li>If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li> <li>If NUMSERIES <math>\geq 1</math>, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample. |
| Parameters  | NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Covariance  | NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the residuals of the regression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| CovarFormat | (Optional) Character vector that specifies the format for the covariance matrix. The choices are: <ul style="list-style-type: none"> <li>'full' — Default method. The covariance matrix is a full matrix.</li> <li>'diagonal' — The covariance matrix is a diagonal matrix.</li> </ul>                                                                                                                                                                                                                                                                                                                                                               |

### Description

`Objective = ecmmvnrobj(Data,Design,Parameters,Covariance,CovarFormat)` computes a log-likelihood function based on current maximum likelihood parameter estimates with missing data. `Objective` is a scalar that contains the least-squares objective function.

### Notes

You can configure `Design` as a matrix if `NUMSERIES = 1` or as a cell array if `NUMSERIES  $\geq 1$` .

- If `Design` is a cell array and `NUMSERIES = 1`, each cell contains a NUMPARAMS row vector.

- If **Design** is a cell array and **NUMSERIES** > 1, each cell contains a **NUMSERIES**-by-**NUMPARAMS** matrix.

## Examples

## Introduced in R2006a

## ecmmvnrstd

Evaluate standard errors for multivariate normal regression model

### Syntax

```
[StdParameters,StdCovariance] = ecmmvnrstd(Data,Design,Covariance)
[StdParameters,StdCovariance] = ecmmvnrstd(___,Method,CovarFormat)
```

### Description

[StdParameters,StdCovariance] = ecmmvnrstd(Data,Design,Covariance) evaluates standard errors for a multivariate normal regression model with missing data. The model has the form

$$Data_k \sim N(Design_k \times Parameters, Covariance)$$

for samples  $k = 1, \dots, \text{NUMSAMPLES}$ .

[StdParameters,StdCovariance] = ecmmvnrstd(\_\_\_,Method,CovarFormat) adds an optional arguments for Method and CovarFormat.

### Examples

#### Compute Standard Errors for Multivariate Normal Regression

This example shows how to compute standard errors for a multivariate normal regression model.

First, load dates, total returns, and ticker symbols for the twelve stocks from the MAT-file.

```
load CAPMuniverse
whos Assets Data Dates

Name          Size            Bytes  Class      Attributes
Assets        1x14           1568   cell
Data          1471x14         164752  double
Dates         1471x1           11768  double

Dates = datetime(Dates, 'ConvertFrom', 'datenum');

The assets in the model have the following symbols, where the last two series are proxies for the market and the riskless asset.

Assets(1:14)

ans = 1x14 cell
Columns 1 through 6

{'AAPL'}    {'AMZN'}    {'CSCO'}    {'DELL'}    {'EBAY'}    {'GOOG'}

Columns 7 through 12
```

```

{'HPQ'}    {'IBM'}    {'INTC'}    {'MSFT'}    {'ORCL'}    {'YHOO'}
Columns 13 through 14

{'MARKET'}    {'CASH'}

```

The data covers the period from January 1, 2000 to November 7, 2005 with daily total returns. Two stocks in this universe have missing values that are represented by NaNs. One of the two stocks had an IPO during this period and, consequently, has significantly less data than the other stocks.

```
[Mean, Covariance] = ecmmnlle(Data);
```

Compute separate regressions for each stock, where the stocks with missing data have estimates that reflect their reduced observability.

```

[NumSamples, NumSeries] = size(Data);
NumAssets = NumSeries - 2;

StartDate = Dates(1);
EndDate = Dates(end);

Alpha = NaN(1, length(NumAssets));
Beta = NaN(1, length(NumAssets));
Sigma = NaN(1, length(NumAssets));
StdAlpha = NaN(1, length(NumAssets));
StdBeta = NaN(1, length(NumAssets));
StdSigma = NaN(1, length(NumAssets));
for i = 1:NumAssets
    % Set up separate asset data and design matrices
    TestData = zeros(NumSamples,1);
    TestDesign = zeros(NumSamples,2);

    TestData(:) = Data(:,i) - Data(:,14);
    TestDesign(:,1) = 1.0;
    TestDesign(:,2) = Data(:,13) - Data(:,14);

    [Param, Covar] = ecmmvnrmle(TestData, TestDesign);

    % Estimate the sample standard errors for model parameters for each asset.
    StdParam = ecmmvnrstd(TestData, TestDesign, Covar, 'hessian')
end

StdParam = 2x1
0.0008
0.0715

StdParam = 2x1
0.0012

## Input Arguments

### Data — Data

matrix

Data, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. Missing values are indicated by NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use `mvnrmle`.)

Data Types: double

### Design — Design model

matrix | cell array

Design model, specified as a matrix or a cell array that handles two model structures:

- If `NUMSERIES` = 1, `Design` is a `NUMSAMPLES`-by-`NUMPARAMS` matrix with known values. This structure is the standard form for regression on a single series.
- If `NUMSERIES`  $\geq$  1, `Design` is a cell array. The cell array contains either one or `NUMSAMPLES` cells. Each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix of known values.

If `Design` has a single cell, it is assumed to have the same `Design` matrix for each sample. If `Design` has more than one cell, each cell contains a `Design` matrix for each sample.

Data Types: double | cell

### Covariance — Estimates for covariance of regression residuals

matrix

Estimates for the covariance of the regression residuals, specified as an `NUMSERIES`-by-`NUMSERIES` matrix.

Data Types: double

### Method — Method of calculation for the information matrix

'hessian' (default) | character vector

(Optional) Method of calculation for the information matrix, specified as a character vector defined as:

- 'hessian' — The expected Hessian matrix of the observed log-likelihood function. This method is recommended since the resultant standard errors incorporate the increased uncertainties due to missing data.
- 'fisher' — The Fisher information matrix.

---

**Note** If `Method` = 'fisher', to obtain more quickly just the standard errors of variance estimates without the standard errors of the covariance estimates, set `CovarFormat` = 'diagonal' regardless of the form of the covariance matrix.

Data Types: char

### CovarFormat — Format for the covariance matrix

'full' (default) | character vector

(Optional) Format for the covariance matrix, specified as a character vector. The choices are:

- 'full' — Compute the full covariance matrix.
- 'diagonal' — Force the covariance matrix to be a diagonal matrix.

Data Types: char

## Output Arguments

**StdParameters** — Standard errors for each element of **Parameters**  
vector

Standard errors for each element of **Parameters**, returned as an NUMPARAMS-by-1 column vector.

**StdCovariance** — Standard errors for each element of **Covariance**  
matrix

Standard errors for each element of **Covariance**, returned as an NUMSERIES-by-NUMSERIES matrix.

### Introduced in R2006a

# ecmnfish

Fisher information matrix

## Syntax

```
Fisher = ecmnfish(Data,Covariance)
Fisher = ecmnfish( ___,InvCovar,MatrixType)
```

## Description

`Fisher = ecmnfish(Data,Covariance)` computes an NUMPARAMS-by-NUMPARAMS Fisher information matrix based on the current maximum likelihood parameter estimates.

Use `ecmnfish` after estimating the mean and covariance of `Data` with `ecmnmlle`.

`Fisher = ecmnfish( ___,InvCovar,MatrixType)` adds optional arguments for `InvCovar` and `MatrixType`.

## Examples

### Compute Fisher Information Matrix Based on Parameter Estimates for Data

This example shows how to compute the Fisher information matrix based on parameter estimates for `Data` for five years of daily total returns for 12 computer technology stocks, with six hardware and six software companies

```
load ecmtechdemo.mat
```

The time period for this data extends from April 19, 2000 to April 18, 2005. The sixth stock in Assets is Google (GOOG), which started trading on August 19, 2004. So, all returns before August 20, 2004 are missing and represented as NaNs. Also, Amazon (AMZN) had a few days with missing values scattered throughout the past five years.

```
[ECMMean, ECMCovar] = ecmnmlle(Data)
```

```
ECMMean = 12×1
```

## Input Arguments

### Data — Data

matrix

Data, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. Missing values are indicated by NaNs.

Data Types: double

### Covariance — Maximum likelihood parameter estimates for covariance of Data

matrix

Maximum likelihood parameter estimates for the covariance of the `Data` using the ECM algorithm, specified as a `NUMSERIES`-by-`NUMSERIES` matrix.

### InvCovar — Cholesky decomposition of covariance matrix

[ ] (default) | matrix

(Optional) Inverse of covariance matrix, specified as a matrix using `inv` as:

```
inv(Covariance)
```

Data Types: double

**MatrixType — Matrix format**

'full' (default) | character vector

(Optional) Matrix format, specified as a character vector with a value of:

- 'full' — Computes the full Fisher information matrix.
- 'meanonly' — Computes only the components of the Fisher information matrix associated with the mean.

Data Types: char

## Output Arguments

**Fisher — Fisher information matrix**

matrix

Fisher information matrix, returned as an  $\text{NUMPARAMS} \times \text{NUMPARAMS}$  matrix based on current parameter estimates, where  $\text{NUMPARAMS} = \text{NUMSERIES} * (\text{NUMSERIES} + 3)/2$  if the `MatrixFormat` = 'full'. If the `MatrixFormat` = 'meanonly', then the `NUMPARAMS` = `NUMSERIES`.

## Introduced before R2006a

## ecmnhess

Hessian of negative log-likelihood function

### Syntax

```
Hessian = ecmnhess(Data,Covariance)
Hessian = ecmnhess(____,InvCovar,MatrixType)
```

### Description

`Hessian = ecmnhess(Data,Covariance)` computes an NUMPARAMS-by-NUMPARAMS Hessian matrix of the observed negative log-likelihood function based on current parameter estimates.

Use `ecmnhess` after estimating the mean and covariance of `Data` with `ecmnmle`.

`Hessian = ecmnhess(____,InvCovar,MatrixType)` adds optional arguments for `InvCovar` and `MatrixType`.

### Examples

#### Compute Hessian for Negative Log-Likelihood Function for Data

This example shows how to compute the Hessian for the negative log-likelihood function for five years of daily total return data for 12 computer technology stocks, with six hardware and six software companies

```
load ecmtechdemo.mat
```

The time period for this data extends from April 19, 2000 to April 18, 2005. The sixth stock in Assets is Google (GOOG), which started trading on August 19, 2004. So, all returns before August 20, 2004 are missing and represented as NaNs. Also, Amazon (AMZN) had a few days with missing values scattered throughout the past five years.

```
[ECMMean, ECMCovar] = ecmnmle(Data)
```

```
ECMMean = 12×1
```

```

## Input Arguments

### Data — Data

matrix

Data, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. Missing values are indicated by NaNs.

Data Types: double

### Covariance — Maximum likelihood parameter estimates for covariance of Data

matrix

Maximum likelihood parameter estimates for the covariance of the `Data` using the ECM algorithm, specified as a `NUMSERIES`-by-`NUMSERIES` matrix.

### InvCovar — Cholesky decomposition of covariance matrix

[ ] (default) | matrix

(Optional) Inverse of covariance matrix, specified as a matrix using `inv` as:

```
inv(Covariance)
```

Data Types: double

**MatrixType — Matrix format**

'full' (default) | character vector

(Optional) Matrix format, specified as a character vector with a value of:

- 'full' — Computes the full Hessian matrix.
- 'meanonly' — Computes only the components of the Hessian matrix associated with the mean.

Data Types: char

## Output Arguments

**Hessian — Hessian matrix**

matrix

Hessian matrix, returned as an  $\text{NUMPARAMS} \times \text{NUMPARAMS}$  matrix of the observed log-likelihood function based on current parameter estimates, where  $\text{NUMPARAMS} = \text{NUMSERIES} * (\text{NUMSERIES} + 3)/2$  if the `MatrixFormat` = 'full'. If the `MatrixFormat` = 'meanonly', then the `NUMPARAMS` = `NUMSERIES`.

"Maximum Likelihood Estimation" on page 9-3

## Introduced before R2006a

# ecmninit

Initial mean and covariance

## Syntax

```
[Mean,Covariance] = ecmninit(Data,InitMethod)
[Mean,Covariance] = ecmninit(___,InitMethod)
```

## Description

`[Mean,Covariance] = ecmninit(Data,InitMethod)` creates initial mean and covariance estimates for the function `ecmnmle`.

`[Mean,Covariance] = ecmninit(___,InitMethod)` adds an optional argument for `InitMethod`.

## Examples

### Compute Initial Mean and Covariance

This example shows how to compute the initial mean and covariance for five years of daily total return data for 12 computer technology stocks, with six hardware and six software companies

```
load ecmtechdemo.mat
```

The time period for this data extends from April 19, 2000 to April 18, 2005. The sixth stock in Assets is Google (GOOG), which started trading on August 19, 2004. So, all returns before August 20, 2004 are missing and represented as NaNs. Also, Amazon (AMZN) had a few days with missing values scattered throughout the past five years.

A naïve approach to the estimation of the mean and covariance for these 12 assets is to eliminate all days that have missing values for any of the 12 assets. Use the `ecminit` function with the '`nanskip`' option to do this.

```
[NaNMean, NaNCovar] = ecmninit(Data, 'nanskip')
```

```
NaNMean = 12×1
```

## Input Arguments

### Data — Data

matrix

Data, specified as an NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are indicated by NaNs.

Data Types: double

### InitMethod — Initialization methods to compute initial estimates for mean and covariance of data

'nanskip' (default) | character vector

(Optional) Initialization methods to compute the initial estimates for the mean and covariance of data, specified as a character vector. The initialization methods are:

- 'nanskip' — Skip all records with NaNs.
- 'twostage' — Estimate mean. Fill NaNs with the mean. Then estimate the covariance.
- 'diagonal' — Form a diagonal covariance.

Data Types: char

## Output Arguments

### Mean — Initial estimate of mean of Data

vector

Initial estimate of the mean of the Data, returned as a NUMSERIES-by-1 column vector.

### Covariance — Initial estimate of covariance of Data

matrix

Initial estimate of covariance of the Data, returned as a NUMSERIES-by-NUMSERIES matrix.

## Algorithms

### Model

The general model is

$$Z \sim N(\text{Mean}, \text{Covariance}),$$

where each row of **Data** is an observation of  $Z$ .

Each observation of  $Z$  is assumed to be iid (independent, identically distributed) multivariate normal, and missing values are assumed to be missing at random (MAR).

### Initialization Methods

This routine has three initialization methods that cover most cases, each with its advantages and disadvantages.

#### **nanskip**

The **nanskip** method works well with small problems (fewer than 10 series or with monotone missing data patterns). It skips over any records with NaNs and estimates initial values from complete-data records only. This initialization method tends to yield fastest convergence of the ECM algorithm. This routine switches to the **twostage** method if it determines that significant numbers of records contain NaN.

#### **twostage**

The **twostage** method is the best choice for large problems (more than 10 series). It estimates the mean for each series using all available data for each series. It then estimates the covariance matrix with missing values treated as equal to the mean rather than as NaNs. This initialization method is robust but tends to result in slower convergence of the ECM algorithm.

#### **diagonal**

The **diagonal** method is a worst-case approach that deals with problematic data, such as disjoint series and excessive missing data (more than 33% missing data). Of the three initialization methods, this method causes the slowest convergence of the ECM algorithm.

### Introduced before R2006a

## ecnmle

Mean and covariance of incomplete multivariate normal data

### Syntax

```
ecnmle(Data)
[Mean,Covariance] = ecnmle(Data)
[Mean,Covariance] = ecnmle(__,InitMethod,MaxIterations,Tolerance,Mean0,
Covar0)
```

### Description

`ecnmle(Data)` with no output arguments, this mode displays the convergence of the ECM algorithm in a plot by estimating objective function values for each iteration of the ECM algorithm until termination.

`[Mean,Covariance] = ecnmle(Data)` estimates the mean and covariance of a data set (`Data`). If the data set has missing values, this routine implements the ECM algorithm of Meng and Rubin [2] with enhancements by Sexton and Swensen [3]. ECM stands for a conditional maximization form of the EM algorithm of Dempster, Laird, and Rubin [4].

`[Mean,Covariance] = ecnmle(__,InitMethod,MaxIterations,Tolerance,Mean0,Covar0)` adds optional arguments for `InitMethod`, `MaxIterations`, `Tolerance`, `Mean0`, and `Covar0`.

### Examples

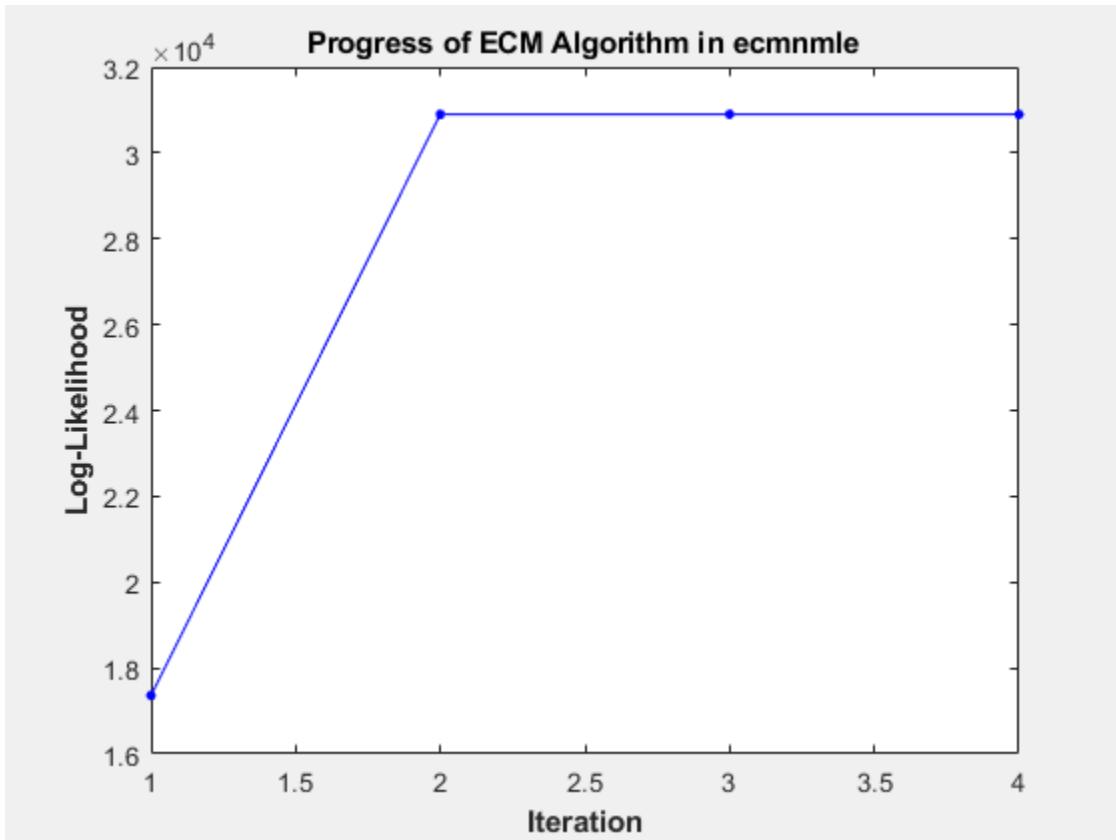

#### Compute Mean and Covariance of Incomplete Multivariate Normal Data

This example shows how to compute the mean and covariance of incomplete multivariate normal data for five years of daily total return data for 12 computer technology stocks, with six hardware and six software companies

```

## Input Arguments

### Data — Data

matrix

Data, specified as an NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are indicated by NaNs.

Data Types: double

### InitMethod — Initialization methods to compute initial estimates for mean and covariance of data

'nanskip' (default) | character vector

(Optional) Initialization methods to compute the initial estimates for the mean and covariance of data, specified as a character vector. The initialization methods are:

- 'nanskip' — Skip all records with NaNs.
- 'twostage' — Estimate mean. Fill NaNs with the mean. Then estimate the covariance.
- 'diagonal' — Form a diagonal covariance.

---

**Note** If you supply Mean0 and Covar0, InitMethod is not executed.

---

Data Types: char

### MaxIterations — Maximum number of iterations

50 (default) | numeric

(Optional) Maximum number of iterations for the expectation conditional maximization (ECM) algorithm, specified as a numeric.

Data Types: double

**Tolerance — Convergence tolerance**

1.0e-8 (default) | numeric

(Optional) Convergence tolerance for the ECM algorithm, specified as a numeric. If **Tolerance**  $\leq 0$ , perform maximum iterations specified by **MaxIterations** and do not evaluate the objective function at each step unless in display mode.

Data Types: double

**Mean0 — Estimate for the mean**

[] (default) | matrix

(Optional) Estimate for the mean, specified as an NUMSERIES-by-1 column vector. If you leave **Mean0** unspecified ([]), the method specified by **InitMethod** is used. If you specify **Mean0**, you must also specify **Covar0**.

Data Types: double

**Covar0 — Estimate for the covariance**

[] (default) | matrix

(Optional) Estimate for the covariance, specified as an NUMSERIES-by-NUMSERIES matrix, where the input matrix must be positive-definite. If you leave **Covar0** unspecified ([]), the method specified by **InitMethod** is used. If you specify **Covar0**, you must also specify **Mean0**.

Data Types: double

## Output Arguments

**Mean — Maximum likelihood parameter estimates for mean of Data**  
vector

Maximum likelihood parameter estimates for the mean of the **Data** using ECM algorithm, returned as a NUMSERIES-by-1 column vector.

**Covariance — Maximum likelihood parameter estimates for covariance of Data**  
matrix

Maximum likelihood parameter estimates for the covariance of the **Data** using ECM algorithm, returned as a NUMSERIES-by-NUMSERIES matrix.

## Algorithms

### Model

The general model is

$$Z \sim N(\text{Mean}, \text{Covariance}),$$

where each row of **Data** is an observation of **Z**.

Each observation of **Z** is assumed to be iid (independent, identically distributed) multivariate normal, and missing values are assumed to be missing at random (MAR). See Little and Rubin [1] for a precise definition of MAR.

This routine estimates the mean and covariance from given data. If data values are missing, the routine implements the ECM algorithm of Meng and Rubin [2] with enhancements by Sexton and Swensen [3].

If a record is empty (every value in a sample is NaN), this routine ignores the record because it contributes no information. If such records exist in the data, the number of nonempty samples used in the estimation is  $\leq \text{NumSamples}$ .

The estimate for the covariance is a biased maximum likelihood estimate (MLE). To convert to an unbiased estimate, multiply the covariance by  $\text{Count}/(\text{Count} - 1)$ , where  $\text{Count}$  is the number of nonempty samples used in the estimation.

## Requirements

This routine requires consistent values for **NUMSAMPLES** and **NUMSERIES** with  $\text{NUMSAMPLES} > \text{NUMSERIES}$ . It must have enough nonmissing values to converge. Finally, it must have a positive-definite covariance matrix. Although the references provide some necessary and sufficient conditions, general conditions for existence and uniqueness of solutions in the missing-data case, do not exist. The main failure mode is an ill-conditioned covariance matrix estimate. Nonetheless, this routine works for most cases that have less than 15% missing data (a typical upper bound for financial data).

## Initialization Methods

This routine has three initialization methods that cover most cases, each with its advantages and disadvantages. The ECM algorithm always converges to a minimum of the observed negative log-likelihood function. If you override the initialization methods, you must ensure that the initial estimate for the covariance matrix is positive-definite.

The following is a guide to the supported initialization methods.

- **nanskip** — The **nanskip** method works well with small problems (fewer than 10 series or with monotone missing data patterns). It skips over any records with NaNs and estimates initial values from complete-data records only. This initialization method tends to yield fastest convergence of the ECM algorithm. This routine switches to the **twostage** method if it determines that significant numbers of records contain NaN.
- **twostage** — The **twostage** method is the best choice for large problems (more than 10 series). It estimates the mean for each series using all available data for each series. It then estimates the covariance matrix with missing values treated as equal to the mean rather than as NaNs. This initialization method is robust but tends to result in slower convergence of the ECM algorithm.
- **diagonal** —

The **diagonal** method is a worst-case approach that deals with problematic data, such as disjoint series and excessive missing data (more than 33% of data missing). Of the three initialization methods, this method causes the slowest convergence of the ECM algorithm. If problems occur with this method, use display mode to examine convergence and modify either **MaxIterations** or **Tolerance**, or try alternative initial estimates with **Mean0** and **Covar0**. If all else fails, try

```
Mean0 = zeros(NumSeries);  
Covar0 = eye(NumSeries, NumSeries);
```

Given estimates for mean and covariance from this routine, you can estimate standard errors with the companion routine **ecmnstd**.

## Convergence

The ECM algorithm does not work for all patterns of missing values. Although it works in most cases, it can fail to converge if the covariance becomes singular. If this occurs, plots of the log-likelihood function tend to have a constant upward slope over many iterations as the log of the negative determinant of the covariance goes to zero. In some cases, the objective fails to converge due to machine precision errors. No general theory of missing data patterns exists to determine these cases. An example of a known failure occurs when two time series are proportional wherever both series contain nonmissing values.

## ecmnobj

Multivariate normal negative log-likelihood function

### Syntax

```
Objective = ecmnobj(Data,Mean,Covariance)
Objective = ecmnobj(___,CholCovariance)
```

### Description

`Objective = ecmnobj(Data,Mean,Covariance)` evaluates the negative log-likelihood function for `ecnnmle`.

Use `ecmnobj` after estimating the mean and covariance of `Data` with `ecnnmle`.

`Objective = ecmnobj(___,CholCovariance)` adds an optional argument for `CholCovariance`.

### Examples

#### Compute Value of the Observed Negative Log-Likelihood Function for Data

This example shows how to compute the value of the observed negative log-likelihood function for five years of daily total return data for 12 computer technology stocks, with six hardware and six software companies

```
load ecmtechdemo.mat
```

The time period for this data extends from April 19, 2000 to April 18, 2005. The sixth stock in Assets is Google (GOOG), which started trading on August 19, 2004. So, all returns before August 20, 2004 are missing and represented as NaNs. Also, Amazon (AMZN) had a few days with missing values scattered throughout the past five years.

```
[ECMMean, ECMCovar] = ecnnmle(Data)
```

```
ECMMean = 12×1
```

```

:

```

To evaluate the negative log-likelihood function for `ecmnmlle`, use `ecmnobj` based on the current maximum likelihood parameter estimates.

```
Objective = ecmnobj(Data,ECMMean,ECMCovar)
```

```
Objective = -3.0898e+04
```

## Input Arguments

### Data — Data

matrix

Data, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. Missing values are indicated by NaNs.

Data Types: double

### Mean — Maximum likelihood parameter estimates for mean of Data

vector

Maximum likelihood parameter estimates for the mean of the Data using the ECM algorithm, specified as a `NUMSERIES`-by-1 column vector.

### Covariance — Maximum likelihood parameter estimates for covariance of Data

matrix

Maximum likelihood parameter estimates for the covariance of the Data using the ECM algorithm, specified as a `NUMSERIES`-by-`NUMSERIES` matrix.

### CholCovariance — Cholesky decomposition of covariance matrix

[ ] (default) | matrix

(Optional) Cholesky decomposition of covariance matrix, specified as a matrix using `chol` as:

```
chol(Covariance)
```

Data Types: double

## Output Arguments

### Objective — Value of the observed negative log-likelihood function over Data

numeric

Value of the observed negative log-likelihood function over the `Data`, returned as a numeric value.

# ecmnstd

Standard errors for mean and covariance of incomplete data

## Syntax

```
[StdMean,StdCovar] = ecmnstd(Data,Mean,Covariance)
[StdMean,StdCovar] = ecmnstd(____,Method)
```

## Description

`[StdMean,StdCovar] = ecmnstd(Data,Mean,Covariance)` computes standard errors for mean and covariance of incomplete data.

Use `ecmnstd` after estimating the mean and covariance of `Data` with `ecmnmle`. If the mean and distinct covariance elements are treated as the parameter  $\theta$  in a complete-data maximum-likelihood estimation, then as the number of samples increases,  $\theta$  attains asymptotic normality such that

$$\theta - E[\theta] \sim N\left(0, I^{-1}(\theta)\right),$$

where  $E[\theta]$  is the mean and  $I(\theta)$  is the Fisher information matrix.

With missing data, the Hessian  $H(\theta)$  is a good approximation for the Fisher information (which can only be approximated when data is missing).

`[StdMean,StdCovar] = ecmnstd(____,Method)` adds an optional argument for `Method`.

## Examples

### Compute Standard Errors for Mean and Covariance of Incomplete Data

This example shows how to compute the standard errors for mean and covariance of incomplete data for five years of daily total return data for 12 computer technology stocks, with six hardware and six software companies

To evaluate the impact of the estimation error and, in particular, the effect of missing data, use `ecmnstd` to calculate standard errors. Although it is possible to estimate the standard errors for both the mean and covariance, the standard errors for the mean estimates alone are usually the main quantities of interest.

```
StdMeanF = ecmnstd(Data, ECMMean, ECMCovar, 'fisher')
```

```
StdMeanF = 12×1

|---------|--------|---------|---------|---------|--------|---------|---------|---------|---------|---------|---------|

The two assets with missing data, AMZN and GOOG, are the only assets to have differences due to missing information.

## Input Arguments

### Data — Data

matrix

Data, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. Missing values are indicated by NaNs.

Data Types: `double`

**Mean — Maximum likelihood parameter estimates for mean of Data vector**

Maximum likelihood parameter estimates for the mean of the **Data** using the ECM algorithm, specified as a NUMSERIES-by-1 column vector.

**Covariance — Maximum likelihood parameter estimates for covariance of Data matrix**

Maximum likelihood parameter estimates for the covariance of the **Data** using the ECM algorithm, specified as a NUMSERIES-by-NUMSERIES matrix.

**Method — Method of estimation for standard error calculations**

'hessian' (default) | character vector

(Optional) Method of estimation for standard error calculations, specified as a character vector. The estimation methods are:

- 'hessian' — The Hessian of the observed negative log-likelihood function. This method is recommended since the resultant standard errors incorporate the increase uncertainties due to missing data. In particular, standard errors calculated with the Hessian are generally larger than standard errors calculated with the Fisher information matrix.
- 'fisher' — The Fisher information matrix.

Data Types: char

## Output Arguments

**StdMean — Standard errors of estimates for each element of Mean vector**

Standard errors of estimates for each element of **Mean** vector, returned as a NUMSERIES-by-1 column vector.

**StdCovar — Standard errors of estimates for each element of Covariance matrix**

Standard errors of estimates for each element of **Covariance** matrix, returned as a NUMSERIES-by-NUMSERIES matrix.

## Introduced before R2006a

# effrr

Effective rate of return

## Syntax

```
Return = effrr(Rate,NumPeriods)
```

## Description

`Return = effrr(Rate,NumPeriods)` calculates the annual effective rate of return. Compounding continuously returns `Return` equivalent to  $(e^{\text{Rate}} - 1)$ .

## Examples

### Compute the Annual Effective Rate of Return

This example shows how to find the effective annual rate of return based on an annual percentage rate of 9% compounded monthly.

```
Return = effrr(0.09, 12)
```

```
Return = 0.0938
```

## Input Arguments

### Rate — Annual percentage rate

scalar numeric decimal

Annual percentage rate, specified as a scalar numeric decimal.

Data Types: double

### NumPeriods — Number of compounding periods per year

scalar integer

Number of compounding periods per year, specified as a scalar integer.

Data Types: double

## Output Arguments

### Return — Annual effective rate of return

scalar numeric decimal

Annual effective rate of return, returned as a scalar numeric decimal.

# elpm

Compute expected lower partial moments for normal asset returns

## Syntax

```
elpm(Mean,Sigma)
elpm(Mean,Sigma,MAR)
elpm(Mean,Sigma,MAR,Order)
Moment = elpm(MeanSigmaMAROrder)
```

## Description

`elpm(Mean,Sigma)` compute expected lower partial moments (`elpm`) relative to a default value of MAR for each asset in a NUMORDERS-by-NUMSERIES matrix.

`elpm(Mean,Sigma,MAR)` computes expected lower partial moments (`elpm`) relative to a MAR for each asset in a NUMORDERS-by-NUMSERIES matrix.

`elpm(Mean,Sigma,MAR,Order)` computes expected lower partial moments (`elpm`) relative to a MAR and Order for each asset in a NUMORDERS-by-NUMSERIES matrix.

`Moment = elpm(MeanSigmaMAROrder)` computes expected lower partial moments (`elpm`) relative to a default value of MAR for each asset in a NUMORDERS-by-NUMSERIES matrix `Moment`.

## Examples

### Compute Expected Lower Partial Moments

This example shows how to compute expected lower partial moments based on the mean and standard deviations of normally distributed asset returns. The `elpm` function works with the mean and standard deviations for multiple assets and multiple orders.

```
load FundMarketCash
Returns = tick2ret(TestData);
MAR = mean(Returns(:,3))

MAR = 0.0017

Mean = mean(Returns)

Mean = 1x3
    0.0038    0.0030    0.0017

Sigma = std(Returns, 1)

Sigma = 1x3
    0.0229    0.0389    0.0009
```

**Assets**

```
Assets = 1x3 cell
    {'Fund'}      {'Market'}     {'Cash'}
```

```
ELPM = elpm(Mean, Sigma, MAR, [0 1 2])
```

```
ELPM = 3x3
```

|        |        |        |
|--------|--------|--------|
| 0.4647 | 0.4874 | 0.5000 |
| 0.0082 | 0.0149 | 0.0004 |
| 0.0002 | 0.0007 | 0.0000 |

Based on the moments of each asset, the expected values for lower partial moments imply better than expected performance for the fund and market and worse than expected performance for cash. The `elpm` function works with either degenerate or nondegenerate normal random variables. For example, if cash were truly riskless, its standard deviation would be 0. You can examine the difference in average shortfall.

```
RisklessCash = elpm(Mean(3), 0, MAR, 1)
```

```
RisklessCash = 0
```

## Input Arguments

**Mean — Mean returns**

vector

Mean returns, specified as a NUMSERIES vector with mean returns for a collection of NUMSERIES assets.

Data Types: double

**Sigma — Standard deviation of returns**

vector

Standard deviation of returns, specified as a NUMSERIES vector with standard deviation of returns for a collection of NUMSERIES assets.

Data Types: double

**MAR — Minimum acceptable return**

0 (default) | numeric

(Optional) Minimum acceptable return, specified as a scalar numeric. MAR is a cutoff level of return such that all returns above MAR contribute nothing to the lower partial moment.

Data Types: double

**Order — Moment orders**

0 (default) | scalar numeric | vector

(Optional) Moment orders, specified as a either a scalar or a NUMORDERS vector of nonnegative integer moment orders. If no order specified, the default Order = 0, which is the shortfall probability. The `elpm` function does not work for negative or a noninteger Order.

Data Types: double

## Output Arguments

**Moment — Expected lower partial moments**  
matrix

Expected Lower partial moments, returned as a NUMORDERS-by-NUMSERIES matrix of expected lower partial moments with NUMORDERS Orders and NUMSERIES series, that is, each row contains expected lower partial moments for a given Order. The output Moment for the lower partial moment represents the moments of asset returns that fall below a minimum acceptable level of return.

---

**Note** To compute upper partial moments, reverse the signs of both the input Mean and MAR (do not reverse the signs of either Sigma or the output). This function computes expected lower partial moments with the mean and standard deviation of normally distributed asset returns. To compute sample lower partial moments from asset returns which have no distributional assumptions, use lpm.

## More About

### Lower Partial Moments

Use *lower partial moments* to examine what is colloquially known as “downside risk.”

The main idea of the lower partial moment framework is to model moments of asset returns that fall below a minimum acceptable level of return. To compute lower partial moments from data, use lpm to calculate lower partial moments for multiple asset return series and for multiple moment orders. To compute expected values for lower partial moments under several assumptions about the distribution of asset returns, use elpm to calculate lower partial moments for multiple assets and for multiple orders.

**Introduced in R2006b**

# emaxdrawdown

Compute expected maximum drawdown for Brownian motion

## Syntax

```
ExpDrawdown = emaxdrawdown(Mu,Sigma,T)
```

## Description

`ExpDrawdown = emaxdrawdown(Mu,Sigma,T)` computes the expected maximum drawdown for a Brownian motion for each time period in `T` using the following equation:

$$dX(t) = \mu dt + \sigma dW(t).$$

If the Brownian motion is geometric with the stochastic differential equation

$$dS(t) = \mu_0 S(t)dt + \sigma_0 S(t)dW(t)$$

then use Ito's lemma with  $X(t) = \log(S(t))$  such that

$$\mu = \mu_0 - 0.5\sigma_0^2,$$

$$\sigma = \sigma_0$$

converts it to the form used here.

## Examples

### Compute Expected Maximum Drawdown

This example shows how to use log-return moments of a fund to compute the expected maximum drawdown (EMaxDD) and then compare it with the realized maximum drawdown (MaxDD).

```
load FundMarketCash
logReturns = log(TestData(2:end,:)./ TestData(1:end-1,:));
Mu = mean(logReturns(:,1));
Sigma = std(logReturns(:,1),1);
T = size(logReturns,1);

MaxDD = maxdrawdown(TestData(:,1),'geometric')

MaxDD = 0.1813

EMaxDD = emaxdrawdown(Mu, Sigma, T)

EMaxDD = 0.1545
```

The drawdown observed in this time period is above the expected maximum drawdown. There is no contradiction here. The expected maximum drawdown is not an upper bound on the maximum losses from a peak, but an estimate of their average, based on a geometric Brownian motion assumption.

## Input Arguments

### Mu — Drift term of a Brownian motion with drift

numeric

Drift term of a Brownian motion with drift., specified as a scalar numeric.

Data Types: double

### Sigma — Diffusion term of a Brownian motion with drift

numeric

Diffusion term of a Brownian motion with drift, specified as a scalar numeric.

Data Types: double

### T — A time period of interest

numeric | vector

A time period of interest, specified as a scalar numeric or vector.

Data Types: double

## Output Arguments

### ExpDrawdown — Expected maximum drawdown

numeric

Expected maximum drawdown, returned as a numeric. ExpDrawdown is computed using an interpolation method. Values are accurate to a fraction of a basis point. Maximum drawdown is nonnegative since it is the change from a peak to a trough.

---

**Note** To compare the actual results from `maxdrawdown` with the expected results of `emaxdrawdown`, set the `Format` input argument of `maxdrawdown` to either of the nondefault values ('`arithmetic`' or '`geometric`'). These are the only two formats that `emaxdrawdown` supports.

---

## Introduced in R2006b

## end

Last date entry

---

**Note** end is not recommended. Use timetable instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

end

## Description

end returns the index to the last date entry in a financial time series object.

## Examples

Consider a financial time series object called MyFts:

```
dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
dates_times = cellstr([dates, repmat(' ',size(dates,1),1),...
                     times]);
myFts = fints(dates_times,(1:6)',{'Data1'},1,'My first FINTS')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints (line 165)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/display (line 66)

myFts =

```
desc: My first FINTS
freq: Daily (1)

'dates: (6)'    'times: (6)'    'Data1: (6)'
'01-Jan-2001'    '11:00'        [      1]
'          '    '12:00'        [      2]
'02-Jan-2001'    '11:00'        [      3]
'          '    '12:00'        [      4]
'03-Jan-2001'    '11:00'        [      5]
'          '    '12:00'        [      6]
```

Use end to return the last date entry in the financial time series object myFts.

myFts(end)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/end (line 57)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/subsref (line 106)

## Introduced before R2006a

# eq (fts)

Multiple financial time series object equality

---

**Note** `eq (fts)` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
tsobj_1 == tsobj_2
iseq = eq(tsobj_1,tsobj_2)
```

## Arguments

|                      |                               |
|----------------------|-------------------------------|
| <code>tsobj_1</code> | Financial time series object. |
| <code>tsobj_2</code> | Financial time series object. |

## Description

`tsobj_1 == tsobj_2` returns True (1) if both financial time series objects have the same dates, frequencies, data series names, and data values. Otherwise, `eq` returns False (0).

---

**Note** The data series names are case-sensitive, but do not have to be in the same order within each object.

---

## Examples

### Determine Multiple Financial Times Series Object Equality

This example shows how to determine if multiple financial times series objects are equal.

```
load disney
```

# estimateAssetMoments

Estimate mean and covariance of asset returns from data

---

**Note** Using a `fints` object for the `AssetReturns` argument of `estimateAssetMoments` is not recommended. Use `timetable` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
obj = estimateAssetMoments(obj, AssetReturns)
obj = estimateAssetMoments(___, Name, Value)
```

## Description

`obj = estimateAssetMoments(obj, AssetReturns)` estimates mean and covariance of asset returns from data for a `Portfolio` object. For details on the workflow, see “Portfolio Object Workflow” on page 4-17.

`obj = estimateAssetMoments(___, Name, Value)` estimates mean and covariance of asset returns from data for a `Portfolio` object with additional options for one or more `Name, Value` pair arguments.

## Examples

### Estimate Mean and Covariance of Asset Returns from Data for a Portfolio Object

To illustrate using the `estimateAssetMoments` function, generate random samples of 120 observations of asset returns for four assets from the mean and covariance of asset returns in the variables `m` and `C` with the `portsim` function. The default behavior `portsim` creates simulated data with estimated mean and covariance identical to the input moments `m` and `C`. In addition to a return series created by the `portsim` function in the variable `X`, a price series is created in the variable `Y`:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
X = portsim(m', C, 120);
Y = ret2tick(X);
```

Given asset returns and prices in the variables `X` and `Y` from above, the following examples demonstrate equivalent ways to estimate asset moments for the `Portfolio` object. A `Portfolio` object is created in `p` with the moments of asset returns set directly in the `Portfolio` object and a second `Portfolio` object is created in `q` to obtain the mean and covariance of asset returns from asset return data in `X` using the `estimateAssetMoments` function.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

X = portsim(m', C, 120);
p = Portfolio('mean',m,'covar',C);
q = Portfolio;
q = estimateAssetMoments(q, X);

[passetmean, passetcovar] = getAssetMoments(p)
passetmean = 4x1
0.0042
0.0083
0.0100
0.0150

passetcovar = 4x4
0.0005    0.0003    0.0002        0
0.0003    0.0024    0.0017    0.0010
0.0002    0.0017    0.0048    0.0028
0    0.0010    0.0028    0.0102

[qassetmean, qassetcovar] = getAssetMoments(q)
qassetmean = 4x1
0.0042
0.0083
0.0100
0.0150

qassetcovar = 4x4
0.0005    0.0003    0.0002   -0.0000
0.0003    0.0024    0.0017    0.0010
0.0002    0.0017    0.0048    0.0028
-0.0000    0.0010    0.0028    0.0102
```

Notice how either approach yields the same moments. The default behavior of the `estimateAssetMoments` function is to work with asset returns. If, instead, you have asset prices, such as in the variable `Y`, the `estimateAssetMoments` function accepts a parameter name `'DataFormat'` with a corresponding value set to `'prices'` to indicate that the input to the method is in the form of asset prices and not returns (the default parameter value for `'DataFormat'` is `'returns'`). The following example compares direct assignment of moments in the `Portfolio` object `p` with estimated moments from asset price data in `Y` in the `Portfolio` object `q`:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
```

```

0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

X = portsim(m', C, 120);
Y = ret2tick(X);

p = Portfolio('mean',m,'covar',C);

q = Portfolio;
q = estimateAssetMoments(q, Y, 'dataformat', 'prices');

[passetmean, passetcovar] = getAssetMoments(p)

passetmean = 4x1

0.0042
0.0083
0.0100
0.0150

passetcovar = 4x4

0.0005    0.0003    0.0002      0
0.0003    0.0024    0.0017    0.0010
0.0002    0.0017    0.0048    0.0028
0    0.0010    0.0028    0.0102

[qassetmean, qassetcovar] = getAssetMoments(q)

qassetmean = 4x1

0.0042
0.0083
0.0100
0.0150

qassetcovar = 4x4

0.0005    0.0003    0.0002   -0.0000
0.0003    0.0024    0.0017    0.0010
0.0002    0.0017    0.0048    0.0028
-0.0000    0.0010    0.0028    0.0102

```

## Estimate Mean and Covariance of Asset Returns from Timetable Data for a Portfolio Object

To illustrate using the `estimateAssetMoments` function with `AssetReturns` data continued in a `timetable` object, use the `CAPMuniverse.mat` which contains a `timetable` object (`AssetTimeTable`) for returns data.

```

load CAPMuniverse
AssetsTimeTable.Properties;
head(AssetsTimeTable,5)

ans=5×14 timetable
    Time      AAPL      AMZN      CSC0      DELL      EBAY      GOOG      HPQ      IBM      INTC      MSFT      ORCL      YHOO      MARKET      CASH
    _____
    03-Jan-2000  0.088805  0.1742  0.008775 -0.002353  0.12829  NaN  0.0
    04-Jan-2000 -0.084331 -0.08324 -0.05608 -0.08353 -0.093805  NaN -0.0
    05-Jan-2000  0.014634 -0.14877 -0.003039  0.070984  0.066875  NaN -0.0
    06-Jan-2000 -0.086538 -0.060072 -0.016619 -0.038847 -0.012302  NaN -0.0
    07-Jan-2000  0.047368  0.061013  0.0587 -0.037708 -0.000964  NaN  0.0

```

Notice that GOOG has missing data (NaN), because it was not listed before Aug 2004. The `estimateAssetMoments` function has a name-value pair argument 'MissingData' that indicates with a Boolean value whether to use the missing data capabilities of Financial Toolbox™ software. The default value for 'MissingData' is false which removes all samples with NaN values. If, however, 'MissingData' is set to true, `estimateAssetMoments` uses the ECM algorithm to estimate asset moments.

```

r = Portfolio;
r = estimateAssetMoments(r,AssetsTimeTable,'dataformat','returns','missingdata',true);

```

In addition, the `estimateAssetMoments` function also extracts asset names or identifiers from a timetable object when the name-value argument 'GetAssetList' set to `true` (its default value is `false`). If the 'GetAssetList' value is `true`, the timetable column identifiers are used to set the `AssetList` property of the `Portfolio` object. To show this, the formation of the `Portfolio` object `r` is repeated with the 'GetAssetList' flag set to `true`.

```

r = estimateAssetMoments(r,AssetsTimeTable,'GetAssetList',true);
disp(r.AssetList')

{'AAPL'}
{'AMZN'}
{'CSCO'}
{'DELL'}
{'EBAY'}
{'GOOG'}
{'HPQ'}
{'IBM'}
{'INTC'}
{'MSFT'}
{'ORCL'}
{'YHOO'}
{'MARKET'}
{'CASH'}

```

### Estimate Mean and Covariance of Asset Returns from Data for a Portfolio Object with Integrality Constraints

Create a `Portfolio` object for three assets.

```

AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;

```

```

0.00022983 0.00049937 0.00019247;
0.00420395 0.00019247 0.00764097 ];
AssetMean = AssetMean/12
AssetMean = 3×1

0.0008
0.0004
0.0011

AssetCovar = AssetCovar/12
AssetCovar = 3×3
10-3 ×

0.2705    0.0192    0.3503
0.0192    0.0416    0.0160
0.3503    0.0160    0.6367

X = portsim(AssetMean', AssetCovar, 120);

p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);

Use setBounds with semi-continuous constraints to set  $x_i=0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i=1,\dots,\text{NumAssets}$ .

p = setBounds(p, 0.02, 0.5, 'BoundType', 'Conditional', 'NumAssets', 3);

When working with a Portfolio object, the setMinMaxNumAssets function enables you to set up cardinality constraints for a long-only portfolio. This sets the cardinality constraints for the Portfolio object, where the total number of allocated assets satisfying the nonzero semi-continuous constraints are between MinNumAssets and MaxNumAssets. By setting MinNumAssets=MaxNumAssets=2, only two of the three assets are invested in the portfolio.

p = setMinMaxNumAssets(p, 2, 2);

Use estimateAssetMoments to estimate mean and covariance of asset returns from data for a Portfolio object.

p = estimateAssetMoments(p, X);
[passetmean, passetcovar] = getAssetMoments(p)

passetmean = 3×1

0.0008
0.0004
0.0011

passetcovar = 3×3
10-3 ×

0.2705    0.0192    0.3503
0.0192    0.0416    0.0160
0.3503    0.0160    0.6367

```

The `estimateAssetMoments` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```
p.solverOptionsMINLP  
ans = struct with fields:  
    MaxIterations: 1000  
    AbsoluteGapTolerance: 1.0000e-07  
    RelativeGapTolerance: 1.0000e-05  
    NonlinearScalingFactor: 1000  
    ObjectiveScalingFactor: 1000  
    Display: 'off'  
    CutGeneration: 'basic'  
    MaxIterationsInactiveCut: 30  
    ActiveCutTolerance: 1.0000e-07  
    IntMasterSolverOptions: [1x1 optim.options.Intlinprog]  
    NumIterationsEarlyIntegerConvergence: 30
```

## Input Arguments

### **obj — Object for portfolio**

object

Object for portfolio, specified using a `Portfolio` object. For more information on creating a portfolio object, see

- `Portfolio`

Data Types: `object`

### **AssetReturns — Matrix, table, or timetable that contains asset price data that can be converted to asset returns**

matrix | table | timetable

Matrix, `table`, or `timetable` that contains asset price data that can be converted to asset returns, specified by a `NumSamples`-by-`NumAssets` matrix.

`AssetReturns` data can be:

- `NumSamples`-by-`NumAssets` matrix.
- Table of `NumSamples` prices or returns at a given periodicity for a collection of `NumAssets` assets
- Timetable object with `NumSamples` observations and `NumAssets` time series

Use the optional `DataFormat` argument to convert `AssetReturns` input data that is asset prices into asset returns. Be careful when using asset price data because portfolio optimization usually requires total returns and not simply price returns.

Data Types: `double` | `table` | `timetable`

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1`, ..., `NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `p = estimateAssetMoments(p, Y, 'dataformat', 'prices')`

**DataFormat — Flag to convert input data as prices into returns**

'Returns' (default) | character vector with values 'Returns' or 'Prices'

Flag to convert input data as prices into returns, specified as the comma-separated pair consisting of 'DataFormat' and a character vector with the values:

- 'Returns' — Data in `AssetReturns` contains asset total returns.
- 'Prices' — Data in `AssetReturns` contains asset total return prices.

Data Types: char

**MissingData — Flag indicating whether to use ECM algorithm or exclude samples with NaN values**

false (default) | logical with value true or false

Flag indicating whether to use ECM algorithm or excludes samples with NaN values, specified as the comma-separated pair consisting of 'MissingData' and a logical with a value of true or false.

To handle time series with missing data (indicated with NaN values), the `MissingData` flag either uses the ECM algorithm to obtain maximum likelihood estimates in the presences of NaN values or excludes samples with NaN values. Since the default is `false`, it is necessary to specify `MissingData` as `true` to use the ECM algorithm.

Acceptable values for `MissingData` are:

- `false` — Do not use ECM algorithm to handle NaN values (exclude NaN values).
- `true` — Use ECM algorithm to handle NaN values.

For more information on the ECM algorithm, see `ecmmnlle` and “Multivariate Normal Regression” on page 9-2.

Data Types: logical

**GetAssetList — Flag indicating which asset names to use for asset list**

false (default) | logical with value true or false

Flag indicating which asset names to use for the asset list, specified as the comma-separated pair consisting of 'GetAssetList' and a logical with a value of true or false. Acceptable values for `GetAssetList` are:

- `false` — Do not extract or create asset names.
- `true` — Extract or create asset names from a table or timetable object.

If a `table` or `timetable` is passed into this function using the `AssetReturns` argument and the `GetAssetList` flag is `true`, the column names from the table or timetable object are used as asset names in `obj.AssetList`.

If a matrix is passed and the `GetAssetList` flag is `true`, default asset names are created based on the `AbstractPortfolio` property `defaultforAssetList`, which is '`Asset`'.

If the `GetAssetList` flag is `false`, no action occurs, which is the default behavior.

Data Types: logical

## Output Arguments

### **obj — Updated portfolio object**

object for portfolio

Updated portfolio object, returned as a `Portfolio` object. For more information on creating a portfolio object, see

- `Portfolio`

## Tips

You can also use dot notation to estimate the mean and covariance of asset returns from data.

```
obj = obj.estimateAssetMoments(AssetReturns);
```

“Portfolio Optimization Theory” on page 4-3

## Introduced in R2011a

# estimateBounds

Estimate global lower and upper bounds for set of portfolios

## Syntax

```
[glb,gub,isbounded] = estimateBounds(obj)
[glb,gub,isbounded] = estimateBounds(obj,obtainExactBounds)
```

## Description

`[glb,gub,isbounded] = estimateBounds(obj)` estimates global lower and upper bounds for set of portfolios for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “[Portfolio Object Workflow](#)” on page 4-17, “[PortfolioCVaR Object Workflow](#)” on page 5-15, and “[PortfolioMAD Object Workflow](#)” on page 6-15.

---

**Note** The `estimateBounds` function does not consider cardinality or semicontinuous constraints. For more information, see “[Working with 'Conditional' BoundType, MinNumAssets, and MaxNumAssets Constraints Using Portfolio Objects](#)” on page 4-78.

---

`[glb,gub,isbounded] = estimateBounds(obj,obtainExactBounds)` estimates global lower and upper bounds for set of portfolios with an additional option specified for `obtainExactBounds`.

## Examples

### Create an Unbounded Portfolio for a Portfolio Object

Create an unbounded portfolio set.

```
p = Portfolio('AInequality', [1 -1; 1 1], 'bInequality', 0);
[lb, ub, isbounded] = estimateBounds(p)
```

`lb = 2x1`

```
-Inf  
-Inf
```

`ub = 2x1`

```
0  
Inf
```

```
isbounded = logical  
0
```

The `estimateBounds` function returns (possibly infinite) bounds and sets the `isbounded` flag to `false`. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

### Create an Unbounded Portfolio for a `PortfolioCVaR` Object

Create an unbounded portfolio set.

```
p = PortfolioCVaR('AInequality', [1 -1; 1 1], 'bInequality', 0);
[lb, ub, isbounded] = estimateBounds(p)

lb = 2×1

    -Inf
    -Inf

ub = 2×1

    0
    Inf

isbounded = logical
    0
```

The `estimateBounds` function returns (possibly infinite) bounds and sets the `isbounded` flag to `false`. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

### Create an Unbounded Portfolio for a `PortfolioMAD` Object

Create an unbounded portfolio set.

```
p = PortfolioMAD('AInequality', [1 -1; 1 1], 'bInequality', 0);
[lb, ub, isbounded] = estimateBounds(p)

lb = 2×1

    -Inf
    -Inf

ub = 2×1

    0
    Inf

isbounded = logical
    0
```

The `estimateBounds` function returns (possibly infinite) bounds and sets the `isbounded` flag to `false`. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

**obtainExactBounds — Flag to specify whether to solve for all bounds or to accept specified bounds whenever available**  
true (default) | logical

Flag to specify whether to solve for all bounds or to accept specified bounds whenever available, specified as a logical with values of `true` or `false`. If bounds are known, set `obtainExactBounds` to `false` to accept known bounds. The default for `obtainExactBounds` is `true`.

Data Types: logical

## Output Arguments

**glb — Global lower bounds for portfolio set**  
vector

Global lower bounds for portfolio set, returned as vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**gub — Global upper bounds for portfolio set**  
vector

Global upper bounds for portfolio set, returned as vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**isbounded — Indicator for whether portfolio set is empty, bounded, or unbounded**  
logical

Indicator for whether portfolio set is empty ([ ]), bounded (`true`), or unbounded (`false`), returned as a logical.

---

**Note** By definition, any portfolio set must be nonempty and bounded:

- If the set is empty, `isbounded` = [ ].

- If the set is nonempty and unbounded, `isbounded = false`.
  - If the set is nonempty and bounded, `isbounded = true`.
  - If the set is empty, `glb` and `gub` are set to NaN vectors.
- 

An `isbounded` value is returned for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## Tips

- You can also use dot notation to estimate the global lower and upper bounds for a given set of portfolios.  
`[glb, gub, isbounded] = obj.estimateBounds;`
- Estimated bounds are accurate in most cases to within `1.0e-8`. If you intend to use these bounds directly in a portfolio object, ensure that if you impose such bound constraints, a lower bound of `0` is probably preferable to a lower bound of, for example, `1.0e-10` for portfolio weights.

### Introduced in R2011a

# estimateFrontier

Estimate specified number of optimal portfolios on the efficient frontier

## Syntax

```
[pwgt,pbuy,psell] = estimateFrontier(obj)
[pwgt,pbuy,psell] = estimateFrontier(obj,NumPorts)
```

## Description

[pwgt,pbuy,psell] = estimateFrontier(obj) estimates the specified number of optimal portfolios on the efficient frontier for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “`Portfolio` Object Workflow” on page 4-17, “`PortfolioCVaR` Object Workflow” on page 5-15, and “`PortfolioMAD` Object Workflow” on page 6-15.

[pwgt,pbuy,psell] = estimateFrontier(obj,NumPorts) estimates the specified number of optimal portfolios on the efficient frontier with an additional option specified for `NumPorts`.

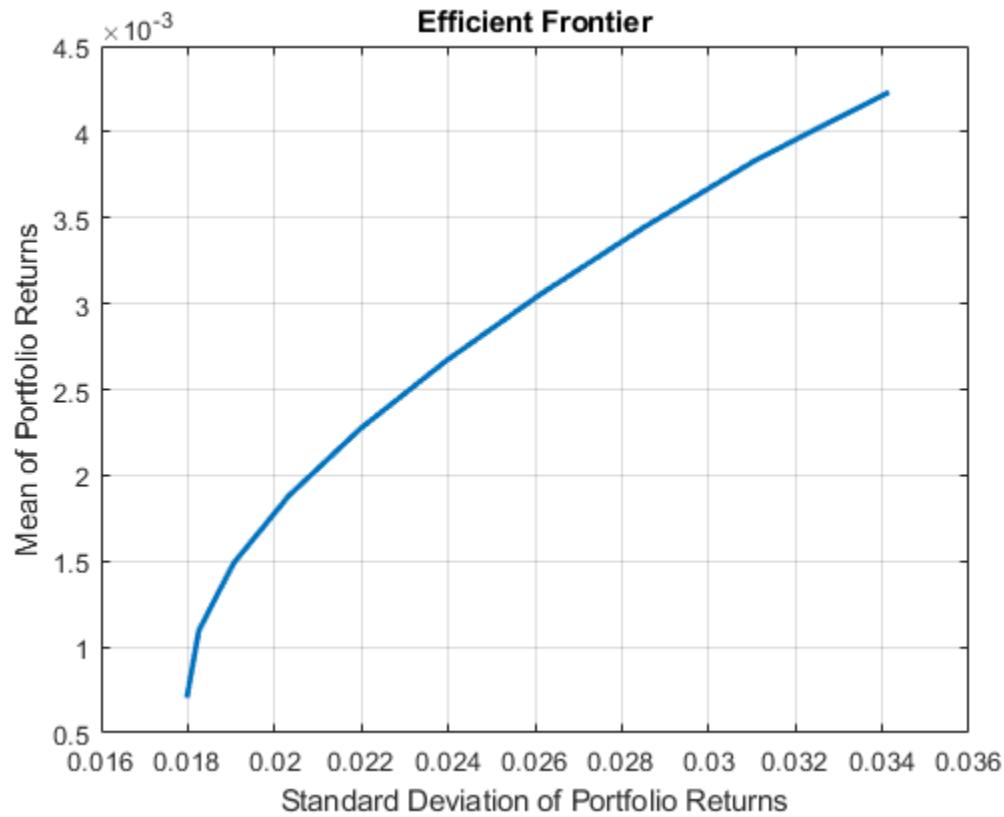

## Examples

### Create a Portfolio Object and Determine Efficient Portfolios

Create efficient portfolios:

```
load CAPMuniverse

p = Portfolio('AssetList',Assets(1:12));
p = estimateAssetMoments(p, Data(:,1:12), 'missingdata',true);
p = setDefaultConstraints(p);
plotFrontier(p);
```

```
pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5
    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([{pwgt},pnames], 'obsnames',p.AssetList);

disp(Blotter);
```

|      | Port1     | Port2    | Port3    | Port4   | Port5 |
|------|-----------|----------|----------|---------|-------|
| AAPL | 0.017926  | 0.058247 | 0.097816 | 0.12955 | 0     |

## Create a Portfolio Object with BoundType and MaxNumAssets Constraints and Determine Efficient Portfolios

Create a `Portfolio` object for 12 stocks based on `CAPMuniverse.mat`.

```
load CAPMuniverse
p0 = Portfolio('AssetList',Assets(1:12));
p0 = estimateAssetMoments(p0, Data(:,1:12), 'missingdata', true);
p0 = setDefaultConstraints(p0);
```

Use `setMinMaxNumAssets` to define a maximum number of 3 assets.

```
p1 = setMinMaxNumAssets(p0, [], 3);
```

Use `setBounds` to define a lower and upper bound and a `BoundType` of 'Conditional'.

```
p1 = setBounds(p1, 0.1, 0.5, 'BoundType', 'Conditional');
pwgt = estimateFrontier(p1, 5);
```

The following table shows that the optimized allocations only have maximum 3 assets invested, and small positions less than 0.1 are avoided.

```
result = table(p0.AssetList', pwgt)
```

|          | Var1    | pwgt    |         |         |
|----------|---------|---------|---------|---------|
| {'AAPL'} | 0       | 0       | 0       | 0.14308 |
| {'AMZN'} | 0       | 0       | 0       | 0       |
| {'CSCO'} | 0       | 0       | 0       | 0       |
| {'DELL'} | 0       | 0       | 0       | 0       |
| {'EBAY'} | 0       | 0       | 0       | 0.5     |
| {'GOOG'} | 0.16979 | 0.29587 | 0.42213 | 0.49998 |
| {'HPQ'}  | 0       | 0       | 0       | 0       |
| {'IBM'}  | 0.49602 | 0.4363  | 0.37309 | 0.35694 |
| {'INTC'} | 0       | 0       | 0       | 0       |
| {'MSFT'} | 0.33419 | 0.26783 | 0.20479 | 0       |
| {'ORCL'} | 0       | 0       | 0       | 0       |
| {'YHOO'} | 0       | 0       | 0       | 0       |

The `estimateFrontier` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```
p1.solverTypeMINLP
```

```
ans =
'OuterApproximation'
```

```
p1.solverOptionsMINLP
```

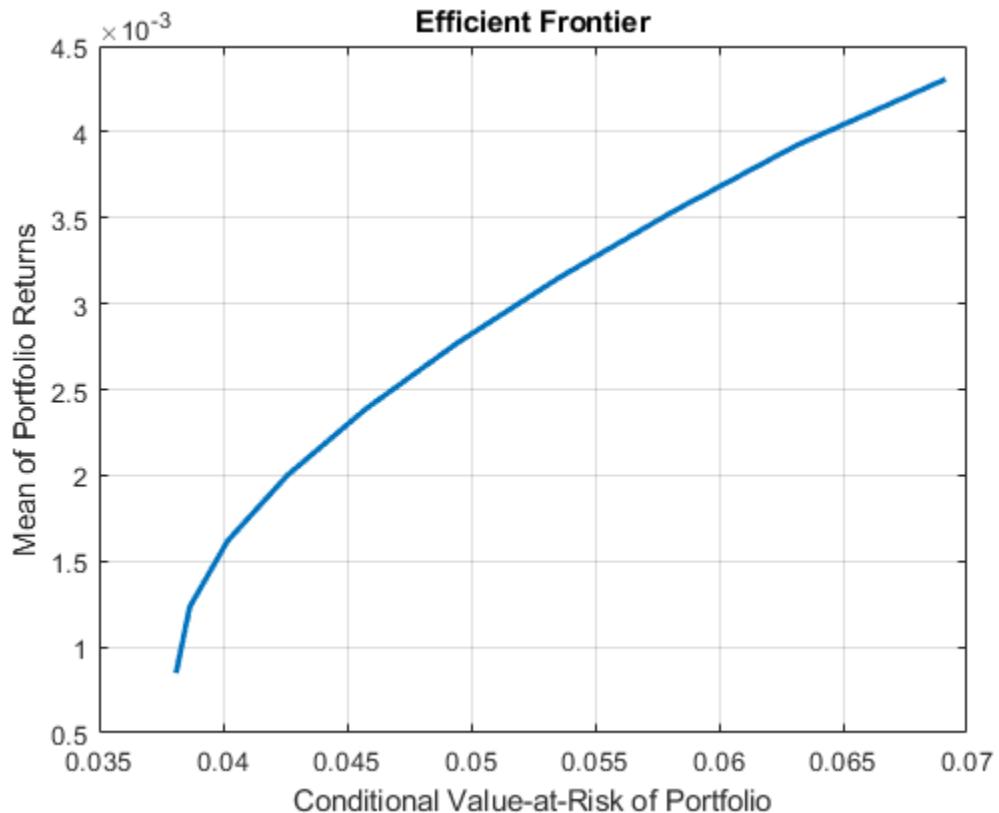

```
ans = struct with fields:
    MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
    Display: 'off'
```

```
CutGeneration: 'basic'  
MaxIterationsInactiveCut: 30  
ActiveCutTolerance: 1.0000e-07  
IntMasterSolverOptions: [1x1 optim.options.Intlinprog]  
NumIterationsEarlyIntegerConvergence: 30
```

### Construct a PortfolioCVaR Object and Determine Efficient Portfolios

Create efficient portfolios:

```
load CAPMuniverse  
  
p = PortfolioCVaR('AssetList',Assets(1:12));  
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 , 'missingdata',true);  
p = setDefaultConstraints(p);  
p = setProbabilityLevel(p, 0.95);  
  
plotFrontier(p);
```

```
pwgt = estimateFrontier(p, 5);  
  
pnames = cell(1,5);  
for i = 1:5
```

```

    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([{pwgt},pnames], 'obsnames',p.AssetList);

disp(Blotter);

|      | Port1    | Port2     | Port3    | Port4   | Port5 |
|------|----------|-----------|----------|---------|-------|
| AAPL | 0.010562 | 0.07364   | 0.11931  | 0.13073 | 0     |
| AMZN | 0        | 0         | 0        | 0       | 0     |
| CSCO | 0        | 0         | 0        | 0       | 0     |
| DELL | 0.022649 | 0         | 0        | 0       | 0     |
| EBAY | 0        | 0         | 0        | 0       | 0     |
| GOOG | 0.203    | 0.38011   | 0.56202  | 0.75919 | 1     |
| HPQ  | 0.042772 | 0.0094711 | 0        | 0       | 0     |
| IBM  | 0.44444  | 0.36456   | 0.26305  | 0.11009 | 0     |
| INTC | 0        | 0         | 0        | 0       | 0     |
| MSFT | 0.27658  | 0.17222   | 0.055624 | 0       | 0     |
| ORCL | 0        | 0         | 0        | 0       | 0     |
| YHOO | 0        | 0         | 0        | 0       | 0     |

```

## Create a PortfolioMAD Object and Determine Efficient Portfolios

Create efficient portfolios:

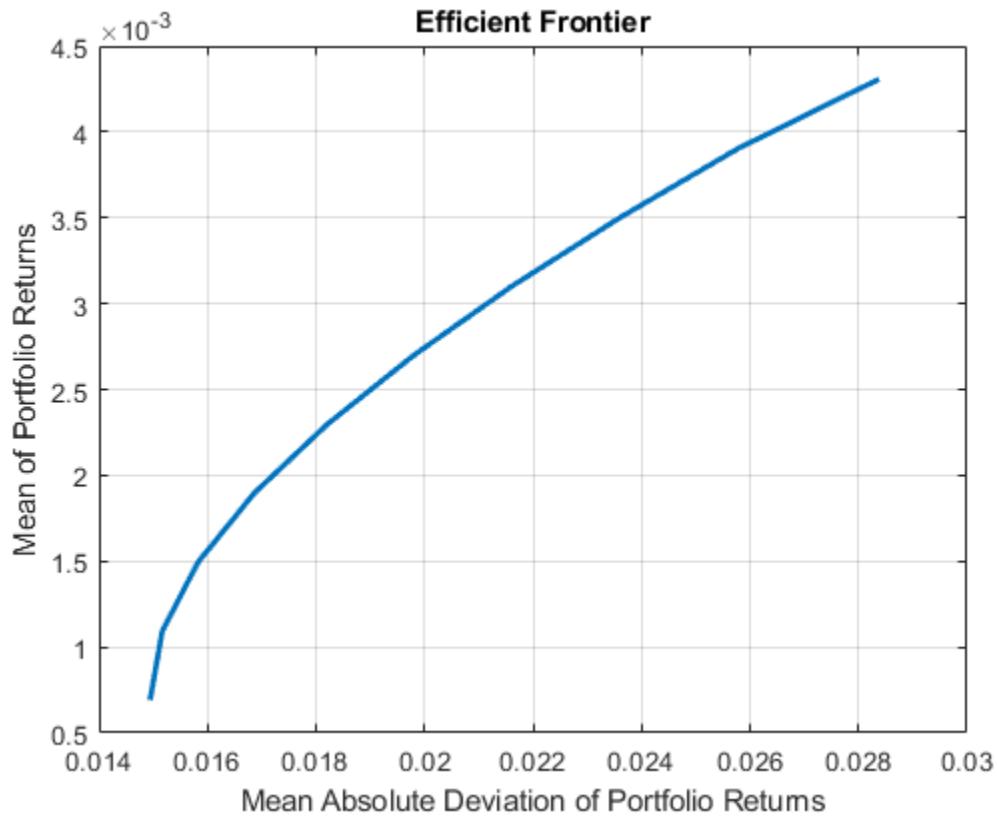

```

load CAPMuniverse

p = PortfolioMAD('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 , 'missingdata',true);
p = setDefaultConstraints(p);

plotFrontier(p);

```

```
pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5
    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([{pwgt},pnames], 'obsnames',p.AssetList);

disp(Blotter);
```

|      | Port1     | Port2    | Port3    | Port4   | Port5 |
|------|-----------|----------|----------|---------|-------|
| AAPL | 0.029787  | 0.076199 | 0.11265  | 0.13397 | 0     |

## Obtain the Default Number of Efficient Portfolios for a Portfolio Object

Obtain the default number of efficient portfolios over the entire range of the efficient frontier.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
```

```
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p);
disp(pwgt);
```

Columns 1 through 7

|        |        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|--------|

## Obtain Purchases and Sales for Portfolios on the Efficient Frontier for a Portfolio Object

Starting from the initial portfolio, the `estimateFrontier` function returns purchases and sales to get from your initial portfolio to each efficient portfolio on the efficient frontier. Given an initial portfolio in `pwgt0`, you can obtain purchases and sales.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
```

```
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontier(p);
```

`display(pwgt);`

`pwgt = 4×10`

|        |        |        |        |        |        |        |        |        |   |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|---|
| 0.8891 | 0.7215 | 0.5540 | 0.3865 | 0.2190 | 0.0515 | 0      | 0      | 0      | 0 |
| 0.0369 | 0.1289 | 0.2209 | 0.3129 | 0.4049 | 0.4969 | 0.4049 | 0.2314 | 0.0579 | 0 |

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Obtain Purchases and Sales for Portfolios on the Efficient Frontier for a PortfolioMAD Object

Starting from the initial portfolio, the `estimateFrontier` function returns purchases and sales to get from your initial portfolio to each efficient portfolio on the efficient frontier. Given an initial portfolio in `pwgt0`, you can obtain purchases and sales.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontier(p);

display(pwgt);

pwgt = 4×10

    0.8817    0.7150    0.5488    0.3812    0.2167    0.0494         0         0         0
    0.0431    0.1285    0.2127    0.2993    0.3832    0.4679    0.3599    0.1758         0
    0.0387    0.0604    0.0826    0.1047    0.1237    0.1480    0.1799    0.2091    0.2266
    0.0366    0.0961    0.1559    0.2148    0.2763    0.3348    0.4601    0.6151    0.7734    1.0000

display(pbuy);

     0         0         0         0         0         0         0    0.0091    0.0266
     0         0    0.0559    0.1148    0.1763    0.2348    0.3601    0.5151    0.6734    0.9000

display(psell);

psell = 4×10

         0         0         0         0    0.0833    0.2506    0.3000    0.3000    0.3000
    0.2569    0.1715    0.0873    0.0007         0         0         0    0.1242    0.3000    0.3000
    0.1613    0.1396    0.1174    0.0953    0.0763    0.0520    0.0201         0         0
    0.0634    0.0039         0         0         0         0         0         0         0         0
```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

### **obj — Object for portfolio** object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **NumPorts — Number of points to obtain on efficient frontier**

value from hidden property `defaultNumPorts` (default value is 10) (default) | scalar integer

Number of points to obtain on the efficient frontier, specified as a scalar integer.

---

**Note** If no value is specified for `NumPorts`, the default value is obtained from the hidden property `defaultNumPorts` (default value is 10). If `NumPorts = 1`, this function returns the portfolio specified by the hidden property `defaultFrontierLimit` (current default value is '`min`').

---

Data Types: double

## Output Arguments

### **pwgt — Optimal portfolios on efficient frontier with specified number of portfolios spaced equally from minimum to maximum portfolio return** matrix

Optimal portfolios on the efficient frontier with specified number of portfolios spaced equally from minimum to maximum portfolio return, returned as a `NumAssets`-by-`NumPorts` matrix. `pwgt` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **pbuy — Purchases relative to initial portfolio for optimal portfolios on efficient frontier** matrix

Purchases relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as `NumAssets`-by-`NumPorts` matrix.

---

**Note** If no initial portfolio is specified in `obj.InitPort`, that value is assumed to be 0 such that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`.

---

`pbuy` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **psell — Sales relative to initial portfolio for optimal portfolios on efficient frontier** matrix

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a NumAssets-by-NumPorts matrix.

---

**Note** If no initial portfolio is specified in `obj.InitPort`, that value is assumed to be 0 such that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`.

---

`psell` is returned for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## Tips

- You can also use dot notation to estimate the specified number of optimal portfolios over the entire efficient frontier.

```
[pwgt, pbuy, psell] = obj.estimateFrontier(NumPorts);
```

- When introducing transaction costs and turnover constraints to the `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object, the portfolio optimization objective contains a term with an absolute value. For more information on how Financial Toolbox handles such cases algorithmically, see “References” on page 19-797.

## Introduced in R2011a

## estimateFrontierByReturn

Estimate optimal portfolios with targeted portfolio returns

### Syntax

```
[pwgt,pbuy,psell] = estimateFrontierByReturn(obj,TargetReturn)
```

### Description

[pwgt,pbuy,psell] = estimateFrontierByReturn(obj,TargetReturn) estimates optimal portfolios with targeted portfolio returns for *Portfolio*, *PortfolioCVaR*, or *PortfolioMAD* objects. For details on the respective workflows when using these different objects, see “*Portfolio Object Workflow*” on page 4-17, “*PortfolioCVaR Object Workflow*” on page 5-15, and “*PortfolioMAD Object Workflow*” on page 6-15.

### Examples

#### Obtain the Portfolio for Targeted Portfolio Returns for a Portfolio Object

To obtain efficient portfolios that have targeted portfolio returns, the *estimateFrontierByReturn* function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of 6%, 9%, and 12%.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierByReturn(p, [0.06, 0.09, 0.12]);

display(pwgt);

pwgt = 4x3
```

| 0.8772 | 0.5032 | 0.1293 |
|--------|--------|--------|
| 0.0434 | 0.2488 | 0.4541 |
| 0.0416 | 0.0780 | 0.1143 |
| 0.0378 | 0.1700 | 0.3022 |

## Obtain Portfolios with Targeted Portfolio Returns for a Portfolio Object with BoundType, MinNumAssets, and MaxNumAssets Constraints

When any one, or any combination of the constraints from 'Conditional' BoundType, MinNumAssets, and MaxNumAssets are active, the portfolio problem is formulated as mixed integer programming problem and the MINLP solver is used.

Create a `Portfolio` object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use `setBounds` with semicontinuous constraints to set  $x_i = 0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i = 1, \dots, \text{NumAssets}$ .

```
p = setBounds(p, 0.02, 0.7, 'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up the limits on the number of assets invested (as known as cardinality) constraints. This sets the total number of allocated assets satisfying the Bound constraints that are between `MinNumAssets` and `MaxNumAssets`. By setting `MinNumAssets` = `MaxNumAssets` = 2, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use `estimateFrontierByReturn` to estimate optimal portfolios with targeted portfolio returns.

```
[pwgt, pbuy, psell] = estimateFrontierByReturn(p, [ 0.0072321, 0.0119084 ])
```

`pwgt` = 3x2

|        |        |
|--------|--------|
| 0      | 0.5000 |
| 0.6922 | 0      |
| 0.3078 | 0.5000 |

`pbuy` = 3x2

|        |        |
|--------|--------|
| 0      | 0.5000 |
| 0.6922 | 0      |
| 0.3078 | 0.5000 |

`psell` = 3x2

|   |   |
|---|---|
| 0 | 0 |
| 0 | 0 |
| 0 | 0 |

The `estimateFrontierByReturn` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```
p.solverTypeMINLP
```

```
ans =
'OuterApproximation'

p.solverOptionsMINLP

ans = struct with fields:
    MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
    Display: 'off'
    CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
    ActiveCutTolerance: 1.0000e-07
    IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

### Obtain the Portfolio for Targeted Portfolio Returns for a PortfolioCVaR Object

To obtain efficient portfolios that have targeted portfolio returns, the `estimateFrontierByReturn` function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of 7%, 10%, and 13%.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

rng(11);

p = PortfolioCVaR;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierByReturn(p, [0.07 0.10, 0.13]);

display(pwgt);

pwgt = 4x3

0.7370    0.3067        0
0.1502    0.3937    0.4396
0.0290    0.0997    0.1360
0.0838    0.1999    0.4244
```

The function `rng(seed)` is used to reset the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Obtain the Portfolio for Targeted Portfolio Returns for a PortfolioMAD Object

To obtain efficient portfolios that have targeted portfolio returns, the `estimateFrontierByReturn` function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of 7%, 10%, and 13%.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

rng(11);

p = PortfolioMAD;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);

pwgt = estimateFrontierByReturn(p, [0.07 0.10, 0.13]);

display(pwgt);

pwgt = 4x3

0.7437    0.3146      0
0.1357    0.3837    0.4425
0.0326    0.0939    0.1319
0.0881    0.2079    0.4255
```

The function `rng(seed)` is used to reset the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

### **obj — Object for portfolio**

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **TargetReturn — Target values for portfolio return**

vector

Target values for portfolio return, specified as a `NumPorts` vector.

---

**Note** `TargetReturn` specifies target returns for portfolios on the efficient frontier. If any `TargetReturn` values are outside the range of returns for efficient portfolios, the `TargetReturn` is

replaced with the minimum or maximum efficient portfolio return, depending upon whether the target return is below or above the range of efficient portfolio returns.

---

Data Types: double

## Output Arguments

**pwgt — Optimal portfolios on efficient frontier with specified target returns**  
matrix

Optimal portfolios on the efficient frontier with specified target returns from `TargetReturn`, returned as a `NumAssets`-by-`NumPorts` matrix. `pwgt` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**pbuy — Purchases relative to initial portfolio for optimal portfolios on efficient frontier**  
matrix

Purchases relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as `NumAssets`-by-`NumPorts` matrix.

---

**Note** If no initial portfolio is specified in `obj.InitPort`, that value is assumed to be 0 such that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`.

---

`pbuy` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**psell — Sales relative to initial portfolio for optimal portfolios on efficient frontier**  
matrix

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a `NumAssets`-by-`NumPorts` matrix.

---

**Note** If no initial portfolio is specified in `obj.InitPort`, that value is assumed to be 0 such that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`.

---

`psell` is returned for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## Tips

You can also use dot notation to estimate optimal portfolios with targeted portfolio returns.

```
[pwgt, pbuy, psell] = obj.estimateFrontierByReturn(TargetReturn);
```

## estimateFrontierByRisk

Estimate optimal portfolios with targeted portfolio risks

### Syntax

```
[pwgt,pbuy,psell] = estimateFrontierByRisk(obj,TargetRisk)  
[pwgt,pbuy,psell] = estimateFrontierByRisk(___,Name,Value)
```

### Description

[pwgt,pbuy,psell] = estimateFrontierByRisk(obj,TargetRisk) estimates optimal portfolios with targeted portfolio risks for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “[Portfolio Object Workflow](#)” on page 4-17, “[PortfolioCVaR Object Workflow](#)” on page 5-15, and “[PortfolioMAD Object Workflow](#)” on page 6-15.

[pwgt,pbuy,psell] = estimateFrontierByRisk(\_\_\_,Name,Value) adds name-optional name-value pair arguments for `Portfolio` or `PortfolioMAD` objects.

### Examples

#### Obtain Portfolios with Targeted Portfolio Risks for a Portfolio Object

To obtain efficient portfolios that have targeted portfolio risks, the `estimateFrontierByRisk` function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 14%, and 16%. This example uses the default ‘`direct`’ method to estimate the optimal portfolios with targeted portfolio risks.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];  
C = [ 0.0064 0.00408 0.00192 0;  
      0.00408 0.0289 0.0204 0.0119;  
      0.00192 0.0204 0.0576 0.0336;  
      0 0.0119 0.0336 0.1225 ];  
  
p = Portfolio;  
p = setAssetMoments(p, m, C);  
p = setDefaultConstraints(p);  
pwgt = estimateFrontierByRisk(p, [0.12, 0.14, 0.16]);  
  
display(pwgt);  
  
pwgt = 4x3
```

| 0.3984 | 0.2659 | 0.1416 |
|--------|--------|--------|
| 0.3064 | 0.3791 | 0.4474 |
| 0.0882 | 0.1010 | 0.1131 |
| 0.2071 | 0.2540 | 0.2979 |

## Obtain Portfolios with Targeted Portfolio Risks for a Portfolio Object with BoundType, MinNumAssets, and MaxNumAssets Constraints

When any one, or any combination of the constraints from 'Conditional' BoundType, MinNumAssets, and MaxNumAssets are active, the portfolio problem is formulated as mixed integer programming problem and the MINLP solver is used.

Create a `Portfolio` object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use `setBounds` with semicontinuous constraints to set  $x_i = 0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i = 1, \dots, \text{NumAssets}$ .

```
p = setBounds(p, 0.02, 0.7, 'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up the limits on the number of assets invested (as known as cardinality) constraints. This sets the total number of allocated assets satisfying the Bound constraints that are between `MinNumAssets` and `MaxNumAssets`. By setting `MinNumAssets` = `MaxNumAssets` = 2, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use `estimateFrontierByRisk` to estimate optimal portfolios with targeted portfolio risks.

```
[pwgt, pbuy, psell] = estimateFrontierByRisk(p, [0.0324241, 0.0694534])
```

`pwgt` = 3×2

|        |        |
|--------|--------|
| 0.0000 | 0.5000 |
| 0.6907 | 0.0000 |
| 0.3093 | 0.5000 |

`pbuy` = 3×2

|        |        |
|--------|--------|
| 0.0000 | 0.5000 |
| 0.6907 | 0.0000 |
| 0.3093 | 0.5000 |

`psell` = 3×2

|   |   |
|---|---|
| 0 | 0 |
| 0 | 0 |
| 0 | 0 |

The `estimateFrontierByRisk` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```
p.solverTypeMINLP
ans =
'OuterApproximation'

p.solverOptionsMINLP
ans = struct with fields:
    MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
    Display: 'off'
    CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
    ActiveCutTolerance: 1.0000e-07
    IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

### Obtain Portfolios with Targeted Portfolio Risks for a Portfolio Object Using the Direct Method and Solver Options

To obtain efficient portfolios that have targeted portfolio risks, the `estimateFrontierByRisk` function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 14%, and 16%. This example uses the default 'direct' method to estimate the optimal portfolios with targeted portfolio risks. The 'direct' method uses `fmincon` to solve the optimization problem that maximizes portfolio return, subject to the target risk as the quadratic nonlinear constraint. `setSolver` specifies the `solverType` and `SolverOptions` for `fmincon`.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);

p = setSolver(p, 'fmincon', 'Display', 'off', 'Algorithm', 'sqp', ...
              'SpecifyObjectiveGradient', true, 'SpecifyConstraintGradient', true, ...
              'ConstraintTolerance', 1.0e-8, 'OptimalityTolerance', 1.0e-8, 'StepTolerance', 1.0e-8);

pwgt = estimateFrontierByRisk(p, [0.12, 0.14, 0.16]);
display(pwgt);

pwgt = 4x3
      0.3984    0.2659    0.1416
      0.3064    0.3791    0.4474
```

```
0.0882    0.1010    0.1131
0.2071    0.2540    0.2979
```

### Obtain Portfolios with Targeted Portfolio Risks for a PortfolioCVaR Object

To obtain efficient portfolios that have targeted portfolio risks, the `estimateFrontierByRisk` function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 20%, and 30%.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

rng(11);

p = PortfolioCVaR;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierByRisk(p, [0.12, 0.20, 0.30]);

display(pwgt);

pwgt = 4x3
```

|        |        |        |
|--------|--------|--------|
| 0.5363 | 0.1387 | 0      |
| 0.2655 | 0.4991 | 0.3830 |
| 0.0570 | 0.1239 | 0.1461 |
| 0.1412 | 0.2382 | 0.4709 |

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Obtain Portfolios with Targeted Portfolio Risks for a PortfolioMAD Object

To obtain efficient portfolios that have targeted portfolio risks, the `estimateFrontierByRisk` function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 20%, and 25%. This example uses the default 'direct' method to estimate the optimal portfolios with targeted portfolio risks.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
```

```
rng(11);

p = PortfolioMAD;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);

pwgt = estimateFrontierByRisk(p, [0.12, 0.20, 0.25]);

display(pwgt);

pwgt = 4x3

0.1610      0      0
0.4784    0.2137  0.0047
0.1116    0.1384  0.1200
0.2490    0.6480  0.8753
```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Obtain Portfolios with Targeted Portfolio Risks for a `PortfolioMAD` Object Using the Direct Method and Solver Options

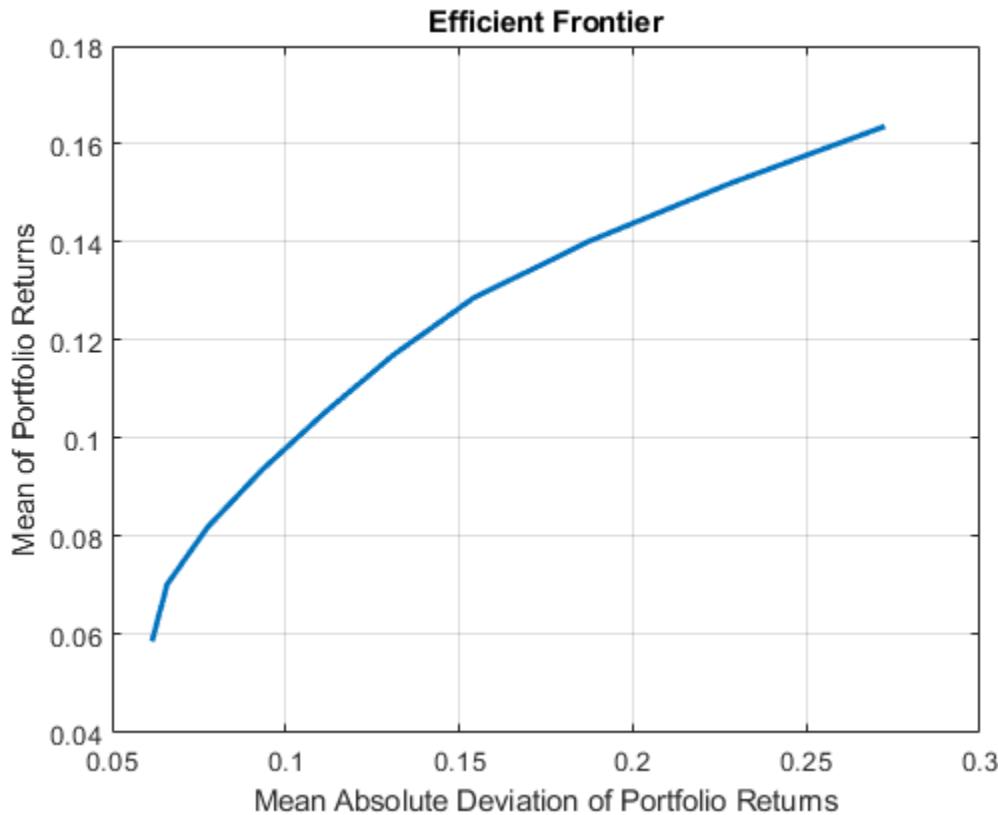

To obtain efficient portfolios that have targeted portfolio risks, the `estimateFrontierByRisk` function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 20%, and 25%. This example uses the default 'direct' method to estimate the optimal portfolios with targeted portfolio risks. The 'direct' method uses `fmincon` to solve the optimization problem that maximizes portfolio return, subject to the target risk as the quadratic nonlinear constraint. `setSolver` specifies the `solverType` and `SolverOptions` for `fmincon`.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

rng(11);

p = PortfolioMAD;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);

p = setSolver(p, 'fmincon', 'Display', 'off', 'Algorithm', 'sqp', ...
             'SpecifyObjectiveGradient', true, 'SpecifyConstraintGradient', true, ...
             'ConstraintTolerance', 1.0e-8, 'OptimalityTolerance', 1.0e-8, 'StepTolerance', 1.0e-8);
plotFrontier(p);
```

```

pwgt = estimateFrontierByRisk(p, [0.12 0.20, 0.25]);
display(pwgt);
pwgt = 4x3

```

|        |        |        |
|--------|--------|--------|
| 0.1613 | 0.0000 | 0.0000 |
| 0.4777 | 0.2139 | 0.0037 |
| 0.1118 | 0.1381 | 0.1214 |
| 0.2492 | 0.6480 | 0.8749 |

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

**Note** If no initial portfolio is specified in `obj.InitPort`, it is assumed to be `0` so that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`. For more information on setting an initial portfolio, see `setInitPort`.

---

Data Types: object

**TargetRisk — Target values for portfolio risk**  
vector

Target values for portfolio risk, specified as a `NumPorts` vector.

**Note** If any `TargetRisk` values are outside the range of risks for efficient portfolios, the target risk is replaced with the minimum or maximum efficient portfolio risk, depending on whether the target risk is below or above the range of efficient portfolio risks.

---

Data Types: double

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[pwgt, pbuy, psell] = estimateFrontierByRisk(p, 'method', 'direct')`

**Method — Method to estimate frontier by risk for Portfolio or PortfolioMAD objects**  
`'direct'` (default) | character vector with value `'direct'` or `'iterative'`

Method to estimate frontier by risk for `Portfolio` or `PortfolioMAD` objects, specified as the comma-separated pair consisting of `'Method'` and a character vector with one of the following values:

- `'direct'` — Construct one optimization problem to maximize the portfolio return with target risk as the nonlinear constraint, and solve it directly using `fmincon`, instead of iteratively exploring the efficient frontier. For an example of using the `'direct'` option, see “Obtain Portfolios with Targeted Portfolio Risks for a Portfolio Object Using the Direct Method and Solver Options” on page 19-806 and “Obtain Portfolios with Targeted Portfolio Risks for a PortfolioMAD Object Using the Direct Method and Solver Options” on page 19-808.
- `'iterative'` — One-dimensional optimization using `fminbnd` to find the portfolio return between min and max return on the frontier that minimizes the difference between the actual risk and target risk. Then the portfolio weights are obtained by solving a frontier by return problem. Consequently, the `'iterative'` method is slower than the `'direct'`.

Data Types: char

**Output Arguments**

**pwgt — Optimal portfolios on efficient frontier with specified target risks**  
matrix

Optimal portfolios on the efficient frontier with specified target returns from `TargetRisk`, returned as a NumAssets-by-NumPorts matrix. `pwgt` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

#### **pbuy — Purchases relative to initial portfolio for optimal portfolios on efficient frontier matrix**

Purchases relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as NumAssets-by-NumPorts matrix.

---

**Note** If no initial portfolio is specified in `obj.InitPort`, that value is assumed to be 0 such that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`.

---

`pbuy` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

#### **psell — Sales relative to initial portfolio for optimal portfolios on efficient frontier matrix**

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a NumAssets-by-NumPorts matrix.

---

**Note** If no initial portfolio is specified in `obj.InitPort`, that value is assumed to be 0 such that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`.

---

`psell` is returned for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## **Tips**

You can also use dot notation to estimate optimal portfolios with targeted portfolio risks.

```
[pwgt,pbuy,psell] = obj.estimateFrontierByRisk(TargetRisk);
```

or

```
[pwgt,pbuy,psell] = obj.estimateFrontierByRisk(TargetRisk,Name,Value);
```

# estimateFrontierLimits

Estimate optimal portfolios at endpoints of efficient frontier

## Syntax

```
[pwgt,pbuy,psell] = estimateFrontierLimits(obj)
[pwgt,pbuy,psell] = estimateFrontierLimits(obj,Choice)
```

## Description

`[pwgt,pbuy,psell] = estimateFrontierLimits(obj)` estimates optimal portfolios at endpoints of efficient frontier for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “`Portfolio` Object Workflow” on page 4-17, “`PortfolioCVaR` Object Workflow” on page 5-15, and “`PortfolioMAD` Object Workflow” on page 6-15.

`[pwgt,pbuy,psell] = estimateFrontierLimits(obj,Choice)` estimates optimal portfolios at endpoints of efficient frontier with an additional option specified for the `Choice` argument.

## Examples

### Obtain Endpoint Portfolios for a Portfolio Object

Given portfolio `p`, the `estimateFrontierLimits` function obtains the endpoint portfolios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);

disp(pwgt);
0.8891      0
0.0369      0
0.0404      0
0.0336    1.0000
```

### Obtain Endpoint Portfolios for a Portfolio Object with BoundType, MinNumAsset, and MaxNumAsset Constraints

When any one, or any combination of the constraints from 'Conditional' BoundType, MinNumAssets, and MaxNumAssets are active, the portfolio problem is formulated as mixed integer programming problem and the MINLP solver is used.

Create a `Portfolio` object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use `setBounds` with semicontinuous constraints to set  $x_i = 0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i = 1, \dots, \text{NumAssets}$ .

```
p = setBounds(p, 0.02, 0.7, 'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up the limits on the number of assets invested (as known as cardinality) constraints. This sets the total number of allocated assets satisfying the Bound constraints that are between `MinNumAssets` and `MaxNumAssets`. By setting `MinNumAssets` = `MaxNumAssets` = 2, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use `estimateFrontierLimits` to estimate the optimal portfolios at endpoints of the efficient frontier.

```
[pwgt, pbuy, psell] = estimateFrontierLimits(p, 'Both')
```

```
pwgt = 3x2
```

```
0.3000    0.3000
0.7000      0
0        0.7000
```

```
pbuy = 3x2
```

```
0.3000    0.3000
0.7000      0
0        0.7000
```

```
psell = 3x2
```

```
0      0
0      0
0      0
```

The `estimateFrontierLimits` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```

p.solverTypeMINLP
ans =
'OuterApproximation'

p.solverOptionsMINLP
ans = struct with fields:
    MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
    Display: 'off'
    CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
    ActiveCutTolerance: 1.0000e-07
    IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30

```

## Obtain Endpoint Portfolios for a PortfolioCVaR Object

Given portfolio p, the `estimateFrontierLimits` function obtains the endpoint portfolios.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);

disp(pwgt);

```

|        |        |
|--------|--------|
| 0.8451 | 0      |
| 0.0613 | 0      |
| 0.0451 | 0      |
| 0.0485 | 1.0000 |

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Obtain Endpoint Portfolios for a PortfolioMAD Object

Given portfolio p, the `estimateFrontierLimits` function obtains the endpoint portfolios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt = estimateFrontierLimits(p);

disp(pwgt);

0.8817      0
0.0431      0
0.0387      0
0.0366    1.0000
```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

**Choice — Indicator for which portfolios to obtain at extreme ends of efficient frontier**  
[] (default) | character vector with values 'Both', 'Min', 'Max' | string with values "Both", "Min", "Max"

(Optional) Indicator which portfolios to obtain at the extreme ends of the efficient frontier, specified as a character vector with values 'Both' or "Both", 'Min' or "Min", or 'Max' or "Max". The options for a `Choice` action are:

- [] — Compute both minimum-risk and maximum-return portfolios.
- 'Both' or "Both" — Compute both minimum-risk and maximum-return portfolios.
- 'Min' or "Min" — Compute minimum-risk portfolio only.
- 'Max' or "Max" — Compute maximum-return portfolio only

Data Types: char | string

## Output Arguments

### **pwgt — Optimal portfolios at endpoints of efficient frontier**

matrix

Optimal portfolios at the endpoints of the efficient frontier TargetReturn, returned as a NumAssets-by-NumPorts matrix. pwgt is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

### **pbuy — Purchases relative to an initial portfolio for optimal portfolios at endpoints of efficient frontier**

matrix

Purchases relative to an initial portfolio for optimal portfolios at the endpoints of the efficient frontier, returned as NumAssets-by-NumPorts matrix.

---

**Note** If no initial portfolio is specified in obj.InitPort, that value is assumed to be 0 such that pbuy = max(0, pwgt) and psell = max(0, -pwgt).

---

pbuy is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

### **psell — Sales relative to an initial portfolio for optimal portfolios at endpoints of efficient frontier**

matrix

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a NumAssets-by-NumPorts matrix.

---

**Note** If no initial portfolio is specified in obj.InitPort, that value is assumed to be 0 such that pbuy = max(0, pwgt) and psell = max(0, -pwgt).

---

psell is returned for Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

## Tips

You can also use dot notation to estimate the optimal portfolios at the endpoints of the efficient frontier.

```
[pwgt, pbuy, psell] = obj.estimateFrontierLimits(Choice);
```

# estimateMaxSharpeRatio

Estimate efficient portfolio to maximize Sharpe ratio for Portfolio object

## Syntax

```
[pwgt,pbuy,psell] = estimateMaxSharpeRatio(obj)
[pwgt,pbuy,psell] = estimateMaxSharpeRatio(___,Name,Value)
```

## Description

[pwgt,pbuy,psell] = estimateMaxSharpeRatio(obj) estimates efficient portfolio to maximize Sharpe ratio for Portfolio object. For details on the workflow, see “Portfolio Object Workflow” on page 4-17.

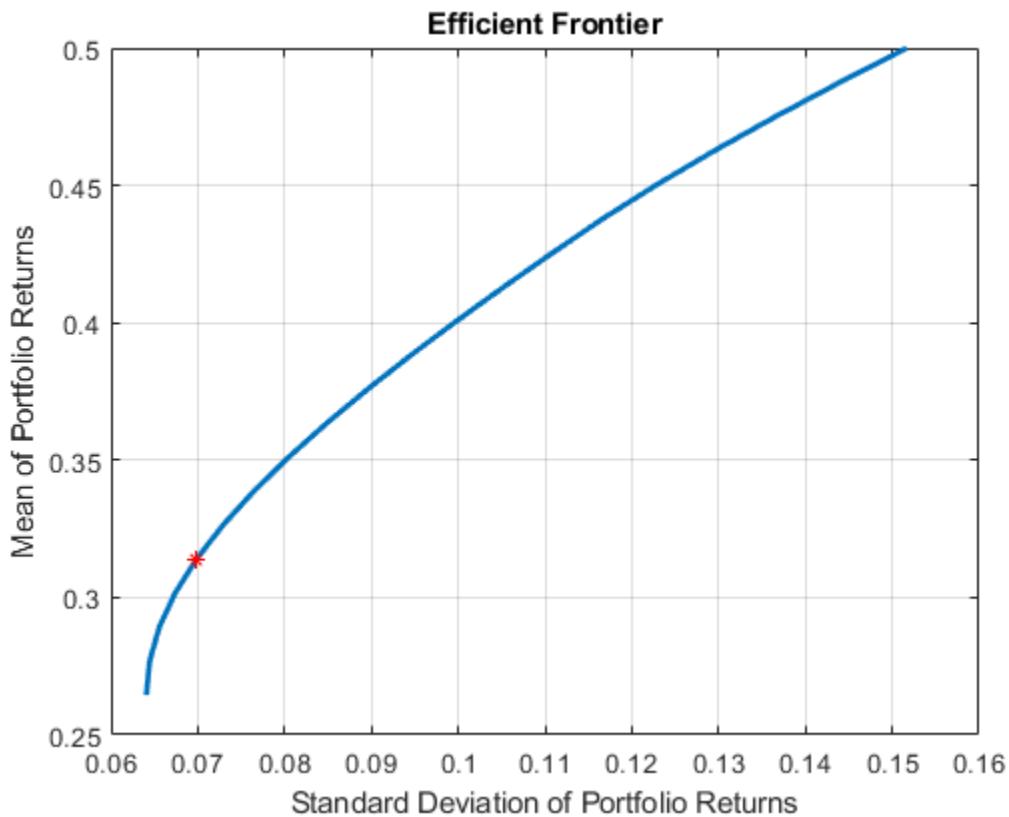

[pwgt,pbuy,psell] = estimateMaxSharpeRatio(\_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object

Estimate the efficient portfolio that maximizes the Sharpe ratio. The `estimateMaxSharpeRatio` function maximizes the Sharpe ratio among portfolios on the efficient frontier. This example uses the default 'direct' method to estimate the maximum Sharpe ratio. For more information on the 'direct' method, see “Algorithms” on page 19-828.

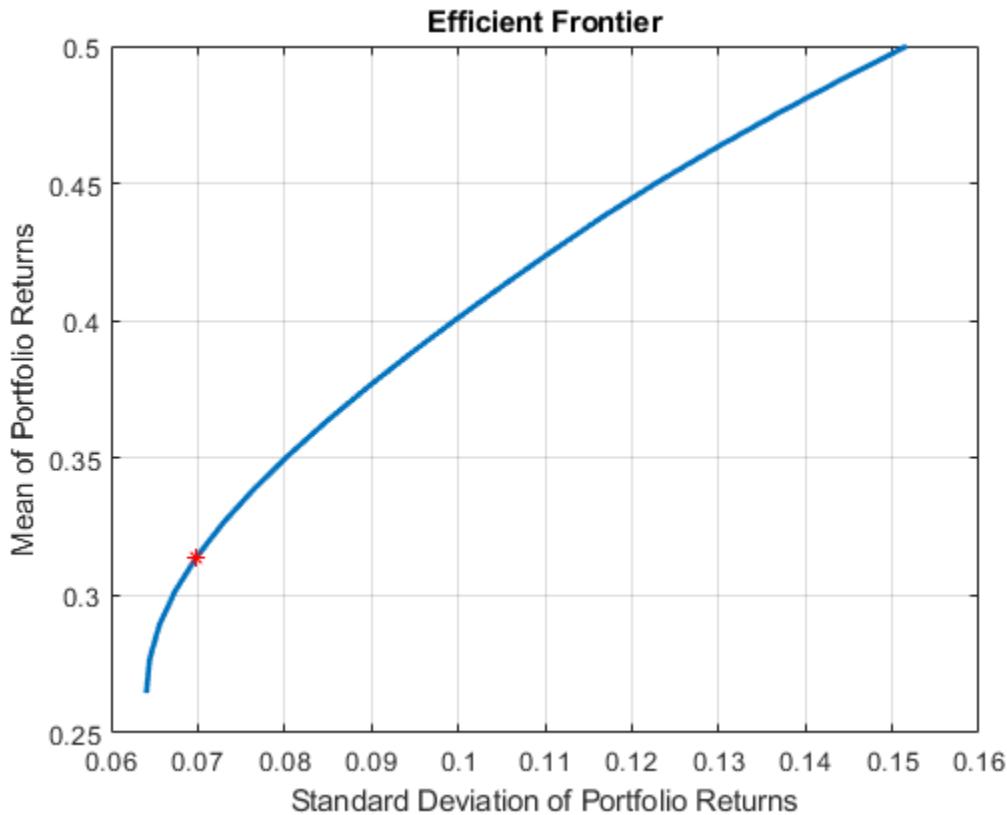

```
p = Portfolio('AssetMean',[0.3, 0.1, 0.5], 'AssetCovar',...
[0.01, -0.010, 0.004; -0.010, 0.040, -0.002; 0.004, -0.002, 0.023]);
p = setDefaultConstraints(p);
plotFrontier(p, 20);
weights = estimateMaxSharpeRatio(p);
[risk, ret] = estimatePortMoments(p, weights);
hold on
plot(risk,ret,'*r');
```

### Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object Using Solver Options with the Direct Method

Estimate the efficient portfolio that maximizes the Sharpe ratio. The `estimateMaxSharpeRatio` function maximizes the Sharpe ratio among portfolios on the efficient frontier. This example uses the '`direct`' method for a `Portfolio` object (`p`) that does not specify a tracking error and only uses linear constraints. The `setSolver` function is used to control the `SolverType` and `SolverOptions`. In this case, the `SolverType` is `quadprog`. For more information on the '`direct`' method, see "Algorithms" on page 19-828.

```
p = Portfolio('AssetMean',[0.3, 0.1, 0.5], 'AssetCovar',...
[0.01, -0.010, 0.004; -0.010, 0.040, -0.002; 0.004, -0.002, 0.023]);
p = setDefaultConstraints(p);
plotFrontier(p, 20);
p = setSolver(p,'quadprog','Display','off','ConstraintTolerance',1.0e-8,'OptimalityTolerance',1.0e-8);
weights = estimateMaxSharpeRatio(p);
[risk, ret] = estimatePortMoments(p, weights);
hold on
plot(risk,ret,'*r');
```

### Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object With Tracking Error Using the Direct Method and Solver Options

Estimate the efficient portfolio that maximizes the Sharpe ratio. The `estimateMaxSharpeRatio` function maximizes the Sharpe ratio among portfolios on the efficient frontier. This example uses the 'direct' method for a `Portfolio` object (`p`) that specifies a tracking error uses nonlinear constraints. The `setSolver` function is used to control the `SolverType` and `SolverOptions`. In this case `fmincon` is the `SolverType`.

```

p = Portfolio('AssetMean',[0.3, 0.1, 0.5], 'AssetCovar',...
[0.01, -0.010, 0.004; -0.010, 0.040, -0.002; 0.004, -0.002, 0.023], 'lb', 0, 'budget', 1);
plotFrontier(p, 20);

p = setSolver(p, 'fmincon', 'Display', 'off', 'Algorithm', 'sqp', ...
'SpecifyObjectiveGradient', true, 'SpecifyConstraintGradient', true, ...
'ConstraintTolerance', 1.0e-8, 'OptimalityTolerance', 1.0e-8, 'StepTolerance', 1.0e-8);

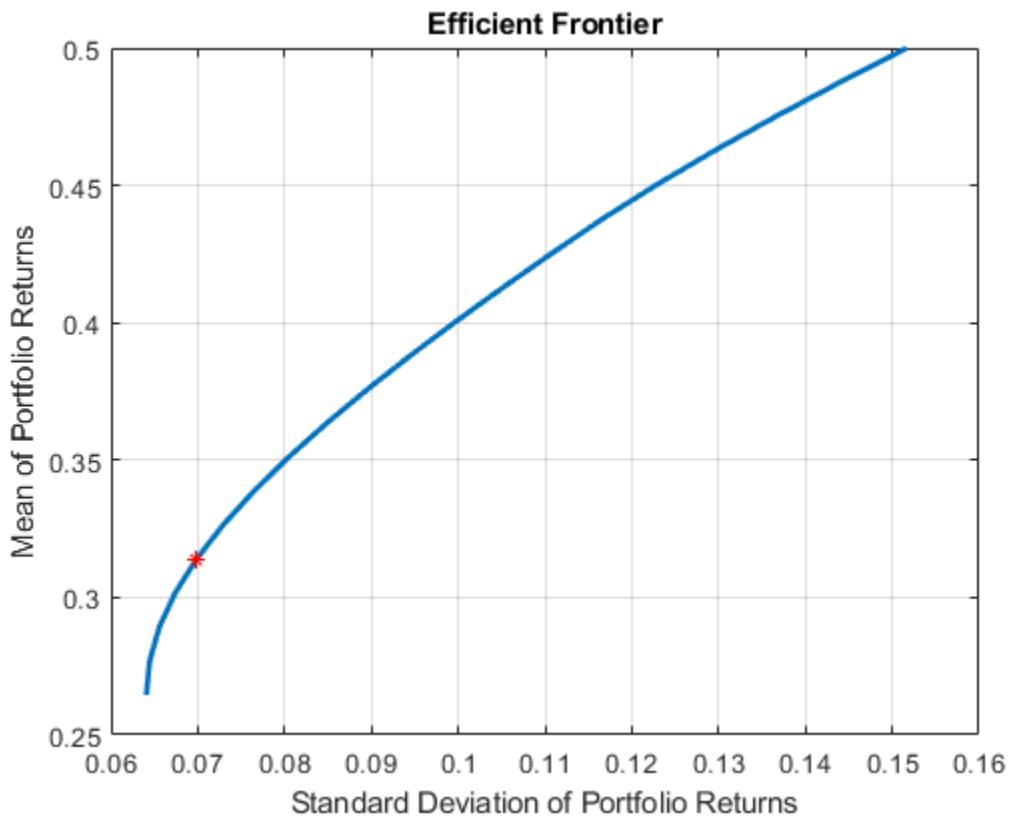

weights = estimateMaxSharpeRatio(p);

te = 0.08;
p = setTrackingError(p, te, weights);

[risk, ret] = estimatePortMoments(p, weights);

```

```
hold on  
plot(risk,ret,'*r');
```

### Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object With a Risk-Free Asset Using the Direct and Iterative Method

The `estimateMaxSharpeRatio` function maximizes the Sharpe ratio among portfolios on the efficient frontier. In the case of `Portfolio` with a risk-free asset, there are multiple efficient portfolios that maximize the Sharpe ratio on the capital asset line. Because of the nature of 'direct' and 'iterative' methods, the portfolio weights (`pwgts`) output from each of these methods might be different, but the Sharpe ratio is the same. This example demonstrates the scenario where the `pwgts` are different and the Sharpe ratio is the same.

```
load BlueChipStockMoments  
  
mret = MarketMean;  
mrsk = sqrt(MarketVar);  
cret = CashMean;  
crsk = sqrt(CashVar);  
  
p = Portfolio('AssetList', AssetList, 'RiskFreeRate', CashMean);  
p = setAssetMoments(p, AssetMean, AssetCovar);  
  
p = setInitPort(p, 1/p.NumAssets);
```

```

[ersk, eret] = estimatePortMoments(p, p.InitPort);

p = setDefaultConstraints(p);
pwgt = estimateFrontier(p, 20);
[prsk, pret] = estimatePortMoments(p, pwgt);
pwgtshpr_fully = estimateMaxSharpeRatio(p, 'Method','direct');
[riskshpr_fully, retshpr_fully] = estimatePortMoments(p,pwgtshpr_fully);

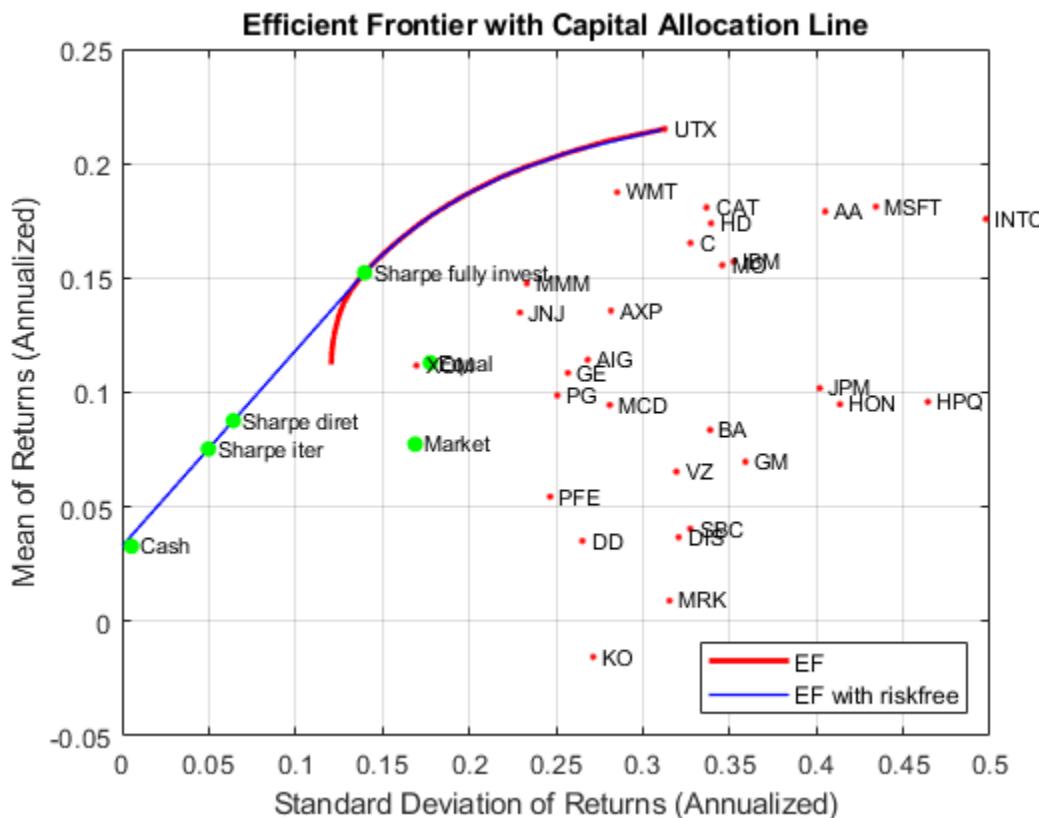

q = setBudget(p, 0, 1);
qwgt = estimateFrontier(q, 20);
[qrsk, qret] = estimatePortMoments(q, qwgt);

Plot the efficient frontier with a tangent line (0 to 1 cash).

pwgtshpr_direct = estimateMaxSharpeRatio(q, 'Method','direct');
pwgtshpr_iter = estimateMaxSharpeRatio(q, 'Method','iterative'); % Default for 'TolX' is 1e-8
[riskshpr_diret, retshpr_diret] = estimatePortMoments(q,pwgtshpr_direct);
[riskshpr_iter, retshpr_iter] = estimatePortMoments(q,pwgtshpr_iter);

clf;
portfolioexamples_plot('Efficient Frontier with Capital Allocation Line', ...
    {'line', prsk, pret, {'EF'}, '-r', 2}, ...
    {'line', qrsk, qret, {'EF with riskfree'}, '-b', 1}, ...
    {'scatter', [mrsk, crsk, ersk, riskshpr_fully, riskshpr_diret, riskshpr_iter], ...
        [mret, cret, eret, retshpr_fully , retshpr_diret, retshpr_iter], {'Market', 'Cash', 'Equal'}, ...
        {'scatter', sqrt(diag(p.AssetCovar)), p.AssetMean, p.AssetList, '.r'}});

```

When a risk-free asset is not available to the portfolio, or in other words, the portfolio is fully invested, the efficient frontier is curved, corresponding to the red line in the above figure. Therefore, there is a unique (risk, return) point that maximizes the Sharpe ratio, which the 'iterative' and 'direct' methods will both find. If the portfolio is allowed to invest in a risk-free asset, part of the red efficient frontier line is replaced by the capital allocation line, resulting in the efficient frontier of a portfolio with a risk-free investment (blue line). All the (risk, return) points on the straight blue line share the same Sharpe ratio. Also, it is likely that the 'iterative' and 'direct' methods end up with different points, therefore there are different portfolio allocations.

When using the 'iterative' method, you can use an optional 'TolX' name-value argument. TolX is a termination tolerance that is related to the possible return levels of the efficient frontier. If the selected TolX value is large compared to the range of returns, then the accuracy of the solution is poor. TolX should be a number smaller than  $0.01 * (\text{maxReturn} - \text{minReturn})$ .

```
maxReturn = max(qret); % Max return portfolio  
minReturn = min(qret); % Min return portfolio  
display(0.01*(maxReturn-minReturn))
```

1.5193e-04

The purpose of increasing the termination tolerance is to speed up the convergence of the 'iterative' algorithm. However, as previously mentioned, the accuracy of the solution will decrease. You can see this in the table that follows.

```
pwtshpr_iter_largerTol = estimateMaxSharpeRatio(q, 'Method', 'iterative',...  
    'TolX', 1e-4);  
display(table(pwtshpr_iter, pwtshpr_iter_largerTol,...  
    'VariableNames', {'Default TolX = 1e-8', 'TolX = 1e-4'}))
```

30x2 table

| Default TolX = 1e-8 | TolX = 1e-4 |
|---------------------|-------------|
| 0                   | 0           |
| 0                   | 0           |

## Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object with Semicontinuous and Cardinality Constraints

Create a `Portfolio` object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use `setBounds` with semicontinuous constraints to set  $x_i = 0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i = 1, \dots, \text{NumAssets}$ .

```
p = setBounds(p, 0.02, 0.5, 'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up cardinality constraints for a long-only portfolio. This sets the cardinality constraints for the `Portfolio` object, where the total number of allocated assets satisfying the nonzero semi-continuous constraints are between `MinNumAssets` and `MaxNumAssets`. By setting `MinNumAssets = MaxNumAssets = 2`, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use `estimateMaxSharpeRatio` to estimate efficient portfolio to maximize Sharpe ratio.

```
weights = estimateMaxSharpeRatio(p, 'Method', 'iterative')
```

```
weights = 3x1
```

```
0.0000
0.5000
0.5000
```

The `estimateMaxSharpeRatio` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```
p.solverOptionsMINLP
```

```
ans = struct with fields:
```

```
    MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
        Display: 'off'
        CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
        ActiveCutTolerance: 1.0000e-07
    IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

## Input Arguments

### **obj — Object for portfolio**

object

Object for portfolio, specified using a `Portfolio` object.

---

**Note** The risk-free rate is obtained from the property `RiskFreeRate` in the `Portfolio` object. If you leave the `RiskFreeRate` unset, it is assumed to be 0. If the max return of portfolio is less than the `RiskFreeRate`, the solution is set as `pwgt` at max return and the resulting Sharpe ratio will be negative.

---

For more information on creating a portfolio object, see

- [Portfolio](#)

Data Types: object

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[pwgt, pbuy, psell] = estimateMaxSharpeRatio(p, 'Method', 'iterative')`

### **Method — Method to estimate Sharpe ratio**

'direct' (default) | character vector with value 'direct' or 'iterative'

Method to estimate Sharpe ratio, specified as the comma-separated pair consisting of '`Method`' and a character vector with one of the following values:

- 'direct' — Transform the Sharpe ratio function into a quadratic one and solve one optimization problem directly, instead of iteratively exploring the efficient frontier. The 'direct' option either uses the solver `quadprog` (for a problem with linear constraints) or `fmincon` (for a problem with nonlinear constraints). For an example of using the 'direct' option, see "Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object Using Solver Options with the Direct Method" on page 19-820 and "Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object With Tracking Error Using the Direct Method and Solver Options" on page 19-821.
- 'iterative' — One-dimensional optimization using `fminbnd` to find the portfolio that maximizes the Sharpe ratio by iteratively exploring the efficient frontier.

---

**Note** If you are using `estimateMaxSharpeRatio` with a `Portfolio` object with semicontinuous and cardinality constraints specified by `setBounds` and `setMinMaxNumAssets`, you can only use the 'iterative' method.

---

Data Types: char

**TolX — Tolerance on the step size for fminbnd convergence when using 'iterative' method**

1e-8 (default) | positive scalar

Tolerance on the step size for fminbnd convergence when using 'iterative' method, specified as the comma-separated pair consisting of 'TolX' and a positive scalar. The step size is related to the return levels achieved on the efficient frontier and tried by fminbnd. If the specified TolX is large compared to the range of returns, the accuracy of the solution is poor. TolX should be a number smaller than 0.01\*(maxReturn - minReturn).

---

**Note** If the 'direct' method is selected, TolX is ignored.

---

Data Types: double

## Output Arguments

**pwgt — Portfolio on efficient frontier with maximum Sharpe ratio**

vector

Portfolio on the efficient frontier with a maximum Sharpe ratio, returned as a NumAssets vector.

**pbuy — Purchases relative to initial portfolio for portfolio on efficient frontier with maximum Sharpe ratio**

vector

Purchases relative to an initial portfolio for a portfolio on the efficient frontier with a maximum Sharpe ratio, returned as a NumAssets vector.

pbuy is returned for a `Portfolio` input object (`obj`).

**psell — Sales relative to initial portfolio for portfolio on efficient frontier with maximum Sharpe ratio**

vector

Sales relative to an initial portfolio for a portfolio on the efficient frontier with maximum Sharpe ratio, returned as a NumAssets vector.

psell is returned for a `Portfolio` input object (`obj`).

## More About

### Sharpe Ratio

The Sharpe ratio is the ratio of the difference between the mean of portfolio returns and the risk-free rate divided by the standard deviation of portfolio returns.

The `estimateMaxSharpeRatio` function maximizes the Sharpe ratio among portfolios on the efficient frontier.

## Tips

You can also use dot notation to estimate an efficient portfolio that maximizes the Sharpe ratio.

```
[pwgt,pbuy,psell] = obj.estimateMaxSharpeRatio;
```

## Algorithms

The maximization of the Sharpe ratio is accomplished by either using the 'direct' or 'iterative' method. For the 'direct' method, consider the following scenario. To maximize the Sharpe ratio is to:

$$\text{Maximize } \frac{\mu^T x - r_f}{\sqrt{x^T C x}}, \text{ s.t. } \sum x_i = 1, \quad 0 \leq x_i \leq 1,$$

where  $\mu$  and  $C$  are the mean and covariance matrix, and  $r_f$  is the risk-free rate.

If  $\mu^T x - r_f \leq 0$  for all  $x$  the portfolio that maximizes the Sharpe ratio is the one with maximum return.

$$\text{If } \mu^T x - r_f > 0, \text{ let } t = \frac{1}{\mu^T x - r_f}$$

and  $y = tx$  (Cornuejols [1] section 8.2). Then after some substitutions, you can transform the original problem into the following form,

$$\text{Minimize } y^T Cy, \text{ s.t. } \sum y_i = t, \quad t > 0, \quad 0 \leq y_i \leq t, \quad \mu^T y - r_f t = 1.$$

Only one optimization needs to be solved, hence the name "direct". The portfolio weights can be recovered by  $x^* = y^* / t^*$ .

For the 'iterative' method, the idea is to iteratively explore the portfolios at different return levels on the efficient frontier and locate the one with maximum Sharpe ratio. Therefore, multiple optimization problems are solved during the process, instead of only one in the 'direct' method. Consequently the 'iterative' method is slow compared to 'direct' method.

## Introduced in R2011b

# estimatePortSharpeRatio

Estimate Sharpe ratio of given portfolio weights for Portfolio object

## Syntax

```
psharpe = estimatePortSharpeRatio(obj, pwgt)
```

## Description

`psharpe = estimatePortSharpeRatio(obj, pwgt)` estimates the Sharpe ratio of given portfolio weights for a `Portfolio` object. For details on the workflow, see “Portfolio Object Workflow” on page 4-17.

## Examples

### Estimate Sharpe Ratios of the Given Portfolio Weights

This example shows how to find efficient portfolios that satisfy the target returns and then find the Sharpe ratios corresponding to each of the portfolios.

To obtain efficient portfolios that have targeted portfolio returns, the `estimateFrontierByReturn` function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of 6%, 9%, and 12%. Use `estimatePortSharpeRatio` to obtain the Sharpe ratio for the collection of portfolios (`pwgt`).

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierByReturn(p, [0.06, 0.09, 0.12]);

display(pwgt);

pwgt = 4x3
```

|        |        |        |
|--------|--------|--------|
| 0.8772 | 0.5032 | 0.1293 |
| 0.0434 | 0.2488 | 0.4541 |
| 0.0416 | 0.0780 | 0.1143 |
| 0.0378 | 0.1700 | 0.3022 |

`pwgt` is a `NumAssets`-by-`NumPorts` matrix where `NumAssets` is the number of asset in the universe and `NumPorts` is the number of portfolios in the collection of portfolios.

```
psharpe = estimatePortSharpeRatio(p, pwgt)
```

```
psharpe = 3×1  
0.7796  
0.8519  
0.7406
```

`psharpe` is a `NumPorts`-by-1 vector, where `NumPorts` is the number of portfolios in the collection of portfolios.

### Estimate Sharpe Ratios of the Given Portfolio Weights Portfolio Object with Integrality Constraints

Create a `Portfolio` object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];  
AssetCovar = [ 0.00324625 0.00022983 0.00420395;  
               0.00022983 0.00049937 0.00019247;  
               0.00420395 0.00019247 0.00764097 ];  
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);  
p = setDefaultConstraints(p);
```

Use `setBounds` with semi-continuous constraints to set  $x_i=0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i=1,\dots,\text{NumAssets}$ .

```
p = setBounds(p, 0.02, 0.5, 'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up cardinality constraints for a long-only portfolio. This sets the cardinality constraints for the `Portfolio` object, where the total number of allocated assets satisfying the nonzero semi-continuous constraints are between `MinNumAssets` and `MaxNumAssets`. By setting `MinNumAssets=MaxNumAssets=2`, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use `estimatePortSharpeRatio` to estimate Sharpe ratio of given portfolio weights for a `Portfolio` object.

```
pwgt = estimateFrontierByReturn(p, [ 0.0072321, 0.0119084 ]);  
psharpe = estimatePortSharpeRatio(p,pwgt)  
  
psharpe = 2×1  
0.2230  
0.1715
```

The `estimatePortSharpeRatio` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```
p.solverOptionsMINLP  
  
ans = struct with fields:  
      MaxIterations: 1000  
      AbsoluteGapTolerance: 1.0000e-07
```

```

    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
        Display: 'off'
        CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
        ActiveCutTolerance: 1.0000e-07
    IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30

```

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using a **Portfolio** object.

---

**Note** The risk-free rate is obtained from the property **RiskFreeRate** in the **Portfolio** object. If you leave the **RiskFreeRate** unset, it is assumed to be 0. For more information on creating a portfolio object, see **Portfolio**.

---

Data Types: object

**pwgt — Collection of portfolios**  
matrix

Collection of portfolios, specified as a **NumAssets**-by- **NumPorts** matrix where **NumAssets** is the number of assets in the universe and **NumPorts** is the number of portfolios in the collection of portfolios.

Data Types: double

## Output Arguments

**psharpe — Sharpe ratios of the given portfolios**  
vector

Sharpe ratios of the given portfolios, returned as a **NumPorts**-by-1 vector.

## More About

### Sharpe Ratio

The Sharpe ratio is the ratio of the difference between the mean of portfolio returns and the risk-free rate divided by the standard deviation of portfolio returns for each portfolio in **pwgt**.

**estimatePortSharpeRatio** computes the Sharpe ratio with mean and standard deviation (which is the square-root of variance) of portfolio returns.

## Tips

You can also use dot notation to estimate the Sharpe ratio of given portfolio weights.

```
psharpe = obj.estimatePortSharpeRatio(pwgt);
```

## See Also

## Introduced in R2018a

# estimatePortMoments

Estimate moments of portfolio returns for Portfolio object

## Syntax

```
[prsk, pret] = estimatePortMoments(obj, pwgt)
```

## Description

[prsk, pret] = estimatePortMoments(obj, pwgt) estimate moments of portfolio returns for a **Portfolio** object. For details on the workflow, see “Portfolio Object Workflow” on page 4-17.

The estimate of port moments is specific to mean-variance portfolio optimization and computes the mean and standard deviation (which is the square-root of variance) of portfolio returns.

## Examples

### Identify the Range of Risks and Returns for Efficient Portfolios for a Portfolio Object

Given portfolio p, use the **estimatePortMoments** function to show the range of risks and returns for efficient portfolios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);

[prsk, pret] = estimatePortMoments(p, pwgt);
disp([prsk, pret]);

0.0769    0.0590
0.3500    0.1800
```

### Identify the Range of Risks and Returns for Efficient Portfolios Portfolio Object with Integrality Constraints

Create a **Portfolio** object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
```

```
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use `setBounds` with semi-continuous constraints to set  $x_i=0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i=1,\dots,\text{NumAssets}$ .

```
p = setBounds(p, 0.02, 0.5, 'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up cardinality constraints for a long-only portfolio. This sets the cardinality constraints for the `Portfolio` object, where the total number of allocated assets satisfying the nonzero semi-continuous constraints are between `MinNumAssets` and `MaxNumAssets`. By setting `MinNumAssets=MaxNumAssets=2`, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use `estimatePortMoments` to estimate moments of portfolio returns for a `Portfolio` object.

```
pwgt = estimateFrontierLimits(p);
[prsk, pret] = estimatePortMoments(p, pwgt)
```

```
prsk = 2x1
```

```
0.0324
0.0695
```

```
pret = 2x1
```

```
0.0072
0.0119
```

The `estimatePortMoments` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```
p.solverOptionsMINLP
```

```
ans = struct with fields:
```

```
    MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
    Display: 'off'
    CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
    ActiveCutTolerance: 1.0000e-07
    IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

## Calculate Portfolio Weights For a Target Risk Level

The `Portfolio` object is able to find an efficient portfolio with respect to a specified target risk.

## Load Portfolio

Load a vector of expected returns and a covariance matrix for 30 stocks.

```
load StockStats
```

## Create Portfolio Object with Default Constraints

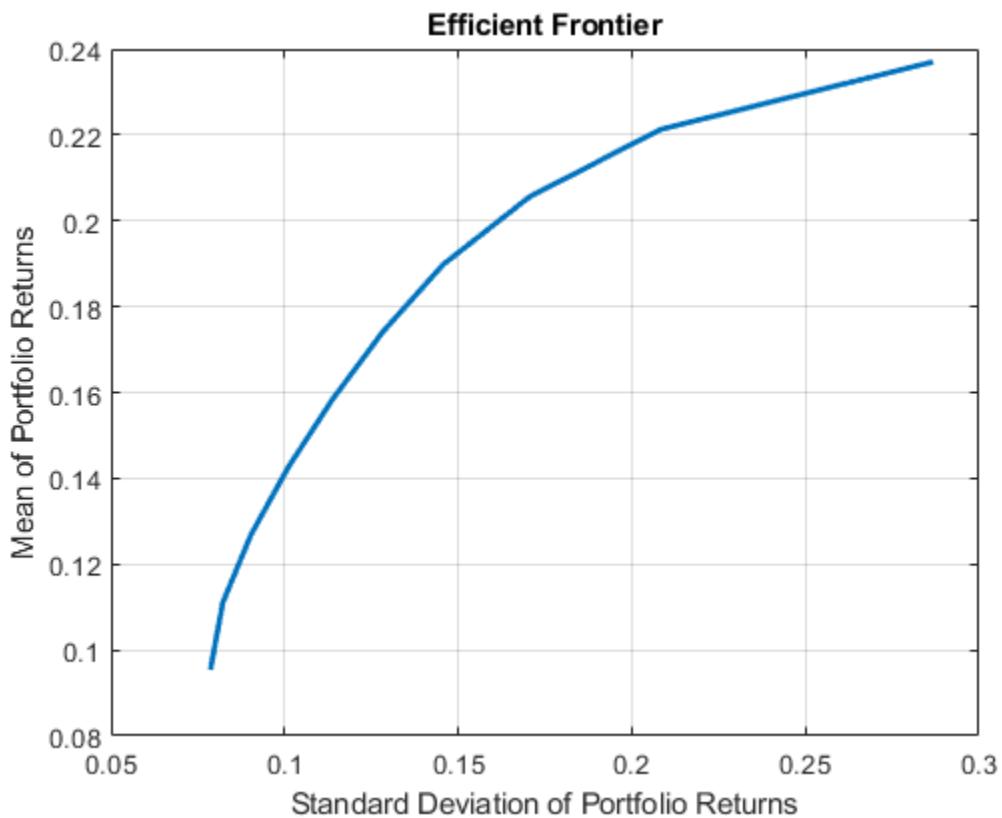

The default constraints for a `Portfolio` object are that it is a long-only portfolio and that it is 100% invested. Many other constraint types are possible.

```
P = Portfolio('mean',expRet,'covar',expCov);
P = setDefaultConstraints(P);
```

## Plot Full Efficient Frontier

Use the `plotFrontier` function with the `Portfolio` object to visualize the full frontier. Other functions exist that allow you to probe into particular portfolios along the frontier.

```
P.plotFrontier
```

## Capture Upper and Lower Bounds of Portfolio Risks and Returns

It is useful to know what are the upper and lower limits of the portfolio moments along the efficient frontier. This information allows you to determine what are feasible targets. Use the `estimateFrontierLimits` function with the `Portfolio` object to identify the weights at these extremes. Then you can use the `estimatePortMoments` function `Portfolio` object to find the limiting moments.

```
P_Weights1 = P.estimateFrontierLimits;
[P_risklimits, P_returnlimits] = P.estimatePortMoments(P_Weights1)

P_risklimits = 2x1

    0.0786
    0.2868

P_returnlimits = 2x1

    0.0954
    0.2370
```

### Estimate Efficient Portfolio with Target Return

Select a target return for the portfolio somewhere in the feasible region. You can estimate its makeup with `estimateFrontierByRisk` and then confirm its moments using `estimatePortMoments`.

```
targetReturn = 0.15;

P_Weights2 = P.estimateFrontierByReturn(targetReturn);
[P_risk2, P_return2] = P.estimatePortMoments(P_Weights2)

P_risk2 = 0.1068
P_return2 = 0.1500
```

The return matches the `targetReturn` value and the risk is in agreement with the efficient frontier plot.

### Estimate Efficient Portfolio with Target Risk

The `Portfolio` object is able to find an efficient portfolio with a specified target risk.

```
targetRisk = 0.2;

P_Weights3 = P.estimateFrontierByRisk(targetRisk);
[P_risk3, P_return3] = P.estimatePortMoments(P_Weights3)

P_risk3 = 0.2000
P_return3 = 0.2182
```

Another useful feature of the `estimateFrontierByReturn` and `estimateFrontierByRisk` functions is what happens if you specify an infeasible (too high or too low) target. In this case, these functions provide a warning message to suggest the best solution.

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using a `Portfolio` object. For more information on creating a portfolio object, see

- Portfolio

Data Types: object

#### **pwgt — Collection of portfolios**

matrix

Collection of portfolios, specified as a NumAssets-by-NumPorts matrix where NumAssets is the number of assets in the universe and NumPorts is the number of portfolios in the collection of portfolios.

Data Types: double

## **Output Arguments**

#### **prsk — Estimates for standard deviations of portfolio returns for each portfolio in pwgt**

vector

Estimates for standard deviations of portfolio returns for each portfolio in pwgt, returned as a NumPorts vector.

prsk is returned for a Portfolio input object (obj).

#### **pret — Estimates for means of portfolio returns for each portfolio in pwgt**

vector

Estimates for means of portfolio returns for each portfolio in pwgt, returned as a NumPorts vector.

pret is returned for a Portfolio input object (obj).

## **Tips**

You can also use dot notation to estimate the moments of portfolio returns.

```
[prsk, pret] = obj.estimatePortMoments(pwgt);
```

## **See Also**

## **Introduced in R2011a**

## estimatePortReturn

Estimate mean of portfolio returns

### Syntax

```
pret = estimatePortReturn(obj, pwgt)
```

### Description

`pret = estimatePortReturn(obj, pwgt)` estimates the mean of portfolio returns (as the proxy for portfolio return) for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “[Portfolio Object Workflow](#)” on page 4-17, “[PortfolioCVaR Object Workflow](#)” on page 5-15, and “[PortfolioMAD Object Workflow](#)” on page 6-15.

### Examples

#### Estimate the Mean of Portfolio Returns for a Portfolio Object

Given portfolio `p`, use the `estimatePortReturn` function to estimate the mean of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);
pret = estimatePortReturn(p, pwgt);
disp(pret)

0.0590
0.1800
```

#### Estimate the Mean of Portfolio Returns for a Portfolio Object with Integrality Constraints

Create a `Portfolio` object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use `setBounds` with semi-continuous constraints to set  $x_i=0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i=1,\dots,\text{NumAssets}$ .

```
p = setBounds(p, 0.02, 0.5, 'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up cardinality constraints for a long-only portfolio. This sets the cardinality constraints for the `Portfolio` object, where the total number of allocated assets satisfying the nonzero semi-continuous constraints are between `MinNumAssets` and `MaxNumAssets`. By setting `MinNumAssets=MaxNumAssets=2`, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use `estimatePortReturn` to estimate the mean of portfolio returns for a `Portfolio` object.

```
pwgt = estimateFrontierLimits(p);
pret = estimatePortReturn(p, pwgt)
```

```
pret = 2×1
```

```
0.0072
0.0119
```

The `estimatePortReturn` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```
p.solverOptionsMINLP
```

```
ans = struct with fields:
```

```
    MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
    Display: 'off'
    CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
    ActiveCutTolerance: 1.0000e-07
    IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

## Estimate the Mean of Portfolio Returns for a `PortfolioCVaR` Object

Given portfolio `p`, use the `estimatePortReturn` function to estimate the mean of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
```

```
rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);
pret = estimatePortReturn(p, pwgt);
disp(pret)

0.0050
0.0154
```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Estimate the Mean of Portfolio Returns for a PortfolioMAD Object

Given portfolio `p`, use the `estimatePortReturn` function to estimate the mean of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt = estimateFrontierLimits(p);
pret = estimatePortReturn(p, pwgt);
disp(pret)

0.0048
0.0154
```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

#### **pwgt — Collection of portfolios**

matrix

Collection of portfolios, specified as a `NumAssets`-by-`NumPorts` matrix, where `NumAssets` is the number of assets in the universe and `NumPorts` is the number of portfolios in the collection of portfolios.

Data Types: `double`

## **Output Arguments**

#### **pret — Estimates for means of portfolio returns for each portfolio in pwgt**

vector

Estimates for means of portfolio returns for each portfolio in `pwgt`, returned as a `NumPorts` vector.

`pret` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note** Depending on whether costs have been set, the portfolio return is either gross or net portfolio returns. For information on setting costs, see `setCosts`.

---

## **Tips**

You can also use dot notation to estimate the mean of portfolio returns (as the proxy for portfolio return).

```
pret = obj.estimatePortReturn(pwgt);
```

**Introduced in R2011a**

# estimatePortRisk

Estimate portfolio risk according to risk proxy associated with corresponding object

## Syntax

```
prsk = estimatePortRisk(obj,pwgt)
```

## Description

`prsk = estimatePortRisk(obj,pwgt)` estimates portfolio risk according to the risk proxy associated with the corresponding object (`obj`) for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-15, and “PortfolioMAD Object Workflow” on page 6-15.

## Examples

### Standard Deviation of Portfolio Returns as the Proxy for Portfolio Risk for a Portfolio Object

Given portfolio `p`, use the `estimatePortRisk` function to show the standard deviation of portfolio returns for each portfolio in `pwgt`.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);
prsk = estimatePortRisk(p, pwgt);
disp(prsk)

0.0769
0.3500
```

### Standard Deviation of Portfolio Returns as the Proxy for Portfolio Risk for a Portfolio Object with Integrality Constraints

Create a `Portfolio` object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
```

```
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use `setBounds` with semi-continuous constraints to set  $x_i=0$  or  $0.02 \leq x_i \leq 0.5$  for all  $i=1,\dots,\text{NumAssets}$ .

```
p = setBounds(p, 0.02, 0.5, 'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up cardinality constraints for a long-only portfolio. This sets the cardinality constraints for the `Portfolio` object, where the total number of allocated assets satisfying the nonzero semi-continuous constraints are between `MinNumAssets` and `MaxNumAssets`. By setting `MinNumAssets=MaxNumAssets=2`, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use `estimatePortRisk` to estimate the portfolio risk according to a risk proxy associated with a `Portfolio` object.

```
pwgt = estimateFrontierLimits(p);
prsk = estimatePortRisk(p, pwgt)

prsk = 2x1

    0.0324
    0.0695
```

The `estimatePortRisk` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```
p.solverOptionsMINLP

ans = struct with fields:
    MaxIterations: 1000
    AbsoluteGapTolerance: 1.0000e-07
    RelativeGapTolerance: 1.0000e-05
    NonlinearScalingFactor: 1000
    ObjectiveScalingFactor: 1000
    Display: 'off'
    CutGeneration: 'basic'
    MaxIterationsInactiveCut: 30
    ActiveCutTolerance: 1.0000e-07
    IntMasterSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

## Conditional Value-at-Risk of Portfolio Returns as the Proxy for Portfolio Risk for a PortfolioCVaR Object

Given a portfolio `pwgt`, use the `estimatePortRisk` function to show the conditional value-at-risk (CVaR) of portfolio returns for each portfolio.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
```

```

0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);
prsk = estimatePortRisk(p, pwgt);
disp(prsk)

0.0407
0.1911

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Mean-Absolute Deviation Returns as the Proxy for Portfolio Risk for a PortfolioMAD Object

Given a portfolio `pwgt`, use the `estimatePortRisk` function to show the mean-absolute deviation of portfolio returns for each portfolio.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt = estimateFrontierLimits(p);
prsk = estimatePortRisk(p, pwgt);
disp(prsk)

0.0177
0.0809

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

### **obj — Object for portfolio**

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

### **pwgt — Collection of portfolios**

matrix

Collection of portfolios, specified as a `NumAssets`-by-`NumPorts` matrix, where `NumAssets` is the number of assets in the universe and `NumPorts` is the number of portfolios in the collection of portfolios.

Data Types: `double`

## Output Arguments

### **prsk — Estimates for portfolio risk according to the risk proxy associated with the corresponding object (obj) for each portfolio in pwgt**

vector

Estimates for portfolio risk according to the risk proxy associated with the corresponding object (`obj`) for each portfolio in `pwgt`, returned as a `NumPorts` vector.

`prsk` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## Tips

You can also use dot notation to estimate portfolio risk according to the risk proxy associated with the corresponding object (`obj`).

```
prsk = obj.estimatePortRisk(pwgt);
```

## estimatePortStd

Estimate standard deviation of portfolio returns

### Syntax

```
pstd = estimatePortStd(obj, pwgt)
```

### Description

`pstd = estimatePortStd(obj, pwgt)` estimate standard deviation of portfolio returns for `PortfolioCVaR` or `PortfolioMAD` objects. For details on the workflows, see “`PortfolioCVaR` Object Workflow” on page 5-15 and “`PortfolioMAD` Object Workflow” on page 6-15.

### Examples

#### Estimate Standard Deviations for Portfolio Returns for a `PortfolioCVaR` Object

Given a portfolio `pwgt`, use the `estimatePortStd` function to show the standard deviation of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);

pstd = estimatePortStd(p, pwgt);
disp(pstd)

0.0223
0.1010
```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Estimate Standard Deviations for Portfolio Returns for a PortfolioMAD Object

Given a portfolio `pwgt`, use the `estimatePortStd` function to show the standard deviation of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt = estimateFrontierLimits(p);

pstd = estimatePortStd(p, pwgt);
disp(pstd)

0.0222
0.1010
```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using a `PortfolioCVaR` or `PortfolioMAD` object.

For more information on creating a `PortfolioCVaR` or `PortfolioMAD` object, see

- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

**pwgt — Collection of portfolios**  
matrix

Collection of portfolios, specified as a `NumAssets`-by-`NumPorts` matrix, where `NumAssets` is the number of assets in the universe and `NumPorts` is the number of portfolios in the collection of portfolios.

Data Types: `double`

## Output Arguments

**pstd — Estimates for standard deviations of portfolio returns for each portfolio in pwgt vector**

Estimates for standard deviations of portfolio returns for each portfolio in pwgt, returned as a NumPorts vector.

## Tips

You can also use dot notation to estimate the standard deviation of portfolio returns.

```
pstd = obj.estimatePortStd(pwgt);
```

## Introduced in R2012b

# estimatePortVaR

Estimate value-at-risk for PortfolioCVaR object

## Syntax

```
pvar = estimatePortVaR(obj, pwgt)
```

## Description

`pvar = estimatePortVaR(obj, pwgt)` estimates value-at-risk for a `PortfolioCVaR` object where the probability level used is from the `PortfolioCVaR` property `ProbabilityLevel`. For details on the workflow, see “`PortfolioCVaR` Object Workflow” on page 5-15.

## Examples

### Estimate Value-at-Risk for a `PortfolioCVaR` Object

Given a portfolio `pwgt`, use the `estimatePortVaR` function to estimate the value-at-risk of portfolio.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);

pvar = estimatePortVaR(p, pwgt);
disp(pvar)

0.0314
0.1483
```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

### **obj — Object for portfolio**

object

Object for portfolio, specified using a `PortfolioCVaR` object.

For more information on creating a `PortfolioCVaR` object, see

- `PortfolioCVaR`

Data Types: object

### **pwgt — Collection of portfolios**

matrix

Collection of portfolios, specified as a `NumAssets`-by-`NumPorts` matrix, where `NumAssets` is the number of assets in the universe and `NumPorts` is the number of portfolios in the collection of portfolios.

Data Types: double

## Output Arguments

### **pvar — Estimates for value-at-risk of portfolio returns for each portfolio in pwgt**

vector

Estimates for value-at-risk of portfolio returns for each portfolio in `pwgt`, returned as a `NumPorts` vector.

## Tips

You can also use dot notation to estimate the value-at-risk of `PortfolioCVaR` object.

```
pvar = obj.estimatePortVaR(pwgt);
```

# estimateScenarioMoments

Estimate mean and covariance of asset return scenarios

## Syntax

```
[ScenarioMean, ScenarioCovar] = estimateScenarioMoments(obj)
```

## Description

[ScenarioMean, ScenarioCovar] = estimateScenarioMoments(obj) estimates mean and covariance of asset return scenarios for PortfolioCVaR or PortfolioMAD objects. For details on the workflows, see “PortfolioCVaR Object Workflow” on page 5-15, and “PortfolioMAD Object Workflow” on page 6-15.

## Examples

### Estimate Mean and Covariance of Asset Return Scenarios for a PortfolioCVaR Object

Given PortfolioCVaR object p, use the estimatePortRisk function to estimate mean and covariance of asset return scenarios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

[ScenarioMean, ScenarioCovar] = estimateScenarioMoments(p)

ScenarioMean = 4x1
0.0039
0.0082
0.0102
0.0154

ScenarioCovar = 4x4
0.0005    0.0003    0.0001   -0.0001
```

```
0.0003    0.0024    0.0017    0.0010  
0.0001    0.0017    0.0048    0.0028  
-0.0001   0.0010    0.0028    0.0102
```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Estimate Mean and Covariance of Asset Return Scenarios for a PortfolioMAD Object

Given PortfolioMAD object `p`, use the `estimatePortRisk` function to estimate mean and covariance of asset return scenarios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];  
C = [ 0.0064 0.00408 0.00192 0;  
      0.00408 0.0289 0.0204 0.0119;  
      0.00192 0.0204 0.0576 0.0336;  
      0 0.0119 0.0336 0.1225 ];  
m = m/12;  
C = C/12;  
  
rng(11);  
  
AssetScenarios = mvnrnd(m, C, 20000);  
  
p = PortfolioMAD;  
p = setScenarios(p, AssetScenarios);  
p = setDefaultConstraints(p);  
  
[ScenarioMean, ScenarioCovar] = estimateScenarioMoments(p)  
  
ScenarioMean = 4x1  
  
0.0039  
0.0082  
0.0102  
0.0154  
  
ScenarioCovar = 4x4  
  
0.0005    0.0003    0.0001   -0.0001  
0.0003    0.0024    0.0017    0.0010  
0.0001    0.0017    0.0048    0.0028  
-0.0001   0.0010    0.0028    0.0102
```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using a `PortfolioCVaR` or `PortfolioMAD` object.

For more information on creating a `PortfolioCVaR` or `PortfolioMAD` object, see

- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

## Output Arguments

### **ScenarioMean — Estimate for mean of scenarios**

[ ] (default) | vector

Estimate for mean of scenarios, returned as a `NumPorts` vector or [ ].

---

**Note** If no scenarios are associated with the specified object, both `ScenarioMean` and `ScenarioCovar` are set to empty [ ].

---

### **ScenarioCovar — Estimate for covariance of scenarios**

[ ] (default) | matrix

Estimate for covariance of scenarios, returned as a `NumAssets`-by-`NumAssets` matrix or [ ].

---

**Note** If no scenarios are associated with the specified object, both `ScenarioMean` and `ScenarioCovar` are set to empty [ ].

---

## Tips

You can also use dot notation to estimate the mean and covariance of asset return scenarios for a portfolio.

```
[ScenarioMean, ScenarioCovar] = obj.estimateScenarioMoments
```

## ewstats

Expected return and covariance from return time series

### Syntax

```
[ExpReturn,ExpCovariance,NumEff0bs] = ewstats(RetSeries)
[ExpReturn,ExpCovariance,NumEff0bs] = ewstats(___,DecayFactor,WindowLength)
```

### Description

[ExpReturn,ExpCovariance,NumEff0bs] = ewstats(RetSeries) computes estimated expected returns (ExpReturn), estimated covariance matrix (ExpCovariance), and the number of effective observations (NumEff0bs). These outputs are maximum likelihood estimates which are biased.

[ExpReturn,ExpCovariance,NumEff0bs] = ewstats(\_\_\_,DecayFactor,WindowLength)  
adds optional input arguments for DecayFactor and WindowLength.

### Examples

#### Compute Estimated Expected Returns and Estimated Covariance Matrix

This example shows how to compute the estimated expected returns and the estimated covariance matrix.

```
RetSeries = [ 0.24 0.08
              0.15 0.13
              0.27 0.06
              0.14 0.13 ];
DecayFactor = 0.98;
[ExpReturn, ExpCovariance] = ewstats(RetSeries, DecayFactor)
ExpReturn = 1×2
    0.1995    0.1002
ExpCovariance = 2×2
    0.0032    -0.0017
   -0.0017     0.0010
```

### Input Arguments

**RetSeries — Return series**  
matrix

Return series, specified the number of observations (NUMOBS) by number of assets (NASSETS) matrix of equally spaced incremental return observations. The first row is the oldest observation, and the last row is the most recent.

Data Types: double

**DecayFactor — Controls how much less each observation is weighted than its successor**

1 (default) | numeric

(Optional) Controls how much less each observation is weighted than its successor, specified as a numeric value. The  $k$ th observation back in time has weight  $\text{DecayFactor}^k$ . DecayFactor must lie in the range:  $0 < \text{DecayFactor} \leq 1$ .

The default value of 1 is the equally weighted linear moving average model (BIS).

Data Types: double

**WindowLength — Number of recent observations in computation**

NUMOBS (default) | numeric

(Optional) Number of recent observations in the computation, specified as a numeric value.

Data Types: double

## Output Arguments

**ExpReturn — Estimated expected returns**

vector

Estimated expected returns, returned as a 1-by-NASSETS vector.

**ExpCovariance — Estimated covariance matrix**

matrix

Estimated covariance matrix, returned as a NASSETS-by-NASSETS matrix.

The standard deviations of the asset return processes are defined as

```
STDVec = sqrt(diag(ExpCovariance))
```

The correlation matrix is

```
CorrMat = ExpCovariance./( STDVec*STDVec' )
```

**NumEffObs — Number of effective observations**

numeric

NumEffObs is the number of effective observations where

$$\text{NumEffObs} = \frac{1 - \text{DecayFactor}^{\text{WindowLength}}}{1 - \text{DecayFactor}}$$

A smaller DecayFactor or WindowLength emphasizes recent data more strongly but uses less of the available data set.

## Algorithms

For a return series  $r(1), \dots, r(n)$ , where  $(n)$  is the most recent observation, and  $w$  is the decay factor, the expected returns (`ExpReturn`) are calculated by

$$E(r) = \frac{(r(n) + wr(n - 1) + w^2r(n - 2) + \dots + w^{n-1}r(1))}{\text{NumEffObs}}$$

where the number of effective observations `NumEffObs` is defined as

$$\text{NumEffObs} = 1 + w + w^2 + \dots + w^{n-1} = \frac{1 - w^n}{1 - w}$$

$E(r)$  is the weighed average of  $r(n), \dots, r(1)$ . The unnormalized weights are  $w, w^2, \dots, w^{(n-1)}$ . The unnormalized weights do not sum up to 1, so `NumEffObs` rescales the unnormalized weights. After rescaling, the normalized weights (which sum up to 1) are used for averaging. When  $w = 1$ , then `NumEffObs` =  $n$ , which is the number of observations. When  $w < 1$ , `NumEffObs` is still interpreted as the sample size, but it is less than  $n$  due to the down-weight on the observations of the remote past.

---

**Note** There is no relationship between `ewstats` function and the RiskMetrics® approach for determining the expected return and covariance from a return time series.

## Introduced before R2006a

# exp

Exponential values

---

**Note** `exp` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = exp(tsobj)
```

## Description

`newfts = exp(tsobj)` calculates the natural exponential (base e) of all the data in the data series of the financial time series object `tsobj` and returns the result in the object `newfts`.

## Examples

### Calculate Exponential Values in Financial Time Series Object

- 1 Create a `fints` object.

```
dates_and_times = (now:now+5)'
dates_and_times =
1.0e+05 *
7.3840
7.3840
7.3840
7.3841
7.3841
7.3841
```

```
tsobj = fints(dates_and_times, randn(6,1))
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see Convert F

```
> In fints (line 169)
```

```
tsobj =
desc: (none)
freq: Unknown (0)

{'dates: (6)'}    {'times: (6)'}    {'series1: (6)'}
{'07-Sep-2021'}    {'12:30'}        {[      0.5377]}
{'08-Sep-2021'}    {'12:30'}        {[      1.8339]}
{'09-Sep-2021'}    {'12:30'}        {[     -2.2588]}
{'10-Sep-2021'}    {'12:30'}        {[      0.8622]}
{'11-Sep-2021'}    {'12:30'}        {[      0.3188]}
{'12-Sep-2021'}    {'12:30'}        {[     -1.3077]}
```

- 2 Calculate exponential values using `exp`.

```
newfts = exp(tsobj)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert FINTS Objects to TIMETABLE.

```
> In fints/exp (line 17)
```

```
newfts =
```

```
desc: EXP of
freq: Unknown (0)
```

```
{'dates: (6)'}    {'times: (6)'}    {'series1: (6)'}

## Topics

“Financial Time Series Operations” on page 13-6

## Introduced before R2006a

# extfield

Data series extraction

---

**Note** `extfield` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
ftse = extfield(tsobj, fieldnames)
```

## Description

`ftse = extfield(tsobj, fieldnames)` extracts from `tsobj` the dates and data series specified by `fieldnames` into a new financial time series object `ftse`. `ftse` has all the dates in `tsobj` but contains a smaller number of data series.

The `extfield` function is the complement of the function `rmfield`.

## Examples

### Extract Data Series

- `extfield` is identical to referencing a field in the object. For example:

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1), 1), ...
                      times]);
myFts = fints(dates_times, (1:6)', {'Data1'}, 1, 'My first FINTS');
ftse = extfield(myFts, 'Data1')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints` (line 165)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints/extfield` (line 26)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints/display` (line 66)

```
ftse =
```

```
desc: My first FINTS
freq: Daily (1)

'dates: (6)'      'times: (6)'      'Data1: (6)'
'01-Jan-2001'      '11:00'          [           1]
'              '      '12:00'          [           2]
'02-Jan-2001'      '11:00'          [           3]
'              '      '12:00'          [           4]
```

```
'03-Jan-2001'    '11:00'      [           5]
'          '    '12:00'      [           6]
```

is the same as:

```
ftse = ftse.Data1
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/subsref (line 106)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/display (line 66)

```
ftse =
```

```
desc: My first FINTS
freq: Daily (1)
```

```
'dates: (6)'    'times: (6)'    'Data1: (6)'

```

## Input Arguments

### **tsobj — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: `object`

### **fieldnames — Data series to be extracted**

character vector | cell array of character vectors

Data series to be extracted, specified as a character vector or a cell array of character vectors.

Data Types: `cell` | `char`

## Output Arguments

### **ftse — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: `object`

## See Also

## fanplot

Plot combined historical and forecast data to visualize possible outcomes

### Syntax

```
fanplot(historical,forecast)
fanplot(____,Name,Value)

fanplot(ax,historical,forecast)
fanplot(____,Name,Value)

h = fanplot(ax,historical,forecast)
h = fanplot(____,Name,Value)
```

### Description

`fanplot(historical,forecast)` generates a fan chart. In time series analysis, a fan chart is a chart that joins a simple line chart for observed past data with ranges for possible values of future data. The historical data and possible future data are joined with a line showing a central estimate or most likely value for the future outcomes.

`fanplot` supports three plotting scenarios:

- Matching — This scenario occurs when the time period perfectly matches for `historical` and `forecast` data.
- Backtest — This scenario occurs when there are overlaps between `historical` and `forecast` data.
- Gap — This scenario occurs when there are `NaN` values in the `historical` or `forecast` data.

`fanplot(____,Name,Value)` generates a fan chart using optional name-value pair arguments.

`fanplot(ax,historical,forecast)` generates a fan chart using an optional `ax` argument.

`fanplot(____,Name,Value)` generates a fan chart using optional name-value pair arguments.

`h = fanplot(ax,historical,forecast)` generates a fan chart and returns the figure handle `h`. In time series analysis, a fan chart is a chart that joins a simple line chart for observed past data with ranges for possible values of future data. The historical data and possible future data are joined with a line showing a central estimate or most likely value for the future outcomes.

`fanplot` supports three plotting scenarios:

- Matching — This scenario occurs when the time period perfectly matches for `historical` and `forecast` data.
- Backtest — This scenario occurs when there are overlaps between `historical` and `forecast` data.
- Gap — This scenario occurs when there are `NaN` values in the `historical` or `forecast` data.

`h = fanplot(____,Name,Value)` generates a fan chart and returns the figure handle `h` using optional name-value pair arguments.

## Examples

### Create a Fan Plot Using Cell Array Data

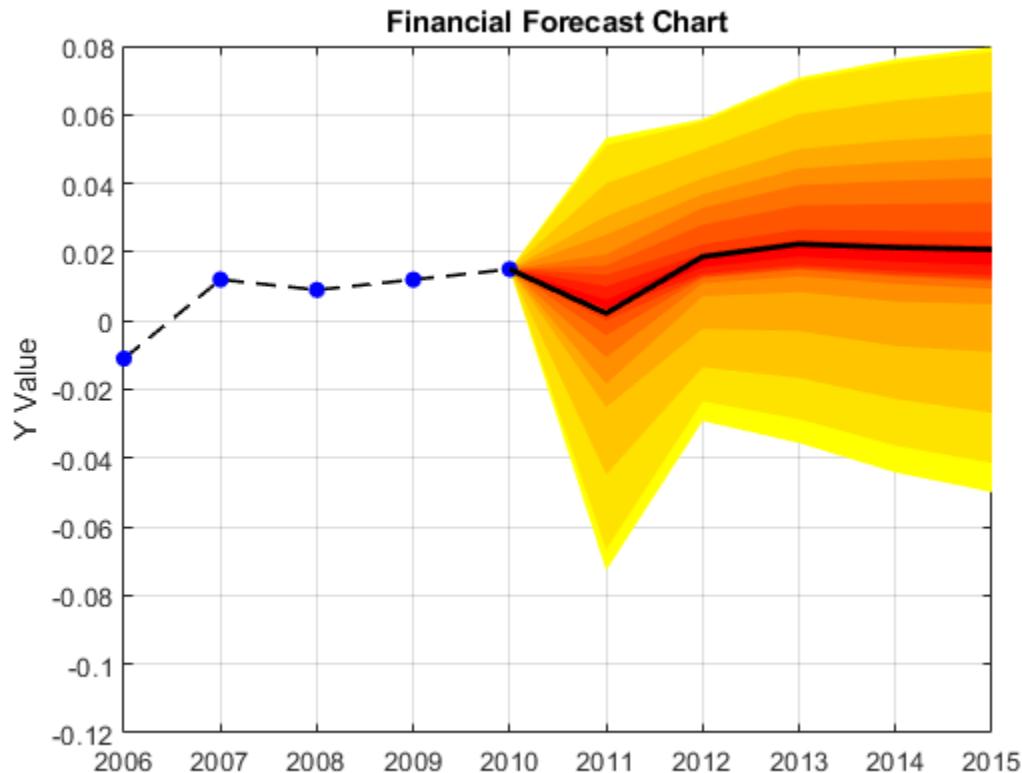

Define the data inputs for `historical` as a 5-by-2 cell array and `forecast` as a 5-by-21 cell array with 20 observations.

```
historical = {[2006]    [-0.0110]
              [2007]    [ 0.0120]
              [2008]    [ 0.0090]
              [2009]    [ 0.0120]
              [2010]    [ 0.0150]};

forecast = {[2011]   [0.0203]    [-0.0155]    [0.0311]    [-0.0026]    [0.0035]    [0.0049]
            [0.0533]   [0.0139]    [0.0037]    [-0.0727]    [-0.0291]    [-0.0053]
            [2012]   [0.0430]    [-0.0094]    [0.0587]    [ 0.0095]    [0.0185]    [0.0205]
            [0.0141]   [0.0337]    [0.0187]    [0.0132]    [-0.0292]    [0.0048]
            [2013]   [0.0518]    [-0.0116]    [0.0708]    [0.0112]    [0.0221]    [0.0246]
            [0.0168]   [0.0405]    [0.0224]    [0.0157]    [-0.0356]    [0.0056]
            [2014]   [0.0546]    [-0.0171]    [0.0762]    [0.0088]    [0.0210]    [0.0239]
            [0.0151]   [0.0419]    [0.0214]    [0.0139]    [-0.0442]    [0.0024]
            [2015]   [0.0565]    [-0.0207]    [0.0797]    [0.0072]    [0.0203]    [0.0234]
            [0.0139]   [0.0428]    [0.0207]    [0.0126]    [-0.0499]    [0.0026]
```

Generate the fan plot.

```
fanplot (historical, forecast);
```

The dotted points are the historical lines and the filled lines indicate the mean for the forecasts. This fanplot represents a matching scenario where the time period perfectly matches for the historical and forecast data.

# Create a Fan Plot Using Matrix Data

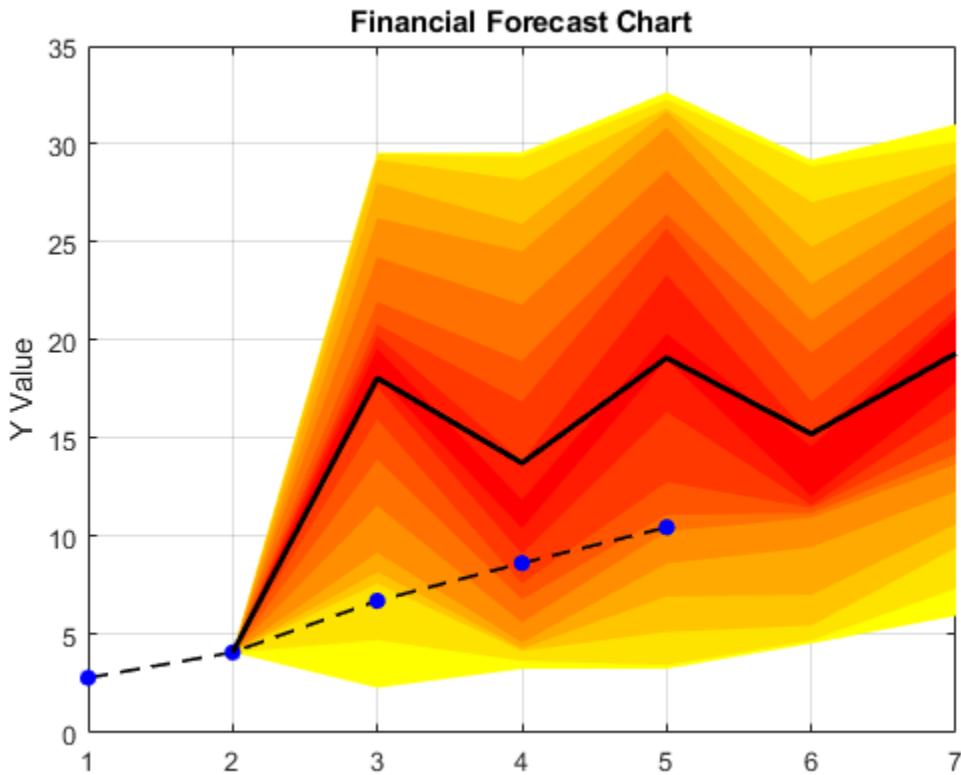

Define the data inputs for `historical` as a 5-by-2 matrix and `forecast` as a 5-by-21 matrix with 20 observations.

```
historical = [ 1.0000    2.8046 ;  
              2.0000    4.1040 ;  
              3.0000    6.7292 ;  
              4.0000    8.6486 ;  
              5.0000   10.4747 ]
```

|                 |          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>forecast</b> | <b>=</b> | [ 3.0000<br>28.9874<br>20.8557<br>27.0691<br>23.0803<br>20.7885<br>18.0205<br>17.2294<br>10.0197<br>29.0000<br>4.8933<br>8.0007<br>27.2659<br>18.7114<br>19.1691<br>24.4703<br>4.2835<br>10.5895<br>4.0676<br>15.0212<br>3.2612<br>29.1137<br>0.0000<br>5.0000<br>31.7996<br>19.7069<br>3.6419<br>11.6862<br>3.2695<br>25.7018<br>10.5487<br>31.8940<br>32.6529<br>7.2664<br>18.8370<br>19.2113<br>0.0000<br>6.0000<br>23.9532<br>11.0069<br>29.1965<br>18.4804<br>4.5551<br>25.5484<br>20.2627<br>4.8747<br>10.9209<br>8.0036<br>15.2675<br>11.5329<br>28.5359<br>11.6807<br>0.0000<br>7.0000<br>21.2390<br>5.9699<br>29.2396<br>11.1486<br>18.4828<br>26.0449<br>28.3945<br>13.4619<br>21.9342<br>21.1196<br>14.4642<br>28.8068<br>17.2613<br>26.2525<br>11.0000<br>0.0000 ] |
|-----------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Generate the fan plot and return the figure handle.

```
h = fanplot(historical, forecast)
```

```

h =
Figure (1) with properties:

    Number: 1
    Name: ''
    Color: [1 1 1]
    Position: [360 502 560 420]
    Units: 'pixels'

```

Show all properties

The dotted points are the historical lines and the filled lines indicate the mean for the forecasts. This fanplot represents a backtest scenario where there is an overlap between the historical and forecast data.

### Create a Fan Plot Using Cell Array Data and Customize the Plot With Name-Value Pair Arguments

Define the data inputs for `historical` as a 5-by-2 cell array and `forecast` as a 5-by-21 cell array with 20 observations.

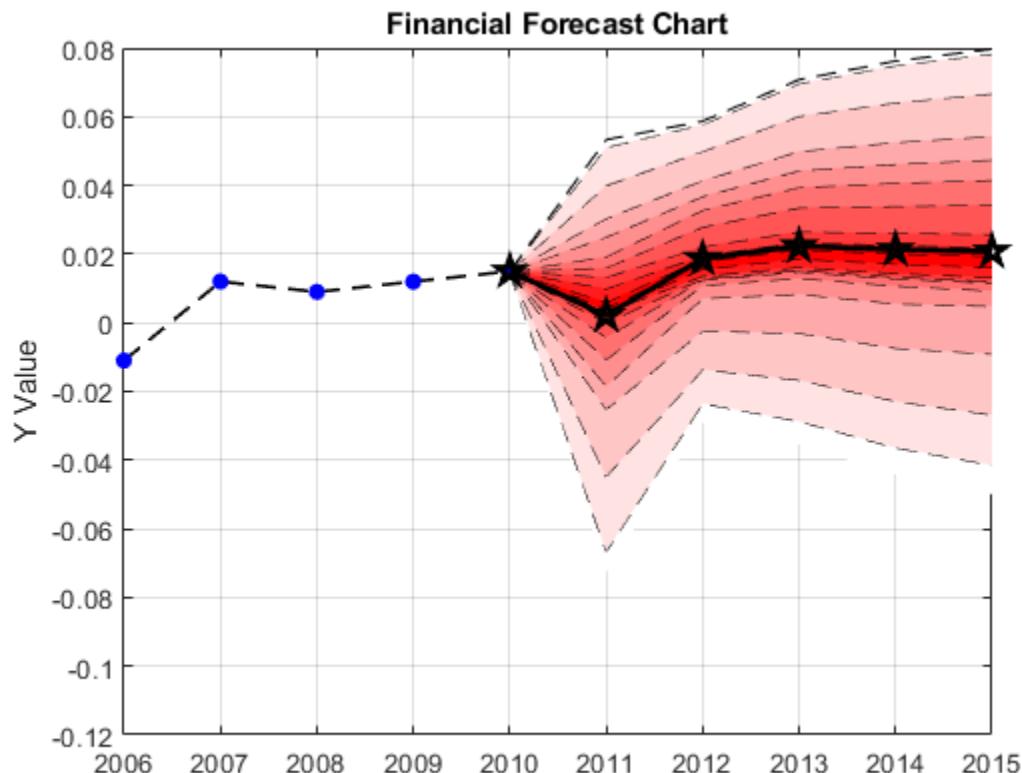

```
historical = {[2006]    [-0.0110]
              [2007]    [ 0.0120]}
```

```
[2008]    [ 0.0090]
[2009]    [ 0.0120]
[2010]    [ 0.0150}];

forecast = {[2011] [0.0203] [-0.0155] [0.0311] [-0.0026] [0.0035] [0.0049]
            [0.0533] [0.0139] [0.0037] [-0.0727] [-0.0291] [-0.0058]
            [0.0430] [-0.0094] [0.0587] [0.0095] [0.0185] [0.0205]
            [0.0141] [0.0337] [0.0187] [0.0132] [-0.0292] [0.0048]
            [0.0518] [-0.0116] [0.0708] [0.0112] [0.0221] [0.0246]
            [0.0168] [0.0405] [0.0224] [0.0157] [-0.0356] [0.0056]
            [0.0546] [-0.0171] [0.0762] [0.0088] [0.0210] [0.0239]
            [0.0151] [0.0419] [0.0214] [0.0139] [-0.0442] [0.0024]
            [0.0565] [-0.0207] [0.0797] [0.0072] [0.0203] [0.0234]
            [0.0139] [0.0428] [0.0207] [0.0126] [-0.0499] [0.0026]
```

Generate the fan plot using name-value pair arguments to customize the presentation.

```
fanplot(historical,forecast,'FanFaceColor',[1 1 1;1 0 0],'FanLineStyle','--','ForecastMarker','p')
```

### Create a Fan Plot Using Table Data

Create table of historical dates and data.

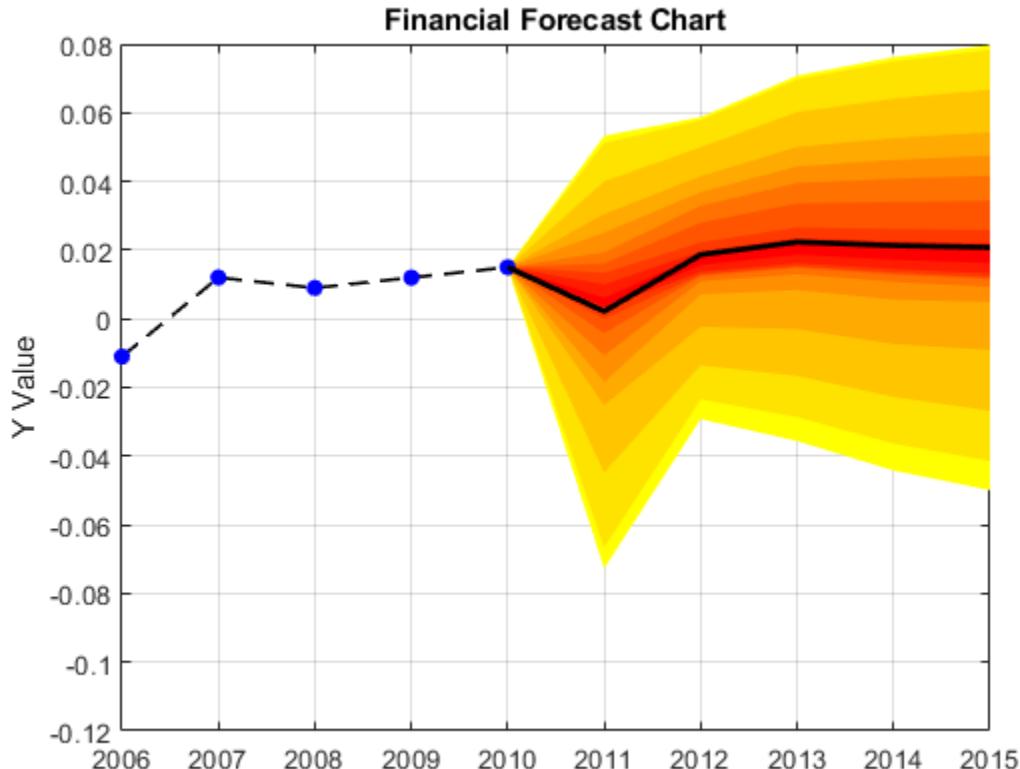

```
historicalDates = datetime(2006:2010,1,1)';
historicalData = [-0.0110;0.0120;0.0090;0.0120;0.0150];
historical = table(historicalDates,historicalData,'VariableNames',{'Dates','Data'});
```

Create table of forecast dates and data.

```
forecastDates = datetime(2011:2015,1,1)';
forecastData = [0.0203 -0.0155 0.0311 -0.0026 0.0035 0.0049 0.0026
               0.0533 0.0139 0.0037 -0.0727 -0.0291 -0.0058 0.0183
               0.0430 -0.0094 0.0587 0.0095 0.0185 0.0205 0.0172
               0.0141 0.0337 0.0187 0.0132 -0.0292 0.0048 0.0400
               0.0518 -0.0116 0.0708 0.0112 0.0221 0.0246 0.0205
               0.0168 0.0405 0.0224 0.0157 -0.0356 0.0056 0.0482
               0.0546 -0.0171 0.0762 0.0088 0.0210 0.0239 0.0193
               0.0151 0.0419 0.0214 0.0139 -0.0442 0.0024 0.0506
               0.0565 -0.0207 0.0797 0.0072 0.0203 0.0234 0.0185
               0.0139 0.0428 0.0207 0.0126 -0.0499 0.0026 0.0522
forecast = [table(forecastDates,'VariableName',{'Dates'}),array2table(forecastData)];
```

Plot the data using fanplot.

```
fanplot(historical,forecast);
```

## Input Arguments

### **historical — Historical dates and data**

matrix | cell array | table | timetable

Historical dates and data, specified as an N-by-2 matrix, cell array, table, or timetable where the first column is the date, and the second column is the data associated for that date. N indicates the

number of dates. By using the cell array format for the input, you can make the first column datetime and produce the same plot as would serial date numbers or date character vectors. For example:

```
historical(:,1) = num2cell(datetime(2006:2010,1,1));
forecast(:,1) = num2cell(datetime(2011:2015,1,1));
fanplot (historical, forecast);
```

Data Types: cell | double | table | timetable

#### **forecast — Forecast dates and data**

matrix | cell array of character vectors | table | timetable

Forecast dates and data, specified as an N-by-M matrix, cell array, table, or timetable where the first column is the date, and the second to the last columns are the data observations. N indicates the number of the dates and (M - 1) is the number for data observations. By using the cell array format for the input, you can make the first column datetime and produce the same plot as would serial date numbers or date character vectors. For example:

```
historical(:,1) = num2cell(datetime(2006:2010,1,1));
forecast(:,1) = num2cell(datetime(2011:2015,1,1));
fanplot (historical, forecast);
```

Data Types: cell | double | table | timetable

#### **ax — Valid axis object**

object

(Optional) Valid axis object, specified as an ax object that is created using `axes`. The plot will be created in the axes specified by the optional ax argument instead of in the current axes (`gca`). The optional argument ax can precede any of the input argument combinations.

Data Types: object

#### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example:

```
fanplot(historical,forecast,'NumQuantiles',14,'FanLineColor','blue','Historic
alLineWidth', 1.8,'ForecastLineColor','red')
```

#### **NumQuantiles — Number of quantiles to display**

20 (default) | positive integer

Number of quantiles to display in fan chart, specified as a positive integer.

Data Types: double

#### **FanLineStyle — Style of the lines separating fans**

'none' (default) | character vector

Style of the lines separating fans, specified as a character vector. For more information on supported character vectors for line styles, see Primitive Line.

Data Types: char

**FanLineColor — Color of lines separating fans**

'black' (default) | character vector for color or RGB triplet

Color of lines separating fans, specified as a character vector for color or an RGB triplet. For more information on supported color character vectors, see Primitive Line.

Data Types: double | char

**FanFaceColor — Color of each fan**

[1 1 0; 1 0 0] (yellow to red) (default) | matrix

Color of each fan, specified as an N-by-3 matrix controlling the color of each fan, where each row is an RGB triplet. There are three possible values of N:

- When N = NumQuantiles, the color of each fan is specified by the corresponding row in the matrix.
- When N = ceil(NumQuantiles/2), the specified colors represent the bottom half of the fans. The colors of the top half are determined by reversing the order of these colors. For more information, see `ceil`.
- When N = 2, the colors in the bottom half of the fan are a linear interpolation between the two specified colors. The pattern is reversed for the top half.

Data Types: double

**HistoricalMarker — Marker symbol of historical line**

'o' (default) | character vector

Marker symbol of historical line, specified as a character vector. For more information on supported character vectors for markers, see Primitive Line.

Data Types: char

**HistoricalMarkerSize — Marker size of historical line**

5 (default) | positive value in point units

Marker size of historical line, specified as a positive value in point units.

Data Types: double | char

**HistoricalMarkerFaceColor — Marker fill color of historical line**

'blue' (default) | character vector with a value of 'none', 'auto', color identifier, or RGB triplet

Marker fill color of historical line, specified as a character vector with a value of 'none', 'auto', a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: double | char

**HistoricalMarkerEdgeColor — Marker outline color of historical line**

'blue' (default) | character vector with a value of 'none', 'auto', color identifier, or RGB triplet

Marker outline color of historical line, specified as a character vector with a value of 'none', 'auto', a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: double | char

**HistoricalLineColor — Color of historical line**

'black' (default) | character vector with a value of 'none', color identifier, or RGB triplet

Color of historical line, specified as a character vector with a value of 'none', a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: double | char

**HistoricalLineStyle — Style of historical line**

'--' (default) | character vector

Style of historical line, specified as a character vector. For more information on supported character vectors for line styles, see Primitive Line.

Data Types: char

**HistoricalLineWidth — Width of historical line**

1.5 (default) | positive value in point units

Width of historical line, specified as a positive value in point units.

Data Types: double

**ForecastMarker — Marker symbol of forecast line**

'none' (default) | character vector

Marker symbol of forecast line, specified as a character vector. For more information on supported character vectors for marker symbols, see Primitive Line.

Data Types: char

**ForecastMarkerSize — Marker size of forecast line**

5 (default) | positive value in point units

Marker size of forecast line, specified as a positive value in point units.

Data Types: double

**ForecastMarkerFaceColor — Marker fill color of forecast line**

'none' (default) | character vector with a value of 'none', 'auto', color identifier, or RGB triplet

Marker fill color of forecast line, specified as a character vector with a value of 'none', 'auto', a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: double | char

**ForecastMarkerEdgeColor — Marker outline color of forecast line**

'auto' (default) | character vector with a value of 'none', 'auto', color identifier, or RGB triplet

Marker outline color of forecast line, specified as a character vector with a value of 'none', 'auto', a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: double | char

**ForecastLineColor — Color of forecast line**

'black' (default) | character vector with a value of 'none', color identifier, or RGB triplet

Color of forecast line, specified as a character vector with a value of 'none', a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: double | char

**ForecastLineStyle — Style of forecast line**

'-' (default) | character vector

Style of forecast line, specified as a character vector. For more information on supported character vectors for line styles, see Primitive Line.

Data Types: char

**ForecastLineWidth — Width of forecast line**

2 (default) | positive value in point units

Width of forecast line, specified as a positive value in point units.

Data Types: double

## Output Arguments

**h — Figure handle for fanplot**

handle object

Figure handle for the fanplot, returned as handle object.

| datetime | ceil | timetable

**Introduced in R2014b**

## fbusdate

First business date of month

### Syntax

```
Date = fbusdate(Year,Month)
Date = fbusdate(___,Holiday,Weekend,outputType)
```

### Description

`Date = fbusdate(Year,Month)` returns the serial date number for the first business date of the given year and month.

`Year` and `Month` can contain multiple values. If one contains multiple values, the other must contain the same number of values or a single value that applies to all. For example, if `Year` is a 1-by-N vector of integers, then `Month` must be a 1-by-N vector of integers or a single integer. `Date` is then a 1-by-N vector of date numbers.

Use the function `datestr` to convert serial date numbers to formatted date character vectors.

`Date = fbusdate(___,Holiday,Weekend,outputType)` returns the serial date number for the first business date of the given year and month using optional input arguments. The optional argument `Holiday` specifies nontrading days.

If neither `Holiday` nor `outputType` are specified, `Date` is returned as a serial date number. If `Holiday` is specified, but not `outputType`, then the type of the `Holiday` variable controls the type of date. If `Holiday` is a serial date number or date character vector, then `Date` is returned as a serial date number.

### Examples

#### Return a Serial Date Number for the First Business Date

This example shows how to return serial date numbers for the first business date, given year and month.

```
Date = fbusdate(2001, 11)
```

```
Date = 731156
```

```
datestr(Date)
```

```
ans =
'01-Nov-2001'
```

```
Year = [2002 2003 2004];
Date = fbusdate(Year, 11)
```

```
Date = 1x3
```

|        |        |        |
|--------|--------|--------|
| 731521 | 731888 | 732252 |
|--------|--------|--------|

```
datestr(Date)

ans = 3x11 char array
'01-Nov-2002'
'03-Nov-2003'
'01-Nov-2004'
```

### **Return a Serial Date Number for the First Business Date Using the Weekend Argument**

This example shows how to return serial date numbers for the first business date, given year and month, and also indicate that Saturday is a business day by setting the `Weekend` argument. March 1, 2003, is a Saturday. Use `fbusdate` to check that this Saturday is actually the first business day of the month.

```
Weekend = [1 0 0 0 0 0];
Date = datestr(fbusdate(2003, 3, [], Weekend))

Date =
'01-Mar-2003'
```

### **Return a datetime array for Date for the First Business Date Using the outputType Argument**

This example shows how to return a datetime array for `Date` using an `outputType` of '`datetime`'.

```
Date = fbusdate(2001, 11,[],[],'datetime')

Date = datetime
01-Nov-2001
```

## **Input Arguments**

### **Year — Year to determine occurrence of weekday**

4-digit integer | vector of 4-digit integers

Year to determine occurrence of weekday, specified as a 4-digit integer or vector of 4-digit integers.

Data Types: `single` | `double`

### **Month — Month to determine occurrence of weekday**

integer with value 1 through 12 | vector of integers with values 1 through 12

Month to determine occurrence of weekday, specified as an integer or vector of integers with values 1 through 12.

Data Types: `single` | `double`

**Holiday — Holidays and nontrading-day dates**

non-trading day vector is determined by the routine `holidays` (default) | serial date number | date character vector | datetime array

Holidays and nontrading-day dates, specified as vector.

All dates in `Holiday` must be the same format: either serial date numbers, or date character vectors, or datetime arrays. (Using serial date numbers improves performance.) The `holidays` function supplies the default vector.

If `Holiday` is a datetime array, then `Date` is returned as a datetime array. If `outputType` is specified, then its value determines the output type of `Date`. This overrides any influence of `Holiday`.

Data Types: double | char | datetime

**Weekend — Weekend days**

[1 0 0 0 0 0 1] (Saturday and Sunday form the weekend) (default) | vector of length 7, containing 0 and 1, where 1 indicates weekend days

Weekend days, specified as a vector of length 7, containing 0 and 1, where 1 indicates weekend days and the first element of this vector corresponds to Sunday.

Data Types: double

**outputType — Year to determine days**

'datenum' (default) | character vector with values 'datenum' or 'datetime'

A character vector specified as either 'datenum' or 'datetime'. The output `Date` is in serial date format if 'datenum' is specified, or datetime format if 'datetime' is specified. By default the output `Date` is in serial date format, or match the format of `Holiday`, if specified.

Data Types: char

## Output Arguments

**Date — Date for the first business date of given year and month**

serial date number | date character vector | datetime array

Date for the first business date of a given year and month, returned as a serial date number, date character vector, or datetime array.

If neither `Holiday` nor `outputType` are specified, `Date` is returned as a serial date number. If `Holiday` is specified, but not `outputType`, then the type of the `holiday` variable controls the type of date:

- If `Holiday` is a serial date number or date character vector, then `Date` is returned as a serial date number
- If `Holiday` is a datetime array, then `Date` is returned as a datetime array.

# fetch

Data from financial time series object

---

**Note** `fetch` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
newfts = fetch(oldfts,StartDate,StartTime,EndDate,EndTime,delta,  
dmySpecifier,timeRef)
```

## Description

`newfts = fetch(oldfts,StartDate,StartTime,EndDate,EndTime,delta,  
dmySpecifier,timeRef)` requests data from a financial time series object beginning from the start date and/or start time to the end date and/or end time, skipping a specified number of days, months, or years.

---

**Note** If time information is present in `oldfts`, using `[]` for start or end times results in `fetch` returning all instances of a specific date.

---

## Examples

### Fetch All Dates and Times

- 1 Create a financial time series object containing both dates and times:

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...  
'02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];  
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];  
dates_times = cellstr([dates, repmat(' ', size(dates, 1), 1), ...  
times]);  
myFts = fints(dates_times, (1:6)', {'Data1'}, 1, 'My first FINTS')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints` (line 165)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints/display` (line 66)

```
myFts =
```

```
desc: My first FINTS  
freq: Daily (1)  
  
'dates: (6)'      'times: (6)'      'Data1: (6)'  
'01-Jan-2001'    '11:00'          [           1]  
'           '       '12:00'          [           2]  
'02-Jan-2001'    '11:00'          [           3]  
'           '       '12:00'          [           4]
```

```
'03-Jan-2001'    '11:00'      [      5]
'          '    '12:00'      [      6]
```

- 2** To fetch all dates and times from this financial time series, enter

```
fetch(myFts,'01-Jan-2001',[],'03-Jan-2001',[],1,'d')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/fetch (line 126)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/display (line 66)

```
ans =
```

```
desc: My first FINTS
freq: Daily (1)

'dates: (6)'    'times: (6)'    'Data1: (6)'
'01-Jan-2001'    '11:00'      [      1]
'          '    '12:00'      [      2]
'02-Jan-2001'    '11:00'      [      3]
'          '    '12:00'      [      4]
'03-Jan-2001'    '11:00'      [      5]
'          '    '12:00'      [      6]
```

or

```
fetch(myFts,'01-Jan-2001','11:00','03-Jan-2001','12:00',1,'d')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/fetch (line 126)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/display (line 66)

```
ans =
```

```
desc: My first FINTS
freq: Daily (1)

'dates: (6)'    'times: (6)'    'Data1: (6)'
'01-Jan-2001'    '11:00'      [      1]
'          '    '12:00'      [      2]
'02-Jan-2001'    '11:00'      [      3]
'          '    '12:00'      [      4]
'03-Jan-2001'    '11:00'      [      5]
'          '    '12:00'      [      6]
```

## Extract Data at 5-Minute Intervals

- 1** Create a financial time series object with time intervals of less than 1 hour:

```
dates2 = ['01-Jan-2001';'01-Jan-2001'; '01-Jan-2001';...
'02-Jan-2001'; '02-Jan-2001';'02-Jan-2001'];
times2 = ['11:00';'11:05';'11:06';'12:00';'12:05';'12:06'];
dates_times2 = cellstr([dates2, repmat(' ',size(dates2,1),1),...
times2]);
myFts2 = fints(dates_times2,(1:6),{'Data1'},1,'My second FINTS')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints (line 165)

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/display (line 66)
```

```
myFts2 =  
  
desc: My second FINTS  
freq: Daily (1)
```

```
'dates: (6)'    'times: (6)'    'Data1: (6)'  
'01-Jan-2001'   '11:00'        [      1]  
'          '       '11:05'        [      2]  
'          '       '11:06'        [      3]  
'02-Jan-2001'   '12:00'        [      4]  
'          '       '12:05'        [      5]  
'          '       '12:06'        [      6]
```

- 2 Use `fetch` to extract data from this time series object at 5-minute intervals for each day starting at 11:00 o'clock on January 1, 2001.

```
fetch(myFts2, '01-Jan-2001', [], '02-Jan-2001', [], 1, 'd', 5)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/fetch (line 126)  
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/display (line 66)
```

```
ans =  
  
desc: My second FINTS  
freq: Daily (1)  
  
'dates: (4)'    'times: (4)'    'Data1: (4)'  
'01-Jan-2001'   '11:00'        [      1]  
'          '       '11:05'        [      2]  
'02-Jan-2001'   '12:00'        [      4]  
'          '       '12:05'        [      5]
```

You can use this version of `fetch` to extract data at specific times. For example, to fetch data only at 11:06 and 12:06 from `myFts2`, enter

```
fetch(myFts2, '01-Jan-2001', [], '02-Jan-2001', [], 1, 'd', ...  
{'11:06'; '12:06'})
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/fetch (line 126)  
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/display (line 66)
```

```
ans =  
  
desc: My second FINTS  
freq: Daily (1)  
  
'dates: (2)'    'times: (2)'    'Data1: (2)'  
'01-Jan-2001'   '11:06'        [      3]  
'02-Jan-2001'   '12:06'        [      6]
```

## Input Arguments

**oldfts — Financial time series object**

fints object

Financial time series object, specified as a fints object.

Data Types: object

**StartDate — First date in range from which data is extracted**

date character vector

First date in the range from which data is extracted, specified as a date character vector.

Data Types: char

**StartTime — Beginning time on each day**

character vector

Beginning time on each day, specified as a character vector. If you do not require specific times or oldfts does not contain time information, use []. If you specify StartTime, you must also specify EndTime.

Data Types: char

**EndDate — Last date in range from which data is extracted**

date character vector

Last date in the range from which data is extracted, specified as a date character vector.

Data Types: char

**EndTime — Ending time on each day**

character vector

Ending time on each day, specified as a character vector. If you do not require specific times or oldfts does not contain time information, use []. If you specify EndTime, you must also specify StartTime.

Data Types: char

**delta — Skip interval**

positive integer

Skip interval, specified as a positive integer. Units for the skip interval specified by dmySpecifier.

Data Types: double

**dmySpecifier — Units for delta**

character vector

Units for delta, specified as a character vector. The units for delta can be any one of the following:

- 'D' or 'd' (Days)
- 'M' or 'm' (Months)
- 'Y' or 'y' (Years)

Data Types: char

**time\_ref — Time reference intervals or specific times**  
character vector

Time reference intervals or specific times, specified as a character vector. Valid time reference intervals are 1, 5, 15, or 60 minutes. Enter specific times as 'hh:mm'.

Data Types: char

## Output Arguments

**newfts — Financial time series object**  
fints object

Financial time series object, specified as a `fints` object.

Data Types: object

## See Also

`extfield` | `ftsbound` | `getfield` | `subsref`

## Topics

“What Is the Financial Time Series App?” on page 14-2

**Introduced before R2006a**

# fieldnames

Get names of fields

---

**Note** `fieldnames` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
fnames = fieldnames(tsobj)
fnames = fieldnames(tsobj,srsnameonly)
```

## Description

`fnames = fieldnames(tsobj)` returns the field names associated with the financial time series object `tsobj` as a cell array of character vectors, including the common fields: `desc`, `freq`, `dates` (and `times` if present).

`fnames = fieldnames(tsobj,srsnameonly)` returns field names depending upon the setting of `srsnameonly`. If `srsnameonly` is 0, the function returns all field names, including the common fields: `desc`, `freq`, `dates`, and `times`. If `srsnameonly` is set to 1, `fieldnames` returns only the data series in `fnames`.

## Examples

### Obtain Names of Fields in Financial Times Series Object

- Create a financial times series (`fints`) object using `dates` and `data`.

```
data = [1:6]';
dates = [today:today+5]';
tsobj = fints(dates, data)
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see Convert FINTS Objects to Timetables.

```
> In fints (line 169)
```

```
tsobj =
desc: (none)
freq: Unknown (0)

{'dates: (6)'}    {'series1: (6)'}
{'01-Sep-2021'}  {[1]}
{'02-Sep-2021'}  {[2]}
{'03-Sep-2021'}  {[3]}
{'04-Sep-2021'}  {[4]}
{'05-Sep-2021'}  {[5]}
{'06-Sep-2021'}  {[6]}
```

- Use `fnames` to obtain the field names.

```
fnames = fieldnames(tsobj)
```

4×1 cell array

```
{'desc'    }  
{'freq'   }  
{'dates'  }  
{'series1'}
```

## Input Arguments

### **tsobj — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

### **srsnameonly — Indicator for field names to return**

0 (all fields) (default) | logical

Indicator for field names to return, specified as a scalar logical with one of the following values:

- 0 = All field names
- 1 = Data series names only

Data Types: logical

## Output Arguments

### **fnames — Field names**

cell array of character vectors

Field names, returned as a cell array of character vectors.

## See Also

`chfield` | `getfield` | `isfield` | `rmfield` | `setfield`

## Topics

“What Is the Financial Time Series App?” on page 14-2

## Introduced before R2006a

# fills

Fill missing values in time series

---

**Note** `fills` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = fills(oldfts,fillmethod)
newfts = fills(oldfts,fillmethod,newdates)
newfts = fills(oldfts,fillmethod,newdates,newtimes)
newfts = fills(___,delta,sortmode)
```

## Description

`newfts = fills(oldfts,fillmethod)` replaces missing values (represented by `Nan`) in the financial time series object `oldfts` with real values, using either a constant or the interpolation process indicated by `fillmethod`.

`newfts = fills(oldfts,fillmethod,newdates)` replaces all the missing values on the specified dates `newdates` added to the financial time series `oldfts` with new values. The values can be a single constant or values obtained through the interpolation process designated by `fillmethod`. If any of the dates in `newdates` exists in `oldfts`, the existing one has precedence.

`newfts = fills(oldfts,fillmethod,newdates,newtimes)` additionally allows the designation of specific times of day for addition or replacement of data.

`newfts = fills(___,delta,sortmode)` adds a spanning time interval, `delta` and `sortmode` denotes whether you want the order of the dates in the output object to stay the same as in the input object or to be sorted chronologically.

## Examples

### Fill Missing Values in Time Series for Financial Time Series Object

- Create a financial time series object with missing data in the fourth and fifth rows.

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
        '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ',size(dates,1),1), ...
                      times]);
OpenFts = fints(dates_times,[(1:3); nan; nan; 6],{'Data1'},1, ...
                'Open Financial Time Series')
```

`OpenFts` looks like this:

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see Convert F

> In `fints` (line 169)

```
OpenFts =  
  
desc: Open Financial Time Series  
freq: Daily (1)  
  
{'dates: (6)'} {'times: (6)'} {'Data1: (6)'}  
{'01-Jan-2001'} {'11:00'} {[ 1]}  
{' " '} {'12:00'} {[ 2]}  
{'02-Jan-2001'} {'11:00'} {[ 3]}  
{' " '} {'12:00'} {[NaN]}  
{'03-Jan-2001'} {'11:00'} {[NaN]}  
{' " '} {'12:00'} {[ 6]}
```

- 2 Fill the missing data in `OpenFts` using cubic interpolation.

```
FilledFts = fillts(OpenFts,'cubic')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert F

> In `fints/fillts` (line 217)

```
FilledFts =  
  
desc: Filled Open Financial Time Series  
freq: Unknown (0)  
  
{'dates: (6)'} {'times: (6)'} {'Data1: (6)'}  
{'01-Jan-2001'} {'11:00'} {[ 1]}  
{' " '} {'12:00'} {[ 2]}  
{'02-Jan-2001'} {'11:00'} {[ 3]}  
{' " '} {'12:00'} {[ 3.0663]}  
{'03-Jan-2001'} {'11:00'} {[ 5.8411]}  
{' " '} {'12:00'} {[ 6]}
```

### Fill Missing Values for Specific Time for Time Series for Financial Time Series Object

- 1 Create a financial time series object with missing data in the fourth and fifth rows.

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...  
        '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];  
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];  
dates_times = cellstr([dates, repmat(' ',size(dates,1),1), ...  
                      times]);  
OpenFts = fints(dates_times,[1:3)', nan; nan; 6],{'Data1'},1,...  
'Open Financial Time Series')
```

`OpenFts` looks like this:

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert F

> In `fints` (line 169)

```
OpenFts =  
  
desc: Open Financial Time Series  
freq: Daily (1)  
  
{'dates: (6)'} {'times: (6)'} {'Data1: (6)'}  
{'01-Jan-2001'} {'11:00'} {[ 1]}  
{' " '} {'12:00'} {[ 2]}  
{'02-Jan-2001'} {'11:00'} {[ 3]}
```

```

{'      "      '}    {'12:00'      }    {[      NaN]}
{'03-Jan-2001'}    {'11:00'      }    {[      NaN]}
{'      "      '}    {'12:00'      }    {[      6]}

```

- 2** Use `fillts` to identify a specific time on a specific day for the replacement of missing data. This example shows how to replace missing data at 12:00 on January 2 and 11:00 on January 3.

```
FilltimeFts = fillts(OpenFts, 'c', ...
{'02-Jan-2001'; '03-Jan-2001'}, {'12:00'; '11:00'}, 0)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert FINTS Objects to TIMETABLE Objects

```
FilltimeFts =
```

```

desc: Filled Open Financial Time Series
freq: Unknown (0)

{'dates: (6)'}    {'times: (6)'}    {'Data1: (6)'}
{'01-Jan-2001'}    {'11:00'      }    {[      1]}
{'      "      '}    {'12:00'      }    {[      2]}
{'02-Jan-2001'}    {'11:00'      }    {[      3]}
{'      "      '}    {'12:00'      }    {[      3.0663]}
{'03-Jan-2001'}    {'11:00'      }    {[      5.8411]}
{'      "      '}    {'12:00'      }    {[      6]}

```

## Spanning time interval to Fill Time Series for Financial Time Series Object

- 1** Create a financial time series object with missing data in the fourth and fifth rows.

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
        '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates, 1), 1), ...
                      times]);
OpenFts = fints(dates_times, [(1:3)'; nan; nan; 6], {'Data1'}, 1, ...
                'Open Financial Time Series')
```

`OpenFts` looks like this:

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert FINTS Objects to TIMETABLE Objects

```
OpenFts =
```

```

desc: Open Financial Time Series
freq: Daily (1)

{'dates: (6)'}    {'times: (6)'}    {'Data1: (6)'}
{'01-Jan-2001'}    {'11:00'      }    {[      1]}
{'      "      '}    {'12:00'      }    {[      2]}
{'02-Jan-2001'}    {'11:00'      }    {[      3]}
{'      "      '}    {'12:00'      }    {[      NaN]}
{'03-Jan-2001'}    {'11:00'      }    {[      NaN]}
{'      "      '}    {'12:00'      }    {[      6]}

```

- 2** Use a spanning time interval to add an additional day to `OpenFts`.

```
SpanFts = fillts(OpenFts, 'c', '04-Jan-2001', 'span', ...
{'11:00'; '12:00'}, 60, 0)
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert F  
> In fints/fillts (line 217)
```

```
SpanFts =  
  
desc: Filled Open Financial Time Series  
freq: Unknown (0)  
  
{'dates: (8)'} {'times: (8)'} {'Data1: (8)'}  
{'01-Jan-2001'} {'11:00'} {[ 1]}  
{' " '} {'12:00'} {[ 2]}  
{'02-Jan-2001'} {'11:00'} {[ 3]}  
{' " '} {'12:00'} {[ 3.0663]}  
{'03-Jan-2001'} {'11:00'} {[ 5.8411]}  
{' " '} {'12:00'} {[ 6]}  
{'04-Jan-2001'} {'11:00'} {[ 9.8404]}  
{' " '} {'12:00'} {[ 9.9994]}
```

## Input Arguments

**oldfts — Financial time series object**  
fints object

Financial time series object, specified as a `fints` object.

Data Types: `object`

**fillmethod — Valid fill methods**  
'linear' (default) | character vector

Valid fill methods (interpolation methods), specified as a character vector.

- '`linear`' — linear
- '`linearExtrap`' — linear with extrapolation
- '`cubic`' — cubic
- '`cubicExtrap`' — cubic with extrapolation
- '`spline`' — spline
- '`splineExtrap`' — spline with extrapolation
- '`nearest`' — nearest
- '`nearestExtrap`' — nearest with extrapolation
- '`pchip`' — pchip
- '`pchipExtrap`' — pchip with extrapolation

(See `interp1` for a discussion of extrapolation.)

To fill with a constant, enter that constant.

A zero-order hold ('`zero`') fills a missing value with the value immediately preceding it. If the first value in the time series is missing, it remains a `NaN`.

Data Types: `char`

**newdates — Dates**

column vector | date character vector | cell array of date character vectors

Dates, specified as a column vector of serial date numbers, a date character vector, or a column cell array of date character vector. If `oldfts` contains time of day information, `newdates` must be accompanied by a time vector (`newtimes`). Otherwise, `newdates` is assumed to have times of '`00:00`'.

If you specify only one date for `newdates`, specifying a start and end time generates only times for that specific date.

Data Types: double | cell | char

**newtimes — Times**

date character vector | cell array of date character vectors

Times, specified as a date character vector or a column cell array of date character vector. If `oldfts` contains time of day information, `newdates` must be accompanied by a time vector (`newtimes`). Otherwise, `newdates` is assumed to have times of '`00:00`'.

If you specify only one date for `newdates`, specifying a start and end time generates only times for that specific date.

Data Types: char | cell

**delta — Time interval in minutes**

positive integer

Time interval in minutes, specified as a positive integer. `delta` is the span between the start time and end time.

Data Types: double

**sortmode — Sort mode**

0 (unsorted) (default) | integer with value 0 or 1

Sort mode, specified as a an integer where 0 is unsorted and 1 is sorted.

- 0 — Unsorted, appends any new dates to the end. The interpolation and zero-order processes that calculate the values for the new dates work on a sorted object. Upon completion, the existing dates are reordered as they were originally, and the new dates are appended to the end.
- 1 — Sorts the output. After interpolation, no reordering of the date sequence occurs.

Data Types: double

## Output Arguments

**newfts — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

# filter

Linear filtering

**Note** `filter` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

## Syntax

```
newfts = filter(B,A,oldfts)
```

## Description

`filter` filters an entire financial time series object with certain filter specifications. The filter is specified in a transfer function expression.

`newfts = filter(B,A,oldfts)` filters the data in the financial time series object `oldfts` with the filter described by vectors `A` and `B` to create the new financial time series object `newfts`. The filter is a “Direct Form II Transposed” implementation of the standard difference equation. `newfts` is a financial time series object containing the same data series (names) as the input `oldfts`.

“Data Transformation and Frequency Conversion” on page 13-11

## Introduced before R2006a

## fints

Construct financial time series object

---

**Note** `fints` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
tsobj = fints(dates_and_data)
tsobj = fints(dates,data)
tsobj = fints(dates,data,datanames)
tsobj = fints(__ freq,desc)
```

### Description

`tsobj = fints(dates_and_data)` creates a financial time series object containing the dates and data from the matrix `dates_and_data`. If the dates contain time-of-day information, the object contains an additional series of times. The date series and each data series must each be a column in the input matrix. The names of the data series default to `series1`, ..., `seriesn`. The `desc` and `freq` fields are set to their defaults.

`fints` constructs a financial time series object. A financial time series object is a MATLAB object that contains a series of dates and one or more series of data. Before you perform an operation on the data, you must set the frequency indicator (`freq`). You can optionally provide a description (`desc`) for the time series.

---

**Note** `fints` only supports hourly and minute time series. Seconds are not supported and will be disregarded when the `fints` object is created (that is, 01-jan-2001 12:00:01 will be considered as 01-jan-2001 12:00). If there are duplicate dates and times, the `fints` constructor sorts the dates and times and chooses the first instance of the duplicate dates and times. The other duplicate dates and times are removed from the object along with their corresponding data.

---

`tsobj = fints(dates,data)` generates a financial time series object containing dates from the `dates` column vector of dates and data from the matrix `data`. If the dates contain time-of-day information, the object contains an additional series of times. The `data` matrix must be column-oriented, that is, each column in the matrix is a data series. The names of the series default to `series1`, ..., `seriesn`, where  $n$  is the total number of columns in `data`. The `desc` and `freq` fields are set to their defaults.

`tsobj = fints(dates,data,datanames)` also allows you to rename the data series. The names are specified in the `datanames` cell array. The number of character vectors in `datanames` must correspond to the number of columns in `data`. The `desc` and `freq` fields are set to their defaults.

`tsobj = fints(__ freq,desc)` sets the frequency (`freq`) or description (`desc`) when you create the object.

## Examples

### Create a Financial Time Series Object Containing Days and Data

Define the data:

```
data = [1:6]'  
data = 6×1
```

```
1  
2  
3  
4  
5  
6
```

Define the dates:

```
dates = [today:today+5]'  
dates = 6×1  
  
738578  
738579  
738580  
738581  
738582  
738583
```

Create the financial times series object:

```
tsobjkt = fints(dates, data)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see ["mat"](#)

```
tsobjkt =  
  
desc: (none)  
freq: Unknown (0)  
  
{'dates: (6)'}    {'series1: (6)' }  
{'26-Feb-2022'}  {[           1]}  
{'27-Feb-2022'}  {[           2]}  
{'28-Feb-2022'}  {[           3]}  
{'01-Mar-2022'}  {[           4]}  
{'02-Mar-2022'}  {[           5]}  
{'03-Mar-2022'}  {[           6]}
```

### Create a Financial Time Series Object Containing Days, Time of Day, and Data

Define the data:

```
data = [1:6]'  
data = 6×1  
  
1  
2  
3  
4  
5  
6
```

Define the dates:

```
dates = [now:now+5]'  
dates = 6×1  
105 ×  
  
7.3858  
7.3858  
7.3858  
7.3858  
7.3858  
7.3858
```

Create the financial times series object:

```
tsobjkt = fints(dates, data)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see ["mat"](#)

```
tsobjkt =  
  
desc: (none)  
freq: Unknown (0)  
  
{'dates: (6)'}    {'times: (6)' }    {'series1: (6)' }  
{'26-Feb-2022'}  {'19:16' }        {[ 1]}  
{'27-Feb-2022'}  {'19:16' }        {[ 2]}  
{'28-Feb-2022'}  {'19:16' }        {[ 3]}  
{'01-Mar-2022'}  {'19:16' }        {[ 4]}  
{'02-Mar-2022'}  {'19:16' }        {[ 5]}  
{'03-Mar-2022'}  {'19:16' }        {[ 6]}
```

### Create a Financial Time Series Object From a Single Input for Dates and Times

Define the dates and times:

```
dates_and_times = (now:now+5)'  
dates_and_times = 6×1  
105 ×
```

```
7.3858
7.3858
7.3858
7.3858
7.3858
7.3858
```

Create the financial times series object:

```
f = fints(dates_and_times, randn(6,1))
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat

```
f =
```

```
desc: (none)
freq: Unknown (0)

{'dates: (6)'}    {'times: (6)'}    {'series1: (6)'}
{'26-Feb-2022'}  {'19:16'}        {[      0.5377]}
{'27-Feb-2022'}  {'19:16'}        {[      1.8339]}
{'28-Feb-2022'}  {'19:16'}        {[     -2.2588]}
{'01-Mar-2022'}  {'19:16'}        {[      0.8622]}
{'02-Mar-2022'}  {'19:16'}        {[      0.3188]}
{'03-Mar-2022'}  {'19:16'}        {[     -1.3077]}
```

This generates a financial time series object, `f`, and obtains the dates and data from the matrix `dates_and_times`. The dates and times in the input matrix must be oriented column-wise (i.e. the date series and each time series are columns in the input matrix). In addition, the dates entered must be in the serial date format (i.e. 01-Jan-2001 is 730852). You can also use the function `now` to enter in date information. The names of the series will default to '`series1`', ..., '`seriesN`' where `N` is the total number of columns in `dates_and_times` less 1 (that is the number of data columns). The default contents of the `desc` and `freq` fields are "" and | 'Unknown' | (0), respectively.

## Input Arguments

### **dates\_and\_data — Dates and data**

column-oriented matrix using serial date number and time format

Financial time series object, specified as a `fints` object.

Dates and data, specified as a column-oriented matrix containing one column of dates and a single column for each series of data. In this format, dates must be entered in serial date number and time format. If the input serial date numbers encode time-of-day information, the output `tsobj` object contains a column labeled '`dates`' containing the date information and another labeled '`times`' containing the time information.

You can use the MATLAB function `today` to enter date information or the MATLAB function `now` to enter date with time information.

Data Types: double

### **dates — Dates**

cell array of date character vectors

Dates, specified as a cell array of date character vectors. Valid date and time character vector formats are:

- 'ddmmmyy hh:mm' or 'ddmmmyyyy hh:mm'
- 'mm/dd/yy hh:mm' or 'mm/dd/yyyy hh:mm'
- 'dd-mmm-yy hh:mm' or 'dd-mmm-yyyy hh:mm'
- 'mmm.dd,yy hh:mm' or 'mmm.dd,yyyy hh:mm'

Dates and times can initially be separate column-oriented vectors, but they must be concatenated into a single column-oriented matrix before being passed to `fints`. You can use the MATLAB functions `today` and `now` to help with entering date and time information.

Data Types: `cell`

**data — Data**

column-oriented matrix

Data, specified as a column-oriented matrix containing a column for each series of data. The number of values in each data series must match the number of dates. If a mismatch occurs, MATLAB does not generate the financial time series object, and you receive an error message.

Data Types: `double`

**datanames — Data series names**

cell array of character vectors

Data series names, specified as a cell array of character vectors for data series names. This argument overrides the default data series names. The default data series names are `series1`, `series2`, and so on.

---

**Note** Not all character vectors are accepted as `datanames` parameters. Supported data series names cannot start with a number and must contain only these characters:

- Lowercase Latin alphabet, `a` to `z`
  - Uppercase Latin alphabet, `A` to `Z`
  - Underscore, `_`
- 

Data Types: `cell`

**freq — Frequency indicator**

'UNKNOWN' (default) | character vector

Frequency indicator, specified using one of the allowed values:

- 'UNKNOWN', 'Unknown', 'unknown', 'U', or 'u'
- 'DAILY', 'Daily', 'daily', 'D', or 'd'
- 'WEEKLY', 'Weekly', 'weekly', 'W', or 'w'
- 'MONTHLY', 'Monthly', 'monthly', 'M', or 'm'
- 'QUARTERLY', 'Quarterly', 'quarterly', 'Q', or 'q'

- 'SEMIANNUAL', 'Semiannual', 'semiannual', 'S', or 's'
- 'ANNUAL', 'Annual', 'annual', 'A', or 'a'

Data Types: char

**desc — Descriptive name for financial time series object**

'' (default) | character vector

descriptive name for financial time series object, specified as a character vector.

Data Types: char

## Output Arguments

**tsobj — Financial time series object**

fints object

Financial time series object, returned as a fints object.

## floatdiscmargin

Discount margin for floating-rate bond

### Syntax

```
Margin = floatdiscmargin(Price,SpreadSettle,Maturity,RateInfo,  
LatestFloatingRate)  
Margin = floatdiscmargin( ___,Name,Value)
```

### Description

`Margin = floatdiscmargin(Price,SpreadSettle,Maturity,RateInfo,  
LatestFloatingRate)` calculates the discount margin or zero discount margin for a floating-rate bond.

The input `RateInfo` determines whether the discount margin or the zero discount margin is calculated. Principal schedules are supported using `Principal`.

`Margin = floatdiscmargin( ___,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Compute the Zero Discount Margin Using a Yield Curve

Use `floatdiscmargin` to compute the discount margin and zero discount margin for a floating-rate note.

Define data for the floating-rate note.

```
Price = 99.99;  
Spread = 50;  
Settle = '20-Jan-2011';  
Maturity = '15-Jan-2012';  
LatestFloatingRate = 0.05;  
StubRate = 0.049;  
SpotRate = 0.05;  
Reset = 4;  
Basis = 2;
```

Compute the discount margin.

```
dMargin = floatdiscmargin(Price, Spread, Settle, Maturity, ...  
[StubRate, SpotRate], LatestFloatingRate,'Reset', Reset, 'Basis', Basis, ...  
'AdjustCashFlowsBasis', true)  
  
dMargin = 48.4810
```

Usually you want to set `AdjustCashFlowsBasis` to `true`, so cash flows are calculated with adjustments on accrual amounts.

Create an annualized zero-rate term structure to calculate the zero discount margin.

```

Rates = [0.0500;
         0.0505;
         0.0510;
         0.0520];
StartDates = ['20-Jan-2011';
              '15-Apr-2011';
              '15-Jul-2011';
              '15-Oct-2011'];
EndDates = ['15-Apr-2011';
             '15-Jul-2011';
             '15-Oct-2011';
             '15-Jan-2012'];
ValuationDate = '20-Jan-2011';
RateSpec = intenvset('Compounding', Reset, 'Rates', Rates, ...
'StartDates', StartDates, 'EndDates', EndDates, ...
'ValuationDate', ValuationDate, 'Basis', Basis);

```

Calculate the zero discount margin using the previous yield curve.

```

dMargin = floatdiscmargin(Price, Spread, Settle, Maturity, ...
RateSpec, LatestFloatingRate,'Reset', Reset, 'Basis', Basis, ...
'AdjustCashFlowsBasis', true)
dMargin = 46.0688

```

## Compute the Zero Discount Margin Using a Yield Curve With datetime Inputs

Use `floatdiscmargin` to compute the discount margin and zero discount margin for a floating-rate note using `datetime` inputs.

```

Price = 99.99;
Spread = 50;
Settle = '20-Jan-2011';
Maturity = '15-Jan-2012';
LatestFloatingRate = 0.05;
StubRate = 0.049;
SpotRate = 0.05;
Reset = 4;
Basis = 2;

Settle = datetime(Settle,'Locale','en_US');
Maturity = datetime(Maturity,'Locale','en_US');
dMargin = floatdiscmargin(Price, Spread, Settle, Maturity, ...
[StubRate, SpotRate], LatestFloatingRate,'Reset', Reset, 'Basis', Basis, ...
'AdjustCashFlowsBasis', true)

dMargin = 48.4810

```

## Input Arguments

**Price – Bond prices where discount margin is to be computed**  
matrix

Bond prices where discount margin is to be computed, specified as a `NINST`-by-1 matrix.

**Note** The spread is calculated against the clean price (the function internally does not add the accrued interest to the price specified by the `Price` input). If the spread is required against the dirty price, the price of a bond that includes the accrued interest, you must supply the dirty price for the `Price` input.

---

Data Types: double

**Spread — Number of basis points over the reference rate**  
numeric

Number of basis points over the reference rate, specified as a NINST-by-1 matrix.

Data Types: double

**Settle — Settlement date of the floating-rate bonds**  
serial date number | date character vector | datetime

Settlement date of the floating-rate bonds, specified as serial date number, date character vector, or datetime array. If supplied as a NINST-by-1 vector of dates, all settlement dates must be the same (only a single settlement date is supported)

Data Types: double | char | datetime

**Maturity — Maturity date of the floating-rate bond**  
serial date number | date character vector | datetime

Maturity date of the floating-rate bond, specified as serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

**RateInfo — Interest-rate information**  
numeric

interest-rate information, specified as NINST-by-2 vector where the:

- First column is the stub rate between the settlement date and the first coupon rate.
- Second column is the reference rate for the term of the floating coupons (for example, the 3-month LIBOR from settlement date for a bond with a `Reset` of 4).

**Note** If the `RateInfo` argument is an annualized zero-rate term structure created by `intenvset`, the zero discount margin is calculated.

---

Data Types: double

**LatestFloatingRate — Rate for next floating payment set at last reset date**  
numeric

Rate for the next floating payment set at the last reset date, specified as NINST-by-1 vector.

Data Types: double

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `Margin = floatdiscmargin(Price, Spread, Settle, Maturity, RateInfo, LatestFloatingRate, 'Reset', 2, 'Basis', 5)`

### Reset — Frequency of payments per year

1 (default) | numeric

Frequency of payments per year, specified as `NINST`-by-1 vector.

Data Types: double

### Basis — Day-count basis used for time factor calculations

0 (actual/actual) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Day-count basis used for time factor calculations, specified as a `NINST`-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

### Principal — Notional principal amounts

100 (default) | numeric

Notional principal amounts, specified as a `NINST`-by-1 vector or a `NINST`-by-1 cell array where each element is a `NUMDATES`-by-2 cell array where the first column is dates and the second column is the associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: double | cell

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as a NINST-by-1 vector. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**AdjustCashFlowsBasis — Adjust cash flows according to accrual amount**

0 (not in effect) (default) | nonnegative integer 0 or 1

Adjusts cash flows according to the accrual amount, specified as a NINST-by-1 vector of logicals.

**Note** Usually you want to set **AdjustCashFlowsBasis** to 1, so cash flows are calculated with adjustments on accrual amounts. The default is set to 0 to be consistent with **floatbyzero**.

---

Data Types: logical

**Holidays — Dates for holidays**`holidays.m` used (default)

Dates for holidays, specified as NHOLIDAYS-by-1 vector of MATLAB dates using serial date numbers, date character vectors, or datetime arrays. Holidays are used in computing business days.

Data Types: double | char | datetime

**BusinessDayConvention — Business day conventions**

'actual' (default) | character vector with values 'actual', 'follow', 'modifiedfollow', 'previous' or 'modifiedprevious'

Business day conventions, specified as a NINST-by-1 cell array of character vectors of business day conventions to be used in computing payment dates. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- 'actual' — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- 'follow' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- 'modifiedfollow' — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- 'previous' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- 'modifiedprevious' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

## Output Arguments

### Margin — Discount margin

numeric

Discount margin, returned as a `NINST`-by-1 vector of the discount margin if `RateInfo` is specified as a `NINST`-by-2 vector of stub and spot rates.

If `RateInfo` is specified as an annualized zero rate term structure created by `intenvset`, `Margin` is returned as a `NINST`-by-`NCURVES` matrix of the zero discount margin.

## floatmargin

Margin measures for floating-rate bond

### Syntax

```
[Margin,AdjPrice] = floatmargin(Price,SpreadSettle,Maturity)  
[Margin,AdjPrice] = floatmargin(___,Name,Value)
```

### Description

`[Margin,AdjPrice] = floatmargin(Price,SpreadSettle,Maturity)` calculates margin measures for a floating-rate bond.

Use `floatmargin` to calculate the following types of margin measures for a floating-rate bond:

- Spread for life
- Adjusted simple margin
- Adjusted total margin

To calculate the discount margin or zero discount margin, see `floatdiscmargin`.

`[Margin,AdjPrice] = floatmargin(___,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Compute Margin Measures for a Floating-Rate Bond

Use `floatmargin` to compute margin measures for `spreadforlife`, `adjustedsimple`, and `adjustedtotal` for a floating-rate note.

Define data for the floating-rate note.

```
Price = 99.99;  
Spread = 50;  
Settle = '20-Jan-2011';  
Maturity = '15-Jan-2012';  
LatestFloatingRate = 0.05;  
StubRate = 0.049;  
SpotRate = 0.05;  
Reset = 4;  
Basis = 2;
```

Calculate `spreadforlife`.

```
Margin = floatmargin(Price, Spread, Settle, Maturity, 'Reset', ...  
Reset, 'Basis', Basis)
```

```
Margin = 51.0051
```

Calculate `adjustedsimple` margin.

```
[Margin, AdjPrice] = floatmargin(Price, Spread, Settle, Maturity, ...
'SpreadType', 'adjustedsimple', 'RateInfo', [StubRate, SpotRate], ...
'LatestFloatingRate', LatestFloatingRate, 'Reset', Reset, 'Basis', Basis)
```

Margin = 53.2830

AdjPrice = 99.9673

Calculate `adjustedtotal` margin.

```
[Margin, AdjPrice] = floatmargin(Price, Spread, Settle, Maturity, ...
'SpreadType', 'adjustedtotal', 'RateInfo', [StubRate, SpotRate], ...
'LatestFloatingRate', LatestFloatingRate, 'Reset', Reset, 'Basis', Basis)
```

Margin = 53.4463

AdjPrice = 99.9673

## Compute Margin Measures for a Floating-Rate Bond Using `datetime` Inputs

Use `floatmargin` to calculate margin measures for `spreadforlife`, `adjustedsimple`, and `adjustedtotal` for a floating-rate note using `datetime` inputs.

```
Price = 99.99;
Spread = 50;
Settle = '20-Jan-2011';
Maturity = '15-Jan-2012';
LatestFloatingRate = 0.05;
StubRate = 0.049;
SpotRate = 0.05;
Reset = 4;
Basis = 2;

Settle = datetime(Settle,'Locale','en_US');
Maturity = datetime(Maturity,'Locale','en_US');
[Margin, AdjPrice] = floatmargin(Price, Spread, Settle, Maturity, ...
'SpreadType', 'adjustedsimple', 'RateInfo', [StubRate, SpotRate], ...
'LatestFloatingRate', LatestFloatingRate, 'Reset', Reset, 'Basis', Basis)

Margin = 53.2830
AdjPrice = 99.9673
```

## Input Arguments

**Price — Bond prices where spreads are to be computed**  
matrix

Bond prices where spreads are to be computed, specified as a NINST-by-1 matrix.

Data Types: double

**Spread — Number of basis points over the reference rate**  
numeric

Number of basis points over the reference rate, specified as a NINST-by-1 matrix.

Data Types: double

**Settle — Settlement date of the floating-rate bonds**  
serial date number | date character vector | datetime

Settlement date of the floating-rate bonds, specified as serial date number, date character vector, or datetime array. If supplied as a NINST-by-1 vector of dates, all settlement dates must be the same (only a single settlement date is supported)

Data Types: double | char | datetime

**Maturity — Maturity date of the floating-rate bond**  
serial date number | date character vector | datetime

Maturity date of the floating-rate bond, specified as serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

**Name-Value Pair Arguments**

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: [Margin,AdjPrice] = floatmargin(Price,Spread,Settle,Maturity,  
'SpreadType','adjustedtotal','RateInfo',  
[StubRate,SpotRate],'LatestFloatingRate',.0445,'Reset',2,'Basis',5)

**SpreadType — Type of spread to calculate**

spreadforlife (default) | adjustedsimple|adjustedtotal

Type of spread to calculates, specified by type, specified as spreadforlife,adjustedsimple, or adjustedtotal.

---

**Note** If the SpreadType is spreadforlife (default), then the name-value arguments LatestFloatingRate and RateInfo are not used. If the SpreadType is adjustedsimple or adjustedtotal, then the name-value arguments LatestFloatingRate and RateInfo must be specified.

---

Data Types: double

**LatestFloatingRate — Rate for next floating payment set at last reset date**  
numeric

Rate for the next floating payment set at the last reset date, specified as NINST-by-1 vector.

---

**Note** This rate must be specified for a SpreadType of adjustedsimple and adjustedtotal.

---

Data Types: double

#### **RateInfo — Interest-rate information**

numeric

interest-rate information, specified as NINST-by-2 vector where the:

- First column is the stub rate between the settlement date and the first coupon rate.
- Second column is the reference rate for the term of the floating coupons (for example, the 3-month LIBOR from settlement date for a bond with a **Reset** of 4).

---

**Note** The RateInfo must be specified for SpreadType of **adjustedsimple** and **adjustedtotal**.

---

Data Types: double

#### **Reset — Frequency of payments per year**

1 (default) | numeric

Frequency of payments per year, specified as NINST-by-1 vector.

Data Types: double

#### **Basis — Day-count basis used for time factor calculations**

0 (actual/actual) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Day-count basis used for time factor calculations, specified as a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

#### **Principal — Notional principal amounts**

100 (default) | numeric

Notional principal amounts, specified as NINST-by-1 vector.

Data Types: double

**EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as a NINST-by-1 vector. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

**Holidays — Dates for holidays**

`holidays.m` used (default)

Dates for holidays, specified as NHOLIDAYS-by-1 vector of MATLAB dates using serial date numbers, date character vectors, or datetime arrays. Holidays are used in computing business days.

Data Types: double | char | datetime

**BusinessDayConvention — Business day conventions**

'actual' (default) | character vector with values 'actual', 'follow', 'modifiedfollow', 'previous' or 'modifiedprevious'

Business day conventions, specified as a NINST-by-1 cell array of character vectors of business day conventions to be used in computing payment dates. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- 'actual' — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- 'follow' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- 'modifiedfollow' — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- 'previous' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- 'modifiedprevious' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

## Output Arguments

**Margin — Spreads for floating-rate bond**

numeric

Spreads for the floating-rate bond, returned as a NINST-by-1 vector.

---

**AdjPrice — Adjusted price used to calculate spreads for SpreadType of adjustedsimple and adjustedtotal**  
numeric

Adjusted price used to calculate spreads for SpreadType of adjustedsimple and adjustedtotal, returned as a NINST-by-1 vector.

## fpctkd

Fast stochastics

---

**Note** `fpctkd` is not recommended. Use `stochosc` instead.

---

### Syntax

```
pkds = fpctkd(highp,lowp,closep)
pkds = fpctkd([highp lowp closep])
pkds = fpctkd(___,kperiods,dperiods,dmamethod)
pkts = fpctkd(tsobj,kperiods,dperiods,dmamethod)
pkts = fpctkd(___,Name,Value)
```

### Description

`pkds = fpctkd(highp,lowp,closep)` calculates the fast stochastics F%K and F%D from the stock price data `highp` (high prices), `lowp` (low prices), and `closep` (closing prices).

`pkds = fpctkd([highp lowp closep])` accepts a three-column matrix of high (`highp`), low (`lowp`), and closing prices (`closep`), in that order.

`pkds = fpctkd(___,kperiods,dperiods,dmamethod)` calculates the fast stochastics F%K and F%D from the stock price data for high (`highp`), low (`lowp`), and closing prices (`closep`). `kperiods` sets the percent K period. `dperiods` sets the percent D period. `dmamethod` specifies the percent D moving average method.

`pkts = fpctkd(tsobj,kperiods,dperiods,dmamethod)` calculates the fast stochastics F%K and F%D from the stock price data in the financial time series object `tsobj`. `tsobj` must minimally contain the series `High` (high prices), `Low` (low prices), and `Close` (closing prices).

`pkts = fpctkd(___,Name,Value)` accepts name-value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s).

### Examples

#### Compute the Stochastic Oscillator

This example shows how to compute the stochastic oscillator for Disney stock and plot the results.

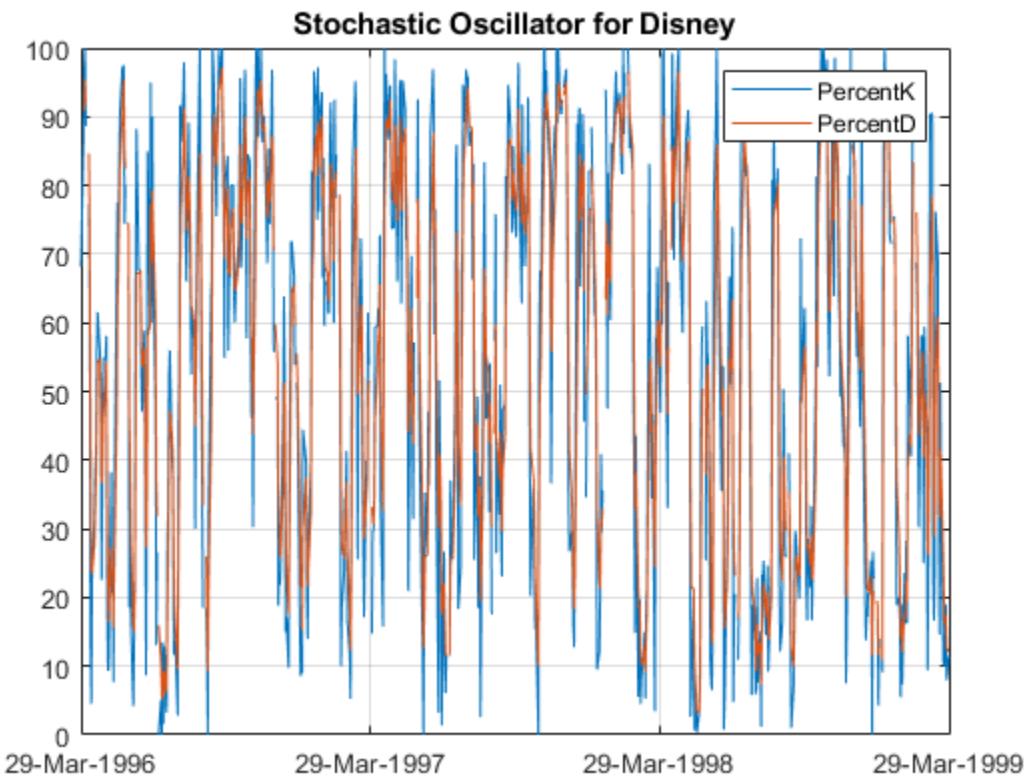

```
load disney.mat
dis_FastStoc = fpctkd(dis);
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see [mat](#)

```
plot(dis_FastStoc)
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see [mat](#)

```
title('Stochastic Oscillator for Disney')
```

## Input Arguments

**tsobj — Financial time series object**  
fints object

Financial time series object, specified as a `fints` object.

Data Types: `object`

**highp — High prices**  
vector

High prices, specified as a vector.

Data Types: `double`

**lowp — Low prices**  
vector

Low prices, specified as a vector.

Data Types: `double`

**closep — Closing prices**  
vector

Closing prices, specified as a vector.

Data Types: double

**kperiods — Percent K period**

10 (default) | numeric

Percent K period, specified as a numeric.

Data Types: double

**dperiods — Percent D period**

3 (default) | vector

Percent D period, specified as a numeric.

Data Types: double

**dmamethod — Percent D moving average method**

'e' (exponential) (default) | character vector with values of 'e' (exponential) or 't' (triangular)

Percent D moving average method, specified as a character vector. See `tsmovavg` for explanations of these methods.

Data Types: char

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `pkds = fpctkd(tsobj, kperiods, dperiods, dmamethod, 'HighName', 'SeriesHigh')`

**HighName — High name**

'' (default) | character vector

High name, specified as the comma-separated pair consisting of 'HighName' and a character vector with a value for the high prices series name.

Data Types: char

**LowName — High name**

'' (default) | character vector

Low name, specified as the comma-separated pair consisting of 'LowName' and a character vector with a value for the low prices series name.

Data Types: char

**CloseName — High name**

'' (default) | character vector

Close name, specified as the comma-separated pair consisting of 'CloseName' and a character vector with a value for the closing prices series name.

Data Types: char

## Output Arguments

### **pkds — Fast stochastics**

vector

Fast stochastics, returned a vector.

### **pkts — Fast stochastics when using tsobj input**

fints object

Fast stochastics when using `tsobj` input, returned a `fints` object. `pkts` is a financial time series object with similar dates to `tsobj` and two data series named `PercentK` and `PercentD`.

## frac2cur

Fractional currency value to decimal value

### Syntax

```
Decimal = frac2cur(Fraction,Denominator)
```

### Description

`Decimal = frac2cur(Fraction,Denominator)` converts a fractional currency value to a decimal value. `Fraction` is the fractional currency value input as a character vector, and `Denominator` is the denominator of the fraction.

### Examples

#### Convert a Fractional Currency Value to a Decimal Value

This example shows how to convert a fractional currency value to a decimal value.

```
Decimal = frac2cur('12.1', 8)
```

```
Decimal = 12.1250
```

### Input Arguments

#### Fraction — Fractional currency values

character vector | cell array of character vectors

Fractional currency values, specified as a character vector or cell array of character vectors.

Data Types: char | cell

#### Denominator — Denominator of the fractions

numeric

Denominator of the fractions, specified as a scalar or vector using numeric values for the denominator.

Data Types: double

### Output Arguments

#### Decimal — Decimal currency value

numeric decimal

Decimal currency value, returned as a scalar or vector with numeric decimal values.

Data Types: double

## freqstr

Convert numeric frequency indicator to character vector representation

**Note** `freqstr` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
sfreq = freqstr(nfreq)
```

### Arguments

|       |   |
|-------|---|
| nfreq | 0 |
|       | 1 |
|       | 2 |
|       | 3 |
|       | 4 |
|       | 5 |
|       | 6 |

### Description

`sfreq = freqstr(nfreq)` converts a numeric frequency indicator into a character vector representation.

| Numeric Frequency Indicator | Character Vector Representation |
|-----------------------------|---------------------------------|
| 0                           | Unknown                         |
| 1                           | Daily                           |
| 2                           | Weekly                          |
| 3                           | Monthly                         |
| 4                           | Quarterly                       |
| 5                           | Semiannual                      |
| 6                           | Annual                          |

## frontier

Rolling efficient frontier

### Syntax

```
[PortWts,AllMean,AllCovariance] = frontier(Universe,Window,Offset,NumPorts)
[PortWts,AllMean,AllCovariance] = frontier(____,ActiveMap,Conset,NumNonNan)
```

### Description

[PortWts,AllMean,AllCovariance] = frontier(Universe,Window,Offset,NumPorts) generates a surface of efficient frontiers showing how asset allocation influences risk and return over time.

[PortWts,AllMean,AllCovariance] = frontier(\_\_\_\_,ActiveMap,Conset,NumNonNan) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Input Arguments

**Universe — Total return data for a group of securities**

array

Total return data for a group of securities, specified as a number of observations (NUMOBS) by number of assets plus one (NASSETS + 1) time series array. Each row represents an observation. Column 1 contains MATLAB serial date numbers. The remaining columns contain the total return data for each security.

Data Types: double

**Window — Number of data periods used to calculate each frontier**

positive integer

Number of data periods used to calculate each frontier, specified as a positive integer value.

Data Types: double

**Offset — Increment in number of periods between each frontier**

numeric

Increment in number of periods between each frontier, specified as a numeric value.

Data Types: double

**NumPorts — Number of portfolios to calculate on each frontier**

positive integer

Number of portfolios to calculate on each frontier, specified as a positive integer.

Data Types: double

**ActiveMap — Indicates if an asset is part of the Universe on the corresponding date**  
NUMOBS-by-NASSETS matrix of 1's (all assets active on all dates) (default) | matrix

(Optional) Indicates if an asset is part of the Universe on the corresponding date, specified as a number of observations (NUMOBS) by number of assets (NASSETS) matrix with Boolean elements corresponding to the Universe.

Data Types: double

**Conset — Constraint matrix for a portfolio of asset investments**  
matrix

Constraint matrix for a portfolio of asset investments, specified using portcons with the 'Default' constraint type. This single constraint matrix is applied to each frontier..

Data Types: double

**NumNonNan — Minimum number of non-NaN points for each active asset in each window of data**

Window - NASSETS (default) | numeric value

Minimum number of non-NaN points for each active asset in each window of data needed to perform the optimization, specified as a numeric value.

Data Types: double

## Output Arguments

**PortWts — Weights allocated to each asset**  
matrix

Weights allocated to each asset., returned as a number of curves (NCURVES)-by-1 cell array, where each element is a NPORTS-by-NASSETS matrix of weights.

**AllMean — Expected asset returns used to generate each curve on the surface**  
vector

Expected asset returns used to generate each curve on the surface, returned as an NCURVES-by-1 cell array, where each element is a 1-by-NASSETS vector of the expected asset returns.

**AllCovariance — Covariance matrix used to generate each curve on the surface**  
vector

Covariance matrix used to generate each curve on the surface, returned as an NCURVES-by-1 cell array, where each element is a NASSETS-by-NASSETS vector.

# fts2ascii

Write elements of time series data into ASCII file

---

**Note** `fts2ascii` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
stat = fts2ascii(filename, tsobj, exttext)
stat = fts2ascii(filename, dates, data, colheads, desc)
```

## Description

`stat = fts2ascii(filename, tsobj, exttext)` writes the financial time series object `tsobj` into an ASCII file `filename`. The data in the file is tab delimited.

`stat = fts2ascii(filename, dates, data, colheads, desc)` writes into an ASCII file `filename` the dates, times, and data contained in the column vector dates and the column-oriented matrix data. The first column in `filename` contains the dates, followed by times (if specified). Subsequent columns contain the data. The data in the file is tab delimited.

## Examples

### Use `fts2ascii` to Write a Time Series to an ASCII File

Create a data file with time information.

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
serial_dates_times = [datenum(dates), datenum(times)];
data = round(10*rand(6,2));
```

Use `fts2ascii` to write the time series to an ascii file.

```
stat = fts2ascii('myfts_file2.txt', serial_dates_times, data, ...
{'dates'; 'times'; 'Data1'; 'Data2'}, 'My FTS with Time')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat"

```
stat = 1
```

Read the data file back and create a financial time series object using `ascii2fts`.

```
MyFts = ascii2fts('myfts_file2.txt', 't', 1, 2, 1)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat"

```
MyFts =
```

```
desc: My FTS with Time
freq: Unknown (0)

{'dates: (6)'}   {'times: (6)'}   {'Data1: (6)'}   {'Data2: (6)'}
{'01-Jan-2001'}  {'11:00'}       {[8]}           {[3]}
{''}             {'12:00'}       {[9]}           {[5]}
{'02-Jan-2001'}  {'11:00'}       {[1]}           {[10]}
{''}             {'12:00'}       {[9]}           {[10]}
{'03-Jan-2001'}  {'11:00'}       {[6]}           {[2]}
{''}             {'12:00'}       {[1]}           {[10]}}
```

## Input Arguments

**filename — Name of ascii file**

character vector

Name of ascii file, specified as a character vector.

Data Types: char

**tsobj — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

**exttext — Extra text written after the description line**

character vector

(Optional) Extra text written after the description line, specified as a character vector.

Data Types: char

**dates — Dates**

column vector

Dates, specified as a column vector containing dates. Dates must be in serial date number format and can specify time of day.

Data Types: double

**data — Data**

column-oriented matrix

Data, specified as column-oriented matrix. Each column is a series.

Data Types: double

**colheads — Column headers**

cell array of character vectors for column headers (names)

(Optional) Column headers, specified as a cell array of character vectors for column headers (names); the first cell must always be the one for the dates column. `colheads` is written to the file just before the data.

Data Types: cell

**desc — Description text**

character vector

(Optional) Description text (which is the first line in the file), specified as a character vector.

Data Types: char

## Output Arguments

**stat — Status of file creation**

logical

Status of file creation, returned as a logical where successful is 1 or not successful is 0.

ascii2fts

### Topics

“Working with Financial Time Series Objects” on page 13-2

“Creating a Financial Time Series Object” on page 14-9

“What Is the Financial Time Series App?” on page 14-2

### Introduced before R2006a

## fts2timetable

Convert financial time series objects (`fints`) to timetable object

### Syntax

```
TT = fts2timetable(FTS)
```

### Description

`TT = fts2timetable(FTS)` converts a M-by-N `fints` object to a M-by-N MATLAB `timetable` object (TT). The date and time information in the `fints` object becomes the TT time vector, while the remaining variables in the `fints` object become variables in TT. The `fints` description property (DESC) is mapped to TT.Properties.Description. The `fints` frequency indicator property (FREQ) is unused and removed from the output TT. For more information, see “Convert Financial Time Series Objects `fints` to Timetables” on page 12-2.

### Examples

#### Convert `fints` Object to a `timetable` Object and Plot the Financial Data

Load the financial data.

```
load SimulatedStockValues
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat

Convert a `fints` object to a `timetable` object.

```
TMW = fts2timetable(TMW_fts);  
TMW.Properties
```

```
ans =  
TimetableProperties with properties:
```

```
    Description: 'Simulated stock OHLCV data.'  
    UserData: []  
    DimensionNames: {'Time'  'Variables'}  
    VariableNames: {'Open'  'High'  'Low'  'Close'  'Volume'}  
    VariableDescriptions: {}  
    VariableUnits: {}

## Input Arguments

**FTS — Financial time series object**  
object

Financial time series object, specified by using a M-by-N `fints` object.

Data Types: object

## Output Arguments

### TT — Timetable

object

Timetable, returned as a M-by-N object.

## See Also

[timetable](#)

## Topics

["Convert Financial Time Series Objects fints to Timetables" on page 12-2](#)

## Introduced in R2018a

# fts2mat

Convert to matrix

---

**Note** `fts2mat` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
tsmat = fts2mat(tsobj)
tsmat = fts2mat(tsobj,datesflag)
tsmat = fts2mat(tsobj,seriesnames)
tsmat = fts2mat(tsobj,datesflag,seriesnames)
```

## Description

`tsmat = fts2mat(tsobj)` takes the data series in the financial time series object `tsobj` and puts them into the matrix `tsmat` as columns. The order of the columns is the same as the order of the data series in the object `tsobj`.

`tsmat = fts2mat(tsobj,datesflag)` specifies whether you want the dates vector included. The dates vector is the first column. The dates are represented as serial date numbers. Dates can include time-of-day information.

`tsmat = fts2mat(tsobj,seriesnames)` extracts the data series named in `seriesnames` and puts its values into `tsmat`. The `seriesnames` argument can be a cell array of character vectors.

`tsmat = fts2mat(tsobj,datesflag,seriesnames)` puts into `tsmat` the specific data series named in `seriesnames`. The `datesflag` argument must be specified. If `datesflag` is set to 1, the dates vector is included. If you specify an empty matrix ([ ]) for `datesflag`, the default behavior is adopted.

## Examples

### Convert `fints` object to Matrix

- 1 Create a `fints` object.

```
dates_and_times = (now:now+5)'
dates_and_times =
1.0e+05 *
7.3840
7.3840
7.3840
7.3841
7.3841
7.3841
```

```
f = fints(dates_and_times, randn(6,1))

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert F
> In fints (line 169)

f =

desc: (none)
freq: Unknown (0)

{'dates: (6)'}    {'times: (6)'}    {'series1: (6)'}
{'03-Sep-2021'}    {'13:02' }    {[ -0.7648]}
{'04-Sep-2021'}    {'13:02' }    {[ -1.4023]}
{'05-Sep-2021'}    {'13:02' }    {[ -1.4224]}
{'06-Sep-2021'}    {'13:02' }    {[  0.4882]}
{'07-Sep-2021'}    {'13:02' }    {[ -0.1774]}
{'08-Sep-2021'}    {'13:02' }    {[ -0.1961]}
```

**2** Convert the `fints` object to a matrix using `fts2mat`.

```
tsmat = fts2mat(f,1)
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert F
> In fints/fts2mat (line 33)
```

```
tsmat =
```

```
1.0e+05 *

7.3840  -0.0000
7.3840  -0.0000
7.3840  -0.0000
7.3841  0.0000
7.3841  -0.0000
7.3841  -0.0000
```

## Input Arguments

**tsobj — Financial time series object**  
`fints` object

Financial time series object, specified as a `fints` object.

Data Types: `object`

**datesflag — Specifies inclusion of dates vector**  
0 (default) | `logical`

Specifies inclusion of dates vector, specified as a `logical`:

- 0 — Excludes dates.
- 1 — Includes dates vector

Data Types: `logical`

**seriesnames — Data series included in matrix**  
character vector | cell array of character vectors

Data series included in matrix, specified as a character vector or cell array of character vectors.

Data Types: char | cell

## Output Arguments

### **tsmat — Matrix**

matrix

Matrix, returned as a matrix as columns. The order of the columns is identical to the order of the data series in the input object **tsobj**.

## Introduced before R2006a

## ftsbound

Start and end dates

**Note** `ftsbound` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
datesbound = ftsbound(tsobj)
datesbound = ftsbound(tsobj,dateform)
```

### Description

`datesbound = ftsbound(tsobj)` returns the start and end dates contained in `tsobj` as serial dates in the column matrix `datesbound`. The first row in `datesbound` corresponds to the start date, and the second corresponds to the end date.

`ftsbound` returns the start and end dates of a financial time series object. If the object contains time-of-day data, `ftsbound` also returns the starting time on the first date and the ending time on the last date.

`datesbound = ftsbound(tsobj,dateform)` returns the starting and ending dates contained in the object, `tsobj`, as date character vectors in the column matrix, `datesbound`. The first row in `datesbound` corresponds to the start date, and the second corresponds to the end date. The `dateform` argument controls the format of the output dates.

### Examples

#### Obtain Start and End Dates for the Financial Time Series Object `tsobj`

- 1 Create a `fints` object.

```
dates_and_times = (now:now+5)'
dates_and_times =
    1.0e+05 *
    7.3840
    7.3840
    7.3840
    7.3841
    7.3841
    7.3841
```

```
tsobj = fints(dates_and_times, randn(6,1))
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see Convert F  
> In `fints` (line 169)

```

tsobj =

desc: (none)
freq: Unknown (0)

{'dates: (6)'}    {'times: (6)'}    {'series1: (6)'}
{'03-Sep-2021'}  {'17:10' }      {[ 1.4193]}
{'04-Sep-2021'}  {'17:10' }      {[ 0.2916]}
{'05-Sep-2021'}  {'17:10' }      {[ 0.1978]}
{'06-Sep-2021'}  {'17:10' }      {[ 1.5877]}
{'07-Sep-2021'}  {'17:10' }      {[ -0.8045]}
{'08-Sep-2021'}  {'17:10' }      {[ 0.6966]}

```

- 2** Obtain the start and end dates using `ftsbound`.

```
datesbound = ftsbound(tsobj)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert FINTS Objects to TIMETABLE.

```
datesbound =
```

```
1.0e+05 *
7.3840
7.3841
```

## Input Arguments

**tsobj — Financial time series object**  
 fints object

Financial time series object, specified as a `fints` object.

Data Types: `object`

**dateform — Format of a date character vector**  
 integer

Format of a date character vector, specified as an integer representing the format of a date character vector. See `datestr` for a description of these formats.

Data Types: `double`

## Output Arguments

**datesbound — Start and end dates contained in tsobj**  
 column matrix

Start and end dates contained in `tsobj`, returned as a column matrix. The first row in `datesbound` corresponds to the start date, and the second corresponds to the end date. The `dateform` argument controls the format of the output dates.

## See Also

`datestr`

**Introduced before R2006a**

# ftsgui

Financial time series GUI

**Note** `ftsgui` will be removed in a future release and will no longer accept a `fints` object.

Use `fts2timetable` to convert a `fints` object to a `timetable` object. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

## Syntax

`ftsgui`

## Description

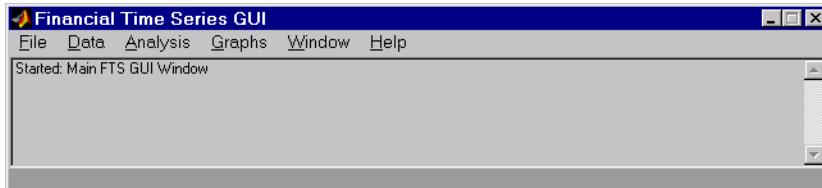

`ftsgui` displays the financial time series graphical user interface (GUI) main window.

The use of the financial time series GUI is described in “Using the Financial Time Series GUI” on page 15-6.

**Note** `Help` menu item is not available for `ftsgui` in MATLAB Online.

## Examples

`ftsgui`

## See Also

`ftstool`

## Topics

**Introduced before R2006a**

## ftsinfo

Financial time series object information

**Note** `ftsinfo` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
ftsinfo(tsobj)
infofts = ftsinfo(tsobj)
```

### Description

`ftsinfo(tsobj)` displays the information of the financial time series object (`tsobj`).

`infofts = ftsinfo(tsobj)` stores information about the financial time series object `tsobj` in the structure `infofts`.

### Examples

#### Financial Time Series Object (`fints`) information

- 1 Convert the supplied file `disney.dat` into a financial time series object named `dis`:

```
dis = ascii2fts('disney.dat', 1, 3);
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In ascii2fts (line 64)
```

Use `ftsinfo` to obtain information about `dis`:

```
ftsinfo(dis)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/ftsinfo (line 64)
```

```
FINTS version: 2.0 or higher
Description: Walt Disney Company (DIS)
Frequency: Unknown
Start date: 29-Mar-1996
End date: 29-Mar-1999
Series names: OPEN
               HIGH
               LOW
               CLOSE
               VOLUME
# of data: 782
# of series: 5
```

- 2 Then, executing

```

infodis = ftsinfo(dis)

creates the structure infodis containing the values

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/ftsinfo (line 64)

infodis =

    struct with fields:

        ver: '2.0 or higher'
        desc: 'Walt Disney Company (DIS)'
        freq: 0
        startdate: '29-Mar-1996'
        enddate: '29-Mar-1999'
        seriesnames: {5x1 cell}
        ndata: 782
        nseries: 5

```

## Input Arguments

### **tsobj — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: `object`

## Output Arguments

### **infofts — Financial time series information**

structure

Financial time series information, returned as a structure with the following fields:

| Field                    | Contents                                                                                                                                                                |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>version</code>     | Financial time series object version.                                                                                                                                   |
| <code>desc</code>        | Description of the time series object ( <code>tsobj.desc</code> ).                                                                                                      |
| <code>freq</code>        | Numeric representation of the time series data frequency ( <code>tsobj.freq</code> ). See <code>freqstr</code> for list of numeric frequencies and what they represent. |
| <code>startdate</code>   | Earliest date in the time series.                                                                                                                                       |
| <code>enddate</code>     | Latest date in the time series.                                                                                                                                         |
| <code>seriesnames</code> | Cell array containing the time series data column names.                                                                                                                |
| <code>ndata</code>       | Number of data points in the time series.                                                                                                                               |
| <code>nseries</code>     | Number of columns of time series data.                                                                                                                                  |

# ftstool

Financial Time Series app

---

**Note** `ftstool` will be removed in a future release and will no longer accept a `fints` object.

Use `fts2timetable` to convert a `fints` object to a `timetable` object. For more information, see “[Convert Financial Time Series Objects fints to Timetables](#)”.

---

## Syntax

`ftstool`

## Description

`ftstool` creates and manages Financial Time Series objects. `ftstool` allows the creation and management of Financial Time Series objects via the Financial Time Series app. `ftstool` can interface with `ftsgui`, meaning Line Plots generated with `ftstool` can be analyzed with `ftsgui`. However, `ftsgui` must be running prior to the generation of any Line Plots.

The use of the Financial Time Series app is described in “[Getting Started with the Financial Time Series App](#)” on page 14-4.

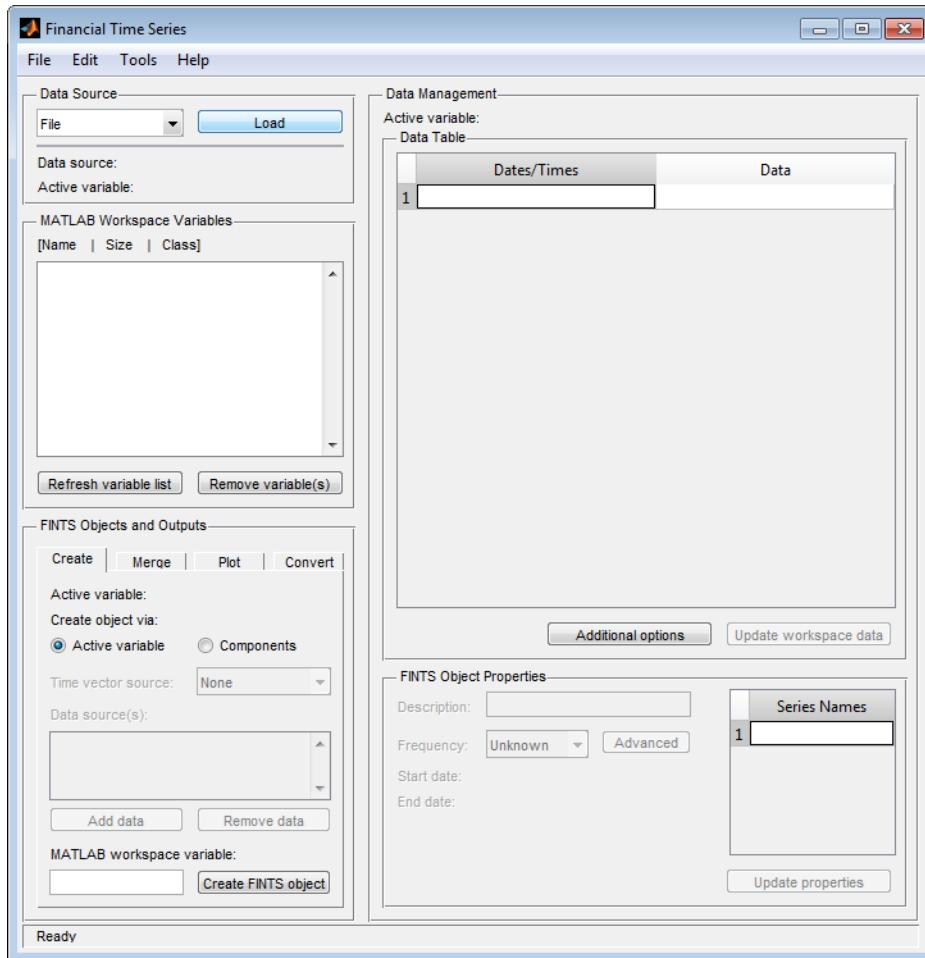

---

**Note** Help menu item is not available for `ftstool` in MATLAB Online.

---

## Examples

`ftstool`

Alternatively, on the MATLAB desktop toolbar, click the **Apps** tab and in the apps gallery, under **Computational Finance**, click **Financial Time Series**. The Financial Time Series app opens. For an overview of the Financial Time Series app, see “What Is the Financial Time Series App?” on page 14-2.

# ftsuniq

Determine uniqueness

**Note** `ftsuniq` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

## Syntax

```
uniq = ftsuniq(dates_and_times)  
[uniq,dup] = ftsuniq(dates_and_times)
```

## Arguments

|                              |                                                                                                             |
|------------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>dates_and_times</code> | A single column vector of serial date numbers. The serial date numbers can include time-of-day information. |
|------------------------------|-------------------------------------------------------------------------------------------------------------|

## Description

`uniq = ftsuniq(dates_and_times)` returns 1 if the dates and times within the financial time series object are unique and 0 if duplicates exist.

`[uniq,dup] = ftsuniq(dates_and_times)` additionally returns a structure `dup`. In the structure

- `dup.DT` contains the character vectors of the duplicate dates and times and their locations in the object.
- `dup.intIdx` contains the integer indices of duplicate dates and times in the object.

## fvdisc

Future value of discounted security

### Syntax

```
FutureVal = fvdisc(Settle,Maturity,Price,Discount)
FutureVal = fvdisc(___,Basis)
```

### Description

`FutureVal = fvdisc(Settle,Maturity,Price,Discount)` finds the amount received at maturity for a fully vested security.

`FutureVal = fvdisc(___,Basis)` specifies options using an optional argument in addition to the input arguments in the previous syntax.

### Examples

#### Find the Amount Received at Maturity for a Fully-Vested Security

This example shows how to find the amount received at maturity for a fully-vested security, using the following data.

```
Settle = '02/15/2001';
Maturity = '05/15/2001';
Price = 100;
Discount = 0.0575;
Basis = 2;

FutureVal = fvdisc(Settle, Maturity, Price, Discount, Basis)

FutureVal = 101.4420
```

#### Find the Amount Received at Maturity for a Fully-Vested Security Using datetime Inputs

This example shows how to use `datetime` inputs to find the amount received at maturity for a fully-vested security, using the following data.

```
Settle = datetime('02/15/2001','Locale','en_US');
Maturity = datetime('05/15/2001','Locale','en_US');
Price = 100;
Discount = 0.0575;
Basis = 2;

FutureVal = fvdisc(Settle, Maturity, Price, Discount, Basis)

FutureVal = 101.4420
```

## Input Arguments

### **Settle — Settlement date**

serial date number | date character vector | datetime

Settlement date, specified as a scalar serial date number, date character vector, or datetime.

Data Types: double | char | datetime

### **Maturity — Maturity date**

serial date number | date character vector | datetime

Maturity date, specified as a scalar serial date number, date character vector, or datetime.

Data Types: double | char | datetime

### **Price — Price (present value) of security**

scalar numeric

Price (present value) of the security, specified as a scalar numeric.

Data Types: double

### **Discount — Bank discount rate of security**

scalar decimal

Bank discount rate of security, specified as a scalar decimal.

Data Types: double

### **Basis — Day-count basis of instrument**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis of the instrument, specified as a scalar integer using one of the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

## Output Arguments

**FutureVal — Amount received at maturity for fully vested security**  
scalar numeric

Amount received at maturity for a fully vested security, returned as a scalar numeric.

Data Types: double

# fvfix

Future value with fixed periodic payments

## Syntax

```
FutureVal = fvfix(Rate,NumPeriods,Payment)
FutureVal = fvfix(____,PresentVal,Due)
```

## Description

`FutureVal = fvfix(Rate,NumPeriods,Payment)` returns the future value of a series of equal payments.

`FutureVal = fvfix(____,PresentVal,Due)` specifies options using one or more optional argument in addition to the input arguments in the previous syntax.

## Examples

### Return the Future Value of a Series of Equal Payments

This example shows how to compute the future value of a series of equal payments using a savings account that has a starting balance of \$1500. \$200 is added at the end of each month for 10 years and the account pays 9% interest compounded monthly.

```
FutureVal = fvfix(0.09/12, 12*10, 200, 1500, 0)
```

```
FutureVal = 4.2380e+04
```

## Input Arguments

### Rate — Interest-rate per period

scalar numeric decimal

Interest-rate per period, specified as a scalar numeric decimal.

Data Types: double

### NumPeriods — Number of payment periods

scalar numeric

Number of payment periods, specified as a scalar numeric.

Data Types: double

### Payment — Payment per period

scalar numeric

Payment per period, specified as a scalar numeric.

Data Types: double

**PresentVal — Present value**

0 (default) | scalar numeric

(Optional) Present value, specified as a scalar numeric.

Data Types: double

**Due — When payments are due**

0 (end of period) (default) | scalar integer with value of 0 or 1

(Optional) When payments are due, specified as a scalar integer with value of 0 (end of period) or 1 (beginning of period).

Data Types: double

## Output Arguments

**FutureVal — Future value of series of equal payments**

scalar numeric

Future value of a series of equal payments, returned as a scalar numeric.

## Introduced before R2006a

# fvvar

Future value of varying cash flow

## Syntax

```
FutureVal = fvvar(CashFlow,Rate)
FutureVal = fvvar(_____,CFDates)
```

## Description

`FutureVal = fvvar(CashFlow,Rate)` returns the future value of a varying cash flow.

`FutureVal = fvvar(_____,CFDates)` specifies options using an optional argument in addition to the input arguments in the previous syntax.

## Examples

### Calculate Future Value of Varying Cash Flows

This cash flow represents the yearly income from an initial investment of \$10,000. The annual interest rate is 2%.

- Year 1 — \$2000
- Year 2 — \$1500
- Year 3 — \$3000
- Year 4 — \$3800
- Year 5 — \$5000

For the future value of this regular (periodic) cash flow:

```
FutureVal = fvvar([-10000 2000 1500 3000 3800 5000], 0.02)
```

```
FutureVal = 4.7131e+03
```

An investment of \$10,000 returns this irregular cash flow. The original investment and its date are included. The periodic interest rate is 3%.

- -\$1000 — January 12, 2000
- \$2500 — February 14, 2001
- \$2000 — March 3, 2001
- \$3000 — June 14, 2001
- \$4000 — December 1, 2001

To calculate the future value of this irregular (nonperiodic) cash flow:

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
```

```
CFDates = ['01/12/2000'  
          '02/14/2001'  
          '03/03/2001'  
          '06/14/2001'  
          '12/01/2001'];  
  
FutureVal = fvvar(CashFlow, 0.03, CFDates)  
  
FutureVal = 1.0731e+03
```

## Input Arguments

### CashFlow — Varying cash flows

vector

Varying cash flows, specified as a vector.

---

**Note** You must include the initial investment as the initial cash flow value (a negative number).

---

Data Types: double

### Rate — Periodic Interest rate

scalar numeric decimal

Periodic interest rate, specified as a scalar numeric decimal.

Data Types: double

### CFDates — Dates on which the cash flows occur

assumes CashFlow contains regular (periodic) cash flows (default) | serial date number | date character vector | datetime

(Optional) Dates on which the cash flows occur, specified as a cell array of date character vectors, a vector of serial date numbers, or a datetime array.

---

**Note** Use CFDates for irregular (nonperiodic) cash flows.

---

Data Types: double | char | datetime

## Output Arguments

### FutureVal — Future value of a varying cash flow

scalar numeric

Future value of a varying cash flow, returned as a scalar numeric.

## fwd2zero

Zero curve given forward curve

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: `InputCompounding`, `InputBasis`, `OutputCompounding`, and `OutputBasis`.

---

### Syntax

```
[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, Settle)
[ZeroRates, CurveDates] = fwd2zero(____, Name, Value)
```

### Description

`[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, Settle)` returns a zero curve given an implied forward rate curve and its maturity dates. If both inputs for `CurveDates` and `Settle` are serial date numbers or date character vectors, `CurveDates` is returned as serial date numbers. However, if either of the inputs for `CurveDates` and `Settle` are a datetime array, `CurveDates` is returned as a datetime array.

`[ZeroRates, CurveDates] = fwd2zero(____, Name, Value)` adds optional name-value pair arguments

### Examples

#### Compute the Zero Curve Given the Forward Curve

This example shows how to compute the zero curve, given an implied forward rate curve over a set of maturity dates, a settlement date, and a compounding rate.

```
ForwardRates = [0.0469
                0.0519
                0.0549
                0.0535
                0.0558
                0.0508
                0.0560
                0.0545
                0.0615
                0.0486];

CurveDates = [datenum('06-Nov-2000')
              datenum('11-Dec-2000')
              datenum('15-Jan-2001')
              datenum('05-Feb-2001')
              datenum('04-Mar-2001')
              datenum('02-Apr-2001')]
```

```

datenum('30-Apr-2001')
datenum('25-Jun-2001')
datenum('04-Sep-2001')
datenum('12-Nov-2001']);

Settle = datenum('03-Nov-2000');

InputCompounding = 1;
InputBasis = 2;
OutputCompounding = 1;
OutputBasis = 2;

Execute the function fwd2zero to return the zero-rate curve ZeroRates at the maturity dates
CurveDates.

[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, ...
Settle, 'InputCompounding',1,'InputBasis',2,'OutputCompounding',1,'OutputBasis',2)

ZeroRates = 10×1

## Input Arguments

### **ForwardRates — Annualized implied forward rates**

decimal fraction

Annualized implied forward rates, specified as a (NUMBONDS)-by-1 vector using decimal fractions. In aggregate, the rates in **ForwardRates** constitute an implied forward curve for the investment horizon represented by **CurveDates**. The first element pertains to forward rates from the settlement date to the first curve date.

Data Types: double

### **CurveDates — Maturity dates**

serial date number | date character vector | datetime

Maturity dates, specified as a NUMBONDS-by-1 vector using serial date numbers, date character vectors, or datetime arrays, that correspond to the **ForwardRates**.

Data Types: double | datetime | char

### **Settle — Common settlement date for ForwardRates**

serial date number | date character vector | datetime

Common settlement date for **ForwardRates**, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | datetime | char

## Name-Value Pair Arguments

Specify optional pairs of arguments as **Name1=Value1**, ..., **NameN=ValueN**, where **Name** is the argument name and **Value** is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, Settle, 'InputCompounding', 3, 'InputBasis', 5, 'OutputCompounding', 4, 'OutputBasis', 5)`

### **InputCompounding — Compounding frequency of input forward rates**

2 (default) | numeric values: 0, 1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of input forward rates, specified with allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding

- -1 — Continuous compounding

---

**Note** If `InputCompounding` is not specified, then `InputCompounding` is assigned the value specified for `OutputCompounding`. If either `InputCompounding` or `OutputCompounding` are not specified, the default is 2

---

Data Types: double

**InputBasis — Day-count basis of input forward rates**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of input forward rates, specified as a numeric value. Allowed values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

---

**Note** If `InputBasis` is not specified, then `InputBasis` is assigned the value specified for `OutputBasis`. If either `InputBasis` or `Outputbasis` are not specified, the default is 0 (actual/actual) for both.

---

Data Types: double

**OutputCompounding — Compounding frequency of output zero rates**

2 (default) | numeric values: 0, 1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of output zero rates, specified with the allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year

- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

---

**Note** If `OutputCompounding` is not specified, then `OutputCompounding` is assigned the value specified for `InputCompounding`. If either `InputCompounding` or `OutputCompounding` are not specified, the default is 2 (semiannual) for both.

---

Data Types: double

#### **OutputBasis — Day-count basis of output zero rates**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of output zero rates, specified as a numeric value. Allowed values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

---

**Note** If `OutputBasis` is not specified, then `OutputBasis` is assigned the value specified for `InputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is 0 (actual/actual) for both.

---

Data Types: double

## **Output Arguments**

**ZeroRates — Zero curve for investment horizon represented by CurveDates**  
numeric

Zero curve for the investment horizon represented by `CurveDates`, returned as a `NUMBONDS`-by-1 vector of decimal fractions. In aggregate, the rates in `ZeroRates` constitute a zero curve for the investment horizon represented by `CurveDates`.

**CurveDates — Maturity dates that correspond to ZeroRates**

serial date number | date character vector | datetime

Maturity dates that correspond to the `ZeroRates`, returned as a `NUMBONDS`-by-1 vector of maturity dates that correspond to the zero rates in `ZeroRates`. This vector is the same as the input vector `CurveDates`, but is sorted by ascending maturity.

If both inputs for `CurveDates` and `Settle` are serial date numbers or date character vectors, `CurveDates` is returned as serial date numbers. However, if either of the inputs for `CurveDates` and `Settle` are a datetime array, `CurveDates` is returned as a datetime array.

# geom2arith

Geometric to arithmetic moments of asset returns

## Syntax

```
[ma,Ca = geom2arith(mg,Cg)
[ma,Ca = geom2arith(____,t)
```

## Description

[ma,Ca = geom2arith(mg,Cg) transforms moments associated with a continuously compounded geometric Brownian motion into equivalent moments associated with a simple Brownian motion with a possible change in periodicity.

[ma,Ca = geom2arith(\_\_\_\_,t) adds an optional argument t.

## Examples

### Obtain Geometric to Arithmetic Moments of Asset Returns

This example shows several variations of using geom2arith.

Given geometric mean m and covariance C of monthly total returns, obtain annual arithmetic mean ma and covariance Ca. In this case, the output period (1 year) is 12 times the input period (1 month) so that the optional input t = 12.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
[ma, Ca] = geom2arith(m, C, 12)
```

ma = 4×1

```
0.5508
1.0021
1.0906
1.4802
```

Ca = 4×4

```
0.0695    0.0423    0.0196      0
0.0423    0.2832    0.1971    0.1095
0.0196    0.1971    0.5387    0.3013
      0       0.1095   0.3013   1.0118
```

Given annual geometric mean  $m$  and covariance  $C$  of asset returns, obtain monthly arithmetic mean  $ma$  and covariance  $Ca$ . In this case, the output period (1 month) is 1/12 times the input period (1 year) so that the optional input  $t = 1/12$ .

```
[ma, Ca] = geom2arith(m, C, 1/12)
```

ma = 4×1

```
0.0038  
0.0070  
0.0076  
0.0103
```

Ca = 4×4

```
0.0005    0.0003    0.0001      0  
0.0003    0.0020    0.0014    0.0008  
0.0001    0.0014    0.0037    0.0021  
0        0.0008    0.0021    0.0070
```

Given geometric mean  $m$  and covariance  $C$  of monthly total returns, obtain quarterly arithmetic return moments. In this case, the output is 3 of the input periods so that the optional input  $t = 3$ .

```
[ma, Ca] = geom2arith(m, C, 3)
```

ma = 4×1

```
0.1377  
0.2505  
0.2726  
0.3701
```

Ca = 4×4

```
0.0174    0.0106    0.0049      0  
0.0106    0.0708    0.0493    0.0274  
0.0049    0.0493    0.1347    0.0753  
0        0.0274    0.0753    0.2530
```

## Input Arguments

**mg — Continuously compounded or geometric mean of asset returns**  
vector

Continuously compounded or geometric mean of asset returns, specified as an  $n$ -vector.

Data Types: double

**Cg — Continuously compounded or geometric covariance of asset returns**  
matrix

Continuously compounded or geometric covariance of asset returns, specified as an n-by-n symmetric, positive semidefinite matrix. If  $C_g$  is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

Data Types: double

**t — Target period of arithmetic moments in terms of periodicity of geometric moments**  
1 (default) | scalar positive numeric

(Optional) Target period of geometric moments in terms of periodicity of arithmetic moments, specified as a scalar positive numeric.

Data Types: double

## Output Arguments

**ma — Arithmetic mean of asset returns over the target period**  
vector

Arithmetic mean of asset returns over the target period ( $t$ ), returned as an  $n$ -vector.

**Ca — Arithmetic covariance of asset returns over the target period**  
matrix

Arithmetic covariance of asset returns over the target period ( $t$ ), returned as an  $n$ -by- $n$  matrix.

## Algorithms

Geometric returns over period  $t_G$  are modeled as multivariate lognormal random variables with moments

$$E[Y] = 1 + m_G$$

and

$$\text{cov}(Y) = C_G$$

Arithmetic returns over period  $t_A$  are modeled as multivariate normal random variables with moments

$$E[X] = m_A$$

$$\text{cov}(X) = C_A$$

Given  $t = t_A / t_G$ , the transformation from geometric to arithmetic moments is

$$C_{A_{ij}} = t \log \left( 1 + \frac{C_{G_{ij}}}{(1 + m_{G_i})(1 + m_{G_j})} \right)$$

$$m_{A_i} = t \log(1 + m_{G_i}) - \frac{1}{2} C_{A_{ii}}$$

For  $i, j = 1, \dots, n$ .

---

**Note** If  $t = 1$ , then  $X = \log(Y)$ .

---

This function requires that the input mean must satisfy  $1 + \text{mg} > 0$  and that the input covariance  $\text{Cg}$  must be a symmetric, positive, semidefinite matrix.

The functions `geom2arith` and `arith2geom` are complementary so that, given  $\text{m}$ ,  $\text{C}$ , and  $\text{t}$ , the sequence

```
[ma,Ca] = geom2arith(m,C,t);  
[mg,Cg] = arith2geom(ma,Ca,1/t);
```

yields  $\text{mg} = \text{m}$  and  $\text{Cg} = \text{C}$ .

## Introduced before R2006a

# getAssetMoments

Obtain mean and covariance of asset returns from Portfolio object

## Syntax

```
[AssetMean,AssetCovar] = getAssetMoments(obj)
```

## Description

Use the `getAssetMoments` function with a `Portfolio` object to obtain mean and covariance of asset returns.

For details on the workflow, see “Portfolio Object Workflow” on page 4-17.

`[AssetMean,AssetCovar] = getAssetMoments(obj)` obtains mean and covariance of asset returns for a `Portfolio` object.

## Examples

### Obtain Asset Moment Properties for a Portfolio Object

Given the mean and covariance of asset returns in the variables `m` and `C`, the asset moment properties can be set and then obtained using the `getAssetMoments` function:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

p = Portfolio;
p = setAssetMoments(p, m, C);
[assetmean, assetcovar] = getAssetMoments(p)

assetmean = 4x1
0.0042
0.0083
0.0100
0.0150

assetcovar = 4x4
0.0005    0.0003    0.0002      0
0.0003    0.0024    0.0017    0.0010
0.0002    0.0017    0.0048    0.0028
      0     0.0010    0.0028    0.0102
```

## Input Arguments

### **obj — Object for portfolio**

object

Object for portfolio, specified using a `Portfolio` object. For more information on creating a portfolio object, see

- `Portfolio`

Data Types: object

## Output Arguments

### **AssetMean — Mean of asset returns**

vector

Mean of asset returns, returned as a vector.

### **AssetCovar — Covariance of asset returns**

matrix

Covariance of asset returns, returned as a matrix.

## Tips

You can also use dot notation to obtain the mean and covariance of asset returns from a `Portfolio` object:

```
[AssetMean, AssetCovar] = obj.getAssetMoments;
```

## See Also

`setAssetMoments`

## Introduced in R2011a

# getBounds

Obtain bounds for portfolio weights from portfolio object

## Syntax

```
[LowerBound,UpperBound] = getBounds(obj)
```

## Description

Use the `getBounds` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain bounds for portfolio weights from portfolio objects.

For details on the respective workflows when using these different objects, see “`Portfolio` Object Workflow” on page 4-17, “`PortfolioCVaR` Object Workflow” on page 5-15, and “`PortfolioMAD` Object Workflow” on page 6-15.

`[LowerBound,UpperBound] = getBounds(obj)` obtains bounds for portfolio weights from portfolio objects.

## Examples

### Obtain Values for Lower and Upper Bounds for a Portfolio Object

Given portfolio `p` with the default constraints set, obtain the values for `LowerBound` and `UpperBound`.

```
p = Portfolio;
p = setDefaultConstraints(p, 5);
[LowerBound, UpperBound] = getBounds(p)
```

`LowerBound = 5x1`

```
0
0
0
0
0
```

`UpperBound =`

```
[]
```

### Obtain Values for Lower and Upper Bounds for a PortfolioCVaR Object

Given a `PortfolioCVaR` object `p` with the default constraints set, obtain the values for `LowerBound` and `UpperBound`.

```
p = PortfolioCVaR;
p = setDefaultConstraints(p, 5);
[LowerBound, UpperBound] = getBounds(p)

LowerBound = 5x1

    0
    0
    0
    0
    0

UpperBound = []

```

### Obtain Values for Lower and Upper Bounds for a PortfolioMAD Object

Given a PortfolioMAD object p with the default constraints set, obtain the values for LowerBound and UpperBound.

```
p = PortfolioMAD;
p = setDefaultConstraints(p, 5);
[LowerBound, UpperBound] = getBounds(p)

LowerBound = 5x1

    0
    0

UpperBound = []

```

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

## Output Arguments

### **LowerBound — Lower-bound weight for each asset**

vector

Lower-bound weight for each asset, returned as a vector for a **Portfolio**, **PortfolioCVaR**, or **PortfolioMAD** input object (**obj**). For more information on creating a portfolio object, see

- **Portfolio**
- **PortfolioCVaR**
- **PortfolioMAD**

### **UpperBound — Upper-bound weight for each asset**

vector

Upper-bound weight for each asset, returned as a vector for a **Portfolio**, **PortfolioCVaR**, or **PortfolioMAD** input object (**obj**). For more information on creating a portfolio object, see

- **Portfolio**
- **PortfolioCVaR**
- **PortfolioMAD**

## Tips

You can also use dot notation to obtain bounds for portfolio weights from portfolio objects.

```
[LowerBound, UpperBound] = obj.getBounds;
```

## See Also

[setBounds](#)

### Introduced in R2011a

## getBudget

Obtain budget constraint bounds from portfolio object

### Syntax

```
[LowerBudget,UpperBudget] = getBudget(obj)
```

### Description

Use the `getBudget` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain budget constraint bounds from portfolio objects.

For details on the respective workflows when using these different objects, see “[Portfolio Object Workflow](#)” on page 4-17, “[PortfolioCVaR Object Workflow](#)” on page 5-15, and “[PortfolioMAD Object Workflow](#)” on page 6-15.

`[LowerBudget,UpperBudget] = getBudget(obj)` obtains budget constraint bounds from portfolio objects.

### Examples

#### Obtain Values for Lower and Upper Budgets for a Portfolio Object

Given portfolio `p` with the default constraints set, obtain the values for `LowerBudget` and `UpperBudget`.

```
p = Portfolio;
p = setDefaultConstraints(p, 5);
[LowerBudget, UpperBudget] = getBudget(p)

LowerBudget = 1
UpperBudget = 1
```

#### Obtain Values for Lower and Upper Budgets for a PortfolioCVaR Object

Given a `PortfolioCVaR` object `p` with the default constraints set, obtain the values for `LowerBudget` and `UpperBudget`.

```
p = PortfolioCVaR;
p = setDefaultConstraints(p, 5);
[LowerBudget, UpperBudget] = getBudget(p)

LowerBudget = 1
UpperBudget = 1
```

## Obtain Values for Lower and Upper Budgets for a PortfolioMAD Object

Given a PortfolioMAD object *p* with the default constraints set, obtain the values for *LowerBudget* and *UpperBudget*.

```
p = PortfolioMAD;
p = setDefaultConstraints(p, 5);
[LowerBudget, UpperBudget] = getBudget(p)

LowerBudget = 1
UpperBudget = 1
```

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using *Portfolio*, *PortfolioCVaR*, or *PortfolioMAD* object. For more information on creating a portfolio object, see

- *Portfolio*
- *PortfolioCVaR*
- *PortfolioMAD*

Data Types: object

## Output Arguments

**LowerBudget — Lower-bound weight for each asset**  
scalar

Lower bound for budget constraint, returned as a scalar for a *Portfolio*, *PortfolioCVaR*, or *PortfolioMAD* input object (*obj*).

**UpperBudget — Upper bound for budget constraint**  
scalar

Upper bound for budget constraint, returned as a scalar for a *Portfolio*, *PortfolioCVaR*, or *PortfolioMAD* input object (*obj*).

## Tips

You can also use dot notation to obtain the budget constraint bounds from portfolio objects.

```
[LowerBudget, UpperBudget] = obj.getBudget;
```

## See Also

*setBudget*

# getCosts

Obtain buy and sell transaction costs from portfolio object

## Syntax

```
[BuyCost,SellCost] = getCosts(obj)
```

## Description

Use the `getCosts` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain buy and sell transaction costs from portfolio objects.

For details on the respective workflows when using these different objects, see “`Portfolio` Object Workflow” on page 4-17, “`PortfolioCVaR` Object Workflow” on page 5-15, and “`PortfolioMAD` Object Workflow” on page 6-15.

`[BuyCost,SellCost] = getCosts(obj)` obtains buy and sell transaction costs from portfolio objects.

## Examples

### Obtain Buy and Sell Costs for a Portfolio Object

Given portfolio `p` with the costs set, obtain the values for `BuyCost` and `SellCost`.

```
p = Portfolio;
p = setCosts(p, 0.001, 0.001, 5);
[BuyCost, SellCost] = getCosts(p)

BuyCost = 1.0000e-03
SellCost = 1.0000e-03
```

### Obtain Buy and Sell Costs for a PortfolioCVaR Object

Given a `PortfolioCVaR` object `p` with the costs set, obtain the values for `BuyCost` and `SellCost`.

```
p = PortfolioCVaR;
p = setCosts(p, 0.001, 0.001, 5);
[BuyCost, SellCost] = getCosts(p)

BuyCost = 1.0000e-03
SellCost = 1.0000e-03
```

## Obtain Buy and Sell Costs for a PortfolioMAD Object

Given a PortfolioMAD object *p* with the costs set, obtain the values for *BuyCost* and *SellCost*.

```
p = PortfolioMAD;
p = setCosts(p, 0.001, 0.001, 5);
[BuyCost, SellCost] = getCosts(p)

BuyCost = 1.0000e-03
SellCost = 1.0000e-03
```

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using *Portfolio*, *PortfolioCVaR*, or *PortfolioMAD* object. For more information on creating a portfolio object, see

- *Portfolio*
- *PortfolioCVaR*
- *PortfolioMAD*

Data Types: object

## Output Arguments

**BuyCost — Proportional transaction cost to purchase each asset**  
vector

Proportional transaction cost to purchase each asset, returned as a vector for a *Portfolio*, *PortfolioCVaR*, or *PortfolioMAD* input object (*obj*).

**SellCost — Proportional transaction cost to sell each asset**  
vector

Proportional transaction cost to sell each asset, returned as a vector for a *Portfolio*, *PortfolioCVaR*, or *PortfolioMAD* input object (*obj*).

## Tips

You can also use dot notation to obtain the buy and sell transaction costs from portfolio objects.

```
[BuyCost, SellCost] = obj.getCosts;
```

**See Also**  
*setCosts*

## getEquality

Obtain equality constraint arrays from portfolio object

### Syntax

```
[AEquality,bEquality] = getEquality(obj)
```

### Description

Use the `getEquality` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain equality constraint arrays from portfolio objects.

For details on the respective workflows when using these different objects, see “`Portfolio` Object Workflow” on page 4-17, “`PortfolioCVaR` Object Workflow” on page 5-15, and “`PortfolioMAD` Object Workflow” on page 6-15.

`[AEquality,bEquality] = getEquality(obj)` obtains equality constraint arrays from portfolio objects.

### Examples

#### Obtain Equality Constraints for a Portfolio Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are exactly 50% of your portfolio. Given a `Portfolio` object `p`, set the linear equality constraints and obtain the values for `AEquality` and `bEquality`:

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = Portfolio;
p = setEquality(p, A, b);
[AEquality, bEquality] = getEquality(p)
```

```
AEquality = 1x5
```

```
1     1     1     0     0
```

```
bEquality = 0.5000
```

#### Obtain Equality Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are 50% of your portfolio. Given a `PortfolioCVaR` object `p`, set the linear equality constraints and obtain the values for `AEquality` and `bEquality`:

```
A = [ 1 1 1 0 0 ];
b = 0.5;
```

```

p = PortfolioCVaR;
p = setEquality(p, A, b);
[AEquality, bEquality] = getEquality(p)

AEquality = 1×5

    1     1     1     0     0

bEquality = 0.5000

```

### Obtain Equality Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are 50% of your portfolio. Given a PortfolioMAD object *p*, set the linear equality constraints and obtain the values for *AEquality* and *bEquality*:

```

A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioMAD;
p = setEquality(p, A, b);
[AEquality, bEquality] = getEquality(p)

AEquality = 1×5

    1     1     1     0     0

bEquality = 0.5000

```

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using *Portfolio*, *PortfolioCVaR*, or *PortfolioMAD* object. For more information on creating a portfolio object, see

- *Portfolio*
- *PortfolioCVaR*
- *PortfolioMAD*

Data Types: object

## Output Arguments

**AEquality — Matrix to form linear equality constraints**  
matrix

Matrix to form linear equality constraints, returned as a matrix for a *Portfolio*, *PortfolioCVaR*, or *PortfolioMAD* input object (*obj*).

**bEquality — Vector to form linear equality constraints**

vector

Vector to form linear equality constraints, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**Tips**

You can also use dot notation to obtain the equality constraint arrays from portfolio objects.

```
[AEquality, bEquality] = obj.getEquality;
```

**Introduced in R2011a**

# getGroupRatio

Obtain group ratio constraint arrays from portfolio object

## Syntax

```
[GroupA,GroupB,LowerRatio,UpperRatio] = getGroupRatio(obj)
```

## Description

Use the `getGroupRatio` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain group ratio constraint arrays from portfolio objects.

For details on the respective workflows when using these different objects, see “[Portfolio Object Workflow](#)” on page 4-17, “[PortfolioCVaR Object Workflow](#)” on page 5-15, and “[PortfolioMAD Object Workflow](#)” on page 6-15.

`[GroupA,GroupB,LowerRatio,UpperRatio] = getGroupRatio(obj)` obtains equality constraint arrays from portfolio objects.

## Examples

### Obtain Group Ratio Constraints for a Portfolio Object

Suppose you want to make sure that the ratio of financial to nonfinancial companies in your portfolios never goes above 50%. Assume you have 6 assets with 3 financial companies (assets 1-3) and 3 nonfinancial companies (assets 4-6). After setting group ratio constraints, obtain the values for `GroupA`, `GroupB`, `LowerRatio`, and `UpperRatio`.

```
GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = Portfolio;
p = setGroupRatio(p, GA, GB, [], 0.5);
[GroupA, GroupB, LowerRatio, UpperRatio] = getGroupRatio(p)
```

`GroupA = 1×6`

```
1     1     1     0     0     0
```

`GroupB = 1×6`

```
0     0     0     1     1     1
```

`LowerRatio =`

```
[]
```

`UpperRatio = 0.5000`

### Obtain Group Ratio Constraints for a PortfolioCVaR Object

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolios never exceeds 50%. Assume you have six assets with three financial companies (assets 1-3) and three nonfinancial companies (assets 4-6). After setting group ratio constraints, obtain the values for `GroupA`, `GroupB`, `LowerRatio`, and `UpperRatio`.

```
GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = PortfolioCVaR;
p = setGroupRatio(p, GA, GB, [], 0.5);
[GroupA, GroupB, LowerRatio, UpperRatio] = getGroupRatio(p)

GroupA = 1×6
    1     1     1     0     0     0

GroupB = 1×6
    0     0     0     1     1     1

LowerRatio =
[]
UpperRatio = 0.5000
```

### Obtain Group Ratio Constraints for a PortfolioMAD Object

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolios never exceeds 50%. Assume you have six assets with three financial companies (assets 1-3) and three nonfinancial companies (assets 4-6). After setting group ratio constraints, obtain the values for `GroupA`, `GroupB`, `LowerRatio`, and `UpperRatio`.

```
GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = PortfolioMAD;
p = setGroupRatio(p, GA, GB, [], 0.5);
[GroupA, GroupB, LowerRatio, UpperRatio] = getGroupRatio(p)

GroupA = 1×6
    1     1     1     0     0     0

GroupB = 1×6
    0     0     0     1     1     1

LowerRatio =
[]
```

---

UpperRatio = 0.5000

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

## Output Arguments

**GroupA — Matrix that forms base groups for comparison**  
matrix

Matrix that forms base groups for comparison, returned as a matrix for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**GroupB — Matrix that forms comparison groups**  
matrix

Matrix that forms comparison groups, returned as a matrix `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**LowerRatio — Lower bound for ratio of GroupB groups to GroupA groups**  
vector

Lower bound for ratio of GroupB groups to GroupA groups, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**UpperRatio — Upper bound for ratio of GroupB groups to GroupA groups**  
vector

Upper bound for ratio of GroupB groups to GroupA groups, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## Tips

You can also use dot notation to obtain group ratio constraint arrays from portfolio objects.

```
[GroupA, GroupB, LowerRatio, UpperRatio] = obj.getGroupRatio;
```

## See Also

# getGroups

Obtain group constraint arrays from portfolio object

## Syntax

```
[GroupMatrix,LowerGroup,UpperGroup] = getGroups(obj)
```

## Description

Use the `getGroups` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain group constraint arrays from portfolio objects.

For details on the respective workflows when using these different objects, see “[Portfolio Object Workflow](#)” on page 4-17, “[PortfolioCVaR Object Workflow](#)” on page 5-15, and “[PortfolioMAD Object Workflow](#)” on page 6-15.

`[GroupMatrix,LowerGroup,UpperGroup] = getGroups(obj)` obtains group constraint arrays from portfolio objects.

## Examples

### Obtain Group Constraints for a Portfolio Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute no more than 30% of your portfolio. Given a `Portfolio` object `p` with the group constraints set, obtain the values for `GroupMatrix`, `LowerGroup`, and `UpperGroup`.

```
G = [ true true true false false ];
p = Portfolio;
p = setGroups(p, G, [], 0.3);
[GroupMatrix, LowerGroup, UpperGroup] = getGroups(p)
```

`GroupMatrix = 1x5`

```
1     1     1     0     0
```

`LowerGroup =`

```
[]
```

`UpperGroup = 0.3000`

### Obtain Group Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 30% of your portfolio. Given a `PortfolioCVaR` object `p` with the group constraints set, obtain the values for `GroupMatrix`, `LowerGroup`, and `UpperGroup`.

```
G = [ true true true false false ];
p = PortfolioCVaR;
p = setGroups(p, G, [], 0.3);
[GroupMatrix, LowerGroup, UpperGroup] = getGroups(p)

GroupMatrix = 1x5

    1     1     1     0     0

LowerGroup =

[]

UpperGroup = 0.3000
```

### Obtain Group Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 30% of your portfolio. Given a PortfolioMAD object *p* with the group constraints set, obtain the values for *GroupMatrix*, *LowerGroup*, and *UpperGroup*.

```
G = [ true true true false false ];
p = PortfolioMAD;
p = setGroups(p, G, [], 0.3);
[GroupMatrix, LowerGroup, UpperGroup] = getGroups(p)

GroupMatrix = 1x5

    1     1     1     0     0

LowerGroup =

[]

UpperGroup = 0.3000
```

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using *Portfolio*, *PortfolioCVaR*, or *PortfolioMAD* object. For more information on creating a portfolio object, see

- *Portfolio*
- *PortfolioCVaR*
- *PortfolioMAD*

Data Types: object

## Output Arguments

### **GroupMatrix – Group constraint matrix**

matrix

Group constraint matrix, returned as a matrix for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **LowerGroup – Lower bound for group constraints**

vector

Lower bound for group constraints, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### **UpperGroup – Upper bound for group constraints**

vector

Upper bound for group constraints, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## Tips

You can also use dot notation to obtain the group constraint arrays from portfolio objects.

```
[GroupMatrix, LowerGroup, UpperGroup] = obj.getGroups;
```

## See Also

`setGroups`

## Introduced in R2011a

# getScenarios

Obtain scenarios from portfolio object

## Syntax

```
Y = getScenarios(obj)
```

## Description

Use the `getScenarios` function with a `PortfolioCVaR` or `PortfolioMAD` objects to obtain scenarios.

For details on the workflows, see “`PortfolioCVaR` Object Workflow” on page 5-15, and “`PortfolioMAD` Object Workflow” on page 6-15.

`Y = getScenarios(obj)` obtains scenarios for `PortfolioCVaR` or `PortfolioMAD` objects.

## Examples

### Obtain Scenarios for a CVaR Portfolio Object

For a given `PortfolioCVaR` object `p`, display the defined scenarios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 10);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

Y = getScenarios(p)

Y = 10x4

-0.0056    0.0440    0.1186    0.0488
-0.0368   -0.0753    0.0087    0.1124
 0.0025    0.0856    0.0484    0.1404
 0.0318    0.0826    0.0377    0.0404
 0.0013   -0.0561   -0.1466   -0.0621
 0.0035    0.0310   -0.0183    0.1225
```

```

-0.0519   -0.1634   -0.0526   0.1528
 0.0029   -0.1163   -0.0627   -0.0760
 0.0192   -0.0182   -0.1243   -0.1346
 0.0440    0.0189    0.0098   0.0821

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Obtain Scenarios for a MAD Portfolio Object

For a given `PortfolioMAD` object `p`, display the defined scenarios.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 10);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

Y = getScenarios(p)

Y = 10×4

-0.0056    0.0440    0.1186    0.0488
-0.0368   -0.0753    0.0087    0.1124
 0.0025    0.0856    0.0484    0.1404
 0.0318    0.0826    0.0377    0.0404
 0.0013   -0.0561   -0.1466   -0.0621
 0.0035    0.0310   -0.0183    0.1225
-0.0519   -0.1634   -0.0526   0.1528
 0.0029   -0.1163   -0.0627   -0.0760
 0.0192   -0.0182   -0.1243   -0.1346
 0.0440    0.0189    0.0098   0.0821

```

The function `rng(seed)` resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

### Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using a `PortfolioCVaR` or `PortfolioMAD` object.

For more information on creating a `PortfolioCVaR` or `PortfolioMAD` object, see

- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

## Output Arguments

### **Y — Scenarios matrix**

matrix

Scenarios matrix, returned as a `NumScenarios`-by-`NumAssets` matrix for a `PortfolioCVaR` or `PortfolioMAD` object.

## Tips

You can also use dot notation to obtain scenarios from a `PortfolioCVaR` or `PortfolioMAD` object.

```
Y = obj.getScenarios;
```

# getfield

Content of specific field

---

**Note** `getfield` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
fieldval = getfield(tsobj,field)
fieldval = getfield(tsobj,field,dates)
```

## Description

`fieldval = getfield(tsobj,field)` returns the contents of the specified field. `getfield` treats the contents of a financial time series object `tsobj` as fields in a structure.

`fieldval = getfield(tsobj,field,dates)` returns the contents of the specified field for the specified dates. `dates` can be individual cells of date character vectors or a cell of a date character vector range using the `::` operator, such as `'03/01/99::03/31/99'`.

## Examples

### Obtain Content of Specific Field in Financial Time Series Object

- 1 Create a financial time series object containing both date and time-of-day information:

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ',size(dates,1),1), ...
                      times]);
AnFts = fints(dates_times,[(1:4)'; nan; 6],{'Data1'},1, ...
               'Yet Another Financial Time Series')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints` (line 165)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints/display` (line 66)

`AnFts =`

```
desc: Yet Another Financial Time Series
freq: Daily (1)

'dates: (6)'    'times: (6)'    'Data1: (6)'
'01-Jan-2001'    '11:00'        [      1]
'          '    '12:00'        [      2]
'02-Jan-2001'    '11:00'        [      3]
'          '    '12:00'        [      4]
'03-Jan-2001'    '11:00'        [      NaN]
'          '    '12:00'        [      6]
```

- 2 Get the contents of the `times` field in `AnFts`:

```
F = datestr(getfield(AnFts, 'times'))
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/getfield (line 67)

```
F =
```

6×8 char array

```
'11:00 AM'  
'12:00 PM'  
'11:00 AM'  
'12:00 PM'  
'11:00 AM'  
'12:00 PM'
```

## Input Arguments

**tsobj — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

**field — Field name within tsobj**

character vector

Field name within `tsobj`, specified as a character vector.

Data Types: char

**dates — Date range**

date character vector | cell array of date character vector

Date range (`dates` can be expanded to include time-of-day information), specified as a date character vector or a cell array of date character vectors.

Data Types: char | cell

## Output Arguments

**fieldval — Specified field contents for the specified dates**

vector

Specified field contents for the specified dates, returned as a vector.

## getInequality

Obtain inequality constraint arrays from portfolio object

### Syntax

```
[AInequality,bInequality] = getInequality(obj)
```

### Description

Use the `getInequality` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain inequality constraint arrays from portfolio objects.

For details on the respective workflows when using these different objects, see “[Portfolio Object Workflow](#)” on page 4-17, “[PortfolioCVaR Object Workflow](#)” on page 5-15, and “[PortfolioMAD Object Workflow](#)” on page 6-15.

`[AInequality,bInequality] = getInequality(obj)` obtains equality constraint arrays from portfolio objects.

### Examples

#### Obtain Inequality Constraints for a Portfolio Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are no more than 50% of your portfolio. Given a `Portfolio` object `p`, set the linear inequality constraints and then obtain values for `AInequality` and `bInequality`.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = Portfolio;
p = setInequality(p, A, b);
[AInequality, bInequality] = getInequality(p)
```

```
AInequality = 1x5
1     1     1     0     0
```

```
bInequality = 0.5000
```

#### Obtain Inequality Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 50% of your portfolio. Given a `PortfolioCVaR` object `p`, set the linear inequality constraints and then obtain values for `AInequality` and `bInequality`.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
```

```
p = PortfolioCVaR;
p = setInequality(p, A, b);
[AInequality, bInequality] = getInequality(p)

AInequality = 1×5

    1     1     1     0     0

bInequality = 0.5000
```

### Obtain Inequality Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 50% of your portfolio. Given a PortfolioMAD object p, set the linear inequality constraints and then obtain values for AInequality and bInequality.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioMAD;
p = setInequality(p, A, b);
[AInequality, bInequality] = getInequality(p)

AInequality = 1×5

    1     1     1     0     0

bInequality = 0.5000
```

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

## Output Arguments

**AInequality — Matrix to form linear inequality constraints**  
matrix

Matrix to form linear inequality constraints, returned as a matrix for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**bInequality – Vector to form linear inequality constraints**

vector

Vector to form linear inequality constraints, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

**Tips**

You can also use dot notation to obtain the inequality constraint arrays from portfolio objects.

```
[AInequality, bInequality] = obj.getInequality;
```

# getOneWayTurnover

Obtain one-way turnover constraints from portfolio object

## Syntax

```
[BuyTurnover,SellTurnover] = getOneWayTurnover(obj)
```

## Description

Use the `getOneWayTurnover` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain one-way turnover constraints from portfolio objects.

For details on the respective workflows when using these different objects, see “`Portfolio` Object Workflow” on page 4-17, “`PortfolioCVaR` Object Workflow” on page 5-15, and “`PortfolioMAD` Object Workflow” on page 6-15.

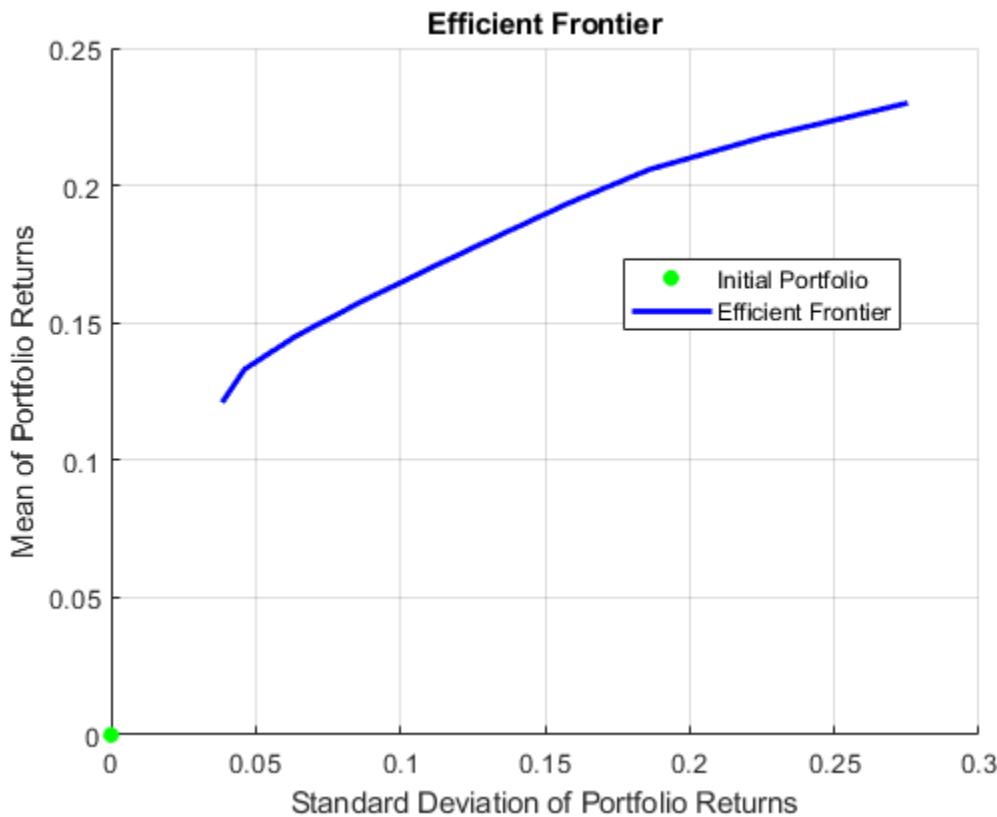

`[BuyTurnover,SellTurnover] = getOneWayTurnover(obj)` obtain one-way turnover constraints from portfolio objects.

## Examples

### Obtain One-Way Turnover Costs for a Portfolio Object

Set one-way turnover costs.

```
p = Portfolio('AssetMean',[0.1, 0.2, 0.15], 'AssetCovar',...
[ 0.005, -0.010,  0.004; -0.010,  0.040, -0.002;  0.004, -0.002,  0.023]);
p = setBudget(p, 1, 1);
p = setOneWayTurnover(p, 1.3, 0.3, 0);    %130-30 portfolio
plotFrontier(p);
```

Obtain one-way turnover costs.

```
[BuyTurnover,SellTurnover] = getOneWayTurnover(p)  
BuyTurnover = 1.3000  
SellTurnover = 0.3000
```

### Obtain One-Way Turnover Costs for a PortfolioCVaR Object

Set one-way turnover costs and obtain the buy and sell turnover values.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];  
C = [ 0.0064 0.00408 0.00192 0;  
      0.00408 0.0289 0.0204 0.0119;  
      0.00192 0.0204 0.0576 0.0336;  
      0 0.0119 0.0336 0.1225 ];  
m = m/12;  
C = C/12;  
  
AssetScenarios = mvnrnd(m, C, 20000);  
  
p = PortfolioCVaR;  
p = setScenarios(p, AssetScenarios);  
p = setDefaultConstraints(p);
```

```

p = setProbabilityLevel(p, 0.95);

p = setBudget(p, 1, 1);
p = setOneWayTurnover(p, 1.3, 0.3, 0); %130-30 portfolio

[BuyTurnover,SellTurnover] = getOneWayTurnover(p)

BuyTurnover = 1.3000

SellTurnover = 0.3000

```

### Obtain One-Way Turnover Costs for a PortfolioMAD Object

Set one-way turnover costs and obtain the buy and sell turnover values.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

p = setBudget(p, 1, 1);
p = setOneWayTurnover(p, 1.3, 0.3, 0); %130-30 portfolio

[BuyTurnover,SellTurnover] = getOneWayTurnover(p)

BuyTurnover = 1.3000

SellTurnover = 0.3000

```

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

## Output Arguments

### BuyTurnover — Turnover constraint on purchases

scalar

Turnover constraint on purchases, returned as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

### SellTurnover — Turnover constraint on sales

scalar

Turnover constraint on sales, returned as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

## More About

### One-way Turnover Constraint

One-way turnover constraints ensure that estimated optimal portfolios differ from an initial portfolio by no more than specified amounts according to whether the differences are purchases or sales.

The constraints take the form

$$\mathbf{1}^T \max\{0, \mathbf{x} - \mathbf{x}_0\} \leq \tau_B$$

$$\mathbf{1}^T \max\{0, \mathbf{x}_0 - \mathbf{x}\} \leq \tau_S$$

with

- $\mathbf{x}$  — The portfolio (`NumAssets` vector)
- $\mathbf{x}_0$  — Initial portfolio (`NumAssets` vector)
- $\tau_B$  — Upper-bound for turnover constraint on purchases (scalar)
- $\tau_S$  — Upper-bound for turnover constraint on sales (scalar)

Specify one-way turnover constraints using the following properties in a supported portfolio object: `BuyTurnover` for  $\tau_B$ , `SellTurnover` for  $\tau_S$ , and `InitPort` for  $\mathbf{x}_0$ .

---

**Note** The average turnover constraint (which is set using `setTurnover`) is not just the combination of the one-way turnover constraints with the same value for the constraint.

---

## Tips

You can also use dot notation to get the one-way turnover constraint for portfolio objects.

```
[BuyTurnover,SellTurnover] = obj.getOneWayTurnover
```

**Introduced in R2011a**

# getnameidx

Find name in list

**Note** `getnameidx` is not recommended. Use `contains` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
nameidx = getnameidx(list, name)
```

## Description

`nameidx = getnameidx(list, name)` finds the occurrence of a name or set of names in a list. It returns an index (order number) indicating where the specified names are located within the list. If `name` is not found, `nameidx` returns 0.

`getnameidx` finds only the first occurrence of the name in the list of names. This function is meant to be used on a list of unique names (character vectors) only. It does not find multiple occurrences of a name or a list of names within `list`.

## Examples

### Find Name in List

**1** Given:

```
poultry = {'duck', 'chicken'}
animals = {'duck', 'cow', 'sheep', 'horse', 'chicken'}
nameidx = getnameidx(animals, poultry)

ans =
    1    5
```

**2** Given:

```
poultry = {'duck', 'goose', 'chicken'}
animals = {'duck', 'cow', 'sheep', 'horse', 'chicken'}
nameidx = getnameidx(animals, poultry)

ans =
    1    0    5
```

## Input Arguments

### **list — List of names**

cell array of character vectors

List of names, specified as a cell array of character vectors.

Data Types: `cell`

**name — Name**

character vector | cell array of character vectors

Name, specified as a character vector or cell array of character vectors.

If name is a cell array of names, getnameidx returns a vector containing the indices (order number) of the name character vectors within list. If none of the names in the name cell array is in list, it returns zero. If some of the names in name are not found, the indices for these names are zeros.

Data Types: char | cell

## Output Arguments

**nameidx — Occurrence of the name in the list of names**

vector

Occurrence of the name in the list of names, returned as a vector.

## hhigh

Highest high

**Note** Using a `fints` object for the `Data` argument of `hhigh` is not recommended. Use a matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
values = hhigh(Data)
values = hhigh(___,Name,Value)
```

### Description

`values = hhigh(Data)` generates a vector of highest high values from the series of high prices for the past  $n$  periods.

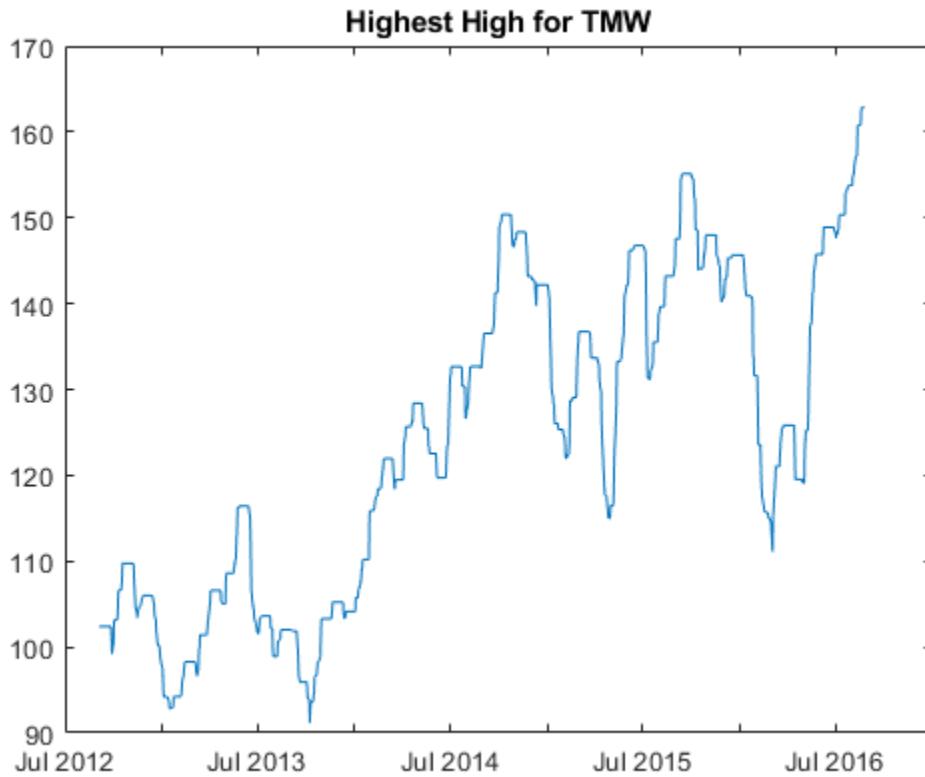

`values = hhigh(___,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Calculate the Highest High for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
values = hhigh(TMW);
plot(values.Time,values.HighestHigh)
title('Highest High for TMW')
```

## Input Arguments

### Data — Data for high prices

matrix | table | timetable

Data for high prices, specified as a matrix, table, or timetable. Timetables and tables with M rows must contain a variable named 'High' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, ..., NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `values = hhigh(TMW_HIGH, 'NumPeriods', 10)`

### NumPeriods — Moving window for the highest high calculation

14 (default) | positive integer

Moving window for the highest high calculation, specified as the comma-separated pair consisting of 'NumPeriods' and a scalar positive integer.

Data Types: double

## Output Arguments

### **values — Highest high series**

matrix | table | timetable

Highest high series, returned with the same number of rows ( $M$ ) and the same type (matrix, table, or timetable) as the input Data.

## Topics

“Using Timetables in Finance” on page 12-7

“Convert Financial Time Series Objects fintts to Timetables” on page 12-2

## Introduced before R2006a

# highlow (fts)

Time series High-Low plot

---

**Note** `highlow (fts)` is not recommended. Use `highlow` instead.

---

## Syntax

```
highlow(tsobj)
highlow(tsobj,color)
highlow(tsobj,color,dateform)
highlow(___,Name,Value)
hhll = highlow(___,Name,Value)
```

## Description

`highlow(tsobj)` generates a High-Low plot of the data in the financial time series object `tsobj`. `tsobj` must contain at least four data series representing the high, low, open, and closing prices. These series must have the names `High`, `Low`, `Open`, and `Close` (case-insensitive).

`highlow(tsobj,color)` additionally specifies the color of the plot.

`highlow(tsobj,color,dateform)` additionally specifies the date format used as the x-axis tick labels. See `datestr` for a list of date formats.

`highlow(___,Name,Value)` indicates the actual names of the required data series if the data series do not have the default names.

`hhll = highlow(___,Name,Value)` returns the handle to the line object that makes up the High-Low plot.

## Examples

### Generate a High-Low Plot

This example shows how to generate a High-Low plot for Disney stock for the dates May 28 to June 18, 1998.

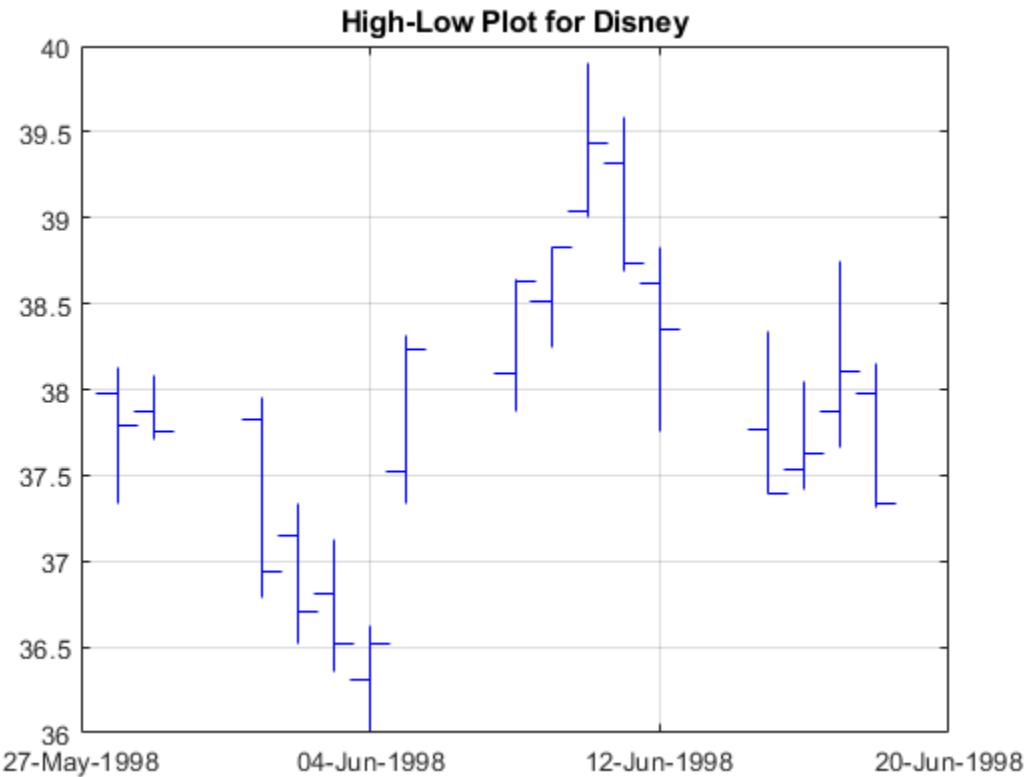

```
load disney.mat
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat"

```
highlow(dis('28-May-1998::18-Jun-1998'))
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat"

```
title('High-Low Plot for Disney')
```

## Input Arguments

**tsobj — Financial time series object**  
fints object

Financial time series object, specified as a `fints` object.

Data Types: object

**color — Three-element row vector representing RGB or a color identifier**  
background color of figure window (default) | color vector [R G B] | character vector

(Optional) A three-element row vector representing RGB color vector or a character vector specifying the color name. The default color differs depending on the background color of the figure window. For more information, see `plot`.

Data Types: double | char

**dateform — Date format used as the x-axis tick labels**  
'dd-mmm-yyyy HH:MM' (default) | character vector

(Optional) Date format used as the x-axis tick labels, specified as a date character vector format. (For more information, see `datetick`.) You can specify a `dateform` only when `tsobj` does not contain time-of-day data. If `tsobj` contains time-of-day data, `dateform` is restricted to 'dd-mmm-yyyy HH:MM'.

Data Types: char

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `highlow(dis('28-May-1998::18-Jun-1998'), 'HighName', 'SeriesHigh')`

#### **HighName — High name**

'' (default) | character vector

High name, specified as the comma-separated pair consisting of 'HighName' and a character vector with a value for the high prices series name.

Data Types: char

#### **LowName — High name**

'' (default) | character vector

Low name, specified as the comma-separated pair consisting of 'LowName' and a character vector with a value for the low prices series name.

Data Types: char

#### **OpenName — Open name**

'' (default) | character vector

Open name, specified as the comma-separated pair consisting of 'OpenName' and a character vector with a value for the open prices series name.

Data Types: char

#### **CloseName — High name**

'' (default) | character vector

Close name, specified as the comma-separated pair consisting of 'CloseName' and a character vector with a value for the closing prices series name.

Data Types: char

## Output Arguments

### **hhll — High-Low plot handle**

handle to line object

High-Low plot handle, returned as the handle to the line object that makes up the High-Low plot.

## See Also

candle

### Introduced before R2006a

# highlow

High, low, open, close chart

---

**Note** `highlow` is updated to accept data input as a matrix, `timetable`, or `table`.

---

## Syntax

```
highlow(Data)
highlow(Data,Color)
h = highlow(ax, __ )
```

## Description

`highlow(Data)` displays a highlow chart from a series of opening, high, low, and closing prices of a security. The plots are vertical lines whose top is the high, bottom is the low, open is a left tick, and close is a right tick.

`highlow(Data,Color)` adds an optional argument for `Color`.

`h = highlow(ax, __ )` adds an optional argument for `ax`.

## Examples

### Generate a Highlow Chart for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock. The highlow chart plots the price data using blue lines.

```
load SimulatedStock.mat
range = 1:25;
highlow(TMW(range,:),'b');
title('High, Low, Open, Close Chart for TMW')
```

## Input Arguments

### Data — Data for opening, high, low, and closing prices

matrix | table | timetable

Data for opening, high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-4 matrix of opening, high, low, and closing prices stored in the corresponding columns. Timetables and tables with M rows must contain variables named 'Open', 'High', 'Low', and 'Close' (case insensitive).

Data Types: double | table | timetable

### Color — Three element color vector

background color of figure window (default) | color vector [R G B] | string

(Optional) Three element color vector, specified as a [R G B] color vector or a string specifying the color name. The default color differs depending on the background color of the figure window.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1]; for example, [0.4 0.6 0.7].

- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

| Color Name | Short Name | RGB Triplet | Hexadecimal Color Code | Appearance |
|------------|------------|-------------|------------------------|------------|
| 'red'      | 'r'        | [1 0 0]     | '#FF0000'              |            |
| 'green'    | 'g'        | [0 1 0]     | '#00FF00'              |            |
| 'blue'     | 'b'        | [0 0 1]     | '#0000FF'              |            |
| 'cyan'     | 'c'        | [0 1 1]     | '#00FFFF'              |            |
| 'magenta'  | 'm'        | [1 0 1]     | '#FF00FF'              |            |
| 'yellow'   | 'y'        | [1 1 0]     | '#FFFF00'              |            |
| 'black'    | 'k'        | [0 0 0]     | '#000000'              |            |
| 'white'    | 'w'        | [1 1 1]     | '#FFFFFF'              |            |

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

| RGB Triplet            | Hexadecimal Color Code | Appearance |
|------------------------|------------------------|------------|
| [0 0.4470 0.7410]      | '#0072BD'              |            |
| [0.8500 0.3250 0.0980] | '#D95319'              |            |

Data Types: double | string

#### ax — Valid axis object

current axes (ax = gca) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The highlow plot is created in the axes specified by ax instead of in the current axes (ax = gca). The option ax can precede any of the input argument combinations.

Data Types: object

## Output Arguments

#### h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

**Introduced before R2006a**

## hist

Histogram for financial time series object

**Note** `hist` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

### Syntax

```
hist(tsobj, numbins)
ftshist = hist(tsobj, numbins)
[ftshist, binpos] = hist(tsobj, numbins)
```

### Description

`hist(tsobj, numbins)` calculates and displays the histogram of the data series contained in the financial time series object `tsobj`.

`ftshist = hist(tsobj, numbins)` calculates, but does not display, the histogram of the data series contained in the financial time series object `tsobj`. The output `ftshist` is a structure with field names similar to the data series names of `tsobj`.

`[ftshist, binpos] = hist(tsobj, numbins)` additionally returns the bin positions `binpos`. The positions are the centers of each bin. `binpos` is a column vector.

### Examples

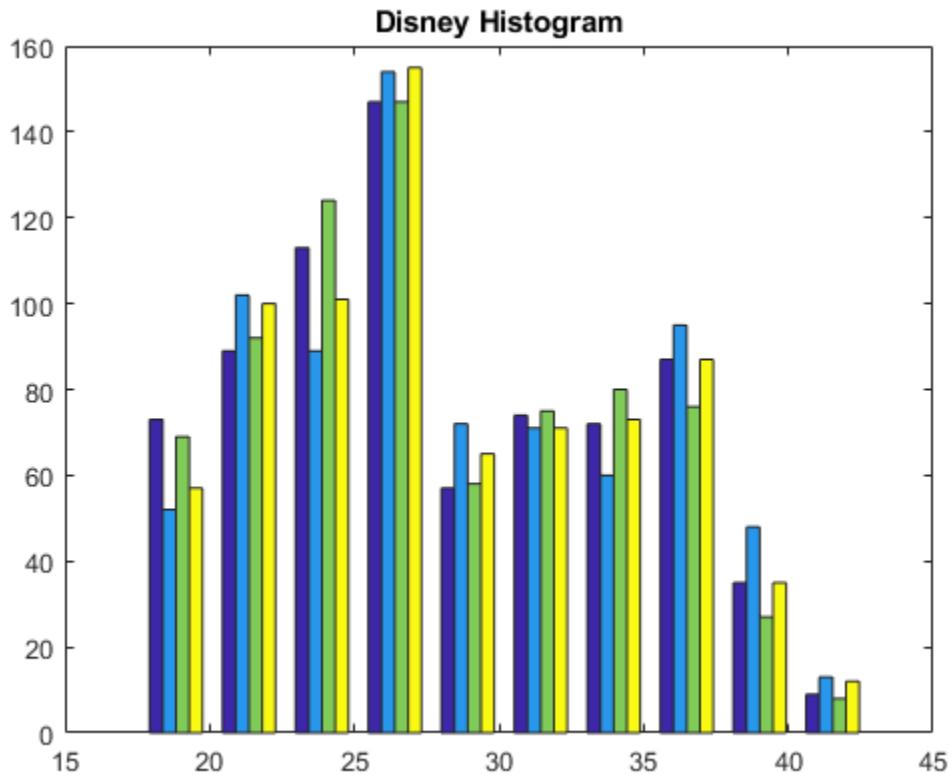

#### Create a Histogram

This example shows how to generate a histogram of Disney open, high, low, and close prices.

```
load disney.mat
dis = rmfield(dis, 'VOLUME'); % Remove VOLUME field
hist(dis)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat">

```
title('Disney Histogram')
```

## Input Arguments

### **tsobj — Financial time series object**

fints object

Financial time series object, specified as a fints object.

Data Types: object

### **numbins — Number of histogram bins**

10 (default) | positive numeric

(Optional) Number of histogram bins, specified as a positive numeric.

Data Types: double

## Output Arguments

### **ftshist — Field names similar to the data series names of tsobj**

struct

Field names similar to the data series names of tsobj, returned as a structure.

### **binpos — Bin positions for centers of bins**

column vector

Bin positions for centers of bins, returned as a column vector.

# holdings2weights

Portfolio holdings into weights

## Syntax

```
Weights = holdings2weights(Holdings,Prices,Budget)
```

## Arguments

|          |                                                                                                                                      |
|----------|--------------------------------------------------------------------------------------------------------------------------------------|
| Holdings | Number of portfolios (NPORTS) by number of assets (NASSETS) matrix with the holdings of NPORTS portfolios containing NASSETS assets. |
| Prices   | NASSETS vector of asset prices.                                                                                                      |
| Budget   | (Optional) Scalar or NPORTS vector of nonzero budget constraints. Default = 1.                                                       |

## Description

`Weights = holdings2weights(Holdings,Prices,Budget)` converts portfolio holdings into portfolio weights. The weights must satisfy a budget constraint such that the weights sum to `Budget` for each portfolio.

`Weights` is a NPORTS by NASSETS matrix containing the normalized weights of NPORTS portfolios containing NASSETS assets.

---

## Notes

- `Holdings` may be negative to indicate a short position, but the overall portfolio weights must satisfy a nonzero budget constraint.
  - The weights in each portfolio sum to the `Budget` value (which is 1 if `Budget` is unspecified.)
-

## Introduced before R2006a

# holidays

Holidays and nontrading days

## Syntax

```
H = holidays  
H = holidays(StartDate,EndDate)  
H = holidays(___,AltHolidays)
```

## Description

`H = holidays` returns a vector or datetime array corresponding to all holidays and nontrading days.

`H = holidays(StartDate,EndDate)` returns a vector or datetime array corresponding to the holidays and nontrading days between `StartDate` and `EndDate`, inclusive.

`H = holidays(___,AltHolidays)` returns a vector or datetime array corresponding to the alternate list of holidays and nontrading days.

## Examples

### Determine Holidays for a Given StartDate and EndDate

Create a vector of serial date numbers corresponding to all holidays and nontrading dates between a specified `StartDate` and `EndDate`:

```
H = holidays('jan 1 2001', 'jun 23 2001')  
H = 5×1  
  
730852  
730866  
730901  
730954  
730999  
  
datestr(H)  
ans = 5x11 char array  
'01-Jan-2001'  
'15-Jan-2001'  
'19-Feb-2001'  
'13-Apr-2001'  
'28-May-2001'
```

Alternatively, using a datetime array for `StartDate` and `EndDate` returns a datetime array for `H`.

```
H = holidays(datetime('1-Jan-2001','Locale','en_US'),...  
datetime('23-Jun-2001','Locale','en_US'))
```

```
H = 5x1 datetime
01-Jan-2001
15-Jan-2001
19-Feb-2001
13-Apr-2001
28-May-2001
```

## Input Arguments

### **StartDate — Start date**

serial date number | date character vector | datetime object

Start date, specified using a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

### **EndDate — End date**

serial date number | date character vector | datetime object

End date, specified using a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

### **AltHolidays — Alternate list of holidays and nontrading days**

serial date number | date character vector | datetime object

Alternate list of holidays and nontrading days, specified using a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

## Output Arguments

### **H — Dates corresponding to all holidays and nontrading days**

vector | datetime

Dates corresponding to all holidays and nontrading days, returned as a vector or a datetime array of dates.

---

**Note** If `StartDate`, `EndDate`, and `AltHolidays` are all either serial date numbers or date character vectors, `H` is returned as serial date numbers. If either `StartDate`, `EndDate`, or `AltHolidays` are datetime arrays, `H` is returned as a datetime array.

---

## More About

### **holidays**

The `holidays` function is based on a modern five-day workweek.

This function contains all holidays and special nontrading days for the New York Stock Exchange from January 1, 1885 to December 31, 2070.

Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures from 1885 to 2070 include Saturday trading days. To capture these dates, use the function `nyseclosures`. The results from `holidays` and `nyseclosures` are identical if the `WorkWeekFormat` in `nyseclosures` is 'Modern'.

## Introduced before R2006a

# horzcat

Concatenate financial time series objects horizontally

---

**Note** `horzcat` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

`horzcat`

## Description

`horzcat` implements horizontal concatenation of financial time series objects. `horzcat` essentially merges the data columns of the financial time series objects. The time series objects must contain the exact same dates and times.

When multiple instances of a data series name occur, concatenation adds a suffix to the current names of the data series. The suffix has the format `_objectname<n>`, where `n` is a number indicating the position of the time series, from left to right, in the concatenation command. The `n` part of the suffix appears only when there is more than one instance of a particular data series name.

The description fields are concatenated as well. They are separated by two forward slashes (//).

## Examples

Construct three financial time series, each containing a data series named `DataSeries`:

```
firstfts = fints((today:today+4)', (1:5)', 'DataSeries', 'd')
secondfts = fints((today:today+4)', (11:15)', 'DataSeries', 'd')
thirdfts = fints((today:today+4)', (21:25)', 'DataSeries', 'd')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints` (line 165)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints/display` (line 66)

```
firstfts =
```

```
desc: (none)
freq: Daily (1)

'dates: (5)'    'DataSeries: (5)'
'02-Oct-2017'   [           1]
'03-Oct-2017'   [           2]
'04-Oct-2017'   [           3]
'05-Oct-2017'   [           4]
'06-Oct-2017'   [           5]
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints` (line 165)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

```
> In fints/display (line 66)

secondfts =

desc: (none)
freq: Daily (1)

'dates: (5)'    'DataSeries: (5)'
'02-Oct-2017'   [           11]
'03-Oct-2017'   [           12]
'04-Oct-2017'   [           13]
'05-Oct-2017'   [           14]
'06-Oct-2017'   [           15]

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints (line 165)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)

thirdffts =

desc: (none)
freq: Daily (1)

'dates: (5)'    'DataSeries: (5)'
'02-Oct-2017'   [           21]
'03-Oct-2017'   [           22]
'04-Oct-2017'   [           23]
'05-Oct-2017'   [           24]
'06-Oct-2017'   [           25]

Concatenate the time series horizontally into a new financial time series newfts:

newfts = [firstfts secondfts thirdffts secondfts]

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/horzcat (line 56)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)

newfts =

desc: // // //
freq: Daily (1)

'dates: (5)'      'DataSeries_firstfts'   'DataSeries_secondft'   'DataSeries_third'
'          '': (5)           's2: (5)           '': (5)
'02-Oct-2017'     [           1]           [           11]           [
'03-Oct-2017'     [           2]           [           12]           [
'04-Oct-2017'     [           3]           [           13]           [
'05-Oct-2017'     [           4]           [           14]           [
'06-Oct-2017'     [           5]           [           15]           [
```

The resulting object `newfts` has data series names `DataSeries_firstfts`, `DataSeries_secondfts2`, `DataSeries_thirdffts`, and `DataSeries_secondfts4`.

Verify this with the command

```
fieldnames(newfts)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/fieldnames (line 21)
```

```
ans =
```

```
'desc'  
'freq'  
'dates'  
'DataSeries_firstfts'  
'DataSeries_secondfts2'  
'DataSeries_thirdffts'  
'DataSeries_secondfts4'  
'times'
```

Use **chfield** to change the data series names.

---

**Note** If all input objects have the same frequency, the new object has that frequency as well. However, if one of the objects concatenated has a different frequency from the others, the frequency indicator of the resulting object is set to Unknown (0).

---

## Introduced before R2006a

# inforatio

Calculate information ratio for one or more assets

## Syntax

```
inforatio(Asset,Benchmark)
[Ratio,TE] = inforatio(Asset,Benchmark)
```

## Description

`inforatio(Asset,Benchmark)` computes the information ratio for each asset relative to the Benchmark.

`[Ratio,TE] = inforatio(Asset,Benchmark)` computes the information ratio and tracking error for each asset relative to the Benchmark.

## Examples

### Compute Information Ratio

This example show how to calculate the information ratio using `inforatio` with example data, where the mean return of the market series is used as the return of the benchmark.

You can use `inforatio` to compute the information ratio for the given asset return data and the riskless asset return.

```
load FundMarketCash
Returns = tick2ret(TestData);
Benchmark = Returns(:,2);
InfoRatio = inforatio(Returns, Benchmark)

InfoRatio = 1x3
    0.0432      NaN     -0.0315
```

Since the market series has no risk relative to itself, the information ratio for the second series is undefined (which is represented as `NaN` in MATLAB®).

### Use Information Ratio to Compute Tracking Error

This example show how to calculate the tracking error using `inforatio` with example data, where the mean return of the market series is used as the return of the benchmark.

Given an asset or portfolio of assets and a benchmark, the relative standard deviation of returns between the asset or portfolio of assets and the benchmark is called tracking error.

```

load FundMarketCash
Returns = tick2ret(TestData);
Benchmark = Returns(:,2);
[InfoRatio, TrackingError] = inforatio(Returns, Benchmark)

InfoRatio = 1x3
    0.0432      NaN     -0.0315

TrackingError = 1x3
    0.0187      0     0.0390

```

Tracking error, also known as active risk, measures the volatility of active returns. Tracking error is a useful measure of performance relative to a benchmark since it is in units of asset returns. For example, the tracking error of 1.87% for the fund relative to the market in this example is reasonable for an actively managed, large-cap value fund.

## Input Arguments

### **Asset — Asset returns**

matrix

Asset returns, specified as a `NUMSAMPLES`  $\times$  `NUMSERIES` matrix with `NUMSAMPLES` observations of asset returns for `NUMSERIES` asset return series.

Data Types: `double`

### **Benchmark — Returns for a benchmark asset**

vector

Returns for a benchmark asset, specified as a `NUMSAMPLES` vector of returns for a benchmark asset. The periodicity must be the same as the periodicity of `Asset`. For example, if `Asset` is monthly data, then `Benchmark` should be monthly returns.

Data Types: `double`

## Output Arguments

### **Ratio — Information ratios**

vector

Information ratios, returned as a `1`  $\times$  `NUMSERIES` row vector of information ratios for each series in `Asset`. Any series in `Asset` with a tracking error of `0` has a `NaN` value for its information ratio.

### **TE — Tracking errors**

vector

Tracking errors, returned as a `1`  $\times$  `NUMSERIES` row vector of tracking errors, that is, the standard deviation of `Asset` relative to `Benchmark` returns, for each series.

---

**Note** `NaN` values in the data are ignored. If the `Asset` and `Benchmark` series are identical, the information ratio is `NaN` since the tracking error is `0`. The information ratio and the Sharpe ratio of an

Asset versus a riskless Benchmark (a Benchmark with standard deviation of returns equal to 0) are equivalent. This equivalence is not necessarily true if the Benchmark is risky.

---

"Performance Metrics Overview" on page 7-2

## Introduced in R2006b

# IRR

Internal rate of return

## Syntax

```
Return = irr(CashFlow)
[Return,AllRates] = irr(__)
```

## Description

`Return = irr(CashFlow)` calculates the internal rate of return for a series of periodic cash flows.

`IRR` uses the following conventions:

- If one or more internal rates of returns (warning if multiple) are strictly positive rates, `Return` sets to the minimum.
- If there is no strictly positive rate of returns, but one or multiple (warning if multiple) returns are nonpositive rates, `Return` sets to the maximum.
- If no real-valued rates exist, `Return` sets to `NaN` (no warnings).

`[Return,AllRates] = irr(__)` calculates the internal rate of return and a vector of all internal rates for a series of periodic cash flows.

## Examples

### Find a Single and Multiple Internal Rates of Return

Find the internal rate of return for a simple investment with a unique positive rate of return. The initial investment is \$100,000 and the following cash flows represent the yearly income from the investment

Year 1 \$10,000

Year 2 \$20,000

Year 3 \$30,000

Year 4 \$40,000

Year 5 \$50,000

Calculate the internal rate of return on the investment:

```
Return = irr([-100000 10000 20000 30000 40000 50000])
```

```
Return = 0.1201
```

If the cash flow payments were monthly, then the resulting rate of return is multiplied by 12 for the annual rate of return.

### Find Multiple Internal Rates of Return

Find the internal rate of return for multiple rates of return. The project has the following cash flows and a market rate of 10%.

```
CashFlow = [-1000 6000 -10900 5800]
```

```
CashFlow = 1x4
```

```
-1000           6000          -10900         5800
```

```
[Return, AllRates] = irr(CashFlow)
```

```
Return = 1.0000
```

```
AllRates = 3x1
```

```
-0.0488  
1.0000  
2.0488
```

The rates of return in **AllRates** are -4.88%, 100%, and 204.88%. Though some rates are lower and some higher than the market rate, based on the work of Hazen, any rate gives a consistent recommendation on the project. However, you can use a present value analysis in these kinds of situations. To check the present value of the project, use **pvvar**:

```
PV = pvvar(CashFlow, 0.10)
```

```
PV = -196.0932
```

The second argument is the 10% market rate. The present value is -196.0932, negative, so the project is undesirable.

### Input Arguments

#### **CashFlow — Stream of periodic cash flows**

vector | matrix

Stream of periodic cash flows, specified as a vector or matrix. The first entry in **CashFlow** is the initial investment. If **CashFlow** is a matrix, **irr** handles each column of **CashFlow** as a separate cash-flow stream.

Data Types: double

### Output Arguments

#### **Return — Internal rate of return**

vector

Internal rate of return associated to **CashFlow**, returned as a vector whose entry *j* is an internal rate of return for column *j* in **CashFlow**

#### **AllRates — All the internal rates of return**

serial date number | matrix

---

All the internal rates of return associated with `CashFlow`, returned as a matrix with the same number of columns as `CashFlow` and one less row. Also, column j in `AllRates` contains all the rates of return associated to column j in `CashFlow` (including complex-valued rates).

## Introduced before R2006a

## isbusday

True for dates that are business days

### Syntax

```
Busday = isbusday(Date)
Busday = isbusday(____, Holiday, Weekend)
```

### Description

`Busday = isbusday(Date)` returns logical true (1) if `Date` is a business day and logical false (0) otherwise.

`Busday = isbusday(____, Holiday, Weekend)`, using optional input arguments, returns logical true (1) if `Date` is a business day, and logical false (0) otherwise.

### Examples

#### Determine If a Given Date Is a Business Day

Determine if `Date` is a business day.

```
Busday = isbusday('16 jun 2001')
```

```
Busday = logical
    0
```

Determine if a `Date` vector are business days.

```
Date = ['15 feb 2001'; '16 feb 2001'; '17 feb 2001'];
Busday = isbusday(Date)
```

```
Busday = 3x1 logical array
```

```
1
1
0
```

Determine if a `Date` vector are business days using a datetime array.

```
Date = ['15-feb-2001'; '16-feb-2001'; '17-feb-2001'];
Busday = isbusday(datetime(Date, 'Locale', 'en_US'))
```

```
Busday = 3x1 logical array
```

```
1
1
0
```

Set June 21, 2003 (a Saturday) as a business day.

```
Weekend = [1 0 0 0 0 0 0];
isbusday('June 21, 2003', [], Weekend)

ans = logical
    1
```

If the second argument, *Holiday*, is empty ([ ]), the default *Holidays* vector (generated with *holidays* and then associated to the NYSE calendar) is used.

## Input Arguments

### Date — Date being checked

serial date number | date character vector | datetime array

Date being checked, specified as a serial date number, date character vector, or datetime array. *Date* can contain multiple dates, but they must all be in the same format. Dates are assumed to be whole date numbers or date stamps with no fractional or time values.

Data Types: double | char | datetime

### Holiday — Holidays and nontrading-day dates

non-trading day vector is determined by the routine *holidays* (default) | serial date number | date character vector | datetime array

Holidays and nontrading-day dates, specified as vector.

All dates in *Holiday* must be the same format: either serial date numbers, or date character vectors, or datetime arrays. (Using serial date numbers improves performance.) The *holidays* function supplies the default vector.

Data Types: double | char | datetime

### Weekend — Weekend days

[1 0 0 0 0 0 1] (Saturday and Sunday form the weekend) (default) | vector of length 7, containing 0 and 1, where 1 indicates weekend days

Weekend days, specified as a vector of length 7, containing 0 and 1, where 1 indicates weekend days and the first element of this vector corresponds to Sunday.

Data Types: double

## Output Arguments

### Busday — Logical true if a business day

logical 0 or 1

Logical true if a business day, returned as a logical true (1) if *Date* is a business day and logical false (0) otherwise.

## See Also

*busdate* | *fbusdate* | *holidays* | *lbusdate* | *datetime*

**Topics**

# iscompatible

Structural equality

**Note** `iscompatible` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

## Syntax

```
iscomp = iscompatible(tsobj_1,tsobj_2)
```

## Arguments

|                               |                                          |
|-------------------------------|------------------------------------------|
| <code>tsobj_1, tsobj_2</code> | A pair of financial time series objects. |
|-------------------------------|------------------------------------------|

## Description

`iscomp = iscompatible(tsobj_1,tsobj_2)` returns 1 if both financial time series objects `tsobj_1` and `tsobj_2` have the same dates and data series names. It returns 0 if any component is different.

`iscomp = 1` indicates that the two objects contain the same number of data points and equal number of data series. However, the values contained in the data series can be different.

**Note** Data series names are case-sensitive.

## See Also

`isequal`

## Topics

## Introduced before R2006a

## isequal

Multiple object equality

---

**Note** `isequal` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

### Syntax

`iseq = isequal(tsobj_1,tsobj_2, ...)`

### Arguments

|                          |                                          |
|--------------------------|------------------------------------------|
| <code>tsobj_1 ...</code> | A list of financial time series objects. |
|--------------------------|------------------------------------------|

### Description

`iseq = isequal(tsobj_1,tsobj_2, ...)` returns `1` if all listed financial time series objects have the same dates, data series names, and values contained in the data series. It returns `0` if any of those components is different.

---

**Note** Data series names are case-sensitive.

---

`iseq = 1` implies that each object contains the same number of dates and the same data. Only the descriptions can differ.

# isempty

True for empty financial time series objects

**Note** `isempty` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

## Syntax

```
tf = isempty(fts)
```

## Arguments

|     |                               |
|-----|-------------------------------|
| fts | Financial time series object. |
|-----|-------------------------------|

## Description

`isempty` for financial time series objects is based on the MATLAB `isempty` function. See `isempty`.

`tf = isempty(fts)` returns true (1) if `fts` is an empty financial time series object and false (0) otherwise. An empty financial time series object has no elements, that is, `length(fts) = 0`.

## See Also

## Introduced before R2006a

## isfield

Check whether character vector is field name

**Note** `isfield` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

### Syntax

```
F = isfield(tsobj, name)
```

### Description

`F = isfield(tsobj, name)` returns true (1) if `name` is the name of a data series in `tsobj`. Otherwise, `isfield` returns false (0).

### See Also

`fieldnames` | `getfield` | `setfield`

“What Is the Financial Time Series App?” on page 14-2

### Introduced before R2006a

# issorted

Check whether dates and times are monotonically increasing

**Note** `issorted` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

## Syntax

```
monod = issorted(tsobj)
```

## Arguments

|       |                              |
|-------|------------------------------|
| tsobj | Financial time series object |
|-------|------------------------------|

## Description

`monod = issorted(tsobj)` returns 1 if the dates and times in `tsobj` are monotonically increasing or 0 if they are not.

## See Also

`sortfts`

## Topics

“What Is the Financial Time Series App?” on page 14-2

## Introduced before R2006a

## kagi

Kagi chart

---

**Note** `kagi` is updated to accept data input as a matrix, `timetable`, or `table`.

The syntax for `kagi` has changed. Previously, when using table input, the first column of dates could be serial date numbers, date character vectors, or datetime arrays, and you were required to have specific number of columns.

When using table input, the new syntax for `kagi` supports:

- No need for time information. If you want to pass in date information, use `timetable` input.
  - No requirement of specific number of columns. However, you must provide valid column names. `kagi` must contain a column named ‘`price`’ (case insensitive).
- 

### Syntax

```
kagi(Data)
h = kagi(ax,Data)
```

### Description

`kagi(Data)` plots a Kagi chart from a series of prices.

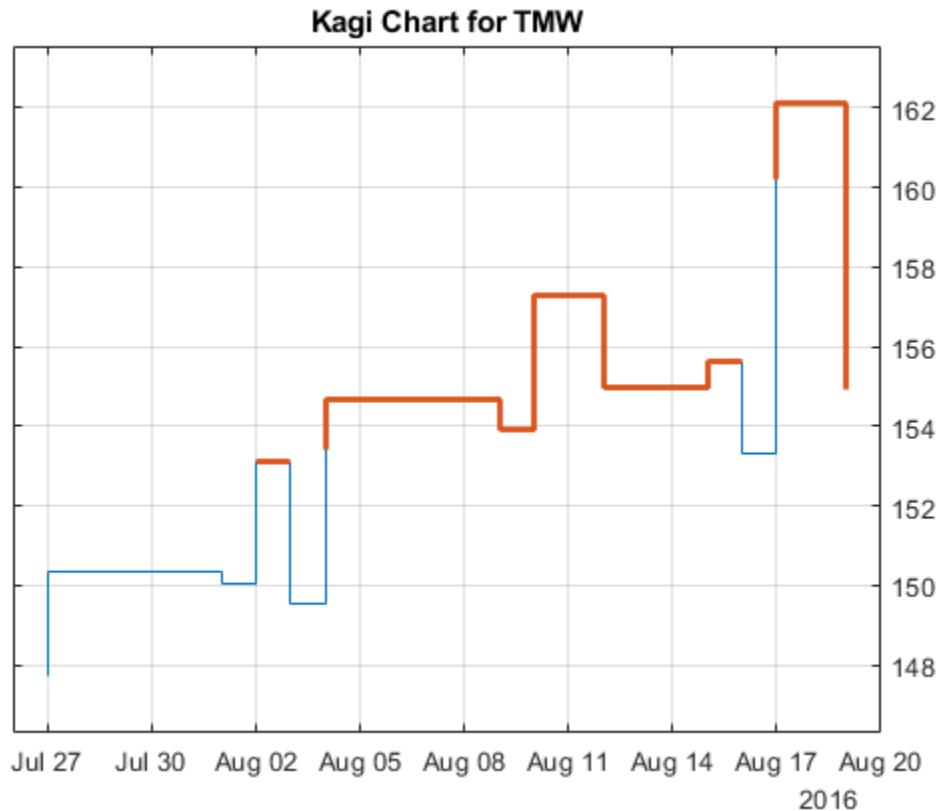

`h = kagi(ax,Data)` adds an optional argument for `ax`.

### Examples

#### Generate a Kagi Chart for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock. This Kagi chart is for closing prices of the stock TMW for the most recent 21 days. Note that the variable name of asset price is be renamed to ‘`Price`’ (case insensitive).

```
load SimulatedStock.mat
TMW.Properties.VariableNames{'Close'} = 'Price';
kagi(TMW(end-20:end,:))
title('Kagi Chart for TMW')
```

## Input Arguments

### Data — Data for a series of prices

matrix | table | timetable

Data for a series of prices, specified as a matrix, table, or timetable. Timetables and tables with M rows must contain a variable named 'Price' (case insensitive).

Data Types: double | table | timetable

### ax — Valid axis object

current axes (ax = gca) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The kagi plot is created in the axes specified by ax instead of in the current axes (ax = gca). The option ax can precede any of the input argument combinations.

Data Types: object

## Output Arguments

### h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

**See Also**

# lagts

Lag time series object

---

**Note** `lagts` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
newfts = lagts(oldfits)
newfts = lagts(oldfits,lagperiod)
newfts = lagts(oldfits,lagperiod,padmode)
```

## Description

`newfts = lagts(oldfits)` delays the data series in `oldfits` by one time series date entry and returns the result in the object `newfts`. The end is padded with zeros, by default.

`newfts = lagts(oldfits,lagperiod)` shifts time series values to the right on an increasing time scale. `lagts` delays the data series to happen later. `lagperiod` is the number of lag periods expressed in the frequency of the time series object `oldfits`. For example, if `oldfits` is a daily time series, `lagperiod` is specified in days. `lagts` pads the data with zeros (default).

`newfts = lagts(oldfits,lagperiod,padmode)` lets you pad the data with an arbitrary value, `Nan`, or `Inf` rather than zeros by setting `padmode` to the desired value.

## Examples

### Lag the Financial Time Series Object

- Create a `fints` object.

```
dates_and_times = (now:now+5)'
dates_and_times =
1.0e+05 *
7.3840
7.3840
7.3840
7.3841
7.3841
7.3841
```

```
tsobj = fints(dates_and_times, randn(6,1))
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert F  
> In fints (line 169)

```
tsobj =  
  
desc: (none)  
freq: Unknown (0)  
  
{'dates: (6)'}    {'times: (6)'}    {'series1: (6)'}  
{'07-Sep-2021'}    {'12:30'}        {[      0.5377]}  
{'08-Sep-2021'}    {'12:30'}        {[      1.8339]}  
{'09-Sep-2021'}    {'12:30'}        {[     -2.2588]}  
{'10-Sep-2021'}    {'12:30'}        {[      0.8622]}  
{'11-Sep-2021'}    {'12:30'}        {[      0.3188]}  
{'12-Sep-2021'}    {'12:30'}        {[     -1.3077]}
```

- 2 Delay a financial time series object by a specified time step using `lagts`.

```
newfts = lagts(tsobj,2)
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see Convert F

> In `fints/lagts` (line 33)

```
newfts =
```

```
desc: LAGTS on  
freq: Unknown (0)  
  
{'dates: (6)'}    {'times: (6)'}    {'series1: (6)'}  
{'07-Sep-2021'}    {'12:30'}        {[      0]}  
{'08-Sep-2021'}    {'12:30'}        {[      0]}  
{'09-Sep-2021'}    {'12:30'}        {[      0.5377]}  
{'10-Sep-2021'}    {'12:30'}        {[      1.8339]}  
{'11-Sep-2021'}    {'12:30'}        {[     -2.2588]}  
{'12-Sep-2021'}    {'12:30'}        {[      0.8622]}
```

## Input Arguments

### **oldfts — Financial time series object**

`fints` object

Financial time series object, specified as a `fints` object.

Data Types: `object`

### **lagperiod — Number of lag periods expressed in the frequency of the time series object**

`integer`

Number of lag periods expressed in the frequency of the time series object, specified as an integer.

Data Types: `double`

### **padmode — Data padding value**

`character vector`

Data padding value, specified as a character vector with a value of '`'NaN'`' or '`'Inf'`'.

Data Types: `char`

## Output Arguments

### **newfts — Financial time series object**

fints object

Financial time series object, returned as a `fints` object.

## See Also

`leadts`

## Topics

“Data Transformation and Frequency Conversion” on page 13-11

## Introduced before R2006a

## lbusdate

Last business date of month

### Syntax

```
Date = lbusdate(Year,Month)
Date = lbusdate(___,Holiday,Weekend,outputType)
```

### Description

`Date = lbusdate(Year,Month)` returns the serial date number for the last business date of the given year and month.

`Year` and `Month` can contain multiple values. If one contains multiple values, the other must contain the same number of values or a single value that applies to all. For example, if `Year` is a 1-by-N vector of integers, then `Month` must be a 1-by-N vector of integers or a single integer. `Date` is then a 1-by-N vector of date numbers.

Use the function `datestr` to convert serial date numbers to formatted date character vectors.

`Date = lbusdate(___,Holiday,Weekend,outputType)` returns the serial date number for the last business date of the given year and month using optional input arguments. The optional argument `Holiday` specifies nontrading days.

If neither `Holiday` nor `outputType` are specified, `Date` is returned as a serial date number. If `Holiday` is specified, but not `outputType`, then the type of the `Holiday` variable controls the type of date. If `Holiday` is a serial date number or date character vector, then `Date` is returned as a serial date number.

### Examples

#### Determine the Last Business Date of a Given Year and Month

Determine the `Date` using an input argument for `Year` and `Month`.

```
Date = lbusdate(2001, 5)
```

```
Date = 731002
```

```
datestr(Date)
```

```
ans =
'31-May-2001'
```

Determine the `Date` using the optional input argument for `outputType`.

```
Date = lbusdate(2001, 11,[],[],'datetime')
```

```
Date = datetime
30-Nov-2001
```

Indicate that Saturday is a business day by appropriately setting the **Weekend** argument. May 31, 2003, is a Saturday. Use **lbusdate** to check that this Saturday is actually the last business day of the month.

```
Weekend = [1 0 0 0 0 0];
Date = datestr(lbusdate(2003, 5, [], Weekend))

Date =
'31-May-2003'
```

## Input Arguments

### **Year — Year to determine occurrence of weekday**

4-digit integer | vector of 4-digit integers

Year to determine occurrence of weekday, specified as a 4-digit integer or vector of 4-digit integers.

Data Types: **single** | **double**

### **Month — Month to determine occurrence of weekday**

integer with value 1 through 12 | vector of integers with values 1 through 12

Month to determine occurrence of weekday, specified as an integer or vector of integers with values 1 through 12.

Data Types: **single** | **double**

### **Holiday — Holidays and nontrading-day dates**

non-trading day vector is determined by the routine **holidays** (default) | serial date number | date character vector | datetime array

Holidays and nontrading-day dates, specified as vector.

All dates in **Holiday** must be the same format: either serial date numbers, or date character vectors, or datetime arrays. (Using serial date numbers improves performance.) The **holidays** function supplies the default vector.

If **Holiday** is a datetime array, then **Date** is returned as a datetime array. If **outputType** is specified, then its value determines the output type of **Date**. This overrides any influence of **Holiday**.

Data Types: **double** | **char** | **datetime**

### **Weekend — Weekend days**

[1 0 0 0 0 0 1] (Saturday and Sunday form the weekend) (default) | vector of length 7, containing 0 and 1, where 1 indicates weekend days

Weekend days, specified as a vector of length 7, containing 0 and 1, where 1 indicates weekend days and the first element of this vector corresponds to Sunday.

Data Types: **double**

### **outputType — Year to determine days**

'datenum' (default) | character vector with values 'datenum' or 'datetime'

A character vector specified as either 'datenum' or 'datetime'. The output **Date** is in serial date format if 'datenum' is specified, or datetime format if 'datetime' is specified. By default the output **Date** is in serial date format, or match the format of **Holiday**, if specified.

Data Types: char

## Output Arguments

### **Date — Date for the last business date of given year and month**

serial date number | date character vector | datetime array

Date for the last business date of a given year and month, returned as a serial date number, date character vector, or datetime array.

If neither **Holiday** nor **outputType** are specified, **Date** is returned as a serial date number. If **Holiday** is specified, but not **outputType**, then the type of the **holiday** variable controls the type of date:

- If **Holiday** is a serial date number or date character vector, then **Date** is returned as a serial date number
- If **Holiday** is a datetime array, then **Date** is returned as a datetime array.

# leadts

Lead time series object

---

**Note** `leadts` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = leadts(oldfits)
newfts = leadts(oldfits, leadperiod)
newfts = leadts(oldfits, leadperiod, padmode)
```

## Description

`newfts = leadts(oldfits)` advances the data series in `oldfits` by one time series date entry and returns the result in the object `newfts`. The end will be padded with zeros, by default.

`newfts = leadts(oldfits, leadperiod)` shifts time series values to the left on an increasing time scale. `leadts` advances the data series to happen at an earlier time. `leadperiod` is the number of lead periods expressed in the frequency of the time series object `oldfits`. For example, if `oldfits` is a daily time series, `leadperiod` is specified in days. `leadts` pads the data with zeros (default).

`newfts = leadts(oldfits, leadperiod, padmode)` lets you pad the data with an arbitrary value, `Nan`, or `Inf` rather than zeros by setting `padmode` to the desired value.

## Examples

### Advance the Financial Time Series Object

- Create a `fints` object.

```
dates_and_times = (now:now+5)'
dates_and_times =
    1.0e+05 *
    7.3840
    7.3840
    7.3840
    7.3841
    7.3841
    7.3841

tsobj = fints(dates_and_times, randn(6,1))
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see Convert F  
> In `fints` (line 169)

```
tsobj =  
  
desc: (none)  
freq: Unknown (0)  
  
{'dates: (6)'} {'times: (6)'} {'series1: (6)'}  
{'07-Sep-2021'} {'12:30'} {[ 0.5377]}  
{'08-Sep-2021'} {'12:30'} {[ 1.8339]}  
{'09-Sep-2021'} {'12:30'} {[ -2.2588]}  
{'10-Sep-2021'} {'12:30'} {[ 0.8622]}  
{'11-Sep-2021'} {'12:30'} {[ 0.3188]}  
{'12-Sep-2021'} {'12:30'} {[ -1.3077]}
```

- 2 Advance a financial time series object by a specified time step using `leadts`.

```
newfts = leadts(tsobj,2)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert FINTS Objects to TIMETABLE.

```
> In fints/leadts (line 33)
```

```
newfts =
```

```
desc: LEADTS on  
freq: Unknown (0)  
  
{'dates: (6)'} {'times: (6)'} {'series1: (6)'}  
{'07-Sep-2021'} {'12:30'} {[ -2.2588]}  
{'08-Sep-2021'} {'12:30'} {[ 0.8622]}  
{'09-Sep-2021'} {'12:30'} {[ 0.3188]}  
{'10-Sep-2021'} {'12:30'} {[ -1.3077]}  
{'11-Sep-2021'} {'12:30'} {[ 0]}  
{'12-Sep-2021'} {'12:30'} {[ 0]}
```

## Input Arguments

### **oldfts — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

### **leadperiod — Number of lead periods expressed in the frequency of the time series object**

integer

Number of lead periods expressed in the frequency of the time series object, specified as an integer.

Data Types: double

### **padmode — Data padding value**

character vector

Data padding value, specified as a character vector with a value of '`'NaN'`' or '`'Inf'`'.

Data Types: char

## Output Arguments

### **newfts — Financial time series object**

fints object

Financial time series object, returned as a `fints` object.

## See Also

`lagts`

## Topics

“Data Transformation and Frequency Conversion” on page 13-11

## Introduced before R2006a

## length

Get number of dates (rows)

---

**Note** `length` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

### Syntax

```
lenfts = length(tsobj)
```

### Description

`lenfts = length(tsobj)` returns the number of dates (rows) in the financial time series object `tsobj`. This is the same as issuing `lenfts = size(tsobj,1)`

### Examples

#### Obtain Number of Dates (Rows) in the Financial Time Series Object

- 1 Create a `fints` object.

```
dates_and_times = (now:now+5)'
dates_and_times =
1.0e+05 *
7.3840
7.3840
7.3840
7.3841
7.3841
7.3841
```

```
tsobj = fints(dates_and_times, randn(6,1))
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert F
> In fints (line 169)
```

```
tsobj =
desc: (none)
freq: Unknown (0)

{'dates: (6)'}    {'times: (6)'}    {'series1: (6)'}
{'07-Sep-2021'}  {'12:30'}        {[      0.5377]}
{'08-Sep-2021'}  {'12:30'}        {[      1.8339]}
{'09-Sep-2021'}  {'12:30'}        {[     -2.2588]}
{'10-Sep-2021'}  {'12:30'}        {[      0.8622]}
{'11-Sep-2021'}  {'12:30'}        {[      0.3188]}
{'12-Sep-2021'}  {'12:30'}        {[     -1.3077]}
```

- 
- 2** Get number of dates (rows) using `length`.

```
lenfts = length(tsobj)
```

```
lenfts =
```

```
6
```

## Input Arguments

### **tsobj — Financial time series object**

`fints` object

Financial time series object, specified as a `fints` object.

Data Types: `object`

## Output Arguments

### **lenfts — Number of dates (rows) in the financial time series object**

`numeric`

Number of dates (rows) in the financial time series object, returned as a numeric.

## See Also

`size | length`

## lifetableconv

Convert life table series into life tables with forced termination

### Syntax

```
[qx, lx, dx] = lifetableconv(x0, lx0)  
[qx, lx, dx] = lifetableconv(x0, y0, y0type)
```

### Description

[qx, lx, dx] = lifetableconv(x0, lx0) converts life table with ages x0 and survival counts lx0 into life tables with termination.

[qx, lx, dx] = lifetableconv(x0, y0, y0type) converts life table with ages x0 and series y0, specified by the optional argument y0type, into life tables with termination.

### Examples

#### Convert Life Table Series into Life Tables with Forced Termination

Load the life table data file.

```
load us_lifetable_2009
```

Convert life table series into life tables with forced termination.

```
[qx, lx, dx] = lifetableconv(x, lx);  
display(qx(1:20,:))
```

plot(x,log(qx))
legend(series)

```

### Convert the Life Table dx Series After Fitting and Generating the Life Table Series

Load the life table data file.

```
load us_lifetable_2009
```

Calibrate life table from survival data with the default Heligman-Pollard parametric model.

```
a = lifetablefit(x,lx)
```

```
a = 8×3
```

|         |         |         |

Plot the dx series and display the legend. The series dx is the number of people who die out of 100,000 alive at birth between age x and the next age in the series.

```
plot((0:119),dx(1:end-1,:));
legend(series, 'location', 'northwest');
title('bfLife Table Yearly Decremnts');
xlabel('Age');
ylabel('Number Dying within a Given Year');
```

## Input Arguments

### **x0 — Increasing ages for raw data**

vector of nonnegative integer values

Increasing ages for raw data, specified as nonnegative integer values in an  $\mathbb{N}0$  vector.

The vector of ages  $x$  must contain nonnegative integer values. If the input series is the discrete survival function  $lx$ , then the starting age need only be nonnegative. Otherwise, the starting age must be 0.

Data Types: double

### **lx0 — Collection of num standardized survivor series**

matrix

Collection of num standardized survivor series, specified as an  $\mathbb{N}0$ -by-num matrix. The input  $lx0$  series is the number of people alive at age  $x$ , given 100,000 alive at birth. Values of 0 or NaN in the input table  $lx0$  are ignored.

Data Types: double

### **y0 — Collection of num life table series to be converted**

matrix

Collection of `num` life table series to be converted, specified as an `N0`-by-`num` matrix. The default `y0` series is `lx0`.

Data Types: double

**`y0type` — Type of mortality series for input `y0` with default '`lx`'**  
`'lx'` (default) | character vector with values '`qx`', '`lx`', '`dx`'

(Optional) Type of mortality series for input `y0`, specified as a character vector with one of the following values:

- '`qx`' — Input is a table of discrete hazards (`qx`).
- '`lx`' — Input is a table of discrete survival counts (`lx`).
- '`dx`' — Input is a table of discrete decrements (`dx`).

Whereas the output series have forced termination, the input series (`y0`) can have one of several types of termination:

- Natural termination runs out to the last person so that `lx` goes to 0, `qx` goes to 1, and `dx` goes to 0. For more information, see "Natural Termination" on page 19-1052.
- Truncated termination stops at a terminal age so that `lx` is positive, `qx` is less than 1, and `dx` is positive. Any ages after the terminal age are NaN values. For more information, see "Truncated Termination" on page 19-1053.

Data Types: char

## Output Arguments

**`qx` — Discrete hazard function**  
matrix

Discrete hazard function, returned as an `N0`-by-`num` matrix with forced termination. For more information, see "Forced Termination" on page 19-1052.

The series `qx` is the conditional probability that a person at age `x` will die between age `x` and the next age in the series.

**`lx` — Discrete survival function**  
matrix

Discrete survival function, returned as an `N0`-by-`num` matrix with forced termination. For more information, see "Forced Termination" on page 19-1052.

The series `lx` is the number of people alive at age `x`, given 100,000 alive at birth.

**`dx` — Discrete decrements function**  
matrix

Discrete decrements function, returned as an `N0`-by-`num` matrix with forced termination. For more information, see "Forced Termination" on page 19-1052.

The series `dx` is the number of people who die out of 100,000 alive at birth, between age `x` and the next age in the series.

## More About

### Forced Termination

Most modern life tables have “forced” termination. Forced termination means that the last row of the life table applies for all persons with ages on or after the last age in the life table.

This sample illustrates forced termination.

#### United States Life Tables 2009

| $x$  | $l_x$ WM | $l_x$ WF | $l_x$ BM | $l_x$ BF | $q_x$ WM | $q_x$ WF | $q_x$ BM | $q_x$ BF |

| 96   | 4200     | 9572     | 3202     | 8930     | 0.27881  | 0.232971 | 0.24391  | 0.198992 |
| 97   | 3029     | 7342     | 2421     | 7153     | 0.299439 | 0.253337 | 0.259397 | 0.214036 |
| 98   | 2122     | 5482     | 1793     | 5622     | 0.320452 | 0.27417  | 0.274958 | 0.229634 |
| 99   | 1442     | 3979     | 1300     | 4331     | 0.341886 | 0.295803 | 0.291538 | 0.245671 |
| 100+ | 949      | 2802     | 921      | 3267     | 1        | 1        | 1        | 1        |

In this case, the last row of the life table applies for all persons aged 100 or older. Specifically,  $q_x$  probabilities are  ${}_1q_x$  for ages less than 100 and, technically,  ${}_\infty q_x$  for age 100.

Forced termination has terminal age values that apply to all ages after the terminal age so that  $l_x$  is positive,  $q_x$  is 1, and  $d_x$  is positive. Ages after the terminal age are NaN values, although  $l_x$  and  $d_x$  can be 0 and  $q_x$  can be 1 for input series. Forced termination is triggered by a naturally terminating series, the last age in a truncated series, or the first NaN value in a series.

### Natural Termination

Before 1970, life tables were often published with data that included all ages for which persons associated with a given series were still alive. Tables in this form have “natural” termination. In natural termination, the last row of the life table for each series counts the deaths or probabilities of deaths of the last remaining person at the corresponding age. Tables in this form can be problematic due to the granularity of the data and the fact that groups of series can terminate at distinct ages. Natural termination is illustrated in the following sample of the last few years of a life table.

#### United States Life Tables 1940

| $x$ | $l_x$ WM | $l_x$ WF | $l_x$ BM | $l_x$ BF | $q_x$ WM | $q_x$ WF | $q_x$ BM | $q_x$ BF |
|-----|----------|----------|----------|----------|----------|----------|----------|----------|
| 103 | 14       | 29       | 59       | 234      | 0.428571 | 0.413793 | 0.389831 | 0.333333 |
| 104 | 8        | 17       | 36       | 156      | 0.5      | 0.470588 | 0.416667 | 0.358974 |
| 105 | 4        | 9        | 21       | 100      | 0.5      | 0.444444 | 0.47619  | 0.38     |
| 106 | 2        | 5        | 11       | 62       | 0.5      | 0.4      | 0.454545 | 0.403226 |
| 107 | 1        | 3        | 6        | 37       | 0        | 0.666667 | 0.5      | 0.432432 |
| 108 | 1        | 1        | 3        | 21       | 1        | 0        | 0.666667 | 0.47619  |
| 109 |          | 1        | 1        | 11       |          | 1        | 1        | 0.454545 |
| 110 |          |          |          | 6        |          |          | 0.5      |          |
| 111 |          |          |          | 3        |          |          | 0.666667 |          |
| 112 |          |          |          | 1        |          |          | 0        |          |
| 113 |          |          |          | 1        |          |          | 1        |          |
| 114 |          |          |          |          |          |          |          |          |

This form for life tables poses a number of issues that go beyond the obvious statistical issues. First, the  $l_x$  table on the left terminates at ages 108, 109, 109, and 113 for the four series in the table. Technically, the numbers after these ages are 0, but can also be NaN values because no person is alive after these terminating ages. Second, the probabilities  $q_x$  on the right terminate with fluctuating probabilities that go from 0 to 1 in some cases. In this case, however, all probabilities are  $1q_x$  probabilities (unlike the forced termination probabilities). You can argue that the probabilities after the ages of termination can be 1 (anyone alive at this age is expected to die in the next year), 0 (the age lies outside the support of the probability distribution), or NaN values.

### Truncated Termination

Truncated termination occurs with truncation of life tables at an arbitrary age. For example, from 1970-1990, United States life tables truncated at age 85. This format is problematic because life table probabilities must either terminate with probability 1 (forced termination) or discard data that exceeds the terminating age. This sample of the last few years of a life table illustrates truncated termination. The raw data for this table is the  $l_x$  series. The  $q_x$  series is derived from this series.

#### United States Life Tables 1980

| $x$ | $l_x$ WM | $l_x$ WF | $l_x$ BM | $l_x$ BF | $q_x$ WM | $q_x$ WF | $q_x$ BM | $q_x$ BF |
|-----|----------|----------|----------|----------|----------|----------|----------|----------|
| 78  | 38558    | 61100    | 25481    | 45776    | 0.078064 | 0.045221 | 0.082689 | 0.054789 |
| 79  | 35548    | 58337    | 23374    | 43268    | 0.084477 | 0.050037 | 0.088303 | 0.059351 |
| 80  | 32545    | 55418    | 21310    | 40700    | 0.091504 | 0.055542 | 0.094603 | 0.064619 |
| 81  | 29567    | 52340    | 19294    | 38070    | 0.099165 | 0.061922 | 0.101741 | 0.070607 |
| 82  | 26635    | 49099    | 17331    | 35382    | 0.107528 | 0.06935  | 0.109746 | 0.077356 |
| 83  | 23771    | 45694    | 15429    | 32645    | 0.116613 | 0.078194 | 0.118608 | 0.084822 |
| 84  | 20999    | 42121    | 13599    | 29876    | 0.126339 | 0.081788 | 0.128392 | 0.093018 |
| 85  | 18346    | 38676    | 11853    | 27097    |          |          |          |          |

This life table format poses problems for termination because, for example, over 27% of the population for the fourth  $l_x$  series is still alive at age 85. To claim that the probability of dying for all ages after age 85 is 100% might be true but is uninformative. Notwithstanding the statistical issues, however, tables in this form are completed by forced termination.

## lifetablefit

Calibrate life table from survival data with parametric models

### Syntax

```
[a,elx] = lifetablefit(x,lx)
[a,elx] = lifetablefit(___,lifemodel,objtype,interpmethod,a0)
```

### Description

`[a,elx] = lifetablefit(x,lx)` calibrates a life table, `x`, from survival data, `lx`, using parametric models.

`[a,elx] = lifetablefit(___,lifemode,objtype,interpmethod,a0)` calibrates a life table, `x`, from survival data, `lx`, using parametric models using optional arguments for `lifemode`, `objtype`, `interpmethod`, and `a0`.

### Examples

#### Calibrate Life Table from Survival Data Using a Heligman-Pollard Parametric Model

Load the life table data file.

```
load us_lifetable_2009
```

Calibrate the life table from survival data using the default `heligman-pollard` parametric model.

```
[a,elx] = lifetablefit(x,lx);
display(a)
```

```
a = 8x3
```

Plot the qx series and display the legend. The series qx is the conditional probability that a person at age x will die between age x and the next age in the series

```
plot(x, log(qx))
legend(series)
```

## Input Arguments

**x — Increasing ages for raw data**

vector of nonnegative integers

Increasing ages for raw data, specified as a N vector for nonnegative integers.

Data Types: double

### **lx — Collection of num discrete survival counts**

matrix

Collection of num discrete survival counts, specified as an N-by-num matrix. The input lx series is the number of people alive at age x, given 100,000 alive at birth. Values of 0 or NaN in the input table lx are ignored.

Data Types: double

### **lifemodel — Parametric mortality model type**

'heligman-pollard' (default) | character vector with values 'heligman-pollard', 'heligman-pollard-2', 'heligman-pollard-3', 'gompertz', 'makeham', 'siler'

(Optional) Parametric mortality model type, specified as a character vector with one of the following values:

- 'heligman-pollard' — Eight-parameter Heligman-Pollard model (version 1), specified in terms of the discrete hazard function:

$$\frac{q(x)}{1 - q(x)} = A^{(x+B)^C} + D \exp(-E(\log \frac{x}{F})^2) + GH^X$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E, F, G, H \geq 0$ .

- 'heligman-pollard-2' — Eight-parameter Heligman-Pollard model (version 2), specified in terms of the discrete hazard function:

$$\frac{q(x)}{1 - q(x)} = A^{(x+B)^C} + D \exp(-E(\log \frac{x}{F})^2) + \frac{GH^X}{1 + GH^X}$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E, F, G, H \geq 0$ .

- 'heligman-pollard-3' — Eight-parameter Heligman-Pollard model (version 3), specified in terms of the discrete hazard function:

$$q(x) = A^{(x+B)^C} + D \exp(-E(\log \frac{x}{F})^2) + GH^X$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E, F, G, H \geq 0$ .

- 'gompertz' — Two-parameter Gompertz model, specified in terms of the continuous hazard function:

$$h(x) = A \exp(Bx)$$

for ages  $x \geq 0$ , with parameters  $A, B \geq 0$ .

- 'makeham' — Three-parameter Gompertz-Makeham model, specified in terms of the continuous hazard function:

$$h(x) = A \exp(Bx) + C$$

for ages  $x \geq 0$ , with parameters  $A, B, C \geq 0$ .

- 'siler' — Five-parameter Siler model, specified in terms of the continuous hazard function:

$$h(x) = A \exp(Bx) + C + D \exp(-Ex)$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E \geq 0$ .

Data Types: char

**objtype — Objective for nonlinear least-squares estimation**

'ratio' (default) | character vector with values 'ratio' 'logratio'

(Optional) Objective for nonlinear least-squares estimation, specified as a character vector with the following values:

- 'ratio' — Given raw data  $q_x$  and model estimates  $\hat{q}_x$  for  $x = 1, \dots, N$ , the first objective (which is the preferred objective) has the form

$$\Phi = \sum_{x=1}^N \left(1 - \frac{\hat{q}_x}{q_x}\right)^2$$

- 'logratio' — Given raw data  $q_x$  and model estimates  $\hat{q}_x$  for  $x = 1, \dots, N$ , the second objective has the form

$$\Phi = \sum_{x=1}^N (\log(\hat{q}_x) - \log(q_x))^2$$

Data Types: char

**interpmethod — Interpolation method to use for abridged life table inputs**

'cubic' (default) | character vector with values 'cubic', 'linear', 'none'

(Optional) Interpolation method to use for abridged life table inputs, specified as a character vector with the following values:

- 'cubic' — Cubic interpolation that uses 'pchip' method in `interp1`.
- 'linear' — Linear interpolation.
- 'none' — No interpolation.

---

**Note** If the ages in  $x$  are not consecutive years and interpolation is set to 'none', then the estimates for the parameters are suitable only for the age vector  $x$ .

If you use the parameter estimates to compute life table values for arbitrary years, interpolate using the default 'cubic' method.

Interpolation with abridged life tables forms internal interpolated full life tables, which usually improves model fits.

---

Data Types: char

**a0 — Initial parameter estimate to be applied to all series**

vector

(Optional) Initial parameter estimate to be applied to all series, specified as a `numparam` vector. This vector must conform to the number of parameters in the model specified using the `lifemode` argument.

Data Types: double

## Output Arguments

### a — Parameter estimates for each num series

matrix

Parameter estimates for each num series, returned as a numparam-by-num matrix.

### elx — Estimated collection of num standardized survivor series

matrix

Estimated collection of num standardized survivor series, returned as an N-by-num matrix. The elx output series is the number of people alive at age x, given 100,000 alive at birth. Values of 0 or NaN in the input table lx are ignored.

"Case Study for Life Tables Analysis" on page 2-49  
"About Life Tables" on page 2-47

## Introduced in R2015a

# **lifetablegen**

Generate life table series from calibrated mortality model

## **Syntax**

```
[qx, lx, dx] = lifetablegen(x, a)
[qx, lx, dx] = lifetablegen(x, a, lifemode)
```

## **Description**

`[qx, lx, dx] = lifetablegen(x, a)` generates a life table series from a calibrated mortality model.

`[qx, lx, dx] = lifetablegen(x, a, lifemode)` generates a life table series from a calibrated mortality model using the optional argument for `lifemode`.

## **Examples**

### **Generate Life Table Series from a Calibrated Mortality Model for Heligman-Pollard**

Load the life table data file.

```
load us_lifetable_2009
```

Calibrate the life table from survival data using the default `heligman-pollard` parametric model.

```
a = lifetablefit(x, lx)
```

```
a = 8x3
```

Plot the  $\text{qx}$  series and display the legend. The series  $\text{qx}$  is the conditional probability that a person at age  $x$  will die between age  $x$  and the next age in the series.

```
plot(x,log(qx))
legend(series)
```

### Prepare Life Table Data Using the $\text{qx}$ Series and Generate the $\text{qx}$ Life Table

Load the life table data file.

```
load us_lifetable_2009
```

Convert the life table series into life tables with forced termination.

```
[~, lx] = lifetableconv(x, qx, 'qx');
```

Calibrate the life table from survival data using the default heligman-pollard parametric model.

```
a = lifetablefit(x, lx)
```

```
a = 8×3
```

Plot the qx series and display the legend. The series qx is the conditional probability that a person at age x will die between age x and the next age in the series.

```
plot((0:100), log(qx));
legend(series, 'location', 'southeast');
title('Conditional Probability of Dying within One Year of Current Age');
xlabel('Age');
ylabel('Log Probability');
```

## Input Arguments

### x — Increasing ages for raw data

vector of nonnegative integers

Increasing ages for raw data, specified as a N vector of nonnegative integer values. The ages must start at 0 (birth).

Data Types: double

### a — Model parameters for num models

matrix

Model parameters for num models, specified as a `numparam`-by-num matrix, where the number of parameters (`numparam`) depends on the model specified using the `lifemode` argument.

Data Types: double

### lifemode — Parametric mortality model type

'heligman-pollard' (default) | character vector with values 'heligman-pollard', 'heligman-pollard-2', 'heligman-pollard-3', 'gompertz', 'makeham', 'siler'

(Optional) Parametric mortality model type, specified as a character vector with one of the following values:

- 'heligman-pollard' — Eight-parameter Heligman-Pollard model (version 1), specified in terms of the discrete hazard function:

$$\frac{q(x)}{1 - q(x)} = A^{(x+B)^C} + D \exp(-E(\log \frac{x}{F})^2) + GH^X$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E, F, G, H \geq 0$ .

- 'heligman-pollard-2' — Eight-parameter Heligman-Pollard model (version 2), specified in terms of the discrete hazard function:

$$\frac{q(x)}{1 - q(x)} = A^{(x+B)^C} + D \exp(-E(\log \frac{x}{F})^2) + \frac{GH^X}{1 + GH^X}$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E, F, G, H \geq 0$ .

- 'heligman-pollard-3' — Eight-parameter Heligman-Pollard model (version 3), specified in terms of the discrete hazard function:

$$q(x) = A^{(x+B)^C} + D \exp(-E(\log \frac{x}{F})^2) + GH^X$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E, F, G, H \geq 0$ .

- 'gompertz' — Two-parameter Gompertz model, specified in terms of the continuous hazard function:

$$h(x) = A \exp(Bx)$$

for ages  $x \geq 0$ , with parameters  $A, B \geq 0$ .

- 'makeham' — Three-parameter Gompertz-Makeham model, specified in terms of the continuous hazard function:

$$h(x) = A \exp(Bx) + C$$

for ages  $x \geq 0$ , with parameters  $A, B, C \geq 0$ .

- 'siler' — Five-parameter Siler model, specified in terms of the continuous hazard function:

$$h(x) = A \exp(Bx) + C + D \exp(-Ex)$$

for ages  $x \geq 0$ , with parameters  $A, B, C, D, E \geq 0$ .

Data Types: char

## Output Arguments

### **qx — Conditional probabilities of dying for N ages and num series**

matrix

Conditional probabilities of dying for N ages and num series, returned as an N-by-num matrix. The series qx is the conditional probability that a person at age x will die between age x and the next age in the series. For the last age, qx represents probabilities or counts for all ages after the last age.

The last row of the N-by-num output for qx is the values for all ages on or after the last age in x (due to "Forced Termination" on page 19-1064). Therefore, the last row of qx contains 1 (100% probability of dying on or after the last age).

**lx — Survival counts for N ages and num series**

matrix

Survival counts for N ages and num series, returned as an N-by-num matrix. The series lx is the number of people alive at age x, given 100,000 alive at birth.

**dx — Decrement counts for N ages and num series**

matrix

Decrement counts for N ages and num series, returned as an N-by-num matrix. The series dx is the number of people out of 100,000 alive at birth who die between age x and the next age in the series. For the last age, dx represent probabilities or counts for all ages after the last age.

The last row of the N-by-num output for dx are values for all ages on or after the last age in x (due to “Forced Termination” on page 19-1064). Therefore, the last row of dx contains the remaining count of 100,000 people alive at birth who have not died by the last age.

## More About

### Forced Termination

Most modern life tables have “forced” termination. Forced termination means that the last row of the life table applies for all persons with ages on or after the last age in the life table.

This sample illustrates forced termination.

#### United States Life Tables 2009

| x    | lx WM | lx WF | lx BM | lx BF | qx WM    | qx WF    | qx BM    | qx BF    |
|------|-------|-------|-------|-------|----------|----------|----------|----------|
| 93   | 9533  | 18368 | 6615  | 15685 | 0.219553 | 0.177156 | 0.200605 | 0.157858 |
| 94   | 7440  | 15114 | 5288  | 13209 | 0.23871  | 0.194852 | 0.214448 | 0.170868 |
| 95   | 5664  | 12169 | 4154  | 10952 | 0.258475 | 0.213411 | 0.229177 | 0.184624 |
| 96   | 4200  | 9572  | 3202  | 8930  | 0.27881  | 0.232971 | 0.24391  | 0.198992 |
| 97   | 3029  | 7342  | 2421  | 7153  | 0.299439 | 0.253337 | 0.259397 | 0.214036 |
| 98   | 2122  | 5482  | 1793  | 5622  | 0.320452 | 0.27417  | 0.274958 | 0.229634 |
| 99   | 1442  | 3979  | 1300  | 4331  | 0.341886 | 0.295803 | 0.291538 | 0.245671 |
| 100+ | 949   | 2802  | 921   | 3267  | 1        | 1        | 1        | 1        |

In this case, the last row of the life table applies for all persons aged 100 or older. Specifically, qx probabilities are  ${}_1q_x$  for ages less than 100 and, technically,  ${}_0q_x$  for age 100.

Forced termination has terminal age values that apply to all ages after the terminal age so that lx is positive, qx is 1, and dx is positive. Ages after the terminal age are NaN values, although lx and dx can be 0 and qx can be 1 for input series. Forced termination is triggered by a naturally terminating series, the last age in a truncated series, or the first NaN value in a series.

"About Life Tables" on page 2-47

## Introduced in R2015a

# linebreak

Line break chart

---

**Note** `linebreak` is updated to accept data input as a matrix, `timetable`, or `table`.

The syntax for `linebreak` has changed. Previously, when using table input, the first column of dates could be serial date numbers, date character vectors, or datetime arrays, and you were required to have specific number of columns.

When using table input, the new syntax for `linebreak` supports:

- No need for time information. If you want to pass in date information, use `timetable` input.
  - No requirement of specific number of columns. However, you must provide valid column names. `linebreak` must contain a column named ‘`price`’ (case insensitive).
- 

## Syntax

```
linebreak(Data)
h = linebreak(ax,Data)
```

## Description

`linebreak(Data)` plots the asset data, in a line break chart.

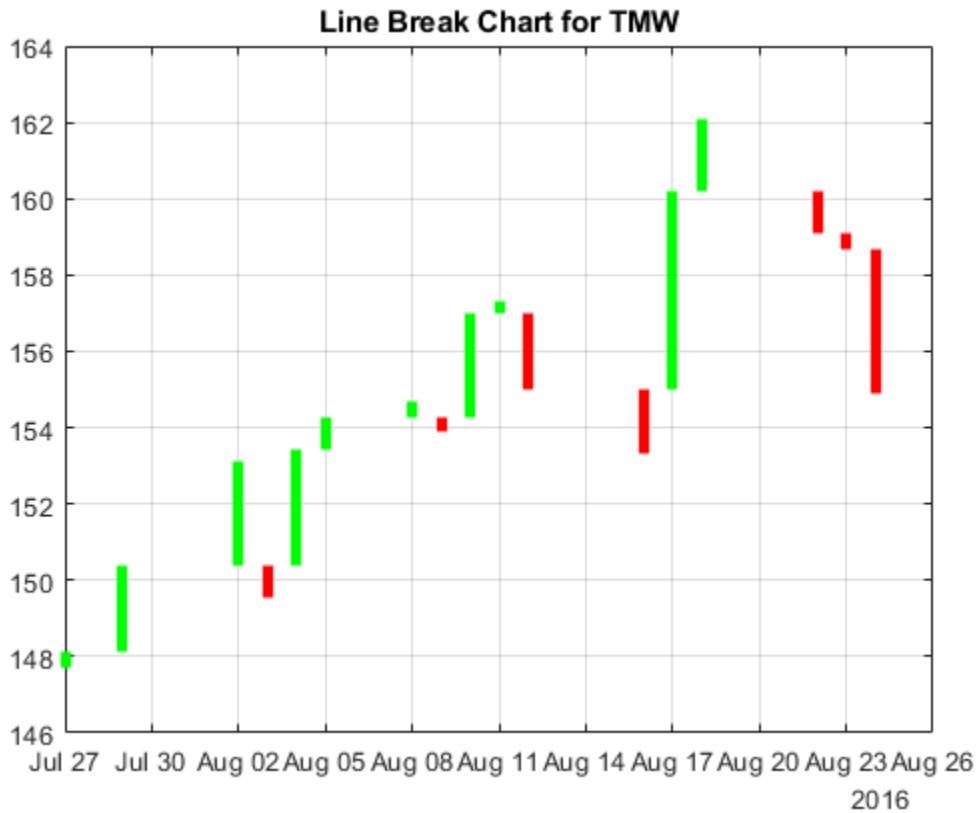

`h = linebreak(ax,Data)` adds an optional argument for `ax`.

## Examples

### Generate a Line Break Chart for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock. This Linebreak chart is for closing prices of the stock TMW for the most recent 21 days. Note that the variable name of asset price is be renamed to ‘`Price`’ (case insensitive).

```
load SimulatedStock.mat
TMW.Properties.VariableNames{'Close'} = 'Price';
linebreak(TMW(end-20:end,:))
title('Line Break Chart for TMW')
```

## Input Arguments

### Data — Data for a series of prices

matrix | table | timetable

Data for a series of prices, specified as a matrix, table, or timetable. Timetables and tables with M rows must contain a variable named 'Price' (case insensitive).

Data Types: double | table | timetable

### ax — Valid axis object

current axes (ax = gca) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The linebreak plot is created in the axes specified by ax instead of in the current axes (ax = gca). The option ax can precede any of the input argument combinations.

Data Types: object

## Output Arguments

### h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

**Topics**

“Using Timetables in Finance” on page 12-7

“Convert Financial Time Series Objects fints to Timetables” on page 12-2

**Introduced in R2008a**

# llow

Lowest low

**Note** Using a `fints` object for the `Data` argument of `llow` is not recommended. Use a matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

## Syntax

```
values = llow(Data)
values = llow(___,Name,Value)
```

## Description

`values = llow(Data)` generates a vector of lowest low values from the series of low prices for the past  $n$  periods.

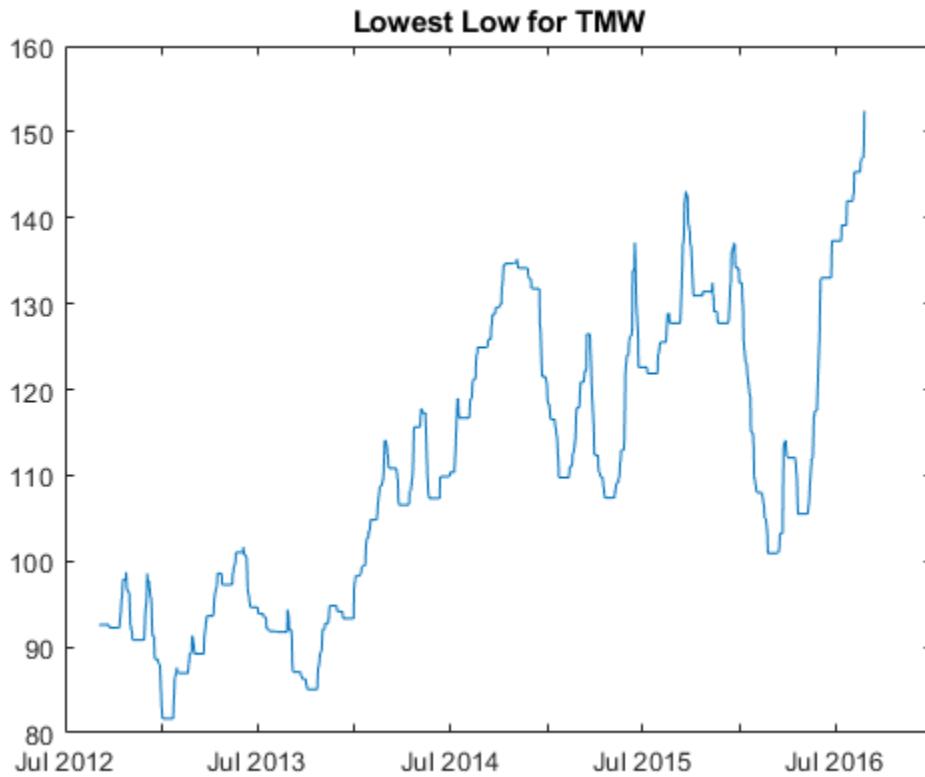

`values = llow(___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Calculate the Lowest Low for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
values = llow(TMW);
plot(values.Time,values.LowestLow)
title('Lowest Low for TMW')
```

## Input Arguments

### Data — Data for low prices

matrix | table | timetable

Data for low prices, specified as a matrix, table, or timetable. Timetables and tables with M rows must contain a variable named 'Low' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, ..., NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `values = llow(TMW_LOW, 'NumPeriods', 10)`

### NumPeriods — Moving window for the lowest low calculation

14 (default) | positive integer

Moving window for the lowest low calculation, specified as the comma-separated pair consisting of 'NumPeriods' and a scalar positive integer.

---

Data Types: double

## Output Arguments

### **values — Lowest low series**

matrix | table | timetable

Lowest low series, returned with the same number of rows ( $M$ ) and the same type (matrix, table, or timetable) as the input Data.

## Introduced before R2006a

## log

Natural logarithm for financial time series object

---

**Note** `log` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

### Syntax

```
newfts = log(tsobj)
```

### Description

`newfts = log(tsobj)` calculates the natural logarithm (log base e) of the data series in a financial time series object `tsobj`. It returns another time series object, `newfts`, containing the natural logarithms.

### Examples

#### Calculate Natural Logarithm for Financial Time Series Object

- 1 Create a `fints` object.

```
dates_and_times = (now:now+5)'  
dates_and_times =  
1.0e+05 *  
7.3840  
7.3840  
7.3840  
7.3841  
7.3841  
7.3841  
7.3841  
tsobj = fints(dates_and_times, randn(6,1))
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert FINTS Objects to Timetables.

```
> In fints (line 169)  
tsobj =  
desc: (none)  
freq: Unknown (0)  
{'dates: (6)'}    {'times: (6)'}    {'series1: (6)' }  
{'07-Sep-2021'}   {'12:30' }      {[ 0.5377]}  
{'08-Sep-2021'}   {'12:30' }      {[ 1.8339]}  
{'09-Sep-2021'}   {'12:30' }      {[ -2.2588]}

# log10

Common logarithm for financial time series object

---

**Note** `log10` is not recommended. Use `timetable` instead. For more information, see "Convert Financial Time Series Objects fints to Timetables".

---

## Syntax

```
newfts = log10(tsobj)
```

## Description

`newfts = log10(tsobj)` calculates the common logarithm (base 10) of all the data in the data series of the financial time series object `tsobj` and returns the result in the object `newfts`.

## Examples

### Calculate Common Logarithm for Financial Time Series Object

- 1 Create a `fints` object.

```
dates_and_times = (now:now+5)'  
dates_and_times =  
1.0e+05 *  
7.3840  
7.3840  
7.3840  
7.3841  
7.3841  
7.3841  
tsobj = fints(dates_and_times, randn(6,1))
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert F
```

## log2

Base 2 logarithm for financial time series object

---

**Note** `log2` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

### Syntax

```
newfts = log2(tsobj)
```

### Description

`newfts = log2(tsobj)` calculates the base 2 logarithm of the data series in a financial time series object `tsobj`. It returns another time series object `newfts` containing the logarithms.

### Examples

#### Calculate Base 2 Logarithm for Financial Time Series Object

- 1 Create a `fints` object.

```
dates_and_times = (now:now+5)'  
dates_and_times =  
    1.0e+05 *  
    7.3840  
    7.3840  
    7.3840  
    7.3841  
    7.3841  
    7.3841  
    tsobj = fints(dates_and_times, randn(6,1))
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert F

> In `fints` (line 169)

```

## lpm

Compute sample lower partial moments of data

### Syntax

```
lpm(Data)
lpm(Data,MAR,Order)
Moment = lpm(Data,MAR,Order)
```

### Description

`lpm(Data)` computes lower partial moments for asset returns `Data` relative to a default value for `MAR` for each asset in a `NUMORDERS`  $\times$  `NUMSERIES` matrix and a default value for `Order`.

`lpm(Data,MAR,Order)` computes lower partial moments for asset returns `Data` relative to `MAR` for each asset in a `NUMORDERS`  $\times$  `NUMSERIES` matrix.

`Moment = lpm(Data,MAR,Order)` computes lower partial moments for asset returns `Data` relative to `MAR` for each asset in a `NUMORDERS`  $\times$  `NUMSERIES` matrix `Moment`.

### Examples

#### Compute Lower Partial Moments

This example shows how to compute the zero-order, first-order, and second-order lower partial moments for the three time series, where the mean of the third time series is used to compute `MAR` (minimum acceptable return) with the so-called risk-free rate.

```
load FundMarketCash
Returns = tick2ret(TestData);
Assets

Assets = 1x3 cell
    {'Fund'}     {'Market'}    {'Cash'}

MAR = mean(Returns(:,3))

MAR = 0.0017

LPM = lpm(Returns, MAR, [0 1 2])

LPM = 3x3

0.4333    0.4167    0.6167
0.0075    0.0140    0.0004
0.0003    0.0008    0.0000
```

The first row of LPM contains zero-order lower partial moments of the three series. The fund and market index fall below MAR about 40% of the time and cash returns fall below its own mean about 60% of the time.

The second row contains first-order lower partial moments of the three series. The fund and market have large average shortfall returns relative to MAR by 75 and 140 basis points per month. On the other hand, cash underperforms MAR by about only four basis points per month on the downside.

The third row contains second-order lower partial moments of the three series. The square root of these quantities provides an idea of the dispersion of returns that fall below the MAR. The market index has a much larger variation on the downside when compared to the fund.

## Input Arguments

### Data — Asset returns

matrix

Asset returns, specified as a NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES observations of NUMSERIES asset returns.

Data Types: double

### MAR — Minimum acceptable return

0 (default) | numeric

(Optional) Minimum acceptable return, specified as a scalar numeric. MAR is a cutoff level of return such that all returns above MAR contribute nothing to the lower partial moment.

Data Types: double

### Order — Moment orders

0 (default) | scalar numeric | vector

(Optional) Moment orders, specified as either a scalar or a NUMORDERS vector of nonnegative integer moment orders. If no order specified, the default Order = 0, which is the shortfall probability. Although the lpm function works for noninteger orders and, in some cases, for negative orders, this falls outside customary usage.

Data Types: double

## Output Arguments

### Moment — Lower partial moments

matrix

Lower partial moments, returned as a NUMORDERS  $\times$  NUMSERIES matrix of lower partial moments with NUMORDERS Orders and NUMSERIES series, that is, each row contains lower partial moments for a given order.

---

**Note** To compute upper partial moments, reverse the signs of both Data and MAR (do not reverse the sign of the output). The lpm function computes sample lower partial moments from data. To compute expected lower partial moments for multivariate normal asset returns with a specified mean

and covariance, use `elpm`. With `lpm`, you can compute various investment ratios such as Omega ratio, Sortino ratio, and Upside Potential ratio, where:

- `Omega = lpm(-Data, -MAR, 1) / lpm(Data, MAR, 1)`
  - `Sortino = (mean(Data) - MAR) / sqrt(lpm(Data, MAR, 2))`
  - `Upside = lpm(-Data, -MAR, 1) / sqrt(lpm(Data, MAR, 2))`
- 

## More About

### Lower Partial Moments

Use *lower partial moments* to examine what is colloquially known as “downside risk.”

The main idea of the lower partial moment framework is to model moments of asset returns that fall below a minimum acceptable level of return. To compute lower partial moments from data, use `lpm` to calculate lower partial moments for multiple asset return series and for multiple moment orders. To compute expected values for lower partial moments under several assumptions about the distribution of asset returns, use `elpm` to calculate lower partial moments for multiple assets and for multiple orders.

“Performance Metrics Overview” on page 7-2

## Introduced in R2006b

# macd

Moving Average Convergence/Divergence (MACD)

**Note** Using a `fints` object for the `Data` argument of `macd` is not recommended. Use a matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

## Syntax

```
[MACDLine,SignalLine] = macd(Data)
```

## Description

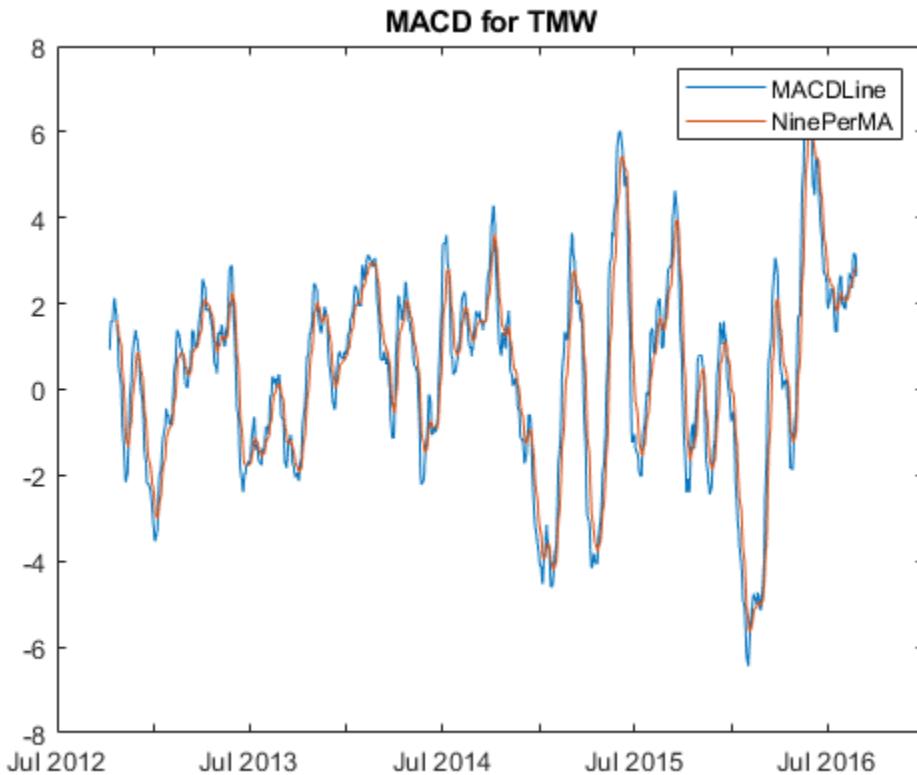

`[MACDLine,SignalLine] = macd(Data)` calculates the Moving Average Convergence/Divergence (MACD) line from the series of data and the nine-period exponential moving average from the `MACDLine`.

## Examples

### Calculate the Moving Average Convergence/Divergence for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
[MACDLine, signalLine]= macd(TMW);
plot(MACDLine.Time,MACDLine.Close,signalLine.Time,signalLine.Close);
legend('MACDLine','NinePerMA')
title('MACD for TMW')
```

## Input Arguments

### Data — Data with high, low, open, close information

matrix | table | timetable

Data with high, low, open, close information, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-4 matrix of high, low, opening, and closing prices. Timetables and tables with M rows must contain variables named 'High', 'Low', 'Open', and 'Close' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### MACDLine — MACD series

matrix | table | timetable

MACD series, returned with the same number of rows (M) and type (matrix, table, or timetable) as the input **Data**. The **MACDLine** is calculated by subtracting the 26-period (7.5%) exponential.

### SignalLine — Nine-period exponential series

matrix | table | timetable

Nine-period exponential series, returned with the same number of rows (M) and type (matrix, table, or timetable) as the input **Data**. The nine-period (20%) exponential moving average of the **MACDLine** is used as the **SignalLine**.

## More About

### MACD

The MACD is calculated by subtracting the 26-period (7.5%) exponential moving average from the 12-period (15%) moving average.

The nine-period (20%) exponential moving average of the MACD line is used as the "signal" line. When the two lines are plotted, they can give you indications on when to buy or sell a stock, when overbought or oversold is occurring, and when the end of trend may occur. For example, when the MACD and the 20-day moving average line have crossed and the MACD line becomes below the other line, it is time to sell.

## max

Maximum value

**Note** `max` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
tsmax = max(tsobj)
```

## Description

`tsmax = max(tsobj)` finds the maximum value in each data series in the financial time series object (`tsobj`) and returns it in a structure `tsmax`. The `tsmax` structure contains field name(s) identical to the data series name(s).

## Examples

### Calculate Maximum Value in Each Data Series in Financial Time Series Object

- 1 Create a `fints` object.

```
dates_and_times = (now:now+5)'  
dates_and_times =  
1.0e+05 *  
  
7.3840  
7.3840  
7.3840

7.3841  
7.3841  
7.3841  
  
tsobj = fints(dates_and_times, randn(6,1))
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see Convert F

> In `fints` (line 169)

```
tsobj =  
  
desc: (none)  
freq: Unknown (0)  
  
{'dates: (6)'}    {'times: (6)'}    {'series1: (6)' }  
{'07-Sep-2021'}    {'12:30' }        {[      0.5377]}  
{'08-Sep-2021'}    {'12:30' }        {[      1.8339]}  
{'09-Sep-2021'}    {'12:30' }        {[     -2.2588]}  
{'10-Sep-2021'}    {'12:30' }        {[      0.8622]}
```

```
{'11-Sep-2021'}    {'12:30'}      }    {[      0.3188]
{'12-Sep-2021'}    {'12:30'}      }    {[     -1.3077]}
```

## 2 Calculate the natural logarithm using `log`.

```
tsmax = max(tsobj)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert FINTS Objects to TIMETABLE.

```
> In fints/max (line 21)
```

```
tsmax =
```

```
struct with fields:
```

```
series1: 1.5877
```

## Input Arguments

### **tsobj — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

## Output Arguments

### **tsmax — Maximum value in each data series in the financial time series object**

structure

Maximum value in each data series in the financial time series object, returned as a structure.

---

**Note** `tsmax` returns only the values and does not return the dates associated with the values. The maximum values are not necessarily from the same date.

---

`min`

### **Topics**

“Financial Time Series Operations” on page 13-6

## Introduced before R2006a

## maxdrawdown

Compute maximum drawdown for one or more price series

### Syntax

```
MaxDD = maxdrawdown(Data)
MaxDD = maxdrawdown(____,Format)
[MaxDD,MaxDDIndex] = maxdrawdown(____)
```

### Description

`MaxDD = maxdrawdown(Data)` computes maximum drawdown for each series in an N-vector `MaxDD` and identifies start and end indexes of maximum drawdown periods for each series in a 2-by-N matrix `MaxDDIndex`.

`MaxDD = maxdrawdown(____,Format)` adds an optional argument for `Format`.

`[MaxDD,MaxDDIndex] = maxdrawdown(____)` adds an optional output for `MaxDDIndex`.

### Examples

#### Calculate Maximum Drawdown

Calculate the maximum drawdown (`MaxDD`) using example data with a fund, market, and cash series:

```
load FundMarketCash
MaxDD = maxdrawdown(TestData)

MaxDD = 1x3
    0.1658    0.3381         0
```

The maximum drop in the given time period was 16.58% for the fund series, and 33.81% for the market series. There was no decline in the cash series, as expected, because the cash account never loses value.

`maxdrawdown` also returns the indices (`MaxDDIndex`) of the maximum drawdown intervals for each series in an optional output argument.

```
[MaxDD, MaxDDIndex] = maxdrawdown(TestData)

MaxDD = 1x3
    0.1658    0.3381         0

MaxDDIndex = 2x3
    2      2      NaN
```

```
18     18    NaN
```

The first two series experience their maximum drawdowns from the second to the 18th month in the data. The indices for the third series are NaNs because it never has a drawdown.

The 16.58% value loss from month 2 to month 18 for the fund series is verified using the reported indices.

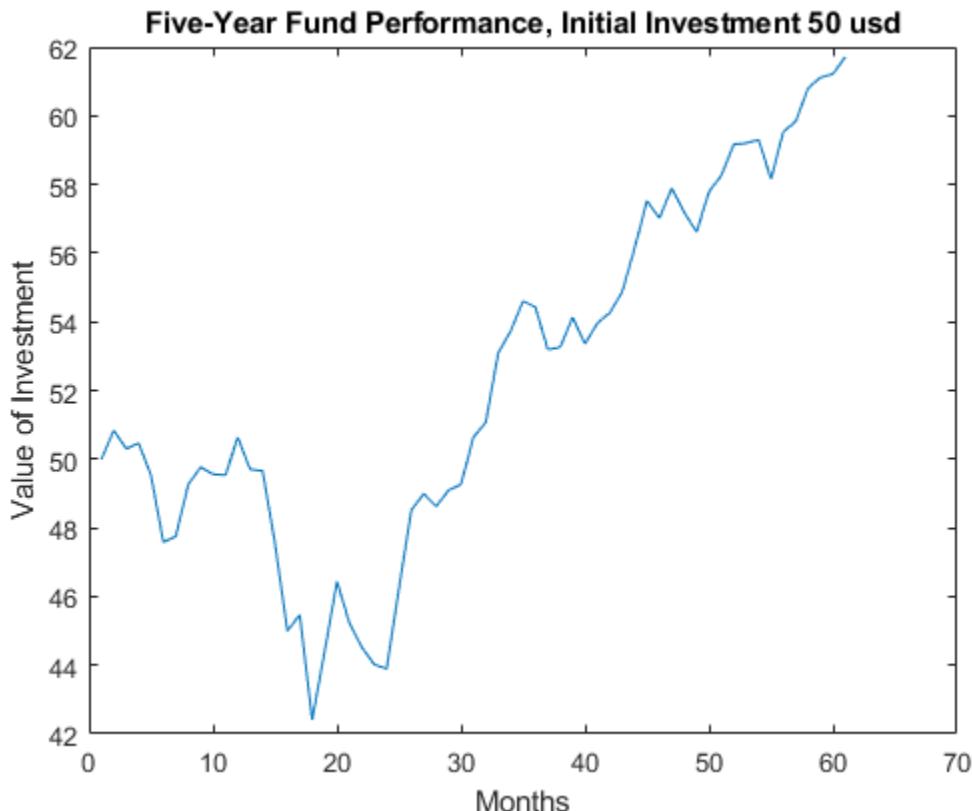

```
Start = MaxDDIndex(1,:);
End = MaxDDIndex(2,:);
(TestData(Start(1),1) - TestData(End(1),1))/TestData(Start(1),1)

ans = 0.1658

ans = 0.1658
```

Although the maximum drawdown is measured in terms of returns, `maxdrawdown` can measure the drawdown in terms of absolute drop in value, or in terms of log-returns. To contrast these alternatives more clearly, you can work with the fund series, assuming an initial investment of 50 dollars:

```
Fund50 = 50*TestData(:,1);
plot(Fund50);
title('Five-Year Fund Performance, Initial Investment 50 usd');
xlabel('Months');
ylabel('Value of Investment');
```

First, compute the standard maximum drawdown, which coincides with the results above because returns are independent of the initial amounts invested.

```
MaxDD50Ret = maxdrawdown(Fund50)
```

```
MaxDD50Ret = 0.1658
```

Next, compute the maximum drop in value, using the 'arithmetic' argument.

```
[MaxDD50Arith, Ind50Arith] = maxdrawdown(Fund50, 'arithmetic')
```

```
MaxDD50Arith = 8.4285
```

```
Ind50Arith = 2x1
```

```
2  
18
```

The value of this investment was \$50.84 in month 2, but by month 18 the value was down to \$42.41, a drop of \$8.43. This is the largest loss in dollar value from a previous high in the given time period. In this case, the maximum drawdown period, from the 2nd to 18th month, is the same independently of whether drawdown is measured as return or as dollar value loss.

```
[MaxDD50LogRet, Ind50LogRet] = maxdrawdown(Fund50, 'geometric')
```

```
MaxDD50LogRet = 0.1813
```

```
Ind50LogRet = 2x1
```

```
2  
18
```

Note, the last measure is equivalent to finding the arithmetic maximum drawdown for the log of the series.

```
MaxDD50LogRet2 = maxdrawdown(log(Fund50), 'arithmetic')
```

```
MaxDD50LogRet2 = 0.1813
```

## Input Arguments

### Data — Total return price series

matrix

Total return price series, specified as a T-by-N matrix with T samples of N total return price series.

Data Types: double

### Format — (Optional) Format of Data

character vector with value of 'return', 'arithmetic', or 'geometric'

Format of Data, specified as character vector with the following possible values:

- 'return' (default) — Maximum drawdown in terms of maximum percentage drop from a peak.

- 'arithmetic'
  - Maximum drawdown of an arithmetic Brownian motion with drift (differences of data from peak to trough) using the equation
 
$$dX(t) = \mu dt + \sigma dW(t).$$
- 'geometric'
  - Maximum drawdown of a geometric Brownian motion with drift (differences of log of data from peak to trough) using the equation
 
$$dS(t) = \mu_0 S(t)dt + \sigma_0 S(t)dW(t)$$

Data Types: char

## Output Arguments

### MaxDD — Maximum drawdown

vector

Maximum drawdown, returned as a 1-by-N vector with maximum drawdown for each of N time series.

---

### Note

- Drawdown is the percentage drop in total returns from the start to the end of a period. If the total equity time series is increasing over an entire period, drawdown is 0. Otherwise, it is a positive number. Maximum drawdown is an ex-ante proxy for downside risk that computes the largest drawdown over all intervals of time that can be formed within a specified interval of time.
  - Maximum drawdown is sensitive to quantization error.
- 

### MaxDDIndex — Start and end indexes for each maximum drawdown period for each total equity time series

vector

Start and end indexes for each maximum drawdown period for each total equity time series, returned as a 2-by-N vector of start and end indexes. The first row of the vector contains the start indexes and the second row contains the end indexes of each maximum drawdown period.

# mean

Arithmetic average

---

**Note** `mean` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
tsmean = mean(tsobj)
```

## Description

`tsmean = mean(tsobj)` computes the arithmetic mean of all data in all series in the financial time series object (`tsobj`) and returns it in a structure `tsmean`. The `tsmean` structure contains field name(s) identical to the data series name(s).

## Examples

### Calculate Arithmetic Mean of All Data in All Series in Financial Time Series Object

- 1 Create a `fints` object.

```
dates_and_times = (now:now+5)'
dates_and_times =
1.0e+05 *
7.3840
7.3840
7.3840
7.3841
7.3841
7.3841
7.3841
tsobj = fints(dates_and_times, randn(6,1))
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see Convert F

> In `fints` (line 169)

```
tsobj =
desc: (none)
freq: Unknown (0)

{'dates: (6)'}    {'times: (6)'}    {'series1: (6)'}
{'07-Sep-2021'}    {'12:30'}        {[      0.5377]}
{'08-Sep-2021'}    {'12:30'}        {[      1.8339]}
{'09-Sep-2021'}    {'12:30'}        {[     -2.2588]}
{'10-Sep-2021'}    {'12:30'}        {[      0.8622]}
```

```
{'11-Sep-2021'}    {'12:30'}      }    {[      0.3188]
{'12-Sep-2021'}    {'12:30'}      }    {[     -1.3077]}
```

- 2** Calculate the natural logarithm using `log`.

```
tsmean = mean(tsobj)
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert F
> In fints/mean (line 22)
```

```
tsmean =
```

```
struct with fields:
```

```
series1: 0.5648
```

## Input Arguments

### **tsobj — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

## Output Arguments

### **tsmean — Arithmetic mean of all data in all series in the financial time series object**

structure

Arithmetic mean of all data in all series in the financial time series object, returned as a structure.

## See Also

`peravg` | `tsmovavg`

## Topics

“Financial Time Series Operations” on page 13-6

## Introduced before R2006a

# medprice

Median price from the series of high and low prices

**Note** Using a `fints` object for the `Data` argument of `medprice` is not recommended. Use a matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

## Syntax

```
MedianPrice = medprice(Data)
```

## Description

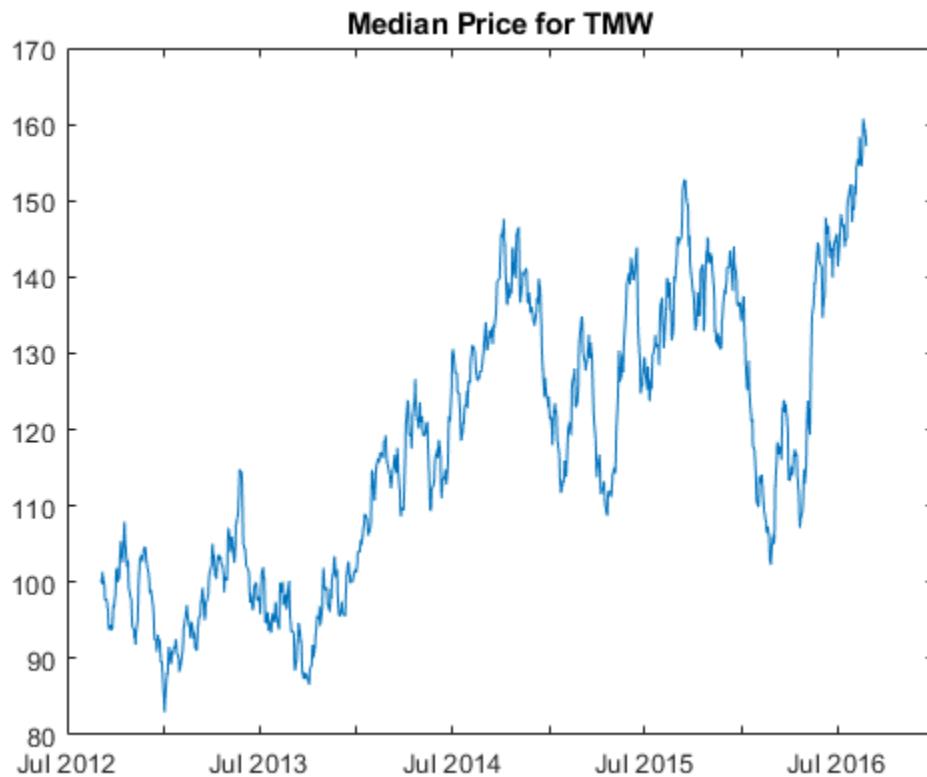

`MedianPrice = medprice(Data)` calculates the median prices from the series of high and low prices. The median price is the average of the high and low prices for each period.

## Examples

### Calculate the Median Prices for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
MedianPrice = medprice(TMW);
plot(MedianPrice.Time,MedianPrice.MedianPrice)
title('Median Price for TMW')
```

## Input Arguments

### Data — Data for high and low prices

matrix | table | timetable

Data for high and low prices, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-2 matrix of high and low prices stored in the corresponding columns. The columns can be in either order because the median price is the average of the high and low prices for each period. Timetables and tables with M rows must contain a variable named 'High' and 'Low' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### MedianPrice — Median price series

matrix | table | timetable

Median price series, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input **Data**.

## merge

Merge multiple financial time series objects

**Note** `merge` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

### Syntax

```
newfts = merge(fts1,fts2)
newfts = merge(____,Name,Value)
```

### Description

`newfts = merge(fts1,fts2)` merges multiple financial time series objects.

`newfts = merge(____,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Create Three Financial Time Series Objects and Merge into a Single Object

Create three financial time series objects and merged into a new time series object `t123`.

```
dates = {'jan-01-2001'; 'jan-02-2001'; 'jan-03-2001'; ...
         'jan-04-2001'; 'jan-06-2001'};
data = [1; 1; 1; 1; 1];
t1 = fints(dates, data);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
dates = {'jan-02-2001'; 'jan-03-2001'; 'jan-04-2001';
         'jan-05-2001'};
data = [2; 2; 2; 2];
t2 = fints(dates, data);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
dates = {'jan-03-2001'; 'jan-04-2001'; 'jan-05-2001';
         'jan-06-2001'};
data = [3; 3; 3; 3];
t3 = fints(dates, data);
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
t123 = merge(t1, t2, t3)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
t123 =
desc: || ||
freq: Unknown (0)

{'dates: (6)'} {'series1: (6)'}
{'01-Jan-2001'} {[ 1]}
{'02-Jan-2001'} {[ 1]}
{'03-Jan-2001'} {[ 1]}
{'04-Jan-2001'} {[ 1]}
{'05-Jan-2001'} {[ 2]}
{'06-Jan-2001'} {[ 1]}
```

If you change the order of input time series, the output may contain different data when duplicate dates exist. Here, for example, is the result of using the same three time series defined above but with the order changed.

```
merge(t3, t2, t1)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat

```
ans =
```

```
desc: || ||
freq: Unknown (0)

{'dates: (6)'} {'series1: (6)'}
{'01-Jan-2001'} {[ 1]}
{'02-Jan-2001'} {[ 2]}
{'03-Jan-2001'} {[ 3]}
{'04-Jan-2001'} {[ 3]}
{'05-Jan-2001'} {[ 3]}
{'06-Jan-2001'} {[ 3]}
```

`t123` contains all 1's except on '`05-Jan-2001`' because `t1` appears first in the list of inputs and takes precedence. The same logic can be applied to `t321`. By changing the order of inputs, you can overwrite old financial time series data with new data by placing the new time series ahead of the old one in the list of inputs to the `merge` function.

## Merge Financial Time Series Objects with Different Headers (Series Names)

Merge time series objects with different headers into a new time series object `t45`.

```
dates = {'jan-01-2001'; 'jan-02-2001'; 'jan-03-2001'; ...
'jan-04-2001'; 'jan-06-2001'};
data = [1; 1; 1; 1; 1];
t4 = fints(dates, data, 'ts4');
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat

```
dates = {'jan-02-2001'; 'jan-03-2001'; 'jan-04-2001'; 'jan-05-2001'};
data = [2; 2; 2; 2];
t5 = fints(dates, data, 'ts5');
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat...

```
t45 = merge(t4, t5)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat...

```
t45 =
```

```
desc:  ||
freq: Unknown (0)

{'dates: (6)'}    {'ts4: (6)'}    {'ts5: (6)'}
{'01-Jan-2001'}  {[      1]}  {[      NaN]}
{'02-Jan-2001'}  {[      1]}  {[      2]}
{'03-Jan-2001'}  {[      1]}  {[      2]}
{'04-Jan-2001'}  {[      1]}  {[      2]}
{'05-Jan-2001'}  {[      NaN]} {[      2]}
{'06-Jan-2001'}  {[      1]}  {[      NaN]}
```

## Merge Two Financial Index Series and Keep Intersecting Dates

Merge two index series into the final merged object (t12) and keep the intersecting dates.

```
dates = {'jan-01-2001'; 'jan-02-2001'; 'jan-03-2001'; 'jan-04-2001'; 'jan-06-2001'};
data = [1; 1; 1; 1; 1];
t1 = fints(dates, data, 'A')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat...

```
t1 =
```

```
desc: (none)
freq: Unknown (0)

{'dates: (5)'}    {'A: (5)'}
{'01-Jan-2001'}  {[      1]}
{'02-Jan-2001'}  {[      1]}
{'03-Jan-2001'}  {[      1]}
{'04-Jan-2001'}  {[      1]}
{'06-Jan-2001'}  {[      1]}
```

```
dates = {'jan-02-2001'; 'jan-03-2001'; 'jan-04-2001'; 'jan-05-2001'};
data = [2; 2; 2; 2];
t2 = fints(dates, data, 'B')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat...

```
t2 =
```

```
desc: (none)
freq: Unknown (0)
```

```

{'dates: (4)'}    {'B: (4)'}
{'02-Jan-2001'}  {[ 2]}
{'03-Jan-2001'}  {[ 2]}
{'04-Jan-2001'}  {[ 2]}
{'05-Jan-2001'}  {[ 2]}

t12 = merge(t1, t2, 'DataSetMethod', 'Intersection')

```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [matlab.mixin.timestruct.FINTS](#).

```

t12 =

desc: ||
freq: Unknown (0)

{'dates: (3)'}    {'A: (3)'}    {'B: (3)'}
{'02-Jan-2001'}  {[ 1]}    {[ 2]}
{'03-Jan-2001'}  {[ 1]}    {[ 2]}
{'04-Jan-2001'}  {[ 1]}    {[ 2]}

```

## Input Arguments

### **fts1 — Financial time series object to merge**

fints object

Financial time series object to merge, specified as a `fints` object.

---

**Note** Multiple Financial Time Series objects can be merged at once. The merged objects must appear in a comma separated list before the name-value argument inputs. The order of the `fints` object inputs is significant.

---

Data Types: object

### **fts2 — Financial time series object**

fints object

Financial time series object to merge, specified as a `fints` object.

---

**Note** Multiple Financial Time Series objects can be merged at once. The merged objects must appear in a comma separated list before the name-value argument inputs. The order of the `fints` object inputs is significant.

---

Data Types: object

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `t12 = merge(t1,t2,'DataSetMethod','Intersection')`

**DataSetMethod — Merge method for dates**

'union' (default) | character vector | RefObj

Merge method for dates, specified as NINST-by-1 vector. Valid merge values are:

- 'union' — Returns the combined values of all merged objects.
- 'intersection' — Returns the values common to all merged objects.
- RefObj — Maps all values to a reference time contained in a Financial Time Series object (RefObj) or vector of date numbers.

Data Types: double

**DataSetMethod — Merge method for data**

'closest' (default) | character vector

Merge method for data, specified as a NINST-by-1 vector. Values are:

Valid merge values are:

- 'closest' — Returns data based on the order of the inputs. However, the first missing data point (NaN value) of a date will be replaced by the closest non-NaN data point that appears on the same date of subsequent merged objects.
- 'order' — Returns data based strictly on the order of the inputs.

Data Types: double

**SortColumns — Sort columns**

True (default) | logical

Sort columns, specified as a logical. Valid merge values are:

- True — Sorts the columns based on the headers (series names). The headers are sorted in alphabetical order.
- False — Columns are not sorted.

Data Types: logical

## Output Arguments

**newfts — Financial time series object**

fints object

Financial time series object to merge, returned as an updated fints object.

## min

Minimum value

**Note** MIN is not recommended. Use timetable instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

### Syntax

```
tsmin = min(tsobj)
```

### Description

`tsmin = min(tsobj)` finds the minimum value in each data series in the financial time series object (`tsobj`) and returns it in the structure `tsmin`. The `tsmin` structure contains field name(s) identical to the data series name(s).

### Examples

#### Calculate Minimum Value in Each Data Series in Financial Time Series Object

- 1 Create a `fints` object.

```
dates_and_times = (now:now+5)'  
dates_and_times =  
1.0e+05 *  
  
7.3840  
7.3840  
7.3840  
7.3841  
7.3841  
7.3841
```

```
tsobj = fints(dates_and_times, randn(6,1))
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert FINTS Objects to Timetables.

```
> In fints (line 169)  
  
tsobj =  
  
desc: (none)  
freq: Unknown (0)  
  
{'dates: (6)'}    {'times: (6)'}    {'series1: (6)' }  
{'07-Sep-2021'}  {'12:30' }        {[      0.5377]}  
{'08-Sep-2021'}  {'12:30' }        {[      1.8339]}  
{'09-Sep-2021'}  {'12:30' }        {[     -2.2588]}  
{'10-Sep-2021'}  {'12:30' }        {[      0.8622]}
```

```
{'11-Sep-2021'}    {'12:30'}      }    {[      0.3188]
{'12-Sep-2021'}    {'12:30'}      }    {[     -1.3077]}
```

## 2 Calculate the natural logarithm using `log`.

```
tsmin = min(tsobj)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert FINTS Objects to TIMETABLE.

```
tsmin =
```

```
struct with fields:
```

```
series1: -0.8045
```

## Input Arguments

### **tsobj — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

## Output Arguments

### **tsmin — Minimum value in each data series in the financial time series object**

structure

Minimum value in each data series in the financial time series object, returned as a structure.

---

**Note** `tsmin` returns only the values and does not return the dates associated with the values. The minimum values are not necessarily from the same date.

---

## See Also

`max`

### Topics

“Financial Time Series Operations” on page 13-6

## Introduced before R2006a

## minus

Financial time series subtraction

**Note** `minus` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

### Syntax

```
newfts = tsobj_1 - tsobj_2  
newfts = tsobj - array  
newfts = array - tsobj
```

### Arguments

|                                             |                                                                                                                                                                                         |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsobj_1</code> , <code>tsobj_2</code> | A pair of financial time series objects .                                                                                                                                               |
| <code>array</code>                          | A scalar value or array with the number of rows equal to the number of dates in <code>tsobj</code> and the number of columns equal to the number of data series in <code>tsobj</code> . |

### Description

`minus` is an element-by-element subtraction of the components.

`newfts = tsobj_1 - tsobj_2` subtracts financial time series objects. If an object is to be subtracted from another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when one financial time series object is subtracted from another, follows the order of the first object.

`newfts = tsobj - array` subtracts an array element by element from a financial time series object.

`newfts = array - tsobj` subtracts a financial time series object element by element from an array.

### See Also

`rdivide` | `plus` | `times`

“Financial Time Series Operations” on page 13-6

### Introduced before R2006a

# mirr

Modified internal rate of return

## Syntax

```
Return = mirr(CashFlow,FinRate,Reinvest)
```

## Description

`Return = mirr(CashFlow,FinRate,Reinvest)` calculates the modified internal rate of return for a series of periodic cash flows. This function calculates only positive rates of return; for nonpositive rates of return, `Return = 0`.

## Examples

### Compute Modified Internal Rate of Return

This cash flow represents the yearly income from an initial investment of \$100,000. The finance rate is 9% and the reinvestment rate is 12%.

Year 1 \$20,000

Year 2 (\$10,000)

Year 3 \$30,000

Year 4 \$38,000

Year 5 \$50,000

To calculate the modified internal rate of return on the investment:

```
Return = mirr([-100000 20000 -10000 30000 38000 50000], 0.09,0.12)
```

```
Return = 0.0832
```

## Input Arguments

### CashFlow — Cash flow

vector | matrix

Cash flow, specified as a vector or matrix. The first entry is the initial investment. If `CashFlow` is entered as a matrix, each column is treated as a separate cash flow.

Data Types: double

### FinRate — Finance rate for negative cash flow values

decimal

Finance rate for negative cash flow values, specified as a decimal.

Data Types: double

**Reinvest — Reinvestment rate for positive cash flow values**

decimal

Reinvestment rate for positive cash flow values, specified as a decimal.

Data Types: double

## Output Arguments

**Return — Modified internal rate of return**

numeric

Modified internal rate of return, returned as a scalar or vector.

## Introduced before R2006a

# movavg

Moving average of a financial time series

---

**Note** `movavg` is updated to accept data input as a matrix, `table`, or `timetable`.

The syntax for `movavg` has changed. There is no longer support for the input arguments `Lead` and `Lag`, only a single `windowSize` is supported, and there is only one output argument (`ma`). If you want to compute the leading and lagging moving averages, you need to run `movavg` twice and adjust the `windowSize`.

---

## Syntax

```
ma = movavg(Data,type,windowSize)
ma = movavg(____,Initialpoints)

ma = movavg(Data,type,weights)
ma = movavg(____,Initialpoints)
```

## Description

`ma = movavg(Data,type,windowSize)` computes the moving average (MA) of a financial time series.

`ma = movavg(____,Initialpoints)` adds an optional argument for `Initialpoints`.

`ma = movavg(Data,type,weights)` computes the moving average (MA) of a financial time series using a 'custom' type and `weights`.

`ma = movavg(____,Initialpoints)` adds an optional argument for `Initialpoints`.

## Examples

### Calculate the Moving Average for a Data Series

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data.

```
load SimulatedStock.mat
type = 'linear';
windowSize = 14;
ma = movavg(TMW_CLOSE,type,windowSize)

ma = 1000x1

97.4133  
96.1133  
:
```

Plot the leading and lagging moving averages.

```
plot(TMW_CLOSE(1:100))  
hold on  
plot(malead(1:100))  
plot(malag(1:100))  
hold off  
legend('Actual','Lead','Lag')
```

## Input Arguments

### Data — Data for a financial series

matrix | table | timetable

Data for a financial series, specified as a column-oriented matrix, table, or timetable. Timetables and tables must contain variables with only a numeric type.

Data Types: double | table | timetable

### type — Type of moving average to compute

character vector with value of 'simple', 'square-root', 'linear', 'square', 'exponential', 'triangular', 'modified', or 'custom' | string with value of "simple", "square-root", "linear", "square", "exponential", "triangular", "modified", or "custom"

Type of moving average to compute, specified as a character vector or string with an associated value.

Data Types: char | string

### windowSize — Number of observations of the input series to include in moving average

positive integer

Number of observations of the input series to include in moving average, specified as a scalar positive integer. The observations include (windowSize - 1) previous data points and the current data point.

**Note** The `windowSize` argument applies only to moving averages whose `type` is 'simple', 'square-root', 'linear', 'square', 'exponential', 'triangular', or 'modified'.

---

Data Types: double

**weights — Custom weights used to compute moving average**  
vector

Custom weights used to compute the moving average, specified as a vector.

**Note** The length of weights ( $N$ ) determines the size of the moving average window (`windowSize`). The `weights` argument applies only to a 'custom' type of moving average.

---

To compute moving average with custom weights, the weights ( $w$ ) are first normalized such that they sum to one:

$$w(i) = w(i)/\text{sum}(w), \text{ for } i = 1, 2, \dots, N$$

The normalized weights ( $w$ ) are then used to form the  $N$ -point weighted moving average ( $y$ ) of the input Data ( $x$ ):

$$y(t) = w(1)*x(t) + w(2)*x(t-1) + \dots + w(N)*x(t-N)$$

The initial moving average values within the window size are then adjusted according to the method specified in the name-value pair argument `Initialpoints`.

Data Types: double

**Initialpoints — Indicates how moving average is calculated at initial points**

'shrink' (default) | character vector with values of 'shrink', 'fill', or 'zero' | string with values of "shrink", "fill", or "zero"

(Optional) Indicates how the moving average is calculated at initial points (before there is enough data to fill the window), specified as a character vector or string using one of the following values:

- 'shrink' - Initializes the moving average such that the initial points include only observed data
- 'zero' - Initializes the initial points with 0
- 'fill' - Fills initial points with NaNs

**Note** The `Initialpoints` argument applies to all type specifications except for the 'exponential' and 'modified' options.

---

Data Types: char | string

## Output Arguments

**ma — Moving average series**

matrix | table | timetable

---

Moving average series, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## Introduced before R2006a

## mrdivide

Financial time series matrix division

**Note** `mrdivide` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

### Syntax

```
newfts = tsobj_1 / tsobj_2
newfts = tsobj / array
newfts = array / tsobj
```

### Arguments

|                                             |                                                                                                                                                                                 |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsobj_1</code> , <code>tsobj_2</code> | A pair of financial time series objects.                                                                                                                                        |
| <code>array</code>                          | A scalar value or array with number of rows equal to the number of dates in <code>tsobj</code> and number of columns equal to the number of data series in <code>tsobj</code> . |

### Description

The `mrdivide` method divides element by element the components of one financial time series object (`tsobj`) by the components of the other. You can also divide the whole object by an array or divide a financial time series object into an array.

If an object is to be divided by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is divided by another object, follows the order of the first object.

`newfts = tsobj_1 / tsobj_2` divides financial time series objects element by element.

`newfts = tsobj / array` divides a financial time series object element by element by an array.

`newfts = array / tsobj` divides an array element by element by a financial time series object.

For financial time series objects, the `mrdivide` operation is identical to the `rdivide` operation.

# mtimes

Financial time series matrix multiplication

---

**Note** `mtimes` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
newfts = tsobj_1 * tsobj_2
newfts = tsobj * array
newfts = array * tsobj
```

## Arguments

|                                             |                                                                                                                                                                                 |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsobj_1</code> , <code>tsobj_2</code> | A pair of financial time series objects.                                                                                                                                        |
| <code>array</code>                          | A scalar value or array with number of rows equal to the number of dates in <code>tsobj</code> and number of columns equal to the number of data series in <code>tsobj</code> . |

## Description

The `mtimes` method multiplies element by element the components of one financial time series object (`tsobj`) by the components of the other. You can also multiply the entire object by an array.

If an object is to be multiplied by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is multiplied by another object, follows the order of the first object.

`newfts = tsobj_1 * tsobj_2` multiplies financial time series objects element by element.

`newfts = tsobj * array` multiplies a financial time series object element by element by an array.

`newfts = array * tsobj` and `newfts = array / tsobj` multiplies an array element by element by a financial time series object.

For financial time series objects, the `mtimes` operation is identical to the `times` operation.

## mvnrfish

Fisher information matrix for multivariate normal or least-squares regression

### Syntax

```
Fisher = mvnrfish(Data,Design,Covariance,MatrixFormat,CovarFormat)
```

### Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data         | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. If a data sample has missing values, represented as NaNs, the sample is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Design       | A matrix or a cell array that handles two model structures: <ul style="list-style-type: none"><li>If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li><li>If NUMSERIES <math>\geq 1</math>, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.<br/>If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.</li></ul> |
| Covariance   | NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the residuals of the regression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| MatrixFormat | (Optional) Character vector that identifies parameters to be included in the Fisher information matrix: <ul style="list-style-type: none"><li><b>full</b> — Default format. Compute the full Fisher information matrix for both model and covariance parameter estimates.</li><li><b>paramonly</b> — Compute only components of the Fisher information matrix associated with the model parameter estimates.</li></ul>                                                                                                                                                                                                                                |
| CovarFormat  | (Optional) Character vector that specifies the format for the covariance matrix. The choices are: <ul style="list-style-type: none"><li>'full' — Default method. The covariance matrix is a full matrix.</li><li>'diagonal' — The covariance matrix is a diagonal matrix.</li></ul>                                                                                                                                                                                                                                                                                                                                                                   |

### Description

`Fisher = mvnrfish(Data,Design,Covariance,MatrixFormat,CovarFormat)` computes a Fisher information matrix based on current maximum likelihood or least-squares parameter estimates.

`Fisher` is a TOTALPARAMS-by-TOTALPARAMS Fisher information matrix. The size of TOTALPARAMS depends on `MatrixFormat` and on current parameter estimates. If `MatrixFormat = 'full'`,

```
TOTALPARAMS = NUMPARAMS + NUMSERIES * (NUMSERIES + 1)/2
```

```
If MatrixFormat = 'paramonly',
```

```
TOTALPARAMS = NUMPARAMS
```

---

**Note** `mvnrfish` operates slowly if you calculate the full Fisher information matrix.

---

## mvnrmle

Multivariate normal regression (ignore missing data)

### Syntax

```
[Parameters,Covariance,Resid,Info] = mvnrmle(Data,Design,MaxIterations,TolParam,TolObj,Covar0,CovType)
```

### Arguments

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data          | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. If a data sample has missing values, represented as NaNs, the sample is ignored. (Use mvnrmle to handle missing data.)                                                                                                                                                                                                                                                                                                                                                                                                            |
| Design        | Matrix or a cell array that handles two model structures: <ul style="list-style-type: none"> <li>If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li> <li>If NUMSERIES ≥ 1, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample. |
| MaxIterations | (Optional) Maximum number of iterations for the estimation algorithm. Default value is 100.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| TolParam      | (Optional) Convergence tolerance for estimation algorithm based on changes in model parameter estimates. Default value is <code>sqrt(eps)</code> which is about 1.0e-8 for double precision. The convergence test for changes in model parameters is<br>$\ Param_k - Param_{k-1}\  < TolParam \times (1 + \ Param_k\ )$                                                                                                                                                                                                                                                                                                            |
|               | where Param represents the output <code>Parameters</code> , and iteration $k = 2, 3, \dots$ . Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam ≤ 0 and TolObj ≤ 0, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.                                                                                                                                                                                                                                                                                                          |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TolObj      | (Optional) Convergence tolerance for estimation algorithm based on changes in the objective function. Default value is $\text{eps} \wedge 3/4$ which is about $1.0e-12$ for double precision. The convergence test for changes in the objective function is<br>$ Obj_k - Obj_{k-1}  < TolObj \times (1 +  Obj_k )$ for iteration $k = 2, 3, \dots$ . Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam $\leq 0$ and TolObj $\leq 0$ , do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests. |
| Covar0      | (Optional) NUMSERIES-by-NUMSERIES matrix that contains a user-supplied initial or known estimate for the covariance matrix of the regression residuals.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| CovarFormat | (Optional) Character vector that specifies the format for the covariance matrix. The choices are: <ul style="list-style-type: none"><li>• 'full' — Default method. Compute the full covariance matrix.</li><li>• 'diagonal' — Force the covariance matrix to be a diagonal matrix.</li></ul>                                                                                                                                                                                                                                                                                                |

## Description

[Parameters, Covariance, Resid, Info] = mvnrmle(Data, Design, MaxIterations, TolParam, TolObj, Covar0, CovarFormat) estimates a multivariate normal regression model without missing data. The model has the form

$$Data_k \sim N(Design_k \times Parameters, Covariance)$$

for samples  $k = 1, \dots, \text{NUMSAMPLES}$ .

mvnrmle estimates a NUMPARAMS-by-1 column vector of model parameters called **Parameters**, and a NUMSERIES-by-NUMSERIES matrix of covariance parameters called **Covariance**.

mvnrmle(Data, Design) with no output arguments plots the log-likelihood function for each iteration of the algorithm.

To summarize the outputs of mvnrmle:

- **Parameters** is a NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model.
- **Covariance** is a NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression model's residuals.
- **Resid** is a NUMSAMPLES-by-NUMSERIES matrix of residuals from the regression. For any row with missing values in **Data**, the corresponding row of residuals is represented as all NaN missing values, since this routine ignores rows with NaN values.

Another output, **Info**, is a structure that contains additional information from the regression. The structure has these fields:

- **Info.Obj** – A variable-extent column vector, with no more than **MaxIterations** elements, that contain each value of the objective function at each iteration of the estimation algorithm. The last

value in this vector, `Obj(end)`, is the terminal estimate of the objective function. If you do maximum likelihood estimation, the objective function is the log-likelihood function.

- `Info.PrevParameters` – NUMPARAMS-by-1 column vector of estimates for the model parameters from the iteration just before the terminal iteration.
- `Info.PrevCovariance` – NUMSERIES-by-NUMSERIES matrix of estimates for the covariance parameters from the iteration just before the terminal iteration.

## Notes

`mvnrmle` does not accept an initial parameter vector, because the parameters are estimated directly from the first iteration onward.

You can configure `Design` as a matrix if `NUMSERIES = 1` or as a cell array if `NUMSERIES ≥ 1`.

- If `Design` is a cell array and `NUMSERIES = 1`, each cell contains a NUMPARAMS row vector.
- If `Design` is a cell array and `NUMSERIES > 1`, each cell contains a NUMSERIES-by-NUMPARAMS matrix.

These points concern how `Design` handles missing data:

- Although `Design` should not have `NaN` values, ignored samples due to `NaN` values in `Data` are also ignored in the corresponding `Design` array.
- If `Design` is a 1-by-1 cell array, which has a single `Design` matrix for each sample, no `NaN` values are permitted in the array. A model with this structure must have `NUMSERIES ≥ NUMPARAMS` with `rank(Design{1}) = NUMPARAMS`.
- Two functions for handling missing data, `ecmmvnrmle` and `ecmlsrmle`, are stricter about the presence of `NaN` values in `Design`.

Use the estimates in the optional output structure `Info` for diagnostic purposes.

## mvnrobj

Log-likelihood function for multivariate normal regression without missing data

### Syntax

```
Objective = mvnrobj(Data,Design,Parameters,Covariance,CovarFormat)
```

### Arguments

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data        | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. If a data sample has missing values, represented as NaNs, the sample is ignored. (Use <code>ecmmvnrml</code> to handle missing data.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Design      | A matrix or a cell array that handles two model structures: <ul style="list-style-type: none"><li>• If <code>NUMSERIES = 1</code>, <code>Design</code> is a <code>NUMSAMPLES</code>-by-<code>NUMPARAMS</code> matrix with known values. This structure is the standard form for regression on a single series.</li><li>• If <code>NUMSERIES ≥ 1</code>, <code>Design</code> is a cell array. The cell array contains either one or <code>NUMSAMPLES</code> cells. Each cell contains a <code>NUMSERIES</code>-by-<code>NUMPARAMS</code> matrix of known values.<br/>If <code>Design</code> has a single cell, it is assumed to have the same <code>Design</code> matrix for each sample. If <code>Design</code> has more than one cell, each cell contains a <code>Design</code> matrix for each sample.</li></ul> |
| Parameters  | <code>NUMPARAMS</code> -by-1 column vector of estimates for the parameters of the regression model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Covariance  | NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the residuals of the regression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| CovarFormat | (Optional) Character vector that specifies the format for the covariance matrix. The choices are: <ul style="list-style-type: none"><li>• '<code>full</code>' — Default method. The covariance matrix is a full matrix.</li><li>• '<code>diagonal</code>' — The covariance matrix is a diagonal matrix.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### Description

`Objective = mvnrobj(Data,Design,Parameters,Covariance,CovarFormat)` computes the log-likelihood function based on current maximum likelihood parameter estimates without missing data. `Objective` is a scalar that contains the log-likelihood function.

### Notes

You can configure `Design` as a matrix if `NUMSERIES = 1` or as a cell array if `NUMSERIES ≥ 1`.

- If `Design` is a cell array and `NUMSERIES = 1`, each cell contains a `NUMPARAMS` row vector.

- If **Design** is a cell array and **NUMSERIES** > 1, each cell contains a **NUMSERIES**-by-**NUMPARAMS** matrix.

Although **Design** should not have NaN values, ignored samples due to NaN values in **Data** are also ignored in the corresponding **Design** array.

## Examples

See “Multivariate Normal Regression” on page 9-13, “Least-Squares Regression” on page 9-14, “Covariance-Weighted Least Squares” on page 9-14, “Feasible Generalized Least Squares” on page 9-15, and “Seemingly Unrelated Regression” on page 9-16.

## Introduced in R2006a

## mvnrstd

Evaluate standard errors for multivariate normal regression model

### Syntax

```
[StdParameters,StdCovariance] = mvnrstd(Data,Design,Covariance,CovarFormat)
```

### Arguments

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data        | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. If a data sample has missing values, represented as NaNs, the sample is ignored. (Use <code>ecmmvnrmlle</code> to handle missing data.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Design      | A matrix or a cell array that handles two model structures: <ul style="list-style-type: none"> <li>If <code>NUMSERIES = 1</code>, <code>Design</code> is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.</li> <li>If <code>NUMSERIES ≥ 1</code>, <code>Design</code> is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.</li> </ul> If <code>Design</code> has a single cell, it is assumed to have the same <code>Design</code> matrix for each sample. If <code>Design</code> has more than one cell, each cell contains a <code>Design</code> matrix for each sample. |
| Covariance  | NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression residuals.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| CovarFormat | (Optional) Character vector that specifies the format for the covariance matrix. The choices are: <ul style="list-style-type: none"> <li>'full' — Default method. The covariance matrix is a full matrix.</li> <li>'diagonal' — The covariance matrix is a diagonal matrix.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### Description

`[StdParameters,StdCovariance] = mvnrstd(Data,Design,Covariance,CovarFormat)` evaluates standard errors for a multivariate normal regression model without missing data. The model has the form

$$Data_k \sim N(Design_k \times Parameters, Covariance)$$

for samples  $k = 1, \dots, \text{NUMSAMPLES}$ .

`mvnrstd` computes two outputs:

- `StdParameters` is a NUMPARAMS-by-1 column vector of standard errors for each element of `Parameters`, the vector of estimated model parameters.

- `StdCovariance` is a `NUMSERIES`-by-`NUMSERIES` matrix of standard errors for each element of `Covariance`, the matrix of estimated covariance parameters.

**Note** `mvnrstd` operates slowly when you calculate the standard errors associated with the covariance matrix `Covariance`.

## Notes

You can configure `Design` as a matrix if `NUMSERIES` = 1 or as a cell array if `NUMSERIES`  $\geq$  1.

- If `Design` is a cell array and `NUMSERIES` = 1, each cell contains a `NUMPARAMS` row vector.
- If `Design` is a cell array and `NUMSERIES` > 1, each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix.

## Examples

## nancov

Covariance ignoring NaNs

**Note** nancov is not recommended. Use timetable instead. For more information, see "Convert Financial Time Series Objects fints to Timetables".

---

### Syntax

```
c = nancov(X)
c = nancov(X,1)
c = nancov(X,Y)
c = nancov(X,Y,1)
c = nancov(_____,Method)
```

### Description

`c = nancov(X)` if `X` is a financial time series object with one series and returns the sample variance of the values in `X`, treating NaNs as missing values. For a financial time series object containing more than one series, where each row is an observation and each series a variable, `nancov(X)` is the covariance matrix computing using rows of `X` that do not contain any NaN values.

`nancov(X)` or `nancov(X,Y)` normalizes by  $(N-1)$  if  $N > 1$ , where  $N$  is the number of observations after removing missing values. This makes `nancov` the best unbiased estimate of the covariance matrix if the observations are from a normal distribution. For  $N = 1$ , `cov` normalizes by  $N$ .

`nancov` for financial time series objects is based on the Statistics and Machine Learning Toolbox function `nancov`. For more information, see `nancov`.

`c = nancov(X,1)` where `nancov(X,1)` or `nancov(X,Y,1)` normalizes by  $N$  and produces the second moment matrix of the observations about their mean. `nancov(X,Y,0)` is the same as `nancov(X,Y)`, and `nancov(X,0)` is the same as `nancov(X)`.

`nancov(X)` or `nancov(X,Y)` normalizes by  $(N-1)$  if  $N > 1$ , where  $N$  is the number of observations after removing missing values. This makes `nancov` the best unbiased estimate of the covariance matrix if the observations are from a normal distribution. For  $N = 1$ , `cov` normalizes by  $N$ .

`c = nancov(X,Y)` where `X` and `Y` are financial time series objects with the same number of elements, is equivalent to `nancov([X(:) Y(:)])`.

`c = nancov(X,Y,1)` where `nancov(X,1)` or `nancov(X,Y,1)` normalizes by  $N$  and produces the second moment matrix of the observations about their mean. `nancov(X,Y,0)` is the same as `nancov(X,Y)`, and `nancov(X,0)` is the same as `nancov(X)`.

`c = nancov(_____,Method)` where `Method` is '`'pairwise'`' computes  $c(i,j)$  using rows with no NaN values in columns  $i$  or  $j$ . The result may not be a positive definite matrix. `c = nancov(..., 'complete')` is the default, and it omits rows with any NaN values, even if they are not in column  $i$  or  $j$ . The mean is removed from each column before calculating the result.

## Examples

### Generate Covariance Ignoring NaNs

- To generate random data having nonzero covariance between column 4 and the other columns:

```
x = randn(30, 4); % uncorrelated data
x(:, 4) = sum(x, 2); % introduce correlation
x(2, 3) = NaN; % introduce one missing value
f = fints((today:today+29)', x); % create a fints object using x
c = nancov(f) % compute sample covariance
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints (line 165)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/nancov (line 43)

c =

|         |         |         |        |

| 1.9143  | 0.6059  | 0.7570  | 4.4895 |

## Input Arguments

### X — Financial time series object

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

### Y — Financial time series object

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

### Method — Computation method

'complete' (default) | character vector with values 'complete' or 'pairwise'

(Optional) Computation method, specified as a character vector.

Data Types: char

## Output Arguments

### c — Covariance that ignores NaNs

vector

Covariance that ignores NaNs, returned as a vector.

## See Also

`cov` | `nanvar` | `var`

**Introduced before R2006a**

# nanmax

Maximum ignoring NaNs

---

**Note** `nanmax` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
m = nanmax(X)
[m,ndx] = nanmax(X)
m = nanmax(X,Y)
[m,ndx] = nanmax(X,DIM)
```

## Description

`m = nanmax(X)` returns the maximum of a financial time series object `X` with NaNs treated as missing. `m` is the largest non-NaN element in `X`.

`nanmax` for financial time series objects is based on the Statistics and Machine Learning Toolbox function `nanmax`. For more information, see `nanmax`.

`[m,ndx] = nanmax(X)` returns the indices of the maximum values in `X`. If the values along the first nonsingleton dimension contain multiple maximal elements, the index of the first one is returned.

`m = nanmax(X,Y)` returns an array the same size as `X` and `Y` with the largest elements taken from `X` or `Y`. Only `Y` can be a scalar double.

`[m,ndx] = nanmax(X,DIM)` operates along the dimension `DIM`.

## Examples

### Compute nanmax

- Compute `nanmax` for the following dates:

```
dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
f = fints(dates, magic(3));
f.series1(1) = nan;
f.series2(3) = nan;
f.series3(2) = nan;

[nmax, maxidx] = nanmax(f)
```

nmax =  
    4      5      6  
  
maxidx =  
    3      2      1
```

## Input Arguments

### X — Financial time series object

fints object

Financial time series object, specified as a `fints` object.

Data Types: `object`

### Y — Financial time series object

fints object

Financial time series object, specified as a `fints` object.

Data Types: `object`

### DIM — Dimension of X

`''` (default) | numeric

(Optional) Dimension of X, specified as a numeric.

Data Types: `double`

## Output Arguments

### m — Largest non-NaN elements in X

vector

Largest non-NaN elements in X, returned as a vector.

### ndx — Indices of the maximum values in X

vector

Indices of the maximum values in X, returned as a vector.

## Introduced before R2006a

# nanmean

Mean ignoring NaNs

---

**Note** nanmean is not recommended. Use timetable instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
m = nanmean(X)
m = nanmean(X,DIM)
```

## Description

`m = nanmean(X)` returns the sample mean of a financial time series object `X`, treating NaNs as missing values. `m` is a row vector containing the mean value of the non-NaN elements in each series.

`nanmean` for financial time series objects is based on the Statistics and Machine Learning Toolbox function `nanmean`. For more information, see `nanmean`.

`m = nanmean(X,DIM)` specifies dimension along which the operation is conducted.

## Examples

### Compute nanmean

- Compute `nanmean` for the following dates:

```
dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
f = fints(dates, magic(3));
f.series1(1) = nan;
f.series2(3) = nan;
f.series3(2) = nan;

nmean = nanmean(f)
```

`nmean =`

3.5000    3.0000    4.0000

## Input Arguments

**X — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

**DIM — Dimension along which the operation is conducted**

' ' (default) | numeric

(Optional) Dimension along which the operation is conducted, specified as a numeric.

Data Types: double

## Output Arguments

**m — Mean value of non-NaN elements in X**

vector

Mean value of non-NaN elements in X, returned as a vector.

**See Also**[mean](#) | [nanmax](#) | [nanmin](#) | [nanstd](#) | [nansum](#) | [nanvar](#)**Introduced before R2006a**

# nanmedian

Median ignoring NaNs

---

**Note** `nanmedian` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
m = nanmedian(X)
m = nanmedian(X,DIM)
```

## Description

`m = nanmedian(X)` returns the sample median of a financial time series object `X`, treating NaNs as missing values. `m` is a row vector containing the median value of non-NaN elements in each column.

`nanmedian` for financial time series objects is based on the Statistics and Machine Learning Toolbox function `nanmedian`. For more information, see `nanmedian`.

`m = nanmedian(X,DIM)` specifies dimension along which the operation is conducted.

## Examples

### Compute `nanmedian`

- Compute `nanmedian` for the following dates:

```
dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007';'04-Jan-2007'};
f = fints(dates, magic(4));
f.series1(1) = nan;
f.series2(2) = nan;
f.series3([1 3]) = nan;

nmedian = nanmedian(f)
```

> In `fints/subsasgn` (line 118)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In `fints/nanmedian` (line 14)

```
nmedian =
    5.0000    7.0000   12.5000   10.0000
```

## Input Arguments

**X — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

**DIM — Dimension along which the operation is conducted**

' ' (default) | numeric

(Optional) Dimension along which the operation is conducted, specified as a numeric.

Data Types: double

## Output Arguments

**m — Mean value of non-NaN elements in X**

vector

Mean value of non-NaN elements in X, returned as a vector.

**See Also**[mean](#) | [nanmax](#) | [nanmin](#) | [nanstd](#) | [nansum](#) | [nanvar](#)**Introduced before R2006a**

# nanmin

Minimum ignoring NaNs

---

**Note** `nanmin` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
m = nanmin(X)
[m,ndx] = nanmin(X)
m = nanmin(X,Y)
[m,ndx] = nanmin(X,DIM)
```

## Description

`m = nanmin(X)` returns the minimum of a financial time series object `X` with NaNs treated as missing. `m` is the smallest non-NaN element in `X`.

`nanmin` for financial time series objects is based on the Statistics and Machine Learning Toolbox function `nanmin`. For more information, see `nanmin`.

`[m,ndx] = nanmin(X)` returns the indices of the minimum values in `X`. If the values along the first nonsingleton dimension contain multiple elements, the index of the first one is returned.

`m = nanmin(X,Y)` returns an array the same size as `X` and `Y` with the smallest elements taken from `X` or `Y`. Only `Y` can be a scalar double.

`[m,ndx] = nanmin(X,DIM)` operates along the dimension `DIM`.

## Examples

### Compute nanmin

- Compute `nanmin` for the following dates:

```
dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
f = fints(dates, magic(3));
f.series1(1) = nan;
f.series2(3) = nan;
f.series3(2) = nan;

[nmin, minidx] = nanmin(f)
```

```

> In fints/nanmin (line 20)  
  
nmin =  
      3     1     2  
minidx =  
      2     1     3
```

## Input Arguments

### X — Financial time series object

fints object

Financial time series object, specified as a `fints` object.

Data Types: `object`

### Y — Financial time series object

fints object

Financial time series object, specified as a `fints` object.

Data Types: `object`

### DIM — Dimension along which the operation is conducted

`''` (default) | numeric

(Optional) Dimension along which the operation is conducted, specified as a numeric.

Data Types: `double`

## Output Arguments

### m — Smallest non-NaN elements in X

vector

Smallest non-NaN elements in X, returned as a vector.

### ndx — Indices of the minimum values in X

vector

Indices of the minimum values in X, returned as a vector.

## See Also

## Introduced before R2006a

# nanstd

Standard deviation ignoring NaNs

---

**Note** `nanstd` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
y = nanstd(X)
y = nanstd(X,1)
m = nanstd(X,flag,dim)
```

## Description

`y = nanstd(X)` returns the sample standard deviation of the values in a financial time series object `X`, treating NaNs as missing values. `y` is the standard deviation of the non-NaN elements of `X`.

`nanstd` normalizes `y` by  $(N - 1)$ , where  $N$  is the sample size. This is the square root of an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples and data are missing at random.

`y = nanstd(X,1)` normalizes by  $N$  and produces the square root of the second moment of the sample about its mean. `nanstd(X,0)` is the same as `nanstd(X)`.

`m = nanstd(X,flag,dim)` takes the standard deviation along the dimension `dim` of `X`. Set the value of `flag` to 0 to normalize the result by  $n - 1$ ; set the value of `flag` to 1 to normalize the result by  $n$ .

## Examples

### Compute nanstd

- Compute `nanstd` for the following dates:

```
dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
f = fints(dates, magic(3));
f.series1(1) = nan;
f.series2(3) = nan;
f.series3(2) = nan;

nstd = nanstd(f)
```

```

```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/nanstd (line 25)
```

```
nstd =  
0.71      2.83      2.83
```

## Input Arguments

**X — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

**flag — Normalization flag**

logical

Normalization flag, specified as a logical.

Data Types: logical

**dim — Dimension along which the operation is conducted**

'' (default) | numeric

(Optional) Dimension along which the operation is conducted, specified as a numeric.

Data Types: double

## Output Arguments

**y — Standard deviation of non-NaN elements in X**

vector

Standard deviation of non-NaN elements in X, returned as a vector.

## Introduced before R2006a

# nansum

Sum ignoring NaNs

---

**Note** nansum is not recommended. Use timetable instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
y = nansum(X)
y = nansum(X,DIM)
```

## Description

`y = nansum(X)` returns the sum of a financial time series object X, treating NaNs as missing values. y is the sum of the non-NaN elements in X.

nansum for financial time series objects is based on the Statistics and Machine Learning Toolbox function nansum. For more information, see nansum.

`y = nansum(X,DIM)` takes the sum along dimension DIM of X.

## Examples

### Compute nansum

- Compute nansum for the following dates:

```
dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
f = fints(dates, magic(3));
f.series1(1) = nan;
f.series2(3) = nan;
f.series3(2) = nan;

nsum = nansum(f)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints (line 165)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/subsasgn (line 118)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/subsasgn (line 118)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/subsasgn (line 118)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/nansum (line 13)

```
nsum =
    7      6      8
```

## Input Arguments

**X — Financial time series object**

fints object

Financial time series object, specified as a `fints` object.

Data Types: object

**DIM — Dimension along which the operation is conducted**

' ' (default) | numeric

(Optional) Dimension along which the operation is conducted, specified as a numeric.

Data Types: double

## Output Arguments

**y — Sum of non-NaN elements in X**

vector

Sum of non-NaN elements in X, returned as a vector.

**See Also**[nanmax](#) | [nanmean](#) | [nanmedian](#) | [nanmin](#) | [nanstd](#) | [nanvar](#)**Introduced before R2006a**

# nanvar

Variance ignoring NaNs

---

**Note** `nanvar` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
y = nanvar(X)
y = nanvar(X,1)
y = nanvar(X,W)
y = nanvar(X,W,DIM)
```

## Description

`y = nanvar(X)` returns the sample variance of the values in a financial time series object `X`, treating NaNs as missing values. `y` is the variance of the non-NaN elements of each series in `X`.

`nanvar` normalizes `y` by  $N - 1$  if  $N > 1$ , where  $N$  is the sample size of the non-NaN elements. This is an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples, and data are missing at random. For  $N = 1$ , `y` is normalized by  $N$ .

`nanvar` for financial time series objects is based on the Statistics and Machine Learning Toolbox function `nanvar`. For more information, see `nanvar`.

`y = nanvar(X,1)` normalizes by  $N$  and produces the second moment of the sample about its mean. `nanvar(X,0)` is the same as `nanvar(X)`.

`y = nanvar(X,W)` computes the variance using the weight vector `W`. The length of `W` must equal the length of the dimension over which `nanvar` operates, and its non-NaN elements must be nonnegative. Elements of `X` corresponding to NaN elements of `W` are ignored.

`y = nanvar(X,W,DIM)` takes the variance along dimension `DIM` of `X`.

## Examples

### Compute `nanvar`

- Compute `nanvar` for the following dates:

```
f = fints((today:today+1)', [4 -2 1; 9 5 7])
f.series1(1) = nan;
f.series3(2) = nan;

nvar = nanvar(f)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/subsasgn (line 118)

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/subsasgn (line 118)  
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/nanvar (line 28)  
  
nvar =  
      0    24.5000          0
```

## Input Arguments

### X — Financial time series object

fints object

Financial time series object, specified as a `fints` object.

Data Types: `object`

### W — Weight vector

vector

Weight vector, specified as a vector.

Data Types: `double`

### DIM — Dimension along which the operation is conducted

' ' (default) | numeric

(Optional) Dimension along which the operation is conducted, specified as a numeric.

Data Types: `double`

## Output Arguments

### y — Variance ignoring NaNs

vector

Variance ignoring NaNs, returned as a vector.

## See Also

`nanmax` | `nanmean` | `nanmedian` | `nanmin` | `nanstd` | `var`

## Introduced before R2006a

# negvolidx

Negative volume index

**Note** Using a `fints` object for the `Data` argument of `negvolidx` is not recommended. Use a matrix, timetable, or table instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

## Syntax

```
volume = negvolidx(Data)
volume = negvolidx(___,Name,Value)
```

## Description

`volume = negvolidx(Data)` calculates the negative volume index from the series of closing stock prices and trade volume.

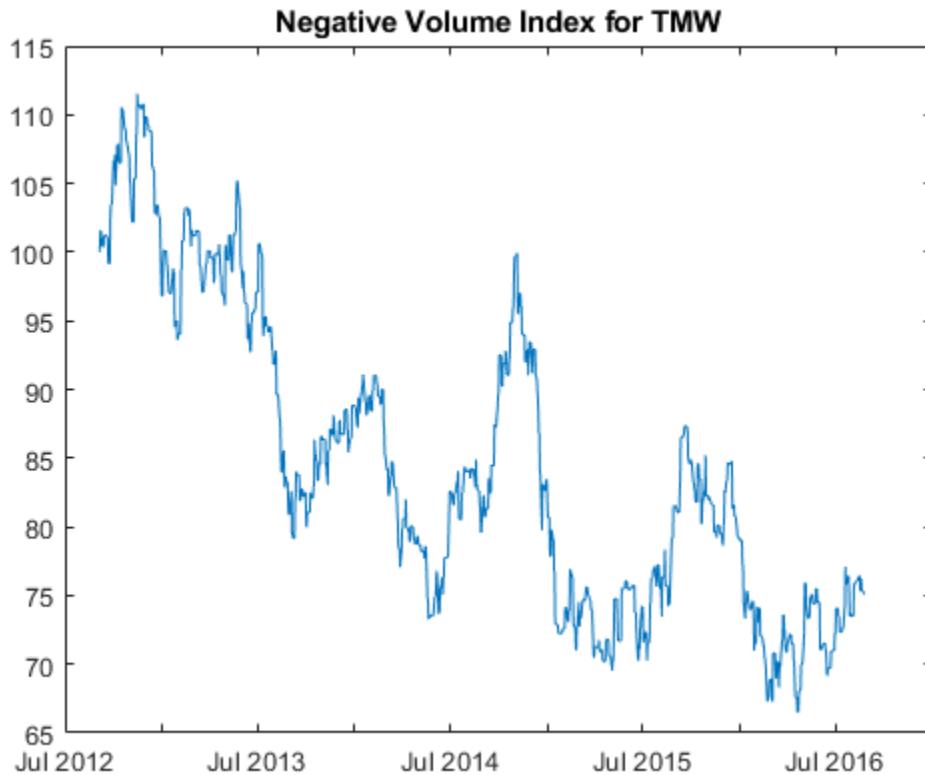

`volume = negvolidx(___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Calculate the Negative Volume Index for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
volume = negvolidx(TMW);
plot(volume.Time,volume.NegativeVolume)
title('Negative Volume Index for TMW')
```

## Input Arguments

### Data — Data with closing prices and trade volume

matrix | table | timetable

Data with closing prices and trade volume, specified as a matrix, table, or timetable. For matrix input, Data is an M-by-2 with closing prices and trade volume stored in the first and second columns.

Timetables and tables with M rows must contain variables named 'Close' and 'Volume' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, ..., NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `volume = negvolidx(TMW, 'InitialValue', 500)`

### InitialValue — Initial value for negative volume index

100 (default) | positive integer

Initial value for negative volume index, specified as the comma-separated pair consisting of 'InitialValue' and a scalar positive integer.

Data Types: double

## Output Arguments

### **volume — Negative volume index**

matrix | table | timetable

Negative volume index, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## More About

### **Negative Volume Index**

Negative volume index shows the days when the trading volume of a particular security is substantially lower than other days.

## nomrr

Nominal rate of return

### Syntax

```
Return = nomrr(Rate,NumPeriods)
```

### Description

`Return = nomrr(Rate,NumPeriods)` calculates the nominal rate of return.

### Examples

#### Calculate the Nominal Rate of Return

This example shows how to calculate the nominal rate of return based on an effective annual percentage rate of 9.38% compounded monthly.

```
Return = nomrr(0.0938, 12)
```

```
Return = 0.0900
```

### Input Arguments

#### Rate — Effective annual percentage rate

decimal

Effective annual percentage rate, specified as a decimal.

Data Types: double

#### NumPeriods — Number of compounding periods per year

scalar numeric

Number of compounding periods per year, specified as a scalar numeric.

Data Types: double

### Output Arguments

#### Return — Nominal rate of return

numeric

Nominal rate of return, returned as a numeric.

# nyseclosures

New York Stock Exchange closures from 1885 to 2070

## Syntax

```
Closures = nyseclosures  
[Closures,SatTransition] = nyseclosures(StartDate,EndDate,WorkWeekFormat)
```

## Description

`Closures = nyseclosures` returns a vector of serial date numbers for all known or anticipated closures from January 1, 1885 to December 31, 2070.

Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures from 1885 to 1952 are based on a 6-day workweek. `nyseclosures` contains all holiday and special non-trading days for the New York Stock Exchange from 1885 through 2070 based on a six-day work week (always closed on Sundays).

`[Closures,SatTransition] = nyseclosures(StartDate,EndDate,WorkWeekFormat)`, using optional input arguments, returns a vector of serial date numbers corresponding to market closures between `StartDate` and `EndDate`, inclusive.

Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures from 1885 to 1952 are based on a 6-day workweek. `nyseclosures` contains all holiday and special non-trading days for the New York Stock Exchange from 1885 through 2070 based on a six-day work week (always closed on Sundays). Use `WorkWeekFormat` to modify the list of dates.

## Examples

### Find NYSE Closures

Find the NYSE closures for 1899:

```
datestr(nyseclosures('1-jan-1899','31-dec-1899'), 'dd-mmm-yyyy ddd')  
  
ans = 16x15 char array  
'02-Jan-1899 Mon'  
'11-Feb-1899 Sat'  
'13-Feb-1899 Mon'  
'22-Feb-1899 Wed'  
'31-Mar-1899 Fri'  
'29-May-1899 Mon'  
'30-May-1899 Tue'  
'03-Jul-1899 Mon'  
'04-Jul-1899 Tue'  
'04-Sep-1899 Mon'  
'29-Sep-1899 Fri'  
'30-Sep-1899 Sat'  
'07-Nov-1899 Tue'  
'25-Nov-1899 Sat'
```

```
'30-Nov-1899 Thu'
'25-Dec-1899 Mon'
```

Find the NYSE closures for 1899 using a datetime array:

```
[Closures,SatTransition] = nyseclosures(datetime('1-jan-1899','Locale','en_US'),'30-Jun-1899')
```

```
Closures = 7x1 datetime
02-Jan-1899
11-Feb-1899
13-Feb-1899
22-Feb-1899
31-Mar-1899
29-May-1899
30-May-1899
```

```
SatTransition = datetime
29-Sep-1952
```

Find the NYSE closure dates using the 'Archaic' value for WorkWeekFormat:

```
datestr(nyseclosures('1-sep-1952','31-oct-1952','a'),1)

ans = 10x11 char array
'01-Sep-1952'
'06-Sep-1952'
'13-Sep-1952'
'20-Sep-1952'
'27-Sep-1952'
'04-Oct-1952'
'11-Oct-1952'
'13-Oct-1952'
'18-Oct-1952'
'25-Oct-1952'
```

The exchange was closed on Saturdays for much of 1952 before the official transition to a 5-day workweek.

## Input Arguments

### **StartDate — Start date**

start of default date range, January 1, 1885 (default) | serial date number | date character vector | datetime object

Start date, specified using a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

### **EndDate — End date**

end of default date range, December 31, 2070 (default) | serial date number | date character vector | datetime object

End date, specified using a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

#### **WorkWeekFormat — Method to handle the workweek**

'Implicit' (default) | date character vector with values 'Modern', 'Implicit', or 'Archaic'

Method to handle the workweek, specified using a date character vector with values 'Modern', 'Implicit', or 'Archaic'. This function accepts the first letter for each method as input and is not case-sensitive. Acceptable values are:

- 'Modern' — 5-day workweek with all Saturday trading days removed.
- 'Implicit' — 6-day workweek until 1952 and 5-day week afterward (no need to exclude Saturdays).
- 'Archaic' — 6-day workweek throughout and Saturdays treated as closures after 1952.

Data Types: char

## **Output Arguments**

#### **Closures — Market closures between StartDate and EndDate, inclusive**

vector

Market closures between the StartDate and EndDate, inclusive, returned as a vector of dates.

If StartDate or EndDate are all either serial date numbers or date character vectors, both Closures and SatTransition are returned as serial date numbers. If either StartDate or EndDate are datetime arrays, both Closures and SatTransition are returned as datetime arrays.

If both StartDate and EndDate are not specified or are empty, Closures contains all known or anticipated closures from January 1, 1885 to December 31, 2070 based on a WorkWeekFormat of 'implicit'.

#### **SatTransition — Date of transition for New York Stock Exchange from 6-day workweek to 5-day workweek**

serial date number | datetime array

Date of transition for the New York Stock Exchange from a 6-day workweek to a 5-day workweek, returned as the date September 29, 1952 (serial date number 713226).

If StartDate or EndDate are all either serial date numbers or date character vectors, both Closures and SatTransition are returned as serial date numbers. If either StartDate or EndDate are datetime arrays, both Closures and SatTransition are returned as datetime arrays.

## **More About**

### **holidays**

The holidays function is based on a modern 5-day workweek.

This function contains all holidays and special nontrading days for the New York Stock Exchange from January 1, 1885 to December 31, 2070.

Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures from 1885 to 2070 should include Saturday trading days. To capture these dates, use

nyseclosures. The results from `holidays` and `nyseclosures` are identical if the `WorkWeekFormat` in `nyseclosures` is 'Modern'.

## Introduced before R2006a

## onbalvol

On-Balance Volume (OBV)

**Note** Using a `fints` object for the `Data` argument of `onbalvol` is not recommended. Use a matrix, timetable, or table instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
volume = onbalvol(Data)
```

### Description

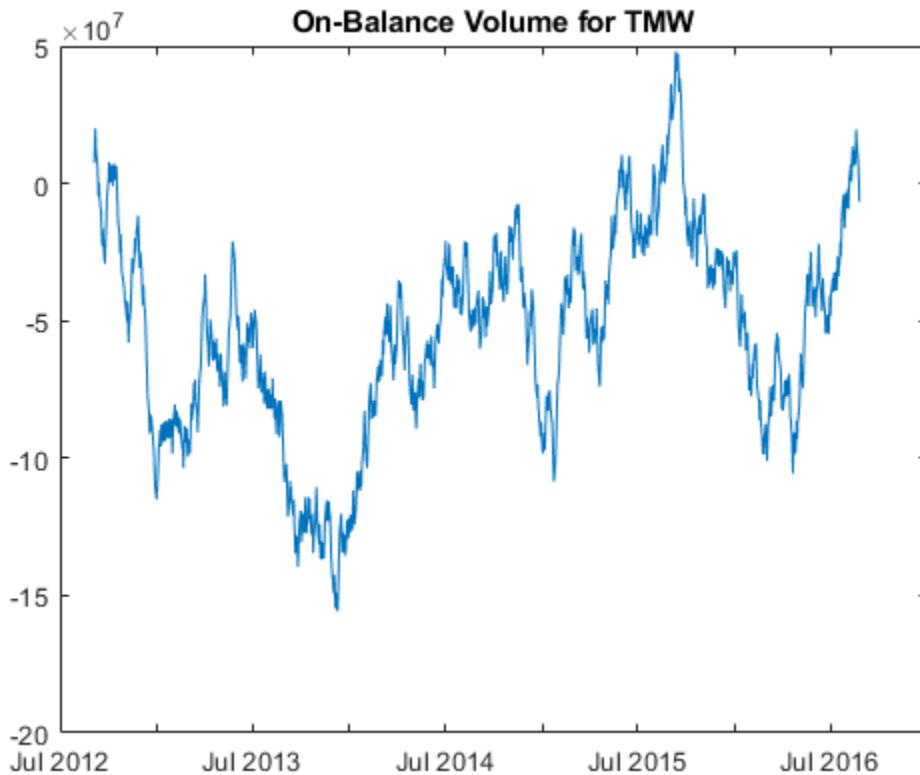

`volume = onbalvol(Data)` calculates the On-Balance Volume from the series of closing stock prices and trade volume.

### Examples

#### Calculate the On-Balance Volume for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
volume = onbalvol(TMW);
plot(volume.Time,volume.OnBalanceVolume)
title('On-Balance Volume for TMW')
```

## Input Arguments

### Data — Data for closing prices and trade volume

matrix | table | timetable

Data for closing prices and trade volume, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-2 matrix of closing prices and trade volume stored in the first and second columns. Timetables and tables with M rows must contain variables named 'Close' and 'Volume' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### volume — On-Balance Volume

matrix | table | timetable

On-Balance Volume, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input **Data**.

# opprofit

Option profit

## Syntax

```
Profit = opprofit(AssetPrice,Strike,Cost,PosFlag,OptType)
```

## Description

Profit = opprofit(AssetPrice,Strike,Cost,PosFlag,OptType) returns the profit of an option.

## Examples

### Calculate the Profit of an Option

This example shows how to return the profit of an option. For example, consider buying (going long on) a call option with a strike price of \$90 on an underlying asset with a current price of \$100 for a cost of \$4.

```
Profit = opprofit(100, 90, 4, 0, 0)
```

```
Profit = 6
```

## Input Arguments

### AssetPrice — Asset price

numeric

Asset price, specified as a scalar or a NINST-by-1 vector.

Data Types: double

### Strike — Strike or exercise price

numeric

Strike or exercise price, specified as a scalar or a NINST-by-1 vector.

Data Types: double

### Cost — Cost of option

numeric

Cost of the option, specified as a scalar or a NINST-by-1 vector.

Data Types: double

### PosFlag — Option position

0 = long | 1 = short

Option position, specified as a scalar or a NINST-by-1 vector using the values 0 (long) or 1 (short).

Data Types: logical

**OptType — Option type**

0 = call option | 1 = put option

Option type, specified as a scalar or a NINST-by-1 vector using the values 0 (call option) or 1 (put option).

Data Types: logical

## Output Arguments

**Profit — Option profit**

vector

Option profit, returned as a scalar or a NINST-by-1 vector.

Periodic payment given number of advance payments

## Syntax

```
Payment = payadv(Rate,NumPeriods,PresentValue,FutureValue,Advance)
```

## Description

`Payment = payadv(Rate,NumPeriods,PresentValue,FutureValue,Advance)` computes the periodic payment given a number of advance payments.

## Examples

### Compute the Periodic Payment

This example shows how to compute the periodic payment, given a number of advance payments. For example, the present value of a loan is \$1000.00 and it will be paid in full in 12 months. The annual interest rate is 10% and three payments are made at closing time.

```
Payment = payadv(0.1/12, 12, 1000, 0, 3)
```

Payment = 85.9389

## Input Arguments

### Rate — Lending or borrowing rate per period

decimal

Lending or borrowing rate per period, specified as a decimal. The Rate must be greater than or equal to 0.

Data Types: double

### NumPeriods — Number of periods in the life of the instrument

integer

Number of periods in the life of the instrument, specified as an integer.

Data Types: double

### PresentValue — Present value of instrument

numeric

Present value of the instrument, specified as a numeric.

Data Types: double

### FutureValue — Future value or target value attained after NumPeriods periods

numeric

Future value or target value to be attained after `NumPeriods` periods, specified as a numeric.

Data Types: `double`

**Advance — Number of advance payments**

`integer`

Number of advance payments, specified as an integer. If the payments are made at the beginning of the period, add 1 to `Advance`.

Data Types: `double`

## Output Arguments

**Payment — Periodic payment**

`numeric`

Periodic payment, returned as the periodic payment given a number of advance payments.

**Introduced before R2006a**

# payodd

Payment of loan or annuity with odd first period

## Syntax

```
Payment = payodd(Rate,NumPeriods,PresentValue,FutureValue,Days)
```

## Description

Payment = payodd(Rate,NumPeriods,PresentValue,FutureValue,Days) computes the payment for a loan or annuity with an odd first period.

## Examples

### Compute the Payment for a Loan or Annuity With an Odd First Period

This example shows how to return the payment for a loan or annuity with an odd first period. For example, consider a two-year loan for \$4000 that has an annual interest rate of 11% and the first payment will be made in 36 days.

```
Payment = payodd(0.11/12, 24, 4000, 0, 36)
```

```
Payment = 186.7731
```

## Input Arguments

### Rate — Interest rate per period

decimal

Interest rate per period, specified as a decimal.

Data Types: double

### NumPeriods — Number of periods in the life of the instrument

integer

Number of periods in the life of the instrument, specified as an integer.

Data Types: double

### PresentValue — Present value of instrument

numeric

Present value of the instrument, specified as a numeric.

Data Types: double

### FutureValue — Future value or target value attained after NumPeriods periods

numeric

Future value or target value to be attained after NumPeriods periods, specified as a numeric.

Data Types: double

**Days — Actual number of days until first payment is made**

integer

Actual number of days until the first payment is made, specified as an integer.

Data Types: double

## Output Arguments

**Payment — Payment**

numeric

Payment, returns the payment for a loan or annuity with an odd first period.

## See Also

[“Analyzing and Computing Cash Flows” on page 2-14](#)

## Introduced before R2006a

# payper

Periodic payment of loan or annuity

## Syntax

```
Payment = payper(Rate,NumPeriods,PresentValue)
Payment = payper(_____,FutureValue,Due)
```

## Description

Payment = payper(Rate,NumPeriods,PresentValue) returns the periodic payment of a loan or annuity.

Payment = payper(\_\_\_\_\_,FutureValue,Due) adds optional arguments.

## Examples

### Compute the Periodic Payment of a Loan or Annuity

This example shows how to find the monthly payment for a three-year loan of \$9000 with an annual interest rate of 11.75%.

```
Payment = payper(0.1175/12, 36, 9000, 0, 0)
```

```
Payment = 297.8553
```

## Input Arguments

### Rate — Interest rate per period

decimal

Interest rate per period, specified as a decimal.

Data Types: double

### NumPeriods — Number of payment periods in life of instrument

integer

Number of payment periods in the life of instrument, specified as an integer.

Data Types: double

### PresentValue — Present value of the instrument

numeric

Present value of the instrument, specified as a numeric.

Data Types: double

**FutureValue — Future value or target value attained after NumPeriods periods**  
0 (default) | numeric

(Optional) Future value or target value to be attained after NumPeriods periods, specified as a numeric.

Data Types: double

**Due — Indicator for when payments are due**  
0 (default) | logical with value of 1 or 0

(Optional) Indicator for when payments are due, specified as a logical with a value of 0 = end of period (default), or 1 = beginning of period.

Data Types: logical

## Output Arguments

**Payment — Periodic payment**  
numeric

Periodic payment, returns the periodic payment of a loan or annuity.

## More About

### Annuity

An annuity is a series of payments over a period of time.

The payments are usually in equal amounts and usually at regular intervals such as quarterly, semiannually, or annually.

“Analyzing and Computing Cash Flows” on page 2-14

### Introduced before R2006a

# payuni

Uniform payment equal to varying cash flow

## Syntax

```
Series = payuni(CashFlow,Rate)
```

## Description

`Series = payuni(CashFlow,Rate)` computes the uniform series value of a varying cash flow.

## Examples

### Calculate the Uniform Series Value

This example shows how to calculate the uniform series value using `payuni`.

The following cash flow represents the yearly income from an initial investment of \$10,000. The annual interest rate is 8%.

Year 1 - \$2000

Year 2 - \$1500

Year 3 - \$3000

Year 4 - \$3800

Year 5 - \$5000

To calculate the uniform series value:

```
Series = payuni([-10000 2000 1500 3000 3800 5000], 0.08)
```

```
Series = 429.6296
```

## Input Arguments

### CashFlow — Cash flows

vector

Cash flows, specified as a vector of varying cash flows. Include the initial investment as the initial cash flow value (a negative number).

Data Types: double

### Rate — Periodic interest rate

decimal

Periodic interest rate, specified as a decimal.

Data Types: double

## Output Arguments

### **Series — Uniform series**

numeric

Uniform series, returned as the value of a varying cash flow.

## Introduced before R2006a

# pcalims

Linear inequalities for individual asset allocation

## Syntax

```
[A,b] = pcalims(AssetMin,AssetMax)
[A,b] = pcalims(___,NumAssets)
```

## Description

As an alternative to `pcalims`, use the Portfolio object (`Portfolio`) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using `Portfolio` objects, see “[Portfolio Object Workflow](#)” on page 4-17.

`[A,b] = pcalims(AssetMin,AssetMax)` specifies the lower and upper bounds of portfolio allocations in each of `NumAssets` available asset investments. `pcalims` specifies the lower and upper bounds of portfolio allocations in each of `NASSETS` available asset investments.

---

**Note** If `pcalims` is called with fewer than two output arguments, the function returns `A` concatenated with `b` `[A,b]`.

---

`[A,b] = pcalims(___,NumAssets)` specifies options using an optional argument in addition to the input arguments in the previous syntax.

## Examples

### Compute Linear Inequalities for Individual Asset Allocation

Set the minimum weight in every asset to 0 (no short-selling), and set the maximum weight of IBM stock to 0.5 and CSCO to 0.8, while letting the maximum weight in INTC float.

Minimum weight:

- IBM — 0
- INTC — 0
- CSCO — 0

Maximum weight:

- IBM — 0.5
- INTC —
- CSCO — 0.8

`AssetMin = 0`

```
AssetMin = 0
AssetMax = [0.5 NaN 0.8]
AssetMax = 1x3
    0.5000      NaN      0.8000

[A,b] = pcalims(AssetMin, AssetMax)
A = 5x3
    1      0      0
    0      0      1
   -1      0      0
    0     -1      0
    0      0     -1

b = 5x1
    0.5000
    0.8000
    0
    0
    0
```

Portfolio weights of 50% in IBM and 50% in INTC satisfy the constraints

Set the minimum weight in every asset to 0 and the maximum weight to 1.

Minimum weight:

- IBM — 0
- INTC — 0
- CSCO — 0

Maximum weight:

- IBM — 1
- INTC — 1
- CSCO — 1

```
AssetMin = 0
AssetMin = 0
AssetMax = 1
AssetMax = 1
NumAssets = 3
NumAssets = 3

[A,b] = pcalims(AssetMin, AssetMax, NumAssets)
```

A = 6×3

```
1     0     0
0     1     0
0     0     1
-1    0     0
0    -1     0
0     0    -1
```

b = 6×1

```
1
1
1
0
0
0
```

Portfolio weights of 50% in IBM and 50% in INTC satisfy the constraints.

## Input Arguments

### **AssetMin — Minimum allocations in each asset**

scalar numeric | vector

Minimum allocations in each asset, specified as a scalar numeric or NASSETS vector. NaN indicates no constraint.

Data Types: double

### **AssetMax — Maximum allocations in each asset**

scalar numeric | vector

Maximum allocations in each asset, specified as a scalar numeric or NASSETS vector. NaN indicates no constraint.

Data Types: double

### **NumAssets — Number of assets**

length of AssetMin or AssetMax (default) | scalar numeric

(Optional) Number of assets, specified as a scalar numeric.

Data Types: double

## Output Arguments

### **A — Lower bound**

matrix

Lower bound, returned as a matrix such that  $A^T \cdot PortWts' \leq b$ , where PortWts is a 1-by-NASSETS vector of asset allocations.

**b — Upper bound**

vector

Upper bound, returned as a vector such that  $A^*PortWts' \leq b$ , where  $PortWts$  is a 1-by-NASSETS vector of asset allocations.

# pcgcomp

Linear inequalities for asset group comparison constraints

## Syntax

```
[A,b] = pcgcomp(GroupA,AtoBmin,AtoBmax,GroupB)
```

## Description

As an alternative to `pcgcomp`, use the Portfolio object (`Portfolio`) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see “[Portfolio Object Workflow](#)” on page 4-17.

`[A,b] = pcgcomp(GroupA,AtoBmin,AtoBmax,GroupB)` specifies that the ratio of allocations in one group to allocations in another group is at least `AtoBmin` to 1 and at most `AtoBmax` to 1. Comparisons can be made between an arbitrary number of group pairs `NGROUPS` comprising subsets of `NASSETS` available investments.

If `pcgcomp` is called with fewer than two output arguments, the function returns `A` concatenated with `b` `[A,b]`.

## Examples

### Linear Inequalities for Asset Group-to-Group Comparison Constraints

Use the following assets and groupings.

|        |               |               |        |
|--------|---------------|---------------|--------|
| Asset  | INTC          | XOM           | RD     |
| Region | North America | North America | Europe |
| Sector | Technology    | Energy        | Energy |

| Group         | Min. Exposure | Max. Exposure |
|---------------|---------------|---------------|
| North America | 0.30          | 0.75          |
| Europe        | 0.10          | 0.55          |
| Technology    | 0.20          | 0.50          |
| Energy        | 0.20          | 0.80          |

Make the North American energy sector compose exactly 20% of the North American investment.

```
%          INTC  XOM  RD
GroupA = [    0    1    0  ]; % North American Energy
GroupB = [    1    1    0  ]; % North America
```

```
AtoBmin = 0.20;
AtoBmax = 0.20;
```

```
[A,b] = pcgcomp(GroupA, AtoBmin, AtoBmax, GroupB)
```

A = 2x3

|         |         |   |
|---------|---------|---|
| 0.2000  | -0.8000 | 0 |
| -0.2000 | 0.8000  | 0 |

b = 2x1

|   |
|---|
| 0 |
| 0 |

Portfolio weights of 40% for INTC, 10% for XOM, and 50% for RD satisfy the constraints.

## Input Arguments

### **GroupA — Grouping A**

vector

Grouping A, specified as a number of groups (**NGROUPS**) by number of assets (**NASSETS**) vector of groups to compare. Each row specifies a group. For a specific group,  $\text{Group}(i, j) = 1$  if the group contains asset  $j$ ; otherwise,  $\text{Group}(i, j) = 0$ .

Data Types: double

### **AtoBmin — Minimum ratios**

scalar | vector

Minimum ratios, specified as a scalar or **NGROUPS**-long vectors of minimum ratios of allocations in **GroupA** to allocations in **GroupB**. NaN indicates no constraint between the two groups. Scalar bounds are applied to all group pairs. The total number of assets allocated to **GroupA** divided by the total number of assets allocated to **GroupB** is  $\geq \text{AtoBmin}$  and  $\leq \text{AtoBmax}$ .

Data Types: double

### **AtoBmax — Maximum ratios**

scalar | vector

Maximum ratios, specified as a scalar or **NGROUPS**-long vectors of maximum ratios of allocations in **GroupA** to allocations in **GroupB**. NaN indicates no constraint between the two groups. Scalar bounds are applied to all group pairs. The total number of assets allocated to **GroupA** divided by the total number of assets allocated to **GroupB** is  $\geq \text{AtoBmin}$  and  $\leq \text{AtoBmax}$ .

Data Types: double

### **GroupB — Grouping A**

vector

Grouping B, specified as a number of groups (**NGROUPS**) by number of assets (**NASSETS**) vector of groups to compare. Each row specifies a group. For a specific group,  $\text{Group}(i, j) = 1$  if the group contains asset  $j$ ; otherwise,  $\text{Group}(i, j) = 0$ .

Data Types: double

## Output Arguments

### A — Lower bound

matrix

Lower bound, returned as a matrix such that  $A^*PortWts' \leq b$ , where  $PortWts$  is a 1-by-NASSETS vector of asset allocations.

### b — Upper bound

vector

Upper bound, returned as a vector such that  $A^*PortWts' \leq b$ , where  $PortWts$  is a 1-by-NASSETS vector of asset allocations.

- “Portfolio Optimization Functions” on page 3-3

## Introduced before R2006a

## pcglims

Linear inequalities for asset group minimum and maximum allocation

### Syntax

```
[A,b] = pcglims(Groups,GroupMin,GroupMax)
```

### Description

As an alternative to `pcglims`, use the Portfolio object (`Portfolio`) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see “[Portfolio Object Workflow](#)” on page 4-17.

`[A,b] = pcglims(Groups,GroupMin,GroupMax)` specifies minimum and maximum allocations to groups of assets. Bounds can be specified for an arbitrary number of groups `NGROUPS`, made up as subsets of the `NASSETS` investments.

If `pcglims` is called with fewer than two output arguments, the function returns `A` concatenated with `b` `[A,b]`.

### Examples

#### Linear Inequalities for Asset Group Minimum and Maximum Allocation

Use the following assets and groupings.

|        |               |               |        |
|--------|---------------|---------------|--------|
| Asset  | INTC          | XOM           | RD     |
| Region | North America | North America | Europe |
| Sector | Technology    | Energy        | Energy |

| Group         | Min. Exposure | Max. Exposure |
|---------------|---------------|---------------|
| North America | 0.30          | 0.75          |
| Europe        | 0.10          | 0.55          |
| Technology    | 0.20          | 0.50          |
| Energy        | 0.50          | 0.50          |

Set the minimum and maximum investment in various groups.

```
%          INTC  XOM  RD
Groups = [ 1    1   0 ; % North America
           0    0   1 ; % Europe
           1    0   0 ; % Technology
           0    1   1 ]; % Energy
```

```
GroupMin = [0.30
            0.10
            0.20
```

```

0.50];

GroupMax = [0.75
            0.55
            0.50
            0.50];

[A,b] = pcglims(Groups, GroupMin, GroupMax)

A = 8x3

-1    -1    0
0    0    -1
-1    0    0
0    -1    -1
1    1    0
0    0    1
1    0    0
0    1    1

b = 8x1

-0.3000
-0.1000
-0.2000
-0.5000
0.7500
0.5500
0.5000
0.5000

```

Portfolio weights of 50% in INTC, 25% in XOM, and 25% in RD satisfy the constraints.

## Input Arguments

### **Groups — Grouping**

vector

Grouping, specified as a number of groups (**NGROUPS**) by number of assets (**NASSETS**) vector of which assets belong to which group. Each row specifies a group. For a specific group, **Group(i,j) = 1** if the group contains asset j; otherwise, **Group(i,j) = 0**.

Data Types: double

### **GroupMin — Minimum allocations**

scalar | vector

Minimum allocations, specified as a scalar or **NGROUPS**-long vectors of minimum combined allocations in each group. **NaN** indicates no constraint. Scalar bounds are applied to all groups.

Data Types: double

### **GroupMax — Maximum allocations**

scalar | vector

Maximum allocations, specified as a scalar or `NGROUPS`-long vectors maximum combined allocations in each group. `NaN` indicates no constraint. Scalar bounds are applied to all groups.

Data Types: double

## Output Arguments

### A — Lower bound

matrix

Lower bound, returned as a matrix such that  $A^*PortWts' \leq b$ , where `PortWts` is a 1-by-`NASSETS` vector of asset allocations.

### b — Upper bound

vector

Upper bound, returned as a vector such that  $A^*PortWts' \leq b$ , where `PortWts` is a 1-by-`NASSETS` vector of asset allocations.

## Introduced before R2006a

# pcpval

Linear inequalities for fixing total portfolio value

## Syntax

```
[A,b] = pcpval(PortValue,NumAssets)
```

## Description

[A,b] = pcpval(PortValue,NumAssets) scales the total value of a portfolio of NumAssets assets to PortValue. All portfolio weights, bounds, return, and risk values except ExpReturn and ExpCovariance (see portopt) are in terms of PortValue.

---

**Note** As an alternative to pcpval, use the **Portfolio** object (**Portfolio**) for mean-variance portfolio optimization. The **Portfolio** object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using **Portfolio** objects, see “[Portfolio Object Workflow](#)” on page 4-17.

---

## Examples

### Scale the Value of a Portfolio

Scale the value of a portfolio of three assets that are equal to 1, so all return values are rates and all weight values are in fractions of the portfolio.

```
PortValue = 1;
NumAssets = 3;

[A,b] = pcpval(PortValue, NumAssets)
```

A = 2×3

$$\begin{matrix} 1 & 1 & 1 \\ -1 & -1 & -1 \end{matrix}$$

b = 2×1

$$\begin{matrix} 1 \\ -1 \end{matrix}$$

Portfolio weights of 40%, 10%, and 50% in the three assets satisfy the constraints.

## Input Arguments

### PortValue — Total value of asset portfolio

numeric

Total value of asset portfolio, specified as a scalar numeric representing the sum of the allocations in all assets. `PortValue = 1` specifies weights as fractions of the portfolio and return and risk numbers as rates instead of value.

Data Types: double

### NumAssets — Number of available asset investments

numeric

Number of available asset investments, specified as a scalar numeric.

Data Types: double

## Output Arguments

### A — Asset allocations

matrix

Asset allocations, returned as a matrix such that  $A * PortWts' \leq b$ , where `PortWts` is a 1-by-`NASSETS` vector of asset allocations.

### b — Asset allocations

vector

Asset allocations, returned as a vector such that  $A * PortWts' \leq b$ , where `PortWts` is a 1-by-`NASSETS` vector of asset allocations.

---

**Note** If `pcpcval` is called with fewer than two output arguments, returns `A` and `b` are concatenated together:

```
Cons = [A, b];
Cons = pcpval(PortValue, NumAssets)
```

---

## Introduced before R2006a

# peravg

Periodic average of FINTS object

---

**Note** peravg is not recommended. Use timetable instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
avgfts = peravg(tsobj)
avgfts = peravg(tsobj,numperiod)
avgfts = peravg(tsobj,daterange)
```

## Arguments

|           |                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------|
| tsobj     | Financial time series object                                                                                |
| numperiod | (Optional) Integer specifying the number of data points over which each periodic average should be averaged |
| daterange | (Optional) Time period over which the data is averaged                                                      |

## Description

peravg calculates periodic averages of a financial time series object. Periodic averages are calculated from the values per period defined. If the period supplied is a character vector, it is assumed as a range of date character vector. If the period is entered as numeric, the number represents the number of data points (financial time series periods) to be included in a period for the calculation. For example, if you enter '01/01/98::01/01/99' as the period input argument, peravg returns the average of the time series between those dates, inclusive. However, if you enter the number 5 as the period input, peravg returns a series of averages from the time series data taken 5 date points (financial time series periods) at a time.

avgfts = peravg(tsobj,numperiod) returns a structure avgfts that contains the periodic (per numperiod periods) average of the financial time series object. avgfts has field names identical to the data series names of tsobj.

avgfts = peravg(tsobj,daterange) returns a structure avgfts that contains the periodic (as specified by daterange) average of the financial time series object. avgfts has field names identical to the data series names of tsobj.

---

**Note** peravg calculates periodic averages of a FINTS object. Periodic averages are calculated from the values per period defined. If the period supplied is a character vector, it is assumed as a range of date character vectors. If the period is entered as numeric, the number represents the number of data points to be included in a period for the calculation.

---

## Examples

If you enter `01-Jan-2001::03-Jan-2001` as the period input argument, `peravg` returns the average of the time series between those dates, inclusive. However, if you enter the number 5 as the period input, `peravg` returns a series of averages from the time series data, taken 5 date points at a time.

```
%% Create the FINTS object %%
dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001'; ...
          '02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates, 1), 1), times]);
data = [(1:6)', 2*(1:6)'];
myFts = fints(dates_times, data, {'Data1', 'Data2'}, 1, 'My first FINTS')

%% Create the FINTS object %%
[p, pFts] = peravg(myFts, 3)

## Introduced before R2006a

## periodicreturns

Periodic total returns from total return prices

### Syntax

```
TotalReturn = periodicreturns(TotalReturnPrices)
TotalReturn = periodicreturns(___,Period)
```

### Description

`TotalReturn = periodicreturns(TotalReturnPrices)` calculates the daily total returns from a daily total return price series.

`TotalReturn = periodicreturns(___,Period)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute TotalReturn Using datetime Input for TotalReturnPrices

Compute `TotalReturn` returned as a table using `datetime` input in a table for `TotalReturnPrices`.

```
Dates = datetime(2015,1,1:10,'Locale','en_US');
Prices = [0.01 0.03 0.1 -0.05 0.02 0.07 0.03 -0.01 -0.02 0.01];
TotalReturnPrices = table(Dates,Prices);
TotalReturn = periodicreturns(TotalReturnPrices)
```

```
TotalReturn=9×2 table
    Dates        Prices
    _____
    02-Jan-2015      2
    03-Jan-2015    2.3333
    04-Jan-2015     -1.5
    05-Jan-2015     -1.4
    06-Jan-2015      2.5
    07-Jan-2015   -0.57143
    08-Jan-2015   -1.3333
    09-Jan-2015       1
    10-Jan-2015     -1.5
```

### Input Arguments

**TotalReturnPrices — Total return prices for a given security**  
matrix | table

Total return prices for a given security, specified as an `NUMOBS`-by-`NASSETS` + 1 matrix where Column 1 contains MATLAB serial date numbers. The remaining columns contain total return price data.

If you specify `TotalReturnPrices` as a table, the first column of the table represents the dates (as either serial date numbers, date character vectors, or datetime arrays) while the other columns represent the returns data. If a table is used, `TotalReturn` is returned as a table.

---

**Note** Although input returns can have dates in either ascending or descending order, output total returns in `TotalReturn` have dates in ascending order, with the earliest date in the first row of `TotalReturn`, and the most recent date in the last row of `TotalReturn`.

---

Data Types: `double` | `table`

#### **Period — Periodicity flag used to compute total returns**

`'d'` (default) | character vector | numeric

(Optional) Periodicity flag used to compute total returns, specified as one of the following values:

- `'d'` = daily values (default)
- `'w'` = weekly values
- `'m'` = monthly values
- `n` = rolling return periodic values, where  $n$  is an integer

Data Types: `char` | `double`

## **Output Arguments**

#### **TotalReturn — Total return values**

`matrix` | `table`

Total return values, returned as a P-by-N matrix or table consisting of either Dates in column 1 and daily return values in the remaining columns or period-end dates in column 1 and monthly return values in the remaining columns. The format of `TotalReturn` matches the format of the input `TotalReturnPrices`.

## plot

Plot data series

**Note** Using a `fints` object for the `tsobj` argument of `plot` is not recommended. Use a `timetable` or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
plot(tsobj)
plot(tsobj, linefmt)
plot(___, volumename, bar)
hp = plot(___)
```

### Description

`plot(tsobj)` plots the data series contained in the object `tsobj`. Each data series is a line. `plot` automatically generates a legend and dates on the x-axis. Grid is turned on by default. `plot` uses the default color order as if plotting a matrix.

The `plot` command automatically creates subplots when multiple time series are encountered, and they differ greatly on their decimal scales. For example, subplots are generated if one time series data set is in the 10s and another is in the 10,000s.

`plot(tsobj, linefmt)` plots the data series in `tsobj` using the line format specified. For a list of possible line formats, see `plot`. The plot legend is not generated, but the dates on the x-axis and the plot grid are. The specified line format is applied to all data series; that is, all data series have the same line type.

`plot(___, volumename, bar)` specifies which data series is the volume. The volume is plotted in a subplot below the other data series. If `bar = 1`, the volume is plotted as a bar chart. Otherwise, a line plot is used.

`hp = plot(___)` also returns the handle(s) to the object(s) inside the plot figure. If there are multiple lines in the plot, `hp` is a vector of multiple handles.

### Examples

#### Plot Financial Time Series Object

- 1 Create a `fints` object.

```
f = fints((today:today+1)', [4 -2 1; 9 5 7])
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see Convert F...
```

> In `fints` (line 169)

```
f =
```

```

desc: (none)
freq: Unknown (0)

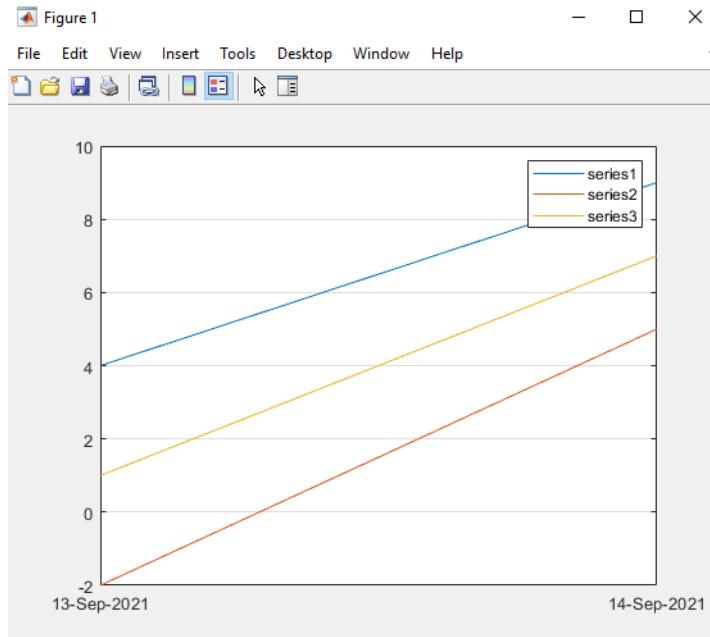

{'dates: (2)'}    {'series1: (2)'}    {'series2: (2)'}    {'series3: (2)'}
{'10-Sep-2021'}    {[        4]}    {[      -2]}    {[       1]}
{'11-Sep-2021'}    {[        9]}    {[       5]}    {[       7]}

```

- 2** Plot data series for the financial time series object using `plot`.

```
plot(f)
```

Warning: `FINTS` is not recommended. Use `TIMETABLE` instead. For more information, see Convert FINTS Objects to TIMETABLE.

## Input Arguments

### **tsobj — Financial time series object**

`fints` object

Financial time series object, specified as a `fints` object.

Data Types: `object`

### **linefmt — Line format**

character vector

Line format, specified as a character vector. For a list of possible line formats, see `plot`. The plot legend is not generated, but the dates on the x-axis and the plot grid are. The specified line format is applied to all data series; that is, all data series have the same line type.

Data Types: `char`

### **volumename — Defines which data series is the volume series**

character vector

Defines which data series is the volume series, specified as a character vector. `volumename` must be the exact data series name for the volume column (case sensitive).

Data Types: `char`

**bar — Chart type**

integer with value of 0 or 1

Chart type, specified as an integer, where:

- 0 — (Default) Plot volume as a line.
- 1 — Plot volume as a bar chart. The width of each bar is the same as the default in `bar`, `barh`.

Data Types: `double`

## Output Arguments

**hp — Handle to plot**

handle object

Handle to plot, returned as a handle object. If `bar = 1`, the handle to the patch for the bars is also returned.

---

**Note** To turn off the legend, enter `legend off` at the MATLAB command line. Once you turn it off, the legend is deleted. To turn it back on, recreate it using the `legend` command as if you are creating it for the first time. To turn off the grid, enter `grid off`. To turn it back on, enter `grid on`.

---

## Introduced before R2006a

# plotFrontier

Plot efficient frontier

## Syntax

```
[prsk,pret] = plotFrontier(obj)

[prsk,pret] = plotFrontier(obj,NumPorts)
[prsk,pret] = plotFrontier(obj,PortWeights)
[prsk,pret] = plotFrontier(obj,PortRisk,PortReturn)
```

## Description

[prsk,pret] = plotFrontier(obj) estimates the efficient frontier with default number of 10 portfolios on the frontier, and plots the corresponding efficient frontier for **Portfolio**, **PortfolioCVaR**, or **PortfolioMAD** objects. For details on the respective workflows when using these different objects, see “**Portfolio Object Workflow**” on page 4-17, “**PortfolioCVaR Object Workflow**” on page 5-15, and “**PortfolioMAD Object Workflow**” on page 6-15.

[prsk,pret] = plotFrontier(obj,NumPorts) estimates the efficient frontier with a specified number portfolios on the frontier, and plots the corresponding efficient frontier. The number of portfolios is defined by **NumPorts**.

[prsk,pret] = plotFrontier(obj,PortWeights) estimates efficient portfolio risks and returns with **PortWeights**, and plots the efficient frontier with those portfolios. This syntax assumes that you provide valid efficient portfolio weights as input. **PortWeights** is a **NumAsset**-by-**NumPorts** matrix.

[prsk,pret] = plotFrontier(obj,PortRisk,PortReturn) plots the efficient frontier with the given risks and returns. This syntax assumes that you provide valid inputs for efficient portfolio risks and returns. **PortRisk** and **PortReturn** are vectors with the same size.

---

**Note** `plotFrontier` handles multiple input formats as described above. Given an asset universe with **NumAssets** assets and an efficient frontier with **NumPorts** portfolios, remember that portfolio weights are **NumAsset**-by-**NumPorts** matrices and that portfolio risks and returns are **NumPorts** column vectors.

---

## Examples

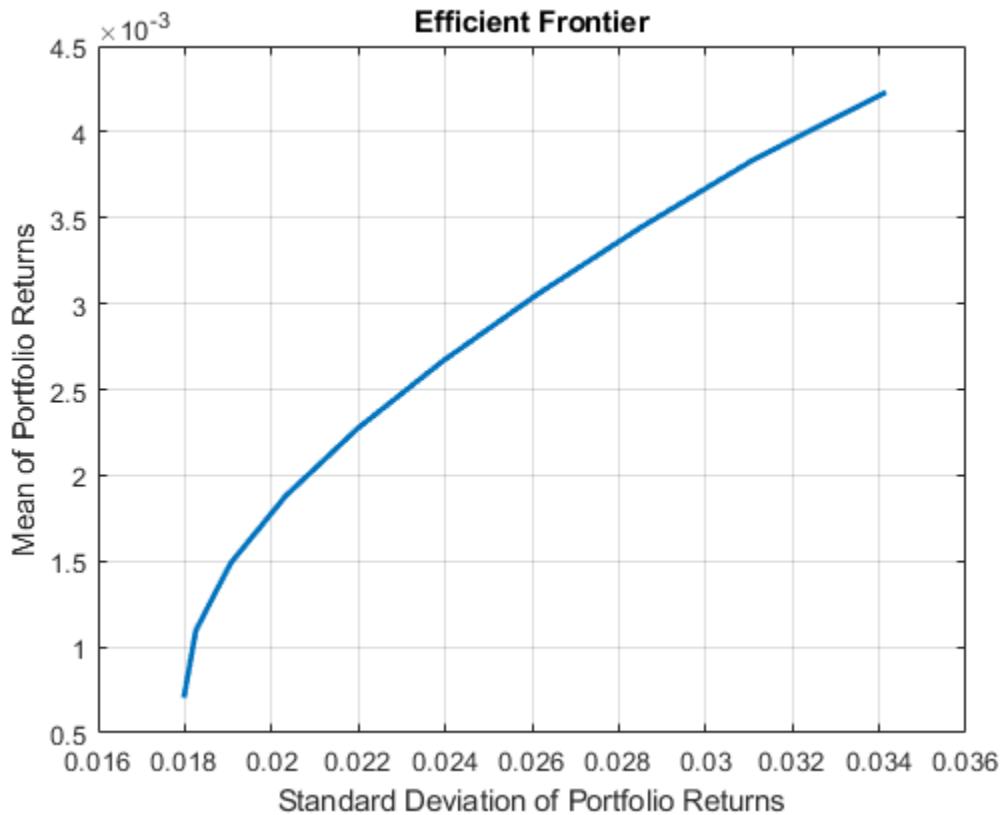

### Plot the Efficient Frontier for the Portfolio Object

Given a portfolio **p**, plot the efficient frontier.

```
load CAPMuniverse

p = Portfolio('AssetList',Assets(1:12));
p = estimateAssetMoments(p, Data(:,1:12), 'missingdata',true);
```

```
p = setDefaultConstraints(p);
plotFrontier(p);
```

### Plot the Efficient Frontier for the Portfolio Object with BoundType and MaxNumAssets Constraints

Create a `Portfolio` object for 12 stocks based on `CAPMuniverse.mat`.

```
load CAPMuniverse
p0 = Portfolio('AssetList',Assets(1:12));
p0 = estimateAssetMoments(p0, Data(:,1:12), 'missingdata', true);
p0 = setDefaultConstraints(p0);
```

Use `setMinMaxNumAssets` to define a maximum number of 3 assets.

```
pWithMaxNumAssets = setMinMaxNumAssets(p0, [], 3);
```

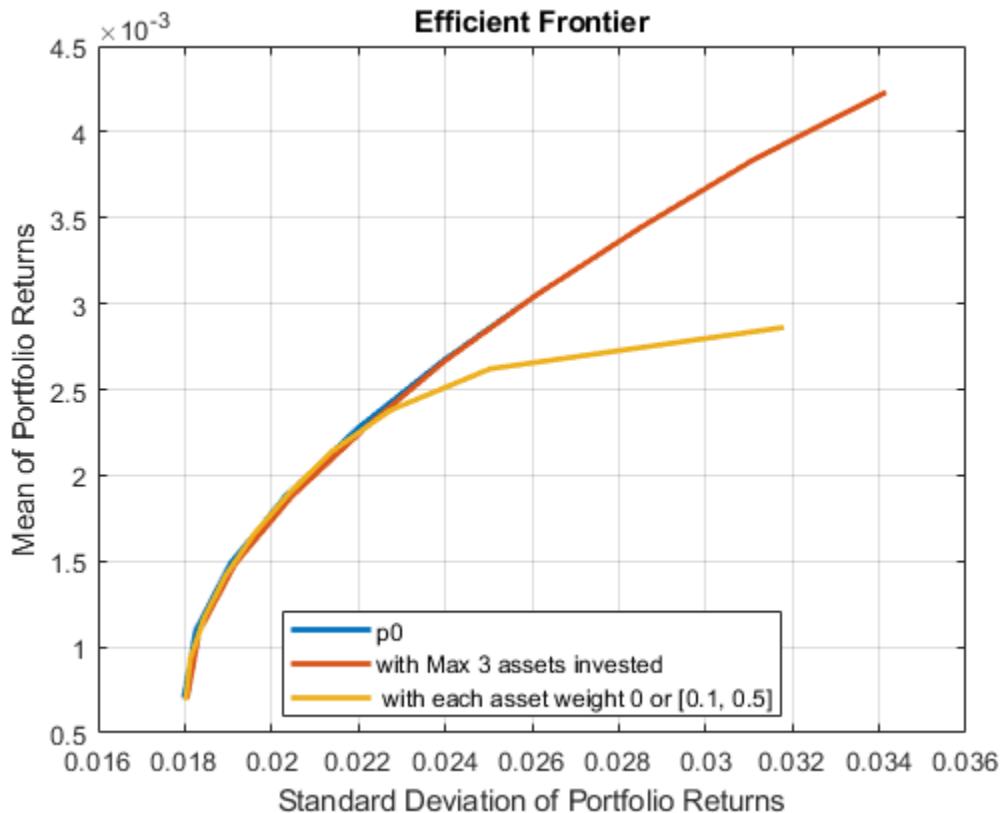

Use `setBounds` to define a lower and upper bound and a `BoundType` of 'Conditional'.

```
pWithConditionalBound = setBounds(p0, 0.1, 0.5, 'BoundType', 'Conditional');
```

Use `plotFrontier` to compare the different portfolio objects.

```
figure;
plotFrontier(p0); hold on;
```

```
plotFrontier(pWithMaxNumAssets); hold on;
plotFrontier(pWithConditionalBound); hold off;
legend('p0', 'with Max 3 assets invested', ' with each asset weight 0 or [0.1, 0.5]', 'location'
```

Define a target return and use `estimateFrontierByReturn` to compare the three portfolio objects.

```
targetRetn = 2.0e-3;
pwgt0 = estimateFrontierByReturn(p0, targetRetn);
pwgtWithMaxNumAssets = estimateFrontierByReturn(pWithMaxNumAssets, targetRetn);
pwgtConditionalBound = estimateFrontierByReturn(pWithConditionalBound, targetRetn);
```

The following table shows the final allocation for specified target return among the three portfolio objects. You can see that the small positions in 'AAPL' and 'HPQ' are avoided in `pwgtConditionalBound`, and only three assets are invested in `pwgtWithMaxNumAssets`.

| result = table(p0.AssetList', pwgt0, pwgtWithMaxNumAssets, pwgtConditionalBound) |          |          |                      |                      |
|----------------------------------------------------------------------------------|----------|----------|----------------------|----------------------|
| result=12x4 table                                                                | Var1     | pwgt0    | pwgtWithMaxNumAssets | pwgtConditionalBound |
|                                                                                  | {'AAPL'} | 0.076791 | 0                    | 0.1                  |
|                                                                                  | {'AMZN'} | 0        | 0                    | 0                    |
|                                                                                  | {'CSCO'} | 0        | 0                    | 0                    |
|                                                                                  | {'DELL'} | 0        | 0                    | 0                    |
|                                                                                  | {'EBAY'} | 0        | 0                    | 0                    |
|                                                                                  | {'GOOG'} | 0.44841  | 0.47297              | 0.44255              |
|                                                                                  | {'HPQ'}  | 0.022406 | 0                    | 0                    |

|          |         |         |         |
|----------|---------|---------|---------|
| {'IBM'}  | 0.31139 | 0.34762 | 0.31592 |
| {'INTC'} | 0       | 0       | 0       |
| {'MSFT'} | 0.14101 | 0.17941 | 0.14153 |
| {'ORCL'} | 0       | 0       | 0       |
| {'YHOO'} | 0       | 0       | 0       |

### Plot the Efficient Frontier for the PortfolioCVaR Object

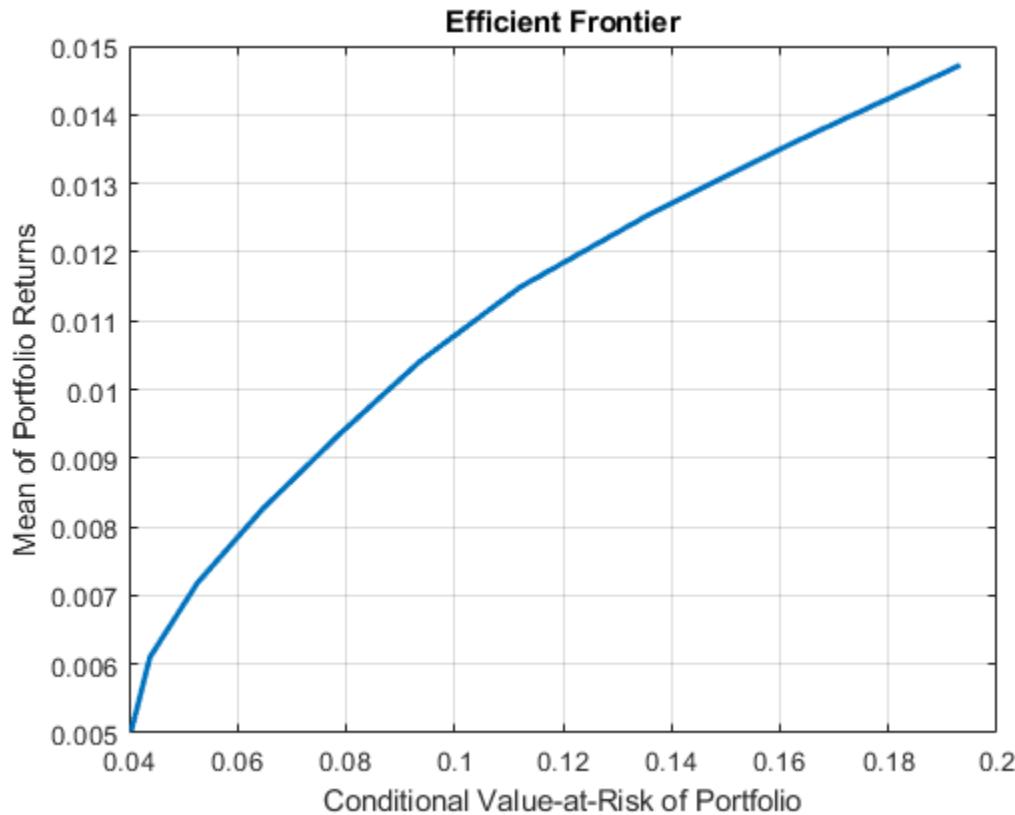

Given a PortfolioCVaR  $p$ , plot the efficient frontier.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

plotFrontier(p);
```

### Plot Efficient Frontier for PortfolioMAD Object

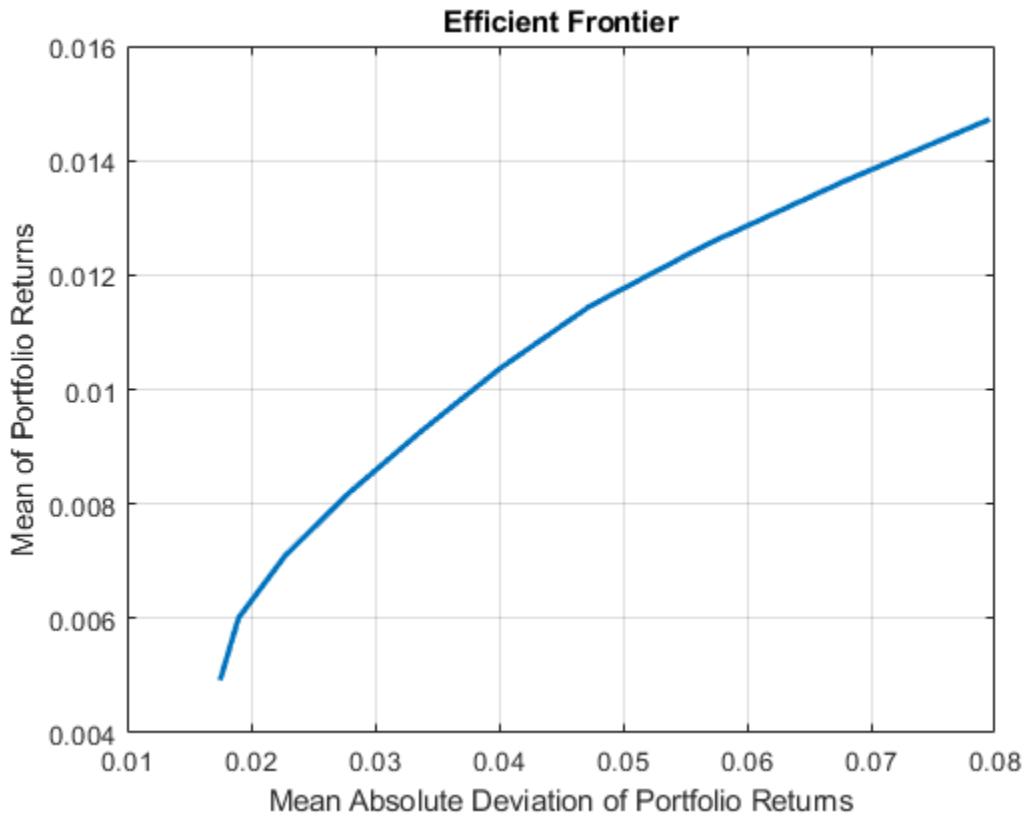

Given a PortfolioMAD  $p$ , plot the efficient frontier.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

plotFrontier(p);
```

## Input Arguments

**obj — Object for portfolio**  
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

**NumPorts — Number of points to obtain on efficient frontier**  
value from hidden property `defaultNumPorts` (default value is 10) (default) | scalar integer

Number of points to obtain on the efficient frontier, specified as a scalar integer.

---

**Note** If no value is specified for `NumPorts`, the default value is obtained from the hidden property `defaultNumPorts` (default value is 10). If `NumPorts = 1`, this function returns the portfolio specified by the hidden property `defaultFrontierLimit` (current default value is '`'min'`).

---

Data Types: double

**PortRisk — Standard deviations of portfolio returns for each portfolio**  
 [ ] (default) | vector

Standard deviations of portfolio returns for each portfolio, specified as a vector.

---

**Note** PortRisk and PortReturn must be vectors with the same size.

---

Data Types: double

**PortReturn — Means of portfolio returns for each portfolio**  
 [ ] (default) | vector

Means of portfolio returns for each portfolio, specified as a vector.

---

**Note** PortRisk and PortReturn must be vectors with the same size.

---

Data Types: double

**PortWeights — Optimal portfolios on the efficient frontier**  
 [ ] (default) | matrix

Optimal portfolios on the efficient frontier, specified as a NumAsset-by-NumPorts matrix.

Data Types: double

## Output Arguments

**prsk — Estimated efficient portfolio risks (standard deviation of returns)**  
 vector

Estimated efficient portfolio risks (standard deviation of returns, returned as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj)).

---

**Note**

- If the portfolio object has a name in the `Name` property, the name is displayed as the title of the plot. Otherwise, the plot is labeled “Efficient Frontier.”
- If the portfolio object has an initial portfolio in the `InitPort` property, the initial portfolio is plotted and labeled.
- If portfolio risks and returns are inputs, make sure that risks come first in the calling sequence. In addition, if portfolio risks and returns are not sorted in ascending order, this method performs the sort. On output, the sorted moments are returned.

---

**pret — Estimated efficient portfolio returns**  
 vector

Estimated efficient portfolio returns, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

---

**Note**

- If the portfolio object has a name in the `Name` property, the name is displayed as the title of the plot. Otherwise, the plot is labeled “Efficient Frontier.”
  - If the portfolio object has an initial portfolio in the `InitPort` property, the initial portfolio is plotted and labeled.
  - If portfolio risks and returns are inputs, make sure that risks come first in the calling sequence. In addition, if portfolio risks and returns are not sorted in ascending order, this method performs the sort. On output, the sorted moments are returned.
- 

**Tips**

You can also use dot notation to plot the efficient frontier.

```
[prsk, pret] = obj.plotFrontier;
```

# plus

Financial time series addition

---

**Note** `plus` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects fints to Timetables”.

---

## Syntax

```
newfts = tsobj_1 + tsobj_2
newfts = tsobj + array
newfts = array + tsobj
```

## Arguments

|                               |                                                                                                                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsobj_1, tsobj_2</code> | A pair of financial time series objects.                                                                                                                                                |
| <code>array</code>            | A scalar value or array with the number of rows equal to the number of dates in <code>tsobj</code> and the number of columns equal to the number of data series in <code>tsobj</code> . |

## Description

`plus` is an element-by-element addition of the components.

`newfts = tsobj_1 + tsobj_2` adds financial time series objects. If an object is to be added to another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when one financial time series object is added to another, follows the order of the first object.

`newfts = tsobj + array` adds an array element by element to a financial time series object.

`newfts = array + tsobj` adds a financial time series object element by element to an array.

## Introduced before R2006a

## pointfig

Point and figure chart

---

**Note** `pointfig` is updated to accept data input as a matrix, `timetable`, or `table`.

---

### Syntax

```
pointfig(Data)
h = pointfig(ax,Data)
```

### Description

`pointfig(Data)` plots a point and figure chart from a series of prices of a security. Upward price movements are plotted as X's and downward price movements are plotted as 0's.

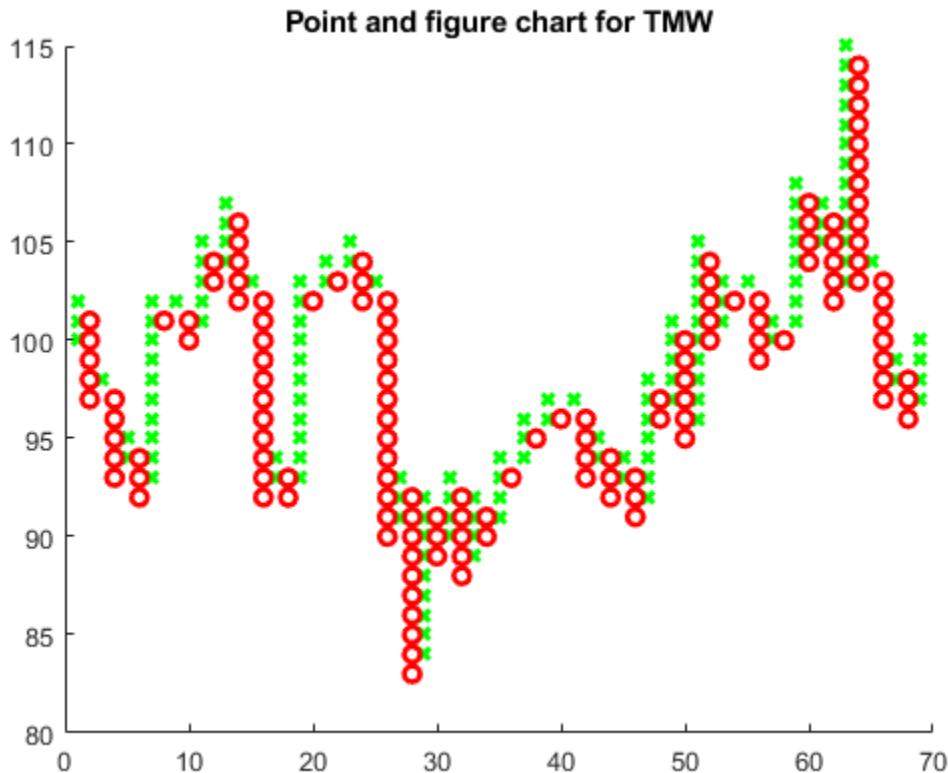

`h = pointfig(ax,Data)` adds an optional argument for `ax`.

### Examples

#### Generate a Point and Figure Chart for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock. This Point and Figure chart is for closing prices of the stock TMW for the most recent 21 days. Note that the variable name of asset price is be renamed to '`Price`' (case insensitive).

```
load SimulatedStock.mat
TMW.Properties.VariableNames{'Close'} = 'Price';
pointfig(TMW(1:200,:))
title('Point and figure chart for TMW')
```

## Input Arguments

### Data — Data for a series of prices

matrix | table | timetable

Data for a series of prices, specified as a matrix, table, or timetable. Timetables and tables with M rows must contain a variable named 'Price' (case insensitive).

Data Types: double | table | timetable

### ax — Valid axis object

current axes (ax = gca) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The point and figure plot is created in the axes specified by ax instead of in the current axes (ax = gca). The option ax can precede any of the input argument combinations.

Data Types: object

## Output Arguments

### h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

# portalloc

Optimal capital allocation to efficient frontier portfolios

## Syntax

```
[RiskyRisk,RiskyReturn,RiskyWts,RiskyFraction,OverallRisk,OverallReturn] =
portalloc(PortRisk,PortReturn,PortWts,RisklessRate)
[RiskyRisk,RiskyReturn,RiskyWts,RiskyFraction,OverallRisk,OverallReturn] =
portalloc(___,BorrowRate,RiskAversion)

portalloc(PortRisk,PortReturn,PortWts,RisklessRate,BorrowRate,RiskAversion)
```

## Description

[RiskyRisk,RiskyReturn,RiskyWts,RiskyFraction,OverallRisk,OverallReturn] = portalloc(PortRisk,PortReturn,PortWts,RisklessRate) calculates the optimal risky portfolio and the optimal allocation of funds between that risky portfolio of *NASSETS* and the risk-free asset.

[RiskyRisk,RiskyReturn,RiskyWts,RiskyFraction,OverallRisk,OverallReturn] = portalloc(\_\_\_,BorrowRate,RiskAversion) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

portalloc(PortRisk,PortReturn,PortWts,RisklessRate,BorrowRate,RiskAversion) when invoked without any output arguments, a graph of the optimal capital allocation decision is displayed.

## Examples

### Compute the Optimal Risky Portfolio

This example shows how to compute the optimal risky portfolio by generating the efficient frontier from the asset data and then finding the optimal risky portfolio and allocate capital. The risk-free investment return is 8%, and the borrowing rate is 12%.

```
ExpReturn = [0.1 0.2 0.15];

ExpCovariance = [0.005 -0.010 0.004
                  -0.010 0.040 -0.002
                  0.004 -0.002 0.023];
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn, ...
ExpCovariance);

RisklessRate = 0.08;
BorrowRate = 0.12;
RiskAversion = 3;

[RiskyRisk, RiskyReturn, RiskyWts, RiskyFraction, ...
OverallRisk, OverallReturn] = portalloc(PortRisk, PortReturn, ...
PortWts, RisklessRate, BorrowRate, RiskAversion)
```

```
RiskyRisk = 0.1283  
RiskyReturn = 0.1788  
RiskyWts = 1x3  
0.0265    0.6023    0.3712
```

```
RiskyFraction = 1.1898  
OverallRisk = 0.1527  
OverallReturn = 0.1899
```

## Input Arguments

**PortRisk — Standard deviation of each risky asset efficient frontier portfolio vector**

Standard deviation of each risky asset efficient frontier portfolio, specified as an NPORTS-by-1 vector.  
Data Types: double

**PortReturn — Expected return of each risky asset efficient frontier portfolio vector**

Expected return of each risky asset efficient frontier portfolio, specified as an NPORTS-by-1 vector.  
Data Types: double

**PortWts — Weights allocated to each asset**  
numeric

Weights allocated to each asset, specified as an NPORTS by number of assets (NASSETS) matrix of weights allocated to each asset. Each row represents an efficient frontier portfolio of risky assets. Total of all weights in a portfolio is 1.

Data Types: double

**RisklessRate — Risk-free lending rate**  
scalar decimal

Risk-free lending rate, specified as a scalar decimal.  
Data Types: double

**BorrowRate — Borrowing rate**  
NaN (default) | scalar decimal

(Optional) Borrowing rate, specified as a scalar decimal. If borrowing is not desired, or not an option, set the BorrowRate to NaN (which is the default value).

Data Types: double

**RiskAversion — Coefficient of investor's degree of risk aversion**  
3 (default) | scalar numeric

(Optional) Coefficient of investor's degree of risk aversion, specified as a scalar numeric. Higher numbers indicate greater risk aversion. Typical coefficients range from `2.0` through `4.0`. The default value of `RiskAversion` is `3`.

---

**Note** Consider that a less risk-averse investor would be expected to accept much greater risk and, consequently, a more risk-averse investor would accept less risk for a given level of return. Therefore, making the `RiskAversion` argument higher reflects the risk-return tradeoff in the data.

---

Data Types: `double`

## Output Arguments

**RiskyRisk — Standard deviation of the optimal risky portfolio**  
numeric

Standard deviation of the optimal risky portfolio, returned as a scalar.

**RiskyReturn — Expected return of the optimal risky portfolio**  
numeric

Expected return of the optimal risky portfolio, returned as a scalar.

**RiskyWts — Weights allocated to the optimal risky portfolio**  
vector

Weights allocated to the optimal risky portfolio, returned a 1-by-NASSETS vector. The total of all weights in the portfolio is `1`.

**RiskyFraction — Fraction of the complete portfolio allocated to the risky portfolio**  
numeric

Fraction of the complete portfolio (that is, the overall portfolio including risky and risk-free assets) allocated to the risky portfolio, returned as a scalar.

**OverallRisk — Standard deviation of the optimal overall portfolio**  
numeric

Standard deviation of the optimal overall portfolio, returned as a scalar.

**OverallReturn — Expected rate of return of the optimal overall portfolio**  
numeric

Expected rate of return of the optimal overall portfolio, returned as a scalar.

# portfolioRiskContribution

Compute individual asset risk contribution to overall portfolio volatility

## Syntax

```
riskCont = portfolioRiskContribution(portWeights,Sigma)
riskCont = portfolioRiskContribution(____,Name=Value)
```

## Description

`riskCont = portfolioRiskContribution(portWeights,Sigma)` computes individual asset risk contribution to overall portfolio volatility and returns `riskCont` as a matrix of risk contributions.

`riskCont = portfolioRiskContribution(____,Name=Value)` specifies an option using a name-value argument in addition to the input arguments in the previous syntax.

## Examples

### Compute Individual Asset Risk Contribution

Use `portfolioRiskContribution` to compute the risk contribution per asset with respect to the portfolio total risk.

Assume the returns covariance matrix is given by the following values.

```
Sigma = [0.0100    0.0075    0.0100    0.0150
        0.0075    0.0225    0.0150    0.0225
        0.0100    0.0150    0.0400    0.0450
        0.0150    0.0225    0.0450    0.0900];
```

The `portWeights` are the following values:

```
portWeights = [0.4101; 0.2734; 0.1899; 0.1266];
```

Use `portfolioRiskContribution` to compute the percent of risk contribution per asset.

```
riskCont = portfolioRiskContribution(portWeights,Sigma)

riskCont = 4×1

0.2500
0.2500
0.2500
0.2500
```

The default is to compute the relative risk contribution. However, you can compute the absolute risk contribution by using the name-value argument `RiskContributionType="absolute"`. Use `portfolioRiskContribution` to compute each asset's relative risk contribution.

```
riskCont = portfolioRiskContribution(portWeights,Sigma,RiskContributionType="relative")
```

```
riskCont = 4x1  
0.2500  
0.2500  
0.2500  
0.2500
```

### Compute Individual Asset Risk Contribution When Returns Contain NaN Values

Use `portfolioRiskContribution` to compute the risk contribution of each asset with respect to the portfolio total risk when the assets returns used to compute the variance have NaN values.

Assume the returns covariance matrix is given by the following values.

```
load('CAPMuniverse.mat','AssetsTimeTable')  
Sigma = cov(AssetsTimeTable{:,1:12}, 'partialrows')  
  
Sigma = 12x12  
  
0.0012  0.0005  0.0005  0.0005  0.0005  0.0001  0.0004  0.0003  0.0006  
0.0005  0.0023  0.0007  0.0005  0.0009  0.0001  0.0005  0.0003  0.0006  
0.0005  0.0007  0.0012  0.0006  0.0007  0.0000  0.0006  0.0004  0.0007  
0.0005  0.0005  0.0006  0.0009  0.0006  0.0000  0.0005  0.0003  0.0006  
0.0005  0.0009  0.0007  0.0006  0.0017  0.0002  0.0005  0.0003  0.0005  
0.0001  0.0001  0.0000  0.0000  0.0002  0.0006 -0.0000  0.0000  0.0000  
0.0004  0.0005  0.0006  0.0005  0.0005 -0.0000  0.0009  0.0003  0.0005  
0.0003  0.0003  0.0004  0.0003  0.0003  0.0000  0.0003  0.0004  0.0003  
0.0006  0.0006  0.0007  0.0006  0.0005  0.0000  0.0005  0.0003  0.0010  
0.0003  0.0004  0.0005  0.0004  0.0004  0.0000  0.0003  0.0002  0.0005  
:  
:
```

The risk parity portfolio is subject to the following weights for all the assets.

```
portWeights = [0.1; 0.1; 0.1; 0.03; 0.1; 0.1; 0.1; 0.05; 0.1; 0.1; 0.1; 0.1];
```

Use `portfolioRiskContribution` to compute the percentage risk contribution per asset.

```
riskCont = portfolioRiskContribution(portWeights,Sigma)
```

```
riskCont = 12x1
```

```
0.0911  
0.1261  
0.1103  
0.0251  
0.1197  
0.0203  
0.0805  
0.0258  
0.0978  
0.0660  
:  
:
```

The default values returned by `portfolioRiskContribution` are the relative risk contribution of the individual assets to the overall portfolio risk. Also, you can compute the absolute risk contribution by using the name-value argument `RiskContributionType="absolute"`. Use `portfolioRiskContribution` to compute each asset's absolute risk contribution.

```
riskCont = portfolioRiskContribution(portWeights,Sigma,RiskContributionType="absolute")
riskCont = 12x1

0.0023
0.0031
0.0027
0.0006
0.0030
0.0005
0.0020
0.0006
0.0024
0.0016
:
:
```

### Compute Individual Asset Risk Contribution When `portWeights` Is Matrix

Use `portfolioRiskContribution` to compute the risk contribution per asset with respect to the portfolio total risk when `portWeights` is a matrix.

Assume the returns covariance matrix is given by the following values.

```
Sigma = [0.0100    0.0075    0.0100    0.0150
        0.0075    0.0225    0.0150    0.0225
        0.0100    0.0150    0.0400    0.0450
        0.0150    0.0225    0.0450    0.0900];
```

The matrix of `portWeights` is the values:

```
portWeights = [0.25    0.10    0.10828;
               0.25    0.20    0.17197;
               0.25    0.30    0.28026;
               0.25    0.40    0.43949];
```

Use `portfolioRiskContribution` to compute the percent of risk contribution per asset.

```
riskCont = portfolioRiskContribution(portWeights,Sigma)
riskCont = 4x3
```

```
0.1083    0.0308    0.0322
0.1720    0.1005    0.0816
0.2803    0.2735    0.2455
0.4395    0.5952    0.6407
```

The default is to compute the relative risk contribution. However, you can compute the absolute risk contribution by using the name-value argument `RiskContributionType="absolute"`. Use `portfolioRiskContribution` to compute each asset's absolute risk contribution.

```
riskCont = portfolioRiskContribution(portWeights,Sigma,RiskContributionType="absolute")  
riskCont = 4x3  
0.0170    0.0060    0.0064  
0.0269    0.0194    0.0162  
0.0439    0.0528    0.0488  
0.0688    0.1149    0.1274
```

## Input Arguments

### **portWeights — Portfolio weights**

matrix

Portfolio weights, specified using an NumAssets-by-NumPortfolios matrix. `portWeights` must be nonempty, numeric, finite, and real. `portWeights` can be negative and does not need to sum to 1. `portWeights` and `Sigma` must have the same number of NumAssets.

Data Types: double

### **Sigma — Covariance matrix of returns**

positive semidefinite covariance matrix

Covariance matrix of returns, specified using an NumAssets-by-NumAssets positive semidefinite covariance matrix. `Sigma` and `portWeights` must have the same number of NumAssets.

---

**Note** If `Sigma` is not a positive symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix.

---

Data Types: double

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `riskCont = portfolioRiskContribution(portWeights,Sigma,RiskContributionType="relative")`

### **RiskContributionType — Type of risk contribution to compute**

"relative" (relative risk contribution) (default) | character vector with value of 'relative' or 'absolute' | string with value of "relative" or "absolute"

Type of risk contribution to compute, specified as `RiskContributionType` and a scalar character vector or string:

- "relative" — Computes the relative contribution.
- "absolute" — Computes the absolute risk contribution.

Data Types: char | string

## Output Arguments

### riskCont — Risk contributions

matrix

Risk contributions, returned as a matrix. The default values returned by `portfolioRiskContribution` are the relative contribution of the assets to the portfolio. However, `portfolioRiskContribution` can also return the absolute risk contribution by passing the name-value argument `RiskContributionType` with a value of "absolute".

## Introduced in R2022a

# riskBudgetingPortfolio

Compute risk budgeting portfolios

## Syntax

```
pwgt = riskBudgetingPortfolio(Sigma)
pwgt = riskBudgetingPortfolio(Sigma,budget)
pwgt = riskBudgetingPortfolio(___,Name=Value)
[pwgt,exitflag] = riskBudgetingPortfolio(___,Name=Value)
```

## Description

`pwgt = riskBudgetingPortfolio(Sigma)` computes risk budgeting portfolios for long-only, fully invested, risk budgeting portfolios. When a budget input argument is not provided, the budget is set the same for all assets.

A risk budgeting portfolio is an allocation strategy that focuses on the allocation of risk without considering the returns. The goal of this strategy is to ensure that each asset in a portfolio contributes a given target risk level to the overall portfolio volatility.

`pwgt = riskBudgetingPortfolio(Sigma,budget)` computes risk budgeting portfolios for the long-only, fully invested, risk budgeting portfolios associated with the target risk budgets (`Budget`).

`pwgt = riskBudgetingPortfolio(___,Name=Value)` specifies options using name-value arguments in addition to the input arguments in the previous syntaxes.

`[pwgt,exitflag] = riskBudgetingPortfolio(___,Name=Value)` add an output argument for `exitflag` and specifies options using name-value arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute Risk Budgeting Portfolio

Use `riskBudgetingPortfolio` to compute long-only, fully invested, risk budgeting portfolios.

Assume the returns covariance matrix is given by the following values.

```
Sigma = [0.0100    0.0075    0.0100    0.0150
         0.0075    0.0225    0.0150    0.0225
         0.0100    0.0150    0.0400    0.0450
         0.0150    0.0225    0.0450    0.0900];
```

When a budget input argument is not provided, by default, the `riskBudgetingPortfolio` function computes a risk parity portfolio. The `riskBudgetingPortfolio` default is to consider that the risk contribution is the same for all assets and the weights are long-only and fully invested.

```
pwgt = riskBudgetingPortfolio(Sigma)
pwgt = 4x1
```

```
0.4101
0.2734
0.1899
0.1266
```

However, if a vector is passed for the optional input `budget`, the `riskBudgetingPortfolio` function computes the long-only, fully invested, risk budgeting portfolios that achieve the target risk contributions specified in `budget`.

```
pwgt = riskBudgetingPortfolio(Sigma, [0.1;0.2;0.3;0.4])
pwgt = 4×1
0.2292
0.2800
0.2633
0.2275
```

### Compute Risk Budgeting Portfolio When Returns Contain NaN Values

Use `riskBudgetingPortfolio` to compute the risk budgeting portfolio when the asset returns contain `NaN` values.

Assume the returns covariance matrix is given by the following values.

```
load('CAPMuniverse.mat','AssetsTimeTable')
Sigma = cov(AssetsTimeTable{:,1:12},'partialrows')

Sigma = 12×12
```

```
0.0012    0.0005    0.0005    0.0005    0.0005    0.0001    0.0004    0.0003    0.0006    0.0006
0.0005    0.0023    0.0007    0.0005    0.0009    0.0001    0.0005    0.0003    0.0006    0.0006
0.0005    0.0007    0.0012    0.0006    0.0007    0.0000    0.0006    0.0004    0.0007    0.0007
0.0005    0.0005    0.0006    0.0009    0.0006    0.0000    0.0005    0.0003    0.0006    0.0006
0.0005    0.0009    0.0007    0.0006    0.0017    0.0002    0.0005    0.0003    0.0005    0.0005
0.0001    0.0001    0.0000    0.0000    0.0002    0.0006    -0.0000    0.0000    0.0000    0.0000
0.0004    0.0005    0.0006    0.0005    0.0005    -0.0000    0.0009    0.0003    0.0005    0.0005
0.0003    0.0003    0.0004    0.0003    0.0003    0.0000    0.0003    0.0004    0.0003    0.0003
0.0006    0.0006    0.0007    0.0006    0.0005    0.0000    0.0005    0.0003    0.0010    0.0010
0.0003    0.0004    0.0005    0.0004    0.0004    0.0000    0.0003    0.0002    0.0005    0.0005
:
:
```

If only the covariance matrix is provided, the `riskBudgetingPortfolio` default is to consider that the risk contribution is the same for all assets and the weights are long-only and fully invested. Basically, the default is to obtain the risk parity portfolio.

```
pwgt = riskBudgetingPortfolio(Sigma)
```

```
pwgt = 12×1
```

```
0.0718

However, if a vector is passed for the optional input `budget`, then the risk budgeting portfolio is computed using the default `ccd` algorithm.

```
pwgt = riskBudgetingPortfolio(Sigma,[0.1; 0.04; 0.2; 0.05; 0.1; 0.1; 0.1; 0.05; 0.1; 0.03; 0.1; 0.02]);

### Compute Risk Budgeting Portfolio When `budget` Is Matrix

This example shows how to use `riskBudgetingPortfolio` to compute the risk budgeting portfolio when the `budget` values are a matrix.

Assume the returns covariance matrix is given by the following values.

```
Sigma = [0.0100    0.0075    0.0100    0.0150;  
        0.0075    0.0225    0.0150    0.0225;  
        0.0100    0.0150    0.0400    0.0450;  
        0.0150    0.0225    0.0450    0.0900];
```

If only the covariance matrix is provided, the `riskBudgetingPortfolio` default is to consider that the risk contribution is the same for all assets and the weights are long-only and fully invested. Basically, the default is to obtain the risk parity portfolio.

```
pwgt = riskBudgetingPortfolio(Sigma)  
pwgt = 4×1  
  
0.4101  
0.2734  
0.1899  
0.1266
```

If a matrix is passed for the optional input **budget**, then the risk budgeting portfolio is computed.

```
B = [0.25    0.10    0.10828;
      0.25    0.20    0.17197;
      0.25    0.30    0.28026;
      0.25    0.40    0.43949];
pwgt = riskBudgetingPortfolio(Sigma,B)

pwgt = 4x3

0.4101    0.2292    0.2500
0.2734    0.2800    0.2500
0.1899    0.2633    0.2500
0.1266    0.2275    0.2500
```

## Input Arguments

### **Sigma — Covariance matrix of returns**

positive semidefinite covariance matrix

Covariance matrix of returns, specified using an **NumAssets**-by-**NumAssets** positive semidefinite covariance matrix.

**Sigma** and **budget** must have the same number of **NumAssets**.

---

**Note** If **Sigma** is not a symmetric positive semidefinite matrix, use **nearcorr** to create a positive semidefinite matrix.

---

Data Types: double

### **budget — Target risk budget for each asset**

matrix

Target risk budget for each asset, specified using an **NumAssets**-by-**NumPortfolios** matrix. **budget** must be nonnegative and all columns must sum to 1 because the values for **budget** represent the percentage of risk that each asset contributes of the total portfolio risk.

**budget** and **Sigma** must have the same number of **NumAssets**.

Data Types: double

### Name-Value Pair Arguments

Specify optional pairs of arguments as **Name1=Value1**, ..., **NameN=ValueN**, where **Name** is the argument name and **Value** is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `pwgt = riskBudgetingPortfolio(Sigma, [0.1;0.2;0.3;0.4],Algorithm="newton",BudgetTolerance=1e6)`

### **Algorithm — Optimization algorithm**

"**ccd**" (default) | character vector with value '**ccd**' or '**newton**' | string with value "**ccd**" or "**newton**"

Optimization algorithm, specified as `Algorithm` and a character vector or string:

- "ccd" — Cyclical coordinate descent algorithm
- "newton" — Newton algorithm with backtracking line-search

Data Types: `char` | `string`

**BudgetTolerance — Deviation tolerance from target budget**

`1e-8` (default) | positive numeric

Deviation tolerance from target budget, specified as `BudgetTolerance` and a scalar positive numeric.

Data Types: `double`

**MaxIterations — Maximum number of iterations allowed for the Algorithm**

`1e6` for "ccd" or `1e3` for "newton" (default) | positive integer

Maximum number of iterations allowed for the `Algorithm`, specified as `MaxIterations` and a scalar positive integer.

Data Types: `double`

## Output Arguments

**pwgt — Portfolio weights**

`matrix`

Portfolio weights, returned as a matrix in which each column represents a portfolio.

**exitflag — Indication of why the algorithm stopped**

`vector`

Indication of why the algorithm stopped, returned as a 1-by-`NumPortfolios` vector with one of the following values:

- 1 — The weights of the portfolio achieve the target risk budget up to `BudgetTolerance` accuracy.
- 0 — The number of iterations exceeded `MaxIterations`.
- -1 — The solver cannot find a descent direction. This value applies only to the "newton" option for the `Algorithm`.

# portalpha

Compute risk-adjusted alphas and returns for one or more assets

## Syntax

```
portalpha(Asset,Benchmark)
portalpha(Asset,Benchmark,Cash)
[Alpha,RAReturn] = portalpha(Asset,Benchmark,Cash,Choice)
```

## Description

`portalpha(Asset,Benchmark)` computes risk-adjusted alphas.

`portalpha(Asset,Benchmark,Cash)` computes risk-adjusted alphas using the optional argument `Cash`.

`[Alpha,RAReturn] = portalpha(Asset,Benchmark,Cash,Choice)` computes risk-adjusted alphas and returns for one or more methods specified by `Choice`.

## Examples

### Calculate the Risk-Adjusted Return

This example shows how to calculate the risk-adjusted return using `portalpha` and compare it with the fund and market's mean returns.

Use the example data with a fund, a market, and a cash series.

```
load FundMarketCash
Returns = tick2ret(TestData);
Fund = Returns(:,1);
Market = Returns(:,2);
Cash = Returns(:,3);
MeanFund = mean(Fund)

MeanFund = 0.0038

MeanMarket = mean(Market)

MeanMarket = 0.0030

[MM, aMM] = portalpha(Fund, Market, Cash, 'MM')

MM = 0.0022
aMM = 0.0052

[GH1, aGH1] = portalpha(Fund, Market, Cash, 'gh1')

GH1 = 0.0013
aGH1 = 0.0025
```

```
[GH2, aGH2] = portalpha(Fund, Market, Cash, 'gh2')
```

```
GH2 = 0.0022
```

```
aGH2 = 0.0052
```

```
[SML, aSML] = portalpha(Fund, Market, Cash, 'sml')
```

```
SML = 0.0013
```

```
aSML = 0.0025
```

Since the fund's risk is much less than the market's risk, the risk-adjusted return of the fund is much higher than both the nominal fund and market returns.

## Input Arguments

### Asset — Asset returns

matrix

Asset returns, specified as a `NUMSAMPLES` × `NUMSERIES` matrix with `NUMSAMPLES` observations of asset returns for `NUMSERIES` asset return series.

Data Types: double

### Benchmark — Returns for a benchmark asset

vector

Returns for a benchmark asset, specified as a `NUMSAMPLES` vector of returns for a benchmark asset. The periodicity must be the same as the periodicity of `Asset`. For example, if `Asset` is monthly data, then `Benchmark` should be monthly returns.

Data Types: double

### Cash — Riskless asset

0 (default) | numeric | vector

(Optional) Riskless asset, specified as either a scalar return for a riskless asset or a vector of asset returns to be a proxy for a “riskless” asset. In either case, the periodicity must be the same as the periodicity of `Asset`. For example, if `Asset` is monthly data, then `Cash` must be monthly returns. If no value is supplied, the default value for `Cash` returns is 0.

Data Types: double

### Choice — Computed measures

'xs' (default) | character vector | cell array of character vectors

(Optional) Computed measures, specified as a character vector or cell array of character vectors to indicate one or more measures to be computed from among various risk-adjusted alphas and return measures. The number of choices selected in `Choice` is `NUMCHOICES`. The list of choices is given in the following table:

| Code | Description                        |
|------|------------------------------------|
| 'xs' | Excess Return (no risk adjustment) |

| Code   | Description                                                                                                                                                                                                                                                                     |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'sml'  | Security Market Line — The security market line shows that the relationship between risk and return is linear for individual securities (that is, increased risk = increased return).                                                                                           |
| 'capm' | Jensen's Alpha — Risk-adjusted performance measure that represents the average return on a portfolio or investment, above or below that predicted by the capital asset pricing model (CAPM), given the portfolio's or investment's beta and the average market return.          |
| 'mm'   | Modigliani & Modigliani — Measures the returns of an investment portfolio for the amount of risk taken relative to some benchmark portfolio.                                                                                                                                    |
| 'gh1'  | Graham-Harvey 1 — Performance measure developed by John Graham and Campbell Harvey. The idea is to lever a fund's portfolio to exactly match the volatility of the S&P 500. The difference between the fund's levered return and the S&P 500 return is the performance measure. |
| 'gh2'  | Graham-Harvey 2 — In this measure, the idea is to lever up or down the fund's recommended investment strategy (using a Treasury bill), so that the strategy has the same volatility as the S&P 500.                                                                             |
| 'all'  | Compute all measures.                                                                                                                                                                                                                                                           |

**Choice** is specified by using the code from the table (for example, to select the Modigliani & Modigliani measure, **Choice** = 'mm'). A single choice is either a character vector or a scalar cell array with a single code from the table.

Multiple choices can be selected with a cell array of character vectors for choice codes (for example, to select both Graham-Harvey measures, **Choice** = {'gh1', 'gh2'}). To select all choices, specify **Choice** = 'all'. If no value is supplied, the default choice is to compute the excess return with **Choice** = 'xs'. **Choice** is not case-sensitive.

Data Types: char | cell

## Output Arguments

### Alpha — Risk-adjusted alphas

matrix

Risk-adjusted alphas, returned as an NUMCHOICES-by-NUMSERIES matrix of risk-adjusted alphas for each series in **Asset** with each row corresponding to a specified measure in **Choice**.

### RAReturn — Risk-adjusted returns

matrix

Risk-adjusted returns, returned as an NUMCHOICES-by-NUMSERIES matrix of risk-adjusted returns for each series in **Asset** with each row corresponding to a specified measure in **Choice**.

---

**Note** NaN values in the data are ignored and, if NaNs are present, some results could be unpredictable. Although the alphas are comparable across measures, risk-adjusted returns depend on whether the **Asset** or **Benchmark** is levered or unlevered to match its risk with the alternative. If **Choice** = 'all', the order of rows in **Alpha** and **RAReturn** follows the order in the table. In addition, **Choice** = 'all' overrides all other choices.

## Introduced in R2006b

# portcons

Portfolio constraints

## Syntax

```
ConSet = portcons(ConstType,consttype_values)
```

## Description

As an alternative to `portcons`, use the Portfolio object (`Portfolio`) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see “Portfolio Object Workflow” on page 4-17.

`ConSet = portcons(ConstType,consttype_values)` generates a matrix of constraints, using linear inequalities, for a portfolio of asset investments. The inequalities are of the type  $A^*Wts' \leq b$ , where `Wts` is the matrix of weights. The matrix `ConSet` is defined as `ConSet = [A b]`.

## Examples

### Generate Matrix of Constraints for Portfolio of Asset Investments

Constrain a portfolio of three assets:

|                |     |     |     |
|----------------|-----|-----|-----|
| Asset          | IBM | HPQ | XOM |
| Group          | A   | A   | B   |
| Minimum Weight | 0   | 0   | 0   |
| Maximum Weight | 0.5 | 0.9 | 0.8 |

```
NumAssets = 3;
PVal = 1; % Scale portfolio value to 1.
AssetMin = 0;
AssetMax = [0.5 0.9 0.8];
GroupA = [1 1 0];
GroupB = [0 0 1];
AtoBmax = 1.5 % Value of assets in Group A at most 1.5 times value
AtoBmax = 1.5000
    % in group B.

ConSet = portcons('PortValue', PVal, NumAssets, 'AssetLims',...
    AssetMin, AssetMax, NumAssets, 'GroupComparison', GroupA, NaN, ...
    AtoBmax, GroupB)

ConSet = 9x4
    1.0000    1.0000    1.0000    1.0000
   -1.0000   -1.0000   -1.0000   -1.0000
```

|         |         |         |        |
|---------|---------|---------|--------|
| 1.0000  | 0       | 0       | 0.5000 |
| 0       | 1.0000  | 0       | 0.9000 |
| 0       | 0       | 1.0000  | 0.8000 |
| -1.0000 | 0       | 0       | 0      |
| 0       | -1.0000 | 0       | 0      |
| 0       | 0       | -1.0000 | 0      |
| 1.0000  | 1.0000  | -1.5000 | 0      |

For instance, one possible solution for portfolio weights that satisfy the constraints is 30% in IBM, 30% in HPQ, and 40% in XOM.

## Input Arguments

### ConstType — Constraint type

character vector with value 'Default', 'PortValue', 'AssetLims', 'GroupLims', 'GroupComparison', or 'Custom'

Constraint type, specified as a character vector defined as follows:

| Constraint Type | Description                                                                                                       | Values                                                                                                                                                                                                                                                                                                                                                             |
|-----------------|-------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'Default'       | All allocations are $\geq 0$ ; no short selling allowed. Combined value of portfolio allocations normalized to 1. | NumAssets (required). Scalar representing number of assets in portfolio.                                                                                                                                                                                                                                                                                           |
| 'PortValue'     | Fix total value of portfolio to PVal.                                                                             | PVal (required). Scalar representing total value of portfolio.<br>NumAssets (required). Scalar representing number of assets in portfolio. See <code>pcpval</code> .                                                                                                                                                                                               |
| 'AssetLims'     | Minimum and maximum allocation per asset.                                                                         | AssetMin (required). Scalar or vector of length NASSETS, specifying minimum allocation per asset.<br>AssetMax (required). Scalar or vector of length NASSETS, specifying maximum allocation per asset.<br>NumAssets (optional). See <code>pclalims</code> .                                                                                                        |
| 'GroupLims'     | Minimum and maximum allocations to asset group.                                                                   | Groups (required). NGROUPS-by-NASSETS matrix specifying which assets belong to each group.<br>GroupMin (required). Scalar or a vector of length NGROUPS, specifying minimum combined allocations in each group.<br>GroupMax (required). Scalar or a vector of length NGROUPS, specifying maximum combined allocations in each group.<br>See <code>pcglims</code> . |

| Constraint Type   | Description                                                        | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'GroupComparison' | Group-to-group comparison constraints.                             | <p>GroupA (required). NGROUPS-by-NASSETS matrix specifying first group in the comparison.</p> <p>AtoBmin (required). Scalar or vector of length NGROUPS specifying minimum ratios of allocations in GroupA to allocations in GroupB.</p> <p>AtoBmax (required). Scalar or vector of length NGROUPS specifying maximum ratios of allocations in GroupA to allocations in GroupB.</p> <p>GroupB (required). NGROUPS-by-NASSETS matrix specifying second group in the comparison.</p> <p>See <code>pcgcomp</code>.</p> |
| 'Custom'          | Custom linear inequality constraints $A * \text{PortWts} \leq b$ . | <p>A (required). NCONSTRAINTS -by-NASSETS matrix, specifying weights for each asset in each inequality equation.</p> <p>b (required). ---

**Note** You can specify multiple 'ConstType' arguments as `ConSet = portcons('ConstType1', consttype_value1, 'ConstType2', consttype_value2, 'ConstTypeN', consttype_valueN)`.

---

Data Types: char

## Output Arguments

### ConSet — Constraints

matrix

Constraints, returned as a matrix. `ConSet` is defined as `ConSet = [A b]`. `A` is a matrix and `b` a vector such that `A * Wts' <= b` sets the value, where `Wts` is the matrix of weights.

# Portfolio

Create Portfolio object for mean-variance portfolio optimization and analysis

## Description

Use the `Portfolio` function to create a `Portfolio` object for mean-variance portfolio optimization.

The main workflow for portfolio optimization is to create an instance of a `Portfolio` object that completely specifies a portfolio optimization problem and to operate on the `Portfolio` object using supported functions to obtain and analyze efficient portfolios. For details on this workflow, see “Portfolio Object Workflow” on page 4-17.

You can use the `Portfolio` object in several ways. To set up a portfolio optimization problem in a `Portfolio` object, the simplest syntax is:

```
p = Portfolio;
```

This syntax creates a `Portfolio` object, `p`, such that all object properties are empty.

The `Portfolio` object also accepts collections of name-value pair arguments for properties and their values. The `Portfolio` object accepts inputs for properties with the general syntax:

```
p = Portfolio('property1',value1,'property2',value2, ... );
```

If a `Portfolio` object exists, the syntax permits the first (and only the first argument) of the `Portfolio` object to be an existing object with subsequent name-value pair arguments for properties to be added or modified. For example, given an existing `Portfolio` object in `p`, the general syntax is:

```
p = Portfolio(p,'property1',value1,'property2',value2, ... );
```

Input argument names are not case-sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see “Shortcuts for Property Names” on page 19-1232). The `Portfolio` object tries to detect problem dimensions from the inputs and, once set, subsequent inputs can undergo various scalar or matrix expansion operations that simplify the overall process to formulate a problem. In addition, a `Portfolio` object is a value object so that, given portfolio `p`, the following code creates two objects, `p` and `q`, that are distinct:

```
q = Portfolio(p, ...)
```

After creating a `Portfolio` object, you can use the associated object functions to set portfolio constraints, analyze the efficient frontier, and validate the portfolio model.

For more detailed information on the theoretical basis for mean-variance optimization, see “Portfolio Optimization Theory” on page 4-3.

## Creation

### Syntax

```
p = Portfolio
```

```
p = Portfolio(Name,Value)  
p = Portfolio(p,Name,Value)
```

### Description

`p = Portfolio` creates an empty `Portfolio` object for mean-variance portfolio optimization and analysis. You can then add elements to the `Portfolio` object using the supported "add" and "set" functions. For more information, see "Creating the Portfolio Object" on page 4-24.

`p = Portfolio(Name,Value)` creates a `Portfolio` object (`p`) and sets Properties on page 19-1218 using name-value pairs. For example, `p = Portfolio('AssetList',Assets(1:12))`. You can specify multiple name-value pairs.

`p = Portfolio(p,Name,Value)` creates a `Portfolio` object (`p`) using a previously created `Portfolio` object `p` and sets Properties on page 19-1218 using name-value pairs. You can specify multiple name-value pairs.

### Input Arguments

**p — Previously constructed Portfolio object**  
object

Previously constructed `Portfolio` object, specified using `Portfolio`.

## Properties

### Setting Up the Object

**AssetList — Names or symbols of assets in universe**  
[] (default) | cell array of character vectors | string array

Names or symbols of assets in the universe, specified as a cell array of character vectors or a string array.

Data Types: cell | string

**InitPort — Initial portfolio**  
[] (default) | vector

Initial portfolio, specified as a vector.

Data Types: double

**Name — Name for instance of Portfolio object**  
[] (default) | character vector | string

Name for instance of the `Portfolio` object, specified as a character vector or a string.

Data Types: char | string

**NumAssets — Number of assets in the universe**  
[] (default) | integer scalar

Number of assets in the universe, specified as an integer scalar.

Data Types: double

**Portfolio Object Constraints****AEquality — Linear equality constraint matrix**

[ ] (default) | matrix

Linear equality constraint matrix, specified as a matrix.

Data Types: double

**AInequality — Linear inequality constraint matrix**

[ ] (default) | matrix

Linear inequality constraint matrix, specified as a matrix.

Data Types: double

**bEquality — Linear equality constraint vector**

[ ] (default) | vector

Linear equality constraint vector, specified as a vector.

Data Types: double

**bInequality — Linear inequality constraint vector**

[ ] (default) | vector

Linear inequality constraint vector, specified as a vector.

Data Types: double

**GroupA — Group A weights to be bounded by weights in group B**

[ ] (default) | matrix

Group A weights to be bounded by weights in group B, specified as a matrix.

Data Types: double

**GroupB — Group B weights**

[ ] (default) | matrix

Group B weights, specified as a matrix.

Data Types: double

**GroupMatrix — Group membership matrix**

[ ] (default) | matrix

Group membership matrix, specified as a matrix.

Data Types: double

**LowerBound — Lower-bound constraint**

[ ] (default) | vector

Lower-bound constraint, specified as a vector.

Data Types: double

**LowerBudget — Lower-bound budget constraint**

[ ] (default) | scalar

Lower-bound budget constraint, specified as a scalar.

Data Types: double

**LowerGroup — Lower-bound group constraint**

[ ] (default) | vector

Lower-bound group constraint, specified as a vector.

Data Types: double

**LowerRatio — Minimum ratio of allocations between Groups A and B**

[ ] (default) | vector

Minimum ratio of allocations between GroupA and GroupB, specified as a vector.

Data Types: double

**TrackingError — Upper bound for tracking error constraint**

[ ] (default) | scalar

Upper bound for tracking error constraint, specified as a scalar.

Data Types: double

**TrackingPort — Tracking portfolio for tracking error constraint**

[ ] (default) | vector

Tracking portfolio for tracking error constraint, specified as a vector.

Data Types: double

**UpperBound — Upper-bound constraint**

[ ] (default) | vector

Upper-bound constraint, specified as a vector.

Data Types: double

**UpperBudget — Upper-bound budget constraint**

[ ] (default) | scalar

Upper-bound budget constraint, specified as a scalar.

Data Types: double

**UpperGroup — Upper-bound group constraint**

[ ] (default) | vector

Upper-bound group constraint, specified as a vector.

Data Types: double

**UpperRatio — Maximum ratio of allocations between Groups A and B**

[ ] (default) | vector

Maximum ratio of allocations between GroupA and GroupB, specified as a vector.

Data Types: double

**BoundType — Type of bounds for each asset weight**

'Simple' (default) | character vector with value 'Simple' or 'Conditional' | string with value "Simple" or "Conditional" | cell array of character vectors with values 'Simple' or 'Conditional' | string array with values "Simple" or "Conditional"

Type of bounds for each asset weight, specified as a scalar character vector or string, or a cell array of character vectors or a string array. For more information, see `setBounds`.

Data Types: char | cell | string

**MinNumAssets — Minimum number of assets allocated in portfolio**

[ ] (default) | numeric

Minimum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinMaxNumAssets`.

Data Types: double

**MaxNumAssets — Maximum number of assets allocated in portfolio**

[ ] (default) | numeric

Maximum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinMaxNumAssets`.

Data Types: double

**SellTurnover — Turnover constraint on sales**

[ ] (default) | scalar

Turnover constraint on sales, specified as a scalar.

Data Types: double

**BuyTurnover — Turnover constraint on purchases**

[ ] (default) | scalar

Turnover constraint on purchases, specified as a scalar.

Data Types: double

**Turnover — Turnover constraint**

[ ] (default) | scalar

Turnover constraint, specified as a scalar.

Data Types: double

**Portfolio Object Modeling****AssetCovar — Covariance of asset returns**

[ ] (default) | square matrix

Covariance of asset returns, specified as a square matrix. If `AssetCovar` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

Data Types: double

**AssetMean — Mean of asset returns**

[ ] (default) | vector

Mean of asset returns, specified as a vector.

Data Types: double

**BuyCost — Proportional purchase costs**

[ ] (default) | vector

Proportional purchase costs, specified as a vector.

Data Types: double

**RiskFreeRate — Risk-free rate**

[ ] (default) | scalar

Risk-free rate, specified as a scalar.

Data Types: double

**SellCost — Proportional sales costs**

[ ] (default) | vector

Proportional sales costs, specified as a vector.

Data Types: double

## Object Functions

|                       |                                                                                       |
|-----------------------|---------------------------------------------------------------------------------------|
| setAssetList          | Set up list of identifiers for assets                                                 |
| setInitPort           | Set up initial or current portfolio                                                   |
| setDefaultConstraints | Set up portfolio constraints with nonnegative weights that sum to 1                   |
| getAssetMoments       | Obtain mean and covariance of asset returns from Portfolio object                     |
| setAssetMoments       | Set moments (mean and covariance) of asset returns for Portfolio object               |
| estimateAssetMoments  | Estimate mean and covariance of asset returns from data                               |
| setCosts              | Set up proportional transaction costs for portfolio                                   |
| addEquality           | Add linear equality constraints for portfolio weights to existing constraints         |
| addGroupRatio         | Add group ratio constraints for portfolio weights to existing group ratio constraints |
| addGroups             | Add group constraints for portfolio weights to existing group constraints             |
| addInequality         | Add linear inequality constraints for portfolio weights to existing constraints       |
| getBounds             | Obtain bounds for portfolio weights from portfolio object                             |
| getBudget             | Obtain budget constraint bounds from portfolio object                                 |
| getCosts              | Obtain buy and sell transaction costs from portfolio object                           |
| getEquality           | Obtain equality constraint arrays from portfolio object                               |
| getGroupRatio         | Obtain group ratio constraint arrays from portfolio object                            |
| getGroups             | Obtain group constraint arrays from portfolio object                                  |
| getInequality         | Obtain inequality constraint arrays from portfolio object                             |
| getOneWayTurnover     | Obtain one-way turnover constraints from portfolio object                             |
| setGroups             | Set up group constraints for portfolio weights                                        |
| setInequality         | Set up linear inequality constraints for portfolio weights                            |
| setBounds             | Set up bounds for portfolio weights for portfolio                                     |
| setBudget             | Set up budget constraints for portfolio                                               |
| setCosts              | Set up proportional transaction costs for portfolio                                   |
| setEquality           | Set up linear equality constraints for portfolio weights                              |

|                          |                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------|
| setGroupRatio            | Set up group ratio constraints for portfolio weights                                 |
| setInitPort              | Set up initial or current portfolio                                                  |
| setOneWayTurnover        | Set up one-way portfolio turnover constraints                                        |
| setTurnover              | Set up maximum portfolio turnover constraint                                         |
| setTrackingPort          | Set up benchmark portfolio for tracking error constraint                             |
| setTrackingError         | Set up maximum portfolio tracking error constraint                                   |
| setMinMaxNumAssets       | Set cardinality constraints on the number of assets invested in a portfolio          |
| checkFeasibility         | Check feasibility of input portfolios against portfolio object                       |
| estimateBounds           | Estimate global lower and upper bounds for set of portfolios                         |
| estimateFrontier         | Estimate specified number of optimal portfolios on the efficient frontier            |
| estimateFrontierByReturn | Estimate optimal portfolios with targeted portfolio returns                          |
| estimateFrontierByRisk   | Estimate optimal portfolios with targeted portfolio risks                            |
| estimateFrontierLimits   | Estimate optimal portfolios at endpoints of efficient frontier                       |
| plotFrontier             | Plot efficient frontier                                                              |
| estimateMaxSharpeRatio   | Estimate efficient portfolio to maximize Sharpe ratio for Portfolio object           |
| estimatePortMoments      | Estimate moments of portfolio returns for Portfolio object                           |
| estimatePortReturn       | Estimate mean of portfolio returns                                                   |
| estimatePortRisk         | Estimate portfolio risk according to risk proxy associated with corresponding object |
| setSolver                | Choose main solver and specify associated solver options for portfolio optimization  |
| setSolverMINLP           | Choose mixed integer nonlinear programming (MINLP) solver for portfolio optimization |

## Examples

### Create an Empty Portfolio Object

You can create a Portfolio object, p, with no input arguments and display it using `disp`.

```
p = Portfolio;
disp(p);
```

Portfolio with properties:

```
    BuyCost: []
    SellCost: []
    RiskFreeRate: []
    AssetMean: []
    AssetCovar: []
    TrackingError: []
    TrackingPort: []
    Turnover: []
    BuyTurnover: []
    SellTurnover: []
    Name: []
    NumAssets: []
    AssetList: []
    InitPort: []
    AInequality: []
    bInequality: []
    AEquality: []
    bEquality: []
```

```
LowerBound: []
UpperBound: []
LowerBudget: []
UpperBudget: []
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
BoundType: []
```

This approach provides a way to set up a portfolio optimization problem with the `Portfolio` function. You can then use the associated set functions to set and modify collections of properties in the `Portfolio` object.

### Create a Portfolio Object Using a Single-Step Setup

You can use the `Portfolio` object directly to set up a “standard” portfolio optimization problem, given a mean and covariance of asset returns in the variables `m` and `C`.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio('assetmean', m, 'assetcovar', C, ...
    'lowerbudget', 1, 'upperbudget', 1, 'lowerbound', 0)

p =
    Portfolio with properties:

        BuyCost: []
        SellCost: []
        RiskFreeRate: []
            AssetMean: [4x1 double]
            AssetCovar: [4x4 double]
        TrackingError: []
        TrackingPort: []
            Turnover: []
        BuyTurnover: []
        SellTurnover: []
            Name: []
        NumAssets: 4
        AssetList: []
        InitPort: []
        AInequality: []
        bInequality: []
        AEquality: []
        bEquality: []
        LowerBound: [4x1 double]
```

```

UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
BoundType: []

```

Note that the `LowerBound` property value undergoes scalar expansion since `AssetMean` and `AssetCovar` provide the dimensions of the problem.

### Create a Portfolio Object Using a Sequence of Steps

Using a sequence of steps is an alternative way to accomplish the same task of setting up a “standard” portfolio optimization problem, given a mean and covariance of asset returns in the variables `m` and `C` (which also illustrates that argument names are not case sensitive).

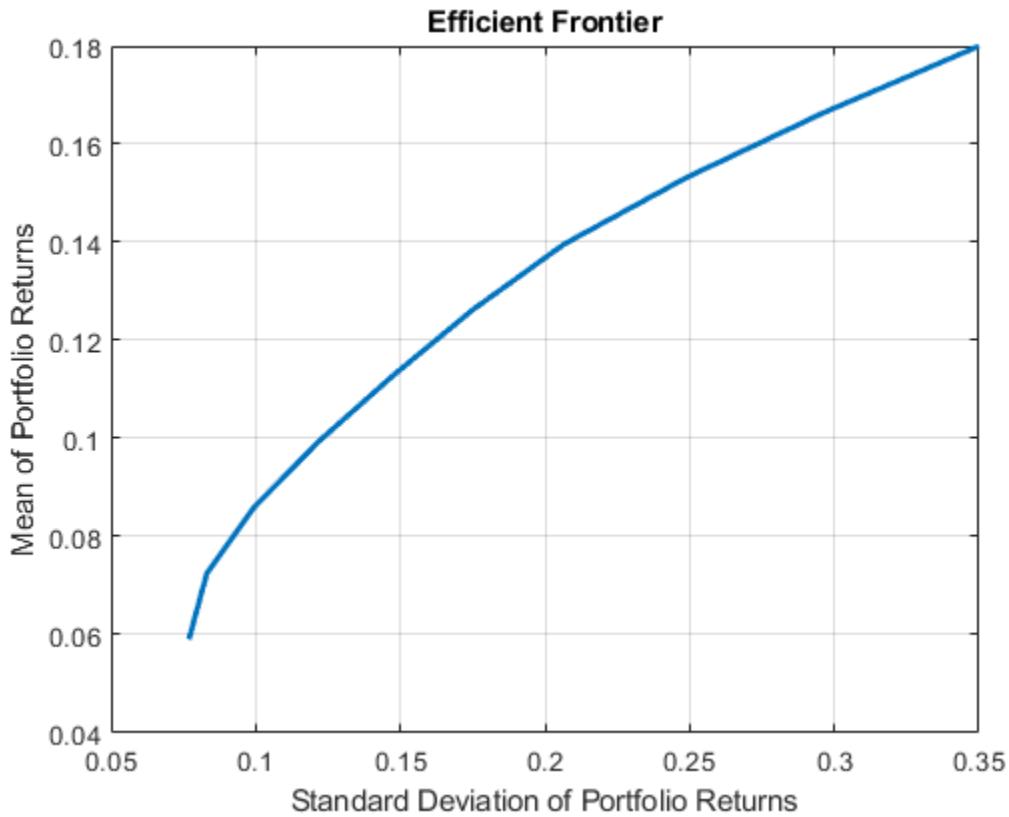

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = Portfolio(p, 'assetmean', m, 'assetcovar', C);
p = Portfolio(p, 'lowerbudget', 1, 'upperbudget', 1);
p = Portfolio(p, 'lowerbound', 0);

plotFrontier(p);

```

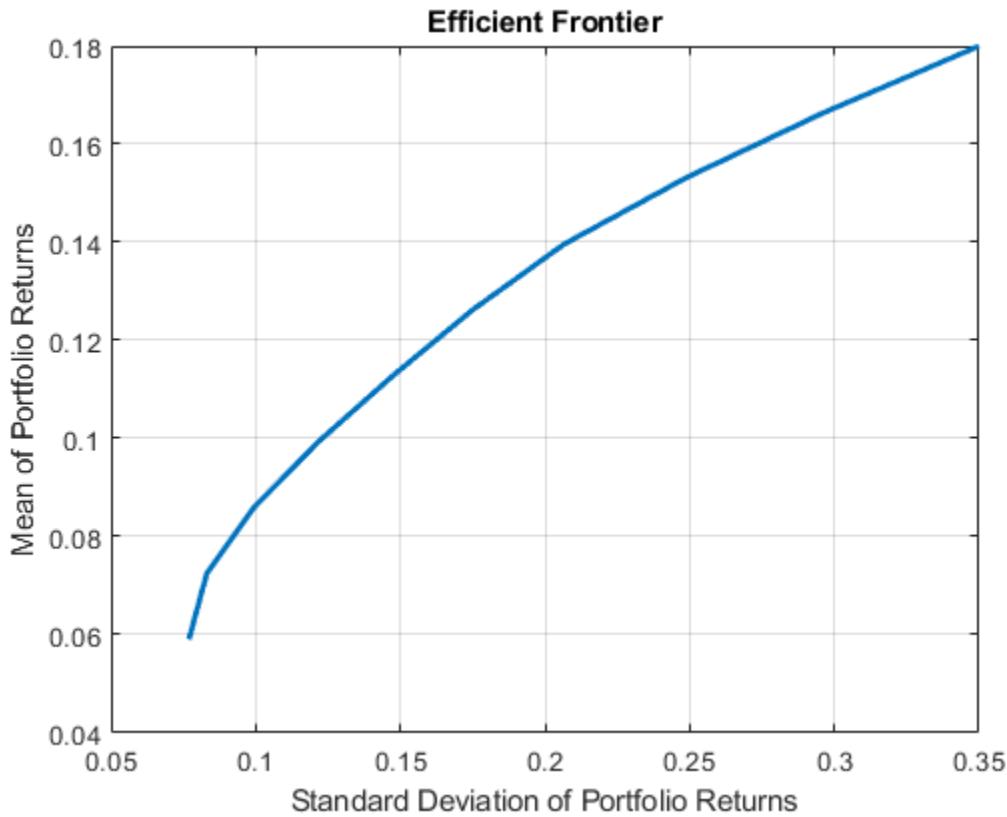

This way works because the calls to `Portfolio` are in this particular order. In this case, the call to initialize `AssetMean` and `AssetCovar` provides the dimensions for the problem. If you were to do this step last, you would have to explicitly dimension the `LowerBound` property as follows:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = Portfolio(p, 'LowerBound', zeros(size(m)));
p = Portfolio(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = Portfolio(p, 'AssetMean', m, 'AssetCovar', C);

plotFrontier(p);
```

If you did not specify the size of `LowerBound` but, instead, input a scalar argument, the `Portfolio` object assumes that you are defining a single-asset problem and produces an error at the call to set asset moments with four assets.

### Create a Portfolio Object Using Shortcuts for Property Names

You can create a `Portfolio` object, `p` with `Portfolio` using shortcuts for property names.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio('mean', m, 'covar', C, 'budget', 1, 'lb', 0)

p =
Portfolio with properties:

    BuyCost: []
    SellCost: []
    RiskFreeRate: []
    AssetMean: [4x1 double]
    AssetCovar: [4x4 double]
    TrackingError: []
```

```
TrackingPort: []
    Turnover: []
BuyTurnover: []
SellTurnover: []
    Name: []
NumAssets: 4
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: [4x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
    GroupA: []
    GroupB: []
LowerRatio: []
UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
BoundType: []
```

### Direct Setting of Portfolio Object Properties

Although not recommended, you can set properties directly, however no error-checking is done on your inputs.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
```

```
p = Portfolio;
p.NumAssets = numel(m);
p.AssetMean = m;
p.AssetCovar = C;
p.LowerBudget = 1;
p.UpperBudget = 1;
p.LowerBound = zeros(size(m));
disp(p)
```

Portfolio with properties:

```
BuyCost: []
SellCost: []
RiskFreeRate: []
AssetMean: [4x1 double]
AssetCovar: [4x4 double]
```

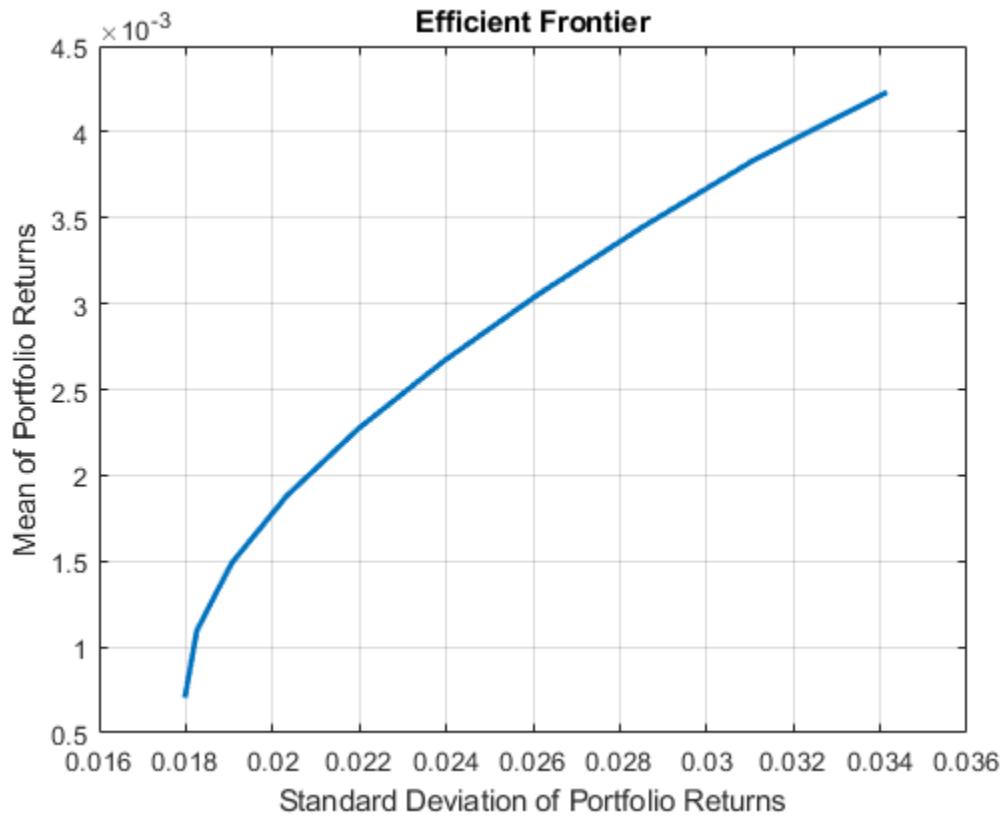

```
TrackingError: []
TrackingPort: []
    Turnover: []
BuyTurnover: []
SellTurnover: []
    Name: []
NumAssets: 4
AssetList: []
InitPort: []

## Create a Portfolio Object and Determine Efficient Portfolios

Create efficient portfolios:

```
load CAPMuniverse

p = Portfolio('AssetList',Assets(1:12));
p = estimateAssetMoments(p, Data(:,1:12), 'missingdata',true);
p = setDefaultConstraints(p);
plotFrontier(p);
```

```
pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5
    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([{pwgt},pnames], 'obsnames',p.AssetList);

disp(Blotter);
```

## More About

### Mean-Variance Portfolio Optimization

A mean-variance optimization problem is completely specified with three elements.

The three elements for a mean-variance optimization problem are:

- A universe of assets with estimates for the prospective mean and covariance of asset total returns for a period of interest.
- A portfolio set that specifies the set of portfolio choices in terms of a collection of constraints.
- A model for portfolio return and risk, which, for mean-variance optimization, is either the gross or net mean of portfolio returns and the standard deviation of portfolio returns.

After you specify these three elements in an unambiguous way, you can solve and analyze portfolio optimization problems. The simplest mean-variance portfolio optimization problem has:

- A mean and covariance of asset total returns
- Nonnegative weights for all portfolios that sum to 1 (the summation constraint is known as a budget constraint)
- Built-in models for portfolio return and risk that use the mean and covariance of asset total returns

For more information on the theory and definition of mean-variance optimization supported by portfolio optimization tools in Financial Toolbox, see “Portfolio Optimization Theory” on page 4-3.

### Portfolio Problem Sufficiency

A mean-variance portfolio optimization is completely specified with the `Portfolio` object if two condition are met.

The following are the two conditions that must be met:

- The moments of asset returns must be specified such that the property `AssetMean` contains a valid finite mean vector of asset returns and the property `AssetCovar` contains a valid symmetric positive-semidefinite matrix for the covariance of asset returns.

The first condition is satisfied by setting the properties associated with the moments of asset returns.

- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded.

The second condition is satisfied by an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed, and several functions, such as `estimateBounds`, provide ways to ensure that your problem is properly formulated.

Given mean and covariance of asset returns in the variables `AssetMean` and `AssetCovar`, this problem is completely specified by:

```
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar, ...
'LowerBound', 0, 'UpperBudget',1, 'LowerBudget',1)
```

or equivalently by:

```
p = Portfolio;
p = setAssetMoments(p, AssetMean, AssetCovar);
p = setDefaultConstraints(p);
```

Although the general sufficiency conditions for mean-variance portfolio optimization go beyond these two conditions, the `Portfolio` object implemented in Financial Toolbox implicitly handles all these additional conditions. For more information on the Markowitz model for mean-variance portfolio optimization, see “Portfolio Optimization” on page A-5.

### Shortcuts for Property Names

The `Portfolio` object has shorter argument names that replace longer argument names associated with specific properties of the `Portfolio` object.

For example, rather than enter '`assetcovar`', the `Portfolio` object accepts the case-insensitive name '`covar`' to set the `AssetCovar` property in a `Portfolio` object. Every shorter argument name corresponds with a single property in the `Portfolio` object. The one exception is the alternative argument name '`budget`', which signifies both the `LowerBudget` and `UpperBudget` properties. When '`budget`' is used, then the `LowerBudget` and `UpperBudget` properties are set to the same value to form an equality budget constraint.

### Shortcuts for Property Names

| Shortcut Argument Name                         | Equivalent Argument / Property Name                   |
|------------------------------------------------|-------------------------------------------------------|
| <code>ae</code>                                | <code>AEquality</code>                                |
| <code>ai</code>                                | <code>AIInequality</code>                             |
| <code>covar</code>                             | <code>AssetCovar</code>                               |
| <code>assetnames</code> or <code>assets</code> | <code>AssetList</code>                                |
| <code>mean</code>                              | <code>AssetMean</code>                                |
| <code>be</code>                                | <code>bEquality</code>                                |
| <code>bi</code>                                | <code>bInequality</code>                              |
| <code>group</code>                             | <code>GroupMatrix</code>                              |
| <code>lb</code>                                | <code>LowerBound</code>                               |
| <code>n</code> or <code>num</code>             | <code>NumAssets</code>                                |
| <code>rfr</code>                               | <code>RiskFreeRate</code>                             |
| <code>ub</code>                                | <code>UpperBound</code>                               |
| <code>budget</code>                            | <code>UpperBudget</code> and <code>LowerBudget</code> |

# PortfolioCVaR

Creates PortfolioCVaR object for conditional value-at-risk portfolio optimization and analysis

## Description

Use `PortfolioCVaR` to create a `PortfolioCVaR` object for conditional value-at-risk portfolio optimization.

The main workflow for CVaR portfolio optimization is to create an instance of a `PortfolioCVaR` object that completely specifies a portfolio optimization problem and to operate on the `PortfolioCVaR` object using supported functions to obtain and analyze efficient portfolios. For details on this workflow, see “[PortfolioCVaR Object Workflow](#)” on page 5-15.

You can use the `PortfolioCVaR` object in several ways. To set up a portfolio optimization problem in a `PortfolioCVaR` object, the simplest syntax is:

```
p = PortfolioCVaR;
```

This syntax creates a `PortfolioCVaR` object, `p`, such that all object properties are empty.

The `PortfolioCVaR` object also accepts collections of name-value pair arguments for properties and their values. The `PortfolioCVaR` function accepts inputs for properties with the general syntax:

```
p = PortfolioCVaR('property1',value1,'property2',value2, ... );
```

If a `PortfolioCVaR` object already exists, the syntax permits the first (and only the first argument) of the `PortfolioCVaR` object to be an existing object with subsequent name-value pair arguments for properties to be added or modified. For example, given an existing `PortfolioCVaR` object in `p`, the general syntax is:

```
p = PortfolioCVaR(p,'property1',value1,'property2',value2, ... );
```

Input argument names are not case sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see “[Shortcuts for Property Names](#)” on page 19-1249). The `PortfolioCVaR` object tries to detect problem dimensions from the inputs and, once set, subsequent inputs can undergo various scalar or matrix expansion operations that simplify the overall process to formulate a problem. In addition, a `PortfolioCVaR` object is a value object so that, given portfolio `p`, the following code creates two objects, `p` and `q`, that are distinct:

```
q = PortfolioCVaR(p, ...)
```

After creating a `PortfolioCVaR` object, you can use the associated object functions to set portfolio constraints, analyze the efficient frontier, and validate the portfolio model.

For more detailed information on the theoretical basis for conditional value-at-risk portfolio optimization, see “[Portfolio Optimization Theory](#)” on page 5-2.

# Creation

## Syntax

```
p = PortfolioCVaR
p = PortfolioCVaR(Name,Value)

p = PortfolioCVaR(p,Name,Value)
```

## Description

`p = PortfolioCVaR` creates an empty `PortfolioCVaR` object for conditional value-at-risk portfolio optimization and analysis. You can then add elements to the `PortfolioCVaR` object using the supported "add" and "set" functions. For more information, see "Creating the `PortfolioCVaR` Object" on page 5-21.

`p = PortfolioCVaR(Name,Value)` creates a `PortfolioCVaR` object (`p`) and sets Properties on page 19-1235 using name-value pairs. For example, `p = PortfolioCVaR('AssetList',Assets(1:12))`. You can specify multiple name-value pairs.

`p = PortfolioCVaR(p,Name,Value)` creates a `PortfolioCVaR` object (`p`) using a previously created `PortfolioCVaR` object `p` and sets Properties on page 19-1235 using name-value pairs. You can specify multiple name-value pairs.

## Input Arguments

**p — Previously constructed `PortfolioCVaR` object**  
object

Previously constructed `PortfolioCVaR` object, specified using `PortfolioCVaR`.

# Properties

## Setting Up the Object

**AssetList — Names or symbols of assets in universe**  
[ ] (default) | cell array of character vectors | string array

Names or symbols of assets in the universe, specified as a cell array of character vectors or a string array.

Data Types: cell | string

**InitPort — Initial portfolio**  
[ ] (default) | vector

Initial portfolio, specified as a vector.

Data Types: double

**Name — Name for instance of `PortfolioCVaR` object**  
[ ] (default) | character vector | string

Name for instance of the `PortfolioCVaR` object, specified as a character vector or string.

Data Types: char | string

**NumAssets — Number of assets in the universe**

[ ] (default) | integer scalar

Number of assets in the universe, specified as an integer scalar.

Data Types: double

**Portfolio Object Constraints****AEquality — Linear equality constraint matrix**

[ ] (default) | matrix

Linear equality constraint matrix, specified as a matrix.

Data Types: double

**AInequality — Linear inequality constraint matrix**

[ ] (default) | matrix

Linear inequality constraint matrix, specified as a matrix.

Data Types: double

**bEquality — Linear equality constraint vector**

[ ] (default) | vector

Linear equality constraint vector, specified as a vector.

Data Types: double

**bInequality — Linear inequality constraint**

[ ] (default) | vector

Linear inequality constraint vector, specified as a vector.

Data Types: double

**GroupA — Group A weights to be bounded by weights in group B**

[ ] (default) | matrix

Group A weights to be bounded by weights in group B, specified as a matrix.

Data Types: double

**GroupB — Group B weights**

[ ] (default) | matrix

Group B weights, specified as a matrix.

Data Types: double

**GroupMatrix — Group membership matrix**

[ ] (default) | matrix

Group membership matrix, specified as a matrix.

Data Types: double

**LowerBound — Lower-bound constraint**

[ ] (default) | vector

Lower-bound constraint, specified as a vector.

Data Types: double

**LowerBudget — Lower-bound budget constraint**

[ ] (default) | scalar

Lower-bound budget constraint, specified as a scalar.

Data Types: double

**LowerGroup — Lower-bound group constraint**

[ ] (default) | vector

Lower-bound group constraint, specified as a vector.

Data Types: double

**LowerRatio — Minimum ratio of allocations between Groups A and B**

[ ] (default) | vector

Minimum ratio of allocations between GroupA and GroupB, specified as a vector.

Data Types: double

**UpperBound — Upper-bound constraint**

[ ] (default) | vector

Upper-bound constraint, specified as a vector.

Data Types: double

**UpperBudget — Upper-bound budget constraint**

[ ] (default) | scalar

Upper-bound budget constraint, specified as a scalar.

Data Types: double

**UpperGroup — Upper-bound group constraint**

[ ] (default) | vector

Upper-bound group constraint, specified as a vector.

Data Types: double

**UpperRatio — Maximum ratio of allocations between Groups A and B**

[ ] (default) | vector

Maximum ratio of allocations between GroupA and GroupB, specified as a vector.

Data Types: double

**BoundType — Type of bounds for each asset weight**

'Simple' (default) | character vector with value 'Simple' or 'Conditional' | string with value "Simple" or "Conditional" | cell array of character vectors with values 'Simple' or 'Conditional' | string array with values "Simple" or "Conditional"

Type of bounds for each asset weight, specified as a scalar character vector or string, or a cell array of character vectors or a string array. For more information, see `setBounds`.

Data Types: char | cell | string

**MinNumAssets — Minimum number of assets allocated in portfolio**

[ ] (default) | numeric

Minimum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinMaxNumAssets`.

Data Types: double

**MaxNumAssets — Maximum number of assets allocated in portfolio**

[ ] (default) | numeric

Maximum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinMaxNumAssets`.

Data Types: double

**Turnover — Turnover constraint**

[ ] (default) | scalar

Turnover constraint, specified as a scalar.

Data Types: double

**SellTurnover — Turnover constraint on sales**

[ ] (default) | scalar

Turnover constraint on sales, specified as a scalar.

Data Types: double

**BuyTurnover — Turnover constraint on purchases**

[ ] (default) | scalar

Turnover constraint on purchases, specified as a scalar.

Data Types: double

**Portfolio Object Modeling****BuyCost — Proportional purchase costs**

[ ] (default) | vector

Proportional purchase costs, specified as a vector.

Data Types: double

**RiskFreeRate — Risk-free rate**

[ ] (default) | scalar

Risk-free rate, specified as a scalar.

Data Types: double

**ProbabilityLevel — Value-at-risk probability level which is 1 – (loss probability)**

[ ] (default) | scalar

Value-at-risk probability level which is 1 – (loss probability), specified as a scalar.

Data Types: double

**NumScenarios — Number of scenarios**

[ ] (default) | integer scalar

Number of scenarios, specified as an integer scalar.

Data Types: double

**SellCost — Proportional sales costs**

[ ] (default) | vector

Proportional sales costs, specified as a vector.

Data Types: double

## Object Functions

|                       |                                                                                       |
|-----------------------|---------------------------------------------------------------------------------------|
| setAssetList          | Set up list of identifiers for assets                                                 |
| setInitPort           | Set up initial or current portfolio                                                   |
| setDefaultConstraints | Set up portfolio constraints with nonnegative weights that sum to 1                   |
| estimateAssetMoments  | Estimate mean and covariance of asset returns from data                               |
| setCosts              | Set up proportional transaction costs for portfolio                                   |
| addEquality           | Add linear equality constraints for portfolio weights to existing constraints         |
| addGroupRatio         | Add group ratio constraints for portfolio weights to existing group ratio constraints |
| addGroups             | Add group constraints for portfolio weights to existing group constraints             |
| addInequality         | Add linear inequality constraints for portfolio weights to existing constraints       |
| getBounds             | Obtain bounds for portfolio weights from portfolio object                             |
| getBudget             | Obtain budget constraint bounds from portfolio object                                 |
| getCosts              | Obtain buy and sell transaction costs from portfolio object                           |
| getEquality           | Obtain equality constraint arrays from portfolio object                               |
| getGroupRatio         | Obtain group ratio constraint arrays from portfolio object                            |
| getGroups             | Obtain group constraint arrays from portfolio object                                  |
| getInequality         | Obtain inequality constraint arrays from portfolio object                             |
| getOneWayTurnover     | Obtain one-way turnover constraints from portfolio object                             |
| setGroups             | Set up group constraints for portfolio weights                                        |
| setInequality         | Set up linear inequality constraints for portfolio weights                            |
| setBounds             | Set up bounds for portfolio weights for portfolio                                     |
| setMinMaxNumAssets    | Set cardinality constraints on the number of assets invested in a portfolio           |
| setBudget             | Set up budget constraints for portfolio                                               |

|                                  |                                                                                               |
|----------------------------------|-----------------------------------------------------------------------------------------------|
| setCosts                         | Set up proportional transaction costs for portfolio                                           |
| setDefaultConstraints            | Set up portfolio constraints with nonnegative weights that sum to 1                           |
| setEquality                      | Set up linear equality constraints for portfolio weights                                      |
| setGroupRatio                    | Set up group ratio constraints for portfolio weights                                          |
| setInitPort                      | Set up initial or current portfolio                                                           |
| setOneWayTurnover                | Set up one-way portfolio turnover constraints                                                 |
| setTurnover                      | Set up maximum portfolio turnover constraint                                                  |
| checkFeasibility                 | Check feasibility of input portfolios against portfolio object                                |
| estimateBounds                   | Estimate global lower and upper bounds for set of portfolios                                  |
| estimateFrontier                 | Estimate specified number of optimal portfolios on the efficient frontier                     |
| estimateFrontierByReturn         | Estimate optimal portfolios with targeted portfolio returns                                   |
| estimateFrontierByRisk           | Estimate optimal portfolios with targeted portfolio risks                                     |
| estimateFrontierLimits           | Estimate optimal portfolios at endpoints of efficient frontier                                |
| plotFrontier                     | Plot efficient frontier                                                                       |
| estimatePortReturn               | Estimate mean of portfolio returns                                                            |
| estimatePortRisk                 | Estimate portfolio risk according to risk proxy associated with corresponding object          |
| setSolver                        | Choose main solver and specify associated solver options for portfolio optimization           |
| setProbabilityLevel              | Set probability level for VaR and CVaR calculations                                           |
| setScenarios                     | Set asset returns scenarios by direct matrix                                                  |
| getScenarios                     | Obtain scenarios from portfolio object                                                        |
| simulateNormalScenariosByData    | Simulate multivariate normal asset return scenarios from data                                 |
| simulateNormalScenariosByMoments | Simulate multivariate normal asset return scenarios from mean and covariance of asset returns |
| estimateScenarioMoments          | Estimate mean and covariance of asset return scenarios                                        |
| estimatePortVaR                  | Estimate value-at-risk for PortfolioCVaR object                                               |
| estimatePortStd                  | Estimate standard deviation of portfolio returns                                              |

## Examples

### Create an Empty PortfolioCVaR Object

You can create a PortfolioCVaR object, p, with no input arguments and display it using `disp`.

```
p = PortfolioCVaR;
disp(p);
```

PortfolioCVaR with properties:

```
BuyCost: []
SellCost: []
RiskFreeRate: []
ProbabilityLevel: []
    Turnover: []
BuyTurnover: []
SellTurnover: []
NumScenarios: []
    Name: []
NumAssets: []
```

```

AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: []
UpperBound: []
LowerBudget: []
UpperBudget: []
GroupMatrix: []
LowerGroup: []
UpperGroup: []
    GroupA: []
    GroupB: []
LowerRatio: []
UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
    BoundType: []

```

This approach provides a way to set up a portfolio optimization problem with the `PortfolioCVaR` function. You can then use the associated set functions to set and modify collections of properties in the `PortfolioCVaR` object.

### Create a `PortfolioCVaR` Object Using a Single-Step Setup

You can use the `PortfolioCVaR` object directly to set up a “standard” portfolio optimization problem. Given scenarios of asset returns in the variable `AssetScenarios`, this problem is completely specified as follows:

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR('Scenarios', AssetScenarios, ...
    'LowerBound', 0, 'LowerBudget', 1, 'UpperBudget', 1, ...
    'ProbabilityLevel', 0.95)

p =
    PortfolioCVaR with properties:

        BuyCost: []
        SellCost: []
        RiskFreeRate: []
    ProbabilityLevel: 0.9500
        Turnover: []
        BuyTurnover: []
        SellTurnover: []

```

```
NumScenarios: 20000
    Name: []
    NumAssets: 4
    AssetList: []
    InitPort: []
    AInequality: []
    bInequality: []
    AEquality: []
    bEquality: []
    LowerBound: [4x1 double]
    UpperBound: []
    LowerBudget: 1
    UpperBudget: 1
    GroupMatrix: []
    LowerGroup: []
    UpperGroup: []
        GroupA: []
        GroupB: []
    LowerRatio: []
    UpperRatio: []
    MinNumAssets: []
    MaxNumAssets: []
    BoundType: []
```

Note that the `LowerBound` property value undergoes scalar expansion since `AssetScenarios` provides the dimensions of the problem.

### Create a PortfolioCVaR Object Using a Sequence of Steps

Using a sequence of steps is an alternative way to accomplish the same task of setting up a "standard" CVaR portfolio optimization problem, given `AssetScenarios` variable is:

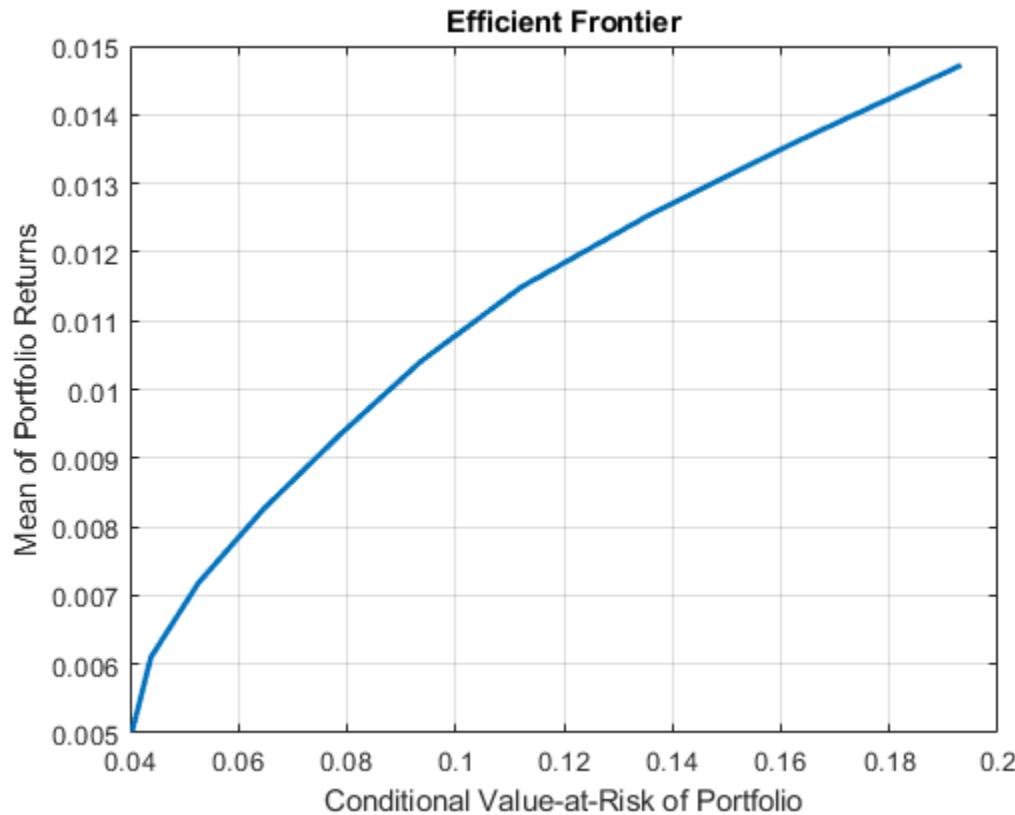

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = PortfolioCVaR(p, 'LowerBound', 0);
p = PortfolioCVaR(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = setProbabilityLevel(p, 0.95);

plotFrontier(p);
```

This way works because the calls to `PortfolioCVaR` are in this particular order. In this case, the call to initialize `AssetScenarios` provides the dimensions for the problem. If you were to do this step last, you would have to explicitly dimension the `LowerBound` property as follows:

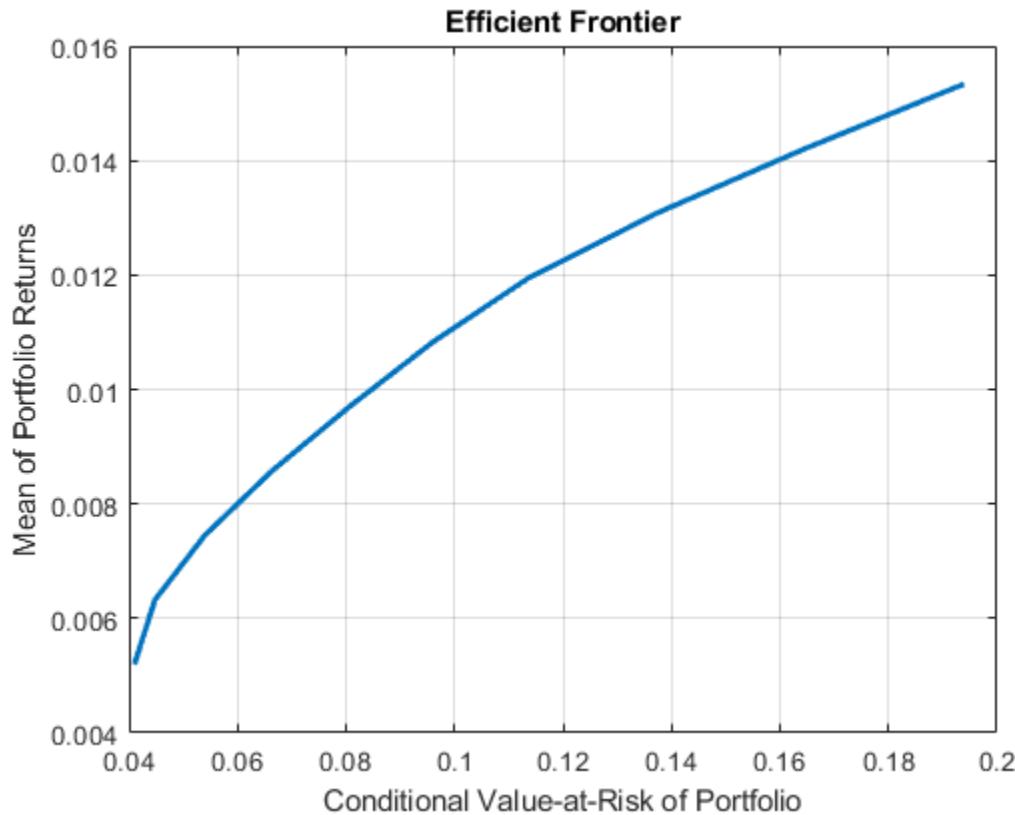

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = PortfolioCVaR(p, 'LowerBound', zeros(size(m)));
p = PortfolioCVaR(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = setProbabilityLevel(p, 0.95);
p = setScenarios(p, AssetScenarios);

plotFrontier(p);
```

If you did not specify the size of `LowerBound` but, instead, input a scalar argument, the `PortfolioCVaR` object assumes that you are defining a single-asset problem and produces an error at the call to set asset scenarios with four assets.

### Create a `PortfolioCVaR` Object Using Shortcuts for Property Names

You can create a `PortfolioCVaR` object, `p` with the `PortfolioCVaR` object using shortcuts for property names.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR('scenario', AssetScenarios, 'lb', 0, 'budget', 1, 'plevel', 0.95)
p =
  PortfolioCVaR with properties:
```

```

        BuyCost: []
        SellCost: []
        RiskFreeRate: []
    ProbabilityLevel: 0.9500
        Turnover: []
        BuyTurnover: []
        SellTurnover: []
    NumScenarios: 20000
        Name: []
        NumAssets: 4
        AssetList: []
        InitPort: []
        AInequality: []
        bInequality: []
        AEquality: []
        bEquality: []
    LowerBound: [4x1 double]
    UpperBound: []
    LowerBudget: 1
    UpperBudget: 1
    GroupMatrix: []
    LowerGroup: []
    UpperGroup: []
        GroupA: []
        GroupB: []
    LowerRatio: []
    UpperRatio: []
    MinNumAssets: []
    MaxNumAssets: []
    BoundType: []

```

## Direct Setting of PortfolioCVaR Object Properties

Although not recommended, you can set properties directly, however no error-checking is done on your inputs.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;

p = setScenarios(p, AssetScenarios);
p.ProbabilityLevel = 0.95;

p.LowerBudget = 1;
p.UpperBudget = 1;

```

```
p.LowerBound = zeros(size(m));
disp(p)
```

PortfolioCVaR with properties:

```
    BuyCost: []
    SellCost: []
    RiskFreeRate: []
ProbabilityLevel: 0.9500
    Turnover: []
    BuyTurnover: []
    SellTurnover: []
NumScenarios: 20000
    Name: []
    NumAssets: 4
    AssetList: []
    InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: [4x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
    GroupA: []
    GroupB: []
LowerRatio: []
UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
    BoundType: []
```

Scenarios cannot be assigned directly to a PortfolioCVaR object. Scenarios must always be set through either the `PortfolioCVaR` function, the `setScenarios` function, or any of the scenario simulation functions.

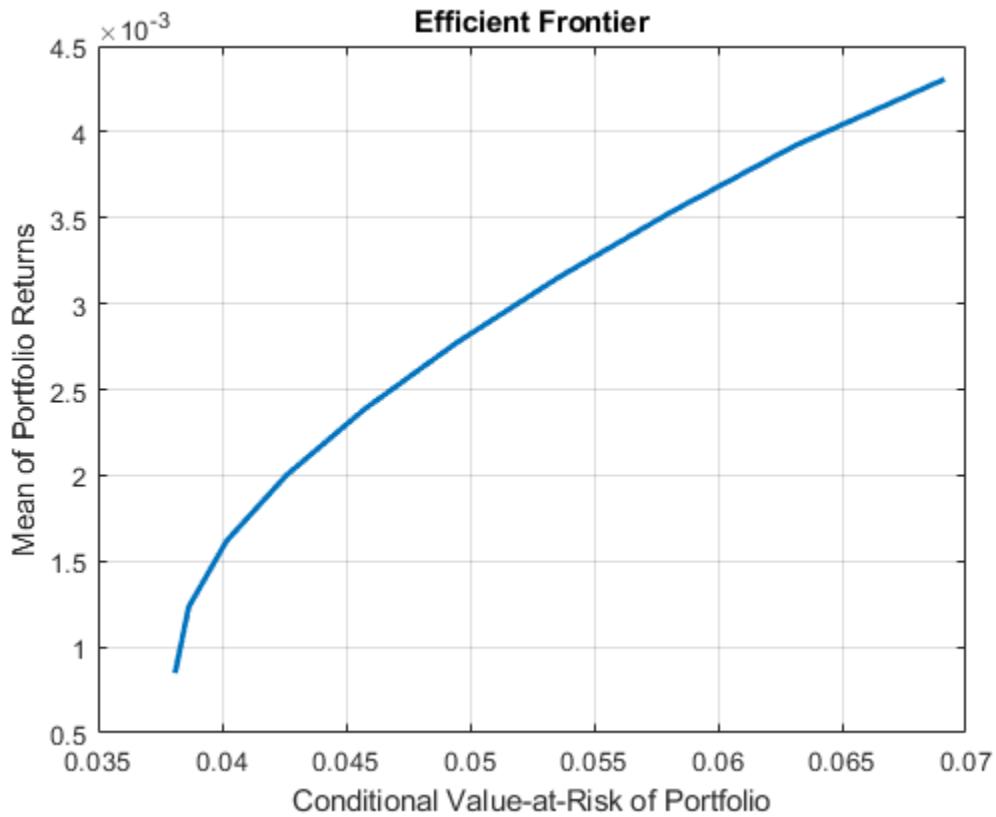

## Construct a PortfolioCVaR Object and Determine Efficient Portfolios

Create efficient portfolios:

```
load CAPMuniverse

p = PortfolioCVaR('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 , 'missingdata',true);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

plotFrontier(p);
```

```

pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5
    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([{pwgt},pnames], 'obsnames',p.AssetList);

disp(Blotter);

```

|      | Port1    | Port2     | Port3    | Port4   | Port5 |
|------|----------|-----------|----------|---------|-------|
| AAPL | 0.010562 | 0.07364   | 0.11931  | 0.13073 | 0     |

## More About

### Conditional Value-at-Risk Portfolio Optimization

A CVaR optimization problem is completely specified with four elements.

The four elements for a CVaR optimization problem are:

- A universe of assets with scenarios of asset total returns for a period of interest, where scenarios comprise a collection of samples from the underlying probability distribution for asset total returns. This collection must be sufficiently large for asymptotic convergence of sample statistics. Asset return moments and related statistics are derived exclusively from the scenarios.
- A portfolio set that specifies the set of portfolio choices in terms of a collection of constraints.
- A model for portfolio return and risk proxies, which, for CVaR optimization, is either the gross or net mean of portfolio returns and the conditional value-at-risk of portfolio returns.
- A probability level that specifies the probability that a loss is less than or equal to the value-at-risk. Typical values are 0.9 and 0.95, which indicate 10% and 5% loss probabilities.

After these four elements have been specified in an unambiguous way, it is possible to solve and analyze CVaR portfolio optimization problems.

The simplest CVaR portfolio optimization problem has:

- Scenarios of asset total returns
- A requirement that all portfolios have nonnegative weights that sum to 1 (the summation constraint is known as a budget constraint)
- Built-in models for portfolio return and risk proxies that use scenarios of asset total returns
- A probability level of 0.95

Given scenarios of asset returns in the variable `AssetScenarios`, this problem is completely specified by:

```
p = PortfolioCVaR('Scenarios', AssetScenarios, 'LowerBound', 0, 'Budget', 1, ...
'ProbabilityLevel', 0.95);
```

or equivalently by:

```
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
```

To confirm that this is a valid portfolio optimization problem, the following function determines whether the set of `PortfolioCVaR` choices is bounded (a necessary condition for portfolio optimization).

```
[lb, ub, isbounded] = estimateBounds(p);
```

Given the problem specified in the `PortfolioCVaR` object `p`, the efficient frontier for this problem can be displayed with:

```
plotFrontier(p);
```

and efficient portfolios can be obtained with:

```
pwgt = estimateFrontier(p);
```

For more information on the theory and definition of conditional value-at-risk optimization supported by portfolio optimization tools in Financial Toolbox, see “Portfolio Optimization Theory” on page 5-2.

### PortfolioCVaR Problem Sufficiency

A CVaR portfolio optimization problem is completely specified with the `PortfolioCVaR` object if three conditions are met.

The following are the three conditions that must be met:

- You must specify a collection of asset returns or prices known as scenarios such that all scenarios are finite asset returns or prices. These scenarios are meant to be samples from the underlying probability distribution of asset returns. This condition can be satisfied by the `setScenarios` function or with several canned scenario simulation functions.
- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded. You can satisfy this condition using an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed and several tools, such as the `estimateBounds` function, provide ways to ensure that your problem is properly formulated.
- You must specify a probability level to locate the level of tail loss above which the conditional value-at-risk is to be minimized. This condition can be satisfied by the `setProbabilityLevel` function.

Although the general sufficient conditions for CVaR portfolio optimization go beyond the first three conditions, the `PortfolioCVaR` object handles all these additional conditions.

### Shortcuts for Property Names

The `PortfolioCVaR` object has shorter argument names that replace longer argument names associated with specific properties of the `PortfolioCVaR` object.

For example, rather than enter '`ProbabilityLevel`', the `PortfolioCVaR` object accepts the case-insensitive name '`plevel`' to set the `ProbabilityLevel` property in a `PortfolioCVaR` object. Every shorter argument name corresponds with a single property in the `PortfolioCVaR` object. The one exception is the alternative argument name '`budget`', which signifies both the `LowerBudget` and `UpperBudget` properties. When '`budget`' is used, then the `LowerBudget` and `UpperBudget` properties are set to the same value to form an equality budget constraint.

### Shortcuts for Property Names

| Shortcut Argument Name      | Equivalent Argument / Property Name |
|-----------------------------|-------------------------------------|
| ae                          | AEquality                           |
| ai                          | AIInequality                        |
| assetnames or assets        | AssetList                           |
| be                          | bEquality                           |
| bi                          | bInequality                         |
| budget                      | UpperBudget and LowerBudget         |
| group                       | GroupMatrix                         |
| lb                          | LowerBound                          |
| n or num                    | NumAssets                           |
| level, problevel, or plevel | ProbabilityLevel                    |
| rfr                         | RiskFreeRate                        |
| scenario or assetsenarios   | Scenarios                           |
| ub                          | UpperBound                          |

# PortfolioMAD

Create PortfolioMAD object for mean-absolute deviation portfolio optimization and analysis

## Description

The `PortfolioMAD` object implements mean-absolute deviation portfolio optimization, where MAD stands for “mean-absolute deviation.” `PortfolioMAD` objects support functions that are specific to MAD portfolio optimization.

The main workflow for MAD portfolio optimization is to create an instance of a `PortfolioMAD` object that completely specifies a portfolio optimization problem and to operate on the `PortfolioMAD` object to obtain and analyze efficient portfolios. For more information on the workflow when using `PortfolioMAD` objects, see “[PortfolioMAD Object Workflow](#)” on page 6-15.

You can use the `PortfolioMAD` object in several ways. To set up a portfolio optimization problem in a `PortfolioMAD` object, the simplest syntax is:

```
p = PortfolioMAD;
```

This syntax creates a `PortfolioMAD` object, `p`, such that all object properties are empty.

The `PortfolioMAD` object also accepts collections of name-value pair arguments for properties and their values. The `PortfolioMAD` object accepts inputs for properties with the general syntax:

```
p = PortfolioMAD('property1',value1,'property2',value2, ... );
```

If a `PortfolioMAD` object exists, the syntax permits the first (and only the first argument) of the `PortfolioMAD` object to be an existing object with subsequent name-value pair arguments for properties to be added or modified. For example, given an existing `PortfolioMAD` object in `p`, the general syntax is:

```
p = PortfolioMAD(p,'property1',value1,'property2',value2, ... );
```

Input argument names are not case-sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see “[Shortcuts for Property Names](#)” on page 19-1267). The `PortfolioMAD` object tries to detect problem dimensions from the inputs and, once set, subsequent inputs can undergo various scalar or matrix expansion operations that simplify the overall process to formulate a problem. In addition, a `PortfolioMAD` object is a value object so that, given portfolio `p`, the following code creates two objects, `p` and `q`, that are distinct:

```
q = PortfolioMAD(p, ...)
```

After creating a `PortfolioMAD` object, you can use the associated object functions to set portfolio constraints, analyze the efficient frontier, and validate the portfolio model.

For more detailed information on the theoretical basis for conditional value-at-risk portfolio optimization, see “[Portfolio Optimization Theory](#)” on page 6-2.

# Creation

## Syntax

```
p = PortfolioMAD
p = PortfolioMAD(Name,Value)

p = PortfolioMAD(p,Name,Value)
```

## Description

`p = PortfolioMAD` creates an empty `PortfolioMAD` object for mean-absolute deviation portfolio optimization and analysis. You can then add elements to the `PortfolioMAD` object using the supported "add" and "set" functions. For more information, see "Creating the `PortfolioMAD` Object" on page 6-21.

`p = PortfolioMAD(Name,Value)` creates a `PortfolioMAD` object (`p`) and sets Properties on page 19-1253 using name-value pairs. For example, `p = PortfolioMAD('AssetList',Assets(1:12))`. You can specify multiple name-value pairs.

`p = PortfolioMAD(p,Name,Value)` creates a `PortfolioMAD` object (`p`) using a previously created `PortfolioMAD` object `p` and sets Properties on page 19-1253 using name-value pairs. You can specify multiple name-value pairs.

## Input Arguments

**p — Previously constructed `PortfolioMAD` object**  
object

Previously constructed `PortfolioMAD` object, specified using `PortfolioMAD`.

# Properties

## Setting Up the Object

**AssetList — Names or symbols of assets in universe**  
[ ] (default) | cell array of character vectors | string array

Names or symbols of assets in the universe, specified as a cell array of character vectors or a string array.

Data Types: cell | string

**InitPort — Initial portfolio**  
[ ] (default) | vector

Initial portfolio, specified as a vector.

Data Types: double

**Name — Name for instance of `PortfolioMAD` object**  
[ ] (default) | character vector | string

Name for instance of the `PortfolioMAD` object, specified as a character vector.

Data Types: char | string

**NumAssets — Number of assets in the universe**

[ ] (default) | integer scalar

Number of assets in the universe, specified as an integer scalar.

Data Types: double

**Portfolio Object Constraints****AEquality — Linear equality constraint matrix**

[ ] (default) | matrix

Linear equality constraint matrix, specified as a matrix.

Data Types: double

**AInequality — Linear inequality constraint matrix**

[ ] (default) | matrix

Linear inequality constraint matrix, specified as a matrix.

Data Types: double

**bEquality — Linear equality constraint vector**

[ ] (default) | vector

Linear equality constraint vector, specified as a vector.

Data Types: double

**bInequality — Linear inequality constraint**

[ ] (default) | vector

Linear inequality constraint vector, specified as a vector.

Data Types: double

**GroupA — Group A weights to be bounded by weights in group B**

[ ] (default) | matrix

Group A weights to be bounded by weights in group B, specified as a matrix.

Data Types: double

**GroupB — Group B weights**

[ ] (default) | matrix

Group B weights, specified as a matrix.

Data Types: double

**GroupMatrix — Group membership matrix**

[ ] (default) | matrix

Group membership matrix, specified as a matrix.

Data Types: double

**LowerBound — Lower-bound constraint**

[ ] (default) | vector

Lower-bound constraint, specified as a vector.

Data Types: double

**LowerBudget — Lower-bound budget constraint**

[ ] (default) | scalar

Lower-bound budget constraint, specified as a scalar.

Data Types: double

**LowerGroup — Lower-bound group constraint**

[ ] (default) | vector

Lower-bound group constraint, specified as a vector.

Data Types: double

**LowerRatio — Minimum ratio of allocations between Groups A and B**

[ ] (default) | vector

Minimum ratio of allocations between GroupA and GroupB, specified as a vector.

Data Types: double

**UpperBound — Upper-bound constraint**

[ ] (default) | vector

Upper-bound constraint, specified as a vector.

Data Types: double

**UpperBudget — Upper-bound budget constraint**

[ ] (default) | scalar

Upper-bound budget constraint, specified as a scalar.

Data Types: double

**UpperGroup — Upper-bound group constraint**

[ ] (default) | vector

Upper-bound group constraint, specified as a vector.

Data Types: double

**UpperRatio — Maximum ratio of allocations between Groups A and B**

[ ] (default) | vector

Maximum ratio of allocations between GroupA and GroupB, specified as a vector.

Data Types: double

**BoundType — Type of bounds for each asset weight**

'Simple' (default) | character vector with value 'Simple' or 'Conditional' | string with value "Simple" or "Conditional" | cell array of character vectors with values 'Simple' or 'Conditional' | string array with values "Simple" or "Conditional"

Type of bounds for each asset weight, specified as a scalar character vector or string, or a cell array of character vectors or a string array. For more information, see `setBounds`.

Data Types: char | cell | string

**MinNumAssets — Minimum number of assets allocated in portfolio**

[ ] (default) | numeric

Minimum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinMaxNumAssets`.

Data Types: double

**MaxNumAssets — Maximum number of assets allocated in portfolio**

[ ] (default) | numeric

Maximum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinMaxNumAssets`.

Data Types: double

**BuyTurnover — Turnover constraint on purchases**

[ ] (default) | scalar

Turnover constraint on purchases, specified as a scalar.

Data Types: double

**SellTurnover — Turnover constraint on sales**

[ ] (default) | scalar

Turnover constraint on sales, specified as a scalar.

Data Types: double

**Turnover — Turnover constraint**

[ ] (default) | scalar

Turnover constraint, specified as a scalar.

Data Types: double

**Portfolio Object Modeling****BuyCost — Proportional purchase costs**

[ ] (default) | vector

Proportional purchase costs, specified as a vector.

Data Types: double

**RiskFreeRate — Risk-free rate**

[ ] (default) | scalar

Risk-free rate, specified as a scalar.

Data Types: double

**ProbabilityLevel — Value-at-risk probability level which is 1 – (loss probability)**

[ ] (default) | scalar

Value-at-risk probability level which is 1 – (loss probability), specified as a scalar.

Data Types: double

**NumScenarios — Number of scenarios**

[ ] (default) | integer scalar

Number of scenarios, specified as an integer scalar.

Data Types: double

**SellCost — Proportional sales costs**

[ ] (default) | vector

Proportional sales costs, specified as a vector.

Data Types: double

## Object Functions

|                       |                                                                                       |
|-----------------------|---------------------------------------------------------------------------------------|
| setAssetList          | Set up list of identifiers for assets                                                 |
| setInitPort           | Set up initial or current portfolio                                                   |
| setDefaultConstraints | Set up portfolio constraints with nonnegative weights that sum to 1                   |
| estimateAssetMoments  | Estimate mean and covariance of asset returns from data                               |
| setCosts              | Set up proportional transaction costs for portfolio                                   |
| addEquality           | Add linear equality constraints for portfolio weights to existing constraints         |
| addGroupRatio         | Add group ratio constraints for portfolio weights to existing group ratio constraints |
| addGroups             | Add group constraints for portfolio weights to existing group constraints             |
| addInequality         | Add linear inequality constraints for portfolio weights to existing constraints       |
| getBounds             | Obtain bounds for portfolio weights from portfolio object                             |
| getBudget             | Obtain budget constraint bounds from portfolio object                                 |
| getCosts              | Obtain buy and sell transaction costs from portfolio object                           |
| getEquality           | Obtain equality constraint arrays from portfolio object                               |
| getGroupRatio         | Obtain group ratio constraint arrays from portfolio object                            |
| getGroups             | Obtain group constraint arrays from portfolio object                                  |
| getInequality         | Obtain inequality constraint arrays from portfolio object                             |
| getOneWayTurnover     | Obtain one-way turnover constraints from portfolio object                             |
| setGroups             | Set up group constraints for portfolio weights                                        |
| setInequality         | Set up linear inequality constraints for portfolio weights                            |
| setBounds             | Set up bounds for portfolio weights for portfolio                                     |
| setMinMaxNumAssets    | Set cardinality constraints on the number of assets invested in a portfolio           |
| setBudget             | Set up budget constraints for portfolio                                               |

|                                  |                                                                                               |
|----------------------------------|-----------------------------------------------------------------------------------------------|
| setCosts                         | Set up proportional transaction costs for portfolio                                           |
| setDefaultConstraints            | Set up portfolio constraints with nonnegative weights that sum to 1                           |
| setEquality                      | Set up linear equality constraints for portfolio weights                                      |
| setGroupRatio                    | Set up group ratio constraints for portfolio weights                                          |
| setInitPort                      | Set up initial or current portfolio                                                           |
| setOneWayTurnover                | Set up one-way portfolio turnover constraints                                                 |
| setTurnover                      | Set up maximum portfolio turnover constraint                                                  |
| checkFeasibility                 | Check feasibility of input portfolios against portfolio object                                |
| estimateBounds                   | Estimate global lower and upper bounds for set of portfolios                                  |
| estimateFrontier                 | Estimate specified number of optimal portfolios on the efficient frontier                     |
| estimateFrontierByReturn         | Estimate optimal portfolios with targeted portfolio returns                                   |
| estimateFrontierByRisk           | Estimate optimal portfolios with targeted portfolio risks                                     |
| estimateFrontierLimits           | Estimate optimal portfolios at endpoints of efficient frontier                                |
| plotFrontier                     | Plot efficient frontier                                                                       |
| estimatePortReturn               | Estimate mean of portfolio returns                                                            |
| estimatePortRisk                 | Estimate portfolio risk according to risk proxy associated with corresponding object          |
| setSolver                        | Choose main solver and specify associated solver options for portfolio optimization           |
| setProbabilityLevel              | Set probability level for VaR and CVaR calculations                                           |
| setScenarios                     | Set asset returns scenarios by direct matrix                                                  |
| getScenarios                     | Obtain scenarios from portfolio object                                                        |
| simulateNormalScenariosByData    | Simulate multivariate normal asset return scenarios from data                                 |
| simulateNormalScenariosByMoments | Simulate multivariate normal asset return scenarios from mean and covariance of asset returns |
| estimateScenarioMoments          | Estimate mean and covariance of asset return scenarios                                        |
| estimatePortStd                  | Estimate standard deviation of portfolio returns                                              |

## Examples

### Create an Empty PortfolioMAD Object

You can create a PortfolioMAD object, *p*, with no input arguments and display it using *disp*.

```
p = PortfolioMAD;
disp(p);
```

PortfolioMAD with properties:

```
BuyCost: []
SellCost: []
RiskFreeRate: []
Turnover: []
BuyTurnover: []
SellTurnover: []
NumScenarios: []
Name: []
NumAssets: []
AssetList: []
InitPort: []
```

```

AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: []
UpperBound: []
LowerBudget: []
UpperBudget: []
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
BoundType: []

```

This approach provides a way to set up a portfolio optimization problem with the **PortfolioMAD** function. You can then use the associated set functions to set and modify collections of properties in the **PortfolioMAD** object.

### Create a PortfolioMAD Object Using a Single-Step Setup

You can use the **PortfolioMAD** object directly to set up a “standard” portfolio optimization problem. Given scenarios of asset returns in the variable **AssetScenarios**, this problem is completely specified as follows:

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD('Scenarios', AssetScenarios, ...
    'LowerBound', 0, 'LowerBudget', 1, 'UpperBudget', 1)

p =
    PortfolioMAD with properties:

        BuyCost: []
        SellCost: []
        RiskFreeRate: []
        Turnover: []
        BuyTurnover: []
        SellTurnover: []
        NumScenarios: 20000
            Name: []
        NumAssets: 4
        AssetList: []

```

```
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: [4x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
    GroupA: []
    GroupB: []
LowerRatio: []
UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
BoundType: []
```

Note that the `LowerBound` property value undergoes scalar expansion since `AssetScenarios` provides the dimensions of the problem.

### Create a PortfolioMAD Object Using a Sequence of Steps

Using a sequence of steps is an alternative way to accomplish the same task of setting up a “standard” MAD portfolio optimization problem, given `AssetScenarios` variable is:

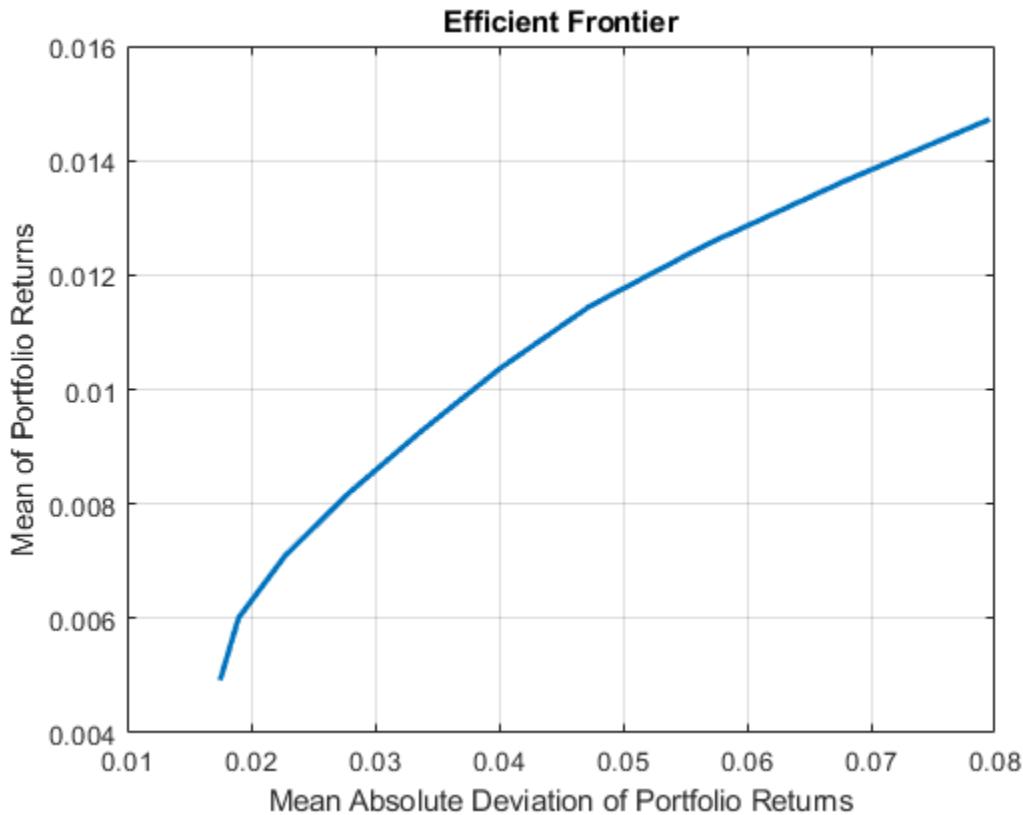

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = PortfolioMAD(p, 'LowerBound', 0);
p = PortfolioMAD(p, 'LowerBudget', 1, 'UpperBudget', 1);

plotFrontier(p);
```

This way works because the calls to `PortfolioMAD` are in this particular order. In this case, the call to initialize `AssetScenarios` provides the dimensions for the problem. If you were to do this step last, you would have to explicitly dimension the `LowerBound` property as follows:

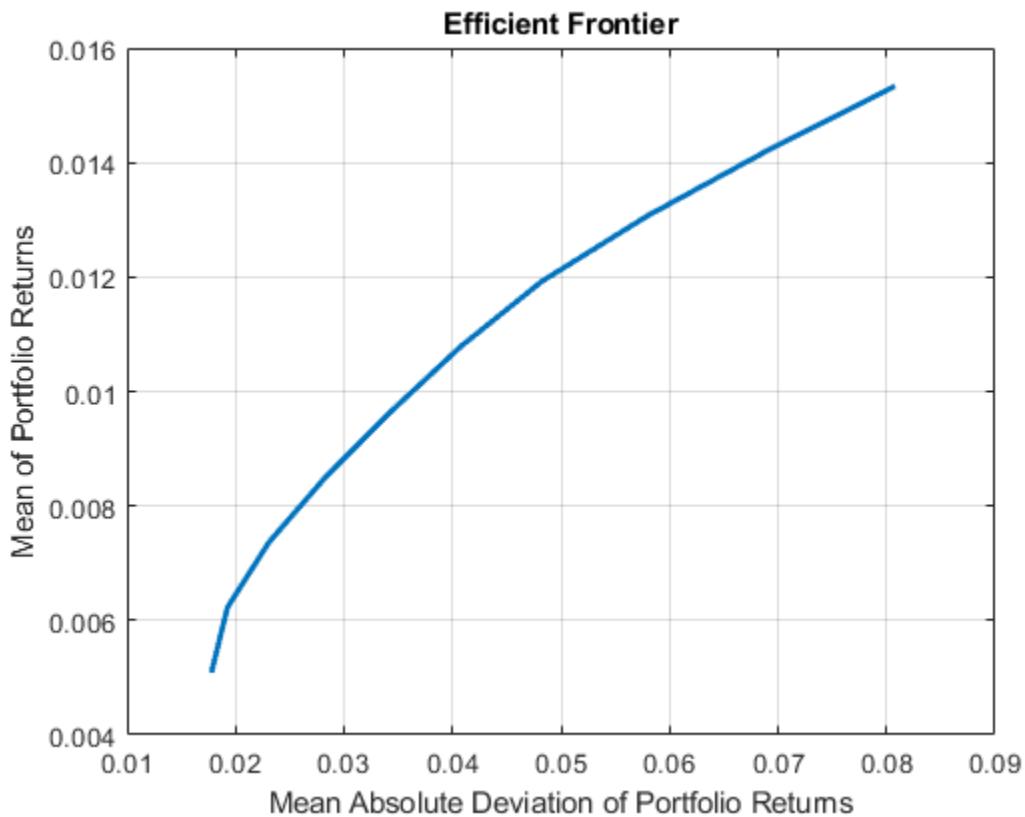

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = PortfolioMAD(p, 'LowerBound', zeros(size(m)));
p = PortfolioMAD(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = setScenarios(p, AssetScenarios);

plotFrontier(p);
```

If you did not specify the size of `LowerBound` but, instead, input a scalar argument, the `PortfolioMAD` object assumes that you are defining a single-asset problem and produces an error at the call to set asset scenarios with four assets.

### Create a `PortfolioMAD` Object Using Shortcuts for Property Names

You can create a `PortfolioMAD` object, `p` with the `PortfolioMAD` object using shortcuts for property names.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD('scenario', AssetScenarios, 'lb', 0, 'budget', 1)
p =
  PortfolioMAD with properties:
```

```

        BuyCost: []
        SellCost: []
    RiskFreeRate: []
        Turnover: []
    BuyTurnover: []
    SellTurnover: []
NumScenarios: 20000
        Name: []
    NumAssets: 4
    AssetList: []
    InitPort: []
AInequality: []
bInequality: []
    AEquality: []
    bEquality: []
LowerBound: [4x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
    LowerGroup: []
    UpperGroup: []
    GroupA: []
    GroupB: []
LowerRatio: []
UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
    BoundType: []

```

## Direct Setting of PortfolioMAD Object Properties

Although not recommended, you can set properties directly, however no error-checking is done on your inputs.

```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;

p = setScenarios(p, AssetScenarios);

p.LowerBudget = 1;
p.UpperBudget = 1;
p.LowerBound = zeros(size(m));
disp(p);

```

PortfolioMAD with properties:

```
BuyCost: []
SellCost: []
RiskFreeRate: []
Turnover: []
BuyTurnover: []
SellTurnover: []
NumScenarios: 20000
    Name: []
NumAssets: 4
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: [4x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
    GroupA: []
    GroupB: []
LowerRatio: []
UpperRatio: []
MinNumAssets: []
MaxNumAssets: []
    BoundType: []
```

Scenarios cannot be assigned directly to a PortfolioMAD object. Scenarios must always be set through either the `PortfolioMAD` function, the `setScenarios` function, or any of the scenario simulation functions.

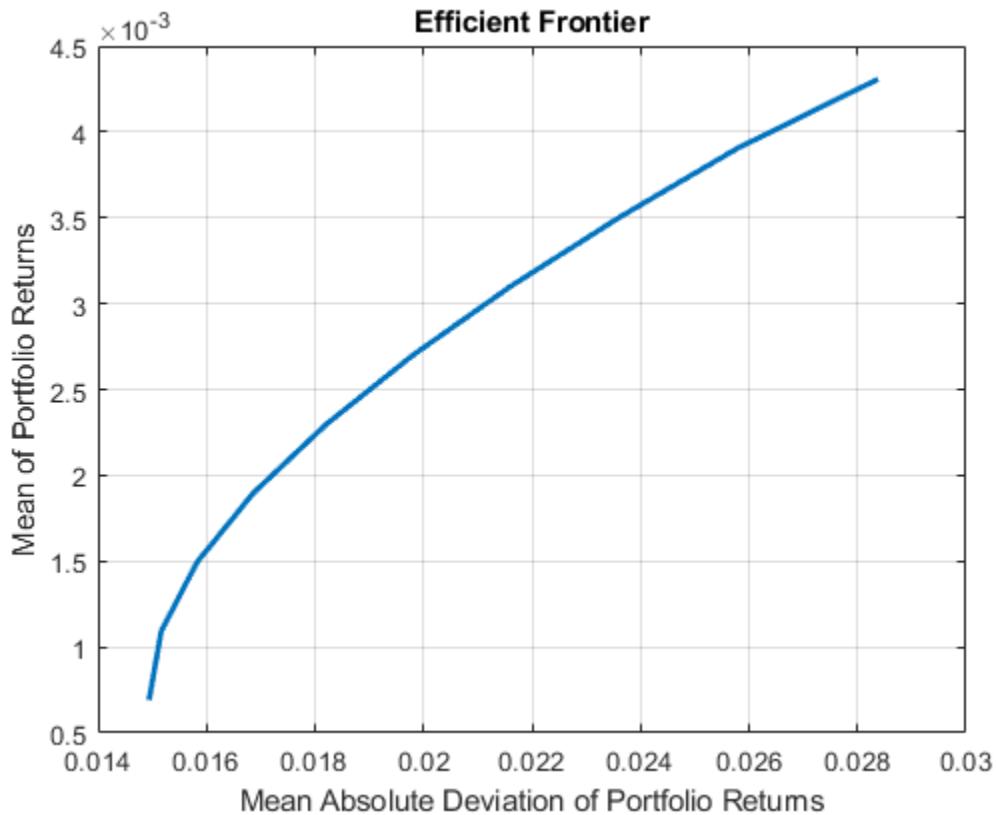

## Create a PortfolioMAD Object and Determine Efficient Portfolios

Create efficient portfolios:

```
load CAPMuniverse

p = PortfolioMAD('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 , 'missingdata',true);
p = setDefaultConstraints(p);

plotFrontier(p);
```

```

pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5
    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([{pwgt},pnames], 'obsnames',p.AssetList);

disp(Blotter);

```

|      | Port1     | Port2    | Port3    | Port4   | Port5 |
|------|-----------|----------|----------|---------|-------|
| AAPL | 0.029787  | 0.076199 | 0.11265  | 0.13397 | 0     |
| AMZN | 0         | 0        | 0        | 0       | 0     |
| CSCO | 0         | 0        | 0        | 0       | 0     |
| DELL | 0.0089177 | 0        | 0        | 0       | 0     |

| YHOO | 0         | 0        | 0        | 0       | 0     |

## More About

### Mean-Absolute Deviation Portfolio Optimization

A MAD optimization problem is completely specified with three elements.

The three elements for a A MAD optimization problem are:

- A universe of assets with scenarios of asset total returns for a period of interest, where scenarios comprise a collection of samples from the underlying probability distribution for asset total returns. This collection must be sufficiently large for asymptotic convergence of sample statistics. Asset return moments and related statistics are derived exclusively from the scenarios.
- A portfolio set that specifies the set of portfolio choices in terms of a collection of constraints.
- A model for portfolio return and risk proxies, which, for MAD optimization, is either the gross or net mean of portfolio returns and the mean-absolute deviation of portfolio returns.

After these three elements have been specified unambiguously, it is possible to solve and analyze MAD portfolio optimization problems.

The simplest MAD portfolio optimization problem has:

- Scenarios of asset total returns
- A requirement that all portfolios have nonnegative weights that sum to 1 (the summation constraint is known as a budget constraint)
- Built-in models for portfolio return and risk proxies that use scenarios of asset total returns

Given scenarios of asset returns in the variable `AssetScenarios`, this problem is completely specified by:

```
p = PortfolioMAD('Scenarios', AssetScenarios, 'LowerBound', 0, 'Budget', 1);
```

or equivalently by:

```
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
```

To confirm that this is a valid portfolio optimization problem, the following function determines whether the set of PortfolioMAD choices is bounded (a necessary condition for portfolio optimization).

```
[lb, ub, isbounded] = estimateBounds(p);
```

Given the problem specified in the `PortfolioMAD` object `p`, the efficient frontier for this problem can be displayed with:

```
plotFrontier(p);
```

and efficient portfolios can be obtained with:

```
pwgt = estimateFrontier(p);
```

For more detailed information on the theoretical basis for mean-absolute deviation optimization, see “Portfolio Optimization Theory” on page 6-2.

## PortfolioMAD Problem Sufficiency

A MAD portfolio optimization problem is completely specified with the `PortfolioMAD` object if three conditions are met.

The following are the three conditions that must be met:

- You must specify a collection of asset returns or prices known as scenarios such that all scenarios are finite asset returns or prices. These scenarios are meant to be samples from the underlying probability distribution of asset returns. This condition can be satisfied by the `setScenarios` function or with several canned scenario simulation functions.
- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded. You can satisfy this condition using an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed and several tools, such as the `estimateBounds` function, provide ways to ensure that your problem is properly formulated.

Although the general sufficient conditions for MAD portfolio optimization go beyond these conditions, the `PortfolioMAD` object handles all these additional conditions.

## Shortcuts for Property Names

The `PortfolioMAD` object has shorter argument names that replace longer argument names associated with specific properties of the `PortfolioMAD` object.

For example, rather than enter '`AInequality`', `PortfolioMAD` accepts the case-insensitive name '`ai`' to set the `AInequality` property in a `PortfolioMAD` object. Every shorter argument name corresponds with a single property in the `PortfolioMAD` function. The one exception is the alternative argument name '`budget`', which signifies both the `LowerBudget` and `UpperBudget` properties. When '`budget`' is used, then the `LowerBudget` and `UpperBudget` properties are set to the same value to form an equality budget constraint.

## Shortcuts for Property Names

| Shortcut Argument Name                               | Equivalent Argument / Property Name                   |
|------------------------------------------------------|-------------------------------------------------------|
| <code>ae</code>                                      | <code>AEquality</code>                                |
| <code>ai</code>                                      | <code>AInequality</code>                              |
| <code>assetnames</code> or <code>assets</code>       | <code>AssetList</code>                                |
| <code>be</code>                                      | <code>bEquality</code>                                |
| <code>bi</code>                                      | <code>bInequality</code>                              |
| <code>budget</code>                                  | <code>UpperBudget</code> and <code>LowerBudget</code> |
| <code>group</code>                                   | <code>GroupMatrix</code>                              |
| <code>lb</code>                                      | <code>LowerBound</code>                               |
| <code>n</code> or <code>num</code>                   | <code>NumAssets</code>                                |
| <code>rfr</code>                                     | <code>RiskFreeRate</code>                             |
| <code>scenario</code> or <code>assetscenarios</code> | <code>Scenarios</code>                                |
| <code>ub</code>                                      | <code>UpperBound</code>                               |

### Introduced in R2013b

# portopt

Portfolios on constrained efficient frontier

---

**Note** `portopt` has been partially removed and will no longer accept `ConSet` or `varargin` arguments. Use `Portfolio` instead to solve portfolio problems that are more than a long-only fully-invested portfolio. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow”. For more information on migrating `portopt` code to `Portfolio`, see “`portopt` Migration to Portfolio Object”.

---

## Syntax

```
[PortRisk,PortReturn,PortWts] = portopt(ExpReturn,ExpCovariance)
[PortRisk,PortReturn,PortWts] = portopt(___,NumPorts,PortReturn)
portopt(___,NumPorts,PortReturn)
```

## Description

`[PortRisk,PortReturn,PortWts] = portopt(ExpReturn,ExpCovariance)` sets up the most basic portfolio problem with weights greater than or equal to 0 that must sum to 1. All that is necessary to solve this problem is the mean and covariance of asset returns. By default, `portopt` returns 10 equally-spaced points on the efficient frontier.

`portopt` solves the "standard" mean-variance portfolio optimization problem for a long-only fully-invested investor with no additional constraints. Specifically, every portfolios on the efficient frontier has non-negative weights that sum to 1.

`[PortRisk,PortReturn,PortWts] = portopt(___,NumPorts,PortReturn)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

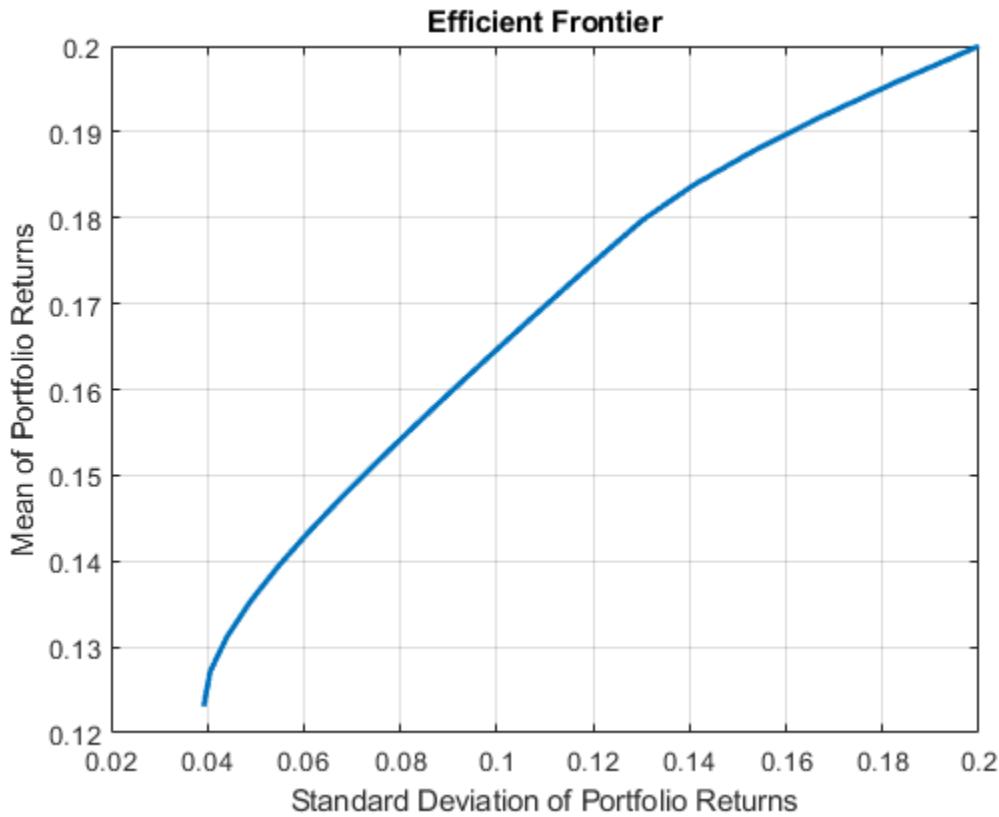

`portopt(___,NumPorts,PortReturn)` returns a plot of the efficient frontier if `portopt` is invoked with no output arguments.

## Examples

### Plot the Risk-Return Efficient Frontier

Use `portopt` to connect 20 portfolios along the efficient frontier having evenly spaced returns. By default, choose among portfolios without short-selling and scale the value of the portfolio to 1.

```
ExpReturn = [0.1 0.2 0.15];
ExpCovariance = [0.005 -0.010 0.004
                 -0.010 0.040 -0.002
                 0.004 -0.002 0.023];
NumPorts = 20;
portopt(ExpReturn, ExpCovariance, NumPorts)
```

## Input Arguments

**ExpReturn — Expected (mean) return of each asset**  
vector

Expected (mean) return of each asset, specified as a 1-by-number of assets (NASSETS) vector.  
Data Types: double

**ExpCovariance — Covariance of the asset returns**  
matrix

Covariance of the asset returns, specified as a NASSETS-by-NASSETS matrix.  
Data Types: double

**NumPorts — Number of portfolios generated along the efficient frontier**  
10 (default) | scalar numeric

(Optional) Number of portfolios generated along the efficient frontier, specified as a scalar numeric. Returns are equally spaced between the maximum possible return and the minimum risk point. If NumPorts is empty (entered as []), portopt computes 10 equally spaced points. If you specify 1, portopt returns the minimum-risk portfolio.

---

**Note** If not over-written by PortReturn, these portfolios are spaced evenly from the minimum to the maximum return on the efficient frontier. If NumPorts = 1, then the minimum-risk portfolio is computed (positive integer).

---

Data Types: double

**PortReturn — Target portfolio returns to be computed on the efficient frontier**  
 [ ] (default) | vector

(Optional) Target portfolio returns to be computed on the efficient frontier, specified as a number of portfolios (NPORTS-by-1 vector). If not entered or empty, NumPorts equally spaced returns between the minimum and maximum possible values are used.

---

**Note** portopt requires that if you set PortReturn, NumPorts should be empty. If you specify PortReturn with a nonempty vector, PortReturn overrides NumPorts. If any returns in PortReturn fall outside the range of returns on the efficient frontier, portopt generates a warning and the efficient portfolios closest to the endpoints of the efficient frontier are computed.

---

Data Types: double

## Output Arguments

**PortRisk — Standard deviation of each portfolio**  
 vector

Standard deviation of each portfolio, returned as a NPORTS-by-1 vector.

PortWts is an NPORTS-by-NASSETS matrix of weights allocated to each asset. Each row represents a portfolio. The total of all weights in a portfolio is 1.

**PortReturn — expected return of each portfolio**  
 vector

Expected return of each portfolio, returned as a NPORTS-by-1 vector.

**PortWts — Weights allocated to each asset**  
 matrix

Weights allocated to each asset, returned as a NPORTS-by-NASSETS matrix. Each row represents a portfolio. The total of all weights in a portfolio is 1.

# portrand

Randomized portfolio risks, returns, and weights

## Syntax

```
[PortRisk,PortReturn,PortWts] = portrand(Asset,Return,Points,Method)
portrand(Asset,Return,Points,Method)
```

## Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Asset  | Matrix of time series data. Each row is an observation and each column represents a single security.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Return | (Optional) Row vector where each column represents the rate of return for the corresponding security in Asset. By default, Return is computed by taking the average value of each column of Asset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Points | (Optional) Scalar that specifies how many random points should be generated. Default = 1000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Method | (Optional) A character vector that specifies how to generate random portfolios from the set of portfolios with two possible methods: <ul style="list-style-type: none"> <li>'uniform' - Uniformly distributed portfolio weights (default method). The 'uniform' method generates portfolio weights that are uniformly distributed on the set of portfolio weights.</li> <li>'geometric' - Concentrated portfolio weights around the geometric center of the set of portfolios. The 'geometric' method generates portfolio weights that are concentrated around the geometric center of the set of portfolio weights.</li> </ul> <p><b>Note</b> The 'uniform' and 'geometric' methods generate weights that are distributed symmetrically around the geometric center of the set of weights.</p> |

## Description

[PortRisk,PortReturn,PortWts] = portrand(Asset,Return,Points,Method) returns the risks, rates of return, and weights of random portfolio configurations.

|            |                                                                                                                     |
|------------|---------------------------------------------------------------------------------------------------------------------|
| PortRisk   | Points-by-1 vector of standard deviations.                                                                          |
| PortReturn | Points-by-1 vector of expected rates of return.                                                                     |
| PortWts    | Points by number of securities matrix of asset weights. Each row of PortWts is a different portfolio configuration. |

portrand(Asset, Return, Points, Method) plots the points representing each portfolio configuration. It does not return any data to the MATLAB workspace.

**Note** Portfolios are selected at random from a set of portfolios such that portfolio weights are nonnegative and sum to 1. The sample mean and covariance of asset returns are used to compute portfolio returns for each random portfolio.

## Introduced before R2006a

# portror

Portfolio expected rate of return

## Syntax

```
R = portror(Return,Weight)
```

## Description

`R = portror(Return,Weight)` returns a 1-by-M vector for the expected rate of return.

## Examples

### Portfolio Expected Rate of Return

This example shows a portfolio that is made up of two assets ABC and XYZ having expected rates of return of 10% and 14%, respectively. If 40% percent of the portfolio's funds are allocated to asset ABC and the remaining funds are allocated to asset XYZ, the portfolio's expected rate of return is:

```
r = portror([.1 .14],[.4 .6])
r = 0.1240
```

## Input Arguments

### Return — Rates of return

matrix

Rates of return, specified as a 1-by-N matrix. Each column of `Return` represents the rate of return for a single security.

Data Types: double

### Weight — Weights

matrix

Weights, specified as a M-by-N matrix. Each row of `Weight` represents a different weighting combination of the assets in the portfolio.

Data Types: double

## Output Arguments

### R — Expected rate of return

vector

Expected rate of return, returned as a 1-by-M vector.

## Introduced before R2006a

# portsim

Monte Carlo simulation of correlated asset returns

## Syntax

```
RetSeries = portsim(ExpReturn,ExpCovariance,NumObs)
RetSeries = portsim(_____,RetIntervals,NumSim,Method)
```

## Description

`RetSeries = portsim(ExpReturn,ExpCovariance,NumObs)` simulates correlated returns of `NASSETS` assets over `NUMOBS` consecutive observation intervals. Asset returns are simulated as the proportional increments of constant drift, constant volatility stochastic processes, thereby approximating continuous-time geometric Brownian motion.

`RetSeries = portsim(_____,RetIntervals,NumSim,Method)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Distinction Between Simulation Methods

This example shows the distinction between the `Exact` and `Expected` methods of simulation.

Consider a portfolio of five assets with the following expected returns, standard deviations, and correlation matrix based on daily asset returns (where `ExpReturn` and `Sigmas` are divided by 100 to convert percentages to returns).

```
ExpReturn      = [0.0246  0.0189  0.0273  0.0141  0.0311]/100;
Sigmas        = [0.9509  1.4259  1.5227  1.1062  1.0877]/100;
Correlations  = [1.0000  0.4403  0.4735  0.4334  0.6855
                  0.4403  1.0000  0.7597  0.7809  0.4343
                  0.4735  0.7597  1.0000  0.6978  0.4926
                  0.4334  0.7809  0.6978  1.0000  0.4289
                  0.6855  0.4343  0.4926  0.4289  1.0000];
```

Convert the correlations and standard deviations to a covariance matrix.

```
ExpCovariance = corr2cov(Sigmas, Correlations)
```

```
ExpCovariance = 5x5
10^-3 x
```

|--------|--------|--------|--------|--------|
| 0.0904 | 0.0597 | 0.0686 | 0.0456 | 0.0709 |
| 0.0597 | 0.2033 | 0.1649 | 0.1232 | 0.0674 |
| 0.0686 | 0.1649 | 0.2319 | 0.1175 | 0.0816 |
| 0.0456 | 0.1232 | 0.1175 | 0.1224 | 0.0516 |
| 0.0709 | 0.0674 | 0.0816 | 0.0516 | 0.1183 |

Assume that there are 252 trading days in a calendar year, and simulate two sample paths (realizations) of daily returns over a two-year period. Since `ExpReturn` and `ExpCovariance` are expressed daily, set `RetIntervals = 1`.

```
StartPrice    = 100;
NumObs        = 504; % two calendar years of daily returns
NumSim        = 2;
RetIntervals  = 1;   % one trading day
NumAssets     = 5;
```

To illustrate the distinction between methods, simulate two paths by each method, starting with the same random number state.

```
rng('default');
RetExact = portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, NumSim, 'Exact');
rng(0);
RetExpected = portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, NumSim, 'Expected');
```

Compare the mean and covariance of `RetExact` with the inputs (`ExpReturn` and `ExpCovariance`), you will observe that they are almost identical.

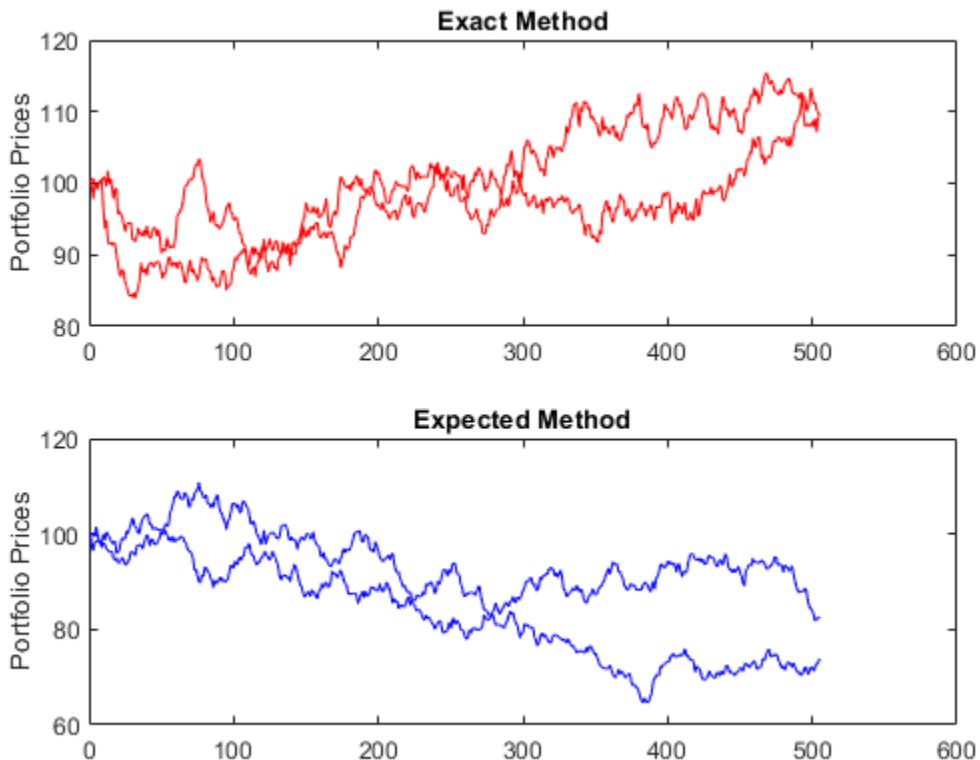

At this point, `RetExact` and `RetExpected` are both 504-by-5-by-2 arrays. Now assume an equally weighted portfolio formed from the five assets and create arrays of portfolio returns in which each column represents the portfolio return of the corresponding sample path of the simulated returns of the five assets. The portfolio arrays `PortRetExact` and `PortRetExpected` are 504-by-2 matrices.

```
Weights        = ones(NumAssets, 1)/NumAssets;
PortRetExact   = zeros(NumObs, NumSim);
PortRetExpected = zeros(NumObs, NumSim);

for i = 1:NumSim
    PortRetExact(:,i) = RetExact(:,:,i) * Weights;
    PortRetExpected(:,i) = RetExpected(:,:,i) * Weights;
end
```

Finally, convert the simulated portfolio returns to prices and plot the data. In particular, note that since the `Exact` method matches expected return and covariance, the terminal portfolio prices are virtually identical for each sample path. This is not true for the `Expected` simulation method. Although this example examines portfolios, the same methods apply to individual assets as well. Thus, `Exact` simulation is most appropriate when unique paths are required to reach the same terminal prices.

```
PortExact    = ret2tick(PortRetExact, ...
repmat(StartPrice,1,NumSim));
PortExpected = ret2tick(PortRetExpected, ...
repmat(StartPrice,1,NumSim));
subplot(2,1,1), plot(PortExact, '-r')
ylabel('Portfolio Prices')
title('Exact Method')
subplot(2,1,2), plot(PortExpected, '-b')
ylabel('Portfolio Prices')
title('Expected Method')
```

### Interaction Between ExpReturn, ExpCovariance, and RetIntervals

This example shows the interplay among `ExpReturn`, `ExpCovariance`, and `RetIntervals`. Recall that `portsim` simulates correlated asset returns over an interval of length  $dt$ , given by the equation

$$\frac{dS}{S} = \mu dt + \sigma dz = \mu dt + \sigma \varepsilon \sqrt{dt},$$

where  $S$  is the asset price,  $\mu$  is the expected rate of return,  $\sigma$  is the volatility of the asset price, and  $\varepsilon$  represents a random drawing from a standardized normal distribution.

The time increment  $dt$  is determined by the optional input `RetIntervals`, either as an explicit input argument or as a unit time increment by default. Regardless, the periodicity of `ExpReturn`, `ExpCovariance`, and `RetIntervals` must be consistent. For example, if `ExpReturn` and `ExpCovariance` are annualized, then `RetIntervals` must be in years. This point is often misunderstood.

To illustrate the interplay among `ExpReturn`, `ExpCovariance`, and `RetIntervals`, consider a portfolio of five assets with the following expected returns, standard deviations, and correlation matrix based on daily asset returns.

```
ExpReturn      = [0.0246  0.0189  0.0273  0.0141  0.0311]/100;
Sigmas        = [0.9509  1.4259  1.5227  1.1062  1.0877]/100;
```

```
Correlations = [1.0000  0.4403  0.4735  0.4334  0.6855
                0.4403  1.0000  0.7597  0.7809  0.4343
                0.4735  0.7597  1.0000  0.6978  0.4926
                0.4334  0.7809  0.6978  1.0000  0.4289
                0.6855  0.4343  0.4926  0.4289  1.0000];
```

Convert the correlations and standard deviations to a covariance matrix of daily returns.

```
ExpCovariance = corr2cov(Sigmas, Correlations);
```

Assume 252 trading days per calendar year, and simulate a single sample path of daily returns over a four-year period. Since the `ExpReturn` and `ExpCovariance` inputs are expressed daily, set `RetIntervals = 1`.

```
StartPrice    = 100;
NumObs        = 1008;    % four calendar years of daily returns
RetIntervals  = 1;       % one trading day
NumAssets     = length(ExpReturn);
randn('state',0);
RetSeries1 = portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, 1, 'Expected');
```

Now annualize the daily data, thereby changing the periodicity of the data, by multiplying `ExpReturn` and `ExpCovariance` by 252 and dividing `RetIntervals` by 252 (`RetIntervals = 1/252` of a year). Resetting the random number generator to its initial state, you can reproduce the results.

```
rng('default');
RetSeries2 = portsim(ExpReturn*252, ExpCovariance*252, ...
NumObs, RetIntervals/252, 1, 'Expected');
```

Assume an equally weighted portfolio and compute portfolio returns associated with each simulated return series.

```
Weights = ones(NumAssets, 1)/NumAssets;

PortRet1 = RetSeries2 * Weights;
PortRet2 = RetSeries2 * Weights;
```

Comparison of the data reveals that `PortRet1` and `PortRet2` are identical.

## Univariate Geometric Brownian Motion

This example shows how to simulate a univariate geometric Brownian motion process. It is based on an example found in Hull, *Options, Futures, and Other Derivatives*, 5th Edition (see example 12.2 on page 236). In addition to verifying Hull's example, it also graphically illustrates the lognormal property of terminal stock prices by a rather large Monte Carlo simulation.

Assume that you own a stock with an initial price of \$20, an annualized expected return of 20% and volatility of 40%. Simulate the daily price process for this stock over the course of one full calendar year (252 trading days).

```
StartPrice    = 20;
ExpReturn    = 0.2;
ExpCovariance = 0.4^2;
NumObs       = 252;
NumSim       = 10000;
RetIntervals = 1/252;
```

`RetIntervals` is expressed in years, consistent with the fact that `ExpReturn` and `ExpCovariance` are annualized. Also, `ExpCovariance` is entered as a variance rather than the more familiar standard deviation (volatility).

Set the random number generator state, and simulate 10,000 trials (realizations) of stock returns over a full calendar year of 252 trading days.

```
rng('default');
RetSeries = squeeze(portsim(ExpReturn, ExpCovariance, NumObs, ...
    RetIntervals, NumSim, 'Expected'));
```

The `squeeze` function reformats the output array of simulated returns from a 252-by-1-by-10000 array to more convenient 252-by-10000 array. (Recall that `portsim` is fundamentally a multivariate simulation engine).

In accordance with Hull's equations 12.4 and 12.5 on page 236

$$E(S_T) = S_0 e^{\mu T}$$

$$\text{var}(S_T) = S_0^2 e^{2\mu T} \left( e^{\sigma^2 T} - 1 \right)$$

convert the simulated return series to a price series and compute the sample mean and the variance of the terminal stock prices.

```
StockPrices = ret2tick(RetSeries, repmat(StartPrice, 1, NumSim));
SampMean = mean(StockPrices(end,:))
SampVar = var(StockPrices(end,:))

SampMean =
24.4489

SampVar =
101.4243
```

Compare these values with the values you obtain by using Hull's equations.

```
ExpValue = StartPrice*exp(ExpReturn)
ExpVar = ...
StartPrice*StartPrice*exp(2*ExpReturn)*(exp((ExpCovariance)) - 1)

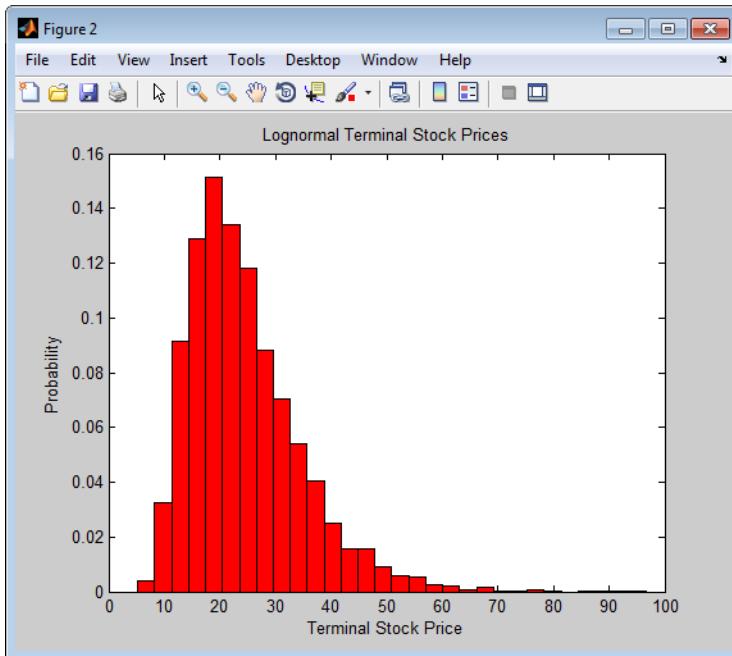

ExpValue =
24.4281

ExpVar =
103.5391
```

These results are very close to the results shown in Hull's example 12.2.

Display the sample density function of the terminal stock price after one calendar year. From the sample density function, the lognormal distribution of terminal stock prices is apparent.

```
[count, BinCenter] = hist(StockPrices(end,:), 30);
figure
bar(BinCenter, count/sum(count), 1, 'r')
xlabel('Terminal Stock Price')
ylabel('Probability')
title('Lognormal Terminal Stock Prices')
```

## Input Arguments

**ExpReturn — Expected (mean) return of each asset**  
vector

Expected (mean) return of each asset, specified as a 1-by-NASSETS vector.

Data Types: double

**ExpCovariance — Asset return covariances**  
matrix

Asset return covariances, specified as an NASSETS-by-NASSETS matrix. **ExpCovariance** must be symmetric and positive semidefinite (no negative eigenvalues). The standard deviations of the returns are  $\text{ExpSigma} = \text{sqrt}(\text{diag}(\text{ExpCovariance}))$ . If **ExpCovariance** is not a symmetric positive semidefinite matrix, use **nearcorr** to create a positive semidefinite matrix for a correlation matrix.

Data Types: double

**NumObs — Number of consecutive observations in the return time series**  
positive scalar integer

number of consecutive observations in the return time series, specified as a positive scalar integer. If **NumObs** is entered as the empty matrix [ ], the length of **RetIntervals** is used.

Data Types: double

**RetIntervals — Interval times between observations**  
1 (default) | positive scalar | vector

(Optional) Interval times between observations, specified as a positive scalar or a number of observations NUMOBS-by-1 vector. If **RetIntervals** is not specified, all intervals are assumed to have length 1.

Data Types: double

**NumSim — Number of simulated sample paths (realizations) of NUMOBS observations**

1 (default) | positive scalar integer

(Optional) Number of simulated sample paths (realizations) of NUMOBS observations, specified as a positive scalar integer. The default value for NumSim is 1 (single realization of NUMOBS correlated asset returns).

Data Types: double

**Method — Type of Monte Carlo simulation**

'Exact' (default) | character vector

(Optional) Type of Monte Carlo simulation, specified as a character vector with one of the following values:

- 'Exact' (default) generates correlated asset returns in which the sample mean and covariance match the input mean (ExpReturn) and covariance (ExpCovariance) specifications.
- 'Expected' generates correlated asset returns in which the sample mean and covariance are statistically equal to the input mean and covariance specifications. (The expected values of the sample mean and covariance are equal to the input mean (ExpReturn) and covariance (ExpCovariance) specifications.)

For either Method, the sample mean and covariance returned are appropriately scaled by RetIntervals.

Data Types: char

## Output Arguments

**RetSeries — Three-dimensional array of correlated, normally distributed, proportional asset returns**

array

Three-dimensional array of correlated, normally distributed, proportional asset returns, returned as a NUMOBS-by-NASSETS-by-NUMSIM three-dimensional array.

Asset returns over an interval of length  $dt$  are given by

$$\frac{dS}{S} = \mu dt + \sigma dz = \mu dt + \sigma \varepsilon \sqrt{dt},$$

where  $S$  is the asset price,  $\mu$  is the expected rate of return,  $\sigma$  is the volatility of the asset price, and  $\varepsilon$  represents a random drawing from a standardized normal distribution.

---

## Notes

- When Method is 'Exact', the sample mean and covariance of all realizations (scaled by RetIntervals) match the input mean and covariance. When the returns are then converted to asset prices, all terminal prices for a given asset are in close agreement. Although all realizations are drawn independently, they produce similar terminal asset prices. Set Method to 'Expected' to avoid this behavior.

- The returns from the portfolios in `PortWts` are given by  
`PortReturn = PortWts * RetSeries(:,:,1)'`, where `PortWts` is a matrix in which each row contains the asset allocations of a portfolio. Each row of `PortReturn` corresponds to one of the portfolios identified in `PortWts`, and each column corresponds to one of the observations taken from the first realization (the first plane) in `RetSeries`. See `portopt` and `portstats` for portfolio specification and optimization.

## Introduced before R2006a

# portstats

Portfolio expected return and risk

## Syntax

```
[PortRisk,PortReturn] = portstats(ExpReturn,ExpCovariance)
[PortRisk,PortReturn] = portstats(___,Wts)
```

## Description

`[PortRisk,PortReturn] = portstats(ExpReturn,ExpCovariance)` computes the expected rate of return and risk for a portfolio of assets.

`[PortRisk,PortReturn] = portstats(___,Wts)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Computes the Expected Rate of Return and Risk for a Portfolio of Assets

This example shows how to calculate the expected rate of return and risk for a portfolio of assets.

```
ExpReturn = [0.1 0.2 0.15];
ExpCovariance = [0.0100    -0.0061     0.0042
                  -0.0061     0.0400    -0.0252
                   0.0042    -0.0252     0.0225 ];
PortWts=[0.4 0.2 0.4; 0.2 0.4 0.2];
[PortRisk, PortReturn] = portstats(ExpReturn, ExpCovariance, ...
PortWts)
```

PortRisk = 2×1

```
0.0560
0.0550
```

PortReturn = 2×1

```
0.1400
0.1300
```

## Input Arguments

**ExpReturn — Expected (mean) return of each asset**  
vector

Expected (mean) return of each asset, specified as a 1-by-NASSETS vector.

Data Types: double

**ExpCovariance — Asset return covariances**

matrix

Asset return covariances, specified as an NASSETS-by-NASSETS matrix.

Data Types: double

**Wts — Weights allocated to each asset**

1/NASSETS (equally weighted) (default) | matrix

(Optional) Weights allocated to each asset, specified as an NPORTS-by-NASSETS matrix. Each row represents a different weighting combination of the assets in the portfolio. If Wts is not entered, weights of 1/NASSETS are assigned to each security.

Data Types: double

## Output Arguments

**PortRisk — Standard deviation of each portfolio**

vector

Standard deviation of each portfolio, returned as an NPORTS-by-1 vector.

**PortReturn — Expected return of each portfolio**

vector

Expected return of each portfolio, returned an NPORTS-by-1 vector.

# portvar

Variance for portfolio of assets

## Syntax

```
V = portvar(Asset,Weight)
```

## Arguments

|        |                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------|
| Asset  | M-by-N matrix of M asset returns for N securities.                                                                        |
| Weight | R-by-N matrix of R portfolio weights for N securities. Each row of Weight constitutes a portfolio of securities in Asset. |

## Description

`V = portvar(Asset,Weight)` returns the portfolio variance as an R-by-1 vector (assuming `Weight` is a matrix of size R-by-N) with each row representing a variance calculation for each row of `Weight`.

`V = portvar(Asset)` assigns each security an equal weight when calculating the portfolio variance.

## portvrisk

Portfolio value at risk (VaR)

### Syntax

```
ValueAtRisk = portvrisk(PortReturn,PortRisk)
ValueAtRisk = portvrisk(___,RiskThreshold,PortValue)
```

### Description

`ValueAtRisk = portvrisk(PortReturn,PortRisk)` returns the maximum potential loss in the value of a portfolio over one period of time (that is, monthly, quarterly, yearly, and so on) given the loss probability level. `portvrisk` calculates `ValueAtRisk` using a normal distribution.

`ValueAtRisk = portvrisk(___,RiskThreshold,PortValue)` adds optional arguments for `RiskThreshold` and `PortValue`.

### Examples

#### Compute the Maximum Potential Loss in the Value of a Portfolio Over One Period of Time

This example shows how to return the maximum potential loss in the value of a portfolio over one period of time, where `ValueAtRisk` is computed on a per-unit basis.

```
PortReturn = 0.29/100;
PortRisk = 3.08/100;
RiskThreshold = [0.01;0.05;0.10];
PortValue = 1;
ValueAtRisk = portvrisk(PortReturn,PortRisk, ...
    RiskThreshold,PortValue)

ValueAtRisk = 3x1
```

```
0.0688
0.0478
0.0366
```

#### Compute the Maximum Potential Loss in the Value of a Portfolio Over One Period of Time Using Actual Values

This example shows how to return the maximum potential loss in the value of a portfolio over one period of time, where `ValueAtRisk` is computed with actual values.

```
PortReturn = [0.29/100;0.30/100];
PortRisk = [3.08/100;3.15/100];
RiskThreshold = 0.10;
PortValue = [1000000000;500000000];
```

```

ValueAtRisk = portvrisk(PortReturn,PortRisk, ...
RiskThreshold,PortValue)

ValueAtRisk = 2×1
107 ×

3.6572
1.8684

```

## Input Arguments

**PortReturn — Expected return of each portfolio over period**  
scalar numeric | vector

Expected return of each portfolio over the period, specified as a scalar numeric or an NPORTS-by-1 vector.

Data Types: double

**PortRisk — Standard deviation of each portfolio over period**  
scalar numeric | vector

Standard deviation of each portfolio over period, specified as a scalar numeric or NPORTS-by-1 vector.

Data Types: double

**RiskThreshold — Loss probability**  
0 .05 (5%) (default) | scalar decimal | vector

(Optional) Loss probability, specified as a scalar decimal or an NPORTS-by-1 vector.

Data Types: double

**PortValue — Total value of asset portfolio**  
1 (default) | scalar numeric | vector

(Optional) Total value of asset portfolio, specified as a scalar numeric or an NPORTS-by-1 vector.

---

**Note** If PortReturn and PortRisk are in dollar units, then PortValue should be 1. If PortReturn and PortRisk are on a percentage basis, then PortValue should be the total value of the portfolio.

---

Data Types: double

## Output Arguments

**ValueAtRisk — Estimated maximum loss in portfolio**  
vector

Estimated maximum loss in the portfolio, returned as an NPORTS-by-1 vector. ValueAtRisk is predicted with a confidence probability of  $1 - \text{RiskThreshold}$ .

**Note** If `PortValue` is not given, `ValueAtRisk` is presented on a per-unit basis. A value of 0 indicates no losses.

# posvolidx

Positive volume index

**Note** Using a `fints` object for the `Data` argument of `posvolidx` is not recommended. Use a matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

## Syntax

```
volume = posvolidx(Data)
volume = posvolidx(___,Name,Value)
```

## Description

`volume = posvolidx(Data)` calculates the positive volume index from the series of closing stock prices and trade volume.

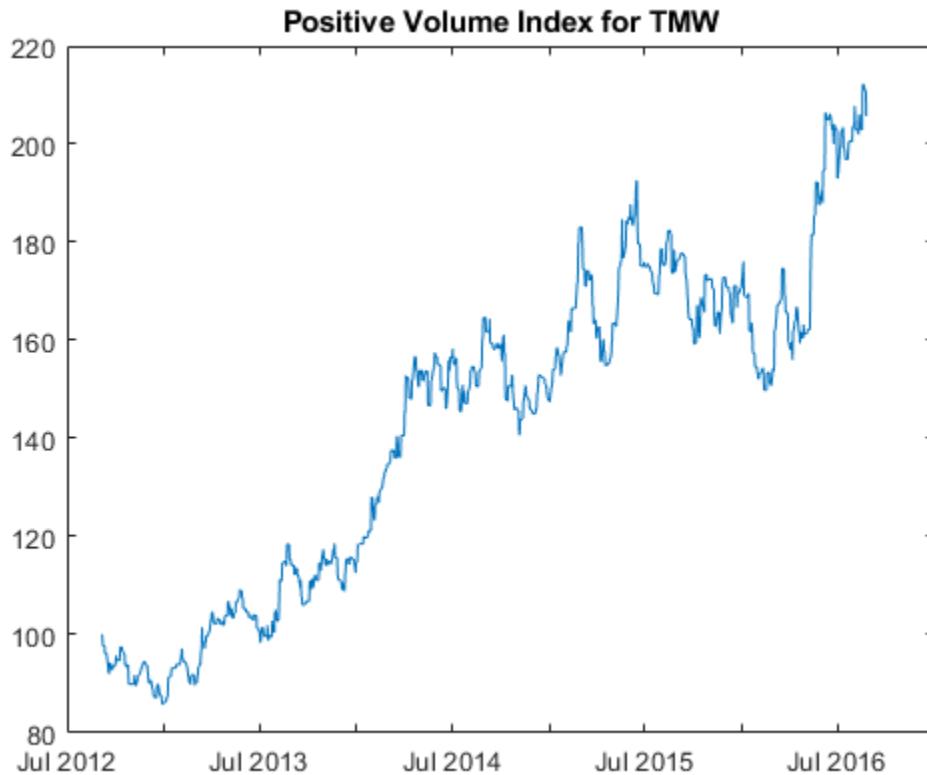

`volume = posvolidx(___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Calculate the Positive Volume Index for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
volume = posvolidx(TMW);
plot(volume.Time,volume.PositiveVolume)
title('Positive Volume Index for TMW')
```

## Input Arguments

### Data — Data with closing prices and trade volume

matrix | table | timetable

Data with closing prices and trade volume, specified as a matrix, table, or timetable. For matrix input, Data is an M-by-2 with closing prices and trade volume stored in the first and second columns.

Timetables and tables with M rows must contain variables named 'Close' and 'Volume' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, ..., NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `volume = posvolidx(TMW, 'InitialValue', 500)`

### InitialValue — Initial value for positive volume index

100 (default) | positive integer

Initial value for positive volume index, specified as the comma-separated pair consisting of 'InitialValue' and a scalar positive integer.

Data Types: double

## Output Arguments

### **volume — Positive volume index**

matrix | table | timetable

Positive volume index, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## More About

### **Positive Volume Index**

Positive volume index shows the days when the trading volume of a particular security is substantially higher than other days.

| <code>array</code>            | Scalar value or array with the number of rows equal to the number of dates in <code>tsobj</code> and the number of columns equal to the number of data series in <code>tsobj</code> . |
| <code>tsobj_1, tsobj_2</code> | Pair of financial time series objects.                                                                                                                                                |

### Description

`newfts = tsobj .^ array` raises all values in the data series of the financial time series object `tsobj` element by element to the power indicated by the array value. The results are stored in another financial time series object `newfts`. The `newfts` object contains the same data series names as `tsobj`.

`newfts = array .^ tsobj` raises the array values element by element to the values contained in the data series of the financial time series object `tsobj`. The results are stored in another financial time series object `newfts`. The `newfts` object contains the same data series names as `tsobj`.

`newfts = tsobj_1 .^ tsobj_2` raises the values in the object `tsobj_1` element by element to the values in the object `tsobj_2`. The data series names, the dates, and the number of data points in both series must be identical. `newfts` contains the same data series names as the original time series objects.

# prbyzero

Price bonds in portfolio by set of zero curves

## Syntax

```
BondPrices = prbyzero(Bonds, Settle, ZeroRates, ZeroDates)
BondPrices = prbyzero(____, Compounding)
```

## Description

`BondPrices = prbyzero(Bonds, Settle, ZeroRates, ZeroDates)` computes the bond prices in a portfolio using a set of zero curves.

`BondPrices = prbyzero(____, Compounding)` adds an optional argument for `Compounding`.

## Examples

### Compute the Bond Prices in a Portfolio Using a Set of Zero Curves

This example uses the function `zbtprice` to compute a zero curve given a portfolio of coupon bonds and their prices. It then reverses the process, using the zero curve as input to the function `prbyzero` to compute the prices.

```
Bonds = [datenum('6/1/1998') 0.0475 100 2 0 0;
          datenum('7/1/2000') 0.06 100 2 0 0;
          datenum('7/1/2000') 0.09375 100 6 1 0;
          datenum('6/30/2001') 0.05125 100 1 3 1;
          datenum('4/15/2002') 0.07125 100 4 1 0;
          datenum('1/15/2000') 0.065 100 2 0 0;
          datenum('9/1/1999') 0.08 100 3 3 0;
          datenum('4/30/2001') 0.05875 100 2 0 0;
          datenum('11/15/1999') 0.07125 100 2 0 0;
          datenum('6/30/2000') 0.07 100 2 3 1;
          datenum('7/1/2001') 0.0525 100 2 3 0;
          datenum('4/30/2002') 0.07 100 2 0 0];

Prices = [ 99.375;
           99.875;
           105.75 ;
           96.875;
           103.625;
           101.125;
           103.125;
           99.375;
           101.0  ;
           101.25 ;
           96.375;
           102.75 ];

Settle = datenum('12/18/1997');
```

Set semiannual compounding for the zero curve, on an actual/365 basis.

```
OutputCompounding = 2;
```

Execute the function `zbtprice` which returns the zero curve at the maturity dates.

```
[ZeroRates, ZeroDates] = zbtprice(Bonds, Prices, Settle, ...  
OutputCompounding)
```

```
ZeroRates = 11x1
```

```

In this example `zbtprice` and `prbyzero` do not exactly reverse each other. Many of the bonds have the end-of-month rule off (`EndMonthRule = 0`). The rule subtly affects the time factor computation.

If you set the rule on (`EndMonthRule = 1`) everywhere in the `Bonds` matrix, then `prbyzero` returns the original prices, except when the two incompatible prices fall on the same maturity date.

### Compute the Bond Prices in a Portfolio Using a Set of Zero Curves and `datetime` Inputs

This example uses the function `zbtprice` to compute a zero curve given a portfolio of coupon bonds and their prices. It then reverses the process, using the zero curve as input to the function `prbyzero` with `datetime` inputs to compute the prices.

```

Bonds = [datenum('6/1/1998') 0.0475 100 2 0 0;
          datenum('7/1/2000') 0.06 100 2 0 0;
          datenum('7/1/2000') 0.09375 100 6 1 0;
          datenum('6/30/2001') 0.05125 100 1 3 1;
          datenum('4/15/2002') 0.07125 100 4 1 0;
          datenum('1/15/2000') 0.065 100 2 0 0;
          datenum('9/1/1999') 0.08 100 3 3 0;
          datenum('4/30/2001') 0.05875 100 2 0 0;
          datenum('11/15/1999') 0.07125 100 2 0 0;
          datenum('6/30/2000') 0.07 100 2 3 1;

## Input Arguments

### Bonds — Coupon bond information to compute prices

table | matrix

Coupon bond information to compute prices, specified as a 6-column table or a NumBonds-by-6 matrix of bond information where the table columns or matrix columns contains:

- **Maturity** (Required) Maturity date of the bond, as a serial date number. Use `datenum` to convert date character vectors to serial date numbers. If the input `Bonds` is a table, the `Maturity` dates can be serial date numbers, date character vectors, or datetime arrays.
- **CouponRate** (Required) Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.
- **Face** (Optional) Face or par value of the bond. Default = 100.
- **Period** (Optional) Coupons per year of the bond. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
- **Basis** (Optional) Day-count basis of the bond. A vector of integers.
  - 0 = actual/actual (default)
  - 1 = 30/360 (SIA)
  - 2 = actual/360
  - 3 = actual/365
  - 4 = 30/360 (BMA)
  - 5 = 30/360 (ISDA)
  - 6 = 30/360 (European)
  - 7 = actual/365 (Japanese)
  - 8 = actual/actual (ICMA)
  - 9 = actual/360 (ICMA)
  - 10 = actual/365 (ICMA)
  - 11 = 30/360E (ICMA)
  - 12 = actual/365 (ISDA)
  - 13 = BUS/252
  - For more information, see “`Basis`” on page 2-19.
- **EndMonthRule** (Optional) End-of-month rule. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month

⋮

---

**Note**

- If **Bonds** is a table, the table columns have the same meaning as when a matrix is used, but the **Maturity** dates can be serial date numbers, date character vectors, or datetime arrays.
  - If **Bonds** is a matrix, it is a **NUMBONDS**-by-6 matrix of bonds where each row describes one bond. The first two columns are required; the remaining columns are optional but must be added in order. All rows in **Bonds** must have the same number of columns. The columns are **Maturity**, **CouponRate**, **Face**, **Period**, **Basis**, and **EndMonthRule**.
- 

Data Types: double | table

**Settle — Settlement date**

serial date number | date character vector | datetime

Settlement date, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | datetime | char

**ZeroRates — Observed zero rates**

decimal fractions

Observed zero rates, specified as **NUMDATES**-by-**NUMCURVES** matrix of decimal fractions. Each column represents a rate curve. Each row represents an observation date.

Data Types: double | datetime | char

**ZeroDates — Observed dates for ZeroRates**

serial date number | date character vector | datetime

Observed dates for **ZeroRates**, specified as a **NUMDATES**-by-1 column using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | datetime | char

**Compounding — Compounding frequency of input ZeroRates when annualized**

2 (default) | numeric values: 1, 2, 3, 4, 6, 12,

(Optional) Compounding frequency of input **ZeroRates** when annualized, specified using the allowed values:

- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

Data Types: double

## Output Arguments

### **BondPrices — Clean bond prices**

numeric

Clean bond prices, returned as a NUMBONDS-by-NUMCURVES matrix. Each column is derived from the corresponding zero curve in `ZeroRates`.

In addition, you can use the Financial Instruments Toolbox method `getZeroRates` for an `IRDataCurve` object with a `Dates` property to create a vector of dates and data acceptable for `prbyzero`. For more information, see “Converting an `IRDataCurve` or `IRFunctionCurve` Object” (Financial Instruments Toolbox).

## prcroc

Price rate of change

---

**Note** Using a `fints` object for the `Data` argument of `prcroc` is not recommended. Use a matrix, timetable, or table instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
PriceChangeRate = prcroc(Data)
PriceChangeRate = prcroc(___,Name,Value)
```

### Description

`PriceChangeRate = prcroc(Data)` calculates the price rate-of-change, `PriceChangeRate`, from the series of closing stock prices. By default, the volume rate-of-change is calculated between the current closing price and the closing price 12 periods ago.

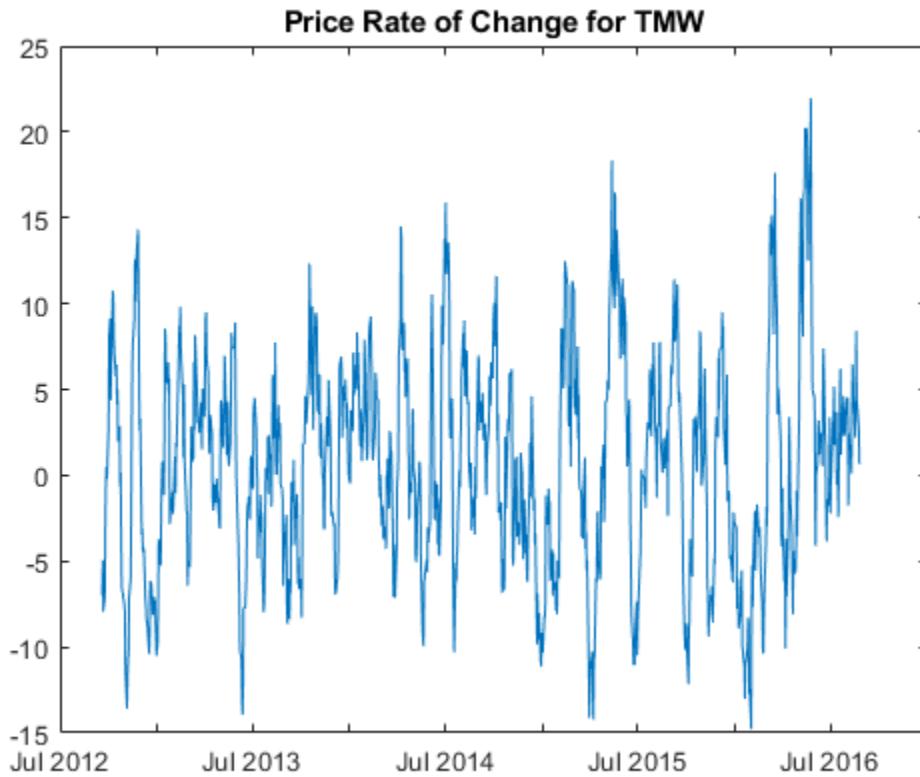

`PriceChangeRate = prcroc(___,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Calculate the Price Rate-of-Change for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
PriceChangeRate = prcroc(TMW);
plot(PriceChangeRate.Time,PriceChangeRate.PriceRoc)
title('Price Rate of Change for TMW')
```

## Input Arguments

### Data — Data for closing prices

matrix | table | timetable

Data for closing prices, specified as a matrix, table, or timetable. For matrix input, Data is an M-by-1 matrix of closing prices. Timetables and tables with M rows must contain a variable named 'Close' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, ..., NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `PriceChangeRate = prcroc(TMW, 'NumPeriods', 18)`

### NumPeriods — Period difference

12 (default) | positive integer

Period difference, specified as the comma-separated pair consisting of 'NumPeriods' and a scalar positive integer.

Data Types: double

## Output Arguments

### PriceChangeRate — Closing price rate-of-change

matrix | table | timetable

Closing price rate-of-change, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input `Data`.

## prdisc

Price of discounted security

### Syntax

```
Price = prdisc(Settle,Maturity,FaceDiscount)
Price = prdisc(___,Basis)
```

### Description

Price = prdisc(Settle,Maturity,FaceDiscount) returns the price of a security whose yield is quoted as a bank discount rate (for example, U. S. Treasury bills).

Price = prdisc(\_\_\_,Basis) adds an optional argument for Basis.

### Examples

#### Calculate the Price of a Security Whose Yield is Quoted as a Bank Discount Rate

This example shows how to return the price of a security whose yield is quoted as a bank discount rate (for example, U. S. Treasury bills).

```
Settle = '10/14/2000';
Maturity = '03/17/2001';
Face = 100;
Discount = 0.087;
Basis = 2;

Price = prdisc(Settle, Maturity, Face, Discount, Basis)

Price = 96.2783
```

#### Calculate the Price of a Security Whose Yield is Quoted as a Bank Discount Rate Using datetime Inputs

This example shows how to use datetime inputs to return the price of a security whose yield is quoted as a bank discount rate (for example, U. S. Treasury bills).

```
Settle = '10/14/2000';
Maturity = '03/17/2001';
Face = 100;
Discount = 0.087;
Basis = 2;

Price = prdisc(datetime(Settle,'Locale','en_US'),datetime(Maturity,'Locale','en_US'), Face, Discount, Basis)

Price = 96.2783
```

## Input Arguments

### **Settle — Settlement date**

serial date number | date character vector | datetime

Settlement date, specified as serial date numbers, date character vectors, or datetime arrays.

Settle must be earlier than **Maturity**.

Data Types: double | datetime | char

### **Maturity — Maturity date**

serial date number | date character vector | datetime

Maturity date, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | datetime | char

### **Face — Redemption (par, face) value**

numeric

Redemption (par, face) value, specified as a numeric value.

Data Types: double

### **Discount — Bank discount rate of the security**

decimal fraction

Bank discount rate of the security, specified as a decimal fraction value.

Data Types: double

### **Basis — Day-count basis of instrument**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

(Optional) Day-count basis of the instrument, specified as a numeric value. Allowed values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

## Output Arguments

### Price — Price of discounted security

numeric

Price of discounted security, returned as a numeric value.

# priceandvol

Price and Volume chart

---

**Note** `priceandvol` is updated to accept data input as a matrix, `timetable`, or `table`.

The syntax for `priceandvol` has changed. Previously, when using table input, the first column of dates could be serial date numbers, date character vectors, or datetime arrays, and you were required to have specific number of columns.

When using table input, the new syntax for `priceandvol` supports:

- No need for time information. If you want to pass in date information, use timetable input.
  - No requirement of specific number of columns. However, you must provide valid column names. `linebreak` must contain columns named 'open', 'high', 'low', 'close', and 'volume' (case insensitive).
- 

## Syntax

```
priceandvol(Data)
h = priceandvol(Data)
```

## Description

`priceandvol(Data)` plots two charts from a series of opening, high, low, closing prices, and traded volume. Opening, high, low, and closing prices are on one axis and the volume series are on a second axis.

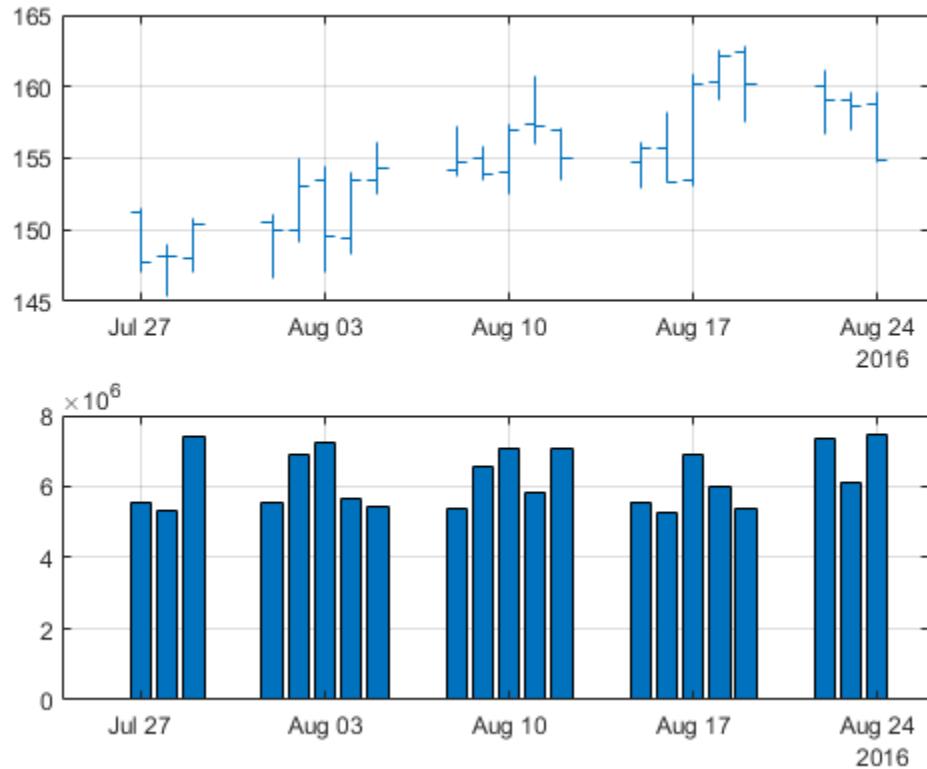

`h = priceandvol(Data)` adds a Graphic handle for the figure.

## Examples

### Generate a Price and Volume Chart for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock. This price and volume chart for the TMW stock contains the open, high, low, close, and volume for the most recent 21 days.

```
load SimulatedStock.mat
priceandvol(TMW(end-20:end,:));
```

## Input Arguments

**Data — Data for opening, high, low, closing prices, and volume traded**  
matrix | table | timetable

Data for opening, high, low, closing prices, and volume traded, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-5 matrix of opening, high, low, closing prices and traded volume. Timetables and tables with M rows must contain variables named 'Open', 'High', 'Low', 'Close', and 'Volume' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

**h — Graphic handle of the figure**  
handle object

Graphic handle of the figure, returned as a handle object.

## See Also

timetable | table | movavg | linebreak | highlow | kagi | volarea | candle | pointfig

## prmat

Price with interest at maturity

### Syntax

```
[Price,AccruInterest] = prmat(Settle,Maturity,Issue,Face,CouponRateYield)
[Price,AccruInterest] = prmat(___,Basis)
```

### Description

[Price,AccruInterest] = prmat(Settle,Maturity,Issue,Face,CouponRateYield) returns the price and accrued interest of a security that pays interest at maturity. This function also applies to zero coupon bonds or pure discount securities by setting CouponRate = 0.

[Price,AccruInterest] = prmat(\_\_\_,Basis) adds an optional argument for Basis.

### Examples

#### Compute Price and Accrued Interest of a Security That Pays Interest at Maturity

This example shows how to compute the price and accrued interest of a security that pays interest at maturity.

```
Settle = '02/07/2002';
Maturity = '04/13/2002';
Issue = '10/11/2001';
Face = 100;
CouponRate = 0.0608;
Yield = 0.0608;
Basis = 1;

[Price, AccruInterest] = prmat(Settle, Maturity, Issue, Face, ...
CouponRate, Yield, Basis)

Price = 99.9784
AccruInterest = 1.9591
```

#### Compute Price and Accrued Interest of a Security That Pays Interest at Maturity Using datetime Inputs

This example shows how to use datetime inputs compute the price and accrued interest of a security that pays interest at maturity.

```
Settle = '7-Feb-2002';
Maturity = '13-Apr-2002';
Issue = '11-Oct-2001';
Face = 100;
```

```

CouponRate = 0.0608;
Yield = 0.0608;
Basis = 1;

[Price, AccruInterest] = prmat(datetime(Settle,'Locale','en_US'), datetime(Maturity,'Locale','en_US'),
Face,CouponRate, Yield, Basis)

Price = 99.9784
AccruInterest = 1.9591

```

## Input Arguments

### **Settle — Settlement date of security**

serial date number | date character vector | datetime

Settlement date of the security, specified as serial date numbers, date character vectors, or datetime arrays. The Settle date must be before the Maturity date.

Data Types: double | char | datetime

### **Maturity — Maturity date of security**

serial date number | date character vector | datetime

Maturity date of the security, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Issue — Issue date**

serial date number | date character vector | datetime

Issue date of the security, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Face — Redemption value**

numeric

Redemption value (par value), specified as a numeric value.

Data Types: double

### **CouponRate — Coupon rate**

decimal fraction

Coupon rate, specified as a decimal fraction value.

Data Types: double

### **Yield — Annual yield**

decimal fraction

Annual yield, specified as a decimal fraction value.

Data Types: double

**Basis — Day-count basis**

0 (actual/actual) (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

(Optional) Day-count basis of the security, specified using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

## Output Arguments

**Price — Security price**

numeric

Security price, returned as a numeric value.

**AccruInterest — Accrued interest**

numeric

Accrued interest for security, returned as a numeric value.

## prtbill

Price of Treasury bill

### Syntax

```
Price = prtbill(Settle,Maturity,Face,Discount)
```

### Description

Price = prtbill(Settle,Maturity,Face,Discount) returns the price for a Treasury bill.

### Examples

#### Calculate the Price for a Treasury Bill

This example shows how to return the price for a Treasury bill, where the settlement date of a Treasury bill is February 10, 2002, the maturity date is August 6, 2002, the discount rate is 3.77%, and the par value is \$1000.

```
Price = prtbill('2/10/2002', '8/6/2002', 1000, 0.0377)  
Price = 981.4642
```

#### Calculate the Price for a Treasury Bill Using datetime Inputs

This example shows how to use `datetime` inputs to return the price for a Treasury bill, where the settlement date of a Treasury bill is February 10, 2002, the maturity date is August 6, 2002, the discount rate is 3.77%, and the par value is \$1000.

```
Price = prtbill(datetime('10-Feb-2002','Locale','en_US'), datetime('6-Aug-2002','Locale','en_US'))  
Price = 981.4642
```

### Input Arguments

#### Settle — Settlement date for Treasury bill

serial date number | date character vector | `datetime`

Settlement date for the Treasury bill, specified as serial date numbers, date character vectors, or `datetime` arrays. The `Settle` date must be before the `Maturity` date.

Data Types: double | char | `datetime`

#### Maturity — Maturity date for Treasury bill

serial date number | date character vector | `datetime`

Maturity date for the Treasury bill, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

#### **Face — Redemption value of Treasury bill**

numeric

Redemption value (par value) of the Treasury bill, specified as a numeric value.

Data Types: double

#### **Discount — Discount rate of Treasury bill**

decimal fraction

Discount rate of the Treasury bill, specified as a decimal fraction value.

Data Types: double

## **Output Arguments**

#### **Price — Treasury bill price**

numeric

Treasury bill price, returned as a numeric value.

## pvfix

Present value with fixed periodic payments

### Syntax

```
PresentVal = pvfix(Rate,NumPeriods,Payment)  
PresentVal = pvfix(_____,ExtraPayment,Due)
```

### Description

PresentVal = pvfix(Rate,NumPeriods,Payment) computes the present value of a series of equal payments.

PresentVal = pvfix(\_\_\_\_\_,ExtraPayment,Due) adds optional arguments.

### Examples

#### Calculate the Present Value of a Series of Equal Payments

This example shows how to return the present value of a series of equal payments, where \$200 is paid monthly into a savings account earning 6%. The payments are made at the end of the month for five years.

```
PresentVal = pvfix(0.06/12, 5*12, 200, 0, 0)
```

```
PresentVal = 1.0345e+04
```

### Input Arguments

#### Rate — Periodic interest rate

decimal

Periodic interest rate, specified as a decimal.

Data Types: double

#### NumPeriods — Number of periods

integer

Number of periods, specified as an integer.

Data Types: double

#### Payment — Periodic payment

numeric

Periodic payment., specified as a numeric.

Data Types: double

**ExtraPayment — Payment received other than Payment in the last period**

0 (default) | numeric

(Optional) Payment received other than Payment in the last period, specified as a numeric.

Data Types: double

**Due — Indicator for when payments are due**

0 (default) | logical with value of 1 or 0

(Optional) Indicator for when payments are due, specified as a logical with a value of 0 = end of period (default), or 1 = beginning of period.

Data Types: logical

## Output Arguments

**PresentVal — Present value**

numeric

Present value, returned as a series of equal payments.

## pvtrend

Price and Volume Trend (PVT)

**Note** Using a `fints` object for the `Data` argument of `pvtrend` is not recommended. Use a matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
trend = pvtrend(Data)
```

### Description

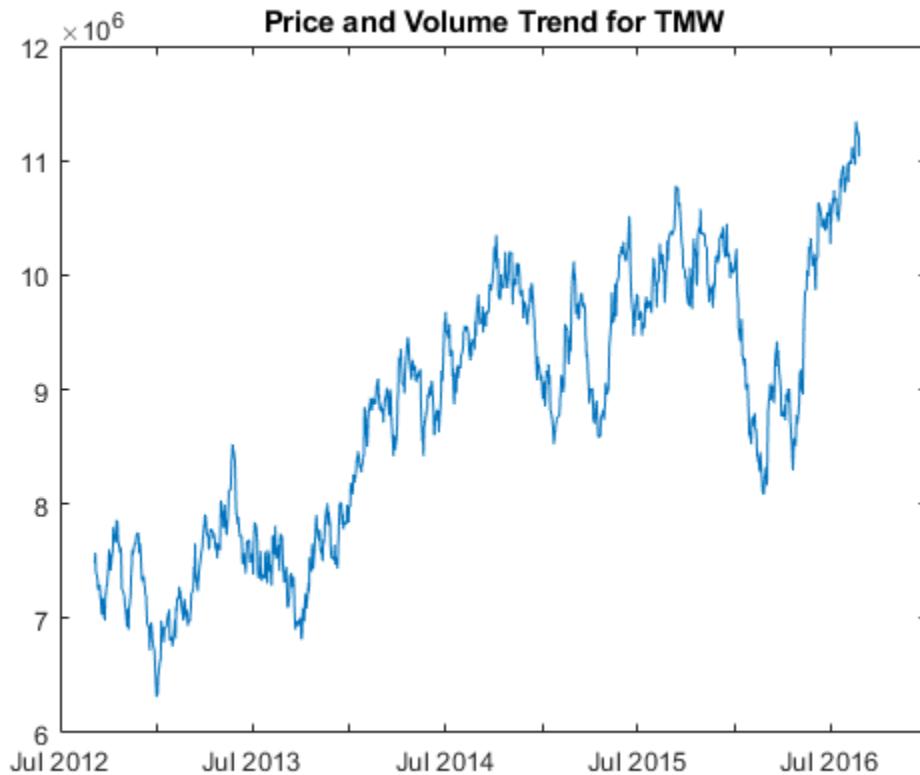

`trend = pvtrend(Data)` calculates the Price and Volume Trend (PVT) from the series of closing stock prices and trade volume.

### Examples

#### Calculate the Price and Volume Trend for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
trend = pvtrend(TMW);
plot(trend.Time,trend.PriceVolumeTrend)
title('Price and Volume Trend for TMW')
```

## Input Arguments

### Data — Data for closing prices and trade volume

matrix | table | timetable

Data for closing prices and trade volume, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-2 matrix of closing prices and trade volume. Timetables and tables with M rows must contain variables named 'Close' and 'Volume' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### trend — Price and volume trend

matrix | table | timetable

Price and volume trend (PVT), returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input **Data**.

## pvvar

Present value of varying cash flow

### Syntax

```
PresentVal = pvvar(CashFlow,Rate)
PresentVal = pvvar(_____,CFDates)
```

### Description

PresentVal = pvvar(CashFlow,Rate) calculates present value of a varying cash flow.

PresentVal = pvvar(\_\_\_\_\_,CFDates) adds an optional argument for CFDates.

### Examples

#### Calculate Present Value for Regular and Irregular Cash Flow

Calculate the net present value for a regular and irregular cash flow.

##### Regular Cash Flow

This cash flow represents the yearly income from an initial investment of \$10,000. The annual interest rate is 8%.

Year 1 - \$2000

Year 2 - \$1500

Year 3 - \$3000

Year 4 - \$3800

Year 5 - \$5000

To calculate the net present value of this regular cash flow:

```
PresentVal = pvvar([-10000 2000 1500 3000 3800 5000], 0.08)
```

```
PresentVal = 1.7154e+03
```

##### Irregular Cash Flow

An investment of \$10,000 returns this irregular cash flow. The original investment and its date are included. The periodic interest rate is 9%.

January 12, 1987 - (\$1000)

February 14, 1988 - \$1500

March 3, 1988 - \$2000

June 14, 1988 - \$3000

December 1, 1988 - \$4000

To calculate the net present value of this irregular cash flow:

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
```

```
CFDates = ['01/12/1987'  
          '02/14/1988'  
          '03/03/1988'  
          '06/14/1988'  
          '12/01/1988'];
```

```
PresentVal = pvvar(CashFlow, 0.09, CFDates)
```

```
PresentVal = 142.1648
```

The net present value of the same investment under different discount rates of 7%, 9%, and 11% is obtained by:

```
PresentVal = pvvar(repmat(CashFlow,3,1)', [.07 .09 .11], CFDates)
```

```
PresentVal = 1x3
```

```
419.0136 142.1648 -122.1275
```

## Input Arguments

### **CashFlow — Cash flow amounts**

vector
