The software described in this document is furnished under a license agreement. The software may be used or copied only under the terms of the license agreement. No part of this manual may be photocopied or reproduced in any form without prior written consent from The MathWorks, Inc.

FEDERAL ACQUISITION: This provision applies to all acquisitions of the Program and Documentation by, for, or through the federal government of the United States. By accepting delivery of the Program or Documentation, the government hereby agrees that this software or documentation qualifies as commercial computer software or commercial computer software documentation as such terms are used or defined in FAR 12.212, DFARS Part 227.72, and DFARS 252.227-7014. Accordingly, the terms and conditions of this Agreement and only those rights specified in this Agreement, shall pertain to and govern the use, modification, reproduction, release, performance, display, and disclosure of the Program and Documentation by the federal government (or other entity acquiring for or through the federal government) and shall supersede any conflicting contractual terms or conditions. If this License fails to meet the government's needs or is inconsistent in any respect with federal procurement law, the government agrees to return the Program and Documentation, unused, to The MathWorks, Inc.

Trademarks

MATLAB and Simulink are registered trademarks of The MathWorks, Inc. See www.mathworks.com/trademarks for a list of additional trademarks. Other product or brand names may be trademarks or registered trademarks of their respective holders.

Patents

MathWorks products are protected by one or more U.S. patents. Please see www.mathworks.com/patents for more information.

Revision History

July 2002	Online only	Revised for Simulink 5 (Release 13)
April 2003	Online only	Revised for Simulink 5.1 (Release 13SP1)
April 2004	Online only	Revised for Simulink 5.1.1 (Release 13SP1+)
June 2004	Online only	Revised for Simulink 6 (Release 14)
October 2004	Online only	Revised for Simulink 6.1 (Release 14SP1)
March 2005	Online only	Revised for Simulink 6.2 (Release 14SP2)
September 2005	Online only	Revised for Simulink 6.3 (Release 14SP3)
March 2006	Online only	Revised for Simulink 6.4 (Release 2006a)
September 2006	Online only	Revised for Simulink 6.5 (Release 2006b)
March 2007	Online only	Revised for Simulink 6.6 (Release 2007a)
September 2007	Online only	Revised for Simulink 7.0 (Release 2007b)
March 2008	Online only	Revised for Simulink 7.1 (Release 2008a)
October 2008	Online only	Revised for Simulink 7.2 (Release 2008b)
March 2009	Online only	Revised for Simulink 7.3 (Release 2009a)
September 2009	Online only	Revised for Simulink 7.4 (Release 2009b)
March 2010	Online only	Revised for Simulink 7.5 (Release 2010a)
September 2010	Online only	Revised for Simulink 7.6 (Release 2010b)
April 2011	Online only	Revised for Simulink 7.7 (Release 2011a)
September 2011	Online only	Revised for Simulink 7.8 (Release 2011b)
March 2012	Online only	Revised for Simulink 7.9 (Release 2012a)
September 2012	Online only	Revised for Simulink 8.0 (Release 2012b)
March 2013	Online only	Revised for Simulink 8.1 (Release 2013a)
September 2013	Online only	Revised for Simulink 8.2 (Release 2013b)
March 2014	Online only	Revised for Simulink 8.3 (Release 2014a)
October 2014	Online only	Revised for Simulink 8.4 (Release 2014b)
March 2015	Online only	Revised for Simulink 8.5 (Release 2015a)
September 2015	Online only	Revised for Simulink 8.6 (Release 2015b)
October 2015	Online only	Rereleased for Simulink 8.5.1 (Release 2015aSP1)
March 2016	Online only	Revised for Simulink 8.7 (Release 2016a)
September 2016	Online only	Revised for Simulink 8.8 (Release 2016b)
March 2017	Online only	Revised for Simulink 8.9 (Release 2017a)
September 2017	Online only	Revised for Simulink 9.0 (Release 2017b)
March 2018	Online only	Revised for Simulink 9.1 (Release 2018a)
September 2018	Online only	Revised for Simulink 9.2 (Release 2018b)
March 2019	Online only	Revised for Simulink 9.3 (Release 2019a)
September 2019	Online only	Revised for Simulink 10.0 (Release 2019b)
March 2020	Online only	Revised for Simulink 10.1 (Release 2020a)
September 2020	Online only	Revised for Simulink 10.2 (Release 2020b)
March 2021	Online only	Revised for Simulink 10.3 (Release 2021a)
September 2021	Online only	Revised for Simulink 10.4 (Release 2021b)
March 2022	Online only	Revised for Simulink 10.5 (Release 2022a)

Model Advisor Checks

9

Simulink Checks	9-2
Simulink Check Overview	9-4
Migrating to Simplified Initialization Mode Overview	9-4
Identify unconnected lines, input ports, and output ports	9-4
Check root model Inport block specifications	9-5
Check optimization settings	9-6
Check diagnostic settings ignored during accelerated model reference simulation	9-8
Check for parameter tunability information ignored for referenced models	9-9
Check for implicit signal resolution	9-9
Check for optimal bus virtuality	9-10
Check for Discrete-Time Integrator blocks with initial condition uncertainty	9-10
Identify disabled library links	9-11
Check for large number of function arguments from virtual bus across model reference boundary	9-12
Identify parameterized library links	9-12
Identify unresolved library links	9-13
Identify configurable subsystem blocks for converting to variant subsystem blocks	9-14
Identify Variant Model blocks and convert those to Variant Subsystem containing Model block choices	9-14
Identify Variant blocks using Variant objects with empty conditions	9-14
Check usage of function-call connections	9-15
Check Data Store Memory blocks for multitasking, strong typing, and shadowing issues	9-15
Check if read/write diagnostics are enabled for data store blocks	9-16
Check data store block sample times for modeling errors	9-17
Check for potential ordering issues involving data store access	9-18
Check structure parameter usage with bus signals	9-19
Check Delay, Unit Delay and Zero-Order Hold blocks for rate transition .	9-20
Check for calls to slDataTypeAndScale	9-21
Check bus signals treated as vectors	9-22

Check for potentially delayed function-call subsystem return values	9-23
Identify block output signals with continuous sample time and non-floating point data type	9-24
Check usage of Merge blocks	9-25
Check usage of Outport blocks	9-27
Check usage of Discrete-Time Integrator blocks	9-34
Check model settings for migration to simplified initialization mode	9-35
Check S-functions in the model	9-36
Check for non-continuous signals driving derivative ports	9-37
Runtime diagnostics for S-functions	9-38
Identify unit mismatches in the model	9-38
Identify automatic unit conversions in the model	9-39
Identify disallowed unit systems in the model	9-39
Identify undefined units in the model	9-40
Identify ambiguous units in the model	9-40
Check model for block upgrade issues	9-41
Check model for block upgrade issues requiring compile time information	9-41
Check if SLX file compression is off	9-42
Check that the model or library is saved in current version	9-43
Check model for SB2SL blocks	9-43
Check Model History properties	9-44
Identify Model Info blocks that can interact with external source control tools	9-45
Identify Model Info blocks that use the Configuration Manager	9-45
Check model for upgradable SerDes Toolbox blocks	9-46
Check model for legacy 3DoF or 6DoF blocks	9-46
Check model for Aerospace Blockset navigation blocks	9-47
Check and update masked blocks in library to use promoted parameters	9-47
Check and update mask image display commands with unnecessary imread() function calls	9-48
Check and update mask to affirm icon drawing commands dependency on mask workspace	9-49
Identify masked blocks that specify tabs in mask dialog using MaskTabNames parameter	9-49
Identify questionable operations for strict single-precision design	9-50
Check get_param calls for block CompiledSampleTime	9-51
Check if all simulation outputs are returned as a single Simulink.SimulationOutput object	9-53
Check model for parameter initialization and tuning issues	9-53
Check for virtual bus across model reference boundaries	9-54
Check model for custom library blocks that rely on frame status of the signal	9-55
Check model for S-function upgrade issues	9-56
Update System object syntax	9-57
Check Rapid accelerator signal logging	9-57
Check virtual bus inputs to blocks	9-58
Check for root outports with constant sample time	9-61
Analyze model hierarchy and continue upgrade sequence	9-61
Check Access to Data Stores	9-63
Check relative execution orders for Data Store Read and Data Store Write blocks	9-63
Check for case mismatches in references to models and libraries	9-64
Check model for Signal Builder blocks	9-64
Check output dimensions of MATLAB Function blocks	9-64

Check model for RF Blockset Divider blocks using Wilkinson power divider component with broken connections	9-65
Identify Environment Controller Blocks and Replace Them with Variant Source Blocks	9-66
Check for machine-parented data	9-67

Performance Advisor Checks

10

Simulink Performance Advisor Checks	10-2
Simulink Performance Advisor Check Overview	10-2
Baseline	10-3
Checks that Require Update Diagram	10-3
Checks that Require Simulation to Run	10-3
Check Simulation Modes Settings	10-3
Check Compiler Optimization Settings	10-3
Check Hardware Acceleration Settings	10-3
Create baseline	10-4
Identify resource-intensive diagnostic settings	10-4
Check optimization settings	10-4
Identify inefficient lookup table blocks	10-4
Check MATLAB System block simulation mode	10-5
Identify Interpreted MATLAB Function blocks	10-5
Identify simulation target settings	10-5
Check model reference rebuild setting	10-6
Identify Scope blocks	10-6
Identify active instrumentation settings on the model	10-6
Check model reference parallel build	10-6
Check Delay block circular buffer setting	10-7
Check continuous and discrete rate coupling	10-8
Check zero-crossing impact on continuous integration	10-8
Check discrete signals driving derivative port	10-9
Check solver type selection	10-9
Select multi-thread co-simulation setting on or off	10-10
Identify co-simulation signals for numerical compensation	10-10
Check Dataflow Domain Settings	10-10
Select simulation mode	10-11
Select compiler optimizations on or off	10-11
Select hardware acceleration setting	10-12
Final Validation	10-12

Block Reference Page Examples

12

Create Mux Signal and Extract Elements	12-5
Manage Bus-to-Vector Conversions	12-6
Initialize Your Model Using the Callback Button Block	12-8
Control a Parameter Value with Callback Button Blocks	12-9
Control the Duty Cycle of a PWM Signal Using Dashboard Blocks	12-10
Control Merging Signals with the Push Button Block	12-12
Tune the Relative Slip for an Anti-Lock Braking System	12-14

Interactively Simulate a Vehicle Climate Control System	12-16
Interactively Simulate a Thermal Model of a House	12-19
Create a Realistic Dashboard Using the Circular Gauge Block	12-21
Solve a Linear System of Algebraic Equations	12-24
Model a Planar Pendulum	12-25
Improved Linearization with Transfer Fcn Blocks	12-28
View Dead Zone Output on Sine Wave	12-29
View Backlash Output on Sine Wave	12-30
Prelookup With External Breakpoint Specification	12-31
Prelookup with Evenly Spaced Breakpoints	12-32
Configure the Prelookup Block to Output Index and Fraction as a Bus	12-33
Approximating the sinh Function Using the Lookup Table Dynamic Block	12-34
Create a Logarithm Lookup Table	12-35
Providing Table Data as an Input to the Direct Lookup Table Block ..	12-36
Specifying Table Data in the Direct Lookup Table Block Dialog Box ..	12-37
Using the Quantizer and Saturation blocks in sldemo_boiler	12-38
Scalar Expansion with the Coulomb and Viscous Friction Block	12-39
Sum Block Reorders Inputs	12-40
Iterated Assignment with the Assignment Block	12-41
View Sample Time Using the Digital Clock Block	12-42
Bit Specification Using a Positive Integer	12-43
Bit Specification Using an Unsigned Integer Expression	12-44
Track Running Minimum Value of Chirp Signal	12-45
Horizontal Matrix Concatenation	12-46
Vertical Matrix Concatenation	12-47
Multidimensional Matrix Concatenation	12-48

Unary Minus of Matrix Input	12-49
Sample Time Math Operations Using the Weighted Sample Time Math Block	12-50
Construct Complex Signal from Real and Imaginary Parts	12-51
Construct Complex Signal from Magnitude and Phase Angle	12-52
Find Nonzero Elements in an Array	12-53
Calculate the Running Minimum Value with the MinMax Running Resettable Block	12-54
Find Maximum Value of Input	12-56
Permute Array Dimensions	12-58
Multiply Inputs of Different Dimensions with the Product Block	12-59
Multiply and Divide Inputs Using the Product Block	12-60
Divide Inputs of Different Dimensions Using the Divide Block	12-61
Complex Division Using the Product of Elements Block	12-62
Element-Wise Multiplication and Division Using the Product of Elements Block	12-63
sin Function with Floating-Point Input	12-64
sincos Function with Fixed-Point Input	12-65
Trigonometric Function Block Behavior for Complex Exponential Output	12-66
Control Algorithm Execution Using Enumerated Signal	12-67
Integer and Enumerated Data Type Support in the Ground Block	12-69
Fixed-Point Data Type Support in the Ground Block	12-70
Read 2-D Signals in Structure Format From Workspace	12-71
Eliminate Singleton Dimension with the Squeeze Block	12-72
Difference Between Time- and Sample-Based Pulse Generation	12-73
Specify a Waveform with the Repeating Sequence Block	12-75
Tune Phase Delay on Pulse Generator During Simulation	12-76
Difference Sine Wave Signal	12-77

Discrete-Time Derivative of Floating-Point Input	12-78
First-Order Sample-and-Hold of a Sine Wave	12-79
Calculate and Display Simulation Step Size using Memory and Clock Blocks	12-80
Capture the Velocity of a Bouncing Ball with the Memory Block	12-81
Implement a Finite-State Machine with the Combinatorial Logic and Memory Blocks	12-83
Discrete-Time Integration Using the Forward Euler Integration Method	12-84
Signal Routing with the From, Goto, and Goto Tag Visibility Blocks ..	12-85
Zero-Based and One-Based Indexing with the Index Vector Block	12-87
Noncontiguous Values for Data Port Indices of Multiport Switch Block	12-88
Using Variable-Size Signals on the Delay Block	12-89
Buses with the Delay Block for Frame-Based Processing	12-90
Control Execution of Delay Block with Enable Port	12-91
Zero-Based Indexing for Multiport Switch Data Ports	12-92
One-Based Indexing for Multiport Switch Data Ports	12-93
Enumerated Names for Data Port Indices of the Multiport Switch Block	12-94
Prevent Block Windup in Multiloop Control	12-95
Bumpless Control Transfer	12-96
Bumpless Control Transfer with a Two-Degree-of-Freedom PID Controller	12-97
Using a Bit Set block	12-98
Using a Bit Clear block	12-99
Two-Input AND Logic	12-100
Circuit Logic	12-101
Unsigned Inputs for the Bitwise Operator Block	12-102
Signed Inputs for the Bitwise Operator Block	12-103

Merge Block with Input from Atomic Subsystems	12-104
Index Options with the Selector Block	12-105
Switch Block with a Boolean Control Port Example	12-106
Merge Block with Unequal Input Widths Example	12-107
Detect Rising Edge of Signals	12-109
Detect Falling Edge Using the Detect Fall Nonpositive Block	12-111
Detect Increasing Signal Values with the Detect Increase Block	12-112
Extract Bits from Stored Integer Value	12-113
Detect Signal Values Within a Dynamically Specified Interval	12-114
Model a Digital Thermometer Using the Polynomial Block	12-116
Convert Data Types in Simulink Models	12-117
Control Data Types with the Data Type Duplicate Block	12-119
Probe Sample Time of a Signal	12-120
Convert Signals Between Continuous Time and Discrete Time	12-121
Convert Mux Signal to Vector	12-123
Create Contiguous Copy of Bus	12-124
Convert Virtual Bus to Nonvirtual Bus	12-125
Convert Nonvirtual Bus to Virtual Bus	12-126
Remove Scaling from a Fixed-Point Signal	12-127
Stop Simulation Block with Relational Operator Block	12-128
Output Simulation Data with Blocks	12-129
Increment and Decrement Real-World Values	12-133
Increment and Decrement Stored Integer Values	12-135
Specify a Vector of Initial Conditions for a Discrete Filter Block	12-136
Generate Linear Models for a Rising Edge Trigger Signal	12-138
Generate Linear Models at Predetermined Times	12-140
Capture Measurement Descriptions in a DocBlock	12-141

Square Root of Negative Values	12-142
Signed Square Root of Negative Values	12-143
rSqrt of Floating-Point Inputs	12-144
rSqrt of Fixed-Point Inputs	12-145
Model a Series RLC Circuit	12-146
Extract Vector Elements and Distribute Evenly Across Outputs	12-149
Extract Vector Elements Using the Demux Block	12-150
Detect Change in Signal Values	12-151
Detect Fall to Negative Signal Values	12-152
Detect Decreasing Signal Values	12-153
Function-Call Blocks Connected to Branches of the Same Function-Call Signal	12-154
Function-Call Feedback Latch on Feedback Signal Between Child and Parent	12-155
Single Function-Call Subsystem	12-156
Function-Call Subsystem with Merged Signal As Input	12-157
Partitioning an Input Signal with the For Each Block	12-158
Specifying the Concatenation Dimension in the For Each Block	12-159
Working with the Initialize Function, Reset Function, and Terminate Function Blocks	12-160
Reading and Writing States with the Initialize Function and Terminate Function Blocks	12-161
PWM Control of a Boost Converter	12-162
Voltage Controlled Oscillator	12-165
Check Signal Lower Bound with Check Dynamic Lower Bound Block	12-167
Check Signal Upper Bound with Check Dynamic Upper Bound Block	12-169
Check Signal Lower Bound with Check Static Lower Bound Block ..	12-171
Check Signal Range with Check Static Range Block	12-173

Check Signal Upper Bound with Check Static Upper Bound Block . . .	12-175
Check Signal Slope with Check Discrete Gradient Block	12-177
Check Signal Value with Check Dynamic Gap Block	12-179
Check Signal Value with Check Static Gap Block	12-181
Check Signal Range with Check Dynamic Range Block	12-183
Check Signal Resolution with Check Input Resolution Block	12-185
Generate Unit-Diagonal and Identity Matrices	12-188
Extract 3-by-2 Submatrix from Input Signal	12-189
Generate Diagonal Matrix from Vector Input	12-191
Permute Matrix by Row or Column	12-192
Extract Diagonal of Matrix	12-193

Simulink Featured Examples

13

Simulation of a Bouncing Ball	13-6
Single Hydraulic Cylinder Simulation	13-12
Thermal Model of a House	13-22
Approximating Nonlinear Relationships: Type S Thermocouple	13-27
Digital Waveform Generation: Approximating a Sine Wave	13-36
Use Model Reference with Local Solver in DC Motor	13-46
Accurate Zero-Crossing Detection	13-52
Spiral Galaxy Formation Simulation Using MATLAB Function Blocks	13-53
Counters Using Conditionally Executed Subsystems	13-57
Friction Model with Hard Stops	13-59
State Events	13-61
Bang-Bang Control Using Temporal Logic	13-62
Inverted Pendulum with Animation	13-63

Double Spring Mass System	13-65
Tank Fill and Empty with Animation	13-67
Simulating Systems with Variable Transport Delay Phenomena	13-70
Modeling a Foucault Pendulum	13-74
Foucault Pendulum Model with VRML Visualization	13-82
Exploring Variable-Step Solvers Using a Stiff Model	13-85
Exploring the Solver Jacobian Structure of a Model	13-91
Double Bouncing Ball: Use of Adaptive Zero-Crossing Location	13-100
Four Hydraulic Cylinder Simulation	13-107
Two Cylinder Model with Load Constraints	13-113
Modeling a Fault-Tolerant Fuel Control System	13-119
Using a Data Dictionary to Manage the Data for a Fuel Control System	13-134
Modeling Engine Timing Using Triggered Subsystems	13-137
Engine Timing Model with Closed Loop Control	13-147
Building a Clutch Lock-Up Model	13-151
Modeling Clutch Lock-Up Using If Blocks	13-162
Modeling an Anti-Lock Braking System	13-167
Automotive Suspension	13-173
Modeling an Automatic Transmission Controller	13-179
Vehicle Electrical System	13-190
Simulating Automatic Climate Control Systems	13-192
Vehicle Electrical and Climate Control Systems	13-197
Power Window Control Project	13-203
Developing the Apollo Lunar Module Digital Autopilot	13-210
Designing a High Angle of Attack Pitch Mode Control	13-218
Six Degrees of Freedom (6-DoF) Motion Platform	13-231
Aircraft Longitudinal Flight Control	13-234

Simulink Model Discretizer	13-236
Radar Tracking Using MATLAB Function Block	13-237
Optical Sensor Image Generation	13-239
Air Traffic Control Radar Design	13-248
Designing a Guidance System in MATLAB and Simulink	13-253
Airframe Trim and Linearize	13-269
Anti-Windup Control Using a PID Controller	13-274
Bumpless Control Transfer Between Manual and PID Control	13-289
Two Degree-of-Freedom PID Control for Setpoint Tracking	13-298
Data Typing in Simulink	13-304
Data Typing Filter	13-308
Explore Simulink Bus Capabilities	13-310
Model Arrays of Buses	13-318
Matrix Signals	13-320
Variable-Size Signal Basic Operations	13-321
Variable-Size Signal Length Adaptation	13-323
Multimode Variable-Size Signal	13-324
Parallel Channel Power Allocation	13-325
Merging Signals	13-327
Share Data Store Between Instances of a Reusable Algorithm	13-340
Attaching Input Data to External Inputs via Custom Input Mappings	13-345
Using Mapping Modes with Custom-Mapped External Inputs	13-349
Converting Harness-Driven Models to Use Harness-Free External Inputs	13-353
Logging States in Structure Format	13-358
Logging Intervals	13-361
Working with Big Data	13-364

Simulink Subsystem Semantics	13-368
If-Then-Else Blocks	13-369
Triggered Subsystems	13-371
Enabled Subsystems	13-373
Advanced Enabled Subsystems	13-375
Resettable Subsystems	13-378
Discrete and Continuous Resettable Subsystems	13-380
Block Priority	13-383
Monitoring Ink Status on a Shared Printer Using Simulink Functions	13-384
Modeling Reusable Components Using Multiply Instanced Simulink Functions	13-386
Dynamic Priority Scheduling of Functions	13-388
Component-Based Modeling with Model Reference	13-389
Viewing Signals in Model Reference Instances	13-393
Visualize Model Reference Hierarchies	13-401
Introduction to Managing Data with Model Reference	13-406
Detailed Workflow for Managing Data with Model Reference	13-417
Interface Specification Using Bus Objects	13-434
Convert Subsystem to Referenced Model	13-441
Using Data Stores Across Multiple Models	13-443
Model Reference Function-Call	13-449
Explore Protected Model Capabilities	13-451
Model Reference Variants	13-456
Assigning Tasks to Cores for Multicore Programming	13-460
Implement an FFT on a Multicore Processor and an FPGA	13-463
Multicore Programming of a Field-Oriented Control on Zynq	13-467
Multicore Deployment of a Plant Model	13-473

Modeling Objects with Identical Dynamics Using For Each Subsystem	13-477
Vectorizing a Scalar Algorithm with a For Each Subsystem	13-482
Tiled Processing of 2D Signals with For Each Subsystem	13-484
Neighborhood Processing Using For Each Subsystems	13-485
Using a Project with SVN	13-488
Using a Project with Git	13-493
Get started with MATLAB Projects	13-498
Perform Impact Analysis with a Project	13-502
Referencing Projects from Another Project	13-509
Automate Label Management in a Project	13-510
Run Custom Tasks with a Project	13-513
Upgrade Simulink Models Using a Project	13-516
Export a Subset of a Project Using an Export Profile	13-518
Create and Reference a Project Programmatically	13-520
Compare and Merge Simulink Models	13-524
Compare and Merge Simulink Models Containing Stateflow	13-526
Resolve Conflicts with Simulink Three-Way Merge	13-529
Call C Functions Using C Caller Block	13-533
Bring Custom Image Filter Algorithms as Reusable Blocks in Simulink	13-537
Custom Code and Hand Coded Blocks using the S-function API	13-539
Inputs Passed by Value or Address to Legacy Functions	13-540
Output Passed by Return Argument from Legacy Functions	13-543
Fixed Point Signals in Legacy Functions	13-545
Fixed Point Parameters in Legacy Functions	13-548
Lookup Tables Implemented in Legacy Functions	13-551
Start and Terminate Actions Within Legacy Functions	13-554

Using Buses with Legacy Functions Having Structure Arguments . . .	13-558
Inherited Signal Dimensions for Legacy Function Arguments	13-561
C++ Object Methods as Legacy Functions	13-564

Blocks

Abs

Output absolute value of input

Library: Simulink / Math Operations
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Math Operations

Description

The Abs block outputs the absolute value of the input.

For signed-integer data types, the absolute value of the most negative value is not representable by the data type. In this case, the **Saturate on integer overflow** check box controls the behavior of the block.

If you...	The block...	And...
Select this check box	Saturates to the most positive value of the integer data type	<ul style="list-style-type: none"> For 8-bit signed integers, -128 maps to 127. For 16-bit signed integers, -32768 maps to 32767. For 32-bit signed integers, -2147483648 maps to 2147483647.
Do not select this check box	Wraps to the most negative value of the integer data type	<ul style="list-style-type: none"> For 8-bit signed integers, -128 remains -128. For 16-bit signed integers, -32768 remains -32768. For 32-bit signed integers, -2147483648 remains -2147483648.

The Abs block supports zero-crossing detection. However, when you select **Enable zero-crossing detection** on the dialog box, the block does not report the simulation minimum or maximum in the Fixed-Point Tool. If you want to use the Fixed-Point Tool to analyze a model, disable zero-crossing detection for all Abs blocks in the model first.

Ports

Input

Port_1 – Input signal

scalar | vector

Input signal to the absolute value block.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Absolute value output signal

scalar | vector

Absolute value of the input signal.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main

Enable zero-crossing detection — Enable zero-crossing detection

on (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector, string

Values: 'off' | 'on'

Default: 'on'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Signal Attributes

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.

- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output data type — Specify the output data type

Inherit: Same as input (default) | Inherit: Inherit via internal rule | Inherit: Inherit via back propagation | | double | single | half | int8 | int32 | uint32 | int64 | uint64 | fixdt(1,16,2^0,0) | <data type expression> | ...

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType.

Dependencies

When input is a floating-point data type smaller than single precision, the `Inherit: Inherit via internal` rule output data type depends on the setting of the “Inherit floating-point output type smaller than single precision” configuration parameter. Data types are smaller than single precision when the number of bits needed to encode the data type is less than the 32 bits needed to encode the single-precision data type. For example, `half` and `int16` are smaller than single precision.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Same as input'` | `'Inherit: Inherit via internal rule'` | `'Inherit: Inherit via back propagation'` | `'single'` | `'half'` | `'int8'` | `'uint8'` | `int16` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `fixdt(1,16,2^0,0)` | `'<data type expression>'`

Default: `'Inherit: Same as input'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Integer rounding mode — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB® rounding function into the mask field.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

Saturate on integer overflow — Choose the behavior when integer overflow occurs

`off` (default) | `on`

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Action	Reason for Taking This Action	What Happens	Example
Select this check box.	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to the maximum value that the data type can represent.	The number 130 does not fit in a signed 8-bit integer and saturates to 127.
Do not select this check box.	You want to optimize efficiency of your generated code.	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	double fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	yes

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder™ provides additional configuration options™ that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).

General	
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , or <code>Zero</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals with floating-point types in **Native Floating Point** mode.

Code generation for the block with complex signals that use fixed-point types is not supported. To calculate the magnitude of a complex number, use the **Complex to Magnitude-Angle** block instead.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Action Port

Control port for action signal to If Action Subsystem or Switch Case Action Subsystem block

Description

The Action Port block controls the execution of these subsystem blocks:

- If Action Subsystem blocks connected to If blocks.
- Switch Case Action Subsystem blocks connected to Switch Case blocks.
- Simulink based states in Stateflow® charts. See “Create and Edit Simulink Based States” (Stateflow).

Parameters

States when execution is resumed — Select handling of internal states

held (default) | reset

Select how to handle internal states when a subsystem with an Action Port block reenables.

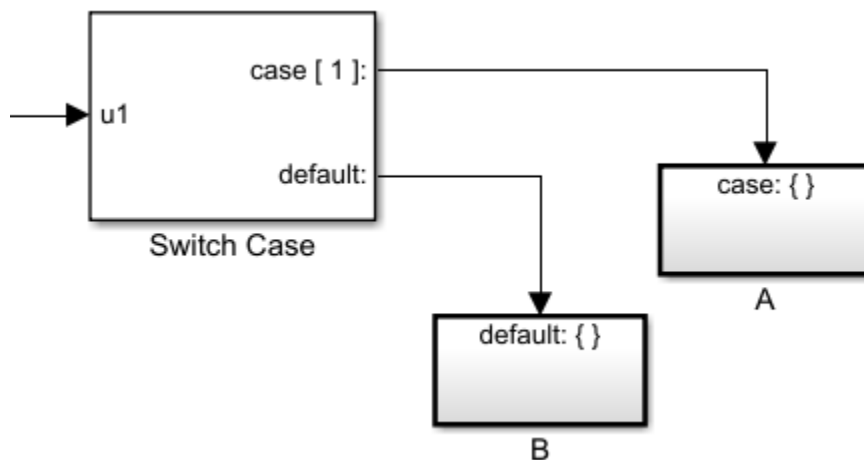

held

When the subsystem reenables, retain the previous state values of the subsystem. Previous state values between calls are retained even if you call other subsystem blocks connected to the If or Switch Case block.

reset

When the subsystem reenables, reinitialize the state values.

A subsystem reenables when the logical expression for its action port evaluates to true after having been previously false. In the following example, the Action Port blocks for both subsystems A and B have the **States when execution is resumed** parameter set to **reset**.

When **case[1]** is **true**, subsystem **A** is executed. Repeated calls to subsystem **A** while **case [1]** continues to be **true**, does not reset its state values. The same behavior applies to subsystem **B**.

Programmatic Use**Block Parameter:** InitializeStates**Type:** character vector**Value:** 'held' | 'reset'**Default:** 'held'**Propagate sizes of variable-size signals — Select when to propagate a variable-size signal**

Only when execution is resumed (default) | During execution

Select when to propagate a variable-size signal.

Only when execution is resumed

Propagate variable-size signals only when reenabling the subsystem containing the Action Port block.

During execution

Propagate variable-size signals at each time step.

Programmatic Use**Block Parameter:** PropagateVarSize**Type:** character vector**Values:** 'Only when execution is resumed' | 'During execution'**Default:** 'Only when execution is resumed'**See Also**

If | If Action Subsystem | Switch Case | Switch Case Action Subsystem

Add, Subtract, Sum of Elements, Sum

Add or subtract inputs

Library: Simulink / Math Operations
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Math Operations

Description

The Sum block performs addition or subtraction on its inputs. The Add, Subtract, Sum of Elements, and Sum blocks are identical blocks. This block can add or subtract scalar, vector, or matrix inputs. It can also collapse the elements of a signal and perform a summation.

You specify the operations of the block with the **List of signs** parameter with plus (+), minus (-), and spacer (|).

- The number of + and - characters equals the number of inputs. For example, +-+ requires three inputs. The block subtracts the second (middle) input from the first (top) input, and then adds the third (bottom) input.
- A spacer character creates extra space between ports on the block icon.
- If performing only addition, you can use a numerical value equal to the number of inputs.
- If only there is only one input port, a single + or - adds or subtracts the elements over all dimensions or in the specified dimension.

The Sum block first converts the input data type to its accumulator data type, then performs the specified operations. The block converts the result to its output data type using the specified rounding and overflow modes.

Calculation of Block Output

Output calculation for the Sum block depends on the number of block inputs and the sign of input ports:

If the Sum block has...	And...	The formula for output calculation is...	Where...
One input port	The input port sign is +	$y = e[0] + e[1] + e[2] \dots + e[m]$	$e[i]$ is the i^{th} element of input u
	The input port sign is -	$y = 0.0 - e[0] - e[1] - e[2] \dots - e[m]$	
Two or more input ports	All input port signs are -	$y = 0.0 - u[0] - u[1] - u[2] \dots - u[n]$	$u[i]$ is the input to the i^{th} input port

If the Sum block has...	And...	The formula for output calculation is...	Where...
	The k^{th} input port is the first port where the sign is +	$y = u[k] - u[0] - u[1] - u[2] - u[k-1] (+/-) u[k+1] \dots (+/-) u[n]$	

Ports

Inputs

The inputs can be of different data types, unless you select the **Require all inputs to have the same data type** parameter.

Port_1 — First input operand signal

scalar | vector | matrix

Input signal to the addition or subtraction operation. If there is only one input signal, then addition or subtraction is performed on the elements over all dimensions or the specified dimension.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_n — nth input operand signal

scalar | vector | matrix

nth input signal to the operations. The number of inputs matches the number of signs in the **List of signs** parameter. The block applies the operations to the inputs in the order listed. You can also use a numerical value equal to the number of input ports as the **List of signs** parameter. The block creates the input ports and applies addition to all inputs. For example, if you assign 5 for the **List of signs** parameter, the block creates 5 input ports and adds them together to produce the output.

All nonscalar inputs must have the same dimensions. Scalar inputs are expanded to have the same dimensions as other inputs.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output signal resulting from addition and/or subtraction operations. The output signal has the same dimension as the input signals.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Icon shape — Block icon shape

`rectangular` (default) | `round`

Designate the icon shape of the block as rectangular or round.

For a rectangular block, the first input port is the top port. For a round Sum block, the first input port is the port closest to the 12 o'clock position going in a counterclockwise direction around the block. Similarly, other input ports appear in counterclockwise order around the block.

Programmatic Use

Block Parameter: IconShape

Type: character vector

Values: 'rectangular' | 'round'

Default: 'round'

List of signs — Operations performed on inputs

`++` (default) | `+` | `-` | `|` | `integer`

Enter addition and subtraction operations performed on the inputs. An input port is created for each operation. A spacer (|) creates extra space between the input ports on the block icon. Addition is the default operation. If you only want to add the inputs, enter the number of input ports. The operations are performed in the order listed.

When you enter only one element, the block enables the **Sum over** parameter. For a single vector input, + or - adds or subtracts the elements over all dimensions or in the specified dimension.

Tips

You can manipulate the positions of the input ports on the block by inserting spacers (|) between the signs in the **List of signs** parameter. For example, “++| - -” creates an extra space between the second and third input ports.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: '+' | '-' | '|' | `integer`

Default: '++'

Sum over — Dimensions for operations on a single vector input

`All dimensions` (default) | `Specified dimension`

Select the dimension over which the block performs the sum-over operation.

For **All dimensions**, all input elements are summed. When you select configuration parameter **Use algorithms optimized for row-major array layout**, Simulink enables row-major algorithms for simulation. To generate row-major code, set configuration parameter **Array layout** (Simulink Coder) to Row-major in addition to selecting **Use algorithms optimized for row-major array layout**. The column-major and row-major algorithms differ only in the summation order. In some cases, due to different operation order on the same data set, you might experience minor numeric differences in the outputs of column-major and row-major algorithms.

When you select **Specified dimensions**, another parameter **Dimension** appears. Choose the specific dimension for summing the vector input.

Dependency

Enabled when you list only one sign in the **List of signs** parameter.

Programmatic Use

Block Parameter: CollapseMode

Type: character vector

Values: 'All dimensions' | 'Specified dimension'

Default: 'All dimensions'

Dimension — Dimension for summation on vector input

1 (default) | integer

When you choose **Specified dimension** for the **Sum over** parameter, specify the dimension over which to perform the operation.

The block follows the same summation rules as the MATLAB `sum` function.

Suppose that you have a 2-by-3 matrix U .

- Setting **Dimension** to 1 results in the output Y being computed as:

$$Y = \sum_{i=1}^2 U(i, j)$$

- Setting **Dimension** to 2 results in the output Y being computed as:

$$Y = \sum_{j=1}^3 U(i, j)$$

If the specified dimension is greater than the dimension of the input, an error message appears.

Dependency

Enabled when you choose Specified dimension for the **Sum over** parameter.

Programmatic Use

Block Parameter: CollapseDim

Type: character vector

Value: integer

Default: '1'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "- 1"

Signal Attributes

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Require all inputs to have the same data type — Require that all inputs have the same data type

off (default) | on

Specify if input signals must all have the same data type. If you enable this parameter, then an error occurs during simulation if the input signal types are different.

Programmatic Use

Block Parameter: InputSameDT

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Accumulator data type — Data type of the accumulator

Inherit: Inherit via internal rule (default) | Inherit: Same as first input | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type of the accumulator. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. When you choose `Inherit: Inherit via internal rule`, Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware.

Programmatic Use

Block Parameter: AccumDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as first input' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output data type — Specify the output data type

Inherit: Inherit via internal rule (default) | Inherit: Keep MSB | Inherit: Keep LSB | Inherit: Inherit via back propagation | Inherit: Same as first input | Inherit: Same as accumulator | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule**—Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware.

Note The accumulator internal rule favors greater numerical accuracy, possibly at the cost of less efficient generated code. To get the same accuracy for the output, set the output data type to **Inherit: Inherit same as accumulator**.

Note When input is a floating-point data type smaller than single precision, the **Inherit: Inherit via internal rule** output data type depends on the setting of the “Inherit floating-point output type smaller than single precision” configuration parameter. Data types are smaller than single precision when the number of bits needed to encode the data type is less than the 32 bits needed to encode the single-precision data type. For example, `half` and `int16` are smaller than single precision.

- **Inherit: Keep MSB**— Simulink chooses a data type that maintains the full range of the operation, then reduces the precision of the output to a size appropriate for the embedded target hardware.

Tip For more efficient generated code, set the **Accumulator data type** to **Inherit: Inherit via internal rule**, and deselect the **Saturate on integer overflow** parameter.

This rule never produces overflows.

- **Inherit: Keep LSB**— Simulink chooses a data type that maintains the precision of the operation, but reduces the range if the full type does not fit on the embedded target hardware.

Tip For more efficient generated code, set the **Accumulator data type** to **Inherit: Inherit via internal rule**, and deselect the **Saturate on integer overflow** parameter.

This rule can produce overflows.

If you change the embedded target settings, the data type selected by these internal rules might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the rules do not meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as first input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- **Inherit: Inherit via back propagation** — Use data type of the driving block.
- **Inherit: Same as first input** — Use data type of the first input signal.
- **Inherit: Inherit same as accumulator**— Use data type of the accumulator.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule'|'Inherit: Keep MSB'|'Inherit: Keep LSB'|'Inherit: Inherit via back propagation'|'Inherit: Same as first input'|'Inherit: Same as accumulator'|'double'|'single'|'half'|'int8'|'uint8'|'int16'|'uint16'|'int32'|'uint32'|'int64'|'uint64'|'fixdt(1,16)'|'fixdt(1,16,0)'|'fixdt(1,16,2^0,0)'|'<data type expression>'

Default: 'Inherit: Inherit via internal rule'**Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types**

off (default) | on

Select to lock data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Values:** 'off' | 'on'**Default:** 'off'**Integer rounding mode — Rounding mode for fixed-point operations**

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'**Saturate on integer overflow — Method of overflow action**

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture of Sum, Add, and Subtract Blocks

The default **Linear** architecture generates a chain of N operations (adders) for N inputs.

HDL Architecture of Sum of Elements Block

For the Sum of Elements block, HDL Coder supports **Tree** and **Cascade** architectures for Sum of Elements blocks that have a single vector input with multiple elements.

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

Architecture	Additional cycles of latency	Description
Linear	0	Generates a linear chain of adders to compute the sum of products. For multiple inputs that have different bit widths, the Linear architecture optimizes the resource utilization by implementing adders in multiple stages with pipelines in between the stages. The output of each stage is calculated based on the width of the inputs to that stage.
Tree	0	Generates a tree structure of adders to compute the sum of products.
Cascade	1, when block has a single vector input port.	This implementation optimizes latency * area and is faster than the Tree implementation. It computes partial sums and cascades adders. See “Cascade Architecture Best Practices” (HDL Coder).

HDL Block Properties

Note To use the **LatencyStrategy** setting in the **Native Floating Point** tab of the HDL Block Properties dialog box, specify **Linear** or **Tree** as the HDL Architecture.

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Note The Sum of Elements block does not support HDL code generation with double data types in the Native Floating Point mode.

Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , <code>Zero</code> , or <code>Custom</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to <code>Custom</code> . HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).

Complex Data Support

The default `Linear` implementation supports complex data.

The `Tree` implementation supports complex data with `+` for the **List of signs** block parameter. With native floating point support, the `Tree` implementation supports complex data with both `+` and `-` for **List of signs**.

Limitations and Considerations

To generate HDL code for multi-input Sum block that has mixed scalar and vector inputs, you must specify vector input at one of the first two inputs of the Sum block.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

“Control Data Types of Signals”

Introduced before R2006a

Algebraic Constraint

Constrain input signal

Library: Simulink / Math Operations

Description

The Algebraic Constraint block constrains the input signal $f(z)$ to z or 0 and outputs an algebraic state z . The block outputs a value that produces 0 or z at the input. The output must affect the input through a direct feedback path. In other words, the feedback path only contains blocks with direct feedthrough. For example, you can specify algebraic equations for index 1 differential-algebraic systems (DAEs).

Ports

Input

$f(z)$ — Input signal

real scalar or vector

Signal is subjected to the constraint $f(z) = 0$ or $f(z) = z$ to solve the algebraic loop.

Data Types: double

Output

z — Output state

real scalar or vector

Solution to the algebraic loop when the input signal $f(z)$ is subjected to the constraint $f(z) = 0$ or $f(z) = z$.

Data Types: double

Parameters

Constraint — Constraint on input signal

$f(z) = 0$ (default) | $f(z) = z$

Type of constraint for which to solve. You can solve for $f(z) = 0$ or $f(z) = z$

Programmatic Use

Block Parameter: Constraint

Type: character vector

Values: 'f(z) = 0' | 'f(z) = z'

Default: 'f(z) = 0'

Solver — Algebraic Loop Solver

auto (default) | Trust region | Line search

Choose between the Trust region [1], [2] or Line search [3] algorithms to solve the algebraic loop. By default this value is set to `auto`, which selects the algebraic loop solver based on the model configuration and switches the solver between the Trust region and Line search algorithm during simulation

Programmatic Use

Block Parameter: Solver

Type: character vector

Values: 'auto' | 'Trust region' | 'Line search'

Default: 'auto'

Tolerance — Solver Tolerance

auto (default) | positive scalar

This option is visible when you explicitly specify a solver to be used (Trust region or Line Search) in the **Solver** drop-down menu. Specify a smaller value for higher accuracy or a larger value for faster execution. By default it is set to `auto`.

Programmatic Use

Block Parameter: Tolerance

Type: character vector

Values: 'auto' | positive scalar

Default: 'auto'

Initial Guess — Initial guess of solution value

0 (default) | scalar

Initial guess for the algebraic state z that is close to the expected solution value to improve the efficiency of the algebraic loop solver. By default, this value is set to 0

Programmatic Use

Block Parameter: InitialGuess

Type: character vector

Values: scalar

Default: '0'

Block Characteristics

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Argument Inport

Argument input port for Simulink Function block

Description

This block is an argument input port for a function that you define in the Simulink Function block.

Ports

Input

u — Argument input

scalar | vector | matrix

The Argument Inport block accepts complex or real signals of any data type that Simulink supports, including fixed-point and enumerated data types. The Argument Inport block also accepts a bus object as a data type.

The complexity and data type of the block output are the same as the argument input. You can specify the signal type and data type of an input argument to an Argument Inport block using the **Signal type** and **Data type** parameters.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Output

out — Block output

scalar | vector | matrix

Block output signal from this block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Parameters

Port number — Specify port number of block

1 (default) | integer

Specify the order in which the port that corresponds to the block appears in the parent subsystem or model block.

1

Specify the first port location for this block.

integer

Specify location of port.

Programmatic Use

Block parameter: Port

Type: character vector
Value: '1' | '<integer>'
Default: '1'

Argument name — Specify input argument name

u (default) | character vector

Specify input argument name for the function prototype displayed on the face of the Simulink Function block.

u

Default name for the input argument.

character vector

Name of the input argument.

Programmatic Use

Block parameter: ArgumentName

Type: character vector

Value: 'u' | '<character vector>'

Default: 'u'

Minimum — Specify minimum value for block output

[] (default) | number

Specify the minimum value for the block output signal.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value to perform Simulation range checking and automatic scaling of fixed-point data types.

[]

Minimum value not specified.

number

Finite real double scalar value.

Programmatic Use

Block parameter: OutMin

Type: character vector

Value: '[]' | '<number>'

Default: '[]'

Maximum — Specify maximum value for block output

[] (default) | number

Specify the maximum value for the block output signal.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of

the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value to perform Simulation range checking and automatic scaling of fixed-point data types.

`[]`

Maximum value not specified.

number

Finite real double scalar value.

Programmatic Use

Block parameter: `OutMax`

Type: character vector

Value: `'[]'` | `'<number>'`

Default: `'[]'`

Data type — Specify block output data type

`double` (default) | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64` | `boolean` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^,0)` | Enum: `<class name>` | Bus: `<object name>` | `<data type expression>`

Specify the block output data type.

`double`

Data type is double.

`single`

Data type is single.

`int8`

Data type is int8.

`uint8`

Data type is uint8.

`int16`

Data type is int16.

`uint16`

Data type is uint16.

`int32`

Data type is int32.

`uint32`

Data type is uint32.

`int64`

Data type is int64.

`uint64`

Data type is uint64.

boolean

Data type is boolean.

fixdt(1,16,0)

Data type is fixed point `fixdt(1,16,0)`.

fixdt(1,16,2^0,0)

Data type is fixed point `fixdt(1,16,2^0,0)`.

Enum: <class name>

Data type is enumerated, for example, Enum: Basic Colors.

Bus: <object name>

Data type is a Simulink.Bus object.

<data type expression>

The name of a data type object, for example `Simulink.NumericType`

Tips

You cannot enter the name of a Simulink.Bus object as a data type expression. To specify the **Data type** for the block using a Bus object, select the Bus: <object name> option and replace <object name> with the name of the Bus object.

Programmatic Use

Block parameter: OutDataTypeStr

Type: character vector

Value: 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'double'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data type

off (default) | on

Control changes to data type settings from the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

On

Locks all data type settings for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change data type settings for this block.

Programmatic Use

Block parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Port dimensions — Specify port dimensions

1 (default) | n | [m n]

Specify the dimensions of the argument input signal to the block. For more information, see Output.

1

Inherit port dimensions.

n

Vector signal of width n.

[m n]

Matrix signal having m rows and n columns.

Programmatic Use

Block parameter: PortDimensions

Type: character vector

Value: '1' | 'n' | '[m n]'

Default: '1'

Signal type — Select real or complex signal

real (default) | complex

Select real or complex signal.

real

Specify the signal type as a real number.

complex

Specify the signal type as a complex number.

Programmatic Use

Block parameter: SignalType

Type: character vector

Value: 'real' | 'complex'

Default: 'real'

Argument Outputport

Argument output port for Simulink Function block

Description

This block is an output argument port for a function that you define in the Simulink Function block.

Ports

Input

in – Block input

scalar | vector | matrix

Block input signal to this block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Output

y – Argument output

scalar | vector | matrix

The Argument Outputport block accepts real or complex signals of any data type that Simulink supports. An Argument Outputport block can also accept fixed-point and enumerated data types when the block is not a root-level output port. The Argument Outputport block also accepts a bus object as a data type.

The complexity and data type of the block input are the same as the argument output. You can specify the signal type and data type of an output argument from an Argument Outputport block using the **Signal type** and **Data type** parameters. For more information, see “Data Types Supported by Simulink”.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Parameters

Port number – Specify port number of block

1 (default) | integer

Specify the order in which the port that corresponds to the block appears in the parent subsystem or model block.

1

Specify the first port location for this block.

integer

Specify location of port.

Programmatic Use**Block parameter:** Port**Type:** character vector**Value:** '1' | '<integer>'**Default:** '1'**Argument name — Specify output argument name**

u (default) | character vector

Specify output argument name for the function prototype displayed on the face of the Simulink Function block.

u

Default name of the output argument.

character vector

Name of the output argument.

Programmatic Use**Block parameter:** ArgumentName**Type:** character vector**Value:** 'u' | '<character vector>'**Default:** 'u'**Minimum — Specify minimum value for block input**

[] (default) | number

Specify the minimum value for the block input signal.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value to perform Simulation range checking (see “Specify Signal Ranges”) and automatic scaling of fixed-point data types.

[]

Minimum value not specified.

number

Finite real double scalar value.

Programmatic Use**Block parameter:** OutMin**Type:** character vector**Value:** '[]' | '<number>'**Default:** '[]'**Maximum — Specify maximum value for block input**

[] (default) | number

Specify the maximum value for the block input signal.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value to perform Simulation range checking (see “Specify Signal Ranges”) and automatic scaling of fixed-point data types.

`[]`

Maximum value not specified.

number

Finite real double scalar value.

Programmatic Use

Block parameter: OutMax

Type: character vector

Value: `'[]'` | `'<number>'`

Default: `'[]'`

Data type — Specify block input data type

`double` (default) | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64` | `boolean` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^,0)` | Enum: `<class name>` | Bus: `<object name>` | `<data type expression>`

Specify block input data type. For more information, see

- Outport
- “Specify Data Types Using Data Type Assistant”

`double`

Data type is double.

`single`

Data type is single.

`int8`

Data type is int8.

`uint8`

Data type is uint8.

`int16`

Data type is int16.

`uint16`

Data type is uint16.

`int32`

Data type is int32.

`uint32`

Data type is uint32.

`int64`

Data type is `int64`.

`uint64`

Data type is `uint64`.

`boolean`

Data type is `boolean`.

`fixdt(1,16,0)`

Data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Data type is fixed point `fixdt(1,16,2^0,0)`.

Enum: `<class name>`

Data type is enumerated, for example, Enum: `Basic Colors`.

Bus: `<object name>`

Data type is a `Simulink.Bus` object.

`<data type expression>`

The name of a data type object, for example `Simulink.NumericType`

Tips

You cannot enter the name of a `Simulink.Bus` object as a data type expression. To specify the **Data type** for the block using a Bus object, select the Bus: `<object name>` option and replace `<object name>` with the name of the Bus object.

Programmatic Use

Block parameter: `OutDataTypeStr`

Type: character vector

Value: `'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | '<fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'`

Default: `'double'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data type

`off` (default) | `on`

Control changes to data type settings from the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

On

Locks all data type settings for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change data type settings for this block.

Programmatic Use

Block parameter: `LockScale`

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Port dimensions — Specify port dimensions

1 (default) | n | [m n]

Specify the dimensions of the output argument signal from the block. For more information, see [Outputport](#).

1

Inherit port dimensions.

n

Vector signal of width n.

[m n]

Matrix signal having m rows and n columns.

Programmatic Use

Block parameter: PortDimensions

Type: character vector

Value: '1' | 'n' | '[m n]'

Default: '1'

Signal type — Select real or complex signal

real (default) | complex

Select real or complex signal. For more information, see [Outputport](#).

real

Specify the signal type as a real number.

complex

Specify the signal type as a complex number.

Programmatic Use

Block parameter: SignalType

Type: character vector

Value: 'real' | 'complex'

Default: 'real'

Introduced in R2014b

ASCII to String

Uint8 vector signal to string signal

Library: Simulink / String

Description

The ASCII to String block converts uint8 vector signals to string signals. The block treats each element in the input vector as an ASCII value during the conversion. For example, the block converts an input vector of [72 101 108 108 111] to the string "Hello".

Ports

Input

Port_1 – ASCII signal
vector

ASCII signal, specified as a vector.

While using dynamic strings, if the length of the input vector exceeds the number of characters specified in the configuration parameter **Buffer size of dynamically-sized string (bytes)** (256 by default), the ASCII to String block truncates the string output to the buffer size-1 (for example, 255), for generated code. To avoid truncation, increase the value of the **Buffer size of dynamically-sized string (bytes)** configuration parameter.

Example: [088 099]

Data Types: uint8

Output

Port_1 – Converted string signal
scalar

Converted string signal from input ASCII signal, specified as a scalar. The block converts each ASCII element in the vector into its alphanumeric equivalent and outputs all elements concatenated into one string.

Data Types: string

Block Characteristics

Data Types	integer string
Direct Feedthrough	yes
Multidimensional Signals	no

Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Assertion

Check whether signal is zero

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Assertion block checks whether any of the elements of the input signal are 0. If all of the elements are nonzero, the assertion is `true` (1) and the block does nothing. If not, the block halts the simulation and returns an error message by default.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal to the assertion check.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Parameters

Enable assertion — Enable or disable check

on (default) | off

Clearing this parameter disables the block and causes the model to behave as if the block does not exist. To enable or disable all verification blocks, regardless of the setting of this option, go to the Configuration Parameters window, click **Diagnostics > Data Validity**, expand the **Advanced parameters** section, and set **Model Verification block enabling** to `Enable all` or `Disable all`.

Programmatic Use

Parameter: enabled

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

"" (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Dependencies

To enable this parameter, select the **Enable assertion** parameter.

Programmatic Use

Parameter: callback

Type: string scalar or character vector

Default: ""

Stop simulation when assertion fails — Whether to stop simulation when check fails

on (default) | off

Select this parameter to stop the simulation when the check fails. Clear this parameter to display a warning and continue the simulation.

Programmatic Use

Parameter: stopWhenAssertionFail

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Block Characteristics

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For information about how Simulink Coder™ generated code handles Model Verification blocks, see “Configure Model for Debugging” (Simulink Coder).

Not recommended for production code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block can be used for checking whether the input signal is zero during simulation, but is not included in the hardware implementation.

Introduced before R2006a

Assignment

Assign values to specified elements of signal

Library: Simulink / Math Operations
HDL Coder / Math Operations

Description

The Assignment block assigns values to specified elements of the signal. You specify the indices of the elements to be assigned values either by entering the indices in the block dialog box or by connecting an external indices source or sources to the block. The signal at the block data port, U, specifies values to be assigned to Y. The block replaces the specified elements of Y with elements from the data signal.

Based on the value you enter for the **Number of output dimensions** parameter, a table of index options is displayed. Each row of the table corresponds to one of the output dimensions in **Number of output dimensions**. For each dimension, you can define the elements of the signal to work with. Specify a vector signal as a 1-D signal and a matrix signal as a 2-D signal. To enable an external index port, in the corresponding row of the table, set **Index Option** to **Index vector (port)** or **Starting index (port)**.

For example, assume a 5-D signal with a one-based index mode. The table in the Assignment block dialog changes to include one row for each dimension. If you define each dimension with the following entries:

Row	Index Option	Index
1	Assign all	
2	Index vector (dialog)	[1 3 5]
3	Starting index (dialog)	4
4	Starting index (port)	
5	Index vector (port)	

The assigned values are $Y(1:\text{end}, [1\ 3\ 5], 4:3+\text{size}(U,3), \text{Idx}4:\text{Idx}4+\text{size}(U,4)-1, \text{Idx}5)=U$, where $\text{Idx}4$ and $\text{Idx}5$ are the input ports for dimensions 4 and 5.

When using the Assignment block in normal mode, Simulink initializes block outputs to zero even if the model does not explicitly initialize them. In accelerator mode, Simulink converts the model into an S-Function. This involves code generation. The code generated may not do implicit initialization of block outputs. In such cases, you must explicitly initialize the model outputs.

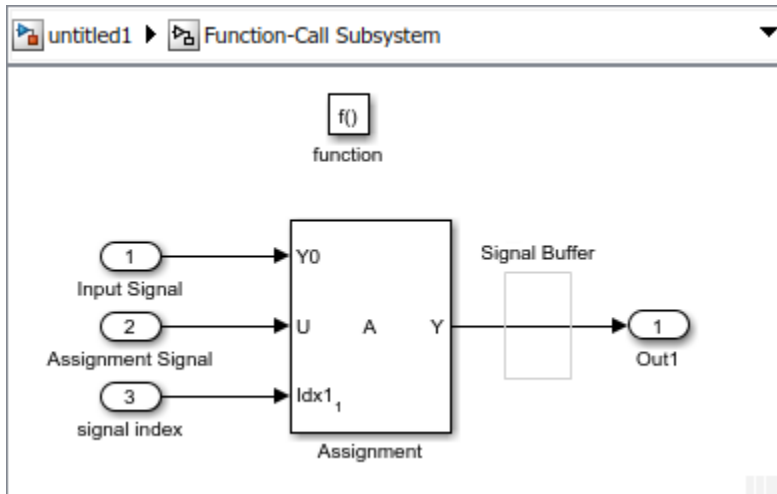

You can use the block to assign values to vector, matrix, or multidimensional signals.

You can use an array of buses as an input signal to an Assignment block.

Assignment Block in Conditional Subsystem

If you place an Assignment block in a conditional subsystem block, a hidden signal buffer (which is equivalent to a Signal Copy block) is inserted in many cases, and merging of signals from Assignment blocks with partial writes can cause an error.

However, if you select the **Ensure output is virtual** parameter for the conditional subsystem Output block, such cases are supported and partial writes to arrays using Assignment blocks are possible. See “Ensure Output is Virtual”.

Limitations

- The **Index** parameter is not tunable during simulation. If the **Index Option** for a dimension is set to **Index vector (dialog)** or **Starting index (dialog)** and you specify a symbolic value, including a `Simulink.Parameter` object, for the corresponding **Index** in the block dialog, then the instantaneous value at the start of simulation will be used throughout the simulation, and the parameter will appear as an inlined value in the generated code. See “Tune and Experiment with Block Parameter Values”. You can adjust the assignment index dynamically by using index ports.

Ports

Input

Y0 — Input initialization signal

scalar | vector

The initialization signal for the output signal. If an element is not assigned another value, then the value of the output element matches this input signal value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed_point` | `Boolean` | `enumerated` | `bus`

U — Input data port

scalar | vector

Value assigned to the output element when specified.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | Boolean | enumerated | bus

IndxN — Nth index signal

scalar | vector

External port specifying an index for the assignment of the corresponding output element.

Dependencies

To enable an external index port, in the corresponding row of the **Index Option** table, set **Index Option** to `Index vector (port)` or `Starting index (port)`.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Output**Y — Output signal with assigned values**

scalar | vector

The output signal with assigned values for the specified elements.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | enumerated | bus

Parameters**Number of output dimensions — Number of dimensions of the output signal**

1 (default) | integer

Enter the number of dimensions of the output signal.

Programmatic Use

Parameter: NumberOfDimensions

Type: character vector

Values: integer

Default: '1'

Index mode — Index mode

One-based (default) | Zero-based

Select the indexing mode. If `One-based` is selected, an index of 1 specifies the first element of the input vector. If `Zero-based` is selected, an index of 0 specifies the first element of the input vector.

Programmatic Use

Parameter: IndexMode

Type: character vector

Values: 'Zero-based' | 'One-based'

Default: 'One-based'

Index Option — Index method for elements

Index vector (dialog) (default) | Assign all | Index vector (port) | Starting index (dialog) | Starting index (port)

Define, by dimension, how the elements of the signal are to be indexed. From the list, select:

Menu Item	Action
Assign all	All elements are assigned.
Index vector (dialog)	Enables the Index column. Enter the indices of elements.
Index vector (port)	The index port defines the indices of elements.
Starting index (dialog)	Enables the Index column. Enter the starting index of the range of elements to be assigned values.
Starting index (port)	The index port defines the starting index of the range of elements to be assigned values.

If you choose **Index vector (port)** or **Starting index (port)** for any dimension in the table, you can specify one of these values for the **Initialize output (Y)** parameter:

- Initialize using input port <Y0>
- Specify size for each dimension in table

Otherwise, Y0 always initializes output port Y.

The **Index** and **Output Size** columns are displayed as relevant.

Programmatic Use

Parameter: IndexOptionArray

Type: character vector

Values: 'Assign all' | 'Index vector (dialog)' | 'Index option (port)' | 'Starting index (dialog)' | 'Starting index (port)'

Default: 'Index vector (dialog)'

Index — Index of elements

1 (default) | integer

If the **Index Option** is **Index vector (dialog)**, enter the index of each element you are interested in.

If the **Index Option** is **Starting index (dialog)**, enter the starting index of the range of elements to be selected. The number of elements from the starting point is determined by the size of this dimension at U.

Programmatic Use

Parameter: IndexParamArray

Type: character vector

Values: cell array

Default: '{ }'

Output Size — Width of block output signal

1 (default) | integer

Enter the width of the block output signal.

Dependencies

To enable this column, select **Specify size for each dimension in table** for the **Initialize output (Y)** parameter.

Programmatic Use**Parameter:** OutputSizeArray**Type:** character vector**Values:** cell array**Default:** '{ }'**Initialize output (Y) — How to initialize output signal**

Initialize using input port <Y0> (default) | Specify size for each dimension in the table

Specify how to initialize the output signal.

- Initialize using input port <Y0> - Signal at the input port Y0 initializes the output.
- Specify size for each dimension in table - Requires you to specify the width of the block output signal in the **Output Size** parameter. If the output has unassigned elements, the value of those elements is undefined.

DependenciesEnabled when you set **Index Option** to Index vector (port) or Starting index (port) for one or more dimensions.**Programmatic Use****Parameter:** OutputInitialize**Type:** character vector**Values:** 'Initialize using input port <Y0>' | 'Specify size for each dimension in table'**Default:** 'Initialize using input port <Y0>'**Action if any output element is not assigned — Option to produce warning or error**

Warning (default) | Error | None

Specify whether to produce a warning or error if you have not assigned all output elements. Options include:

- Warning — Simulink displays a warning and continues the simulation.
- Error — Simulink terminates the simulation and displays an error.
- None — Simulink takes no action.

DependenciesTo enable this parameter, set **Index Option** to Index vector (port) or Starting index (port) for one or more dimensions, then set **Initialize output (Y)** to Specify size for each dimension in table.**Programmatic Use****Parameter:** DiagnosticForDimensions**Type:** character vector**Values:** 'Error' | 'Warning' | 'None'**Default:** 'Warning'**Sample time — Sample time value other than -1**

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Check for out-of-range index in accelerated simulation — Option to check for out-of-range index values in accelerator and rapid accelerator simulation modes

off (default) | on

Select this check box to have Simulink check during simulation in accelerator or rapid accelerator mode whether any index values are outside the range of valid indices for the relevant dimension of the input signal. If an index is out of range, Simulink stops the simulation and displays an error message.

Note If you do not select this check box, out-of-range index values could lead to undefined behavior during accelerator or rapid accelerator mode simulation.

Simulink performs this check during normal mode simulation regardless of whether you select this check box.

Programmatic Use

Parameter: RuntimeRangeChecks

Type: character vector

Values: 'Off' | 'On'

Default: 'Off'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Restrictions

- 3-dimensional matrix inputs are not supported. You can use 1-D vectors and 2-D matrices with the block.
- Variable-size signals are not supported for code generation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Backlash

Model behavior of system with play

Library: Simulink / Discontinuities
HDL Coder / Discontinuities

Description

The Backlash block implements a system in which a change in input causes an equal change in output, except when the input changes direction. When the input changes direction, the initial change in input has no effect on the output. The amount of side-to-side play in the system is referred to as the *deadband*. The deadband is centered about the output. This figure shows an initial state, with the default deadband width of 1 and initial output of 0.

A system with play can be in one of three modes.

Mode	Input	Output
Disengaged	Inside deadband zone.	Remains constant.
Engaged-positive direction	Outside deadband zone and increasing.	Equals input <i>minus</i> half of deadband width.
Engaged-negative direction	Outside deadband zone and decreasing.	Equals input <i>plus</i> half of deadband width.

The **Initial output** parameter value defines the initial center of the deadband zone.

This table shows output values when initial conditions are: **Deadband width** = 2 and **Initial output** = 5.

Output Value	Condition
5	$4 \leq \text{input} \leq 6$
$\text{input} + 1$	$\text{input} < 4$
$\text{input} - 1$	$\text{input} > 6$

For example, you can use the Backlash block to model the meshing of two gears. The input and output are both shafts with a gear on one end, and the input shaft drives the output shaft. Extra space between the gear teeth introduces *play*. The width of this spacing is the **Deadband width** parameter. If the system is disengaged initially, the **Initial output** parameter defines the output.

These figures illustrate operation when the initial input is within the deadband and the system begins in disengaged mode.

When the input increases and reaches the end of the deadband, it engages the output. The output remains at its previous value.

After the input engages the output, the output changes by the same amount as the input.

If the input reverses direction, it disengages from the output. The output remains constant until the input reaches the end of the deadband and engages again.

Ports

Input

Port_1 — Input signal

scalar | vector

Input signal to the backlash algorithm. The value of this signal is either in the deadband or engaging the output in a positive or negative direction.

Data Types: double | single | int8 | int16 | int32 | uint8 | uint16 | uint32

Output

Port_1 — Output signal

scalar | vector

Output signal after the backlash algorithm is applied to the input signal. When the input is in the deadband, then the output remains unchanged. If the input is engaged with the output, then the output changes an equal amount as the input.

Data Types: double | single | int8 | int16 | int32 | uint8 | uint16 | uint32

Parameters

Deadband width — Specify the width of the deadband

1 (default) | scalar | vector

Specify the size of the deadband zone centered on the output value. When the input signal is inside the deadband, then a change in input does not cause a change in output. When the input signal is outside of the deadband, then the output changes an equal amount as the input.

Programmatic Use

Block Parameter: BacklashWidth

Type: character vector

Values: real scalar or vector

Default: '1'

Initial output — Specify the initial output value

0 (default) | scalar | vector

Specify the initial center of the deadband zone. If the initial input value is in the deadband zone, then the output value is equal to **Initial output**. If the initial input value is outside of the deadband zone, then the output value is **Initial output** plus or minus half of the deadzone width.

Programmatic Use

Block Parameter: InitialOutput

Type: character vector

Values: real scalar or vector

Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox™ license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Enable zero-crossing detection — Enable zero-crossing detection

on (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use**Block Parameter:** ZeroCross**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'on'**Block Characteristics**

Data Types	double integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	yes

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Generated code relies on memcpy or memset function (string.h) in certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Restrictions

- The **Deadband width** and **Initial output** parameters support only scalar values.

- Backlash is not supported for zero-crossing detection in fixed-step simulation. Simulink will not detect zero-crossings associated with this block.

Band-Limited White Noise

Introduce white noise into continuous system

Library: Simulink / Sources

Description

The Band-Limited White Noise block generates normally distributed random numbers that are suitable for use in continuous or hybrid systems.

Simulation of White Noise

Theoretically, continuous white noise has a correlation time of 0, a flat power spectral density (PSD), and a total energy of infinity. In practice, physical systems are never disturbed by white noise, although white noise is a useful theoretical approximation when the noise disturbance has a correlation time that is very small relative to the natural bandwidth of the system.

In Simulink software, you can simulate the effect of white noise by using a random sequence with a correlation time much smaller than the shortest time constant of the system. The Band-Limited White Noise block produces such a sequence. The correlation time of the noise is the sample rate of the block. For accurate simulations, use a correlation time much smaller than the fastest dynamics of the system. You can get good results by specifying

$$tc \approx \frac{1}{100} \frac{2\pi}{f_{max}}$$

where f_{max} is the bandwidth of the system in rad/sec.

Comparison with the Random Number Block

The primary difference between this block and the Random Number block is that the Band-Limited White Noise block produces output at a specific sample rate. This rate is related to the correlation time of the noise.

Usage with the Averaging Power Spectral Density Block

The Band-Limited White Noise block specifies a two-sided spectrum, where the units are Hz. The Averaging Power Spectral Density block specifies a one-sided spectrum, where the units are the square of the magnitude per unit radial frequency: $\text{mag}^2/(\text{rad}/\text{sec})$. When you feed the output of a Band-Limited White Noise block into an Averaging Power Spectral Density block, the average PSD value is π times smaller than the **Noise power** of the Band-Limited White Noise block. This difference is the result of converting the units of one block to the units of the other, $1/(1/2)(2\pi) = 1/\pi$, where:

- $1/2$ is the factor for converting from a two-sided to one-sided spectrum.
- 2π is the factor for converting from Hz to rad/sec.

Ports

Output

Port_1 — Normally distributed random numbers

scalar | vector | matrix | N-D array

Normally distributed random numbers specified as a scalar, vector, matrix, or N-D array.

Data Types: double

Parameters

Noise power — Height of PSD of white noise

[0.1] (default) | scalar | vector | matrix | N-D array

Specify the height of the PSD of the white noise as a scalar, vector, matrix, or N-D array of positive values.

Programmatic Use

Block Parameter: Cov

Type: character vector

Values: scalar | vector | matrix | N-D array

Default: '[0.1]'

Sample time — Correlation time of noise

0.1 (default) | scalar | vector

Correlation time of the noise. For more information, see “Specify Sample Time”.

Programmatic Use

Block Parameter: Ts

Type: character vector

Values: scalar | vector

Default: '0.1'

Seed — Starting seed

[23341] (default) | scalar | vector | matrix | N-D array

Specify the starting seed for the random number generator as a scalar, vector, matrix, or N-D array. Values must be positive, real-valued, and finite.

Programmatic Use

Block Parameter: seed

Type: character vector

Values: scalar | vector | matrix | N-D array

Default: '[23341]'

Interpret vector parameters as 1-D — Treat vector parameters as 1-D

on (default) | off

Select to output a 1-D array when the block parameters are vectors. Otherwise, output a 2-D array one of whose dimensions is 1. For more information, see “Determine the Output Dimensions of Source Blocks”.

Programmatic Use**Block Parameter:** VectorParams1D**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Block Characteristics**

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

To produce the correct intensity of this noise, the covariance of the noise is scaled to reflect the implicit conversion from a continuous PSD to a discrete noise covariance. The appropriate scale factor is $1/tc$, where tc is the correlation time of the noise. This scaling ensures that the response of a continuous system to the approximate white noise has the same covariance as the system would have to true white noise. Because of this scaling, the covariance of the signal from the Band-Limited White Noise block is not the same as the **Noise power** (intensity) parameter. This parameter is actually the height of the PSD of the white noise. This block approximates the covariance of white noise as the **Noise power** divided by tc .

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Cannot use inside a triggered subsystem hierarchy.

Bias

Add bias to input

Library: Simulink / Math Operations
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Math Operations

Description

The Bias block adds a bias, or offset, to the input signal according to

$$Y = U + bias$$

where U is the block input and Y is the output.

Ports

Input

Port_1 — Input signal

scalar | vector

Input signal to which the bias is added to create the output signal.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Output signal

scalar | vector

Output signal resulting from adding the bias to the input signal.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Bias — Offset to add to the input signal

0.0 (default) | scalar | vector

Specify the value of the offset to add to the input signal.

Programmatic Use

Block Parameter: Bias

Type: character vector

Values: real, finite

Default: '0.0'

Saturate on integer overflow — Choose the behavior when integer overflow occurs

off (default) | on

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: DoSatur

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	double fixed point half integer single
-------------------	--

Direct Feedthrough	yes

Bit Clear

Set specified bit of stored integer to zero

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Bit Clear block sets the specified bit, given by its index, of the stored integer to zero. Scaling is ignored.

You can specify the bit to be set to zero with the **Index of bit** parameter, where bit zero is the least significant bit.

Ports

The Bit Clear block supports Simulink integer, fixed-point, and Boolean data types. The block does not support true floating-point data types or enumerated data types.

Input

Port_1 — Input signal

scalar or vector

The input signal is the specified bit of the stored integer.

Data Types: `single` | `double` | `Boolean` | `fixed point`

Output

Port_1 — Output signal

scalar or vector

The output consists of the specified bit set to zero.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Index of bit — Index of bit

0 (default) | scalar or vector

Index of bit where bit 0 is the least significant bit.

Programmatic Use**Block Parameter:** iBit**Type:** scalar or vector**Values:** {'0'}**Default:** '0'**Block Characteristics**

Data Types	Boolean ^a fixed point integer
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

^a Bit operations are not recommended for use with Boolean signals.

Bit Set

Set specified bit of stored integer to one

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Bit Set block sets the specified bit of the stored integer to one. Scaling is ignored.

You can specify the bit to be set to one with the **Index of bit** parameter, where bit zero is the least significant bit.

Ports

Input

Port_1 — Input signal

scalar or vector

Input signal with the specified bit of the stored integer.

Data Types: `single` | `double` | `Boolean` | `fixed point`

Output

Port_1 — Output signal

scalar or vector

Output signal with the specified bit set to 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Index of bit — Index of bit

0 (default) | scalar or vector

Index of bit where bit 0 is the least significant bit.

Programmatic Use

Block Parameter: `iBit`

Type: character vector

Values: positive integer

Default: '0'

Block Characteristics

Data Types	Boolean ^a fixed point integer
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Bit Clear | Bitwise Operator | Bit Rotate | Bit Shift

Introduced before R2006a

Bit to Integer Converter

Map vector of bits to corresponding vector of integers

Library: Simulink / Logic and Bit Operations
Communications Toolbox / Utility Blocks

Description

The Bit to Integer Converter block maps groups of bits in the input vector to integers in the output vector.

If M is specified by the **Number of bits per integer(M)** parameter:

- For unsigned integers, the block maps each group of M bits to an integer in the range $[0, (2^M - 1)]$. As a result, the output vector length is $1/M$ times the input vector length.
- For signed integers, the block maps each group of M bits to an integer in the range $[(-2^{M-1}), (2^{M-1} - 1)]$.

Ports

Input

In — Input signal

bit scalar | column vector of bits

Input signal, specified as a scalar or column vector of bits with a length that is a multiple of the value specified in the **Number of bits per integer(M)** parameter. The input must be bits with values of 0 or 1.

Data Types: double

Output

Out — Output signal

integer | column vector of integers

Output signal, returned as an integer or column vector of integers. The **After bit packing, treat resulting integer values as** parameter specifies whether input bits are treated as unsigned or signed.

- When the input bits are treated as unsigned, each integer output is in the range $[0, (2^M - 1)]$.
- When the input bits are treated as signed, each integer output is in the range $[(-2^{M-1}), (2^{M-1} - 1)]$.

Parameters

Number of bits per integer(M) — Number of bits per integer

3 (default) | integer in the range [1, 32]

Number of input bits mapped to each integer in the output, specified as an integer in the range [1, 32].

Programmatic Use

Block Parameter: nbits

Type: character vector

Values: integer in the range [1, 32]

Default: '3'

Input bit order — Input bit order

MSB first (default) | LSB first

Input bit order, specified as 'MSB first' or 'LSB first'.

- 'MSB first' -- First bit of the input signal is the most significant bit (MSB).
- 'LSB first' -- First bit of the input signal is the least significant bit (LSB).

Programmatic Use

Block Parameter: bitOrder

Type: character vector

Values: 'MSB first' | 'LSB first'

Default: 'MSB first'

After bit packing, treat resulting integer values as — Flag for signed integer values after bit packing

Unsigned (default) | Signed

Specify whether the resulting integer values are treated as signed or unsigned after bit packing. This parameter setting determines which **Output data type** selections are available.

Programmatic Use

Block Parameter: signedOutputValues

Type: character vector

Values: 'Unsigned' | 'Signed'

Default: 'Unsigned'

Output data type — Output data type

Inherit via internal rule (default) | Smallest integer | Same as input | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32

The **Output data type** options change depending on the desired signedness of the output.

If the output integers are Signed, you can choose from the following **Output data type** options:

- Inherit via internal rule
- Smallest integer
- double
- single

- int8
- int16
- int32

If the output integers are Unsigned, you can choose from the following options in addition to the Signed options:

- Same as input
- uint8
- uint16
- uint32

When you set the parameter to `Inherit via internal rule`, the block determines the output data type based on the input data type.

- If the input signal is floating-point (either `double` or `single`), the output data type is the same as the input data type.
- If the input data type is not floating-point, the output data type is determined as if the parameter is set to `Smallest integer`.

When you set the parameter to `Smallest integer`, the block selects the output data type based on the settings used in the “Hardware Implementation Pane” of the Configuration Parameters dialog box.

- If you select ASIC/FPGA for the device vendor, the output data type is the smallest ideal integer or fixed-point data type, based on the setting for the **Number of bits per integer(M)** parameter.
- For all other device vendor selections, the output data type is the smallest available (signed or unsigned) integer word length that is large enough to fit the ideal minimum bit size.

Programmatic Use

Block Parameter: outDtype

Type: character vector

Values: 'Inherit via internal rule' | 'Smallest integer' | 'Same as input' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32'

Default: 'Inherit via internal rule'

Block Characteristics

Data Types	Boolean double fixed point ^{a, b} integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

^a Fixed-point inputs must be `ufix(1)`.

^b `ufix(N)` or `sfix(N)` when ASIC/FPGA is selected in the Hardware Implementation Pane and output data-type is set to either (a) `Smallest integer` or, (b) `Inherit via internal rule` and at the same time input is non floating-point.

Compatibility Considerations

Bit to Integer Converter Block Added to Simulink Logic and Bit Operations Library

Behavior changed in R2022a

The Bit to Integer Converter block has been added from the **Communications Toolbox > Utility Blocks** library to the **Simulink > Logic and Bit Operations** library. All existing models continue to work.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Blocks

Integer to Bit Converter

Functions

bit2int | int2bit

Introduced before R2006a

Bitwise Operator

Specified bitwise operation on inputs

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Bitwise Operator block performs the bitwise operation that you specify on one or more operands. Unlike logic operations of the Logical Operator block, bitwise operations treat the operands as a vector of bits rather than a single value.

Restrictions on Block Operations

The Bitwise Operator block does not support shift operations. For shift operations, use the Shift Arithmetic block.

When configured as a multi-input XOR gate, this block performs modulo-2 addition according to the IEEE® Standard for Logic Elements.

Ports

Input

Port_1 — Input signal

scalar | vector

Input signal, specified as a scalar or vector.

- The NOT operator accepts only one input, which can be a scalar or a vector. If the input is a vector, the output is a vector of the same size containing the bitwise logical complements of the input vector elements.
- For a single vector input, the block applies the operation (except the NOT operator) to all elements of the vector.
- For two or more inputs, the block performs the operation between all of the inputs. If the inputs are vectors, the block performs the operation between corresponding elements of the vectors to produce a vector output.

Data Types: int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

scalar | vector

The output signal specified as the output data type, which the block inherits from the driving block, must represent zero exactly. Data types that satisfy this condition include signed and unsigned integer data types.

The size of the block output depends on the number of inputs, the vector size, and the operator you select. If you do not specify a bit mask, the output is a scalar. If you do specify a bit mask, the output is a vector.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Operator – Bitwise logical operator

`AND` (default) | `OR` | `NOR` | `NAND` | `XOR` | `NOT`

Specify the bitwise logical operator for the block operands.

You can select one of these bitwise operations:

Bitwise Operation	Description
AND	TRUE if the corresponding bits are all TRUE
OR	TRUE if at least one of the corresponding bits is TRUE
NAND	TRUE if at least one of the corresponding bits is FALSE
NOR	TRUE if no corresponding bits are TRUE
XOR	TRUE if an odd number of corresponding bits are TRUE
NOT	TRUE if the input is FALSE (available only for single input)

Programmatic Use

Block Parameter: `logicop`

Type: character vector

Values: `'AND'` | `'OR'` | `'NAND'` | `'NOR'` | `'XOR'` | `'NOT'`

Default: `'AND'`

Use bit mask – Select to use bit mask

`checked` (default) | `unchecked`

Select to use the bit mask. Clearing this check box enables **Number of input ports** and disables **Bit Mask** and **Treat mask as**.

Programmatic Use

Block Parameter: `UseBitMask`

Type: character vector

Values: `'off'` | `'on'`

Default: `'on'`

Number of input ports – Number of input signals

`1` (default) | integer

Specify the number of inputs. You can have more than one input ports.

Dependency

Clearing the **Use bit mask** check box enables **Number of input ports** and disables **Bit Mask** and **Treat mask as**.

Programmatic Use

Block Parameter: NumInputPorts

Type: character vector

Values: positive integer

Default: '1'

Bit Mask – Bit mask to associate with a single input

bin2dec (default)

Specify the bit mask to associate with a single input. This parameter reads values as hexadecimal values.

You can use the bit mask to set, get, or clear a bit on the input.

To perform a...	Set the Operator parameter to...	And create a bit mask with...
Bit set	OR	A 1 for each corresponding input bit that you want to set to 1
Bit clear	AND	A 0 for each corresponding input bit that you want to set to 0
Bit get	AND	A 1 for each corresponding input bit that you want to get

Suppose you want to set the fourth bit of an 8-bit input vector. The bit mask would be 00010000, which you can specify as 2^4 for the **Bit Mask** parameter. To clear the bit, the bit mask would be 11101111, which you can specify as $2^7+2^6+2^5+2^3+2^2+2^1+2^0$ for the **Bit Mask** parameter.

Tip Do not use a mask greater than 53 bits. Otherwise, an error message appears during simulation.

Dependency

This parameter is available only when you select **Use bit mask**.

Programmatic Use

Block Parameter: BitMask

Type: character vector

Values: positive integer

Default: 'bin2dec('11011001')'

Treat mask as – Treat the mask as a real-world value or a stored integer

Stored Integer (default) | Real World Value

Specify whether to treat the mask as a real-world value or a stored integer.

The encoding scheme is $V = SQ + B$, as described in “Scaling” (Fixed-Point Designer) in the Fixed-Point Designer™ documentation. Real World Value treats the mask as V . Stored Integer treats the mask as Q .

Dependency

This parameter is available only when you select **Use bit mask**.

Programmatic Use

Block Parameter: BitMaskRealWorld

Type: character vector

Values: 'Real World Value' | 'Stored Integer'

Default: 'Stored Integer'

Block Characteristics

Data Types	Boolean ^a fixed point integer
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

^a Bit operations are not recommended for use with Boolean signals.

Extended Capabilities

C/C++ Code Generation

Bus Assignment

Assign new values to specified bus elements

Library: Simulink / Signal Routing
HDL Coder / Signal Routing

Description

The Bus Assignment block assigns the values of input signals to selected bus elements. Use a Bus Assignment block to change bus element values without adding Bus Selector and Bus Creator blocks that select bus elements and reassemble the elements into a bus. A Bus Assignment block simplifies updating a bus to reflect the processing that occurs in a separate component, such as a subsystem or referenced model.

The Bus Assignment block assigns elements connected to its assignment input ports to specified elements of the bus connected to its bus input port. The block replaces the elements previously assigned to those elements. The change does not affect the composition of the bus; it affects only the values of the elements themselves. Signals not replaced are unaffected by the replacement of other elements.

The elements to which you assign values can be nonbus signals or buses, including arrays of buses. The new values must match the attributes of the elements in the original bus.

By default, Simulink repairs broken selections for a Bus Assignment block that are due to upstream bus hierarchy changes. Simulink generates a warning to highlight that it modified the model. To prevent Simulink from making these repairs automatically:

- 1 On the **Modeling** tab of the Simulink Toolstrip, click **Model Settings**.
- 2 Navigate to the **Diagnostics > Connectivity** pane.
- 3 Set the **Repair bus selections** configuration parameter to **Error without repair**.

Limitations

- The Bus Assignment block does not support messages.
- A Bus Assignment block cannot replace a bus in an array of buses. Use an Assignment block instead. For more information, see “Assign Values into Arrays of Buses”.
- A Bus Assignment block cannot replace an element of a bus in an array of buses. To select the index of the bus that you want to modify with the Bus Assignment block, use a Selector block. Then, use that selected bus with the Bus Assignment block.

Ports

Input

Bus — Input bus with elements to reassign

bus

The input virtual or nonvirtual bus can have elements with real or complex values of any data type supported by Simulink, including bus objects, fixed-point data types, and enumerated data types. The bus can also contain arrays of buses.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `string`

:= — New value to assign to bus element

scalar | vector | matrix | array | bus

Each element in the **Elements that are being assigned** list receives an assignment port. The port label indicates the bus element that corresponds to the port. For an element named `signal1`, the port label is **:= signal1**.

Connect the signal that you want to assign to the bus element to its corresponding assignment port. The signal connected to the assignment port must have the same structure, data type, and sample time as the corresponding bus element. To change the sample time of one or more elements, use a Rate Transition block. For more information, see “Modify Sample Times for Nonvirtual Buses”.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `string`

Output

Bus — Output bus

bus

The output virtual or nonvirtual bus includes the assigned bus element values for the selected elements and the unmodified bus element values for the other elements.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `string`

Parameters

Elements in the bus — Elements of input bus

list of element names

This property is read-only.

Select elements in the input bus to operate on them.

An arrow next to an element name indicates that an element is a nested bus. To display the elements in a nested bus, click the arrow.

With one or more elements selected, click:

- **Find** — Find the source of the selected elements. Simulink opens and highlights the system containing the element source.

- **Select** — Add the selected elements to the list of elements to be assigned values. For more information, see **Elements that are being assigned**.

To refresh the list to reflect modifications to the input bus, click **Refresh**.

Programmatic Use

Block Parameter: InputSignals

Type: cell array | cell array of cell arrays

Values: names of input bus elements

Default: none

Filter by name — Filter for input elements

text

Specify a search term to use for filtering a long list of input elements. Do not enclose the search term in quotation marks. The filter does a partial string search.

To access filtering options, such as using a regular expression for specifying the search term, click the **Show filtering options** button  to the right of the **Filter by name** box.

Enable regular expression — Option to filter input elements with regular expressions

off (default) | on

Enable the use of MATLAB regular expressions for filtering element names. For example, enter `t$` in the **Filter by name** box to display all elements whose names end with a lowercase `t` and their immediate parents. For more information, see “Regular Expressions”.

Dependencies

To access this parameter, click the **Show filtering options** button  to the right of the **Filter by name** box.

Show filtered results as a flat list — Option to display filtered input elements in a flat list

off (default) | on

By default, the list of input elements displays elements in a hierarchical tree. To display filtered elements in a flat list that uses dot notation to reflect the bus hierarchy, select this parameter.

Dependencies

To access this parameter, click the **Show filtering options** button  on the right of the **Filter by name** box.

Elements that are being assigned — Bus elements to be assigned new values

list of element names

For each element in this list, the block has an assignment port. The port label contains the name of the corresponding element.

To add assignment ports for elements:

- 1 Select one or more elements from the **Elements in the bus** list.

If you select multiple elements from the **Elements in the bus** list, the order in which you select them sets their order in the **Elements that are being assigned** list.

- 2 Optionally, specify where you want the elements to appear in the **Elements that are being assigned** list. Select the element below which you want the added elements to appear. If you do not select an element, added elements appear at the end of the list.
- 3 Click **Select**.

To change the order of the assignment ports, select an element or multiple contiguous elements in the list, then click **Up** or **Down**. Port connectivity is maintained when you change the element order.

To remove assignment ports, select the corresponding elements in the list, then click **Remove**.

If an element in the list is not in the input bus, the element name starts with three question marks (???). Modify the input bus to include an element of the specified name or remove the element from the list.

Programmatic Use

Block Parameter: AssignedSignals

Type: character vector | string scalar

Values: comma-separated list of element names

Default: none

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

To learn more about using buses for HDL code generation, see “Buses” (HDL Coder) and “Use Bus Signals to Improve Readability of Model and Generate HDL Code” (HDL Coder).

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Introduced before R2006a

Bus Creator

Create bus from input elements

Library: Simulink / Commonly Used Blocks
 Simulink / Signal Routing
 HDL Coder / Signal Routing

Description

The Bus Creator block combines a set of input elements into a bus. You can connect any element types to the input ports, including other buses. You can access elements in a bus by using a Bus Selector block.

Elements of a bus must have unique names. By default, each element of the bus inherits the name of the element connected to the Bus Creator block. If duplicate names are present, the Bus Creator block appends the port number to all input element names. For elements that do not have names, the Bus Creator block generates names in the form `signaln`, where `n` is the port number connected to the element. You can refer to elements by name when you search for their sources or select elements for connection to other blocks. For element naming guidelines, see “Signal Names and Labels”.

The Bus Creator block does not support mixing message and signal elements as inputs.

Ports

Input

Port_1 – Input element to include in bus

scalar | vector | matrix | array | bus

The input ports accept the elements to include in the bus. The number of input ports is driven by the **Number of inputs** parameter.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus

Output

Port_1 – Output virtual or nonvirtual bus

bus

The output bus is composed of the input elements. The **Output as nonvirtual bus** parameter specifies whether the output bus is a virtual or nonvirtual bus. For information about the types of buses, see “Types of Composite Signals”.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus

Parameters

Number of inputs — Number of input elements

2 (default) | integer

The number of input elements must be an integer greater than or equal to 2. Increasing the number of inputs adds empty input ports to the block. Before you simulate the model, make sure that an input element is connected to each input port.

When you modify the **Number of inputs** parameter, click **Refresh** to update the list of elements.

If all input ports are already connected, you can add an input port to the Bus Creator block by connecting another line to it.

Interactively adding a port updates the **Number of inputs** parameter and adds the new element to the list of elements in the bus.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: integer greater than or equal to 2, comma-separated list of element names

Default: ' 2 '

By default, the Inputs parameter specifies the number of inputs. When you use it to specify the names of elements in the bus, the number of inputs matches the number of element names you specify.

Elements in the bus — List of input elements

list of element names

The list of input elements includes all elements that enter the block, including the elements of nested buses. An arrow next to an element indicates that an input element is a bus. To display the contents of that bus, click the arrow.

To highlight the source of an element that enters the block, select the element in the list and click **Find**.

If you change an element name while the dialog box is open, click **Refresh** to update the name in the list.

To rearrange the elements in the output bus, use the **Up** and **Down** buttons. You can select multiple top-level adjacent elements in the **Elements in the bus** list to reorder or remove.

To add or remove input elements, click **Add** or **Remove**, respectively. Then, update the block icon by clicking **Apply** or **OK**. Before you simulate the model, make sure that an input element is connected to each input port.

Programmatic Use**Block Parameter:** Inputs**Type:** character vector**Values:** integer greater than or equal to 2, comma-separated list of element names**Default:** '2'

By default, the Inputs parameter specifies the number of inputs. When you use it to specify the names of elements in the bus, the number of inputs matches the number of element names you specify.

Filter by name — Search term for filtering displayed input elements

text

To filter the displayed input elements, enter a search term. The filter does a partial-string search. Do not enclose the search term in quotation marks.

To access the filtering options, click the **Show filtering options**  button to the right of the **Filter by name** box.

Enable regular expression — Option to filter displayed input elements by regular expression

off (default) | on

Select this parameter to filter the displayed input elements with either regular expressions or partial search strings. By default, you can filter the displayed input elements with only partial search strings.

Regular expressions let you filter based on whether the input elements match a pattern. For example, enter `t$` in the **Filter by name** box to display all elements whose names end with a lowercase `t` (and their immediate parents). For more information, see “Regular Expressions”.

Dependencies

To access this parameter, click the **Show filtering options**  button to the right of the **Filter by name** box.

Show filtered results as a flat list — Option to display filtered results as a flat list

off (default) | on

Select this parameter to display filtered results as a flat list that uses dot notation to reflect the bus hierarchy. By default, the filtered results appear in a hierarchical tree.

Dependencies

To access this parameter, click the **Show filtering options**  button to the right of the **Filter by name** box.

Output data type — Data type of output bus

'Inherit: auto' (default) | 'Bus: <object name>' | <data type expression>

Specify the data type of the output bus.

If you select `Bus: <object name>`, replace `<object name>` with the name of a Simulink.Bus object. The Bus object must be accessible when you edit the model.

To define a Bus object using the **Bus Editor**, click the **Show data type assistant** button , set **Mode** to **Bus object**, and then click the **Edit** button.

If you select `<data type expression>`, specify an expression that evaluates to a Bus object.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: auto' | 'Bus: <object name>'`

Default: `'Inherit: auto'`

Require names of inputs to match names above — Option to check that input element names match names listed in dialog box

`off (default) | on`

This parameter might be removed in a future release. To enforce strong data typing, use the **Use names from inputs instead of from bus object** parameter.

When selected, this parameter checks that the input element names match the names listed in the Block Parameters dialog box. If the element names do not match, Simulink returns an error.

Dependencies

- This parameter is ignored if you select **Use names from inputs instead of from bus object**.
- This parameter reverts to `off` if you programmatically change **Number of inputs**.

Rename selected signal — New name for selected input element

`' ' (default) | character vector`

Specify a new name for the selected input element. See “Signal Names and Labels” for name guidelines.

Dependencies

To enable this parameter, select **Require names of inputs to match names above**.

Use names from inputs instead of from bus object — Option to use names from input elements instead of from bus object

`on (default) | off`

By default, the Bus Creator block uses the input element names as the output bus element names, even when you specify a `Simulink.Bus` object as the data type.

To inherit bus element names from the Bus object, clear this parameter. Clearing the parameter:

- Enforces strong data typing.
- Avoids having to enter an element name multiple times: in the Bus object and in the model. Entering the name multiple times can accidentally create element name mismatches.
- Supports the array of buses requirement to have consistent element names across array elements.

Alternatively, you can enforce strong data typing by checking that input element names match the Bus object element names. Keep this parameter selected and set the **Element name mismatch** configuration parameter to `error`.

Dependencies

To enable this parameter, set **Output data type** to a Bus object.

Programmatic Use

Block Parameter: InheritFromInputs

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Output as nonvirtual bus — Option to output nonvirtual bus

off (default) | on

Select this parameter to output a nonvirtual bus instead of a virtual bus.

All elements in a nonvirtual bus must have the same sample time, even if the elements of the associated Bus object specify inherited sample times for some elements. Any operation resulting in a nonvirtual bus containing elements with different sample rates generates an error. To change the sample time of an element or bus that has a different sample time than the other nonvirtual bus input elements, use a Rate Transition block. For details, see “Modify Sample Times for Nonvirtual Buses”.

To generate code that uses a C structure to define the structure of the bus that this block creates, enable this parameter.

Dependencies

To enable this parameter, set **Output data type** to a Bus object.

Programmatic Use

Block Parameter: NonVirtualBus

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Tips

For buses at subsystem and model interfaces, you can use Out Bus Element blocks instead of a Bus Creator block with an Outport block. Out Bus Element blocks:

- Reduce line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.

Compatibility Considerations

Require names of inputs to match names above parameter is not recommended

Not recommended starting in R2014b

The **Require names of inputs to match names above** parameter might be removed in a future release. To enforce strong data typing, use the **Use names from inputs instead of from bus object** parameter instead.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

To learn more about using buses for HDL code generation, see “Buses” (HDL Coder) and “Use Bus Signals to Improve Readability of Model and Generate HDL Code” (HDL Coder).

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).

Bus Selector

Select elements from incoming bus

Library: Simulink / Commonly Used Blocks
 Simulink / Signal Routing
 HDL Coder / Signal Routing

Description

The Bus Selector block outputs the elements you select from the input bus. The block can output the selected elements separately or in a new virtual bus.

The Bus Selector block does not support mixing message and signal elements as outputs.

Ports

Input

Port_1 — Input virtual or nonvirtual bus

bus

The input virtual or nonvirtual bus contains the elements to be selected.

For arrays of buses, use a Selector block to select the bus that you want to use with the Bus Selector block.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus

Output

Port_1 — Selected elements of input bus

scalar | vector | matrix | array | bus

By default, the block outputs each of the selected elements from a separate output port that is labeled with the corresponding bus element name. When the **Output as virtual bus** parameter is enabled, the block outputs the selected elements from one port, grouped in a virtual bus.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus

Parameters

To interactively edit the block parameters, double-click the block.

Elements in the bus – List of elements in input bus

list of element names

This property is read-only.

The list of input elements includes all elements that enter the block, including the elements of nested buses. An arrow next to an element indicates that an input element is a bus. To display the contents of that bus, click the arrow.

To highlight the source of an element that enters the block, select the element in the list and click **Find**.

If you change an element name while the dialog box is open, click **Refresh** to update the name in the list.

Programmatic Use**Block Parameter:** InputSignals**Type:** cell array**Values:** element names**Filter by name – Search term for filtering displayed input elements**

text

To filter the displayed input elements, enter a search term. The filter does a partial-string search. Do not enclose the search term in quotation marks.

To access the filtering options, click the **Show filtering options**  button to the right of the **Filter by name** box.

Enable regular expression – Option to filter displayed input elements by regular expression

off (default) | on

Select this parameter to filter the displayed input elements with either regular expressions or partial search strings. By default, you can filter the displayed input elements with only partial search strings.

Regular expressions let you filter based on whether the input elements match a pattern. For example, enter `t$` in the **Filter by name** box to display all elements whose names end with a lowercase `t` (and their immediate parents). For more information, see “Regular Expressions”.

Dependencies

To access this parameter, click the **Show filtering options**  button on the right side of the **Filter by name** box.

Show filtered results as a flat list – Option to display filtered results as a flat list

off (default) | on

Select this parameter to display filtered results as a flat list that uses dot notation to reflect the bus hierarchy. By default, the filtered results appear in a hierarchical tree.

Dependencies

To access this parameter, click the **Show filtering options**  button on the right side of the **Filter by name** box.

Selected elements — Selected elements of input bus

list of elements names

Each element in this list is included in the block output.

To add elements to the block output:

- 1 Select one or more elements from the **Elements in the bus** list.

If you select multiple elements from the **Elements in the bus** list, the order in which you select them sets their order in the **Selected elements** list.

- 2 Optionally, specify where you want the elements to appear in the **Selected elements** list. Select the element below which you want the added elements to appear. If you do not select an element, added elements appear at the end of the list.
- 3 Click **Select**.

Alternatively, in the Simulink Editor, draw a new line close to the output side of the Bus Selector block when the input port receives a bus and all output ports connect to other ports. Simulink prompts you to specify an element to select and adds a port for the element you specify. You cannot create ports in this way when **Output as virtual bus** is selected.

To change the order of the output elements, select an element or multiple contiguous elements in the list, then click **Up** or **Down**. Port connectivity is maintained when you change the element order.

To remove elements from the block output, select the elements in the list, then click **Remove**.

If an element in the list is not in the input bus, the element name starts with three question marks (???). Modify the input bus to include an element of the specified name or remove the element from the list.

Programmatic Use

Block Parameter: OutputSignals

Type: character vector

Values: character vector in the form of 'signal1, signal2'

Default: none

Output as virtual bus — Option to output selected elements as virtual bus

off (default) | on

By default, the block outputs each of the selected elements from a separate output port that is labeled with the corresponding bus element name. Select this parameter to output the selected elements from one port, grouped in a virtual bus.

To convert the output to a nonvirtual bus, insert a Signal Conversion block after the Bus Selector block. Set the Signal Conversion block **Output** parameter to `Nonvirtual bus` and set the **Data type** to a `Simulink.Bus` object.

When the **Selected elements** list includes only one element and you enable **Output as virtual bus**, then that element is not wrapped in a bus. For example, if the element is a bus, the output element is that bus. If the element is not a bus, the output element is not a bus.

Programmatic Use

Block Parameter: OutputAsBus

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Tips

For buses at subsystem and model interfaces, you can use In Bus Element blocks instead of an Inport block with a Bus Selector block. In Bus Element blocks:

- Reduce line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Bus to Vector

Convert virtual bus to vector

Library: Simulink / Signal Attributes
HDL Coder / Signal Attributes

Description

The Bus to Vector block converts a virtual bus to a vector signal. The input bus must consist of scalars or 1-D, row, or column vectors that have the same data type, signal type, and sampling mode. If the input bus contains row or column vectors, the output is a row or column vector, respectively. Otherwise, the output is a 1-D array.

Use the Bus to Vector block only to replace an implicit bus-to-vector conversion with an explicit conversion. To identify and correct buses used as vectors without manually inserting Bus to Vector blocks, you can use Model Advisor check Check bus signals treated as vectors. Alternatively, you can use the `Simulink.BlockDiagram.addBusToVector` function, which automatically inserts Bus to Vector blocks wherever needed.

Note If you use **Save As** to save a model in a version of the Simulink product before R2007a, a null subsystem that outputs nothing replaces each Bus to Vector block. Before you can use the model, reconnect or otherwise correct each path that used to contain a Bus to Vector block but now is interrupted by a null subsystem.

Ports

Input

Port_1 — Bus to convert to vector

scalar | vector | bus

An input bus must consist of scalars or 1-D, row, or column vectors that have the same data type, signal type, and sampling mode. If the input is a nonbus signal, the block does no conversion.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Output vector

vector

The dimensions of the output vector depend on the dimensions of the input bus elements. If the input bus contains row or column vectors, the block output is a row or column vector, respectively. Otherwise, the output is a 1-D vector.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

Block Characteristics

Data Types	<code>Boolean</code> <code>bus</code> <code>double</code> <code>enumerated</code> <code>fixed point</code> <code>half</code> <code>integer</code> <code>single</code>
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

C Caller

Integrate C code in Simulink

Library: Simulink / User-Defined Functions

Description

The C Caller block integrates your external C code into Simulink. This block imports and lists the functions in your external C code, and allows you to select your resolved C functions to integrate in your Simulink models. The C Caller block standalone supports code generation. For more complex models, code generation depends on the capabilities of your Simulink model.

To use the C Caller block, define your source code and any supporting files using **Simulation Target** under **Configuration Parameters**. Then, bring a C Caller block to the Simulink canvas, using **Library Browser > Simulink > User Defined Functions**. To change the defined source code file and its dependencies, go to **Simulation Target** tab in **Configuration Parameters** by clicking the

from the block dialog. After changing your source code or any of its dependencies, refresh the

list of functions by clicking the  on the block dialog. To browse the function definitions in your source code, use the  icon to access your source files.

Ports

Input

Input argument — Input argument for the corresponding C Caller block

scalar | vector | matrix

Input argument to the C Caller block.

Number of input arguments and their names are inferred through the selected function in your external C code. To receive data to a C Caller block, connect an input signal to the input ports.

Input label has the same name as your input argument unless changed by editing the **Label** column under **Port Specification** from the **Block Dialog**. If you rename the label to an input port, the C Caller block changes the name of the port.

For input variables, you can change the input scope to parameters or constants using the **Scope** column.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Output argument — Output argument for the corresponding C Caller block

scalar | vector | matrix

Output argument from the C Caller block.

Number of output arguments and their names are inferred through the selected function in your external C code. To send data from your C Caller block, connect a block to the output port of your C Caller block.

Output port label has the same name as your output argument unless you change it by editing the **Label** column under **Port Specification** from the **Block Dialog**. If you rename the label to an input port, the C Caller block changes the name of the port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus

Parameters

Function name — Name of function

character vector

Name of the function parsed for the C Caller block. For a list of available functions, see “Available Functions” on page 1-0 .

Tunable: Yes

Programmatic Use

Block Parameter: FunctionName

Type: character vector

```
myFunctionName = get_param(gcb, 'FunctionName')
```

```
myFunctionName =
```

```
    'mean_filter'
```

Port specification — Specify port properties

table

The `Port specification` table indicates the attributes of each input and output element for the selected block. These properties include Argument name, scope, input/output label, type and size of the input/output variables. Argument name, scope, type, and size are inferred from your source code. If the scope is an input, you can modify this variable to a parameter or a constant.

Name — Demonstrates the variable name inferred from your source code.

A bold argument name indicates that the port or parameter is a global argument.

Scope — Indicates the role of the variables from your source code. If the variable is an input argument in the C Caller block source code, you can change the scope type to a constant or a parameter. If the variable is an output argument in the source code, you cannot change the scope type.

Label — Labels the input or output variable for the Simulink model. You can change the labels using this table. If the scope is a parameter, enter the parameter name in this field. If the scope is a constant, enter the constant value.

Type — Indicates the data type coming from the ports.

Size — Indicates the size of the input and output data.

Programmatic Use

Block Parameter: FunctionPortSpecification

Type: FunctionPortSpecification object

Available Functions — List of available functions

cell array

List of all available functions that can be mapped to a C Caller block.

The C Caller block in your model imports all functions in your external source code, and shows the function names next to the “Function name” on page 1-0 on the block dialog. To select and use a function in your block, confirm that the function name appears in the Available Functions table.

If you are missing one of the functions, reload the source code by clicking  on the block dialog. To change the names of functions, modify your source code and click the **Refresh** button to reload.

Programmatic Use

Block Parameter: AvailableFunctions

Type: character vector

```
allAvailableFunctions = get_param(gcb, 'AvailableFunctions')
```

```
allAvailableFunctions =
```

```
    1×1 cell array
```

```
    {'add'}
```

Block Characteristics

“Integrate C Code Using C Caller Blocks”

Introduced in R2018b

C Function

Integrate and call external C/C++ code from a Simulink model

Library: Simulink / User-Defined Functions

Description

The C Function block integrates and calls external C/C++ code from a Simulink model. Use this block to define external code and customize the integration of your code by preprocessing or postprocessing the data. In addition, you can specify customized code for simulation and C code generation. You can conditionally call functions defined in your code, and you can also call multiple functions in one block. Using this block, you can initialize persistent data and pass it to an external function.

The C Function block supports initializing persistent data and calling external functions from the block dialog box. Persistent data can include an object of a C++ class defined in your custom code. See “Interface with C++ Classes Using C Function Block”. The block supports only initializing and terminating persistent data. The block does not support updating the data during simulation. To model a dynamic system with continuous states, use an S-Function block. To learn more about S-functions, see “What Is an S-Function?”

Define the source code and supporting files to be called by the C Function block in the **Simulation Target** pane of the Model Configuration Parameters dialog box. See “Model Configuration Parameters: Simulation Target”.

Note C99 is the standard version of C language supported for custom C code integration into Simulink.

Call C Library Functions

You can call these C Math Library functions directly from the C Function block.

abs	acos	asin	atan	atan2	ceil
cos	cosh	exp	fabs	floor	fmod
labs	ldexp	log	log10	pow	sin
sinh	sqrt	tan	tanh		

When you call these functions, double precision applies unless all the input arguments are explicitly single precision. When a type mismatch occurs, a cast of the input arguments to the expected type replaces the original arguments. For example, if you call the `sin` function with an integer argument, a cast of the input argument to a floating-point number of type `double` replaces the original argument.

To call other C library functions, create and call an external wrapper function that calls the C library function.

Call the `abs`, `fabs`, and `labs` Functions

Interpretation of the `abs`, `fabs`, and `labs` functions in C Function block goes beyond the standard C version to include integer and floating-point arguments:

- If `x` is an integer, the standard C function `abs` applies to `x`, or `abs(x)`.
- If `x` is a double, the standard C function `labs` applies to `x`, or `labs(x)`.
- If `x` is a single, the standard C function `fabs` applies to `x`, or `fabs(x)`.

Code Replacement Library (CRL) Based on Type

The call to the function should call the correct CRL based on the type of data passed into the function. If no CRL is specified, the call to the function should call to type-specific library. The CRL for C99 generates a type-specific function. For example:

Type passed in	Code generation call
<code>sin(doubleIn)</code>	<code>sin(doubleIn)</code>
<code>sin(floatIn)</code>	<code>sinf(floatIn)</code>

Limitations

These features of Simulink are not compatible with the C Function block.

- Simulink Coverage™
Only execution coverage is measured.
- Simulink Code Inspector™
- Simulink Design Verifier™
- Simulink Test™
- Test harness

If a C Function block uses a symbol with `Persistent` scope, the block cannot be used with continuous sample time.

These limitations apply to the C code that you specify in a C Function block.

- Local static variables using the `static` keyword are not supported. To cache values across time steps, define a symbol as `Persistent` in the **Symbols** table of the block dialog box.
- You cannot `#include` files in the code. Files containing external functions must be specified in the **Simulation Target** pane of the Model Configuration Parameters dialog box.
- Taking the address of a `Constant` symbol is not supported.
- Directly calling C library functions other than the C Math Library functions listed above under Call C Library Functions is not supported. To call other C library functions, create and call a wrapper function that calls the C library function.

Ports

Input

Input port — Input to the C Function block

scalar | vector | matrix

The number of input ports is determined by the number of symbols with **Input** or **InputOutput** scope defined in the **Symbols** table in the block parameters dialog box. Each input port label is the same as the name of the **Input** or **InputOutput** symbol unless you change it by editing the **Label** field in the **Symbols** table of the block dialog box.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus

Output

Output port — Output from the C Function block

scalar | vector | matrix

The number of output ports is determined by the number of symbols with **Output** or **InputOutput** scope defined in the **Symbols** table in the block parameters dialog box. Each output port label is the same as the name of the **Input** or **InputOutput** symbol unless you change it by editing the **Label** field in the **Symbols** table of the block dialog box.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus

Parameters

Output Code — Output code

character vector | string scalar

Specify C code that the block executes at each time step during simulation. For example, you can call a function from external C code, make modifications to the results, and perform operations to pass the results to other blocks.

Programmatic Use

Block Parameter: OutputCode

Type: character vector or string scalar

Value: ' ' | C code

Default: ' '

Start Code — Initialization code

character vector | string scalar

Specify C code that the block executes one time at the start of simulation. For example, you can initialize persistent data.

Programmatic Use

Block Parameter: StartCode

Type: character vector or string scalar

Value: ' ' | C code

Default: ' '

Initialize Conditions Code — Reinitialization code

character vector | string scalar

Specify C code for the block to execute when enabling a subsystem or model in which the block is placed. The code executes one time at the start of simulation, and if the block is inside a subsystem or model containing an Enable block with the **States when enabling** parameter set to reset, the code also executes each time the subsystem or model switches from disabled to enabled. See “Using Enabled Subsystems”. You can use this code, for example, to set an initial output value or reset the value of a persistent variable.

Programmatic Use**Block Parameter:** InitializeConditionsCode**Type:** character vector or string scalar**Value:** '' | C code**Default:** ''**Terminate Code — Termination code**

character vector | string scalar

Specify C code that the block executes one time at the end of simulation. For example, use this code to free the memory cached on persistent symbols specified as void pointers.

Programmatic Use**Block Parameter:** TerminateCode**Type:** character vector or string scalar**Value:** '' | C code**Default:** ''**Symbols — Specify symbol properties**

table

The **Symbols** table specifies the attributes of the symbols in the C code that you specify in the block. You must enter the attributes of each symbol in the table.

- **Name** — Symbol name in the code.

If the symbol represents a C++ class object, the **Name** field serves as a call to the class constructor:

```
ObjectName(Argument1,Argument2,...)
```

- **Scope** — Scope of the symbol. These scopes are available:
 - **Input** — Input to the block.
 - **Output** — Output to the block.
 - **InputOutput** — Both input and output to the block.

Use the **InputOutput** scope to map an input passed by a pointer in your C code. Ports created using an **InputOutput** scope have the same name for input and output ports. **InputOutput** scope enables buffer reuse for input and output ports. Buffer reuse may optimize memory use and improve code simulation and code generation efficiency, depending on the signal size and the block layout. Limitations include:

- An **InputOutput** symbol cannot be used in **Start Code**, **Initialize Conditions Code**, or **Terminate Code**.

- InputOutput symbols do not support the `void*` data type.
- InputOutput symbols do not support `size()` expressions.
- **Parameter** — Block parameter that appears on the block parameter mask. The parameter name is defined by the **Label** of the symbol.
- **Persistent** — Persistent block data, which retains its value from one time step to the next during simulation.

You can define a void pointer using the **Persistent** scope. A *void pointer* is a pointer that can store any type of data that you create or allocate.

You can instantiate an object of a C++ class defined in your custom code by defining a symbol with **Persistent** scope and using `Class: ClassName` as the **Type** for the symbol. See “Interface with C++ Classes Using C Function Block”.

- **Constant** — Constant value, defined using value-size or numeric expressions.
- **Label** — Label of the symbol. For a symbol with Input, InputOutput, or Output scope, the label appears as the port name on the block. For a symbol with Parameter scope, the label appears on the block parameter mask. If the scope is Constant, the label is the constant expression. You cannot define a label for Persistent scope symbols.
- **Type** — Data type of the symbol. Select a data type from the drop-down list or specify a custom data type.

C++ class types defined in your custom code are supported, as are `Simulink.Bus`, `Simulink.Enum`, and `Simulink.AliasType` types. Enter the **Type** as shown in this table.

Custom type	Specification in Type field
C++ class	<code>Class: <i>CplusplusClassName</i></code>
<code>Simulink.Bus</code>	<code>Bus: <i>BusTypeName</i></code>
<code>Simulink.Enum</code>	<code>Enum: <i>EnumTypeName</i></code>
<code>Simulink.AliasType</code>	<code><i>AliasTypeName</i></code>

- **Size** — Size of the symbol data. You can use a size expression to define the size of an output or use `-1` to inherit size.
- **Port** — Port index of the symbol. For an Input, InputOutput, or Output symbol, **Port** specifies the port index on the block of the port or ports corresponding to the symbol. For a Parameter symbol, **Port** specifies the order that the symbol appears in the block parameter mask.

Programmatic Use

Block Parameter: `SymbolSpec`

Type: `SymbolSpec` object

Value: `SymbolSpec` object

Default: Empty array of `Symbol` objects

Block Characteristics

Data Types	<code>Boolean^a bus^a double^a enumerated^a integer^a single^a</code>

Callback Button

Execute MATLAB code using button with customizable appearance

Library: Simulink / Dashboard / Customizable Blocks

Description

The Callback Button block executes MATLAB code in response to a click or a press of the button. When you press the button, the code executes after a time span that you specify has elapsed or at time intervals that you specify. You can configure the block to execute different code for a click versus for a press. When you use the Callback Button block from the Customizable Blocks library, you can also customize the appearance of the block to look like a button in your real system.

Double-clicking the Callback Button block does not open its dialog box during simulation or when the block is selected. To edit the block parameters, you can use the **Property Inspector** or open the block dialog box by:

- Double-clicking the block when the block is not selected and the model is not simulating.
- Right-clicking the block and selecting **Block Parameters** from the context menu.

Customize Callback Button Blocks

When you add a Callback Button block to your model, the block is preconfigured with a default design. You can use the block with the default design or customize the appearance of the block. When you design a Callback Button block, you configure the block appearance for each possible state. When you configure the **Block Type** as **Momentary**, the block has two states, and when you configure the **Block Type** as **Latch**, the block has four. For each state, you can:

- Add an image that defines the appearance of the block in that state.
- Specify text for the button label and configure its color and position within the block.
- Add an icon and specify the position of the icon relative to the label.

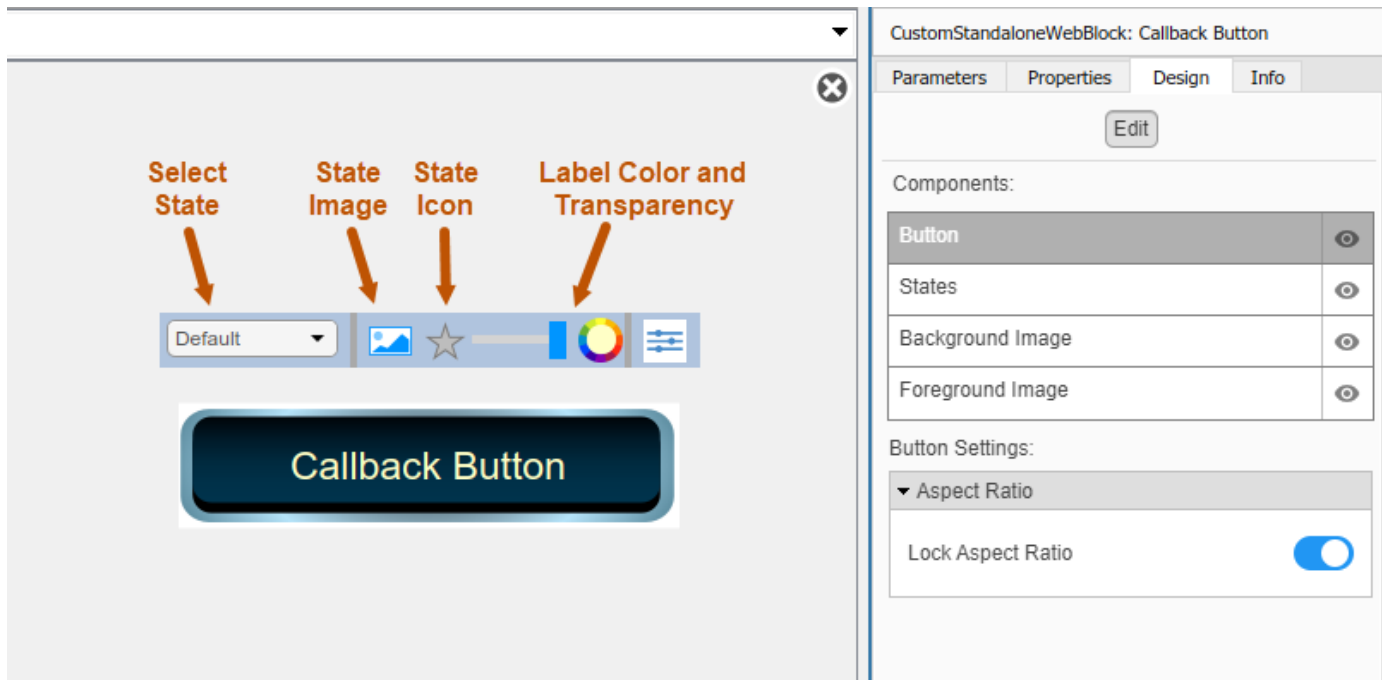

When you want an aspect of the block, such as the label text or color, to indicate the state of the block, configure that aspect of the design differently for each state. When you want an aspect of the block to remain the same for all states, configure that aspect of the block design so it is the same for all states.

You can also design the block background and foreground, which apply for all states. To configure the foreground for the block, upload a foreground image. To configure the background for the block, you can upload a background image or use a solid background color.

To customize the appearance of the block, use design mode. You can enter design mode in one of three ways after selecting the block:

- On the **Button** tab, under **Design**, click **Edit**.
- In the **Property Inspector**, on the **Design** tab, click **Edit Design**.
- Pause on the ellipsis that appears above the block and click the **Edit Custom Block** button.

Design mode gives you access to block parameters and settings that allow you to customize the appearance of the block. You can use the toolbar above the block to configure the image, the icon, and the label color and opacity for each state. For more customization options, use the **Design** tab in the Property Inspector.

When you finish designing the button, click **Exit** in the upper-right of the canvas to exit design mode.

Parameters

To modify the block parameters of a customizable Callback Button, use the Block Parameters dialog box.

Button Type — Button response to click

Momentary (default) | Latch

Specify how the block responds to a click.

- **Momentary** — The button changes state only while pressed. When you release the mouse, the button returns to its default state.
- **Latch** — The button latches the state change when clicked. The button remains in the pressed state until you click it again.

When you configure **Button Type** as **Momentary**, the block has these states:

- **Default** — Default state for the block when it is not pressed
- **Pressed** — Block state when the block is pressed

When you configure **Button Type** as **Latch**, the block has these states:

- **Default** — Default state for the block when it is not pressed.

- **Pressed** — Transitional state when you press the button while it is in the **Default** state. The block transitions to the **Latched** state when you release the mouse.
- **Latched** — Latched state for the block when it is not pressed.
- **Latched and Pressed** — Transitional state when you press the button while it is in the **Latched** state. The block transitions to the **Default** state when you release the mouse.

Programmatic Use**Block Parameter:** ButtonType**Type:** string or character array**Value:** 'Momentary' | 'Latch'**Button Text — Label for button**

'Callback Button' (default) | string | character array

Text label for the button. When you want the button to have the same label text for all states, specify the text using the **Button Text** parameter. To specify a different button label for each state, use the **Design** tab.

ClickFcn — MATLAB code that executes in response to click

MATLAB code

MATLAB code that executes in response to a click of the button.

Every time you click the button, the **ClickFcn** code executes once, at the point in time when you release the click.

To specify code for the **ClickFcn**, select **ClickFcn** from the drop-down menu. Enter the code in the text box below the menu.

PressFcn — MATLAB code that executes in response to press

MATLAB code

MATLAB code that executes in response to a press of the button.

While the button is in the pressed state, the **PressFcn** code executes once when the **Press Delay** time has elapsed and periodically at every **Repeat Interval**.

To specify code for the **PressFcn**, select **PressFcn** from the drop-down menu. Enter the code in the text box below the menu.

How you press the button to execute the **PressFcn** code depends on the **Button Type**.

- If the **Button Type** is **Momentary**, hold down your click for the duration that you want to press the button.
- If the **Button Type** is **Latch**, click to press the button, but do not hold down your click. The button remains pressed until you click it again.

Note Every time that you click on the button, even when you do so as part of the process for pressing the button, the **ClickFcn** code executes once, at the point in time when you release the click.

Press Delay (ms) — Time to hold button for press

500 (default) | scalar

Amount of time required to cause the PressFcn code to execute.

Dependencies

Press Delay (ms) is visible only when PressFcn is selected as the **Mouse Action**.

Repeat Interval (ms) — Time interval to repeat PressFcn code

0 (default) | scalar

Time interval after which the PressFcn code executes again if the Callback Button block is still pressed.

Dependencies

Repeat Interval (ms) is visible only when PressFcn is selected as the **Mouse Action**.

Block Characteristics

Data Types	
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Tips

To design a button that changes the value of a variable or parameter in your model, use the Push Button block.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Introduced in R2021b

Callback Button

Execute MATLAB code using button

Library: Simulink / Dashboard

Description

The Callback Button block executes MATLAB code in response to a click or press of the button. When you press the button, the code executes after a time span that you specify has elapsed or at time intervals that you specify. You can configure the block to execute different code for a click versus for a press.

Double-clicking the Callback Button block does not open its dialog box during simulation or when the block is selected. To edit the block parameters, you can use the **Property Inspector** or open the block dialog box by:

- Double-clicking the block when the block is not selected and the model is not simulating.
- Right-clicking the block and selecting **Block Parameters** from the context menu.

The Callback Button block in the Customizable Blocks library provides the same functionality as this Callback Button block and provides additional capabilities to:

- Design the appearance of the block to look like a button in a real system.
- Configure the button type as momentary or latch.

Parameters

To modify the block parameters of a Callback Button, use the Block Parameters dialog box.

Button Text — Label for button

'Callback Button' (default) | character array

Text label for the button.

Tips

To design a button that displays different text depending on the state of the block, use the Callback Button block in the Customizable Blocks library.

Programmatic Use

Block Parameter: ButtonText

Type: string or character array

Default: 'Callback Button'

ClickFcn — MATLAB code that executes in response to click

MATLAB code

MATLAB code that executes in response to a click of the button.

Every time you click the button, the ClickFcn code executes once, at the point in time when you release the click.

To specify code for the ClickFcn, select ClickFcn from the drop-down menu. Enter the code in the text box below the menu.

PressFcn — MATLAB code that executes in response to press

MATLAB code

MATLAB code that executes in response to a press of the button.

While the button is in the pressed state, the PressFcn code executes once when the **Press Delay** time has elapsed and periodically at every **Repeat Interval**.

To specify code for the PressFcn, select PressFcn from the drop-down menu. Enter the code in the text box below the menu.

To execute the PressFcn code, hold down your click for the length of time that you want to press the button.

Note Every time that you click on the button, even when you do so as part of the process for pressing the button, the ClickFcn code executes once, at the point in time when you release the click.

Press Delay (ms) — Time to hold button for press

500 (default) | scalar

Amount of time required to cause the PressFcn code to execute.

Dependency

Press Delay (ms) is visible only when PressFcn is selected as the **Mouse Action**.

Repeat Interval (ms) — Time interval to repeat PressFcn code

0 (default) | scalar

Time interval after which the PressFcn code executes again if the Callback Button block is still pressed.

Dependency

Repeat Interval (ms) is visible only when PressFcn is selected as the **Mouse Action**.

Block Characteristics

Data Types	
Direct Feedthrough	no

Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Introduced in R2017b

Check Box

Select parameter or variable value

Library: Simulink / Dashboard

Description

The Check Box block allows you to set the value of a parameter or variable during simulation by checking or clearing the box. Use the Check Box block with other Dashboard blocks to create an interactive dashboard for your model.

Double-clicking the Check Box block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, select the block. Then, on the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect

mode, the dashboard block does not display the connected value until the you uncomment the block.

- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection

Connection — Select a variable or block parameter to connect

variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify `a.b` to connect to scalar element `b` of the structure or bus `a` nested inside the selected composite variable or parameter.

- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: Simulink.HMI.ParamSourceInfo

Default: []

Main

Check Box Label — Description of check box action

Label (default) | character vector

Label that appears next to the check box. You can use the **Check Box Label** to describe what happens in your model when you check the check box.

Example: Enable sound

Programmatic Use

Block Parameter: Label

Type: character vector

Default: 'Label'

Checked/Unchecked Values — Values to assign for checked and unchecked states

Unchecked: 0 Checked: 1 (default) | scalar

Value to assign to the connected variable or parameter for the checked and unchecked block states.

- Unchecked — Value assigned to the connected parameter when the Check Box block is not checked.
- Checked — Value assigned to the connected parameter when the Check Box block is checked.

Programmatic Use

You set the **Unchecked** and **Checked** values programmatically using a 2-by-1 vector that contains the **Unchecked** and **Checked** values, in that order.

Block Parameter: Values

Type: 2x1 vector

Default: [0 1]

Label — Block label position

Hide (default) | Bottom | Top

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Hide' | 'Bottom' | 'Top'

Default: 'Hide'

Format

Opacity — Block background opacity

1 (default) | scalar

Block background opacity, specified as a scalar value between 0 and 1.

Example: 0.5

Programmatic Use**Block Parameter:** Opacity**Type:** scalar**Default:** 1**Foreground Color — Block foreground color**`[r g b]` vector

Block foreground color, including the text. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 `[r g b]` vector with values between 0 and 1.

Block Parameter: `ForegroundColor`**Type:** character vector | string**Values:** `[r g b]` vector**Background Color — Block background color**`[r g b]` vector

Block background color. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 `[r g b]` vector with values between 0 and 1.

Block Parameter: `BackgroundColor`**Type:** character vector | string**Values:** `[r g b]` vector**Block Characteristics**

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Check Discrete Gradient

Check that absolute value of difference between successive samples of discrete signal is less than specified value

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Discrete Gradient block checks each signal element and determines whether the absolute value of the difference between successive values of the element is less than an specified value. The block then executes an assertion after comparison. You can specify the value of gradient (1 by default) by adjusting the **Maximum gradient** parameter. If the input signal difference is less than the absolute value of the **Maximum gradient**, the assertion is `true` (1) and the block does nothing. If not, the block halts the simulation and returns an error message by default.

Note To run simulations, the Check Discrete Gradient block requires a fixed-step discrete solver. If another solver is selected, an error prompts.

Ports

Input

Port_1 — Input signal checked against gradient

scalar | vector | matrix

Input signal the block checks to determine if the difference of each element between successive samples is less than the absolute value of the **Maximum gradient** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Assertion output signal

scalar

Output signal that is `true` (1) if the assertion succeeds, and `false` (0) if the assertion fails. If, in the Configuration Parameters window, in the **Math and Data Types** section, under **Advanced parameters**, you select **Implement logic signals as Boolean data**, then the output data type is Boolean. Otherwise, the data type of the signal is double.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Maximum gradient — Maximum value of allowed differences

1 (default) | scalar

Specify the value on the allowed gradient of the input signal.

Programmatic Use

Parameter: gradient

Type: string scalar or character vector

Values: real scalar

Default: "1"

Enable assertion — Enable or disable check

on (default) | off

Clearing this parameter disables the block and causes the model to behave as if the block does not exist. To enable or disable all verification blocks, regardless of the setting of this option, go to the Configuration Parameters window, click **Diagnostics > Data Validity**, expand the **Advanced parameters** section, and set **Model Verification block enabling** to **Enable all** or **Disable all**.

Programmatic Use

Parameter: enabled

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

"" (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Dependencies

To enable this parameter, select the **Enable assertion** parameter.

Programmatic Use

Parameter: callback

Type: string scalar or character vector

Default: ""

Stop simulation when assertion fails — Whether to stop simulation when check fails

on (default) | off

Select this parameter to stop the simulation when the check fails. Clear this parameter to display a warning and continue the simulation.

Programmatic Use

Parameter: stopWhenAssertionFail

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Output assertion signal — Create output signal

off (default) | on

Select this parameter to enable the output port.

Programmatic Use

Parameter: export

Type: string scalar or character vector

Values: "on" | "off"

Default: "off"

Select icon type – Select icon type

graphic (default) | text

Specify the style of the block icon. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition.

Programmatic Use

Parameter: icon

Type: string scalar or character vector

Values: "graphic" | "text"

Default: "graphic"

Block Characteristics

Data Types	double fixed point integer single

[Check Dynamic Range](#) | [Check Dynamic Gap](#)

Introduced before R2006a

Check Dynamic Gap

Check that gap of possibly varying width occurs in range of signal's amplitudes

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Dynamic Gap block checks that a signal falls outside a range of values at each time step and executes an assertion after comparison. The width of the gap can vary from time step to time step. The **u** port is the tested input signal. The inputs **min** and **max** specify the lower and upper bounds of the gap, respectively. If **u** falls outside of the gap defined by **min** and **max**, the assertion is `true` (1) and the block does nothing. If not, the block halts the simulation and returns an error message by default.

The input signals can be scalars, vectors, or matrices. All three input signals must be the same data type. The block compares the value of **u** to the bounds differently depending on the signal.

- When comparing scalars to vectors or matrices, the block compares the scalar signal to each element of the non-scalar signal.
- When comparing vectors or matrix signals to other vectors or matrices, the block compares the input to the bounds element-by-element.
- For models with more than one vector or matrix input signal, the vectors or matrices must have the same dimensions.

Ports

Input

max — Upper bound of dynamic gap

scalar | vector | matrix

Signal specifying the upper bound of the gap.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

min — Lower bound of dynamic gap

scalar | vector | matrix

Signal specifying the lower bound of the gap.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

u — Input signal checked against gap

scalar | vector | matrix

Input signal checked for a gap of width specified by **max** and **min**.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 – Assertion output signal

scalar

Output signal that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters window, in the **Math and Data Types** section, under **Advanced parameters**, you select **Implement logic signals as Boolean data**, then the output data type is Boolean. Otherwise, the data type of the signal is double.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Enable assertion – Enable or disable check

on (default) | off

Clearing this parameter disables the block and causes the model to behave as if the block does not exist. To enable or disable all verification blocks, regardless of the setting of this option, go to the Configuration Parameters window, click **Diagnostics > Data Validity**, expand the **Advanced parameters** section, and set **Model Verification block enabling** to Enable all or Disable all.

Programmatic Use

Parameter: enabled

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Simulation callback when assertion fails (optional) – Expression to evaluate when assertion fails

"" (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Dependencies

To enable this parameter, select the **Enable assertion** parameter.

Programmatic Use

Parameter: callback

Type: string scalar or character vector

Default: ""

Stop simulation when assertion fails – Whether to stop simulation when check fails

on (default) | off

Select this parameter to stop the simulation when the check fails. Clear this parameter to display a warning and continue the simulation.

Programmatic Use

Parameter: stopWhenAssertionFail

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Output assertion signal – Create output signal

off (default) | on

Select this parameter to enable the output port.

Programmatic Use

Parameter: export

Type: string scalar or character vector

Values: "on" | "off"

Default: "off"

Select icon type – Select icon type

graphic (default) | text

Specify the style of the block icon. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition.

Programmatic Use

Parameter: icon

Type: string scalar or character vector

Values: "graphic" | "text"

Default: "graphic"

[Check Dynamic Lower Bound](#) | [Check Dynamic Upper Bound](#) | [Check Dynamic Range](#)

Introduced before R2006a

Check Dynamic Lower Bound

Check that one signal is always less than another signal

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Dynamic Lower Bound block checks if a reference signal, **min**, is less than the amplitude of an input signal, **u** at each time step and executes an assertion after comparison. If **min** is less than **u**, the assertion is `true` (1) and the block does nothing. If not, the block halts the simulation and returns an error message by default.

The input signals can be scalars, vectors, or matrices. Both input signals must be the same data type. The block compares the value of **u** to the bound differently depending on the signal.

- When comparing scalars to vectors or matrices, the block compares the scalar signal to each element of the non-scalar signal.
- When comparing a vector or matrix signal to another vector or matrix signal, the block checks the signals element-by-element.
- For models with an input and bound that are both vectors or matrices, the input and bound must have the same dimensions.

Ports

Input

min — Lower bound of dynamic range check

scalar | vector | matrix

Signal specifying the lower bound of the check against the input signal **u** amplitude. Signal data type and dimension must be the same as **u**.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

u — Input signal checked against bound

scalar | vector | matrix

Input signal checked against the lower bound specified by **min**. Both input signals must be the same data type and dimension.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Assertion output signal

scalar

Output signal that is `true` (1) if the assertion succeeds and `false` (0) if the assertion fails. If, in the Configuration Parameters window, in the **Math and Data Types** section, under **Advanced parameters**, you select **Implement logic signals as Boolean data**, then the output data type is Boolean. Otherwise, the data type of the signal is double.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Enable assertion — Enable or disable check

on (default) | off

Clearing this parameter disables the block and causes the model to behave as if the block does not exist. To enable or disable all verification blocks, regardless of the setting of this option, go to the Configuration Parameters window, click **Diagnostics > Data Validity**, expand the **Advanced parameters** section, and set **Model Verification block enabling** to `Enable all` or `Disable all`.

Programmatic Use

Parameter: enabled

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

"" (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Dependencies

To enable this parameter, select the **Enable assertion** parameter.

Programmatic Use

Parameter: callback

Type: string scalar or character vector

Default: ""

Stop simulation when assertion fails — Whether to stop simulation when check fails

on (default) | off

Select this parameter to stop the simulation when the check fails. Clear this parameter to display a warning and continue the simulation.

Programmatic Use

Parameter: stopWhenAssertionFail

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Output assertion signal — Create output signal

off (default) | on

Select this parameter to enable the output port.

Programmatic Use

Parameter: export

Type: string scalar or character vector

Values: "on" | "off"

Default: "off"

Select icon type — Select icon type

graphic (default) | text

Specify the style of the block icon. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition.

Programmatic Use

Parameter: icon

Type: string scalar or character vector

Values: "graphic" | "text"

Check Dynamic Upper Bound | Check Dynamic Range

Introduced before R2006a

Check Dynamic Range

Check that signal falls inside range of amplitudes that varies from time step to time step

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Dynamic Range block checks that a signal falls inside a range of values at each time step and executes an assertion after comparison. The width of the range can vary from time step to time step. The **u** port is the tested input signal. The **min** and **max** ports are the lower and upper bounds of the range, respectively. If **u** is between **max** and **min**, the assertion is `true` (1) and the block does nothing. If not, the block halts the simulation and returns an error message by default.

The input signals can be scalars, vectors, or matrices. All three input signals must be the same data type. The block compares the value of **u** to the bounds differently depending on the signal.

- When comparing scalars to vectors or matrices, the block compares the scalar signal to each element of the non-scalar signal.
- When comparing vectors or matrix signals to other vectors or matrices, the block checks the inputs element-by-element.
- For models with more than one vector or matrix input signal, the vectors or matrices must have the same dimensions.

Ports

Input

max — Upper bound of dynamic range check

scalar | vector | matrix

Signal specifying the upper bound of the range.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

min — Lower bound of dynamic range check

scalar | vector | matrix

Signal specifying the lower bound of the range.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

u — Input signal checked against range

scalar | vector | matrix

Signal checked against the range specified by the **max** and **min** ports.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Assertion output signal

scalar

Output signal that is `true` (1) if the assertion succeeds and `false` (0) if the assertion fails. If, in the Configuration Parameters window, in the **Math and Data Types** section, under **Advanced parameters**, you select **Implement logic signals as Boolean data**, then the output data type is Boolean. Otherwise, the data type of the signal is double.

Dependencies

To enable this port, select the **Output assertion signal** parameter.

Data Types: double | Boolean

Parameters

Enable assertion — Enable or disable check

on (default) | off

Clearing this parameter disables the block and causes the model to behave as if the block does not exist. To enable or disable all verification blocks, regardless of the setting of this option, go to the Configuration Parameters window, click **Diagnostics > Data Validity**, expand the **Advanced parameters** section, and set **Model Verification block enabling** to `Enable all` or `Disable all`.

Programmatic Use

Parameter: enabled

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

"" (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Dependencies

To enable this parameter, select the **Enable assertion** parameter.

Programmatic Use

Parameter: callback

Type: string scalar or character vector

Default: ""

Stop simulation when assertion fails — Whether to stop simulation when check fails

on (default) | off

Select this parameter to stop the simulation when the check fails. Clear this parameter to display a warning and continue the simulation.

Programmatic Use**Parameter:** stopWhenAssertionFail**Type:** string scalar or character vector**Values:** "on" | "off"**Default:** "on"**Output assertion signal – Create output signal**

off (default) | on

Select this parameter to enable the output port.

Programmatic Use**Parameter:** export**Type:** string scalar or character vector**Values:** "on" | "off"**Default:** "off"**Select icon type – Select icon type**

graphic (default) | text

Specify the style of the block icon. The graphic option displays a graphical representation of the assertion condition on the icon. The text option displays a mathematical expression that represents the assertion condition.

Programmatic Use**Parameter:** icon**Type:** string scalar or character vector**Values:** "graphic" | "text"**Default:** "graphic"**Block Characteristics**

Check Dynamic Upper Bound

Check that one signal is always greater than another signal

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Dynamic Upper Bound block checks if the a reference signal, **max**, is greater than the amplitude of an input signal, **u**, at each time step and executes an assertion after comparison. If **max** is greater than **u**, the assertion is `true` (1) and the block does nothing. If not, the block halts the simulation and returns an error message by default.

The input signals can be scalars, vectors, or matrices. Both input signals must be the same data type. The block compares the value of **u** to **max** differently depending on the signal.

- When comparing scalars to vectors or matrices, the block compares the scalar signal to each element of the non-scalar signal.
- When comparing a vector or matrix signal to another vector or matrix signal, the block checks the signals element-by-element.
- For models with an input signal and bound that are both vectors or matrices, the input signal and bound must have the same dimensions.

Ports

Input

max — Upper bound of range check

scalar | vector | matrix

Signal specifying the lower bound of the range that the block checks the input signal **u** amplitude. Signal data type and dimension must be the same as **u**.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

u — Input signal checked against bound

scalar | vector | matrix

Input signal checked against the lower bound specified by **min**.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Assertion output signal

scalar

Output signal that is `true` (1) if the assertion succeeds and `false` (0) if the assertion fails. If, in the Configuration Parameters window, in the **Math and Data Types** section, under **Advanced parameters**, you select **Implement logic signals as Boolean data**, then the output data type is Boolean. Otherwise, the data type of the signal is double.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Enable assertion — Enable or disable check

on (default) | off

Clearing this parameter disables the block and causes the model to behave as if the block does not exist. To enable or disable all verification blocks, regardless of the setting of this option, go to the Configuration Parameters window, click **Diagnostics > Data Validity**, expand the **Advanced parameters** section, and set **Model Verification block enabling** to `Enable all` or `Disable all`.

Programmatic Use

Parameter: enabled

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

"" (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Dependencies

To enable this parameter, select the **Enable assertion** parameter.

Programmatic Use

Parameter: callback

Type: string scalar or character vector

Default: ""

Stop simulation when assertion fails — Whether to stop simulation when check fails

on (default) | off

Select this parameter to stop the simulation when the check fails. Clear this parameter to display a warning and continue the simulation.

Programmatic Use

Parameter: stopWhenAssertionFail

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Output assertion signal — Create output signal

off (default) | on

Select this parameter to enable the output port.

Programmatic Use

Parameter: export

Type: string scalar or character vector

Values: "on" | "off"

Default: "off"

Select icon type — Select icon type

graphic (default) | text

Specify the style of the block icon. The graphic option displays a graphical representation of the assertion condition on the icon. The text option displays a mathematical expression that represents the assertion condition.

Programmatic Use

Parameter: icon

Type: string scalar or character vector

Values: "graphic" | "text"

Default: "graphic"

Check Input Resolution

Check that input signal has specified resolution

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Input Resolution block checks whether the input signal has a specified resolution. The block input and resolution can be either a scalar or vector. The input and resolution must be the same data type.

If the **Resolution** parameter is a scalar, the block calculates the modulus of the input signal over the provided scalar resolution. The calculated modulus is then compared to a tolerance of $10e-3$, and executes an assertion after comparison. If the modulus is less than the tolerance, the assertion is `true (1)` and the block does nothing. If not, the block halts the simulation and returns an error message by default. If the **Resolution** parameter is a vector, it asserts `true (1)` if the value of the input signal is equal to any of the resolution vector elements.

The block compares the input to the resolution in several additional ways depending on the dimensions of the signal and resolution.

- When comparing a scalar input signal or resolution to a vector input signal or resolution, the block compares the scalar to each element of the vector.
- When comparing a vector input signal to a vector resolution, the block compares the input signal to the resolution element-by-element.
- For models with an input signal and resolution that are both vectors, the input signal and resolution must have the same dimensions.

Ports

Input

Port_1 – Input signal checked against resolution

scalar | vector

Input signal that the block checks against the resolution specified by the **Resolution** parameter.

Data Types: double

Output

Port_1 – Assertion output signal

scalar

Output signal that is `true (1)` if the assertion succeeds and `false (0)` if the assertion fails. If, in the Configuration Parameters window, in the **Math and Data Types** section, under **Advanced**

parameters, you select **Implement logic signals as Boolean data**, then the output data type is Boolean. Otherwise, the data type of the signal is double.

Dependencies

To enable this port, select **Output assertion signal**.

Data Types: double | Boolean

Parameters

Resolution — Resolution value to compare to input signal

scalar | vector

Specify the resolution requirement for the input signal.

Programmatic Use

Parameter: resolution

Type: string scalar or character vector

Default: "1"

Enable assertion — Enable or disable check

on (default) | off

Clearing this parameter disables the block and causes the model to behave as if the block does not exist. To enable or disable all verification blocks, regardless of the setting of this option, go to the Configuration Parameters window, click **Diagnostics > Data Validity**, expand the **Advanced parameters** section, and set **Model Verification block enabling** to **Enable all** or **Disable all**.

Programmatic Use

Parameter: enabled

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

"" (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Dependencies

To enable this parameter, select the **Enable assertion** parameter.

Programmatic Use

Parameter: callback

Type: string scalar or character vector

Default: ""

Stop simulation when assertion fails — Whether to stop simulation when check fails

on (default) | off

Select this parameter to stop the simulation when the check fails. Clear this parameter to display a warning and continue the simulation.

Programmatic Use**Parameter:** stopWhenAssertionFail**Type:** string scalar or character vector**Values:** "on" | "off"**Default:** "on"**Output assertion signal – Create output signal**

Check Static Gap

Check that gap exists in signal's range of amplitudes

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Static Gap block checks that an input signal is less than (or optionally equal to) a static lower bound or greater than (or optionally equal to) a static upper bound at the current time step. The **Upper bound** and **Lower bound** parameters define the upper and lower bounds of the gap. The block then executes an assertion after comparison. If the signal falls outside of the gap, the assertion is `true` (1) and the block does nothing. If not, the block halts the simulation and returns an error message by default.

The input signal and bounds can be scalars, vectors, or matrices. The input and the bounds must be the same data type. The block compares the value of the input to the bounds differently depending on the signal.

- When comparing scalars to vectors or matrices, the block compares the scalar to each element of the non-scalar input signal or bound.
- When comparing vectors or matrix signals to other vectors or matrices, the block compares the input signal and the bounds element-by-element.
- For models with more than one vector or matrix as the input signal or bounds, the vectors or matrices must have the same dimensions.

Ports

Input

Port_1 — Input signal checked against gap

scalar | vector | matrix

Input signal the block checks if the signal value is less than a static lower bound or greater than a static upper bound.

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

Port_1 — Assertion output signal

scalar

Output signal that is `true` (1) if the assertion succeeds, and `false` (0) if the assertion fails. If, in the Configuration Parameters window, in the **Math and Data Types** section, under **Advanced**

parameters, you select **Implement logic signals as Boolean data**, then the output data type is Boolean. Otherwise, the data type of the signal is double.

Dependencies

To enable this output port, set the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Upper bound — Upper boundary value

scalar | vector | matrix

Specify the upper bound on the range of amplitudes that the input signal can have.

Programmatic Use

Parameter: max

Type: string scalar or character vector

Default: "0"

Inclusive upper bound — Include the upper bound in range

on (default) | off

Select this check box to make the range of valid input amplitudes include the upper bound.

Programmatic Use

Parameter: max_included

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Lower bound — Lower boundary value

scalar | vector | matrix

Specify the lower bound on the range of amplitudes that the input signal can have.

Programmatic Use

Parameter: min

Type: string scalar or character vector

Default: "0"

Inclusive lower bound — Include the lower bound in range

on (default) | off

Select this check box to make the range of valid input amplitudes include the lower bound.

Programmatic Use

Parameter: min_included

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Enable assertion — Enable or disable check

on (default) | off

Clearing this parameter disables the block and causes the model to behave as if the block does not exist. To enable or disable all verification blocks, regardless of the setting of this option, go to the Configuration Parameters window, click **Diagnostics > Data Validity**, expand the **Advanced parameters** section, and set **Model Verification block enabling** to **Enable all** or **Disable all**.

Programmatic Use

Parameter: enabled

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

" " (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Dependencies

To enable this parameter, select the **Enable assertion** parameter.

Programmatic Use

Parameter: callback

Type: string scalar or character vector

Default: " "

Stop simulation when assertion fails — Whether to stop simulation when check fails

on (default) | off

Select this parameter to stop the simulation when the check fails. Clear this parameter to display a warning and continue the simulation.

Programmatic Use

Parameter: stopWhenAssertionFail

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Output assertion signal — Create output signal

off (default) | on

Select this parameter to enable the output port.

Programmatic Use

Parameter: export

Type: string scalar or character vector

Values: "on" | "off"

Default: "off"

Select icon type — Select icon type

graphic (default) | text

Specify the style of the block icon. The **graphic** option displays a graphical representation of the assertion condition on the icon. The **text** option displays a mathematical expression that represents the assertion condition.

Programmatic Use**Parameter:** icon**Type:** string scalar or character vector**Values:** "graphic" | "text"**Default:** "graphic"**Block Characteristics**

Introduced before R2006a

Check Static Lower Bound

Check that signal is greater than (or optionally equal to) static lower bound

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Static Lower Bound block checks if an input signal is greater than (or optionally equal to) a specified lower bound at each time step and executes an assertion after comparison. The **Lower bound** parameter defines the lower bound. If the input signal is greater than the lower bound, the assertion is `true` (1) and the block does nothing. If not, the block halts the simulation and returns an error message by default.

The input signal and bound can be scalars, vectors, or matrices. The input and the bound must be the same data type. The block compares the value of the input to the bound differently depending on the signal.

- When comparing scalars to vectors or matrices, the block compares the scalar to each element of the non-scalar input signal or bound.
- When comparing a vector or matrix input signal to a vector or matrix bound, the block compares the input signal to the bound element-by-element.
- For models with an input signal and bound that are both vectors or matrices, the input signal and bound must have the same dimensions.

Ports

Input

Port_1 — Input signal checked against bound

scalar | vector | matrix

Input signal checked against the lower bound specified by the **Lower bound** parameter.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Assertion output signal

scalar

Output signal that is `true` (1) if the assertion succeeds and `false` (0) if the assertion fails. If, in the Configuration Parameters window, in the **Math and Data Types** section, under **Advanced parameters**, you select **Implement logic signals as Boolean data**, then the output data type is Boolean. Otherwise, the data type of the signal is double.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Lower bound — Lower boundary value

scalar | vector | matrix

Specify the lower bound on the range of amplitudes that the input signal can have.

Programmatic Use

Parameter: min

Type: string scalar or character vector

Default: "0"

Inclusive boundary — Include the lower bound in range

on (default) | off

Select this check box to make the range of valid input amplitudes include the lower bound.

Programmatic Use

Parameter: min_included

Type: string scalar character vector

Values: "on" | "off"

Default: "on"

Enable assertion — Enable or disable check

on (default) | off

Clearing this parameter disables the block and causes the model to behave as if the block does not exist. To enable or disable all verification blocks, regardless of the setting of this option, go to the Configuration Parameters window, click **Diagnostics > Data Validity**, expand the **Advanced parameters** section, and set **Model Verification block enabling** to **Enable all** or **Disable all**.

Programmatic Use

Parameter: enabled

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

"" (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Dependencies

To enable this parameter, select the **Enable assertion** parameter.

Programmatic Use

Parameter: callback

Type: string scalar or character vector

Default: ""

Stop simulation when assertion fails — Whether to stop simulation when check fails

on (default) | off

Select this parameter to stop the simulation when the check fails. Clear this parameter to display a warning and continue the simulation.

Programmatic Use

Parameter: stopWhenAssertionFail

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Output assertion signal — Create output signal

off (default) | on

Select this parameter to enable the output port.

Programmatic Use

Parameter: export

Type: string scalar or character vector

Values: "on" | "off"

Default: "off"

Select icon type — Select icon type

graphic (default) | text

Specify the style of the block icon. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition.

Programmatic Use

Parameter: icon

Type: string scalar or character vector

Values: "graphic" | "text"

Default: "graphic"

Introduced before R2006a

Check Static Range

Check that signal falls inside fixed range of amplitudes

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Static Range block checks that each element of the input signal falls inside the same range of amplitudes at each time step. The **Upper bound** and **Lower bound** parameters define the upper and lower bounds of the range. The block then executes an assertion after comparison. If the signal falls inside the bounds, the assertion is `true` (1) and the block does nothing. If not, the block halts the simulation and returns an error message by default.

The input signal and bounds can be scalars, vectors, or matrices. All three must be the same data type. The block compares the value of the input to the bounds differently depending on the signal.

- When comparing scalars to vectors or matrices, the block compares the scalar to each element of the non-scalar input signal or bounds.
- When comparing vectors or matrix signals to other vectors or matrices, the block compares the input signal to the bounds element-by-element.
- For models with more than one vector or matrix input signal or bounds, the vectors or matrices must have the same dimensions.

Ports

Input

Port_1 — Input signal checked against range

scalar | vector | matrix

Input signal checked against the range specified by the **Upper bound** and **Lower bound** parameters.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Assertion output signal

scalar

Output signal that is `true` (1) if the assertion succeeds, and `false` (0) if the assertion fails. If, in the Configuration Parameters window, in the **Math and Data Types** section, under **Advanced parameters**, you select **Implement logic signals as Boolean data**, then the output data type is Boolean. Otherwise, the data type of the signal is double.

Dependencies

To enable this output port, set the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters**Upper bound — Upper bound compared to input signal**

scalar | vector | matrix

Specify the upper bound on the range of amplitudes that the input signal can have.

Programmatic Use

Parameter: max

Type: string scalar or character vector

Default: "0"

Inclusive upper boundary — Include the upper bound in range

on (default) | off

Select this check box to make the range of valid input amplitudes include the lower bound.

Programmatic Use

Parameter: min_included

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Lower bound — Lower bound compared to input signal

scalar | vector | matrix

Specify the lower bound on the range of amplitudes that the input signal can have.

Programmatic Use

Parameter: min

Type: string scalar or character vector

Default: "0"

Inclusive lower bound — Include the lower bound in range

on (default) | off

Select this check box to make the range of valid input amplitudes include the lower bound.

Programmatic Use

Parameter: min_included

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Enable assertion — Enable or disable check

on (default) | off

Clearing this parameter disables the block and causes the model to behave as if the block does not exist. To enable or disable all verification blocks, regardless of the setting of this option, go to the Configuration Parameters window, click **Diagnostics > Data Validity**, expand the **Advanced parameters** section, and set **Model Verification block enabling** to **Enable all** or **Disable all**.

Introduced before R2006a

Check Static Upper Bound

Check that signal is less than (or optionally equal to) static upper bound

Library: Simulink / Model Verification
HDL Coder / Model Verification

Description

The Check Static Upper Bound block checks if an input signal is less than (or optionally equal to) a specified lower bound at each time step and executes an assertion after comparison. The **Upper bound** parameter defines the upper bound. If the input signal is less than the upper bound, the assertion is `true` (1) and the block does nothing. If not, the block halts the simulation and returns an error message by default.

The input signal and bound can be scalars, vectors, or matrices. The input and the bound must be the same data type. The block compares the value of the input to the bound differently depending on the signal.

- When comparing scalars to vectors or matrices, the block compares the scalar to each element of the non-scalar input signal or bound.
- When comparing a vector or matrix signal to a vector or matrix upper bound, the block compares the input signal to the bound element-by-element.
- For models with an input signal and bound that are both vectors or matrices, the input signal and bound must have the same dimensions.

Ports

Input

Port_1 — Input signal checked against bound

scalar | vector | matrix

Input signal checked against the upper bound specified by the **Upper bound** parameter.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Assertion output signal

scalar

Output signal that is `true` (1) if the assertion succeeds and `false` (0) if the assertion fails. If, in the Configuration Parameters window, in the **Math and Data Types** section, under **Advanced parameters**, you select **Implement logic signals as Boolean data**, then the output data type is Boolean. Otherwise, the data type of the signal is double.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Upper bound — Upper boundary value

scalar | vector | matrix

Specify the upper bound on the range of amplitudes that the input signal can have.

Programmatic Use

Parameter: max

Type: string scalar or character vector

Default: "0"

Inclusive boundary — Include the upper bound in range

on (default) | off

Select this check box to make the range of valid input amplitudes include the upper bound.

Programmatic Use

Parameter: max_included

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Enable assertion — Enable or disable check

on (default) | off

Clearing this parameter disables the block and causes the model to behave as if the block does not exist. To enable or disable all verification blocks, regardless of the setting of this option, go to the Configuration Parameters window, click **Diagnostics > Data Validity**, expand the **Advanced parameters** section, and set **Model Verification block enabling** to **Enable all** or **Disable all**.

Programmatic Use

Parameter: enabled

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

"" (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Dependencies

To enable this parameter, select the **Enable assertion** parameter.

Programmatic Use

Parameter: callback

Type: string scalar or character vector

Default: ""

Stop simulation when assertion fails — Whether to stop simulation when check fails

on (default) | off

Select this parameter to stop the simulation when the check fails. Clear this parameter to display a warning and continue the simulation.

Programmatic Use

Parameter: stopWhenAssertionFail

Type: string scalar or character vector

Values: "on" | "off"

Default: "on"

Output assertion signal — Create output signal

off (default) | on

Select this parameter to enable the output port.

Programmatic Use

Parameter: export

Type: string scalar or character vector

Values: "on" | "off"

Default: "off"

Select icon type — Select icon type

graphic (default) | text

Specify the style of the block icon. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition.

Programmatic Use

Parameter: icon

Type: string scalar or character vector

Values: "graphic" | "text"

Default: "graphic"

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single

Introduced before R2006a

Chirp Signal

Generate sine wave with increasing frequency

Library: Simulink / Sources

Description

The Chirp Signal block generates a sine wave whose frequency increases at a linear rate with time. You can use this block for spectral analysis of nonlinear systems. The block generates a scalar or vector output.

The parameters, **Initial frequency**, **Target time**, and **Frequency at target time**, determine the block's output. You can specify any or all of these variables as scalars or arrays. All the parameters specified as arrays must have the same dimensions. The block expands scalar parameters to have the same dimensions as the array parameters. The block output has the same dimensions as the parameters unless you select the **Interpret vector parameters as 1-D** check box. If you select this check box and the parameters are row or column vectors, the block outputs a vector (1-D array) signal.

Limitations

- The start time of the simulation must be 0. To confirm this value, go to the **Solver** pane in the Configuration Parameters dialog box and view the **Start time** field.
- Suppose that you use a Chirp Signal block in an enabled subsystem. Whenever the subsystem is enabled, the block output matches what would appear if the subsystem were enabled throughout the simulation.

Ports

Output

Port_1 – Chirp signal

scalar | vector | matrix | N-D array

Sine wave whose frequency increases at a linear rate with time. The chirp signal can be a scalar, vector, matrix, or N-D array.

Data Types: double

Parameters

Initial frequency – Initial frequency (Hz)

0.1 (default) | scalar | vector | matrix | N-D array

The initial frequency of the signal, specified as a scalar, vector, matrix, or N-D array.

Programmatic Use**Block Parameter:** f1**Type:** character vector**Values:** scalar | vector | matrix | N-D array**Default:** '0.1'**Target time — Target time (seconds)**

100 (default) | scalar | vector | matrix | N-D array

Time, in seconds, at which the frequency reaches the **Frequency at target time** parameter value. You specify the **Target time** as a scalar, vector, matrix, or N-D array. After the target time is reached, the frequency continues to change at the same rate.

Programmatic Use**Block Parameter:** T**Type:** character vector**Values:** scalar | vector | matrix | N-D array**Default:** '100'**Frequency at target time — Frequency (Hz)**

1 (default) | scalar | vector | matrix | N-D array

Frequency, in Hz, of the signal at the target time, specified as a scalar, vector, matrix, or N-D array.

Programmatic Use**Block Parameter:** f2**Type:** character vector**Values:** scalar | vector | matrix | N-D array**Default:** '1'**Interpret vector parameters as 1-D — Treat vector parameters as 1-D**

on (default) | off

When you select this check box, any column or row matrix values you specify for the **Initial frequency**, **Target time**, and **Frequency at target time** parameters result in a vector output whose elements are the elements of the row or column. For more information, see “Determine the Output Dimensions of Source Blocks”.

Programmatic Use**Block Parameter:** VectorParams1D**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Block Characteristics**

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no

Zero-Crossing Detection	no
--------------------------------	----

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Circular Gauge

Display signal value during simulation on circular gauge with customizable appearance

Library: Simulink / Dashboard / Customizable Blocks

Description

The Circular Gauge block displays the value of the connected signal on a circular gauge that you can design to look like a gauge in a real system.

The Circular Gauge block displays the instantaneous value of the connected signal throughout simulation. You can modify the range and tick values on the Circular Gauge block to fit your data. Use the Circular Gauge block with other dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Customize Circular Gauge Blocks

When you add a Circular Gauge block to your model, the block is preconfigured with a default design. You can use the block with the default design or customize the appearance of the block using design mode. You can enter design mode in one of three ways after selecting the block:

- On the **Gauge** tab, under **Design**, click **Edit**.
- In the **Property Inspector**, on the **Design** tab, click **Edit**.
- Pause on the ellipsis that appears over the block and click the **Edit Custom Block** button.

Design mode gives you access to block parameters and settings that allow you to customize the appearance of the block. You can use the toolbar above the block to change the background image or needle image and to set the color and opacity of the gauge scale, tick labels, and value bar. To design the appearance of the scale, select the aspect of the scale you want to edit in the middle section of the toolbar. Use the controls on the right of the toolbar to set the color and opacity.

You can also click and drag to reposition the scale and needle. The movement of the needle is limited to the radial line that goes from the center of the block to the minimum value on the scale. You can adjust the angle of the scale arc and the scale size by clicking and dragging the grab points highlighted in design mode.

For fine control over the design of the Circular Gauge block, use the **Design** tab in the **Property Inspector**. You can use the **Property Inspector** to enter exact values for design settings. The **Design** tab also includes design parameters that are not available through the toolbar or interactive editing, such as the ability to add a foreground image to the block.

When you finish designing the gauge, click **Exit** in the upper-right of the canvas to exit design mode.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, select a dashboard block to connect. Then, on the block tab, click **Connect**. In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- You cannot connect a dashboard block to state activity or chart data in Stateflow during simulation.
- You cannot programmatically connect a dashboard block to state activity or chart data in Stateflow.

- Some signals do not have data available during simulation due to block reduction or optimization for accelerator mode simulations. To view such a signal using a dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the Maximum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Tick Interval — Interval between major tick marks

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to auto, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the Tick Interval parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the auto value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Scale Colors — Color indications on gauge scale**

colors for scale ranges

Color specifications for value ranges on the scale. Press the + button to add a scale color. For each color added, specify the minimum and maximum values of the range in which you want to display that color.

Programmatic Use

To programmatically specify the Scale Colors parameter, use an array of structures with the fields:

- Min — Minimum value for the color range on the scale
- Max — Maximum value for the color range on the scale
- Color — 1-by-3 vector of double values between 0 and 1 that specify the color for the range in the form [r g b]

Include a structure in the array for each scale range for which you want to specify a color.

```
range1.Min = 0;  
range1.Max = 10;  
range1.Color = [0 0 1];  
range2.Min = 10;  
range2.Max = 15;  
range2.Color = [0 1 0];  
scaleRanges = [range1 range2];
```

Block Parameter: ScaleColors**Type:** structure array**Default:** 0x1 struct array**Lock Aspect Ratio — Option to maintain block aspect ratio**

on (default) | off

Turn on this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tips

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.

- When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Scale Direction — Direction of increasing scale values

Clockwise (default) | Counterclockwise

Set the direction of increasing scale values.

Programmatic Use

Block Parameter: ScaleDirection

Type: character vector

Values: 'Clockwise' | 'Counterclockwise'

Default: 'Clockwise'

Opacity — Block background opacity

1 (default) | scalar

Block background opacity, specified as a scalar value between 0 and 1. Specify the background opacity using the **Design** tab in the Property Inspector.

- 1 On the **Design** tab, click **Edit Design**.
- 2 Select the **Background** component.
- 3 In the **Background Color** section, specify the desired opacity.

Example: 0.5

Programmatic Use

Block Parameter: Opacity

Type: scalar

Default: 1

Foreground Color — Block foreground color

[r g b] vector

Block foreground color, excluding the text. The **Foreground Color** applies to the scale and the block name. To specify the color for the block text, use the **Font Color**.

Specify the **Foreground Color** for the block using the **Design** tab in the Property Inspector.

- 1 On the **Design** tab, click **Edit Design**.
- 2 Select the **Scale** component.

- 3 In the **Ticks** section, open the **Color** menu. You can choose from the palette of standard colors or specify a custom color.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 `[r g b]` vector with values between 0 and 1.

Block Parameter: `ForegroundColor`

Type: character vector | string

Values: `[r g b]` vector

Background Color — Block background color

`[r g b]` vector

Block background color. You can choose to select a solid background color instead of providing a background image. To design a block that uses a solid background, use the **Design** tab in the Property Inspector.

- 1 On the **Design** tab, click **Edit Design**.
- 2 Select the **Background** component.
- 3 Select **Use background color**.
- 4 Choose a background color from the palette of standard colors or specify a custom color.
- 5 Adjust the **Offset from scale** option until the solid background is the desired size.

Changing the background color using the toolbar removes the background image and enables the **Use background color** option.

When you use a solid background with the Circular Gauge block, you can design noncircular gauges. When the scale arc angle is 180° or smaller, the background shape conforms to the scale.

**Programmatic Use**

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 `[r g b]` vector with values between 0 and 1.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: `[r g b]` vector

Font Color — Block font color

`[r g b]` vector

Block font color. The **Font Color** applies to the scale labels. To specify the color of the scale, use the **Foreground Color**.

Specify the **Font Color** for the block using the **Design** tab in the Property Inspector.

- 1 On the **Design** tab, click **Edit Design**.
- 2 Select the **Scale** component.
- 3 In the **Labels** section, open the **Color** menu. You can choose from the palette of standard colors or specify a custom color.

Clock

Display and provide simulation time

Library: Simulink / Sources

Description

The Clock block outputs the current simulation time at each simulation step. This block is useful for other blocks that need the simulation time.

When you need the current time within a discrete system, use the Digital Clock block.

Ports

Output

Port_1 — Sample time

scalar

Sample time, specified as the current simulation time at each simulation time step.

Data Types: `double`

Parameters

Display time — Display simulation time on block icon

`off` (default) | `on`

Select this check box to display the simulation time as part of the Clock block icon. When you clear this check box, the simulation time does not appear on the block icon.

Programmatic Use

Block Parameter: `DisplayTime`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Decimation — Interval at which to update block icon

`10` (default) | positive integer

Specify the interval at which Simulink updates the Clock icon as a positive integer.

Suppose that the decimation is 1000. For a fixed integration step of 1 millisecond, the Clock icon updates at 1 second, 2 seconds, and so on.

Dependencies

To display the simulation time on the block icon, you must select the **Display time** check box.

Programmatic Use**Block Parameter:** Decimation**Type:** character vector**Value:** scalar**Default:** '10'**Block Characteristics**

Data Types	double
Direct Feedthrough	no

Combinatorial Logic

Implement truth table

Library: Simulink / Logic and Bit Operations

Description

The Combinatorial Logic block implements a standard truth table for modeling programmable logic arrays (PLAs), logic circuits, decision tables, and other Boolean expressions. You can use this block in conjunction with Memory blocks to implement finite-state machines or flip-flops.

Ports

Input

Port_1 — Input signal

vector

Input signal, specified as a vector. The type of signals accepted by a Combinatorial Logic block depends on whether you selected the Boolean logic signals option (see “Implement logic signals as Boolean data (vs. double)”). If this option is enabled, the block accepts real signals of type `Boolean` or `double`.

Data Types: `double` | `Boolean`

Output

Port_2 — Output signal

scalar | vector

Output signal, `double` if the truth table contains non-Boolean values of type `double`; `Boolean` otherwise. The type of the output is the same as that of the input except that the block outputs `double` if the input is `Boolean` and the truth table contains non-Boolean values.

Data Types: `double` | `Boolean`

Parameters

Truth table — Matrix of outputs

matrix

You specify a matrix that defines all possible block outputs as the **Truth table** parameter. Each row of the matrix contains the output for a different combination of input elements. You must specify outputs for every combination of inputs. The number of columns is the number of block outputs.

The **Truth table** parameter can have Boolean values (0 or 1) of any data type, including fixed-point data types. If the table contains non-Boolean values, the data type of the table must be `double`.

The relationship between the number of inputs and the number of rows is:

$$\text{number of rows} = 2^{(\text{number of inputs})}$$

Simulink returns a row of the matrix by computing the row's index from the input vector elements. Simulink computes the index by building a binary number where input vector elements having zero values are 0 and elements having nonzero values are 1, then adding 1 to the result. For an input vector, u , of m elements:

$$\text{row index} = 1 + u(m) \cdot 2^0 + u(m-1) \cdot 2^1 + \dots + u(1) \cdot 2^{m-1}$$

Programmatic Use

Block Parameter: TruthTable

Type: character vector

Values: matrix

Default: '[0 0;0 1;0 1;1 0;0 1;1 0;1 0;1 1]'

Block Characteristics

Data Types	Boolean double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Combo Box

Select parameter value from drop-down menu

Library: Simulink / Dashboard

Description

The Combo Box block lets you set the value of a parameter to one of several values. You can define each selectable value and its label through the Combo Box block parameters. Use the Combo Box block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Double-clicking the Combo Box block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

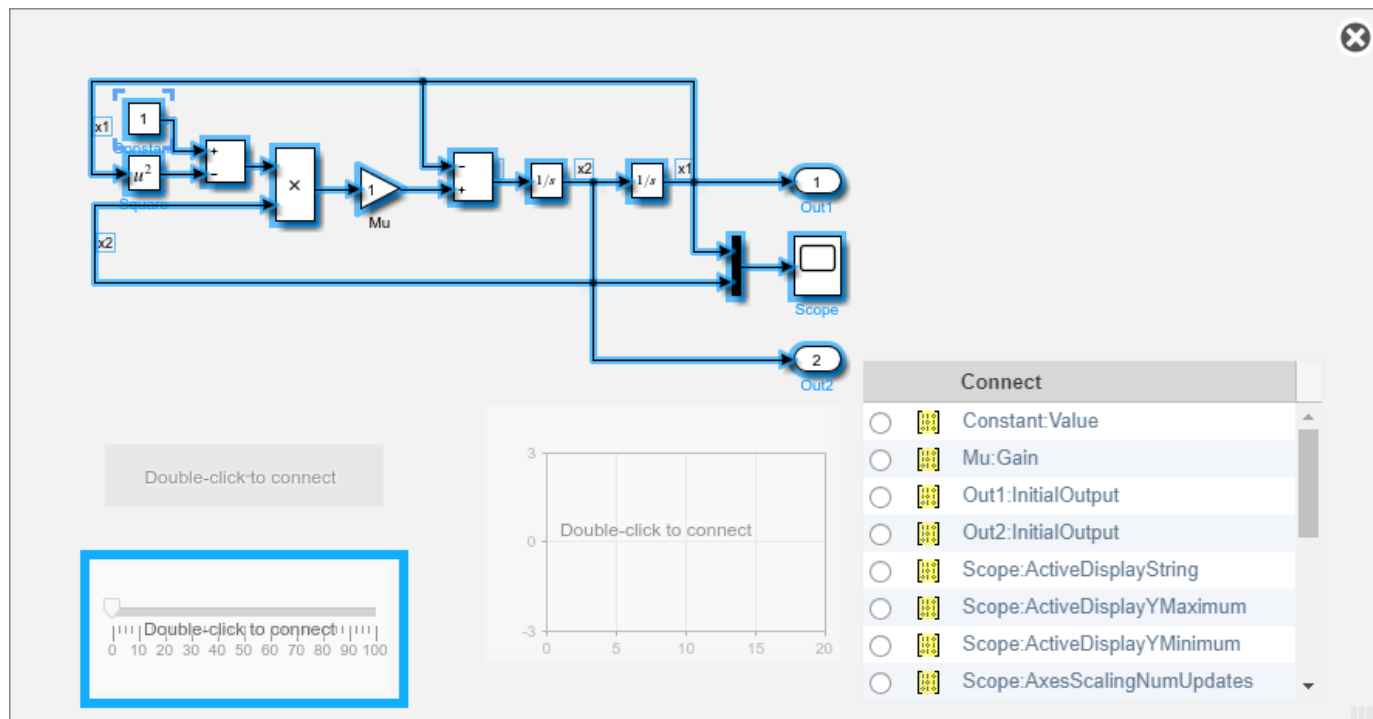

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, select the block. Then, on the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect

mode, the dashboard block does not display the connected value until the you uncomment the block.

- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection

Connection — Select a variable or block parameter to connect

variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify `a.b` to connect to scalar element `b` of the structure or bus `a` nested inside the selected composite variable or parameter.

- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding**Type:** Simulink.HMI.ParamSourceInfo**Default:** []**Main****Enumerated Data Type — Specify state values and labels using an enumerated data type**

off (default) | on

You can use an enumerated data type that pairs a numeric value with each enumeration to configure the state values and labels for the block. To specify the states for the block using an enumerated data type, first select the **Enumerated Data Type** option. Then, specify the name of the enumerated data type in the text box. The definition for the specified enumerated data type must be saved on the MATLAB path or in the base workspace.

Example: myEnumType

Programmatic Use

To programmatically specify the state labels and values for the block using an enumerated data type, specify 'on' for the UseEnumeratedDataType parameter and the name of the enumerated data type for the EnumeratedDataType parameter.

Block Parameter: UseEnumeratedDataType**Type:** string or character array**Values:** 'on' | 'off'**Default:** 'off'**Block Parameter:** EnumeratedDataType**Type:** string or character array**Default:** ''**Label — Block label position**

Hide (default) | Bottom | Top

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use**Block Parameter:** LabelPosition**Type:** character vector**Values:** 'Hide' | 'Bottom' | 'Top'**Default:** 'Hide'**States — Set of states to select for connected parameter**

scalar and character vector

Set of states from which to select a value for the connected parameter. Each **State** consists of a **State Value** and a **State Label**.

- **State Value** — Value assigned to the connected variable or parameter when you select the state with the corresponding **Label**.
- **State Label** — Label for each state. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the bottom, or you can enter a descriptive text label.

Click the + button to add additional **States**.

The default configuration for the block includes these **States**.

States

State Value	State Label
0	Label1
1	Label2
2	Label3

Programmatic Use

To programmatically configure the **States** for a block, use an array of structures containing the fields **Value** and **Label**. Include a structure in the array for each state you want to configure on the block.

```
state1.Value = 1;
state1.Label = 'State 1';
state2.Value = 2;
state2.Label = 'State 2';
radioStates = [state1 state2];
```

Block Parameter: States

Type: structure

Default: 3x1 structure array

Format

Opacity — Block background opacity

1 (default) | scalar

Block background opacity, specified as a scalar value between 0 and 1.

Example: 0.5

Programmatic Use

Block Parameter: Opacity

Type: scalar

Default: 1

ForegroundColor — Block foreground color

[r g b] vector

Block foreground color, including the text. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the **ForegroundColor** parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: ForegroundColor

Type: character vector | string

Values: [r g b] vector

BackgroundColor — Block background color

[r g b] vector

Block background color. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: [r g b] vector

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Compare To Constant

Determine how signal compares to specified constant

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Compare To Constant block compares an input signal to a constant. Specify the constant in the **Constant value** parameter. Specify how the input is compared to the constant value with the **Operator** parameter.

Ports

Input

Port_1 — Input signal

scalar

Input signal, specified as a scalar, is compared with zero. The block first converts its **Constant value** parameter to the input data type, and then performs the specified operation.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Output signal

0 | 1

The output is 0 if the comparison is false, and 1 if it is true.

Data Types: uint8 | Boolean

Parameters

Operator — Logical operator

<= (default) | == | ~= | < | >= | >

This parameter can have these values:

- == — Determine whether the input is equal to the specified constant.
- ~= — Determine whether the input is not equal to the specified constant.
- < — Determine whether the input is less than the specified constant.
- <= — Determine whether the input is less than or equal to the specified constant.

- > — Determine whether the input is greater than the specified constant.
- >= — Determine whether the input is greater than or equal to the specified constant.

Programmatic Use**Block Parameter:** relop**Type:** character vector**Values:** '==' | '~=' | '<' | '<=' | '>=' | '>'**Default:** '<='**Constant value — Constant to compare with**

constant

Specify the constant value to which the input is compared.

Programmatic Use**Block Parameter:** const**Type:** character vector**Value:** scalar | vector | matrix | N-D array**Default:** '3.0'**Output data type — Data type of the output**

boolean (default) | uint8

Specify the data type of the output, boolean or uint8.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector**Values:** 'boolean' | 'uint8'**Default:** 'boolean'**Enable zero-crossing detection — Select to enable zero-crossing detection**

'on' (default) | 'off'

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use**Block Parameter:** ZeroCross**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'**Block Characteristics**

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes

Zero-Crossing Detection	yes
--------------------------------	-----

Extended Capabilities

C/C++ Code Generation

Compare To Zero | Logical Operator | Combinatorial Logic

Introduced before R2006a

Compare To Zero

Determine how signal compares to zero

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Compare To Zero block compares an input signal to zero. Specify how the input is compared to zero with the **Operator** parameter.

The output is 0 if the comparison is false, and 1 if it is true.

Ports

Input

Port_1 — Input signal

scalar

Input signal, specified as scalar, is compared with zero. If the input data type cannot represent zero, parameter overflow occurs. To detect this overflow, go to the **Diagnostics > Data Validity** pane of the Configuration Parameters dialog box and set **Parameters > Detect overflow** to warning or error.

In this case, the block compares the input signal to the *ground value* of the input data type. For example, if you have an input signal of type `fixdt(0,8,2^0,10)`, the input data type can represent unsigned 8-bit integers from 10 to 265 due to a bias of 10. The ground value is 10, instead of 0.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

0 | 1

The output is 0 if the comparison is false, and 1 if it is true.

The block output is `uint8` or `boolean`, depending on your selection for the **Output data type** parameter.

Data Types: uint8 | Boolean

Parameters

Operator — Logical operator

`<=` (default) | `==` | `~=` | `<` | `>=` | `>`

This parameter can have the following values:

- `==` — Determine whether the input is equal to zero.
- `~=` — Determine whether the input is not equal to zero.
- `<` — Determine whether the input is less than zero.
- `<=` — Determine whether the input is less than or equal to zero.
- `>` — Determine whether the input is greater than zero.
- `>=` — Determine whether the input is greater than or equal to zero.

Programmatic Use

Block Parameter: `relop`

Type: character vector

Values: `'=='` | `'~='` | `'<'` | `'<='` | `'>='` | `'>'`

Default: `'<='`

Output data type — Data type of the output

`boolean` (default) | `uint8`

Specify the data type of the output, `boolean` or `uint8`.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'boolean'` | `'uint8'`

Default: `'boolean'`

Enable zero-crossing detection — Select to enable zero-crossing detection

`on` (default) | `off`

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use

Block Parameter: `ZeroCross`

Type: character vector

Values: `'off'` | `'on'`

Default: `'on'`

Block Characteristics

Complex to Magnitude-Angle

Compute magnitude and/or phase angle of complex signal

Library: Simulink / Math Operations

Description

The Complex to Magnitude-Angle block outputs the magnitude and/or phase angle of the input signal, depending on the setting of the **Output** parameter. The outputs are real values of the same data type as the block input. The input can be an array of complex signals, in which case the output signals are also arrays. The magnitude signal array contains the magnitudes of the corresponding complex input elements. The angle output similarly contains the angles of the input elements.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

Complex input signal that the block computes and outputs the magnitude and/or the phase angle.

Data Types: single | double

Output

Port_1 – Output signal

scalar | vector | matrix

Output signal that is the magnitude and/or phase angle of the input signal. To choose the output, set the **Output** parameter.

Data Types: single | double

Parameters

Output – Magnitude and/or phase angle output specification

Magnitude and angle (default) | Magnitude | Angle

Specify if the output is the magnitude and/or the phase angle in radians of the input signal.

Command-Line Information

Parameter: Output

Type: character vector

Values: 'Magnitude and angle' | 'Magnitude' | 'Angle'

Default: 'Magnitude and angle'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Block Characteristics**

Data Types	double single

Complex to Real-Imag | Real-Imag to Complex

Introduced before R2006a

Complex to Real-Imag

Output real and imaginary parts of complex input signal

Library: Simulink / Math Operations
HDL Coder / Math Operations

Description

The Complex to Real-Imag block outputs the real and/or imaginary part of the input signal, depending on the setting of the **Output** parameter. The real outputs are of the same data type as the complex input. The input can be an array (vector or matrix) of complex signals, in which case the output signals are arrays of the same dimensions. The real array contains the real parts of the corresponding complex input elements. The imaginary output similarly contains the imaginary parts of the input elements.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Complex input signal that the block computes and outputs the real and/or imaginary part.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output signal that is the real and/or imaginary part of the input signal. To choose which part is output, set the **Output** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Output — Real and/or imaginary output specification

Real and imag (default) | Real | Imag

Specify if the output is the real and/or imaginary part of the input signal.

Command-Line Information**Parameter:** Output**Type:** character vector**Values:** 'Real and imag' | 'Real' | 'Imag'**Default:** 'Real and imag'**Sample time — Sample time value other than -1**

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

Compose String

Compose output string signal based on specified format and input signals

Library: Simulink / String

Description

The Compose String block composes output string signal based on the format specifier listed in the **Format** parameter. The **Format** parameter determines the number of input signals. If there are multiple inputs, the block constructs the string by combining these multiple inputs in order, and applying the associated format specifier, one format specifier for each input. Each format specifier starts with a percent sign, %, followed by the conversion character. For example, %f formats the input as a floating point output. To supplement the string output, you can also add a character to the format specification. Use this block to compose and format an output string signal from a multiple inputs.

For example, if the **Format** parameter contains "%s is %f", the block expects two inputs, a string signal and a single or double signal. If the first input is the string "Pi" and the second input is a double value 3.14, the output is "Pi is 3.14".

When a MinGW® compiler compiles code generated from the block, running the compiled code may produce nonstandard results for floating-point inputs. For example, a numeric input of 501.987 returns the string "5.019870e+002" instead of the expected string "5.019870e+02".

Ports

Input

d — Data for first part of string

scalar

Data for the first part of string, specified as a scalar. The **Format** parameter determines the port label and the format of the input data. For example, if the first item in the **Format** parameter is %d, the port label is d.

The data type of the input signal must be compatible with the format specifier in the **Format** parameter. For more information, see the **Format** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

f — Data for second part of string

scalar

Data for the second part of string, specified as a scalar. The **Format** parameter determines the port label and the format of the input data. For example, if the first item in the **Format** parameter is %f, the port label is f.

The data type of the input signal must be compatible with the format specifier specified in the **Format** parameter. For more information, see the **Format** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Port_N — Data for N parts of string

`scalar` (default)

Data for N parts of string, specified as a scalar. The **Format** parameter determines the port label and the format of the input data. For example, if the corresponding item in the **Format** parameter is `%f`, the port label is `f`.

The data type of the input signal must be compatible with the format specifier in the **Format** parameter. For more information, see the **Format** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

str — Output string

`scalar`

Output string composed of inputs, specified as a scalar.

Data Types: `string`

Parameters

Format — Format input data

`"%d %f"` (default) | `scalar`

Format of input data, specified as a scalar.

For more information about acceptable format specifiers, see the Algorithms section.

Output data type — Output data type

`string` (default) | `<data type expression>` | `scalar`

Output data type, specified using the string data type to specify a string with no maximum length.

To specify a string data type with a maximum length, specify `stringtype(N)`. For example, `stringtype(31)` creates a string data type with a maximum length of 31 characters.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Block Characteristics

Data Types	<code>double</code> <code>integer</code> <code>single</code> <code>string</code>
Direct Feedthrough	<code>yes</code>
Multidimensional Signals	<code>no</code>

Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

A formatting specifier starts with a percent sign, %, and ends with a conversion character. The conversion character is required. Optionally, you can specify identifier, flags, field width, precision, and subtype specifiers between % and the conversion character. (Spaces are invalid between specifiers and are shown here only for readability).

The Compose String block uses this format specifier prototype:

```
%[flags][width][.precision][length]specifier
```

Conversion Character

This table shows conversion characters to format numeric and character data as text.

Value Type	Conversion	Details
Integer, signed	%d or %i	Base 10
Integer, unsigned	%u	Base 10
	%o	Base 8 (octal)
	%x	Base 16 (hexadecimal), lowercase letters a-f
	%X	Same as %x, uppercase letters A-F
Floating-point number	%f	Floating-point notation (Use a precision operator to specify the number of digits after the decimal point.)
	%e	Exponential notation, such as 3.141593e+00 (Use a precision operator to specify the number of digits after the decimal point.)
	%E	Same as %e, but uppercase, such as 3.141593E+00 (Use a precision operator to specify the number of digits after the decimal point.)
	%g	The more compact of %e or %f, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
	%G	The more compact of %E or %f, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
String	%s	The type of the output text is the same as the type of Format .

Optional Operators

The optional identifier, flags, field width, precision, and operators further define the format of the output text.

- **Flags**

'-'	Left-justify. Works with all specifiers. Example: %-5.2f Example: %-10s
'+'	Always print a sign character (+ or -) for any numeric value. Works with all specifiers except u, o, x, X, and s. Example: %+5.2f Right-justify text. Example: %+10s
' '	Insert a space before the value. Works with all specifiers except u, o, x, X, and s. Example: % 5.2f
'0'	Pad to field width with zeros before the value. Works with all specifiers except s. Example: %05.2f
'#'	Modify selected numeric conversions: <ul style="list-style-type: none"> • For %o, %x, or %X, print 0, 0x, or 0X prefix. • For %f, %e, or %E, print decimal point even when precision is 0. • For %g or %G, do not remove trailing zeros or decimal point. Works with all specifiers except d, i, u, and s. Example: %#5.0f

- **Field Width**

Minimum number of characters to print.

The function pads to field width with spaces before the value unless otherwise specified by flags.

- **Precision**

For %f, %e, or %E	Number of digits to the right of the decimal point Example: "%.4f" prints pi as '3.1416'
d, i, o, u, x, X	Minimum number of digits to be written. Outputs shorter than the specified precision are padded with leading zeros. Example: "%.4d" prints 5 as '0005'
For %g or %G	Number of significant digits Example: "%.4g" prints pi as '3.142'
s	Maximum number of characters to be written to the output. Example: "%.2s" prints "Hello!" as "He"

Note If you specify a precision operator for floating-point values that exceeds the precision of the input numeric data type, the results might not match the input values to the precision you specified. The result depends on your computer hardware and operating system.

Text Before or After Formatting Operators

Special Character	Representation
Single quotation mark	' '
Percent character	%%
Backslash	\\
Alarm	\a
Backspace	\b
Form feed	\f
New line	\n
Carriage return	\r
Horizontal tab	\t
Vertical tab	\v
Character whose Unicode® numeric value can be represented by the hexadecimal number, N	\xN Example: <code>printf('\x5A')</code> returns 'Z'
Character whose Unicode numeric value can be represented by the octal number, N	\N Example: <code>printf('\132')</code> returns 'Z'

Format can also include additional text before a percent sign, %, or after a conversion character. The text can be:

- Ordinary text to print.
- Special characters that you cannot enter as ordinary text. This table shows how to represent special characters in `formatSpec`.

Length Specifiers

The Format String block supports the `h` and `l` length subspecifiers. These specifiers can change according to the **Configuration Parameters > Hardware Implementation > Number of bits** settings

Length	<code>d i</code>	<code>u o x X</code>	<code>f e E g G</code>	<code>s</code>
No length specifier	<code>int</code>	<code>unsigned int</code>	<code>double (default), single</code>	<code>string</code>
<code>h</code>	<code>short</code>	<code>unsigned short</code>	—	—
<code>l</code>	<code>long</code>	<code>unsigned long</code>	—	—

Note for Specifiers that Specify Integer Data Types (`d`, `i`, `u`, `o`, `x`, `X`)

Target `int`, `long`, and `short` type sizes are controlled by settings in the **Configuration Parameters > Hardware Implementation** pane. For example, if the target `int` is 32 bits and the specifier is `%u`, then the expected input type will be `uint32`. However, the input port accepts any built-in integer type of that size or smaller with the `%u` specifier

Notes for Specifiers that Specify Floating Point Data Types (f, e, E, g, F)

- Do not use `l` and `h` with these specifiers. Do not use the length subspecifier (for example, `%f` is allowed, but `%hf` and `%lf` are not allowed).
- Ports that correspond with these specifiers accept both single and double data types.

Note for Specifiers that Specify the String Data Type (s)

- The `s` specifier does not work with the `l` or `h` subspecifiers, and only accepts a string input data type.

Introduced in R2018a

Configurable Subsystem

Represent any block selected from user-specified library of blocks

Library: Simulink / Ports & Subsystems

Description

Note Configurable Subsystem block will be removed in a future release. It is recommended to use Variant Subsystem instead of Configurable Subsystem. Variant Subsystems offer more capabilities than Configurable Subsystems with these advantages:

- You can mix Model blocks and Subsystem blocks as variant choices.
- You can specify variants that have different numbers of input and output ports.

For more information on converting Configurable Subsystem block to a Variant Subsystem block, see “Convert Configurable Subsystem to Variant Subsystem”.

For more information on Variant Subsystem, see Variant Subsystem, Variant Model.

If your model contains a Configurable Subsystem block, you will see a warning message. To change the warning message to an error message set the string command line parameter `ConfigurableSubsystemUsage` to `error`.

```
set_param(bdroot, 'ConfigurableSubsystemUsage', 'error');
```

To revert it to a warning, set the `ConfigurableSubsystemUsage` to `warning`.

The Configurable Subsystem block represents one of a set of blocks contained in a specified library of blocks. The context menu of the Configurable Subsystem block lets you choose which block the configurable subsystem represents.

Configurable Subsystem blocks simplify creation of models that represent families of designs. For example, suppose that you want to model an automobile that offers a choice of engines. To model such a design, you would first create a library of models of the engine types available with the car. You would then use a Configurable Subsystem block in your car model to represent the choice of engines. To model a particular variant of the basic car design, a user need only choose the engine type, using the configurable engine block's dialog box.

To create a configurable subsystem in a model, you must first create a library containing a master configurable subsystem and the blocks that it represents. You can then create configurable instances of the master subsystem by dragging copies of the master subsystem from the library and dropping them into models.

You can add any type of block to a master configurable subsystem library. Simulink derives the port names for the configurable subsystem by making a unique list from the port names of all the choices. However, Simulink uses default port names for non-subsystem block choices.

You cannot break library links in a configurable subsystem because Simulink uses those links to reconfigure the subsystem when you choose a new configuration. Breaking links would be useful only if you do not intend to reconfigure the subsystem. In this case, you can replace the configurable subsystem with a nonconfigurable subsystem that implements the permanent configuration.

Creating a Master Configurable Subsystem

To create a master configurable subsystem:

- 1 Create a library of blocks representing the various configurations of the configurable subsystem.
- 2 Save the library.
- 3 Create an instance of the Configurable Subsystem block in the library.

To do so, drag a copy of the Configurable Subsystem block from the Simulink Ports & Subsystems library into the library you created in the previous step.

- 4 Display the Configurable Subsystem block dialog box by double-clicking it. The dialog box displays a list of the other blocks in the library.
- 5 Under **List of block choices** in the dialog box, select the blocks that represent the various configurations of the configurable subsystems you are creating.
- 6 To apply the changes and close the dialog box, click the **OK** button.
- 7 Select **Block Choice** from the context menu of the Configurable Subsystem block.

The context menu displays a submenu listing the blocks that the subsystem can represent.

- 8 Select the block that you want the subsystem to represent by default.
- 9 Save the library.

Note If you add or remove blocks from a library, you must recreate any Configurable Subsystem blocks that use the library.

If you modify a library block that is the default block choice for a configurable subsystem, the change does not immediately propagate to the configurable subsystem. To propagate this change, do one of the following:

- Change the default block choice to another block in the subsystem, then change the default block choice back to the original block.
- Recreate the configurable subsystem block, including the selection of the updated block as the default block choice.

If a configurable subsystem in your model contains a broken link to a library block, editing the link and saving the model does not fix the broken link the next time you open the model. To fix a broken library link in your configurable subsystem, use one of the following approaches.

- Convert the configurable subsystem to a variant subsystem. Right-click the configurable subsystem, and select **Subsystem and Model Reference > Convert Subsystem to > Variant Subsystem**.
- Remove the library block from the master configurable subsystem library, add the library block back to the master configurable subsystem library, and then resave the master configurable subsystem library.

Creating an Instance of a Configurable Subsystem

To create an instance of a configurable subsystem in a model:

- 1 Open the library containing the master configurable subsystem.
- 2 Drag a copy of the master into the model.
- 3 Select **Block Choice** from the context menu of that Configurable Subsystem instance.
- 4 Select the block that you want the configurable subsystem to represent.

The instance of the configurable system displays the icon and parameter dialog box of the block that it represents.

Setting Instance Block Parameters

As with other blocks, you can use the parameter dialog box of a configurable subsystem instance to set its parameters interactively and the `set_param` command to set the parameters from the MATLAB command line or in a MATLAB file. If you use `set_param`, you must specify the full path name of the configurable subsystem's current block choice as the first argument of `set_param`, for example:

```
curr_choice = get_param('mymod/myconfigsys', 'BlockChoice');
curr_choice = ['mymod/myconfigsys/' curr_choice];
set_param(curr_choice, 'MaskValues', ...);
```

Mapping I/O Ports

A configurable subsystem displays a set of input and output ports corresponding to input and output ports in the selected library. Simulink uses the following rules to map library ports to Configurable Subsystem block ports:

- Map each uniquely named input/output port in the library to a separate input/output port of the same name on the Configurable Subsystem block.
- Map all identically named input/output ports in the library to the same input/output ports on the Configurable Subsystem block.
- Terminate any input/output port not used by the currently selected library block with a Terminator/Ground block.

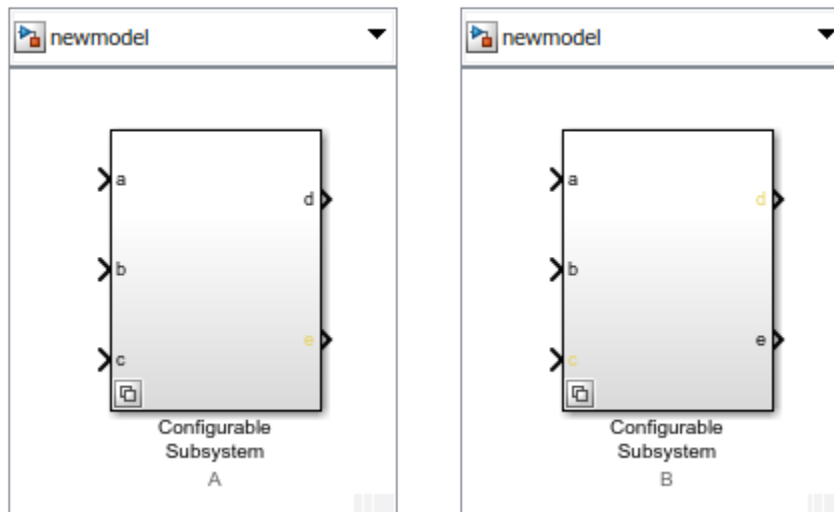

This mapping allows a user to change the library block represented by a Configurable Subsystem block without having to rewire connections to the Configurable Subsystem block.

For example, suppose that a library contains two blocks A and B and that block A has input ports labeled a, b, and c and an output port labeled d and that block B has input ports labeled a and b and an output port labeled e.

A Configurable Subsystem block based on this library would have three input ports labeled a, b, and c, respectively, and two output ports labeled d and e.

In this example, port a on the Configurable Subsystem block connects to port a of the selected library block no matter which block is selected. Port c on the Configurable Subsystem block functions only if library block A is selected. Otherwise, it simply terminates.

Note A Configurable Subsystem block does not provide ports that correspond to non-I/O ports, such as the trigger and enable ports on triggered and enabled subsystems. Thus, you cannot use a Configurable Subsystem block directly to represent blocks that have such ports. You can do so indirectly, however, by wrapping such blocks in subsystem blocks that have input or output ports connected to the non-I/O ports.

Convert to Variant Subsystem

Right-click a configurable subsystem and select **Subsystems and Model Reference > Convert Subsystem To > Variant Subsystem**.

During conversion, Simulink performs the following operations:

- Replaces the Subsystem block with a Variant Subsystem block, preserving ports and connections.
- Adds the original subsystem as a variant choice in the Variant Subsystem block.
- Overrides the Variant Subsystem block to use the subsystem that was originally the active choice.
- Preserves links to libraries. For linked subsystems, Simulink adds the linked subsystem as a variant choice.

Simulink also preserves the subsystem block masks, and it copies the masks to the variant choice.

See Variant Subsystem for more information on variant choices.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix | N-D array | bus

Input signal to the Configurable Subsystem. The block that the Configurable Subsystem represents determines the supported data types and dimensions of the input signal.

Dependencies

The number of input ports depends on the blocks in the library that the Configurable Subsystem represents. For more information, see “Mapping I/O Ports” on page 1-197.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 – Output signal

scalar | vector | matrix | N-D array | bus

Output signal from the Configurable Subsystem. The block that the Configurable Subsystem represents determines the output data types and dimensions.

Dependencies

The number of output ports depends on the blocks in the library that the Configurable Subsystem represents. For more information, see “Mapping I/O Ports” on page 1-197.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

List of block choices – Block members of the configurable subsystem

no default

Select the blocks you want to include as members of the configurable subsystem. You can include user-defined subsystems as blocks.

Programmatic Use

Block Parameter: MemberBlocks

Type: cell array of character vectors

Values: cell array of block names as character vectors

Default: { ' ' }

Port names – Port names

no default

Lists of input and output ports of member blocks. In the case of multiports, you can rearrange selected port positions by clicking the **Up** and **Down** buttons.

Block Characteristics

Constant

Generate constant value

Library: Simulink / Commonly Used Blocks
 Simulink / Sources
 DSP System Toolbox / Sources
 HDL Coder / Commonly Used Blocks
 HDL Coder / Sources

Description

The Constant block generates a real or complex constant value signal. Use this block to provide a constant signal input. The block generates scalar, vector, or matrix output, depending on:

- The dimensionality of the **Constant value** parameter
- The setting of the **Interpret vector parameters as 1-D** parameter

The output of the block has the same dimensions and elements as the **Constant value** parameter. If you specify for this parameter a vector that you want the block to interpret as a vector, select the **Interpret vector parameters as 1-D** check box. Otherwise, if you specify a vector for the **Constant value** parameter, the block treats that vector as a matrix.

Tip To output a constant enumerated value, consider using the Enumerated Constant block instead. The Constant block provides block parameters that do not apply to enumerated types, such as **Output minimum** and **Output maximum**.

Using Bus Objects as the Output Data Type

The Constant block supports nonvirtual buses as the output data type. Using a bus object as the output data type can help simplify your model. If you use a bus object as the output data type, set the **Constant value** to \emptyset or to a MATLAB structure that matches the bus object.

Using Structures for the Constant Value of a Bus

The structure you specify must contain a value for every element of the bus represented by the bus object. The block output is a nonvirtual bus signal.

You can use the `Simulink.Bus.createMATLABStruct` to create a full structure that corresponds to a bus.

You can use `Simulink.Bus.createObject` to create a bus object from a MATLAB structure.

If the signal elements in the output bus use numeric data types other than `double`, you can specify the structure fields by using typed expressions such as `uint16(37)` or untyped expressions such as

37. To control the field data types, you can use the bus object as the data type of a `Simulink.Parameter` object. To decide whether to use typed or untyped expressions, see “Control Data Types of Initial Condition Structure Fields”.

Setting Configuration Parameters to Support Using a Bus Object Data Type

To enable the use of a bus object as an output data type, before you start a simulation, set **Configuration Parameters > Diagnostics > Data Validity > Advanced parameters > Underspecified initialization detection** to Simplified. For more information, see “Underspecified initialization detection”.

Ports

Output

Port_1 — Constant value

scalar | vector | matrix | N-D array

Constant value, specified as a real or complex valued scalar, vector, matrix, or N-D array. By default, the Constant block outputs a signal whose dimensions, data type, and complexity are the same as those of the **Constant value** parameter. However, you can specify the output to be any data type that Simulink supports, including fixed-point and enumerated data types.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For more information, see `Simulink.BusElement`.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

Constant value — Constant output value

1 (default) | scalar | vector | matrix | N-D array

Specify the constant value output of the block.

- You can enter any expression that MATLAB evaluates as a matrix, including the Boolean keywords `true` and `false`.
- If you set the **Output data type** to be a bus object, you can specify one of these options:
 - A full MATLAB structure corresponding to the bus object
 - `0` to indicate a structure corresponding to the ground value of the bus object

For details, see “Using Bus Objects as the Output Data Type” on page 1-201.

- For nonbus data types, Simulink converts this parameter from its value data type to the specified output data type offline, using a rounding method of nearest and overflow action of saturate.

Programmatic Use**Block Parameter:** Value**Type:** character vector**Value:** scalar | vector | matrix | N-D array**Default:** '1'**Interpret vector parameters as 1-D — Treat vectors as 1-D**

on (default) | off

Select this check box to output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

- When you select this check box, the block outputs a vector of length N, provided the **Constant value** parameter evaluates to an N-element row or column vector.
- When you clear this check box, the block outputs a matrix of dimension 1-by-N or N-by-1, provided the **Constant value** parameter evaluates to an N-element row or column vector. For example, the block outputs a matrix of dimension 1-by-N or N-by-1.

Programmatic Use**Block Parameter:** VectorParams1D**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Sample time — Sampling interval**

inf (default) | scalar | vector

Specify the interval between times that the Constant block output can change during simulation (for example, due to tuning the **Constant value** parameter).

The default value of `inf` indicates that the block output can never change. This setting speeds simulation and generated code by avoiding the need to recompute the block output.

See “Specify Sample Time” for more information.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar | vector**Default:** 'inf'**Signal Attributes****Output minimum — Minimum output value for range checking**

[] (default) | scalar

Specify the lower value of the output range that Simulink checks as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Specify the upper value of the output range that Simulink checks as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** scalar**Default:** '[]'**Output data type — Output data type**

Inherit: Inherit from 'Constant value' (default) | Inherit: Inherit via back propagation | double | single | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | Bus: <object name> | <data type expression>

Specify the output data type. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit from 'Constant value'' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>'

Default: 'Inherit: Inherit from 'Constant value''**Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point half integer single
Direct Feedthrough	no

Variable-Size Signals	no

Zero-Crossing Detection	no
--------------------------------	----

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Tunable Parameters

You can use a tunable parameter in a Constant block intended for HDL code generation. For details, see “Generate DUT Ports for Tunable Parameters” (HDL Coder).

HDL Architecture

Architecture	Parameters	Description
default Constant	None	This implementation emits the value of the Constant block.
Logic Value	None	By default, this implementation emits the character 'Z' for each bit in the signal. For example, for a 4-bit signal, the implementation would emit 'ZZZZ'.
	{'Value', 'Z'}	If the signal is in a high-impedance state, use this parameter value. This implementation emits the character 'Z' for each bit in the signal. For example, for a 4-bit signal, the implementation would emit 'ZZZZ'.
	{'Value', 'X'}	If the signal is in an unknown state, use this parameter value. This implementation emits the character 'X' for each bit in the signal. For example, for a 4-bit signal, the implementation would emit 'XXXX'.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).

OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
-----------------------	--

Complex Data Support

This block supports code generation for complex signals.

Restrictions

- The `Logic Value` implementation does not support the `double` data type. If you specify this implementation for a constant value of type `double`, a code generation error occurs.
- For **Sample time**, enter -1. Delay balancing does not support an `inf` sample time.

PLC Code Generation

Coulomb and Viscous Friction

Model discontinuity at zero, with linear gain elsewhere

Library: Simulink / Discontinuities
HDL Coder / Discontinuities

Description

The Coulomb and Viscous Friction block models Coulomb (static) and viscous (dynamic) friction. The block models a discontinuity at zero and a linear gain otherwise.

The block output matches the MATLAB result for:

$$y = \text{sign}(x) .* (\text{Gain} .* \text{abs}(x) + \text{Offset})$$

where y is the output, x is the input, Gain is the signal gain for nonzero input values, and Offset is the Coulomb friction.

The block accepts one input and generates one output. The input can be a scalar, vector, or matrix with real and complex elements.

- For a scalar input, Gain and Offset can have dimensions that differ from the input. The output is a scalar, vector, or matrix depending on the dimensions of Gain and Offset .
- For a vector or matrix input, Gain and Offset must be scalar or have the same dimensions as the input. The output is a vector or matrix of the same dimensions as the input.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

The input signal to the model of Coulomb and viscous friction.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 – Output signal

scalar | vector | matrix

The output signal calculated by applying the friction models to the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

To edit the parameters for the Coulomb and Viscous Friction block, double-click the block icon.

Coulomb friction value — Static friction offset

[1320] (default) | real values

Specify the offset that applies to all input values.

Programmatic Use

Block Parameter: offset

Type: character vector

Value: real values

Default: '[1 3 2 0]'

Coefficient of viscous friction — Dynamic friction coefficient

1 (default) | real values

Specify the signal gain for nonzero input values.

Programmatic Use

Block Parameter: gain

Type: character vector

Value: real values

Default: '1'

Block Characteristics

Counter Free-Running

Count up and overflow back to zero after reaching maximum value for specified number of bits

Library: Simulink / Sources
HDL Coder / Sources

Description

The Counter Free-Running block counts up until reaching the maximum value, $2^{Nbits} - 1$, where $Nbits$ is the number of bits. Then the counter overflows to zero and begins counting up again.

After overflow, the counter always initializes to zero. However, if you select the global doubles override, the Counter Free-Running block does not wrap back to zero.

Note This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

Ports

Output

Port_1 — Count value

scalar

Count value, specified as an unsigned integer of 8 bits, 16 bits, or 32 bits.

Data Types: `uint8` | `uint16` | `uint32`

Parameters

Number of Bits — Number of bits

16 (default) | scalar

Specify the number of bits as a finite, real-valued. When you specify:

- A positive integer, for example 8, the block counts up to $2^8 - 1$, which is 255.
- An unsigned integer expression, for example `uint8(8)`, the block counts up to `uint8(2uint8(8) - 1)`, which is 254.

Programmatic Use

Block Parameter: NumBits

Type: character vector

Values: scalar

Default: '16'

Sample time — Interval between samples

-1 (default) | scalar | vector

Specify the time interval between samples as a scalar (sampling period), or a two-element vector ([sampling period, initial offset]). To inherit the sample time, set this parameter to -1. For more information, see “Specify Sample Time”.

Programmatic Use

Block Parameter: tsamp

Type: character vector

Values: scalar | vector

Default: '-1'

Block Characteristics

Data Types	fixed point integer
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

Counter Limited | MATLAB Function

Introduced before R2006a

Counter Limited

Count up and wrap back to zero after outputting specified upper limit

Library: Simulink / Sources
HDL Coder / Sources

Description

The Counter Limited block counts up until the specified upper limit is reached. Then the counter wraps back to zero, and restarts counting up. The counter always initializes to zero.

Note This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

Ports

Output

Port_1 — Count value

scalar

Count value, specified as an unsigned integer of 8 bits, 16 bits, or 32 bits. The block uses the smallest number of bits required to represent the upper limit.

Data Types: `uint8` | `uint16` | `uint32`

Parameters

Upper limit — Upper limit

7 (default) | scalar

Specify the upper limit for the block to count to as a finite, real-valued scalar.

Programmatic Use

Block Parameter: `uplimit`

Type: character vector

Values: scalar

Default: '7'

Sample time — Interval between samples

-1 (default) | scalar | vector

Specify the time interval between samples as a scalar (**sampling period**), or a two-element vector (**sampling period**, **initial offset**). To inherit the sample time, set this parameter to -1. For more information, see “Specify Sample Time”.

Programmatic Use**Block Parameter:** tsamp**Type:** character vector**Values:** scalar | vector**Default:** '-1'**Block Characteristics**

Data Types	Boolean fixed point integer
Direct Feedthrough	no

Create Diagonal Matrix

Create square diagonal matrix from diagonal elements

Library: Simulink / Matrix Operations

Description

The Create Diagonal Matrix block populates the diagonal of the M -by- M matrix output with the elements contained in the length- M vector input D . The elements off the diagonal are zero.

$A = \text{diag}(D)$ % Equivalent MATLAB code

Ports

Input

Port_1 — Input signal

vector

Input to convert into a diagonal matrix, specified as an M -element vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Complex Number Support: Yes

Output

Port_1 — Output signal

matrix

Output specified as an M -by- M matrix, where M is the length of the input vector.

The output is equivalent to:

$A = \text{diag}(D)$ % Equivalent MATLAB code

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Complex Number Support: Yes

Block Characteristics

Data Types	<code>Boolean</code> <code>double</code> <code>fixed point</code> <code>integer</code> <code>single</code>
Direct Feedthrough	no
Multidimensional Signals	no

Variable-Size Signals	no
Zero-Crossing Detection	no

Compatibility Considerations

Create Diagonal Matrix Block Moved to Simulink Matrix Operations Library

Behavior changed in R2021b

The Create Diagonal Matrix block has been moved from the **DSP System Toolbox > Math Functions > Matrices and Linear Algebra > Matrix Operations** library to the **Simulink > Matrix Operations** library. All existing models continue to work.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (`string.h`) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Cross Product

Cross product of two vectors

Library: Simulink / Matrix Operations

Description

The Cross Product block returns the cross product, or vector product, of two 3-by-1 vectors.

Ports

Input

Port_1 – First input vector

3-element vector

First input vector, specified as a 3-element vector.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | enumerated | bus

Port_2 – Second input vector

3-element vector

Second input vector, specified as a 3-element vector.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 – Cross product of input vectors

3-element vector

Cross product of input vectors, returned as a 3-element vector.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Block Characteristics

Data Types	Boolean double fixed point half integer single

Dashboard Scope

Trace signals on scope display during simulation

Library: Simulink / Dashboard

Description

The Dashboard Scope block plots connected signals during simulation on a scope display. You can use the Dashboard Scope block with other dashboard blocks to build an interactive dashboard of controls and indicators for your model. Signals connected to the Dashboard Scope block log to the Simulation Data Inspector for analysis during or after simulation. The Dashboard Scope block can display signals of any data type that Simulink supports, including enumerated data types, and up to eight signals from an array or bus.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, select a dashboard block to connect and then, on the block tab, click **Connect**. In connect mode, when you select one or more signals, a list of signals that are available for connection appears. Select a signal from the list to connect the signal to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Analyze Signal Data

You can use the subplot menu or the context menu for the Dashboard Scope block to:

- Show or hide data cursors.
- Zoom out by a fixed amount.
- Configure the mouse interaction to pan and select or to zoom in time, in y , or in both time and y .
- Perform a fit-to-view in time, in y , or in both time and y .

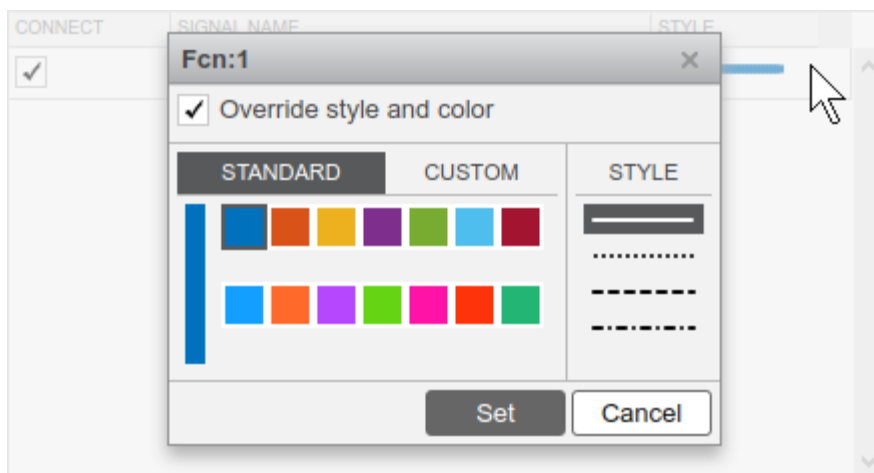

To access the subplot menu, select the Dashboard Scope block then click the three dots that appear when you pause on the plot area.

Configure Signal Line Style and Color

You can modify the color and line style for signals connected to a Dashboard Scope block using the **Connection** table in the Block Parameters dialog box or the Property Inspector. To modify the appearance of a connected signal:

- 1 Click the preview of the signal appearance in the **Style** column of the **Connection** table.

- 2 Choose a color from the palette of standard colors or select the **Custom** tab to specify a custom color using RGB values between 0 and 255.
- 3 Select the line style from the solid, dotted, dashed, and dot-dashed options in the **Style** column.
- 4 Click **Set**.

When you mark a signal connected to the Dashboard Scope block for signal logging, you can also configure the signal color and line style using the **Instrumentation Properties** dialog box. In the signal color and line style menu for the Dashboard Scope block, the **Override style and color** option is selected by default and specifies whether signal appearance options you choose using the **Connection** table for the Dashboard Scope block override signal appearance options configured in the instrumentation properties for the connected signals.

When you connect signals to the Dashboard Scope block using the Block Parameters dialog box, the connection table shows the default signal color and line style for each signal you connect. As you select signals to connect, the **Connection** table updates the style and color for signals that are not selected to indicate the style and color for the next signal you connect.

CONNECT	SIGNAL NAME	STYLE
<input checked="" type="checkbox"/>	Fcn:1	
<input checked="" type="checkbox"/>	Mu:1	
<input type="checkbox"/>	Mux:1	
<input type="checkbox"/>	Product:1	
<input type="checkbox"/>	Sum:1	
<input type="checkbox"/>	x1	
<input type="checkbox"/>	x2	

Configure Complex Signal Format

When you connect a complex signal to the Dashboard Scope block, you can configure how the signal is displayed by specifying the **Complex Format** property for the signal:

- 1 Mark the complex signal for signal logging.
- 2 Right-click the logging badge for the complex signal and select **Properties**.
- 3 Specify the **Complex Format**.
- 4 Click **OK**.

When you specify the **Complex Format** for a signal as Real - Imaginary or Magnitude - Phase, the Dashboard Scope block displays both components of the signal. The real or magnitude component is displayed using the color indicated in the **Connection** table. The imaginary or phase component is displayed using a different shade of the color indicated in the **Connection** table.

Limitations

- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- The toolstrip does not support dashboard blocks that are in a panel.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- You cannot connect a dashboard block to state activity or chart data in Stateflow during simulation.
- You cannot programmatically connect a dashboard block to state activity or chart data in Stateflow.

- Some signals do not have data available during simulation due to block reduction or optimization for accelerator mode simulations. To view such a signal using a dashboard block, mark the signal for logging.

Parameters

Connection

Connection — Signals to connect and display

signal connection options

Use the **Connection** table to select one or more signals to display. Populate the **Connection** table by selecting signals in the model. To connect a signal, select the check box next to the signal you want to connect, then click **Apply**.

Tips

- You can connect signals to a Dashboard Scope block during simulation.
- You can configure the line style and color for signals connected to a Dashboard Scope block using the **Connection** table. For more information, see “Configure Signal Line Style and Color” on page 1-223.

Programmatic Use

To programmatically specify one or more signals to connect to the Dashboard Scope block, use a cell array of `Simulink.HMI.SignalSpecification` objects.

Block Parameter: Binding

Type: cell array of `Simulink.HMI.SignalSpecification` objects

Default: []

To programmatically configure the line style and color for connected signals, use the `Colors` parameter. Specify the value for the `Colors` parameter as an array of structures, where each structure specifies the line style and color for one signal. Settings specified using the `Colors` parameter apply to the signal at the same index in the value for the `Binding` parameter.

Specify the line style and color for each signal as a structure with the fields:

- `Color` — 1-by-3 [r g b] vector with values between 0 and 1.
- `LineStyle` — Character vector that specifies one of these line style options:
 - Solid: '-'
 - Dashed: '—'
 - Dotted: ':'
 - Dash-dotted: '-.'

```
sig1Colors.Color = [0 0 1];
sig1Colors.LineStyle = '--';
sig2Colors.Color = [1 0 1];
sig2Colors.LineStyle = '-.';
sigColors = [sig1Colors sig2Colors];
```

Block Parameter: Colors

Type: array of structures

Main

Time Span — Time axis span

auto (default) | scalar

A finite, real, double, scalar value that sets the time span of the plot.

When **Time Span** is set to auto, the block sets its time span to the simulation stop time.

Tips

When you set the **Time Span** to a value that is less than the duration of the simulation, use the **Update Mode** parameter to control whether the display wraps or scrolls when the simulation time exceeds the specified time span.

Programmatic Use

Block Parameter: TimeSpan

Type: string | character array

Values: 'auto' or numeric value

Default: 'auto'

Update Mode — Display update behavior

Wrap (default) | Scroll

How the display updates during simulation, specified as Wrap or Scroll.

- Wrap — Display wraps to show incoming data after simulation time reaches end of time span.
- Scroll — Display scrolls to show incoming data after simulation time reaches end of time span.

Programmatic Use

Block Parameter: UpdateMode

Type: string | character array

Values: 'Wrap' | 'Scroll'

Default: 'Wrap'

Min — Vertical axis minimum

-3 (default) | scalar

A finite, real, double, scalar value that sets the minimum of the vertical axis.

Programmatic Use

To specify the Min parameter for the Dashboard Scope block programmatically, create a 1-by-2 vector that contains the minimum y-axis value and maximum y-axis value, in that order.

Block Parameter: YLimits

Type: 1x2 vector

Default: [-3 3]

Max — Vertical axis maximum

3 (default) | scalar

A finite, real, double, scalar value that sets the maximum of the vertical axis.

Programmatic Use

To specify the Max parameter for the Dashboard Scope block programmatically, create a 1-by-2 vector that contains the minimum y-axis value and maximum y-axis value, in that order.

Block Parameter: YLimits**Type:** 1x2 vector**Default:** [-3 3]**Normalize y-axis limits — Option to normalize y-axis**

off (default) | on

When enabled, the connected signal data is normalized to display on a y-axis range of [0, 1].

Programmatic Use**Block Parameter:** NormalizeYAxis**Type:** string | character vector**Values:** 'on' | 'off'**Default:** 'off'**Scale axes limits at stop — Option to perform fit-to-view upon simulation stop**

on (default) | off

When enabled, performs a fit-to-view operation on the data displayed in the plot when the simulation stops.

Programmatic Use**Block Parameter:** ScaleAtStop**Type:** string | character vector**Values:** 'on' | 'off'**Default:** 'on'**Show "Double-click to connect" message — Connection instructions visibility**

on (default) | off

When enabled, shows instructional text if the block is not connected. When the block is not connected, you can specify this parameter as off to hide the text.

Programmatic Use**Block Parameter:** ShowInitialText**Type:** string | character vector**Values:** 'on' | 'off'**Default:** 'on'**Display****Ticks — Axes tick positions**

Outside (default) | Inside | None

Axes tick positions, specified as Outside, Inside, or None.

- Outside — Ticks are drawn on the outside of the x- and y-axes.
- Inside — Ticks are drawn on the inside of the x- and y-axes.
- None — No ticks are shown on the x- or y-axes.

Programmatic Use**Block Parameter:** TicksPosition**Type:** string | character vector**Values:** 'Outside' | 'Inside' | 'None'**Default:** 'Outside'

Tick Labels — Tick label visibility

All (default) | T-Axis | Y-Axis | None

Visibility of tick labels on the x- and y-axes.

- All — Ticks labels are shown on the x- and y-axes.
- T-Axis — Tick labels are shown on the x-axis only.
- Y-Axis — Tick labels are shown on the y-axis only.
- None — No tick labels are shown on the x- or y-axis.

Programmatic Use**Block Parameter:** TickLabels**Type:** string | character vector**Values:** 'All' | 'T-Axis' | 'Y-Axis' | 'None'**Default:** 'All'**Legend — Legend position**

Top (default) | Right | Inside top | Inside right | Hide

You can position the legend at the top of the plot inside or outside the plot area or on the right of the plot inside or outside the plot area. You can also hide the legend. The legend shows the color chosen for each connected signal next to the signal name.

Programmatic Use**Block Parameter:** LegendPosition**Type:** string | character vector**Values:** 'Top' | 'Right' | 'InsideTop' | 'InsideRight' | 'Hide'**Default:** 'Top'**Horizontal — Horizontal grid line visibility**

on (default) | off

Visibility of horizontal grid lines.

- on — Horizontal grid lines are visible on Dashboard Scope.
- off — Horizontal grid lines are not shown on Dashboard Scope.

Programmatic Use**Block Parameter:** Grid**Type:** string | character vector**Values:** 'All' | 'Horizontal' | 'Vertical' | 'None'**Default:** 'All'**Vertical — Vertical grid line visibility**

on (default) | off

Visibility of vertical grid lines.

- on — Vertical grid lines are visible on Dashboard Scope.
- off — Vertical grid lines are not shown on Dashboard Scope.

Programmatic Use**Block Parameter:** Grid**Type:** string | character vector

Values: 'All' | 'Horizontal' | 'Vertical' | 'None'
Default: 'All'

Border — Plot border visibility

on (default) | off

Plot border visibility.

- on — Plot border is shown on Dashboard Scope.
- off — Plot border is not shown on Dashboard Scope.

Programmatic Use

Block Parameter: Border

Type: string | character vector

Values: 'on' | 'off'

Default: 'on'

Markers — Option to show signal data markers

off (default) | on

When enabled, data markers are shown for signals plotted on the Dashboard Scope block.

Programmatic Use

Block Parameter: Markers

Type: string | character vector

Values: 'on' | 'off'

Default: 'off'

Style

Foreground Color — Grid lines color

[r g b] vector

Select the color for the grid lines from a palette of standard colors or specify a custom color using RGB values between 0 and 255.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `ForegroundColor`

Type: string | character vector

Values: [r g b] vector

Background Color — Plot area color

[r g b] vector

Select the color for the plot area from a palette of standard colors or specify a custom color using RGB values between 0 and 255.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `BackgroundColor`

Type: string | character vector

Values: [r g b] vector

Font Color — Ticks and tick labels color

[r g b] vector

Select the color for the ticks and tick labels from a palette of standard colors or specify a custom color using RGB values between 0 and 255.

Programmatic Use

Specify the `FontColor` parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `FontColor`

Type: [r g b] vector

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Introduced in R2015a

Data Store Memory

Define data store

Library: Simulink / Signal Routing

Description

The Data Store Memory block defines and initializes a named shared data store, which is a memory region usable by Data Store Read and Data Store Write blocks that specify the same data store name.

The location of the Data Store Memory block that defines a data store determines which Data Store Read and Data Store Write blocks can access the data store:

- If the Data Store Memory block is in the *top-level system*, Data Store Read and Data Store Write blocks anywhere in the model can access the data store.
- If the Data Store Memory block is in a *subsystem*, Data Store Read and Data Store Write blocks in the same subsystem or in any subsystem below it in the model hierarchy can access the data store.

Data Store Read or Data Store Write blocks cannot access a Data Store Memory block that is either in a model that contains a Model block or in a referenced model.

Do not include a Data Store Memory block in a For Each subsystem.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. For details, see:

- “Order Data Store Access”
- “Data Store Diagnostics”
- “Log Data Stores”

You can use `Simulink.Signal` objects in addition to, or instead of, Data Store Memory blocks to define data stores. A data store defined in the *base* workspace with a signal object is a *global* data store. Global data stores are accessible to every model, including all referenced models. See “Data Stores” for more information.

You can select a Data Store Read, Data Store Write, or Data Store Memory block to highlight blocks related to it. To show a related block in an open diagram or new tab, pause on the ellipsis that

appears after selection. Then, select **Related Blocks**  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list of related blocks by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Parameters

Main

Data store name — Name for the data store

A (default) | character vector | string

Specify a name for the data store you are defining with this block. Data Store Read and Data Store Write blocks with the same name can read from, and write to, the data store initialized by this block. The name can represent a Data Store Memory block or a sign object defined to be a data store.

Programmatic Use

Block Parameter: DataStoreName

Type: character vector

Values: 'A' | ...

Default: 'A'

Rename All — Rename this data store throughout the model

button

Rename this data store everywhere the Data Store Read and Data Store Write blocks use it in a model.

Limitations

You cannot use **Rename All** to rename a data store if you:

- Use a `Simulink.Signal` object in a workspace to control the code generated for the data store
- Use a `Simulink.Signal` object instead of a Data Store Memory block to define the data store

You must instead rename the corresponding `Simulink.Signal` object from Model Explorer. For an example, see “Rename Data Store Defined by Signal Object”.

Corresponding Data Store Read/Write blocks — Path to connected Data Store Read/Write blocks

block path

List all the Data Store Read and Data Store Write blocks that have the same data store name as the current block, and that are in the current system or in any subsystem below it in the model hierarchy. Clicking a block path displays and highlights that block in your model.

Signal Attributes

Initial value — Initial value of data store

0 (default) | scalar | vector | matrix | N-D array

Specify the initial value or values of the data store. The **Minimum** parameter specifies the minimum value for this parameter, and the **Maximum** parameter specifies the maximum value.

If you specify a nonscalar value and set **Dimensions** to -1 (the default), the data store has the same dimensions as the array. Data that you write to the data store (by using Data Store Write blocks) must have these dimensions.

If you set the **Dimensions** parameter to a value other than -1, the initial value dimensions must match the dimensions that you specify, unless the initial value is a scalar or a MATLAB structure. If

you specify a scalar, each element of the data store uses the scalar as the initial value. Use this technique to apply the same initial value (the scalar that you specify) to each element without manually matching the dimensions of the initial value with the dimensions of the data store.

To use this block to initialize a nonvirtual bus signal, specify the initial value as a MATLAB structure and set the model configuration parameter “Underspecified initialization detection” to *Simplified*. For more information about initializing nonvirtual bus signals using structures, see “Specify Initial Conditions for Bus Elements”.

Programmatic Use

Block Parameter: InitialValue

Type: character vector

Values: scalar | vector | matrix | N-D array

Default: '0'

Minimum — Minimum output value for range checking

[] (default) | scalar

Specify the minimum value that the block should output. The default value is [] (unspecified). This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink uses the minimum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: scalar

Default: '[]'

Maximum — Maximum output value for range checking

[] (default) | scalar

Specify the maximum value that the block should output. The default value is [] (unspecified). This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus

elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: scalar

Default: '[]'

Data type — Output data type

Inherit: auto (default) | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16,0) | fixdt(1,16,2^0,0) | string | Enum: <class name> | Simulink.ImageType(480,640,3)

Specify the output data type. You can set it to:

- A rule that inherits a data type (for example, Inherit: auto).
- The name of a built-in data type (for example, single).
- The name of a data type object (for example, a Simulink.NumericType object).
- An expression that evaluates to a data type (for example, fixdt(1,16,0)). Do not specify a bus object as the data type in an expression; use Bus: <object name> to specify a bus data type.
- If you have Computer Vision Toolbox™, use the constructor for the Simulink.ImageType object and specify the properties to describe the image. By default, the data type uses the Simulink.ImageType(480,640,3) expression that represents the rows, columns, and channels of the image respectively.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: auto' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'string' | 'Enum: <class name>' | 'Simulink.ImageType(480,640,3)'

Default: 'Inherit: auto'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Dimensions (-1 to infer from Initial value) — Dimensions of data store

-1 (default) | scalar | vector | matrix

Dimensions of the data store. The default value, -1, enables you to set the dimensions of the data store by using the **Initial value** parameter. However, in this case, you cannot use scalar expansion with the initial value. You must specify the initial value by using an array that has the dimensions that you want.

If you use a value other than -1, specify the same dimensions as the dimensions of the **Initial value** parameter, unless you specify the initial value as a scalar (for scalar expansion) or a MATLAB structure. If the data store represents an array of buses, and if you use a MATLAB structure for the initial value, you can specify dimensions to initialize the array of buses with this structure.

Programmatic Use

Block Parameter: Dimensions

Type: character vector

Values: scalar | vector | matrix

Default: '-1'

Interpret vector parameters as 1-D — Interpret vectors as 1-D

on (default) | off

Specify that the data store interpret vector initial values as one-dimensional.

By default, MATLAB represents vector data as matrices, which have two dimensions. For example, MATLAB represents the vector [1 2 3] as a 1-by-3 matrix.

When you select this parameter, the data store represents vector data by using only one dimension instead of two. For example, if you specify an initial value of [1 2 3], the data store stores a one-dimensional vector with three elements.

For more information, see “Determine the Output Dimensions of Source Blocks”.

Programmatic Use

Block Parameter: VectorParams1D

Type: character vector

Values: 'off' | 'on'

Default: 'on'

Signal type — Complexity of data store values

auto (default) | real | complex

Specify the numeric type, real or complex, of the values in the data store.

Programmatic Use

Block Parameter: SignalType

Type: character vector

Values: 'auto' | 'real' | 'complex'

Default: 'auto'

Share across model instances — Allow Model blocks to read from the same data store

off (default) | on

In a single model reference hierarchy, when you use multiple Model blocks to refer to a model that contains a Data Store Memory block, by default, each instance of the referenced model (each Model block) reads from and writes to a separate copy of the data store. When you select **Share across model instances**, instead of interacting with a separate copy, all of the instances read from and write to the same data store.

When you set the model configuration parameter **Code interface packaging** to Reusable function to generate reentrant code from a model (Simulink Coder), a data store with **Share across model instances** selected appears in the code as a global symbol that the generated entry-point functions access directly. For example, a global symbol is a global variable or a field of a global structure variable. Therefore, each call that your code makes to the entry-point functions (each instance of the model) shares the data.

For an example, see “Share Data Store Between Instances of a Reusable Algorithm” on page 13-340. For more information, see “Share Data Among Referenced Model Instances”.

Programmatic Use

Block Parameter: ShareAcrossModelInstances

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Data store name must resolve to Simulink signal object — Require data store name resolve to Simulink signal object

off (default) | on

Specify that Simulink software, when compiling the model, searches the model and base workspace for a Simulink.Signal object having the same name, as described in “Symbol Resolution”. If Simulink does not find such an object, the compilation stops with an error. Otherwise, Simulink compares the attributes of the signal object to the corresponding attributes of the Data Store Memory block. If the block and the object attributes are inconsistent, Simulink halts model compilation and displays an error.

Programmatic Use

Block Parameter: StateMustResolveToSignalObject

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Diagnostics

Detect Read Before Write — Action when model attempts to read data before writing in current time step

warning (default) | none | error

Select the diagnostic action to take if the model attempts to read data from a data store to which it has not written data in this time step. See also the “Detect read before write” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters > Diagnostics > Data Validity** pane.

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

Programmatic Use

Block Parameter: ReadBeforeWriteMsg

Type: character vector

Values: 'none' | 'warning' | 'error'

Default: 'warning'

Detect Write After Read — Action when block attempts to write after reading in same time step

warning (default) | none | error

Select the diagnostic action to take if the model attempts to write data to the data store after previously reading data from it in the current time step. See also the “Detect write after read” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters > Diagnostics > Data Validity** pane.

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

Programmatic Use

Block Parameter: WriteAfterReadMsg

Type: character vector

Values: 'none' | 'warning' | 'error'

Default: 'warning'

Detect Write After Write — Action when model writes twice in same time step

warning (default) | none | error

Select the diagnostic action to take if the model attempts to write data to the data store twice in succession in the current time step. See also the “Detect write after write” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters > Diagnostics > Data Validity** pane.

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

Programmatic Use

Block Parameter: WriteAfterWriteMsg

Type: character vector

Values: 'none' | 'warning' | 'error'

Default: 'warning'

Logging**Log data store data — Log data store data**

off (default) | on

Select this option to save the values of this signal to the MATLAB workspace during simulation. See “Signal Logging” for details.

Programmatic Use**Block Parameter:** DataLogging**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Logging name — Name associated with logged signal data**

Use data store name (default) | Custom

Use this pair of controls, consisting of a list box and an edit field, to specify the name associated with logged signal data.

Simulink uses the signal name as its logging name by default. To specify a custom logging name, select Custom from the list box and enter the custom name in the adjacent edit field.

Programmatic Use**Block Parameter:** DataLoggingNameMode**Type:** character vector**Values:** 'SignalName' | 'Custom'**Default:** ''

Note If you set DataLoggingNameMode to Custom, you must specify the name associated with logged signal data using the DataLoggingName parameter.

Block Parameter: DataLoggingName**Type:** character vector**Values:** character vector**Default:** ''**Limit data points to last — Discard all but the last N data points**

5000 | non-zero integer

Discard all but the last N data points, where N is the number that you enter in the adjacent edit field. For more information, see “Log Data Stores”.

Programmatic Use**Block Parameter:** DataLoggingMaxPoints**Type:** character vector**Values:** nonzero integer**Default:** '5000'**Decimation — Log every Nth data point**

2 (default) | integer

Log every Nth data point, where N is the number that you enter in the adjacent edit field. For example, suppose that your model uses a fixed-step solver with a step size of 0.1 s. If you select this

option and accept the default decimation value (2), Simulink records data points for this signal at times 0.0, 0.2, 0.4, and so on. For more information, see “Log Data Stores”.

Programmatic Use

Block Parameter: DataLoggingLimitDataPoints

Type: character vector

Values: non-zero integer

Default: '2'

Block Characteristics

Data Store Read

Read data from data store

Library: Simulink / Signal Routing

Description

The Data Store Read block copies data from the named data store or a selected portion thereof to its output. More than one Data Store Read block can read from the same data store.

The data store from which the data is read is determined by the location of the Data Store Memory block or signal object that defines the data store. For more information, see “Data Stores” and Data Store Memory.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. See “Order Data Store Access” and “Data Store Diagnostics” for details.

You can select a Data Store Read, Data Store Write, or Data Store Memory block to highlight blocks related to it. To show a related block in an open diagram or new tab, pause on the ellipsis that appears after selection. Then, select **Related Blocks**  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list of related blocks by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Ports

Input

IdxN — Nth index signal

scalar | vector

External port specifying an index for the selection of the corresponding data store subelements.

Dependencies

To enable an external index port, on the **Element Selection** tab, select **Enable indexing**. Then, in the Nth row of the **Index Option** table, set **Index Option** to Index vector (port) or Starting index (port).

Data Types: int8 | int16 | int32 | uint8 | uint16

Output

Port_1 — Values from specified data store

scalar | vector | matrix | N-D array

Values from the specified data store, output with the same data type and number of dimensions as in the data store. The block supports both real and complex signals. You can choose whether to output the entire data store or only selected elements.

You can use arrays of buses with a Data Store Read block. For details about defining and using an array of buses, see “Group Nonvirtual Buses in Arrays of Buses”.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Parameters

Parameters

Data store name — Name of data store from which block reads

A (default) | name of data store

Specify the name of the data store from which this block reads data. The adjacent list provides the names of Data Store Memory blocks that exist at the same level in the model as the Data Store Read block or at higher levels. The list also includes all `Simulink.Signal` objects in the base and model workspaces. To change the name, select a name from the list or enter the name directly in the edit field.

When compiling a model containing this block, Simulink searches the model upwards from the level of the block for a Data Store Memory block having the specified data store name. If Simulink does not find such a block, it searches the model workspace and the MATLAB workspace for a `Simulink.Signal` object having the same name. If Simulink finds the signal object, it creates a hidden Data Store Memory block at the root level of the model with the properties specified by the signal object and an initial value set to an array of zeros. The dimensions of that array are inherited from the `Dimensions` property of the signal object.

If Simulink finds neither the Data Store Memory block nor the signal object, it halts the compilation and displays an error. See “Symbol Resolution” for more information about the search path.

Programmatic Use

Block Parameter: `DataStoreName`

Type: character vector

Values: data store name

Default: 'A'

Data store memory block — Data Store Memory block name

block path

This property is read-only.

This field lists the Data Store Memory block that initialized the store from which this block reads.

Corresponding Data Store Write blocks — List of corresponding Data Store Write blocks

block path

This property is read-only.

This field lists the path to all Data Store Write blocks with the same data store name as this block that are in the same (sub)system or in any subsystem below it in the model hierarchy. Click any entry in this list to highlight the corresponding block in your model.

Sample time – Sample time

-1 (default) | scalar | vector

The sample time, which controls when the block reads from the data store. A value of -1 indicates that the sample time is inherited. See “Specify Sample Time” for more information.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '-1'

Element Selection

Elements in the array (Signals in the bus) – Elements in associated data store

character vector (no default)

List of elements in the associated data store. For data stores containing arrays, you can read the whole data store, or you can specify one or more elements of the data store. For data stores with a bus data type, you can expand the tree to view and select the bus elements. The list displays the maximum dimensions for each element in parentheses.

If **Enable indexing** is not selected, select an element and use one of the following approaches:

- Click **Select>>** to display that element and all its subelements in the **Selected element(s)** list.
- Use the **Specify element(s) to select** edit box to specify the subelements that you want to select for reading. Then click **Select>>**.

To select multiple elements, repeat the above procedure for each element.

Alternatively, you can select **Enable indexing**, then select a single element and specify the subelements dynamically using the **Index Option** parameter.

To refresh the display and reflect modifications to the array or bus used in the data store, click **Refresh**.

Dependencies

The prompt for this section (**Elements in the array** or **Signals in the bus**) depends on the type of data in the data store.

Programmatic Use

Block Parameter: DataStoreElements

Type: character vector

Values: pound-delimited list of elements (See “Specification using the command line”.)

Default: ''

Specify element(s) to select – MATLAB expression defining element to select

character vector (no default)

Enter a MATLAB expression to define a specific element that you want to read, then click **Select>>** to add the element to the **Selected elements(s)** table. Repeat to select additional elements.

For example, for a data store named DSM that has maximum dimensions of [3,5], you could enter expressions such as DSM(2,4) or DSM([1 3],2) in the edit box. See “Accessing Specific Bus and Matrix Elements”.

To apply the element selection, click **OK** or **Apply**.

Dependencies

The **Specify element(s) to select** edit box appears only if **Enable indexing** is not selected.

Programmatic Use

Block Parameter: DataStoreElements

Type: character vector

Values: pound-delimited list of elements (See “Specification using the command line”.)

Default: ''

Selected element(s) — List of selected elements

character vector (no default)

Elements that you select from the data store. The Data Store Read block icon displays an output port for each element that you specify.

To change the order of bus or matrix elements in the list, select the element in the list and click **Up** or **Down**. Changing the order of the elements in the list changes the order of the ports. To remove an element, click **Remove**.

Dependencies

The **Selected element(s)** table appears only if **Enable indexing** is not selected.

Programmatic Use

Block Parameter: DataStoreElements

Type: character vector

Values: pound-delimited list of elements (See “Specification using the command line”.)

Default: ''

Enable indexing — Enable indexing to specify subelements of data store element to read

'off' (default) | 'on'

Select this parameter to enable indexing similar to that used by the Selector block, whereby you can dynamically specify indices of subelements to read by using one or more index input ports, as well as specifying indices by using the block dialog. A Data Store Read block can read from only a single element of a data store (that is, a single signal in a bus) when this parameter is selected. To read from multiple elements of a data store using dynamic indexing, use multiple Data Store Read blocks.

Clear this parameter to disable Selector block-style indexing. You can select multiple data store elements to read, but you can specify which subelements to read only by using the block dialog.

Note Do not select **Enable indexing** if the associated data store contains only a single, scalar element.

Programmatic Use

Block Parameter: EnableIndexing

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Number of dimensions — Number of dimensions of data store element

1 (default) | positive integer

Number of dimensions of selected data store element. You must explicitly indicate this number.

Dependencies

This parameter is enabled only if **Enable indexing** is selected.

Programmatic Use

Block Parameter: NumberOfDimensions

Type: character vector

Values: positive integer

Default: '1'

Index mode — Index mode

One-based (default) | Zero-based

Select the indexing mode. If One-based is selected, an index of 1 specifies the first element of the input vector. If Zero-based is selected, an index of 0 specifies the first element of the input vector.

Dependencies

This parameter is enabled only if **Enable indexing** is selected.

Programmatic Use

Parameter: IndexMode

Type: character vector

Values: 'Zero-based' | 'One-based'

Default: 'One-based'

Index Option — Index method for subelements

Index vector (dialog) (default) | Select all | Index vector (port) | Starting index (dialog) | Starting index (port)

Define, by dimension, how the subelements of the selected data store element are to be indexed.

From the list, select:

Menu Item	Action
Select all	All subelements are read.
Index vector (dialog)	Enables the Index column. Enter a vector containing the indices of subelements to be read.
Index vector (port)	The relevant index port defines the indices of subelements to be read.
Starting index (dialog)	Enables the Index and Output Size columns. Enter the starting index and size of the range of subelements to be read.

Menu Item	Action
Starting index (port)	Enables the Output Size column. The relevant index port defines the starting index of the range of elements to be read. Enter the size of the range.

The **Index** and **Output Size** columns are displayed as relevant.

Dependencies

This parameter is enabled only if **Enable indexing** is selected.

Programmatic Use

Parameter: IndexOptionArray

Type: character vector

Values: 'Select all' | 'Index vector (dialog)' | 'Index vector (port)' | 'Starting index (dialog)' | 'Starting index (port)'

Default: 'Index vector (dialog)'

Index — Indices or starting index of subelements

1 (default) | integer | vector of integers

If the **Index Option** is Index vector (dialog), enter a vector containing the indices of each subelement to read.

If the **Index Option** is Starting index (dialog), enter the starting index of the range of subelements to read.

Dependencies

This parameter is enabled only if **Enable indexing** is selected and the **Index Option** for the dimension is Index vector (dialog) or Starting index (dialog).

Programmatic Use

Parameter: IndexParamArray

Type: character vector

Values: cell array

Default: '{ }'

Output Size — Size of range of subelements to read

1 (default) | integer

If the **Index Option** is Starting index (dialog) or Starting index (port), enter the size of the range of subelements to read.

Dependencies

This parameter is enabled only if **Enable indexing** is selected and the **Index Option** for the dimension is Starting index (dialog) or Starting index (port).

Programmatic Use

Block Parameter: OutputSizeArray

Type: character vector

Values: cell array

Default: '{ }'

Data Store Write

Write data to data store

Library: Simulink / Signal Routing

Description

The Data Store Write block copies the value at its input to the named data store. Each write operation performed by a Data Store Write block writes over the data store or a selected portion thereof and replaces the previous contents.

The data store to which this block writes is determined by the location of the Data Store Memory block or signal object that defines the data store. For more information, see “Data Stores” and Data Store Memory. The size of the data store is set by the signal object or the Data Store Memory block that defines and initializes the data store. Each Data Store Write block that writes to that data store can write up to the amount of data in the data store.

More than one Data Store Write block can write to the same data store. However, if two Data Store Write blocks attempt to write to the same data store during the same simulation step, results are unpredictable.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. For details, see “Order Data Store Access” and “Data Store Diagnostics”.

You can log the values of a local or global data store data variable for all the steps in a simulation. For details, see “Log Data Stores”.

You can select a Data Store Read, Data Store Write, or Data Store Memory block to highlight blocks related to it. To show a related block in an open diagram or new tab, pause on the ellipsis that

appears after selection. Then, select **Related Blocks**  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list of related blocks by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Ports

Input

Port_1 — Values to write to data store

scalar | vector | matrix | N-D array

Values to write to the specified data store. The Data Store Write block accepts a real or complex signal.

You can use an array of buses with a Data Store Write block. For details about defining and using an array of buses, see “Group Nonvirtual Buses in Arrays of Buses”.

To assign a subset of the bus or matrix elements to the associated data store, use the **Element Assignment** pane. The Data Store Write block icon reflects the elements that you specify. For details, see “Accessing Specific Bus and Matrix Elements”.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

IdxN — Nth index signal

scalar | vector

External port specifying an index for the assignment of the corresponding data store subelements.

Dependencies

To enable an external index port, on the **Element Assignment** tab, select **Enable indexing**. Then, in the Nth row of the **Index Option** table, set **Index Option** to `Index vector (port)` or `Starting index (port)`.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16`

Parameters

Parameters

Data store name — Name of data store to which block writes

A (default) | name of data store

Specify the name of the data store to which this block writes data. The adjacent list provides the names of Data Store Memory blocks that exist at the same level in the model as the Data Store Write block or at higher levels. The list also includes all `Simulink.Signal` objects in the base and model workspaces. To change the name, select a name from the list or enter the name directly in the edit field.

When compiling a model containing this block, Simulink searches the model upwards from the level of the block for a Data Store Memory block having the specified data store name. If Simulink does not find such a block, it searches the model workspace and the MATLAB workspace for a `Simulink.Signal` object having the same name. If Simulink finds a signal object, it creates a hidden Data Store Memory block at the root level of the model with the properties specified by the signal object and an initial value set to an array of zeros. The dimensions of that array are inherited from the `Dimensions` property of the signal object.

If Simulink finds neither the Data Store Memory block nor the signal object, it halts the compilation and displays an error. See “Symbol Resolution” for more information about the search path.

Programmatic Use

Block Parameter: `DataStoreName`

Type: character vector

Values: data store name

Default: 'A'

Data store memory block — Data Store Memory block name

block path

This property is read-only.

This field lists the Data Store Memory block that initialized the store to which this block writes.

Corresponding Data Store Read blocks – List of corresponding Data Store Read blocks block path

This property is read-only.

This field lists the path to all Data Store Read blocks with the same data store name as this block that are in the same (sub)system or in any subsystem below it in the model hierarchy. Click any entry in this list to highlight the corresponding block in your model.

Sample time – Sample time

-1 (default) | scalar | vector

The sample time, which controls when the block writes to the data store. A value of -1 indicates that the sample time is inherited. See “Specify Sample Time” for more information.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '-1'

Element Assignment

Elements in the array (Signals in the bus) – Elements in associated data store

character vector (no default)

List of elements in the associated data store. For data stores with arrays, you can write the whole data store, or you can assign one or more elements to the whole data store. For data stores with a bus data type, you can expand the tree to view and select the bus elements. The list displays the maximum dimensions for each element in parentheses.

If **Enable indexing** is not selected, select an element and use one of the following approaches:

- Click **Select>>** to display that element and all its subelements in the **Selected element(s)** list.
- Use the **Specify element(s) to assign** edit box to specify the subelements that you want to select for writing. Then click **Select>>**.

To select multiple elements, repeat the above procedure for each element.

Alternatively, you can select **Enable indexing**, then select a single element and specify the subelements dynamically using the **Index Option** parameter.

To refresh the display and reflect modifications to the array or bus used in the data store, click **Refresh**.

Dependencies

The prompt for this section (**Elements in the array** or **Signals in the bus**) depends on the type of data in the data store.

Programmatic Use**Block Parameter:** DataStoreElements**Type:** character vector**Values:** pound-delimited list of elements (See “Specification using the command line”.)**Default:** ''**Specify element(s) to assign — MATLAB expression defining the elements to assign**

character vector (no default)

Enter a MATLAB expression to define the specific element that you want to write, then click **Select>>** to add the element to the **Assigned element(s)** table. Repeat to select additional elements.

For example, for a data store named DSM that has maximum dimensions of [3,5], you could enter expressions such as DSM(2,4) or DSM([1 3],2) in the edit box. See “Accessing Specific Bus and Matrix Elements”.

To apply the element selection, click **OK** or **Apply**.

Dependencies

The **Specify element(s) to assign** edit box appears only if **Enable indexing** is not selected.

Programmatic Use**Block Parameter:** DataStoreElements**Type:** character vector**Values:** pound-delimited list of elements (See “Specification using the command line”.)**Default:** ''**Assigned element(s) — List of selected elements**

character vector (no default)

Elements that you select for assignment. The Data Store Write block icon displays an input port for each element that you specify.

To change the order of bus or matrix elements in the list, select the element in the list and click **Up** or **Down**. Changing the order of the elements in the list changes the order of the ports. To remove an element, click **Remove**.

Dependencies

The **Assigned element(s)** table appears only if **Enable indexing** is not selected.

Programmatic Use**Block Parameter:** DataStoreElements**Type:** character vector**Values:** pound-delimited list of elements (See “Specification using the command line”.)**Default:** ''**Enable indexing — Enable indexing to specify subelements of data store element to write**

'off' (default) | 'on'

Select this parameter to enable indexing similar to that used by the Assignment block, whereby you can dynamically specify indices of subelements to write by using one or more index input ports, as well as specifying indices by using the block dialog. A Data Store Write block can write to only a single element of a data store (that is, a single signal in a bus) when this parameter is selected. To

write to multiple elements of a data store using dynamic indexing, use multiple Data Store Write blocks.

Clear this parameter to disable Assignment block-style indexing. You can select multiple data store elements to write, but you can specify which subelements to write only by using the block dialog.

Note Do not select **Enable indexing** if the associated data store contains only a single, scalar element.

Programmatic Use

Block Parameter: EnableIndexing

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Number of dimensions — Number of dimensions of data store element

1 (default) | positive integer

Number of dimensions of selected data store element. You must explicitly indicate this number.

Dependencies

This parameter is enabled only if **Enable indexing** is selected.

Programmatic Use

Block Parameter: NumberOfDimensions

Type: character vector

Values: positive integer

Default: '1'

Index mode — Index mode

One-based (default) | Zero-based

Select the indexing mode. If One-based is selected, an index of 1 specifies the first element of the input vector. If Zero-based is selected, an index of 0 specifies the first element of the input vector.

Dependencies

This parameter is enabled only if **Enable indexing** is selected.

Programmatic Use

Parameter: IndexMode

Type: character vector

Values: 'Zero-based' | 'One-based'

Default: 'One-based'

Index Option — Index method for subelements

Index vector (dialog) (default) | Select all | Index vector (port) | Starting index (dialog) | Starting index (port)

Define, by dimension, how the subelements of the selected data store element are to be indexed. From the list, select:

Menu Item	Action
Select all	Disables the Index column. All subelements are assigned.
Index vector (dialog)	Enables the Index column. Enter a vector containing the indices of subelements to be assigned values.
Index vector (port)	Disables the Index column. The relevant index port defines the indices of subelements to be assigned values.
Starting index (dialog)	Enables the Index column. Enter the starting index of the range of subelements to be assigned values. The size of the range is inherited from the size of relevant dimension of the input data signal.
Starting index (port)	Disables the Index column. The relevant index port defines the starting index of the range of elements to be assigned values. The size of the range is inherited from the size of relevant dimension of the input data signal.

The **Index** column is displayed as relevant.

Dependencies

This parameter is enabled only if **Enable indexing** is selected.

Programmatic Use

Parameter: IndexOptionArray

Type: character vector

Values: 'Select all' | 'Index vector (dialog)' | 'Index vector (port)' | 'Starting index (dialog)' | 'Starting index (port)'

Default: 'Index vector (dialog)'

Index — Indices or starting index of subelements

1 (default) | integer | vector of integers

If the **Index Option** is `Index vector (dialog)`, enter a vector containing the indices of each subelement to write.

If the **Index Option** is `Starting index (dialog)`, enter the starting index of the range of subelements to write.

Dependencies

This parameter is enabled only if **Enable indexing** is selected and the **Index Option** for the dimension is `Index vector (dialog)` or `Starting index (dialog)`.

Programmatic Use

Parameter: IndexParamArray

Type: character vector

Values: cell array

Default: '{ }'

Block Characteristics

Data Type Conversion

Convert input signal to specified data type

Library: Simulink / Commonly Used Blocks
 Simulink / Signal Attributes
 HDL Coder / Commonly Used Blocks
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Signal Attributes

Description

The Data Type Conversion block converts an input signal of any Simulink data type to the data type that you specify.

Note To control the output data type by specifying block parameters, or to inherit a data type from a downstream block, use the Data Type Conversion block. To inherit a data type from a different signal in the model, use the Data Type Conversion Inherited block.

Convert Fixed-Point Signals

When you convert between fixed-point data types, the **Input and output to have equal** parameter controls block behavior. This parameter does not change the behavior of the block when:

- The input and output do not have a fixed-point data type.
- The input or output has a fixed-point data type with trivial scaling.

For more information about fixed-point numbers, see “Fixed-Point Numbers in Simulink” (Fixed-Point Designer).

To convert a signal from one data type to another by attempting to preserve the real-world value of the input signal, select **Real World Value (RWV)**, the default setting. The block accounts for the limits imposed by the scaling of the input and output and attempts to generate an output of equal real-world value.

To change the real-world value of the input signal by performing a scaling reinterpretation of the stored integer value, select **Stored Integer (SI)**. Within the limits of the specified data types, the block attempts to preserve the stored integer value of the signal during conversion. A best practice is to specify input and output data types using the same word length and signedness. Doing so ensures that the block changes only the scaling of the signal. Specifying a different signedness or word length for the input and output could produce unexpected results such as range loss or unexpected sign extensions. For an example, see “Convert Data Types in Simulink Models” on page 12-117.

If you select **Stored Integer (SI)**, the block does not perform a lower-level bit reinterpretation of a floating-point input signal. For example, if the input is `single` and has value 5, the bits that store the input in memory are given in hexadecimal by the following command.

```
num2hex(single(5))
```

40a00000

However, the Data Type Conversion block does not treat the stored integer value as 40a00000, but instead as the real-world value, 5. After conversion, the stored integer value of the output is 5.

Cast Enumerated Signals

Use a Data Type Conversion block to cast enumerated signals as follows:

- 1 To cast a signal of enumerated type to a signal of any numeric type.

The underlying integers of all enumerated values input to the Data Type Conversion block must be within the range of the numeric type. Otherwise, an error occurs during simulation.

- 2 To cast a signal of any integer type to a signal of enumerated type.

The value input to the Data Type Conversion block must match the underlying value of an enumerated value. Otherwise, an error occurs during simulation.

You can enable the **Saturate on integer overflow** parameter so that Simulink uses the default value of the enumerated type when the value input to the block does not match the underlying value of an enumerated value. See “Type Casting for Enumerations” (Simulink Coder).

You cannot use a Data Type Conversion block in these cases:

- To cast a noninteger numeric signal to an enumerated signal.
- To cast a complex signal to an enumerated signal, regardless of the data types of the real and imaginary parts of the complex signal.

See “Simulink Enumerations” for information on working with enumerated types.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array. The input can be any real- or complex-valued signal. If the input is real, the output is real. If the input is complex, the output is complex. The block converts the input signal to the **Output data type** you specify.

When you are converting fixed-point data types, use the **Input and output to have equal** parameter to determine whether the conversion happens based on the Real World Value (RWV) or Stored Integer (SI) value of the signal. For more information, see “Convert Fixed-Point Signals” on page 1-254.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Output signal

scalar | vector | matrix | N-D array

Output signal, converted to the data type you specify, with the same dimensions as the input signal.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Parameters

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output data type — Output data type**

Inherit: Inherit via back propagation (default) | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | '<data type expression>'

Default: 'Inherit: Inherit via back propagation'**Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Input and output to have equal — Constraint for converting fixed-point data types**

Real World Value (RWV) (default) | Stored Integer (SI)

Specify which type of input and output must be equal, in the context of fixed-point data representation.

- Real World Value (RWV) — Specifies the goal of making the Real World Value (RWV) of the input equal to the Real World Value (RWV) of the output.
- Stored Integer (SI) — Specifies the goal of making the Stored Integer (SI) value of the input equal to the Stored Integer (SI) value of the output.

Programmatic Use**Block Parameter:** ConvertRealWorld**Type:** character vector**Values:** 'Real World Value (RWV)' | 'Stored Integer (SI)'**Default:** 'Real World Value (RWV)'

Integer rounding mode — Specify the rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Choose one of these rounding modes.

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use**Block Parameter:** `RndMeth`**Type:** character vector**Values:** `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`**Default:** `'Floor'`**See Also**

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow — Method of overflow action`off` (default) | `on`

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Note If you use double data types in your model, use this block for conversion between double and single data types. You cannot use the block to convert between double and fixed-point data types.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Note With the HDL Code Advisor, you can replace Data Type Conversion blocks that use the Stored Integer (SI) mode and convert between floating-point and fixed-point data types with Float Typecast blocks.

Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , <code>Zero</code> , or <code>Custom</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to <code>Custom</code> . HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).

Enumeration Data Support

This block supports code generation for enumerated signals. Use this block to cast a signal of an enumerated type to any integer type or to cast a signal of any integer type to an enumerated type.

Complex Data Support

This block supports code generation for complex signals.

Restrictions

If you configure a Data Type Conversion block for double to fixed-point conversion or fixed-point to double conversion, a warning is displayed during code generation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Data Type Conversion Inherited

Convert from one data type to another using inherited data type and scaling

Library: Simulink / Signal Attributes

Description

The Data Type Conversion Inherited block converts one input to the data type and scaling of the other input. The first input is used as the reference signal. The second input, **u**, is converted to the reference type by inheriting the data type and scaling information. (For a description of the port order for various block orientations, see “Port Location After Rotating or Flipping”.)

Inheriting the data type and scaling provides these advantages:

- It makes reusing existing models easier.
- It allows you to create new fixed-point models with less effort since you can avoid the detail of specifying the associated parameters.

Ports

Input

Port_1 – Reference signal

scalar | vector | matrix | N-D array

Reference signal, defining the data type used to convert input signal **u**.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

u – Input signal to convert

scalar | vector | matrix | N-D array

Input signal to convert to the reference data type, specified as a scalar, vector, matrix, or N-D array.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

y – Output signal

scalar | vector | matrix | N-D array

Output is the input signal **u**, converted to the reference data type.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Parameters

Input and Output to have equal — Constraint for converting fixed-point data types

Real World Value (RWV) (default) | Stored Integer (SI)

Specify which type of input and output must be equal, in the context of fixed-point data representation.

- Real World Value (RWV) — Specifies the goal of making the Real World Value (RWV) of the input equal to the Real World Value (RWV) of the output.
- Stored Integer (SI) — Specifies the goal of making the Stored Integer (SI) value of the input equal to the Stored Integer (SI) value of the output.

Programmatic Use

Block Parameter: ConvertRealWorld

Type: character vector

Values: 'Real World Value (RWV)' | 'Stored Integer (SI)'

Default: 'Real World Value (RWV)'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate to max or min when overflows occur — Method of overflow action

off (default) | on

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: DoSatur

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	yes

Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Data Type Duplicate

Force all inputs to same data type

Library: Simulink / Signal Attributes
HDL Coder / Signal Attributes

Description

The Data Type Duplicate block forces all inputs to have the same data type. Other attributes of input signals, such as dimension, complexity, and sample time, are independent.

You can use the Data Type Duplicate block to check for consistency of data types among blocks. If all signals do not have the same data type, the block returns an error message.

The Data Type Duplicate block is typically used such that one signal to the block controls the data type for all other blocks. The other blocks are set to inherit their data types via backpropagation.

The block can also be useful in a user created library. These library blocks can be placed in any model, and the data type for all library blocks are configured according to the usage in the model. To create a library block with more complex data type rules than duplication, use the Data Type Propagation block.

Ports

Input

Port_1 — First input signal

scalar | vector | matrix | N-D array

First input signal, specified as a scalar, vector, matrix, or N-D array. If all signals do not have the same data type, the block returns an error message.

Data Types: single | double | half | int8 | int16 | int32 | uint8 | uint16 | uint32 | string | Boolean | fixed point | enumerated

Port_N — Nth input signal

scalar | vector | matrix | N-D array

Nth input signal, specified as a scalar, vector, matrix, or N-D array. If all signals do not have the same data type, the block returns an error message.

Data Types: single | double | half | int8 | int16 | int32 | uint8 | uint16 | uint32 | string | Boolean | fixed point | enumerated

Parameters

Number of input ports — Number of block inputs

2 (default) | real-valued positive integer

Specify the number of inputs to this block as a real-valued positive integer.

Programmatic Use

Block Parameter: NumInputPorts

Type: character vector

Values: real-valued positive integer

Default: '2'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block can be used to force inputs to have same data type in subsystems that generate code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Data Type Propagation

Set data type and scaling of propagated signal based on information from reference signals

Library: Simulink / Signal Attributes
HDL Coder / Signal Attributes

Description

The Data Type Propagation block allows you to control the data type and scaling of signals in your model. You can use this block along with fixed-point blocks that have their **Output data type** parameter configured to **Inherit: Inherit via back propagation**.

The block has three inputs: **Ref1** and **Ref2** are the reference inputs, while the **Prop** input back-propagates the data type and scaling information gathered from the reference inputs. This information is then passed on to other fixed-point blocks.

The block provides many choices for propagating data type and scaling information. For example, you can use:

- The number of bits from the **Ref1** reference signal or the number of bits from widest reference signal
- The range from the **Ref2** reference signal or the range of the reference signal with the greatest range
- A bias of zero, regardless of the biases used by the reference signals
- The precision of the reference signal with the least precision

You specify how data type information is propagated using the **Propagated data type** parameter:

- If you select **Specify via dialog**, then you manually specify the data type via the **Propagated data type** edit field.
- If you select **Inherit via propagation rule**, then you must use the parameters described in “Parameters” on page 1-269.

You specify how scaling information is propagated using the **Propagated scaling** parameter:

- If you select **Specify via dialog**, then you manually specify the scaling via the **Propagated scaling** edit field.
- If you select **Inherit via propagation rule**, then you must use the parameters described in “Parameters” on page 1-269.

After you use the information from the reference signals, you can apply a second level of adjustments to the data type and scaling. To do so, use individual multiplicative and additive adjustments. This flexibility has various uses. For example, if you are targeting a DSP, then you can configure the block

so that the number of bits associated with a multiply and accumulate (MAC) operation is twice as wide as the input signal, and has a specific number of guard bits added to it.

The Data Type Propagation block also provides a mechanism to force the computed number of bits to a useful value. For example, if you are targeting a 16-bit micro, then the target C compiler is likely to support sizes of only 8 bits, 16 bits, and 32 bits. The block forces these three choices to be used. For example, suppose that the block computes a data type size of 24 bits. Since 24 bits is not directly usable by the target chip, the signal is forced up to 32 bits, which is natively supported.

There is also a method for dealing with floating-point reference signals. This method makes it easier to create designs that are easily retargeted between fixed-point chips and floating-point chips.

The Data Type Propagation block allows you to set up libraries of useful subsystems that are properly configured based on the connected signals. Without this data type propagation process, subsystems from a library are unlikely to work as desired with most integer or fixed-point signals. Manual intervention would be required to configure the data type and scaling. In many situations, this block can eliminate the manual intervention.

Precedence Rules

The precedence of the dialog box parameters decreases from top to bottom. Also:

- Double-precision reference inputs have precedence over all other data types.
- Single-precision reference inputs have precedence over integer and fixed-point data types.
- Multiplicative adjustments are carried out before additive adjustments.
- The number of bits is determined before the precision or positive range is inherited from the reference inputs.
- PosRange is one bit higher than the exact maximum positive range of the signal.
- The computed number-of-bits are promoted to the smallest allowable value that is greater than or equal to the computation. If none exists, then the block returns an error.

Ports

Input

Ref1 — First reference signal

scalar | vector | matrix | N-D array

First reference signal, from which to gather data type and scaling information.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Ref2 — Second reference signal

scalar | vector | matrix | N-D array

Second reference signal from which to gather data type and scaling information.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Prop — Propagated data type and scaling

data type and scaling

Data type and scaling information, back-propagated to the model. After the block gathers data type and scaling information from the reference signals, you can apply a second level of adjustments to the data type and scaling. To do so, specify individual multiplicative and additive adjustments in the block dialog box.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Propagated Type

1. Propagated data type — Mode of specifying propagated data type

Inherit via propagation rule (default) | Specify via dialog

Specify whether to propagate the data type via the dialog box, or inherit the data type from the reference signals.

Dependencies

Setting this parameter to `Specify via dialog` enables the **1.1. Propagated data type (e.g. `fixdt(1,16)`, `fixdt('single')`)**.

Programmatic Use

Block Parameter: `PropDataTypeMode`

Type: character vector

Values: `'Specify via dialog'` | `'Inherit via propagation rule'`

Default: `'Inherit via propagation rule'`

1.1. Propagated data type (e.g. `fixdt(1,16)`, `fixdt('single')`) — Propagated data type

`fixdt(1,16)` (default) | data type string

Specify the data type to propagate.

Dependencies

To enable this parameter, set **1. Propagated data type** to `Specify via dialog`.

Programmatic Use

Block Parameter: `PropDataTypeMode`

Type: character vector

Values: `'Specify via dialog'` | `'Inherit via propagation rule'`

Default: `'Inherit via propagation rule'`

1.1 If any reference input is double, output is — Output data type when a reference input is double

`double` (default) | `single`

Specify the output data type as `single` or `double`. This parameter makes it easier to create designs that are easily retargeted between fixed-point chips and floating-point chips.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit via propagation rule`.

Programmatic Use**Block Parameter:** IfRefDouble**Type:** character vector**Values:** 'double' | 'single'**Default:** 'double'**1.2 If any reference input is single, output is – Output data type when a reference input is single**

single (default) | double

Specify the output data type as `single` or `double`. This parameter makes it easier to create designs that are easily retargeted between fixed-point chips and floating-point chips.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit` via propagation rule.

Programmatic Use**Block Parameter:** IfRefSingle**Type:** character vector**Values:** 'double' | 'single'**Default:** 'single'**1.3 Is-Signed – Signedness of propagated data type**

IsSigned1 or IsSigned2 (default) | IsSigned1 | IsSigned2 | TRUE | FALSE

Specify the sign of **Prop** as one of the following values.

Parameter Value	Description
IsSigned1	Prop is a signed data type if Ref1 is a signed data type.
IsSigned2	Prop is a signed data type if Ref2 is a signed data type.
IsSigned1 or IsSigned2	Prop is a signed data type if either Ref1 or Ref2 are signed data types.
TRUE	Ref1 and Ref2 are ignored, and Prop is always a signed data type.
FALSE	Ref1 and Ref2 are ignored, and Prop is always an unsigned data type.

For example, if the **Ref1** signal is `ufix(16)`, the **Ref2** signal is `sfix(16)`, and the **Is-Signed** parameter is `IsSigned1 or IsSigned2`, then **Prop** is forced to be a signed data type.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit` via propagation rule.

Programmatic Use**Block Parameter:** IsSigned**Type:** character vector**Values:** 'IsSigned1' | 'IsSigned2' | 'IsSigned1 or IsSigned2' | 'TRUE' | 'FALSE'**Default:** 'IsSigned1 or IsSigned2'**1.4.1 Number-of-bits: Base – Number of bits for the base of the propagated data type**

$$\max([\text{NumBits1 } \text{NumBits2}]) \text{ (default) } | \text{NumBits1} | \text{NumBits2} | \min([\text{NumBits1 } \text{NumBits2}]) | \text{NumBits1} + \text{NumBits2}$$

Specify the number of bits used by **Prop** for the base data type as one of the following values.

Parameter Value	Description
NumBits1	The number of bits for Prop is given by the number of bits for Ref1 .
NumBits2	The number of bits for Prop is given by the number of bits for Ref2 .
max([NumBits1 NumBits2])	The number of bits for Prop is given by the reference signal with largest number of bits.
min([NumBits1 NumBits2])	The number of bits for Prop is given by the reference signal with smallest number of bits.
NumBits1+NumBits2	The number of bits for Prop is given by the sum of the reference signal bits.

For more information about the base data type, refer to Targeting an Embedded Processor (Fixed-Point Designer).

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: NumBitsBase

Type: character vector

Values: 'NumBits1' | 'NumBits2' | 'max([NumBits1 NumBits2])' | 'min([NumBits1 NumBits2])' | 'NumBits1+NumBits2'

Default: 'max([NumBits1 NumBits2])'

1.4.2 Number-of-bits: Multiplicative adjustment — Number of bits for multiplicative adjustment of propagated data type

1 (default) | positive integer

Specify the number of bits used by **Prop** by including a multiplicative adjustment that uses a data type of `double`. For example, suppose that you want to guarantee that the number of bits associated with a multiply and accumulate (MAC) operation is twice as wide as the input signal. To do this, set this parameter to 2.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: NumBitsMult

Type: character vector

Values: positive integer

Default: '1'

1.4.3 Number-of-bits: Additive adjustment — Number of bits for additive adjustment of propagated data type

0 (default) | positive integer

Specify the number of bits used by **Prop** by including an additive adjustment that uses a data type of `double`. For example, if you are performing multiple additions during a MAC operation, the result could overflow. To prevent overflow, you can associate guard bits with the propagated data type. To associate four guard bits, you specify the value 4.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: `NumBitsAdd`

Type: character vector

Values: scalar

Default: `'0'`

1.4.4 Number-of-bits: Allowable final values — Allowable number of bits in propagated data type

`'1:128'` (default) | scalar or vector of positive integers

Force the computed number of bits used by **Prop** to a useful value. For example, if you are targeting a processor that supports only 8 bits, 16 bits, and 32 bits, then you configure this parameter to `[8,16,32]`. The block always propagates the smallest specified value that fits. If you want to allow all fixed-point data types, you would specify the value `1:128`.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: `NumBitsAllowFinal`

Type: character vector

Values: scalar or vector of positive integers

Default: `'1:128'`

Propagated Scaling**2. Propagated scaling — Propagated scaling mode**

`Inherit via propagation rule` (default) | `Specify via dialog` | `Obtain via best precision`

Choose to propagate the scaling via the dialog box, inherit the scaling from the reference signals, or calculate the scaling to obtain best precision.

Programmatic Use

Block Parameter: `PropScalingMode`

Type: character vector

Values: `Inherit via propagation rule` | `Specify via dialog` | `Obtain via best precision`

Default: `Inherit via propagation rule`

2.1. Propagated scaling (Slope or [Slope Bias]) — Slope or slope and bias

`2^-10` | `Slope` | `[Slope Bias]`

Specify the scaling as either a slope or a slope and bias.

Dependencies

To enable this parameter, set **Propagated scaling** to `Specify via dialog`.

Programmatic Use

Block Parameter: `PropScaling`

Type: character vector
Values: Slope | [Slope Bias]
Default: '2^-10'

2.1. Values used to determine best precision scaling — Values to constrain precision

[5 -7] (default)

Specify any values to be used to constrain the precision, such as the upper and lower limits on the propagated input. Based on the data type, the block selects a scaling such that these values can be represented with no overflow error and minimum quantization error.

Dependencies

To enable this parameter, set **Propagated scaling** to Obtain via best precision.

Programmatic Use

Block Parameter: ValuesUsedBestPrec

Type: character vector

Values: vector of values

Default: '[5 -7]'

2.1.1. Slope: Base — Slope for base of the propagated data type

min([Slope1 Slope2]) (default) | Slope1 | Slope2 | min([Slope1 Slope2]) | max([Bias1 Bias2]) | Slope1*Slope2 | Slope1/Slope2 | PosRange1 | PosRange2 | max([PosRange1 PosRange2]) | min([PosRange1 PosRange2]) | PosRange1*PosRange2 | PosRange1/PosRange2

Specify the slope used by **Prop** for the base data type as one of the following values.

Parameter Value	Description
Slope1	The slope of Prop is given by the slope of Ref1 .
Slope2	The slope of Prop is given by the slope of Ref2 .
max([Slope1 Slope2])	The slope of Prop is given by the maximum slope of the reference signals.
min([Slope1 Slope2])	The slope of Prop is given by the minimum slope of the reference signals.
Slope1*Slope2	The slope of Prop is given by the product of the reference signal slopes.
Slope1/Slope2	The slope of Prop is given by the ratio of the Ref1 slope to the Ref2 slope.
PosRange1	The range of Prop is given by the range of Ref1 .
PosRange2	The range of Prop is given by the range of Ref2 .
max([PosRange1 PosRange2])	The range of Prop is given by the maximum range of the reference signals.
min([PosRange1 PosRange2])	The range of Prop is given by the minimum range of the reference signals.
PosRange1*PosRange2	The range of Prop is given by the product of the reference signal ranges.

Parameter Value	Description
PosRange1/PosRange2	The range of Prop is given by the ratio of the Ref1 range to the Ref2 range.

You control the precision of **Prop** with `Slope1` and `Slope2`, and you control the range of **Prop** with `PosRange1` and `PosRange2`. Also, `PosRange1` and `PosRange2` are one bit higher than the maximum positive range of the associated reference signal.

Dependencies

To enable this parameter, set **Propagated scaling** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: `SlopeBase`

Type: character vector

Values: `'Slope1'` | `'Slope2'` | `'max([Slope1 Slope2])'` | `'min([Slope1 Slope2])'` | `'Slope1*Slope2'` | `'Slope1/Slope2'` | `'PosRange1'` | `'PosRange2'` | `'max([PosRange1 PosRange2])'` | `'min([PosRange1 PosRange2])'` | `'PosRange1*PosRange2'` | `'PosRange1/PosRange2'`

Default: `'min([Slope1 Slope2])'`

2.1.2. Slope: Multiplicative adjustment — Slope of multiplicative adjustment of propagated data type

1 (default) | scalar

Specify the slope used by **Prop** by including a multiplicative adjustment that uses a data type of `double`. For example, if you want 3 bits of additional precision (with a corresponding decrease in range), the multiplicative adjustment is 2^{-3} .

Dependencies

To enable this parameter, set **Propagated scaling** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: `SlopeMult`

Type: character vector

Values: scalar

Default: `'1'`

2.1.3. Slope: Additive adjustment — Slope of additive adjustment of propagated data type

0 (default) | scalar

Specify the slope used by **Prop** by including an additive adjustment that uses a data type of `double`. An additive slope adjustment is often not needed. The most likely use is to set the multiplicative adjustment to 0, and set the additive adjustment to force the final slope to a specified value.

Dependencies

To enable this parameter, set **Propagated scaling** to `Inherit` via propagation rule.

Programmatic Use

Block Parameter: `SlopeAdd`

Type: character vector

Values: scalar

Default: '0'

2.2.1. Bias: Base — Base bias for Prop

Bias1 (default) | Bias2 | max([Bias1 Bias2]) | min([Bias1 Bias2]) | Bias1*Bias2 | Bias1/Bias2 | Bias1+Bias2 | Bias1-Bias2

Specify the bias used by **Prop** for the base data type. The parameter values are described as follows:

Parameter Value	Description
Bias1	The bias of Prop is given by the bias of Ref1 .
Bias2	The bias of Prop is given by the bias of Ref2 .
max([Bias1 Bias2])	The bias of Prop is given by the maximum bias of the reference signals.
min([Bias1 Bias2])	The bias of Prop is given by the minimum bias of the reference signals.
Bias1*Bias2	The bias of Prop is given by the product of the reference signal biases.
Bias1/Bias2	The bias of Prop is given by the ratio of the Ref1 bias to the Ref2 bias.
Bias1+Bias2	The bias of Prop is given by the sum of the reference biases.
Bias1-Bias2	The bias of Prop is given by the difference of the reference biases.

Dependencies

To enable this parameter, set **Propagated scaling** to **Inherit** via propagation rule.

Programmatic Use

Block Parameter: BiasBase

Type: character vector

Values: 'Bias1' | 'Bias2' | 'max([Bias1 Bias2])' | 'min([Bias1 Bias2])' | 'Bias1*Bias2' | 'Bias1/Bias2' | 'Bias1+Bias2' | 'Bias1-Bias2'

Default: 'Bias1'

2.2.2. Bias: Multiplicative adjustment — Multiplicative bias for propagated data type

1 (default) | scalar

Specify the bias used by Prop by including a multiplicative adjustment that uses a data type of double.

This parameter is visible only when you set **Propagated scaling** to **Inherit** via propagation rule.

Programmatic Use

Block Parameter: BiasMult

Type: character vector

Values: scalar

Default: '1'

2.3.2. Bias: Additive adjustment — Additive bias for propagated data type

0 (default) | scalar

Specify the bias used by **Prop** by including an additive adjustment that uses a data type of double.

If you want to guarantee that the bias associated with **Prop** is zero, configure both the multiplicative adjustment and the additive adjustment to 0.

Dependencies

To enable this parameter, set **Propagated scaling** to Inherit via propagation rule.

Programmatic Use

Block Parameter: BiasAdd

Type: character vector

Values: scalar

Default: '0'

Block Characteristics

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block can be used to control scaling and data types of signals that are part of subsystems that generate HDL code, but is not included in the hardware implementation.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Data Type Scaling Strip

Remove scaling and map to built in integer

Library: Simulink / Signal Attributes

Description

The Data Type Scaling Strip block strips the scaling off a fixed-point signal. It maps the input data type to the smallest built-in data type that has enough data bits to hold the input. The stored integer value of the input is the value of the output. The output always has nominal scaling (slope = 1.0 and bias = 0.0), so the output does not distinguish between real world value and stored integer value.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The block strips the scaling off a fixed-point input signal, and outputs the stored integer value with the smallest possible built-in data type.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Input signal mapped to built-in data type

scalar | vector | matrix

Stored integer value of the input signal with the smallest possible built-in data type, and the same dimensions as the input.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes

Zero-Crossing Detection	no

Dead Zone

Provide region of zero output

Library: Simulink / Discontinuities
HDL Coder / Discontinuities

Description

The Dead Zone block generates zero output within a specified region, called its dead zone. You specify the lower limit (LL) and upper limit (UL) of the dead zone as the **Start of dead zone** and **End of dead zone** parameters. The block output depends on the input (U) and the values for the lower and upper limits.

Input	Output
$U \geq LL$ and $U \leq UL$	Zero
$U > UL$	$U - UL$
$U < LL$	$U - LL$

Ports

Input

Port_1 – Input signal

scalar | vector

Input signal to the dead-zone algorithm.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 – Output signal

scalar | vector

Output signal after the dead-zone algorithm is applied to the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Start of dead zone – Specify the lower bound of the dead zone

'-0.5' (default) | scalar | vector

Specify dead zone lower limit. Set the value for **Start of dead zone** less than or equal to **End of dead zone**. When the input value is less than **Start of dead zone**, then the block shifts the output value down by the **Start of dead zone** value.

Programmatic Use

Block Parameter: LowerValue

Type: character vector

Value: scalar or vector less than or equal to UpperValue.

Default: '-0.5'

End of dead zone — Specify the upper limit of the dead zone

'0.5' (default) | scalar | vector

Specify dead zone upper limit. Set the value for **End of dead zone** greater than or equal to **Start of dead zone**. When the input value is greater than **End of dead zone**, then the block shifts the output value down by the **End of dead zone** value.

Programmatic Use

Block Parameter: UpperValue

Type: character vector

Value: scalar or vector greater than or equal to LowerValue.

Default: '0.5'

Saturate on integer overflow — Choose the behavior when integer overflow occurs

off (default) | on

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: DoSatur

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Treat as gain when linearizing – Specify the gain value

On (default) | boolean

The linearization commands in Simulink software treat this block as a gain in state space. Select this check box to cause the commands to treat the gain as 1. Clear the box to have the commands treat the gain as 0.

Programmatic Use

Block Parameter: LinearizeAsGain

Type: character vector

Value: 'off' | 'on'

Default: 'on'

Enable zero-crossing detection – Enable zero-crossing detection

on (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector, string

Values: 'off' | 'on'

Default: 'on'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Block Characteristics**

Data Types	double fixed point integer single

Dead Zone Dynamic | Backlash

Introduced before R2006a

Dead Zone Dynamic

Provide dynamic region of zero output

Library: Simulink / Discontinuities
HDL Coder / Discontinuities

Description

The Dead Zone Dynamic block generates a region of zero output based on dynamic input signals that specify the upper and lower limit. The block output depends on the input **u**, and the values of the input signals **up** and **lo**.

Input	Output
$u \geq lo$ and $u \leq up$	Zero
$u > up$	$u - up$
$u < lo$	$u - lo$

The Dead Zone Dynamic block is a masked subsystem and does not have any parameters.

Ports

Input

u – Input signal

scalar | vector

Input signal to the dead zone algorithm.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

lo – Lower limit for the dead zone

scalar | vector

Dynamic value providing the lower bound of the region of zero output. When the input is less than **lo** then the output value is shifted down by value of **lo**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

up – Upper limit for the dead zone

scalar

Dynamic value providing the upper bound of the region of zero output. When the input is greater than **up** then the output value is shifted down by value of **up**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output**y — Output signal**

scalar | vector

Output signal after the dynamic dead zone algorithm is applied to the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Block Characteristics

Data Types	double fixed point integer single

Decrement Real World

Decrease real-world value of signal by one

Library: Simulink / Additional Math & Discrete / Additional Math:
Increment - Decrement
HDL Coder / Math Operations

Description

The Decrement Real World block decreases the real-world value of the signal by one. Overflows always wrap.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 – Output signal

scalar | vector | matrix

Output is the real-world value of the input signal decreased by one. Overflows always wrap. The output has the same data type and dimensions as the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes

Decrement Stored Integer

Decrease stored integer value of signal by one

Library: Simulink / Additional Math & Discrete / Additional Math:
Increment - Decrement
HDL Coder / Math Operations

Description

The Decrement Stored Integer block decreases the stored integer value of a signal by one.

Floating-point signals also decrease by one, and overflows always wrap.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output is the stored integer value of the input signal decreased by one. Floating-point signals also decrease by one, and overflows always wrap. The output has the same data type and dimensions as the input.

Decrement Time To Zero

Decrease real-world value of signal by sample time, but only to zero

Library: Simulink / Additional Math & Discrete / Additional Math:
Increment - Decrement

Description

The Decrement Time To Zero block decreases the real-world value of the signal by the sample time, T_s . The output never goes below zero.

Limitations

The Decrement Time To Zero block works only with fixed sample rates and does not work inside a triggered subsystem.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output is the real-world value of the input signal decreased by the sample time, T_s . The output never goes below zero. The output has the same data type and dimensions as the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Delay

Delay input signal by fixed or variable sample periods

Library: Simulink / Commonly Used Blocks
 Simulink / Discrete
 HDL Coder / Commonly Used Blocks
 HDL Coder / Discrete

Description

The Delay block outputs the input of the block after a delay. The block determines the delay time based on the value of the **Delay length** parameter. The block supports:

- Variable delay length
- Specification of the initial condition from an input port
- State storage
- Using a circular buffer instead of an array buffer for state storage
- Resetting the state to the initial condition with an external reset signal
- Controlling execution of the block at every time step with an external enable signal

The initial block output depends on several factors such as the **Initial condition** parameter and the simulation start time. For more information, see “Initial Block Output” on page 1-296. The **External reset** parameter determines if the block output resets to the initial condition on triggering. The **Show enable port** parameter determines if the block execution is controlled in every time step by an external enable signal.

Initial Block Output

The output in the first few time steps of the simulation depends on the block sample time, the delay length, and the simulation start time. The block supports specifying or inheriting discrete sample times to determine the time interval between samples. For more information, see “Specify Sample Time”.

The table shows the Delay block output for the first few time steps with these settings. The block inherits a discrete sample time as $[T_{\text{sampling}}, T_{\text{offset}}]$, where T_{sampling} is the sampling period and T_{offset} is the initial time offset. n is the value of the **Delay length** parameter and T_{start} is the simulation start time for the model

Simulation Time Range	Block Output
(T_{start}) to $(T_{\text{start}} + T_{\text{offset}})$	Zero
$(T_{\text{start}} + T_{\text{offset}})$ to $(T_{\text{start}} + T_{\text{offset}} + n * T_{\text{sampling}})$	Initial condition parameter
After $(T_{\text{start}} + T_{\text{offset}} + n * T_{\text{sampling}})$	Input signal

Behavior with External Enable Signal

Selecting the **Show enable port** check box enables the Enable port. If the enable port is enabled, the block operates in this order

- 1 Checks if the enable condition is satisfied.
- 2 If the reset port is enabled, checks the reset condition.
- 3 Performs the Delay block functionality.

The block has this operation with the Enable port:

- At the first block enable, the block output is the initial condition value ($x0$).
- For consecutive enable signals, the block takes the last state of the input signal u .
- If the port is not enabled at the start of simulation, the Delay block outputs 0 .
- During simulation, if the port becomes disabled after having been enabled, the block does not execute and holds its last value.

Variable-Size Support

The Delay block provides the following support for variable-size signals:

- The data input port u accepts variable-size signals. The other input ports do not accept variable-size signals.
- The output port has the same signal dimensions as the data input port u for variable-size inputs.

The rules that apply to variable-size signals depend on the input processing mode of the Delay block.

Input Processing Mode	Rules for Variable-Size Signal Support
Elements as channels (sample based)	<ul style="list-style-type: none"> • The signal dimensions change only during state reset when the block is enabled. • The initial condition must be scalar.
Columns as channels (frame based)	<ul style="list-style-type: none"> • No support

Bus Support

The Delay block provides the following support for bus signals:

- The data input u accepts virtual and nonvirtual bus signals. Other than input port $x0$, the other input ports do not accept bus signals.
- The initial condition $x0$ port accepts nonvirtual bus signals.
- The output port has the same bus type as the data input port u for bus inputs.
- Buses work with:
 - Sample-based and frame-based processing
 - Fixed and variable delay length
 - Array and circular buffers

To use a bus signal as the input to a Delay block, specify the initial condition on the dialog box or through the $x0$ port. Support for virtual and nonvirtual buses depends on the initial condition that

you specify and whether the **State name** parameter is empty or not. For the x0 input port, only nonvirtual buses are supported.

Initial Condition	State Name	
	Empty	Not Empty
Zero	Virtual and nonvirtual bus support	Nonvirtual bus support only
Nonzero scalar	Virtual and nonvirtual bus support	No bus support
Nonscalar	No bus support	No bus support
Structure	Virtual and nonvirtual bus support	Nonvirtual bus support only
Partial structure	Virtual and nonvirtual bus support	Nonvirtual bus support only

String Support

The Delay block can accept and output string data type only if:

- The block is configured for the default value of the **Initial condition** parameter (0).
- The **Delay length** value is 1 or less.

Ports

Input

u — Data input signal

scalar | vector

Input data signal delayed according to parameters settings.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus

d — Delay length

scalar

Delay length specified as inherited from an input port. Enabled when you select the **Delay length: Source** parameter as **Input port**.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Enable — External enable signal

scalar

Enable signal that enables or disables execution of the block. To create this port, select the **Show enable port** parameter.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

External reset — External reset signal

scalar

External signal that resets execution of the block to the initial condition. To create this port, select the **External reset** parameter.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

x0 — Initial condition

scalar | vector

Initial condition specified as inherited from an input port. Enabled when you select the **Initial Condition: Source** parameter as Input port.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | bus

Output**Port_1 — Output signal**

scalar | vector

Output signal that is the input signal delayed by the length of time specified by the parameter **Delay length**. The initial value of the output signal depends on several conditions. See “Initial Block Output” on page 1-296.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus

Parameters**Main****Delay length — Delay length**

Dialog (default) | Input port

Specify whether to enter the delay length directly on the dialog box (fixed delay) or to inherit the delay from an input port (variable delay).

- If you set **Source** to Dialog, enter the delay length in the edit field under **Value**.
- If you set **Source** to Input port, verify that an upstream signal supplies a delay length for the d input port. You can also specify its maximum value by specifying the parameter **Upper limit**.

Specify the scalar delay length as a real, non-negative integer. An out-of-range or non-integer value in the dialog box (fixed delay) returns an error. An out-of-range value from an input port (variable delay) casts it into the range. A noninteger value from an input port (variable delay) truncates it to the integer.

Programmatic Use**Block Parameter:** DelayLengthSource**Type:** character vector**Values:** 'Dialog' | 'Input port'**Default:** 'Dialog'**Block Parameter:** DelayLength

Type: character vector

Values: scalar

Default: '2'

Block Parameter: DelayLengthUpperLimit

Type: character vector

Values: scalar

Default: '100'

Initial condition — Initial condition

Dialog (default) | Input port

Specify whether to enter the initial condition directly on the dialog box or to inherit the initial condition from an input port.

- If you set **Source** to **Dialog**, enter the initial condition in the edit field under **Value**.
- If you set **Source** to **Input port**, verify that an upstream signal supplies an initial condition for the x_0 input port.

Simulink converts offline the data type of **Initial condition** to the data type of the input signal u using a round-to-nearest operation and saturation.

Note When **State name must resolve to Simulink signal object** is selected on the **State Attributes** pane, the block copies the initial value of the signal object to the **Initial condition** parameter. However, when the source for **Initial condition** is **Input port**, the block ignores the initial value of the signal object.

Programmatic Use

Block Parameter: InitialConditionSource

Type: character vector

Values: 'Dialog' | 'Input port'

Default: 'Dialog'

Block Parameter: InitialCondition

Type: character vector

Values: scalar

Default: '0.0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Use circular buffer for state – Circular buffer for storing state

off (default) | on

Select to use a circular buffer for storing the state in simulation and code generation. Otherwise, an array buffer stores the state.

Using a circular buffer can improve execution speed when the delay length is large. For an array buffer, the number of copy operations increases as the delay length goes up. For a circular buffer, the number of copy operations is constant for increasing delay length.

If one of the following conditions is true, an array buffer always stores the state because a circular buffer does not improve execution speed.

- For sample-based signals, the delay length is 1.
- For frame-based signals, the delay length is no larger than the frame size.

Programmatic Use

Block Parameter: UseCircularBuffer

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Prevent direct feedthrough – Prevent direct feedthrough

off (default) | on

Select to increase the delay length from zero to the lower limit for the **Input processing** mode.

- For sample-based signals, increase the minimum delay length to 1.
- For frame-based signals, increase the minimum delay length to the frame length.

Selecting this check box prevents direct feedthrough from the input port, u , to the output port. However, this check box cannot prevent direct feedthrough from the initial condition port, x_0 , to the output port.

Dependency

To enable this parameter, set **Delay length: Source** to Input port.

Programmatic Use

Block Parameter: PreventDirectFeedthrough

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Remove delay length check in generated code – Remove delay length out-of-range check

off (default) | on

Select to remove code that checks for out-of-range delay length.

Check Box	Result	When to Use
Selected	Generated code does not include conditional statements to check for out-of-range delay length.	For code efficiency
Cleared	Generated code includes conditional statements to check for out-of-range delay length.	For safety-critical applications

Dependency

To enable this parameter, set **Delay length: Source** to Input port.

Programmatic Use

Block Parameter: RemoveDelayLengthCheckInGeneratedCode

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Diagnostic for delay length – Diagnostic checks for delay length

None (default) | Warning | Error

Specify whether to produce a warning or error when the input d is less than the lower limit or greater than the **Delay length: Upper limit**. The lower limit depends on the setting for **Prevent direct feedthrough**.

- If the check box is cleared, the lower limit is zero.
- If the check box is selected, the lower limit is 1 for sample-based signals and frame length for frame-based signals.

Options for the diagnostic include:

- None — Simulink software takes no action.
- Warning — Simulink software displays a warning and continues the simulation.
- Error — Simulink software terminates the simulation and displays an error.

Dependency

To enable this parameter, set **Delay length: Source** to Input port.

Programmatic Use

Block Parameter: DiagnosticForDelayLength

Type: character vector

Values: 'None' | 'Warning' | 'Error'

Default: 'None'

Show enable port – Create enable port

off (default) | on

Select to control execution of this block with an enable port. The block is considered enabled when the input to this port is nonzero, and is disabled when the input is 0. The value of the input is checked at the same time step as the block execution.

Programmatic Use

Block Parameter: ShowEnablePort

Type: character vector

Values: 'off' | 'on'

Default: 'off'

External reset — External state reset

None (default) | Rising | Falling | Either | Level | Level hold

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset
Rising	Reset on a rising edge
Falling	Reset on a falling edge
Either	Reset on either a rising or falling edge
Level	Reset in either of these cases: <ul style="list-style-type: none"> When the reset signal is nonzero at the current time step When the reset signal value changes from nonzero at the previous time step to zero at the current time step
Level hold	Reset when the reset signal is nonzero at the current time step

Programmatic Use

Block Parameter: ExternalReset

Type: character vector

Values: 'None' | 'Rising' | 'Falling' | 'Either' | 'Level' | 'Level hold'

Default: 'None'

Sample time (-1 for inherited) — Discrete interval between sample time hits

-1 (default) | scalar

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. This block supports discrete sample time, but not continuous sample time.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Value: real scalar

Default: '-1'

State Attributes

State name — Unique name for block state

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

Programmatic Use

Block Parameter: StateName

Type: character vector

Values: unique name

Default: ' '

State name must resolve to Simulink signal object — Require state name resolve to a signal object

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use

Block Parameter: StateMustResolveToSignalObject

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides configuration options that affect HDL implementation and synthesized logic.

Block Parameter Setting	Description
Set External reset to <code>Level</code> .	Generates a reset port in the HDL code.
Select Show enable port .	Generates an enable port in the HDL code.
For Initial condition , set Source to <code>Dialog</code> and enter the value.	Specifies an initial condition for the block.
Set Input processing to <code>Columns as channels (frame based)</code> or <code>Elements as channels (sample based)</code> .	Expects vector input data, where each element of the vector represents a sample in time.

Additional Settings When Using State Control Block

If you use a State Control block with the Delay block inside a subsystem in your Simulink model, use these additional settings.

Block Parameter Setting	Description
Set External reset to <code>Level hold</code> for Synchronous mode and <code>Level</code> for Classic mode of the State Control block.	Generates a reset port in the HDL code.
Set Delay length to zero for a Delay block with an external enable port.	Treated as a wire in only Synchronous mode of the State Control block.
Set Delay length to zero for a Delay block with an external reset port.	Treated as a wire in Synchronous and Classic modes of the State Control block.

For more information about the State Control block, see State Control (HDL Coder).

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see "OutputPipeline" (HDL Coder).
ResetType	Suppress reset logic generation. The default is <code>default</code> , which generates reset logic. See also "ResetType" (HDL Coder).
UseRAM	Map delays to RAM instead of registers. The default is <code>off</code> . See also "UseRAM" (HDL Coder).

Variable Integer Delay Support

- You can generate HDL code for the Delay block that has **Delay Length** set through the Input port. Input delay length can be integer types or floating-point types.
- The code generation supports positive integer values at the 'd' port of the delay block. The delay length set through the input port must be between 0 and Upper Limit, specified in the Block Parameters dialog box.
- For negative delay length values, HDL Coder translates these negative delay length to 0.
- Similarly, if you specify delay length greater than the upper limit, HDL Coder translates the delay length to the Upper Limit value.
- Upper limit range is defined by the range of the delay length input data type. For example, if you specify delay length input data type as uint8, then the upper limit must not exceed 255.
- You can use enable and reset ports for the variable integer Delay block.

Complex Data Support

This block supports code generation for complex signals.

Restrictions

- For **Initial condition**, **Source** set to Input port is not supported for HDL code generation.
- HDL code generation supports only the Boolean data type at the Reset and Enable ports.
- HDL Block Property **UseRAM** for RAM mapping is not supported for Delay block that has **Delay Length** set through the Input port.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Demux

Extract and output elements of virtual vector signal

Library: Simulink / Commonly Used Blocks
 Simulink / Signal Routing
 HDL Coder / Commonly Used Blocks
 HDL Coder / Signal Routing

Description

The Demux block extracts the components of an input vector signal and outputs separate signals. The output signal ports are ordered from top to bottom. For information about creating and decomposing vectors, see “Mux Signal”.

Ports

Input

Port_1 — Accept nonbus vector signal to extract and output signals from
 real or complex values of any nonbus data type supported by Simulink

Vector input signal from which the Demux block selects scalar signals or smaller vectors.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | image

Output

Port_1 — Output signals extracted from input vector signal
 nonbus signal with real or complex values of any data type supported by Simulink

Output signals extracted from the input vector. The output signal ports are ordered from top to bottom. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | image

Parameters

Number of outputs — Number of outputs
 2 (default) | scalar | vector

Specify the number and, optionally, the dimensionality of each output port. If you do not specify the dimensionality of the outputs, the block determines the dimensionality of the outputs.

The value can be a scalar specifying the number of outputs or a vector whose elements specify the widths of the block output ports. The block determines the size of its outputs from the size of the input signal and the value of the **Number of outputs** parameter.

If you specify a scalar for the **Number of outputs** parameter and all of the output ports are connected, as you draw a new signal line close to output side of a Demux block, Simulink adds a port and updates the **Number of outputs** parameter.

For an input vector of width n , here is what the block outputs.

Parameter Value	Block outputs...	Examples and Comments
$p = n$	p scalar signals	If the input is a three-element vector and you specify three outputs, the block outputs three scalar signals.
$p > n$	Error	This value is not supported.
$p < n$ $n \bmod p = 0$	p vector signals each having n/p elements	If the input is a six-element vector and you specify three outputs, the block outputs three two-element vectors.
$p < n$ $n \bmod p = m$	m vector signals each having $(n/p) + 1$ elements and $p - m$ signals having n/p elements	If the input is a five-element vector and you specify three outputs, the block outputs two two-element vector signals and one scalar signal.
$[p_1 \ p_2 \ \dots \ p_m]$ $p_1 + p_2 + \dots + p_m = n$ $p_i > 0$	m vector signals having widths p_1, p_2, \dots, p_m	If the input is a five-element vector and you specify $[3, 2]$ as the output, the block outputs three of the input elements on one port and the other two elements on the other port.
An array that has one or more of m elements with a value of -1, which specifies that Simulink infers the size for the element. For example, suppose that you have a four-element array with a total width of 14 and you specify the parameter to be $[p_1 \ p_2 \ -1 \ p_4]$. The value for the third element (the -1 element) is $14 - (p_1 + p_2 + p_4)$	m vector signals	If p_i is greater than zero, the corresponding output has width p_i . If p_i is -1, the width of the corresponding output is computed dynamically.
$[p_1 \ p_2 \ \dots \ p_m]$ $p_1 + p_2 + \dots + p_m \neq n$ $p_i = > 0$	Error	This value is not supported

If you specify the number of outputs that is smaller than the number of input elements, the block distributes the elements as evenly as possible over the outputs. For examples, see "Extract Vector

Elements and Distribute Evenly Across Outputs” on page 12-149 and “Extract Vector Elements Using the Demux Block” on page 12-150.

Programmatic Use

Block Parameter: Outputs

Type: scalar or vector

Values: character vector

Default: { '2' } or vector

Display option — Displayed block icon

bar (default) | none

By default, the block icon is a solid bar of the block foreground color. To display the icon as a box containing the block type name, select none.

Programmatic Use

Block Parameter: Display option

Type: character vector

Values: 'bar' | 'none'

Default: 'bar'

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Derivative

Output time derivative of input

Library: Simulink / Continuous

Description

The Derivative block approximates the derivative of the input signal u with respect to the simulation time t . You obtain the approximation of

$$\frac{du}{dt},$$

by computing a numerical difference $\Delta u/\Delta t$, where Δu is the change in input value and Δt is the change in time since the previous simulation (major) time step.

This block accepts one input and generates one output. The initial output for the block is zero.

The precise relationship between the input and output of this block is:

$$y(t) = \frac{\Delta u}{\Delta t} = \frac{u(t) - u(T_{previous})}{t - T_{previous}} \Big|_{t > T_{previous}},$$

where t is the current simulation time and $T_{previous}$ is the time of the last output time of the simulation. The latter is the same as the time of the last major time step.

The Derivative block output might be sensitive to the dynamics of the entire model. The accuracy of the output signal depends on the size of the time steps taken in the simulation. Smaller steps allow for a smoother and more accurate output curve from this block. However, unlike with blocks that have continuous states, the solver does not take smaller steps when the input to this block changes rapidly. Depending on the dynamics of the driving signal and model, the output signal of this block might contain unexpected fluctuations. These fluctuations are primarily due to the driving signal output and solver step size.

Because of these sensitivities, structure your models to use integrators (such as Integrator blocks) instead of Derivative blocks. Integrator blocks have states that allow solvers to adjust the step size and improve simulation accuracy. See “Circuit Model” for an example of choosing the best-form mathematical model to avoid using Derivative blocks in your models.

If you must use the Derivative block with a variable step solver, set the solver maximum step size to a value such that the Derivative block can generate answers with adequate accuracy. To determine this value, you might need to repeatedly run the simulation using different solver settings.

If the input to this block is a discrete signal, the continuous derivative of the input exhibits an impulse when the value of the input changes. Otherwise, it is 0. Alternatively, you can define the discrete derivative of a discrete signal using the difference of the last two values of the signal:

$$y(k) = \frac{1}{\Delta t}(u(k) - u(k - 1))$$

Taking the z -transform of this equation results in:

$$\frac{Y(z)}{u(z)} = \frac{1 - z^{-1}}{\Delta t} = \frac{z - 1}{\Delta t \cdot z}$$

The Discrete Derivative block models this behavior. Use this block instead of the Derivative block to approximate the discrete-time derivative of a discrete signal.

Ports

Input

Port_1 – Input signal

real scalar or vector

Signal to be differentiated, specified as a real scalar or vector.

Data Types: double

Output

Port_1 – Time derivative of input signal

real scalar or vector

Time derivative of input signal, specified as a real scalar or vector. The input signal is differentiated with respect to time as:

$$y(t) = \frac{\Delta u}{\Delta t} = \frac{u(t) - u(T_{previous})}{t - T_{previous}} \Big|_{t > T_{previous}},$$

where t is the current simulation time and $T_{previous}$ is the time of the last output time of the simulation. The latter is the same as the time of the last major time step.

Data Types: double

Parameters

Coefficient c in the transfer function approximation $s/(c*s + 1)$ used for linearization – Specify the time constant c to approximate the linearization of your system

inf (default)

The exact linearization of the Derivative block is difficult because the dynamic equation for the block is $y = \dot{u}$, which you cannot represent as a state-space system. However, you can approximate the linearization by adding a pole to the Derivative block to create a transfer function $s/(c * s + 1)$. The addition of a pole filters the signal before differentiating it, which removes the effect of noise.

The default value `inf` corresponds to a linearization of θ .

Tips

- As a best practice, change the value of c to $\frac{1}{f_b}$, where f_b is the break frequency of the filter.

- The parameter must be a finite positive value.

Programmatic Use

Block Parameter: CoefficientInTFapproximation

Type: character vector, string

Values: 'inf'

Default: 'inf'

Block Characteristics

Data Types	double
Direct Feedthrough	no

Descriptor State-Space

Model linear implicit systems

Library: Simulink / Continuous

Description

The Descriptor State-Space block allows you to model linear implicit systems that can be expressed in the form $E\dot{x} = Ax + Bu$ where E is the mass matrix of the system. When E is nonsingular and therefore invertible, the system can be written in its explicit form $\dot{x} = E^{-1}Ax + E^{-1}Bu$ and modeled using the State-Space block.

When the mass matrix E is singular, one or more derivatives of the dependent variables of the system are not present in the equations. These variables are called algebraic variables. Differential equations that contain such algebraic variables are called differential algebraic equations. Their state space representation is of the form

$$\begin{aligned} E\dot{x} &= Ax + Bu \\ y &= Cx + Du \end{aligned}$$

where the variables have the following meanings:

- x is the state vector
- u is the input vector
- y is the output vector

Ports

Input

Input 1 — Input signal

scalar | vector

Real-valued input vector of type `double` whose width is the number of columns in the **B** and **D** matrices.

Data Types: `double`

Output

Output 1 — Output vector

scalar | vector

Real-valued input vector of type `double` whose width is the number of rows in the **C** and **D** matrices.

Data Types: `double`

Parameters

E — Mass matrix

1 (default) | scalar | matrix

Specify the mass matrix E as a real-valued n -by- n matrix, where n is the number of states in the system. E must be the same size as A . E can be singular or non-singular.

Programmatic Use

Block Parameter: E

Type: character vector, string

Values: scalar | matrix

Default: ' 1 '

A — Matrix coefficient, A

1 (default) | scalar | matrix

Specify the matrix coefficient A as a real-valued n -by- n matrix, where n is the number of states in the system. A must be the same size as E .

Programmatic Use

Block Parameter: A

Type: character vector, string

Values: scalar | matrix

Default: ' 1 '

B — Matrix coefficient, B

1 (default) | scalar | vector | matrix

Specify the matrix coefficient B as a real-valued n -by- m matrix, where n is the number of states in the system and m is the number of inputs.

Programmatic Use

Block Parameter: B

Type: character vector, string

Values: scalar | vector | matrix

Default: ' 1 '

C — Matrix coefficient, C

1 (default) | scalar | vector | matrix

Specify the matrix coefficient C as a real-valued r -by- n matrix, where n is the number of states in the system and r is the number of outputs.

Programmatic Use

Block Parameter: C

Type: character vector, string

Values: scalar | vector | matrix

Default: ' 1 '

D — Matrix coefficient, D

1 (default) | scalar | vector | matrix

Specify the matrix coefficient D as a real-valued r -by- m matrix, where r is the number of outputs of the system and m is the number of inputs to the system.

Programmatic Use**Block Parameter:** D**Type:** character vector, string**Values:** scalar | vector | matrix**Default:** '1'**Initial condition — Initial condition of states**

0 (default) | scalar | vector | matrix

Specify initial condition of the block states. The minimum and maximum values are bound by the **Output minimum** and **Output maximum** block parameters.

Tip Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

To enable this parameter, set the **Initial condition source** to `internal`.

Programmatic Use**Block Parameter:** InitialCondition**Type:** character vector, string**Values:** scalar | vector | matrix**Default:** '0'**Direct feedthrough — Set output signal dependency on input**

true (default) | false

Specify whether the output of the block has a direct dependency on the input signal. Use this parameter for systems having more than 500 continuous states in order to speed up simulation. For systems with 500 continuous states or less, Simulink automatically determines this setting.

Programmatic Use**Block Parameter:** DirectFeedthrough**Type:** character vector, string**Values:** 'True' | 'False'**Default:** 'True'**Linearize to sparse model — Linearize states to sparse matrices**

on (default) | off

For Simulink Control Design™ workflows, linearize the system represented by the Descriptor State-Space block to a sparse model during linearization.

Disable this parameter to linearize the system to a non-sparse explicit state-space model.

Data Types: Boolean

Absolute tolerance — Absolute tolerance for computing block states

auto (default) | scalar | vector

Absolute tolerance for computing block states, specified as a positive, real-valued, scalar or vector. To inherit the absolute tolerance from the Configuration Parameters, specify `auto` or `-1`.

- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.

- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.

Programmatic Use**Block Parameter:** `AbsoluteTolerance`**Type:** character vector, string**Values:** `'auto'` | `-1` | any positive real-valued scalar or vector**Default:** `'auto'`**State Name (e.g., 'position') – Assign unique name to each state**`' '` (default) | `'position'` | `{'a', 'b', 'c'}` | `a` | ...

Assign a unique name to each state. If this field is blank (`' '`), no name assignment occurs.

- To assign a name to a single state, enter the name between quotes, for example, `'position'`.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, `{'a', 'b', 'c'}`. Each name must be unique.
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, cell array, or structure.

Limitations

- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

Programmatic Use**Block Parameter:** `ContinuousStateAttributes`**Type:** character vector, string**Values:** `' '` | user-defined**Default:** `' '`**Block Characteristics**

Data Types	double
Direct Feedthrough	yes

HDL Coder / Logic and Bit Operations

Description

The Detect Change block determines if an input signal does not equal its previous value. The initial condition determines the initial value of the previous input U/z .

This block supports only discrete sample times.

Ports

Input

Port_1 — Input signal

signal value

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `built-in integer` | `floating point`

Output

Port_1 — Output signal

0 | 1

Output signal, true (equal to 1) when the input signal does not equal its previous value; false (equal to 0) when the input signal equals its previous value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Initial condition — Initial condition for the previous input

0 (default) | scalar | vector

Set the initial condition for the previous input U/z .

Programmatic Use

Block Parameter: `vinit`

Type: character vector

Values: scalar | vector

Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Output data type — Data type of the output

boolean (default) | uint8

Set the output data type to boolean or uint8.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'boolean' | 'uint8'

Default: 'boolean'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Detect Decrease

Detect decrease in signal value

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Detect Decrease block determines if an input is strictly less than its previous value.

This block supports only discrete sample times.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Output signal

0 | 1

Output signal, true (equal to 1) when the input signal is less than its previous value; false (equal to 0) when the input signal is greater than or equal to its previous value.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Parameters

Initial condition — Initial condition for the previous input

0 (default) | scalar | vector

Set the initial condition for the previous input U/z.

Programmatic Use

Block Parameter: vinit

Type: character vector

Values: scalar | vector

Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Output data type — Data type of the output

boolean (default) | uint8

Set the output data type to boolean or uint8.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'boolean' | 'uint8'

Default: 'boolean'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).

Introduced before R2006a

Detect Fall Negative

Detect falling edge when signal value decreases to strictly negative value, and its previous value was nonnegative

Library: Simulink / Logic and Bit Operations

Description

The Detect Fall Negative block determines if the input is less than zero, and its previous value is greater than or equal to zero.

This block supports only discrete sample times.

Ports

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Input

Port_1 — Input signal

signal value

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

Output

Port_1 — Output signal

0 | 1

Output signal, true (equal to 1) when the input signal is less than zero, and its previous value was greater than or equal to zero; false (equal to 0) when the input signal is greater than or equal to zero, or if the input signal is negative, its previous value was also negative.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Initial condition — Initial condition for the previous input

0 (default) | scalar | vector

Set the initial condition of the Boolean expression $U/z < 0$.

Detect Decrease | Detect Change | Detect Fall Nonpositive | Detect Increase | Detect Rise Nonnegative | Detect Rise Positive

Introduced before R2006a

Detect Fall Nonpositive

Detect falling edge when signal value decreases to nonpositive value, and its previous value was strictly positive

Library: Simulink / Logic and Bit Operations

Description

The Detect Fall Nonpositive block determines if the input is less than or equal to zero, and its previous value was greater than zero.

- The output is true (equal to 1) when the input signal is less than or equal to zero, and its previous value was greater than zero.
- The output is false (equal to 0) when the input signal is greater than zero, or if it is nonpositive, its previous value was also nonpositive.

This block supports only discrete sample times.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output signal that detects a falling edge, specified as a scalar, vector, or matrix.

- The output is true (equal to 1) when the input signal is less than or equal to zero, and its previous value was greater than zero.
- The output is false (equal to 0) when the input signal is greater than zero, or if it is nonpositive, its previous value was also nonpositive.

Data Types: uint8 | Boolean

Parameters

Initial condition — Initial condition of Boolean expression $U/z \leq 0$

0 (default) | scalar | vector | matrix

Set the initial condition of the Boolean expression $U/z \leq 0$.

Programmatic Use

Block Parameter: vinit

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Output data type — Output data type

boolean (default) | uint8

Specify the output data type as boolean or uint8.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'boolean' | 'uint8'

Default: 'boolean'

Block Characteristics

Data Types	Boolean double fixed point integer single
-------------------	---

Direct Feedthrough	yes

Detect Increase

Detect increase in signal value

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Detect Increase block determines if an input is strictly greater than its previous value.

- The output is true (equal to 1) when the input signal is greater than its previous value.
- The output is false (equal to 0) when the input signal is less than or equal to its previous value.

This block supports only discrete sample times.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Output signal

scalar | vector | matrix

Output signal, detecting an increase in signal value, specified as a scalar, vector, or matrix.

- The output is true (equal to 1) when the input signal is greater than its previous value.
- The output is false (equal to 0) when the input signal is less than or equal to its previous value.

Data Types: uint8 | Boolean

Parameters

Initial condition — Initial condition of previous input

0.0 (default) | scalar | vector | matrix

Set the initial condition for the previous input U/z.

Programmatic Use**Block Parameter:** `vinit`**Type:** character vector**Values:** scalar | vector | matrix**Default:** `'0.0'`**Input processing — Specify sample- or frame-based processing**`Elements as channels (sample based) (default) | Columns as channels (frame based)`

Detect Change | Detect Decrease | Detect Fall Negative | Detect Fall Nonpositive | Detect Rise Nonnegative | Detect Rise Positive

Introduced before R2006a

Detect Rise Nonnegative

Detect rising edge when signal value increases to nonnegative value, and its previous value was strictly negative

Library: Simulink / Logic and Bit Operations

Description

The Detect Rise Nonnegative block determining if the input is greater than or equal to zero, and its previous value was less than zero.

- The output is true (equal to 1) when the input signal is greater than or equal to zero, and its previous value was less than zero.
- The output is false (equal to 0) when the input signal is less than zero, or if the input signal is nonnegative, its previous value was also nonnegative.

This block supports only discrete sample times.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output signal that indicates a rising edge whenever the signal value increases to a nonnegative value, and its previous value was strictly negative. The output can be a scalar, vector, or matrix.

- The output is true (equal to 1) when the input signal is greater than or equal to zero, and its previous value was less than zero.
- The output is false (equal to 0) when the input signal is less than zero, or if the input signal is nonnegative, its previous value was also nonnegative.

Data Types: uint8 | Boolean

Parameters

Initial condition — Initial condition of Boolean expression $U/z \geq 0$

0 (default) | scalar | vector | matrix

Set the initial condition of the Boolean expression $U/z \geq 0$.

Programmatic Use

Block Parameter: vinit

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Output data type — Output data type

boolean (default) | uint8

Specify the output data type as boolean or uint8.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'boolean' | 'uint8'

Default: 'boolean'

Block Characteristics

Data Types	Boolean double fixed point integer single

Detect Change | Detect Decrease | Detect Fall Negative | Detect Fall Nonpositive | Detect Increase | Detect Rise Positive

Introduced before R2006a

Detect Rise Positive

Detect rising edge when signal value increases to strictly positive value, and its previous value was nonpositive

Library: Simulink / Logic and Bit Operations

Description

The Detect Rise Positive block detects a rising edge by determining if the input is strictly positive, and its previous value was nonpositive.

- The output is true (equal to 1) when the input signal is greater than zero, and the previous value was less than or equal to zero.
- The output is false (equal to 0) when the input is negative or zero, or if the input is positive, the previous value was also positive.

This block supports only discrete sample times.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output signal that detects a rising edge whenever the input is strictly positive, and its previous value was nonpositive. The output can be a scalar, vector, or matrix.

- The output is true (equal to 1) when the input signal is greater than zero, and the previous value was less than or equal to zero.
- The output is false (equal to 0) when the input is negative or zero, or if the input is positive, the previous value was also positive.

Data Types: uint8 | Boolean

Parameters

Initial condition — Initial condition of Boolean expression $U/z > 0$

0 (default) | scalar | vector | matrix

Set the initial condition of the Boolean expression $U/z > 0$.

Programmatic Use

Block Parameter: vinit

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Output data type — Output data type

boolean (default) | uint8

Specify the output data type as boolean or uint8.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'boolean' | 'uint8'

Default: 'boolean'

Block Characteristics

Data Types	Boolean double fixed point integer single
-------------------	---

Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Difference

Calculate change in signal over one time step

Library: Simulink / Discrete

Description

The Difference block outputs the current input value minus the previous input value.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array.

Dependencies

When you set **Input processing** to `Columns as channels (frame based)`, the input signal must have two dimensions or less.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Current input minus previous input

scalar | vector | matrix | N-D array

Current input minus previous input, specified as a scalar, vector, matrix, or N-D array.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Initial condition for previous input — Initial condition

0.0 (default) | scalar | vector | matrix | N-D array

Set the initial condition for the previous input.

Programmatic Use

Parameter: ICPprevInput

Type: character vector

Values: scalar | vector | matrix | N-D array

Default: '0.0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Signal Attributes

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output maximum — Maximum output value for range checking**

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output data type — Output data type**

Inherit: `Inherit via internal rule (default)` | `Inherit via back propagation` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

When input is a floating-point data type smaller than single precision, the `Inherit: Inherit via internal` rule output data type depends on the setting of the “Inherit floating-point output type

smaller than single precision” configuration parameter. Data types are smaller than single precision when the number of bits needed to encode the data type is less than the 32 bits needed to encode the single-precision data type. For example, half and int16 are smaller than single precision.

Programmatic Use

Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate to max or min when overflows occur — Method of overflow action

off (default) | on

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: DoSatur

Type: character vector
Values: 'off' | 'on'
Default: 'off'

Block Characteristics

Data Types	Boolean ^a double fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

^a This block is not recommended for use with Boolean signals.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the Treat as atomic unit option.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Digital Clock

Output simulation time at specified sampling interval

Library: Simulink / Sources

Description

The Digital Clock block outputs the simulation time only at the specified sampling interval. At other times, the block holds the output at the previous value. To control the precision of this block, use the **Sample time** parameter in the block dialog box.

Use this block rather than the Clock block (which outputs continuous time) when you need the current simulation time within a discrete system.

Ports

Output

Port_1 — Sample time

scalar

Sample time, in seconds, at the specified sampling interval. At other times, the block holds the output at the previous value.

Data Types: double

Parameters

Sample time — Sampling interval

1 (default) | scalar | vector

Specify the sampling interval in seconds. You can specify the sampling interval in one of two ways:

- As the period, specified as a real-valued scalar with data type double.
- As the period and offset, specified as a real-valued vector of length 2 with data type double. The period and offset must be finite and non-negative, and the offset value must be less than the period.

For more information, see [Specifying Sample Time](#).

Tip Do not specify a continuous sample time, either 0 or [0, 0]. Also, avoid specifying -1 (inheriting the sample time) because this block is a source.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar | vector**Default:** '1'**Block Characteristics**

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Direct Lookup Table (n-D)

Index into n-dimensional table to retrieve element, vector, or 2-D matrix

Library: Simulink / Lookup Tables
HDL Coder / Lookup Tables

Description

The Direct Lookup Table (n-D) block indexes into an n-dimensional table to retrieve an element, vector, or 2-D matrix. The first selection index corresponds to the top (or left) input port. You can choose to provide the table data as an input to the block, or define the table data on the block dialog box. The number of input ports and the size of the output depend on the number of table dimensions and the output slice you select.

If you select a vector from a 2-D table, the output vector can be a column or a row, depending on the model configuration parameter setting **Math and Data Types > Use algorithms optimized for row-major array layout**. The block inputs are zero-based indices (for more information, see the **Inputs select this object from table** parameter).

The Direct Lookup Table block supports symbolic dimensions.

Block Inputs and Outputs

The Direct Lookup Table (n-D) block uses inputs as zero-based indices into an n -dimensional table. The number of inputs varies with the shape of the output: an element, vector, or 2-D matrix.

You define a set of output values as the **Table data** parameter. For the default column-major algorithm behavior, the first input specifies the zero-based index to the table dimension that is one higher than the output dimensionality. The next input specifies the zero-based index to the next table dimension, and so on.

Output Shape	Output Dimensionality	Table Dimension that Maps to the First Input
Element	0	1
Vector	1	2
Matrix	2	3

Suppose that you want to select a vector of values from a 4-D table.

The following mapping of block input port to table dimension applies.

This input port...	Is the index for this table dimension...
1	2
2	3
3	4

Changes in Block Icon Appearance

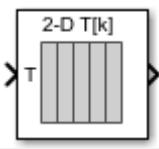

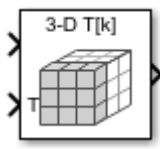

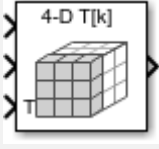

Depending on parameters you set, the block icon changes appearance. For table dimensions higher than 4, the icon matches the 4-D version but shows the exact number of dimensions at the top.

When you use the **Table data** parameter, you see these icons for the default column-major behavior. Some icons are different when you select the configuration parameter **Math and Data Types > Use algorithms optimized for row-major array layout**.

Object that Inputs Select from the Table	Number of Table Dimensions			
	1	2	3	4
Element				
Vector				
2-D Matrix	Not applicable			

When you use the table input port, you see these icons.

Object that Inputs Select from the Table	Number of Table Dimensions			
	1	2	3	4
Element				
Vector				

Object that Inputs Select from the Table	Number of Table Dimensions			
	1	2	3	4
2-D Matrix	Not applicable			

Ports

Input

Port_1 – Index i1 input values

scalar | vector

For the default column-major algorithm, the first input port, specifying the zero-based index to the table dimension that is one higher than the output dimensionality (0, 1, or 2). The next input specifies the zero-based index to the next table dimension, and so on. All index inputs must be real-valued.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Port_N – Index N input values

scalar | vector

For the default column-major algorithm, the N-th input port, specifying the zero-based index to the table dimension that is N higher than the output dimensionality (0, 1, or 2). The number of inputs varies with the shape of the output. All index inputs must be real-valued.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

T – Table data

vector | matrix | N-D array

Table data, specified as a vector, matrix, or N-D array. The table size must match the dimensions of the **Number of dimensions** parameter. The block's output data type is the same as the table data type.

Dependencies

To enable this port, select the **Make table an input** check box.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 – Output element, vector, or 2-D matrix

scalar | vector | 2-D matrix

Output slice, provided as a scalar, vector, or 2-D matrix. The size of the block output is determined by the setting of the **Inputs select this object from table** parameter. The output data type is the same as the table data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

Parameters

Main

Table

Number of table dimensions — Number of dimensions of table data

2 (default) | 1 | 3 | 4

Number of dimensions that the **Table data** parameter must have. This value determines the number of independent variables for the table and the number of inputs to the block.

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

Programmatic Use

Block Parameter: NumberOfTableDimensions

Type: character vector

Values: '1' | '2' | '3' | '4' | ... | '30'

Default: '2'

Make table an input — Provide table data as a block input

off (default) | on

Select this check box to provide table data to the Direct Lookup Table (n-D) block as a block input. When you select this check box, a new input port, T, appears. Use this port to input the table data.

Programmatic Use

Block Parameter: TableIsInput

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Table data — Table of output values

[4 5 6; 16 19 20; 10 18 23] (default) | scalar, vector, matrix, or N-D array

Specify the table of output values. The table size must match the dimensions of the **Number of table dimensions** parameter.

Tip During block diagram editing, you can leave the **Table data** field empty. But for simulation, you must match the number of dimensions in **Table data** to the **Number of table dimensions**. For details on how to construct multidimensional MATLAB arrays, see “Multidimensional Arrays”.

Click **Edit** to open the Lookup Table Editor. For more information, see “Edit Lookup Tables”.

Dependencies

To enable the **Table data** field, clear the **Make table an input** check box.

Programmatic Use

Block Parameter: Table

Type: character vector

Values: scalar, vector, matrix, or N-D array

Default: '[4 5 6;16 19 20;10 18 23]'

Algorithm

Inputs select this object from table — Specify whether output is an element, vector, or 2-D matrix

Element (default) | Vector | 2-D Matrix

Specify whether the output data is a single element, a vector, or a 2-D matrix. The number of input ports for indexing depends on your selection.

Selection	Number of Input Ports for Indexing
Element	Number of table dimensions
Vector	Number of table dimensions -1
2-D Matrix	Number of table dimensions -2

This numbering matches MATLAB indexing. For example, if you have a 4-D table of data, follow these guidelines.

To access...	Specify...	As in...
An element	Four indices	array(1,2,3,4)
A vector	Three indices	array(:,2,3,4) (default column-major algorithm)
A 2-D matrix	Two indices	array(:, :, 3,4) (default column-major algorithm)

Tips

When the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter is set, the Direct Lookup Table block behavior changes from column-major to row-major. For this block, the column-major and row-major algorithms may differ semantically in output calculations, resulting in different numerical values. For example, assume that **Inputs select this object from table** parameter is set to **Vector**. The elements of the selected vector are contiguous in the table storage memory. This table shows the column-major and row-major algorithm depending on the table dimension:

Table Dimension	Column-Major Algorithm	Row-Major Algorithm
2-D table	Column vector is selected	Row vector is selected
3-D and higher table	Output vector is selected from the first dimension of the table	Output vector is selected from the last dimension of the table

Consider the row-major and column-major direct lookup algorithms with vector output from a 3-D table. The last dimension is the third dimension of a 3-D table. Due to semantic changes, column-major and row-major direct lookup may output different vector size and numerical values.

This figure shows a Direct Lookup Table (n-D) block configured with a 3-D table and a vector output. By default, the block icon shows the column-major algorithm.

To have the same block use the row-major algorithm, change the **Math and Data Types > Use algorithm optimized for row-major layout** configuration parameter of the model and recompile. The block icon changes to reflect the change to the algorithm optimized for row-major behavior.

For more information on row-major support, see “Row-Major Array Layout: Simplify integration with external C/C++ code for Lookup Table and other blocks” (Simulink Coder).

Programmatic Use

Block Parameter: InputsSelectThisObjectFromTable

Type: character vector

Values: 'Element' | 'Vector' | '2-D Matrix'

Default: 'Element'

Diagnostic for out-of-range input — Block action when input is out of range

Warning (default) | None | Error

Specify whether to show a warning or error when an index is out of range with respect to the table dimension. Options include:

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

When you select None or Warning, the block clamps out-of-range indices to fit table dimensions. For example, if the specified index is 5.3 and the maximum index for that table dimension is 4, the block clamps the index to 4.

Programmatic Use

Block Parameter: DiagnosticForOutOfRangeInput

Type: character vector

Values: 'None' | 'Warning' | 'Error'

Default: 'Warning'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Code generation****Remove protection against out-of-range input in generated code — Remove code that checks for out-of-range input values**

off (default) | on

Specify whether or not to include code that checks for out-of-range input values.

Check Box	Result	When to Use
on	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input is out-of-range, it may cause undefined behavior for generated code.	For code efficiency
off	Generated code includes conditional statements to check for out-of-range inputs.	For safety-critical applications

If your input is not out of range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to Error.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input is out of range, the behavior is undefined for generated code.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Advisor Checks”.

Additionally, to determine if it is safe to select this check box, if you have a Simulink Design Verifier license, consider using the “Detect Block Input Range Violations” (Simulink Design Verifier) check.

Programmatic Use

Block Parameter: RemoveProtectionInput

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Table Attributes

Note The parameters in the **Table Attributes** pane are not available if you select **Make table an input**. In this case, the block inherits all table attributes from the input port with the label T.

Table minimum — Minimum value table data can have

[] (default) | finite, real, double, scalar

Specify the minimum value for table data. The default value is [] (unspecified).

Programmatic Use

Block Parameter: TableMin

Type: character vector

Values: scalar

Default: ' [] '

Table maximum — Maximum value table data can have

[] (default) | finite, real, double, scalar

Specify the maximum value for table data. The default value is [] (unspecified).

Programmatic Use

Block Parameter: TableMax

Type: character vector

Values: scalar

Default: ' [] '

Table data type — Data type of table data

Inherit: Inherit from 'Table data' (default) | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | <data type expression>

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit from 'Table data'`
- The name of a built-in data type, for example, `single`
- The name of a data type class, for example, an enumerated data type class
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: `TableDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit from 'Table data'' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | '<data type expression>'`

Default: `'Inherit: Inherit from 'Table data''`

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

`off (default) | on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: `'off' | 'on'`

Default: `'off'`

Block Characteristics

Data Types	Boolean double enumerated fixed point ^a half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

^a This block supports fixed-point data types for 'Table' data only.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Restrictions

MAX 10 Device Settings

If you use Intel® MAX 10 device, to map the lookup table to RAM, add this Tcl command when creating the project in the Quartus tool:

```
set_global_assignment -name INTERNAL_FLASH_UPDATE_MODE "SINGLE IMAGE WITH ERAM"
```

Required Block Settings

- **Number of table dimensions:** Select the table dimension between 1 to 30.
- **Inputs select this object from table:** Select Element.
- **Make table an input:** Clear this check box.
- **Diagnostic for out-of-range input:** Select None, Warning (default), or Error (recommended). Select Error for efficient HDL code generation. If you select None or Warning, HDL Coder generates additional logic to handle out-of-range inputs.

Table Data Typing and Sizing

- It is good practice to size each dimension in the table to be a power of two. If the length of a dimension (*except* the innermost dimension) is not a power of two, HDL Coder issues a warning. By following this practice, you can avoid multiplications during table indexing operations and realize a more efficient table in hardware.
- All ports on the block require scalar values.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block supports fixed-point data types for **Table data** only. In addition to built-in data types, the index input also supports fixed-point data type with bias equal to 0, slope equal to 1.0, fractional length equal to 0, and word length less than or equal to 128.

Introduced before R2006a

Discrete Derivative

Compute discrete-time derivative

Library: Simulink / Discrete

Description

The Discrete Derivative block computes an optionally scaled discrete time derivative as follows

$$y(t_n) = K \left(\frac{u(t_n) - u(t_{n-1})}{T_s} \right)$$

where

- $u(t_n)$ and $y(t_n)$ are the block input and output at the current time step, respectively.
- $u(t_{n-1})$ is the block input at the previous time step.
- K is an optional scaling factor, specified using the **Gain value** parameter.
- T_s is the simulation's discrete step size, which must be fixed.

Note Do not use this block in subsystems with a nonperiodic trigger (for example, nonperiodic function-call subsystems). This configuration produces inaccurate results.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Scaled discrete time derivative

scalar | vector | matrix

Optionally scaled discrete-time derivative, specified as a scalar, vector, or matrix. For more information on how the block computes the discrete-time derivative, see “Description” on page 1-358. You specify the data type of the output signal with the **Output data type** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main

Gain value — Scaling factor

1.0 (default) | scalar

Scaling factor applied to the computed derivative, specified as a real scalar value.

Programmatic Use

Block Parameter: gainval

Type: character vector

Values: scalar

Default: '1.0'

Initial condition for previous weighted input $K*u/T_s$ — Initial condition

0.0 (default) | scalar

Initial condition for the previous scaled input, specified as a scalar.

Programmatic Use

Block Parameter: ICPprevScaledInput

Type: character vector

Values: scalar

Default: '0.0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Signal Attributes

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output data type — Output data type**

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | fixdt(1,16,2^0,0)

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via back propagation
- The name of a built-in data type, for example, single
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'

Default: 'Inherit: Inherit via internal rule'**Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Integer rounding mode — Rounding mode for fixed-point operations**

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector**Values:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'**Default:** 'Floor'**Saturate to max or min when overflows occur – Method of overflow action**

off (default) | on

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** DoSatur**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

- Depends on absolute time when used inside a triggered subsystem hierarchy.
- Generated code relies on memcpy or memset functions (string.h) under certain conditions.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Discrete Filter

Model Infinite Impulse Response (IIR) filters

Library: Simulink / Discrete

Description

The Discrete Filter block independently filters each channel of the input signal with the specified digital IIR filter. You can specify the filter structure as **Direct form I**, **Direct form I transposed**, **Direct form II**, or **Direct form II transposed**. The block implements static filters with fixed coefficients. You can tune the coefficients of these static filters.

This block filters each channel of the input signal independently over time. The **Input processing** parameter allows you to specify how the block treats each element of the input. You can specify treating input elements as an independent channel (sample-based processing), or treating each column of the input as an independent System channel (frame-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

The output dimensions equal the input dimensions, except when you specify a matrix of filter taps for the **Numerator coefficients** parameter. When you do so, the output dimensions depend on the number of different sets of filter taps you specify.

Use the **Numerator coefficients** parameter to specify the coefficients of the discrete filter numerator polynomial. Use the **Denominator coefficients** parameter to specify the coefficients of the denominator polynomial of the function. The **Denominator coefficients** parameter must be a vector of coefficients.

Specify the coefficients of the numerator and denominator polynomials in ascending powers of z^{-1} . The Discrete Filter block lets you use polynomials in z^{-1} (the delay operator) to represent a discrete system. Signal processing engineers typically use this method. Conversely, the Discrete Transfer Fcn block lets you use polynomials in z to represent a discrete system. Control engineers typically use this method. When the numerator and denominator polynomials have the same length, the two methods are identical.

Specifying Initial States

In **Dialog parameters** and **Input port(s)** modes, the block initializes the internal filter states to zero by default, which is equivalent to assuming past inputs and outputs are zero. You can optionally use the **Initial states** parameter to specify nonzero initial states for the filter delays.

To determine the number of initial state values you must specify, and how to specify them, see the following table on valid initial states and Number of Delay Elements (Filter States). The **Initial states** parameter can take one of four forms as described in the following table.

Valid Initial States

Initial state	Examples	Description
Scalar	5 Each delay element for each channel is set to 5.	The block initializes all delay elements in the filter to the scalar value.
Vector (for applying the same delay elements to each channel)	For a filter with two delay elements: [$d_1 d_2$] The delay elements for all channels are d_1 and d_2 .	Each vector element specifies a unique initial condition for a corresponding delay element. The block applies the same vector of initial conditions to each channel of the input signal. The vector length must equal the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)).
Vector or matrix (for applying different delay elements to each channel)	For a three-channel input signal and a filter with two delay elements: [$d_1 d_2 D_1 D_2 d_1 d_2$] or $\begin{bmatrix} d_1 & D_1 & d_1 \\ d_2 & D_2 & d_2 \end{bmatrix}$ <ul style="list-style-type: none"> The delay elements for channel 1 are d_1 and d_2. The delay elements for channel 2 are D_1 and D_2. The delay elements for channel 3 are d_1 and d_2. 	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel: <ul style="list-style-type: none"> The vector length must be equal to the product of the number of input channels and the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)). The matrix must have the same number of rows as the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)), and must have one column for each channel of the input signal.
Empty matrix	[] Each delay element for each channel is set to 0.	The empty matrix, [], is equivalent to setting the Initial conditions parameter to the scalar value 0.

The number of delay elements (filter states) per input channel depends on the filter structure, as indicated in the following table.

Number of Delay Elements (Filter States)

Filter Structure	Number of Delay Elements Per Channel
Direct form I Direct form I transposed	<ul style="list-style-type: none"> number of zeros - 1 number of poles - 1
Direct form II Direct form II transposed	$\max(\text{number of zeros, number of poles}) - 1$

The following tables describe the valid initial states for different sizes of input and different number of channels depending on whether you set the **Input processing** parameter to frame based or sample based.

Frame-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> Column vector (K-by-1) Unoriented vector (K) 	1	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) 	<ul style="list-style-type: none"> Scalar Column vector (M-by-1)
<ul style="list-style-type: none"> Row vector (1-by-N) Matrix (K-by-N) 	N	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) Matrix (M-by-N) 	<ul style="list-style-type: none"> Scalar Matrix (M-by-N)

Sample-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> Scalar 	1	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) 	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M)
<ul style="list-style-type: none"> Row vector (1-by-N) Column vector (N-by-1) Unoriented vector (N) 	N	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) Matrix (M-by-N) 	<ul style="list-style-type: none"> Scalar
<ul style="list-style-type: none"> Matrix (K-by-N) 	$K \times N$	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) Matrix (M-by-$(K \times N)$) 	<ul style="list-style-type: none"> Scalar

When the **Initial states** is a scalar, the block initializes all filter states to the same scalar value. Enter 0 to initialize all states to zero. When the **Initial states** is a vector or a matrix, each vector or matrix element specifies a unique initial state. This unique state corresponds to a delay element in a corresponding channel:

- The vector length must equal the number of delay elements in the filter, $M = \max(\text{number of zeros, number of poles})$.
- The matrix must have the same number of rows as the number of delay elements in the filter, $M = \max(\text{number of zeros, number of poles})$. The matrix must also have one column for each channel of the input signal.

The “Specify a Vector of Initial Conditions for a Discrete Filter Block” on page 12-136 example shows the relationship between the initial filter output and the initial input and state. Given an initial input u_1 , the first output y_1 is related to the initial state $[x_1, x_2]$ and initial input by:

$$y_1 = b_1 \left[\frac{(u_1 - a_2 x_1 - a_3 x_2)}{a_1} \right] + b_2 x_1 + b_3 x_2$$

Ports

Input

u — Input signal

scalar | vector | matrix

Input signal to filter, specified as a scalar, vector, or matrix.

Dependencies

The name of this port depends on the source you specify for the numerator coefficients, denominator coefficients and initial states. When you set **Numerator**, **Denominator**, and **Initial states** to **Dialog**, there is only one input port, and the port is unlabeled. When you set **Numerator**, **Denominator**, or **Initial states** to **Input** port, this port is labeled **u**.

Data Types: single | double | int8 | int16 | int32 | fixed point

Num — Numerator coefficients

scalar | vector | matrix

Numerator coefficients of the discrete filter, specified as descending powers of z . Use a row vector to specify the coefficients for a single numerator polynomial.

Dependencies

To enable this port, set **Numerator** to **Input** port.

Data Types: single | double | int8 | int16 | int32 | fixed point

Den — Denominator coefficients

scalar | vector

Specify the denominator coefficients of the discrete filter as descending powers of z . Use a row vector to specify the coefficients for a single denominator polynomial.

Dependencies

To enable this port, set **Denominator** to **Input** port.

Data Types: single | double | int8 | int16 | int32 | fixed point

x0 — Initial states

scalar | vector | matrix

Initial states, specified as a scalar, vector, or matrix. For more information about specifying states, see “Specifying Initial States” on page 1-364.

Dependencies

To enable this port, set the **Filter structure** to **Direct form II** or **Direct form II transposed**, and set **Initial states** to **Input** port.

Data Types: single | double | int8 | int16 | int32 | fixed point

Output

Port_1 — Filtered output signal

scalar | vector | matrix

Filtered output signal. The output dimensions equal the input dimensions, except when you specify a matrix of filter taps for the **Numerator coefficients** parameter. When you do so, the output dimensions depend on the number of different sets of filter taps you specify.

Data Types: single | double | int8 | int16 | int32 | fixed point

Parameters

Main

Filter structure — Filter structure

Direct form II (default) | Direct form I transposed | Direct form I | Direct form II transposed

Specify the discrete IIR filter structure.

Dependencies

To use any filter structure other than `Direct form II`, you must have an available DSP System Toolbox license.

Programmatic Use

Block Parameter: FilterStructure

Type: character vector

Values: 'Direct form II' | 'Direct form I transposed' | 'Direct form I' | 'Direct form II transposed'

Default: 'Direct form II'

Numerator Source — Source of numerator coefficients

Dialog (default) | Input port

Specify the source of the numerator coefficients as `Dialog` or `Input port`.

Programmatic Use

Block Parameter: NumeratorSource

Type: character vector

Values: 'Dialog' | 'Input port'

Default: 'Dialog'

Numerator Value — Numerator coefficients

[1] (default) | scalar | vector | matrix

Specify the numerator coefficients of the discrete filter as descending powers of z . Use a row vector to specify the coefficients for a single numerator polynomial.

Dependencies

To enable this parameter, set the **Numerator Source** to `Dialog`.

Programmatic Use

Block Parameter: Numerator

Type: character vector
Values: scalar | vector | matrix
Default: '[1]'

Denominator Source — Source of denominator coefficients

Dialog (default) | Input port

Specify the source of the denominator coefficients as Dialog or Input port.

Programmatic Use

Block Parameter: DenominatorSource

Type: character vector

Values: 'Dialog' | 'Input port'

Default: 'Dialog'

Denominator Value — Denominator coefficients

[1 0.5] (default) | vector

Specify the denominator coefficients of the discrete filter as descending powers of z . Use a row vector to specify the coefficients for a single denominator polynomial.

Dependencies

To enable this parameter, set the **Denominator Source** to Dialog.

Programmatic Use

Block Parameter: Denominator

Type: character vector

Values: scalar | vector

Default: '[1 0.5]'

Initial states Source — Source of initial states

Dialog (default) | Input port

Specify the source of the initial states as Dialog or Input port.

Programmatic Use

Block Parameter: InitialStatesSource

Type: character vector

Values: 'Dialog' | 'Input port'

Default: 'Dialog'

Initial states Value — Initial filter states

0 (default) | scalar | vector | matrix

Specify the initial filter states as a scalar, vector, or matrix. To learn how to specify initial states, see “Specifying Initial States” on page 1-364.

Dependencies

To enable this parameter, set the **Filter structure** to Direct form II or Direct form II transposed, and set **Initial states Source** to Dialog.

Programmatic Use

Block Parameter: InitialStates

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Initial states on numerator side — Initial numerator states

0 (default) | scalar | vector | matrix

Specify the initial numerator filter states as a scalar, vector, or matrix. To learn how to specify initial states, see “Specifying Initial States” on page 1-364.

Dependencies

To enable this port, set the **Filter structure** to Direct form I or Direct form I transposed.

Programmatic Use

Block Parameter: InitialStates

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Initial states on denominator side — Initial denominator states

0 (default) | scalar | vector | matrix

Specify the initial denominator filter states as a scalar, vector, or matrix. To learn how to specify initial states, see “Specifying Initial States” on page 1-364.

Dependencies

To enable this port, set the **Filter structure** to Direct form I or Direct form I transposed.

Programmatic Use

Block Parameter: InitialDenominatorStates

Type: character vector

Values: scalar | vector | matrix

Default: '0'

External reset — External state reset

None (default) | Rising | Falling | Either | Level | Level hold

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset
Rising	Reset on a rising edge
Falling	Reset on a falling edge
Either	Reset on either a rising or falling edge
Level	Reset in either of these cases: <ul style="list-style-type: none"> When the reset signal is nonzero at the current time step When the reset signal value changes from nonzero at the previous time step to zero at the current time step

Reset Mode	Behavior
Level hold	Reset when the reset signal is nonzero at the current time step

Programmatic Use**Block Parameter:** ExternalReset**Type:** character vector**Values:** 'None' | 'Rising' | 'Falling' | 'Either' | 'Level' | 'Level hold'**Default:** 'None'**Input processing — Sample- or frame-based processing**

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing.

- Elements as channels (sample based) — Process each element of the input as an independent channel.
- Columns as channels (frame based) — Process each column of the input as an independent channel.

Dependencies

Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use**Block Parameter:** InputProcessing**Type:** character vector**Values:** 'Columns as channels (frame based)' | 'Elements as channels (sample based)'**Default:** 'Elements as channels (sample based)'**Optimize by skipping divide by leading denominator coefficient (a₀) — Skip divide by a₀**

off (default) | on

Select when the leading denominator coefficient, a_0 , equals one. This parameter optimizes your code.When you select this check box, the block does not perform a divide-by- a_0 either in simulation or in the generated code. An error occurs if a_0 is not equal to one.When you clear this check box, the block is fully tunable during simulation. It performs a divide-by- a_0 in both simulation and code generation.**Programmatic Use****Block Parameter:** a0EqualsOne**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Sample time (-1 for inherited) — Interval between samples**

-1 (default) | scalar | vector

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. For more information, see “Specify Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '-1'

Data Types

State — State data type

Inherit: Same as input (default) | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the state data type. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Same as input
- A built-in integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: StateDataTypeStr

Type: character vector

Values: 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Same as input'

Numerator coefficients — Numerator coefficient data type

Inherit: Inherit via internal rule (default) | int8 | int16 | int32 | int64 | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the numerator coefficient data type. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in signed integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: NumCoeffDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>
Default: 'Inherit: Inherit via internal rule'

Numerator coefficient minimum – Minimum value of numerator coefficients

[] (default) | scalar

Specify the minimum value that a numerator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: NumCoeffMin

Type: character vector

Values: scalar

Default: '[]'

Numerator coefficient maximum – Maximum value of numerator coefficients

[] (default) | scalar

Specify the maximum value that a numerator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: NumCoeffMax

Type: character vector

Values: scalar

Default: '[]'

Numerator product output – Numerator product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the product output data type for the numerator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: NumProductDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Numerator accumulator — Numerator accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the accumulator data type for the numerator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: NumAccumDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'Inherit: Same as product output' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Denominator coefficients — Denominator coefficient data type

Inherit: Inherit via internal rule (default) | int8 | int16 | int32 | int64 | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the denominator coefficient data type. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: DenCoeffDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Denominator coefficient minimum — Minimum value of denominator coefficients

[] (default) | scalar

Specify the minimum value that a denominator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** DenCoeffMin**Type:** character vector**Values:** scalar**Default:** ' [] '**Denominator coefficient maximum — Maximum value of denominator coefficients**

[] (default) | scalar

Specify the maximum value that a denominator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** DenCoeffMax**Type:** character vector**Values:** scalar**Default:** ' [] '**Denominator product output — Denominator product output data type**

Inherit: Inherit via internal rule (default) | Inherit: Same as input | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the product output data type for the denominator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** DenProductDataTypeStr**Type:** character vector**Values:** 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'**Default:** 'Inherit: Inherit via internal rule'

Denominator accumulator — Denominator accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the accumulator data type for the denominator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: DenAccumDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'Inherit: Same as product output' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Output — Output data type

Inherit: Inherit via internal rule (default) | int8 | int16 | int32 | int64 | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the output data type. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Output minimum — Minimum value of output

[] (default) | scalar

Specify the minimum value that the block can output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** scalar**Default:** ' [] '**Output maximum — Maximum value of output**

[] (default) | scalar

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** scalar**Default:** ' [] '**Multiplicand data type — Multiplicand data type**

Inherit: Same as input (default) | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the multiplicand data type. You can set this parameter to:

- A rule that inherits a data type, for example, Inherit: Same as input
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, set the **Filter structure** to Direct form I transposed

Programmatic Use**Block Parameter:** MultiplicandDataTypeStr**Type:** character vector

Values: 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Same as input'**Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types**

off (default) | on

Select to lock data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Rationale	Impact on Overflows	Example
Do not select this check box (off).	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

State Attributes

State name — Assign unique name to each state

' ' (default) | 'position' | {'a', 'b', 'c'} | a | ...

Assign a unique name to each state. If this field is blank (' '), no name assignment occurs.

- To assign a name to a single state, enter the name between quotes, for example, 'position'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, cell array, or structure.

Limitations

- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

Dependencies

To enable this parameter, set **Filter structure** to `Direct form II`.

Programmatic Use**Block Parameter:** StateName**Type:** character vector**Values:** ' ' | user-defined**Default:** ' '**State name must resolve to Simulink signal object – Require state name resolve to a signal object**

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, set **Filter structure** to `Direct form II` and specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Programmatic Use**Block Parameter:** StateMustResolveToSignalObject**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Data Types	double fixed point ^a integer ^a single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

^a This block only supports signed fixed-point data types.

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block only supports signed fixed-point data types.

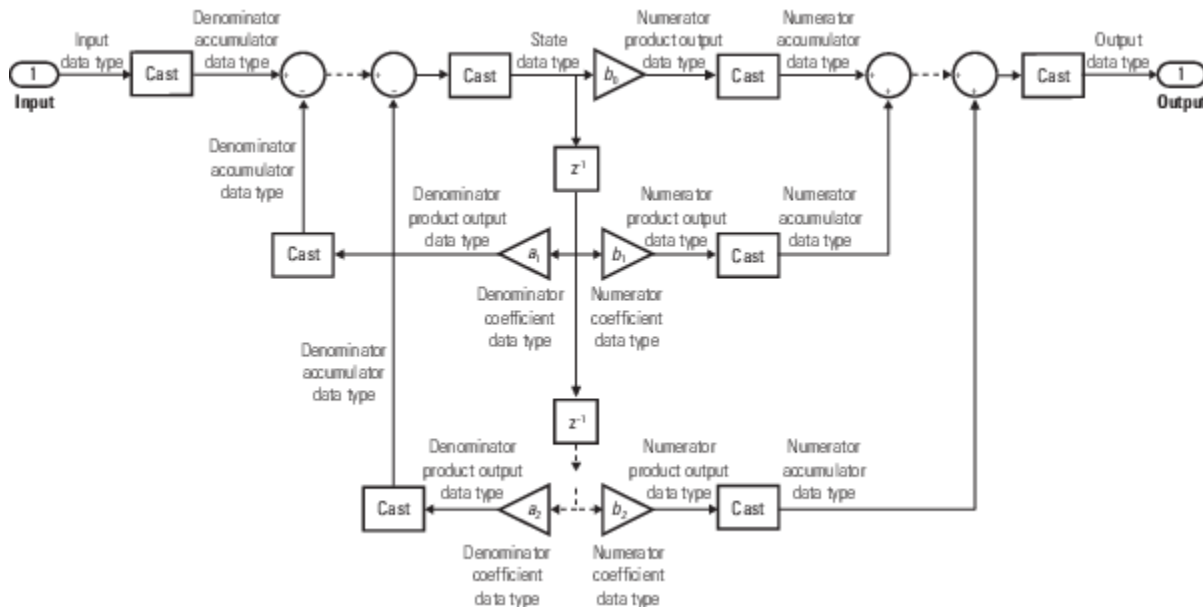

The Discrete Filter block accepts and outputs real and complex signals of any signed numeric data type that Simulink supports. The block supports the same types for the numerator and denominator coefficients.

Numerator and denominator coefficients must have the same complexity. They can have different word lengths and fraction lengths.

The following diagrams show the filter structure and the data types used within the Discrete Filter block for fixed-point signals.

The block omits the dashed divide when you select the **Optimize by skipping divide by leading denominator coefficient (a0)** parameter.

Discrete FIR Filter

Model FIR filters

Library: Simulink / Discrete
 HDL Coder / Discrete
 HDL Coder / HDL Floating Point Operations

Description

The Discrete FIR Filter block independently filters each channel of the input signal with the specified digital FIR filter. The block can implement static filters with fixed coefficients, and time-varying filters with coefficients that change over time. You can tune the coefficients of a static filter during simulation.

This block filters each channel of the input signal independently over time. The **Input processing** parameter allows you to specify whether the block treats each element of the input as an independent channel (sample-based processing), or each column of the input as an independent channel (frame-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

The output dimensions equal the input dimensions, except when you specify a matrix of filter taps for the **Coefficients** parameter. When you do so, the output dimensions depend on the number of different sets of filter taps you specify.

This block supports custom state attributes to customize and generate code more efficiently. For an example, see “Custom State Attributes in Discrete FIR Filter block”. Under certain conditions, the block also supports SIMD code generation. For details, see “Code Generation” on page 1-394.

The outputs of this block numerically match the outputs of the DSP System Toolbox Digital Filter Design block.

This block supports the Simulink state logging feature. For more information, see “State”.

Filter Structure Support

You can change the filter structure implemented with the Discrete FIR Filter block by selecting one of the following from the **Filter structure** parameter:

- Direct form
- Direct form symmetric
- Direct form antisymmetric
- Direct form transposed
- Lattice MA

You must have an available DSP System Toolbox license to run a model with any of these filter structures other than `Direct form`.

Specifying Initial States

The Discrete FIR Filter block initializes the internal filter states to zero by default, which has the same effect as assuming that past inputs and outputs are zero. You can optionally use the **Initial states** parameter to specify nonzero initial conditions for the filter delays.

To determine the number of initial states you must specify and how to specify them, see the table on valid initial states. The **Initial states** parameter can take one of the forms described in the next table.

Valid Initial States

Initial Condition	Description
Scalar	The block initializes all delay elements in the filter to the scalar value.
Vector or matrix (for applying different delay elements to each channel)	<p>Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel:</p> <ul style="list-style-type: none"> The vector length equals the product of the number of input channels and the number of delay elements in the filter, <code>#_of_filter_coeffs-1</code> (or <code>#_of_reflection_coeffs</code> for Lattice MA). The matrix must have the same number of rows as the number of delay elements in the filter, <code>#_of_filter_coeffs-1</code> (<code>#_of_reflection_coeffs</code> for Lattice MA), and must have one column for each channel of the input signal.

Ports

Input

In — Input signal

scalar | vector | matrix

Input signal to filter, specified as a scalar, vector, or matrix.

Dependencies

When you set **Coefficient source** to `Dialog` parameters, the port for the input signal is unlabeled. When you set **Coefficient source** to `Input` port, the port for the input signal is labeled **In**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Num — Filter coefficients

scalar | vector | matrix

Specify the filter coefficients as a scalar, vector, or matrix. When you specify a row vector of filter taps, the block applies a single filter to the input. To apply multiple filters to the same input, specify a matrix of coefficients, where each row represents a different set of filter taps.

Dependencies

To enable this port, set **Coefficient source** to `Input` port.

To implement multiple filters, **Filter structure** must be `Direct` form, and the input must be a scalar.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

External reset — External reset signal

scalar

External reset signal, specified as a scalar. When the specified trigger event occurs, the block resets the states to their initial conditions.

Tip The icon for this port changes based on the value of the **External reset** parameter.

Dependencies

To enable this port, set **External reset** to Rising, Falling, Either, Level, or Level hold.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

— Enable signal

scalar

Enable signal, specified as a scalar. This port can control execution of the block. The block is enabled when the input to this port is nonzero, and is disabled when the input is 0. The value of the input is checked at the same time step as the block execution.

Dependencies

To enable this port, select the **Show enable port** check box.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Filtered output signal

scalar | vector | matrix

Filtered output signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main

Coefficient source — Source of coefficients

Dialog parameters (default) | Input port

Choose to specify the filter coefficients using tunable dialog parameters or through an input port, which is useful for time-varying coefficients.

Programmatic Use

Block Parameter: CoefSource

Type: character vector

Values: 'Dialog parameters' | 'Input port'

Default: 'Dialog parameters'

Filter structure – Filter structure

Direct form (default) | Direct form symmetric | Direct form antisymmetric | Direct form transposed | Lattice MA

Select the filter structure you want the block to implement.

Dependencies

You must have an available DSP System Toolbox license to run a model with a Discrete FIR Filter block that implements any filter structure other than Direct form.

Programmatic Use

Block Parameter: FilterStructure

Type: character vector

Values: 'Direct form' | 'Direct form symmetric' | 'Direct form antisymmetric' | 'Direct form transposed' | 'Lattice MA'

Default: 'Direct form'

Coefficients – Filter coefficients

[0.5 0.5] (default) | vector | matrix

Specify the coefficient vector for the transfer function. Filter coefficients must be specified as a row vector. When you specify a row vector of filter taps, the block applies a single filter to the input. To apply multiple filters to the same input, specify a matrix of coefficients, where each row represents a different set of filter taps.

Dependencies

To enable this parameter, set **Coefficient source** to Dialog parameters.

To implement multiple filters, **Filter structure** must be Direct form, and the input must be a scalar.

Programmatic Use

Block Parameter: Coefficients

Type: character vector

Values: vector

Default: '[0.5 0.5]'

Input processing – Sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- Elements as channels (sample based) — Treat each element of the input as an independent channel (sample-based processing).
- Columns as channels (frame based) — Treat each column of the input as an independent channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Initial states — Initial conditions of filter states

0 (default) | scalar | vector | matrix

Specify the initial conditions of the filter states. To learn how to specify initial states, see “Specifying Initial States” on page 1-384.

Programmatic Use

Block Parameter: InitialStates

Type: character vector

Values: scalar | vector | matrix

Default: '0'

Show enable port — Create enable port

off (default) | on

Select to control execution of this block with an enable port. The block is considered enabled when the input to this port is nonzero, and is disabled when the input is 0. The value of the input is checked at the same time step as the block execution.

Programmatic Use

Block Parameter: ShowEnablePort

Type: character vector

Values: 'off' | 'on'

Default: 'off'

External reset — External state reset

None (default) | Rising | Falling | Either | Level | Level hold

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset
Rising	Reset on a rising edge
Falling	Reset on a falling edge
Either	Reset on either a rising or falling edge
Level	Reset in either of these cases: <ul style="list-style-type: none"> When the reset signal is nonzero at the current time step When the reset signal value changes from nonzero at the previous time step to zero at the current time step

Reset Mode	Behavior
Level hold	Reset when the reset signal is nonzero at the current time step

Programmatic Use**Block Parameter:** ExternalReset**Type:** character vector**Values:** 'None' | 'Rising' | 'Falling' | 'Either' | 'Level' | 'Level hold'**Default:** 'None'**Sample time (-1 for inherited) – Time interval between samples**

-1 (default) | scalar | vector

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. For more information, see “Specify Sample Time”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar | vector**Default:** '-1'**Data Types****Tap sum – Tap sum data type**

Inherit: Same as input (default) | Inherit: Inherit via internal rule | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | <data type expression>

Specify the tap sum data type of a direct form symmetric or direct form antisymmetric filter, which is the data type the filter uses when it sums the inputs prior to multiplication by the coefficients. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

This parameter is only visible when you set the **Filter structure** to Direct form symmetric or Direct form antisymmetric.

Programmatic Use**Block Parameter:** TapSumDataTypeStr**Type:** character vector

Values: 'Inherit: Same as input' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Same as input'

Coefficients — Coefficient data type

Inherit: Same wordlength as input (default) | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | <data type expression>

Specify the coefficient data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Same word length as input
- A built-in integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: CoeffDataTypeStr

Type: character vector

Values: 'Inherit: Same word length as input' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Same wordlength as input'

Coefficients minimum — Minimum value of coefficients

[] (default) | scalar

Specify the minimum value that a filter coefficient should have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: CoeffMin

Type: character vector

Values: scalar

Default: '[]'

Coefficients maximum — Maximum value of coefficients

[] (default) | scalar

Specify the maximum value that a filter coefficient should have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** CoeffMax**Type:** character vector**Values:** scalar**Default:** '[]'**Product output — Product output data type**

Inherit: Inherit via internal rule (default) | Inherit: Same as input | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | <data type expression>

Specify the product output data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** ProductDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'**Accumulator — Accumulator data type**

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | <data type expression>

Specify the accumulator data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** AccumDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'Inherit: Same as product output' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

State — State data type

Inherit: Same as accumulator (default) | Inherit: Same as input | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | <data type expression>

Specify the state data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Same as accumulator
- A built-in integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Dependencies

To enable this parameter, set the **Filter structure** to Lattice MA.

Programmatic Use

Block Parameter: StateDataTypeStr

Type: character vector

Values: 'Inherit: Same as accumulator' | 'Inherit: Same as input' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Same as accumulator'

Output — Output data type

Inherit: Same as accumulator (default) | Inherit: Same as input | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Same as accumulator
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Same as accumulator' | 'Inherit: Same as input' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Same as accumulator'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output maximum — Maximum output value for range checking**

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Rationale	Impact on Overflows	Example
Do not select this check box (off).	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block supports custom state attributes to customize and generate code more efficiently. To access or set these attributes, open the Model Data Editor. On the **Modeling** tab, click **Model Data Editor**. For an example, see “Custom State Attributes in Discrete FIR Filter block”.

The Discrete FIR Filter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Filter structure** is set to `Direct form` or `Direct form transposed`.

- **Input processing** is set to `Columns as channels (frame based)`.
- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

For hardware-friendly valid and reset control signals, and to model exact hardware latency behavior in Simulink, use the Discrete FIR Filter block instead.

To reduce area or increase speed, the Discrete FIR Filter block supports either block-level optimizations or subsystem-level optimizations. For details of available block-level optimization parameters, see “Block Optimizations” on page 1-396. When you enable block optimizations, the block cannot participate in subsystem optimizations. Use block optimizations when your design is a single one-channel filter. Use subsystem optimizations to share resources across multiple channels or multiple filters. For the block to participate in subsystem-level optimizations, set the **Architecture** to `Fully parallel`. See “Subsystem Optimizations for Filters” (HDL Coder).

Multichannel Filter Support

HDL Coder supports the use of vector inputs to Discrete FIR Filter blocks, where each element of the vector represents an independent channel.

- 1 Connect a vector signal to the Discrete FIR Filter block input port.
- 2 Specify **Input processing** as `Elements as channels (sample based)`.
- 3 To reduce area by sharing the filter kernel between channels, set the **ChannelSharing** property to the number of channels.

Programmable Filter Support

HDL Coder supports programmable filters for Discrete FIR Filter blocks.

- 1 On the filter block mask, set **Coefficient source** to **Input port**.
- 2 Connect a vector signal to the Num coefficient port.

Programmable filters are not supported for:

- distributed arithmetic (DA)
- **CoeffMultipliers** set to `csd` or `factored-csd`

Frame-Based Input Support

HDL Coder supports the use of vector inputs to Discrete FIR Filter blocks, where each element of the vector represents a sample in time. You can use an input vector of up to 512 samples. The frame-based implementation supports fixed-point input and output data types, and uses full-precision internal data types. You can use real input signals with real coefficients, complex input signals with real coefficients, or real input signals with complex coefficients. You can also use frame-based input with programmable coefficients.

- 1 Connect a vector signal to the Discrete FIR Filter block input port.
- 2 Specify **Input processing** as Columns as channels (frame based), and set **Filter structure** to Direct form.
- 3 Right-click the block and open **HDL Code > HDL Block Properties**. Set the **Architecture** to Frame Based. The block implements a direct form parallel HDL architecture. Other architectures, including fully- or partly-serial, are not supported. See “Frame-Based Architecture” (HDL Coder).

Frame-based input filters are not supported for:

- Optional block-level reset and enable control signals
- Resettable and enabled subsystems
- Complex input signals with complex coefficients. You can use either complex input signals and real coefficients, or complex coefficients and real input signals.
- Multichannel input
- Sharing and streaming optimizations
- distributed arithmetic (DA)

Control Ports

You can generate HDL code for filters with or without the optional enable port, and with or without the optional reset port.

Complex Data Support

You can use any combination of complex input and complex coefficients with fully-parallel filter structures, when you use non-frame-based input data.

Complex coefficients are not supported with serial filter architectures.

When you use frame-based input data you can use either complex input signals and real coefficients, or complex coefficients and real input signals.

You cannot use distributed arithmetic (DA) or **CoeffMultipliers** set to csd or factored-csd with complex coefficients.

Block Optimizations

Area and Speed Optimizations	
Serial Architecture	<p>To use block-level optimizations to reduce hardware resources, set Architecture to one of the serial options. See “HDL Filter Architectures” (HDL Coder).</p> <p>When you specify SerialPartition and ReuseAccum for a Discrete FIR Filter block, set Filter structure to Direct form, Direct form symmetric, or Direct form antisymmetric. The Direct form transposed structure is not supported with serial architectures.</p>

Area and Speed Optimizations	
Distributed Arithmetic	<p>To minimize multipliers by replacing them with LUTs and shift registers, use a distributed arithmetic (DA) filter implementation. See “Distributed Arithmetic for HDL Filters” (HDL Coder).</p> <p>When you select the Distributed Arithmetic (DA) architecture and use the DALUTPartition and DARadix distributed arithmetic properties, set Filter structure to Direct form, Direct form symmetric, or Direct form antisymmetric. The Direct form transposed structure is not supported with distributed arithmetic.</p>
Multichannel Area Reduction	<p>To share filter logic between channels, set the ChannelSharing property to the number of channels. Using ChannelSharing excludes the filter from other optimizations.</p> <p>You can achieve the same logic sharing across all eligible logic in a subsystem by using the StreamingFactor property. This option also enables the filter to participate in other subsystem optimizations. See the Streaming section of “Subsystem Optimizations for Filters” (HDL Coder).</p>
Pipelining	<p>To improve clock speed, use AddPipelineRegisters to use a pipelined adder tree rather than the default linear adder. You can also specify the number of pipeline stages before and after the multipliers. See “HDL Filter Architectures” (HDL Coder).</p>

HDL Filter Properties	
AddPipelineRegisters	Insert a pipeline register between stages of computation in a filter. See also AddPipelineRegisters (HDL Coder).
ChannelSharing	For a multichannel filter, generate a single filter implementation to be shared between channels. See also ChannelSharing (HDL Coder).
CoeffMultipliers	Specify the use of canonical signed digit (CSD) optimization to decrease filter area by replacing coefficient multipliers with shift-and-add logic. When you choose a fully parallel filter implementation, you can set CoeffMultipliers to <code>csd</code> or <code>factored-csd</code> . The default is <code>multipliers</code> , which retains multipliers in the HDL. See also CoeffMultipliers (HDL Coder).
DALUTPartition	Specify distributed arithmetic partial-product LUT partitions as a vector of the sizes of each partition. The sum of all vector elements must be equal to the filter length. The maximum size for a partition is 12 taps. Set DALUTPartition to a scalar value equal to the filter length to generate DA code without LUT partitions. See also DALUTPartition (HDL Coder).
DARadix	Specify how many distributed arithmetic bit sums are computed in parallel. A DA radix of 8 (2^3) generates a DA implementation that computes three sums at a time. The default value is 2^1 , which generates a fully serial DA implementation. See also DARadix (HDL Coder).
MultiplierInputPipeline	Specify the number of pipeline stages to add at filter multiplier inputs. See also MultiplierInputPipeline (HDL Coder).
MultiplierOutputPipeline	Specify the number of pipeline stages to add at filter multiplier outputs. See also MultiplierOutputPipeline (HDL Coder).

HDL Filter Properties	
ReuseAccum	Enable or disable accumulator reuse in a serial filter implementation. Set ReuseAccum to on to use a cascade-serial implementation. See also ReuseAccum (HDL Coder).
SerialPartition	Specify partitions for partly serial or cascade-serial filter implementations as a vector of the lengths of each partition. For a fully serial implementation, set this parameter to the length of the filter. See also SerialPartition (HDL Coder).

HDL Block Properties	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Restrictions

- HDL code generation is not supported for:
 - Unsigned input data.
 - Nonzero initial states. You must set **Initial states** to 0.
 - **Filter Structure:** Lattice MA.
- **CoeffMultipliers** options are supported only when using a fully parallel architecture. When you select a serial architecture, **CoeffMultipliers** is hidden from the HDL Block Properties dialog box.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

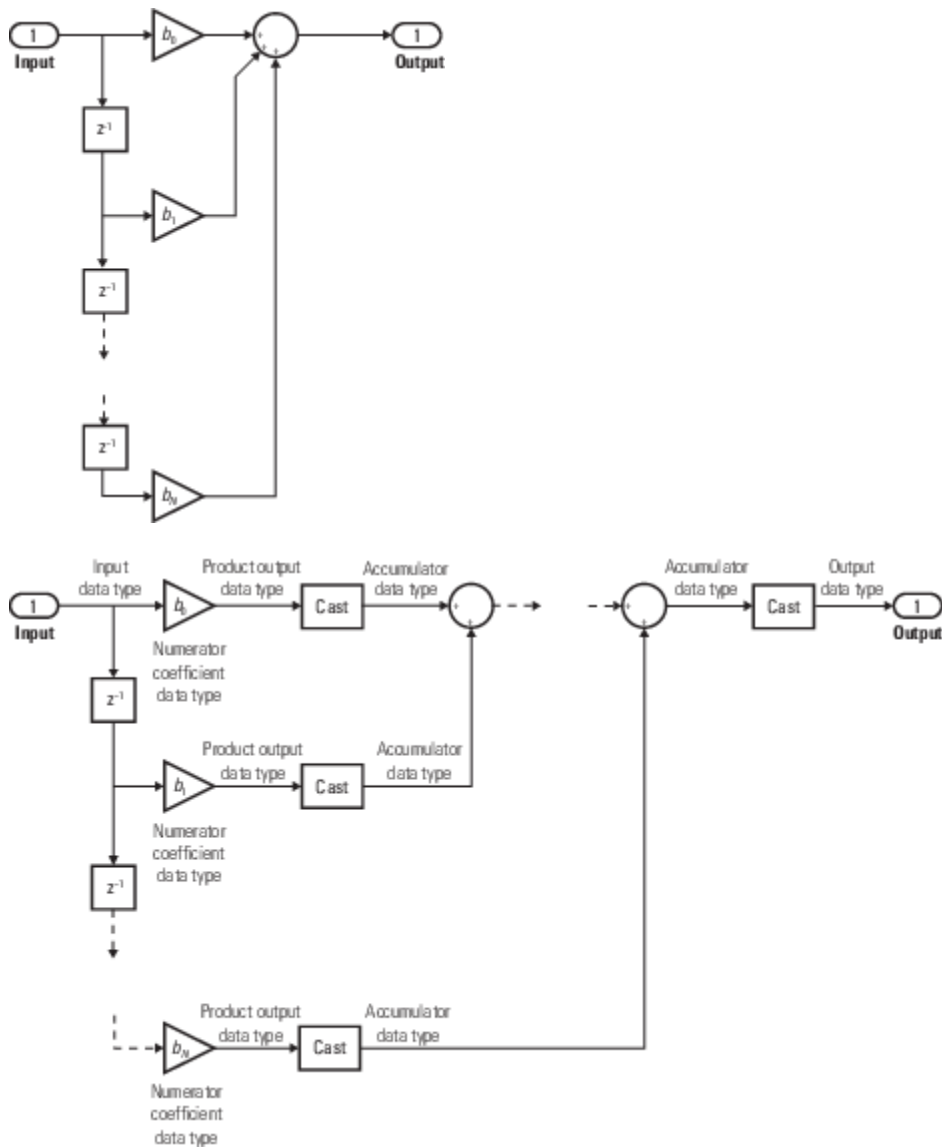

Design and simulate fixed-point systems using Fixed-Point Designer™.

The Discrete FIR Filter block accepts and outputs real and complex signals of any numeric data type supported by Simulink. The block supports the same types for the coefficients.

The following diagrams show the filter structure and the data types used within the Discrete FIR Filter block for fixed-point signals.

Direct Form

You cannot specify the state data type on the block mask for this structure because the input states have the same data types as the input.

Direct Form Symmetric

You cannot specify the state data type on the block mask for this structure because the input states have the same data types as the input.

It is assumed that the filter coefficients are symmetric. The block only uses the first half of the coefficients for filtering.

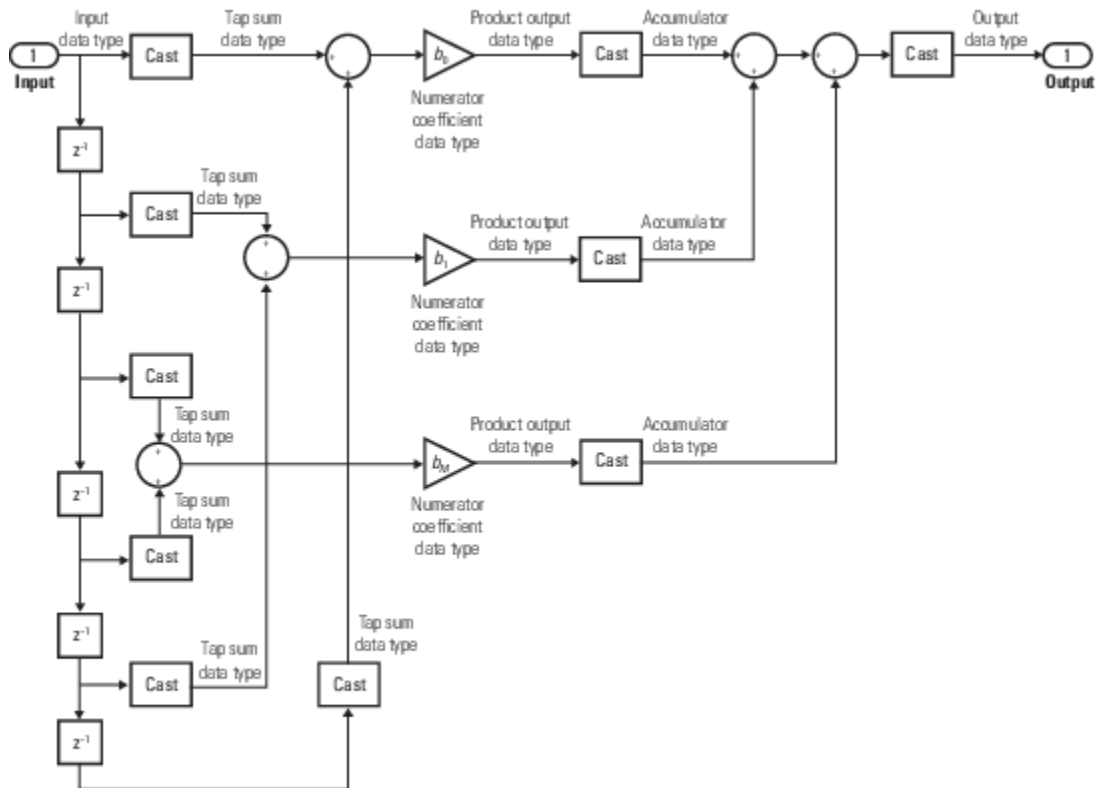

Even Order - Type I

Odd Order - Type II

Even Order - Type I

Odd Order - Type II

Direct Form Antisymmetric

You cannot specify the state data type on the block mask for this structure because the input states have the same data types as the input.

It is assumed that the filter coefficients are antisymmetric. The block only uses the first half of the coefficients for filtering.

Even Order - Type III

Odd Order - Type IV

Even Order - Type III

Odd Order - Type IV

Direct Form Transposed

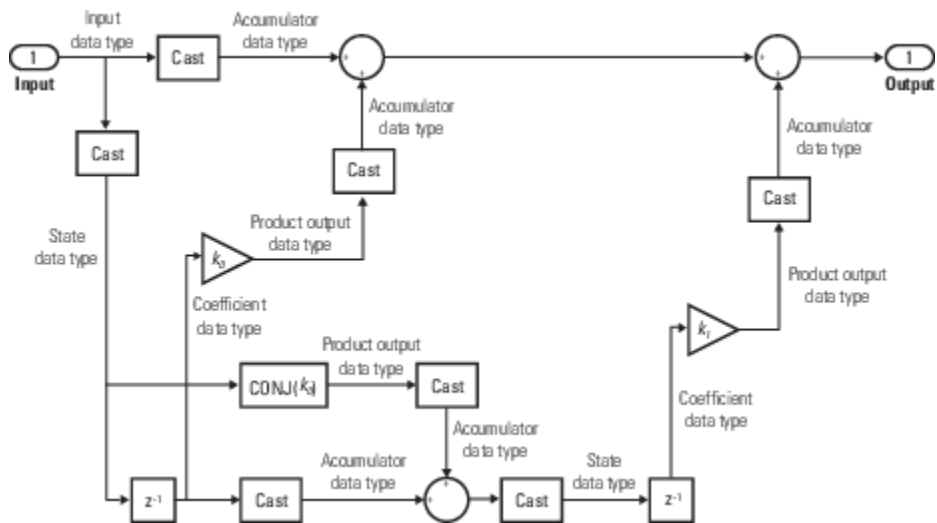

States are complex when either the inputs or the coefficients are complex.

Lattice MA

Discrete PID Controller

Discrete-time or continuous-time PID controller

Library: Simulink / Discrete
HDL Coder / Discrete
HDL Coder / HDL Floating Point Operations

Description

The Discrete PID Controller block implements a PID controller (PID, PI, PD, P only, or I only). The block is identical to the PID Controller block with the **Time domain** parameter set to **Discrete-time**.

The block output is a weighted sum of the input signal, the integral of the input signal, and the derivative of the input signal. The weights are the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action.

The block supports several controller types and structures. Configurable options in the block include:

- Controller type (PID, PI, PD, P only, or I only) — See the **Controller** parameter.
- Controller form (Parallel or Ideal) — See the **Form** parameter.
- Time domain (continuous or discrete) — See the **Time domain** parameter.
- Initial conditions and reset trigger — See the **Source** and **External reset** parameters.
- Output saturation limits and built-in anti-windup mechanism — See the **Limit output** parameter.
- Signal tracking for bumpless control transfer and multiloop control — See the **Enable tracking mode** parameter.

As you change these options, the internal structure of the block changes by activating different variant subsystems. (For more information, see “Variant Subsystems”). To examine the internal structure of the block and its variant subsystems, right-click the block and select **Mask > Look Under Mask**.

Control Configuration

In one common implementation, the PID Controller block operates in the feedforward path of a feedback loop.

The input of the block is typically an error signal, which is the difference between a reference signal and the system output. For a two-input block that permits setpoint weighting, see Discrete PID Controller (2DOF).

PID Gain Tuning

The PID controller gains are tunable either manually or automatically. Automatic tuning requires Simulink Control Design software. For more information about automatic tuning, see the **Select tuning method** parameter.

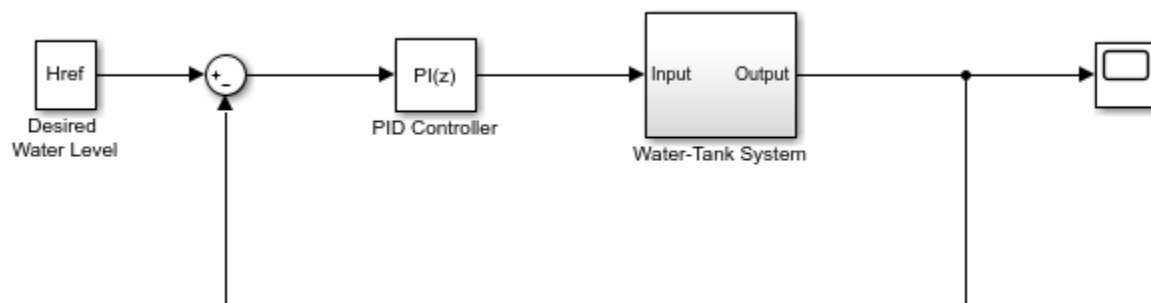

Ports

Input

Port_1(u) – Error signal input

scalar | vector

Difference between a reference signal and the output of the system under control, as shown.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

P – Proportional gain

scalar | vector

Proportional gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to external.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

I — Integral gain

scalar | vector

Integral gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral gain are also integrated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to external, and set **Controller** to a controller type that has integral action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

I*T_s — Integral gain multiplied by sample time

scalar | vector

Integral gain multiplied by the controller sample time, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculations in your model and feed them to the block.

Note PID tuning tools, such as the **PID Tuner** app and Closed-Loop PID Autotuner block, tune the gain **I** but not **I*T_s**. Therefore, multiply the integral gain value you obtain from a tuning tool by the sample time before you supply it to this port.

When you use **I*T_s** instead of **I**, the block requires fewer calculations to perform integration. This improves the execution time of the generated code.

Dependencies

To enable this port, set **Controller parameters Source** to external, set **Controller** to a controller type that has integral action, and enable the **Use I*T_s** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

D — Derivative gain

scalar | vector

Derivative gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You

can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the derivative gain are also differentiated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

N — Filter coefficient

scalar | vector

Derivative filter coefficient, provided from a source external to the block. External coefficient input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has a filtered derivative.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Reset — External reset trigger

scalar

Trigger to reset the integrator and filter to their initial conditions. The value of the **External reset** parameter determines whether reset occurs on a rising signal, a falling signal, or a level signal. The port icon indicates the selected trigger type. For example, the following illustration shows a continuous-time PID block with **External reset** set to `rising`.

When the trigger occurs, the block resets the integrator and filter to the initial conditions specified by the **Integrator Initial condition** and **Filter Initial condition** parameters or the **I₀** and **D₀** ports.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA®) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller block.

Dependencies

To enable this port, set **External reset** to any value other than none.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | Boolean

 I_0 — Integrator initial condition

scalar | vector

Integrator initial condition, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to external, and set **Controller** to a controller type that has integral action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

 D_0 — Filter initial condition

scalar | vector

Initial condition of the derivative filter, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to external, and set **Controller** to a controller type that has derivative action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

up — Output saturation upper limit

scalar | vector

Upper limit of the block output, provided from a source external to the block. If the weighted sum of the proportional, integral, and derivative actions exceeds the value provided at this port, the block output is held at that value.

Dependencies

To enable this port, select **Limit output** and set the output saturation **Source** to external.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

lo — Output saturation lower limit

scalar | vector

Lower limit of the block output, provided from a source external to the block. If the weighted sum of the proportional, integral, and derivative actions goes below the value provided at this port, the block output is held at that value.

Dependencies

To enable this port, select **Limit output** and set the output saturation **Source** to external.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

TR — Tracking signal

scalar | vector

Signal for controller output to track. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input. Signal tracking is useful for implementing bumpless control transfer in systems that switch between two controllers. It can also be useful to prevent block windup in multiloop control systems. For more information, see the **Enable tracking mode** parameter.

Dependencies

To enable this port, select the **Enable tracking mode** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

T_{DTI} — Discrete-integrator time

scalar

Discrete-integrator time, provided as a scalar to the block. You can use your own value of discrete-time integrator sample time that defines the rate at which the block is going to be run either in Simulink or on external hardware. The value of the discrete-time integrator time should match the average sampling rate of the external interrupts, when the block is used inside a conditionally-executed subsystem.

In other words, you can specify T_s for any of the integrator methods below such that the value matches the average sampling rate of the external interrupts. In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

$$\alpha(z) = \frac{T_s}{z - 1} \cdot$$

Backward Euler

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

Trapezoidal

$$\alpha(z) = \frac{T_s}{2} \frac{z + 1}{z - 1} \cdot$$

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page. For more information on conditionally executed subsystems, see “Conditionally Executed Subsystems Overview”.

Dependencies

To enable this port, set **Time Domain** to Discrete-time and select the **PID Controller is inside a conditionally executed subsystem** option.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Output**Port_1(y) – Controller output**

scalar | vector

Controller output, generally based on a sum of the input signal, the integral of the input signal, and the derivative of the input signal, weighted by the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action. Which terms are present in the controller signal depends on what you select for the **Controller** parameter. The base controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask. Other parameters modify the block output, such as saturation limits specified by the **Upper Limit** and **Lower Limit** saturation parameters.

The controller output is a vector signal when any of the inputs is a vector signal. In that case, the block acts as N independent PID controllers, where N is the number of signals in the input vector.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters**Controller – Controller type**

PID (default) | PI | PD | P | I

Specify which of the proportional, integral, and derivative terms are in the controller.

PID

Proportional, integral, and derivative action.

PI

Proportional and integral action only.

PD

Proportional and derivative action only.

P

Proportional action only.

I

Integral action only.

Tip The controller transfer function for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector
Values: "PID", "PI", "PD", "P", "I"
Default: "PID"

Form — Controller structure

Parallel (default) | Ideal

Specify whether the controller structure is parallel or ideal.

Parallel

The controller output is the sum of the proportional, integral, and derivative actions, weighted independently by **P**, **I**, and **D**, respectively. For example, for a continuous-time parallel-form PID controller, the transfer function is:

$$C_{par}(s) = P + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s+N}\right).$$

For a discrete-time parallel-form controller, the transfer function is:

$$C_{par}(z) = P + I\alpha(z) + D\left[\frac{N}{1+N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Ideal

The proportional gain **P** acts on the sum of all actions. For example, for a continuous-time ideal-form PID controller, the transfer function is:

$$C_{id}(s) = P\left[1 + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s+N}\right)\right].$$

For a discrete-time ideal-form controller, the transfer function is:

$$C_{id}(z) = P\left[1 + I\alpha(z) + D\frac{N}{1+N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $a(z)$ and $b(z)$, respectively.

Tip The controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector

Values: "Parallel", "Ideal"

Default: "Parallel"

Time domain — Specify discrete-time or continuous-time controller

Discrete-time (default) | Continuous-time

When you select **Discrete-time**, it is recommended that you specify an explicit sample time for the block. See the **Sample time (-1 for inherited)** parameter. Selecting **Discrete-time** also enables the **Integrator method**, and **Filter method** parameters.

When the PID Controller block is in a model with synchronous state control (see the State Control block), you cannot select **Continuous-time**.

Note The PID Controller and Discrete PID Controller blocks are identical except for the default value of this parameter.

Programmatic Use**Block Parameter:** TimeDomain**Type:** string, character vector**Values:** "Continuous-time", "Discrete-time"**Default:** "Discrete-time"**PID Controller is inside a conditionally executed subsystem — Enable the discrete-integrator time port**

off (default) | on

For discrete-time PID controllers, enable the discrete-time integrator port to use your own value of discrete-time integrator sample time. To ensure proper integration, use the T_{DTI} port to provide a scalar value of Δt for accurate discrete-time integration.

Dependencies

To enable this parameter, set **Time Domain** to **Discrete-time**.

Programmatic Use**Block Parameter:** UseExternalTs**Type:** string, character vector**Values:** "on", "off"**Default:** "off"**Sample time (-1 for inherited) — Discrete interval between samples**

-1 (default) | positive scalar

Specify a sample time by entering a positive scalar value, such as 0.1. The default discrete sample time of -1 means that the block inherits its sample time from upstream blocks. However, it is recommended that you set the controller sample time explicitly, especially if you expect the sample time of upstream blocks to change. The effect of the controller coefficients P, I, D, and N depend on the sample time. Thus, for a given set of coefficient values, changing the sample time changes the performance of the controller.

See “Specify Sample Time” for more information.

To implement a continuous-time controller, set **Time domain** to **Continuous-time**.

Tip If you want to run the block with an externally specified or variable sample time, set this parameter to -1 and put the block in a Triggered Subsystem. Then, trigger the subsystem at the desired sample time.

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Block Parameter: SampleTime

Type: scalar

Values: -1, positive scalar

Default: -1

Integrator method — Method for computing integral in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the integral term of the controller transfer function is $I\alpha(z)$, where $\alpha(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1} \cdot$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Note For the BackwardEuler or Trapezoidal methods, you cannot generate HDL code for the block if either:

- **Limit output** is selected and **Anti-Windup Method** is anything other than none.
 - **Enable tracking mode** is selected.
-

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and set **Controller** to a controller type with integral action.

Programmatic Use

Block Parameter: IntegratorMethod

Type: string, character vector

Values: "Forward Euler", "Backward Euler", "Trapezoidal"

Default: "Forward Euler"

Filter method – Method for computing derivative in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the filter method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1}.$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and enable **Use filtered derivative**.

Programmatic Use**Block Parameter:** FilterMethod**Type:** string, character vector**Values:** "Forward Euler", "Backward Euler", "Trapezoidal"**Default:** "Forward Euler"**Main****Source — Source for controller gains and filter coefficient**

internal (default) | external

Enabling external inputs for the parameters allows you to compute PID gains and filter coefficients externally to the block and provide them to the block as signal inputs.

internal

Specify the controller gains and filter coefficient using the block parameters **P**, **I**, **D**, and **N**.

external

Specify the PID gains and filter coefficient externally using block inputs. An additional input port appears on the block for each parameter that is required for the current controller type.

External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID gains by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. This result occurs because in both continuous time and discrete time, the gains are applied to the signal before integration or differentiation. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.

Within the block, the input signal u is multiplied by the externally supplied integrator gain, I , before integration. This implementation yields:

$$y_i = \int uI dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain D to be differentiated.

Programmatic Use**Block Parameter:** ControllerParametersSource**Type:** string, character vector**Values:** "internal", "external"**Default:** "internal"

Proportional (P) — Proportional gain

1 (default) | scalar | vector

Specify a finite, real gain value for the proportional gain. When **Controller form** is:

- **Parallel** — Proportional action is independent of the integral and derivative actions. For instance, for a continuous-time parallel PID controller, the transfer function is:

$$C_{par}(s) = P + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s + N}\right).$$

For a discrete-time parallel-form controller, the transfer function is:

$$C_{par}(z) = P + I\alpha(z) + D\left[\frac{N}{1 + N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

- **Ideal** — The proportional gain multiplies the integral and derivative terms. For instance, for a continuous-time ideal PID controller, the transfer function is:

$$C_{id}(s) = P\left[1 + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s + N}\right)\right].$$

For a discrete-time ideal-form controller, the transfer function is:

$$C_{id}(z) = P\left[1 + I\alpha(z) + D\frac{N}{1 + N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal** and set **Controller** to **PID**, **PD**, **PI**, or **P**.

Programmatic Use

Block Parameter: P

Type: scalar, vector

Default: 1

Integral (I) — Integral gain

1 (default) | scalar | vector

Specify a finite, real gain value for the integral gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: I

Type: scalar, vector

Default: 1

Integral (I*Ts) — Integral gain multiplied by sample time

1 (default) | scalar | vector

Specify a finite, real gain value for the integral gain multiplied by the sample time.

Note PID tuning tools, such as the **PID Tuner** app and Closed-Loop PID Autotuner block, tune the gain **I** but not **I*Ts**. Therefore, multiply the integral gain value you obtain from a tuning tool by the sample time before you write it to this parameter.

When you use **I*Ts** instead of **I**, the block requires fewer calculations to perform integration. This improves the execution time of the generated code.

Tunable: No

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, set **Controller** to a type that has integral action, and enable the **Use I*Ts** parameter.

Programmatic Use

Block Parameter: I

Type: scalar, vector

Default: 1

Use I*Ts — Use integral gain multiplied by sample time

off (default) | on

For discrete-time controllers with integral action, the block takes the integral gain as an input and multiplies it by the sample time internally as a part of performing the integration. You can enable this parameter to specify integral gain multiplied by sample time as input (**I*Ts**) in place of the integral gain (**I**). Doing so reduces the number of internal calculations and is useful when you want to improve the execution time of your generated code.

Dependencies

To enable this parameter, set **Controller** to a controller type that has integral action.

Programmatic Use

Block Parameter: UseKiTs

Type: string, character vector

Values: "on", "off"

Default: "on"

Derivative (D) — Derivative gain

0 (default) | scalar | vector

Specify a finite, real gain value for the derivative gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal**, and set **Controller** to PID or PD.

Programmatic Use

Block Parameter: D

Type: scalar, vector

Default: 0

Use filtered derivative – Apply filter to derivative term

on (default) | off

For discrete-time PID controllers only, clear this option to replace the filtered derivative with an unfiltered discrete-time differentiator. When you do so, the derivative term of the controller transfer function becomes:

$$D \frac{z - 1}{zT_s} \cdot$$

For continuous-time PID controllers, the derivative term is always filtered.

Dependencies

To enable this parameter, set **Time domain** to **Discrete-time**, and set **Controller** to a type that has derivative action.

Programmatic Use

Block Parameter: UseFilter

Type: string, character vector

Values: "on", "off"

Default: "on"

Filter coefficient (N) — Derivative filter coefficient

100 (default) | scalar | vector

Specify a finite, real gain value for the filter coefficient. The filter coefficient determines the pole location of the filter in the derivative action of the block. The location of the filter pole depends on the **Time domain** parameter.

- When **Time domain** is Continuous-time, the pole location is $s = -N$.
- When **Time domain** is Discrete-time, the pole location depends on the **Filter method** parameter.

Filter Method	Location of Filter Pole
Forward Euler	$z_{pole} = 1 - NT_s$
Backward Euler	$z_{pole} = \frac{1}{1 + NT_s}$
Trapezoidal	$z_{pole} = \frac{1 - NT_s/2}{1 + NT_s/2}$

The block does not support $N = \text{Inf}$ (ideal unfiltered derivative). When the **Time domain** is Discrete-time, you can clear **Use filtered derivative** to remove the derivative filter.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal** and set **Controller** to **PID** or **PD**.

Programmatic Use

Block Parameter: N

Type: scalar, vector

Default: 100

Select tuning method — Tool for automatic tuning of controller coefficients

Transfer Function Based (PID Tuner App) (default) | Frequency Response Based

If you have Simulink Control Design software, you can automatically tune the PID coefficients. To do so, use this parameter to select a tuning tool, and click **Tune**.

Transfer Function Based (PID Tuner App)

Use **PID Tuner**, which lets you interactively tune PID coefficients while examining relevant system responses to validate performance. By default, **PID Tuner** works with a linearization of your plant model. For models that cannot be linearized, you can tune PID coefficients against a plant model estimated from simulated or measured response data. For more information, see "Introduction to Model-Based PID Tuning in Simulink" (Simulink Control Design).

Frequency Response Based

Use **Frequency Response Based PID Tuner**, which tunes PID controller coefficients based on frequency-response estimation data obtained by simulation. This tuning approach is especially

useful for plants that are not linearizable or that linearize to zero. For more information, see “Design PID Controller from Plant Frequency-Response Data” (Simulink Control Design).

Both of these tuning methods assume a single-loop control configuration. Simulink Control Design software includes other tuning approaches that suit more complex configurations. For information about other ways to tune a PID Controller block, see “Choose a Control Design Approach” (Simulink Control Design).

Enable zero-crossing detection — Detect zero crossings on reset and on entering or leaving a saturation state

on (default) | off

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate **External reset** in your PID Controller block, activating zero-crossing detection can reduce computation time in your simulation. Selecting this parameter activates zero-crossing detection:

- At initial-state reset
- When entering an upper or lower saturation state
- When leaving an upper or lower saturation state

For more information about zero-crossing detection, see “Zero-Crossing Detection”.

Programmatic Use

Block Parameter: ZeroCross

Type: string, character vector

Values: "on", "off"

Default: "on"

Initialization

Source — Source for integrator and derivative initial conditions

internal (default) | external

Simulink uses initial conditions to initialize the integrator and derivative-filter (or the unfiltered derivative) output at the start of a simulation or at a specified trigger event. (See the **External reset** parameter.) These initial conditions determine the initial block output. Use this parameter to select how to supply the initial condition values to the block.

internal

Specify the initial conditions using the **Integrator Initial condition** and **Filter Initial condition** parameters. If **Use filtered derivative** is not selected, use the **Differentiator** parameter to specify the initial condition for the unfiltered differentiator instead of a filter initial condition.

external

Specify the initial conditions externally using block inputs. Additional input ports **I₀** and **D₀** appear on the block. If **Use filtered derivative** is not selected, supply the initial condition for the unfiltered differentiator at **D₀** instead of a filter initial condition.

Programmatic Use

Block Parameter: InitialConditionSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Integrator — Integrator initial condition

0 (default) | scalar | vector

Simulink uses the integrator initial condition to initialize the integrator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The integrator initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: `InitialConditionForIntegrator`

Type: scalar, vector

Default: 0

Filter — Filter initial condition

0 (default) | scalar | vector

Simulink uses the filter initial condition to initialize the derivative filter at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The filter initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and use a controller that has a derivative filter.

Programmatic Use

Block Parameter: `InitialConditionForFilter`

Type: scalar, vector

Default: 0

Differentiator — Initial condition for unfiltered derivative

0 (default) | scalar | vector

When you use an unfiltered derivative, Simulink uses this parameter to initialize the differentiator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the derivative initial condition determine the initial output of the PID controller block.

The derivative initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, set **Time domain** to `Discrete-time`, clear the **Use filtered derivative** check box, and in the **Initialization** tab, set **Source** to `internal`.

Programmatic Use

Block Parameter: `DifferentiatorICPrevScaledInput`

Type: scalar, vector

Default: 0

Initial condition setting — Location at which initial condition is applied

Auto (default) | Output

Use this parameter to specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. You can change this parameter at the command line only, using `set_param` to set the `InitialConditionSetting` parameter of the block.

Auto

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

Output

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

For more information about the **Initial condition setting** parameter, see the Discrete-Time Integrator block.

This parameter is only accessible through programmatic use.

Programmatic Use

Block Parameter: `InitialConditionSetting`

Type: string, character vector

Values: "Auto", "Output"

Default: "Auto"

External reset — Trigger for resetting integrator and filter values

none (default) | rising | falling | either | level

Specify the trigger condition that causes the block to reset the integrator and filter to initial conditions. (If **Use filtered derivative** is not selected, the trigger resets the integrator and differentiator to initial conditions.) Selecting any option other than `none` enables the **Reset** port on the block for the external reset signal.

none

The integrator and filter (or differentiator) outputs are set to initial conditions at the beginning of simulation, and are not reset during simulation.

rising

Reset the outputs when the reset signal has a rising edge.

falling

Reset the outputs when the reset signal has a falling edge.

either

Reset the outputs when the reset signal either rises or falls.

level

Reset the outputs when the reset signal either:

- Is nonzero at the current time step
- Changes from nonzero at the previous time step to zero at the current time step

This option holds the outputs to the initial conditions while the reset signal is nonzero.

Dependencies

To enable this parameter, set **Controller** to a type that has derivative or integral action.

Programmatic Use

Block Parameter: ExternalReset

Type: string, character vector

Values: "none", "rising", "falling", "either", "level"

Default: "none"

Ignore reset when linearizing – Force linearization to ignore reset

off (default) | on

Select to force Simulink and Simulink Control Design linearization commands to ignore any reset mechanism specified in the **External reset** parameter. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the block to reset.

Programmatic Use

Block Parameter: IgnoreLimit

Type: string, character vector

Values: "off", "on"

Default: "off"

Enable tracking mode – Activate signal tracking

off (default) | on

Signal tracking lets the block output follow a tracking signal that you provide at the **TR** port. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input with a gain K_t , specified by the **Tracking gain (Kt)** parameter. Signal tracking has several applications, including bumpless control transfer and avoiding windup in multiloop control structures.

Bumpless control transfer

Use signal tracking to achieve bumpless control transfer in systems that switch between two controllers. Suppose you want to transfer control between a PID controller and another controller. To do so, connecting the controller output to the **TR** input as shown in the following illustration.

For more information, see “Bumpless Control Transfer” on page 12-96.

Multiloop control

Use signal tracking to prevent block windup in multiloop control approaches, as in the following model.

The Inner Loop subsystem contains the blocks shown in the following diagram.

Because the PID controller tracks the output of the inner loop, its output never exceeds the saturated inner-loop output. For more details, see “Prevent Block Windup in Multiloop Control” on page 12-95.

Dependencies

To enable this parameter, set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: TrackingMode

Type: string, character vector

Values: "off", "on"

Default: "off"

Tracking coefficient (Kt) — Gain of signal-tracking feedback loop

1 (default) | scalar

When you select **Enable tracking mode**, the difference between the signal **TR** and the block output is fed back to the integrator input with a gain K_t . Use this parameter to specify the gain in that feedback loop.

Dependencies

To enable this parameter, select **Enable tracking mode**.

Programmatic Use

Block Parameter: Kt

Type: scalar

Default: 1

Output saturation

Limit Output — Limit block output to specified saturation values

off (default) | on

Activating this option limits the block output, so that you do not need a separate Saturation on page 1-1574 block after the controller. It also allows you to activate the anti-windup mechanism built into the block (see the **Anti-windup method** parameter). Specify the output saturation limits using the **Lower limit** and **Upper limit** parameters. You can also specify the saturation limits externally as block input ports.

Programmatic Use

Block Parameter: LimitOutput

Type: string, character vector

Values: "off", "on"

Default: "off"

Source — Source for output saturation limits

internal (default) | external

Use this parameter to specify how to supply the upper and lower saturation limits of the block output.

internal

Specify the output saturation limits using the **Upper limit** and **Lower limit** parameters.

external

Specify the output saturation limits externally using block input ports. The additional input ports **up** and **lo** appear on the block. You can use the input ports to implement the upper and lower output saturation limits determined by logic or other calculations in the Simulink model and passed to the block.

Programmatic Use

Block Parameter: SatLimitsSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Upper limit — Upper saturation limit for block output

Inf (default) | scalar

Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: UpperSaturationLimit

Type: scalar

Default: Inf

Lower limit — Lower saturation limit for block output

-Inf (default) | scalar

Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: LowerSaturationLimit

Type: scalar

Default: -Inf

Ignore saturation when linearizing — Force linearization to ignore output limits

off (default) | on

Force Simulink and Simulink Control Design linearization commands to ignore block output limits specified in the **Upper limit** and **Lower limit** parameters. Ignoring output limits allows you to linearize a model around an operating point even if that operating point causes the block to exceed the output limits.

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: LinearizeAsGain

Type: string, character vector

Values: "off", "on"

Default: "off"

Anti-windup method — Integrator anti-windup method

none (default) | back-calculation | clamping

When you select **Limit output** and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator windup), increasing the difference between the block output and the sum of the block components. In other words, the internal signals in the block can be unbounded even if the output appears bounded by saturation limits. Without a mechanism to prevent integrator windup, two results are possible:

- If the sign of the input signal never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the input signal changes once the weighted sum has grown beyond the output limits, it can take a long time to unwind the integrator and return the weighted sum within the block saturation limit.

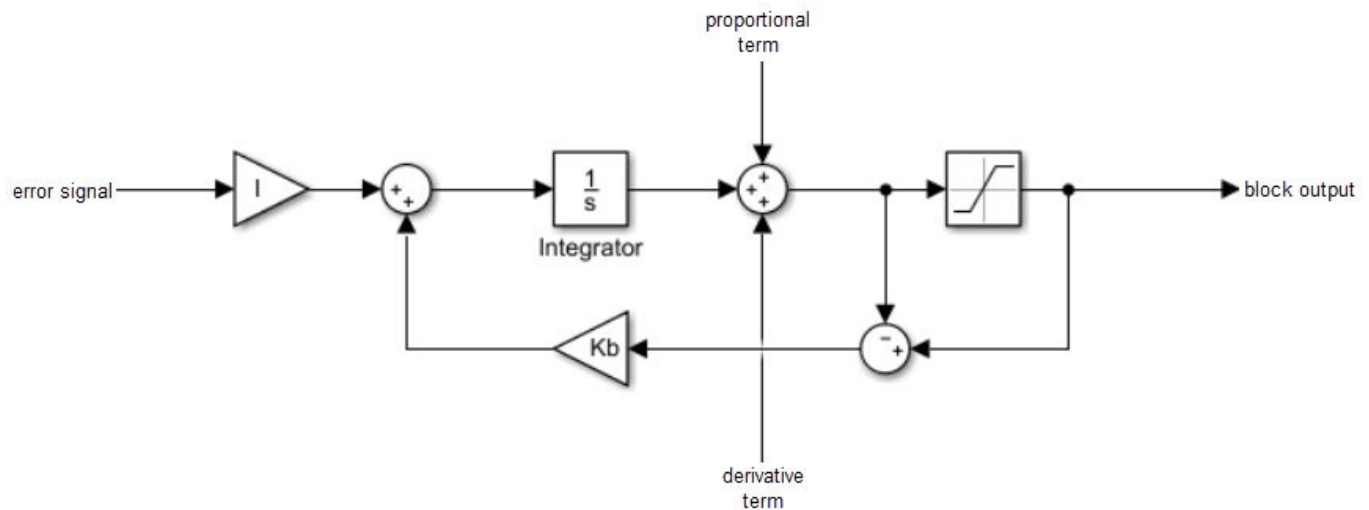

In either case, controller performance can suffer. To combat the effects of windup without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. To avoid this problem, activate an anti-windup mechanism using this parameter.

none

Do not use an anti-windup mechanism.

back-calculation

Unwind the integrator when the block output saturates by feeding back to the integrator the difference between the saturated and unsaturated control signal. The following diagram represents the back-calculation feedback circuit for a continuous-time controller. To see the actual feedback circuit for your controller configuration, right-click on the block and select **Mask > Look Under Mask**.

Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. It is usually satisfactory to set $K_b = I$, or for controllers with derivative action, $K_b = \sqrt{I \cdot D}$. Back-calculation can be effective for plants with relatively large dead time [1].

clamping

Integration stops when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Integration resumes when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. Clamping is sometimes referred to as conditional integration.

Clamping can be useful for plants with relatively small dead times, but can yield a poor transient response for large dead times [1].

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: AntiWindupMode

Type: string, character vector

Values: "none", "back-calculation", "clamping"

Default: "none"

Back-calculation coefficient (Kb) — Gain coefficient of anti-windup feedback loop

1 (default) | scalar

The back-calculation anti-windup method unwinds the integrator when the block output saturates. It does so by feeding back to the integrator the difference between the saturated and unsaturated control signal. Use the **Back-calculation coefficient (Kb)** parameter to specify the

gain of the anti-windup feedback circuit. For more information, see the **Anti-windup method** parameter.

Dependencies

To enable this parameter, select the **Limit output** parameter, and set the **Anti-windup method** parameter to back-calculation.

Programmatic Use

Block Parameter: Kb

Type: scalar

Default: 1

Data Types

The parameters in this tab are primarily of use in fixed-point code generation using Fixed-Point Designer. They define how numeric quantities associated with the block are stored and processed when you generate code.

If you need to configure data types for fixed-point code generation, click **Open Fixed-Point Tool** and use that tool to configure the rest of the parameters in the tab. For information about using Fixed-Point Tool, see “Autoscaling Data Objects Using the Fixed-Point Tool” (Fixed-Point Designer).

After you use Fixed-Point Tool, you can use the parameters in this tab to make adjustments to fixed-point data-type settings if necessary. For each quantity associated with the block, you can specify:

- Floating-point or fixed-point data type, including whether the data type is inherited from upstream values in the block.
- The minimum and maximum values for the quantity, which determine how the quantity is scaled for fixed-point representation.

For assistance in selecting appropriate values, click  to open the Data Type Assistant for the corresponding quantity. For more information, see “Specify Data Types Using Data Type Assistant”.

Main	Initialization	Output saturation	Data Types	State Attributes
Fixed-point operational parameters				
Integer rounding mode: Floor ▼				
<input type="checkbox"/> Saturate on integer overflow				
<input type="checkbox"/> Lock data type settings against changes by the fixed-point tools Open Fixed-Point Tool...				
Data Type				
			Minimum	Maximum
P product output:	Inherit: Inherit via internal rule ▼	>>	[] ⋮	[] ⋮
I product output:	Inherit: Inherit via internal rule ▼	>>	[] ⋮	[] ⋮
D product output:	Inherit: Inherit via internal rule ▼	>>	[] ⋮	[] ⋮
N product output:	Inherit: Inherit via internal rule ▼	>>	[] ⋮	[] ⋮
b product output:	Inherit: Inherit via internal rule ▼	>>	[] ⋮	[] ⋮
c product output:	Inherit: Inherit via internal rule ▼	>>	[] ⋮	[] ⋮
Sum output:	Inherit: Inherit via internal rule ▼	>>	[] ⋮	[] ⋮
▶ Additional data types				

The specific quantities listed in the Data Types tab vary depending on how you configure the PID controller block. In general, you can configure data types for the following types of quantities:

- Product output — Stores the result of a multiplication carried out under the block mask. For example, **P product output** stores the output of the gain block that multiplies the block input with the proportional gain **P**.
- Parameter — Stores the value of a numeric block parameter, such as **P**, **I**, or **D**.
- Block output — Stores the output of a block that resides under the PID controller block mask. For example, use **Integrator output** to specify the data type of the output of the block called Integrator. This block resides under the mask in the Integrator subsystem, and computes integrator term of the controller action.
- Accumulator — Stores values associated with a sum block. For example, **SumI2 Accumulator** sets the data type of the accumulator associated with the sum block SumI2. This block resides under the mask in the Back Calculation subsystem of the Anti-Windup subsystem.

In general, you can find the block associated with any listed parameter by looking under the PID Controller block mask and examining its subsystems. You can also use the Model Explorer to search under the mask for the listed parameter name, such as SumI2. (See **Model Explorer**.)

Matching Input and Internal Data Types

By default, all data types in the block are set to `Inherit: Inherit via internal rule`. With this setting, Simulink chooses data types to balance numerical accuracy, performance, and generated code size, while accounting for the properties of the embedded target hardware.

Under some conditions, incompatibility can occur between data types within the block. For instance, in continuous time, the Integrator block under the mask can accept only signals of type `double`. If the block input signal is a type that cannot be converted to `double`, such as `uint16`, the internal rules for type inheritance generate an error when you generate code.

To avoid such errors, you can use the Data Types settings to force a data type conversion. For instance, you can explicitly set **P product output**, **I product output**, and **D product output** to `double`, ensuring that the signals reaching the continuous-time integrators are of type `double`.

In general, it is not recommended to use the block in continuous time for code generation applications. However, similar data type errors can occur in discrete time, if you explicitly set some values to data types that are incompatible with downstream signal constraints within the block. In such cases, use the Data Types settings to ensure that all data types are internally compatible.

Fixed-Point Operational Parameters

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.
For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
 - In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.
-

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**State Attributes**

The parameters in this tab are primarily of use in code generation.

State name (e.g., 'position') – Name for continuous-time filter and integrator states

' ' (default) | character vector

Assign a unique name to the state associated with the integrator or the filter, for continuous-time PID controllers. (For information about state names in a discrete-time PID controller, see the **State name** parameter.) The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters.

Dependencies

To enable this parameter, set **Time domain** to Continuous-time.

Programmatic Use**Parameter:** IntegratorContinuousStateAttributes, FilterContinuousStateAttributes**Type:** character vector**Default:** ' '**State name – Names for discrete-time filter and integrator states**

empty string (default) | string | character vector

Assign a unique name to the state associated with the integrator or the filter, for discrete-time PID controllers. (For information about state names in a continuous-time PID controller, see the **State name (e.g., 'position')** parameter.)

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters. The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

For more information about the use of state names in code generation, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Parameter: IntegratorStateIdentifier, FilterStateIdentifier

Type: string, character vector

Default: ""

State name must resolve to Simulink signal object — Require that state name resolve to a signal object

off (default) | on

Select this parameter to require that the discrete-time integrator or filter state name resolves to a Simulink signal object.

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

- 1 Set **Time domain** to Discrete-time.
- 2 Specify a value for the integrator or filter **State name**.
- 3 Set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use

Block Parameter: IntegratorStateMustResolveToSignalObject, FilterStateMustResolveToSignalObject

Type: string, character vector

Values: "off", "on"

Default: "off"

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no

Zero-Crossing Detection	no
--------------------------------	----

Compatibility Considerations

ReferenceBlock parameter returns different path

Behavior changed in R2021b

Starting in R2021b, the `get_param` function returns a different value for the `ReferenceBlock` parameter. The `ReferenceBlock` parameter is a property common to all Simulink blocks and gives the path of the library block to which a block links. The PID Controller and Discrete PID Controller blocks now link to `'slpidlib/PID Controller'`. Previously, the blocks linked to `'pid_lib/PID Controller'`.

This change does not affect any other functionality or workflows. You can still use the previous path with the `set_param` function.

ReferenceBlock parameter returns different path

Behavior changed in R2020b

Starting in R2020b, the `get_param` function returns a different value for the `ReferenceBlock` parameter. The `ReferenceBlock` parameter is a property common to all Simulink blocks and gives the path of the library block to which a block links. The PID Controller and Discrete PID Controller blocks now link to `'pid_lib/PID Controller'`. Previously, the blocks linked to `'simulink/Continuous/PID Controller'`.

This change does not affect any other functionality or workflows. You can still use the previous path with the `set_param` function.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For continuous-time PID controllers (**Time domain** set to `Continuous-time`):

- Consider using "Model Discretizer" to map continuous-time blocks to discrete equivalents that support code generation. To access Model Discretizer, from your model, in the **Apps** tab, under **Control Systems**, click **Model Discretizer**.
- Not recommended for production code.

For discrete-time PID controllers (**Time domain** set to `Discrete-time`):

- Depends on absolute time when placed inside a triggered subsystem hierarchy.
- Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Restrictions

- HDL code generation is supported for discrete-time PID controllers only (**Time domain** set to Discrete-time).
- If the **Integrator method** is set to BackwardEuler or Trapezoidal, you cannot generate HDL code for the block under either of the following conditions:
 - **Limit output** is selected and the **Anti-Windup Method** is anything other than none.
 - **Enable tracking mode** is selected.
- To generate HDL code:
 - Use a discrete-time PID controller. On the **Time domain** section, specify **Discrete-time**.
 - Leave the **Use filtered derivative** check box selected.
 - Specify the initial conditions of the filter and integrator internally. On the **Initialization** tab, specify **Source** as internal.

You can specify the filter coefficients internally and externally for HDL code generation. On the **Main** tab, for **Source**, you can use internal or external.

- Set **External reset** to none.
- When you use double inputs, do not set **Anti-windup Method** to clamping.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Fixed-point code generation is supported for discrete-time PID controllers only (**Time domain** set to **Discrete-time**).

Introduced in R2009b

Discrete PID Controller (2DOF)

Discrete-time or continuous-time two-degree-of-freedom PID controller

Library: Simulink / Discrete

Description

The Discrete PID Controller (2DOF) block implements a two-degree-of-freedom PID controller (PID, PI, or PD). The block is identical to the PID Controller (2DOF) block with the **Time domain** parameter set to **Discrete-time**.

The block generates an output signal based on the difference between a reference signal and a measured system output. The block computes a weighted difference signal for the proportional and derivative actions according to the setpoint weights (**b** and **c**) that you specify. The block output is the sum of the proportional, integral, and derivative actions on the respective difference signals, where each action is weighted according to the gain parameters **P**, **I**, and **D**. A first-order pole filters the derivative action.

The block supports several controller types and structures. Configurable options in the block include:

- Controller type (PID, PI, or PD) — See the **Controller** parameter.
- Controller form (Parallel or Ideal) — See the **Form** parameter.
- Time domain (discrete or continuous) — See the **Time domain** parameter.
- Initial conditions and reset trigger — See the **Source** and **External reset** parameters.
- Output saturation limits and built-in anti-windup mechanism — See the **Limit output** parameter.
- Signal tracking for bumpless control transfer and multiloop control — See the **Enable tracking mode** parameter.

As you change these options, the internal structure of the block changes by activating different variant subsystems. (See “Variant Subsystems”.) To examine the internal structure of the block and its variant subsystems, right-click the block and select **Mask > Look Under Mask**.

Control Configuration

In one common implementation, the PID Controller block operates in the feedforward path of a feedback loop.

For a single-input block that accepts an error signal (a difference between a setpoint and a system output), see Discrete PID Controller.

PID Gain Tuning

The PID controller coefficients and the setpoint weights are tunable either manually or automatically. Automatic tuning requires Simulink Control Design software. For more information about automatic tuning, see the **Select tuning method** parameter.

Ports

Input

Ref — Reference signal

scalar | vector

Reference signal for plant to follow, as shown.

When the reference signal is a vector, the block acts separately on each signal, vectorizing the PID coefficients and producing a vector output signal of the same dimensions. You can specify the PID coefficients and some other parameters as vectors of the same dimensions as the input signal. Doing so is equivalent to specifying a separate PID controller for each entry in the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Port_1(y) — Measured system output

scalar | vector

Feedback signal for the controller, from the plant output.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

P — Proportional gain

scalar | vector

Proportional gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to external.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

I — Integral gain

scalar | vector

Integral gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral gain are also integrated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to external, and set **Controller** to a controller type that has integral action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

 $I \cdot T_s$ — Integral gain multiplied by sample time

scalar | vector

Integral gain multiplied by the controller sample time, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculations in your model and feed them to the block.

Note PID tuning tools, such as the **PID Tuner** app and Closed-Loop PID Autotuner block, tune the gain **I** but not $I \cdot T_s$. Therefore, multiply the integral gain value you obtain from a tuning tool by the sample time before you supply it to this port.

When you use $I \cdot T_s$ instead of **I**, the block requires fewer calculations to perform integration. This improves the execution time of the generated code.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, set **Controller** to a controller type that has integral action, and enable the **Use I*Ts** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

D – Derivative gain

`scalar` | `vector`

Derivative gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the derivative gain are also differentiated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

N – Filter coefficient

`scalar` | `vector`

Derivative filter coefficient, provided from a source external to the block. External coefficient input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has a filtered derivative.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

b – Proportional setpoint weight

`scalar` | `vector`

Proportional setpoint weight, provided from a source external to the block. External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

c – Derivative setpoint weight

scalar | vector

Derivative setpoint weight, provided from a source external to the block. External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Reset – External reset trigger

scalar

Trigger to reset the integrator and filter to their initial conditions. Use the **External reset** parameter to specify what kind of signal triggers a reset. The port icon indicates the trigger type specified in that parameter. For example, the following illustration shows a continuous-time PID Controller (2DOF) block with **External reset** set to `rising`.

When the trigger occurs, the block resets the integrator and filter to the initial conditions specified by the **Integrator Initial condition** and **Filter Initial condition** parameters or the **I₀** and **D₀** ports.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller block.

Dependencies

To enable this port, set **External reset** to any value other than `none`.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | Boolean

I₀ – Integrator initial condition

scalar | vector

Integrator initial condition, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to `external`, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

D₀ — Filter initial condition

`scalar` | `vector`

Initial condition of the derivative filter, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

up — Output saturation upper limit

`scalar` | `vector`

Upper limit of the block output, provided from a source external to the block. If the weighted sum of the proportional, integral, and derivative actions exceeds the value provided at this port, the block output is held at that value.

Dependencies

To enable this port, select **Limit output** and set the output saturation **Source** to `external`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

lo — Output saturation lower limit

`scalar` | `vector`

Lower limit of the block output, provided from a source external to the block. If the weighted sum of the proportional, integral, and derivative actions goes below the value provided at this port, the block output is held at that value.

Dependencies

To enable this port, select **Limit output** and set the output saturation **Source** to `external`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

TR — Tracking signal

`scalar` | `vector`

Signal for controller output to track. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input. Signal tracking is useful for implementing bumpless control transfer in systems that switch between two controllers. It can also be useful to prevent block windup in multiloop control systems. For more information, see the **Enable tracking mode** parameter.

Dependencies

To enable this port, select the **Enable tracking mode** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

T_{DTI} — Discrete-integrator time
scalar

Discrete-integrator time, provided as a scalar to the block. You can use your own value of discrete-time integrator sample time that defines the rate at which the block is going to be run either in Simulink or on external hardware. The value of the discrete-time integrator time should match the average sampling rate of the external interrupts, when the block is used inside a conditionally-executed subsystem.

In other words, you can specify T_s for any of the integrator methods below such that the value matches the average sampling rate of the external interrupts. In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

$$\alpha(z) = \frac{T_s}{z - 1}.$$

Backward Euler

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

Trapezoidal

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page. For more information on conditionally executed subsystems, see “Conditionally Executed Subsystems Overview”.

Dependencies

To enable this port, set **Time Domain** to Discrete-time and select the **PID Controller is inside a conditionally executed subsystem** option.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Output

Port_1(u) – Controller output

scalar | vector

Controller output, generally based on a sum of the input signal, the integral of the input signal, and the derivative of the input signal, weighted by the setpoint weights and by the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action. Which terms are present in the controller signal depends on what you select for the **Controller** parameter. The base controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask. Other parameters modify the block output, such as saturation limits specified by the **Upper Limit** and **Lower Limit** saturation parameters.

The controller output is a vector signal when any of the inputs is a vector signal. In that case, the block acts as N independent PID controllers, where N is the number of signals in the input vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Controller — Controller type

PID (default) | PI | PD

Specify which of the proportional, integral, and derivative terms are in the controller.

PID

Proportional, integral, and derivative action.

PI

Proportional and integral action only.

PD

Proportional and derivative action only.

Tip The controller output for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector

Values: "PID", "PI", "PD"

Default: "PID"

Form — Controller structure

Parallel (default) | Ideal

Specify whether the controller structure is parallel or ideal.

Parallel

The proportional, integral, and derivative gains **P**, **I**, and **D**, are applied independently. For example, for a continuous-time 2-DOF PID controller in parallel form, the controller output u is:

$$u = P(br - y) + I\frac{1}{s}(r - y) + D\frac{N}{1 + N\frac{1}{s}}(cr - y),$$

where r is the reference signal, y is the measured plant output signal, and b and c are the setpoint weights.

For a discrete-time 2-DOF controller in parallel form, the controller output is:

$$u = P(br - y) + I\alpha(z)(r - y) + D\frac{N}{1 + N\beta(z)}(cr - y),$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Ideal

The proportional gain **P** acts on the sum of all actions. For example, for a continuous-time 2-DOF PID controller in ideal form, the controller output is:

$$u = P \left[(br - y) + I \frac{1}{s} (r - y) + D \frac{N}{1 + N \frac{1}{s}} (cr - y) \right].$$

For a discrete-time 2-DOF PID controller in ideal form, the transfer function is:

$$u = P \left[(br - y) + I\alpha(z)(r - y) + D \frac{N}{1 + N\beta(z)} (cr - y) \right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tip The controller output for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector

Values: "Parallel", "Ideal"

Default: "Parallel"

Time domain — Specify discrete-time or continuous-time controller

Discrete-time (default) | Continuous-time

When you select **Discrete-time**, it is recommended that you specify an explicit sample time for the block. See the **Sample time (-1 for inherited)** parameter. Selecting **Discrete-time** also enables the **Integrator method**, and **Filter method** parameters.

When the PID Controller block is in a model with synchronous state control (see the State Control block), you cannot select **Continuous-time**.

Note The PID Controller (2DOF) and Discrete PID Controller (2DOF) blocks are identical except for the default value of this parameter.

Programmatic Use

Block Parameter: TimeDomain

Type: string, character vector

Values: "Continuous-time", "Discrete-time"

Default: "Discrete-time"

PID Controller is inside a conditionally executed subsystem — Enable the discrete-integrator time port

off (default) | on

For discrete-time PID controllers, enable the discrete-time integrator port to use your own value of discrete-time integrator sample time. To ensure proper integration, use the T_{DTI} port to provide a scalar value of Δt for accurate discrete-time integration.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time.

Programmatic Use

Block Parameter: UseExternalTs

Type: string, character vector

Values: "on", "off"

Default: "off"

Sample time (-1 for inherited) – Discrete interval between samples

-1 (default) | positive scalar

Specify a sample time by entering a positive scalar value, such as 0.1. The default discrete sample time of -1 means that the block inherits its sample time from upstream blocks. However, it is recommended that you set the controller sample time explicitly, especially if you expect the sample time of upstream blocks to change. The effect of the controller coefficients P, I, D, and N depend on the sample time. Thus, for a given set of coefficient values, changing the sample time changes the performance of the controller.

See “Specify Sample Time” for more information.

To implement a continuous-time controller, set **Time domain** to Continuous-time.

Tip If you want to run the block with an externally specified or variable sample time, set this parameter to -1 and put the block in a Triggered Subsystem. Then, trigger the subsystem at the desired sample time.

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Block Parameter: SampleTime

Type: scalar

Values: -1, positive scalar

Default: -1

Integrator method – Method for computing integral in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the integral term of the controller transfer function is $Ia(z)$, where $a(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1} \cdot$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1}.$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and set **Controller** to a controller type with integral action.

Programmatic Use

Block Parameter: IntegratorMethod

Type: string, character vector

Values: "Forward Euler", "Backward Euler", "Trapezoidal"

Default: "Forward Euler"

Filter method — Method for computing derivative in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the filter method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1} \cdot$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and enable **Use filtered derivative**.

Programmatic Use

Block Parameter: FilterMethod

Type: string, character vector

Values: "Forward Euler", "Backward Euler", "Trapezoidal"

Default: "Forward Euler"

Main

Source — Source for controller gains and filter coefficient

internal (default) | external

internal

Specify the controller gains, filter coefficient, and setpoint weights using the block parameters **P**, **I**, **D**, **N**, **b**, and **c** respectively.

external

Specify the PID gains, filter coefficient, and setpoint weights externally using block inputs. An additional input port appears on the block for each parameter that is required for the current controller type.

Enabling external inputs for the parameters allows you to compute their values externally to the block and provide them to the block as signal inputs.

External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control.

In gain-scheduled control, you determine the PID gains by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. The derivative setpoint weight c is also differentiated. This result occurs because in both continuous time and discrete time, the gains are applied to the signal before integration or differentiation. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.

Within the block, the input signal u is multiplied by the externally supplied integrator gain, I , before integration. This implementation yields:

$$u_i = \int (r - y)I dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain D and the derivative setpoint weight c to be differentiated.

Programmatic Use

Block Parameter: ControllerParametersSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Proportional (P) — Proportional gain

1 (default) | scalar | vector

Specify a finite, real gain value for the proportional gain. When **Controller form** is:

- **Parallel** — Proportional action is independent of the integral and derivative actions. For example, for a continuous-time 2-DOF PID controller in parallel form, the controller output u is:

$$u = P(br - y) + I\frac{1}{s}(r - y) + D\frac{N}{1 + N\frac{1}{s}}(cr - y),$$

where r is the reference signal, y is the measured plant output signal, and b and c are the setpoint weights.

For a discrete-time 2-DOF controller in parallel form, the controller output is:

$$u = P(br - y) + I\alpha(z)(r - y) + D\frac{N}{1 + N\beta(z)}(cr - y),$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

- **Ideal** — The proportional gain multiplies the integral and derivative terms. For example, for a continuous-time 2-DOF PID controller in ideal form, the controller output is:

$$u = P \left[(br - y) + I \frac{1}{s} (r - y) + D \frac{N}{1 + N \frac{1}{s}} (cr - y) \right].$$

For a discrete-time 2-DOF PID controller in ideal form, the transfer function is:

$$u = P \left[(br - y) + I\alpha(z)(r - y) + D \frac{N}{1 + N\beta(z)} (cr - y) \right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tunable: Yes

Dependencies

To enable this parameter, set the Controller parameters **Source** to **internal**.

Programmatic Use

Block Parameter: P

Type: scalar, vector

Default: 1

Integral (I) — Integral gain

1 (default) | scalar | vector

Specify a finite, real gain value for the integral gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal**, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: I

Type: scalar, vector

Default: 1

Integral (I*Ts) — Integral gain multiplied by sample time

1 (default) | scalar | vector

Specify a finite, real gain value for the integral gain multiplied by the sample time.

Note PID tuning tools, such as the **PID Tuner** app and Closed-Loop PID Autotuner block, tune the gain **I** but not **I*Ts**. Therefore, multiply the integral gain value you obtain from a tuning tool by the sample time before you write it to this parameter.

When you use **I*Ts** instead of **I**, the block requires fewer calculations to perform integration. This improves the execution time of the generated code.

Tunable: No

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, set **Controller** to a type that has integral action, and enable the **Use I*Ts** parameter.

Programmatic Use

Block Parameter: I

Type: scalar, vector

Default: 1

Use I*Ts — Use integral gain multiplied by sample time

`off` (default) | `on`

For discrete-time controllers with integral action, the block takes the integral gain as an input and multiplies it by the sample time internally as a part of performing the integration. You can enable this parameter to specify integral gain multiplied by sample time as input (**I*Ts**) in place of the integral gain (**I**). Doing so reduces the number of internal calculations and is useful when you want to improve the execution time of your generated code.

Dependencies

To enable this parameter, set **Controller** to a controller type that has integral action.

Programmatic Use

Block Parameter: UseKiTs

Type: string, character vector

Values: "on", "off"

Default: "on"

Derivative (D) — Derivative gain

0 (default) | scalar | vector

Specify a finite, real gain value for the derivative gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to PID or PD.

Programmatic Use

Block Parameter: D

Type: scalar, vector

Default: 0

Use filtered derivative — Apply filter to derivative term

`on` (default) | `off`

For discrete-time PID controllers only, clear this option to replace the filtered derivative with an unfiltered discrete-time differentiator. When you do so, the derivative term of the controller output becomes:

$$D \frac{z - 1}{z T_s} (cr - y) .$$

For continuous-time PID controllers, the derivative term is always filtered.

Dependencies

To enable this parameter, set **Time domain** to Discrete-time, and set **Controller** to a type that has a derivative term.

Programmatic Use

Block Parameter: UseFilter

Type: string, character vector

Values: "on", "off"

Default: "on"

Filter coefficient (N) – Derivative filter coefficient

100 (default) | scalar | vector

Specify a finite, real gain value for the filter coefficient. The filter coefficient determines the pole location of the filter in the derivative action of the block. The location of the filter pole depends on the **Time domain** parameter.

- When **Time domain** is Continuous-time, the pole location is $s = -N$.
- When **Time domain** is Discrete-time, the pole location depends on the **Filter method** parameter.

Filter Method	Location of Filter Pole
Forward Euler	$z_{pole} = 1 - NT_s$
Backward Euler	$z_{pole} = \frac{1}{1 + NT_s}$
Trapezoidal	$z_{pole} = \frac{1 - NT_s/2}{1 + NT_s/2}$

The block does not support $N = \text{Inf}$ (ideal unfiltered derivative). When the **Time domain** is Discrete-time, you can clear **Use filtered derivative** to remove the derivative filter.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to internal and set **Controller** to PID or PD.

Programmatic Use**Block Parameter:** N**Type:** scalar, vector**Default:** 100**Setpoint weight (b) — Proportional setpoint weight**

1 (default) | scalar | vector

Setpoint weight on the proportional term of the controller. The proportional term of a 2-DOF controller output is $P(br-y)$, where r is the reference signal and y is the measured plant output. Setting b to 0 eliminates proportional action on the reference signal, which can reduce overshoot in the system response to step changes in the setpoint. Changing the relative values of b and c changes the balance between disturbance rejection and setpoint tracking.

Tunable: Yes**Dependencies**

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal**.

Programmatic Use**Block Parameter:** b**Type:** scalar, vector**Default:** 1**Setpoint weight (c) — Derivative setpoint weight**

1 (default) | scalar | vector

Setpoint weight on the derivative term of the controller. The derivative term of a 2-DOF controller acts on $cr-y$, where r is the reference signal and y is the measured plant output. Thus, setting c to 0 eliminates derivative action on the reference signal, which can reduce transient response to step changes in the setpoint. Setting c to 0 can yield a controller that achieves both effective disturbance rejection and smooth setpoint tracking without excessive transient response. Changing the relative values of b and c changes the balance between disturbance rejection and setpoint tracking.

Tunable: Yes**Dependencies**

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal** and set **Controller** to a type that has derivative action.

Programmatic Use**Block Parameter:** c**Type:** scalar, vector**Default:** 1**Select tuning method — Tool for automatic tuning of controller coefficients**

Transfer Function Based (PID Tuner App) (default) | Frequency Response Based

If you have Simulink Control Design software, you can automatically tune the PID coefficients when they are internal to the block. To do so, use this parameter to select a tuning tool, and click **Tune**.

Transfer Function Based (PID Tuner App)

Use **PID Tuner**, which lets you interactively tune PID coefficients while examining relevant system responses to validate performance. **PID Tuner** can tune all the coefficients **P**, **I**, **D**, and **N**,

and the setpoint coefficients **b** and **c**. By default, **PID Tuner** works with a linearization of your plant model. For models that cannot be linearized, you can tune PID coefficients against a plant model estimated from simulated or measured response data. For more information, see “Design Two-Degree-of-Freedom PID Controllers” (Simulink Control Design).

Frequency Response Based

Use **Frequency Response Based PID Tuner**, which tunes PID controller coefficients based on frequency-response estimation data obtained by simulation. This tuning approach is especially useful for plants that are not linearizable or that linearize to zero. **Frequency Response Based PID Tuner** tunes the coefficients **P**, **I**, **D**, and **N**, but does not tune the setpoint coefficients **b** and **c**. For more information, see “Design PID Controller from Plant Frequency-Response Data” (Simulink Control Design).

Both of these tuning methods assume a single-loop control configuration. Simulink Control Design software includes other tuning approaches that suit more complex configurations. For information about other ways to tune a PID Controller block, see “Choose a Control Design Approach” (Simulink Control Design).

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`.

Enable zero-crossing detection — Detect zero crossings on reset and on entering or leaving a saturation state

`on` (default) | `off`

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate **External reset** in your PID Controller block, activating zero-crossing detection can reduce computation time in your simulation. Selecting this parameter activates zero-crossing detection:

- At initial-state reset
- When entering an upper or lower saturation state
- When leaving an upper or lower saturation state

For more information about zero-crossing detection, see “Zero-Crossing Detection”.

Programmatic Use

Block Parameter: `ZeroCross`

Type: string, character vector

Values: "on", "off"

Default: "on"

Initialization

Source — Source for integrator and derivative initial conditions

`internal` (default) | `external`

Simulink uses initial conditions to initialize the integrator and derivative-filter (or the unfiltered derivative) output at the start of a simulation or at a specified trigger event. (See the **External reset** parameter.) These initial conditions determine the initial block output. Use this parameter to select how to supply the initial condition values to the block.

`internal`

Specify the initial conditions using the **Integrator Initial condition** and **Filter Initial condition** parameters. If **Use filtered derivative** is not selected, use the **Differentiator**

parameter to specify the initial condition for the unfiltered differentiator instead of a filter initial condition.

external

Specify the initial conditions externally using block inputs. Additional input ports I_0 and D_0 appear on the block. If **Use filtered derivative** is not selected, supply the initial condition for the unfiltered differentiator at D_0 instead of a filter initial condition.

Programmatic Use

Block Parameter: InitialConditionSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Integrator — Integrator initial condition

0 (default) | scalar | vector

Simulink uses the integrator initial condition to initialize the integrator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The integrator initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: InitialConditionForIntegrator

Type: scalar, vector

Default: 0

Filter — Filter initial condition

0 (default) | scalar | vector

Simulink uses the filter initial condition to initialize the derivative filter at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The filter initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and use a controller that has a derivative filter.

Programmatic Use

Block Parameter: InitialConditionForFilter

Type: scalar, vector

Default: 0

Differentiator — Initial condition for unfiltered derivative

0 (default) | scalar | vector

When you use an unfiltered derivative, Simulink uses this parameter to initialize the differentiator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the derivative initial condition determine the initial output of the PID controller block.

The derivative initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, set **Time domain** to Discrete-time, clear the **Use filtered derivative** check box, and in the **Initialization** tab, set **Source** to internal.

Programmatic Use

Block Parameter: DifferentiatorICPrevScaledInput

Type: scalar, vector

Default: 0

Initial condition setting — Location at which initial condition is applied

Auto (default) | Output

Use this parameter to specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. You can change this parameter at the command line only, using `set_param` to set the `InitialConditionSetting` parameter of the block.

Auto

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

Output

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

For more information about the **Initial condition setting** parameter, see the Discrete-Time Integrator block.

This parameter is only accessible through programmatic use.

Programmatic Use

Block Parameter: InitialConditionSetting

Type: string, character vector

Values: "Auto", "Output"

Default: "Auto"

External reset — Trigger for resetting integrator and filter values

none (default) | rising | falling | either | level

Specify the trigger condition that causes the block to reset the integrator and filter to initial conditions. (If **Use filtered derivative** is not selected, the trigger resets the integrator and differentiator to initial conditions.) Selecting any option other than none enables the **Reset** port on the block for the external reset signal.

none

The integrator and filter (or differentiator) outputs are set to initial conditions at the beginning of simulation, and are not reset during simulation.

rising

Reset the outputs when the reset signal has a rising edge.

falling

Reset the outputs when the reset signal has a falling edge.

either

Reset the outputs when the reset signal either rises or falls.

level

Reset the outputs when the reset signal either:

- Is nonzero at the current time step
- Changes from nonzero at the previous time step to zero at the current time step

This option holds the outputs to the initial conditions while the reset signal is nonzero.

Dependencies

To enable this parameter, set **Controller** to a type that has derivative or integral action.

Programmatic Use

Block Parameter: ExternalReset

Type: string, character vector

Values: "none", "rising", "falling", "either", "level"

Default: "none"

Ignore reset when linearizing — Force linearization to ignore reset

off (default) | on

Select to force Simulink and Simulink Control Design linearization commands to ignore any reset mechanism specified in the **External reset** parameter. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the block to reset.

Programmatic Use

Block Parameter: IgnoreLimit

Type: string, character vector

Values: "off", "on"

Default: "off"

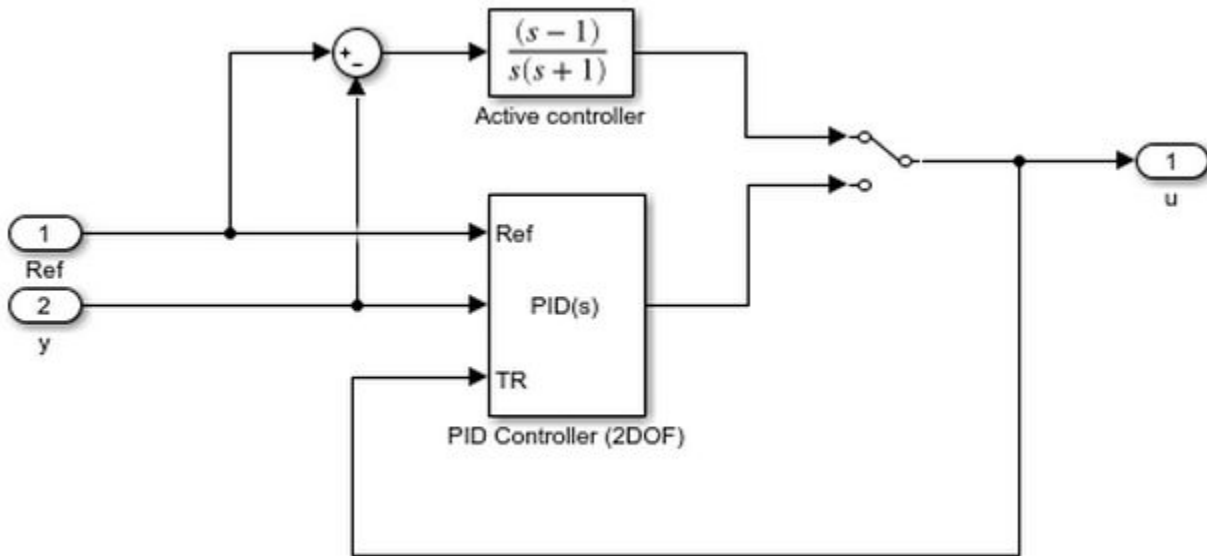

Enable tracking mode — Activate signal tracking

off (default) | on

Signal tracking lets the block output follow a tracking signal that you provide at the **TR** port. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input with a gain K_t , specified by the **Tracking gain (Kt)** parameter. Signal tracking has several applications, including bumpless control transfer and avoiding windup in multiloop control structures.

Bumpless control transfer

Use signal tracking to achieve bumpless control transfer in systems that switch between two controllers. Suppose you want to transfer control between a PID controller and another controller. To do so, connecting the controller output to the **TR** input as shown in the following illustration.

For more information, see “Bumpless Control Transfer with a Two-Degree-of-Freedom PID Controller” on page 12-97.

Multiloop control

Use signal tracking to prevent block windup in multiloop control approaches. For an example illustrating this approach with a 1DOF PID controller, see “Prevent Block Windup in Multiloop Control” on page 12-95.

Dependencies

To enable this parameter, set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: TrackingMode

Type: string, character vector

Values: "off", "on"

Default: "off"

Tracking coefficient (Kt) – Gain of signal-tracking feedback loop

1 (default) | scalar

When you select **Enable tracking mode**, the difference between the signal **TR** and the block output is fed back to the integrator input with a gain K_t . Use this parameter to specify the gain in that feedback loop.

Dependencies

To enable this parameter, select **Enable tracking mode**.

Programmatic Use

Block Parameter: Kt

Type: scalar

Default: 1

Output saturation

Limit Output — Limit block output to specified saturation values

off (default) | on

Activating this option limits the block output, so that you do not need a separate Saturation on page 1-1574 block after the controller. It also allows you to activate the anti-windup mechanism built into the block (see the **Anti-windup method** parameter). Specify the output saturation limits using the **Lower limit** and **Upper limit** parameters. You can also specify the saturation limits externally as block input ports.

Programmatic Use

Block Parameter: LimitOutput

Type: string, character vector

Values: "off", "on"

Default: "off"

Source — Source for output saturation limits

internal (default) | external

Use this parameter to specify how to supply the upper and lower saturation limits of the block output.

internal

Specify the output saturation limits using the **Upper limit** and **Lower limit** parameters.

external

Specify the output saturation limits externally using block input ports. The additional input ports **up** and **lo** appear on the block. You can use the input ports to implement the upper and lower output saturation limits determined by logic or other calculations in the Simulink model and passed to the block.

Programmatic Use

Block Parameter: SatLimitsSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Upper limit — Upper saturation limit for block output

Inf (default) | scalar

Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: UpperSaturationLimit

Type: scalar

Default: Inf

Lower limit — Lower saturation limit for block output

-Inf (default) | scalar

Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: LowerSaturationLimit

Type: scalar

Default: -Inf

Ignore saturation when linearizing — Force linearization to ignore output limits

off (default) | on

Force Simulink and Simulink Control Design linearization commands to ignore block output limits specified in the **Upper limit** and **Lower limit** parameters. Ignoring output limits allows you to linearize a model around an operating point even if that operating point causes the block to exceed the output limits.

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: LinearizeAsGain

Type: string, character vector

Values: "off", "on"

Default: "off"

Anti-windup method — Integrator anti-windup method

none (default) | back-calculation | clamping

When you select **Limit output** and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator windup), increasing the difference between the block output and the sum of the block components. In other words, the internal signals in the block can be unbounded even if the output appears bounded by saturation limits. Without a mechanism to prevent integrator windup, two results are possible:

- If the sign of the signal entering the integrator never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the signal entering the integrator changes once the weighted sum has grown beyond the output limits, it can take a long time to unwind the integrator and return the weighted sum within the block saturation limit.

In either case, controller performance can suffer. To combat the effects of windup without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. To avoid this problem, activate an anti-windup mechanism using this parameter.

none

Do not use an anti-windup mechanism.

back-calculation

Unwind the integrator when the block output saturates by feeding back to the integrator the difference between the saturated and unsaturated control signal. The following diagram represents the back-calculation feedback circuit for a continuous-time controller. To see the actual feedback circuit for your controller configuration, right-click on the block and select **Mask > Look Under Mask**.

Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. It is usually satisfactory to set $K_b = I$, or for controllers with derivative action, $K_b = \sqrt{I \cdot D}$. Back-calculation can be effective for plants with relatively large dead time [1].

clamping

Integration stops when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Integration resumes when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. Clamping is sometimes referred to as conditional integration.

Clamping can be useful for plants with relatively small dead times, but can yield a poor transient response for large dead times [1].

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: AntiWindupMode

Type: string, character vector

Values: "none", "back-calculation", "clamping"

Default: "none"

Back-calculation coefficient (Kb) — Gain coefficient of anti-windup feedback loop

1 (default) | scalar

The back-calculation anti-windup method unwinds the integrator when the block output saturates. It does so by feeding back to the integrator the difference between the saturated and

unsaturated control signal. Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. For more information, see the **Anti-windup method** parameter.

Dependencies

To enable this parameter, select the **Limit output** parameter, and set the **Anti-windup method** parameter to back-calculation.

Programmatic Use

Block Parameter: Kb

Type: scalar

Default: 1

Data Types

The parameters in this tab are primarily of use in fixed-point code generation using Fixed-Point Designer. They define how numeric quantities associated with the block are stored and processed when you generate code.

If you need to configure data types for fixed-point code generation, click **Open Fixed-Point Tool** and use that tool to configure the rest of the parameters in the tab. For information about using Fixed-Point Tool, see “Autoscaling Data Objects Using the Fixed-Point Tool” (Fixed-Point Designer).

After you use Fixed-Point Tool, you can use the parameters in this tab to make adjustments to fixed-point data-type settings if necessary. For each quantity associated with the block, you can specify:

- Floating-point or fixed-point data type, including whether the data type is inherited from upstream values in the block.
- The minimum and maximum values for the quantity, which determine how the quantity is scaled for fixed-point representation.

For assistance in selecting appropriate values, click  to open the Data Type Assistant for the corresponding quantity. For more information, see “Specify Data Types Using Data Type Assistant”.

Main	Initialization	Output saturation	Data Types	State Attributes
Fixed-point operational parameters				
Integer rounding mode: Floor ▾

<input type="checkbox"/> Lock data type settings against changes by the fixed-point tools Open Fixed-Point Tool...				
Data Type				
			Minimum	Maximum
P product output:	Inherit: Inherit via internal rule ▾	>>	[] ⋮	[] ⋮
I product output:	Inherit: Inherit via internal rule ▾	>>	[] ⋮	[] ⋮
D product output:	Inherit: Inherit via internal rule ▾	>>	[] ⋮	[] ⋮
N product output:	Inherit: Inherit via internal rule ▾	>>	[] ⋮	[] ⋮
b product output:	Inherit: Inherit via internal rule ▾	>>	[] ⋮	[] ⋮
c product output:	Inherit: Inherit via internal rule ▾	>>	[] ⋮	[] ⋮
Sum output:	Inherit: Inherit via internal rule ▾	>>	[] ⋮	[] ⋮
▶ Additional data types				

The specific quantities listed in the Data Types tab vary depending on how you configure the PID controller block. In general, you can configure data types for the following types of quantities:

- Product output — Stores the result of a multiplication carried out under the block mask. For example, **P product output** stores the output of the gain block that multiplies the block input with the proportional gain **P**.
- Parameter — Stores the value of a numeric block parameter, such as **P**, **I**, or **D**.
- Block output — Stores the output of a block that resides under the PID controller block mask. For example, use **Integrator output** to specify the data type of the output of the block called Integrator. This block resides under the mask in the Integrator subsystem, and computes integrator term of the controller action.
- Accumulator — Stores values associated with a sum block. For example, **SumI2 Accumulator** sets the data type of the accumulator associated with the sum block SumI2. This block resides under the mask in the Back Calculation subsystem of the Anti-Windup subsystem.

In general, you can find the block associated with any listed parameter by looking under the PID Controller block mask and examining its subsystems. You can also use the Model Explorer to search under the mask for the listed parameter name, such as SumI2. (See **Model Explorer**.)

Matching Input and Internal Data Types

By default, all data types in the block are set to `Inherit: Inherit via internal rule`. With this setting, Simulink chooses data types to balance numerical accuracy, performance, and generated code size, while accounting for the properties of the embedded target hardware.

Under some conditions, incompatibility can occur between data types within the block. For instance, in continuous time, the Integrator block under the mask can accept only signals of type `double`. If the block input signal is a type that cannot be converted to `double`, such as `uint16`, the internal rules for type inheritance generate an error when you generate code.

To avoid such errors, you can use the Data Types settings to force a data type conversion. For instance, you can explicitly set **P product output**, **I product output**, and **D product output** to `double`, ensuring that the signals reaching the continuous-time integrators are of type `double`.

In general, it is not recommended to use the block in continuous time for code generation applications. However, similar data type errors can occur in discrete time, if you explicitly set some values to data types that are incompatible with downstream signal constraints within the block. In such cases, use the Data Types settings to ensure that all data types are internally compatible.

Fixed-Point Operational Parameters

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.
For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
 - In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.
-

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**State Attributes**

The parameters in this tab are primarily of use in code generation.

State name (e.g., 'position') – Name for continuous-time filter and integrator states

' ' (default) | character vector

Assign a unique name to the state associated with the integrator or the filter, for continuous-time PID controllers. (For information about state names in a discrete-time PID controller, see the **State name** parameter.) The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters.

Dependencies

To enable this parameter, set **Time domain** to Continuous-time.

Programmatic Use**Parameter:** IntegratorContinuousStateAttributes, FilterContinuousStateAttributes**Type:** character vector**Default:** ' '**State name – Names for discrete-time filter and integrator states**

empty string (default) | string | character vector

Assign a unique name to the state associated with the integrator or the filter, for discrete-time PID controllers. (For information about state names in a continuous-time PID controller, see the **State name (e.g., 'position')** parameter.)

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters. The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

For more information about the use of state names in code generation, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Parameter: IntegratorStateIdentifier, FilterStateIdentifier

Type: string, character vector

Default: ""

State name must resolve to Simulink signal object — Require that state name resolve to a signal object

off (default) | on

Select this parameter to require that the discrete-time integrator or filter state name resolves to a Simulink signal object.

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

- 1 Set **Time domain** to Discrete-time.
- 2 Specify a value for the integrator or filter **State name**.
- 3 Set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use

Block Parameter: IntegratorStateMustResolveToSignalObject, FilterStateMustResolveToSignalObject

Type: string, character vector

More About

Decomposition of 2-DOF PID Controllers

A 2-DOF PID controller can be interpreted as a PID controller with a prefilter, or a PID controller with a feedforward element.

Prefilter Decomposition

In parallel form, a two-degree-of-freedom PID controller can be equivalently modeled by the following block diagram, where C is a single degree-of-freedom PID controller and F is a prefilter on the reference signal.

Ref is the reference signal, y is the feedback from the measured system output, and u is the controller output. For a continuous-time 2-DOF PID controller in parallel form, the transfer functions for F and C are

$$F_{par}(s) = \frac{(bP + cDN)s^2 + (bPN + I)s + IN}{(P + DN)s^2 + (PN + I)s + IN},$$

$$C_{par}(s) = \frac{(P + DN)s^2 + (PN + I)s + IN}{s(s + N)},$$

where b and c are the setpoint weights.

For a 2-DOF PID controller in ideal form, the transfer functions are

$$F_{id}(s) = \frac{(b + cDN)s^2 + (bN + I)s + IN}{(1 + DN)s^2 + (N + I)s + IN},$$

$$C_{id}(s) = P \frac{(1 + DN)s^2 + (N + I)s + IN}{s(s + N)}.$$

A similar decomposition applies for a discrete-time 2-DOF controller.

Feedforward Decomposition

Alternatively, the parallel two-degree-of-freedom PID controller can be modeled by the following block diagram.

In this realization, Q acts as feed-forward conditioning on the reference signal. For a continuous-time 2-DOF PID controller in parallel form, the transfer function for Q is

$$Q_{par}(s) = \frac{((b-1)P + (c-1)DN)s + (b-1)PN}{s + N}.$$

For a 2-DOF PID controller in ideal form, the transfer function is

$$Q_{id}(s) = P \frac{((b-1) + (c-1)DN)s + (b-1)N}{s + N}.$$

The transfer functions for C are the same as in the filter decomposition.

A similar decomposition applies for a discrete-time 2-DOF controller.

Compatibility Considerations

ReferenceBlock parameter returns different path

Behavior changed in R2021b

Starting in R2021b, the `get_param` function returns a different value for the `ReferenceBlock` parameter. The `ReferenceBlock` parameter is a property common to all Simulink blocks and gives the path of the library block to which a block links. The PID Controller (2DOF) and Discrete PID Controller (2DOF) blocks now link to 'slpidlib/PID Controller (2DOF)'. Previously, the blocks linked to 'pid_lib/PID Controller (2DOF)'.

This change does not affect any other functionality or workflows. You can still use the previous path with the `set_param` function.

ReferenceBlock parameter returns different path

Behavior changed in R2020b

Starting in R2020b, the `get_param` function returns a different value for the `ReferenceBlock` parameter. The `ReferenceBlock` parameter is a property common to all Simulink blocks and gives the path of the library block to which a block links. The PID Controller (2DOF) and Discrete PID Controller (2DOF) blocks now link to 'pid_lib/PID Controller (2DOF)'. Previously, the blocks linked to 'simulink/Continuous/PID Controller (2DOF)'.

This change does not affect any other functionality or workflows. You can still use the previous path with the `set_param` function.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For continuous-time PID controllers (**Time domain** set to **Continuous-time**):

- Consider using "Model Discretizer" to map continuous-time blocks to discrete equivalents that support code generation. To access Model Discretizer, in the **Apps** tab, under **Control Systems**, click **Model Discretizer**.
- Not recommended for production code.

For discrete-time PID controllers (**Time domain** set to **Discrete-time**):

- Depends on absolute time when placed inside a triggered subsystem hierarchy.
- Generated code relies on memcpy or memset functions (`string.h`) under certain conditions.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Discrete State-Space

Implement discrete state-space system

Library: Simulink / Discrete

Description

Block Behavior for Non-Empty Matrices

The Discrete State-Space block implements the system described by

$$\begin{aligned}x(n+1) &= Ax(n) + Bu(n) \\ y(n) &= Cx(n) + Du(n),\end{aligned}$$

where u is the input, x is the state, and y is the output. The matrix coefficients must have these characteristics, as illustrated in the following diagram:

- **A** must be an n -by- n matrix, where n is the number of states.
- **B** must be an n -by- m matrix, where m is the number of inputs.
- **C** must be an r -by- n matrix, where r is the number of outputs.
- **D** must be an r -by- m matrix.

The block accepts one input and generates one output. The width of the input vector is the number of columns in the **B** and **D** matrices. The width of the output vector is the number of rows in the **C** and **D** matrices. To define the initial state vector, use the **Initial conditions** parameter.

To specify a vector or matrix of zeros for **A**, **B**, **C**, **D**, or **Initial conditions**, use the zeros function.

Block Behavior for Empty Matrices

When the matrices **A**, **B**, and **C** are empty (for example, `[]`), the functionality of the block becomes $y(n) = Du(n)$. If the **Initial conditions** vector is also empty, the block uses an initial state vector of zeros.

Ports

Input

Port_1 – Input signal

scalar | vector

Input vector, where the width equals the number of columns in the **B** and **D** matrices. For more information, see “Description” on page 1-477.

Tip For integer and fixed-point input signals, use the Fixed-Point State-Space block.

Data Types: single | double

Output

Port_1 — Output vector

scalar | vector

Output vector, with width equal to the number of rows in the **C** and **D** matrices. For more information, see “Description” on page 1-477.

Data Types: single | double

Parameters

Main

A — Matrix coefficient A

1 (default) | scalar | vector | matrix

Specify the matrix coefficient A, as a real-valued n -by- n matrix, where n is the number of states. For more information on the matrix coefficients, see “Description” on page 1-477.

Programmatic Use

Block Parameter: A

Type: character vector

Values: scalar | vector | matrix

Default: '1'

B — Matrix coefficient B

1 (default) | scalar | vector | matrix

Specify the matrix coefficient B, as a real-valued n -by- m matrix, where n is the number of states, and m is the number of inputs. For more information on the matrix coefficients, see “Description” on page 1-477.

Programmatic Use

Block Parameter: B

Type: character vector

Values: scalar | vector | matrix

Default: '1'

C — Matrix coefficient, C

1 (default) | scalar | vector | matrix

Specify the matrix coefficient C, as a real-valued r -by- n matrix, where r is the number of outputs, and n is the number of states. For more information on the matrix coefficients, see “Description” on page 1-477.

Programmatic Use

Block Parameter: C

Type: character vector

Values: scalar | vector | matrix

Default: '1'

D — Matrix coefficient, D

1 (default) | scalar | vector | matrix

Specify the matrix coefficient **D**, as a real-valued r -by- m matrix, where r is the number of outputs, and m is the number of inputs. For more information on the matrix coefficients, see “Description” on page 1-477.

Programmatic Use

Block Parameter: D

Type: character vector

Values: scalar | vector | matrix

Default: '1'

Initial conditions — Initial state vector

0 (default) | scalar | vector

Specify the initial state vector as a scalar or vector. The initial state vector cannot include `inf` or `NaN` values.

Programmatic Use

Block Parameter: InitialCondition

Type: character vector

Values: scalar | vector

Default: '0'

Sample time (-1 for inherited) — Interval between samples

-1 (default) | scalar | vector

Specify the time interval between samples. See “Specify Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '-1'

State Attributes

State name — Unique name for block state

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

Programmatic Use**Block Parameter:** StateName**Type:** character vector**Values:** unique name**Default:** ''**State name must resolve to Simulink signal object – Require state name resolve to a signal object**

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use**Block Parameter:** StateMustResolveToSignalObject**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Data Types	double single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Generated code relies on memcpy or memset functions (string.h) under certain conditions.

Discrete-Time Integrator

Perform discrete-time integration or accumulation of signal

Library: Simulink / Commonly Used Blocks
 Simulink / Discrete
 HDL Coder / Discrete
 HDL Coder / HDL Floating Point Operations

Description

Use the Discrete-Time Integrator block in place of the Integrator block to create a purely discrete model. With the Discrete-Time Integrator block, you can:

- Define initial conditions on the block dialog box or as input to the block
- Define an input gain (K) value
- Output the block state
- Define upper and lower limits on the integral
- Reset the state with an additional reset input

Output Equations

With the first time step, block state $n = 0$, with either initial output $y(0) = IC$ or initial state $x(0) = IC$, depending on the **Initial condition setting** parameter value.

For a given step $n > 0$ with simulation time $t(n)$, Simulink updates output $y(n)$ as follows:

- Forward Euler method:

$$y(n) = y(n-1) + K*[t(n) - t(n-1)]*u(n-1)$$

- Backward Euler method:

$$y(n) = y(n-1) + K*[t(n) - t(n-1)]*u(n)$$

- Trapezoidal method:

$$y(n) = y(n-1) + K*[t(n)-t(n-1)]*[u(n)+u(n-1)]/2$$

Simulink automatically selects a state-space realization of these output equations depending on the block sample time, which can be explicit or triggered. When using explicit sample time, $t(n) - t(n-1)$ reduces to the sample time T for all $n > 0$.

Integration and Accumulation Methods

This block can integrate or accumulate a signal using a forward Euler, backward Euler, or trapezoidal method. Assume that u is the input, y is the output, and x is the state. For a given step n , Simulink updates $y(n)$ and $x(n+1)$. In integration mode, T is the block sample time (delta T in the case of

triggered sample time). In accumulation mode, $T = 1$. The block sample time determines when the output is computed but not the output value. K is the gain value. Values clip according to upper or lower limits.

Forward Euler Method

Forward Euler method (default), also known as forward rectangular, or left-hand approximation

The software approximates $1/s$ as $T/(z-1)$. The expressions for the output of the block at step n are:

$$\begin{aligned}x(n+1) &= x(n) + K*T*u(n) \\y(n) &= x(n)\end{aligned}$$

The block uses these steps to compute the output:

$$\begin{aligned}\text{Step } 0: & & y(0) &= \text{IC (clip if necessary)} \\ & & x(1) &= y(0) + K*T*u(0)\end{aligned}$$

$$\begin{aligned}\text{Step } 1: & & y(1) &= x(1) \\ & & x(2) &= x(1) + K*T*u(1)\end{aligned}$$

$$\begin{aligned}\text{Step } n: & & y(n) &= x(n) \\ & & x(n+1) &= x(n) + K*T*u(n) \text{ (clip if necessary)}\end{aligned}$$

Using this method, input port 1 does not have direct feedthrough.

Backward Euler Method

Backward Euler method, also known as backward rectangular or right-hand approximation

The software approximates $1/s$ as $T*z/(z-1)$. The resulting expression for the output of the block at step n is

$$y(n) = y(n-1) + K*T*u(n).$$

Let $x(n) = y(n-1)$. The block uses these steps to compute the output.

- If the parameter **Initial condition setting** is set to Output or Auto for triggered and function-call subsystems:

$$\begin{aligned}\text{Step } 0: & & y(0) &= \text{IC (clipped if necessary)} \\ & & x(1) &= y(0)\end{aligned}$$

- If the parameter **Initial condition setting** is set to Auto for non-triggered subsystems:

$$\begin{aligned}\text{Step } 0: & & x(0) &= \text{IC (clipped if necessary)} \\ & & x(1) &= y(0) = x(0) + K*T*u(0)\end{aligned}$$

$$\begin{aligned}\text{Step } 1: & & y(1) &= x(1) + K*T*u(1) \\ & & x(2) &= y(1)\end{aligned}$$

$$\begin{aligned}\text{Step } n: & & y(n) &= x(n) + K*T*u(n) \\ & & x(n+1) &= y(n)\end{aligned}$$

Using this method, input port 1 has direct feedthrough.

Trapezoidal Method

For this method, the software approximates $1/s$ as $T/2*(z+1)/(z-1)$.

When T is fixed (equal to the sampling period), the expressions to compute the output are:

$$\begin{aligned}x(n) &= y(n-1) + K*T/2*u(n-1) \\y(n) &= x(n) + K*T/2*u(n)\end{aligned}$$

- If the parameter **Initial condition setting** is set to Output or Auto for triggered and function-call subsystems:

$$\begin{aligned}\text{Step } 0: \quad & y(0) = \text{IC (clipped if necessary)} \\ & x(1) = y(0) + K*T/2*u(0)\end{aligned}$$

- If the parameter **Initial condition setting** is set to Auto for non-triggered subsystems:

$$\begin{aligned}\text{Step } 0: \quad & x(0) = \text{IC (clipped if necessary)} \\ & y(0) = x(0) + K*T/2*u(0) \\ & x(1) = y(0) + K*T/2*u(0)\end{aligned}$$

$$\begin{aligned}\text{Step } 1: \quad & y(1) = x(1) + K*T/2*u(1) \\ & x(2) = y(1) + K*T/2*u(1)\end{aligned}$$

$$\begin{aligned}\text{Step } n: \quad & y(n) = x(n) + K*T/2*u(n) \\ & x(n+1) = y(n) + K*T/2*u(n)\end{aligned}$$

Here, $x(n+1)$ is the best estimate of the next output. It is not the same as the state, in that $x(n)$ is not equal to $y(n)$.

Using this method, input port 1 has direct feedthrough.

When T is a Variable

When T is a variable (for example, obtained from the triggering times), the block uses these steps to compute the output.

- If the parameter **Initial condition setting** is set to Output or Auto for triggered and function-call subsystems:

$$\begin{aligned}\text{Step } 0: \quad & y(0) = \text{IC (clipped if necessary)} \\ & x(1) = y(0)\end{aligned}$$

- If the parameter **Initial condition setting** is set to Auto for non-triggered subsystems:

$$\begin{aligned}\text{Step } 0: \quad & x(0) = \text{IC (clipped if necessary)} \\ & x(1) = y(0) = x(0) + K*T/2*u(0)\end{aligned}$$

$$\begin{aligned}\text{Step } 1: \quad & y(1) = x(1) + T/2*(u(1) + u(0)) \\ & x(2) = y(1)\end{aligned}$$

$$\begin{aligned}\text{Step } n: \quad & y(n) = x(n) + T/2*(u(n) + u(n-1)) \\ & x(n+1) = y(n)\end{aligned}$$

Define Initial Conditions

You can define the initial conditions as a parameter on the block dialog box or input them from an external signal:

- To define the initial conditions as a block parameter, set the **Initial condition source** parameter to `internal` and enter the value in the **Initial condition** text box.
- To provide the initial conditions from an external source, set the **Initial condition source** parameter to `external`. An additional input port appears on the block.

When to Use the State Port

Use the state port instead of the output port:

- When the output of the block is fed back into the block through the reset port or the initial condition port, causing an algebraic loop. For an example, see the `sldemo_bounce_two_integrators` model.
- When you want to pass the state from one conditionally executed subsystem to another, which can cause timing problems. For an example, see “Building a Clutch Lock-Up Model” on page 13-151.

You can work around these problems by passing the state through the state port rather than the output port. Simulink generates the state at a slightly different time from the output, which protects your model from these problems. To output the block state, select the **Show state port** check box. The state port appears on the top of the block.

Limit the Integral

To keep the output within certain levels, select the **Limit output** check box and enter the limits in the corresponding text box. Doing so causes the block to function as a limited integrator. When the output reaches the limits, the integral action turns off to prevent integral windup. During a simulation, you can change the limits but you cannot change whether the output is limited. The table shows how the block determines output.

Integral	Output
Less than or equal to the Lower saturation limit and the input is negative	Held at the Lower saturation limit
Between the Lower saturation limit and the Upper saturation limit	The integral
Greater than or equal to the Upper saturation limit and the input is positive	Held at the Upper saturation limit

To generate a signal that indicates when the state is being limited, select the **Show saturation port** check box. A new saturation port appears below the block output port.

The saturation signal has one of three values:

- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.
- -1 indicates that the lower limit is being applied.

Reset the State

The block resets its state to the specified initial condition, based on an external signal. To cause the block to reset its state, select one of the **External reset** parameter options. A reset port appears that indicates the reset trigger type.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results. To resolve this loop, feed the output of the block state port into the reset port instead. To access the block state, select the **Show state port** check box.

Reset Trigger Types

The **External reset** parameter lets you determine the attribute of the reset signal that triggers the reset. The trigger options include:

- **rising** - Resets the state when the reset signal has a rising edge. For example, this figure shows the effect that a rising reset trigger has on backward Euler integration.

- **falling** — Resets the state when the reset signal has a falling edge. For example, this figure shows the effect that a falling reset trigger has on backward Euler integration.

- **either** — Resets the state when the reset signal rises or falls. For example, the following figure shows the effect that an either reset trigger has on backward Euler integration.

- **level** — Resets and holds the output to the initial condition while the reset signal is nonzero. For example, this figure shows the effect that a level reset trigger has on backward Euler integration.

- **sampled level** — Resets the output to the initial condition when the reset signal is nonzero. For example, this figure shows the effect that a sampled level reset trigger has on backward Euler integration.

The sampled level reset option requires fewer computations, making it more efficient than the level reset option.

Note For the Discrete-Time Integrator block, all trigger detections are based on signals with positive values. For example, a signal changing from -1 to 0 is not considered a rising edge, but a signal changing from 0 to 1 is.

Behavior in Simplified Initialization Mode

Simplified initialization mode is enabled when you set **Underspecified initialization detection** to **Simplified** in the Configuration Parameters dialog box. If you use simplified initialization mode, the behavior of the Discrete-Time Integrator block differs from classic initialization mode. The new initialization behavior is more robust and provides more consistent behavior in these cases:

- In algebraic loops
- On enable and disable
- When comparing results using triggered sample time against explicit sample time, where the block is triggered at the same rate as the explicit sample time

Simplified initialization mode enables easier conversion from Continuous-Time Integrator blocks to Discrete-Time Integrator blocks, because the initial conditions have the same meaning for both blocks.

For more information on classic and simplified initialization modes, see “Underspecified initialization detection”.

Enable and Disable Behavior with Initial Condition Setting set to Output

When you use simplified initialization mode with **Initial condition setting** set to **Output** for triggered and function-call subsystems, the enable and disable behavior of the block is simplified as follows.

At disable time τ_d :

$$y(\tau_d) = y(\tau_d - 1)$$

At enable time τ_e :

- If the parent subsystem control port has **States when enabling** set to **reset**:

$$y(t_e) = IC.$$

- If the parent subsystem control port has **States when enabling** set to held:

$$y(t_e) = y(t_d).$$

The following figure shows this condition.

Iterator Subsystems

When using simplified initialization mode, you cannot place the Discrete-Time Integrator block in an iterator subsystem block.

In simplified initialization mode, Iterator subsystems do not maintain elapsed time. Thus, if a Discrete-Time Integrator block, which needs elapsed time, is placed inside an iterator subsystem block, Simulink reports an error.

Behavior in an Enabled Subsystem Inside a Function-Call Subsystem

Suppose you have a function-call subsystem that includes an enabled subsystem, which contains a Discrete-Time Integrator block. The following behavior applies.

Integrator Method	Sample Time Type of Function-Call Trigger Port	Value of delta T When Function-Call Subsystem Executes for the First Time After Enabled	Reason for Behavior
Forward Euler	Triggered	$t - t_{start}$	When the function-call subsystem executes for the first time, the integrator algorithm uses t_{start} as the previous simulation time.
Backward Euler and Trapezoidal	Triggered	$t - t_{previous}$	When the function-call subsystem executes for the first time, the integrator algorithm uses $t_{previous}$ as the previous simulation time.
Forward Euler, Backward Euler, and Trapezoidal	Periodic	Sample time of the function-call generator	In periodic mode, the Discrete-Time Integrator block uses sample time of the function-call generator for ΔT .

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

IC – Initial conditions of the states

scalar | vector | matrix

Initial conditions of the states, specified as a finite scalar, vector, or matrix.

Dependencies

To enable this port, set **Initial condition source** to external.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 – Discrete-time integration or accumulation of input

scalar | vector | matrix

Discrete-time integration or accumulation of the input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Port_2 – Saturation output

`scalar` | `vector` | `matrix`

Signal indicating when the state is being limited, specified as a scalar, vector, or matrix. The signal has one of three values:

- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.
- -1 indicates that the lower limit is being applied.

Dependencies

To enable this port, select the **Show saturation port** check box.

Data Types: `single` | `double` | `int8`

Port_3 – State output

`scalar` | `vector` | `matrix`

Block states, output as a scalar, vector, or matrix. By default, the block adds this port to the top of the block icon. Use the state port when:

- The output of the block is fed back into the block through the reset port or the initial condition port, causing an algebraic loop. For an example, see the `sldemo_bounce_two_integrators` model.
- You want to pass the state from one conditionally executed subsystem to another, which can cause timing problems. For an example, see the `sldemo_clutch` model.

For more information, see “When to Use the State Port” on page 1-485.

Dependencies

To enable this port, select the **Show state port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Main

Integrator method – Accumulation method

Integration: `Forward Euler (default)` | `Integration: Backward Euler` | `Integration: Trapezoidal` | `Accumulation: Forward Euler` | `Accumulation: Backward Euler` | `Accumulation: Trapezoidal`

Specify the integration or accumulation method. See “Output Equations” on page 1-482 and “Integration and Accumulation Methods” on page 1-482 for more information.

Programmatic Use

Block Parameter: `IntegratorMethod`

Type: character vector

Values: 'Integration: Forward Euler' | 'Integration: Backward Euler' | 'Integration: Trapezoidal' | 'Accumulation: Forward Euler' | 'Accumulation: Backward Euler' | 'Accumulation: Trapezoidal'
Default: 'Integration: Forward Euler'

Gain value — Value to multiply with integrator input

1.0 (default) | scalar | vector

Specify a scalar, vector, or matrix by which to multiply the integrator input. Each element of the gain must be a positive real number.

- Specifying a value other than 1.0 (the default) is semantically equivalent to connecting a Gain block to the input of the integrator.
- Valid entries include:
 - `double(1.0)`
 - `single(1.0)`
 - `[1.1 2.2 3.3 4.4]`
 - `[1.1 2.2; 3.3 4.4]`

Tip Using this parameter to specify the input gain eliminates a multiplication operation in the generated code. However, this parameter must be nontunable to realize this benefit. If you want to tune the input gain, set this parameter to 1.0 and use an external Gain block to specify the input gain.

Programmatic Use

Block Parameter: `gainval`

Type: character vector

Values: scalar | vector

Default: '1.0'

External reset — Select when to reset states to initial conditions

`none` (default) | `rising` | `falling` | `either` | `level` | `sampled level`

Select the type of trigger event that resets the states to their initial conditions:

- `none` — Do not reset the state to initial conditions.
- `rising` — Reset the state when the reset signal has a rising edge.
- `falling` — Reset the state when the reset signal has a falling edge.
- `either` — Reset the state when the reset signal rises or falls.
- `level` — Reset and hold the output to the initial condition while the reset signal is nonzero.
- `sampled level` — Reset the output to the initial condition when the reset signal is nonzero.

For more information, see “Reset the State” on page 1-486 and “Reset Trigger Types” on page 1-486.

Programmatic Use

Block Parameter: `ExternalReset`

Type: character vector

Values: 'none' | 'rising' | 'falling' | 'either' | 'level' | 'sampled level'

Default: 'none'

Initial condition source — Select source of initial condition

internal (default) | external

Select source of initial condition:

- internal — Get the initial conditions of the states from the **Initial condition** block parameter.
- external — Get the initial conditions of the states from an external block, via the **IC** input port.

DependenciesSelecting **internal** enables the **Initial condition** parameter.Selecting **external** disables the **Initial condition** parameter and enables the **IC** input port.**Programmatic Use****Block Parameter:** InitialConditionSource**Type:** character vector, string**Values:** 'internal' | 'external'**Default:** 'internal'**Initial condition — Initial condition of states**

0 (default) | scalar | vector | matrix

Specify initial condition of the block states. The minimum and maximum values are bound by the **Output minimum** and **Output maximum** block parameters.

Tip Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

DependenciesTo enable this parameter, set the **Initial condition source** to **internal**.**Programmatic Use****Block Parameter:** InitialCondition**Type:** character vector, string**Values:** scalar | vector | matrix**Default:** '0'**Initial condition setting — Select where to apply the initial condition**

Auto (default) | Output | Compatibility

Select whether to apply the value of the **Initial condition** parameter to the block state or block output. The initial condition is also the reset value.

- Auto — Block chooses where to apply the **Initial condition** parameter.
 - If the block is in a non-triggered subsystem and **Integrator method** is set to an integration method, set initial conditions:

$$x(0) = IC$$

At reset:

$$x(n) = IC$$

- If the block is in a triggered or function-call subsystem and **Integrator method** is set to an integration method, set initial conditions as if **output** was selected.
- **Output** — Use this option when the block is in a triggered or a function-call subsystem and **Integrator method** is set to an integration method.

Set initial conditions:

$$y(0) = IC$$

At reset:

$$y(n) = IC$$

- **Compatibility** — This option is present to provide backward compatibility. You cannot select this option for Discrete-Time Integrator blocks in Simulink models but you can select it for Discrete-Time Integrator blocks in a library. Use this option to maintain compatibility with Simulink models created before R2014a.

Prior to R2014a, the option **Auto** was known as **State only (most efficient)**. The option **Output** was known as **State and output**. The behavior of the block with the option **Compatibility** is as follows.

- If **Underspecified initialization detection** is set to **Classic**, the **Initial condition setting** parameter behaves as **Auto**.
- If **Underspecified initialization detection** is set to **Simplified**, the **Initial condition setting** parameter behaves as **Output**.

Note This parameter was named **Use initial condition as initial and reset value for** in Simulink before R2014a.

Programmatic Use

Block Parameter: InitialConditionSetting

Type: character vector

Value: 'Auto' | 'Output' | 'Compatibility'

Default: 'Auto'

Sample time (-1 for inherited) — Interval between samples

-1 (default) | scalar | vector

Enter the discrete time interval between steps.

By default, the block uses a discrete sample time of 1. To set a different sample time, enter another discrete value, such as 0.1.

See “Specify Sample Time” for more information.

Tips

- Do not specify a sample time of 0. This value specifies a continuous sample time, which the Discrete-Time Integrator block does not support.
- Do not specify a sample time of **inf** or **NaN** because these values are not discrete.

- If you specify -1 to inherit the sample time from an upstream block, verify that the upstream block uses a discrete sample time. For example, the Discrete-Time Integrator block cannot inherit a sample time of 0.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar | vector**Default:** '-1'**Limit output — Limit block output values to specified range**

off (default) | on

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

- Selecting this check box limits the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.
- Clearing this check box does not limit the block's output values.

Dependencies

Selecting this parameter enables the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use**Block Parameter:** LimitOutput**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Upper saturation limit — Upper limit for the integral**

inf (default) | scalar | vector | matrix

Specify the upper limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use**Block Parameter:** UpperSaturationLimit**Type:** character vector, string**Values:** scalar | vector | matrix**Default:** 'inf'**Lower saturation limit — Lower limit for the integral**

-inf (default) | scalar | vector | matrix

Specify the lower limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use**Block Parameter:** LowerSaturationLimit**Type:** character vector , string**Values:** scalar | vector | matrix**Default:** '-inf'**Show saturation port — Enable saturation output port**

off (default) | on

Select this check box to add a saturation output port to the block. When you clear this check box, the block does not have a saturation output port.

Dependencies

Selecting this parameter enables a saturation output port.

Programmatic Use**Block Parameter:** ShowSaturationPort**Type:** character vector , string**Values:** 'off' | 'on'**Default:** 'off'**Show state port — Enable state output port**

off (default) | on

Select this check box to add a state output port to the block. When you clear this check box, the block does not have a state output port.

Dependencies

Selecting this parameter enables a state output port.

Programmatic Use**Block Parameter:** ShowStatePort**Type:** character vector , string**Values:** 'off' | 'on'**Default:** 'off'**Ignore limit and reset when linearizing — Treat block as not resettable**

off (default) | on

Select this check box to have Simulink linearization commands treat this block as not resettable and as having no limits on its output, regardless of the settings of the block reset and output limitation options.

Tip Ignoring the limit and resetting allows you to linearize a model around an operating point. This point may cause the integrator to reset or saturate.

Programmatic Use**Block Parameter:** IgnoreLimit**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'

Signal Attributes

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Data type — Output data type**

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType. For more information, see “Control Data Types of Signals”.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule** — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and ASIC/FPGA is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, i.e., a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- **Inherit: Inherit via back propagation** — Use data type of the driving block.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'**Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Specify the rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Choose one of these rounding modes.

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

See Also

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- **off** — Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- **on** — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
 - In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.
-

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

State Attributes**State name — Unique name for block state**

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

For more information, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

Dependencies

When you specify a value for **State name** and click **Apply**, you enable the **State name must resolve to Simulink signal object** parameter.

Programmatic Use

Parameter: StateName

Type: character vector

Values: unique name

Default: ''

State name must resolve to Simulink signal object — Require state names resolve to signal object

Off (default) | Boolean

Specify if requiring that state name resolve to Simulink signal objects or not. If selected, the software generates an error at run time if you specify a state name that does not match the name of a Simulink signal object.

Dependency

Enabled when you give the parameter **State name** a value and set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

Programmatic Use

Block Parameter: StateMustResolveToSignalObject

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Depends on absolute time when used inside a triggered subsystem hierarchy.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
Native Floating Point	
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is <code>inherit</code> . See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , or <code>Zero</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
MantissaMultiplyStrategy	Specify how to implement the mantissa multiplication operation during code generation. By using different settings, you can control the DSP usage on the target FPGA device. The default is <code>inherit</code> . See also “MantissaMultiplyStrategy” (HDL Coder).

Restrictions

- State ports are not supported for HDL code generation. Clear the **Show state port** option.
- External initial conditions are not supported for HDL code generation. Set **Initial condition source** to `Internal`.
- **External Reset** must be set to `none`, `rising`, or `falling`.
- Continuous sample time is not supported. Use a discrete sample time for the block.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Discrete Transfer Fcn

Implement discrete transfer function

Library: Simulink / Discrete
 HDL Coder / Discrete
 HDL Coder / HDL Floating Point Operations

Description

The Discrete Transfer Fcn block implements the z -transform transfer function as follows:

$$H(z) = \frac{\text{num}(z)}{\text{den}(z)} = \frac{\text{num}_0 z^m + \text{num}_1 z^{m-1} + \dots + \text{num}_m}{\text{den}_0 z^n + \text{den}_1 z^{n-1} + \dots + \text{den}_n}$$

where $m+1$ and $n+1$ are the number of numerator and denominator coefficients, respectively. num and den contain the coefficients of the numerator and denominator in descending powers of z . num can be a vector or matrix, while den must be a vector. The order of the denominator must be greater than or equal to the order of the numerator.

Specify the coefficients of the numerator and denominator polynomials in descending powers of z . This block lets you use polynomials in z to represent a discrete system, a method that control engineers typically use. Conversely, the Discrete Filter block lets you use polynomials in z^{-1} (the delay operator) to represent a discrete system, a method that signal processing engineers typically use. The two methods are identical when the numerator and denominator polynomials have the same length.

The Discrete Transfer Fcn block applies the z -transform transfer function to each independent channel of the input. The **Input processing** parameter allows you to specify whether the block treats each column of the input as an individual channel (frame-based processing) or each element of the input as an individual channel (sample-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

Specifying Initial States

Use the **Initial states** parameter to specify initial filter states. To determine the number of initial states you must specify and how to specify them, use the following tables.

Frame-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> Column vector (K-by-1) Unoriented vector (K) 	1	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) 	<ul style="list-style-type: none"> Scalar Column vector (M-by-1)
<ul style="list-style-type: none"> Row vector (1-by-N) Matrix (K-by-N) 	N	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) Matrix (M-by-N) 	<ul style="list-style-type: none"> Scalar Matrix (M-by-N)

Sample-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> Scalar 	1	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) 	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M)
<ul style="list-style-type: none"> Row vector (1-by-N) Column vector (N-by-1) Unoriented vector (N) 	N	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) Matrix (M-by-N) 	<ul style="list-style-type: none"> Scalar
<ul style="list-style-type: none"> Matrix (K-by-N) 	$K \times N$	<ul style="list-style-type: none"> Scalar Column vector (M-by-1) Row vector (1-by-M) Matrix (M-by-$(K \times N)$) 	<ul style="list-style-type: none"> Scalar

When the **Initial states** is a scalar, the block initializes all filter states to the same scalar value. To initialize all states to zero, enter 0. When the **Initial states** is a vector or a matrix, each vector or matrix element specifies a unique initial state for a corresponding delay element in a corresponding channel:

- The vector length must equal the number of delay elements in the filter, $M = \max(\text{number of zeros, number of poles})$.
- The matrix must have the same number of rows as the number of delay elements in the filter, $M = \max(\text{number of zeros, number of poles})$. The matrix must also have one column for each channel of the input signal.

The following example shows the relationship between the initial filter output and the initial input and state. Given an initial input u_1 , the first output y_1 is related to the initial state $[x_1, x_2]$ and initial input by as follows:

$$y1 = 4x1$$

$$x2 = 1/2(u1 - 3x1)$$

Ports

Input

u – Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | fixed point

Num – Numerator coefficients

scalar | vector | matrix

Coefficients of the numerator polynomial specified as a vector or matrix in descending powers of z . Use a row vector to specify the coefficients for a single numerator polynomial. Use a matrix to specify

coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps. The order of the denominator must be greater than or equal to the order of the numerator.

Dependencies

To enable this port, set **Numerator Source** to Input port.

Numerator and denominator coefficients must have the same complexity. They can have different word lengths and fraction lengths.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Den — Denominator coefficients

`scalar` | `vector` | `matrix`

Coefficients of the denominator polynomial specified as a vector in descending powers of z . Use a row vector to specify the coefficients for a single denominator polynomial. Use a matrix to specify coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps. The order of the denominator must be greater than or equal to the order of the numerator. The leading denominator coefficient cannot be 0.

Dependencies

To enable this port, set **Denominator Source** to Input port.

Numerator and denominator coefficients must have the same complexity. They can have different word lengths and fraction lengths.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

External reset — External reset signal

`scalar`

External reset signal, specified as a scalar. When the specified trigger event occurs, the block resets the states to their initial conditions.

Tip The icon for this port changes based on the value of the **External reset** parameter.

Dependencies

To enable this port, set **External reset** to Rising, Falling, Either, Level, or Level hold.

Limitations

The reset signal must be a scalar of type `single`, `double`, `Boolean`, or `integer`. Fixed-point data types, except for `ufix1`, are not supported.

Data Types: `single` | `double` | `Boolean` | `int8` | `int16` | `int32` | `fixed point`

x0 — Initial states

`scalar` | `vector` | `matrix`

Initial states, specified as a scalar, vector, or matrix. For more information about specifying states, see “Specifying Initial States” on page 1-504. States are complex when either the input or the coefficients are complex.

Dependencies

To enable this port, set **Initial states Source** to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Output**Port_1 — Output signal**

`scalar` | `vector` | `matrix`

Output signal specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Parameters**Main****Numerator Source — Source of numerator coefficients**

`Dialog` (default) | `Input port`

Specify the source of the numerator coefficients as `Dialog` or `Input port`.

Programmatic Use

Block Parameter: `NumeratorSource`

Type: character vector

Values: `'Dialog'` | `'Input port'`

Default: `'Dialog'`

Numerator Value — Numerator coefficients

`[1]` (default) | `scalar` | `vector` | `matrix`

Numerator coefficients of the discrete transfer function. To specify the coefficients, set the **Source** to `Dialog`. Then, enter the coefficients in **Value** as descending powers of z . Use a row vector to specify the coefficients for a single numerator polynomial. Use a matrix to specify coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps.

Dependencies

To enable this parameter, set the **Numerator Source** to `Dialog`.

Programmatic Use

Block Parameter: `Numerator`

Type: character vector

Values: `scalar` | `vector` | `matrix`

Default: `'[1]'`

Denominator Source — Source of denominator coefficients

`Dialog` (default) | `Input port`

Specify the source of the denominator coefficients as `Dialog` or `Input port`.

Programmatic Use

Block Parameter: `DenominatorSource`

Type: character vector

Values: 'Dialog' | 'Input port'
Default: 'Dialog'

Denominator Value — Denominator coefficients

[1 0.5] (default) | scalar | vector | matrix

Denominator coefficients of the discrete transfer function. To specify the coefficients, set the **Source** to **Dialog**. Then, enter the coefficients in **Value** as descending powers of z . Use a row vector to specify the coefficients for a single denominator polynomial. Use a matrix to specify coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps.

Dependencies

To enable this parameter, set the **Denominator Source** to **Dialog**.

Programmatic Use

Block Parameter: Denominator

Type: character vector

Values: scalar | vector | matrix

Default: '[1 0.5]'

Initial states Source — Source of initial states

Dialog (default) | Input port

Specify the source of the initial states as **Dialog** or **Input port**.

Programmatic Use

Block Parameter: InitialStatesSource

Type: character vector

Values: 'Dialog' | 'Input port'

Default: 'Dialog'

Initial states Value — Initial filter states

0 (default) | scalar | vector | matrix

Specify the initial filter states as a scalar, vector, or matrix. To learn how to specify initial states, see “Specifying Initial States” on page 1-504.

Dependencies

To enable this parameter, set **Initial states Source** to **Dialog**.

Programmatic Use

Block Parameter: InitialStates

Type: character vector

Values: scalar | vector | matrix

Default: '0'

External reset — External state reset

None (default) | Rising | Falling | Either | Level | Level hold

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset

Reset Mode	Behavior
Rising	Reset on a rising edge
Falling	Reset on a falling edge
Either	Reset on either a rising or falling edge
Level	Reset in either of these cases: <ul style="list-style-type: none"> • When the reset signal is nonzero at the current time step • When the reset signal value changes from nonzero at the previous time step to zero at the current time step
Level hold	Reset when the reset signal is nonzero at the current time step

Programmatic Use**Block Parameter:** ExternalReset**Type:** character vector**Values:** 'None' | 'Rising' | 'Falling' | 'Either' | 'Level' | 'Level hold'**Default:** 'None'**Input processing — Sample- or frame-based processing**

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing.

- Elements as channels (sample based) — Process each element of the input as an independent channel.
- Columns as channels (frame based) — Process each column of the input as an independent channel.

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use**Block Parameter:** InputProcessing**Type:** character vector**Values:** 'Elements as channels (sample based)' | 'Columns as channels (frame based)'**Default:** 'Elements as channels (sample based)'**Optimize by skipping divide by leading denominator coefficient (a0) — Skip divide by a0**

off (default) | on

Select when the leading denominator coefficient, a_0 , equals 1. This parameter optimizes your code.When you select this check box, the block does not perform a divide-by- a_0 either in simulation or in the generated code. An error occurs if a_0 is not equal to one.

When you clear this check box, the block is fully tunable during simulation, and performs a divide-by- a_0 in both simulation and code generation.

Programmatic Use

Block Parameter: `a0EqualsOne`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Sample time (-1 for inherited) – Interval between samples

-1 (default) | scalar | vector

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. For more information, see “Specify Sample Time”.

Programmatic Use

Block Parameter: `SampleTime`

Type: character vector

Values: scalar | vector

Default: '-1'

Data Types

State – State data type

Inherit: Same as input (default) | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the state data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Numerator coefficients – Numerator coefficient data type

Inherit: Inherit via internal rule (default) | int8 | int16 | int32 | int64 | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the numerator coefficient data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** NumCoeffDataTypeStr**Type:** character vector**Values:** 'Inherit: Inherit via internal rule' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'**Default:** 'Inherit: Inherit via internal rule'**Numerator coefficient minimum — Minimum value of numerator coefficients**

[] (default) | scalar

Specify the minimum value that a numerator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** NumCoeffMin**Type:** character vector**Values:** scalar**Default:** '[]'**Numerator coefficient maximum — Maximum value of numerator coefficients**

[] (default) | scalar

Specify the maximum value that a numerator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** NumCoeffMax**Type:** character vector**Values:** scalar**Default:** '[]'**Numerator product output — Numerator product output data type**

Inherit: Inherit via internal rule (default) | Inherit: Same as input | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the product output data type for the numerator coefficients. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** NumProductDataTypeStr**Type:** character vector**Values:** 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'**Default:** 'Inherit: Inherit via internal rule'**Numerator accumulator — Numerator accumulator data type**

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the accumulator data type for the numerator coefficients. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** NumAccumDataTypeStr**Type:** character vector**Values:** 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'Inherit: Same as product output' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'**Default:** 'Inherit: Inherit via internal rule'**Denominator coefficients — Denominator coefficient data type**

Inherit: Inherit via internal rule (default) | int8 | int16 | int32 | int64 | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the denominator coefficient data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in integer, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** DenCoeffDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>
Default: 'Inherit: Same wordlength as input'

Denominator coefficient minimum — Minimum value of denominator coefficients

[] (default) | scalar

Specify the minimum value that a denominator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: DenCoeffMin

Type: character vector

Values: scalar

Default: '[]'

Denominator coefficient maximum — Maximum value of denominator coefficients

[] (default) | scalar

Specify the maximum value that a denominator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: DenCoeffMax

Type: character vector

Values: scalar

Default: '[]'

Denominator product output — Denominator product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the product output data type for the denominator coefficients. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: DenProductDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Denominator accumulator — Denominator accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | int8 | int16 | int32 | int64 | fixdt(1,16,0) | <data type expression>

Specify the accumulator data type for the denominator coefficients. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: DenAccumDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'Inherit: Same as product output' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Output — Output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | int8 | int16 | int32 | int64 | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- A built-in data type, for example, int8
- A data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'int64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via interal rule'

Output minimum — Minimum value of output

[] (default) | scalar

Specify the minimum value that the block can output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: scalar

Default: '[]'

Output maximum — Maximum value of output

[] (default) | scalar

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: scalar

Default: '[]'

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector**Values:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'**Default:** 'Floor'**Saturate on integer overflow — Method of overflow action**

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'

State Attributes

State name — Unique name for block state

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

Programmatic Use

Block Parameter: StateName

Type: character vector

Values: unique name

Default: ' '

State name must resolve to Simulink signal object — Require state name resolve to a signal object

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use

Block Parameter: StateMustResolveToSignalObject

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	double fixed point ^a integer ^a single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

^a This block only supports signed fixed-point data types.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

General	
ConstMultiplierOptimization	Canonical signed digit (CSD) or factored CSD optimization. The default is none. See also “ConstMultiplierOptimization” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Native Floating Point	
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is inherit. See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to inherit, Max, Min, or Zero for the floating-point operator. The default is inherit. See also “LatencyStrategy” (HDL Coder).
MantissaMultiplyStrategy	Specify how to implement the mantissa multiplication operation during code generation. By using different settings, you can control the DSP usage on the target FPGA device. The default is inherit. See also “MantissaMultiplyStrategy” (HDL Coder).

Restrictions

- Double data types are not supported for this block. Use single data types instead.

- Frame, matrix, and vector input data types are not supported.
- The leading denominator coefficient (a0) must be 1 or -1.

The Discrete Transfer Fcn block is excluded from the following optimizations:

- Resource sharing
- Distributed pipelining

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block only supports signed fixed-point data types.

Discrete Zero-Pole

Model system defined by zeros and poles of discrete transfer function

Library: Simulink / Discrete

Description

The Discrete Zero-Pole block models a discrete system defined by the zeros, poles, and gain of a z-domain transfer function. This block assumes that the transfer function has the following form:

$$H(z) = K \frac{Z(z)}{P(z)} = K \frac{(z - Z_1)(z - Z_2)\dots(z - Z_m)}{(z - P_1)(z - P_2)\dots(z - P_n)},$$

where Z represents the zeros vector, P the poles vector, and K the gain. The number of poles must be greater than or equal to the number of zeros ($n \geq m$). If the poles and zeros are complex, they must be complex conjugate pairs.

The block displays the transfer function depending on how the parameters are specified. See Zero-Pole for more information.

Modeling a Single-Output System

For a single-output system, the input and the output of the block are scalar time-domain signals. To model this system:

- 1 Enter a vector for the zeros of the transfer function in the **Zeros** field.
- 2 Enter a vector for the poles of the transfer function in the **Poles** field.
- 3 Enter a 1-by-1 vector for the gain of the transfer function in the **Gain** field.

Modeling a Multiple-Output System

For a multiple-output system, the block input is a scalar and the output is a vector, where each element is an output of the system. To model this system:

- 1 Enter a matrix of zeros in the **Zeros** field.

Each *column* of this matrix contains the zeros of a transfer function that relates the system input to one of the outputs.

- 2 Enter a vector for the poles common to all transfer functions of the system in the **Poles** field.
- 3 Enter a vector of gains in the **Gain** field.

Each element is the gain of the corresponding transfer function in **Zeros**.

Each element of the output vector corresponds to a column in **Zeros**.

Ports

Input

Port_1 — Input signal

scalar

Input signal specified as a real-valued scalar.

Data Types: `single` | `double`

Output

Port_1 — Model of discrete system

scalar | vector

Model of system as defined by zeros, poles, and gain of discrete transfer function. The width of the output is equal to the number of columns in the **Zeros** matrix, or one if **Zeros** is a vector.

Data Types: `single` | `double`

Parameters

Main

Zeros — Matrix of zeros

[1] (default) | vector | matrix

Specify the vector or matrix of zeros. The number of zeros must be less than or equal to the number of poles. If the poles and zeros are complex, they must be complex conjugate pairs.

- For a single-output system, enter a vector for the zeros of the transfer function.
- For a multiple-output system, enter a matrix. Each column of the matrix contains the zeros of a transfer function that relates the system input to one of the outputs.

Programmatic Use

Block Parameter: Zeros

Type: character vector

Values: vector

Default: ' [1] '

Poles — Vector of poles

[0 0.5] (default) | vector

Specify the vector of poles. The number of poles must be greater than or equal to the number of zeros. If the poles and zeros are complex, they must be complex conjugate pairs.

- For a single-output system, enter a vector for the poles of the transfer function.
- For a multiple-output system, enter a vector for the poles common to all transfer functions of the system.

Programmatic Use

Block Parameter: Poles

Type: character vector

Values: vector

Default: '[0 0.5]'

Gain — Gain value

1 (default) | scalar | vector

Specify vector of gain values.

- For a single-output system, enter a scalar or 1-by-1 vector for the gain of the transfer function.
- For a multiple-output system, enter a vector of gains. Each element is the gain of the corresponding transfer function in **Zeros**.

Programmatic Use

Block Parameter: Gain

Type: character vector

Values: scalar | vector

Default: '1'

Sample time (-1 for inherited) — Interval between samples

-1 | scalar | vector

Specify the time interval between samples. For more information, see [Specifying Sample Time](#).

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '-1'

State Attributes

State name — Unique name for block state

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

Programmatic Use

Block Parameter: StateName

Type: character vector

Values: unique name

Default: ''

State name must resolve to Simulink signal object — Require state name resolve to a signal object

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than **None**.

Programmatic Use

Block Parameter: StateMustResolveToSignalObject

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	double single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on memcpy or memset functions (string.h) under certain conditions.

Display

Display signal value during simulation

Library: Simulink / Dashboard

Description

The Display block connects to a signal in your model and displays its value during simulation. You can configure the appearance and format of the Display block to make intuitive sense for the value it displays. You can edit the parameters of the Display block during simulation. The Display block can display complex, vector, and 2-D matrix signals. Use the Display block with other dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, select a dashboard block to connect. Then, on the block tab, click **Connect**. In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- You cannot use the **Connection** table to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- The toolstrip does not support dashboard blocks that are in a panel.
- Dashboard blocks cannot connect to signals inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- You cannot connect a dashboard block to state activity or chart data in Stateflow during simulation.
- You cannot programmatically connect a dashboard block to state activity or chart data in Stateflow.
- Some signals do not have data available during simulation due to block reduction or optimization for accelerator mode simulations. To view such a signal using a dashboard block, mark the signal for logging.

Parameters

Connection

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Main

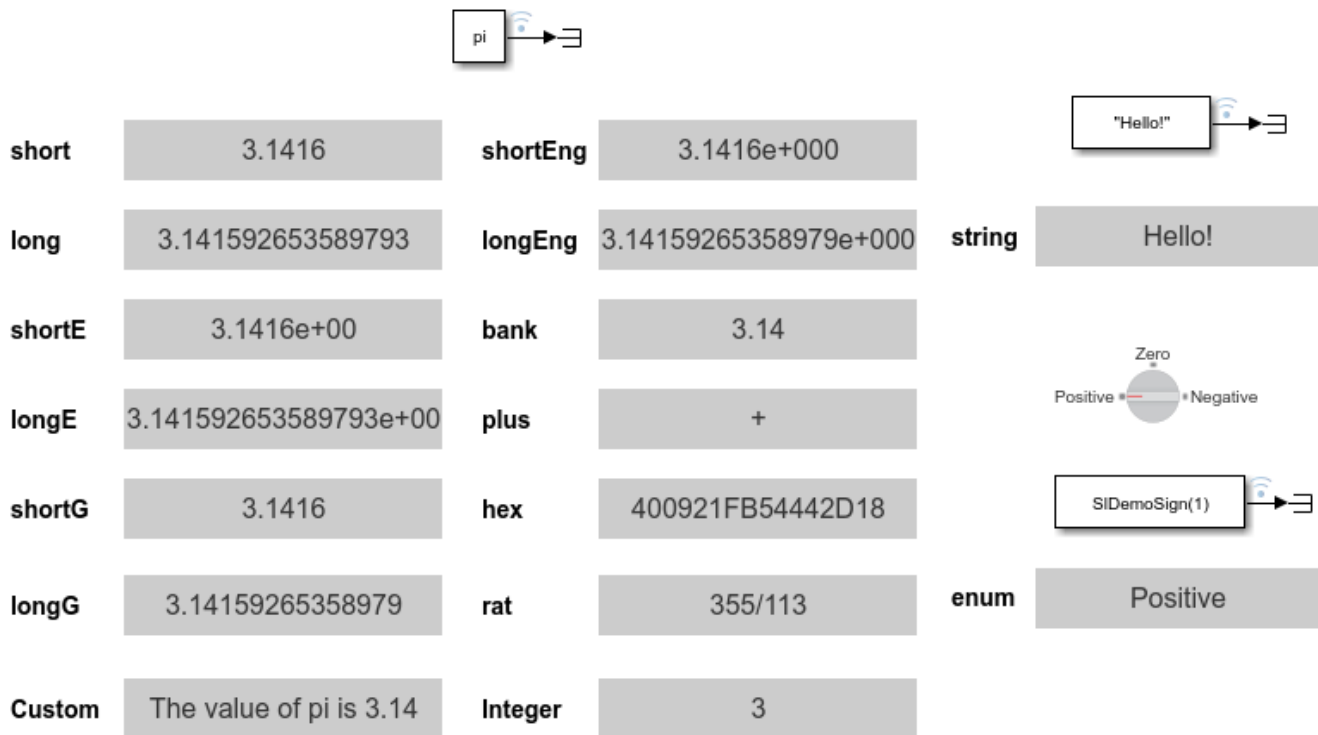

Format — Format for displaying signal values

short (default) | long | shortE | longE | ...

Format for displaying signal values, specified as one of these values:

- **short** — Scaled fixed-decimal format with four digits after the decimal point
- **long** — Scaled fixed-decimal format with fifteen digits after the decimal point for **double** values and seven digits after the decimal point for **single** values
- **shortE** — Scientific notation format with four digits
- **longE** — Scientific notation format with fifteen digits after the decimal point for **double** values and seven digits after the decimal point for **single** values
- **shortG** — Data takes the more compact format between fixed-decimal or scientific notation, with a total of five digits
- **longG** — Data takes the more compact format between fixed-decimal or scientific notation, with a total of fifteen digits for **double** values and seven digits for **single** values
- **shortEng** — Engineering notation where the exponent is a multiple of 3, with 4 digits after the decimal point
- **longEng** — Engineering notation where the exponent is a multiple of 3, with 15 significant digits
- **+** — Positive/negative format. +, -, and blank characters are displayed for positive, negative, and zero values, respectively
- **bank** — Currency format with 2 digits after the decimal point
- **hex** — Hexadecimal representation
- **rat** — Ratio
- **Custom** — Custom string format. Data is displayed in a custom string that you specify using the **Format String** parameter.

- Integer — Data rounded to the nearest whole number.

Programmatic Use

Block Parameter: Format

Type: character array | string

Values: 'short' | 'long' | 'shortE' | 'longE' | 'shortG' | 'longG' | 'shortEng' | 'longEng' | 'bank' | '+' | 'hex' | 'rat' | 'Custom' | 'Integer'

Default: 'short'

Format String — Custom string to format data

'%d' (default) | string

Custom string to format displayed signal data, specified as a string. The format string consists of text and format operators, which start with a % sign and end with a conversion character. Use the format operators at the place in the string where you want the signal data to display. For more information about supported formatting operators, see the `formatSpec` input of the `compose` function.

Example: The value of pi is %.2f displays the value of the connected signal within a sentence.

Example: \$%.2f displays the value of the connected signal with a dollar sign and two decimal places.

Dependencies

To enable this parameter, set the **Format** parameter to Custom.

Programmatic Use

Block Parameter: FormatString

Type: character array | string

Default: '%d'

Alignment — Text alignment in block

Center (default) | Left | Right

Text alignment in the Display block.

Programmatic Use**Block Parameter:** Alignment**Type:** character array**Values:** 'Left' | 'Center' | 'Right'**Default:** 'Center'**Label — Block label position**

Hide (default) | Bottom | Top

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use**Block Parameter:** LabelPosition**Type:** character vector**Values:** 'Hide' | 'Bottom' | 'Top'**Default:** 'Hide'**Layout — How to arrange elements of non-scalar data**

Preserve dimensions (default) | Fill available space

How to arrange elements of non-scalar data, specified as one of these options:

- Preserve dimensions — Display elements arranged to match signal dimensions.
- Fill available space — Display as many elements as possible within available space.

Programmatic Use**Block Parameter:** Layout**Type:** character array | string**Values:** 'Preserve dimensions' | 'Fill available space'**Default:** 'Preserve dimensions'**Format****Show grid for non-scalar signals — Whether to show grid**

on (default) | off

Whether to show a grid on the block when the block displays non-scalar data. Specify the color of the grid using the **Grid Color** parameter.

Programmatic Use**Block Parameter:** ShowGrid**Type:** character array | string**Values:** 'on' | 'off'**Default:** 'on'**Opacity — Block background opacity**

1 (default) | scalar

Block background opacity, specified as a scalar value between 0 and 1.

Example: 0.5

Programmatic Use

Block Parameter: Opacity

Type: scalar

Default: 1

Foreground Color — Block foreground color

[r g b] vector

Block foreground color, including the text. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `ForegroundColor`

Type: character vector | string

Values: [r g b] vector

Background Color — Block background color

[r g b] vector

Block background color. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: [r g b] vector

Grid Color — Block grid color

[r g b] vector

Block grid color. The grid shows when the block displays non-scalar data. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `GridColor` parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `GridColor`

Type: [r g b] vector

Default: [0.502 0.502 0.502]

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single string
Direct Feedthrough	no

Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Introduced in R2017b

Display

Show value of input

Library: Simulink / Sinks
HDL Coder / Sinks

Description

The Display block shows the value of the input data. You can specify the frequency of the display. For numeric input data, you can also specify the format of display.

If the block input is an array, you can resize the block vertically or horizontally to show more than just the first element. If the block input is a vector, the block sequentially adds display fields from left to right and top to bottom. The block displays as many values as possible. A black triangle indicates that the block is not displaying all input array elements.

The Display block shows the first 200 elements of a vector signal and the first 20 rows and 10 columns of a matrix signal.

Note If you specify a numeric display format that is not large enough to display all the digits of a value, the displayed values may lose precision. The result depends on your computer hardware and operating system.

Display Abbreviations

The following abbreviations appear on the Display block to help you identify the format of the value.

When You See...	The Value That Appears Is...
(SI)	The stored integer value
	Note (SI) does not appear when the signal is of an integer data type.
hex	In hexadecimal format
bin	In binary format
oct	In octal format

Displaying Strings

When working with strings, the Display block displays:

- Strings with double quotes.
- Special characters such as newline are shown as escaped sequences, for example '\n'.
- Non-displayable characters as escaped octal number, for example '\201'.

If the incoming signal is of type string, the **Numeric display format** parameter selection does not affect the display of the string.

Ports

Input

Port_1 – Input data

scalar | vector

Input data to display.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated

Parameters

Numeric display format – Format to display numeric input data

short (default) | long | short_e | long_e | bank | hex (Stored Integer) | binary (Stored Integer) | decimal (Stored Integer) | octal (Stored Integer)

Specify the format of the numeric data that appears.

If You Select...	The Block Displays...
short	A 5-digit scaled value with fixed decimal point
long	A 15-digit scaled value with fixed decimal point
short_e	A 5-digit value with a floating decimal point
long_e	A 16-digit value with a floating decimal point
bank	A value in fixed dollars and cents format (but with no \$ or commas)
hex (Stored Integer)	The stored integer value of a fixed-point input in hexadecimal format
binary (Stored Integer)	The stored integer value of a fixed-point input in binary format
decimal (Stored Integer)	The stored integer value of a fixed-point input in decimal format
octal (Stored Integer)	The stored integer value of a fixed-point input in octal format

If the numeric input to a Display block has an enumerated data type (see “Simulink Enumerations” and “Define Simulink Enumerations”):

- The block displays enumerated values, not the values of underlying integers.
- Setting **Numeric display format** to any of the Stored Integer settings causes an error.

If the incoming signal is of type string, the selection of the **Numeric display format** parameter does not affect the display of the string.

Programmatic Use**Block Parameter:** Format**Type:** character vector**Values:** 'short' | 'long' | 'short_e' | 'long_e' | 'bank' | 'hex (Stored Integer)' | 'binary (Stored Integer)' | 'decimal (Stored Integer)' | 'octal (Stored Integer)'**Default:** 'short'**Decimation — Display rate**

1 (default) | integer

Specify how often to display data.

The amount of data that appears and the time steps at which the data appears depend on the **Decimation** block parameter and the `SampleTime` property.

- The **Decimation** parameter enables you to display data at every n th sample, where n is the decimation factor. The default decimation, 1, displays data at every time step.

Note The Display block updates its display at the initial time, even when the **Decimation** value is greater than one.

- The `SampleTime` property, which you can set with `set_param`, enables you to specify a sampling interval at which to display points. This property is useful when you are using a variable-step solver where the interval between time steps is not the same. The default sample time, -1, causes the block to ignore the sampling interval when determining the points to display.

Note If the block inherits a sample time of `Inf`, the **Decimation** parameter is ignored.

Programmatic Use**Block Parameter:** Decimation**Type:** character vector**Values:** '1' | integer**Default:** '1'**Floating display — Floating display**

off (default) | on

To use the block as a floating display, select the **Floating display** check box. The block input port disappears and the block displays the value of the signal on a selected line.

If you select **Floating display**:

- Turn off signal storage reuse for your model. See “Signal storage reuse” (Simulink Coder) for more information.
- Do not connect a multidimensional signal to a floating display.

Programmatic Use**Block Parameter:** Floating**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single string
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Ignored for code generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Introduced before R2006a

Divide

Divide one input by another

Library: Simulink / Math Operations
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Math Operations

Description

The Divide block outputs the result of dividing its first input by its second. The inputs can be scalars, a scalar and a nonscalar, or two nonscalars that have the same dimensions. This block supports only complex input values at division ports when all ports have the same single or double data type.

The Divide block is functionally a Product block that has two block parameter values preset:

- **Multiplication** — `Element-wise(.*)`
- **Number of Inputs** — `*/`

Setting nondefault values for either of those parameters can change a Divide block to be functionally equivalent to a Product block or a Product of Elements block.

Ports

Input

X — Input signal to multiply

scalar | vector | matrix | N-D array

Input signal to be multiplied with other inputs.

Dependencies

To enable one or more **X** ports, specify one or more * characters for the **Number of inputs** parameter and set the **Multiplication** parameter to `Element-wise(.*)`.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

÷ — Input signal to divide or invert

scalar | vector | matrix | N-D array

Input signal for division or inversion operations.

Dependencies

To enable one or more **÷** ports, specify one or more / characters for the **Number of inputs** parameter and set the **Multiplication** parameter to `Element-wise(.*)`.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_1 – First input to multiply or divide

scalar | vector | matrix | N-D array

First input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_N – Nth input to multiply or divide

scalar | vector | matrix | N-D array

Nth input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

*** – Input signal to multiply**

scalar | vector | matrix | N-D array

Input signal to be multiplied with other inputs.

Dependencies

To enable one or more * ports, specify one or more * characters for the **Number of inputs** parameter and set the **Multiplication** parameter to `Matrix(*)`.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Inv – Input signal to divide or invert

scalar | vector | matrix | N-D array

Input signal for division or inversion operations.

Dependencies

To enable one or more **Inv** ports, specify one or more / characters for the **Number of inputs** parameter and set the **Multiplication** parameter to `Matrix(*)`.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 – Output computed by multiplying, dividing, or inverting inputs

scalar | vector | matrix | N-D array

Output computed by multiplying, dividing, or inverting inputs.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Number of inputs — Control number of inputs and type of operation

`*/` (default) | positive integer scalar | `*` or `/` for each input port

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

When you specify:

- **1 or * or /**

The block has one input port. In element-wise mode, the block processes the input as described for the Product of Elements block. In matrix mode, if the parameter value is 1 or `*`, the block outputs the input value. If the value is `/`, the input must be a square matrix (including a scalar as a degenerate case) and the block outputs the matrix inverse. See “Element-Wise Mode” on page 1-1335 and “Matrix Mode” on page 1-1336 for more information.

- **Integer value > 1**

The block has the number of inputs given by the integer value. The inputs are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1335 and “Matrix Mode” on page 1-1336 for more information.

- **Unquoted string of two or more * and / characters**

The block has the number of inputs given by the length of the character vector. Each input that corresponds to a `*` character is multiplied into the output. Each input that corresponds to a `/` character is divided into the output. The operations occur in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1335 and “Matrix Mode” on page 1-1336 for more information.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: `'2'` | `'*'` | `'**'` | `'*/'` | `'*/*'` | ...

Default: `'*/'`

Multiplication — Element-wise (.*) or Matrix (*) multiplication

`Element-wise(.*)` (default) | `Matrix(*)`

Specify whether the block performs `Element-wise(.*)` or `Matrix(*)` multiplication.

Programmatic Use

Block Parameter: Multiplication

Type: character vector

Values: `'Element-wise(.*)'` | `'Matrix(*)'`

Default: `'Element-wise(.*)'`

Multiply over — All dimensions or specified dimension

All dimensions (default) | Specified dimension

Specify the dimension to multiply over as **All dimensions**, or **Specified dimension**. When you select **Specified dimension**, you can specify the **Dimension** as 1 or 2.

Dependencies

To enable this parameter, set **Number of inputs** to * and **Multiplication** to **Element-wise (.*)**.

Programmatic Use

Block Parameter: CollapseMode

Type: character vector

Values: 'All dimensions' | 'Specified dimension'

Default: 'All dimensions'

Dimension — Dimension to multiply over

1 (default) | 2 | ... | N

Specify the dimension to multiply over as an integer less than or equal to the number of dimensions of the input signal.

Dependencies

To enable this parameter, set:

- **Number of inputs** to *
- **Multiplication** to **Element-wise (.*)**
- **Multiply over** to **Specified dimension**

Programmatic Use

Block Parameter: CollapseDim

Type: character vector

Values: '1' | '2' | ...

Default: '1'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Signal Attributes

Require all inputs to have the same data type — Require that all inputs have the same data type

off (default) | on

Specify if input signals must all have the same data type. If you enable this parameter, then an error occurs during simulation if the input signal types are different.

Programmatic Use**Block Parameter:** InputSameDT**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Output minimum — Minimum output value for range checking**

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output maximum — Maximum output value for range checking**

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output data type — Specify the output data type

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | Inherit: Same as first input | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType. For more information, see “Control Data Types of Signals”.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule** — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and ASIC/FPGA is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- **Inherit: Inherit via back propagation** — Use data type of the driving block.
- **Inherit: Same as first input** — Use data type of first input signal.

Dependencies

When input is a floating-point data type smaller than single precision, the **Inherit: Inherit via internal rule** output data type depends on the setting of the “Inherit floating-point output type smaller than single precision” configuration parameter. Data types are smaller than single precision when the number of bits needed to encode the data type is less than the 32 bits needed to encode the single-precision data type. For example, `half` and `int16` are smaller than single precision.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector**Values:** 'Inherit: Inherit via internal rule' | 'Inherit: Same as first input' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'**Default:** 'Inherit: Inherit via internal rule'**Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Integer rounding mode — Rounding mode for fixed-point operations**

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations. You can select:

Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Expected Differences Between Simulation and Code Generation

These conditions may yield different results between simulation and the generated code:

- The Divide block inputs contain a NaN or inf value
- The Divide block generates NaN or inf during execution

This difference is due to the nonfinite NaN or inf values. In such cases, inspect your model configuration and eliminate the conditions that produce NaN or inf.

Code Optimizations

The Simulink Coder build process provides efficient code for matrix inverse and division operations. This table describes the benefits and when each benefit is available.

Benefit	Small Matrices (2-by-2 to 5-by-5)	Medium Matrices (6-by-6 to 20-by-20)	Large Matrices (larger than 20- by-20)
Faster code execution time, compared to R2011a and earlier releases	Yes	No	Yes
Reduced ROM and RAM usage, compared to R2011a and earlier releases	Yes, for real values	Yes, for real values	Yes, for real values
Reuse of variables	Yes	Yes	Yes
Dead code elimination	Yes	Yes	Yes

Benefit	Small Matrices (2-by-2 to 5-by-5)	Medium Matrices (6-by-6 to 20-by-20)	Large Matrices (larger than 20- by-20)
Constant folding	Yes	Yes	Yes
Expression folding	Yes	Yes	Yes
Consistency with MATLAB Coder results	Yes	Yes	Yes

For blocks that have three or more inputs of different dimensions, the code might include an extra buffer to store temporary variables for intermediate results.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Note When you deploy the generated HDL code onto the target hardware, make sure that you set the **signed integer division rounds to** parameter in the **Hardware Implementation** pane of the Configuration Parameters dialog box to **Zero** or **Floor**.

To perform an HDL-optimized divide operation, connect a Product block to a Divide block in reciprocal mode.

HDL Architecture

The Divide block is the same as a Product block with **Number of Inputs** set to */.

Architecture	Parameters	Description
Linear (Default)	None	Generate a divide (/) operator in the HDL code.

Architecture	Parameters	Description
ShiftAdd	UsePipelines	<p>Perform divide operations on fixed-point types by using a non-restoring division algorithm that performs multiple shift and add operations to compute the quotient. This architecture provides improved accuracy compared to the Newton-Raphson approximation method.</p> <p>When you use this architecture, to achieve a higher maximum clock frequency on the target FPGA device, leave the UsePipelines HDL block property to on.</p> <p>When you use fixed-point data types, following criteria must be satisfied for generating the HDL code:</p> <ul style="list-style-type: none"> Inputs word length (WL) must be less than 63. [Max(WL input1, WL input2) + Abs(FL Difference)] must be less than 63. Where, Fractional length (FL) Difference is given by, $\text{FL Difference} = \text{FL input1} - (\text{FL input2} + \text{FL output})$

Reciprocal Mode

When **Number of Inputs** is set to /, the Divide block is in reciprocal mode.

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

In reciprocal mode, the Divide block has the HDL block implementations described in the following table.

Architectures	Parameters	Additional cycles of latency	Description
Linear(default)	None	0	When you compute a reciprocal, use the HDL divide (/) operator to implement the division.

Architectures	Parameters	Additional cycles of latency	Description
ReciprocalRsqrBasedNewton	Iterations	Signed input: Iterations + 5 Unsigned input: Iterations + 3	Use the iterative Newton method. Select this option to optimize area. The default value for Iterations is 3. The recommended value for Iterations is between 2 and 10. If Iterations is outside the recommended range, HDL Coder displays a message.
ReciprocalRsqrBasedNewtonSingleRate	Iterations	Signed input: (Iterations * 4) + 8 Unsigned input: (Iterations * 4) + 6	Use the single rate pipelined Newton method. Select this option to optimize speed, or if you want a single rate implementation. The default value for Iterations is 3. The recommended value for Iterations is between 2 and 10. If Iterations is outside the recommended range, the coder displays a message.

Architectures	Parameters	Additional cycles of latency	Description
ShiftAdd	UsePipelines	<p>Signed input: (Input word length + 4)</p> <p>Unsigned input: (Input word length + 4)</p>	<p>Perform reciprocal operation on a fixed-point input by using a non-restoring division algorithm that performs multiple shift and add operations to compute the reciprocal. This architecture provides improved accuracy compared to the Newton-Raphson approximation method.</p> <p>When you use this architecture, to achieve a higher maximum clock frequency on the target FPGA device, leave the UsePipelines HDL block property to on.</p> <p>When you use fixed-point data types, following criteria must be satisfied for generating the HDL code:</p> <ul style="list-style-type: none"> • Input word length (WL) must be less than or equal to 63. • [WL input + Abs (FL Sum)] must be less than or equal to 63. Where, FL Sum is given by, <p>FL sum = FL input + FL output</p>

The Newton-Raphson iterative method:

$$x_{i+1} = x_i - \frac{f(x_i)}{f'(x_i)} = x_i(1.5 - 0.5ax_i^2)$$

ReciprocalRsqrBasedNewton and ReciprocalRsqrBasedNewtonSingleRate implement the Newton-Raphson method with:

$$f(x) = \frac{1}{x^2} - 1$$

HDL code generation supports different output data types for `divide` (`*/`) and `reciprocal` (`/`) operations in `ShiftAdd`. You can use these output data types for the blocks:

- Inherit: Inherit via internal rule
- Inherit: Keep MSB
- Inherit: Match scaling
- Inherit: Inherit via back propagation
- Inherit: Same as first input
- Integer types (`uint8`, `int8`, `uint16`, `int16`, `uint32`, `int32`, `uint64`, `int64`)
- Fixed point types

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is none. See also “DSPStyle” (HDL Coder). Use this property with: <ul style="list-style-type: none"> • Product block • Divide and Reciprocal blocks with Linear architecture
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
LatencyStrategy	To enable this property, set HDL architecture to <code>ShiftAdd</code> . Specify whether to map the blocks in your design to <code>MAX</code> , <code>CUSTOM</code> , or <code>ZERO</code> latency for fixed-point and floating-point types. The default is <code>MAX</code> . See also “LatencyStrategy” (HDL Coder).
CustomLatency	To enable this property, set HDL architecture to <code>ShiftAdd</code> . When LatencyStrategy is set to <code>CUSTOM</code> , use this property to specify a custom latency value between <code>ZERO</code> and <code>MAX</code> for fixed-point types. See also “LatencyStrategy” (HDL Coder).

Native Floating Point	
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is <code>inherit</code> . See also “HandleDenormals” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to <code>Custom</code> . HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).
MantissaMultiplyStrategy	Specify how to implement the mantissa multiplication operation during code generation. By using different settings, you can control the DSP usage on the target FPGA device. The default is <code>inherit</code> . See also “MantissaMultiplyStrategy” (HDL Coder).
DivisionAlgorithm	Specify whether to use the Radix-2 or Radix-4 algorithm to perform the floating-point division. The Radix-2 mode offers a trade-off between latency and frequency. The Radix-4 mode offers a trade-off between latency and resource usage. For more information, see “DivisionAlgorithm” (HDL Coder).

To see the latency calculation for fixed-point types with Divide and Reciprocal blocks, at the MATLAB command prompt, enter:

```
HDLMathLib
```

Complex Data Support

This block does not support code generation for division with complex signals.

Restrictions

When you use the Divide block in reciprocal mode, the following restrictions apply:

- When you use fixed-point types, the input and output must be scalar. To use vector inputs, specify the `Math` architecture and input a floating-point value.
- Only the Zero rounding mode is supported.
- You must select the **Saturate on integer overflow** option on the block.

For the Divide block, only the Zero and Simplest rounding modes are supported.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

DocBlock

Create text that documents model and save text with model

Library: Simulink / Model-Wide Utilities
HDL Coder / Model-Wide Utilities

Description

The DocBlock allows you to create and edit text that documents a model, and save that text with the model. Double-clicking an instance of the block creates a temporary file containing the text associated with this block and opens the file in an editor. Use the editor to modify the text and save the file. Simulink software stores the contents of the saved file in the model file.

The DocBlock supports HTML, Rich Text Format (RTF), and ASCII text document types. The default editors for these different document types are

- HTML — Microsoft® Word (if available). Otherwise, the DocBlock opens HTML documents using the editor specified on the **Editor/Debugger Preferences** pane of the Preferences dialog box.
- RTF — Microsoft Word (if available). Otherwise, the DocBlock opens RTF documents using the editor specified on the **Editor/Debugger Preferences** pane of the Preferences dialog box.
- Text — The DocBlock opens text documents using the editor specified on the **Editor/Debugger Preferences** pane of the Preferences dialog box.

Use the `docblock` command to change the default editors.

Tip To edit the block parameters of the DocBlock, right-click the block icon and select **Mask > Mask Parameters...**

Parameters

Code generation template symbol — Template symbol for generated code

' ' | Abstract | Description | History | Modified History | Notes

Enter a template symbol name in this field. Embedded Coder® software uses this symbol to add comments to the code generated from the model. For more information, see “Add Global Comments in the Generated Code” (Embedded Coder).

Dependencies

For comments to appear in the generated code, you must also set the **Document type** to Text.

Programmatic Use

Block Parameter: `ECoderFlag`

Type: character vector

Values: Abstract | Description | History | Modified History | Notes

Default: '0'

Document type — Type of document

Text (default) | RTF | HTML

Select the type of document associated with the DocBlock. The options are:

- Text
- RTF
- HTML

Dependencies

If you are using a DocBlock to add comments to your code during code generation, ensure that you set the **Document Type** as Text. If you set the **Document Type** as RTF or HTML, your comments will not appear in the code.

Programmatic Use

Block Parameter: DocumentType

Type: character vector

Values: Text | RTF | HTML

Default: 'Text'

Block Characteristics

Data Types	
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Uses the template symbol you specify for the Embedded Coder Flag block parameter to add comments to generated code. Requires an Embedded Coder license. For more information, see “Use a Simulink DocBlock to Add a Comment” (Embedded Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. See also “Generate Code with Annotations or Comments” (HDL Coder) and “Integrate Custom HDL Code by Using DocBlock” (HDL Coder).

HDL Architecture

Architecture	Description
Annotation (default)	Insert text as comment in the generated code.
HDLText	Integrate text as custom HDL code.
No HDL	Do not generate HDL code for this block.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
TargetLanguage	Language of the text, either Verilog [®] or VHDL [®] . The default is VHDL. When Architecture is HDLText, this property is available. To learn more, see “Integrate Custom HDL Code by Using DocBlock” (HDL Coder).

Restrictions

- **Document type** must be Text.

HDL Coder does not support the HTML or RTF options.

- You can have a maximum of two DocBlock blocks with **Architecture** set to HDLText in the same subsystem.

If you have two DocBlock blocks, one must have **TargetLanguage** set to VHDL, and the other must have **TargetLanguage** set to Verilog. When generating code, HDL Coder only integrates the custom code from the DocBlock that matches the target language for code generation.

PLC Code Generation

Generate Structured Text code using Simulink[®] PLC Coder[™].

Introduced before R2006a

Dot Product

Generate dot product of two vectors

Library: Simulink / Math Operations
HDL Coder / Math Operations

Description

The Dot Product block generates the dot product of the input vectors. The scalar output, y , is equal to the MATLAB operation

$$y = \text{sum}(\text{conj}(u1) .* u2)$$

where $u1$ and $u2$ represent the input vectors. The inputs can be vectors, column vectors (single-column matrices), or scalars. If both inputs are vectors or column vectors, they must be the same length. If $u1$ and $u2$ are both column vectors, the block outputs the equivalent of the MATLAB expression $u1' * u2$.

The elements of the input vectors can be real- or complex-valued signals. The signal type (complex or real) of the output depends on the signal types of the inputs.

Input 1	Input 2	Output
real	real	real
real	complex	complex
complex	real	complex
complex	complex	complex

Ports

Input

Port_1 — First operand input signal

scalar | vector

Signal representing the first operand to the dot product calculation.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Port_2 — Second operand input signal

scalar | vector

Signal representing the second operand to the dot product calculation.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Dot product output signal

scalar | vector

Output signal resulting from the dot product calculation of the two input signals.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Require all inputs to have the same data type — Require all inputs to have the same data type

on (default) | off

Clear this check box for all the inputs to have different data types.

Programmatic Use

Block Parameter: InputSameDT

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Specify the upper value of the output range that Simulink checks as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: scalar

Default: '[]'

Output data type — Specify the output data type

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | Inherit: Same as first input | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. For more information, see “Control Data Types of Signals”.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule** — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a

gain of int16 and ASIC/FPGA is specified as the targeted hardware type, the output data type is sfix24. If Unspecified (assume 32-bit Generic), in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is int32. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of `Inherit: Same as input`.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.

Note When input is a floating-point data type smaller than single precision, `Inherit: Inherit via internal rule` depends on the setting of the “Inherit floating-point output type smaller than single precision” configuration parameter. Data types are smaller than single precision when the number of bits needed to encode the data type is less than the 32 bits needed to encode the single-precision data type. For example, `half` and `int16` are smaller than single precision.

- `Inherit: Inherit via back propagation` — Use data type of the driving block.
- `Inherit: Same as first input` — Use data type of first input signal.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Same as first input'` | `'Inherit: Inherit via back propagation'` | `'double'` | `'single'` | `'half'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`

Default: `'Inherit: Inherit via internal rule'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Integer rounding mode — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow – Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- **off** — Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- **on** — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
 - In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.
-

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	yes

Multidimensional Signals	yes
Variable-Size Signals	no

Edit

Enter new value for parameter

Library: Simulink / Dashboard

Description

The Edit block allows you to type in new values for block parameters during simulation. Use the Edit block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Double-clicking the Edit block does not open its dialog box during simulation and when the block is selected. To edit the block parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

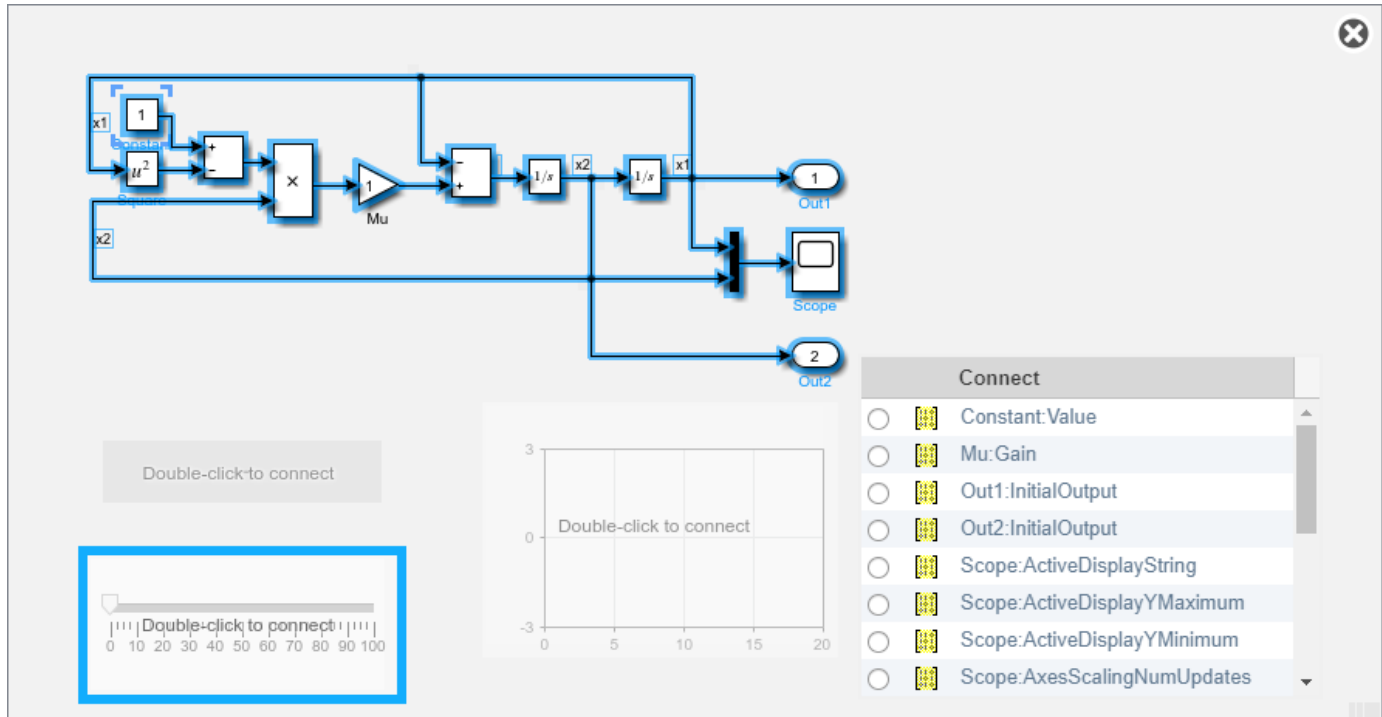

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, select the block. Then, on the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect

mode, the dashboard block does not display the connected value until the you uncomment the block.

- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection

Connection — Select a variable or block parameter to connect

variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify `a.b` to connect to scalar element `b` of the structure or bus `a` nested inside the selected composite variable or parameter.

- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding
Type: Simulink.HMI.ParamSourceInfo
Default: []

Main

Align — Text alignment
Center (default) | Left | Right

Alignment of the text in the Edit block.

Programmatic Use
Block Parameter: Alignment
Type: string or character vector
Values: 'Center' | 'Left' | 'Right'
Default: 'Center'

Label — Block label position
Hide (default) | Bottom | Top

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use
Block Parameter: LabelPosition
Type: character vector
Values: 'Hide' | 'Bottom' | 'Top'
Default: 'Hide'

Format

Opacity — Block background opacity
1 (default) | scalar

Block background opacity, specified as a scalar value between 0 and 1.

Example: 0.5

Programmatic Use
Block Parameter: Opacity
Type: scalar
Default: 1

ForegroundColor — Block foreground color
[r g b] vector

Block foreground color, including the text. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the ForegroundColor parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: ForegroundColor
Type: character vector | string
Values: [r g b] vector

Background Color — Block background color

[r g b] vector

Block background color. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: [r g b] vector

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Enable

Add enable port to subsystem or model

Library: Simulink / Ports & Subsystems
HDL Coder / Ports & Subsystems

Description

The Enable block allows an external signal to control execution of a subsystem or a model. To enable this functionality, add the block to a Subsystem block or at the root level of a model that is referenced in a Model block.

If you use an enable port at the root-level of a model:

- For multi-rate models, set the solver to single-tasking.
- For models with a fixed-step size, at least one block in the model must run at the specified fixed-step size rate.

Ports

Output

Enable signal — External enable signal for a subsystem or model

scalar

Enable signal attached externally to the outside of an Enabled Subsystem block and passed to the inside of the subsystem. An enable signal port is added to an Enable block when you select the **Show output port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `expression`

Parameters

States when enabling — Select block states when subsystem or model is disabled

`held` (default) | `reset`

When a Subsystem block or Model block is disabled, select what happens to block states for the blocks within the subsystem or model.

`held`

Hold block states at their previous values.

`reset`

Reset block states to their initial conditions (zero if not defined).

Programmatic Use**Block parameter:** StatesWhenEnabling**Type:** character vector**Values:** 'held' | 'reset'**Default:** 'held'**Propagate sizes of variable-size signals — Select when to propagate a variable-size signal**

Only when enabling (default) | During execution

Select when to propagate a variable-size signal.

Only when enabling

Propagate a variable-size signal when reenabling a Subsystem block or Model block containing an Enable port block. When you select this option, sample time must be periodic.

During execution

Propagate variable-size signals at each time step.

Programmatic Use**Block parameter:** PropagateVarSize**Type:** character vector**Values:** 'Only when enabling' | 'During execution'**Default:** 'Only when enabling'**Show output port — Control display of output port for enable signal**

off (default) | on

The output port passes the enable signal attached externally to the outside of an Enabled Subsystem block or enabled Model block to the inside.

 off

Remove the output port on the Enable port block.

 on

Display an output port on the Enable port block. Selecting this option allows the subsystem or model to process the enable signal.

Programmatic Use**Block parameter:** ShowOutputPort**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Enable zero-crossing detection — Control zero-crossing detection**

on (default) | off

Control zero-crossing detection for a model.

 on

Detect zero crossings.

off

Do not detect zero crossings.

Programmatic Use

Block parameter: ZeroCross

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Port dimensions — Specify dimensions for the enable signal

1 (default) | [n] | [m n]

Specify dimensions for the enable signal attached externally to a Model block and passed to the inside of the block.

1

Scalar signal.

[n]

Vector signal of width n.

[m n]

Matrix signal having m rows and n columns.

Programmatic Use

Block parameter: PortDimensions

Type: character vector

Values: '1' | '[n]' | '[m n]'

Default: '1'

Sample time — Specify time interval

-1 (default) | Ts | [Ts, To]

Specify time interval between block method execution. See “Specify Sample Time”.

-1

Sample time inherited from the model.

Ts

Scalar where Ts is the time interval.

[Ts, To]

Vector where Ts is the time interval and To is the initial time offset.

Programmatic Use

Block parameter: SampleTime

Type: character vector

Values: '-1' | 'Ts' | '[Ts, To]'

Default: '-1'

Minimum — Specify minimum output value for the enable signal

[] (default) | real scalar

Specify minimum value for the enable signal attached externally to a Model block and passed to the inside of the block.

Simulink uses this value to perform:

- Simulation range checking. See “Specify Signal Ranges”.
- Automatic scaling of fixed-point data types.
- Optimization of generated code. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. See “Optimize using the specified minimum and maximum values” (Embedded Coder).

[]

Unspecified minimum value.

real scalar

Real double scalar value.

Programmatic Use

Block parameter: OutMin

Type: character vector

Values: '[]' | '<real scalar>'

Default: '[]'

Maximum — Specify maximum output value for the enable signal

[] (default) | real scalar

Specify maximum value for the enable signal attached externally to a Model block and passed to the inside of the block.

Simulink uses this value to perform:

- Simulation range checking. See “Specify Signal Ranges”.
- Automatic scaling of fixed-point data types.
- Optimization of generated code. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. See “Optimize using the specified minimum and maximum values” (Embedded Coder).

[]

Unspecified maximum value.

real scalar

Real double scalar value.

Programmatic Use

Block parameter: OutMax

Type: character vector

Values: '[]' | '<real scalar>'

Default: '[]'

Data type — Specify output data type for the enable signal

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^,0) | <data type expression>

Specify data type for the enable signal attached externally to a Model block and passed to the inside of the block.

double

Double-precision floating point.

single

Single-precision floating point.

int8

Signed 8-bit integer.

uint8

Unsigned 8-bit integer.

int16

Signed 16-bit integer.

uint16

Unsigned 16-bit integer.

int32

Signed 32-bit integer.

uint32

Unsigned 32-bit integer.

int64

Signed 64-bit integer.

uint64

Unsigned 64-bit integer.

boolean

Boolean with a value of true or false.

fixdt(1,16)

Signed 16-bit fixed point number with binary point undefined.

fixdt(1,16,0)

Signed 16-bit fixed point number with binary point set to zero.

fixdt(1,16,2^0,0)

Signed 16-bit fixed point number with slope set to 2^0 and bias set to 0.

<data type expression>

Data type object, for example `Simulink.NumericType`. You cannot enter the name of a `Simulink.Bus` object as a data type expression.

Programmatic Use

Block parameter: `OutDataTypeStr`

Type: character vector

Values: `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'boolean'` | `'<fixdt(1,16)>'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`

Default: `'double'`

Mode — Select data type category

Build in (default) | Fixed point | Expression

Select data type category and display drop-down lists to help you define the data type.

Build in

Display drop-down lists for data type and Data type override.

Fixed point

Display drop-down lists for Signedness, Scaling, and Data type override.

Expression

Display text box for entering an expression.

Dependency

To enable this parameter, select the Show data type assistant button.

Programmatic Use

No equivalent command-line parameter.

Interpolate data — Specify value of missing workspace data

on (default) | off

Specify value of missing workspace data when loading data from the workspace.

on

Linearly Interpolate output at time steps for which no corresponding workspace data exists.

off

Do not interpolate output at time steps. The current output equals the output at the most recent time step for which data exists.

Programmatic Use

Block parameter: Interpolate

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Enabled and Triggered Subsystem

Subsystem whose execution is enabled and triggered by external inputs

Library: Simulink / Ports & Subsystems

Description

The Enabled and Triggered Subsystem block is a subsystem block preconfigured as a starting point for creating a subsystem that executes when both of these conditions occur:

- Enable control signal has a positive value.
- Trigger control signal has a trigger value.

Use Enabled and Triggered Subsystem blocks to model:

- Optional functionality.
- Alternative functionality.

For an explanation of the Enabled and Triggered Subsystem block parameters, see [Subsystem](#).

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Enable — Control signal input to a subsystem block

scalar

Placing an Enable block in a subsystem block adds an external input port to the block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Trigger — Control signal input to a subsystem block

scalar

Placing a Trigger block in a subsystem block adds an external input port to the block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output**Out — Signal output from a subsystem**

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a half ^a integer ^a single ^a string ^a
Direct Feedthrough	no
Multidimensional Signals	limited ^a
Variable-Size Signals	limited ^a
Zero-Crossing Detection	no

^a Actual data type or capability support depends on block implementation.

Enabled Subsystem

Subsystem whose execution is enabled by external input

Library: Simulink / Ports & Subsystems
HDL Coder / Ports & Subsystems

Description

The Enabled Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes when a control signal has a positive value.

Use Enabled Subsystem blocks to model:

- Discontinuities
- Optional functionality
- Alternative functionality

For an explanation of the Enabled Subsystem block parameters, see [Subsystem](#).

Ports

Input

In — Signal input to Subsystem block

scalar | vector | matrix

Signal input to a Subsystem block, specified as a scalar, vector, or matrix. Placing an Inport block in a Subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to receive signals from the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Enable — Control signal input to Subsystem block

scalar | vector | matrix

An Enable block in a Subsystem block adds an external input port to the block and makes the block an Enabled Subsystem block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output**Out — Signal output from Subsystem block**

scalar | vector | matrix

Signal output from a Subsystem block, returned as a scalar, vector, or matrix. Placing an Output block in a Subsystem block adds an external output port to the block. The port label matches the name of the Output block.

Use Output blocks to send signals to the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a half ^a integer ^a single ^a string ^a

Variable-Size Signals	limited ^a
Zero-Crossing Detection	no

^a Actual data type or capability support depends on block implementation.

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Best Practices

When using enabled subsystems in models targeted for HDL code generation, it is good practice to consider the following:

- For synthesis results to match Simulink results, the Enable port must be driven by registered logic (with a synchronous clock) on the FPGA.
- Put unit delays on Enabled Subsystem output signals. Doing so prevents the code generator from inserting extra bypass registers in the HDL code.
- Enabled subsystems can affect synthesis results in the following ways:
 - In some cases, the system clock speed can drop by a small percentage.
 - Generated code uses more resources, scaling with the number of enabled subsystem instances and the number of output ports per subsystem.

HDL Architecture

Architecture	Description
Module (default)	Generate code for the subsystem and the blocks within the subsystem.
BlackBox	Generate a black box interface. The generated HDL code includes only the input/output port definitions for the subsystem. Therefore, you can use a subsystem in your model to generate an interface to existing, manually written HDL code. The black-box interface generation for subsystems is similar to the Model block interface generation without the clock signals.
No HDL	Remove the subsystem from the generated code. You can use the subsystem in simulation, however, treat it as a “no-op” in the HDL code.

HDL Block Properties

General	
AdaptivePipelining	Automatic pipeline insertion based on the synthesis tool, target frequency, and multiplier word-lengths. The default is <code>inherit</code> . See also “AdaptivePipelining” (HDL Coder).
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . See also “BalanceDelays” (HDL Coder).
ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <code>inherit</code> . See also “ClockRatePipelining” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>off</code> . See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is <code>none</code> . See also “DSPStyle” (HDL Coder).
FlattenHierarchy	Remove subsystem hierarchy from generated HDL code. The default is <code>inherit</code> . See also “FlattenHierarchy” (HDL Coder).

General	
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is 0, which implements fully parallel data paths. See also “Streaming” (HDL Coder).

Target Specification

This block cannot be the DUT, so the block property settings in the **Target Specification** tab are ignored.

Restrictions

HDL Coder supports HDL code generation for enabled subsystems that meet the following conditions:

- The enabled subsystem is not the DUT.
- The subsystem is not *both* triggered *and* enabled.
- The enable signal is a scalar.
- The input datatype for the enable signal is boolean.
- Outputs of the enabled subsystem have an initial value of 0.
- All inputs and outputs of the enabled subsystem (including the enable signal) run at the same rate.
- The **Show output port** parameter of the Enable block is set to **Off**.
- The **States when enabling** parameter of the Enable block is set to **held** (i.e., the Enable block does not reset states when enabled).
- The **Output when disabled** parameter for the enabled subsystem output ports is set to **held** (i.e., the enabled subsystem does not reset output values when disabled).
- If the DUT contains the following blocks, **RAMArchitecture** is set to **WithClockEnable**:
 - Dual Port RAM
 - Simple Dual Port RAM
 - Single Port RAM
- The enabled subsystem does not contain the following blocks:
 - CIC Decimation
 - CIC Interpolation
 - FIR Decimation
 - FIR Interpolation

- Downsample
- Upsample
- HDL FIFO
- HDL Cosimulation blocks (HDL Verifier™)
- Rate Transition
- NR Polar Encoder and NR Polar Decoder (Wireless HDL Toolbox™)

Enumerated Constant

Generate enumerated constant value

Library: Simulink / Sources
HDL Coder / Sources

Description

The Enumerated Constant block outputs a scalar, array, or matrix of enumerated values. You can also use the Constant block to output enumerated values, but it provides block parameters that do not apply to enumerated types, such as **Output minimum** and **Output maximum**. When you need a block that outputs only constant enumerated values, use Enumerated Constant rather than Constant. For more information, see “Simulink Enumerations”.

Ports

Output

Port_1 — Enumerated constant

scalar | vector | matrix

Enumerated constant value, specified as a scalar, vector, or matrix.

Data Types: enumerated

Parameters

Output data type — Output data type

Enum: SlDemoSign (default) | Enum:<ClassName>

Specify the enumerated type from which you want the block to output one or more values. The initial value, Enum:SlDemoSign, is a dummy enumerated type that prevents a newly cloned block from causing an error. To specify the desired enumerated type, select it from the drop-down list or enter Enum:ClassName in the **Output data type** field, where *ClassName* is the name of the MATLAB class that defines the type.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Enum:<ClassName>'

Default: 'Enum: SlDemoSign'

Mode — Category of data to specify

Enumerated (default)

Select the category of data to specify.

Enumerated

Enumerated data types. Selecting Enumerated enables a second menu/text box to the right, where you can enter the class name.

Value — Enumerated value

`SlDemoSign.Positive` (default) | Enum:<ClassName.Value>

Specify the value or values that the block outputs. The output of the block has the same dimensions and elements as the **Value** parameter. The initial value, `SlDemoSign.Positive`, is a dummy enumerated value that prevents a newly cloned block from causing an error.

To specify the desired enumerated values, select from the drop-down list or enter any MATLAB expression that evaluates to the desired result, including an expression that uses tunable parameters. All specified values must be of the type indicated by the **Output data type**. To specify an array that includes every value in the enumerated type, use the enumeration function.

Programmatic Use

Block Parameter: Value

Type: character vector

Values: 'Enum:<ClassName.Value>'

Default: 'SlDemoSign.Positive'

Sample time — Sample time

`inf` (default) | scalar | vector

Specify the interval between times that the block output can change during simulation (for example, due to tuning the **Value** parameter). The default value of `inf` indicates that the block output can never change. A sample time of `inf` speeds the simulation and generated code by avoiding the need to recompute the block output. For more information, see “Specify Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: 'inf'

Block Characteristics

Data Types	enumerated
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Environment Controller

(Removed) Create branches of block diagram that apply only to simulation or only to code generation

Note Environment Controller block has been removed. Use the Variant Source block instead. For more information, see “Compatibility Considerations”.

Library: Simulink / Signal Routing

Description

The Environment Controller block outputs the signal at its **Sim** port only if the model that contains it is being simulated. It outputs the signal at its **Coder** port only if code is being generated from the model. This option enables you to create branches of a block diagram that apply only to simulation or code generation. This table describes various scenarios where either the **Sim** or **Coder** port applies.

Scenario	Output
Normal mode simulation	Sim
Accelerator mode simulation	Sim
Rapid accelerator mode simulation	Sim
Simulation of a referenced model in normal or accelerator modes	Sim
Simulation of a referenced model in processor-in-the-loop (PIL) mode	Coder (uses the same code generated for a referenced model)
External mode simulation	Coder
Standard code generation	Coder
Code generation of a referenced model	Coder

Simulink Coder software does not generate code for blocks connected to the **Sim** port if these conditions hold:

- On the **Code Generation > Optimization** pane of the Configuration Parameters dialog box, you set **Default parameter behavior** to **Inlined**.
- The blocks connected to the Sim port do not have external signals.
- The Sim port input path does not contain an S-function or an Interpreted MATLAB Function block.

If you enable block reduction optimization, Simulink eliminates blocks in the branch connected to the Coder port when compiling the model for simulation. For more information, see “Block reduction”.

Note Simulink Coder code generation eliminates the blocks connected to the Sim branch only if the Sim branch has the same signal dimensions as the Coder branch. Regardless of whether it eliminates

the Sim branch, Simulink Coder uses the sample times on the Sim branch as well as the Coder branch to determine the fundamental sample time of the generated code and might, in some cases, generate sample-time handling code that applies only to sample times specified on the Sim branch.

Ports

Input

Sim — Simulation input

scalar | vector | matrix

Simulation input values, specified as a scalar, vector, or matrix. Input signal must have the same width as the input to the **Coder** port.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Coder — Code generation input

scalar | vector | matrix

Code generation input values, specified as a scalar, vector, or matrix. Input signal must have the same width as the input to the **Sim** port.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Out — Values from Sim or Coder input port

scalar | vector | matrix

Values from the **Sim** or **Coder** input port, depending on the current environment. For more information on what the block outputs in various simulation and code generation modes, see “Description” on page 1-584.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Compatibility Considerations

Environment Controller block has been removed

Warns starting in R2021b

The Environment Controller block has been removed from the Signal Routing library. Existing models that use this block continue to work with a warning. Use the Variant Source block with the **Variant control mode** parameter set to `sim_codegen_switching` instead. You can use Model Advisor or Upgrade Advisor to automatically identify and replace all instances of the Environment Controller block with the Variant Source block. For information on the Model advisor check, see “Identify Environment Controller Blocks and Replace Them with Variant Source Blocks” on page 9-66.

Variant blocks offer these advantages over the Environment Controller block:

- Variant Source block with the **Variant control mode** parameter set to `sim_codegen_switching` allows you to automatically switch between simulation and code generation workflows. In this mode, Variant Source block supports these activation times:

Variant activation time	Behavior
update diagram	Simulink sets the active choice during update diagram before the propagation of signal attributes. Inactive choices are removed prior to propagation of signal attributes, so the generated code contains only the active choice.
update diagram analyze all choices	Simulink sets the active choice during update diagram after the propagation of signal attributes. Signal attributes are propagated to both active and inactive choices to check for consistency. Inactive choices are removed at the end of update diagram before model start occurs. The generated code contains only active choices.

- Variant Sink block enables branching on the output side (destination of a signal).
- Variant blocks highlight the path of the active variant choice during simulation and code generation.
- Variant Source block offers optimal code generation compared to the Environment Controller block. The Environment Controller block can retain blocks connected to the Sim port in the generated code.
- Variant blocks can be centrally managed using the Variant Manager tool, which offers these key capabilities:
 - Visualize the variant model hierarchy.
 - Define and validate multiple variant configurations of the model.
 - Generate a simplified model for a variant configuration using the Variant Reducer tool. For variant blocks with the **Variant control mode** parameter set to `sim_codegen_switching`, you can choose to retain the simulation branch or the code generation branch in the reduced model.
 - Compare variant configurations using the Variant Configuration Analysis tool.

For more information, see “Variant Manager Overview”.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Event Listener

Event port for Initialize Function, Reinitialize Function, Reset Function, and Terminate Function blocks

Description

The Event Listener block serves as an event port for the Initialize Function, Reinitialize Function, Reinitialize Function, Reset Function, and Terminate Function blocks.

Parameters

Event type — Select event type for subsystem

`Initialize` (default) | `Reinitialize` | `Reset` | `Terminate`

Select event type for subsystem to execute initialize, reinitialize, reset, or terminate algorithms.

Initialize

Select to trigger the execution of an Initialize Function block with an initialize event.

Reinitialize

Select to trigger the execution of an Reinitialize Function block with an reinitialize event.

Reset

Select to trigger the execution of a Reset Function block with a reset event.

Terminate

Select to trigger the execution of a Terminate Function block with a terminate event.

Programmatic Use

Block Parameter: EventType

Type: character vector

Value: 'Initialize' | 'Reinitialize' | 'Reset' | 'Terminate'

Default: 'Initialize'

Event name — Specify event name

`reinit` | `reset` | `event name`

Specify event name for Reinitialize Function or Reset Function block. Simulink displays the name on the face of the Reinitialize Function or Reset Function block. The event name is also the name of the reinitialize event port on the Model or Subsystem block containing the Reinitialize Function block or the name of the reset event port on the Model block containing the Reset Function block.

reinit

Default event name when **Event type** is set to Reinitialize.

reset

Default event name when **Event type** is set to Reset.

When entering the **Event name**, the auto-completion list provides some suggestions. The list is not complete.

The **Event name** must be a valid MATLAB variable name.

Dependency

To enable this parameter, set the **Event type** parameter to Reinitialize or Reset.

Programmatic Use

Block Parameter: EventName

Type: character vector

Value: 'reinit' | 'reset' | '<event name>'

Default: 'reinit' or 'reset'

Enable variant condition — Control activating the variant control (condition)

off (default) | on

Control activating the variant control (condition) defined with the **Variant control** parameter.

off

Deactivate variant control of subsystem.

on

Activate variant control of subsystem.

When you select **Enable variant condition**, a badge indicates the change:

Programmatic Use

Block Parameter: Variant

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Note

- A reinitialize event port of a Model or Subsystem block can be conditional and propagates the net variant conditions defined on the corresponding Reinitialize Function block in the referenced model or subsystem.
- A reset event port of a Model block can be conditional and propagates the net variant conditions defined on the corresponding Reset Function block in the referenced model.
- Initialize and terminate event ports are always unconditional because they control both the model default and block-specific initialize and terminate events of the referenced model. If you define an Initialize Function block in the referenced model, it corresponds to an explicit initialize event.

Variant control — Specify variant control (condition) expression

Variant (default) | logical expression

Specify variant control (condition) expression that executes a variant Initialize Function, Reinitialize Function, Reset Function, or Terminate Function block when the expression evaluates to `true`.

Variant

Default name for a logical (Boolean) expression.

logical expression

A logical (Boolean) expression or a `Simulink.Variant` object representing a Boolean expression.

If you want to generate code for your model, define the variables in the expression as `Simulink.Parameter` objects.

Dependency

To enable this parameter, select the **Enable variant condition** parameter.

Programmatic Use

Block Parameter: VariantControl

Type: character vector

Value: 'Variant' | '<logical expression>'

Default: 'Variant'

Generate preprocessor conditionals — Select if variant choices are enclosed within C preprocessor conditional statements

off (default) | on

Select if variant choices are enclosed within C preprocessor conditional statements.

off

Do not enclose variant choices within C preprocessor conditional statements.

on

When generating code for an ERT target, enclose variant choices within C preprocessor conditional statements (`#if`).

Dependency

To enable this parameter, select the **Enable variant condition** parameter.

When you select **Generate preprocessor conditionals**, a badge indicates the change:

Programmatic Use

Block Parameter: GeneratePreprocessorConditionals

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Extract Bits

Output selection of contiguous bits from input signal

Library: Simulink / Logic and Bit Operations
HDL Coder / Logic and Bit Operations

Description

The Extract Bits block allows you to output a contiguous selection of bits from the stored integer value of the input signal. Use the **Bits to extract** parameter to define the method for selecting the output bits.

- Select **Upper half** to output the half of the input bits that contain the most significant bit. If there is an odd number of bits in the input signal, the number of output bits is given by the equation

$$\text{number of output bits} = \text{ceil}(\text{number of input bits}/2)$$
- Select **Lower half** to output the half of the input bits that contain the least significant bit. If there is an odd number of bits in the input signal, the number of output bits is given by the equation

$$\text{number of output bits} = \text{ceil}(\text{number of input bits}/2)$$
- Select **Range starting with most significant bit** to output a certain number of the most significant bits of the input signal. Specify the number of most significant bits to output in the **Number of bits** parameter.
- Select **Range ending with least significant bit** to output a certain number of the least significant bits of the input signal. Specify the number of least significant bits to output in the **Number of bits** parameter.
- Select **Range of bits** to indicate a series of contiguous bits of the input to output in the **Bit indices** parameter. You indicate the range in `[start end]` format, and the indices of the input bits are labeled contiguously starting at 0 for the least significant bit.

This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array. Floating-point inputs are passed through the block unchanged. `boolean` inputs are treated as `uint8` signals.

Note Performing bit operations on a signed integer is difficult. You can avoid difficulty by converting the data type of your input signals to unsigned integer types.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

Port_1 – Extracted bits

scalar | vector | matrix | N-D array

Contiguous selection of extracted bits, specified as a scalar, vector, matrix, or N-D array. Floating-point inputs are passed through the block unchanged.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Bits to extract – Method for extracting bits

Upper half (default) | Lower half | Range starting with most significant bit | Range ending with least significant bit | Range of bits

Select the method for extracting bits from the input signal.

Consider an input signal that is represented in binary by 110111001:

- If you select `Upper half` for the **Bits to extract** parameter, the output is 11011 in binary.
- If you select `Lower half` for the **Bits to extract** parameter, the output is 11001 in binary.
- If you select `Range starting with most significant bit` for the **Bits to extract** parameter, and specify 3 for the **Number of bits** parameter, the output is 110 in binary.
- If you select `Range ending with least significant bit` for the **Bits to extract** parameter, and specify 8 for the **Number of bits** parameter, the output is 10111001 in binary.
- If you select `Range of bits` for the **Bits to extract** parameter, and specify [4 7] for the **Bit indices** parameter, the output is 1011 in binary.

Programmatic Use

Block Parameter: `bitsToExtract`

Type: character vector

Values: `'Upper half'` | `'Lower half'` | `'Range starting with most significant bit'` | `'Range ending with least significant bit'` | `'Range of bits'`

Default: `'Upper half'`

Number of bits – Number of bits to output

8 (default) | positive integer

Select the number of bits to output from the input signal. Signed integer data types must have at least two bits. Unsigned data integer types can be as short as a single bit.

Dependencies

To enable this parameter, set **Bits to extract** to `Range starting with most significant bit` or `Range ending with least significant bit`.

Programmatic Use**Block Parameter:** numBits**Type:** character vector**Values:** positive integer**Default:** '8'**Bit indices — Contiguous range of bits to output**

[0 7] (default) | contiguous range

Specify a contiguous range of bits of the input signal to output. Specify the range in [start end] format. The indices are assigned to the input bits starting with 0 at the least significant bit.

Dependencies

To enable this parameter, set **Bits to extract** to Range of bits.

Programmatic Use**Block Parameter:** bitIdxRange**Type:** character vector**Values:** contiguous range**Default:** '[0 7]'**Output scaling mode — Output scaling mode**

Preserve fixed-point scaling (default) | Treat bit field as an integer

Select the scaling mode to use on the output bit selection:

- When you select `Preserve fixed-point scaling`, the fixed-point scaling of the input is used to determine the output scaling during the data type conversion.
- When you select `Treat bit field as an integer`, the fixed-point scaling of the input is ignored, and only the stored integer is used to compute the output data type.

Programmatic Use**Block Parameter:** outScalingMode**Type:** character vector**Values:** 'Preserve fixed-point scaling' | 'Treat bit field as an integer'**Default:** 'Preserve fixed-point scaling'**Block Characteristics**

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extract Diagonal

Extract main diagonal of input matrix

Library: Simulink / Matrix Operations

Description

The Extract Diagonal block populates the unoriented output vector with the elements on the main diagonal of the M -by- N input matrix A . Equivalent MATLAB code is given by:

$$D = \text{diag}(A)$$

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input matrix to extract the diagonal from, specified as a scalar, vector, or matrix .

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Output

Port_1 — Output signal

vector

Output vector of each diagonal element.

The output is the same data type and complexity as the input. The output vector has length $\min(M,N)$.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Compatibility Considerations

Create Extract Diagonal Block Moved to Simulink Matrix Operations Library

Behavior changed in R2021b

The Extract Diagonal block has been moved from the **DSP System Toolbox > Math Functions > Matrices and Linear Algebra > Matrix Operations** library to the **Simulink > Matrix Operations** library. All existing models continue to work.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (`string.h`) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Find Nonzero Elements

Find nonzero elements in array

Library: Simulink / Math Operations

Description

The Find Nonzero Elements block locates all nonzero elements of the input signal and returns the linear indices of those elements. If the input is a multidimensional signal, the Find Nonzero Elements block can also return the subscripts of the nonzero input elements. In both cases, you can show an output port with the nonzero input values.

The Find Nonzero Elements block outputs a variable-size signal. The sample time for any variable-size signal must be discrete. If your model does not already use a fixed-step solver, you may need to select a fixed-step solver in the Configuration Parameters dialog. For more information, see “Compare Solvers” and “Choose a Solver”.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix | N-D array

Input signal from which the block finds all nonzero elements.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 – Indices of nonzero elements

variable-size signal

The Find Nonzero Elements block outputs the indices of nonzero elements as a variable-size signal. You control the data type of the output using the **Output data type** block parameter.

Dependencies

By default, the block outputs linear indices from the first output port. When you change the **Index output format** to **Subscripts**, the block instead provides the element indices of a two-dimension or larger signal in a subscript form. In this mode, you must specify the **Number of input dimensions**, and the block creates a separate output port for each dimension.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_2 – Values of nonzero elements

variable-size signal

The Find block can optionally output the values of all nonzero elements as a variable-size signal.

Dependencies

To enable this port, select **Show output port for nonzero input values**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Main

Index output format — Format for indices of nonzero elements

`Linear indices` (default) | `Subscripts`

Select the output format for the indices of the nonzero input values.

- Selecting `Linear indices` provides the element indices of any dimension signal in a vector form. For one dimension (vector) signals, indices correspond to the position of nonzero values within the vector. For signals with more than one dimension, the conversion of subscripts to indices is along the first dimension. You do not need to know the signal dimension of the input signal.
- Selecting `Subscripts` provides the element indices of a two-dimension or larger signal in a subscript form. Because the block shows an output port for each dimension, this option requires you to specify the **Number of input dimensions**.

Programmatic Use

Block Parameter: `IndexOutputFormat`

Type: character vector

Values: `'Linear indices'` | `'Subscripts'`

Default: `'Linear indices'`

Number of input dimensions — Number of dimensions for the input signal

`1` (default) | scalar

Specify the number of dimensions for the input signal as a positive integer value from 1 to 32.

Dependencies

To enable this parameter, set **Index output format** to `Subscripts`.

Programmatic Use

Block Parameter: `NumberOfInputDimensions`

Type: character vector

Values: scalar

Default: `'1'`

Index mode — Specify zero- or one-based indexing

`Zero-based` (default) | `One-based`

Specify the indexing mode as `Zero-based` or `One-based`.

- For `Zero-based` indexing, an index of 0 specifies the first element of the input vector. An index of 1 specifies the second element, and so on.

- For One-based indexing, an index of 1 specifies the first element of the input vector. An index of 2, specifies the second element, and so on.

Programmatic Use**Block Parameter:** IndexMode**Type:** character vector**Values:** 'Zero-based' | 'One-based'**Default:** 'Zero-based'**Show output port for nonzero input values — Enable output port for nonzero values**

off (default) | on

Show or hide the output port for nonzero input values.

- When you clear this check box (off), the block hides the output port for nonzero input values.
- When you select this check box (on), the block displays the output port for nonzero input values. The additional output port provides values of the nonzero input elements.

Programmatic Use**Block Parameter:** ShowOutputPortForNonzeroInputValues**Type:** character vector**Values:** 'on' | 'off'**Default:** 'off'**Sample time — Sample time value other than -1**

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Data Types****Output data type — Output data type**

Inherit: Inherit via internal rule (default) | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | <data type expression>

Specify the output data type.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

First Order Hold

Implement linearly extrapolated first order hold on input signal

Library: Simulink / Continuous

Description

The First Order Hold block outputs a continuous piecewise linear approximation of its input signal. Use the First Order Hold block to convert a sampled discrete signal to a continuous signal without triggering a solver reset.

You can also use the First Order Hold block to break algebraic loops in your model.

Ports

Input

Port 1 – Input signal

scalar | vector | matrix

Input signal, specified as a real-valued scalar, vector, or matrix.

Data Types: double

Output

Port 1 – Linearly approximated output signal

scalar | vector | matrix

Piecewise linear approximation of the input signal.

Data Types: double

Parameters

Initial output – Initial output

0 (default) | scalar | vector

Specify the output that the block generates until the simulation time exceeds the first sample hit time of the discrete input.

Dependencies

- The initial output of this block cannot be `inf` or `NaN`.
- A Run-to-run tunable parameter cannot be changed during simulation run time. However, changing it before a simulation begins does not cause Accelerator or Rapid Accelerator to regenerate code.

Programmatic Use**Block Parameter:** InitialOutput**Type:** character vector, string**Values:** scalar | vector**Default:** '0'**Output algorithm — Approximation technique for output signal**

Slow (Avoid Overshoot) (default) | Fast (Minimize Error)

Specify the approximation technique to use to smooth the input signal. The slow, or low pass algorithm aims to avoid overshoots when smoothing the input signal. The fast, or high pass algorithm minimizes error by attempting to predict the next input during the update method of the block. This error reduction in predicted output of the block is traded off against a tendency to overshoot the reference, or input signal.

Programmatic Use**Block Parameter:** OutputAlgorithm**Type:** character vector, string**Values:** Slow (Avoid Overshoot)|Fast (Minimize Error)**Default:** 'Slow (Avoid Overshoot)'**Reset if relative extrapolation error exceeds — Error tolerance for solver reset**

inf (default) | nonnegative real scalar

Specify the tolerance level for the extrapolation error of the Output Algorithm. Extrapolation error greater than this value will cause Simulink to reset the solver for the model.

Tip Enabling the **Allow continuous input** parameter when this parameter is set to inf can lead to numerical inaccuracies in simulation.

Programmatic Use**Block Parameter:** ErrorTolerance**Type:** character vector, string**Values:** scalar**Default:** 'inf'**Allow continuous input — Apply hold on continuous signals**

off (default) | on

Select this parameter to enable the block to accept continuous signals as input. Enabling this parameter creates a delay between the input and output continuous signals.

Note Enable this parameter when using this block to break an algebraic loop.

Programmatic Use**Block Parameter:** AllowContinuousInput**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'off'

Block Characteristics

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

Slow (Avoid overshoot)

The linear extrapolation performed by the slow or low pass algorithm can be described as:

$$y(t) = M_k(t - T_k) + C_k \quad \forall \quad T_k \leq t < t_{k+1}$$

where:

- T_k is the time at k^{th} major step.
- U_k is the input at k^{th} major step.
- C_k and M_k are the linear extrapolation coefficients.
- y_k is the continuous output at time T_k .

The coefficients, or slope M_k and y-intercept C_k , are calculated as follows

$$H_k = T_k - T_{k-1}$$

$$M_{k+1} = \frac{U_k - U_{k-1}}{H_k}$$

$$C_k = y_k$$

Fast (Minimize Error)

The linear extrapolation performed by the fast, or high pass, algorithm can be described as:

$$y(t) = N_k(t - T_k) + C_k \quad \forall \quad T_k \leq t < T_{k+1}$$

where:

- T_k is the time at k^{th} major step.
- U_k is the input at k^{th} major step.
- \hat{U} is the predicted value of the input at $(k+1)^{\text{th}}$ major step.
- (C_k and N_k are the linear extrapolation coefficients.
- y_k is the continuous output at time T_k .

The coefficients, or slope N_k and y-intercept C_k , are calculated as follows

$$H_k = T_k - T_{k-1}$$

$$M_{k+1} = \frac{U_k - U_{k-1}}{H_k}$$

$$\hat{U} = U_k + M_{k+1}(H_K)$$

$$N_{k+1} = \frac{\hat{U} - y_k}{H_K}$$

$$C_k = y_k$$

The fast algorithm minimizes error by attempting to predict the next input during the update method of the block. This error reduction in predicted output of the block is traded off against a tendency to overshoot the input signal.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code generation.

Consider discretizing your model.

Memory | Zero-Order Hold

Introduced in R2019b

Fixed-Point State-Space

Implement discrete-time state space

Library: Simulink / Additional Math & Discrete / Additional Discrete

$$\begin{cases} y(n) = Cx(n) + Du(n) \\ x(n+1) = Ax(n) + Bu(n) \end{cases}$$

Description

The Fixed-Point State-Space block implements the system described by

$$y(n) = Cx(n) + Du(n)$$

$$x(n + 1) = Ax(n) + Bu(n)$$

where u is the input, x is the state, and y is the output. Both equations have the same data type.

- **A** must be an n -by- n matrix, where n is the number of states.
- **B** must be an n -by- m matrix, where m is the number of inputs.
- **C** must be an r -by- n matrix, where r is the number of outputs.
- **D** must be an r -by- m matrix.

In addition:

- The state x must be an n -by-1 vector.
- The input u must be an m -by-1 vector.
- The output y must be an r -by-1 vector.

The block accepts one input and generates one output. The width of the input vector is the number of columns in the **B** and **D** matrices. The width of the output vector is the number of rows in the **C** and **D** matrices. To define the initial state vector, use the **Initial conditions** parameter.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input vector, where the width equals the number of columns in the **B** and **D** matrices. For more information, see “Description” on page 1-606.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output signal, with width equal to the number of rows in the **C** and **D** matrices. For more information, see “Description” on page 1-606.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

State Matrix A — Matrix of states

[2.6020 -2.2793 0.6708; 1 0 0; 0 1 0] (default) | scalar | vector | matrix

Specify the matrix of states as an n -by- n matrix of real or complex values, where n is the number of states. For more information on the matrix coefficients, see “Description” on page 1-606.

Programmatic Use

Block Parameter: A

Type: character vector

Values: scalar | vector | matrix

Default: '[2.6020 -2.2793 0.6708; 1 0 0; 0 1 0]'

Input Matrix B — Column vector of inputs

[1; 0; 0] (default) | scalar | vector | matrix

Specify the column vector of inputs as an n -by- m matrix of real or complex values, where n is the number of states, and m is the number of inputs. For more information on the matrix coefficients, see “Description” on page 1-606.

Programmatic Use

Block Parameter: B

Type: character vector

Values: scalar | vector | matrix

Default: '[1; 0; 0]'

Output Matrix C — Column vector of outputs

[0.0184 0.0024 0.0055] (default) | scalar | vector | matrix

Specify the column vector of outputs as an r -by- n matrix of real or complex values, where r is the number of outputs, and n is the number of states. For more information on the matrix coefficients, see “Description” on page 1-606.

Programmatic Use

Block Parameter: C

Type: character vector

Values: scalar | vector | matrix

Default: '[0.0184 0.0024 0.0055]'

Direct Feedthrough Matrix D — Matrix for direct feedthrough

[0.0033] (default) | scalar | vector | matrix

Specify the matrix for direct feedthrough as an r -by- m matrix of real or complex values, where r is the number of outputs, and m is the number of inputs. For more information on the matrix coefficients, see “Description” on page 1-606.

Programmatic Use**Block Parameter:** D**Type:** character vector**Values:** scalar | vector | matrix**Default:** '[0.0033]'**Initial condition for state — Initial state vector**

0.0 (default) | scalar | vector | matrix

Specify the initial condition for the state.

Limitations

The initial state cannot be `inf` or `NaN`.

Programmatic Use**Block Parameter:** X0**Type:** character vector**Values:** scalar | vector | matrix**Default:** '0.0'**Signal Attributes****Data type for internal calculations — Data type for internal calculations**

fixdt('double') (default) | data type string

Specify the data type the block uses for internal calculations.

Programmatic Use**Block Parameter:** InternalDataType**Type:** character vector**Values:** data type string**Default:** 'fixdt('double')'**Scaling for State Equation $AX+BU$ — Scaling for state equations**2⁰ (default) | scalar

Specify the scaling for the state equation $AX+BU$.

Programmatic Use**Block Parameter:** StateEqScaling**Type:** character vector**Values:** scalar**Default:** '2⁰'**Scaling for Output Equation $CX+DU$ — Scaling for output equations**2⁰ (default) | scalar

Specify the scaling for the output equation $CX+DU$.

Programmatic Use**Block Parameter:** InternalDataType

Type: character vector

Values: scalar

Default: '2^0'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate to max or min when overflows occur — Method of overflow action

off (default) | on

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: DoSatur

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean ^a double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no

Variable-Size Signals	yes
Zero-Crossing Detection	no

a This block is not recommended for use with Boolean signals.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

If you use the block in matrix multiplication mode, you can specify the **DotProductStrategy**. This setting determines whether you want to implement the matrix multiplication by using a tree of adders and multipliers, or use the Multiply-Accumulate block implementation. The default is Fully Parallel.

Note The **DotProductStrategy** must be set to Fully Parallel when you use the Native Floating Point mode.

For more information, see “DotProductStrategy” (HDL Coder).

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is none. See also “DSPStyle” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Introduced before R2006a

Floating Scope and Scope Viewer

Display signals generated during simulation without signal lines

Library: Simulink / Sinks
HDL Coder / Sinks

Description

The Simulink Scope Viewer and Floating Scope block display time domain signals with respect to simulation time. The Scope Viewer and Floating Scope block have the same functionality as the Scope block, but they are not connected to signal lines.

For information on controlling a Floating Scope block from the command line, see “Control Scope Blocks Programmatically” in the Simulink documentation.

Connect Signals

In the Floating Scope window or Scope viewer window, use the  button to connect signals.

To add a viewer with a connected signal, select a signal in the model. Then, on the **Simulation** tab, in the **Prepare** gallery, click **Add Viewer**.

For more details, see “Add Signals to an Existing Floating Scope or Scope Viewer”.

Key Features

- Multiple y-axes (displays) — Display multiple y-axes with multiple input ports. All the y-axes have a common time range on the x-axis.
- Multiple signals — Show multiple signals on the same y-axis (display) from one or more input ports.
- Modify parameters — Modify scope parameter values before and during a simulation.
- Display data after simulation — If a scope is closed at the start of a simulation, scope data is still written to the scope during the simulation. If you open the scope after a simulation, the scope displays simulation results for input signals.

Oscilloscope Measurements

- Triggers — Set triggers on repeating signals and pause the display when events occur.
- Cursor Measurements — Measure signal values using vertical and horizontal cursors.
- Signal Statistics¹ — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.
- Peak Finder^a — Find maxima, showing the x-axis values at which they occur.
- Bilevel Measurements^a — Measure transitions, overshoots, undershoots, and cycles.

Limitations

When you use model configuration parameters that optimize the simulation, such as **Signal storage reuse** or **Block reduction**, Simulink eliminates storage for some signals during simulation. You are unable to apply a Floating Scope to these eliminated signals. To work around this issue, configure an eliminated signal as a test point. You can then apply a Floating Scope to the signal regardless of optimization settings. To configure test points, see “Configure Signals as Test Points”.

- If you step back the simulation after adding or removing a signal, the Floating Scope clears the existing data. New data does not appear until the simulation steps forward again.
- When connected to a constant signal, the scope plots a single point.
- Simulink messages are not supported for Floating Scope block and Scope Viewer.
- You cannot connect signals from ForEach subsystems.
- Scope displays have limitations in Rapid Accelerator mode. See “Behavior of Scopes and Viewers with Rapid Accelerator Mode”

Ports

Input

Port_1 — Signal or signals to visualize

scalar | vector | matrix | array | bus | nonvirtual bus

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals can have these characteristics:

¹ You must have a Simscape™ or DSP System Toolbox license to use the Peak Finder, Bilevel Measurements, and Signal Statistics.

- **Type** — Continuous (sample-based) or discrete (sample-based and frame-based).
- **Data type** — Any data type that Simulink supports. See “Data Types Supported by Simulink”.
- **Dimension** — Scalar, one dimensional (vector), two dimensional (matrix), or multidimensional (array). Display multiple channels within one signal depending on the dimension. See “Signal Dimensions” and “Determine Signal Dimensions”.

Input Limitations

- When the input is a constant signal, the scope plots a single point.
- The scope shows gaps in the display when the signal value is NaN.
- When you visualize multiple frame-based signals in the scope, some samples of signals with a frame size of 1 might not be displayed. To visualize these signals, move the signals with frame size of 1 to a separate scope.

Bus Support

You can connect nonvirtual bus and arrays of bus signals to a scope. To display the bus signals, use normal or accelerator simulation mode. The scope displays each bus element signal in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened.

To log nonvirtual bus signals with a scope, set the **Save format** parameter to `Dataset`. You can use any **Save format** to log virtual bus signals.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Properties

Configuration Properties

The Configuration Properties dialog box controls various properties about the scope displays. From the scope menu, select **View > Configuration Properties**.

Main

Open at simulation start — Specify when scope window opens

`off` (default) | `on`

Select this check box to open the scope window when simulation starts.

Programmatic Use

See `OpenAtSimulationStart`.

Display the full path — Display block path on scope title bar

`off` (default) | `on`

Select this check box to display the block path in addition to the block name.

Layout — Number and arrangement of displays

1-by-1 display (default) | an arrangement of m -by- n displays

Specify number and arrangement of displays. To expand the layout grid beyond 4 by 4, click within the dialog box and drag. The maximum layout is 16 rows by 16 columns.

If the number of displays is equal to the number of ports, signals from each port appear on separate displays. If the number of displays is less than the number of ports, signals from additional ports appear on the last display. For layouts with multiple columns and rows, ports are mapped down and then across.

Programmatic Use

See `LayoutDimensions`.

Input processing — Channel or element signal processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

- Elements as channels (sample based) — Process each element as a unique sample.
- Columns as channels (frame based) — Process signal values in a column as a group of values from multiple time intervals. Frame-based processing is available only with discrete input signals.

Programmatic Use

See `FrameBasedProcessing`.

Maximize axes — Maximize size of plots

Off (default) | Auto | On

- Auto — If “Title” on page 1-0 and “Y-label” on page 1-0 properties are not specified, maximize all plots.
- On — Maximize all plots. Values in **Title** and **Y-label** are hidden.
- Off — Do not maximize plots.

Programmatic Use

See `MaximizeAxes`.

Time

Time span — Length of x-axis to display

Auto (default) | User defined | One frame period

- Auto — Difference between the simulation start and stop times.

The block calculates the beginning and end times of the time range using the “Time display offset” on page 1-0 and “Time span” on page 1-0 properties. For example, if you set the **Time display offset** to 10 and the **Time span** to 20, the scope sets the time range from 10 to 30.

- **User defined** — Enter any value less than the total simulation time.
- **One frame period** — Use the frame period of the input signal to the Time Scope block. This option is only available when the **Input processing** parameter is set to **Columns as channels** (frame based).

Programmatic Use

See `TimeSpan`.

Time span overrun action — Display data beyond visible x-axis

`Wrap` (default) | `Scroll`

Specify how to display data beyond the visible x-axis range.

You can see the effects of this option only when plotting is slow with large models or small step sizes.

- **Wrap** — Draw a full screen of data from left to right, clear the screen, and then restart drawing the data from the left.
- **Scroll** — Move data to the left as new data is drawn on the right. This mode is graphically intensive and can affect run-time performance.

Programmatic Use

See `TimeSpanOverrunAction`.

Time units — x-axis units

`None` (default for Scope) | `Metric` (default for Time Scope) | `Seconds`

- **Metric** — Display time units based on the length of “Time span” on page 1-0 .
- **Seconds** — Display time in seconds.
- **None** — Do not display time units.

Programmatic Use

See `TimeUnits`.

Time display offset — x-axis offset

`0` (default) | `scalar` | `vector`

Offset the x-axis by a specified time value, specified as a real number or vector of real numbers.

For input signals with multiple channels, you can enter a scalar or vector:

- **Scalar** — Offset all channels of an input signal by the same time value.
- **Vector** — Independently offset the channels.

Programmatic Use

See `TimeDisplayOffset`.

Time-axis labels — Display of x-axis labels

`Bottom Displays Only` (default for Scope) | `All` (default for Time Scope) | `None`

Specify how x-axis (time) labels display:

- All — Display x-axis labels on all y-axes.
- None — Do not display labels. Selecting None also clears the **Show time-axis label** check box.
- Bottom displays only — Display x-axis label on the bottom y-axis.

Dependencies

To enable this property, set:

- “Show time-axis label” on page 1-0 to on.
- “Maximize axes” on page 1-0 to off.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See TimeAxisLabels.

Show time-axis label — Display or hide x-axis labels

off (default for Scope) | on (default for Time Scope)

Select this check box to show the x-axis label for the active display

Dependencies

To enable this property, set “Time-axis labels” on page 1-0 to All or Bottom Displays Only.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowTimeAxisLabel.

Display

Active display — Selected display

1 (default) | positive integer

Selected display. Use this property to control which display is changed when changing style properties and axes-specific properties.

Specify the desired display using a positive integer that corresponds to the column-wise placement index. For layouts with multiple columns and rows, display numbers are mapped down and then across.

Programmatic Use

See ActiveDisplay.

Title — Display name

%<SignalLabel> (default) | string

Title for a display. The default value %<SignalLabel> uses the input signal name for the title.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See Title.

Show Legend — Display signal legend

off (default) | on

Toggle signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. Continuous signals have straight lines before their names, and discrete signals have step-shaped lines.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** properties. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **Esc**.

Note The legend only shows the first 20 signals. Any additional signals cannot be controlled from the legend.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowLegend.

Show grid — Show internal grid lines

on (default) | off

Select this check box to show grid lines.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowGrid.

Plot signals as magnitude and phase — Split display into magnitude and phase plots

off (default) | on

- On — Display magnitude and phase plots. If the signal is real, plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values. This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude.
- Off — Display signal plot. If the signal is complex, plots the real and imaginary parts on the same y-axis.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See `PlotAsMagnitudePhase`.

Y-limits (Minimum) — Minimum y-axis value

-10 (default) | real scalar

Specify the minimum value of the y-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The y-axis limits of the phase plot are always [-180 180].

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See `YLimits`.

Y-limits (Maximum) — Maximum y-axis value

10 (default) | real scalar

Specify the maximum value of the y-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The y-axis limits of the phase plot are always [-180 180].

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See `YLimits`.

Y-label — Y-axis label

none (default for Scope) | Amplitude (default for Time Scope) | string

Specify the text to display on the y-axis. To display signal units, add (`%<SignalUnits>`) to the label. At the beginning of a simulation, Simulink replaces (`%SignalUnits`) with the units associated with the signals.

Example: For a velocity signal with units of m/s, enter `Velocity (%<SignalUnits>)`.

Dependency

If you select **Plot signals as magnitude and phase**, this property does not apply. The y-axes are labeled Magnitude and Phase.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See `YLabel`.

Logging

Limit data points to last — Limit buffered data values

off (default) | on

Limit buffered data values before plotting and saving signals. Data values are from the end of a simulation. To use this property, you must also specify the number of data values by entering a positive integer in the text box.

- On — Specify the number of data values saved for each signal (5000 by default). If the signal is frame-based, the number of buffered data values is the specified number of data values multiplied by the frame size.

For simulations with **Stop time** set to `inf`, consider selecting **Limit data points to last**.

Sometimes, selecting this parameter cause signals to be plotted for less than the entire time range of a simulation. For example, where the sample time is small. If a scope plots a portion of your signals, consider increasing the number of data values the simulation saves.

- Off — Save and plot all data values. Clearing **Limit data points to last** can cause an out-of-memory error for simulations that generate a large amount of data or for systems without enough available memory.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 1-0 .

Programmatic Use

See `DataLoggingLimitDataPoints` and `DataLoggingMaxPoints`.

Decimation — Reduce amount of scope data to display and save

off (default) | on

- On — Plot and log (save) scope data every N^{th} data point, where N is the decimation factor entered in the text box. The default decimation factor is 2. A value of 1 buffers all data values.
- Off — Save all scope data values.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 1-0 .

Programmatic Use

See `DataLoggingDecimateData` and `DataLoggingDecimation`.

Log/Unlog Viewed Signals to Workspace — Toggle logging

on | off

For signals selected with the Signal Selector, clicking this button toggles the state of the **Log signal data** check boxes in the Signals Properties dialog boxes.

Axes Scaling Properties

The Axes Scaling Properties dialog controls the axes limits of the scope. To open the Axes Scaling properties, in the scope menu, select **Tools > Axes Scaling > Axes Scaling Properties**.

Axes scaling — Y-axis scaling mode

Manual (default) | Auto | After N Updates

- **Manual** — Manually scale the y-axis range with the **Scale Y-axis Limits** toolbar button.
- **Auto** — Scale the y-axis range during and after simulation. Selecting this option displays the **Do not allow Y-axis limits to shrink** check box. If you want the y-axis range to increase and decrease with the maximum value of a signal, set **Axes scaling** to Auto and clear the **Do not allow Y-axis limits to shrink** check box.
- **After N Updates** — Scale y-axis after the number of time steps specified in the **Number of updates** text box (10 by default). Scaling occurs only once during each run.

Programmatic Use

See AxesScaling.

Do not allow Y-axis limits to shrink — When y-axis limits can change

on (default) | off

Allow y-axis range limits to increase but not decrease during a simulation.

Dependency

To use this property, set **Axes scaling** to Auto.

Number of updates — Number of updates before scaling

10 (default) | integer

Set this property to delay auto scaling the y-axis.

Dependency

To use this property, set **Axes scaling** to After N Updates.

Programmatic Use

See AxesScalingNumUpdates.

Scale axes limits at stop — When y-axis limits can change

on (default) | off

- **On** — Scale axes when simulation stops.
- **Off** — Scale axes continually.

Dependency

To use this property, set **Axes scaling** to Auto.

Y-axis Data range (%) — Percent of y-axis to use for plotting

80 (default) | integer between [1, 100]

Specify the percentage of the y-axis range used for plotting data. If you set this property to 100, the plotted data uses the entire y-axis range.

Y-axis Align — Alignment along y-axis

Center (default) | Top | Bottom

Specify where to align plotted data along the y-axis data range when **Y-axis Data range** is set to less than 100 percent.

- Top — Align signals with the maximum values of the y-axis range.
- Center — Center signals between the minimum and maximum values.
- Bottom — Align signals with the minimum values of the y-axis range.

Autoscale X-axis limits — Scale x-axis range limits

off (default) | on

Scale x-axis range to fit all signal values. If **Axes scaling** is set to Auto, the data currently within the axes is scaled, not the entire signal in the data buffer.

X-axis Data range (%) — Percent of x-axis to use for plotting

100 (default) | integer in the range [1, 100]

Specify the percentage of the x-axis range to plot data on. For example, if you set this property to 100, plotted data uses the entire x-axis range.

X-axis Align — Alignment along x-axis

Center (default) | Top | Bottom

Specify where to align plotted data along the x-axis data range when **X-axis Data range** is set to less than 100 percent.

- Top — Align signals with the maximum values of the x-axis range.
- Center — Center signals between the minimum and maximum values.
- Bottom — Align signals with the minimum values of the x-axis range.

Style Properties

To open the Style dialog box, from the scope menu, select **View > Style**.

Figure color — Background color for window

black (default) | color

Background color for the scope.

Plot type — How to plot signal

Auto (default for Scope) | Line (default for Time Scope) | Stairs | Stem

When you select Auto, the plot type is a line graph for continuous signals, a stair-step graph for discrete signals, and a stem graph for Simulink message signals.

Axes colors — Background and axes color for individual displays

black (default) | color

Select the background color for axes (displays) with the first color palette. Select the grid and label color with the second color palette.

Preserve colors for copy to clipboard — Copy scope without changing colors

off (default) | on

Specify whether to use the displayed color of the scope when copying.

When you select **File > Copy to Clipboard**, the software changes the color of the scope to be printer friendly (white background, visible lines). If you want to copy and paste the scope with the colors displayed, select this check box.

Properties for line – Line to change

Channel 1 (default)

Select active line for setting line style properties.

Visible – Line visibility

on (default) | off

Show or hide a signal on the plot.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

Line – Line style

solid line (default style) | 0.75 (default width) | yellow (default color)

Select line style, width, and color.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

Marker – Data point marker style

None (default) | marker shape

Select marker shape.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to `double` for display.

For Each

Control block for For Each subsystem

Description

The For Each block serves as a control block for the For Each Subsystem block. Specifically, the For Each block enables the blocks inside the For Each subsystem to process the elements of either input signals or mask parameters independently. Each block inside this subsystem that has states maintains a separate set of states for each element or subarray that it processes. As the set of blocks in the subsystem processes the elements or subarrays, the subsystem concatenates the results to form output signals.

Use a For Each subsystem to iteratively compute outputs after changing inputs or mask parameters. To do so, configure the partitioning of input signals or mask parameters in the For Each block dialog box.

Partition Input Signals to the Subsystem

To specify which input signals to partition for each iteration in a For Each subsystem, use the **Input Partition** tab in the dialog box of the For Each block. When specifying a signal to be partitioned, specify the **Partition Dimension**, **Partition Width**, and **Partition Offset** parameters.

Partition Mask Parameters of the Subsystem

You can partition the mask parameters of a For Each Subsystem block. Partitioning is useful for systems that have identical structures in each iteration but different parameter values. In this case, changing the model to partition extra input signals for each parameter is cumbersome. Instead, add a mask parameter to a For Each subsystem. For more information, see "Create a Simple Mask". To select the mask parameter for partitioning, use the **Parameter Partition** tab of the For Each block dialog box. For more information, see "Select Partition Parameters" on page 1-626, below.

Concatenate Output

Define the dimension along which to concatenate the results by specifying the **Concatenation Dimension** in the **Output Concatenation** tab.

The results generated by the block for each subarray are stacked along the concatenation dimension. By default, dimension 1 (y-axis) is used, meaning that the results are stacked vertically. However, if you specify a concatenation dimension of 2, the results concatenate along the horizontal direction (x-

axis). Thus, if the process generates row vectors, then the concatenated result is a matrix in the first case and a row vector in the second case.

Select Partition Parameters

When selecting an input signal or subsystem mask parameter for partitioning, you need to specify how to decompose it into elements or subarrays for each iteration. Do this by setting integer values for the **Partition Dimension**, **Partition Width**, and **Partition Offset** parameters.

As an illustration, consider an input signal matrix A of the form:

The labels d_1 and d_2 , respectively, define dimensions 1 and 2. If you retain the default setting of 1 for both the partition dimension and the partition width, and 0 for the partition offset, then Simulink slices perpendicular to partition dimension 1 at a width equal to the partition width, that is one element:

Matrix A decomposes into these three row vectors:

$$\begin{bmatrix} A_{11} & A_{12} & A_{13} \end{bmatrix}$$

$$\begin{bmatrix} A_{21} & A_{22} & A_{23} \end{bmatrix}$$

$$\begin{bmatrix} A_{31} & A_{32} & A_{33} \end{bmatrix}$$

If instead you specify 2 as the partition dimension, Simulink slices perpendicular to dimension 2 to form three column vectors:

$$\begin{bmatrix} A_{11} \\ A_{21} \\ A_{31} \end{bmatrix} \quad \begin{bmatrix} A_{12} \\ A_{22} \\ A_{32} \end{bmatrix} \quad \begin{bmatrix} A_{13} \\ A_{23} \\ A_{33} \end{bmatrix}$$

In addition to setting the **Partition Dimension** to 2, if you set the **Partition Width** to 2 and the **Partition Offset** to -1, Simulink uses two overlapping 3-by-2 partitions for processing.

For an example using the **Partition Offset** parameter, see “Neighborhood Processing Using For Each Subsystems” on page 13-485.

By default, all partitions of the input signal or mask parameter are processed. To process a subset of the partitions, enter the number of partitions to process as the **Number of iterations**. In the matrix examples above, if **Partition Offset** is set to 0 (the default) and **Number of iterations** is set to 2, only the first 2 rows or columns of the input matrix A are processed.

Note Only signals are considered one-dimensional in Simulink. Mask parameters are row or column vectors, according to their orientation. To partition a row vector, specify the partition dimension as 2 (along the columns). To partition a column vector, specify the partition dimension as 1 (along the rows).

Ports

Output

Partition index — Index of current partition

scalar

Index of current partition (starting at zero), returned as a scalar.

Dependencies

To enable this port, select **Show partition index output port**.

Data Types: int32 | double

Parameters

Input Partition Tab

Select each input signal you want to partition and specify the corresponding **Partition Dimension**, **Partition Width**, and **Partition offset** parameters. See the Inport block reference page for more information.

Port — List of input ports

no default (default) | input port name

This property is read-only.

List of input ports connected to the For Each Subsystem block.

Partition — Select input port signals to partition

off (default) | on

Select input port signals connected to the For Each Subsystem block to partition into subarrays or elements. For each port listed in the **Port** column, select the corresponding check box to partition that signal.

Programmatic Use

Block Parameter: InputPartition

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Partition Dimension — Specify dimension

1 (default) | 2 | positive integer

Specify the dimension through which to slice the selected input signal array. The resulting slices are perpendicular to the dimension that you specify. The slices partition the array into subarrays or elements, as appropriate.

1

Slice input array along the columns.

2

Slice input array along the rows.

n

Slice input array along dimension n.

Dependencies

To enable this parameter, select **Partition** for the relevant input port.

Programmatic Use

Block Parameter: InputPartitionDimension

Type: character vector

Values: '1' | '2' | '<positive integer>'

Default: '1'

Partition Width — Specify width

1 (default) | positive integer

Specify the width of each partition slice of the selected input signal.

Dependencies

To enable this parameter, select **Partition** for the relevant input port.

Programmatic Use

Block Parameter: InputPartitionWidth

Type: character vector

Values: '1' | '<integer>'

Default: '1'

Partition Offset — Specify partition offset

0 (default) | integer

Specify the offset for each partition slice of the selected input signal.

0

No offset between partition slices, that is, partition slices have no gaps between them and do not overlap.

integer

Specify partition offset, using a positive integer to specify a gap between slices or a negative integer to indicate an overlap. The sum of the **Partition Width** and the **Partition Offset** must be a positive integer.

For example, a **Partition Width** of 3 and a **Partition Offset** of -2 indicates that each 3-element slice overlaps its neighboring slices by 2 elements; whereas a **Partition Width** of 2 and a **Partition Offset** of 1 indicates that there is a 1-element-wide gap between each pair of neighboring 2-element-wide slices.

Dependencies

To enable this parameter, select **Partition** for the relevant input port.

Programmatic Use**Block Parameter:** InputPartitionOffset**Type:** character vector**Values:** '0' | '<integer>'**Default:** '0'**Parameter Partition Tab**

Select each mask parameter you want to partition and specify the corresponding **Partition Dimension** and **Partition Width** parameters.

Parameter — List of mask parameters

parameter name

This property is read-only.

List of mask parameters for the For Each Subsystem block. Mask parameters appear in the list only if you have added an editable parameter to the mask of the For Each Subsystem block. See “Create Block Masks”.

Partition — Select mask parameters to partition

off (default) | on

Select mask parameters for the For Each Subsystem block to partition into subarrays or elements. For each port listed in the **Parameter** column, select the corresponding check box to partition that mask parameter.

Programmatic Use**Block Parameter:** SubsysMaskParameterPartition**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'

Partition Dimension — Specify dimension

1 (default) | 2 | positive integer

Specify the dimension through which to slice the selected mask parameter array. The resulting slices are perpendicular to the dimension that you specify. The slices partition the array into subarrays or elements, as appropriate.

1

Slice mask parameter array along the columns.

2

Slice mask parameter array along the rows.

n

Slice mask parameter array along dimension n.

Dependencies

To enable this parameter, select **Partition** for the relevant mask parameter.

Programmatic Use**Block Parameter:** SubsysMaskParameterPartitionDimension**Type:** character vector**Values:** '1' | '<integer>'**Default:** '1'**Partition Width — Specify partition width**

1 (default) | positive integer

Specify the width of each partition slice of the selected mask parameter array.

Dependencies

To enable this parameter, select **Partition** for the relevant mask parameter.

Programmatic Use**Block Parameter:** SubsysMaskParameterPartitionWidth**Type:** character vector**Values:** '1' | '<positive integer>'**Default:** '1'**Output Concatenation Tab**

For each output port, specify the dimension along which to stack (concatenate) the For Each Subsystem block results. See the Outputport block reference page for more information.

Port — List of output ports

none (default) | output port name

This property is read-only.

List of output ports connected to the For Each Subsystem block.

Concatenation Dimension — Specify dimension

1 (default) | 2 | positive integer

For each output port, specify the dimension along which to stack the results of the For Each Subsystem block .

1

Stack the results in the d_1 direction, that is, vertically. If the block generates column vectors, the concatenation process results in a single column vector. If the block generates row vectors, the concatenation process results in a matrix.

2

Stack the results in the d_2 direction, that is, horizontally. If the block generates row vectors, the concatenation process results in a single row vector. If the block generates row vectors, the concatenation process results in a matrix.

n

Stack the results in the d_n direction.

Programmatic Use

Block Parameter: OutputConcatenationDimension

Type: character vector

Values: '1' | '<integer>'

Default: '1'

Other Parameters

Show partition index output port (zero-based indexing) — Control display of output port

off (default) | on

Control display of output port for partition index.

off

Hide output port.

on

Display output port on block.

Programmatic Use

Block Parameter: ShowIterationIndex

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Partition index output data type — Specify partition index data type

'int32' (default) | 'double'

Specify partition index data type for output port.

int32

Select signed 32-bit integer.

double

Select double real.

Dependencies

To enable this parameter, select **Show partition index output port**.

Programmatic Use**Block Parameter:** IterationIndexDataType**Type:** character vector**Values:** 'int32' | 'double'**Default:** 'int32'**Number of iterations — Specify number of partitions to process**

-1 (default) | integer

To process a subset of data, specify the number of partition slices of the input signal or mask parameter array to process, else specify -1 to process all slices. The number must not be greater than the total number of slices available.

-1

Process all slices

integer

Number of slices to process

For example, a **Number of iterations** of 3 indicates that only the first 3 slices are to be processed.

Programmatic Use**Block Parameter:** SpecifiedNumIters**Type:** character vector**Values:** '-1' | '<integer>'**Default:** '-1'**See Also****Blocks**

For Each Subsystem

Apply algorithm to individual elements or subarrays of input signals or mask parameters

Library: Simulink / Ports & Subsystems
HDL Coder / Ports & Subsystems

Description

The For Each Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that repeats execution during a simulation time step on each element or subarray of an input signal or mask parameter array.

Note A model utilizing a local solver cannot be placed inside For Each Subsystem.

The set of blocks within the subsystem represents the algorithm applied to a single element or subarray of the original signal or mask parameter array. Inside the subsystem, each block that has states maintains separate sets of states for each element or subarray that it processes. Consequently, the operation of this subsystem is similar in behavior to copying the contents of the subsystem for each element in the original input signal or mask parameter array and then processing each element using its respective copy of the subsystem. As the set of blocks in the subsystem processes the elements or subarrays, the subsystem concatenates the results to form output signals.

Configuring the Subsystem

The For Each Subsystem block contains a For Each block that acts as a control block for the subsystem. Specify the parameters of the For Each block to configure the decomposition of the subsystem inputs or mask parameters into elements or subarrays and to configure the concatenation of the individual results into output signals. The block parameters **Partition Dimension** and **Partition Width** specify the dimension through which to slice the input signal or mask parameter array and the width of each slice, respectively. To partition a row vector, specify the **Partition Dimension** as 2. To partition a column vector, specify the **Partition Dimension** as 1. Use the parameter **Partition Offset** to specify a gap or an overlap between partitions. Specify a **Number of iterations** to limit processing to a subset of the data. To learn more about the block parameters, see For Each.

Partition Input Signals to the Subsystem

To specify which input signals to partition for each iteration in a For Each subsystem, use the **Input Partition** tab in the dialog box of the For Each block. When specifying a signal to be partitioned, specify the **Partition Dimension**, **Partition Width**, and **Partition Offset** parameters.

Partition Mask Parameters of the Subsystem

You can partition the mask parameters of a For Each Subsystem block. Partitioning is useful for systems that have identical structures in each iteration but different parameter values. In this case, changing the model to partition extra input signals for each parameter is cumbersome. Instead, add a mask parameter to a For Each subsystem. For more information, see “Create a Simple Mask”. To select the mask parameter for partitioning, use the **Parameter Partition** tab of the For Each block dialog box. For more information, see “Select Partition Parameters” on page 1-626, below.

Concatenate Output

Define the dimension along which to concatenate the results by specifying the **Concatenation Dimension** in the **Output Concatenation** tab.

The results generated by the block for each subarray are stacked along the concatenation dimension. By default, dimension 1 (y-axis) is used, meaning that the results are stacked vertically. However, if you specify a concatenation dimension of 2, the results concatenate along the horizontal direction (x-axis). Thus, if the process generates row vectors, then the concatenated result is a matrix in the first case and a row vector in the second case.

Select Partition Parameters

When selecting an input signal or subsystem mask parameter for partitioning, you must specify how to decompose it into elements or subarrays for each iteration. Set integer values for the **Partition Dimension**, **Partition Width**, and **Partition Offset** parameters.

As an illustration, consider an input signal matrix A of the form:

The labels d_1 and d_2 define dimensions 1 and 2, respectively. If you retain the default setting of 1 for both the partition dimension and the partition width and 0 for the partition offset, then Simulink slices perpendicular to partition dimension 1 at a width equal to the partition width, that is one element:

Matrix A decomposes into these three row vectors:

$$\begin{bmatrix} A_{11} & A_{12} & A_{13} \end{bmatrix}$$

$$\begin{bmatrix} A_{21} & A_{22} & A_{23} \end{bmatrix}$$

$$\begin{bmatrix} A_{31} & A_{32} & A_{33} \end{bmatrix}$$

If you specify 2 as the partition dimension instead, Simulink slices perpendicular to dimension 2 to form three column vectors:

$$\begin{bmatrix} A_{11} \\ A_{21} \\ A_{31} \end{bmatrix} \quad \begin{bmatrix} A_{12} \\ A_{22} \\ A_{32} \end{bmatrix} \quad \begin{bmatrix} A_{13} \\ A_{23} \\ A_{33} \end{bmatrix}$$

In addition to setting the **Partition Dimension** to 2, if you set the **Partition Width** to 2 and the **Partition Offset** to -1, Simulink uses two overlapping 3-by-2 partitions for processing.

$$\begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ A_{31} & A_{32} & A_{33} \end{bmatrix}$$

For an example using the **Partition Offset** parameter, open the model `slexForEachOverlapExample`.

By default, all partitions of the input signal or mask parameter are processed. To process a subset of the partitions, enter the number of partitions to process as the **Number of iterations**. In the matrix examples above, if **Partition Offset** is set to 0 (the default) and **Number of iterations** is set to 2, only the first 2 rows or columns of the input matrix A are processed.

Note Only signals are considered one-dimensional in Simulink. Mask parameters are row or column vectors, according to their orientation. To partition a row vector, specify the partition dimension as 2, along the columns. To partition a column vector, specify the partition dimension as 1, along the rows.

Code Reuse Support

For certain models, the For Each Subsystem block improves code reuse in Simulink Coder generated code. Consider a model containing two reusable Atomic Subsystem blocks with the same scalar algorithm applied to each element of the signal. If the input signal dimensions of these subsystems are different, Simulink Coder generated code includes two distinct functions. You can replace these two subsystems with two identical For Each Subsystem blocks that are configured to process each

element of their respective inputs using the same algorithm. In this case, Simulink Coder generated code consists of a single function parameterized by the number of input signal elements. This function is invoked twice, once for each unique instance of the For Each Subsystem block in the model. For each of these cases, the input signal elements have different values.

Multicore Execution Support

When you simulate your model in rapid accelerator mode, Simulink uses multicore execution for faster simulation of For Each subsystems. Simulink automatically profiles each eligible For Each subsystem the first two time steps it runs in rapid accelerator mode to compare parallel and serial execution times. Simulink then designates the For Each subsystem for parallel, multicore execution in subsequent time steps of the simulation run if doing so would speed up execution time. For nested For Each subsystems, multicore execution applies only to the top-level subsystem. Multicore execution does not apply to For Each subsystems containing continuous states or Function Caller blocks.

To suppress multicore execution for a given For Each subsystem, set the `MultithreadedSim` parameter of the For Each block within the subsystem to `'off'`.

```
set_param(ForEachBlockName, 'MultithreadedSim', 'off')
```

Note that this is a parameter of the For Each block within the subsystem, not the For Each Subsystem block itself. To suppress multicore execution for all For Each subsystems in a model, set the `MultithreadedSim` parameter of the model to `'off'`.

```
set_param(ModelName, 'MultithreadedSim', 'off')
```

To re-enable multicore execution, set the relevant `MultithreadedSim` parameter to its default value of `'auto'`.

For an example, see “Multithreaded Simulation Using For Each Subsystem”.

Note If you simulate your model in rapid accelerator mode or generate code from your model, and you partition mask parameters in a For Each subsystem, then any expression inside the For Each subsystem that references a partitioned parameter must be a tunable expression. See “Tunable Expression Limitations” (Simulink Coder).

S-Function Support

The For Each Subsystem block supports both C-MEX S-functions and Level-2 MATLAB S-functions, provided that the S-function supports multiple execution instances using one of these techniques:

- A C-MEX S-function must declare `ssSupportsMultipleExecInstances(S, true)` in the `mdlSetWorkWidths` method.
- A Level-2 MATLAB S-function must declare `block.SupportsMultipleExecInstances = true` in the `setup` method.

If you use these specifications:

- Do not cache run-time data such as `DWork` and Block I/O using global or persistent variables or within the user data of the S-function.
- In a For Each Subsystem block, every S-function execution method from `mdlStart` up to `mdlTerminate` is called once for each element processed by the S-function. Consequently, you

must make sure not to free the same memory on repeated calls to `mdlTerminate`. For example, consider a C-MEX S-function that allocates memory for a run-time parameter within `mdlSetWorkWidths`. The memory only needs to be freed once in `mdlTerminate`. As a solution, set the pointer to be empty after the first call to `mdlTerminate`.

Limitations

For information regarding limitations of the For Each Subsystem block, see “Limitations of For-Each Subsystems”.

Ports

Input

In — Signal input to Subsystem block

scalar | vector | matrix

Signal input to a Subsystem block, specified as a scalar, vector, or matrix. Placing an Inport block in a Subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to receive signals from the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Out — Signal output from Subsystem block

scalar | vector | matrix

Signal output from a Subsystem block, returned as a scalar, vector, or matrix. Placing an Outport block in a Subsystem block adds an external output port to the block. The port label matches the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a half ^a integer ^a single ^a
Direct Feedthrough	no

Variable-Size Signals	no
Zero-Crossing Detection	no

^a Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

When you generate HDL code for the For Each Subsystem, the code generator attempts to use a **for-generate** loop that iterates through elements of the input and output signals. The for-generate loop improves readability and reduces the number of lines of code, which could otherwise be hundreds of lines of code for large vector signals. The subsystem supports vector and 2D matrix input signals. See “Generate HDL Code for Blocks Inside For Each Subsystem” (HDL Coder).

You can use a nonzero partition offset for HDL code generation. The code generator supports a scalar, vector, or matrix as mask parameter values. You can generate HDL code for element, 1D, and 2D partitions of mask parameters inside a For Each Subsystem block. Inside the For Each Subsystem block, use the mask parameter as the **Constant value** parameter in Constant blocks or as the **Gain** parameter in Gain blocks.

Limitations

- You cannot use the For Each Subsystem block as the DUT.
- You must clear the **Show partition index output port (zero-based indexing)** check box on the For Each block for HDL code generation.
- You cannot set the `SpecifiedNumIters` parameter of the For Each block for HDL code generation. HDL code generation returns an error when the value of `SpecifiedNumIters` is not equal to the default value of -1.

HDL Architecture

Architecture	Description
Module (default)	Generate code for the subsystem and the blocks within the subsystem.
BlackBox	Generate a black box interface. The generated HDL code includes only the input/output port definitions for the subsystem. Therefore, you can use a subsystem in your model to generate an interface to existing, manually written HDL code. The black-box interface generation for subsystems is similar to the Model block interface generation without the clock signals.
No HDL	Remove the subsystem from the generated code. You can use the subsystem in simulation, however, treat it as a “no-op” in the HDL code.

Black Box Interface Customization

For the BlackBox architecture, you can customize port names and set attributes of the external component interface. See “Customize Black Box or HDL Cosimulation Interface” (HDL Coder).

HDL Block Properties

General	
AdaptivePipelining	Automatic pipeline insertion based on the synthesis tool, target frequency, and multiplier word-lengths. The default is <code>inherit</code> . See also “AdaptivePipelining” (HDL Coder).
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . See also “BalanceDelays” (HDL Coder).
ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <code>inherit</code> . See also “ClockRatePipelining” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is <code>0</code> . For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>off</code> . See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is <code>none</code> . See also “DSPStyle” (HDL Coder).
FlattenHierarchy	Remove subsystem hierarchy from generated HDL code. The default is <code>inherit</code> . See also “FlattenHierarchy” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see “OutputPipeline” (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is <code>0</code> . See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is <code>0</code> , which implements fully parallel data paths. See also “Streaming” (HDL Coder).

Target Specification

This block cannot be the DUT, so the block property settings in the **Target Specification** tab are ignored.

Complex Data Support

The block does not support complex data signals for HDL code generation. To input complex signals, convert the complex signal to an array of signals, and then input to the block. To learn more, see “Generate HDL Code for Blocks Inside For Each Subsystem” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type support depends on block implementation.

For Iterator

Control block for For Iterator subsystem

Description

The For Iterator block, when placed in a Subsystem block, repeats the execution of a subsystem during the current time step until an iteration variable exceeds the specified iteration limit. You can use this block to implement the block diagram equivalent of a `for` loop in a programming language.

The output of a For Iterator Subsystem block cannot be a function-call signal. Simulink displays an error message when the model updates.

Ports

Input

Number of Iterations — External value for iterator variable

scalar | vector, size 1 | matrix, size 1x1

- The input port accepts data of mixed numeric types.
- If the input port value is non-integer, it is first truncated to an integer.
- Internally, the input value is cast to an integer of the type specified for the iteration variable output port.
- If no output port is specified, the input port value is cast to type `int32`.
- If the input port value exceeds the maximum value of the output port type, the overflow wraps around.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

Iterator value — Value of iterator variable during time step

scalar | vector, size 1 | matrix, size 1-by-1

Selecting the **Show iteration variable** parameter check box adds an output port to this block.

Data Types: `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Parameters

States when starting — Select block states between time steps

`held` (default) | `reset`

Select how to handle block states between time steps.

`held`

Hold block states between time steps. Block state values persist across time steps.

reset

Reset block states to their initial values at the beginning of each time step and before the first iteration loop.

Programmatic Use

Block Parameter: ResetStates

Type: character vector

Values: 'held' | 'reset'

Default: 'held'

Iteration limit source — Select source for number of iterations

internal (default) | external

Select source for number of iterations.

internal

Value of the **Iteration limit** parameter determines the number of iterations.

external

Value of the signal at the **N** port determines the number of iterations. The signal source must reside outside the For Iterator Subsystem block.

Dependencies

Selecting `internal` displays and enables the **Iteration limit** parameter. Selecting `external` adds an input port labeled **N**.

Programmatic Use

Block Parameter: IterationSource

Type: character vector

Values: 'internal' | 'external'

Default: 'internal'

Iteration limit — Specify number of iterations

5 (default) | integer

Specify the number of iterations. This parameter supports storage classes. You can define the named constant in the base workspace of the Model Explorer as a `Simulink.Parameter` object of the built-in storage class `Define (custom)` type.

5

Iterate blocks in the For Iterator Subsystem block 5 times.

integer

Specify an integer or a named constant variable.

Dependencies

To enable this parameter, select `internal` from the **Iteration limit source** drop-down list.

Programmatic Use

Block Parameter: IterationLimit

Type: character vector

Values: '5' | '<integer>'

Default: '5'

Set Next i (iteration variable) externally – Control display of input port

off (default) | on

Control display of an input port.

off

Remove input port.

on

Add input port labeled **Next_i** for connecting to an external iteration variable source. The value of the input at the current iteration is used as the value of the iteration variable at the next iteration.

Dependencies

To enable this parameter, select the **Show iteration variable** parameter which also displays an output port labeled **1:N**.

Programmatic Use**Block Parameter:** ExternalIncrement**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Show iteration variable – Control display of output port**

on (default) | off

Control the display of an output port with the current iterator value for a loop.

on

Add output port labeled **1:N** to the For Iterator block.

off

Remove output port.

Dependencies

Selecting this parameter enables the **Set next i (iteration variable) externally** parameter.

Programmatic Use**Block Parameter:** ShowIterationPort**Type:** character vector**Value:** 'on' | 'off'**Default:** 'on'**Index mode – Select initial iteration number**

One-based (default) | Zero-based

Select an initial iteration number of 0 or 1.

One-based

Iteration number starts at one.

Zero-based

Iteration number starts at zero.

Programmatic Use**Block Parameter:** IndexMode**Type:** character vector**Values:** 'One-based' | 'Zero-based'**Default:** 'One-based'**Iteration variable data type — Select data type**

int32 (default) | uint32 | int16 | uint16 | int8 | uint8 | double

Set the data type for the iteration value output from the iteration number port.

int32

Set data type to int32.

uint32

Set data type to uint32.

int16

Set data type to int16.

uint16

Set data type to uint16.

int8

Set data type to int8.

uint8

Set data type to uint8.

double

Set data type to double.

Programmatic Use**Block Parameter:** IterationVariableDataType**Type:** character vector**Value:** 'int32' | 'uint32' | 'int16' | 'uint16' | 'int8' | 'uint8' | 'double'**Default:** 'int32'**See Also****Blocks**

For Iterator Subsystem | Subsystem

Iterator Subsystem Execution

Introduced before R2006a

For Iterator Subsystem

Repeat subsystem execution during simulation time step for specified number of iterations

Library: Simulink / Ports & Subsystems

Description

The For Iterator Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that repeats the execution during a simulation time step for a specified number of iterations. The number of iterations is controlled by a For Iterator block inside the subsystem. For an example, see `ex_for_iterator_block`.

When using simplified initialization mode, if you place a block that needs elapsed time (such as a Discrete-Time Integrator block) in a For Iterator Subsystem block, Simulink displays an error.

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a Subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Output

Out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outputport block in a Subsystem block adds an output port from the block. The port label on the Subsystem block is the name of the Outputport block.

Use Outputport blocks to send signals to the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a half ^a integer ^a single ^a string ^a
Direct Feedthrough	no
Multidimensional Signals	limited ^a
Variable-Size Signals	limited ^a
Zero-Crossing Detection	no

^a Actual data type or capability support depends on block implementation.

Introduced before R2006a

From

Accept input from Goto block

Library: Simulink / Signal Routing
HDL Coder / Signal Routing

Description

The From block accepts a signal from a corresponding Goto block, then passes it as output. The data type of the output is the same as that of the input from the Goto block. From and Goto blocks allow you to pass a signal from one block to another without actually connecting them.

For example, this model uses a Goto block and a From block.

An equivalent model passes the Sine Wave block signal directly to the Gain block.

A From block can receive its signal from only one Goto block, although a Goto block can pass its signal to more than one From block.

To associate a Goto block with a From block, enter the Goto block tag in the **Goto Tag** parameter.

The visibility of a Goto block tag determines the From blocks that can receive its signal. For more information, see [Goto and Goto Tag Visibility](#). The block indicates the visibility of the Goto block tag:

- A local tag name is enclosed in brackets ([]).
- A scoped tag name is enclosed in braces ({}).
- A global tag name appears without additional characters.

The From block supports signal label propagation. For more information, see [“Signal Label Propagation”](#).

Ports

Output

Port_1 — Signal from connected Goto block

scalar | vector | matrix | N-D array

Signal from connected Goto block, output with the same dimensions and data type as the input to the Goto block.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Parameters

Goto Tag — Tag of the Goto block that forwards its signal to this block

A (default) | <More Tags...> | ...

Specify the tag of the Goto block that forwards its signal to this From block. To change the tag, select a new tag from the drop-down list.

The drop-down list displays the Goto tags that the From block can currently see. An item labeled <More Tags...> appears at the end of the list the first time you display the list in a Simulink session. Selecting this item causes the block to update the tags list to include the tags of Goto blocks residing in library subsystems referenced by the model containing this From block. Simulink software displays a progress bar while building the list of library tags. Simulink saves the updated tags list for the duration of the Simulink session or until the next time you select the adjacent **Update Tags** button. You need to update the tags list again in the current session only if the libraries referenced by the model have changed since the last time you updated the list.

Tip If you use multiple From and Goto Tag Visibility blocks to refer to the same Goto tag, you can simultaneously rename the tag in all of the blocks. To do so, use the **Rename All** button in the Goto block dialog box. Alternatively, when you change the tag on the Goto block icon, propagate the new name to all corresponding From and Goto Tag Visibility blocks by pressing **Shift+Enter**.

To find the relevant Goto block, use the **Goto Source** hyperlink in the From block dialog box.

Programmatic Use

Block Parameter: GotoTag

Type: character vector

Values: 'A' | ...

Default: 'A'

Update Tags — Update list of visible tags

Updates the list of tags visible to this From block, including tags residing in libraries referenced by the model containing this From block. Update the tags list again in the current session only if the libraries referenced by the model have changed since the last time you updated the list.

Goto Source — Path to connected Goto block

block path

Path of the Goto block connected to this From block. Clicking the path displays and highlights the Goto block in your model.

In the Simulink Editor, selecting the From block highlights the corresponding Goto and Goto Tag Visibility blocks.

When a corresponding Goto or Goto Tag Visibility block is not in the current diagram, the Subsystem block that contains the block is highlighted.

To show a corresponding block in an open diagram or new tab, select the From block and pause on the ellipsis. Then, select **Related Blocks**  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list of related blocks by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Icon Display — Text to display on block icon

Tag | Tag and signal name | Signal name

Specifies the text to display on the From block icon. The options are the block tag, the name of the signal that the block represents, or both the tag and the signal name.

Programmatic Use

Block Parameter: IconDisplay

Type: character vector

Values: 'Signal name' | 'Tag' | 'Tag and signal name'

Default: 'Tag'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About

Search for Goto Tags

To search for Goto tags in libraries referenced by the model when opening the From block dialog box, use the FollowLinksWhenOpeningFromGotoBlocks model parameter with the set_param function.

- 'off' — Do not search for Goto tags (default).
- 'on' — Search for Goto tags.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. See also “Required HDL Settings for Goto and From Blocks” (HDL Coder).

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

“Signal Label Propagation”

Introduced before R2006a

From File

Load data from MAT file into Simulink model

Library: Simulink / Sources

Description

The From File block reads data into a Simulink model from a MAT file and provides the data as a signal or nonvirtual bus at the block output. You can load data from a MAT file that is on or off the MATLAB path. A model can contain multiple From File blocks that load data from the same MAT file.

You can specify how the block constructs the output from the data in the file, including the sample time for the output, interpolation and extrapolation behavior, and whether to use zero-crossing detection.

The From File block icon shows the name of the MAT file that supplies the data to the block. For example, if you use the From File block to load data from the file `myData.mat`, the block displays `myData.mat`.

MAT File Data

The From File block can load data from a MAT file that is stored in a `timeseries` object or in an array where the first row contains time data and subsequent rows contain data for a scalar or vector signal. Loading data stored in a `timeseries` object supports a wider range of data and output types and requires that the MAT file is Version 7.3.

Note Logging outputs or states or a signal connected to a To Workspace block using the Array format generates an array in a different format than the From File block expects. In the Array format for logging, the first column contains time values, and in the array format for the From File block, the first row contains time values. The From File block and To File block use the same array format.

Data Consideration	timeseries Format	Array Format
Supported signal data types	<ul style="list-style-type: none"> Any built-in data types except <code>half</code>, <code>int64</code>, and <code>uint64</code> Enumerated data type Fixed-point data type with up to a 32-bit word length 	double
Signal data complexity	Real or complex	Real
Signal data requirements	Must not contain NaN, Inf, or -Inf values	Must not contain NaN, Inf, or -Inf values

Data Consideration	timeseries Format	Array Format
Type of output	<ul style="list-style-type: none"> Scalar, vector, or multidimensional signal Bus 	Scalar or vector signal
Time data requirements	<ul style="list-style-type: none"> Data type must be double Values must increase monotonically 	<ul style="list-style-type: none"> Data type must be double Values must increase monotonically
MAT file version	Version 7.3	All versions

The From File block loads data from only one variable in the MAT file, regardless of the number of variables the MAT file contains. When you load data from a Version 7.3 MAT file that contains multiple variables, the From File block loads the data in the variable that is first alphabetically. The ordering algorithm used by Version 7.0 and earlier MAT files is more complicated, so ensure that the MAT file only contains data for a single variable when you load data from a Version 7.0 or earlier MAT file.

MAT File Version

The version of the MAT file also affects how the From File block loads the data. When you load data from a Version 7.3 MAT file, data is loaded incrementally during simulation. When you load data from a Version 7.0 or earlier MAT file, all the data is loaded into memory at the start of simulation.

To convert a MAT file to Version 7.3, use the `load` function to load the data in the Version 7.0 or earlier MAT file into the base workspace, then save the data to a Version 7.3 MAT file using the `save` function with the version specified as `'-v7.3'`. For example, suppose you want to convert the file `myData.mat` that contains the variable `inputData` to Version 7.3. Use these commands:

```
load('myData.mat');
save('myData.mat','inputData','-v7.3');
```

For more information, see “MAT-File Versions”.

Ports

Output

Port_1 — Output created using MAT file data

scalar | vector | matrix | array

Output created using data loaded from the specified MAT file. Depending on the data you load, the output may be a scalar or multidimensional signal or a nonvirtual bus. The From File block supports loading real and complex data of all built-in data types except `half`, `int64`, and `uint64`.

The From File block does not support loading data for an array of buses.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

File name — MAT file name or path to MAT file

`untitled.mat` (default) | MAT file name | path to MAT file

MAT file name or path to MAT file with data you want to load. Specify the path to the file when the file is not on the MATLAB path or in the current working directory.

You can type the path or file name into the text box, or you can browse to the MAT file by clicking the

Browse for a MAT-file button.  On UNIX® systems, the path can start with a tilde (~), which indicates your home folder.

You cannot load data from a file to which the model logs data.

Tips

- The From File block supports loading data from a file created using a To File block without any modification to the data or file.
- To determine the current working directory, enter `pwd` into the MATLAB Command Window.
- For information about data requirements for C/C++ code generation with the From File block, see “Code Generation” on page 1-661.

Programmatic Use

Block Parameter: FileName

Type: character vector

Values: MAT file name | path to MAT file

Default: 'untitled.mat'

Output data type — Data type of data in MAT file

Inherit: auto (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | boolean | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class_name> | Bus: <bus_object> | <data type expression>

Data type of the data in the MAT file loaded by the From File block. By default, the From File block inherits the output signal data type from the data in the file or from a downstream block that defines the data type for the signal. An error occurs if the data type of the data in the MAT file does not match the inherited data type.

When you load data for a scalar or multidimensional signal, you can choose to inherit the output data type, or you can specify the output data type to match the data type of the data in the MAT file.

To load data for a bus, set the **Output data type** to Bus: <bus object> and specify the name of the Simulink.Bus object that defines the output bus.

To load enumerated data, set the **Output data type** to Enum: <class name> and specify the name of the enumeration class that defines the enumerated data values.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: auto' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16,0)' |

'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>' | '<data type expression>'

Default: 'Inherit: auto'

Sample time — Output sample period and optional time offset

0 | scalar | vector

The **Sample time** parameter specifies when the block computes a new output value during simulation. For details, see “Specify Sample Time”.

Specify the **Sample time** parameter as a scalar when you do not want the output to have a time offset. To add a time offset to the output, specify the **Sample time** parameter as a 1-by-2 vector where the first element is the sampling period and the second element is the offset.

By default, the **Sample time** parameter value is 0, which indicates continuous sample time with no time offset. For a discrete signal, specify the **Sample time** as the discrete sampling interval. For example, specify the **Sample time** as 0.1 to model a discrete signal sampled every 100ms. Specify the **Sample time** as -1 to inherit the value.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

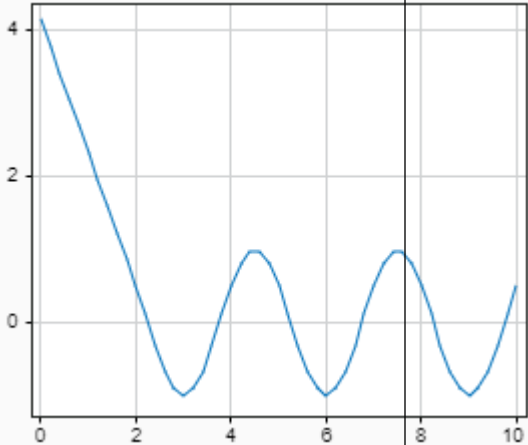

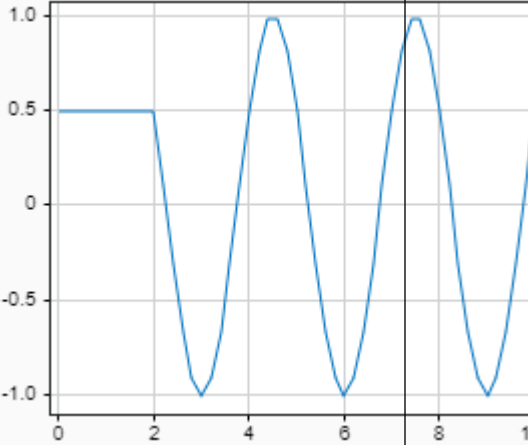

Values: scalar | vector

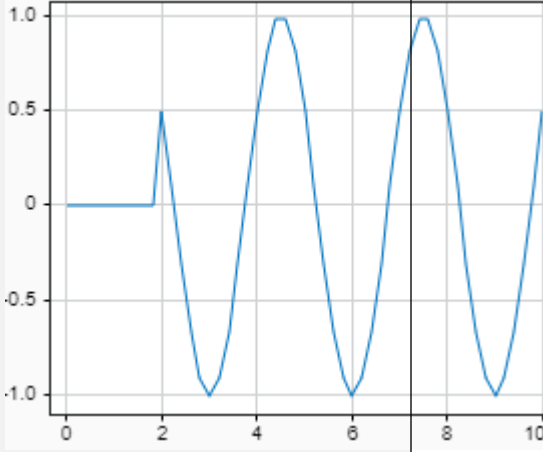

Default: '0'

Data extrapolation before first data point — Method to determine block output before first data point in MAT file

Linear extrapolation (default) | Hold first value | Ground value

Extrapolation method used to determine output values for simulation times before the first sample in the MAT file data.

Method	Description	Example
<p>Linear extrapolation</p>	<p>How the block determines the output value depends on the type of data in the MAT file.</p> <ul style="list-style-type: none"> • For double data, the From File block linearly extrapolates the output value using the first two samples. • For Boolean data, the From File block uses the first value in MAT file data for the output value. • For all other built-in data types, the From File block: <ol style="list-style-type: none"> 1 Upcasts the data to double. 2 Linearly extrapolates the output value using the first two samples in the MAT file data. 3 Downcasts the extrapolated data value to the original data type. <p>If the MAT file data only contains one sample, the From File block provides that value at the output.</p> <p>Do not use the Linear extrapolation option when the From File block loads enumerated or fixed-point data.</p> <p>The extrapolation setting is applied to all signals in a bus. If any signal in the bus contains enumerated or fixed-point data, do not use the Linear extrapolation option.</p>	
<p>Hold first value</p>	<p>The From File block uses the first data value in the MAT file as the output value.</p>	

Method	Description	Example
Ground value	<p>The From File block output value depends on the type of data in the MAT file.</p> <ul style="list-style-type: none"> • Built-in numeric types — 0 • Boolean — false • Fixed-point data types — Representation for value of 0, which may not be exactly 0 due to scaling and limited precision. • Enumerated data types — Default value 	

Tips

To generate code that builds ERT or GRT targets or uses SIL or PIL simulation modes, specify **Data extrapolation before first data point** as **Linear extrapolation**. For more information about C/C++ code generation with the From File block, see “Code Generation” on page 1-661.

Programmatic Use

Block Parameter: ExtrapolationBeforeFirstDataPoint

Type: character vector

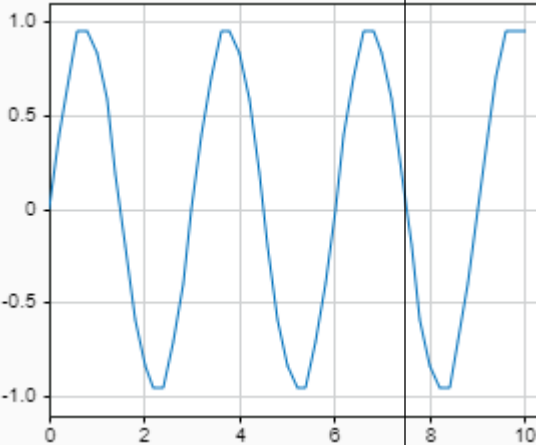

Values: 'Linear extrapolation' | 'Hold first value' | 'Ground value'

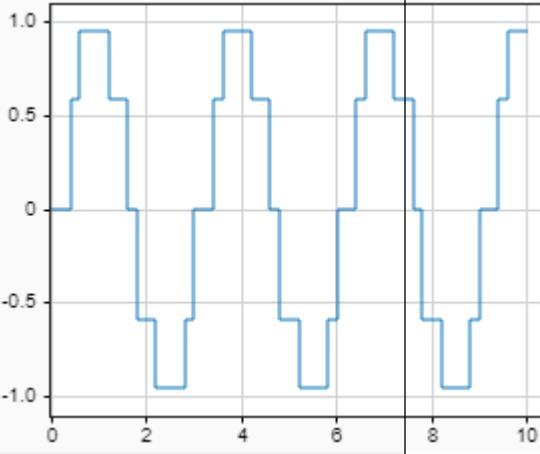

Default: 'Linear extrapolation'

Data interpolation within time range — Interpolation method

Linear interpolation (default) | Zero order hold

Interpolation method used to determine output values for simulation times between samples in the MAT file data.

Method	Description	Example
<p>Linear interpolation</p>	<p>How the block determines the output value depends on the type of data in the MAT file.</p> <ul style="list-style-type: none"> • For double data, the From File block linearly interpolates the output value using data values before and after the simulation time that needs an output value. • For all other built-in numeric data types, the From File block: <ol style="list-style-type: none"> 1 Upcasts the data to double. 2 Linearly interpolates the output value using the MAT file data values before and after the simulation time that needs an output value. 3 Downcasts the extrapolated data value to the original data type. • For Boolean data, if the simulation time is between two workspace data points with different values, the From File block positions the value transition halfway between the MAT file data points. For example, if the data transitions from true to false, the From File block provides an output value of true for simulation times in the first half of the interval between the MAT file data points and an output value of false for simulation times in the latter half of the interval. <p>If the MAT file data only contains one sample, the From File block provides that value at the output.</p> <p>Do not use the Linear interpolation option when the From File block loads enumerated data.</p> <p>The interpolation setting is applied to all signals in a bus. If any signal in the bus contains enumerated data, do not use the Linear interpolation option.</p>	

Method	Description	Example
Zero order hold	The From File block holds each data value from one sample to the next. The output value for a simulation time between two samples in the MAT file data is the value of the sample that precedes the simulation time.	

Tips

To generate code that builds ERT or GRT targets or uses SIL or PIL simulation modes, specify **Data interpolation within time range** as `Linear interpolation`. For more information on C/C++ code generation with the From File block, see “Code Generation” on page 1-661.

Programmatic Use

Block Parameter: `InterpolationWithinTimeRange`

Type: character vector

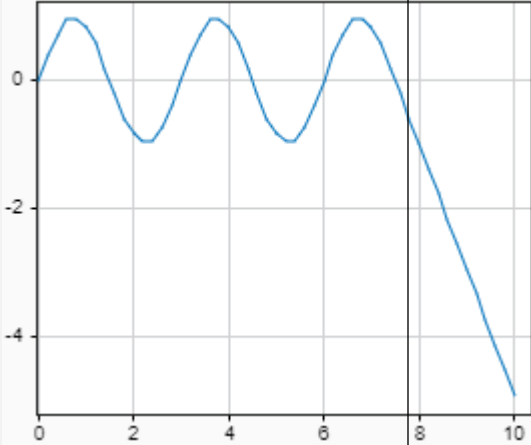

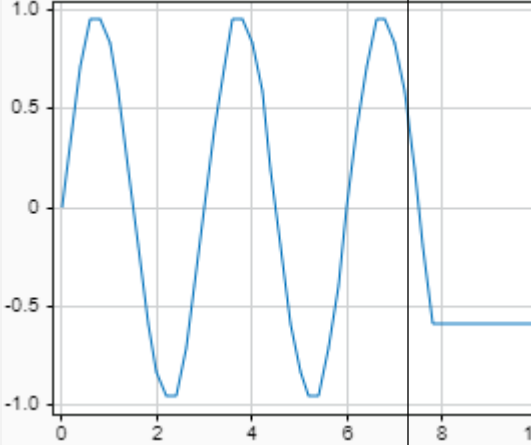

Values: `'Linear interpolation'` | `'Zero order hold'`

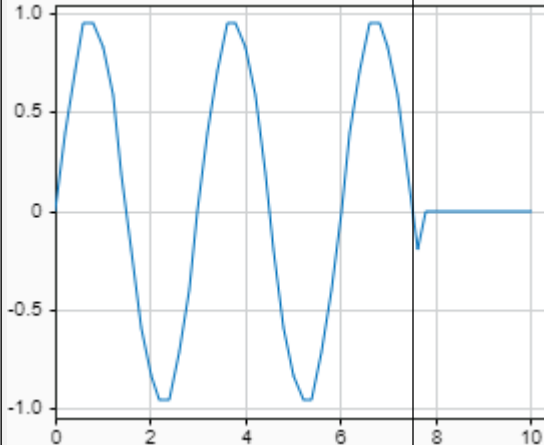

Default: `'Linear interpolation'`

Data extrapolation after last data point – Method to determine block output after final data point in MAT file

`Linear extrapolation (default)` | `Hold last value` | `Ground value`

Extrapolation method used to determine output values for simulation times after the last sample in the MAT file data.

Method	Description	Example
<p>Linear extrapolation</p>	<p>How the block determines the output value depends on the type of data in the MAT file.</p> <ul style="list-style-type: none"> • For double data, the From File block linearly extrapolates the output value using the last two samples in the MAT file. • For Boolean data, the From File block uses the sample value in MAT file for the output value. • For all other built-in data types, the From File block: <ol style="list-style-type: none"> 1 Upcasts the data to double. 2 Linearly extrapolates the output value using the last two samples in the MAT file data. 3 Downcasts the extrapolated data value to the original data type. <p>If the MAT file data only contains one sample, the From File block uses that value as the output.</p> <p>Do not use the Linear extrapolation option when the From File block loads enumerated data.</p> <p>The extrapolation setting is applied to all signals in a bus. If any signal in the bus contains enumerated data, do not use the Linear extrapolation option.</p>	
<p>Hold last value</p>	<p>The From File block uses the last data value in the MAT file as the output value.</p>	

Method	Description	Example
Ground value	<p>The From File block output value depends on the type of data in the MAT file.</p> <ul style="list-style-type: none"> Built-in numeric types — 0 Boolean — false Fixed-point data types — Representation for value of 0, which may not be exactly 0 due to scaling and limited precision. Enumerated data types — Default value 	

Tips

To generate code that builds ERT or GRT targets or uses SIL or PIL simulation modes, specify **Data extrapolation after last data point** as `Linear extrapolation`. For more information on C/C++ code generation with the From File block, see “Code Generation” on page 1-661.

Programmatic Use

Block Parameter: `ExtrapolationAfterLastDataPoint`

Type: character vector

Values: 'Linear extrapolation' | 'Hold last value' | 'Ground value'

Default: 'Linear extrapolation'

Enable zero-crossing detection — Zero-crossing detection

off (default) | on

Zero-crossing detection locates discontinuities, or zero crossings, in the block output and prevents excessively small time steps near the discontinuities, which can slow down a simulation. You can enable zero-crossing detection for the From File block when the **Sample time** parameter is set to 0 for continuous sample time.

The loaded data creates a discontinuity in the block output when the data includes multiple samples with the same time. For example, for this input data, a discontinuity occurs at time 2.

```
time:    0 1 2 2 3
signal:  2 3 4 5 6
```

The From File block can also create discontinuities in the output based on how you configure interpolation and extrapolation.

- Setting **Data extrapolation before first data point** to `Ground value` can create a discontinuity at the first sample in the loaded data.
- Setting **Data extrapolation after the last data point** to `Ground value` can create a discontinuity at the last sample in the loaded data.
- Setting **Data interpolation within time range** to `Zero-order hold` creates a discontinuity at each sample in the loaded data, including the last.

From File is not supported for zero-crossing detection in fixed-step simulation. Simulink will not detect zero-crossings associated with this block.

For more information, see “Zero-Crossing Detection”.

Tips

To generate code that builds ERT or GRT targets or uses SIL or PIL simulation modes, clear this check box. For more information on C/C++ code generation with the From File block, see “Code Generation” on page 1-661.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector

Values: 'off' | 'on'

Default: 'on'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point ^a integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	yes

^a Supports up to 32-bit fixed-point data types.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code.

Generating code for an RSim target has no special requirements or limitations. All other code generation targets only support loading real, double, one-dimensional signal data from an array in a MAT file where the first column contains time data and subsequent columns contain the signal data. Generating code that builds ERT or GRT targets or uses SIL or PIL simulation modes requires that:

- The loaded MAT file contains an array with at least two rows and no NaN, Inf, or -Inf values.
- The **Data extrapolation before first data point** and **Data extrapolation after last data point** parameters are set to `Linear` extrapolation.
- The **Data interpolation within time range** parameter is set to `Linear` interpolation.
- The **Enable zero-crossing detection** parameter is cleared.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The From File block supports fixed-point data types up to 32 bits.

Introduced before R2006a

From Spreadsheet

Read data from spreadsheet

Library: Simulink / Sources

Description

The From Spreadsheet block reads data from Microsoft Excel® (all platforms) or CSV (Microsoft Windows® platform with Microsoft Office installed only) spreadsheets and outputs the data as a signal. The From Spreadsheet block does not support Microsoft Excel spreadsheet charts.

The From Spreadsheet icon displays the spreadsheet file name and sheet name specified in the block **File name** and **Sheet name** parameters.

Storage Formats

The data that the From Spreadsheet block reads from a spreadsheet must be appropriately formatted.

For Microsoft Excel spreadsheets:

- The From Spreadsheet block interprets the first row as a signal name. If you do not specify a signal name, the From Spreadsheet block assigns a default one with the format Signal #, where # increments with each additional unnamed signal.
- The From Spreadsheet block interprets the first column as time. In this column, the time values must monotonically increase.
- The From Spreadsheet block interprets the remaining columns as signals.

This example shows an acceptably formatted Microsoft Excel spreadsheet. The first column is Time and the first row contains signal names. Each worksheet contains a signal group.

1	Time	DC In	Trigger	AC In	
2	0	1	2	3	
3	1	2	3	4	
4	2	3	4	5	
5	3	4	5	6	
6	4	5	6	7	
7	5	6	7	8	
8	6	7	8	9	
9	7	8	9	10	
10	8	9	10	11	
11	9	10	11	12	
12	10	11	12	13	
13	11	12	13	14	
14	12	13	14	15	
15	13	14	15	16	
16	14	15	16	17	
17	15	16	17	18	
18					

Navigation: < > Group1 Group2 Group3

For CSV text files (Microsoft platform with Microsoft Office installed only):

- The From Spreadsheet block interprets the first column as time. In this column, the time values must increase.
- The From Spreadsheet block interprets the remaining columns as signals.
- Each column must have the same number of entries.
- The From Spreadsheet block interprets each file as one signal group.

This example shows an acceptably formatted CSV file. The contents represent one signal group.

```
0,0,0,5,0
1,0,1,5,0
2,0,1,5,0
3,0,1,5,0
4,5,1,5,0
5,5,1,5,0
6,5,1,5,0
7,0,1,5,0
8,0,1,5,1
9,0,1,5,1
10,0,1,5,0
```

Block Behavior During Simulation

The From Spreadsheet block incrementally reads data from the spreadsheet during simulation.

The **Sample time** parameter specifies the sample time that the From Spreadsheet block uses to read data from the spreadsheet. For details, see “Parameters” on page 1-666. The time stamps in the file must be monotonically nondecreasing.

For each simulation time hit for which the spreadsheet contains no matching time stamp, Simulink software interpolates or extrapolates to obtain the needed data using the selected method. For details, see “Simulation Time Hits That Have No Corresponding Spreadsheet Time Stamps” on page 1-665.

Simulation Time Hits That Have No Corresponding Spreadsheet Time Stamps

If the simulation time hit does not have a corresponding spreadsheet time stamp, the From Spreadsheet block output depends on:

- Whether the simulation time hit occurs before the first time stamp, within the range of time stamps, or after the last time stamp
- The interpolation or extrapolation methods that you select
- The data type of the spreadsheet data

For details about interpolation and extrapolation options, see the descriptions of these parameters:

- “Data extrapolation before first data point” on page 1-0
- “Data interpolation within time range” on page 1-0
- “Data extrapolation after last data point” on page 1-0

Sometimes the spreadsheet includes two or more data values that have the same time stamp. In such cases, the From Spreadsheet block action depends on when the simulation time hit occurs, relative to the duplicate time stamps in the spreadsheet.

For example, suppose that the spreadsheet contains this data. Three data values have a time stamp value of 2.

```
time stamps:  0 1 2 2 2 3 4
data values:  2 3 6 4 9 1 5
```

The table describes the From Spreadsheet block output.

Simulation Time, Relative to Duplicate Time Stamp Values in Spreadsheet	From Spreadsheet Block Action
Before the duplicate time stamps	Performs the same actions as when the time stamps are distinct, using the first of the duplicate time stamp values as the basis for interpolation. (In this example, the time stamp value is 6.)
At or after the duplicate time stamps	Performs the same actions as when the times stamps are distinct, using the last of the duplicate time stamp values as the basis for interpolation. (In this example, that time stamp value is 9.)

Ports

Output

Port_1 — Data from spreadsheet

scalar | vector | matrix

Incremental data from the specified spreadsheet.

The **Sample time** parameter specifies the sample time that the From Spreadsheet block uses to read data from the spreadsheet. For details, see “Parameters” on page 1-666. The time stamps in the file must be monotonically nondecreasing.

For each simulation time hit for which the spreadsheet contains no matching time stamp, Simulink software interpolates or extrapolates to obtain the needed data using the selected method. For details, see “Simulation Time Hits That Have No Corresponding Spreadsheet Time Stamps” on page 1-665.

The From Spreadsheet block accepts data type specifications at a block level. If you want to specify different data types for each signal, consider selecting **Output Data Type > Inherit: Auto**. This option resolves back signal data types using back propagation. For example, assume that there are two signals in the From Spreadsheet block, In1 and In2, which the block sends to ports that have int8 and Boolean data types. With back propagation, the block recasts In1 as int8 and In2 as Boolean.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

Parameters

File name — Full path and file name

`untitled.xlsx` (default) | full path and file name

Enter full path and file name of a spreadsheet file, including the file extension. If you do not include a file extension, the block assumes `.xlsx` as the extension.

This block supports non-English full paths and file names only on Microsoft platforms.

Programmatic Use

Block Parameter: `FileName`

Type: character vector

Value: full path and file name

Default: `'untitled.xlsx'`

Sheet name — Name of sheet in spreadsheet

`Sheet1` (default) | sheet name

Enter the name of the sheet in the spreadsheet. You can type the sheet name in this edit box or select the sheet name after you open the sheet.

If your spreadsheet is the CSV format, the block populates this parameter with the name of the CSV file without the extension. Do not change this value.

To open the sheet, click . In the sheet, you can select the range of data by dragging over the desired range of values.

Range Selection - From Spreadsheet

Scenario1

Alternatively, you can select the range of data by specifying the range of values in the **Range** parameter.

Programmatic Use

Block Parameter: SheetName

Type: character vector

Value: Sheet name

Default: 'Sheet1'

Range — Cell range

entire range of used cells in sheet (default) | comma-separated list of *column:row*

To specify the range, use the format *column:row*, with multiple specifications separated by commas. For example, A1:B3,D1:D3,A7:B9,D7:D9. If unspecified, or empty, the block automatically detects the used range, which is all the data in the sheet.

	A	B	C	D	E	F	G	H	I	J	K
	Time	Signal1	Signal2	Signal3	Signal4	Signal5	Signal6	Signal7	Signal8	Signal9	Signal10
	Number	Number	Number	Number	Number	Number	Number	Number	Number	Number	Number
1	Time	Signal1	Signal2	Signal3	Signal4	Signal5	Signal6	Signal7	Signal8	Signal9	Signal10
2	0	1.1008	1.5774	2.5733	3.69	5.19	5.8712	6.6145	7.6217	8.9888	9.7016

4	5.5556	1.4038	1.9424	3.0091	4.4612	4.9577	6.1982	6.9004	8.1338	8.6296	10.2585
5	8.3333	0.56689	1.5482	3.0697	4.0333	4.5459	5.6497	7.182	7.7123	8.8344	9.5369
6	11.1111	0.88305	2.4625	2.8027	4.0957	5.4559	5.6548	6.5501	7.6782	9.3752	9.8517
7	13.8889	1.4181	1.7568	2.579	3.5821	4.5151	5.7424	7.2375	7.5058	9.4361	10.3232
8	16.6667	1.4352	1.6601	3.2009	3.5572	5.2831	6.431	7.1034	7.7896	9.0152	9.7239
9	19.4444	0.58446	2.0186	3.055	4.3965	4.6682	6.0019	7.1016	7.548	9.0634	9.667
10	22.2222	0.88934	2.0304	2.8024	3.6859	4.9812	5.8476	6.9719	8.1404	9.2989	10.4111
11	25	1.0712	2.0016	2.9639	3.7118	4.5929	5.9932	7.0083	7.971	8.7347	9.678

If the selections overlap, the block resolves the selection information as appropriate. For example, if you specify multiple ranges that overlap, such as A1:B4, B1:E7, the block resolves the selection to A1 to E7, inclusive.

Selection/History contains the list of selected ranges during this session. The block does not store the ranges after you close **Range Selection**.

An alternate to using the **Range** parameter is to open the sheet, by clicking . In the sheet, you can select the range of data by dragging over the desired range of values. The range selection reflects in the **Range** parameter text box.

To apply a new range from the block dialog, click **Apply**.

Programmatic Use

Block Parameter: Range

Type: character vector

Value: entire range of used cells in sheet | comma-separated list of *column:row*

Default: ''

Output data type — Output data type

Inherit: auto (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class_name> | <data type expression>

The data type for the From Spreadsheet block output. The From Spreadsheet block accepts spreadsheets that contain many data types. However, the block reads the spreadsheet data type as doubles. It then outputs the data type according to the value of **Output data type**.

If you want to specify different data types for each signal, consider selecting **Output Data Type** > **Inherit: auto**. This option resolves back signal data types using back propagation. For example,

assume that there are two signals in the From Spreadsheet block, In1 and In2, which the block sends to ports that have int8 and Boolean data types. With back propagation, the block recasts In1 as int8 and In2 as boolean.

To allow the block to cast the output data type to match that of the receiving block, use `Inherit: auto`.

For more information, see “Control Data Types of Signals”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: auto' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | '<data type expression>'

Default: 'Inherit: auto'

Treat first column as — Time or data

Time (default) | Data

Select how the block should treat the first column of the spreadsheet:

- Time — Treat first column as time.
- Data — Treat first column as data.

Dependencies

When you select Data, the block disables:

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

And enables:

- **Output after last data point**

Programmatic Use

Block Parameter: TreatFirstColumnAs

Type: character vector

Value: 'Time' | 'Data'

Default: 'Time'

Sample time — Sampling period and offset

0 (default) | scalar | vector

The sample period and offset.

The From Spreadsheet block reads data from a spreadsheet using a sample time that either:

- You specify for the From Spreadsheet block
- The From Spreadsheet block inherits from the blocks into which the From Spreadsheet block feeds data

The default is 0, which specifies a continuous sample time. The spreadsheet is read at the base (fastest) rate of the model. For details, see “Specify Sample Time”.

Programmatic Use

Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '0'

Data extrapolation before first data point — Extrapolation method for simulation times before initial time stamp in MAT-file

Linear extrapolation (default) | Hold first value | Ground value

Extrapolation method that Simulink uses for a simulation time hit that is before the first time stamp in the spreadsheet. Choose one of these extrapolation methods.

Method	Description
Linear extrapolation	<p>(Default)</p> <p>If the spreadsheet contains only one sample, the From Spreadsheet block outputs the corresponding data value.</p> <p>If the spreadsheet contains more than one sample, the From Spreadsheet block linearly extrapolates using the first two samples:</p> <ul style="list-style-type: none"> • For double data, linearly extrapolates the value using the first two samples • For Boolean data, outputs the first data value • For a built-in data type other than double or Boolean: <ul style="list-style-type: none"> • Upcasts the data to double • Performs linear extrapolation (as described above for double data) • Downcasts the extrapolated data value to the original data type <p>You cannot use the Linear extrapolation option with enumerated (enum) data.</p>
Hold first value	Uses the first data value in the file
Ground value	<p>Uses a value that depends on the data type of spreadsheet sample data values:</p> <ul style="list-style-type: none"> • Fixed-point data types — Uses the ground value • Numeric types other than fixed-point — Uses 0 • Boolean — Uses false • Enumerated data types — Uses default value

Dependencies

To enable this parameter, set **Treat first column as to Time**.

Programmatic Use**Parameter:** ExtrapolationBeforeFirstDataPoint**Type:** character vector**Values:** 'Linear extrapolation' | 'Hold first value' | 'Ground value'**Default:** 'Linear extrapolation'**Data interpolation within time range – Interpolation method for simulation times that fall between two time stamps in the MAT-file**

Linear interpolation (default) | Zero order hold

The interpolation method that Simulink uses for a simulation time hit between two time stamps in the spreadsheet. Choose one of the following interpolation methods.

Method	Description
Linear interpolation	<p>(Default)</p> <p>The From Spreadsheet block interpolates using the two corresponding spreadsheet samples:</p> <ul style="list-style-type: none"> For <code>double</code> data, linearly interpolates the value using the two corresponding samples For Boolean data, if the simulation time is between two spreadsheet data points with different values, the From Spreadsheet block positions the value transition halfway between the spreadsheet data points. For example, if the spreadsheet data transitions from true to false, the From Spreadsheet data provides an output value of true for simulation times in the first half of the interval between the spreadsheet data points. It provides an output value of false for simulation times in the latter half of the interval. For a built-in data type other than <code>double</code> or <code>Boolean</code>: <ul style="list-style-type: none"> Upcasts the data to <code>double</code> Performs linear interpolation (as described above for <code>double</code> data) Downcasts the interpolated value to the original data type <p>You cannot use the <code>Linear interpolation</code> option with enumerated (<code>enum</code>) data.</p>
Zero order hold	Uses the data from the first of the two samples

Dependencies

To enable this parameter, set **Treat first column as** to `Time`.

Programmatic Use**Parameter:** InterpolationWithinTimeRange**Type:** character vector**Values:** 'Linear interpolation' | 'Zero order hold'**Default:** 'Linear interpolation'

Data extrapolation after last data point — Extrapolation method for simulation times after last time stamp in MAT-file

Linear extrapolation (default) | Hold last value | Ground value

The extrapolation method that Simulink uses for a simulation time hit that is after the last time stamp in the spreadsheet. Choose one of the following extrapolation methods.

Method	Description
Linear extrapolation	<p>(Default)</p> <p>If the spreadsheet contains only one sample, the From Spreadsheet block outputs the corresponding data value.</p> <p>If the spreadsheet contains more than one sample, the From Spreadsheet block linearly extrapolates using data values of the last two samples:</p> <ul style="list-style-type: none"> • For double data, extrapolates the value using the last two samples • For Boolean data, outputs the last data value • For a built-in data type other than double or Boolean: <ul style="list-style-type: none"> • Upcasts the data to double. • Performs linear extrapolation (as described above for double data). • Downcasts the extrapolated value to the original data type. <p>You cannot use the Linear extrapolation option with enumerated (enum) data.</p>
Hold last value	Uses the last data value in the file
Ground value	<p>Uses a value that depends on the data type of spreadsheet sample data values:</p> <ul style="list-style-type: none"> • Fixed-point data types — Uses the ground value • Numeric types other than fixed-point — uses 0 • Boolean — Uses false • Enumerated data types — Uses default value

Dependencies

To enable this parameter, set **Treat first column as** to **Time**.

Programmatic Use

Parameter: ExtrapolationAfterLastDataPoint

Type: character vector

Values: 'Linear extrapolation' | 'Hold last value' | 'Ground value'

Default: 'Linear extrapolation'

Output after last data point — Action after last data point

Repeating sequence (default) | Hold final value | Ground value

Select action after last data point:

- **Repeating sequence** — Repeat the sequence by reading the data from the first row of the range specified in **Range**
- **Hold final value** — Output the last defined value for the remainder of the simulation.
- **Ground value** — Output a ground value depending on the data type value specified in **Output data type**.

Dependencies

To enable this parameter, set **Treat first column as** to Data.

Programmatic Use

Parameter: OutputAfterLastPoint

Type: character vector

Values: 'Repeating sequence' | 'Hold final value' | 'Ground value'

Default: 'Repeating sequence'

Enable zero-crossing detection — Enable zero-crossing detection

off (default) | on

Select to enable zero-crossing detection.

The “Zero-Crossing Detection” parameter applies only if the **Sample time** parameter is set to 0 (continuous).

Simulink uses a technique known as zero-crossing detection to locate accurately a discontinuity, without resorting to excessively small time steps. In this context, zero-crossing is used to represent discontinuities.

For the From Spreadsheet block, zero-crossing detection can only occur at time stamps in the file. Simulink examines only the time stamps, not the data values.

If the input array contains duplicate time stamps (more than one entry with the same time stamp), Simulink detects a zero crossing at that time stamp. For example, suppose that the input array has this data.

```
time:    0 1 2 2 3
signal:  2 3 4 5 6
```

At time 2, there is a zero crossing from the input signal discontinuity.

For data with nonduplicate time stamps, zero-crossing detection depends on the settings of the following parameters:

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

The block applies the following rules when determining when:

- Zero-crossing occurs for the first time stamp
- For time stamps between the first and last time stamp
- For the last time stamp

Time Stamp	When Zero-Crossing Detection Occurs
First	Data extrapolation before first data point is set to Ground value.
Between first and last	Data interpolation within time range is set to Zero-order hold.
Last	One or both of these settings occur: <ul style="list-style-type: none"> • Data extrapolation after last data point is set to Ground value. • Data interpolation within time range is set to Zero-order hold.

The following figure illustrates zero-crossing detection for data accessed by a From Spreadsheet block that has these settings:

- **Data extrapolation before first data point** – Linear extrapolation
- **Data interpolation within time range** (for internal points) – Zero order hold
- **Data extrapolation after last data point** – Linear extrapolation

The following figure is another illustration of zero-crossing detection for data accessed by a From Spreadsheet block. The block has these settings for the time stamps (points):

- **Data extrapolation before first data point** – Hold first value
- **Data interpolation within time range** – Zero order hold
- **Data extrapolation after last data point** – Hold last value

From Spreadsheet is not supported for zero-crossing detection in fixed-step simulation. Simulink will not detect zero-crossings associated with this block.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double enumerated fixed point ^a integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	yes

^a Supports up to 32-bit fixed-point data types.

Algorithms

When the From Spreadsheet block reads data from a spreadsheet, it reads all signals with double precision and then casts them to the data type specified in the **Output data type** parameter for the

output signal. During casting, the block uses rounding mode and saturation on integer overflow as follows.

Rounding Mode

The From Spreadsheet block rounds positive and negative numbers toward negative infinity. This mode is equivalent to the MATLAB `floor` function.

Saturation on Integer Overflow

For data type conversion, the From Spreadsheet block deals with saturation overflow by wrapping to the appropriate value that the data type can represent. For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- Not recommended for production code.
- Code generation for RSim target provides identical support as Simulink; all other code generation targets support only double, one-dimensional, real signals in array with time format.
- Simulating in accelerator, rapid accelerator, model reference accelerator mode, or model reference rapid accelerator mode behaves the same way, and has the same requirements, as simulating in normal mode.
- The From Spreadsheet block does not support generating code that involves building ERT or GRT targets, or using SIL or PIL simulation modes.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Supports up to 32-bit fixed-point data types.

From Workspace

Load signal data from workspace into Simulink model

Library: Simulink / Sources

Description

The From Workspace block reads data into a Simulink model from a workspace and provides the data as a signal or a nonvirtual bus at the block's output. You can load data from the base workspace, model workspace, or mask workspace. You can use the From Workspace block to load signal data into any model or subsystem in a model hierarchy from a workspace accessible to the referenced model or subsystem.

You can specify how the block constructs the output from the workspace data, including the output sample period, interpolation and extrapolation behavior, and whether to use zero-crossing detection.

The From Workspace block icon shows the value of the **Data** parameter. For example, if you use the From Workspace block to load data in the variable *x*, you specify *x* as the value for the **Data** parameter, and the block displays *x*.

Specify Data to Load

Specify data for the From Workspace block to load using the **Data** parameter. You can specify the value of the **Data** parameter as a MATLAB expression, such as a variable name. The expression in the **Data** parameter must evaluate to data in a format that the From Workspace block supports. For details about how the expression is evaluated, see “Symbol Resolution”.

The From Workspace block does not load data from a data dictionary. Use a data dictionary to store only design data for a model, not simulation input data. You can store design data related to the From Workspace block, such as the value for the **Sample time** parameter, in a data dictionary.

Ports

Output

Port_1 — Data loaded from workspace

scalar | vector | matrix | array

Data loaded from workspace, provided at the block output as a signal or a nonvirtual bus. Depending on the data you load, the output signal may be a scalar, vector, multidimensional, or variable-size signal, a bus, or an array of buses. The From Workspace block supports loading real and complex data of all built-in data types except `int64` and `uint64`.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Data — Data to load from workspace

timeseries object | timetable object | structure | 2-D array | MATLAB expression

Data to load from workspace, specified as a variable name or MATLAB expression that evaluates to data in a format supported by the From Workspace block. The expression could create the data the From Workspace block provides at its output, or it could reference a workspace variable that contains the data to load. For more information about how the expression is evaluated, see “Symbol Resolution”.

The From Workspace block can load data for scalar, multidimensional, and variable-size signals as well as data for a bus or array of buses. The From Workspace block supports loading data in these formats:

- timeseries object
- timetable object
- Simulink.SimulationData.Signal object
- Structure that represents bus data. The structure hierarchy must match the hierarchy of the bus and use timeseries and timetable objects to represent the signal data.
- Structure that represents data for a single signal, with fields and hierarchy that match the Structure or Structure with time logging format.
- Two-dimensional array that represents data for a single signal. The first column in the array represents time and one or more additional columns contain the signal data.

For details, see “Load Data Using the From Workspace Block”.

When you load data for a bus, specify the **Output data type** parameter as the Simulink.Bus object that defines the bus.

Real signals of type double can be in any data format that the From Workspace block supports. For complex signals and real signals of a data type other than double, use any format except Array.

The From Workspace block supports loading variable-size signal data in the Structure or Structure with time formats.

Programmatic Use

Block Parameter: VariableName

Type: character vector

Values: MATLAB expression | timeseries object | timetable object | structure | 2-D array

Default: 'simin'

Output data type — Loaded workspace data type

Inherit: auto (default) | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | boolean | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class_name> | Bus: <bus_object> | <data type expression>

Data type of the workspace data the From Workspace block loads. By default, the From Workspace block inherits the output signal data type from the workspace data or from a downstream block that defines the data type for the signal.

When you load data for a scalar or multidimensional signal, you can choose to inherit the output data type or you can specify the output data type to match the data type of the workspace data.

To load data for a bus or an array of buses, set the **Output data type** to Bus: <bus_object> and specify the name of the Simulink.Bus object that defines the output bus.

When you load enumerated data, set the **Output data type** to Enum: <class_name> and specify the name of the enumeration class that defines the enumerated data values.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: auto' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>' | '<data type expression>'

Default: 'Inherit: auto'

Sample time — Output sample period and optional time offset

0 (default) | scalar | vector

The **Sample time** parameter specifies when the block computes a new output value during simulation. For details, see “Specify Sample Time”.

Specify the **Sample time** parameter as a scalar when you do not want the output to have a time offset. To add a time offset to the output, specify the **Sample time** parameter as a 1-by-2 vector where the first element is the sampling period and the second element is the offset.

By default, the **Sample time** parameter value is 0, which indicates continuous sample time with no time offset. For a discrete signal, specify the **Sample time** as the discrete sampling interval. For example, specify the **Sample time** as 0.1 to model a discrete signal sampled every 100ms. Specify the **Sample time** as -1 to inherit the value.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '0'

Interpolate data — Interpolation method

on (default) | off

Interpolation method used to provide output values for simulation times that are in between time values in the loaded workspace data. When you select **Interpolate data**, the From Workspace block linearly interpolates an output value using adjacent values in the loaded workspace data. When **Interpolate data** is not selected, the From Workspace block provides the value of the previous data point in the loaded workspace data. For more information about the interpolation algorithm, see “Interpolation” on page 1-682.

When you load enumerated, fixed-point, or variable-size signal data, clear the **Interpolate data** parameter.

To provide output values after the last value in the loaded workspace data, the From Workspace block uses a combination of the **Interpolate data** parameter and the **Form output after final data value by** parameter.

The **Interpolate data** parameter value also affects how the From Workspace block extrapolates output values for simulation times prior to the first data point in the loaded workspace data. When **Interpolate data** is selected, the From Workspace block uses the first two data points in the workspace data to linearly extrapolate output values for simulation times prior to the first data point. When **Interpolate data** is not selected, the block provides ground as the output value for simulation times prior to the first workspace data point. For complete information regarding the From Workspace block extrapolation behavior, see “Extrapolation” on page 1-683.

Programmatic Use**Block Parameter:** Interpolate**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'**Enable zero-crossing detection — Zero-crossing detection**

on (default) | off

Zero-crossing detection is a technique used to locate discontinuities in the block output and avoid using excessively small time steps near the discontinuities, which can slow down a simulation. A zero crossing refers to a discontinuity in the data. You can enable zero-crossing detection for the From Workspace block when the sample time is continuous (0).

The loaded workspace data creates a discontinuity in the block output when the data includes multiple samples with the same time. For example, for this input data, a discontinuity occurs at time 2.

```
time:    0 1 2 2 3
signal:  2 3 4 5 6
```

The From Workspace block can also create a discontinuity in the output at the last sample in the workspace data when you set **Form output after final data value by** to Setting to zero.

When you load input data for a bus, the From Workspace block detects zero crossings for all bus elements.

For more information, see “Zero-Crossing Detection”.

Programmatic Use**Block Parameter:** ZeroCross**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'**Form output after final data value by — Method to determine block output after final data point**

Extrapolation (default) | Setting to zero | Holding final value | Cyclic repetition

The From Workspace block uses the **Interpolate data** and **Form output after final data value by** settings to determine the block output for simulation times after the last sample available in the workspace data.

Setting for Form output after final data value by	Setting for Interpolate data	Block Output After Final Data
Extrapolation	On	Extrapolated from final data value
	Off	Error
Setting to zero	On	Zero
	Off	
Holding final value	On	Final value from workspace
	Off	
Cyclic repetition	On	Error
	Off	When the loaded workspace data uses the structure without time format, repeats workspace data from the first value. Errors for workspace data formats other than structure with time.

For complete information regarding the From Workspace block extrapolation behavior, see “Extrapolation” on page 1-683.

Programmatic Use

Block Parameter: OutputAfterFinalValue

Type: character vector

Values: 'Extrapolation' | 'Setting to zero' | 'Holding final value' | 'Cyclic repetition'

Default: 'Extrapolation'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point ^a half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	yes

^a Supports input via fi objects created using Fixed-Point Designer.

Tips

- The From Workspace block supports loading partially specified data for a bus. To partially specify bus data, set bus elements for which you do not need to load data to [].
- To load data that was logged in array format using the To File block, transpose the array so that the time values are in a single column rather than a single row. You can use the `transpose` function and save the transposed data to a new file.
- For programmatic simulations using the `sim`, `parsim`, or `batchsim` functions, you can use the `Simulink.SimulationInput` object to specify the data for the From Workspace block to load.

Algorithms

Interpolation

Interpolation is the process the From Workspace block uses to provide output values for simulation times that are between sample times in the loaded workspace data. When you select **Interpolate data**, the From Workspace block linearly interpolates the output value using two adjacent points in the workspace data. When you do not select **Interpolate data**, the From Workspace block uses the value of the prior workspace data point as the output value. For example, this model has one From Workspace block with **Interpolate data** selected and another with **Interpolate data** cleared. Both blocks load the same sine wave data from the base workspace.

When you select the **Interpolate data** parameter, the From Workspace block performs different steps, depending on the type of data you load.

For **double** data, the From Workspace block linearly interpolates the value using the workspace data values before and after the simulation time.

For **Boolean** data, if the simulation time is between two workspace data points with different values, the From Workspace block positions the value transition halfway between the workspace data points. For example, if the workspace data transitions from **true** to **false**, the From Workspace data provides an output value of **true** for simulation times in the first half of the interval between the workspace data points and provides an output value of **false** for simulation times in the latter half of the interval.

For built-in data types other than **double** and **Boolean**, the From Workspace block performs these steps:

- 1 Upcast the data to **double** data type.

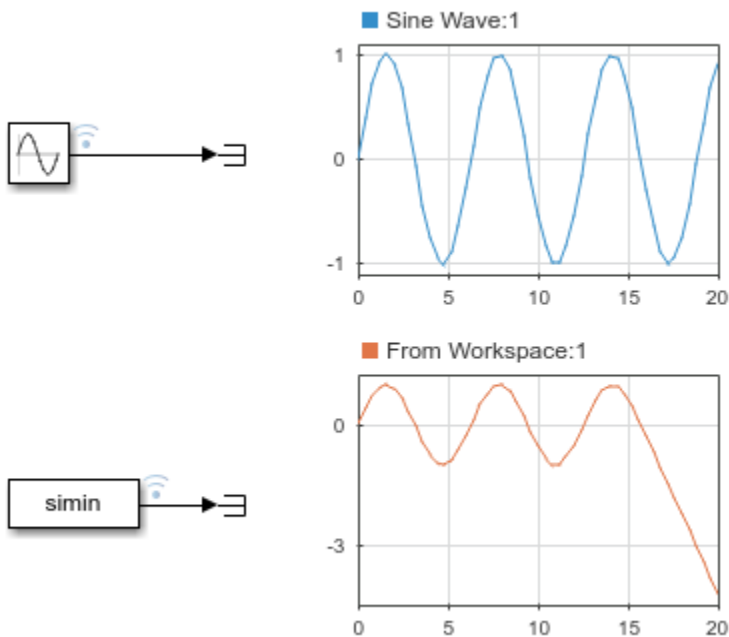

- 2 Linearly interpolate the output value using the double values.
- 3 Downcast the interpolated value to the original data type.

Extrapolation

Extrapolation is the process the From Workspace block uses to provide output values for simulation times that are before the first data point and after the last data point in the loaded workspace data. You can control how the From Workspace block extrapolates output values before the first workspace data value using the **Interpolate data** parameter. Use the **Interpolate data** and **Form output after final data value by** parameters to specify how the block extrapolates output values for simulation times after the final workspace data point.

Interpolate data	Output Before First Data Point	Form output value after final data by	Output After Final Data Point
On	Linearly extrapolated using first two workspace data points	Extrapolation	Linearly extrapolated using final two workspace data values
		Setting to zero	Zero
		Holding final value	Final workspace data value
		Cyclic repetition	Error
Off	Zero	Extrapolation	Error
		Setting to zero	Zero
		Holding final data value	Final workspace data value
		Cyclic repetition	When the loaded workspace data uses the structure without time format, repeats workspace data from the first value. Errors for workspace data formats other than structure with time.

For example, consider this model that has a From Workspace block with **Interpolate data** enabled and **Form output after final data value by** set to **Extrapolation**. The From Workspace block reads workspace data that was created by logging the output of the Sine Wave block for a 16-second simulation. The Dashboard Scope blocks display the Sine Wave block output and the From Workspace block output for a 20-second simulation. After the simulation reaches 16 seconds, the From Workspace block output diverges from the Sine Wave block output as the From Workspace block linearly extrapolates output values for the remainder of the simulation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code.

The workspace data the From Workspace block loads is hard coded in the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Supports input via `fi` objects created using Fixed-Point Designer.

Function-Call Feedback Latch

Break feedback loop involving data signals between function-call blocks

Library: Simulink / Ports & Subsystems

Description

Use the Function-Call Feedback Latch block to break a feedback loop of data signals between one or more function-call blocks. Specifically, break a feedback loop formed in one of the following ways.

- **When function-call blocks connect to branches of the same function-call signal**

Place the Function-Call Feedback Latch block on the feedback signal between the branched blocks. As a result, the latch block delays the signal at the input of the destination function-call block, and the destination function-call block executes prior to the source function-call block of the latch block.

To run this model, see “Function-Call Blocks Connected to Branches of the Same Function-Call Signal” on page 12-154.

- **When the loop involves parent and child function-call blocks, where the child initiator is inside the parent**

Place the Function-Call Feedback Latch block on the feedback signal between the child and the parent. This arrangement prevents the signal value, read by the parent (FCSS1), from changing during execution of the child. In other words, the parent reads the value from the previous execution of the child (FCSS2).

To run this model, see “Function-Call Feedback Latch on Feedback Signal Between Child and Parent” on page 12-155.

Using the latch block is equivalent to selecting the **Latch input for function-call feedback signals** check box on the Inport block in the destination function-call subsystem or model. However, an advantage of the latch block over using the dialog parameter is that one can design the destination function-call subsystem or model in a modular fashion and then use it either in or out of the context of loops.

The Function-Call Feedback Latch block is better suited than Unit Delay or Memory blocks in breaking function-call feedback loops for the following reasons:

- The latch block delays the feedback signal for exactly one execution of the source function-call block. This behavior is different from the Unit Delay or Memory blocks for cases where the function-call subsystem blocks may execute multiple times in a given simulation step.
- Unlike the Unit Delay or Memory blocks, the latch block may be used to break loops involving asynchronous function-call subsystems.
- The latch block can result in better performance, in terms of memory optimization, for generated code.

Ports

Topics

“Using Function-Call Subsystems”

Introduced in R2011a

Function-Call Generator

Provide function-call events to control execution of subsystem or model

Library: Simulink / Ports & Subsystems

Description

The Function-Call Generator block provides function-call events that execute a function-call subsystem or function-call model at the rate you specify with the **Sample time** parameter. A function-call subsystem or function-call model is a subsystem or model containing a Trigger block with its **Trigger type** parameter set to `function-call`.

To iteratively execute each function-call subsystem or function-call model multiple times at each time step, use the **Number of iterations** parameter.

To execute multiple function-call subsystems or function-call models in a specified order, use the Function-Call Generator block with a Function-Call Split block. For an example, see Function-Call Split.

To execute a function-call subsystem or function-call model intermittently, meaning not at every time step, select the **Show enable port** parameter. You can then use the input at the enable port to control when the block outputs function-call events. In effect, you can turn the block on and off as needed.

Ports

Input

Enable — Control signal input

scalar

The block outputs function-call events only when the input at this port is a positive number.

Dependencies

To enable this port, select the **Show enable port** check box.

Output

Function Call — Function-call event output

scalar | vector

Sends function-call events to the function-call input port of a function-call subsystem or function-call model.

Parameters

Sample time — Specify time interval

1 (default) | scalar | vector | -1

Specify the time interval between function-call events to a function-call subsystem or function-call model. If the actual calling rate for the subsystem or model differs from the time interval this parameter specifies, Simulink displays an error.

By default, the block uses a time interval of 1. To set a different interval, enter a valid sample time based on the table in “Types of Sample Time”, or specify -1 to inherit the time interval from the model.

Dependencies

To enable this parameter, clear the **Show enable port** check box. If you select **Show enable port**, sample time is automatically set to -1 (inherited).

Programmatic Use

Block Parameter: sample_time

Type: character vector

Values: '1' | scalar expression | vector expression | '-1'

Default: '1'

Number of iterations — Specify number of times to provide a function-call at each time step

1 (default) | integer

The value of this parameter can be a vector, where each element of the vector specifies a number of times to execute a function-call subsystem or model. If a vector is specified, then the block outputs a vector of function-call events, which can be split into individual function-call events using a Demux block and used to drive multiple function-call subsystems or models.

Suppose that you specify **Number of iterations** to be [3 2] and connect the output of this block to a Demux block, which is connected to the control ports of two function-call subsystems. In this case, the first function-call subsystem executes three times at each time step, and the second function-call subsystem executes two times at each time step.

If, however, you connect the output of this block to a single function-call subsystem or model, the total number of times that the function-call subsystem or model executes per time step is equal to the sum of the vector element values. So in the example above, specifying **Number of iterations** to be [3 2] and connecting the output of this block to a single function-call subsystem results in the function-call subsystem executing five times at each time step.

Settings

1

Provide function-call once during each time step.

integer

Signed or unsigned integer number. Provide the specified number of function calls at each time step.

Programmatic Use

Block Parameter: numberOfIterations

Type: character vector

Values: '1' | '<integer>'<vector of integers>'

Default: '1'

Disallow wide output — Prevent implicit expansion of output signal

off (default) | on

Unless this parameter is selected, the output of this block is expanded into a vector, if necessary, to drive the blocks to which it is connected. For example, if **Number of iterations** is set to 2 and **Disallow wide output** is not selected, and the output of this block is connected to a Demux block, which is in turn connected to three separate function-call subsystems, then each function-call subsystem receives two function-call events at each time step. A similar result occurs if the output of this block is connected to a Stateflow chart with multiple events. If **Disallow wide output** is selected in these situations, Simulink produces an error.

Select this parameter to prevent implicit expansion of the output signal.

Clear this parameter to allow implicit expansion of the output signal when appropriate.

Programmatic Use

Block Parameter: DisallowWideOutput

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Show enable port — Add input port for control signal

off (default) | on

Select this parameter to add a control signal input port to the block. The block outputs function-call events only when the value at the control signal input port is a positive number.

Clear this parameter to remove the control signal input port. The block outputs function-call events at every time step.

Programmatic Use

Block Parameter: ShowEnablePort

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Topics

[“Using Function-Call Subsystems”](#)

Introduced before R2006a

Function-Call Split

Provide junction for splitting function-call line

Library: Simulink / Ports & Subsystems

Description

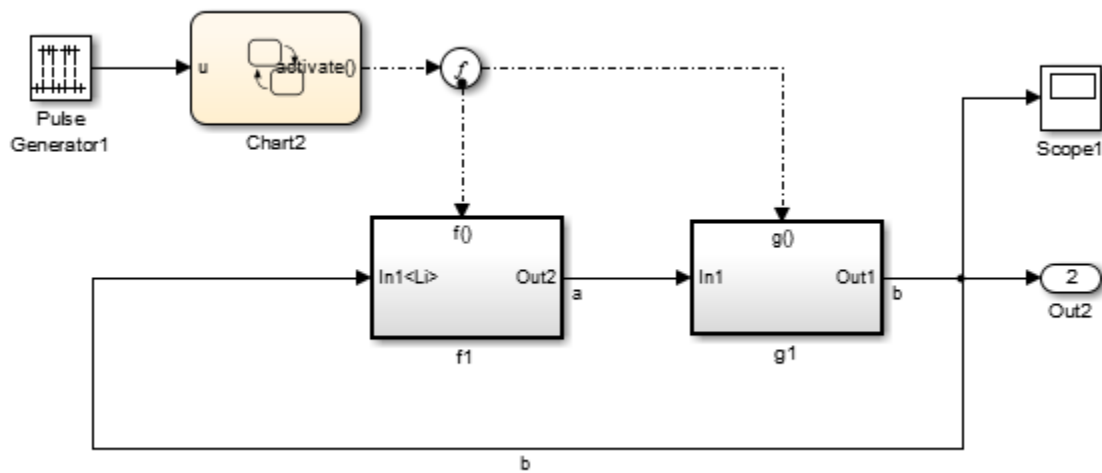

The Function-Call Split block allows a function-call line to branch and connect to several function-call subsystems or function-call models.

The function-call subsystem or function-call model connected to the output port of the Function-Call Split block that is marked with a dot executes before the subsystems or models connected to other output ports. If data dependencies between subsystems or models do not support the specified execution order, the Function-Call Split block returns an error. To eliminate this error, consider selecting the **Latch input for feedback signals of function-call subsystem outputs** parameter on one or more Inport blocks of the function-call subsystems or models involved in a data-dependency loop. Selecting this option delays the corresponding function-call, thereby eliminating the data-dependency loop.

If you select the model menu option **Display > Blocks > Sorted Execution Order**, then the execution order of function-call subsystems connected to branches of a given function-call signal appears on the blocks. Each subsystem has an execution order of the form $s : [B\#]$, where $\#$ is a number that ranges from 0 to one less than the total number of subsystems or models connected to branches of a given signal. The subsystems execute in ascending order based on this number.

The Function-Call Split block supports "Signal Label Propagation".

The following model shows how to apply the **Latch input for feedback signals of function-call subsystem outputs** parameter to work around a data-dependency error caused by a Function-Call Split block. By turning this parameter on in the f1 subsystem's Inport block, the Function-Call Split block ignores the data dependency of signal b. The block breaks the loop of data dependencies between subsystems f1 and g1. The model achieves the behavior of consistently calling f1 to execute before g1. For a given execution step, subsystem f1 uses the g1 output computed at the previous execution step.

Limitations

The Function-Call Split block has these limitations:

- All function-call subsystems and models connected to a given function-call signal must reside within the same nonvirtual layer of the model hierarchy.
- You cannot connect branched function-call subsystems or models and their children directly back to the function-call initiator.
- Function-call subsystems and models connected to branches of a function-call signal cannot have multiple (muxed) initiators.
- A Function-Call Split block cannot have its input from a signal with multiple function-call elements.

Ports

Input

Function Call – Function-call line

scalar

A Function-Call Generator block, an S-Function block, a Hit Crossing block, or a Stateflow chart can provide function-call events.

Output

Function Call – Function-call signal

scalar

Function-call line connected to a function-call subsystem or function-call model.

Parameters

Icon shape — Select block icon shape

`distinctive` (default) | `round`

Select block icon shape.

Settings

`distinctive`

Rectangular block icon.

`round`

Circular block icon.

Programmatic Use

Block Parameter: `IconShape`

Type: character vector

Values: `'distinctive'` | `'round'`

Default: `'distinctive'`

Number of output ports — Specify number of output ports

`2` (default) | `integer`

Specify the number of function-call signal output ports.

Settings

`2`

Two function-call output ports.

`integer`

Integer number

Programmatic Use

Block Parameter: `NumOutputPorts`

Type: character vector

Values: `'2'` | `'<integer>'`

Default: `'2'`

Output port layout — Select order of output ports

`default` (default) | `reverse`

Select the order of function-call output ports with respect to which port provides a function-call first.

Settings

`default`

Top port provides function-call first.

`reverse`

Bottom port provides function-call first.

Programmatic Use

Block Parameter: `OutputPortLayout`

Type: character vector

Values: 'default' | 'reverse'

Default: 'default'

Block Characteristics

Library: Simulink / Ports & Subsystems

Description

The Function-Call Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes when a function-call input port receives a function-call event. A Stateflow chart, Function-Call Generator block, S-Function block, or Hit Crossing block can provide function-call events. See “Using Function-Call Subsystems”.

Use Function-Call Subsystem blocks to:

- Schedule the execution order of model components.
- Control the rate of model component execution.

Simulink ignores any priority set on a Function-Call Subsystem block, but you can set the priority on a block connected to the subsystem's function-call port. The function-call port can receive a function-call event from a Stateflow chart, MATLAB Function block, Function-Call Generator block, S-Function block, or Hit Crossing block.

For an explanation of the Function-Call Subsystem block parameters, see Subsystem.

Ports

Input

In — Signal input to Subsystem block

scalar | vector | matrix

Signal input to a Subsystem block, specified as a scalar, vector, or matrix. Placing an Inport block in a Subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to receive signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Function Call – Function-call input to Subsystem block

scalar

A Trigger block in a Subsystem block adds an external input port to the block. A **Trigger type** of `function-call` makes the block a Function-Call port block that accepts function-call events.

Output

Out – Signal output from Subsystem block

scalar | vector | matrix

Signal output from a Subsystem block, returned as a scalar, vector, or matrix. Placing an Outport block in a Subsystem block adds an external output port to the block. The port label matches the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Block Characteristics

Function Caller

Call Simulink or exported Stateflow function

Library: Simulink / User-Defined Functions

Function Caller

Description

A Function Caller block calls and executes a function defined with a Simulink Function block or an exported Stateflow function. Using Function Caller blocks, you can call a function from anywhere in a model or chart hierarchy.

You can select a Simulink Function or Function Caller block to highlight blocks related to it. To show a related block in an open diagram or new tab, pause on the ellipsis that appears after selection.

Then, select **Related Blocks**  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list of related blocks by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Ports

Input

Input argument — Input signal for an input argument

scalar | vector | matrix

Input signal for an input argument that is sent to the function.

The function prototype determines the number and name of input ports that appear on the Function Caller block. Connect signal lines to the input ports to send data to a function through the function input arguments.

For example, `y = myfunction(u)` creates one input port (u) on the Function Caller block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Output argument — Output signal for an output argument

scalar | vector | matrix

Output signal for an output argument that the function returns.

The function prototype determines the number and name of output ports that appear on the Function Caller block. Connect signal lines to the output ports to receive data from a function through the function output arguments.

For example, `y = myfunction(u)` creates one output port (`y`) on the Function Caller block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Function prototype — Specify function interface

`y=f(u)` (default) | `<function prototype>`

Specify the function interface between a Function Caller block and a Simulink function. A Simulink function can be a Simulink Function block, an exported Stateflow graphical function, or an exported Stateflow MATLAB function. For a call to a Simulink Function block:

- Function call argument names must match the function arguments.
- Function names, input arguments, and output arguments must be valid MATLAB identifiers.

Programmatic Use

Block Parameter: `FunctionPrototype`

Type: character vector

Values: `'y=f(u)'` | `'<function prototype>'`

Default: `'y=f(u)'`

Input argument specifications — Specify input argument data type, dimensions, and complexity

`<Enter example>` (default) | `<MATLAB expression>`

Specify a comma-separated list of MATLAB expressions that combine data type, dimensions, and complexity (real or imaginary) for each input argument. For examples, see “Argument Specification for Simulink Function Blocks”.

This specification must match the Simulink Function block data type specified with the **Data type** parameter of the Argument Inport block.

Programmatic Use

Block Parameter: `'InputArgumentSpecifications'`

Type: character vector

Values: `''` | `'<MATLAB expression>'`

Default: `''`

Output argument specifications — Specify output argument data type, dimensions, and complexity

`<Enter example>` (default) | `<MATLAB Expression>`

Specify a comma-separated list of MATLAB expressions that combine data type, dimensions, and complexity (real or imaginary) for each output argument. For examples, see “Argument Specification for Simulink Function Blocks”.

This specification must match the Simulink Function block data type specified with the **Data type** parameter of the Argument Outport Block.

Programmatic Use

Block Parameter: `'OutputArgumentSpecifications'`

Type: character vector

Values: '' | '<MATLAB expression>'

Default: ''

Sample time — Time interval between function calls

-1 (default) | <sample time>

Specify the interval between times that the Function Caller block calls the specified Simulink function.

By default, the block inherits its sample time based on the context of the block in the model.

To set a different sample time, enter a value using a sample time format from the table in “Specify Sample Time”.

If the Function Caller block has any inputs, it is a nonsource block, and you must set the sample time to -1.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: '-1' | *sample time*

Default: '-1'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Function Element

Specify function to be called via exporting function port

Library: Simulink / Ports & Subsystems

Description

The Function Element block allows a Simulink function in a referenced model to be called by a function caller in another referenced model. The Function Element block, when placed at the root level of a model referenced by a Model block, creates an exporting function port in the Model block. When the exporting function port is connected to an invoking function port of another Model block, a function caller in that other Model block can issue function calls and receive return values through the respective function ports of the Model blocks.

By using multiple Function Element blocks, multiple Simulink functions in a referenced model can be called through a single exporting function port. All Function Element blocks that use the same port share a dialog box. A model can have more than one exporting function port.

A Function Element block must be placed at the root level of model designated as an export-function model. See “Export-Function Models Overview”. For each Function Element block, a port-scoped Simulink Function block should also be placed at the root level of the model, defining the function to be called through the Function Element block.

Create Port and Related Blocks

When you insert an Function Element block, the block label populates with default values. The label consists of two interactive text fields: the port name and the function element name. To change the name of the port associated with the block, edit the first text field in the label by clicking the text.

To allow multiple functions to be called through a port, create a Function Element block for each

function that you want to include. In the block dialog box, you can click the **Add a new function**  button. Alternatively, hold **Ctrl** while you drag an existing Function Element block to a new location. Upon releasing the pointer, select **Use Existing Port**.

If multiple blocks are associated with the same port and you change the name of the port, all blocks that share the port update to reflect the new port name.

To create a port, hold **Ctrl** while you drag an existing Function Element block to a new location. Upon releasing the pointer, select **Create New Port**.

Modify Port Characteristics

In the block dialog box, you can:

- Change port and function element names.
- Reorder function elements by dragging an element into the list of elements.
- Remove blocks associated with selected function elements by clicking the **Remove blocks of selected function elements** button .
- Use the **Filter** box to specify a search term to use for filtering a long list of function elements. Do not enclose the search term in quotation marks. The filter does a partial string search and supports regular expressions. To use a regular expression character as a literal, include an escape character (\). For example, to use a question mark, type `fcn\?1`.

Specify Function Element Name

To change the name of the function element associated with the block, edit the second text field in the label by clicking the text.

All function element names associated with the port must be unique. Each function element name should match the function name of one of the Simulink Function blocks to be called through the port.

Specify Service Interface

To associate the port with a service interface authored in System Composer™, in the block dialog box, pause on the name of the port where it appears at the top of the list of function elements. Then, click the pencil button that appears next to the port name.

Select a service interface from the **Data type** list or enter it as `Bus: ServiceInterfaceName`. The service interface name now appears in parentheses next to the port name.

You can associate a service interface definition only with the port as a whole, not with individual function elements within the port.

Parameters

Port name — Name of exporting function port

server (default) | port name

Specify a port name that is not already in use by another port. The name appears as a port label on the parent Model block. The name also appears next to the block. Multiple blocks can access the same port.

Use the same port name in the **Scope to port** parameter of the Trigger block inside the port-scoped Simulink Function block to be called through the port.

Programmatic Use

Block Parameter: PortName

Type: character vector

Values: 'server' | '<port name>'

Default: 'server'

Port number — Position of port on parent block

1 (default) | real integer

Specify the order in which the port that corresponds to the block appears on the parent Model block.

- If you add a block that creates another port, the port number is the next available number.
- Deleting all blocks associated with a port deletes the port. Other ports are renumbered so that they are sequential and do not skip any numbers.
- Specifying a port number that exceeds the number of ports creates a port for that number and for any skipped sequential numbers.

Programmatic Use

Block Parameter: Port

Type: character vector

Values: real integer

Default: '1'

Set color — Specify block background color

Black (default) | White | Red | Green | Blue | Cyan | Magenta | Yellow | Gray | Light Blue | Orange | Dark Green | More Colors

Specify the block background color. This specification sets the color of blocks associated with selected function elements, or of all blocks associated with the port if you do not select any function elements.

Programmatic Use

Block Parameter: BackgroundColor

Type: character vector

Values: 'black' | 'white' | 'red' | 'green' | 'blue' | 'cyan' | 'magenta' | 'yellow' | 'gray' | 'lightBlue' | 'orange' | 'darkGreen' | '[r,g,b]' where r, g, and b, are the red, green, blue values of the color in the range 0.0 to 1.0

Default: 'black'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

Function Element Call

Specify function call to be issued via invoking function port

Library: Simulink / Ports & Subsystems

client.f1 

Description

The Function Element Call block allows a Function Caller block in a referenced model to call a Simulink function in another referenced model. The Function Element Call block, when placed at the root level of a model referenced by a Model block, creates an invoking function port in the Model block. When the invoking function port is connected to an exporting function port of another Model block, a Function Caller block in the Model block can issue function calls to Simulink functions in that other Model block and receive return values through the respective function ports of the Model blocks.

By using multiple Function Element Call blocks, multiple Function Caller blocks in a referenced model can issue function calls through a single invoking function port. All Function Element Call blocks that use the same port share a dialog box. A model can have more than one invoking function port.

A Function Element Call block must be placed at the root level of model designated as an export-function model. See “Export-Function Models Overview”. For each Function Element Call block, a Function-Call Subsystem block should also be placed at the root level of the model, and a Function Caller block should be placed inside the subsystem, designating the function to call through the Function Element Call block.

Create Port and Related Blocks

When you insert an Function Element Call block, the block label populates with default values. The label consists of two interactive text fields: the port name and the function element name. To change the name of the port associated with the block, edit the first text field in the label by clicking the text.

client.f1 

To allow multiple functions to be called through a port, create a Function Element Call block for each function that you want to include. In the block dialog box, you can click the **Add a new function**  button. Alternatively, hold **Ctrl** while you drag an existing Function Element Call block to a new location. Upon releasing the pointer, select **Use Existing Port**.

If multiple blocks are associated with the same port and you change the name of the port, all blocks that share the port update to reflect the new port name.

To create a port, hold **Ctrl** while you drag an existing Function Element Call block to a new location. Upon releasing the pointer, select **Create New Port**.

Modify Port Characteristics

In the block dialog box, you can:

- Change port and function element names.
- Reorder function elements by dragging an element into the list of elements.
- Remove blocks associated with selected function elements by clicking the **Remove blocks of selected function elements** button .
- Use the **Filter** box to specify a search term to use for filtering a long list of function elements. Do not enclose the search term in quotation marks. The filter does a partial string search and supports regular expressions. To use a regular expression character as a literal, include an escape character (\). For example, to use a question mark, type `fcn\?1`.

Specify Function Element Name

To change the name of the function element associated with the block, edit the second text field in the label by clicking the text.

client.f1 

All function element names associated with the port must be unique. Each function element name should match the function name of one of the Simulink Function blocks to call through the port.

Use the function element name as the function name in the **Function prototype** parameter of the Function Caller block issuing function calls through the port, qualified by the port name. See “Port name” on page 1-0 .

Specify Service Interface

To associate the port with a service interface authored in System Composer, in the block dialog box, pause on the name of the port where it appears at the top of the list of function elements. Then, click the pencil button that appears next to the port name.

Select a service interface from the **Data type** list or enter it as `Bus: ServiceInterfaceName`. The service interface name now appears in parentheses next to the port name.

You can associate a service interface definition only with the port as a whole, not with individual function elements within the port.

Parameters

Port name — Name of invoking function port

`client` (default) | port name

Specify a port name that is not already in use by another port. The name appears as a port label on the parent Model block. The name also appears next to the block. Multiple blocks can access the same port.

Use the same port name to qualify, with dot notation, the function name in the **Function prototype** parameter of the Function Caller block issuing function calls through the port:

```
[OutputArg1,OutputArg2,...] = PortName.FunctionElementName(InputArg1,InputArg2,...)
```

Programmatic Use

Block Parameter: PortName

Type: character vector

Values: 'client' | '<port name>'

Default: 'client'

Port number — Position of port on parent block

1 (default) | real integer

Specify the order in which the port that corresponds to the block appears on the parent Model block.

- If you add a block that creates another port, the port number is the next available number.
- Deleting all blocks associated with a port deletes the port. Other ports are renumbered so that they are sequential and do not skip any numbers.
- Specifying a port number that exceeds the number of ports creates a port for that number and for any skipped sequential numbers.

Programmatic Use**Block Parameter:** Port**Type:** character vector**Values:** real integer**Default:** '1'**Set color — Specify block background color**

Black (default) | White | Red | Green | Blue | Cyan | Magenta | Yellow | Gray | Light Blue | Orange | Dark Green | More Colors

Specify the block background color. This specification sets the color of blocks associated with selected function elements, or of all blocks associated with the port if you do not select any function elements.

Programmatic Use**Block Parameter:** BackgroundColor**Type:** character vector

Values: 'black' | 'white' | 'red' | 'green' | 'blue' | 'cyan' | 'magenta' | 'yellow' | 'gray' | 'lightBlue' | 'orange' | 'darkGreen' | '[r,g,b]' where r, g, and b, are the red, green, blue values of the color in the range 0.0 to 1.0

Default: 'black'**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Introduced in R2022a

Gain

Multiply input by constant

Library: Simulink / Commonly Used Blocks
Simulink / Math Operations
HDL Coder / Commonly Used Blocks
HDL Coder / HDL Floating Point Operations
HDL Coder / Math Operations

Description

The Gain block multiplies the input by a constant value (gain). The input and the gain can each be a scalar, vector, or matrix.

You specify the value of gain in the **Gain** parameter. The **Multiplication** parameter lets you specify element-wise or matrix multiplication. For matrix multiplication, this parameter also lets you indicate the order of the multiplicands.

Gain is converted from doubles to the data type specified in the block mask offline using round-to-nearest and saturation. The input and gain are then multiplied, and the result is converted to the output data type using the specified rounding and overflow modes.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

The Gain block accepts real or complex-valued scalar, vector, or matrix input. The Gain block supports fixed-point data types. If the input of the Gain block is real and gain is complex, the output is complex.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Input multiplied by gain

scalar | vector | matrix

The Gain block outputs the input multiplied by a constant gain value. When the input to the Gain block is real and gain is complex, the output is complex.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Gain — Value by which to multiply the input

1 (default) | real or complex-valued scalar, vector, or matrix

Specify the value by which to multiply the input. Gain can be a real or complex-valued scalar, vector, or matrix.

Programmatic Use

Block Parameter: Gain

Type: character vector

Values: '1' | real- or complex-valued scalar, vector, or matrix

Default: '1'

Multiplication — Specify the multiplication mode

Element-wise(K.*u) (default) | Matrix(K*u) | Matrix(u*K) | Matrix(K*u) (u vector)

Specify one of these multiplication modes:

- **Element-wise(K.*u)** — Each element of the input is multiplied by each element of the gain. The block performs expansions, if necessary, so that the input and gain have the same dimensions.
- **Matrix(K*u)** — The input and gain are matrix-multiplied with the input as the second operand.
- **Matrix(u*K)** — The input and gain are matrix-multiplied with the input as the first operand.
- **Matrix(K*u) (u vector)** — The input and gain are matrix multiplied with the input as the second operand. This mode is identical to **Matrix(K*u)**, except for how dimensions are determined.

Suppose that K is an m-by-n matrix. **Matrix(K*u) (u vector)** sets the input to a vector of length n and the output to a vector of length m. In contrast, **Matrix(K*u)** uses propagation to determine dimensions for the input and output. For an m-by-n gain matrix, the input can propagate to an n-by-q matrix, and the output becomes an m-by-q matrix.

Programmatic Use

Parameter: Multiplication

Type: character vector

Value: 'Element-wise(K.*u)' | 'Matrix(K*u)' | 'Matrix(u*K)' | 'Matrix(K*u) (u vector)'

Default: 'Element-wise(K.*u)'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "- 1"

Signal Attributes

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output data type — Specify the output data type**

Inherit: Inherit via internal rule (default) | Inherit: Keep MSB | Inherit: Match scaling | Inherit: Inherit via back propagation | Inherit: Same as input | double | single | half | int8 | uint8 | int16 | uint16 | int32 | int64 | uint64 | uint32 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select an inherited option, the block exhibits these behaviors:

- **Inherit: Inherit via internal rule** — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and ASIC/FPGA is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.
- **Inherit: Keep MSB**— Simulink chooses a data type that maintains the full range of the operation, then reduces the precision of the output to a size appropriate for the embedded target hardware.

Tip For more efficient generated code, deselect the **Saturate on integer overflow** parameter.

This rule never produces overflows.

- **Inherit: Match scaling**— Simulink chooses a data type whose scaling matches the scaling of the input types. If the full range of the type does not fit on the embedded target hardware, the range is reduced yielding a type appropriate for the embedded target hardware. This rule can produce overflows.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If these internal rules do not meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- **Inherit: Inherit via back propagation** — Use data type of the driving block.

- **Inherit:** Same as `input` — Use data type of input signal.

Dependencies

When `input` is a floating-point data type smaller than single precision, the **Inherit: Inherit via internal** rule output data type depends on the setting of the “Inherit floating-point output type smaller than single precision” configuration parameter. Data types are smaller than single precision when the number of bits needed to encode the data type is less than the 32 bits needed to encode the single-precision data type. For example, `half` and `int16` are smaller than single precision.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Keep MSB'` | `'Inherit: Match scaling'` | `'Inherit: Same as input'` | `'Inherit: Inherit via back propagation'` | `'single'` | `'half'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`

Default: `'Inherit: Inherit via internal rule'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Integer rounding mode — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

Saturate on integer overflow — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Parameter Attributes

Parameter `minimum` — Specify the minimum value of gain

[] (default) | scalar

Specify the minimum value of gain. The default value is [] (unspecified). Simulink uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** ParamMin**Type:** character vector**Value:** scalar**Default:** '[]'**Parameter maximum — Specify the maximum value of gain**

[] (default) | scalar

Specify the maximum value of gain. The default value is [] (unspecified). Simulink uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use**Block Parameter:** ParamMax**Type:** character vector**Value:** scalar**Default:** '[]'**Parameter data type — Specify the data type of the Gain parameter**

Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Inherit from 'Gain' | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the data type of the **Gain** parameter.

Tuning Gain Parameter Value When Parameter Data Type is set to Inherit via internal rule

Setting **Parameter Data type** to Inherit: Inherit via internal rule lets the Gain block select a data type based on an internal heuristic that looks at the current gain value and provides a full precision data type to represent the current gain value. When you update the diagram, Simulink deduces a data type to fit the gain value 3 with high precision and no range loss. For example, with this heuristic, if the specified gain value is 3, the Gain block deduces a selected data type of `sfix32_En29`. Consequently, this deduced data type cannot hold values greater than 4. During simulation, if you tune the gain value to 6, an overflow occurs in the selected data type and the behavior is unexpected.

While tuning a parameter with this **Parameter Data type** setting, specify the **Parameter Minimum** and **Parameter Maximum** parameters. These settings tell Simulink about the range of values you want during the simulation and allows Simulink to provide a full precision data type with sufficient range to allow safe tuning of the gain value within the specified range.

Programmatic Use**Block Parameter:** ParamDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'Inherit: Inherit via back propagation' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Block Characteristics

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Tunable Parameters

You can use a tunable parameter in a Gain block intended for HDL code generation. For details, see “Generate DUT Ports for Tunable Parameters” (HDL Coder).

HDL Architecture

ConstMultiplierOptimization	Description
none(<i>Default</i>)	By default, HDL Coder does not perform CSD or FCSD optimizations. Code generated for the Gain block retains multiplier operations.
csd	When you specify this option, the generated code decreases the area used by the model while maintaining or increasing clock speed, using canonical signed digit (CSD) techniques. CSD replaces multiplier operations with add and subtract operations. CSD minimizes the number of addition operations required for constant multiplication by representing binary numbers with a minimum count of nonzero digits.
fcsd	This option uses factored CSD (FCSD) techniques, which replace multiplier operations with shift and add/subtract operations on certain factors of the operands. These factors are generally prime but can also be a number close to a power of 2, which favors area reduction. You can achieve a greater area reduction with FCSD at the cost of decreasing clock speed.

ConstMultiplierOptimization	Description
auto	When you specify this option, the coder chooses between the CSD or FCSO optimizations. The coder chooses the optimization that yields the most area-efficient implementation, based on the number of adders required. When you specify <code>auto</code> , the coder does not use multipliers, unless conditions are such that CSD or FCSO optimizations are not possible (for example, if the design uses floating-point arithmetic).

HDL Block Properties

General	
ConstMultiplierOptimization	Canonical signed digit (CSD) or factored CSD optimization. The default is none. See also “ConstMultiplierOptimization” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is none. See also “DSPStyle” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Note For certain values of the **Gain** parameter, native floating point implements the algorithm differently instead of using multipliers. For example, if you set the **Gain** parameter to 1, the generated model uses a wire to pass the input to the output. If you set the **Gain** parameter to -1, the generated model shows a Unary Minus block that inverts the polarity of the input signal. This implementation reduces the latency and resource usage on the target platform.

Native Floating Point	
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is <code>inherit</code> . See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , <code>Zero</code> , or <code>Custom</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to <code>Custom</code> . HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).

Native Floating Point	
MantissaMultiplyStrategy	Specify how to implement the mantissa multiplication operation during code generation. By using different settings, you can control the DSP usage on the target FPGA device. The default is <code>inherit</code> . See also “MantissaMultiplyStrategy” (HDL Coder).

Gauge

Display signal value on circular scale

Library: Simulink / Dashboard

Description

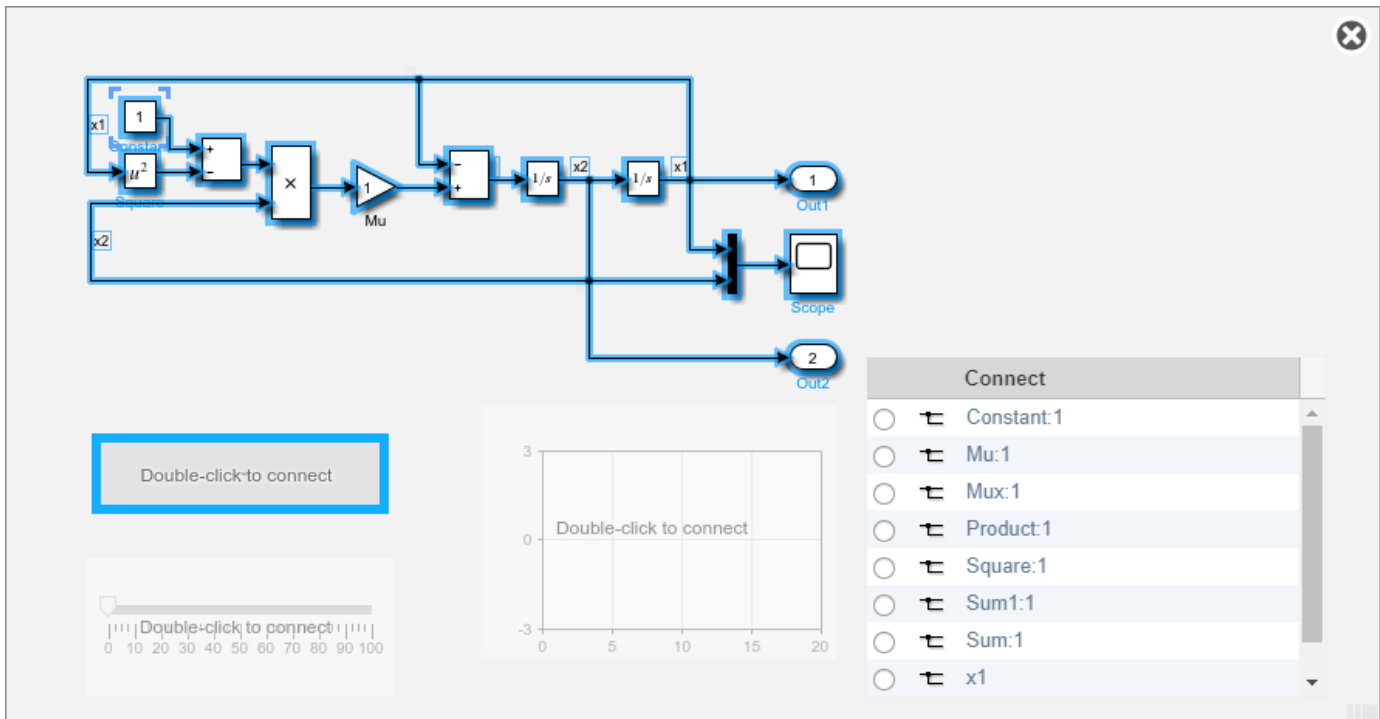

The Gauge block displays the connected signal on a circular scale during simulation. You can use the Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Gauge block to fit your data. You can also change the appearance of the dial to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, select a dashboard block to connect. Then, on the block tab, click **Connect**. In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- You cannot connect a dashboard block to state activity or chart data in Stateflow during simulation.
- You cannot programmatically connect a dashboard block to state activity or chart data in Stateflow.

- Some signals do not have data available during simulation due to block reduction or optimization for accelerator mode simulations. To view such a signal using a dashboard block, mark the signal for logging.

Parameters

Signal

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Main

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the auto value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the Maximum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the auto value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Tick Interval — Interval between major tick marks**

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the `Tick Interval` parameter, use a 1-by-3 vector containing values for the `Minimum`, `Tick Interval`, and `Maximum` parameters, in that order. To use the `auto` value for the `Tick Interval`, leave the `Tick Interval` position in the vector empty or specify `-1`.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Scale Colors — Color indications on gauge scale**

colors for scale ranges

Color specifications for value ranges on the scale. Press the **+** button to add a scale color. For each color added, specify the minimum and maximum values of the range in which you want to display that color.

Programmatic Use

To programmatically specify the `Scale Colors` parameter, use an array of structures with the fields:

- `Min` — Minimum value for the color range on the scale
- `Max` — Maximum value for the color range on the scale
- `Color` — 1-by-3 vector of double values between 0 and 1 that specify the color for the range in the form [r g b]

Include a structure in the array for each scale range for which you want to specify a color.

```
range1.Min = 0;
range1.Max = 10;
range1.Color = [0 0 1];
range2.Min = 10;
range2.Max = 15;
range2.Color = [0 1 0];
scaleRanges = [range1 range2];
```

Block Parameter: ScaleColors**Type:** structure array**Default:** 0x1 struct array**Label — Block label position**

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use**Block Parameter:** LabelPosition**Type:** character vector**Values:** 'Top' | 'Bottom' | 'Hide'**Default:** 'Top'**Scale Direction — Gauge scale direction**

Clockwise (default) | Counterclockwise

Gauge scale direction.

Programmatic Use**Block Parameter:** ScaleDirection**Type:** character vector**Values:** 'Clockwise' | 'Counterclockwise'**Default:** 'Clockwise'**Format****Opacity — Block background opacity**

1 (default) | scalar

Block background opacity, specified as a scalar value between 0 and 1.

Example: 0.5

Programmatic Use**Block Parameter:** Opacity**Type:** scalar**Default:** 1**Foreground Color — Block foreground color**

[r g b] vector

Block foreground color, excluding the text. The **Foreground Color** applies to the scale and the block name. You can select a color from a palette of standard colors or specify a custom color. To specify the color for the block text, use the **Font Color**.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: ForegroundColor**Type:** character vector | string**Values:** [r g b] vector**Background Color — Block background color**

[r g b] vector

Block background color. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: BackgroundColor

Type: character vector | string

Values: [r g b] vector

Font Color — Block font color

[r g b] vector

Block font color. The **Font Color** applies to the tick labels on the scale. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the FontColor parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: FontColor

Type: [r g b] vector

Block Characteristics

Goto

Pass block input to From blocks

Library: Simulink / Signal Routing
HDL Coder / Signal Routing

Description

The Goto block passes its input to its corresponding From blocks. The input can be a real- or complex-valued signal or vector of any data type. From and Goto blocks allow you to pass a signal from one block to another without actually connecting them.

A Goto block can pass its input signal to more than one From block, although a From block can receive a signal from only one Goto block. The input to that Goto block is passed to the From blocks associated with it as though the blocks were physically connected.

For example, this model uses a Goto block and a From block.

An equivalent model passes the Sine Wave block signal directly to the Gain block.

Goto blocks and From blocks are matched by the use of Goto tags.

The **Tag visibility** parameter determines where From blocks can access the signal.

The Goto block supports signal label propagation. For more information, see “Signal Label Propagation”.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix | N-D array

Input signal to be passed to the corresponding From block, specified as a scalar, vector, matrix, or N-D array.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Parameters

Goto tag — Block identifier

`A` (default) | ...

The Goto block identifier. This parameter identifies the Goto block whose scope is defined in this block.

Programmatic Use

Block Parameter: `GotoTag`

Type: character vector

Values: `'A'` | ...

Default: `'A'`

Tag visibility — Scope of the Goto block tag

`local` (default) | `scoped` | `global`

The scope of the Goto block tag, specified as `local`, `scoped`, or `global`. When you set this parameter to `scoped`, you must use a Goto Tag Visibility block to define the scope of tag visibility.

- `local` (default) — From and Goto blocks that use the same tag must be in the same subsystem. A local tag name is enclosed in brackets (`[]`).
- `scoped` — From and Goto blocks that use the same tag must be either:
 - In the same subsystem.
 - At any level in the model hierarchy below the Goto Tag Visibility block that does not entail crossing a nonvirtual subsystem boundary. In other words, they must be within the boundary of an atomic, conditionally executed, or function-call subsystem or a model reference.

A scoped tag name is enclosed in braces (`{}`).

- `global` — From and Goto blocks using the same tag can be anywhere in the model except in locations that span nonvirtual subsystem boundaries.

The rule that From-Goto block connections cannot cross nonvirtual subsystem boundaries has the following exception. A Goto block connected to a state port in one conditionally executed subsystem is visible to a From block inside another conditionally executed subsystem.

Note A `scoped` Goto block in a masked system is visible only in that subsystem and in the nonvirtual subsystems it contains. Simulink generates an error if you run or update a diagram that has a Goto Tag Visibility block at a higher level in the block diagram than the corresponding `scoped` Goto block in the masked subsystem.

Use local tags when the Goto and From blocks using the same tag name reside in the same subsystem. You must use `global` or `scoped` tags when the Goto and From blocks using the same tag name reside in different subsystems. When you define a tag as `global`, all uses of that tag access the same signal. A tag defined as `scoped` can be used in more than one place in the model.

Programmatic Use**Block Parameter:** TagVisibility**Type:** character vector**Values:** 'local' | 'scoped' | 'global'**Default:** 'local'**Icon display — Text to display on block icon**

Tag (default) | Signal name | Tag and signal name

Specifies the text to display on the block icon. The options are the block tag, the name of the signal that the block represents, or both the tag and the signal name.

Programmatic Use**Block Parameter:** IconDisplay**Type:** character vector**Values:** 'Signal name' | 'Tag' | 'Tag and signal name'**Default:** 'Tag'**Rename All — Propagate name throughout model**

button

Rename the Goto tag. The new name propagates to all From and Goto Tag Visibility blocks that are listed in the **Corresponding blocks** box.

Alternatively, when you change the tag on the Goto block icon, propagate the new name to all corresponding From and Goto Tag Visibility blocks by pressing **Shift+Enter**.

Corresponding blocks — Blocks connected to this Goto block

block path | ...

List of the From blocks and Goto Tag Visibility blocks connected to this Goto block. Click an entry in the list to display and highlight the corresponding From and Goto Tag Visibility blocks.

Alternatively, in the Simulink Editor, select the Goto block to highlight the corresponding From and Goto Tag Visibility blocks.

When a corresponding From or Goto Tag Visibility block is not in the current diagram, the Subsystem block that contains the block is highlighted.

To show a corresponding block in an open diagram or new tab, select the Goto block and pause on the ellipsis. Then, select **Related Blocks**  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list of related blocks by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Goto Tag Visibility

Define scope of Goto block tag

Library: Simulink / Signal Routing

Description

The Goto Tag Visibility block defines the accessibility of Goto block tags that have **scoped** visibility. The value you specify for the **Goto tag** block parameter is accessible by From blocks in the same subsystem that contains the Goto Tag Visibility block and in subsystems below it in the model hierarchy.

A Goto Tag Visibility block is required for Goto blocks whose **Tag Visibility** parameter value is **scoped**. No Goto Tag Visibility block is needed if the tag visibility is either **local** or **global**. The block shows the tag name enclosed in braces ({}).

Note A **scoped** Goto block in a masked system is visible only in that subsystem and in the nonvirtual subsystems it contains. Simulink generates an error if you run or update a diagram that has a Goto Tag Visibility block at a lower level in the block diagram than the corresponding **scoped** Goto block in the masked subsystem.

In the Simulink Editor, select the Goto Tag Visibility block to highlight the corresponding Goto and From blocks. When a corresponding From or Goto block is not in the current diagram, the Subsystem block that contains the block is highlighted.

To show a corresponding block in an open diagram or new tab, select the Goto Tag Visibility block and pause on the ellipsis. Then, select **Related Blocks**  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list of related blocks by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Parameters

Goto tag — Goto block tag whose visibility is defined by the location of this block

A (default) | ...

The Goto block tag whose visibility is defined by the location of this block. From and Goto blocks using the specified tag must be in the same subsystem or at any level in the model hierarchy below the Goto Tag Visibility block that does not entail crossing a nonvirtual subsystem boundary, in other words, the boundary of an atomic, conditionally executed, or function-call subsystem or a model reference. A **scoped** tag name is enclosed in braces ({}).

Tip If you use multiple From and Goto Tag Visibility blocks to refer to the same Goto tag, you can simultaneously rename the tag in all of the blocks. Use the **Rename All** button in the Goto block dialog box. Alternatively, when you change the tag on the Goto block icon, propagate the new name to all corresponding From and Goto Tag Visibility blocks by pressing **Shift+Enter**.

Ground

Ground unconnected input port

Library: Simulink / Commonly Used Blocks
 Simulink / Sources
 HDL Coder / Sources

Description

The Ground block connects to blocks whose input ports do not connect to other blocks. If you run a simulation with blocks that have unconnected input ports, Simulink issues warnings. Using a Ground block to ground those unconnected blocks can prevent these warnings.

Working with Fixed-Point Data Types

When working with fixed-point data types, there may be instances where the fixed-point data type cannot represent zero exactly. In these cases, the Ground block outputs a nonzero value that is the closest possible value to zero. This behavior applies only to fixed-point data types with nonzero bias. These expressions are examples of fixed-point data types that cannot represent zero:

- `fixdt(0, 8, 1, 1)` — an unsigned 8-bit type with slope of 1 and bias of 1
- `fixdt(1, 8, 6, 3)` — a signed 8-bit type with slope of 6 and bias of 3

Working with Enumerated Data Types

When working with enumerated data types, the Ground block outputs the default value of the enumeration. This behavior applies whether:

- The enumeration can represent zero
- The default value of the enumeration is zero

If the enumerated type does not have a default value, the Ground block outputs the first enumeration value in the type definition.

Ports

Output

Port_1 — Ground signal

scalar

The Ground block outputs a scalar signal with zero value, and the same data type as the port to which it connects.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `string` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Half Gauge

Display input value on semicircular scale

Library: Simulink / Dashboard

Description

The Half Gauge block displays the connected signal on a semicircular scale during simulation. You can use the Half Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Half Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Half Gauge block to fit your data. You can also customize the appearance of the Half Gauge block to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, select a dashboard block to connect. Then, on the block tab, click **Connect**. In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- You cannot connect a dashboard block to state activity or chart data in Stateflow during simulation.
- You cannot programmatically connect a dashboard block to state activity or chart data in Stateflow.

- Some signals do not have data available during simulation due to block reduction or optimization for accelerator mode simulations. To view such a signal using a dashboard block, mark the signal for logging.

Parameters

Signal

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Main

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the auto value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the Maximum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the auto value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Tick Interval — Interval between major tick marks**

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the `Tick Interval` parameter, use a 1-by-3 vector containing values for the `Minimum`, `Tick Interval`, and `Maximum` parameters, in that order. To use the `auto` value for the `Tick Interval`, leave the `Tick Interval` position in the vector empty or specify `-1`.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Scale Colors — Color indications on gauge scale**

colors for scale ranges

Color specifications for value ranges on the scale. Press the **+** button to add a scale color. For each color added, specify the minimum and maximum values of the range in which you want to display that color.

Programmatic Use

To programmatically specify the `Scale Colors` parameter, use an array of structures with the fields:

- `Min` — Minimum value for the color range on the scale
- `Max` — Maximum value for the color range on the scale
- `Color` — 1-by-3 vector of double values between 0 and 1 that specify the color for the range in the form [r g b]

Include a structure in the array for each scale range for which you want to specify a color.

```
range1.Min = 0;  
range1.Max = 10;  
range1.Color = [0 0 1];  
range2.Min = 10;  
range2.Max = 15;  
range2.Color = [0 1 0];  
scaleRanges = [range1 range2];
```

Block Parameter: ScaleColors**Type:** structure array**Default:** 0x1 struct array**Label — Block label position**

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use**Block Parameter:** LabelPosition**Type:** character vector**Values:** 'Top' | 'Bottom' | 'Hide'**Default:** 'Top'**Scale Direction — Gauge scale direction**

Clockwise (default) | Counterclockwise

Gauge scale direction.

Programmatic Use**Block Parameter:** ScaleDirection**Type:** character vector**Values:** 'Clockwise' | 'Counterclockwise'**Default:** 'Clockwise'**Format****Opacity — Block background opacity**

1 (default) | scalar

Block background opacity, specified as a scalar value between 0 and 1.

Example: 0.5

Programmatic Use**Block Parameter:** Opacity**Type:** scalar**Default:** 1**Foreground Color — Block foreground color**

[r g b] vector

Block foreground color, excluding the text. The **Foreground Color** applies to the scale and the block name. You can select a color from a palette of standard colors or specify a custom color. To specify the color for the block text, use the **Font Color**.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: ForegroundColor**Type:** character vector | string**Values:** [r g b] vector**Background Color — Block background color**

[r g b] vector

Block background color. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: BackgroundColor

Type: character vector | string

Values: [r g b] vector

Font Color — Block font color

[r g b] vector

Block font color. The **Font Color** applies to the tick labels on the scale. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the FontColor parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: FontColor

Type: [r g b] vector

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Hermitian Transpose

Compute hermitian transpose of matrix

Library: Simulink / Matrix Operations

Description

The Hermitian Transpose block computes the hermitian transpose of an M -by- N matrix.

Ports

Input

Port_1 — Matrix

M -by- N matrix

Matrix, specified as an M -by- N matrix.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Transposed matrix

N -by- M matrix

Transposed matrix, returned as an N -by- M matrix.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Block Characteristics

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Hit Crossing

Detect crossing point

Library: Simulink / Discontinuities
 Simulink / Messages & Events
 HDL Coder / Discontinuities
 SimEvents

Description

The Hit Crossing block detects when the input reaches the **Hit crossing offset** parameter value in the direction specified by the **Hit crossing direction** property.

You can configure the block to output a 1 or 0 signal, a SimEvents® message, or a function-call event. See “Output” on page 1-743 for more information.

Ports

Input

Port_1 – Input signal

scalar | vector

Input signal that the block detects when it reaches the offset in the specified direction.

Data Types: double

Output

Port_1 – Output signal

scalar | vector | SimEvents message | function-call event

Output indicating if the input signal crossed the hit offset. This port is visible only when you select the **Show output port** parameter check box.

Signal Output

If you select the **Show output port** check box and set the **Output type** parameter to Signal, the block output indicates when the crossing occurs.

- If the input signal is exactly the value of the offset value after the hit crossing is detected in the specified direction, the block continues to output a value of 1.
- If the input signals at two adjacent points brackets the offset value, the block outputs a value of 1 at the second time step.
- If the **Show output port** check box is *not* selected, the block ensures that the simulation finds the crossing point but does not generate output.
- If the initial signal is equal to the offset value, the block outputs 1 only if the **Hit crossing direction** property is set to either.

- If Boolean logic signals are enabled, then the output is a Boolean.

SimEvents Message Output

The Hit Crossing block can also output a SimEvents message when the **Output type** parameter is set to Message.

- If the input signal crosses the offset value in the specified direction, the block outputs a message.
- If the input signal reaches the offset value in the specified direction and remains there, block outputs one message at the hit time and one message when the signal leaves the offset value.
- If the initial input signal is equal to the offset value, the block outputs a message with Crossing Type value None only if the **Hit crossing direction** is set to either.

The SimEvents message output signal is a struct with four fields.

Function-Call Output

The Hit Crossing block can also output a function-call event when the **Output type** parameter is set to Function-Call.

- Each time the input signal crosses the offset value in the specified direction, the block outputs a single function-call event.
- The function-call event can be sent to the function-call input port of a function-call subsystem or function-call model.
- The output is equivalent to the output of a Function-Call Generator block at each time step with the **Number of iterations** parameter of that block set to 1.

CrossingType — Direction of zero-crossing

None | NegativeToPositive | NegativeToZero | ZeroToPositive | PositiveToNegative | PositiveToZero | ZeroToNegative

This field shows the direction in which the signal crosses the **Hit crossing offset** value. Negative, Zero, and Positive are defined relative to the offset value. The data type is `slHitCrossingType` which is an enumerated data type. See “Use Enumerated Data in Simulink Models” for more information. For example, if `HitCrossingOffset` is set to 2, a rising signal crossing this offset value would be recorded as a `NegativeToPositive` hit crossing.

Note A hit crossing is recorded based on the **Hit crossing direction** setting. In other words, if you set **Hit crossing direction** to detect a falling hit crossing, a `NegativeToPositive` hit is not recorded.

Note In a SimEvents block, if the Crossing Type of an entity is a `NegativeToPositive` hitcrossing then `entity.CrossingType == slHitCrossingType.NegativeToPositive` returns logical 1 (true).

If the signal reaches the `HitCrossingOffset` value and holds it, a single `NegativeToZero` or `PositiveToZero`, depending on the direction, hit is registered at the time of the hit crossing.

Data Types: `slHitCrossingType`

Index — Index of the input signal at which the hit crossing event occurs

nonnegative integer

For n signals being passed to the Hit Crossing block, this field denotes which signal had a hit crossing event. For a matrix input, this field follows MATLAB linear indexing. See “Array Indexing”.

Data Types: `uint32`

Time — Time of hit crossing event

real, finite

Time T of the hit crossing event.

Data Types: `double`

Offset — Hit crossing value for detection

0 (default) | real values

Hit crossing offset value as specified by the “Hit crossing offset” on page 1-0 parameter.

Data Types: `double`

Data Types: `double` | `Boolean` | `struct`

Note If the SimEvents message output signal crosses model reference boundaries or is used as an input to a Stateflow chart, you need to create a bus object for the message. See “Tips” on page 1-747.

Parameters

Hit crossing offset — Hit crossing value for detection

0 (default) | real values

Specify the value the block detects when the input crosses in the direction specified by **Hit crossing direction**.

Programmatic Use

Block Parameter: `HitCrossingOffset`

Type: character vector

Values: real values

Default: '0'

Hit crossing direction — Input signal direction to hit crossing

either (default) | falling | rising

Direction from which the input signal approaches the hit crossing offset for a crossing to be detected.

When set to `either`, the block serves as an *almost equal* block, useful in working around limitations in finite mathematics and computer precision. Used for these reasons, this block might be more convenient than adding logic to your model to detect this condition.

When the **Hit crossing direction** property is set to `either` and the model uses a fixed-step solver, the block has the following behavior. If the output signal is 1, the block sets the output signal to 0 at the next time step, unless the input signal equals the offset value.

Programmatic Use

Block Parameter: `HitCrossingDirection`

Type: character vector
Values: 'either' | 'rising' | 'falling'
Default: 'either'

Show output port — Display an output port

off (default) | on

If selected, create an output port on the block icon.

Programmatic Use

Block Parameter: ShowOutputPort

Type: character vector

Values: 'off' | 'on'

Default: 'on'

Output type — Choose signal, message, or function-call output

Signal (default for Simulink) | Message (default for SimEvents) | Function-Call

When **Output type** is set to Signal, the output signal is set to one whenever the input signal crosses the **Hit crossing offset** value in the **Hit crossing direction** and is zero at other times.

When the **Output type** is set to Message, the output signal becomes a SimEvents message.

When **Output type** is set to Function-Call, the output signal becomes a function-call event.

Programmatic Use

Block Parameter: HitCrossingOutputType

Type: character vector

Values: 'Signal' | 'Message' | 'Function-Call'

Default: 'Signal'

Enable zero-crossing detection — Enable zero-crossing detection

on (default) | off

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection”.

Programmatic Use

Parameter: ZeroCross

Type: character vector, string

Values: 'on' | 'off'

Default: 'on'

Block Characteristics

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	yes

Tips

If the Hit Crossing block is configured to output a SimEvents message and the output signal:

- Crosses into or out of a referenced model
- Is fed to the input of a Stateflow chart

then you need to create a bus object for the message signal. In the MATLAB Command Window, run `Simulink.createHitCrossMessage` to check for and, if needed, create a hit crossing message bus object in the base workspace.

Set the data type of the corresponding port to Bus: `HitCrossMessage`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code.

Does not support non-floating data type for ert targets.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Restriction

The Hit crossing direction must be rising or falling.

HDL code generation is not supported when the Output Type is set to Message.

Introduced before R2006a

Horizontal Gauge

Display signal value during simulation on horizontal gauge with customizable appearance

Library: Simulink / Dashboard / Customizable Blocks

Description

The Horizontal Gauge block displays the value of the connected signal on a linear gauge that you can customize to look like a gauge in a real system.

The Horizontal Gauge block displays the instantaneous value of the connected signal throughout simulation. You can modify the range and tick values on the Horizontal Gauge block to fit your data. Use the Horizontal Gauge block with other dashboard blocks to build an interactive dashboard of controls and indicators for your model.

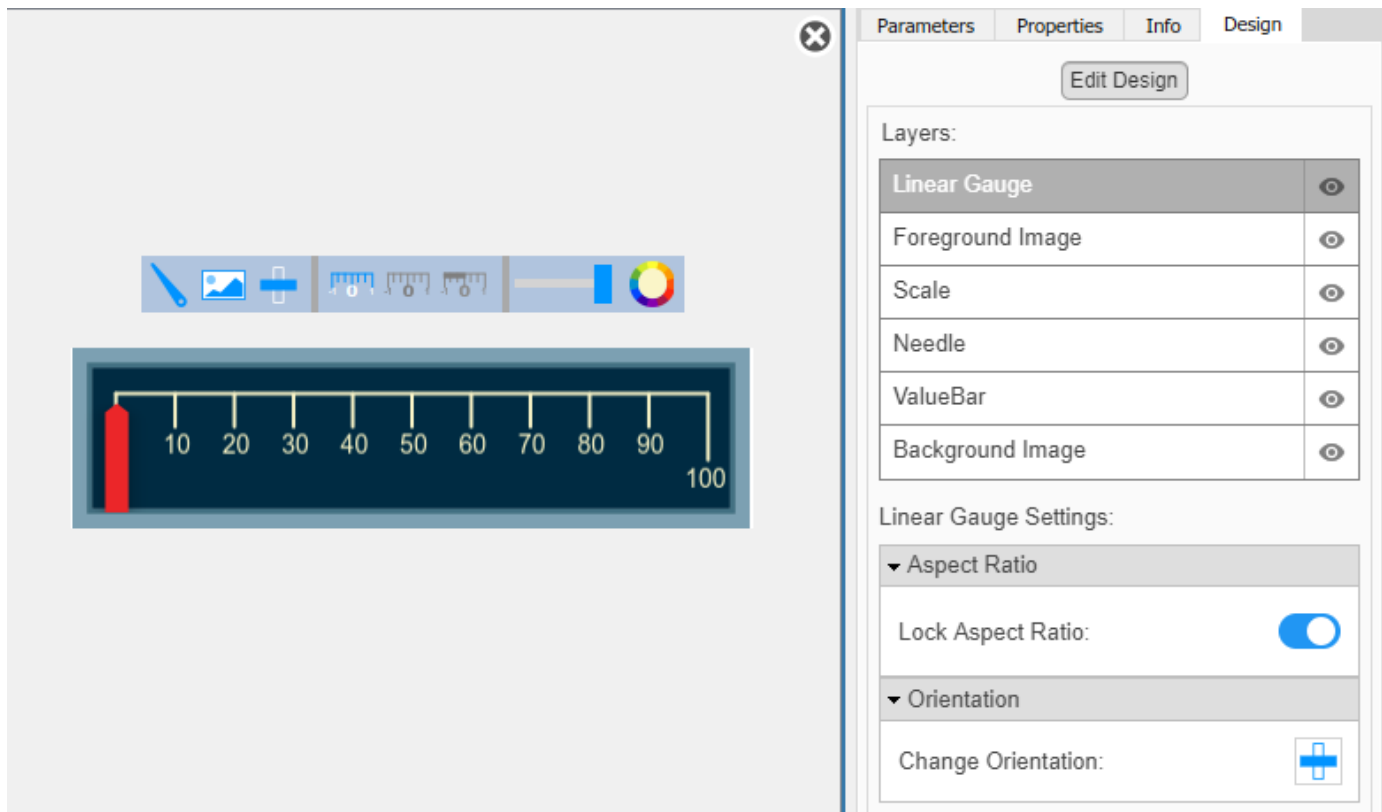

Customize Horizontal Gauge Blocks

When you add a Horizontal Gauge block to your model, the block is preconfigured with a default design. You can use the block with the default design or customize the appearance of the block using design mode. You can enter design mode in one of three ways after selecting the block:

- On the **Gauge** tab, under **Design**, click **Edit**.
- In the **Property Inspector**, on the **Design** tab, click **Edit**.
- Pause on the ellipsis that appears above the block and click the **Edit Custom Block** button.

In design mode, you have access to block parameters and settings that allow you to design the appearance of the block. You can use the toolbar above the block to change the background image or needle image and to set the opacity and color for the scale, tick labels, and value bar. To design the appearance of the scale, select the aspect of the scale you want to edit in the middle section of the toolbar. Use the controls on the right of the toolbar to set the color and opacity. You can also click and drag to reposition the needle or the scale.

For fine control of the block design, use the **Design** tab in the **Property Inspector**. You can use the **Property Inspector** to enter exact values for design settings. The **Design** tab also includes design parameters that are not available through the toolbar or interactive editing, such as the ability to add a foreground image to the block.

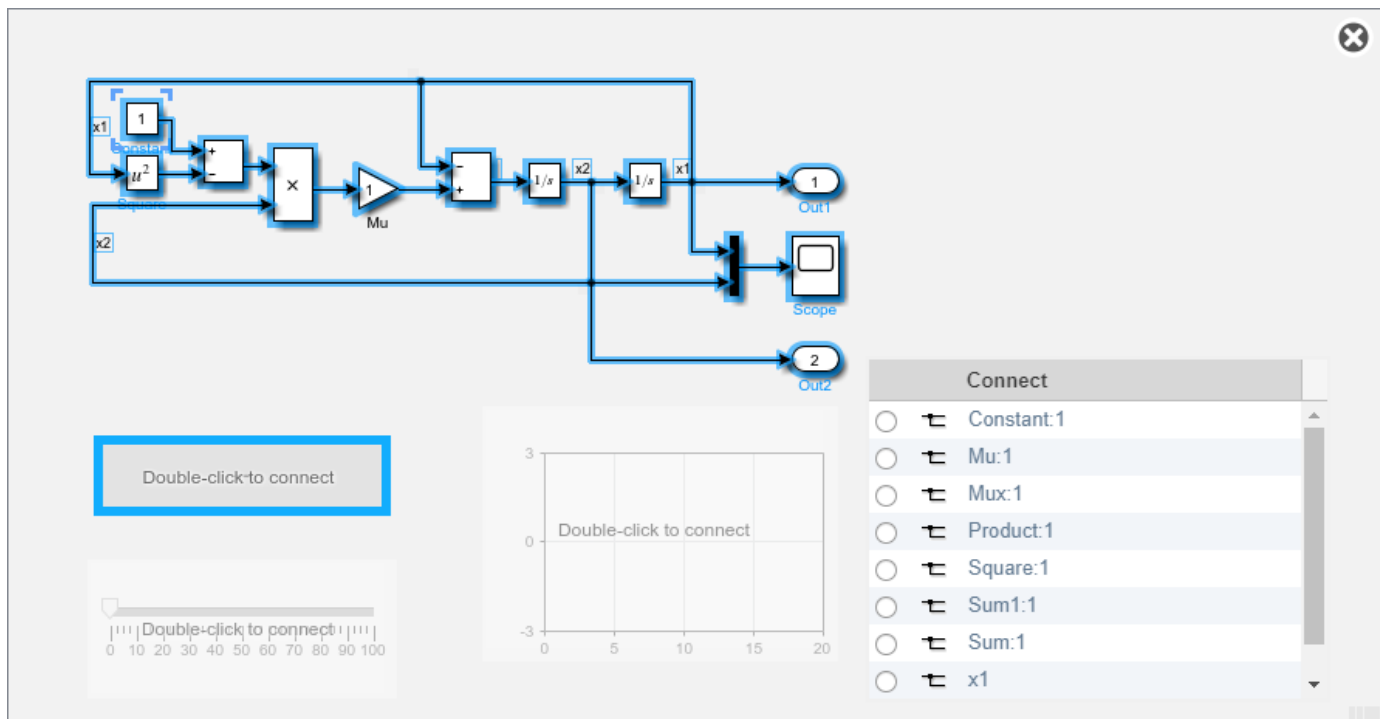

When you finish editing the design, click **Exit** in the upper-right of the canvas to exit design mode.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, select a dashboard block to connect. Then, on the block tab, click **Connect**. In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- You cannot connect a dashboard block to state activity or chart data in Stateflow during simulation.
- You cannot programmatically connect a dashboard block to state activity or chart data in Stateflow.

- Some signals do not have data available during simulation due to block reduction or optimization for accelerator mode simulations. To view such a signal using a dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the Maximum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Tick Interval — Interval between major tick marks

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to auto, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the Tick Interval parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the auto value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Scale Colors — Color indications on gauge scale**

colors for scale ranges

Color specifications for value ranges on the scale. Press the + button to add a scale color. For each color added, specify the minimum and maximum values of the range in which you want to display that color.

Programmatic Use

To programmatically specify the Scale Colors parameter, use an array of structures with the fields:

- **Min** — Minimum value for the color range on the scale
- **Max** — Maximum value for the color range on the scale
- **Color** — 1-by-3 vector of double values between 0 and 1 that specify the color for the range in the form [r g b]

Include a structure in the array for each scale range for which you want to specify a color.

```
range1.Min = 0;
range1.Max = 10;
range1.Color = [0 0 1];
range2.Min = 10;
range2.Max = 15;
range2.Color = [0 1 0];
scaleRanges = [range1 range2];
```

Block Parameter: ScaleColors**Type:** structure array**Default:** 0x1 struct array**Lock Aspect Ratio — Option to maintain block aspect ratio**

on (default) | off

Turn on this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tips

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.

- When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use**Block Parameter:** LabelPosition**Type:** character vector**Values:** 'Top' | 'Bottom' | 'Hide'**Default:** 'Top'**Scale Direction — Direction of increasing scale values**

'Left to right' (default) | 'Right to left'

Set the direction of increasing scale values.

Programmatic Use**Block Parameter:** ScaleDirection**Type:** character vector**Values:** 'Clockwise' | 'Counterclockwise'**Default:** 'Clockwise'**Opacity — Block background opacity**

1 (default) | scalar

Block background opacity, specified as a scalar value between 0 and 1. Specify the background opacity using the **Design** tab in the Property Inspector.

- 1 On the **Design** tab, click **Edit Design**.
- 2 Select the **Background** component.
- 3 In the **Background Color** section, specify the desired opacity.

Example: 0.5

Programmatic Use**Block Parameter:** Opacity**Type:** scalar**Default:** 1**Foreground Color — Block foreground color**

[r g b] vector

Block foreground color, excluding the text. The **Foreground Color** applies to the scale and the block name. To specify the color for the block text, use the **Font Color**.

Specify the **Foreground Color** for the block using the **Design** tab in the Property Inspector.

- 1 On the **Design** tab, click **Edit Design**.
- 2 Select the **Scale** component.

- 3 In the **Ticks** section, open the **Color** menu. You can choose from the palette of standard colors or specify a custom color.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `ForegroundColor`

Type: character vector | string

Values: [r g b] vector

Background Color — Block background color

[r g b] vector

Block background color. You can choose to select a solid background color instead of providing a background image. To design a block that uses a solid background, use the **Design** tab in the Property Inspector.

- 1 On the **Design** tab, click **Edit Design**.
- 2 Select the **Background** component.
- 3 Select **Use background color**.
- 4 Choose a background color from the palette of standard colors or specify a custom color.
- 5 Adjust the **Offset from scale** option until the solid background is the desired size.

Changing the background color using the toolbar removes the background image and enables the **Use background color** option.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: [r g b] vector

Font Color — Block font color

[r g b] vector

Block font color. The **Font Color** applies to the scale labels. To specify the color of the scale, use the **Foreground Color**.

Specify the **Font Color** for the block using the **Design** tab in the Property Inspector.

- 1 On the **Design** tab, click **Edit Design**.
- 2 Select the **Scale** component.
- 3 In the **Labels** section, open the **Color** menu. You can choose from the palette of standard colors or specify a custom color.

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single
-------------------	---

Introduced in R2020a

Horizontal Slider

Change parameter or variable value using horizontal slider with customizable appearance

Library: Simulink / Dashboard / Customizable Blocks

Description

Use the Horizontal Slider block to tune the value of a variable or block parameter during simulation. You can customize the appearance of the Horizontal Slider block to look like a control in a real system. You can adjust the scale range and tick values to fit the desired range for the value you want to tune. Use the Horizontal Slider block with other dashboard blocks to create an interactive dashboard to control your model.

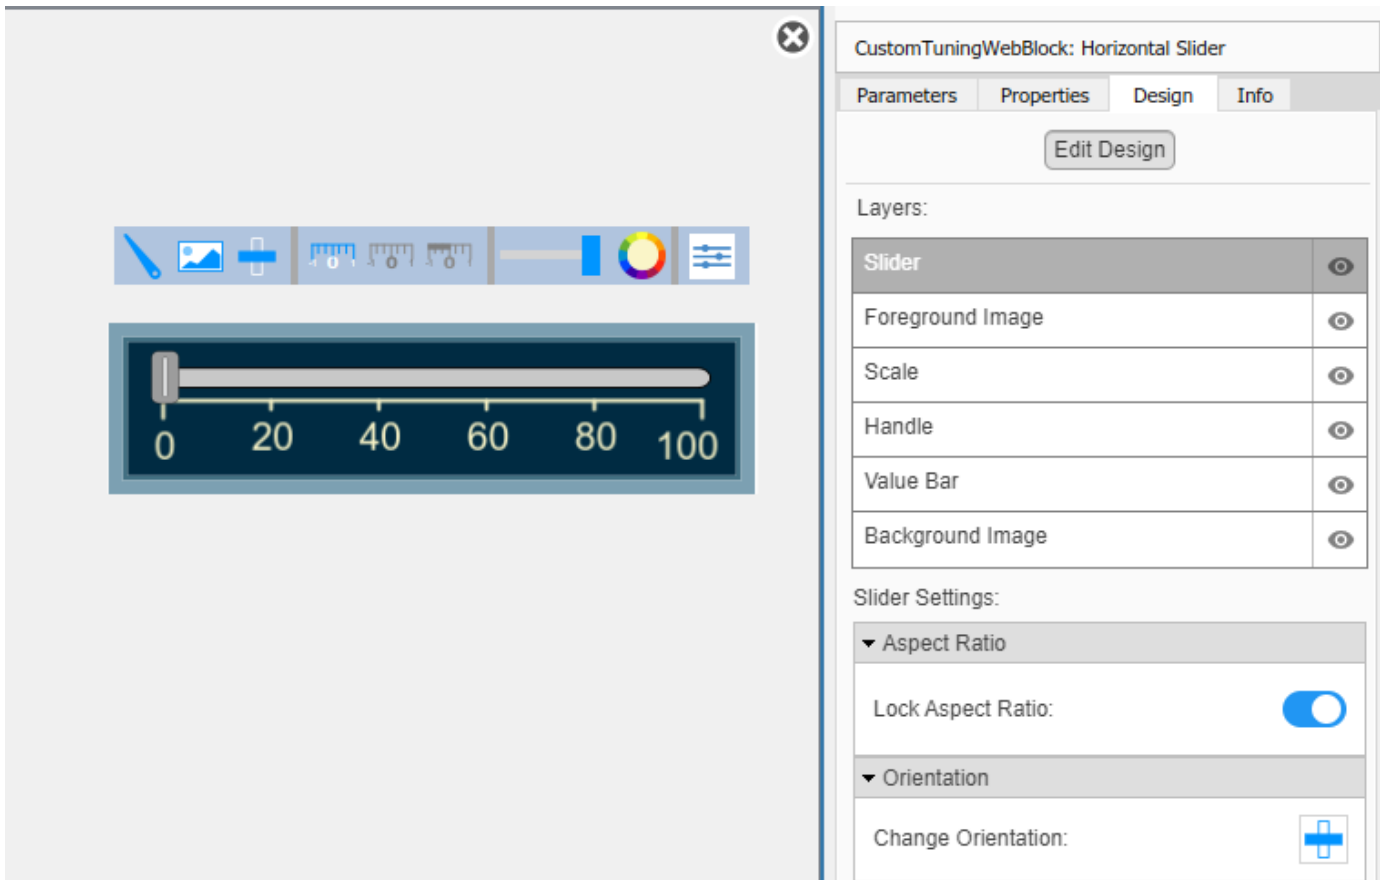

Customize Horizontal Slider Blocks

When you add a Horizontal Slider block to your model, the block is preconfigured with a default design. You can use the block with the default design or customize the appearance of the block using design mode. You can enter design mode in one of three ways after selecting the block:

- On the **Slider** tab, under **Design**, click **Edit**.
- In the **Property Inspector**, on the **Design** tab, click **Edit**.
- Pause on the ellipsis that appears above the block and click the **Edit Custom Block** button.

In design mode, you have access to block parameters and settings that allow you to design the appearance of the block. You can use the toolbar above the block to change the background image or needle image and to set the opacity and color for the scale, tick labels, and value bar. To design the appearance of the scale, select the aspect of the scale you want to edit in the middle section of the toolbar. Use the controls on the right of the toolbar to set the color and opacity. You can also click and drag to reposition the needle or the scale.

For fine control of the block design, use the **Design** tab in the **Property Inspector**. You can use the **Property Inspector** to enter exact values for design settings. The **Design** tab also includes design parameters that are not available through the toolbar or interactive editing, such as the ability to add a foreground image to the block.

When you finish editing the design, click **Exit** in the upper-right of the canvas to exit design mode.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, select the block. Then, on the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1,3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

The screenshot displays the Simulink dashboard connection interface. The main window shows a control system model with blocks like gain, sum, product, and integrators. A 'Connect' table on the right lists available elements for connection. A 'Scope' block is highlighted, and its connection table is visible. A 'Horizontal Slider' block is also shown with its own connection table.

<input type="radio"/>	Scope: ActiveDisplayYMaximum
<input type="radio"/>	Scope: ActiveDisplayYMinimum
<input type="radio"/>	Scope: AxesScalingNumUpdates

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection — Select a variable or block parameter to connect

variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1,3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: []

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the Maximum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Tick Interval — Interval between major tick marks

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the Tick Interval parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Scale Direction — Direction of increasing scale values

'Left to right' (default) | 'Right to left'

Set the direction of increasing scale values.

Programmatic Use

Block Parameter: ScaleDirection

Type: character vector

Values: 'Clockwise' | 'Counterclockwise'

Default: 'Clockwise'

Foreground Color — Block foreground color

[r g b] vector

Block foreground color, excluding the text. The **Foreground Color** applies to the scale and the block name. To specify the color for the block text, use the **Font Color**.

Specify the **Foreground Color** for the block using the **Design** tab in the Property Inspector.

- 1 On the **Design** tab, click **Edit Design**.
- 2 Select the **Scale** component.
- 3 In the **Ticks** section, open the **Color** menu. You can choose from the palette of standard colors or specify a custom color.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: ForegroundColor

Type: character vector | string

Values: [r g b] vector

Background Color — Block background color

[r g b] vector

Block background color. You can choose to select a solid background color instead of providing a background image. To design a block that uses a solid background, use the **Design** tab in the Property Inspector.

- 1 On the **Design** tab, click **Edit Design**.

- 2 Select the **Background** component.
- 3 Select **Use background color**.
- 4 Choose a background color from the palette of standard colors or specify a custom color.
- 5 Adjust the **Offset from scale** option until the solid background is the desired size.

Changing the background color using the toolbar removes the background image and enables the **Use background color** option.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 `[r g b]` vector with values between 0 and 1.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: `[r g b]` vector

Font Color — Block font color

`[r g b]` vector

Block font color. The **Font Color** applies to the scale labels. To specify the color of the scale, use the **Foreground Color**.

Specify the **Font Color** for the block using the **Design** tab in the Property Inspector.

- 1 On the **Design** tab, click **Edit Design**.
- 2 Select the **Scale** component.
- 3 In the **Labels** section, open the **Color** menu. You can choose from the palette of standard colors or specify a custom color.

IC

Set initial value of signal

Library: Simulink / Signal Attributes

Description

The IC block sets the initial condition of the signal at its input port, for example, the value of the signal at the simulation start time (t_{start}). To do so, the block outputs the specified initial condition when you start the simulation, regardless of the actual value of the input signal. Thereafter, the block outputs the actual value of the input signal.

The IC block is useful for providing an initial guess for the algebraic state variables in a loop. For more information, see “Algebraic Loop Concepts”.

Behavior for Nonzero Sample Time Offset

If an IC block has a nonzero sample time offset (t_{offset}), the IC block outputs its initial value at time t ,

$$t = n * t_{period} + t_{offset}$$

where n is the smallest integer such that $t \geq t_{start}$.

That is, the IC block outputs its initial value the first-time blocks with sample time $[t_{period}, t_{offset}]$ execute, which can be after t_{start} .

Ports

Input

Port_1 – Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array. The block sets the initial condition of this signal to the **Initial value** you specify.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 – Output signal

scalar | vector | matrix | N-D array

Output signal provided as the **Initial value** you specify, followed by the actual values of the input signal. See “Behavior for Nonzero Sample Time Offset” on page 1-765 for more information.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Initial value — Initial value

1 (default) | real, finite scalar, vector, matrix, or N-D array

Specify the initial value of the input signal as a finite, real-valued scalar, vector, matrix, or N-D array. The value must be a scalar, or have the same dimensions as the input signal.

Programmatic Use

Block Parameter: Value

Type: character vector

Values: scalar | vector | matrix | N-D array

Default: '1'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Block Characteristics

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and

freeing of memory, recursion, additional memory overhead, and widely varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Identity Matrix

Generate matrix with ones on main diagonal and ground values elsewhere

Library: Simulink / Matrix Operations

Description

The Identity Matrix block outputs an identity matrix, similar to the MATLAB `eye` function. The block generates a square or rectangular matrix with ones on the main diagonal and zeros elsewhere.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

Input signal used to determine dimensions of the output matrix, specified as a scalar, vector, or matrix. When the input signal is an M -by- N matrix, the block generates an M -by- N matrix output with the same sample period as the input. The values in the input matrix are ignored.

Dependencies

To enable this port, select the **Inherit output port attributes from input port** check box.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 – Identity matrix

scalar | vector | matrix

Identity matrix, specified as a scalar, vector, or matrix.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Inherit output port attributes from input port – Option for output port to inherit attributes from input port

off (default) | on

Select this check box for the output port to inherit its dimensions, sample period, and data type from the input port. Otherwise, clear this check box.

Programmatic Use**Block Parameter:** InheritOutputPortAttributes**Type:** character vector**Values:** 'on' | 'off'**Default:** 'off'**Output dimensions — Size of output matrix**

5 (default) | scalar | two-element vector

The number of rows and columns in the output matrix. You can specify:

- A positive integer scalar M to create a square M -by- M output.
- A vector of positive integers, $[M N]$, to create an M -by- N output.

Dependencies

To enable this parameter, clear the **Inherit output port attributes from input port** check box.

Programmatic Use**Block Parameter:** OutputDimensions**Type:** character vector**Values:** scalar | two-element vector**Default:** '5'**Output data type — Output data type**

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16,0) | Inherit: Inherit via back propagation | <data type expression>

Specify the output data type for this block. You can select one of these options:

- A rule that inherits a data type, for example, Inherit: Inherit via back propagation. When you select this option, the output data type and scaling matches that of the next downstream block.
- A built-in data type, such as double.
- An expression that evaluates to a valid data type, for example, fixdt(1,16).

For help setting data type parameters, display the **Data Type Assistant** by clicking the **Show data type assistant** button .

See “Control Data Types of Signals” for more information.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'double'**Mode — Data type mode**

Inherit (default) | Built in | Fixed point | Expression

Select how you would like to specify the data type properties of the **Output data type**. You can choose:

- **Inherit** — Specify a rule for inheriting a data type, for example, `Inherit: Same as input`.
- **Built in**— Specify a built-in data type, for example, `double`.
- **Fixed point** — Specify the fixed-point attributes of the data type.
- **Expression** — Specify an expression that evaluates to a valid data type, for example, `fixdt(1,16)`.

For more information, see “Specify Data Types Using Data Type Assistant”.

Signedness — Signedness of fixed-point data

`Signed (default) | Unsigned`

Specify whether the fixed-point data is signed or unsigned. **Signed** data can represent positive and negative values, but **Unsigned** data represents positive values only. For more information, see “Specify Data Types Using Data Type Assistant”.

Scaling — Method for scaling fixed-point data

`Best precision (default) | Binary point`

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, set **Mode** to `Fixed point`

Word length — Bit size of word that holds quantized integer

`16 (default) | integer from 2 to 128`

Specify the bit size of the word that holds the quantized integer as a positive integer from 2 to 128. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, set **Mode** to `Fixed point`.

Fraction length — Fraction length for fixed-point data type

`0 (default) | integer scalar`

Specify the fraction length of the fixed-point data type as a positive or negative integer scalar.

Dependencies

To enable this parameter, set **Mode** to `Fixed point` and **Scaling** to `Binary point`.

Data type override — Data type override mode

`Inherit (default) | Off`

Select the data type override mode for this signal. You can select:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify.

Dependencies

To enable this parameter, set **Mode** to **Built in** or **Fixed point**. For more information, see “Specify Data Types Using Data Type Assistant”.

Sample time — Output sample period

1 (default) | scalar

The discrete sample period of the output, specified as a real-valued scalar.

Dependencies

To enable this parameter, clear the **Inherit output port attributes from input port** check box.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar or vector

Default: '1'

Block Characteristics

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	no

If

Select subsystem execution using logic similar to `if-else` statement

Library: Simulink / Ports & Subsystems

Description

The If block, along with If Action Subsystem blocks containing an Action Port block, implements if-else logic to control subsystem execution. For an example using the If block, see If Action Subsystems.

Limitations

The If block has the following limitations:

- It does not support tunable parameters. Values for an `if` or `elseif` expression cannot be tuned during a simulation in normal or accelerator mode, or when running generated code.

To implement tunable if-else expressions, tune the expression outside the If block. For example, use the Relational Operator block to evaluate the expression outside of the If block or add the tunable parameter as an input to the If block.

- It does not support custom storage classes. See “Organize Parameter Data into a Structure by Using Struct Storage Class” (Embedded Coder).
- The **If expression** and **Elseif expressions** cannot accept certain operators, such as `+`, `-`, `*`, and `/`.

Ports

Input

Logical operands — Values for evaluating logical expressions

scalar | vector

Inputs u_1, u_2, \dots, u_n must have the same data type. The inputs cannot be of any user-defined type, such as an enumerated type.

The If block does not directly support fixed-point data types. However, you can use the Compare To Constant block to work around this limitation. See Support for Fixed-Point Data Type in If Action Subsystems.

The If block does not support a boolean data type. If you want to input a boolean signal to an If block, convert the signal to an integer type using the Data Type Conversion block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Output

Action — Action signal for an If Action Subsystem block

scalar

Outputs from the `if`, `else`, and `elseif` ports are action signals to If Action Subsystem blocks.

Parameters

Number of inputs — Specify number of input ports

1 (default) | integer

1

Specify one input port.

integer

Specify the number of input ports. Block ports are labeled with a 'u' character followed by a number, $1, 2, \dots, n$, where n equals the number of inputs that you specify.

Programmatic Use

Block Parameter: NumInputs

Type: character vector

Values: '1' | '<integer>'

Default: '1'

If expression — Specify logical expression

$u_1 > 0$ (default) | logical expression

The If Action Subsystem attached to the `if` port executes when its associated expression evaluates to true.

$u_1 > 0$

Specify sending an action signal on the output port when the input u_1 is greater than 0.

logical expression

Specify logical expression. This expression appears on the If block adjacent to the **if** output port.

The expression can include only the operators `<`, `<=`, `==`, `~=`, `>`, `>=`, `&`, `|`, `~`, `()`, unary-minus. Operators such as `+`, `-`, `*`, `/`, and `^` are not allowed. The expression must not contain data type expressions, for example, `int8(6)`, and must not reference workspace variables whose data type is other than `double` or `single`.

Programmatic Use

Block Parameter: IfExpression

Type: character vector

Values: `'u1 > 0'` | `'<logical expression>'`

Default: `'u1 > 0'`

Elseif expressions — Specify logical expression

empty (default) | list of logical expressions

The If Action Subsystem attached to an **elseif** port executes when its expression evaluates to `true` and all `if` and `elseif` expressions are false.

empty

Logical expressions not specified.

list of logical expressions

Specify a list of logical expressions delimited by commas. The expressions appear on the If block below the **if** port and above the **else** port when you select the **Show else condition** check box.

Expressions can include only the operators `<`, `<=`, `==`, `~=`, `>`, `>=`, `&`, `|`, `~`, `()`, unary-minus. Operators such as `+`, `-`, `*`, `/`, and `^` are not allowed. The expressions must not contain data type expressions, for example, `int8(6)`, and must not reference workspace variables whose data type is other than `double` or `single`.

Programmatic Use

Block Parameter: ElseIfExpressions

Type: character vector

Values: `''` | `'<list of logical expressions>'`

Default: `''`

Show else condition — Control display of else port

on (default) | off

When the **if** port and all **elseif** port expressions are false, the **else** port sends an action signal to execute the attached If Action Subsystem block.

on

Display **else** port.

off

Hide **else** port.

Programmatic Use

Block Parameter: ShowElse

Type: character vector

Values: `'on'` | `'off'`

Default: `'on'`

Enable zero-crossing detection — Control zero-crossing detection

on (default) | off

Control zero-crossing detection.

on

Detect zero crossings.

off

Do not detect zero crossings.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Block Characteristics

Data Types	Boolean double integer single
Direct Feedthrough	yes

Blocks

Subsystem | Action Port | If Action Subsystem

Topics

Select Subsystem Execution

Introduced before R2006a

If Action Subsystem

Subsystem whose execution is enabled by If block

Library: Simulink / Ports & Subsystems

Description

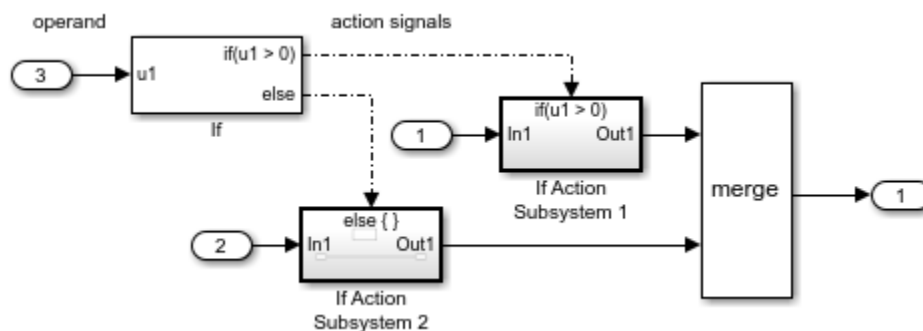

The If Action Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem whose execution is controlled by an If block. The If block evaluates a logical expression and then, depending on the result of the evaluation, outputs an action signal. Execution of the subsystem is controlled by an Action Port block placed inside the subsystem.

Simulink ignores a priority set on an If Action Subsystem block. Instead, set the priority on the If block that initiates execution of the subsystem.

Merge signals from If Action Subsystem blocks

This example shows how to merge signals controlled by an If block. The If block selects the execution of an If Action Subsystem block from a set of subsystems. Regardless of which subsystem the If block selects, you can create a single signal with a Merge block. To open the model, see `ex_if_block`.

All blocks in an If Action Subsystem block must execute at the same rate as the driving If block. You can satisfy this requirement by setting the sample time parameter for each block to either inherited (-1) or the same value as the If block sample time.

Support for Fixed-Point Data Type

The If block does not directly support fixed-point data types. However, you can use the Compare To Constant block to work around this limitation.

Consider the following floating-point model without fixed-point data types. To open model, see `ex_if_block_floating_point`.

In this model, the If Action Subsystem blocks use their default configurations. The simulation parameters are set to their default values except for the parameters listed in the following table.

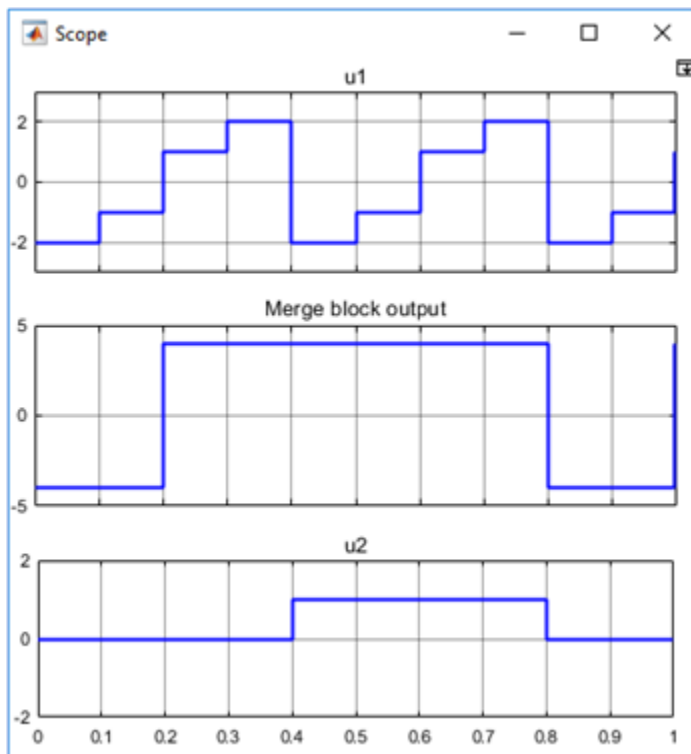

Configuration Parameter Pane	Parameter	Setting
Solver	Start time	0.0
	Stop time	1.0
	Type	Fixed-step
	Solver	discrete (no continuous states)
	Fixed-step size	0.1

The block parameters are set to their default values except for the parameters listed in the following table.

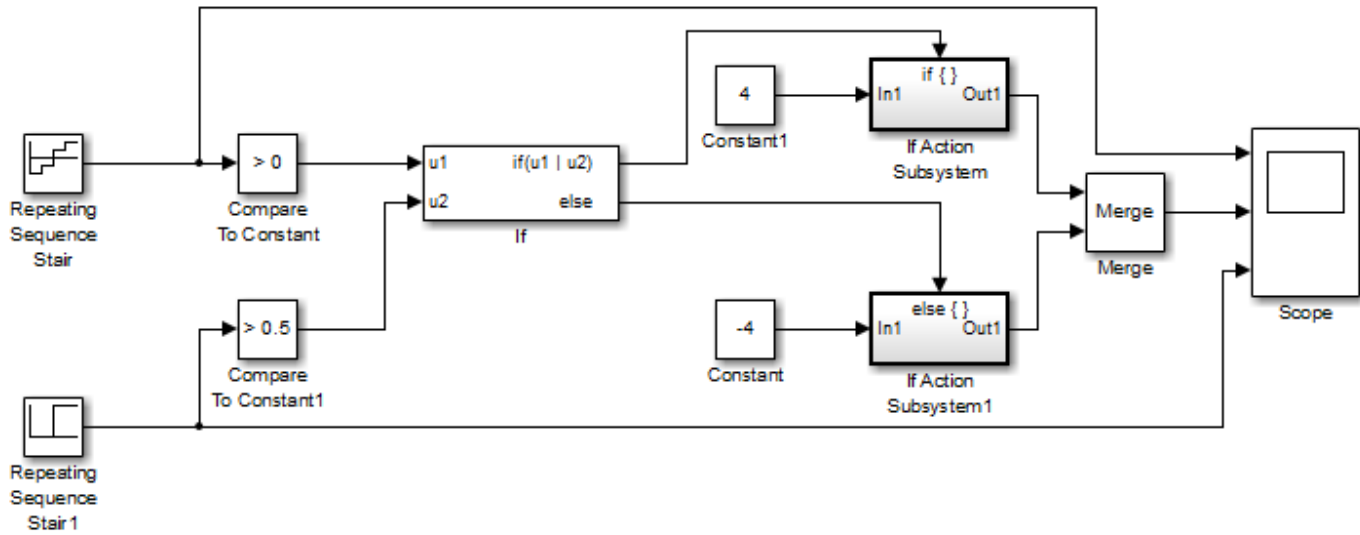

Block	Parameter	Setting
Repeating Sequence Stair	Vector of output values	<code>[-2 -1 1 2].'</code>
Repeating Sequence Stair1	Vector of output values	<code>[0 0 0 0 1 1 1 1].'</code>
If	Number of inputs	2
	If expression	<code>(u1 > 0) (u2 > 0.5)</code>
	Show else condition	Selected

Block	Parameter	Setting
Constant	Constant value	-4
Constant1	Constant value	4
Scope	Number of axes	3
	Time range	1

For this model, when input $u1$ is greater than 0 or input $u2$ is greater than 0.5, the output is 4. Otherwise, the output is -4. The Scope block displays the output from the Merge block with inputs $u1$, and $u2$.

You can implement this block diagram as a model with fixed-point data types. To open model, see `ex_if_block_fixed_point`.

The Repeating Sequence Stair blocks output fixed-point data types.

The Compare To Constant blocks implement two parts of the **If expression** that is used in the If block in the floating-point version of the model, ($u1 > 0$) and ($u2 > 0.5$). The OR operation, ($u1 | u2$), can still be implemented inside the If block. For a fixed-point model, the expression must be partially implemented outside of the If block as it is in this model.

The block and simulation parameters for the fixed-point model are the same as for the floating-point model with the following exceptions and additions:

Block	Parameter	Setting
Compare To Constant	Operator	>
	Constant value	0
	Output data type mode	Boolean
	Enable zero-crossing detection	off
Compare To Constant1	Operator	>
	Constant value	0.5
	Output data type mode	Boolean
	Enable zero-crossing detection	off
If	Number of inputs	2
	If expression	$u1 u2$

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Action – Control signal input to a subsystem block

`scalar` | `vector` | `matrix`

Placing an Action Port block in a subsystem block adds an external input port to the block and changes the block to an If Action Subsystem.

Dot-dash lines from a Switch Case block to an Switch Case Action Subsystem block represent *action* signals. An action signal is a control signal connected to the action port of a Switch Case Action Subsystem block. A message on the action signal initiates execution of the subsystem.

Data Types: `action`

Output

Out – Signal output from a subsystem

`scalar` | `vector` | `matrix`

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Block Characteristics

Data Types	<code>Boolean^a</code> <code>bus^a</code> <code>double^a</code> <code>enumerated^a</code> <code>fixed point^a</code> <code>half^a</code> <code>integer^a</code> <code>single^a</code> <code>string^a</code>
Direct Feedthrough	no

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

Architecture	Description
Module (default)	Generate code for the subsystem and the blocks within the subsystem.
BlackBox	Generate a black box interface. The generated HDL code includes only the input/output port definitions for the subsystem. Therefore, you can use a subsystem in your model to generate an interface to existing, manually written HDL code. The black-box interface generation for subsystems is similar to the Model block interface generation without the clock signals.
No HDL	Remove the subsystem from the generated code. You can use the subsystem in simulation, however, treat it as a “no-op” in the HDL code.

HDL Block Properties

General	
AdaptivePipelining	Automatic pipeline insertion based on the synthesis tool, target frequency, and multiplier word-lengths. The default is <code>inherit</code> . See also “AdaptivePipelining” (HDL Coder).
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . See also “BalanceDelays” (HDL Coder).
ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <code>inherit</code> . See also “ClockRatePipelining” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>off</code> . See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is <code>none</code> . See also “DSPStyle” (HDL Coder).
FlattenHierarchy	Remove subsystem hierarchy from generated HDL code. The default is <code>inherit</code> . See also “FlattenHierarchy” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

General	
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is 0, which implements fully parallel data paths. See also “Streaming” (HDL Coder).

Target Specification

This block cannot be the DUT, so the block property settings in the **Target Specification** tab are ignored.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

In Bus Element, Bus Element In

Select input from external port

Library: Simulink / Ports & Subsystems
 Simulink / Sources
 HDL Coder / Ports & Subsystems
 HDL Coder / Sources

InBus.signal1 

Description

The In Bus Element block, also known as the Bus Element In block, combines the functionality of an Inport block and a Bus Selector block. This block is of the Inport block type and all In Bus Element blocks that use the same port share a Block Parameters dialog box.

You can use an In Bus Element block to select a bus element, bus, nonbus signal, or message associated with the port. To select multiple elements from a bus, use multiple In Bus Element blocks.

The In Bus Element block does not support mixing message and signal elements as outputs.

Create Port and Related Blocks

When you insert an In Bus Element block, the block label populates with default values. The label consists of two interactive text fields: the port name and the bus element. To change the name of the port associated with the block, edit the first text field in the label by clicking in it.

InBus. signal1 

To create related In Bus Element blocks, in the Block Parameters dialog box, you can select the **Add blocks for selected signals**  button.

If multiple blocks are associated with the same port and you change the name of the port, all blocks that share the port update to reflect the new port name.

You can create additional ports by holding **Ctrl** while you drag an existing In Bus Element block to a new location. Upon releasing the mouse, you have the option to create a port or use the existing port associated with the block being copied.

Examine Port Input

You can view the elements associated with a port in the Block Parameters dialog box for any of the related In Bus Element blocks.

▼ InBus

a

b

c

d

Black element names are already associated with an In Bus Element block. Grey element names are available, but are not being used. Red element names are not available in the input bus, despite being specified by an In Bus Element block.

You can create In Bus Element blocks for each selected element by clicking the **Add blocks for selected signals** button .

To remove blocks associated with selected elements, such as elements which are unavailable in the input bus, click the **Remove blocks of selected signals** button .

Select Element

To change the bus element associated with the block, edit the second text field in the label by clicking in it.

If a bus is connected to the port, you can select an element of the bus from the list that appears. To see all elements of the bus along with the previously specified element name, clear the text. The list of elements is filtered to include only the elements that contain the existing text.

Each dot in the part of the label that describes the bus element indicates a new level of bus hierarchy. To reduce the size of the label, you can display only the element name by selecting the block, pausing over the ellipsis, and selecting **Compact Notation** from the action bar. To show the bus hierarchy again, select **Expanded Notation** from the action bar.

You can pass through the entire input connected to the port, including nonbus signals, by deleting the text from the second text field.

Referenced models support passing through an entire bus with an In Bus Element block in either of these scenarios:

- The bus is defined by a `Simulink.Bus` object.
- Additional In Bus Element blocks pass each leaf element of the bus into the referenced model.

You can select an In Bus Element block that has duplicates to highlight the duplicate blocks. To show a related block in an open diagram or new tab, pause on the ellipsis that appears after selection.

Then, select **Related Blocks**  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list of related blocks by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Specify Attributes

To specify attributes, such as data type, pause on the name of a bus, signal, or message. Then, click the pencil button that appears.

When you specify attributes, they appear next to the name of the bus, signal, or message. Click an attribute summary to edit the attributes of the bus, signal, or message.

Specify Queue Attributes

Queue attributes are visible only when the block is at the top level of a model and you set the **Data mode** parameter to `message`.

To specify queue attributes, such as queue type, click the envelope button next to the name of a bus or bus element.

Load Input Data

You can use an In Bus Element block to load external input data for a bus. An In Bus Element block can load data for an element of a bus or for an entire bus. When you use an In Bus Element block to load data for an entire bus, you must specify the data type for the block using a `Simulink.Bus` object. For more information about loading input data for bus elements, see "Load Input Data for a Bus Using In Bus Element Blocks".

You can load simulation input data for a group of root-level In Bus Element blocks by using a structure of `timeseries`, `timetable`, or `SimulationDatastore` objects. In Bus Element blocks interpolate loaded data for all data types except `string`, `enumerated`, and `fixed point`.

Ports

Output

Port_1 — Selected input from external port

`scalar` | `vector` | `matrix` | `array` | `bus`

Select a bus, signal, or message from the corresponding external input port of the parent subsystem or model.

While you can select bus elements, you cannot select elements of arrays of buses.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `string` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

To interactively edit the parameters of the block and the corresponding port, double-click the block.

Port name — Name of input port

`InBus` (default) | port name

Specify a port name that is not already in use by another block or port. The name appears on the parent Subsystem or Model block. The name also appears next to the block. Multiple blocks can access the same port.

Programmatic Use

Block Parameter: `PortName`

Type: character vector

Values: `'InBus'` | `'<port name>'`

Default: `'InBus'`

Port number — Position of port on parent block

1 (default) | real integer

Specify the order in which the port that corresponds to the block appears on the parent Subsystem or Model block.

- If you add a block that creates another port, the port number is the next available number.
- Deleting all blocks associated with a port deletes the port. Other ports are renumbered so that they are sequential and do not skip any numbers.
- Specifying a port number that exceeds the number of ports creates a port for that number and for any skipped sequential numbers.

Programmatic Use

Block Parameter: `Port`

Type: character vector

Values: real integer

Default: `'1'`

Set color — Specify block background color

Black (default) | White | Red | Green | Blue | Cyan | Magenta | Yellow | Gray | Light Blue | Orange | Dark Green | More Colors

Specify the block background color. This specification sets the color of blocks associated with selected bus elements, or of all blocks associated with the port if you do not select any bus elements.

Programmatic Use

Block Parameter: BackgroundColor

Type: character vector

Values: 'black' | 'white' | 'red' | 'green' | 'blue' | 'cyan' | 'magenta' | 'yellow' | 'gray' | 'lightBlue' | 'orange' | 'darkGreen' | '[r,g,b]' where r, g, and b, are the red, green, blue values of the color in the range 0.0 to 1.0

Default: 'black'

Filter — Filter set of displayed signals

text

Specify a search term to use for filtering a long list of bus elements. Do not enclose the search term in quotation marks. The filter does a partial string search and supports regular expressions. To use a regular expression character as a literal, include an escape character (\). For example, to use a question mark, type sig\?1.

Attributes

To specify attributes, click the pencil button or attribute summary next to the name of a bus, signal, or message.

Data type — Data type

Inherit: auto (default) | double | single | half | int8 | uint8 | int16 | uint16 | ...

The data type can be inherited, specified directly, or expressed as a data type object such as a Simulink.NumericType object.

You can specify any of these options:

- Inherited data type
- Built-in Simulink data type — For example, specify single or uint8. See “Data Types Supported by Simulink”.
- Fixed-point data type — Use the fixdt function. For example, specify fixdt(1,16,0).
- Enumerated data type — Use the name of the type preceded by Enum:. For example, specify Enum: myEnumType.
- Bus data type — Use the name of the Simulink.Bus object preceded by Bus:. For example, specify Bus: myBusObject.
- Value type — Use the name of the Simulink.ValueType object preceded by ValueType:. For example, specify ValueType: windVelocity.
- Custom data type — Use a MATLAB expression that specifies the type. For example, you can specify a Simulink.NumericType object whose DataTypeMode property is set to a value other than 'Fixed-point: unspecified scaling'.

When you specify a Simulink.ValueType or Simulink.Bus object, the object defines more than the data type. The object also defines properties such as **Min**, **Max**, and **Unit**. The property values

specified by the `ValueType` object override the corresponding property values specified by a block. For example, suppose a block sets **Unit** to ft/s. When the **Data type** of the block specifies a `ValueType` object that has m/s as its unit, the block uses m/s instead of ft/s.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: auto' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'string' | 'Enum: <class name>' | 'Bus: <object name>' | 'ValueType: <object name>' | '<data type expression>'`

Default: `'Inherit: auto'`

Data mode — Data mode of bus elements

`inherit (default) | signal | message`

Specify the data mode of the elements of the bus.

- `inherit` — Bus elements inherit their data modes.
- `signal` — Bus elements must be signals.
- `message` — Bus elements must be messages.

For the In Bus Element block, if you choose `message` as the data mode, an envelope button appears next to the bus or bus element. Use the envelope button to specify custom queue properties for each message element. The Out Bus Element block does not support queue specifications.

Dependencies

To enable this parameter, the block must be at the top level of a model.

Programmatic Use

Block Parameter: `DataMode`

Type: character vector

Values: `'inherit' | 'signal' | 'message'`

Default: `'inherit'`

Bus virtuality — Virtual or nonvirtual bus

`inherit (default) | virtual | nonvirtual`

Specify whether to inherit the bus virtuality or define the bus as virtual or nonvirtual. For more information, see “Types of Composite Signals”.

This parameter determines whether the blocks inherit or define the bus virtuality. If the blocks define the bus virtuality and the virtuality of the input bus does not match, compiling the model produces an error.

Dependencies

To enable this parameter, set **Data type** to a Bus object.

Programmatic Use

Block Parameter: `BusVirtuality`

Type: character vector

Values: `'inherit' | 'virtual' | 'nonvirtual'`

Default: 'inherit'

Dimensions — Signal dimensions

-1 (default) | integer | [integer, integer]

Specify the dimensions of a signal.

- -1 — The signal can have any dimensions.
- N — The signal must be a vector of size N.
- [R C] — The signal must be a matrix having R rows and C columns.

Programmatic Use

Block Parameter: PortDimensions

Type: character vector

Values: '-1' | integer | [integer, integer]

Default: '-1'

Dims mode — Option to allow only variable-size or fixed-size signals

Inherit (default) | Fixed | Variable

Specify the type of signals allowed.

- Inherit — Allow variable-size and fixed-size signals.
- Variable — Allow only variable-size signals.
- Fixed — Allow only fixed-size signals. Do not allow variable-size signals.

When the signal is variable-sized, the **Dimensions** parameter specifies the maximum dimensions of the signal.

Programmatic Use

Parameter: VarSizeSig

Type: character vector

Value: 'Inherit' | 'No' | 'Yes'

Default: 'Inherit'

Unit — Physical unit

inherit (default) | <Enter unit>

Specify the physical unit of the signal. For a list of supported units, see Allowed Unit Systems.

Programmatic Use

Block Parameter: Unit

Type: character vector

Values: 'inherit' | '<Enter unit>'

Default: 'inherit'

Sample time — Sample time

-1 (default) | scalar

Specify the discrete interval between sample time hits or specify another appropriate sample time such as continuous or inherited.

By default, the signal inherits its sample time. To set a different sample time, enter a valid sample time based on the table in “Types of Sample Time”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar**Default:** '-1'**Complexity — Numeric type**

auto (default) | real | complex

Specify the numeric type of the signal. To choose the numeric type of the signal, select auto. Otherwise, choose a real or complex signal type.

Programmatic Use**Block Parameter:** SignalType**Type:** character vector**Values:** 'auto' | 'real' | 'complex'**Default:** 'auto'**Minimum — Minimum value**

[] (default) | scalar

Lower value of the range that Simulink checks.

This number must be a finite real double scalar value.

Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Maximum — Maximum value**

[] (default) | scalar

Upper value of the range that Simulink checks.

This number must be a finite real double scalar value.

Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Description — Description of bus or bus elements

no default

Use the description to document information about the bus or bus element, such as where it is used. This information does not affect Simulink processing.

Programmatic Use

Block Parameter: Description

Type: character vector

Values: ' ' | '<Enter text>'

Default: ' '

Queue Attributes

Queue attributes are visible only when the block is at the top level of a model and you set the **Data mode** parameter to message.

To specify queue attributes, click the envelope button next to the name of a bus or message.

Use default queue attributes — Default or custom queue specifications

on (default) | off

Use this parameter to select between default or custom queue specifications.

To use the default queue properties, leave the parameter selected. In this case, for each message bus element, a LIFO overwriting queue of capacity 1 is automatically inserted.

To use custom specifications, clear the parameter and configure the queue properties. Queue attributes are applicable if there is no storage block placed outside a component.

For more information, see “Specify Queue Properties for Message Interface”.

Dependencies

To enable this parameter, set the **Data mode** parameter to message.

Programmatic Use

Block Parameter: MessageQueueUseDefaultAttributes

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Queue capacity — Message storage capacity

1 (default) | scalar

Specify the number of messages elements the queue can store.

Dependencies

This parameter is visible when you set the **Data mode** parameter to message.

Programmatic Use

Block Parameter: MessageQueueCapacity

Type: character vector

Values: '1' | scalar

Default: '1'

Queue type — Choose FIFO or LIFO queue

LIFO (default) | FIFO

Choose one of these queue types:

- FIFO — First-in-first-out
- LIFO — Last-in-first-out

Dependencies

This parameter is visible when you set the **Data mode** parameter to message.

Programmatic Use

Block Parameter: MessageQueueType

Type: character vector

Values: 'FIFO' | 'LIFO'

Default: 'LIFO'

Queue overwriting — Queue message overwriting policy

on (default) | off

Select this parameter to choose between two queue overwriting policies.

- If you select the parameter, an incoming message element overwrites the oldest message if the queue is full.
- If you clear the parameter, the block does not accept new messages if the queue is full.

Dependencies

To enable this parameter, set the **Data mode** parameter to message.

Programmatic Use

Block Parameter: MessageQueueOverwriting

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes

Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used to simplify the Subsystem bus interfaces when you use the block in subsystems that generate HDL code, but is not included in the hardware implementation.

To learn more about using buses for HDL code generation, see “Buses” (HDL Coder) and “Use Bus Signals to Improve Readability of Model and Generate HDL Code” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Increment Real World

Increase real-world value of signal by one

Library: Simulink / Additional Math & Discrete / Additional Math:
Increment - Decrement
HDL Coder / Math Operations

Description

The Increment Real World block increases the real-world value of the signal by one.

Overflows always wrap.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 – Output signal

scalar | vector | matrix

Output is the real-world value of the input signal increased by one. Overflows always wrap. The output has the same data type and dimensions as the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes

Zero-Crossing Detection	no
--------------------------------	----

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Index Vector

Switch output between different inputs based on value of first input

Library: Simulink / Signal Routing
HDL Coder / Signal Routing

Description

The Index Vector block is a special configuration of the Multiport Switch block in which you specify one data input and the control input is zero-based. The block output is the element of the input vector whose index matches the control input. For example, if the input vector is [18 15 17 10] and the control input is 3, the element that matches the index of 3 (zero-based) is 10, and that becomes the output value.

To configure a Multiport Switch block to work as an Index Vector block set **Number of data ports** to 1 and **Data port order** to Zero-based contiguous.

For more information about the Multiport Switch block, see the Multiport Switch block reference page.

Ports

Input

Port_1 — Control signal

scalar

Control signal, specified as a scalar. When the control input is not an integer value, the block truncates the value to an integer by rounding to zero.

For information on control signals of enumerated type, see “Guidelines on Setting Parameters for Enumerated Control Port” on page 1-1189 on the Multiport Switch block ref page.

Limitations

- If the control signal is numeric, the control signal cannot be complex.
- If the control signal is an enumerated signal, the block uses the value of the underlying integer to select a data port.
- If the underlying integer does not correspond to a data input, an error occurs.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

0 or 1 — First data input

scalar | vector

First data input, specified as a scalar or vector. The port is labeled **0** when you set **Data port order** to **Zero-based contiguous**, and labeled **1** when you set **Data port order** to **One-based contiguous**.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `bus` | `enumerated` | `string`

Output

Port_1 — Selected data input, based on control signal value

scalar

The block outputs the selected value from the input data vector, according to the control signal value. The output is a scalar.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

Data port order — Type of ordering for data input ports

`Zero-based contiguous` (default) | `One-based contiguous` | `Specify indices`

Specify the type of ordering for your data input ports.

- **Zero-based contiguous** — Block uses zero-based indexing for ordering contiguous data ports. This is the default value of the Index Vector block.
- **One-based contiguous** — Block uses one-based indexing for ordering contiguous data ports. This is the default value of the Multiport Switch block.
- **Specify indices** — Block uses noncontiguous indexing for ordering data ports. This value is supported only for configurations with two or more input data ports.

Tips

- When the control port is of enumerated type, select `Specify indices`.
- If you select `Zero-based contiguous` or `One-based contiguous`, verify that the control port is not of enumerated type. This configuration is deprecated and produces an error. You can run the Upgrade Advisor on your model to replace each Multiport Switch block of this configuration with a block that explicitly specifies data port indices. See “Model Upgrades”.
- Avoid situations where the block contains unused data ports for simulation or code generation. When the control port is of fixed-point or built-in data type, verify that all data port indices are representable with that type. Otherwise, the following block behavior occurs:

If the block has unused data ports and data port order is:	The block produces:
<code>Zero-based contiguous</code> or <code>One-based contiguous</code>	A warning
<code>Specify indices</code>	An error

Dependencies

Selecting Zero-based contiguous or One-based contiguous enables the **Number of data ports** parameter.

Selecting Specify indices enables the **Data port indices** parameter.

Programmatic Use

Block Parameter: DataPortOrder

Type: character vector

Values: 'Zero-based contiguous' | 'One-based contiguous' | 'Specify indices'

Default: 'Zero-based contiguous'

Number of data ports — Number of data input ports

1 (default) | integer between 1 and 65536

Specify the number of data input ports to the block.

Dependencies

To enable this parameter, set **Data port order** to Zero-based contiguous or One-based contiguous.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: integer between 1 and 65536

Default: '1'

Signal Attributes**Require all data port inputs to have the same data type — Require all inputs to have the same data type**

off (default) | on

Select this check box to require that all data input ports have the same data type. When you clear this check box, the block allows data port inputs to have different data types.

Programmatic Use

Block Parameter: InputSameDT

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).

- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output data type — Specify the output data type

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | Inherit: Same as first data input | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | string | Simulink.ImageType(480,640,3) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule**—Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:
 - Specify the output data type explicitly.
 - Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
 - To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- **Inherit: Inherit via back propagation** — Uses the data type of the driving block.
- **Inherit: Same as first data input** — Uses the data type of the first data input port.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule'|'Inherit: Inherit via back propagation'|'Inherit: Same as first input'|'double'|'single'|'half'|'int8'|'uint8'|'int16'|'uint16'|'int32'|'uint32'|'int64'|'uint64'|'fixdt(1,16)|'fixdt(1,16,0)|'fixdt(1,16,2^0,0)|'string'|Simulink.ImageType(480,640,3)|'<data type expression>'`

Default: `'Inherit: Inherit via internal rule'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: `'off'|'on'`

Default: `'off'`

Integer rounding mode — Specify the rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Choose one of these rounding modes.

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

See Also

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow – Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.

- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Allow different data input sizes (Results in variable-size output signal) — Allow input signals with different sizes

off (default) | on

Select this check box to allow input signals with different sizes.

- On — Allows input signals with different sizes, and propagate the input signal size to the output signal. In this mode, the block produces a variable-size output signal.
- Off — Requires that all nonscalar data input signals be the same size.

Programmatic Use

Parameter: AllowDiffInputSizes

Type: character vector

Value: 'on' | 'off'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single

Initialize Function

Execute subsystem on model initialize event

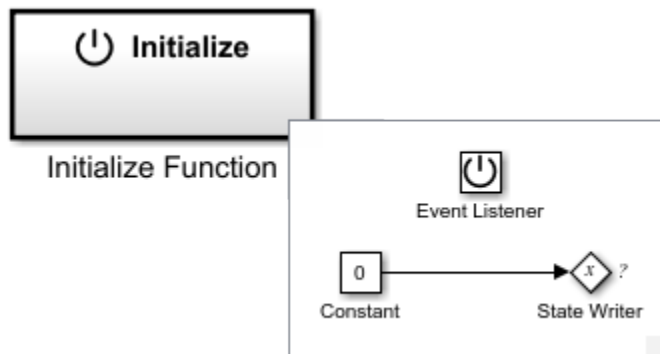

Library: Simulink / User-Defined Functions

Description

The Initialize Function block is a pre-configured subsystem block that executes on a model initialize event. By default, the Initialize Function block includes:

- An Event Listener block with the **Event type** set to Initialize
- A Constant block with the **Constant value** set to 0
- A State Writer block with no **State owner block** set

Customize the contents of the Initialize Function block by, for example, replacing the Constant block with source blocks that generate the state value for the State Writer block and specifying a **State owner block** for the State Writer block.

Conditionally executed subsystem blocks with output ports are fully supported within Initialize Function blocks.

For a list of unsupported blocks and features, see “Initialize, Reinitialize, Reset, and Terminate Function Limitations”.

The input and output ports of a component containing Initialize Function and Terminate Function blocks must connect to input and output port blocks.

The code generated from this block is part of the `model_initialize` function that is called once at the beginning of model execution.

You can select an Initialize Function, Reinitialize Function, Reset Function, or Terminate Function block or a corresponding state owner block to highlight blocks related to it. To show a related block in an open diagram or new tab, pause on the ellipsis that appears after selection. Then, select

Related Blocks  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list of related blocks by entering a search term in the

text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Block Characteristics

Inport

Create input port for subsystem or external input

Library: Simulink / Commonly Used Blocks
 Simulink / Ports & Subsystems
 Simulink / Sources
 HDL Coder / Commonly Used Blocks
 HDL Coder / Ports & Subsystems
 HDL Coder / Sources

Description

Inport blocks link signals from outside a system into the system.

Simulink software assigns Inport block port numbers according to these rules:

- It numbers the Inport blocks within a top-level system or subsystem sequentially, starting with 1.
- If you add an Inport block, the label is the next available number.
- If you delete an Inport block, other port numbers are renumbered to ensure that the Inport blocks are in sequence and that no numbers are omitted.
- If you copy an Inport block into a system, its port number is not renumbered unless its current number conflicts with an inport already in the system. If the copied Inport block port number is not in sequence, renumber the block. Otherwise, you get an error message when you run the simulation or update the block diagram.

Inport Blocks in a Top-Level System

You can use an Inport block in a top-level system to:

- Supply external inputs from the workspace using one of these approaches. If no external outputs are supplied, then the default output is the ground value.
 - Use the **Configuration Parameters > Data Import/Export > Input** parameter. See “Load Data to Root-Level Input Ports”.

Tip To import many signals to root-level input ports, consider using the Root Inport Mapper tool. See “Map Data Using Root Inport Mapper Tool”.

- Use the `ut` argument of the `sim` command to specify the inputs.
- Provide a means for perturbation of the model by the `linmod` and `trim` analysis functions.
 - Use Inport blocks to inject inputs into the system. See “Linearizing Models”.
- To load logged signal data using root Inport blocks, use the `createInputDataset` function to create a `Dataset` object that contains elements corresponding to root-level Inport blocks.

Inport Blocks in a Subsystem

Inport blocks in a subsystem represent inputs to the subsystem. A signal arriving at an input port on a Subsystem block flows out of the associated Inport block in that subsystem. The Inport block associated with an input port on a Subsystem block is the block whose **Port number** parameter matches the relative position of the input port on the Subsystem block. For example, the Inport block whose **Port number** parameter is 1 gets its signal from the block connected to the topmost port on the Subsystem block.

If you renumber the **Port number** of an Inport block, the block becomes connected to a different input port. The block continues to receive its signal from the same block outside the subsystem.

Inport blocks inside a subsystem support signal label propagation, but root-level Inport blocks do not.

You can directly edit port labels on a Subsystem block. For more information, see “Edit Port Labels on Subsystems”.

Tip For models that include buses composed of many bus elements, consider using In Bus Element and Out Bus Element blocks. These blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

The In Bus Element block is of block type Inport and the Out Bus Element block is of block type Output.

Create Duplicate Inport Blocks

You can create any number of duplicates of an Inport block. The duplicates are graphical representations of the original intended to simplify block diagrams by eliminating unnecessary lines. The duplicate has the same port number, properties, and output as the original.

To create a duplicate of an Inport block:

- 1** In the block diagram, select the unconnected Inport block that you want to duplicate.
- 2** Press and hold the **Ctrl** key and drag the block.
- 3** Release the mouse, and then select **Duplicate** from the context menu.

You can select an Inport block that has duplicates to highlight the duplicate blocks. To show a related block in an open diagram or new tab, pause your cursor on the ellipsis that appears after selection.

Then, select **Related Blocks**  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list of related blocks by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Connect Buses to Root-Level Inport Blocks

If you want a root-level Inport block of a model to produce a bus, set the **Data type** parameter to the name of a bus object that defines the bus that the Inport block produces. For more information, see “Specify Bus Properties with Simulink.Bus Object Data Types”.

Ports

Output

Port_1 — Inport signal

scalar | vector

Input signal that flows through the inport into the system.

You can use a subsystem inport to supply fixed-point data in a structure or any other format.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus | image

Parameters

Main

Port number — Position of port on parent block

1 (default) | real integer

Specify the order in which the port that corresponds to the block appears on the parent Subsystem or Model block.

- If you add a block that creates another port, the port number is the next available number.
- Deleting all blocks associated with a port deletes the port. Other ports are renumbered so that they are sequential and do not skip any numbers.
- Specifying a port number that exceeds the number of ports creates a port for that number and for any skipped sequential numbers.

Programmatic Use

Block Parameter: Port

Type: character vector

Values: real integer

Default: '1'

Icon display — Icon display

Port number (default) | Signal name | Port number and signal name

Specify the information displayed on the block icon.

Programmatic Use

Block Parameter: IconDisplay

Type: character vector

Values: 'Signal name' | 'Port number' | 'Port number and signal name'

Default: 'Port number'

Latch input by delaying outside signal – Latch signal by delay

off (default) | on

Select to specify the block outputs the value of the input signal at the previous time step.

Selecting this check box enables Simulink to resolve data dependencies among triggered subsystems that are part of a loop.

The Inport block indicates that this option is selected by displaying <Lo>.

Dependency

Enabled in a triggered subsystem.

Programmatic Use

Block Parameter: LatchByDelaying OutsideSignal

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Latch input for feedback signals of function-call subsystem outputs – Latch signal from changing

off (default) | on

Select to specify the block latches the value of the input to this subsystem and prevents this value from changing during the execution of the subsystem. For a single function call that is branched to invoke multiple function-call subsystems, this option breaks a loop formed by a signal fed back from one of these function-call subsystems into the other. This option prevents any change to the values of a feedback signal from a function-call subsystem that is invoked during the execution of this subsystem.

The Inport block indicates that this option is selected by displaying .

Dependency

Enabled when Inport block is in a function-call subsystem.

Programmatic Use

Block Parameter: LatchInputFor FeedbackSignals

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Interpolate data — Interpolate output data

on (default) | off

When loading data from the workspace to a root-level Inport block, specify whether the block linearly interpolates and extrapolates output at time steps for which no corresponding data exists.

To load discrete signal data from the workspace, in the Inport block dialog box:

- 1 Set the **Sample time** parameter to a discrete value, such as 2.
- 2 Clear the **Interpolate data** parameter.

Specifying the discrete sample time causes the simulation to have hit times exactly at those instances when the discrete data is sampled. You specify the data values, not time values.

Turning interpolation off avoids unexpected data values at other simulation time points as a result of double precision arithmetic processing. For more information, see “Load Data to Test a Discrete Algorithm”.

Simulink uses the following interpolation and extrapolation:

- For time steps between the first specified data point and the last specified data point — zero-order hold
- For time steps before the first specified data point and after the last specified data point — ground value
- For variable-size signals for time steps before the first specified data point — a NaN is logged for single or double data types and ground for other data types. For time steps after the last specified data point, uses ground values.

Programmatic Use

Block Parameter: Interpolate

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Connect Inputs — Tool to help map signals to inports

button

To import, visualize, and map signal and bus data to root-level inports, click this button. The Root Inport Mapper tool displays.

Dependency

This button appears only if this block is a root inport block.

Signal Attributes

Output function call — Output function-call trigger signal

off (default) | on

Specify that the input signal outputs a function-call trigger signal.

Select this option if it is necessary for a current model to accept a function-call trigger signal when referenced in the top model.

Dependency

Enabled in an asynchronous function call.

Minimum — Minimum output value

[] (default) | scalar

Lower value of the output range that Simulink checks.

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Maximum — Maximum output value

[] (default) | scalar

Upper value of the output range that Simulink checks.

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Data type — Output data type

Inherit: auto (default) | double | single | half | int8 | uint8 | int16 | uint16 | ...

Specify the output data type of the external input. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

You can specify any of these options:

- Inherited data type
- Built-in Simulink data type — For example, specify `single` or `uint8`. See “Data Types Supported by Simulink”.
- Fixed-point data type — Use the `fixdt` function. For example, specify `fixdt(1,16,0)`.
- Enumerated data type — Use the name of the type preceded by `Enum:`. For example, specify `Enum: myEnumType`.
- Bus data type — Use the name of the `Simulink.Bus` object preceded by `Bus:`. For example, specify `Bus: myBusObject`.
- Simulink image data type — If you have Computer Vision Toolbox, use the constructor for the `Simulink.ImageType` object and specify the properties to describe the image. By default, the data type uses the `Simulink.ImageType(480,640,3)` expression that represents the rows, columns, and channels of the image respectively.
- Value type — Use the name of the `Simulink.ValueType` object preceded by `ValueType:`. For example, specify `ValueType: windVelocity`.
- Custom data type — Use a MATLAB expression that specifies the type. For example, you can specify a `Simulink.NumericType` object whose `DataTypeMode` property is set to a value other than 'Fixed-point: unspecified scaling'.

When you specify a `Simulink.ValueType` or `Simulink.Bus` object, the object defines more than the data type. The object also defines properties such as **Min**, **Max**, and **Unit**. The property values specified by the `ValueType` object override the corresponding property values specified by a block. For example, suppose a block sets **Unit** to ft/s. When the **Data type** of the block specifies a `ValueType` object that has m/s as its unit, the block uses m/s instead of ft/s.

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Output as nonvirtual bus — Specify virtual or nonvirtual bus output

off (default) | on

Specify whether the output for a top-level Inport block used to load bus data is virtual or nonvirtual.

- Select this parameter to specify a nonvirtual bus output.
- Clear this parameter to specify a virtual bus output.

Tips

- All signals in a nonvirtual bus must have the same sample time, even if the associated bus object specifies inherited sample time for some elements. Any operation that would result in a nonvirtual bus containing signals with different sample rates generates an error. You cannot load multirate data for a nonvirtual bus. See “Modify Sample Times for Nonvirtual Buses” for details on how to pass signals with different sample rates into a referenced model as a nonvirtual bus.

To load multirate data for a bus, clear the **Output as nonvirtual bus** parameter, and set the **Sample time** parameter to inherited (-1).

- For the top model in a model reference hierarchy, code generation creates a C structure to represent the nonvirtual bus output.
- For referenced models, select this option to create a C structure in generated code. Otherwise, code generation creates an argument for each leaf element of the bus.

Dependency

This parameter is only available for top-level Inport blocks with Bus: <object name> selected for the **Data type** parameter.

Programmatic Use

Block Parameter: BusOutputAsStruct

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Unit (e.g., m, m/s², N*m) — Physical unit of the input signal to the block

inherit (default) | <Enter unit>

Specify the physical unit of the input signal to the block. To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For a list of supported units, see Allowed Unit Systems.

To constrain the unit system, click the link to the right of the parameter:

- If a Unit System Configuration block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.
- If a Unit System Configuration block does not exist in the component, the model Configuration Parameters dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

Programmatic Use

Block Parameter: Unit

Type: character vector

Values: 'inherit' | '<Enter unit>'

Default: 'inherit'

Port dimensions (-1 for inherited) – Port dimensions

-1 (default) | integer | [integer integer]

Specify the dimensions of the output signal for this Inport block.

-1	The port can load data for a signal with any dimensions. The port inherits dimensions from the connected signal.
N	The port can load data for a signal that is a vector of size N.
[R C]	The port can load data for a matrix signal having R rows and C columns.

Programmatic Use

Block Parameter: PortDimensions

Type: character vector

Values: '-1' | integer | [integer integer]

Default: '-1'

Variable-size signal – Allow variable-size signals

Inherit (default) | No | Yes

Specify the type of signals allowed out of this port. To allow variable-size and fixed-size signals, select `Inherit`. To allow only variable-size signals, select `Yes`. To allow only fixed-size signals, select `No`.

Dependencies

When the signal at this port is a variable-size signal, the **Port dimensions** parameter specifies the maximum dimensions of the signal.

Command-Line Information

Parameter: VarSizeSig

Type: character vector

Value: 'Inherit' | 'No' | 'Yes'

Default: 'Inherit'

Sample time (-1 for inherited) – Specify sample time

-1 (default) | scalar

Specify the discrete interval between sample time hits or specify another appropriate sample time such as continuous or inherited.

By default, the block inherits its sample time based upon the context of the block within the model. To set a different sample time, enter a valid sample time based upon the table in “Types of Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar

Default: '-1'

Signal type – Output signal type

auto (default) | real | complex

Specify the numeric type of the signal output. To choose the numeric type of the signal that is connected to its input, select auto. Otherwise, choose a real or complex signal type.

Programmatic Use

Block Parameter: SignalType

Type: character vector

Values: 'auto' | 'real' | 'complex'

Default: 'auto'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

General		
BidirectionalPort	BidirectionalPort Setting	Description
	on	<p>Specify the port as bidirectional.</p> <p>The following requirements apply:</p> <ul style="list-style-type: none"> • The port must be in a Subsystem block with black box implementation. • There must also be no logic between the bidirectional port and the corresponding top-level DUT subsystem port. <p>For more information, see “Specify Bidirectional Ports” (HDL Coder).</p>
	off (default)	Do not specify the port as bidirectional.
Target Specification		
IOInterface	<p>Target platform interface type for DUT ports, specified as a character vector. The IOInterface block property is ignored for Inport and Outport blocks that are not DUT ports.</p> <p>To specify valid IOInterface settings, use the HDL Workflow Advisor:</p> <ol style="list-style-type: none"> 1 In the HDL Workflow Advisor, in the Set Target > Set Target Interface step, in the Target platform interface table, in the Target Platform Interfaces column, use the drop-down list to set the target platform interface type. 2 Save the model. <p>The IOInterface value is saved as an HDL block property of the port.</p> <p>For example, to view the IOInterface value, if the full path to your DUT port is hdlcoder_led_blinking/led_counter/LED, enter:</p> <pre>hdlget_param('hdlcoder_led_blinking/led_counter/LED', 'IOInterface')</pre>	

Target Specification	
IOInterfaceMapping	<p>Target platform interface port mapping for DUT ports, specified as a character vector. The <code>IOInterfaceMapping</code> block property is ignored for Inport and Outport blocks that are not DUT ports.</p> <p>To specify valid <code>IOInterfaceMapping</code> settings, use the HDL Workflow Advisor:</p> <ol style="list-style-type: none"> 1 In the HDL Workflow Advisor, in the Set Target > Set Target Interface step, in the Target platform interface table, in the Target Platform Interfaces column, use the drop-down list to set the target platform interface type. 2 In the Bit Range / Address / FPGA Pin column, if you want to change the default value, enter a target platform interface mapping. 3 Save the model. <p>The <code>IOInterfaceMapping</code> value is saved as an HDL block property of the port.</p> <p>For example, to view the <code>IOInterfaceMapping</code> value, if the full path to your DUT port is <code>hdlcoder_led_blinking/led_counter/LED</code>, enter:</p> <pre>hdlget_param('hdlcoder_led_blinking/led_counter/LED',... Integer to Bit Converter

Map vector of integers to vector of bits

Library: Simulink / Logic and Bit Operations
Communications Toolbox / Utility Blocks

Description

The Integer to Bit Converter block maps each integer (or fixed-point value) in the input vector to a group of bits in the output vector.

This block is single-rate and single-channel. The block maps each integer value (or stored integer when you use a fixed point input) to a group of M bits, using the selection for the **Output bit order** to determine the most significant bit. The resulting output vector length is M times the input vector length.

Ports

Input

In — Input signal

integer | column vector of integers

Input signal, specified as an integer or a length N column vector of integers.

If M is specified by the **Number of bits per integer(M)** parameter:

- When the **Number of bits per integer** parameter is set to **Unsigned**, input values must be integers in the range $[0, (2^M - 1)]$.
- When the **Number of bits per integer** parameter is set to **Signed**, input values must be integers in the range $[(-2^{M-1}), (2^{M-1} - 1)]$.

During simulation, the block performs a run-time check and issues an error if any input value is outside of the appropriate range. When the block generates code, it does not perform this run-time check.

Data Types: double

Output

Out — Output signal

bit scalar | column vector of bits

Output signal, returned as a scalar or column vector of bits of length $M \cdot N$.

Parameters

Number of bits per integer(M) — Number of bits per integer

3 (default) | integer in the range [1, 32]

Number of input bits mapped to each integer in the input, specified as an integer in the range [1, 32].

Programmatic Use

Block Parameter: nbits

Type: character vector

Values: integer in the range [1, 32]

Default: '3'

Treat input values as — Treat input values as

Unsigned (default) | Signed

Indicate if the integer value input ranges should be treated as signed or unsigned.

Programmatic Use

Block Parameter: signedInputValues

Type: character vector

Values: 'Unsigned' | 'Signed'

Default: 'Unsigned'

Output bit order — Output bit order

MSB first (default) | LSB first

Define whether the first bit of the output signal is the most significant bit (MSB) or the least significant bit (LSB).

Programmatic Use

Block Parameter: bitOrder

Type: character vector

Values: 'MSB first' | 'LSB first'

Default: 'MSB first'

Output data type — Output data type

Inherit via internal rule (default) | Smallest unsigned integer | Same as input | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | boolean

Specify the data type of the output bits. You can choose one of the following **Output data type** options:

- `Inherit via internal rule` -- The block determines the output data type based on the input data type.
 - If the input signal is floating-point (either `single` or `double`), the output data type is the same as the input data type.
 - If the input data type is not floating-point, the output data type is determined as if the parameter is set to `Smallest integer`.
- `Smallest integer` -- The block selects the output data type based on settings used in the “Hardware Implementation Pane” of the Configuration Parameters dialog box.
 - If you select ASIC/FPGA for the device vendor, the output data type is the ideal one-bit size (`ufix1`).

- For all other device vendor selections, the output data type is an unsigned integer with the smallest available word length, as defined in the Hardware Implementation settings (for example, uint8)
- Same as input
- double
- single
- uint8
- uint16
- uint32

Programmatic Use**Block Parameter:** outDtype**Type:** character vector**Values:** 'Inherit via internal rule' | 'Smallest unsigned integer' | 'Same as input' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean'**Default:** 'Inherit via internal rule'**Block Characteristics**

Data Types	Boolean double fixed point ^a integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

^a ufix(1) only at the output when ASIC/FPGA is selected in the Hardware Implementation Pane.

Compatibility Considerations**Integer to Bit Converter Block Added to Simulink Logic and Bit Operations Library***Behavior changed in R2022a*

The Integer to Bit Converter block has been added from the **Communications Toolbox > Utility Blocks** library to the **Simulink > Logic and Bit Operations** library. All existing models continue to work.

Integrator

Integrate signal

Library: Simulink / Commonly Used Blocks
Simulink / Continuous

Description

The Integrator block outputs the value of the integral of its input signal with respect to time.

Simulink treats the Integrator block as a dynamic system with one state. The block dynamics are given by:

$$\begin{cases} \dot{x}(t) = u(t) \\ y(t) = x(t) \end{cases} \quad x(t_0) = x_0$$

where:

- u is the block input.
- y is the block output.
- x is the block state.
- x_0 is the initial condition of x .

While these equations define an exact relationship in continuous time, Simulink uses numerical approximation methods to evaluate them with finite precision. Simulink can use several different numerical integration methods to compute the output of the block, each with advantages in particular applications. Use the **Solver** pane of the Configuration Parameters dialog box (see “Solver Pane”) to select the technique best suited to your application.

The selected solver computes the output of the Integrator block at the current time step, using the current input value and the value of the state at the previous time step. To support this computational model, the Integrator block saves its output at the current time step for use by the solver to compute its output at the next time step. The block also provides the solver with an initial condition for use in computing the block's initial state at the beginning of a simulation. The default value of the initial condition is 0. Use the block parameter dialog box to specify another value for the initial condition or create an initial value input port on the block.

Use the parameter dialog box to:

- Define upper and lower limits on the integral
- Create an input that resets the block's output (state) to its initial value, depending on how the input changes
- Create an optional state output so that the value of the block's output can trigger a block reset

Use the Discrete-Time Integrator block to create a purely discrete system.

Defining Initial Conditions

You can define the initial conditions as a parameter on the block dialog box or input them from an external signal:

- To define the initial conditions as a block parameter, specify the **Initial condition source** parameter as `internal` and enter the value in the **Initial condition** field.
- To provide the initial conditions from an external source, specify the **Initial condition source** parameter as `external`. An additional input port appears under the block input.

Note If the integrator limits its output (see “Limiting the Integral” on page 1-828), the initial condition must fall inside the integrator's saturation limits. If the initial condition is outside the block saturation limits, the block displays an error message.

Limiting the Integral

To prevent the output from exceeding specifiable levels, select the **Limit output** check box and enter the limits in the appropriate parameter fields. This action causes the block to function as a limited integrator. When the output reaches the limits, the integral action is turned off to prevent integral wind up. During a simulation, you can change the limits but you cannot change whether the output is limited. The block determines output as follows:

- When the integral is less than or equal to the **Lower saturation limit**, the output is held at the **Lower saturation limit**.
- When the integral is between the **Lower saturation limit** and the **Upper saturation limit**, the output is the integral.
- When the integral is greater than or equal to the **Upper saturation limit**, the output is held at the **Upper saturation limit**.

To generate a signal that indicates when the state is being limited, select the **Show saturation port** check box. A saturation port appears below the block output port.

The signal has one of three values:

- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.
- -1 indicates that the lower limit is being applied.

When you select this check box, the block has three zero crossings: one to detect when it enters the upper saturation limit, one to detect when it enters the lower saturation limit, and one to detect when it leaves saturation.

Note For the Integrator Limited block, by default, **Limit output** is selected, **Upper saturation limit** is set to 1, and **Lower saturation limit** is set to 0.

Wrapping Cyclic States

Several physical phenomena are cyclic, periodic, or rotary in nature. Objects or machinery that exhibit rotational movement and oscillators are examples of such phenomena.

Modeling these phenomena in Simulink involves integrating the rate of change of the periodic or cyclic signals to obtain the state of the movement.

The drawback with this approach, however, is that over long simulation time spans, the states representing periodic or cyclic signals integrate to large values. Further, computing the sine or cosine of these signals takes an increasingly large amount of time because of angle reduction. The large signals values also negatively impact solver performance and accuracy.

One approach for overcoming this drawback is to reset the angular state to 0 when it reaches 2π (or to $-\pi$ when it reaches π , for numerical symmetry). This approach improves the accuracy of sine and cosine computations and reduces angle reduction time. But it also requires zero-crossing detection and introduces solver resets, which slow down the simulation for variable step solvers, particularly in large models.

To eliminate solver resets at wrap points, the Integrator block supports wrapped states that you can enable by checking **Wrap state** on the block parameter dialog box. When you enable **Wrap state**, the block icon changes to indicate that the block has wrapping states.

Simulink allows wrapping states that are bounded by upper and lower values parameters of the wrapped state. The algorithm for determining wrapping states is given by:

$$y = \begin{cases} x & x \in [x_l, x_u) \\ x - (x_u - x_l) \left\lfloor \frac{x - x_l}{x_u - x_l} \right\rfloor & \text{otherwise} \end{cases}$$

where:

- x_l is the lower value of the wrapped state.
- x_u is the upper value of the wrapped state.
- y is the output.

The support for wrapping states provides these advantages.

- It eliminates simulation instability when your model approaches large angles and large state values.
- It reduces the number of solver resets during simulation and eliminates the need for zero-crossing detection, improving simulation time.
- It eliminates large angle values, speeding up computation of trigonometric functions on angular states.
- It improves solver accuracy and performance and enables unlimited simulation time.

Resetting the State

The block can reset its state to the specified initial condition based on an external signal. To cause the block to reset its state, select one of the **External reset** choices. A trigger port appears below the block's input port and indicates the trigger type.

- Select **rising** to reset the state when the reset signal rises from a negative or zero value to a positive value.
- Select **falling** to reset the state when the reset signal falls from a positive value to a zero or negative value.
- Select **either** to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.
- Select **level** to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.
- Select **level hold** to reset the state when the reset signal is nonzero at the current time step.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results (see "Algebraic Loop Concepts"). Use the Integrator block's state port to feed back the block's output without creating an algebraic loop.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of Integrator blocks.

About the State Port

Selecting the **Show state port** check box on the Integrator block's parameter dialog box causes an additional output port, the state port, to appear at the top of the Integrator block.

The output of the state port is the same as the output of the block's standard output port except for the following case. If the block is reset in the current time step, the output of the state port is the

value that would have appeared at the block's standard output if the block had not been reset. The state port's output appears earlier in the time step than the output of the Integrator block's output port. Use the state port to avoid creating algebraic loops in these modeling scenarios:

- Self-resetting integrators (see “Creating Self-Resetting Integrators” on page 1-831)
- Handing off a state from one enabled subsystem to another (see “Handing Off States Between Enabled Subsystems” on page 1-832)

Note When updating a model, Simulink checks that the state port applies to one of these two scenarios. If not, an error message appears. Also, you cannot log the output of this port in a referenced model that executes in Accelerator mode. If logging is enabled for the port, Simulink generates a "signal not found" warning during execution of the referenced model.

Creating Self-Resetting Integrators

The Integrator block's state port helps you avoid an algebraic loop when creating an integrator that resets itself based on the value of its output. Consider, for example, the following model.

This model tries to create a self-resetting integrator by feeding the integrator's output, subtracted from 1, back into the integrator's reset port. However, the model creates an algebraic loop. To compute the integrator block's output, Simulink software needs to know the value of the block's reset signal, and vice versa. Because the two values are mutually dependent, Simulink software cannot determine either. Therefore, an error message appears if you try to simulate or update this model.

The following model uses the integrator's state port to avoid the algebraic loop.

In this version, the value of the reset signal depends on the value of the state port. The value of the state port is available earlier in the current time step than the value of the integrator block's output

port. Therefore, Simulink can determine whether the block needs to be reset before computing the block's output, thereby avoiding the algebraic loop.

Handing Off States Between Enabled Subsystems

The state port helps you avoid an algebraic loop when passing a state between two enabled subsystems. Consider, for example, the following model.

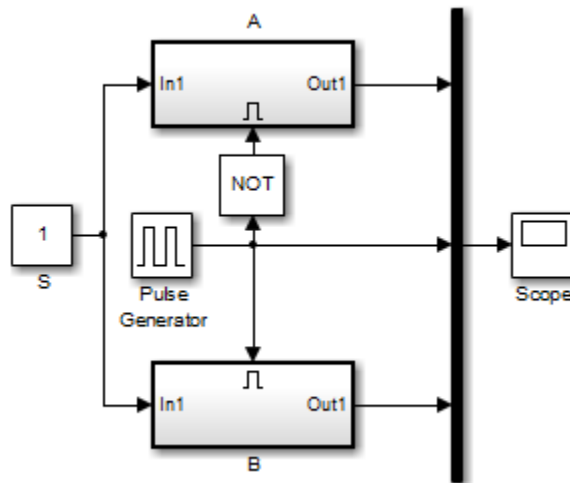

The enabled subsystems, A and B, contain the following blocks:

In this model, a constant input signal drives two enabled subsystems that integrate the signal. A pulse generator generates an enabling signal that causes execution to alternate between the two subsystems. The enable port of each subsystem is set to reset, which causes the subsystem to reset its integrator when it becomes active. Resetting the integrator causes the integrator to read the value of its initial condition port. The initial condition port of the integrator in each subsystem is connected to the output port of the integrator in the other subsystem.

This connection is intended to enable continuous integration of the input signal as execution alternates between two subsystems. However, the connection creates an algebraic loop. To compute the output of A, Simulink needs to know the output of B, and vice versa. Because the outputs are mutually dependent, Simulink cannot compute the output values. Therefore, an error message appears if you try to simulate or update this model.

The following version of the same model uses the integrator state port to avoid creating an algebraic loop when handing off the state.

The enabled subsystems, A and B, contain the following blocks:

In this model, the initial condition of the integrator in A depends on the value of the state port of the integrator in B, and vice versa. The values of the state ports are updated earlier in the simulation time step than the values of the integrator output ports. Therefore, Simulink can compute the initial condition of either integrator without knowing the final output value of the other integrator. For another example of using the state port to hand off states between conditionally executed subsystems, see “Building a Clutch Lock-Up Model” on page 13-151.

Specifying the Absolute Tolerance for the Block Outputs

By default Simulink software uses the absolute tolerance value specified in the Configuration Parameters dialog box (see “Error Tolerances for Variable-Step Solvers”) to compute the output of the Integrator block. If this value does not provide sufficient error control, specify a more appropriate value in the **Absolute tolerance** field of the Integrator block dialog box. The value that you specify is used to compute all the block outputs.

Selecting All Options

When you select all options, the block icon looks like this.

Ports

The Integrator block accepts and outputs signals of type `double` on its data ports. The external reset port accepts signals of type `double` or `Boolean`.

Input

Port_1 — Integrand signal

real scalar or array

Signal that needs to be integrated.

Data Types: `double`

External Reset — Reset state to initial conditions

real scalar or array

Reset the state to the specified initial conditions based on an external signal. See “Resetting the State” on page 1-830.

Dependencies

To enable this port, enable the **External Reset** parameter.

Data Types: `Boolean`

x_0 — Initial condition

real scalar or array

Set the initial condition of the block's state from an external signal.

Dependencies

To enable this port, set the **Initial Conditions** parameter to `external`.

Data Types: `double`

Output

Port_1 — Output signal

real scalar or array

Output the integrated state.

Data Types: `double`

Port_2 — Show output saturation

-1 | 0 | 1

Indicate when the state is being limited. The signal has a value of 1 when the integral is limited by the specified **Upper saturation limit**. When the signal is limited by the **Lower saturation limit**, the

signal value is -1. When the integral is between the saturation limits, the signal value is 0. See “Limiting the Integral” on page 1-828.

Data Types: double

Port_3 – State

real scalar or array

Output the state of the block. See “About the State Port” on page 1-830.

Dependencies

Enable this port by enabling the **Show state port** parameter.

Data Types: double

Parameters

External reset – Reset states to their initial conditions

none (default) | rising | falling | either | level | level hold

Specify the type of trigger to use for the external reset signal.

- Select **rising** to reset the state when the reset signal rises from a negative or zero value to a positive value, or a negative value to zero value.
- Select **falling** to reset the state when the reset signal falls from a positive value to a zero or negative value, or from a zero value to negative value.
- Select **either** to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.
- Select **level** to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.
- Select **level hold** to reset the state when the reset signal is nonzero at the current time step.

Programmatic Use

Block Parameter: ExternalReset

Type: character vector , string

Values: 'none' | 'rising' | 'falling' | 'either' | 'level' | 'level hold'

Default: 'none'

Initial condition source – Select source of initial condition

internal (default) | external

Select source of initial condition:

- **internal** — Get the initial conditions of the states from the **Initial condition** block parameter.
- **external** — Get the initial conditions of the states from an external block, via the **IC** input port.

Dependencies

Selecting **internal** enables the **Initial condition** parameter.

Selecting **external** disables the **Initial condition** parameter and enables the **IC** input port.

Programmatic Use**Block Parameter:** InitialConditionSource**Type:** character vector, string**Values:** 'internal' | 'external'**Default:** 'internal'**Initial condition — Initial state**

0 (default) | real scalar or array

Set the initial state of the Integrator block.

TipsSimulink software does not allow the initial condition of this block to be `inf` or `NaN`.**Dependencies**Setting **Initial condition source** to `internal` enables this parameter.Setting **Initial condition source** to `external` disables this parameter.**Programmatic Use****Block Parameter:** InitialCondition**Type:** scalar or vector**Default:** '0'**Limit output — Limit block output values to specified range**`off` (default for Integrator) | `on` (default for Integrator Limited)Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

- Selecting this check box limits the block output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.
- Clearing this check box does not limit the block output values.

DependenciesSelecting this parameter enables the **Lower saturation limit** and **Upper saturation limit** parameters.**Programmatic Use****Block Parameter:** LimitOutput**Type:** character vector , string**Values:** 'off' | 'on'**Default:** 'off'**Upper saturation limit — Upper limit for the integral**`inf` (default) | scalar | vector | matrixSpecify the upper limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.**Dependencies**To enable this parameter, select the **Limit output** check box.

Programmatic Use**Block Parameter:** UpperSaturationLimit**Type:** character vector, string**Values:** scalar | vector | matrix**Default:** 'inf'**Lower saturation limit — Lower limit for the integral**

-inf (default) | scalar | vector | matrix

Specify the lower limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use**Block Parameter:** LowerSaturationLimit**Type:** character vector, string**Values:** scalar | vector | matrix**Default:** '-inf'**Wrap state — Enable wrapping of states**

off (default) | on

Enable wrapping of states between the **Wrapped state upper value** and **Wrapped state lower value** parameters. Enabling wrap states eliminates the need for zero-crossing detection, reduces solver resets, improves solver performance and accuracy, and increases simulation time span when modeling rotary and cyclic state trajectories.

If you specify **Wrapped state upper value** as inf and **Wrapped state lower value** as -inf, wrapping does not occur.

Dependencies

Selecting this parameter enables **Wrapped state upper value** and **Wrapped state lower value** parameters.

Programmatic Use**Block Parameter:** WrapState**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'off'**Wrapped state upper value — Specify upper value for wrapped state**

pi (default) | scalar or vector

Upper limit of the block output.

Dependencies

Selecting **Wrap state** enables this parameter.

Programmatic Use**Block Parameter:** WrappedStateUpperValue**Type:** scalar or vector

Values: '2*pi'

Default: 'pi'

Wrapped state lower value — Specify lower value for wrap state

-pi (default) | scalar or vector

Lower limit of the block output.

Dependencies

Selecting **Wrap state** enables this parameter.

Programmatic Use

Block Parameter: WrappedStateLowerValue

Type: scalar or vector

Values: '0'

Default: '-pi'

Show saturation port — Enable saturation output port

off (default) | on

Select this check box to add a saturation output port to the block. When you clear this check box, the block does not have a saturation output port.

Dependencies

Selecting this parameter enables a saturation output port.

Programmatic Use

Block Parameter: ShowSaturationPort

Type: character vector , string

Values: 'off' | 'on'

Default: 'off'

Show state port — Enable state output port

off (default) | on

Select this check box to add a state output port to the block. When you clear this check box, the block does not have a state output port.

Dependencies

Selecting this parameter enables a state output port.

Programmatic Use

Block Parameter: ShowStatePort

Type: character vector , string

Values: 'off' | 'on'

Default: 'off'

Absolute tolerance — Absolute tolerance for block states

auto (default) | real scalar or vector

- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.

- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

Programmatic Use

Block Parameter: AbsoluteTolerance

Type: character vector, string, scalar, or vector

Values: 'auto' | '-1' | any positive real scalar or vector

Default: 'auto'

Ignore limit and reset when linearizing — Treat block as unresettable and output unlimited

off (default) | on

Cause Simulink linearization commands to treat this block as unresettable and as having no limits on its output, regardless of the settings of the reset and output limitation options of the block.

Tip

Use this check box to linearize a model around an operating point that causes the integrator to reset or saturate.

Programmatic Use

Block Parameter: IgnoreLimit

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Enable zero-crossing detection — Enable zero-crossing detection

on (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector, string

Values: 'off' | 'on'

Default: 'on'

State Name (e.g., 'position') — Assign unique name to each state

' ' (default) | character vector | string

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, cell array, or structure.

Programmatic Use**Block Parameter:** ContinuousStateAttributes**Type:** character vector, string**Values:** ' ' | user-defined**Default:** ' '**Block Characteristics**

Discrete-Time Integrator | Second-Order Integrator

Introduced before R2006a

Integrator Limited

Integrate signal

Library: Simulink / Continuous

Description

The Integrator Limited block is identical to the Integrator block with the exception that the output of the block is limited based on the upper and lower saturation limits. See “Limiting the Integral” on page 1-843 for details.

Simulink treats the Integrator block as a dynamic system with one state. The block dynamics are given by:

$$\begin{cases} \dot{x}(t) = u(t) \\ y(t) = x(t) \end{cases} \quad x(t_0) = x_0$$

where:

- u is the block input.
- y is the block output.
- x is the block state.
- x_0 is the initial condition of x .

While these equations define an exact relationship in continuous time, Simulink uses numerical approximation methods to evaluate them with finite precision. Simulink can use several different numerical integration methods to compute the output of the block, each with advantages in particular applications. Use the **Solver** pane of the Configuration Parameters dialog box (see “Solver Pane”) to select the technique best suited to your application.

The selected solver computes the output of the Integrator block at the current time step, using the current input value and the value of the state at the previous time step. To support this computational model, the Integrator block saves its output at the current time step for use by the solver to compute its output at the next time step. The block also provides the solver with an initial condition for use in computing the block's initial state at the beginning of a simulation. The default value of the initial condition is 0. Use the block parameter dialog box to specify another value for the initial condition or create an initial value input port on the block.

Use the parameter dialog box to:

- Define upper and lower limits on the integral
- Create an input that resets the block's output (state) to its initial value, depending on how the input changes
- Create an optional state output so that the value of the block's output can trigger a block reset

Use the Discrete-Time Integrator block to create a purely discrete system.

Defining Initial Conditions

You can define the initial conditions as a parameter on the block dialog box or input them from an external signal:

- To define the initial conditions as a block parameter, specify the **Initial condition source** parameter as `internal` and enter the value in the **Initial condition** field.
- To provide the initial conditions from an external source, specify the **Initial condition source** parameter as `external`. An additional input port appears under the block input.

Note If the integrator limits its output (see “Limiting the Integral” on page 1-843), the initial condition must fall inside the integrator's saturation limits. If the initial condition is outside the block saturation limits, the block displays an error message.

Wrapping Cyclic States

Several physical phenomena are cyclic, periodic, or rotary in nature. Objects or machinery that exhibit rotational movement and oscillators are examples of such phenomena.

Modeling these phenomena in Simulink involves integrating the rate of change of the periodic or cyclic signals to obtain the state of the movement.

The drawback with this approach, however, is that over long simulation time spans, the states representing periodic or cyclic signals integrate to large values. Further, computing the sine or cosine of these signals takes an increasingly large amount of time because of angle reduction. The large signals values also negatively impact solver performance and accuracy.

One approach for overcoming this drawback is to reset the angular state to 0 when it reaches 2π (or to $-\pi$ when it reaches π , for numerical symmetry). This approach improves the accuracy of sine and cosine computations and reduces angle reduction time. But it also requires zero-crossing detection and introduces solver resets, which slow down the simulation for variable step solvers, particularly in large models.

To eliminate solver resets at wrap points, the Integrator block supports wrapped states that you can enable by checking **Wrap state** on the block parameter dialog box. When you enable **Wrap state**, the block icon changes to indicate that the block has wrapping states.

Simulink allows wrapping states that are bounded by upper and lower values parameters of the wrapped state. The algorithm for determining wrapping states is given by:

$$y = \begin{cases} x & x \in [x_l, x_u) \\ x - (x_u - x_l) \left\lfloor \frac{x - x_l}{x_u - x_l} \right\rfloor & \text{otherwise} \end{cases}$$

where:

- x_l is the lower value of the wrapped state.
- x_u is the upper value of the wrapped state.
- y is the output.

The support for wrapping states provides these advantages.

- It eliminates simulation instability when your model approaches large angles and large state values.
- It reduces the number of solver resets during simulation and eliminates the need for zero-crossing detection, improving simulation time.
- It eliminates large angle values, speeding up computation of trigonometric functions on angular states.
- It improves solver accuracy and performance and enables unlimited simulation time.

Limiting the Integral

To prevent the output from exceeding specifiable levels, select the **Limit output** check box and enter the limits in the appropriate parameter fields. This action causes the block to function as a limited integrator. When the output reaches the limits, the integral action is turned off to prevent integral wind up. During a simulation, you can change the limits but you cannot change whether the output is limited. The block determines output as follows:

- When the integral is less than or equal to the **Lower saturation limit**, the output is held at the **Lower saturation limit**.
- When the integral is between the **Lower saturation limit** and the **Upper saturation limit**, the output is the integral.
- When the integral is greater than or equal to the **Upper saturation limit**, the output is held at the **Upper saturation limit**.

To generate a signal that indicates when the state is being limited, select the **Show saturation port** check box. A saturation port appears below the block output port.

The signal has one of three values:

- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.

- -1 indicates that the lower limit is being applied.

When you select this check box, the block has three zero crossings: one to detect when it enters the upper saturation limit, one to detect when it enters the lower saturation limit, and one to detect when it leaves saturation.

Note For the Integrator Limited block, by default, **Limit output** is selected, **Upper saturation limit** is set to 1, and **Lower saturation limit** is set to 0.

Resetting the State

The block can reset its state to the specified initial condition based on an external signal. To cause the block to reset its state, select one of the **External reset** choices. A trigger port appears below the block's input port and indicates the trigger type.

- Select **rising** to reset the state when the reset signal rises from a negative or zero value to a positive value.
- Select **falling** to reset the state when the reset signal falls from a positive value to a zero or negative value.
- Select **either** to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.
- Select **level** to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.
- Select **level hold** to reset the state when the reset signal is nonzero at the current time step.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results (see "Algebraic Loop Concepts"). Use the Integrator block's state port to feed back the block's output without creating an algebraic loop.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of Integrator blocks.

About the State Port

Selecting the **Show state port** check box on the Integrator block's parameter dialog box causes an additional output port, the state port, to appear at the top of the Integrator block.

The output of the state port is the same as the output of the block's standard output port except for the following case. If the block is reset in the current time step, the output of the state port is the

value that would have appeared at the block's standard output if the block had not been reset. The state port's output appears earlier in the time step than the output of the Integrator block's output port. Use the state port to avoid creating algebraic loops in these modeling scenarios:

- Self-resetting integrators (see “Creating Self-Resetting Integrators” on page 1-845)
- Handing off a state from one enabled subsystem to another (see “Handing Off States Between Enabled Subsystems” on page 1-846)

Note When updating a model, Simulink checks that the state port applies to one of these two scenarios. If not, an error message appears. Also, you cannot log the output of this port in a referenced model that executes in Accelerator mode. If logging is enabled for the port, Simulink generates a "signal not found" warning during execution of the referenced model.

Creating Self-Resetting Integrators

The Integrator block's state port helps you avoid an algebraic loop when creating an integrator that resets itself based on the value of its output. Consider, for example, the following model.

This model tries to create a self-resetting integrator by feeding the integrator's output, subtracted from 1, back into the integrator's reset port. However, the model creates an algebraic loop. To compute the integrator block's output, Simulink software needs to know the value of the block's reset signal, and vice versa. Because the two values are mutually dependent, Simulink software cannot determine either. Therefore, an error message appears if you try to simulate or update this model.

The following model uses the integrator's state port to avoid the algebraic loop.

In this version, the value of the reset signal depends on the value of the state port. The value of the state port is available earlier in the current time step than the value of the integrator block's output

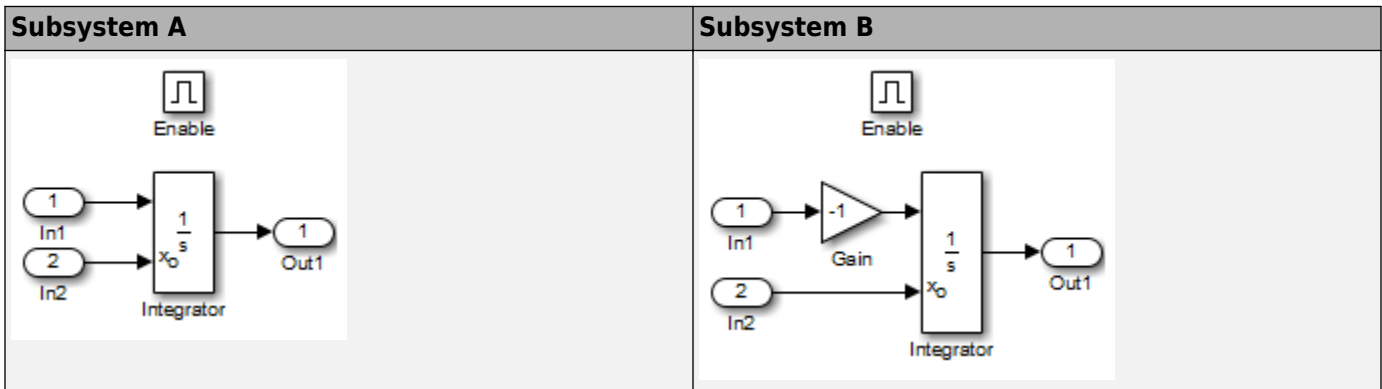

port. Therefore, Simulink can determine whether the block needs to be reset before computing the block's output, thereby avoiding the algebraic loop.

Handing Off States Between Enabled Subsystems

The state port helps you avoid an algebraic loop when passing a state between two enabled subsystems. Consider, for example, the following model.

The enabled subsystems, A and B, contain the following blocks:

In this model, a constant input signal drives two enabled subsystems that integrate the signal. A pulse generator generates an enabling signal that causes execution to alternate between the two subsystems. The enable port of each subsystem is set to reset, which causes the subsystem to reset its integrator when it becomes active. Resetting the integrator causes the integrator to read the value of its initial condition port. The initial condition port of the integrator in each subsystem is connected to the output port of the integrator in the other subsystem.

This connection is intended to enable continuous integration of the input signal as execution alternates between two subsystems. However, the connection creates an algebraic loop. To compute the output of A, Simulink needs to know the output of B, and vice versa. Because the outputs are mutually dependent, Simulink cannot compute the output values. Therefore, an error message appears if you try to simulate or update this model.

The following version of the same model uses the integrator state port to avoid creating an algebraic loop when handing off the state.

The enabled subsystems, A and B, contain the following blocks:

In this model, the initial condition of the integrator in A depends on the value of the state port of the integrator in B, and vice versa. The values of the state ports are updated earlier in the simulation time step than the values of the integrator output ports. Therefore, Simulink can compute the initial condition of either integrator without knowing the final output value of the other integrator. For another example of using the state port to hand off states between conditionally executed subsystems, see “Building a Clutch Lock-Up Model” on page 13-151.

Specifying the Absolute Tolerance for the Block Outputs

By default Simulink software uses the absolute tolerance value specified in the Configuration Parameters dialog box (see “Error Tolerances for Variable-Step Solvers”) to compute the output of the Integrator block. If this value does not provide sufficient error control, specify a more appropriate value in the **Absolute tolerance** field of the Integrator block dialog box. The value that you specify is used to compute all the block outputs.

Selecting All Options

When you select all options, the block icon looks like this.

Ports

Input

Port_1 — Integrand signal

real scalar or array

Signal that needs to be integrated.

Data Types: double

External Reset — Reset state to initial conditions

real scalar or array

Reset the state to the specified initial conditions based on an external signal. See “Resetting the State” on page 1-844.

Dependencies

To enable this port, enable the **External Reset** parameter.

Data Types: Boolean

x_0 — Initial condition

real scalar or array

Set the initial condition of the block's state from an external signal.

Dependencies

To enable this port, set the **Initial Conditions** parameter to external.

Data Types: double

Output

Port_1 — Output signal

real scalar or array

Output the integrated state.

Data Types: double

Port_2 — Show output saturation

-1 | 0 | 1

Indicate when the state is being limited. The signal has a value of 1 when the integral is limited by the specified **Upper saturation limit**. When the signal is limited by the **Lower saturation limit**, the signal value is -1. When the integral is between the saturation limits, the signal value is 0. See “Limiting the Integral” on page 1-843.

Data Types: double

Port_3 – State

real scalar or array

Output the state of the block. See “About the State Port” on page 1-844.

Dependencies

Enable this port by enabling the **Show state port** parameter.

Data Types: double

Parameters

External reset – Reset states to their initial conditions

none (default) | rising | falling | either | level | level hold

Specify the type of trigger to use for the external reset signal.

- Select **rising** to reset the state when the reset signal rises from a negative or zero value to a positive value, or a negative value to zero value.
- Select **falling** to reset the state when the reset signal falls from a positive value to a zero or negative value, or from a zero value to negative value.
- Select **either** to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.
- Select **level** to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.
- Select **level hold** to reset the state when the reset signal is nonzero at the current time step.

Programmatic Use

Block Parameter: ExternalReset

Type: character vector , string

Values: 'none' | 'rising' | 'falling' | 'either' | 'level' | 'level hold'

Default: 'none'

Initial condition source – Select source of initial condition

internal (default) | external

Select source of initial condition:

- **internal** — Get the initial conditions of the states from the **Initial condition** block parameter.
- **external** — Get the initial conditions of the states from an external block, via the **IC** input port.

Dependencies

Selecting **internal** enables the **Initial condition** parameter.

Selecting **external** disables the **Initial condition** parameter and enables the **IC** input port.

Programmatic Use

Block Parameter: InitialConditionSource

Type: character vector, string

Values: 'internal' | 'external'

Default: 'internal'

Initial condition — Initial state

0 (default) | real scalar or array

Set the initial state of the Integrator block.

Tips

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

Setting **Initial condition source** to `internal` enables this parameter.

Setting **Initial condition source** to `external` disables this parameter.

Programmatic Use

Block Parameter: `InitialCondition`

Type: scalar or vector

Default: '0'

Limit output — Limit block output values to specified range

`off` (default for Integrator) | `on` (default for Integrator Limited)

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

- Selecting this check box limits the block output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.
- Clearing this check box does not limit the block output values.

Dependencies

Selecting this parameter enables the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use

Block Parameter: `LimitOutput`

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Upper saturation limit — Upper limit for the integral

`inf` (default) | scalar | vector | matrix

Specify the upper limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use

Block Parameter: `UpperSaturationLimit`

Type: character vector, string

Values: scalar | vector | matrix

Default: 'inf'

Lower saturation limit — Lower limit for the integral

-inf (default) | scalar | vector | matrix

Specify the lower limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use

Block Parameter: LowerSaturationLimit

Type: character vector , string

Values: scalar | vector | matrix

Default: '-inf'

Wrap state — Enable wrapping of states

off (default) | on

Enable wrapping of states between the **Wrapped state upper value** and **Wrapped state lower value** parameters. Enabling wrap states eliminates the need for zero-crossing detection, reduces solver resets, improves solver performance and accuracy, and increases simulation time span when modeling rotary and cyclic state trajectories.

If you specify **Wrapped state upper value** as inf and **Wrapped state lower value** as -inf, wrapping does not occur.

Dependencies

Selecting this parameter enables **Wrapped state upper value** and **Wrapped state lower value** parameters.

Programmatic Use

Block Parameter: WrapState

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Wrapped state upper value — Specify upper value for wrapped state

pi (default) | scalar or vector

Upper limit of the block output.

Dependencies

Selecting **Wrap state** enables this parameter.

Programmatic Use

Block Parameter: WrappedStateUpperValue

Type: scalar or vector

Values: '2*pi'

Default: 'pi'

Wrapped state lower value — Specify lower value for wrap state

-pi (default) | scalar or vector

Lower limit of the block output.

Dependencies

Selecting **Wrap state** enables this parameter.

Programmatic Use

Block Parameter: WrappedStateLowerValue

Type: scalar or vector

Values: '0'

Default: '-pi'

Show saturation port — Enable saturation output port

off (default) | on

Select this check box to add a saturation output port to the block. When you clear this check box, the block does not have a saturation output port.

Dependencies

Selecting this parameter enables a saturation output port.

Programmatic Use

Block Parameter: ShowSaturationPort

Type: character vector , string

Values: 'off' | 'on'

Default: 'off'

Show state port — Enable state output port

off (default) | on

Select this check box to add a state output port to the block. When you clear this check box, the block does not have a state output port.

Dependencies

Selecting this parameter enables a state output port.

Programmatic Use

Block Parameter: ShowStatePort

Type: character vector , string

Values: 'off' | 'on'

Default: 'off'

Absolute tolerance — Absolute tolerance for block states

auto (default) | real scalar or vector

- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

Programmatic Use**Block Parameter:** AbsoluteTolerance**Type:** character vector, string, scalar, or vector**Values:** 'auto' | '-1' | any positive real scalar or vector**Default:** 'auto'**Ignore limit and reset when linearizing — Treat block as unresettable and output unlimited**

off (default) | on

Cause Simulink linearization commands to treat this block as unresettable and as having no limits on its output, regardless of the settings of the reset and output limitation options of the block.

Tip

Use this check box to linearize a model around an operating point that causes the integrator to reset or saturate.

Programmatic Use**Block Parameter:** IgnoreLimit**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'off'**Enable zero-crossing detection — Enable zero-crossing detection**

on (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use**Block Parameter:** ZeroCross**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'on'**State Name (e.g., 'position') — Assign unique name to each state**

' ' (default) | character vector | string

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, cell array, or structure.

Programmatic Use**Block Parameter:** ContinuousStateAttributes

Type: character vector, string

Values: ' ' | user-defined

Default: ' '

Block Characteristics

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	yes

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Interpolation Using Prelookup

Use precalculated index and fraction values to accelerate approximation of N-dimensional function

Library: Simulink / Lookup Tables

Description

The Interpolation Using Prelookup block is most efficient when used with the Prelookup block. The Prelookup block calculates the index and interval fraction that specify how its input value u relates to the breakpoint data set. Feed the resulting index and fraction values into an Interpolation Using Prelookup block to interpolate an n -dimensional table. These two blocks have distributed algorithms. When combined together, they perform the same operation as the integrated algorithm in the n -D Lookup Table block. However, the Prelookup and Interpolation Using Prelookup blocks offer greater flexibility that can provide more efficient simulation and code generation. For more information, see “Efficiency of Performance”.

Supported Block Operations

To use the Interpolation Using Prelookup block, you specify a set of table data values directly on the dialog box or feed values into the **T** input port. Typically, these table values correspond to the breakpoint data sets specified in Prelookup blocks. The Interpolation Using Prelookup block generates output by looking up or estimating table values based on index and interval fraction values fed from Prelookup blocks. Labels for the index and interval fraction appear as k and f on the Interpolation Using Prelookup block icon.

When inputs for index and interval fraction...	The Interpolation Using Prelookup block...
Map to values in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not map to values in breakpoint data sets, but are within range	Interpolates appropriate table values using the Interpolation method you select
Do not map to values in breakpoint data sets, and are out of range	Extrapolates the output value using the Extrapolation method you select

How The Block Interpolates a Subset of Table Data

You can use the **Number of sub-table selection dimensions** parameter to specify that interpolation occur only on a subset of the table data. To activate this interpolation mode, set this parameter to a positive integer. This value defines the number of dimensions to select, starting from the highest dimension of table data for the default column-major algorithm. Therefore, the value must be less than or equal to the **Number of table dimensions**.

For row-major algorithms, the interpolation starts from the first or lowest dimension of the table data.

For nonzero values, the subtable selection behavior is optimized for row-major layout when you select the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter.

Suppose that you have 3-D table data in your Interpolation Using Prelookup block. This behavior applies for the column-major algorithm.

Number of Selection Dimensions	Action by the Block	Block Appearance
0	Interpolates the entire table and does not activate subtable selection	Does not change
1	Interpolates the first two dimensions and selects the third dimension	Displays an input port with the label <code>s3</code> that you use to select and interpolate 2-D tables
2	Interpolates the first dimension and selects the second and third dimensions	Displays two input ports with the labels <code>s2</code> and <code>s3</code> that you use to select and interpolate 1-D tables

Subtable selection uses zero-based indexing. For an example of interpolating a subset of table data, see “Using the Prelookup and Interpolation Blocks” on page 13-583.

For 2-D or n-D interpolation without subtable selection, the column-major and row-major algorithms may differ in the order of output calculations, causing slight different numerical results.

Ports

Input

k1 – Index, k, for the first dimension of the table

scalar | vector | matrix

Zero-based index, `k`, specifying the interval containing the input `u` for the first dimension of the table.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

f1 – Fraction, f, for the first dimension of the table

scalar | vector | matrix

Fraction, `f`, representing the normalized position of the input within the interval, `k`, for the first dimension of the table.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

kn – Index, k, for the n-th dimension of the table

scalar | vector | matrix

Zero-based index, `k`, specifying the interval containing the input `u` for the n-th dimension of the table.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

fn — Fraction, f, for the n-th dimension of the table

scalar | vector | matrix

Fraction, *f*, representing the normalized position of the input within the interval, *k*, for the *n*-th dimension of the table.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

kf1 — Input containing index k and fraction f

bus object

Inputs to the **kf1** port contain index *k* and fraction *f* specified as a bus object.

Dependencies

To enable this port, select the **Require index and fraction as a bus** check box.

The number of available **kf** input ports depends on the value of the **Number of dimensions** and **Number of sub-table selection dimensions** parameters.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | bus

kfn — Input containing index k and fraction f

bus object

Inputs to the **kfn** port contain index *k* and fraction *f* for the *n*-th dimension of the input, specified as a bus object.

Dependencies

To enable this port, select the **Require index and fraction as a bus** check box.

The number of available **kf** input ports depends on the value of the **Number of dimensions** and **Number of sub-table selection dimensions** parameters.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | bus

sm — Select and interpolate a subset of the table data

scalar | vector | matrix

For column-major algorithm, the block uses inputs to the *sm*, *sm*+1, ... *sn* port to perform selection and interpolation within the subtables. *m* maps to the *m*th dimension of the table. *n* equals the **Number of dimensions**.

For row-major algorithm, the block uses inputs to the *s1*, *s2*, ... ,*sm* port to perform selection and interpolation within the subtables. *m* maps to the *m*th dimension of the table. *m* equals the **Number of sub-table selection dimensions**.

Dependencies

To enable this port, the **Number of sub-table selection dimensions** must be a positive integer less than or equal to the **Number of dimensions**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

T — Table data

scalar | vector | matrix | n-d array

Table data values provided as input to port **T**. Typically, these table values correspond to the breakpoint data sets specified in Prelookup blocks. The Interpolation Using Prelookup block generates output by looking up or estimating table values based on index (k) and interval fraction (f) values fed from Prelookup blocks.

Dependencies

To enable this port, set **Source** to Input port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output**Port_1 — Approximation of N-dimensional function**

scalar | vector | matrix

Approximation of N-dimensional function, computed by interpolating (or extrapolating) table data using values from the input index, k, and fraction, f.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters**Main****Table data****Number of dimensions — Number of table data dimensions**

2 (default) | integer between 1 and 30

Specify the number of dimensions that the table data must have. The **Number of dimensions** defines the number of independent variables for the table.

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

Programmatic Use**Block Parameter:** NumberOfTableDimensions**Type:** character vector**Values:** '1' | '2' | '3' | '4' | ... | '30'**Default:** '2'**Require index and fraction as bus — Index and fraction inputs can be combined in a bus**

off (default) | on

Select this check box to combine index and fraction inputs in a bus.

To enable the Prelookup block to supply input to the Interpolation Using Prelookup block, set:

- **Output selection** to Index and fraction as bus
- **Output** to Bus: <object name>, where <object name> must be a valid bus object name accessible to the model

Regardless of this check box setting, the selection port always operates in nonbus mode.

Programmatic Use

Block Parameter: RequireIndexFractionAsBus

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Specification — Choose how to enter table data

Explicit values (default) | Lookup table object

Specify whether to enter table data directly or use a lookup table object. If you set this parameter to:

- Explicit values, the **Source** and **Value** parameters are visible on the dialog box.
- Lookup table object, the **Name** parameter is visible on the dialog box.

Programmatic Use

Block Parameter: TableSpecification

Type: character vector

Values: 'Explicit values' | 'Lookup table object'

Default: 'Explicit values'

Source — Source of table data

Dialog (default) | Input port

Specify whether to enter table data in the dialog box or to inherit the data from an input port. If you set **Source** to:

- Dialog, enter table data in the text box under **Value**
- Input port, verify that an upstream signal supplies table data to the table input port

Dependencies

To enable this parameter, set **Specification** to Explicit values.

Programmatic Use

Block Parameter: TableSource

Type: character vector

Values: 'Dialog' | 'Input port'

Default: 'Dialog'

Value — Specify table data values

$\text{sqrt}([1:11]' * [1:11])$ (default) | multidimensional array of table data

Specify table data as an N-D array, where N is the value of the **Number of dimensions** parameter. You can edit the block diagram without specifying a correctly dimensioned matrix by entering an empty matrix ([]) or an undefined workspace variable in the **Value** edit field. For information about how to construct multidimensional arrays in MATLAB, see “Multidimensional Arrays”.

If you set **Source** to Input port, verify that an upstream signal supplies table data to the **T** input port. The size of table data must match the **Number of table dimensions**. For this option, the block inherits table attributes from the **T** input port.

To edit lookup tables using the Lookup Table Editor, click **Edit** (see “Edit Lookup Tables”).

Dependencies

To enable this parameter and explicitly specify table values on the dialog box, you must set **Specification** to Explicit values and **Source** to Dialog.

Programmatic Use

Block Parameter: Table

Type: character vector

Values: scalar, vector, matrix, or N-D array

Default: 'sqrt([1:11]' * [1:11])'

Name — Name of a Simulink.LookupTable object

Simulink.LookupTable object

Specify the name of a Simulink.LookupTable object. A lookup table object references Simulink

breakpoint objects. If a Simulink.LookupTable object does not exist, click the action button  and select **Create**. The corresponding parameters of the new lookup table object are automatically populated with the block information.

Dependencies

To enable this parameter, set **Specification** to Lookup table object.

Programmatic Use

Block Parameter: LookupTableObject

Type: character vector

Value: Simulink.LookupTable object

Default: ''

Algorithm

Interpolation method — Select Linear point-slope, Flat, Nearest, or Linear Lagrange

Linear point-slope (default) | Nearest | Flat | Linear Lagrange

Specify the method the block uses to interpolate table data. You can select Linear point-slope, Flat, Nearest, or Linear Lagrange. See “Interpolation Methods” for more information.

Programmatic Use

Block Parameter: InterpMethod

Type: character vector

Values: 'Flat' | 'Linear point-slope' | 'Nearest' | 'Linear Lagrange'

Default: 'Linear point-slope'

Extrapolation method — Method of handling input that falls outside the range of the breakpoint data set

Linear (default) | Clip

Specify the method the block uses to extrapolate values for all inputs that fall outside the range of the breakpoint data set. You can select **Clip** or **Linear**. See “Extrapolation Methods” for more information.

If the extrapolation method is **Linear**, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is **Linear Lagrange**, the extrapolation method inherits the **Linear Lagrange** equation to compute the extrapolated value.

Dependencies

To enable the **Extrapolation method** parameter, set the **Interpolation method** to **Linear**.

The Interpolation Using Prelookup block does not support **Linear** extrapolation when the input or output signals specify integer or fixed-point data types.

Programmatic Use

Block Parameter: ExtrapMethod

Type: character vector

Values: 'Clip' | 'Linear'

Default: 'Linear'

Valid index input may reach last index — Allow inputs to access the last elements of table data

off (default) | on

Specify how block inputs for index (**k**) and interval fraction (**f**) access the last elements of *n*-dimensional table data. Index values are zero based.

This check box is relevant if the input index is equal to or larger than the table's last index for that dimension. Due to rounding, selecting and clearing this check box may result in differing results for the last index between simulation and code generation.

Check Box	Block Behavior
on	Returns the value of the last element in a dimension of its table when: <ul style="list-style-type: none"> • k indexes the last table element in the corresponding dimension • f is 0
off	Returns the value of the last element in a dimension of its table when: <ul style="list-style-type: none"> • k indexes the next-to-last table element in the corresponding dimension • f is 1

Dependencies

This check box is visible only when:

- **Interpolation method** is **Linear point-slope** or **Linear Lagrange**
- **Extrapolation method** is **Clip**

Tip When you select **Valid index input may reach last index** for an Interpolation Using Prelookup block, you must also select **Use last breakpoint for input at or above upper limit** for all Prelookup blocks that feed it. This action allows the blocks to use the same indexing convention when accessing the last elements of their breakpoint and table data sets.

Programmatic Use**Block Parameter:** ValidIndexMayReachLast**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Diagnostic for out-of-range input — Block action when input is out of range**

None (default) | Warning | Error

Specify whether to produce a warning or error when the input is out of range. Options include:

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

Programmatic Use**Block Parameter:** DiagnosticForOutOfRangeInput**Type:** character vector**Values:** 'None' | 'Warning' | 'Error'**Default:** 'None'**Number of sub-table selection dimensions — Number of dimensions of the output computation subtable**

0 (default) | positive integer, less than or equal to the number of table dimensions

Specify the number of dimensions of the subtable that the block uses to compute the output. Follow these rules:

- To enable subtable selection, enter a positive integer.

This integer must be less than or equal to the **Number of table dimensions**.

- To disable subtable selection, enter 0 to interpolate the entire table.

For nonzero values, the subtable selection behavior is optimized for row-major layout when you select the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter.

For more information, see “How The Block Interpolates a Subset of Table Data” on page 1-855.

Programmatic Use**Block Parameter:** NumSelectionDims**Type:** character vector**Values:** '0' | '1' | '2' | '3' | '4' | ... | Number of table dimensions**Default:** '0'**Code generation****Remove protection against out-of-range index in generated code — Remove code that checks for out-of-range index inputs**

off (default) | on

Check Box	Result	When to Use
on	Generated code does not include conditional statements to check for out-of-range index inputs. When the input k or f is out of range, it may cause undefined behavior for generated code.	For code efficiency
off	Generated code includes conditional statements to check for out-of-range index inputs.	For safety-critical applications

If your input is not out of range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to Error.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input k or f is out of range, the behavior is undefined for generated code.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Advisor Checks”.

Additionally, to determine if it is safe to select this check box, if you have a Simulink Design Verifier license, consider using the “Detect Block Input Range Violations” (Simulink Design Verifier) check.

This check box has no effect on the generated code when one of the following is true:

- The Prelookup block feeds index values to the Interpolation Using Prelookup block.

Because index values from the Prelookup block are always valid, no check code is necessary.

- The data type of the input k restricts the data to valid index values.

For example, unsigned integer data types guarantee nonnegative index values. Therefore, unsigned input values of k do not require check code for negative values.

Programmatic Use**Block Parameter:** RemoveProtectionIndex**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Sample time — Sample time value other than -1**`-1 (default) | scalar | vector`

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Data Types****Table data — Data type of table values**`Inherit: Same as output (default) | Inherit: Inherit from 'Table data' | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>`

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the table data type.

Tip Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
 - Sharing of prescaled table data between two Interpolation Using Prelookup blocks with different output data types
 - Sharing of custom storage table data in Simulink Coder generated code for blocks with different output data types
-

Programmatic Use**Block Parameter:** TableDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit from table data' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as input'**Table minimum — Minimum value of table data**

[] (default) | scalar

Specify the minimum value for table data as a finite, real, double, scalar. The default value is [] (unspecified).

Programmatic Use**Block Parameter:** TableMin**Type:** character vector**Values:** scalar**Default:** '[]'**Table maximum — Maximum value of table data**

[] (default) | scalar

Specify the maximum value for table data as a finite, real, double, scalar. The default value is [] (unspecified).

Programmatic Use**Block Parameter:** TableMax**Type:** character vector**Values:** scalar**Default:** '[]'**Intermediate results — Data type of intermediate results**

Inherit: Inherit via internal rule (default) | Inherit: Same as output | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Use this parameter to specify higher precision for internal computations than for table data or output data.

Programmatic Use**Block Parameter:** IntermediateResultsDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as input'**Output — Output data type**

Inherit: Inherit from 'Table data' (default) | Inherit: Inherit via back propagation | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via back propagation
- The name of a built-in data type, for example, single
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the output data type.

See “Control Data Types of Signals” in the *Simulink User's Guide* for more information.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via back propagation' | 'Inherit: Inherit from table data' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Inherit from table data'**Output minimum — Minimum value the block can output**

[] (default) | scalar

Specify the minimum value that the block should output as a finite, real-valued scalar. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use**Block Parameter:** OutMin

Type: character vector

Values: scalar

Default: ' [] '

Output maximum — Maximum value the block can output

[] (default) | scalar

Specify the maximum value that the block should output as a finite, real-valued scalar. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: scalar

Default: ' [] '

Internal rule priority — Internal rule for intermediate calculations

Speed (default) | Precision

Specify the internal rule for intermediate calculations. Select Speed for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Programmatic Use

Block Parameter: InternalRulePriority

Type: character vector

Values: 'Speed' | 'Precision'

Default: 'Speed'

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Convergent | Ceiling | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function in the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Simulink PLC Coder™ has limited support for lookup table blocks. The coder does not support:

- Number of dimensions greater than 2
- Cubic spline interpolation method
- Begin index search using a previous index mode
- Cubic spline extrapolation method

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Interpreted MATLAB Function

Apply MATLAB function or expression to input

Library: Simulink / User-Defined Functions

Description

The Interpreted MATLAB Function block applies the specified MATLAB function or expression to the input. The output of the function must match the output dimensions of the block.

Some valid expressions for this block are:

```
sin
atan2(u(1), u(2))
u(1)^u(2)
```

Note This block is slow because it calls the MATLAB parser during each integration step. Consider using built-in blocks (such as the Math Function block) instead. Alternatively, you can write the function as a MATLAB S-function or MEX-file S-function, then access it using the S-Function block.

Ports

Input

In — Input of a Interpreted MATLAB function

scalar | vector | matrix

The Interpreted MATLAB Function block accepts one real or complex input of type `double` and generates real or complex output of type `double`, depending on the setting of the **Output signal type** parameter.

Data Types: `double`

Output

Out — Output of a Interpreted MATLAB function

scalar | vector | matrix

The Interpreted MATLAB Function block accepts one real or complex input of type `double` and generates real or complex output of type `double`, depending on the setting of the **Output signal type** parameter.

Data Types: `double`

Parameters

MATLAB Function — Specify the function or expression

function (default)

Specify the function or expression. If you specify a function only, it is not necessary to include the input argument in parentheses.

Output dimensions — Specify the dimensions of the block output signal

scalar | matrix | vector | inherited

Specify the dimensions of the block output signal, for example, 2 for a two-element vector. The output dimensions must match the dimensions of the value returned by the function or expression in the **MATLAB function** field.

Specify -1 to inherit the dimensions from the output of the specified function or expression. To determine the output dimensions, Simulink runs the function or expression once before simulation starts.

Note If you specify -1 for this parameter and your function has persistent variables, then the variables might update before the simulation starts. If you need to use persistent variables, consider setting this parameter to a value other than -1.

Output signal type — Specify the block output signal type

auto (default) | real | complex

Specify the output signal type of the block as real, complex, or auto. A value of auto sets the output type to be the same as the type of the input signal.

Collapse 2-D results to 1-D — Output a 2-D array as a 1-D array

off (default) | on

Select this check box to output a 2-D array as a 1-D array containing the 2-D array's elements in column-major order.

Sample time — Specify sample time in the block

scalar

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Block Characteristics

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no

Zero-Crossing Detection	no

Interval Test

Determine if signal is in specified interval

Library: Simulink / Logic and Bit Operations

Description

The Interval Test block outputs true (1) if the input is between the values specified by the **Lower limit** and **Upper limit** parameters. The block outputs false (0) if the input is outside those values. The output of the block when the input is equal to the **Lower limit** or the **Upper limit** is determined by whether you select the **Interval closed on left** and **Interval closed on right** check boxes.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array.

Limitations

When the input signal is an enumerated type, the **Upper limit** and **Lower limit** values must be of the same enumerated type.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 – Output signal

scalar | vector | matrix | N-D array

Output signal indicating whether the input values fall within the specified interval. You can specify the **Output data type** as boolean or uint8.

Data Types: uint8 | Boolean

Parameters

Interval closed on right – Include upper limit value

on (default) | off

When you select this check box, the **Upper limit** is included in the interval for which the block outputs true (1).

Programmatic Use

Block Parameter: IntervalClosedRight

Type: character vector
Values: 'on' | 'off'
Default: 'on'

Upper limit – Upper limit of interval

0.5 (default) | scalar | vector | matrix | N-D array

The upper limit of the interval for which the block outputs true (1).

Programmatic Use

Block Parameter: uplimit

Type: character vector

Values: scalar | vector | matrix | N-D array

Default: '0.5'

Interval closed on left – Include lower limit value

on (default) | off

When you select this check box, the **Lower limit** is included in the interval for which the block outputs true (1).

Programmatic Use

Block Parameter: IntervalClosedLeft

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Lower limit – Lower limit of interval

-0.5 (default) | scalar | vector | matrix | N-D array

The lower limit of the interval for which the block outputs true (1).

Programmatic Use

Block Parameter: lowlimit

Type: character vector

Values: scalar | vector | matrix | N-D array

Default: '-0.5'

Output data type – Output data type

boolean (default) | uint8

Specify the output data type as boolean or uint8.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'boolean' | 'uint8'

Default: 'boolean'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	yes

Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

Architecture	Description
Module (default)	Generate code for the subsystem and the blocks within the subsystem.
BlackBox	Generate a black box interface. The generated HDL code includes only the input/output port definitions for the subsystem. Therefore, you can use a subsystem in your model to generate an interface to existing, manually written HDL code. The black-box interface generation for subsystems is similar to the Model block interface generation without the clock signals.
No HDL	Remove the subsystem from the generated code. You can use the subsystem in simulation, however, treat it as a “no-op” in the HDL code.

Black Box Interface Customization

For the BlackBox architecture, you can customize port names and set attributes of the external component interface. See “Customize Black Box or HDL Cosimulation Interface” (HDL Coder).

HDL Block Properties

General	
AdaptivePipelining	Automatic pipeline insertion based on the synthesis tool, target frequency, and multiplier word-lengths. The default is <code>inherit</code> . See also “AdaptivePipelining” (HDL Coder).
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . See also “BalanceDelays” (HDL Coder).
ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <code>inherit</code> . See also “ClockRatePipelining” (HDL Coder).

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is off. See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is none. See also “DSPStyle” (HDL Coder).
FlattenHierarchy	Remove subsystem hierarchy from generated HDL code. The default is inherit. See also “FlattenHierarchy” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is 0, which implements fully parallel data paths. See also “Streaming” (HDL Coder).

If this block is not the DUT, the block property settings in the **Target Specification** tab are ignored. In the HDL Workflow Advisor, if you use the **IP Core Generation** workflow, these target specification block property values are saved with the model. If you specify these target specification block property values using `hdlset_param`, when you open HDL Workflow Advisor, the fields are populated with the corresponding values.

Target Specification	
AdditionalTargetInterfaces	<p>Additional target interfaces, specified as a character vector.</p> <p>To save this block property on the model, in the Set Target Interface task of the IP Core Generation workflow, corresponding to the DUT ports that you want to add more interfaces, select Add more.... You can then add more interfaces in the Add New Target Interfaces dialog box. Specify the type of interface, number of additional interfaces, and a unique name for each additional interface.</p> <p>Values: ' ' (default) cell array of character vectors</p> <p>Example: <code>'{'AXI4-Stream', 'InterfaceID', 'AXI4-Stream1'}'</code></p>

Target Specification	
ProcessorFPGASynchronization	<p>Processor/FPGA synchronization mode, specified as a character vector.</p> <p>To save this block property on the model, specify the Processor/FPGA Synchronization in the Set Target Interface task of the IP Core Generation workflow.</p> <p>Values: Free running (default) Coprocessing - blocking</p> <p>Example: 'Free running'</p>
TestPointMapping	<p>To save this block property on the model, specify the mapping of test point ports to target platform interfaces in the Set Target Interface task of the IP Core Generation workflow.</p> <p>Values: '' (default) cell array of character vectors</p> <p>Example: '{{ 'TestPoint', 'AXI4-Lite', 'x"108"' }}</p>
TunableParameterMapping	<p>To save this block property on the model, specify the mapping of tunable parameter ports to target platform interfaces in the Set Target Interface task of the IP Core Generation workflow.</p> <p>Values: '' (default) cell array of character vectors</p> <p>Example: '{{ 'myParam', 'AXI4-Lite', 'x"108"' }}</p>
AXI4RegisterReadback	<p>To save this block property on the model, specify whether you want to enable readback on AXI4 subordinate write registers in the Generate RTL Code and IP Core task of the IP Core Generation workflow. To learn more, see “Model Design for AXI4 Slave Interface Generation” (HDL Coder).</p> <p>Values: 'off' (default) 'on'</p>
AXI4SlaveIDWidth	<p>To save this block property on the model, specify the number of AXI manager interfaces that you want to connect the DUT IP core to by using the AXI4 Slave ID Width setting in the Generate RTL Code and IP Core task of the IP Core Generation workflow. To learn more, see “Define Multiple AXI Master Interfaces in Reference Designs to access DUT AXI4 Slave Interface” (HDL Coder).</p> <p>Values: 'off' (default) 'on'</p>
AXI4SlavePortToPipelineRegisterRatio	<p>To save this block property on the model, specify the number of AXI4 subordinate ports for which you want a pipeline register to be inserted by using the AXI4 Slave port to pipeline register ratio setting in the Generate RTL Code and IP Core task of the IP Core Generation workflow. To learn more, see “Model Design for AXI4 Slave Interface Generation” (HDL Coder).</p> <p>Values: 'off' (default) 'on'</p>

Target Specification	
GenerateDefaultAXI4 Slave	<p>To save this block property on the model, specify whether you want to disable generation of default AXI4 subordinate interfaces in the Generate RTL Code and IP Core task of the IP Core Generation workflow.</p> <p>Values: 'on' (default) 'off'</p>
IPCoreAdditionalFiles	<p>Verilog or VHDL files for black boxes in your design. Specify the full path to each file, and separate file names with a semicolon (;).</p> <p>You can set this property in the HDL Workflow Advisor, in the Additional source files field.</p> <p>Values: '' (default) character vector</p> <p>Example: 'C:\myprojfiles \led_blinking_file1.vhd;C:\myprojfiles \led_blinking_file2.vhd;'</p>
IPCoreName	<p>IP core name, specified as a character vector.</p> <p>You can set this property in the HDL Workflow Advisor, in the IP core name field. If this property is set to the default value, the HDL Workflow Advisor constructs the IP core name based on the name of the DUT.</p> <p>Values: '' (default) character vector</p> <p>Example: 'my_model_name'</p>
IPCoreVersion	<p>IP core version number, specified as a character vector.</p> <p>You can set this property in the HDL Workflow Advisor, in the IP core version field. If this property is set to the default value, the HDL Workflow Advisor sets the IP core version.</p> <p>Values: '' (default) character vector</p> <p>Example: '1.3'</p>
IPDataCaptureBuffer Size	<p>FPGA Data Capture buffer size, specified as a character vector. Use FPGA Data Capture to observe signals in a design when running on an FPGA.</p> <p>The buffer size uses values that are $128 \cdot 2^n$, where n is an integer. By default, the buffer size is 128 (n=0). The maximum value of n is 13, which means that the maximum value for buffer size is 1048576 ($=128 \cdot 2^{13}$).</p> <p>Values: '' (default) character vector</p> <p>Example: '1.3'</p>

Interval Test Dynamic

Introduced before R2006a

Interval Test Dynamic

Determine if signal is in specified interval

Library: Simulink / Logic and Bit Operations

Description

The Interval Test Dynamic block outputs true (1) if the input is between the values of the external signals **up** and **lo**. The block outputs false (0) if the input is outside those values. To control how the block handles input values that are equal to the signal **lo** or the signal **up**, use the **Interval closed on left** and **Interval closed on right** check boxes.

Ports

Input

up — Upper limit of interval

scalar | vector | matrix | N-D array

Upper limit of interval, specified as a scalar, vector, matrix, or N-D array.

Limitations

When the input signal is an enumerated type, the **up** and **lo** signals must be of the same enumerated type.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

u — Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array.

Limitations

When the input signal is an enumerated type, the **up** and **lo** signals must be of the same enumerated type.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

lo — Lower limit of interval

scalar | vector | matrix | N-D array

Lower limit of interval, specified as a scalar, vector, matrix, or N-D array.

Limitations

When the input signal is an enumerated type, the **up** and **lo** signals must be of the same enumerated type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

Output

y — Output signal

scalar | vector | matrix | N-D array

Output signal indicating whether the input values fall within the specified interval. You can specify the **Output data type** as `boolean` or `uint8`.

Data Types: `uint8` | `Boolean`

Parameters

Interval closed on right — Include upper limit value

`on` (default) | `off`

When you select this check box, the value of the signal connected to the **up** input port is included in the interval for which the block outputs true (1).

Programmatic Use

Block Parameter: `IntervalClosedRight`

Type: character vector

Values: `'on'` | `'off'`

Default: `'on'`

Interval closed on left — Include lower limit value

`on` (default) | `off`

When you select this check box, the value of the signal connected to the **lo** input port is included in the interval for which the block outputs true (1).

Programmatic Use

Block Parameter: `IntervalClosedLeft`

Type: character vector

Values: `'on'` | `'off'`

Default: `'on'`

Output data type — Output data type

`boolean` (default) | `uint8`

Specify the output data type as `boolean` or `uint8`.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'boolean'` | `'uint8'`

Default: `'boolean'`

Block Characteristics

Data Types	<code>Boolean</code> <code>double</code> <code>enumerated</code> <code>fixed point</code> <code>integer</code> <code>single</code>
Direct Feedthrough	yes

Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Interval Test

Introduced before R2006a

IsHermitian

Check if matrix is Hermitian or skew-Hermitian

Library: Simulink / Matrix Operations

Description

The IsHermitian block determines if the input is a Hermitian or a skew-Hermitian matrix.

Ports

Input

Port_1 — Input matrix

matrix

Input matrix, specified as a matrix.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Hermitian or skew-Hermitian matrix

real scalar Boolean

A Hermitian or skew-Hermitian matrix, returned as a real scalar Boolean.

Data Types: Boolean

Parameters

Mode — Whether matrix is Hermitian or skew-Hermitian

Hermitian (default) | Skew-Hermitian

Identify the matrix as Hermitian or Skew-Hermitian.

Programmatic Use

Block Parameter: Mode

Type: character vector

Values: 'Hermitian' | 'Skew-Hermitian'

Default: 'Hermitian'

Block Characteristics

Data Types	Boolean double fixed point half integer ^a single
-------------------	---

Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

a This block only supports signed integer types for the skew-symmetric mode.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

IsSymmetric

Check if matrix is symmetric or skew-symmetric

Library: Simulink / Matrix Operations

Description

The IsSymmetric block determines if the input is a symmetric or skew-symmetric matrix.

Ports

Input

Port_1 — Input matrix

matrix

Input, specified as a matrix.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Symmetric or skew-symmetric matrix

real scalar boolean

A symmetric or skew-symmetric matrix, returned as a real scalar boolean.

Data Types: Boolean

Parameters

Mode — Whether matrix is symmetric or skew-symmetric

Symmetric (default) | Skew-Symmetric

Identify the matrix as Symmetric or Skew-Symmetric.

Programmatic Use

Block Parameter: Mode

Type: character vector

Values: 'Symmetric' | 'Skew-Symmetric'

Default: 'Symmetric'

Block Characteristics

Data Types	Boolean double fixed point half integer ^a single
-------------------	---

Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

a This block only supports signed integer types for the skew-symmetric mode.

Extended Capabilities

IsTriangular

Check if matrix is upper or lower triangular

Library: Simulink / Matrix Operations

Description

The IsTriangular block determines if the input is an upper triangular or lower triangular matrix.

Ports

Input

Port_1 — Input matrix

matrix

Input matrix, specified as a matrix.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_2 — Upper triangular or lower triangular matrix

real scalar boolean

Upper triangular or lower triangular matrix, specified scalar, returned as a real scalar boolean.

Data Types: Boolean

Parameters

Mode — Whether matrix is upper triangular or lower triangular

Upper (default) | Lower

Identify the matrix as Upper or Lower.

Programmatic Use

Block Parameter: Mode

Type: character vector

Values: 'Upper' | 'Lower'

Default: 'Upper'

Block Characteristics

Data Types	Boolean double fixed point half integer single
-------------------	--

Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

Knob

Change parameter or variable value using knob with customizable appearance

Library: Simulink / Dashboard / Customizable Blocks

Description

Use the Knob block to tune the value of a variable or block parameter to during simulation. When you use the Knob block in the Customizable Blocks library, you can customize the appearance of the block so that it looks like a control in a real system. You can modify the range and tick values on the Knob block to fit the desired range for the value you want to tune. Use the Knob block with other dashboard blocks to create an interactive dashboard to control your model.

Customize Knob Blocks

When you add a Knob block to your model, the block is preconfigured with a default design. You can use the block with the default design or customize the appearance of the block using design mode. You can enter design mode in one of three ways after selecting the block:

- On the **Knob** tab, under **Design**, click **Edit**.
- In the **Property Inspector**, on the **Design** tab, click **Edit Design**.
- Pause on the ellipsis that appears above the block and click the **Edit Custom Block** button.

In design mode, you have access to block parameters and settings that allow you to design the appearance of the block. You can use the toolbar above the block to change the background image or needle image and to set the opacity and color for the scale, tick labels, and value bar. To design the appearance of the scale, select the aspect of the scale you want to edit in the middle section of the toolbar. Use the controls on the right of the toolbar to set the color and opacity. You can also click and drag to reposition the needle or the scale.

For fine control of the block design, use the **Design** tab in the **Property Inspector**. You can use the **Property Inspector** to enter exact values for design settings. The **Design** tab also includes design parameters that are not available through the toolbar or interactive editing, such as the ability to add a foreground image to the block.

When you finish editing the design, click **Exit** in the upper-right of the canvas to exit design mode.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, select the block. Then, on the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect

mode, the dashboard block does not display the connected value until the you uncomment the block.

- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection — Select a variable or block parameter to connect

variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: Simulink.HMI.ParamSourceInfo

Default: []

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the Maximum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Tick Interval — Interval between major tick marks

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the Tick Interval parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use**Block Parameter:** LabelPosition**Type:** character vector**Values:** 'Top' | 'Bottom' | 'Hide'**Default:** 'Top'**Scale Direction — Direction of increasing scale values**

Clockwise (default) | Counterclockwise

Set the direction of increasing scale values.

Programmatic Use**Block Parameter:** ScaleDirection**Type:** character vector**Values:** 'Clockwise' | 'Counterclockwise'**Default:** 'Clockwise'**Lock Aspect Ratio — Option to maintain block aspect ratio**

on (default) | off

Turn on this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tips

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
- When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.

Foreground Color — Block foreground color

[r g b] vector

Block foreground color, excluding the text. The **Foreground Color** applies to the scale and the block name. To specify the color for the block text, use the **Font Color**.

Specify the **Foreground Color** for the block using the **Design** tab in the Property Inspector.

- 1 On the **Design** tab, click **Edit Design**.
- 2 Select the **Scale** component.
- 3 In the **Ticks** section, open the **Color** menu. You can choose from the palette of standard colors or specify a custom color.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: ForegroundColor**Type:** character vector | string**Values:** [r g b] vector**Background Color — Block background color**

[r g b] vector

Block background color. You can choose to select a solid background color instead of providing a background image. To design a block that uses a solid background, use the **Design** tab in the Property Inspector.

- 1 On the **Design** tab, click **Edit Design**.
- 2 Select the **Background** component.
- 3 Select **Use background color**.
- 4 Choose a background color from the palette of standard colors or specify a custom color.
- 5 Adjust the **Offset from scale** option until the solid background is the desired size.

Changing the background color using the toolbar removes the background image and enables the **Use background color** option.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: [r g b] vector

Font Color — Block font color

[r g b] vector

Block font color. The **Font Color** applies to the scale labels. To specify the color of the scale, use the **Foreground Color**.

Specify the **Font Color** for the block using the **Design** tab in the Property Inspector.

- 1 On the **Design** tab, click **Edit Design**.
- 2 Select the **Scale** component.
- 3 In the **Labels** section, open the **Color** menu. You can choose from the palette of standard colors or specify a custom color.

Knob

Tune parameter value with dial

Library: Simulink / Dashboard

Description

The Knob block tunes the value of the connected block parameter to during simulation. For example, you can connect the Knob block to a Gain block in your model and adjust its value during simulation. You can modify the range of the Knob block's scale to fit your data. Use the Knob block with other Dashboard blocks to create an interactive dashboard to control your model.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, select the block. Then, on the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.

- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection — Select a variable or block parameter to connect

variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify `a.b` to connect to scalar element `b` of the structure or bus `a` nested inside the selected composite variable or parameter.

- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: []

Scale Type — Type of scale

Linear (default) | Log

Type of scale displayed on the block. **Linear** specifies a linear scale, and **Log** specifies a logarithmic scale.

Programmatic Use

Block Parameter: ScaleType

Type: string or character vector

Values: 'Linear' | 'Log'

Default: 'Linear'

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1×3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the Maximum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1×3 vector

Default: [0 -1 100]

Tick Interval — Interval between major tick marks

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the Tick Interval parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1×3 vector

Default: [0 -1 100]

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Lamp

Display color that reflects signal value on lamp with customizable appearance

Library: Simulink / Dashboard / Customizable Blocks

Description

The Lamp block displays a color that reflects the value of the connected signal. To configure the Lamp block to provide the information you need during simulation, specify one or more states, which pair a signal value with a color for the Lamp block to display. When you use the Lamp block in the Customizable Blocks library, you can modify the appearance of the block so it looks like a real indicator lamp in your system. Use the Lamp block with other dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Customize Lamp Blocks

When you add a Lamp block to your model, the block is preconfigured with a default design. You can use the block with the default design or customize the appearance of the block. When you design a custom Lamp block, you can:

- Select a shape for the region that changes color to reflect the value of the connected signal.
- Select an icon from a built-in set of shapes, wireless icons, and automotive indicator lamps or upload your own custom icon.
- Specify how to combine the shape and the icon.
 - Simple — Overlay the icon on top of the shape.
 - Intersect — Retain the intersection of the shape and icon as the area that changes color to reflect the signal value.
 - Subtract — Subtract the icon from the shape, producing a cut out in the shape of the icon in the area that changes color to reflect the signal value.

Icon

Simple

Intersect

Subtract

Note The intersect and subtract combination styles use transparency in the icon asset to produce the area that changes color. When you design a Lamp block that uses a custom icon, consider

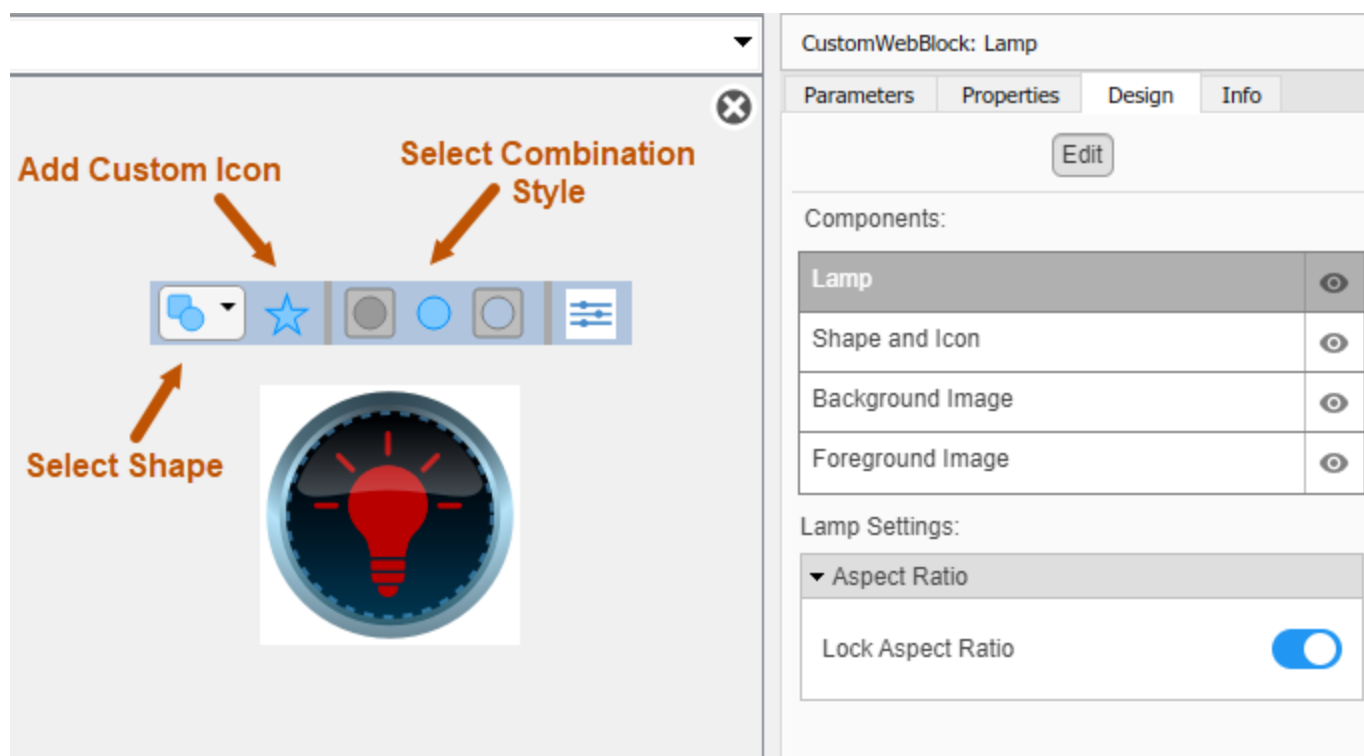

using an SVG or PNG file for the icon if you want your design to use the intersect or subtract options. Both formats support transparency, and SVG files also scale well in response to zoom operations.

- Upload a background image or specify a background color to provide a background for the shape and icon.
- Upload a foreground image that overlays the rest of the lamp design.

To customize the appearance of the block, use design mode. You can enter design mode in one of three ways after selecting the block:

- On the **Lamp** tab, under **Design**, click **Edit**.
- In the **Property Inspector**, on the **Design** tab, click **Edit Design**.
- Pause on the ellipsis that appears above the block and click the **Edit Custom Block** button.

Design mode gives you access to block parameters and settings that allow you to customize the appearance of the block. You can use the toolbar above the block to change the icon and how the icon combines with the shape. To select a shape, background image or color, and foreground image, use the **Design** tab in the Property Inspector.

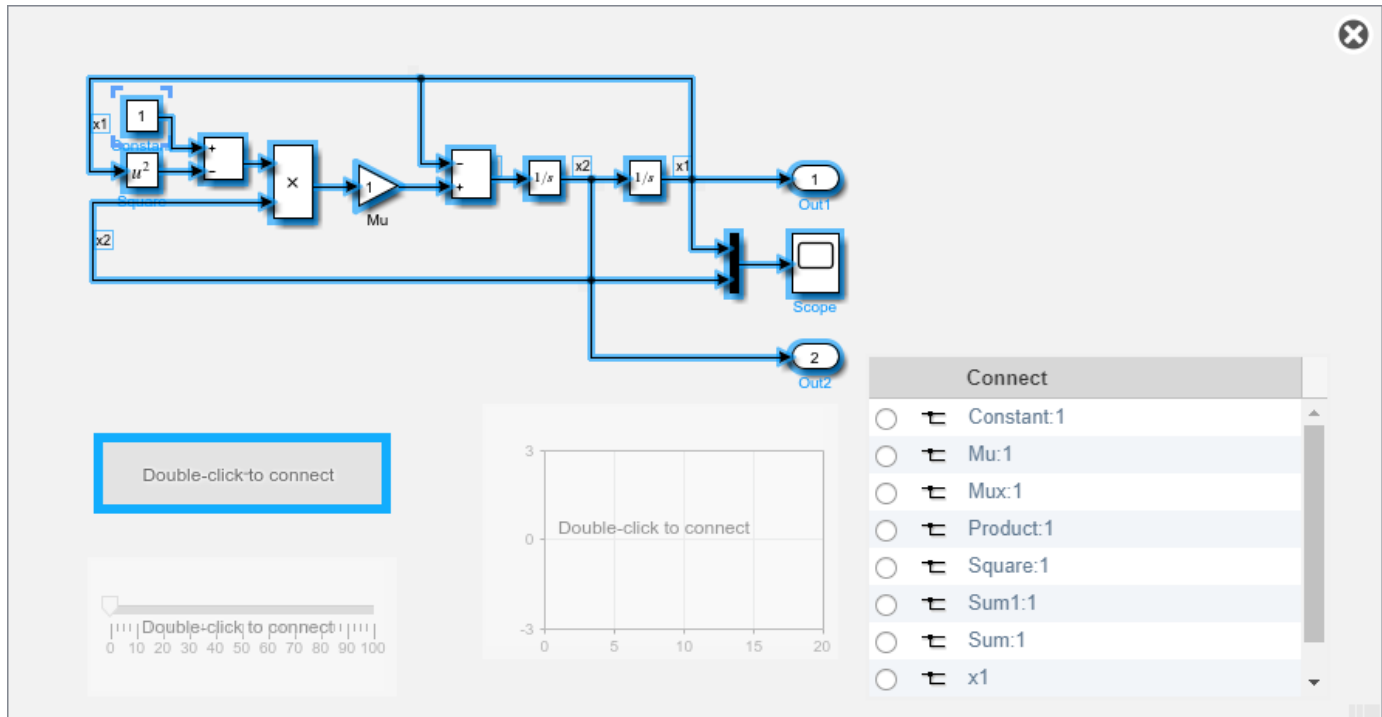

When you finish designing the lamp, click **Exit** in the upper-right of the canvas to exit design mode.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, select a dashboard block to connect. Then, on the block tab, click **Connect**. In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.

- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- You cannot connect a dashboard block to state activity or chart data in Stateflow during simulation.
- You cannot programmatically connect a dashboard block to state activity or chart data in Stateflow.
- Some signals do not have data available during simulation due to block reduction or optimization for accelerator mode simulations. To view such a signal using a dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Lock Aspect Ratio — Option to maintain block aspect ratio

on (default) | off

Turn on this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tips

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.

- When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.

Specify State Values as Ranges — Option to specify ranges of values that activate states

On | Off

Rather than specifying signal values that activate the Lamp block states, you can also specify ranges of signal values that activate the states. Select **Specify State Values as Ranges** and specify the minimum and maximum of the value range that activates each state.

Programmatic Use

To programmatically specify whether the states are each activated by a signal value or by a range of signal values, specify the `StateValueType` parameter as a string or a character vector. To activate each state with a signal value, set `StateValueType` to "Discrete". To activate each state with a range of signal values, set `StateValueType` to "Range".

Block Parameter: `StateValueType`

Type: character vector | string

Values: "Discrete" | "Range"

Default: "Discrete"

States — Signal value and color pairs

scalar and RGB vector

States match a display color to the value of the connected signal. Each state consists of a **State** and a **Color**.

- **State** — Connected signal value or range of signal values that cause the Lamp block to display the specified color. To specify a range of values, select **Specify State Values as Ranges** and specify the minimum and maximum of the range of values that activates each state.
- **Color** — Lamp color when the connected signal value matches the corresponding **State** value. You can select from a palette of standard colors or specify a custom color with RGB values.

The [undefined] state specifies the color of the Lamp block when the connected signal value does not match any of the values specified in the **States** table. Click the + button to add another state.

Programmatic Use

To programmatically specify the **State** and **Color** parameter values for a Lamp block, use an array of structures that contain these fields:

- **Value** — Scalar `double` signal value or vector specifying the minimum and maximum of a range of `double` signal values that cause the Lamp block to display the specified color indication.

Note Specifying a vector enables the **Specify State Values as Ranges** option.

- **Color** — 1-by-3 [r g b] vector with values between 0 and 1 that specifies the color for the Lamp block to display.

```
lampState1.Value = [1 2];
lampState1.Color = [0 0 1];
lampState2.Value = [2 3];
lampState2.Color = [1 0 0];
lampStates = [lampState1 lampState2];
```

Block Parameter: StateColors

Type: structure array

Default: structure

The ColorDefault parameter specifies the color for the Lamp block when the value of the connected signal does not match any of the specified state values. Specify the ColorDefault parameter as a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: ColorDefault

Type: [r g b] vector

Default: [0.7529 0.7529 0.7529]

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no

Introduced in R2021b

Lamp

Display color that reflects signal value on lamp

Library: Simulink / Dashboard

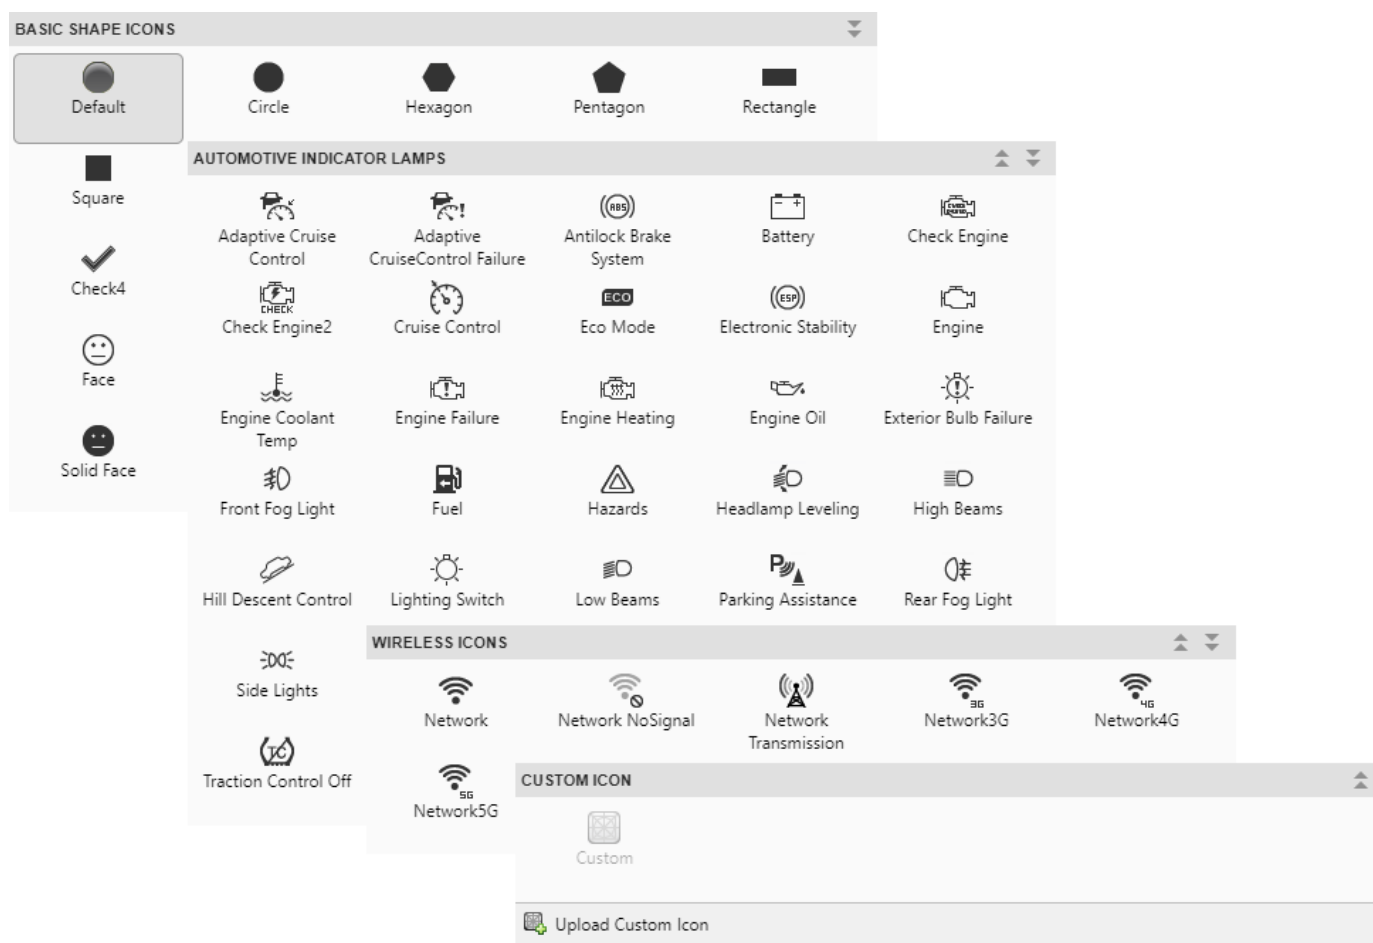

Description

The Lamp block displays a color that indicates the value of the connected signal. To configure the Lamp block to provide the information you need during simulation, specify one or more states, which pair a signal value with a color for the Lamp block to display. You can use the Lamp block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Lamp Icons

You can change the appearance of the Lamp block by selecting one of the built-in icons or uploading your own custom icon. The built-in icons include basic shapes, automotive indicator lamps, and wireless icons. You can change the icon for a Lamp block by using the **Icon** parameter or by using the block tab in the toolstrip. The Dashboard library also includes libraries that have a preconfigured version of the Lamp block for each icon. For complete details, see “Icon” on page 1-0 .

If you want to customize the appearance of the Lamp block beyond the ability to select an icon, consider designing your own indicator lamp using the Lamp block in the Customizable Blocks library.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, select a dashboard block to connect. Then, on the block tab, click **Connect**. In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- You cannot connect a dashboard block to state activity or chart data in Stateflow during simulation.
- You cannot programmatically connect a dashboard block to state activity or chart data in Stateflow.

- Some signals do not have data available during simulation due to block reduction or optimization for accelerator mode simulations. To view such a signal using a dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

States — Signal value and color pairs

scalar and RGB vector

States match a display color to the value of the connected signal. Each state consists of a **State** and a **Color**.

- **State** — Connected signal value that causes the Lamp block to display the specified color.
- **Color** — Lamp color when the connected signal value matches the corresponding **State** value. You can select from a palette of standard colors or specify a custom color with RGB values.

The [undefined] state specifies the color of the Lamp block when the connected signal value does not match any of the values specified in the **States** table. Click the **+** button to add another state.

Programmatic Use

To programmatically specify the **State** and **Color** parameter values for a Lamp block, use an array of structures that contain these fields:

- **Value** — Scalar double signal value that causes the Lamp block to display the specified color indication.
- **Color** — 1-by-3 [r g b] vector with values between 0 and 1 that specifies the color for the Lamp block to display.

```
lampState1.Value = 1;
lampState1.Color = [0 0 1];
lampState2.Value = 2;
lampState2.Color = [1 0 0];
lampStates = [lampState1 lampState2];
```

Block Parameter: StateColors

Type: structure array

Default: structure

The `ColorDefault` parameter specifies the color for the Lamp block when the value of the connected signal does not match any of the specified state values. Specify the `ColorDefault` parameter as a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `ColorDefault`

Type: [r g b] vector

Default: [0.7529 0.7529 0.7529]

Icon — Lamp block appearance

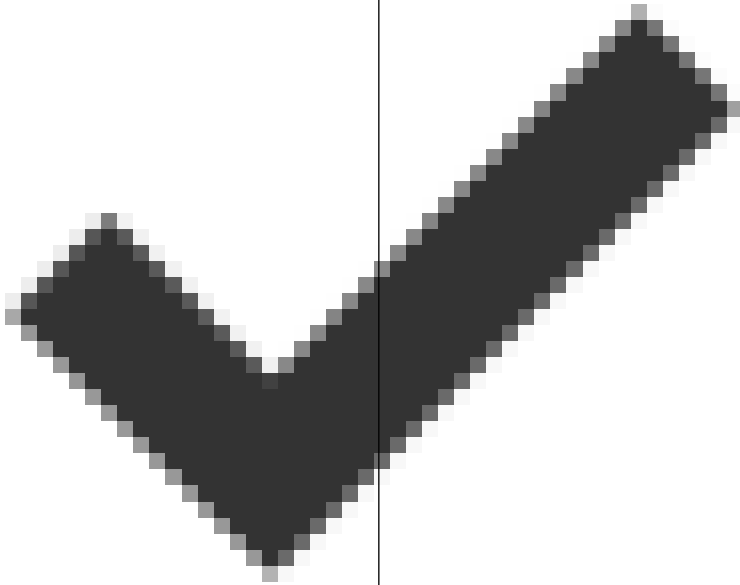

SVG image

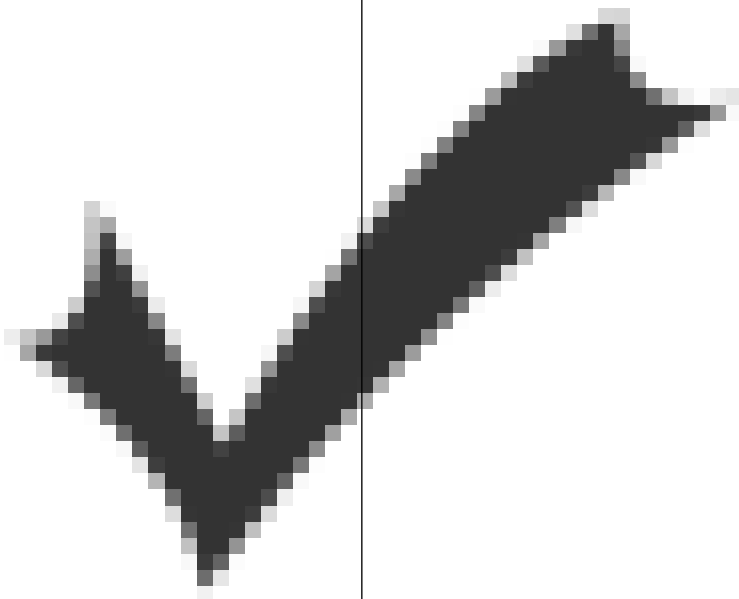

Use an icon to configure the appearance of the Lamp block in the model. You can choose from built-in shape, automotive, and wireless icons, or you can upload your own custom SVG file as an icon.

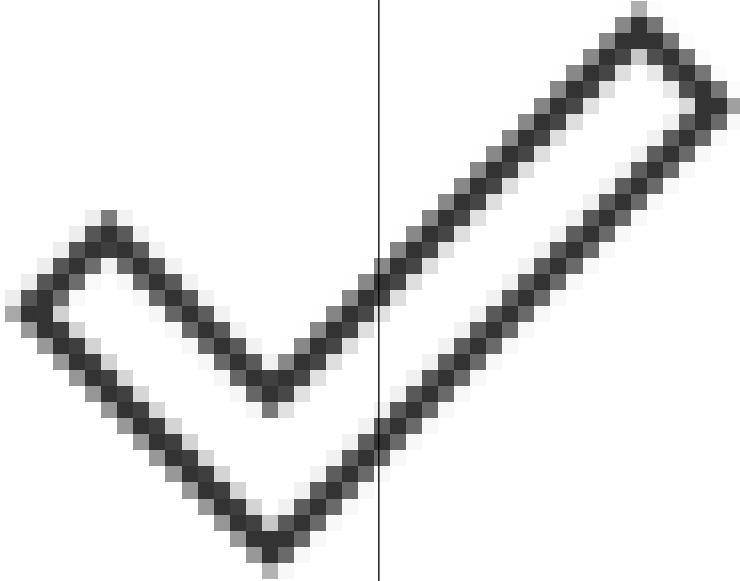

To view icon options, on the **Icon** tab, select an **Icon Type**. To use your own SVG file as the block icon, select `Custom` as the **Icon Type** and upload the SVG file. The state colors for the Lamp block can apply to these SVG elements:

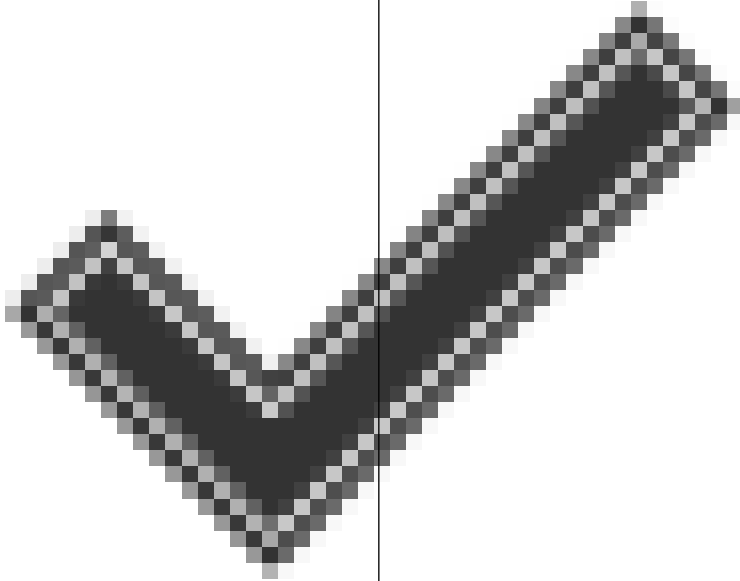

- `altGlyph`
- `circle`
- `ellipse`
- `path`
- `polygon`
- `rect`
- `text`
- `textPath`
- `tref`
- `tspan`

	Network4G	Network4G

Icon	Wireless Icons Library Block Name	Programmatic Use Value
	Network5G	Network5G

Tips

- You can change the icon for a Lamp block using the block tab in the toolbar.
- The Dashboard library has libraries with a preconfigured Lamp block for each icon.
- If you want to customize the appearance of the Lamp block beyond the ability to select an icon, consider designing your own indicator lamp using the Lamp block in the Customizable Blocks library.

Programmatic Use

Block Parameter: Icon

Type: string | character vector

Default: 'Default'

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Opacity — Block opacity

1 (default) | scalar

Block opacity, specified as a scalar value between 0 and 1.

Example: 0.5

Programmatic Use

Block Parameter: Opacity

Type: scalar

Default: 1

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Level-2 MATLAB S-Function

Use Level-2 MATLAB S-function in model

Library: Simulink / User-Defined Functions

Description

This block allows you to use a Level-2 MATLAB S-function (see “Write Level-2 MATLAB S-Functions”) in a model. To do this, create an instance of this block in the model. Then enter the name of the Level-2 MATLAB S-function in the **S-function name** field of the block's parameter dialog box.

Note Use the S-Function block to include a Level-1 MATLAB S-function in a block.

If the Level-2 MATLAB S-function defines any additional parameters, you can enter them in the **Parameters** field of the block's parameter dialog box. Enter the parameters as MATLAB expressions that evaluate to their values in the order defined by the MATLAB S-function. Use commas to separate each expression.

If a model includes a Level-2 MATLAB S-Function block, and an error occurs in the S-function, the Level-2 MATLAB S-Function block displays MATLAB stack trace information for the error in a dialog box. Click **OK** to close the dialog box.

Parameters

S-Function Name — Specify S-Function name

matlabfile (default) | S-Function name

Specify the name of a MATLAB function that defines the behavior of this block. The MATLAB function must follow the Level-2 standard for writing MATLAB S-functions (see “Write Level-2 MATLAB S-Functions” for details).

Programmatic Use

Block Parameter: FunctionName

Type: character vector

Values: 'matlabfile' | S-Function name

Default: 'matlabfile'

Parameters — Specify values of parameters for this block

no default (default)

Specify values of parameters for this block.

Programmatic Use

Block Parameter: Parameters

Type: character vector
Values: values of block parameters
Default: ' '

Block Characteristics

Data Types	Boolean ^a double ^a fixed point ^a integer ^a single ^a
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

^a Level-1 MATLAB S-functions support only the double data type. Level-2 MATLAB S-functions support all data types that Simulink supports.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- If a corresponding TLC file is available, the Level-2 MATLAB S-Function block uses the TLC file to generate code, otherwise code generation throws an error.
- Real-time code generation does not support S-functions that call MATLAB.
- Actual data type or capability support depends on block implementation.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Level-1 MATLAB S-functions support only the double data type. Level-2 MATLAB S-functions support all data types that Simulink supports.

Linear Gauge

Display input value on linear scale

Library: Simulink / Dashboard

Description

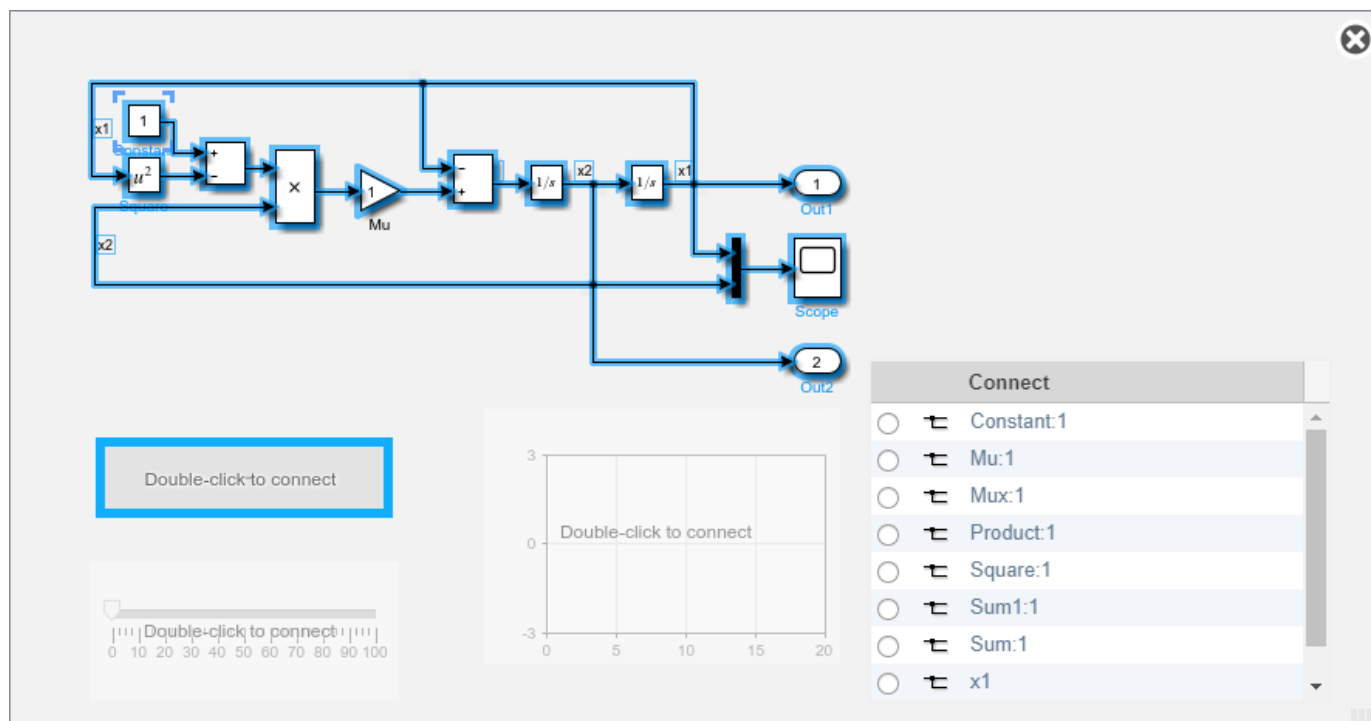

The Linear Gauge block displays the connected signal on a straight linear scale during simulation. Use the Linear Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Linear Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Linear Gauge block to fit your data. You can also customize the appearance of the Linear Gauge block to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, select a dashboard block to connect. Then, on the block tab, click **Connect**. In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- You cannot connect a dashboard block to state activity or chart data in Stateflow during simulation.
- You cannot programmatically connect a dashboard block to state activity or chart data in Stateflow.

- Some signals do not have data available during simulation due to block reduction or optimization for accelerator mode simulations. To view such a signal using a dashboard block, mark the signal for logging.

Parameters

Signal

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Main

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the auto value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the Maximum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the auto value for the Tick Interval, leave the Tick Interval position in the vector empty or specify -1.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Tick Interval — Interval between major tick marks**

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the `Tick Interval` parameter, use a 1-by-3 vector containing values for the `Minimum`, `Tick Interval`, and `Maximum` parameters, in that order. To use the `auto` value for the `Tick Interval`, leave the `Tick Interval` position in the vector empty or specify `-1`.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Scale Colors — Color indications on gauge scale**

colors for scale ranges

Color specifications for value ranges on the scale. Press the **+** button to add a scale color. For each color added, specify the minimum and maximum values of the range in which you want to display that color.

Programmatic Use

To programmatically specify the `Scale Colors` parameter, use an array of structures with the fields:

- `Min` — Minimum value for the color range on the scale
- `Max` — Maximum value for the color range on the scale
- `Color` — 1-by-3 vector of double values between 0 and 1 that specify the color for the range in the form [r g b]

Include a structure in the array for each scale range for which you want to specify a color.

```
range1.Min = 0;
range1.Max = 10;
range1.Color = [0 0 1];
range2.Min = 10;
range2.Max = 15;
range2.Color = [0 1 0];
scaleRanges = [range1 range2];
```

Block Parameter: ScaleColors**Type:** structure array**Default:** 0x1 struct array**Label — Block label position**

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use**Block Parameter:** LabelPosition**Type:** character vector**Values:** 'Top' | 'Bottom' | 'Hide'**Default:** 'Top'**Format****Opacity — Block background opacity**

1 (default) | scalar

Block background opacity, specified as a scalar value between 0 and 1.

Example: 0.5

Programmatic Use**Block Parameter:** Opacity**Type:** scalar**Default:** 1**ForegroundColor — Block foreground color**

[r g b] vector

Block foreground color, excluding the text. The **ForegroundColor** applies to the scale and the block name. You can select a color from a palette of standard colors or specify a custom color. To specify the color for the block text, use the **Font Color**.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: ForegroundColor**Type:** character vector | string**Values:** [r g b] vector**BackgroundColor — Block background color**

[r g b] vector

Block background color. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: BackgroundColor**Type:** character vector | string**Values:** [r g b] vector**Font Color — Block font color**

[r g b] vector

Block font color. The **Font Color** applies to the tick labels on the scale. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `FontColor` parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `FontColor`

Type: [r g b] vector

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Logical Operator

Perform specified logical operation on input

Library: Simulink / Commonly Used Blocks
 Simulink / Logic and Bit Operations
 HDL Coder / Commonly Used Blocks
 HDL Coder / Logic and Bit Operations

Description

The Logical Operator block performs the specified logical operation on its inputs. An input value is true (1) if it is nonzero and false (0) if it is zero.

You select the Boolean operation connecting the inputs with the **Operator** parameter list. If you select **rectangular** as the **Icon shape** property, the name of the selected operator displays on the block icon. If you select **distinctive** as the **Icon shape** property, the name of the selected operator does not display on the block icon. This table shows supported operations:

Operation	Description
AND	TRUE if all inputs are TRUE
OR	TRUE if at least one input is TRUE
NAND	TRUE if at least one input is FALSE
NOR	TRUE when no inputs are TRUE
XOR	TRUE if an odd number of inputs are TRUE
NXOR	TRUE if an even number of inputs are TRUE
NOT	TRUE if the input is FALSE

If you select **distinctive** as the **Icon shape**, the block appearance indicates its function. Simulink software displays a distinctive shape for the selected operator, conforming to the IEEE Standard Graphic Symbols for Logic Functions.

To specify the number of input ports, use the **Number of input ports** parameter. The output type is specified using the **Output data type** parameter. An output value is 1 if TRUE and 0 if FALSE.

Note The output data type should represent zero exactly. Data types that satisfy this condition include signed and unsigned integers, and any floating-point data type.

The size of the output depends on input vector size and the selected operator:

- If the block has more than one input, any nonscalar inputs must have the same dimensions. For example, if any input is a 2-by-2 array, all other nonscalar inputs must also be 2-by-2 arrays.

Scalar inputs are expanded to have the same dimensions as the nonscalar inputs.

If the block has more than one input, the output has the same dimensions as the inputs (after scalar expansion) and each output element is the result of applying the specified logical operation to the corresponding input elements. For example, if the specified operation is AND and the inputs are 2-by-2 arrays, the output is a 2-by-2 array whose top left element is the result of applying AND to the top left elements of the inputs, and so on.

- For a single vector input, the block applies the operation (except the NOT operator) to all elements of the vector. The output is always a scalar.
- The NOT operator accepts only one input, which can be a scalar or a vector. If the input is a vector, the output is a vector of the same size containing the logical complements of the input vector elements.

When configured as a multi-input XOR gate, this block performs an addition modulo two operation as mandated by the IEEE Standard for Logic Elements.

Ports

Input

Port_1 — First input signal

scalar | vector | matrix

First input signal, specified as a scalar, vector, or matrix.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_2 — Second input signal

scalar | vector | matrix

Second input signal, specified as a scalar, vector, or matrix.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_N — Nth input signal

scalar | vector | matrix

Nth input signal, specified as a scalar, vector, or matrix.

Dependencies

To enable additional input ports, use the **Number of input ports** parameter.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

scalar | vector | matrix

Output signal, consisting of zeros and ones, with the same dimensions as the input. You control the output data type with the **Require all inputs and output to have the same data type** and **Output data type** parameters.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Operator — Logical operator

AND (default) | OR | NAND | NOR | XOR | NXOR | NOT

Select the logical operator to apply to block inputs.

- AND — T if all inputs are TRUE
- OR — TRUE if at least one input is TRUE
- NAND — TRUE if at least one input is FALSE
- NOR — TRUE when no inputs are TRUE
- XOR — TRUE if an odd number of inputs are TRUE
- NXOR — TRUE if an even number of inputs are TRUE
- NOT — TRUE if the input is FALSE

Programmatic Use

Block Parameter: Operator

Type: character vector

Values: 'AND' | 'OR' | 'NAND' | 'NOR' | 'XOR' | 'NXOR' | 'NOT'

Default: 'AND'

Number of input ports — Number of inputs

2 (default) | positive integer

Specify the number of block inputs as a positive integer.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: positive integer

Default: '2'

Dependencies

This parameter is not available when you set the **Operator** to NOT.

Icon shape — Icon shape

rectangular (default) | distinctive

Specify the shape of the block icon.

- `rectangular` — Results in a rectangular block that displays the name of the selected operator.
- `distinctive` — Use the graphic symbol for the selected operator as specified by the IEEE standard.

Programmatic Use**Block Parameter:** `IconShape`**Type:** character vector**Values:** `'rectangular'` | `'distinctive'`**Default:** `'rectangular'`**Sample time — Sample time value other than -1**`-1` (default) | scalar | vector

Specify the sample time as a value other than `-1`. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** `SampleTime`**Type:** string scalar or character vector**Default:** `"-1"`**Data Type****Require all inputs and output to have the same data type — Require all ports to have same data type**`off` (default) | `on`

To require that all block inputs and the output have the same data type, select this check box. When you clear this check box, the inputs and output can have different data types.

Programmatic Use**Block Parameter:** `AllPortsSameDT`**Type:** character vector**Values:** `'off'` | `'on'`**Default:** `'off'`**Output data type — Output data type**`boolean` (default) | `Inherit: Logical` (see Configuration Parameters: Optimization) | `fixdt(1,16)` | `<data type expression>`

Specify the output data type. When you select:

- `boolean` — The block output has data type `boolean`.
- `Inherit: Logical` (see Configuration Parameters: Optimization) — The block uses the **Implement logic signals as Boolean data** configuration parameter to specify the output data type (see “Implement logic signals as Boolean data (vs. double)”).

Note This option supports models created before the `boolean` option was available. Use one of the other options, preferably `boolean`, for new models.

- `fixdt(1,16)` — The block output has the specified fixed-point data type `fixdt(1,16)`.

Tip Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

- `<data type expression>` — The block output has the data type you specify as a data type expression, for example, `Simulink.NumericType`.

Tip To enter a built-in data type (`double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`), enclose the expression in single quotes. For example, enter `'double'` instead of `double`.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Logical (see Configuration Parameters: Optimization)'` | `'boolean'` | `'fixdt(1,16)'` | `'<data type expression>'`

Default: `'boolean'`

Block Characteristics

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

1-D Lookup Table

Approximate one-dimensional function

Library: Simulink / Lookup Tables
HDL Coder / Lookup Tables

Description

Supported Block Operations

The 1-D, 2-D, and n-D Lookup Table blocks evaluate a sampled representation of a function in N variables

$$y = F(x_1, x_2, x_3, \dots, x_N)$$

where the function F can be empirical. The block maps inputs to an output value by looking up or interpolating a table of values you define with block parameters. The block supports flat (constant), linear (linear point-slope), Lagrange (linear Lagrange), nearest, cubic-spline, and Akima spline interpolation methods. You can apply these methods to a table of any dimension from 1 through 30.

In the following block, the first input identifies the first dimension (row) breakpoints, the second input identifies the second dimension (column) breakpoints, and so on.

See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

When the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter is set, the 2-D and n-D Lookup Table block behavior changes from column-major to row-major. For these blocks, the column-major and row-major algorithms may differ in the order of the output calculations, possibly resulting in slightly different numerical values. This capability requires a Simulink Coder or Embedded Coder license. For more information on row-major support, see “Code Generation of Matrices and Arrays” (Simulink Coder).

Specification of Breakpoint and Table Data

These block parameters define the breakpoint and table data.

Block Parameter	Purpose
Number of table dimensions	Specifies the number of dimensions of your lookup table.
Breakpoints	Specifies a breakpoint vector that corresponds to each dimension of your lookup table.
Table data	Defines the associated set of output values.

Tip Evenly spaced breakpoints can make the generated code division-free. For more information, see `fixpt_evenspace_cleanup` and “Identify questionable fixed-point operations” (Embedded Coder).

How the Block Generates Output

The n-D, 1-D and 2-D Lookup Table blocks generate output by looking up or estimating table values based on the input values.

Block Inputs	n-D Lookup Table Block Behavior
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the Interpolation method you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the Extrapolation method you select

Other Blocks that Perform Equivalent Operations

You can use the Interpolation Using Prelookup block with the Prelookup block to perform the equivalent operation of one n-D Lookup Table block. This combination of blocks offers greater flexibility that can result in more efficient simulation performance for linear interpolations.

When the lookup operation is an array access that does not require interpolation, use the Direct Lookup Table (n-D) block. For example, if you have an integer value k and you want the k th element of a table, $y = \text{table}(k)$, interpolation is unnecessary.

Ports

Input

u1 — First-dimension (row) inputs

scalar | vector | matrix

Real-valued inputs to the **u1** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: `0:10`

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `enumerated` | `fixed point`

T — Define the table of output values

matrix of values with dimensions that match the **Number of table dimensions** and the breakpoint lengths for each dimension of the table

Specify the table of output values with a signal that is tunable at runtime.

During simulation, the matrix size must match the dimensions defined by the **Number of table dimensions** parameter. However, during block diagram editing, you can enter an empty matrix (specified as []) or an undefined workspace variable. This technique lets you postpone specifying a correctly dimensioned matrix for the table data and continue editing the block diagram.

Dependencies

To enable this port, set:

- **Data specification** to Table and breakpoints.
- **Table data** to Input port.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

bp1 — Explicit breakpoint values

1-by-n or n-by-1 vector of monotonically increasing values

Specify the breakpoint data explicitly, based on the value of the **Breakpoints specification** parameter, with a signal that is tunable at runtime.

- If you set **Breakpoints specification** to Explicit values, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.

Note To specify breakpoints in the even spacing specification format, set **Breakpoints specification** to Even spacing and use the **Breakpoints First** point and **Spacing** parameters.

Dependencies

To enable this port, set:

- **Data specification** to Table and breakpoints.
- **Breakpoints specification** to Explicit values.
- **Breakpoints 1** to Input port.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | enumerated | fixed point

Output**Port_1 — Output computed by looking up or estimating table values**

scalar | vector | matrix

Output generated by looking up or estimating table values based on the input values.

When block inputs...	The n-D Lookup Table block...
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the Interpolation method you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the Extrapolation method you select

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Table and Breakpoints

Number of table dimensions — Number of lookup table dimensions

1 (default) | 2 | 3 | 4 | ... | 30

Enter the number of dimensions of the lookup table. This parameter determines:

- The number of independent variables for the table and the number of block inputs
- The number of breakpoint sets to specify

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

For example, a table with a size of $M \times N \times \dots$ means that the size of dimension 1 is M , the size of dimension 2 is N , and so forth. M must match the first breakpoint length, N must match the second breakpoint length, and so forth.

Programmatic Use

Block Parameter: NumberOfTableDimensions

Type: character vector

Values: '1' | '2' | '3' | '4' | ... | 30

Default: '1'

Data specification — Method of table and breakpoint specification

Table and breakpoints (default) | Lookup table object

From the list, select:

- **Table and breakpoints** — Specify the table data and breakpoints. Selecting this option enables these parameters:
 - **Table data**
 - **Breakpoints specification**

- **Breakpoints 1**
- **Edit table and breakpoints**

To specify the table and breakpoints using input ports, see the **Source** parameter.

- **Lookup table object** — Use an existing lookup table (`Simulink.LookupTable`) object. Selecting this option enables the **Name** field and **Edit table and breakpoints** button.

Programmatic Use

Block Parameter: `DataSpecification`

Type: character vector

Values: 'Table and breakpoints' | 'Lookup table object'

Default: 'Table and breakpoints'

Name — Name of the lookup table object

`[]` (default) | `Simulink.LookupTable` object

Enter the name of the lookup table (`Simulink.LookupTable`) object. If a `Simulink.LookupTable`

object does not exist, click the action button  and select **Create**. The corresponding parameters of the new lookup table object are automatically populated with the block information.

Dependencies

To enable this parameter, set **Data specification** to `Lookup table object`.

Programmatic Use

Block Parameter: `LookupTableObject`

Type: character vector

Values: name of a `Simulink.LookupTable` object

Default: ''

Breakpoints specification — Method of breakpoint specification

`Explicit values` (default) | `Even spacing`

Specify whether to enter data as explicit breakpoints or as parameters that generate evenly spaced breakpoints.

- To explicitly specify breakpoint data, set this parameter to `Explicit values` and enter breakpoint data in the text box next to the **Breakpoints** parameters.
- To specify parameters that generate evenly spaced breakpoints, set this parameter to `Even spacing` and enter values for the **First point** and **Spacing** parameters for each dimension of breakpoint data. The block calculates the number of points to generate from the table data.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`.

Programmatic Use

Block Parameter: `BreakpointsSpecification`

Type: character vector

Values: 'Explicit values' | 'Even spacing'

Default: 'Explicit values'

Source — Source of table and breakpoint data

`Dialog` (default) | `Input port`

Source of table and breakpoint data, specified as:

- **Dialog** — Specify the table or breakpoint data in **Value** parameter.
- **Input port** — Specify the table or breakpoint data through the associated input port.

You can create up to three breakpoint data input ports. For breakpoints 4 to 30, you can specify breakpoints data only through the corresponding **Breakpoints** parameter.

Note Using the input port to specify table or breakpoint data might negatively affect block performance for simulation due to runtime checks.

Dependencies

- To enable this parameter, set **Data specification** to **Table** and **breakpoints**.
- To enable the associated **Value**, set this parameter to **Dialog**.
- To enable the associated input port, set this parameter to **Input port**.
- Setting this parameter to **Input port** disables the **Value** field and hides the corresponding parameter on the **Data Types** tab.
- Setting this parameter to **Input port** for any one of the parameters disables the **Edit Table and Breakpoints** button.

Programmatic Use

Block Parameter: TableSource | BreakpointsForDimension1Source | BreakpointsForDimension2Source | BreakpointsForDimension3Source

Type: character vector

Values: Dialog | Input port

Default: 'Dialog'

Table data — Define the table of output values

`tanh([-5:5])` (default) | vector of values

Enter the table of output values in the associated **Value** field.

During simulation, the matrix size must match the dimensions defined by the **Number of table dimensions** parameter. However, during block diagram editing, you can enter an empty matrix (specified as `[]`) or an undefined workspace variable. This technique lets you postpone specifying a correctly dimensioned matrix for the table data and continue editing the block diagram.

Dependencies

To enable this parameter, set:

- **Data specification** to **Table** and **breakpoints**.
- **Table data: Source** to **Dialog**.

Programmatic Use

Block Parameter: Table

Type: character vector

Values: vector of table values

Default: 'tanh([-5:5])'

Breakpoints — Explicit breakpoint values, or first point and spacing of breakpoints

[-5:5] (default) | 1-by-n or n-by-1 vector of monotonically increasing values

Specify the breakpoint data explicitly or as evenly-spaced breakpoints, based on the value of the **Breakpoints specification** parameter.

- If you set **Breakpoints specification** to `Explicit` values, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.
- If you set **Breakpoints specification** to `Even spacing`, enter the parameters **First point** and **Spacing** in each **Breakpoints** row to generate evenly spaced breakpoints in the respective dimension. Your table data determines the number of evenly spaced points.

Dependencies

- To enable this parameter, set:
 - **Data specification** to `Table` and breakpoints.
 - **Table data: Source** to `Dialog`.
- When the **Breakpoints specification** parameter is set to `Even spacing`, you can only specify breakpoints data through the dialog.

Programmatic Use**Block Parameter:** BreakpointsForDimension1**Type:** character vector**Values:** 1-by-n or n-by-1 vector of monotonically increasing values**Default:** '[10, 22, 31]'**First point — First point in evenly spaced breakpoint data**

1 (default) | scalar

Specify the first point in your evenly spaced breakpoint data as a real-valued, finite, scalar. This parameter is available when **Breakpoints specification** is set to `Even spacing`.

Dependencies

To enable this parameter, set **Data specification** to `Table` and breakpoints, and **Breakpoints specification** to `Even spacing`.

Programmatic Use**Block Parameter:** BreakpointsForDimension1FirstPoint**Type:** character vector**Values:** real-valued, finite, scalar**Default:** '1'**Spacing — Spacing between evenly spaced breakpoints**

1 (default) | scalar

Specify the spacing between points in your evenly spaced breakpoint data.

Dependencies

To enable this parameter, set **Data specification** to `Table` and breakpoints, and **Breakpoints specification** to `Even spacing`.

Programmatic Use**Block Parameter:** BreakpointsForDimension1Spacing**Type:** character vector**Values:** positive, real-valued, finite, scalar**Default:** '1'**Edit table and breakpoints — Launch Lookup Table Editor dialog box**

button

Click this button to open the Lookup Table Editor. For more information, see “Edit Lookup Tables” in the Simulink documentation.

Clicking this button for a lookup table object lets you edit the object and save the new values for the object.

Algorithm**Lookup method****Interpolation method — Method of interpolation between breakpoint values**

Linear point-slope (default) | Flat | Nearest | Linear Lagrange | Cubic spline | Akima spline

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. For more information on interpolation methods, see “Interpolation Methods”.

Dependencies

- If you select `Cubic spline`, the block supports only scalar signals. The other interpolation methods support nonscalar signals.
- If you select `Akima spline`, the extrapolation method can only be `Akima spline`.

When set to the modified Akima interpolation method, this block does not support:

- Row-major array layout and algorithms optimized for row-major array layout
- Scaled double and fixed-point data types
- `Simulink.LookupTable` objects
- Code generation when the configuration parameter **Code Generation > Interface > Support non-finite numbers** check box is selected

When set to the modified Akima interpolation method, this block is known to run more slowly when these conditions are true:

- Code generation-based simulation targets, such as those for accelerator mode, rapid accelerator mode, protected models, and so forth.
- Code generated for large breakpoint and data table sizes. For example with a table size of 629x1601.

Programmatic Use**Block Parameter:** InterpMethod**Type:** character vector

Values: 'Linear point-slope' | 'Flat' | 'Nearest' | 'Linear Lagrange' | 'Cubic spline' | 'Akima spline'
Default: 'Linear point-slope'

Extrapolation method — Method of handling input values that fall outside the range of a breakpoint data set

Linear (default) | Clip | Cubic spline | Akima spline

Select Clip, Linear, or Cubic spline. See “Extrapolation Methods” for more information.

If the extrapolation method is Linear, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is linear Lagrange, the extrapolation method inherits the linear Lagrange equation to compute the extrapolated value.

Dependencies

- To select Cubic spline for **Extrapolation method**, you must also select Cubic spline for **Interpolation method**.
- To select Akima spline for **Extrapolation method**, you must also select Akima spline for **Interpolation method**.

Programmatic Use

Block Parameter: ExtrapMethod

Type: character vector

Values: 'Linear' | 'Clip' | 'Cubic spline' | 'Akima spline'

Default: 'Linear'

Index search method — Method of calculating table indices

Evenly spaced points (default) | Linear search | Binary search

Select Evenly spaced points, Linear search, or Binary search. Each search method has speed advantages in different circumstances:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting Evenly spaced points to calculate table indices.

This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.

Note Set **Index search method** to Evenly spaced points when using the Simulink.LookupTable object to specify table data and the **Breakpoints Specification** parameter of the referenced Simulink.LookupTable object is set to Even spacing.

- For unevenly spaced breakpoint sets, follow these guidelines:
 - If input signals do not vary much between time steps, selecting Linear search with **Begin index search using previous index result** produces the best performance.
 - If input signals jump more than one or two table intervals per time step, selecting Binary search produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

Note The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
 - The index search method is Evenly spaced points.
-

Programmatic Use

Block Parameter: IndexSearchMethod

Type: character vector

Values: 'Binary search' | 'Evenly spaced points' | 'Linear search'

Default: 'Binary search'

Begin index search using previous index result — Start using the index from the previous time step

off (default) | on

Select this check box when you want the block to start its search using the index found at the previous time step. For inputs that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

Dependencies

To enable this parameter, set **Index search method** to Linear search or Binary search.

Programmatic Use

Block Parameter: BeginIndexSearchUsing PreviousIndexResult

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Diagnostic for out-of-range input — Block action when input is out of range

None (default) | Warning | Error

Specify whether to produce a warning or error when the input is out of range. Options include:

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

Programmatic Use

Block Parameter: DiagnosticForOutOfRangeInput

Type: character vector

Values: 'None' | 'Warning' | 'Error'

Default: 'None'

Apply full precision fixed-point algorithm when possible — More accurate fixed-point table lookup

off (default) | on

Use this check box to enable full-precision fixed-point algorithm lookup for linear interpolation lookup when possible. This algorithm generally achieves better precision for hardware-efficient fixed-point rounding modes.

Dependencies

To enable this parameter, set:

- **Number of table dimensions** to 1.
- **Interpolation method** to Linear point-slope.
- **Extrapolation method** to Clip.

Programmatic Use

Block Parameter: ApplyFullPrecisionForLinearInterpolation

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Use last table value for inputs at or above last breakpoint – Method for computing output for inputs at or above last breakpoint

off (default) | on

Using this check box, specify the indexing convention that the block uses to address the last element of a breakpoint set and its corresponding table value. This check box is relevant if the input is equal to or larger than the last element of the breakpoint data. Due to rounding, selecting and clearing this check box may result in differing results for the last breakpoint between simulation and code generation.

Check Box	Index Used by Block	Interval Fraction
Selected	Last element of breakpoint data on the Table and Breakpoints tab	0
Cleared	Next-to-last element of breakpoint data on the Table and Breakpoints tab	1

Given an input u within range of a breakpoint set bp , the interval fraction f , in the range $0 \leq f < 1$, is computed as shown below.

Suppose the breakpoint set is [1 4 5] and input u is 5.5. If you select this check box, the index is that of the last element (5) and the interval fraction is 0. If you clear this check box, the index is that of the next-to-last element (4) and the interval fraction is 1.

Dependencies

To enable this parameter, set:

- **Interpolation method** to Linear.
- **Extrapolation method** to Clip.

Programmatic Use

Block Parameter: UseLastTableValue

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Input settings**Use one input port for all input data — Use only one input port**

off (default) | on

Select this check box to use only one input port that expects a signal that is n elements wide for an n -dimensional table. This option is useful for removing line clutter on a block diagram with many lookup tables.

Note When you select this check box, one input port with the label u appears on the block.

Programmatic Use

Block Parameter: UseOneInputPortForAllInputData

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Code generation**Remove protection against out-of-range input in generated code — Remove code that checks for out-of-range input values**

off (default) | on

Specify whether or not to include code that checks for out-of-range input values.

Check Box	Result	When to Use
on	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input is out-of-range, it may cause undefined behavior for generated code.	For code efficiency
off	Generated code includes conditional statements to check for out-of-range inputs.	For safety-critical applications

If your input is not out of range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-

critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to Error.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input is out of range, the behavior is undefined for generated code.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Advisor Checks”.

Additionally, to determine if it is safe to select this check box, if you have a Simulink Design Verifier license, consider using the “Detect Block Input Range Violations” (Simulink Design Verifier) check.

Programmatic Use

Block Parameter: RemoveProtectionInput

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Support tunable table size in code generation – Enable tunable table size in the generated code

off (default) | on

Select this check box to enable tunable table size in the generated code. This option enables you to change the size and values of the lookup table and breakpoint data in the generated code without regenerating or recompiling the code. You can only decrease the size of the lookup table and breakpoint data.

Dependencies

If you set **Interpolation method** to Cubic spline, this check box is not available.

Programmatic Use

Block Parameter: SupportTunableTableSize

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Maximum indices for each dimension — Maximum index value for each table dimension**

[] (default) | scalar or vector of positive integer values

Example: [4 6] for a 5-by-7 table

Specify the maximum index values for each table dimension using zero-based indexing. You can specify a scalar or vector of positive integer values using the following data types:

- Built-in floating-point types: `double` and `single`
- Built-in integer types: `int8`, `int16`, `int32`, `uint8`, `uint16`, and `uint32`

Examples of valid specifications include:

- [4 6] for a 5-by-7 table
- [`int8(2)` `int16(5)` `int32(9)`] for a 3-by-6-by-10 table
- A `Simulink.Parameter` whose value on generating code is one less than the dimensions of the table data. For more information, see “Tunable Table Size in the Generated Code” on page 1-1012.

Dependencies

To enable this parameter, select **Support tunable table size in code generation**. On tuning this parameter in the generated code, provide the new table data and breakpoints along with the tuned parameter value.

Programmatic Use**Block Parameter:** MaximumIndicesForEachDimension**Type:** character vector**Values:** scalar or vector of positive integer values**Default:** '[]'**Data Types****Table data — Data type of table data**

Inherit: Same as output (default) | `double` | `single` | `half` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | <data type expression>

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`

- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
 - Sharing of prescaled table data between two n-D Lookup Table blocks with different output data types
 - Sharing of custom storage table data in the generated code for blocks with different output data types
-

Dependencies

To enable this parameter, set **Table data** from the **Table and Breakpoints** tab to **Dialog**.

Programmatic Use

Block Parameter: `TableDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit from 'Table data''` | `'Inherit: Same as output'` | `'double'` | `'single'` | `'half'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`

Default: `'Inherit: Same as output'`

Table data Minimum — Minimum value of the table data

`[]` | scalar

Specify the minimum value for table data. The default value is `[]` (unspecified).

Programmatic Use

Block Parameter: `TableMin`

Type: character vector

Values: scalar

Default: `'[]'`

Table data Maximum — Maximum value of the table data

`[]` | scalar

Specify the maximum value for table data. The default value is `[]` (unspecified).

Programmatic Use

Block Parameter: `TableMax`

Type: character vector

Values: scalar

Default: `'[]'`

Breakpoints — Breakpoint data type

Inherit: Same as corresponding input (default) | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | <data type expression>

Specify the data type for a set of breakpoint data. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as corresponding input`
- The name of a built-in data type, for example, `single`
- The name of a data type class, for example, an enumerated data type class
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Tip

- Breakpoints support unordered enumerated data. As a result, linear searches are also unordered, which offers flexibility but can impact performance. The search begins from the first element in the breakpoint.
- If the **Begin index search using previous index result** check box is selected, you must use ordered monotonically increasing data. This ordering improves performance.
- For enumerated data, **Extrapolation method** must be `Clip`.
- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.

This is a limitation for using enumerated data with this block:

- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a breakpoint data type different from the corresponding input data type for these cases:

- Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal
- Sharing of prescaled breakpoint data between two n-D Lookup Table blocks with different input data types
- Sharing of custom storage breakpoint data in the generated code for blocks with different input data types

Specify the same slope and bias for a breakpoint data type and its corresponding input data type if either of them has a fixed-point data type.

Dependencies

To enable this parameter, set the corresponding **Breakpoints** parameter from the **Table and Breakpoints** tab to Dialog.

Programmatic Use

Block Parameter: BreakpointsForDimension1DataTypeStr | BreakpointsForDimension2DataTypeStr | ... | BreakpointsForDimension30DataTypeStr

Type: character vector

Values: 'Inherit: Same as corresponding input' | 'Inherit: Inherit from 'Breakpoint data'' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as corresponding input'

Breakpoints Minimum — Minimum value breakpoint data can have

[] | scalar

Specify the minimum value that a set of breakpoint data can have. The default value is [] (unspecified).

Programmatic Use

Block Parameter: BreakpointsForDimension1Min | BreakpointsForDimension2Min | ... | BreakpointsForDimension30Min

Type: character vector

Values: scalar

Default: '[]'

Breakpoints Maximum — Maximum value breakpoint data can have

[] | scalar

Specify the maximum value that a set of breakpoint data can have. The default value is [] (unspecified).

Programmatic Use

Block Parameter: BreakpointsForDimension1Max | BreakpointsForDimension2Max | ... | BreakpointsForDimension30Max

Type: character vector

Values: scalar

Default: '[]'

Fraction — Fraction data type

Inherit: Inherit via internal rule (default) | double | single | fixdt(1,16,0) | <data type expression>

Specify the fraction data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- The name of a built-in data type, for example, single
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: FractionDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'double' | 'single' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Intermediate results – Intermediate results data type

Inherit: Same as output (default) | Inherit: Inherit via internal rule | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Same as output
- The name of a built-in data type, for example, single
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Use this parameter to specify higher (or lower) precision for internal computations than for table data or output data.

Programmatic Use

Block Parameter: IntermediateResultsDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as output'

Output – Output data type

Inherit: Same as input (default) | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via back propagation
- The name of a built-in data type, for example, single
- The name of a data type object, for example, a Simulink.NumericType object

- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: 'Inherit: Inherit via back propagation' | 'Inherit: Inherit from table data' | 'Inherit: Same as first input' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression'

Default: 'Inherit: Same as first input'

Output Minimum — Minimum value the block can output

`[]` | scalar

Specify the minimum value that the block outputs. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

Programmatic Use

Block Parameter: `OutMin`

Type: character vector

Values: scalar

Default: `[]`

Output Maximum — Maximum value the block can output

`[]` | scalar

Specify the maximum value that the block can output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

Programmatic Use

Block Parameter: `OutMax`

Type: character vector

Values: scalar

Default: `[]`

Internal rule priority — Internal rule for intermediate calculations

Speed (default) | Precision

Specify the internal rule for intermediate calculations. Select Speed for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Programmatic Use**Block Parameter:** InternalRulePriority**Type:** character vector**Values:** 'Speed' | 'Precision'**Default:** 'Speed'**Require all inputs to have the same data type — Require all inputs to have the same data type**

on (default) | off

Select to require all inputs to have the same data type.

Programmatic Use**Block Parameter:** InputSameDT**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'**Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Integer rounding mode — Rounding mode for fixed-point operations**

Simplest (default) | Ceiling | Convergent | Floor | Nearest | Round | Zero

Specify the rounding mode for fixed-point lookup table calculations that occur during simulation or execution of code generated from the model. For more information, see “Rounding” (Fixed-Point Designer).

This option does not affect rounding of values of block parameters. Simulink rounds such values to the nearest representable integer value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the edit field on the block dialog box.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector**Values:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'**Default:** 'Simplest'

Saturate on integer overflow – Method of overflow action

off (default) | on

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box (on).	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	An overflow associated with a signed 8-bit integer can saturate to -128 or 127.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

Tip If you save your model as version R2009a or earlier, this check box setting has no effect and no saturation code appears. This behavior preserves backward compatibility.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Data Types	double enumerated fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

More About**Tunable Table Size in the Generated Code**

Suppose that you have a lookup table and want to make the size tunable in the generated code. When you use `Simulink.LookupTable` and `Simulink.Breakpoint` objects to configure lookup table

data for calibration in the generated code, use the `SupportTunableSize` property of the objects to enable a tunable table size. When you do not use these classes, use the **Support tunable table size in code generation** parameter in an n-D Lookup Table block to enable a tunable table size.

Assume that:

- You define a `Simulink.Parameter` structure in the preload function of your model:

```
p = Simulink.Parameter;
p.Value.MaxIdx = [2 2];
p.Value.BP1 = [1 2 3];
p.Value.BP2 = [1 4 16];
p.Value.Table = [4 5 6; 16 19 20; 10 18 23];
p.DataType = 'Bus: slLookupTable';
p.CoderInfo.StorageClass = 'ExportedGlobal';

% Create bus object slBus1 from MATLAB structure
Simulink.Bus.createObject(p.Value);
slLookupTable = slBus1;
slLookupTable.Elements(1).DataType = 'uint32';
```

- These block parameters apply in the n-D Lookup Table block.

Parameter	Value
Number of table dimensions	2
Table data	p.Table
Breakpoints 1	p.BP1
Breakpoints 2	p.BP2
Support tunable table size in code generation	on
Maximum indices for each dimension	p.MaxIdx

The generated `model_types.h` header file contains a type definition that looks something like this.

```
typedef struct {
    uint32_T MaxIdx[2];
    real_T BP1[3];
    real_T BP2[3];
    real_T Table[9];
} slLookupTable;
```

The generated `model.c` file contains code that looks something like this.

```
/* Exported block parameters */
slLookupTable p = {
    { 2U, 2U },

    { 1.0, 2.0, 3.0 },

    { 1.0, 4.0, 16.0 },

    { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 }
};

/* More code */
```

```

/* Model output function */
static void ex_lut_nd_tunable_table_output(int_T tid)
{
  /* Lookup_n-D: '<Root>/n-D Lookup Table' incorporates:
   * Inport: '<Root>/In1'
   * Inport: '<Root>/In2'
   */
  Y = look2_binlcpw(U1, U2, p.BP1, p.BP2, p.Table, ...
p.MaxIdx, p.MaxIdx[0] + 1U);

  /* Outport: '<Root>/Out1' */
  ex_lut_nd_tunable_table_Y.Out1 = Y;

  /* tid is required for a uniform function interface.
   * Argument tid is not used in the function. */
  UNUSED_PARAMETER(tid);
}

```

The highlighted line of code specifies a tunable table size for the lookup table. You can change the size and values of the lookup table and breakpoint data without regenerating or recompiling the code.

Enumerated Values in Lookup Tables

Suppose that you have a lookup table with an enumerated class like this defined:

```

classdef(Enumeration) Gears < Simulink.IntEnumType
  enumeration
    GEAR1(1),
    GEAR2(2),
    GEAR3(4),
    GEAR4(8),
    SPORTS(16),
    REVERSE(-1),
    NEUTRAL(0)
  end
end

```

n-D Lookup block has these settings:

- **Number of dimensions** to 1.
- **Table data** value is [5 10 20 40 80 -5 0].
- **Breakpoints 1** value is enumeration('Gears').
- Interpolation method is Flat.
- For an unordered search, set **Index search method** to Linear search and clear the **Begin index search using previous index result** check box.

Simulation produces a vector [10 -5 80], which correspond to GEAR2, REVERSE, and SPORTS.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For information about HDL code generation support for 1-D Lookup Table blocks, see “HDL Code Generation” on page 1-1065 .

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

2-D Lookup Table

Approximate two-dimensional function

Library: Simulink / Lookup Tables
HDL Coder / Lookup Tables

Description

Supported Block Operations

The 1-D, 2-D, and n-D Lookup Table blocks evaluate a sampled representation of a function in N variables

$$y = F(x_1, x_2, x_3, \dots, x_N)$$

where the function F can be empirical. The block maps inputs to an output value by looking up or interpolating a table of values you define with block parameters. The block supports flat (constant), linear (linear point-slope), Lagrange (linear Lagrange), nearest, cubic-spline, and Akima spline interpolation methods. You can apply these methods to a table of any dimension from 1 through 30.

In the following block, the first input identifies the first dimension (row) breakpoints, the second input identifies the second dimension (column) breakpoints, and so on.

See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

When the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter is set, the 2-D and n-D Lookup Table block behavior changes from column-major to row-major. For these blocks, the column-major and row-major algorithms may differ in the order of the output calculations, possibly resulting in slightly different numerical values. This capability requires a Simulink Coder or Embedded Coder license. For more information on row-major support, see “Code Generation of Matrices and Arrays” (Simulink Coder).

Specification of Breakpoint and Table Data

These block parameters define the breakpoint and table data.

Block Parameter	Purpose
Number of table dimensions	Specifies the number of dimensions of your lookup table.
Breakpoints	Specifies a breakpoint vector that corresponds to each dimension of your lookup table.
Table data	Defines the associated set of output values.

Tip Evenly spaced breakpoints can make the generated code division-free. For more information, see `fixpt_evenspace_cleanup` and “Identify questionable fixed-point operations” (Embedded Coder).

How the Block Generates Output

The n-D, 1-D and 2-D Lookup Table blocks generate output by looking up or estimating table values based on the input values.

Block Inputs	n-D Lookup Table Block Behavior
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the Interpolation method you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the Extrapolation method you select

Other Blocks that Perform Equivalent Operations

You can use the Interpolation Using Prelookup block with the Prelookup block to perform the equivalent operation of one n-D Lookup Table block. This combination of blocks offers greater flexibility that can result in more efficient simulation performance for linear interpolations.

When the lookup operation is an array access that does not require interpolation, use the Direct Lookup Table (n-D) block. For example, if you have an integer value k and you want the k th element of a table, $y = \text{table}(k)$, interpolation is unnecessary.

Ports

Input

u1 — First-dimension (row) inputs

scalar | vector | matrix

Real-valued inputs to the **u1** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: `0:10`

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `enumerated` | `fixed point`

u2 — Second-dimension (column) inputs

scalar | vector | matrix

Real-valued inputs to the **u2** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: 0:10

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | enumerated | fixed point

T – Define the table of output values

matrix of values with dimensions that match the **Number of table dimensions** and the breakpoint lengths for each dimension of the table

Specify the table of output values with a signal that is tunable at runtime.

During simulation, the matrix size must match the dimensions defined by the **Number of table dimensions** parameter and the breakpoint lengths for each dimension of the table. However, during block diagram editing, you can enter an empty matrix (specified as []) or an undefined workspace variable. This technique lets you postpone specifying a correctly dimensioned matrix for the table data and continue editing the block diagram.

Dependencies

To enable this port, set:

- **Data specification** to Table and breakpoints.
- **Table data** to Input port.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

bp1 – Explicit breakpoint values

1-by-n or n-by-1 vector of monotonically increasing values

Specify the breakpoint data explicitly, based on the value of the **Breakpoints specification** parameter, with a signal that is tunable at runtime.

- If you set **Breakpoints specification** to Explicit values, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.

Note To specify breakpoints in the even spacing specification format, set **Breakpoints specification** to Even spacing and use the **Breakpoints First** point and **Spacing** parameters.

Dependencies

To enable this port, set:

- **Data specification** to Table and breakpoints.
- **Breakpoints specification** to Explicit values.
- **Breakpoints 1** to Input port.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | enumerated | fixed point

bp2 — Explicit breakpoint values

1-by-n or n-by-1 vector of monotonically increasing values

Specify the breakpoint data explicitly, based on the value of the **Breakpoints specification** parameter, with a signal that is tunable at runtime.

- If you set **Breakpoints specification** to `Explicit` values, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.

Note To specify evenly spaced breakpoint data, use the **Breakpoints** parameter. You cannot specify evenly spaced breakpoint data through the input port.

Dependencies

To enable this port, set:

- **Data specification** to `Table` and `breakpoints`.
- **Breakpoints specification** to `Explicit` values.
- **Breakpoints 2** to `Input` port.

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `enumerated` | `fixed point`

Output**Port_1 — Output computed by looking up or estimating table values**

scalar | vector | matrix

Output generated by looking up or estimating table values based on the input values.

When block inputs...	The n-D Lookup Table block...
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the Interpolation method you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the Extrapolation method you select

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters**Table and Breakpoints****Number of table dimensions — Number of lookup table dimensions**

2 (default) | 1 | 3 | 4 | ... | 30

Enter the number of dimensions of the lookup table. This parameter determines:

- The number of independent variables for the table and the number of block inputs
- The number of breakpoint sets to specify

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

For example, a table with a size of $M \times N \times \dots$ means that the size of dimension 1 is M , the size of dimension 2 is N , and so forth. M must match the first breakpoint length, N must match the second breakpoint length, and so forth.

Programmatic Use

Block Parameter: NumberOfTableDimensions

Type: character vector

Values: '1' | '2' | '3' | '4' | ... | 30

Default: '2'

Data specification — Method of table and breakpoint specification

Table and breakpoints (default) | Lookup table object

From the list, select:

- Table and breakpoints — Specify the table data and breakpoints. Selecting this option enables these parameters:
 - **Table data**
 - **Breakpoints specification**
 - **Breakpoints 1**
 - **Breakpoints 2**
 - **Edit table and breakpoints**

To specify the table and breakpoints using input ports, see the **Source** parameter.

- Lookup table object — Use an existing lookup table (`Simulink.LookupTable`) object. Selecting this option enables the **Name** field and **Edit table and breakpoints** button.

Programmatic Use

Block Parameter: DataSpecification

Type: character vector

Values: 'Table and breakpoints' | 'Lookup table object'

Default: 'Table and breakpoints'

Name — Name of the lookup table object

[] (default) | `Simulink.LookupTable` object

Enter the name of the lookup table (`Simulink.LookupTable`) object. If a `Simulink.LookupTable`

object does not exist, click the action button  and select **Create**. The corresponding parameters of the new lookup table object are automatically populated with the block information.

Dependencies

To enable this parameter, set **Data specification** to `Lookup table object`.

Programmatic Use

Block Parameter: `LookupTableObject`

Type: character vector

Values: name of a `Simulink.LookupTable` object

Default: `''`

Breakpoints specification — Method of breakpoint specification

`Explicit values (default) | Even spacing`

Specify whether to enter data as explicit breakpoints or as parameters that generate evenly spaced breakpoints.

- To explicitly specify breakpoint data, set this parameter to `Explicit values` and enter breakpoint data in the text box next to the **Breakpoints** parameters.
- To specify parameters that generate evenly spaced breakpoints, set this parameter to `Even spacing` and enter values for the **First point** and **Spacing** parameters for each dimension of breakpoint data. The block calculates the number of points to generate from the table data.

Dependencies

To enable this parameter, set **Data specification** to `Table` and `breakpoints`.

Programmatic Use

Block Parameter: `BreakpointsSpecification`

Type: character vector

Values: `'Explicit values' | 'Even spacing'`

Default: `'Explicit values'`

Source — Source of table and breakpoint data

`Dialog (default) | Input port`

Source of table and breakpoint data, specified as:

- `Dialog` — Specify the table or breakpoint data in **Value** parameter.
- `Input port` — Specify the table or breakpoint data through the associated input port. Through the input port, you can specify only up to three sets of breakpoint data. To specify breakpoint data above three, use the **Value** parameter.

Note Using the input port to specify table or breakpoint data might negatively affect block performance for simulation due to runtime checks.

Dependencies

- To enable this parameter, set **Data specification** to `Table` and `breakpoints`.
- To enable the associated **Value**, set this parameter to `Dialog`.
- To enable the associated input port, set this parameter to `Input port`.
- Setting this parameter to `Input port` disables the **Value** field and hides the corresponding parameter on the **Data Types** tab.

- Setting this parameter to `Input port` for any one of the parameters disables the **Edit Table and Breakpoints** button.

Programmatic Use

Block Parameter: `TableSource` | `BreakpointsForDimension1Source` | `BreakpointsForDimension2Source` | `BreakpointsForDimension3Source`

Type: character vector

Values: `Dialog` | `Input port`

Default: `'Dialog'`

Table data — Define the table of output values

`[4 5 6; 16 19 20; 10 18 23]` (default) | matrix of values

Enter the table of output values in the associated **Value** field.

During simulation, the matrix size must match the dimensions defined by the **Number of table dimensions** parameter. However, during block diagram editing, you can enter an empty matrix (specified as `[]`) or an undefined workspace variable. This technique lets you postpone specifying a correctly dimensioned matrix for the table data and continue editing the block diagram.

Dependencies

To enable this parameter, set:

- **Data specification** to `Table` and breakpoints.
- **Table data: Source** to `Dialog`.

Programmatic Use

Block Parameter: `Table`

Type: character vector

Values: matrix of table values

Default: `'[4 5 6; 16 19 20; 10 18 23]'`

Breakpoints — Explicit breakpoint values, or first point and spacing of breakpoints

`[1:3]` (default) | 1-by-n or n-by-1 vector of monotonically increasing values

Specify the breakpoint data explicitly or as evenly-spaced breakpoints, based on the value of the **Breakpoints specification** parameter.

- If you set **Breakpoints specification** to `Explicit values`, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row in the associated **Value** field. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.
- If you set **Breakpoints specification** to `Even spacing`, enter the parameters **First point** and **Spacing** in each **Breakpoints** row to generate evenly-spaced breakpoints in the respective dimension. Your table data determines the number of evenly spaced points.

Dependencies

- To enable this parameter, set
 - **Data specification** to `Table` and breakpoints.
 - **Breakpoints: Source** to `Dialog`.
- When the **Breakpoints specification** parameter is set to `Even spacing`, you can only specify breakpoints data through the dialog.

Programmatic Use**Block Parameter:** BreakpointsForDimension1**Type:** character vector**Values:** 1-by-n or n-by-1 vector of monotonically increasing values**Default:** '[1:3]'**First point — First point in evenly spaced breakpoint data**

1 (default) | scalar

Specify the first point in your evenly spaced breakpoint data as a real-valued, finite, scalar. This parameter is available when **Breakpoints specification** is set to Even spacing.

Dependencies

To enable this parameter, set **Data specification** to Table and breakpoints, and **Breakpoints specification** to Even spacing.

Programmatic Use**Block Parameter:** BreakpointsForDimension1FirstPoint | BreakpointsForDimension2FirstPoint**Type:** character vector**Values:** real-valued, finite, scalar**Default:** '1'**Spacing — Spacing between evenly spaced breakpoints**

1 (default) | scalar

Specify the spacing between points in your evenly-spaced breakpoint data.

Dependencies

To enable this parameter, set **Data specification** to Table and breakpoints, and **Breakpoints specification** to Even spacing.

Programmatic Use**Block Parameter:** BreakpointsForDimension1Spacing | BreakpointsForDimension2Spacing**Type:** character vector**Values:** positive, real-valued, finite, scalar**Default:** '1'**Edit table and breakpoints — Launch Lookup Table Editor dialog box**

button

Click this button to open the Lookup Table Editor. For more information, see “Edit Lookup Tables” in the Simulink documentation.

Clicking this button for a lookup table object lets you edit the object and save the new values for the object.

Algorithm**Lookup method****Interpolation method — Method of interpolation between breakpoint values**

Linear point-slope (default) | Flat | Nearest | Linear Lagrange | Cubic spline | Akima spline

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. For more information on interpolation methods, see “Interpolation Methods”.

Dependencies

- If you select `Cubic spline`, the block supports only scalar signals. The other interpolation methods support nonscalar signals.
- If you select `Akima spline`, the extrapolation method can only be `Akima spline`.

When set to the modified Akima interpolation method, this block does not support:

- Row-major array layout and algorithms optimized for row-major array layout
- Scaled double and fixed-point data types
- `Simulink.LookupTable` objects
- Code generation when the configuration parameter **Code Generation > Interface > Support non-finite numbers** check box is selected

When set to the modified Akima interpolation method, this block is known to run more slowly when these conditions are true:

- Code generation-based simulation targets, such as those for accelerator mode, rapid accelerator mode, protected models, and so forth.
- Code generated for large breakpoint and data table sizes. For example with a table size of 629x1601.

Programmatic Use

Block Parameter: `InterpMethod`

Type: character vector

Values: `'Linear point-slope'` | `'Flat'` | `'Nearest'` | `'Linear Lagrange'` | `'Cubic spline'` | `'Akima spline'`

Default: `'Linear point-slope'`

Extrapolation method — Method of handling input values that fall outside the range of a breakpoint data set

`Linear (default)` | `Clip` | `Cubic spline` | `Akima spline`

Select `Clip`, `Linear`, or `Cubic spline`. See “Extrapolation Methods” for more information.

If the extrapolation method is `Linear`, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is linear Lagrange, the extrapolation method inherits the linear Lagrange equation to compute the extrapolated value.

Dependencies

- To select `Cubic spline` for **Extrapolation method**, you must also select `Cubic spline` for **Interpolation method**.
- To select `Akima spline` for **Extrapolation method**, you must also select `Akima spline` for **Interpolation method**.

Programmatic Use

Block Parameter: `ExtrapMethod`

Type: character vector

Values: 'Linear' | 'Clip' | 'Cubic spline' | 'Akima spline'
Default: 'Linear'

Index search method — Method of calculating table indices

Evenly spaced points (default) | Linear search | Binary search

Select Evenly spaced points, Linear search, or Binary search. Each search method has speed advantages in different circumstances:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting Evenly spaced points to calculate table indices.

This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.

Note Set **Index search method** to Evenly spaced points when using the Simulink.LookupTable object to specify table data and the **Breakpoints Specification** parameter of the referenced Simulink.LookupTable object is set to Even spacing.

- For unevenly spaced breakpoint sets, follow these guidelines:
 - If input signals do not vary much between time steps, selecting Linear search with **Begin index search using previous index result** produces the best performance.
 - If input signals jump more than one or two table intervals per time step, selecting Binary search produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

Note The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
 - The index search method is Evenly spaced points.
-

Programmatic Use

Block Parameter: IndexSearchMethod

Type: character vector

Values: 'Binary search' | 'Evenly spaced points' | 'Linear search'

Default: 'Binary search'

Begin index search using previous index result — Start using the index from the previous time step

off (default) | on

Select this check box when you want the block to start its search using the index found at the previous time step. For inputs that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

Dependencies

To enable this parameter, set **Index search method** to Linear search or Binary search.

Programmatic Use

Block Parameter: BeginIndexSearchUsing PreviousIndexResult

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Diagnostic for out-of-range input — Block action when input is out of range

None (default) | Warning | Error

Specify whether to produce a warning or error when the input is out of range. Options include:

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

Programmatic Use

Block Parameter: DiagnosticForOutOfRangeInput

Type: character vector

Values: 'None' | 'Warning' | 'Error'

Default: 'None'

Apply full precision fixed-point algorithm when possible — More accurate fixed-point table lookup

off (default) | on

Use this check box to enable full-precision fixed-point algorithm lookup for linear interpolation lookup when possible. This algorithm generally achieves better precision for hardware-efficient fixed-point rounding modes.

Dependencies

To enable this parameter, set:

- **Number of table dimensions** to 1.
- **Interpolation method** to Linear point-slope.
- **Extrapolation method** to Clip.

Programmatic Use

Block Parameter: ApplyFullPrecisionForLinearInterpolation

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Use last table value for inputs at or above last breakpoint — Method for computing output for inputs at or above last breakpoint

off (default) | on

Using this check box, specify the indexing convention that the block uses to address the last element of a breakpoint set and its corresponding table value. This check box is relevant if the input is equal to or larger than the last element of the breakpoint data. Due to rounding, selecting and clearing this

check box may result in differing results for the last breakpoint between simulation and code generation.

Check Box	Index Used by Block	Interval Fraction
Selected	Last element of breakpoint data on the Table and Breakpoints tab	0
Cleared	Next-to-last element of breakpoint data on the Table and Breakpoints tab	1

Given an input u within range of a breakpoint set bp , the interval fraction f , in the range $0 \leq f < 1$, is computed as shown below.

Suppose the breakpoint set is [1 4 5] and input u is 5.5. If you select this check box, the index is that of the last element (5) and the interval fraction is 0. If you clear this check box, the index is that of the next-to-last element (4) and the interval fraction is 1.

Dependencies

To enable this parameter, set:

- **Interpolation method** to Linear.
- **Extrapolation method** to Clip.

Programmatic Use

Block Parameter: UseLastTableValue

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Input settings

Use one input port for all input data – Use only one input port

off (default) | on

Select this check box to use only one input port that expects a signal that is n elements wide for an n -dimensional table. This option is useful for removing line clutter on a block diagram with many lookup tables.

Note When you select this check box, one input port with the label `u` appears on the block.

Programmatic Use

Block Parameter: UseOneInputPortForAllInputData

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Code generation

Remove protection against out-of-range input in generated code — Remove code that checks for out-of-range input values

off (default) | on

Specify whether or not to include code that checks for out-of-range input values.

Check Box	Result	When to Use
on	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input is out-of-range, it may cause undefined behavior for generated code.	For code efficiency
off	Generated code includes conditional statements to check for out-of-range inputs.	For safety-critical applications

If your input is not out of range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to Error.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input is out of range, the behavior is undefined for generated code.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**

- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Advisor Checks”.

Additionally, to determine if it is safe to select this check box, if you have a Simulink Design Verifier license, consider using the “Detect Block Input Range Violations” (Simulink Design Verifier) check.

Programmatic Use

Block Parameter: RemoveProtectionInput

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Support tunable table size in code generation – Enable tunable table size in the generated code

off (default) | on

Select this check box to enable tunable table size in the generated code. This option enables you to change the size and values of the lookup table and breakpoint data in the generated code without regenerating or recompiling the code. You can only decrease the size of the lookup table and breakpoint data.

Dependencies

If you set **Interpolation method** to Cubic spline, this check box is not available.

Programmatic Use

Block Parameter: SupportTunableTableSize

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Sample time – Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Maximum indices for each dimension – Maximum index value for each table dimension

[] (default) | scalar or vector of positive integer values

Example: [4 6] for a 5-by-7 table

Specify the maximum index values for each table dimension using zero-based indexing. You can specify a scalar or vector of positive integer values using the following data types:

- Built-in floating-point types: double and single

- Built-in integer types: `int8`, `int16`, `int32`, `uint8`, `uint16`, and `uint32`

Examples of valid specifications include:

- `[4 6]` for a 5-by-7 table
- `[int8(2) int16(5) int32(9)]` for a 3-by-6-by-10 table
- A `Simulink.Parameter` whose value on generating code is one less than the dimensions of the table data. For more information, see “Tunable Table Size in the Generated Code” on page 1-1037.

Dependencies

To enable this parameter, select **Support tunable table size in code generation**. On tuning this parameter in the generated code, provide the new table data and breakpoints along with the tuned parameter value.

Programmatic Use

Block Parameter: `MaximumIndicesForEachDimension`

Type: character vector

Values: scalar or vector of positive integer values

Default: `[]`

Data Types

Table data — Data type of table data

Inherit: `Same as output (default) | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>`

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
 - Sharing of prescaled table data between two n-D Lookup Table blocks with different output data types
 - Sharing of custom storage table data in the generated code for blocks with different output data types
-

Dependencies

To enable this parameter, set **Table data** from the **Table and Breakpoints** tab to **Dialog**.

Programmatic Use**Block Parameter:** TableDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit from 'Table data'' | 'Inherit: Same as output' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as output'**Table data Minimum — Minimum value of the table data**

[] | scalar

Specify the minimum value for table data. The default value is [] (unspecified).

Programmatic Use**Block Parameter:** TableMin**Type:** character vector**Values:** scalar**Default:** '[]'**Table data Maximum — Maximum value of the table data**

[] | scalar

Specify the maximum value for table data. The default value is [] (unspecified).

Programmatic Use**Block Parameter:** TableMax**Type:** character vector**Values:** scalar**Default:** '[]'**Breakpoints — Breakpoint data type**

Inherit: Same as corresponding input (default) | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | <data type expression>

Specify the data type for a set of breakpoint data. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as corresponding input`
- The name of a built-in data type, for example, `single`
- The name of a data type class, for example, an enumerated data type class
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Tip

- Breakpoints support unordered enumerated data. As a result, linear searches are also unordered, which offers flexibility but can impact performance. The search begins from the first element in the breakpoint.
- If the **Begin index search using previous index result** check box is selected, you must use ordered monotonically increasing data. This ordering improves performance.
- For enumerated data, **Extrapolation method** must be `Clip`.

- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the enumeration function.

This is a limitation for using enumerated data with this block:

- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the enumeration function.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a breakpoint data type different from the corresponding input data type for these cases:

- Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal
- Sharing of prescaled breakpoint data between two n-D Lookup Table blocks with different input data types
- Sharing of custom storage breakpoint data in the generated code for blocks with different input data types

Specify the same slope and bias for a breakpoint data type and its corresponding input data type if either of them has a fixed-point data type.

Dependencies

To enable this parameter, set the corresponding **Breakpoints** parameter from the **Table and Breakpoints** tab to Dialog.

Programmatic Use

Block Parameter: BreakpointsForDimension1DataTypeStr | BreakpointsForDimension2DataTypeStr | ... | BreakpointsForDimension30DataTypeStr

Type: character vector

Values: 'Inherit: Same as corresponding input' | 'Inherit: Inherit from 'Breakpoint data'' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as corresponding input'

Breakpoints Minimum — Minimum value breakpoint data can have

[] | scalar

Specify the minimum value that a set of breakpoint data can have. The default value is [] (unspecified).

Programmatic Use

Block Parameter: BreakpointsForDimension1Min | BreakpointsForDimension2Min
| ... | BreakpointsForDimension30Min

Type: character vector

Values: scalar

Default: '[]'

Breakpoints Maximum — Maximum value breakpoint data can have

[] | scalar

Specify the maximum value that a set of breakpoint data can have. The default value is [] (unspecified).

Programmatic Use

Block Parameter: BreakpointsForDimension1Max | BreakpointsForDimension2Max
| ... | BreakpointsForDimension30Max

Type: character vector

Values: scalar

Default: '[]'

Fraction — Fraction data type

Inherit: Inherit via internal rule (default) | double | single | fixdt(1,16,0) | <data type expression>

Specify the fraction data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: FractionDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'double' | 'single' |
'fixdt(1,16,0)' | <data type expression>

Default: 'Inherit: Inherit via internal rule'

Intermediate results — Intermediate results data type

Inherit: Same as output (default) | Inherit: Inherit via internal rule | double |
single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) |
fixdt(1,16,2^0,0) | <data type expression>

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object

- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Use this parameter to specify higher (or lower) precision for internal computations than for table data or output data.

Programmatic Use

Block Parameter: `IntermediateResultsDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'`

Default: `'Inherit: Same as output'`

Output — Output data type

`Inherit: Same as input (default) | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>`

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via back propagation' | 'Inherit: Inherit from table data' | 'Inherit: Same as first input' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'`

Default: `'Inherit: Same as first input'`

Output Minimum — Minimum value the block can output

`[] | scalar`

Specify the minimum value that the block outputs. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** scalar**Default:** ' [] '**Output Maximum — Maximum value the block can output**

[] | scalar

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** scalar**Default:** ' [] '**Internal rule priority — Internal rule for intermediate calculations**

Speed (default) | Precision

Specify the internal rule for intermediate calculations. Select Speed for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Programmatic Use**Block Parameter:** InternalRulePriority**Type:** character vector**Values:** 'Speed' | 'Precision'**Default:** 'Speed'**Require all inputs to have the same data type — Require all inputs to have the same data type**

on (default) | off

Select to require all inputs to have the same data type.

Programmatic Use**Block Parameter:** InputSameDT**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'

Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Integer rounding mode – Rounding mode for fixed-point operations**

Simplest (default) | Ceiling | Convergent | Floor | Nearest | Round | Zero

Specify the rounding mode for fixed-point lookup table calculations that occur during simulation or execution of code generated from the model. For more information, see “Rounding” (Fixed-Point Designer).

This option does not affect rounding of values of block parameters. Simulink rounds such values to the nearest representable integer value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the edit field on the block dialog box.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector**Values:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'**Default:** 'Simplest'**Saturate on integer overflow – Method of overflow action**

off (default) | on

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box (on).	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	An overflow associated with a signed 8-bit integer can saturate to -128 or 127.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

Tip If you save your model as version R2009a or earlier, this check box setting has no effect and no saturation code appears. This behavior preserves backward compatibility.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	double enumerated fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Tunable Table Size in the Generated Code

Suppose that you have a lookup table and want to make the size tunable in the generated code. When you use `Simulink.LookupTable` and `Simulink.Breakpoint` objects to configure lookup table data for calibration in the generated code, use the `SupportTunableSize` property of the objects to enable a tunable table size. When you do not use these classes, use the **Support tunable table size in code generation** parameter in an n-D Lookup Table block to enable a tunable table size.

Assume that:

- You define a `Simulink.Parameter` structure in the preload function of your model:

```
p = Simulink.Parameter;
p.Value.MaxIdx = [2 2];
p.Value.BP1 = [1 2 3];
p.Value.BP2 = [1 4 16];
p.Value.Table = [4 5 6; 16 19 20; 10 18 23];
p.DataType = 'Bus: slLookupTable';
p.CoderInfo.StorageClass = 'ExportedGlobal';

% Create bus object slBus1 from MATLAB structure
Simulink.Bus.createObject(p.Value);
slLookupTable = slBus1;
slLookupTable.Elements(1).DataType = 'uint32';
```

- These block parameters apply in the n-D Lookup Table block.

Parameter	Value
Number of table dimensions	2

Parameter	Value
Table data	p.Table
Breakpoints 1	p.BP1
Breakpoints 2	p.BP2
Support tunable table size in code generation	on
Maximum indices for each dimension	p.MaxIdx

The generated `model_types.h` header file contains a type definition that looks something like this.

```
typedef struct {
    uint32_T MaxIdx[2];
    real_T BP1[3];
    real_T BP2[3];
    real_T Table[9];
} sLookupTable;
```

The generated `model.c` file contains code that looks something like this.

```
/* Exported block parameters */
sLookupTable p = {
    { 2U, 2U },

    { 1.0, 2.0, 3.0 },

    { 1.0, 4.0, 16.0 },

    { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 }
};

/* More code */

/* Model output function */
static void ex_lut_nd_tunable_table_output(int_T tid)
{
    /* Lookup_n-D: '<Root>/n-D Lookup Table' incorporates:
     * Inport: '<Root>/In1'
     * Inport: '<Root>/In2'
     */
    Y = look2_binlcpw(U1, U2, p.BP1, p.BP2, p.Table, ...
p.MaxIdx, p.MaxIdx[0] + 1U);

    /* Outport: '<Root>/Out1' */
    ex_lut_nd_tunable_table_Y.Out1 = Y;

    /* tid is required for a uniform function interface.
     * Argument tid is not used in the function. */
    UNUSED_PARAMETER(tid);
}
```

The highlighted line of code specifies a tunable table size for the lookup table. You can change the size and values of the lookup table and breakpoint data without regenerating or recompiling the code.

Enumerated Values in Lookup Tables

Suppose that you have a lookup table with an enumerated class like this defined:

```
classdef(Enumeration) Gears < Simulink.IntEnumType
    enumeration
        GEAR1(1),
        GEAR2(2),
        GEAR3(4),
        GEAR4(8),
        SPORTS(16),
        REVERSE(-1),
        NEUTRAL(0)
    end
end
```

n-D Lookup block has these settings:

- **Number of dimensions** to 1.
- **Table data** value is [5 10 20 40 80 -5 0].
- **Breakpoints 1** value is enumeration('Gears').
- Interpolation method is Flat.
- For an unordered search, set **Index search method** to Linear search and clear the **Begin index search using previous index result** check box.

Simulation produces a vector [10 -5 80], which correspond to GEAR2, REVERSE, and SPORTS.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For information about HDL code generation support for 2-D Lookup Table blocks, see “HDL Code Generation” on page 1-1065 .

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

n-D Lookup Table

Approximate n-dimensional function

Library: Simulink / Lookup Tables
HDL Coder / Lookup Tables

Description

Supported Block Operations

The 1-D, 2-D, and n-D Lookup Table blocks evaluate a sampled representation of a function in N variables

$$y = F(x_1, x_2, x_3, \dots, x_N)$$

where the function F can be empirical. The block maps inputs to an output value by looking up or interpolating a table of values you define with block parameters. The block supports flat (constant), linear (linear point-slope), Lagrange (linear Lagrange), nearest, cubic-spline, and Akima spline interpolation methods. You can apply these methods to a table of any dimension from 1 through 30.

In the following block, the first input identifies the first dimension (row) breakpoints, the second input identifies the second dimension (column) breakpoints, and so on.

See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

When the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter is set, the 2-D and n-D Lookup Table block behavior changes from column-major to row-major. For these blocks, the column-major and row-major algorithms may differ in the order of the output calculations, possibly resulting in slightly different numerical values. This capability requires a Simulink Coder or Embedded Coder license. For more information on row-major support, see “Code Generation of Matrices and Arrays” (Simulink Coder).

Specification of Breakpoint and Table Data

These block parameters define the breakpoint and table data.

Block Parameter	Purpose
Number of table dimensions	Specifies the number of dimensions of your lookup table.
Breakpoints	Specifies a breakpoint vector that corresponds to each dimension of your lookup table.
Table data	Defines the associated set of output values.

Tip Evenly spaced breakpoints can make the generated code division-free. For more information, see `fixpt_evenspace_cleanup` and “Identify questionable fixed-point operations” (Embedded Coder).

How the Block Generates Output

The n-D, 1-D and 2-D Lookup Table blocks generate output by looking up or estimating table values based on the input values.

Block Inputs	n-D Lookup Table Block Behavior
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the Interpolation method you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the Extrapolation method you select

Other Blocks that Perform Equivalent Operations

You can use the Interpolation Using Prelookup block with the Prelookup block to perform the equivalent operation of one n-D Lookup Table block. This combination of blocks offers greater flexibility that can result in more efficient simulation performance for linear interpolations.

When the lookup operation is an array access that does not require interpolation, use the Direct Lookup Table (n-D) block. For example, if you have an integer value k and you want the k th element of a table, $y = \text{table}(k)$, interpolation is unnecessary.

Ports

Input

u1 — First-dimension (row) inputs

scalar | vector | matrix

Real-valued inputs to the **u1** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: `0:10`

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `enumerated` | `fixed point`

uN — n-th dimension input values

scalar | vector | matrix

Real-valued inputs to the **uN** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: 0:10

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | enumerated | fixed point

T – Define the table of output values

matrix of values with dimensions that match the **Number of table dimensions** and the breakpoint lengths for each dimension of the table

Specify the table of output values with a signal that is tunable at runtime.

During simulation, the matrix size must match the dimensions defined by the **Number of table dimensions** parameter. However, during block diagram editing, you can enter an empty matrix (specified as []) or an undefined workspace variable. This technique lets you postpone specifying a correctly dimensioned matrix for the table data and continue editing the block diagram.

Dependencies

To enable this port, set:

- **Data specification** to Table and breakpoints.
- **Table data** to Input port.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

bp1 – Explicit breakpoint values

1-by-n or n-by-1 vector of monotonically increasing values

Specify the breakpoint data explicitly, based on the value of the **Breakpoints specification** parameter, with a signal that is tunable at runtime

- If you set **Breakpoints specification** to Explicit values, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.

You can create up to three breakpoint data input ports. For breakpoints 4 to 30, you can specify breakpoint data only through the corresponding **Breakpoints** parameter.

Note To specify breakpoints in the even spacing specification format, set **Breakpoints specification** to Even spacing and use the **Breakpoints First** point and **Spacing** parameters.

Dependencies

To enable this port, set:

- **Data specification** to Table and breakpoints.
- **Breakpoints specification** to Explicit values.
- **Breakpoints 1** to Input port.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | enumerated | fixed point

bp2 — Explicit breakpoint values

1-by-n or n-by-1 vector of monotonically increasing values

Specify the breakpoint data explicitly, based on the value of the **Breakpoints specification** parameter, with a signal that is tunable at runtime.

- If you set **Breakpoints specification** to `Explicit values`, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.

You can create up to three breakpoint data input ports. For breakpoints 4 to 30, you can specify breakpoint data only through the corresponding **Breakpoints** parameter.

Note To specify evenly spaced breakpoint data, use the **Breakpoints** parameter. You cannot specify evenly spaced breakpoint data through the input port.

Dependencies

To enable this port, set:

- **Data specification** to `Table` and `breakpoints`.
- **Breakpoints specification** to `Explicit values`.
- **Breakpoints 2** to `Input port`.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | enumerated | fixed point

bp3 — Explicit breakpoint values

1-by-n or n-by-1 vector of monotonically increasing values

Specify the breakpoint data explicitly, based on the value of the **Breakpoints specification** parameter, with a signal that is tunable at runtime.

- If you set **Breakpoints specification** to `Explicit values`, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.

You can create up to three breakpoint data input ports. For breakpoints 4 to 30, you can specify breakpoint data only through the corresponding **Breakpoints** parameter.

Note To specify evenly spaced breakpoint data, use the **Breakpoints** parameter. You cannot specify evenly spaced breakpoint data through the input port.

Dependencies

To enable this port, set:

- **Data specification** to Table and breakpoints.
- **Breakpoints specification** to Explicit values.
- **Breakpoints 3** to Input port.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | enumerated | fixed point

Output

Port_1 – Output computed by looking up or estimating table values

scalar | vector | matrix

Output generated by looking up or estimating table values based on the input values:

When block inputs...	The n-D Lookup Table block...
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the Interpolation method you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the Extrapolation method you select

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Table and Breakpoints

Number of table dimensions – Number of lookup table dimensions

3 (default) | 1 | 2 | 4 | ... | 30

Enter the number of dimensions of the lookup table. This parameter determines:

- The number of independent variables for the table and the number of block inputs
- The number of breakpoint sets to specify

Value	Setting
1, 2, 3, or 4	Select the value from the drop-down list.
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

For example, a table with a size of $M \times N \times \dots$ means that the size of dimension 1 is M , the size of dimension 2 is N , and so forth. M must match the first breakpoint length, N must match the second breakpoint length, and so forth.

Programmatic Use

Block Parameter: NumberOfTableDimensions

Type: character vector

Values: '1' | '2' | '3' | '4' | ... | 30
Default: '3'

Data specification — Method of table and breakpoint specification

Table and breakpoints (default) | Lookup table object

From the list, select:

- Table and breakpoints — Specify the table data and breakpoints. Selecting this option enables the following parameters:
 - Table data
 - Breakpoints specification
 - Breakpoints 1
 - Breakpoints 2
 - Breakpoints 3
 - Edit table and breakpoints

To specify the table and breakpoints using input ports, see the **Source** parameter.

- Lookup table object — Use an existing lookup table (`Simulink.LookupTable`) object. Selecting this option enables the **Name** field and **Edit table and breakpoints** button.

Programmatic Use

Block Parameter: DataSpecification

Type: character vector

Values: 'Table and breakpoints' | 'Lookup table object'

Default: 'Table and breakpoints'

Name — Name of the lookup table object

[] (default) | `Simulink.LookupTable` object

Enter the name of the lookup table (`Simulink.LookupTable`) object. If a `Simulink.LookupTable`

object does not exist, click the action button  and select **Create**. The corresponding parameters of the new lookup table object are automatically populated with the block information.

Dependencies

To enable this parameter, set **Data specification** to Lookup table object.

Programmatic Use

Block Parameter: LookupTableObject

Type: character vector

Values: name of a `Simulink.LookupTable` object

Default: ''

Breakpoints specification — Method of breakpoint specification

Explicit values (default) | Even spacing

Specify whether to enter data as explicit breakpoints or as parameters that generate evenly spaced breakpoints.

- To explicitly specify breakpoint data, set this parameter to `Explicit values` and enter breakpoint data in the text box next to the **Breakpoints** parameters.

- To specify parameters that generate evenly spaced breakpoints, set this parameter to **Even spacing** and enter values for the **First point** and **Spacing** parameters for each dimension of breakpoint data. The block calculates the number of points to generate from the table data.

Dependencies

- To enable this parameter, set **Data specification** to **Table** and **breakpoints**.
- When this parameter is set to **Even spacing**, you can only specify breakpoint data through the dialog.

Programmatic Use

Block Parameter: BreakpointsSpecification

Type: character vector

Values: 'Explicit values' | 'Even spacing'

Default: 'Explicit values'

Source — Source of table and breakpoint data

Dialog (default) | Input port

Specify the source of the table and breakpoint data as:

- **Dialog** — Specify the table or breakpoint data in **Value** parameter.
- **Input port** — Specify the table or breakpoint data through the associated input port.

You can create up to three breakpoint data input ports. For breakpoints 4 to 30, you can specify breakpoint data only through the corresponding **Breakpoints** parameter.

Note Using the input port to specify table or breakpoint data might negatively affect block performance for simulation due to runtime checks.

Dependencies

- To enable this parameter, set **Data specification** to **Table** and **breakpoints**.
- To enable the associated **Value**, set this parameter to **Dialog**.
- To enable the associated input port, set this parameter to **Input port**.
- Setting this parameter to **Input port** disables the **Value** field and hides the corresponding parameter on the **Data Types** tab.
- Setting this parameter to **Input port** for any one of the parameters disables the **Edit Table and Breakpoints** button.

Programmatic Use

Block Parameter: TableSource | BreakpointsForDimension1Source | BreakpointsForDimension2Source | BreakpointsForDimension3Source

Type: character vector

Values: Dialog | Input port

Default: 'Dialog'

Table data — Define the table of output values

reshape(repmat([4 5 6;16 19 20;10 18 23],1,2),[3,3,2]) (default) | matrix of values with dimensions that match the **Number of table dimensions**

Enter the table of output values in the associated **Value** field.

During simulation, the matrix size must match the dimensions defined by the **Number of table dimensions** parameter. However, during block diagram editing, you can enter an empty matrix (specified as []) or an undefined workspace variable. This technique lets you postpone specifying a correctly dimensioned matrix for the table data and continue editing the block diagram.

Dependencies

To enable this parameter, set:

- **Data specification** to Table and breakpoints.
- **Table data: Source** to Dialog.

Programmatic Use

Block Parameter: Table

Type: character vector

Values: matrix of table values

Default: 'reshape repmat([4 5 6;16 19 20;10 18 23],1,2),[3,3,2])'

Breakpoints — Explicit breakpoint values or first point and spacing of breakpoints

[10,22,31] (default) | 1-by-n or n-by-1 vector of monotonically increasing values

Specify the breakpoint data explicitly or as evenly-spaced breakpoints, based on the value of the **Breakpoints specification** parameter.

- If you set **Breakpoints specification** to `Explicit` values, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row in the associated **Value** field. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.
- If you set **Breakpoints specification** to `Even spacing`, enter the parameters **First point** and **Spacing** in each **Breakpoints** row to generate evenly-spaced breakpoints in the respective dimension. Your table data determines the number of evenly spaced points.

Dependencies

- To enable this parameter, set:
 - **Data specification** to Table and breakpoints.
 - **Table data: Source** to Dialog.
- When the **Breakpoints specification** parameter is set to `Even spacing`, you can only specify breakpoint data through the dialog.

Programmatic Use

Block Parameter: BreakpointsForDimension1 | BreakpointsForDimension2 | ... | BreakpointsForDimension30 |

Type: character vector

Values: 1-by-n or n-by-1 vector of monotonically increasing values

Default: '[10, 22, 31]'

First point — First point in evenly spaced breakpoint data

1 (default) | scalar

Specify the first point in your evenly spaced breakpoint data as a real-valued, finite scalar. This parameter is available when **Breakpoints specification** is set to `Even spacing`.

Dependencies

To enable this parameter, set **Data specification** to `Table` and `breakpoints`, and **Breakpoints specification** to `Even spacing`.

Programmatic Use

Block Parameter: `BreakpointsForDimension1FirstPoint` | `BreakpointsForDimension2FirstPoint` | ... | `BreakpointsForDimension30FirstPoint` |

Type: character vector

Values: real-valued, finite, scalar

Default: `'1'`

Spacing — Spacing between evenly spaced breakpoints

`1` (default) | scalar

Specify the spacing between points in your evenly-spaced breakpoint data.

Dependencies

To enable this parameter, set **Data specification** to `Table` and `breakpoints`, and **Breakpoints specification** to `Even spacing`.

Programmatic Use

Block Parameter: `BreakpointsForDimension1Spacing` | `BreakpointsForDimension2Spacing` | ... | `BreakpointsForDimension30Spacing` |

Type: character vector

Values: positive, real-valued, finite, scalar

Default: `'1'`

Edit table and breakpoints — Open Lookup Table Editor dialog box

button

Click this button to open the Lookup Table Editor. For more information, see “Edit Lookup Tables” in the Simulink documentation.

Clicking this button for a lookup table object lets you edit the object and save the new values for the object.

Algorithm**Lookup method****Interpolation method — Method of interpolation between breakpoint values**

`Linear point-slope` (default) | `Flat` | `Nearest` | `Linear Lagrange` | `Cubic spline` | `Akima spline`

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. For more information on interpolation methods, see “Interpolation Methods”.

Dependencies

- If you select `Cubic spline`, the block supports only scalar signals. The other interpolation methods support nonscalar signals.
- If you select `Akima spline`, the extrapolation method can only be `Akima spline`.

When set to the modified Akima interpolation method, this block does not support:

- Row-major array layout and algorithms optimized for row-major array layout
- Scaled double and fixed-point data types
- Simulink.LookupTable objects
- Code generation when the configuration parameter **Code Generation > Interface > Support non-finite numbers** check box is selected

When set to the modified Akima interpolation method, this block is known to run more slowly when these conditions are true:

- Code generation-based simulation targets, such as those for accelerator mode, rapid accelerator mode, protected models, and so forth.
- Code generated for large breakpoint and data table sizes. For example with a table size of 629x1601.

Programmatic Use

Block Parameter: InterpMethod

Type: character vector

Values: 'Linear point-slope' | 'Flat' | 'Nearest' | 'Linear Lagrange' | 'Cubic spline' | 'Akima spline'

Default: 'Linear point-slope'

Extrapolation method — Method of handling input values that fall outside the range of a breakpoint data set

Linear (default) | Clip | Cubic spline | Akima spline

Select Clip, Linear, or Cubic spline. See “Extrapolation Methods” for more information.

If the extrapolation method is Linear, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is linear Lagrange, the extrapolation method inherits the linear Lagrange equation to compute the extrapolated value.

Dependencies

- To select Cubic spline for **Extrapolation method**, you must also select Cubic spline for **Interpolation method**.
- To select Akima spline for **Extrapolation method**, you must also select Akima spline for **Interpolation method**.

Programmatic Use

Block Parameter: ExtrapMethod

Type: character vector

Values: 'Linear' | 'Clip' | 'Cubic spline' | 'Akima spline'

Default: 'Linear'

Index search method — Method of calculating table indices

Evenly spaced points (default) | Linear search | Binary search

Select Evenly spaced points, Linear search, or Binary search. Each search method has speed advantages in different circumstances:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting Evenly spaced points to calculate table indices.

This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.

Note Set **Index search method** to `Evenly spaced points` when using the `Simulink.LookupTable` object to specify table data and the **Breakpoints Specification** parameter of the referenced `Simulink.LookupTable` object is set to `Even spacing`.

- For unevenly spaced breakpoint sets, follow these guidelines:
 - If input signals do not vary much between time steps, selecting `Linear search` with **Begin index search using previous index result** produces the best performance.
 - If input signals jump more than one or two table intervals per time step, selecting `Binary search` produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

Note The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
 - The index search method is `Evenly spaced points`.
-

Programmatic Use

Block Parameter: `IndexSearchMethod`

Type: character vector

Values: `'Binary search'` | `'Evenly spaced points'` | `'Linear search'`

Default: `'Binary search'`

Begin index search using previous index result — Start using the index from the previous time step

`off` (default) | `on`

Select this check box when you want the block to start its search using the index found at the previous time step. For inputs that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

Dependencies

To enable this parameter, set **Index search method** to `Linear search` or `Binary search`.

Programmatic Use

Block Parameter: `BeginIndexSearchUsing PreviousIndexResult`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Diagnostic for out-of-range input — Block action when input is out of range

`None` (default) | `Warning` | `Error`

Specify whether to produce a warning or error when the input is out of range. Options include:

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

Programmatic Use**Block Parameter:** DiagnosticForOutOfRangeInput**Type:** character vector**Values:** 'None' | 'Warning' | 'Error'**Default:** 'None'**Apply full precision fixed-point algorithm when possible — More accurate fixed-point table lookup**

off (default) | on

Use this check box to enable full-precision fixed-point algorithm lookup for linear interpolation lookup when possible. This algorithm generally achieves better precision for hardware-efficient fixed-point rounding modes.

Dependencies

To enable this parameter, set:

- **Number of table dimensions** to 1.
- **Interpolation method** to Linear point-slope.
- **Extrapolation method** to Clip.

Programmatic Use**Block Parameter:** ApplyFullPrecisionForLinearInterpolation**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Use last table value for inputs at or above last breakpoint — Method for computing output for inputs at or above last breakpoint**

off (default) | on

Using this check box, specify the indexing convention that the block uses to address the last element of a breakpoint set and its corresponding table value. This check box is relevant if the input is equal to or larger than the last element of the breakpoint data. Due to rounding, selecting and clearing this check box may result in differing results for the last breakpoint between simulation and code generation.

Check Box	Index Used by Block	Interval Fraction
Selected	Last element of breakpoint data on the Table and Breakpoints tab	0
Cleared	Next-to-last element of breakpoint data on the Table and Breakpoints tab	1

Given an input u within range of a breakpoint set bp , the interval fraction f , in the range $0 \leq f < 1$, is computed as shown below.

Suppose the breakpoint set is [1 4 5] and input u is 5.5. If you select this check box, the index is that of the last element (5) and the interval fraction is 0. If you clear this check box, the index is that of the next-to-last element (4) and the interval fraction is 1.

Dependencies

To enable this parameter, set:

- **Interpolation method** to Linear.
- **Extrapolation method** to Clip.

Programmatic Use

Block Parameter: UseLastTableValue

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Input settings

Use one input port for all input data – Use only one input port

off (default) | on

Select this check box to use only one input port that expects a signal that is n elements wide for an n -dimensional table. This option is useful for removing line clutter on a block diagram with many lookup tables.

Note When you select this check box, one input port with the label u appears on the block.

Programmatic Use

Block Parameter: UseOneInputPortForAllInputData

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Code generation

Remove protection against out-of-range input in generated code — Remove code that checks for out-of-range input values

off (default) | on

Specify whether or not to include code that checks for out-of-range input values.

Check Box	Result	When to Use
on	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input is out-of-range, it may cause undefined behavior for generated code.	For code efficiency
off	Generated code includes conditional statements to check for out-of-range inputs.	For safety-critical applications

If your input is not out of range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to Error.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input is out of range, the behavior is undefined for generated code.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Advisor Checks”.

Additionally, to determine if it is safe to select this check box, if you have a Simulink Design Verifier license, consider using the “Detect Block Input Range Violations” (Simulink Design Verifier) check.

Programmatic Use**Block Parameter:** RemoveProtectionInput**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Support tunable table size in code generation — Enable tunable table size in the generated code**

off (default) | on

Select this check box to enable tunable table size in the generated code. This option enables you to change the size and values of the lookup table and breakpoint data in the generated code without regenerating or recompiling the code. You can only decrease the size of the lookup table and breakpoint data.

Dependencies

If you set **Interpolation method** to Cubic spline, this check box is not available.

Programmatic Use**Block Parameter:** SupportTunableTableSize**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Sample time — Sample time value other than -1**

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Maximum indices for each dimension — Maximum index value for each table dimension**

[] (default) | scalar or vector of positive integer values

Example: [4 6] for a 5-by-7 table

Specify the maximum index values for each table dimension using zero-based indexing. You can specify a scalar or vector of positive integer values using the following data types:

- Built-in floating-point types: double and single
- Built-in integer types: int8, int16, int32, uint8, uint16, and uint32

Examples of valid specifications include:

- [4 6] for a 5-by-7 table
- [int8(2) int16(5) int32(9)] for a 3-by-6-by-10 table

- A `Simulink.Parameter` whose value on generating code is one less than the dimensions of the table data. For more information, see “Tunable Table Size in the Generated Code” on page 1-1063.

Dependencies

To enable this parameter, select **Support tunable table size in code generation**. On tuning this parameter in the generated code, provide the new table data and breakpoints along with the tuned parameter value.

Programmatic Use

Block Parameter: `MaximumIndicesForEachDimension`

Type: character vector

Values: scalar or vector of positive integer values

Default: `[]`

Data Types

Table data — Data type of table data

Inherit: `Same as output (default) | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>`

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
 - Sharing of prescaled table data between two n-D Lookup Table blocks with different output data types
 - Sharing of custom storage table data in the generated code for blocks with different output data types
-

Dependencies

To enable this parameter, set **Table data** from the **Table and Breakpoints** tab to `Dialog`.

Programmatic Use

Block Parameter: `TableDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit from 'Table data'' | 'Inherit: Same as output' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' |`

'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' |
 'fixdt(1,16,2^0,0)' | '<data type expression>'
Default: 'Inherit: Same as output'

Table data Minimum — Minimum value of the table data

[] | scalar

Specify the minimum value for table data. The default value is [] (unspecified).

Programmatic Use

Block Parameter: TableMin

Type: character vector

Values: scalar

Default: '[]'

Table data Maximum — Maximum value of the table data

[] | scalar

Specify the maximum value for table data. The default value is [] (unspecified).

Programmatic Use

Block Parameter: TableMax

Type: character vector

Values: scalar

Default: '[]'

Breakpoints — Breakpoint data type

Inherit: Same as corresponding input (default) | double | single | half | int8 | uint8 |
 int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) |
 fixdt(1,16,2^0,0) | Enum: <class name> | <data type expression>

Specify the data type for a set of breakpoint data. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as corresponding input`
- The name of a built-in data type, for example, `single`
- The name of a data type class, for example, an enumerated data type class
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Tip

- Breakpoints support unordered enumerated data. As a result, linear searches are also unordered, which offers flexibility but can impact performance. The search begins from the first element in the breakpoint.
 - If the **Begin index search using previous index result** check box is selected, you must use ordered monotonically increasing data. This ordering improves performance.
 - For enumerated data, **Extrapolation method** must be `Clip`.
 - The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.
-

This is a limitation for using enumerated data with this block:

- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the enumeration function.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a breakpoint data type different from the corresponding input data type for these cases:

- Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal
- Sharing of prescaled breakpoint data between two n-D Lookup Table blocks with different input data types
- Sharing of custom storage breakpoint data in the generated code for blocks with different input data types

Specify the same slope and bias for a breakpoint data type and its corresponding input data type if either of them has a fixed-point data type.

Dependencies

To enable this parameter, set the corresponding **Breakpoints** parameter from the **Table and Breakpoints** tab to Dialog.

Programmatic Use

Block Parameter: BreakpointsForDimension1DataTypeStr | BreakpointsForDimension2DataTypeStr | ... | BreakpointsForDimension30DataTypeStr

Type: character vector

Values: 'Inherit: Same as corresponding input' | 'Inherit: Inherit from 'Breakpoint data' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as corresponding input'

Breakpoints Minimum — Minimum value breakpoint data can have

[] | scalar

Specify the minimum value that a set of breakpoint data can have. The default value is [] (unspecified).

Programmatic Use

Block Parameter: BreakpointsForDimension1Min | BreakpointsForDimension2Min | ... | BreakpointsForDimension30Min

Type: character vector

Values: scalar

Default: '[]'

Breakpoints Maximum — Maximum value breakpoint data can have

[] | scalar

Specify the maximum value that a set of breakpoint data can have. The default value is [] (unspecified).

Programmatic Use

Block Parameter: BreakpointsForDimension1Max | BreakpointsForDimension2Max
| ... | BreakpointsForDimension30Max

Type: character vector

Values: scalar

Default: '[]'

Fraction — Fraction data type

Inherit: Inherit via internal rule (default) | double | single | fixdt(1,16,0) | <data type expression>

Specify the fraction data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- The name of a built-in data type, for example, single
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: FractionDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'double' | 'single' | 'fixdt(1,16,0)' | <data type expression>

Default: 'Inherit: Inherit via internal rule'

Intermediate results — Intermediate results data type

Inherit: Same as output (default) | Inherit: Inherit via internal rule | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Same as output
- The name of a built-in data type, for example, single
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Use this parameter to specify higher (or lower) precision for internal computations than for table data or output data.

Programmatic Use

Block Parameter: IntermediateResultsDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as output'

Output — Output data type

Inherit: Same as input (default) | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via back propagation' | 'Inherit: Inherit from table data' | 'Inherit: Same as first input' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as first input'

Output Minimum — Minimum value the block can output

[] | scalar

Specify the minimum value that the block outputs. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** scalar**Default:** ' [] '**Output Maximum — Maximum value the block can output**

[] | scalar

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** scalar**Default:** ' [] '**Internal rule priority — Internal rule for intermediate calculations**

Speed (default) | Precision

Specify the internal rule for intermediate calculations. Select Speed for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Programmatic Use**Block Parameter:** InternalRulePriority**Type:** character vector**Values:** 'Speed' | 'Precision'**Default:** 'Speed'**Require all inputs to have the same data type — Require all inputs to have the same data type**

on (default) | off

Select to require all inputs to have the same data type.

Programmatic Use**Block Parameter:** InputSameDT**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'**Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Integer rounding mode — Rounding mode for fixed-point operations**

Simplest (default) | Ceiling | Convergent | Floor | Nearest | Round | Zero

Specify the rounding mode for fixed-point lookup table calculations that occur during simulation or execution of code generated from the model. For more information, see “Rounding” (Fixed-Point Designer).

This option does not affect rounding of values of block parameters. Simulink rounds such values to the nearest representable integer value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the edit field on the block dialog box.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector**Values:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'**Default:** 'Simplest'**Saturate on integer overflow — Method of overflow action**

off (default) | on

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box (on).	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	An overflow associated with a signed 8-bit integer can saturate to -128 or 127.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

Tip If you save your model as version R2009a or earlier, this check box setting has no effect and no saturation code appears. This behavior preserves backward compatibility.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Data Types	double enumerated fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

More About**Tunable Table Size in the Generated Code**

Suppose that you have a lookup table and want to make the size tunable in the generated code. When you use `Simulink.LookupTable` and `Simulink.Breakpoint` objects to configure lookup table data for calibration in the generated code, use the `SupportTunableSize` property of the objects to enable a tunable table size. When you do not use these classes, use the **Support tunable table size in code generation** parameter in an n-D Lookup Table block to enable a tunable table size.

Assume that:

- You define a `Simulink.Parameter` structure in the preload function of your model:

```
p = Simulink.Parameter;
p.Value.MaxIdx = [2 2];
p.Value.BP1 = [1 2 3];
p.Value.BP2 = [1 4 16];
p.Value.Table = [4 5 6; 16 19 20; 10 18 23];
p.DataType = 'Bus: slLookupTable';
p.CoderInfo.StorageClass = 'ExportedGlobal';

% Create bus object slBus1 from MATLAB structure
Simulink.Bus.createObject(p.Value);
slLookupTable = slBus1;
slLookupTable.Elements(1).DataType = 'uint32';
```

- These block parameters apply in the n-D Lookup Table block.

Parameter	Value
Number of table dimensions	2
Table data	p.Table
Breakpoints 1	p.BP1
Breakpoints 2	p.BP2

Parameter	Value
Support tunable table size in code generation	on
Maximum indices for each dimension	p.MaxIdx

The generated `model_types.h` header file contains a type definition that looks something like this.

```
typedef struct {
    uint32_T MaxIdx[2];
    real_T BP1[3];
    real_T BP2[3];
    real_T Table[9];
} sLookupTable;
```

The generated `model.c` file contains code that looks something like this.

```
/* Exported block parameters */
sLookupTable p = {
    { 2U, 2U },

    { 1.0, 2.0, 3.0 },

    { 1.0, 4.0, 16.0 },

    { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 }
};

/* More code */

/* Model output function */
static void ex_lut_nd_tunable_table_output(int_T tid)
{
    /* Lookup_n-D: '<Root>/n-D Lookup Table' incorporates:
     * Inport: '<Root>/In1'
     * Inport: '<Root>/In2'
     */
    Y = look2_binlcpw(U1, U2, p.BP1, p.BP2, p.Table, ...
p.MaxIdx, p.MaxIdx[0] + 1U);

    /* Output: '<Root>/Out1' */
    ex_lut_nd_tunable_table_Y.Out1 = Y;

    /* tid is required for a uniform function interface.
     * Argument tid is not used in the function. */
    UNUSED_PARAMETER(tid);
}
```

The highlighted line of code specifies a tunable table size for the lookup table. You can change the size and values of the lookup table and breakpoint data without regenerating or recompiling the code.

Enumerated Values in Lookup Tables

Suppose that you have a lookup table with an enumerated class like this defined:

```
classdef(Enumeration) Gears < Simulink.IntEnumType
    enumeration
        GEAR1(1),
```

```

    GEAR2(2),
    GEAR3(4),
    GEAR4(8),
    SPORTS(16),
    REVERSE(-1),
    NEUTRAL(0)
end
end

```

n-D Lookup block has these settings:

- **Number of dimensions** to 1.
- **Table data** value is [5 10 20 40 80 -5 0].
- **Breakpoints 1** value is enumeration('Gears').
- Interpolation method is Flat.
- For an unordered search, set **Index search method** to Linear search and clear the **Begin index search using previous index result** check box.

Simulation produces a vector [10 -5 80], which correspond to GEAR2, REVERSE, and SPORTS.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).

General	
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
MapToRAM	Map lookup tables (LUTs) to RAM. The default is on. See also “MapToRAM” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Note The block supports single, double, and half data types for HDL code generation.

Native Floating Point	
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is <code>inherit</code> . See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , or <code>Zero</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
MantissaMultiplyStrategy	Specify how to implement the mantissa multiplication operation during code generation. By using different settings, you can control the DSP usage on the target FPGA device. The default is <code>inherit</code> . See also “MantissaMultiplyStrategy” (HDL Coder).
PrecomputeCoefficients	<p>To enable this property, set Interpolation method to <code>Linear point-slope</code>.</p> <p>When you enable this property, the slope and bias coefficients are statically precomputed depending on the table data and breakpoints. This setting reduces the number of division operations that are performed during runtime to compute the coefficients. It also reduces the overall number of floating-point addition and multiplication operations that are performed.</p> <p>Enabling this property reduces the latency and saves area number of lookup table resources that are required. However, this property reorders the floating-point operations, which might result in small numeric differences. You can observe these numerical differences in the generated validation model.</p>

Native Floating Point	
AreaOptimization	For 4-D and 5-D LUT, HDL code generation supports fully parallel and serial implementations. To enable this property, use linear interpolation method for 4-D and 5-D LUT. When you set this property to either <code>Parallel</code> or <code>Serial</code> , HDL Coder manipulates the resources for your design. To reduce the area of your design, use serial implementation for minimizing the resources. To observe the results of fully parallel and serial implementation, compare the resource utilization report of native floating-point operators for your design. You can also compare the synthesis results of the design for fully parallel and serial implementation.

Complex Data Support

This block supports code generation for complex signals.

Required Block Settings

Block Setting	HDL Coder Support
Number of table dimensions	Select the table dimension between 1 to 30.
Breakpoints specification	Select either <code>Explicit values</code> or <code>Even spacing</code> .
Extrapolation method	Select <code>Clip</code> or <code>Linear</code> . The code generator does not support extrapolation beyond even bounds.
Interpolation method	Select <code>Flat</code> or <code>Linear point-slope</code> .
Diagnostic for out-of-range input	Select <code>Error</code> . If you specify other options, HDL Coder generates a warning.
Use last table value for inputs at or above last breakpoint	Select this check box.
Require all inputs to have the same data type	Select this check box.
Fraction	Select <code>Inherit: Inherit via internal rule</code> .
Integer rounding mode	Select <code>Zero</code> , <code>Floor</code> , or <code>Simplest</code> .
Use one input port for all input data	Clear this check box.

MAX 10 Device Settings

If you use Intel MAX 10 device, to map the lookup table to RAM, add this Tcl command when creating the project in the Quartus tool:

```
set_global_assignment -name INTERNAL_FLASH_UPDATE_MODE "SINGLE IMAGE WITH ERAM"
```

Avoid Generation of Divide Operator

If HDL Coder encounters conditions under which a division operation is required to match the model simulation behavior, a warning is displayed. The conditions described cause this block to emit a divide operator. When you use this block for HDL code generation, avoid these conditions:

- If the block is configured to use interpolation, a division operator is required. To avoid this requirement, set **Interpolation method** to `Flat`.

- Uneven table spacing. HDL code generation requires the block to use the evenly spaced points algorithm. The block mapping from the input data type to the zero-based table index in general requires a division. When the breakpoint spacing is an exact power of 2, this divide is implemented as a shift instead of as a divide. To adjust the breakpoint spacing, adjust the number of breakpoints in the table, or the difference between the left and right bounds of the breakpoint range.

Table Data Typing and Sizing

- It is good practice to structure your table such that the spacing between breakpoints is a power of two. If the breakpoint spacing does not meet this condition, HDL Coder issues a warning. When the breakpoint spacing is a power of two, you can replace division operations in the prelookup step with right-shift operations.
- All ports on the block require scalar values.

Restrictions

- When you set the **Interpolation method** to **Flat**, the block supports half data types for data inputs, breakpoints, and outputs. Linear interpolation is not supported for half data types.
- HDL code generation for n-D Lookup Table blocks with **fixed-point** data type supports only **Evenly spaced points** as the index search method.
- HDL code generation does not support LUTs with more than 131072 table elements.
- HDL Code generation supports fixed-point data types for only 1-D and 2-D look up table blocks.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Simulink PLC Coder has limited support for lookup table blocks. The coder does not support:

- Number of dimensions greater than 2
- Cubic spline interpolation method
- Begin index search using a previous index mode
- Cubic spline extrapolation method

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Lookup Table Dynamic

Approximate a one-dimensional function using dynamic table

Library: Simulink / Lookup Tables

Description

How This Block Differs from Other Lookup Table Blocks

The Lookup Table Dynamic block computes an approximation of a function $y = f(x)$ using `xdat` and `ydat` vectors. The lookup method can use interpolation, extrapolation, or the original values of the input.

Using the Lookup Table Dynamic block, you can change the table data without stopping the simulation. For example, you can incorporate new table data if the physical system you are simulating changes.

Inputs for Breakpoint and Table Data

The `xdat` vector is the breakpoint data, which must be *strictly monotonically increasing*. The value of the next element in the vector must be greater than the value of the preceding element after conversion to a fixed-point data type. Due to quantization, `xdat` can be strictly monotonic for a floating-point data type, but not after conversion to a fixed-point data type.

The `ydat` vector is the table data, which is an evaluation of the function at the breakpoint values.

Note The inputs to `xdat` and `ydat` cannot be scalar (one-element array) values. If you provide a scalar value to either of these inputs, you see an error upon simulation. Provide a 1-by-n vector to both the `xdat` and `ydat` inputs.

Lookup Table Definition

You define the lookup table by feeding `xdat` and `ydat` as 1-by-n vectors to the block. To reduce ROM usage in the generated code for this block, you can use different data types for `xdat` and `ydat`. However, these restrictions apply:

- The `xdat` breakpoint data and the `x` input vector must have the same sign, bias, and fractional slope. Also, the precision and range for `x` must be greater than or equal to the precision and range for `xdat`.
- The `ydat` table data and the `y` output vector must have the same sign, bias, and fractional slope.

Tip Breakpoints with even spacing can make Simulink Coder generated code division-free. For more information, see `fixpt_evenspace_cleanup` in the Simulink documentation and “Identify questionable fixed-point operations” (Embedded Coder) in the Simulink Coder documentation.

How the Block Generates Output

The block uses the input values to generate output using the method you select for **Lookup Method**:

Lookup Method	Block Action
Interpolation-Extrapolation	<p>Performs linear interpolation and extrapolation of the inputs.</p> <ul style="list-style-type: none"> • If the input matches a breakpoint, the output is the corresponding element in the table data. • If the input does not match a breakpoint, the block performs linear interpolation between two elements of the table to determine the output. If the input falls outside the range of breakpoint values, the block extrapolates using the first two or last two points. <p>Note If you select this lookup method, Simulink Coder software cannot generate code for this block.</p>
Interpolation-Use End Values (default)	Performs linear interpolation but does not extrapolate outside the end points of the breakpoint data. Instead, the block uses the end values.
Use Input Nearest	Finds the element in <code>xdat</code> nearest the current input. The corresponding element in <code>ydat</code> is the output.
Use Input Below	Finds the element in <code>xdat</code> nearest and below the current input. The corresponding element in <code>ydat</code> is the output. If there is no element in <code>xdat</code> below the current input, the block finds the nearest element.
Use Input Above	Finds the element in <code>xdat</code> nearest and above the current input. The corresponding element in <code>ydat</code> is the output. If there is no element in <code>xdat</code> above the current input, the block finds the nearest element.

Note The Use Input Nearest, Use Input Below, and Use Input Above methods perform the same action when the input `x` matches a breakpoint value.

Some continuous solvers subdivide the simulation time span into major and minor time steps. A minor time step is a subdivision of the major time step. The solver produces a result at each major time step and uses results at minor time steps to improve the accuracy of the result at the major time step. For continuous solvers, the output of the Lookup Table Dynamic block can appear like a stair step because the signal is fixed in minor time step to avoid incorrect results. For more information about the effect of solvers on block output, see “Compare Solvers” in the Simulink documentation.

Ports

Input

x — input vector

scalar | vector | 2-D array

The block accepts real-valued or complex-valued inputs.

Example: 2:12

Dependencies

The **x** input vector and the **xdat** breakpoint data must have the same sign, bias, and fractional slope. Also, the precision and range for **x** must be greater than or equal to the precision and range for **xdat**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | bus

xdat — breakpoint data

1-by-n vector of strictly monotonically increasing values

The **xdat** vector is the breakpoint data, which must be strictly monotonically increasing. The value of the next element in the vector must be greater than the value of the preceding element after conversion to a fixed-point data type. Due to quantization, **xdat** can be strictly monotonic for a floating-point data type, but not after conversion to a fixed-point data type.

Tip Breakpoints with even spacing can make Simulink Coder generated code division-free. For more information, see `fixpt_evenspace_cleanup` in the Simulink documentation and “Identify questionable fixed-point operations” (Embedded Coder) in the Simulink Coder documentation.

Example: 1:10

Dependencies

The **xdat** breakpoint data and the **x** input vector must have the same sign, bias, and fractional slope. Also, the precision and range for **x** must be greater than or equal to the precision and range for **xdat**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | bus

ydat — table data

1-by-n vector

The **ydat** input is a 1-by-n vector of real-valued or complex-valued table data, which is an evaluation of the function at the breakpoint values.

Example: [0 3 12 27 48 75 108 147 192 243 300]

Dependencies

The **ydat** table data and the **y** output vector must have the same sign, bias, and fractional slope.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | bus

Output

y — Approximation of $y = f(x)$ using dynamic table data

1-by-n vector

The block computes an approximation of a function $y = f(x)$ using the `xdat` and `ydat` input vectors. The lookup method can use interpolation, extrapolation, or the original values of the input.

Dependencies

The `ydat` table data and the `y` output vector must have the same sign, bias, and fractional slope.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Main Tab

Lookup Method — Specify the lookup method

`Interpolation-Use End Values (default)` | `Interpolation-Extrapolation` | `Use Input Nearest` | `Use Input Below` | `Use Input Above`

The block computes output by applying the **Lookup Method** you select to the input vectors of breakpoint data (`xdat`) and table data (`ydat`). For details, see “How the Block Generates Output” on page 1-1070.

Programmatic Use

Block Parameter: `LookUpMeth`

Type: character vector

Values: `'Interpolation-Extrapolation'` | `'Interpolation-Use End Values'` | `'Use Input Nearest'` | `'Use Input Below'` | `'Use Input Above'`

Default: `'Interpolation-Use End Values'`

Signal Attributes Tab

Output data type — Output data type

`double (default)` | `'Inherit: Inherit via back propagation'` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64` | `boolean` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the data type of the output signal `y`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

The `ydat` table data and the `y` output vector must have the same sign, bias, and fractional slope.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | <data type expression>
Default: 'double'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate to max or min when overflows occur — Method of overflow action

off (default) | on

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: DoSatur

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point integer single
-------------------	---

Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

The Simulink PLC Coder software does not support the Simulink Lookup Table Dynamic block. For your convenience, the pplib/Simulink/Lookup Tables library contains an implementation of a dynamic table lookup block using the Prelookup and Interpolation Using Prelookup blocks.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Magnitude-Angle to Complex

Convert magnitude and/or a phase angle signal to complex signal

Library: Simulink / Math Operations
HDL Coder / HDL Floating Point Operations

Description

Supported Operations

The Magnitude-Angle to Complex block converts magnitude and phase angle inputs to a complex output. The angle input must be in rad.

When there are two block inputs, the block supports these combinations of input dimensions:

- Two inputs of equal dimensions
- One scalar input and the other an n-dimensional array

If the block input is an array, the output is an array of complex signals. The elements of a magnitude input vector map to the magnitudes of the corresponding complex output elements. Similarly, the elements of an angle input vector map to the angles of the corresponding complex output elements. If one input is a scalar, it maps to the corresponding component (magnitude or angle) of all the complex output signals.

Effect of Out-of-Range Input on CORDIC Approximations

If you use the CORDIC approximation method [1], the block input for phase angle has these restrictions:

- For signed fixed-point types, the input angle must fall within the range $[-2\pi, 2\pi]$ rad.
- For unsigned fixed-point types, the input angle must fall within the range $[0, 2\pi]$ rad.

This table summarizes the effects of an out-of-range input:

Block Usage	Effect of Out-of-Range Input
Simulation modes	An error appears.
Generated code	Undefined behavior occurs.

When you use the CORDIC approximation, ensure that you use an in-range input for the Magnitude-Angle to Complex block. Avoid relying on undefined behavior for generated code or accelerator modes.

Ports

Input

$|u|$ — Magnitude

scalar | vector | matrix

Magnitude, specified as a real-valued scalar, vector, or matrix.

Dependencies

- To enable this port, set **Input** to Magnitude and angle.

Limitations

- If one input has a floating-point data type, the other input must use the same data type. For example, both signals must be `double` or `single`.
- Fixed-point data types are supported only when you set the **Approximation method** to CORDIC. When one input has a fixed-point data type, the other input must also have a fixed-point data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

$\angle u$ — Radian phase angle

scalar | vector | matrix

Radian phase angle, specified as a real-valued scalar, vector, or matrix. To compute the CORDIC approximation, the input angle must be between:

- $[-2\pi, 2\pi)$ rad, for signed fixed-point types
- $[0, 2\pi)$ rad, for unsigned fixed-point types

For more information, see “Effect of Out-of-Range Input on CORDIC Approximations” on page 1-1075.

Dependencies

- To enable this port, set **Input** to Magnitude and angle.

Limitations

- If one input has a floating-point data type, the other input must use the same data type. For example, both signals must be `double` or `single`.
- Fixed-point data types are supported only when you set the **Approximation method** to CORDIC. If one input has a fixed-point data type, the other input must also have a fixed-point data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Port_1 — Magnitude or radian phase angle

scalar | vector | matrix

Magnitude, or radian phase angle, specified as a real-valued scalar, vector, or matrix.

- When you set **Input** to Magnitude, you specify the magnitude at the input port, and the angle on the dialog box.

- When you set **Input** to **Angle**, you specify the angle at the input port, and the magnitude on the dialog box.

Dependencies

To enable this port, set **Input** to **Magnitude** or **Angle**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Port_1 — Complex signal

`scalar` | `vector` | `matrix`

Complex signal, formed from the magnitude and phase angle you specify.

If the block input is an array, the output is an array of complex signals. The elements of a magnitude input vector map to the magnitudes of the corresponding complex output elements. Similarly, the elements of an angle input vector map to the angles of the corresponding complex output elements. If one input is a scalar, it maps to the corresponding component (magnitude or angle) of all the complex output signals.

Data Types: `single` | `double` | `fixed point`

Parameters

Input — Type of input

`Magnitude (default)` | `Angle` | `Magnitude and angle`

Specify the kind of input: a magnitude input, an angle input, or both.

Programmatic Use

Block Parameter: `Input`

Type: `character vector`

Values: `'Magnitude'` | `'Angle'` | `'Magnitude and angle'`

Default: `'Magnitude and angle'`

Angle — Phase angle of output

`0` (default) | `real-valued scalar, vector, or matrix`

Constant phase angle of the output signal, in rad. To compute the CORDIC approximation, the input angle must be between:

- $[-2\pi, 2\pi)$ rad, for signed fixed-point types
- $[0, 2\pi)$ rad, for unsigned fixed-point types

For more information, see “Effect of Out-of-Range Input on CORDIC Approximations” on page 1-1075.

Dependencies

To enable this parameter, set **Input** to **Magnitude**.

Programmatic Use

Block Parameter: `ConstantPart`

Type: `character vector`

Values: constant scalar

Default: '0'

Magnitude — Magnitude of output

0 (default) | real-valued scalar, vector, or matrix

Constant magnitude of the output signal, specified as a real-valued scalar, vector, or matrix.

Dependencies

To enable this parameter, set **Input** to Angle.

Programmatic Use

Block Parameter: ConstantPart

Type: character vector

Values: real-valued scalar, vector, or matrix

Default: '0'

Approximation method — CORDIC or none

None (default) | CORDIC

Specify the type of approximation for computing output.

Approximation Method	Data Types Supported	When to Use This Method
None (default)	Floating point	You want to use the default Taylor series algorithm.
CORDIC	Floating point and fixed point	You want a fast, approximate calculation.

When you use the CORDIC approximation, follow these guidelines for the input angle:

- For signed fixed-point types, the input angle must fall within the range $[-2\pi, 2\pi)$ rad.
- For unsigned fixed-point types, the input angle must fall within the range $[0, 2\pi)$ rad.

The block uses the following data type propagation rules:

Data Type of Magnitude Input	Approximation Method	Data Type of Complex Output
Floating point	None or CORDIC	Same as input
Signed, fixed point	CORDIC	$\text{fixdt}(1, WL + 2, FL)$ where WL and FL are the word length and fraction length of the magnitude
Unsigned, fixed point	CORDIC	$\text{fixdt}(1, WL + 3, FL)$ where WL and FL are the word length and fraction length of the magnitude

Programmatic Use

Block Parameter: ApproximationMethod

Type: character vector

Values: 'None' | 'CORDIC'

Default: 'None'

Number of iterations — Number of iterations for CORDIC algorithm

11 (default) | positive integer, less than or equal to word length of fixed-point input

Number of iterations to perform the CORDIC algorithm. The range of possible values depends on the data type of the input:

Data Type of Block Inputs	Value You Can Specify
Floating point	A positive integer
Fixed point	A positive integer that does not exceed the word length of the magnitude input or the word length of the phase angle input, whichever value is smaller

Dependencies

To enable this parameter, set **Approximation method** to CORDIC.

Programmatic Use

Block Parameter: NumberOfIterations

Type: character vector

Values: positive integer, less than or equal to word length of fixed-point input

Default: '11'

Scale output by reciprocal of gain factor — Scale real and imaginary parts of complex output

on (default) | off

Select this check box to scale the real and imaginary parts of the complex output by a factor of (1/ CORDIC gain). This value depends on the number of iterations you specify. As the number of iterations goes up, the value approaches 1.647.

This check box is selected by default, which leads to a more numerically accurate result for the complex output, $X + iY$. However, scaling the output adds two extra multiplication operations, one for X and one for Y .

Dependencies

To enable this parameter, set **Approximation method** to CORDIC.

Programmatic Use

Block Parameter: ScaleReciprocalGainFactor

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Block Characteristics**

Data Types	double single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About**CORDIC**

CORDIC is an acronym for COordinate Rotation DIgital Computer. The Givens rotation-based CORDIC algorithm is one of the most hardware-efficient algorithms available because it requires only iterative shift-add operations (see References). The CORDIC algorithm eliminates the need for explicit multipliers. Using CORDIC, you can calculate various functions such as sine, cosine, arc sine, arc cosine, arc tangent, and vector magnitude. You can also use this algorithm for divide, square root, hyperbolic, and logarithmic functions.

Increasing the number of CORDIC iterations can produce more accurate results, but doing so increases the expense of the computation and adds latency.

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

For a block that has additional latency, the **Approximation method** is CORDIC. The number of additional cycles iterations is +1.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Restrictions

The Magnitude-Angle to Complex block supports only the HDL code generation for a floating-point data type. Fixed-point data types are supported only when you set **Approximation method** to CORDIC.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The Magnitude-Angle to Complex block supports fixed-point and base integer data types when you set **Approximation method** to CORDIC.

Introduced before R2006a

Manual Switch

Switch between two inputs

Library: Simulink / Signal Routing

Description

The Manual Switch block is a toggle switch that selects one of its two inputs to pass through to the output. To toggle between inputs, double-click the block. You control the signal flow by setting the switch before you start the simulation or by changing the switch while the simulation is executing. The Manual Switch block retains its current state when you save the model.

To programmatically toggle the switch, set the `set_param sw` property to '0' or '1'. For example, to connect the second input to the output:

```
set_param(gcb, 'sw', '0')
```

To connect the first input to the output:

```
set_param(gcb, 'sw', '1')
```

Note Double-clicking the Manual Switch block does not open the block dialog box. Instead, it toggles the input choice.

Ports

Input

Port_1 — First input signal

scalar | vector

First of two inputs to the Manual Switch block. The block propagates the selected input to the output. To select the input signal, toggle the switch by double-clicking the block.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Port_2 — Second input signal

scalar | vector

Second of two inputs to the Manual Switch block. The block propagates the selected input to the output. To select the input signal, toggle the switch by double-clicking the block.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Output signal

scalar | vector

Output signal propagated from either the first or second input signal.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

To view the block parameters, right-click the block and select **Block Parameters** (ManualSwitch).

Allow the two inputs to differ in size (Results in variable-size output signal) — Allow inputs of different sizes

off (default) | on

Select this check box to allow inputs with different sizes and propagate the selected input signal size to the output signal. If you clear the box, the block expands scalar inputs to have the same dimensions as nonscalar inputs. See “Scalar Expansion of Inputs and Parameters”.

Programmatic Use

Parameter: varsize

Type: character vector

Value: 'on' | 'off'

Default: 'off'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes

Zero-Crossing Detection	no
--------------------------------	----

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code.

Fixed-Point Conversion

Manual Variant Sink

Switch between multiple variant choices at output

Library: Simulink / Signal Routing

Description

The Manual Variant Sink block is a toggle switch that activates one of its variant choices at the output to pass the input.

The block can have two or more output ports and has one input port. Each output port is associated with a variant control. To change the number of output ports, right-click the block and select **Mask Parameters**, then type a value in the **Number of choices** box.

To toggle between the variant choices at output, double-click the block. The block displays the active choice with a line connecting the input to the output. The block propagates the active variant choice at output and discards the blocks connected to inactive output ports during simulation.

Note

- Double-clicking the Manual Variant Sink block does not open the block dialog box instead it toggles the output choice.
 - Changing the active choice during compile, simulation, or paused states is not supported.
-

Ports

Input

Port_1 – Input signal

scalar | vector

Input signal passed to the active output port.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 – First variant output

scalar | vector

First variant output signal. The block passes the input signal to this output port when you connect the toggle switch to this port.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Port_n — nth variant output

scalar | vector

nth variant output signal. The block passes the input signal to this output port when you connect the toggle switch to this port.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

To access the block parameter, right-click the block and select **Mask > Mask Parameters**.

Number of choices — Number of output choices

2 (default) | scalar

Specify the number of variant output ports.

Programmatic Use

Block Parameter: NumChoices

Type: character vector

Value: integer

Default: '2'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

Manual Variant Source

Switch between multiple variant choices at input

Library: Simulink / Signal Routing

Description

The Manual Variant Source block is a toggle switch that activates one of its variant choices at the input to pass through to the output.

A Manual Variant Source block can have two or more input ports and has one output port. Each input port is associated with a variant control. To change the number of input ports, right-click the block and select **Mask Parameters**, then type a value in the **Number of choices** box.

To toggle between the variant choices at input, double-click the block. The block displays the active choice with a line connecting the input to the output. The block propagates the active variant choice at input directly to the output and discards the blocks connected to inactive input ports during simulation.

Note

- Double-clicking the Manual Variant Source block does not open the block dialog box instead it toggles the output choice.
 - Changing the active choice during compile, simulation, or paused states is not supported.
-

Ports

Input

Port_1 — First variant input signal

scalar | vector

First variant input signal. The block passes this input signal to the output port when you connect the toggle switch to this port.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Port_n — nth variant input signal

scalar | vector

nth variant input signal. The block passes this input signal to the output port when you connect the toggle switch to this port.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 – Output signal

scalar | vector

Output signal passed from the active variant input signal.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

To access the block parameter, right-click the block and select **Mask > Mask Parameters**.

Number of choices – Number of input choices

2 (default) | scalar

Specify the number of variant input ports.

Programmatic Use

Block Parameter: NumChoices

Type: character vector

Value: integer

Default: '2'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no

Math Function

Perform mathematical function

Library: Simulink / Math Operations
HDL Coder / Math Operations

Description

The Math Function block performs many common mathematical functions.

You can select one of these functions from the **Function** parameter list in Math Function block.

Function	Description	Mathematical Expression	MATLAB Equivalent
exp	Exponential	e^u	exp
log	Natural logarithm	$\ln u$	log
10^u	Power of base 10	10^u	10.^u (see power)
log10	Common (base 10) logarithm	$\log u$	log10
magnitude^2	Complex modulus	$ u ^2$	real(u).^2 + imag(u).^2 (see real, imag, and power)
square	Power 2	u^2	u.^2 (see power)
pow	Power	$\text{sign}(u) * u ^v$ (default, applied only for even-order roots) or u^v	power
conj	Complex conjugate	\bar{u}	conj
reciprocal with Exact method	Reciprocal	$1/u$	1./u (see rdivide)
reciprocal with Newton-Raphson method	Reciprocal	See "Newton-Raphson Reciprocal Algorithm Method" on page 1-1093	None
hypot	Square root of sum squares	$(u^2+v^2)^{0.5}$	hypot
rem	Remainder after division	—	rem
mod	Modulus after division	—	mod

Function	Description	Mathematical Expression	MATLAB Equivalent Expression
transpose	Transpose	u^T	<code>u.'</code> (see "Array vs. Matrix Operations")
hermitian	Complex conjugate transpose	u^H	<code>u'</code> (see "Array vs. Matrix Operations")

Tip To perform square root calculations, use the Sqrt block.

The block output is the result of the operation of the function on the input or inputs. The functions support these types of operations.

Function	Scalar Operations	Element-Wise Vector and Matrix Operations	Vector and Matrix Operations
exp	Yes	Yes	Not applicable
log	Yes	Yes	Not applicable
10 ^u	Yes	Yes	Not applicable
log10	Yes	Yes	Not applicable
magnitude ²	Yes	Yes	Not applicable
square	Yes	Yes	Not applicable
pow	Yes	Yes	Not applicable
conj	Yes	Yes	Not applicable
reciprocal with Exact method	Yes	Yes	Not applicable
reciprocal with Newton-Raphson method	Yes	Yes	Not applicable
hypot	Yes, on two inputs	Yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	—
rem	Yes, on two inputs	Yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	Not applicable
mod	Yes, on two inputs	Yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	Not applicable
transpose	Yes	—	Yes

Function	Scalar Operations	Element-Wise Vector and Matrix Operations	Vector and Matrix Operations
hermitian	Yes	—	Yes

The name of the function and the appropriate number of input ports appear on the block.

Tip Use the Math Function block when you want vector or matrix output.

Newton-Raphson Reciprocal Algorithm Method

The reciprocal function that has the Newton-Raphson algorithm method calculates the reciprocal by using the Newton-Raphson approximation method. The function uses recursive approximation to find better approximations to the roots of a real-value function.

The reciprocal of a real number a is defined as a zero of the function:

$$f(x) = \frac{1}{x} - a$$

Simulink chooses an initial estimate in the range $0 < x_0 < \frac{2}{a}$, because this is the domain of convergence for the function.

To successively calculate the roots of the function, specify the **Number of iterations** parameter. The process is repeated as follows:

$$x_{i+1} = x_i - \frac{f(x_i)}{f'(x_i)} = x_i + (x_i - ax_i^2) = x_i \cdot (2 - ax_i)$$

$f'(x)$ is the derivative of the function $f(x)$.

Data Type Support

This table lists the input data types that each function of the block can support.

Function	Single	Double	Half*	Boolean	Built-In Integer	Fixed Point
exp	Yes	Yes	Yes	—	—	—
log	Yes	Yes	Yes	—	—	—
10 ^u	Yes	Yes	Yes	—	—	—
log10	Yes	Yes	Yes	—	—	—
magnitude ²	Yes	Yes	Yes	—	Yes	Yes
square	Yes	Yes	Yes	—	Yes	Yes
pow	Yes	Yes	Yes	—	—	—
conj	Yes	Yes	Yes	—	Yes	Yes

Function	Single	Double	Half*	Boolean	Built-In Integer	Fixed Point
reciprocal with Exact method	Yes	Yes	Yes	—	Yes	Yes
reciprocal with Newton-Raphson method (for more information, see “Output” on page 1-1095)	Yes	Yes	—	—	Yes	Yes
hypot	Yes	Yes	Yes	—	—	—
rem	Yes	Yes	Yes	—	Yes	—
mod	Yes	Yes	Yes	—	Yes	—
transpose	Yes	Yes	Yes	Yes	Yes	Yes
hermitian	Yes	Yes	Yes	—	Yes	Yes

For more information on half-precision arithmetic operations, see “The Half-Precision Data Type in Simulink” (Fixed-Point Designer).

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal specified as a scalar, vector, or matrix. Supported modes accept real and complex inputs, except for `reciprocal`, which does not accept complex fixed-point inputs. See Description on page 1-1091.

Dependencies

Data type support for this block depends on the **Function** that you select and the size of the inputs. For more information, see “Data Type Support” on page 1-1093.

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Port_2 — Input signal

scalar | vector | matrix

Input signal specified as a scalar, vector, or matrix. Supported modes accept real and complex inputs, except for `reciprocal`, which does not accept complex fixed-point inputs.

Dependencies

To enable this port, set **Function** to `hypot`, `rem`, or `mod`.

Data type support for this block depends on the **Function** that you select, and the size of the inputs. For more information, see “Data Type Support” on page 1-1093.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Result of the operation of the function on the input or inputs

scalar | vector | matrix

Output signal specified as a scalar, vector, or matrix. The dimensions of the block output depend on the **Function** that you select and the size of the inputs. The block output is real or complex, depending on what you select for **Output signal type**. See Description on page 1-1091.

reciprocal with Newton-Raphson Method

The reciprocal with Newton-Raphson method output data type depends on the input data type:

Input Data Type	Output Data Type
single	single
double	double
built-in integer	built-in integer
built-in fixed-point	built-in fixed-point
fi (value, 0, word_length, fraction_length)	fi (value, 0, word_length, word_length-fraction_length-1)
fi (value, 1, word_length, fraction_length)	fi (value, 1, word_length, word_length-fraction_length-2)

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Function — Math function

exp (default) | log | 10^u | log10 | magnitude² | square | pow | conj | reciprocal | hypot | rem | mod | transpose | hermitian

Specify the mathematical function. For more information about the options for this parameter, see Description on page 1-1091.

Dependency

Setting **Function** to pow enables the **Signed power** parameter.

Programmatic Use

Block Parameter: Operator

Type: character vector

Values: 'exp' | 'log' | '10^u' | 'log10' | 'magnitude²' | 'square' | 'pow' | 'conj' | 'reciprocal' | 'hypot' | 'rem' | 'mod' | 'transpose' | 'hermitian'

Default: 'exp'

Algorithm method — Algorithm method for reciprocal function

Exact (default) | Newton-Raphson

Algorithm method for reciprocal function, specified as Exact or Newton-Raphson. To calculate reciprocal with the Newton-Raphson approximation method, select Newton-Raphson. Otherwise, select Exact.

Dependency

Setting **Function** to reciprocal enables this parameter.

Programmatic Use

Block Parameter: AlgorithmType

Type: character vector

Values: 'Exact' | 'Newton-Raphson'

Default: 'Exact'

Signed power — Power signedness

on (default) | off

When calculating power, specified as on or off, take into account sign of the input signal.. This parameter applies only for even-order roots, such as $u^{1/2}$, $u^{1/4}$, and so forth.

- on — Calculate power of the absolute value of the input, multiplied by the sign of the input.
- off — Calculate power of the actual input value. If the first input is negative and the second input is an even-order root, returns nan.

Dependency

Setting **Function** to pow enables this parameter.

Programmatic Use

Block Parameter: SignedPower

Type: character vector

Values: 'on' | 'off' |

Default: 'on'

Output signal type — Complexity of output signal

auto (default) | real | complex

Specify the output signal type of the Math Function block as auto, real, or complex.

Function	Input Signal Type	Output Signal Type		
		Auto	Real	Complex
exp, log, 10u, log10, square, pow, reciprocal, conjugate, transpose, hermitian	real	real	real	complex
	complex	complex	error	complex

Function	Input Signal Type	Output Signal Type		
		Auto	Real	Complex
magnitude squared	real	real	real	complex
	complex	real	real	complex
hypot, rem, mod	real	real	real	complex
	complex	error	error	error

Programmatic Use**Block Parameter:** OutputSignalType**Type:** character vector**Values:** 'auto' | 'real' | 'complex'**Default:** 'auto'**Number of iterations — Number of Newton-Raphson iterations**

3 (default) | scalar

Number of Newton-Raphson iterations, specified as a scalar.

Dependencies

To enable this parameter, set:

- **Function** to reciprocal.
- **Algorithm method** to Newton-Raphson.

Programmatic Use**Block Parameter:** Iterations**Type:** character vector**Values:** '3' | scalar**Default:** '3'**Sample time — Sample time value other than -1**

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see "Specify Sample Time".

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see "Blocks for Which Sample Time Is Not Recommended".

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Signal Attributes****Output minimum — Minimum output value for range checking**

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output data type — Specify the output data type

Inherit: Same as first input (default) | Inherit: Inherit via internal rule |

Inherit: Inherit via back propagation | double | single | half | int8 | uint8 | int16 |

```
uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) |
fixdt(1,16,2^0,0) | <data type expression>
```

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

- To enable this parameter, set the **Function** to `magnitude^2`, `square`, or `reciprocal`.
- For the `magnitude^2` and `square`, when input is a floating-point data type smaller than single precision, the `Inherit: Inherit via internal rule` output data type depends on the setting of the “Inherit floating-point output type smaller than single precision” configuration parameter. Data types are smaller than single-precision when the number of bits needed to encode the data type is less than the 32 bits needed to encode the single precision data type. For example, `half` and `int16` are smaller than single precision.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Same as first input'` | `'Inherit: Inherit via back propagation'` | `'double'` | `'single'` | `'half'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`

Default: `'Inherit: Same as first input'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Dependencies

To enable this parameter, set the **Function** to `magnitude^2`, `square`, or `reciprocal`.

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Integer rounding mode — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Dependencies

To enable this parameter, set the **Function** to `magnitude^2`, `square`, or `reciprocal`.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Choose the behavior when integer overflow occurs

`on` (default) | `boolean`

Action	Rationale	Overflows	Example
Select Saturate on integer overflow check box.	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select Saturate on integer overflow check box.	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. The code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Dependencies

To enable this parameter, set the **Function** to `magnitude^2`, `square`, `conj`, `reciprocal`, or `hermitian`.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Value: `'off'` | `'on'`

Default: `'on'`

Block Characteristics

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

Function	Architecture	Description
<code>conj</code>	<code>ComplexConjugate</code>	Calculate complex conjugate.
<code>hermitian</code>	<code>Hermitian</code>	Calculate hermitian.
<code>transpose</code>	<code>Transpose</code>	Calculate array transpose. See Math Function in the Simulink documentation.

Reciprocal Architecture

You can generate HDL code for single-precision floating-point data types in native floating-point mode by using Math architecture for `reciprocal` function. The `reciprocal` function in the Math Function block also supports the architectures listed in the table.

Architecture	Parameters	Additional Cycles of Latency	Description
Reciprocal	None	0	Calculate reciprocal as 1/N, using the HDL divide (/) operator to implement the division.
ReciprocalRsqrBasedNewton	Iterations	Signed input: Iterations + 5 Unsigned input: Iterations + 3	Use the iterative Newton method. Select this option to optimize area. The default value for Iterations is 3. The recommended value for Iterations is from 2 through 10. If Iterations is outside the recommended range, HDL Coder generates a message.
ReciprocalRsqrBasedNewtonSingleRate	Iterations	Signed input: (Iterations * 4) + 8 Unsigned input: (Iterations * 4) + 6	Use the single rate pipelined Newton method. Select this option to optimize speed, or if you want a single rate implementation. The default value for Iterations is 3. The recommended value for Iterations is from 2 through 10. If Iterations is outside the recommended range, the coder generates a message.

Architecture	Parameters	Additional Cycles of Latency	Description
ShiftAdd	UsePipelines	<p>Signed input: (Input word length + 4)</p> <p>Unsigned input: (Input word length + 4)</p>	<p>Perform reciprocal operation on a fixed-point input by using a non-restoring division algorithm that performs multiple shift and add operations to compute the reciprocal. This architecture provides improved accuracy compared to the Newton-Raphson approximation method.</p> <p>When you use this architecture, to achieve a higher maximum clock frequency on the target FPGA device, leave the UsePipelines HDL block property to on.</p> <p>When you use fixed-point data types, following criteria must be satisfied for generating the HDL code:</p> <ul style="list-style-type: none"> • Input word length (WL) must be less than or equal to 63. • $[WL \text{ input} + \text{Abs}(\text{FL Sum})]$ must be less than or equal to 63. Where, FL Sum is given by, $\text{FL sum} = \text{FL input} + \text{FL output}$

When you set the algorithm method to Exact, you can select these options in HDL Block properties of this block.

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

HDL code generation also supports the Newton-Raphson algorithm method for reciprocal function. Select the **Algorithm method** as Newton-Raphson to use these architectures for reciprocal function in the Math Function block.

Architecture	Additional Cycles of Latency	Description
ReciprocalNewton (default)	Iterations + 1	<p>Use the multirate implementation of the iterative Newton method. Select this option to optimize area for your design.</p> <p>The default value for <code>Iterations</code> is 3.</p> <p>The recommended value for <code>Iterations</code> is from 2 through 10. If <code>Iterations</code> value is outside the recommended range, HDL Coder displays a message.</p>
ReciprocalNewtonSingleRate	(Iterations * 2) + 1	<p>Use the single rate pipelined Newton method. Select this option to optimize speed for your design, or if you want a single rate implementation.</p> <p>The default value for <code>Iterations</code> is 3.</p> <p>The recommended value for <code>Iterations</code> is between 2 and 10. If <code>Iterations</code> value is outside the recommended range, HDL Coder displays a message.</p>

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Native Floating Point	
CheckResetToZero	Use this property for the <code>mod</code> and <code>rem</code> functions of the Math Function block. If you have numbers <code>a</code> and <code>b</code> such that the quotient <code>a/b</code> is close to an integer, this setting treats <code>a</code> as an integral multiple of <code>b</code> , and <code>rem(a, b) = 0</code> . This result is numerically accurate and matches the simulation results. Calculating this result uses additional resources and increases the area footprint on the target FPGA device. For more information, see “CheckResetToZero” (HDL Coder).
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is <code>inherit</code> . See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , <code>Zero</code> , or <code>Custom</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to <code>Custom</code> . HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).
MaxIterations	Use this property for the <code>mod</code> and <code>rem</code> functions of the Math Function block. If you have numbers <code>a</code> and <code>b</code> that are significantly large integers, you can increase MaxIterations to match the simulation results. Calculating this result uses additional resources and increases the area footprint on the target FPGA device. For more information, see “MaxIterations” (HDL Coder).

Supported Datatypes and Functions in Native Floating-Point

In the Math Function block, these functions are the supported functions with Native Floating-Point.

Math Functions	Supported Floating-Point Datatypes			Complex Data Support
	Half	Single	Double	
<code>exp</code>	No	Yes	No	No

Math Functions	Supported Floating-Point Datatypes			Complex Data Support
	Half	Single	Double	
hermitian	No	Yes	No	Yes

Restrictions

When you use a reciprocal implementation:

- Input must be scalar and must have integer or fixed-point (signed or unsigned) data type.
- The output must be scalar and have integer or fixed-point (signed or unsigned) data type.
- Only the Zero rounding mode is supported.
- The **Saturate on integer overflow** option on the block must be selected.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The Math Function block only supports fixed-point conversion in certain configurations. For more information, see the Block Support Table.

MATLAB Function

Include MATLAB code in models that generate embeddable C code

Library: Simulink / User-Defined Functions
HDL Coder / User-Defined Functions

Description

With a MATLAB Function block, you can write a MATLAB function for use in a Simulink model. The MATLAB function executes for simulation and generates code for a Simulink Coder target. If you are new to Simulink and MATLAB products, see “Implement MATLAB Functions in Simulink with MATLAB Function Blocks” for an overview.

Double-clicking the MATLAB Function block opens the **MATLAB Function Block Editor**, where you write the MATLAB function. The example model `call_stats_block2` discussed in “Implement MATLAB Functions in Simulink with MATLAB Function Blocks” uses the following function in the **MATLAB Function Block Editor**:

```
function [mean,stdev] = stats(vals)

% Calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals,len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals,"-+");

function mean = avg(array,size)
mean = sum(array)/size;
```

The function specifies the input and output data in the function declaration statement as arguments and return values. The argument and return values of the preceding example function correspond to the inputs and outputs of the block in the `call_stats_block2` model.

You can also define variables, add an input trigger, and create function call outputs by using the Model Explorer or the **Symbols** pane. For more information, see “Create and Define MATLAB

Function Block Variables”, “Manage the Input Trigger of a MATLAB Function Block”, and “Manage Function Call Outputs of a MATLAB Function Block”.

The MATLAB Function block generates efficient embeddable code based on an analysis that determines the size, class, and complexity of each variable. This analysis imposes the following restrictions:

- The first assignment to a variable defines its, size, class, and complexity.

See “Best Practices for Defining Variables for C/C++ Code Generation”.

- You cannot reassign variable properties after the initial assignment except when using variable-size data or reusing variables in the code for different purposes.

See “Reassignment of Variable Properties”.

In addition to language restrictions, the MATLAB Function block supports a subset of the functions available in MATLAB. These functions include functions in common categories, such as:

- Arithmetic operators like `plus`, `minus`, and `power`. For more information, see “Array vs. Matrix Operations”.
- Matrix operations like `size`, and `length`
- Advanced matrix operations like `lu`, `inv`, `svd`, and `chol`
- Trigonometric functions like `sin`, `cos`, `sinh`, and `cosh`

For more information, see “Functions and Objects Supported for C/C++ Code Generation”.

Note Although the code for this block attempts to produce exactly the same results as MATLAB, differences might occur due to rounding errors. These numerical differences, which might be a few eps initially, can magnify after repeated operations. Reliance on the behavior of `nan` is not recommended. Different C compilers can yield different results for the same computation.

Note New MATLAB Function blocks do not include the `%#codegen` directive, but check for errors as if it is included. Adding the `%#codegen` directive to a MATLAB Function block does not affect error checking. For more information see “Compilation Directive `%#codegen`”.

To support visualization of data, the MATLAB Function block supports calls to MATLAB functions for simulation only. See “Use MATLAB Engine to Execute a Function Call in Generated Code” to understand some of the limitations of this capability, and how it integrates with code analysis for this block. If these function calls do not directly affect any of the Simulink inputs or outputs, the calls do not appear in Simulink Coder generated code.

From MATLAB Function blocks, you can also call functions defined in a Simulink Function block. You can call Stateflow functions with **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** checked in the chart Properties dialog box.

In the **Symbols** pane, you can declare a block input to be a Simulink parameter instead of a port. The MATLAB Function block also supports inheritance of types and size for inputs, outputs, and parameters. You can also specify these properties explicitly. See “Define and Modify Variable Data Types”, “Specify Size of MATLAB Function Block Variables”, and “Configure MATLAB Function Block Parameter Variables” for descriptions of variables that you use in MATLAB Function blocks.

Recursive calls are not allowed in MATLAB Function blocks.

By default, MATLAB Function blocks have direct feedthrough enabled. To disable it, clear the **Allow direct feedthrough** property. Nondirect feedthrough semantics ensure that outputs rely only on the current state. Using nondirect feedthrough enables you to use MATLAB Function blocks in a feedback loop and prevent algebraic loops. For more information, see “Use Nondirect Feedthrough in a MATLAB Function Block”.

Ports

Input

u — Input port

scalar | vector | matrix

Input port, specified as a scalar, vector, or matrix. Each input variable that you create has a corresponding input port.

Data types supported by MATLAB but not supported by Simulink may not be passed between the Simulink model and the function within the MATLAB Function block. These types may be used within the MATLAB Function block.

For more information on fixed-point support for this block, refer to “Fixed-Point Data Types with MATLAB Function Block” (Fixed-Point Designer) and “MATLAB Function Block with Data Type Override” (Fixed-Point Designer).

Dependencies

To create input ports, open the block and create input variables in the **Symbols** pane. See “Create and Define MATLAB Function Block Variables”.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | string | fixed point | enumerated | bus

Output

y — Output port

scalar | vector | matrix

Output port, specified as a scalar, vector, or matrix. Each output variable that you create has a corresponding output port.

Dependencies

To create output ports, open the block and create output variables in the **Symbols** pane. See “Create and Define MATLAB Function Block Variables”.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | string | fixed point | enumerated | bus

Parameters

Main

Show port labels — Display options for port labels

FromPortIcon (default) | none | FromPortBlockName | SignalName

Select how to display port labels on the MATLAB Function block icon.

- none - Do not display port labels.
- FromPortIcon - Display the name of the input and output variables.
- FromPortBlockName - Display the name of the input and output variables.
- SignalName - If the signal connected to the port is named, display the signal name. Otherwise, display the name of the variables.

Programmatic Use

Parameter: ShowPortLabels

Type: string scalar or character vector

Value: "none" | "FromPortIcon" | "FromPortBlockName" | "SignalName"

Default: "FromPortIcon"

Read/Write permissions — Levels of access to contents of block

ReadWrite (default) | ReadOnly | NoReadOrWrite

Control user access to the contents of the MATLAB Function block.

- ReadWrite - Enable opening and modifying of MATLAB Function block contents.
- ReadOnly - Enable opening of the MATLAB Function block.
- NoReadOrWrite - Disable opening or modifying of the MATLAB Function block.

Note When you attempt to view the contents of a MATLAB Function block whose **Read/Write permissions** parameter is NoReadOrWrite, the block does not respond. For example, when you double-click the MATLAB Function block, Simulink does not open the table contents and does not display messages.

Programmatic Use

Parameter: Permissions

Type: string scalar or character vector

Value: "ReadWrite" | "ReadOnly" | "NoReadOrWrite"

Default: "ReadWrite"

Minimize algebraic loop occurrences — Option to eliminate artificial algebraic loops

off (default) | on

Whether the block attempts to eliminate artificial algebraic loops that include the atomic unit during simulation.

- **off** - Do not try to eliminate any artificial algebraic loops that include the atomic unit.
- **on** - Try to eliminate any artificial algebraic loops that include the atomic unit.

Programmatic Use

Parameter: MinAlgLoopOccurrences

Type: string scalar or character vector

Value: "off" | "on"

Default: "off"

Schedule as — Type of scheduling

Sample Time (default) | Periodic Partition | Aperiodic Partition

Specify how to schedule the MATLAB Function block.

- **Sample time** - Specify whether code in the MATLAB Function block must run at the same rate or can run at different rates.
- **Periodic Partition** - Schedule the MATLAB Function block code with a periodic partition. Specify a partition name and a sample time corresponding to the rate at which the partition runs.
- **Aperiodic Partition** - Schedule the MATLAB Function block code with an aperiodic partition. Specify a partition name.

Programmatic Use

Parameter: ScheduleAs

Type: string scalar or character vector

Value: "SampleTime" | "DiscretePartition" | "UnconstrainedPartition"

Default: "SampleTime"

Sample time (-1 for inherited) — Specify time interval

-1 (default) | [Ts 0]

Specify whether variables in this block must run at the same rate or can run at different rates.

- If variables in the MATLAB Function block can run at different rates, specify the sample time as inherited (-1).
- If variables must run at the same rate, specify the sample time, Ts, corresponding to this rate.

Programmatic Use

Parameter: SystemSampleTime

Type: string scalar or character vector

Value: "-1" | "[Ts 0]"

Default: "-1"

Code Generation

To enable these parameters, you must have a Simulink Coder or Embedded Coder license.

Function packaging — Code format

Auto (default) | Inline | Nonreusable function | Reusable function

Select the code format the block uses to generate code for an atomic (nonvirtual) unit.

- **Auto** - Simulink Coder and Embedded Coder choose the optimal format for you based on the type and number of instances of the MATLAB Function block that exist in the model.
- **Inline** - Simulink Coder and Embedded Coder inline the MATLAB Function block unconditionally.
- **Nonreusable function** - Simulink Coder explicitly generates a separate function in a separate file.
- **Reusable function** - Simulink Coder and Embedded Coder generate a function with arguments that allows reuse of block code when a model includes multiple instances of the block.

This option also generates a function with arguments that allows MATLAB Function block code to be reused in the generated code of a model reference hierarchy that includes multiple instances of a MATLAB Function block across referenced models. In this case, the block must be in a library.

For more information, see:

- “Generate Code and Executables for Individual Subsystems” (Simulink Coder)
- “Generate Subsystem Code as Separate Function and Files” (Simulink Coder)
- “Generate Reusable Code from Library Subsystems Shared Across Models” (Simulink Coder)

Tips

- When you want to represent multiple instances of a MATLAB Function block to be represented as one reusable function, you can designate each one of them as `Auto` or as `Reusable function`. It is best to use one or the other, as using both creates two reusable functions, one for each designation. The outcomes of these choices differ only when reuse is not possible. Selecting `Auto` does not allow control of the function or file name for the MATLAB Function block code.
- The `Reusable function` and `Auto` options both try to determine if multiple instances of a MATLAB Function block exist and if the code can be reused. The difference between the options' behavior is that when reuse is not possible:
 - `Auto` yields inlined code, or if circumstances prohibit inlining, separate functions for each MATLAB Function block instance.
 - `Reusable function` yields a separate function with arguments for each MATLAB Function block instance in the model.
- If you select `Reusable function` while your generated code is under source control, set **File name options** to `Use subsystem name`, `Use function name`, or `User specified`. Otherwise, the names of your code files change whenever you modify your model, which prevents source control on your files.

Programmatic Use

Parameter: RTWSystemCode

Type: string scalar or character vector

Value: "Auto" | "Inline" | "Nonreusable function" | "Reusable function"

Default: "Auto"

Function name options — How to name generated function

Auto (default) | Use subsystem name | User specified

Select how Simulink Coder names the function it generates for the block.

If you have an Embedded Coder license, you can control function names with options on the Configuration Parameter **Code Generation > Identifiers** pane.

- `Auto` - Assign a unique function name using the default naming convention, `model_block()`, where `model` is the name of the model and `block` is the name of the block (or that of an identical one when code is being reused).
- `Use subsystem name` - Use the MATLAB Function block name as the function name. By default, the function name uses the naming convention `model_block`.

Note When a MATLAB Function block is in a library block and the **Function packaging** parameter is set to `Reusable function`, if you set the `Use subsystem name` option, the code generator uses the name of the library block for the function name and file name.

- `User specified` - Enable the **Function name** field. Enter any legal C or C++ function name, which must be unique.

For more information, see “Generate Subsystem Code as Separate Function and Files” (Simulink Coder).

Dependencies

To enable this parameter, set **Function packaging** to `Nonreusable function` or `Reusable function`.

Programmatic Use

Parameter: `RTWFcnNameOpts`

Type: string scalar or character vector

Value: `"Auto" | "Use subsystem name" | "User specified"`

Default: `"Auto"`

Function name — Name of function for block code

`"" (default) | function name`

Name of the function for the block code.

Use this parameter if you want to give the function a specific name instead of using an autogenerated name or the block name. For more information, see “Generate Subsystem Code as Separate Function and Files” (Simulink Coder).

Dependencies

To enable this parameter, set the **Function name options** parameter to `User specified`.

Programmatic Use

Parameter: `RTWFcnName`

Type: string scalar or character vector

Value: `"" | "<function name>"`

Default: `" "`

File name options — How to name generated file

`Auto (default) | Use subsystem name | Use function name | User specified`

How Simulink Coder names the separate file for the function it generates for the block.

- `Auto` - Depending on the configuration of the block and how many instances are in the model, `Auto` yields different results:
 - If the code generator does *not* generate a separate file for the block, the block code is generated within the code module generated from the block parent system. If the block parent is the model itself, the block code is generated within `model.c` or `model.cpp`.
 - If you select `Reusable function` for the **Function packaging** parameter and your generated code is under source control, consider specifying a **File name options** value other than `Auto`. This prevents the generated file name from changing due to unrelated model modifications, which is problematic for using source control to manage configurations.
 - If you select `Reusable function` for the **Function packaging** parameter and there are multiple instances of the block in a model reference hierarchy, in order to generate reusable code for the block, **File name options** must be set to `Auto`.
- `Use subsystem name` - The code generator generates a separate file, using the block name as the file name.

Note When **File name options** is set to `Use subsystem name`, the block file changes if the model contains Model blocks, or if a model reference target is being generated for the model. In

these situations, the file name for the MATLAB Function block consists of the block name prefixed by the model name.

- **Use function name** - The code generator uses the function name specified by **Function name options** as the file name.
- **User specified** - This option enables the **File name (no extension)** text entry field. The code generator uses the name you enter as the file name. Enter any file name, but do not include the .c or .cpp (or any other) extension. This file name need not be unique.

Note While a MATLAB Function block source file name need not be unique, you must avoid giving nonunique names that result in cyclic dependencies (for example, sys_a.h includes sys_b.h, sys_b.h includes sys_c.h, and sys_c.h includes sys_a.h).

Dependencies

To enable this parameter, set **Function packaging** to Nonreusable function or Reusable function.

Programmatic Use

Parameter: RTWFileNameOpts

Type: string scalar or character vector

Value: "Auto" | "Use subsystem name" | "Use function name" | "User specified"

Default: "Auto"

File name (no extension) – Name of generated file

"" (default) | file name

Name of the generated file. The file name that you specify does not have to be unique. However, avoid giving non-unique names that result in cyclic dependencies (for example, sys_a.h includes sys_b.h, sys_b.h includes sys_c.h, and sys_c.h includes sys_a.h).

For more information, see “Generate Subsystem Code as Separate Function and Files” (Simulink Coder).

Dependencies

To enable this parameter, set **File name options** to User specified.

Programmatic Use

Parameter: RTWFileName

Type: string scalar or character vector

Value: "" | "<file name>"

Default: ""

Block Characteristics

--------------------------------	----

a Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. Actual data type or capability support depends on block implementation. For best practices of using the MATLAB Function block, see:

- “Design Guidelines for the MATLAB Function Block” (HDL Coder)
- “Generate Instantiable Code for Functions” (HDL Coder)
- “Optimize MATLAB Loops” (HDL Coder)
- “Pipeline MATLAB Expressions” (HDL Coder)

HDL Architecture

MATLAB Function (Default)	This is the default architecture for MATLAB Function blocks with fixed-point data types. When you use this architecture, you can use speed and area optimizations for blocks that surround the MATLAB Function block. The code inside the MATLAB Function block is not optimized.
MATLAB Datapath	This is the default architecture for MATLAB Function blocks with floating-point data types. When you use this architecture, the code generator treats the MATLAB Function block like a regular Subsystem block. By enabling this architecture for fixed-point types, you can use speed and area optimizations for blocks inside the MATLAB Function block and across the MATLAB Function block with other Simulink blocks. This capability enables you to specify additional properties for the MATLAB Function block that you would specify for a Subsystem such as ClockRatePipelining and FlattenHierarchy .

HDL Block Properties

AdaptivePipelining	Automatic pipeline insertion based on the synthesis tool, target frequency, and multiplier word-lengths. The default is <code>inherit</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “AdaptivePipelining” (HDL Coder).
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “BalanceDelays” (HDL Coder).

ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <code>inherit</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “ClockRatePipelining” (HDL Coder).
ConstMultiplierOptimization	Canonical signed digit (CSD) or factored CSD optimization. The default is <code>none</code> . See also “ConstMultiplierOptimization” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is <code>0</code> . For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>off</code> . See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is <code>none</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “DSPStyle” (HDL Coder).
FlattenHierarchy	Remove MATLAB Function block hierarchy from generated HDL code. The default is <code>inherit</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “FlattenHierarchy” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see “InputPipeline” (HDL Coder).
InstantiateFunctions	Generate a VHDL entity or Verilog module for each function. The default is <code>off</code> . See also “InstantiateFunctions” (HDL Coder).
LoopOptimization	Unroll, stream, or do not optimize loops. The default is <code>none</code> . If you set Architecture to <code>MATLAB Datapath</code> , you can only unroll loops. If you want to use loop streaming with the <code>MATLAB Datapath</code> architecture, you can use the streaming optimization by specifying a StreamingFactor . See also “LoopOptimization” (HDL Coder).
MapPersistentVarsToRAM	Map persistent arrays to RAM. The default is <code>off</code> . See also “MapPersistentVarsToRAM” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see “OutputPipeline” (HDL Coder).
ResetType	Suppress reset logic generation. The default is <code>default</code> , which generates reset logic. See also “ResetType” (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is <code>0</code> . See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is <code>0</code> , which implements fully parallel data paths. To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “Streaming” (HDL Coder).

VariablesToPipeline	Warning VariablesToPipeline is not recommended. Use <code>coder.hdl.pipeline</code> instead.
	Insert a pipeline register at the output of the specified variable or variables. Specify the list of variables as a character vector, with spaces separating the variables. To specify this property, set Architecture to MATLAB Function.

Data Type Support

HDL code generation supports half-precision data types for these functions in MATLAB Function block:

all	and, &	any	cast	conj	ctranspose
end	=	eq	==	ge, >=	gt, >
half	inf	int8	int16	int32	int64
isa	iscolumn	isempty	isequal	isfinite	isfloat
isinf	isinteger	islogical	isnan	isnumeric	isreal
isrow	isscalar	isvector	le, <=	length	logical
lt, <	max	min	minus, -	NaN	ndims
ne, ~=	not	numel	or,	plus, +	prod
reshape	single	size	sqrt	sum	times, .*
transpose	uint8	uint16	uint32	uint64	uminus
uplus	vertconcat	-	-	-	-

Complex Data Support

This block supports code generation for complex signals.

See also “Complex Data Type Support” (HDL Coder).

Tunable Parameter Support

HDL Coder supports both tunable and non-tunable parameters with the following data types:

- Scalar
- Vector
- Complex
- Structure
- Enumeration

For details, see “Generate DUT Ports for Tunable Parameters” (HDL Coder) and “Design Guidelines for the MATLAB Function Block” (HDL Coder)

Restrictions

- If the block contains a System object™, block inputs cannot have non-discrete (constant or Inf) sample time.

- HDL Coder does not support a MATLAB Function that contains the same variable as the input and output of the function. For example, this MATLAB code is not supported.

```
function y = myFun(y)
    %#codegen
```

```
y = 3 * y;
```

- The block supports floating-point data types only in the Native Floating Point mode.

For the MATLAB language subset supported for HDL code generation from a MATLAB Function block, see “Supported MATLAB Data Types, Operators, and Control Flow Statements” (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type or capability support depends on block implementation.

MATLAB System

Include System object in model

Library: Simulink / User-Defined Functions
HDL Coder / User-Defined Functions

Description

The MATLAB System block brings existing System objects (based on `matlab.System`) into Simulink. It also enables you to use System object APIs to develop new blocks for Simulink. For more information on this block, see “MATLAB System Block”.

For interpreted execution, the model simulates the block using the MATLAB execution engine.

For code generation, the model simulates the block using code generation (using the subset of MATLAB code supported for code generation). The MATLAB System block supports only a subset of the functions available in MATLAB. See “Functions and Objects Supported for C/C++ Code Generation” for a complete list of functions. These functions include those in common categories, such as:

- “Array vs. Matrix Operations”, like `plus`, `minus`, and `power`
- Matrix operations, like `size` and `length`
- Advanced matrix operations, like `lu`, `inv`, `svd`, and `chol`
- Trigonometric functions, like `sin`, `cos`, `sinh`, and `cosh`

System Objects

To use the MATLAB System block, you must first have a new System object or use an existing one. For more information, see “Integrate System Objects Using MATLAB System Block”.

Ports

Input

In — Signal input to a MATLAB System block

scalar | vector | matrix

The MATLAB System block accepts inputs of the types listed in the Block Characteristics table. It does not support virtual buses as input or output. It does not support nonvirtual buses that contain variable-size signals. For more information, see “Data Types Supported by Simulink”.

For information on fixed-point support for this block, see “Code Acceleration and Code Generation from MATLAB” (Fixed-Point Designer).

The MATLAB System block supports Simulink frames. For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Out — Signal output of a MATLAB System block

`scalar` | `vector` | `matrix`

Signal output of a MATLAB System block that the System object returns.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

System Object Name — Name of the System object

`cell array` (default)

Specify the full name of the user-defined System object class without the file extension. This entry is case sensitive. The class name must exist on the MATLAB path.

You can specify a System object name in one of these ways:

- Enter the name in the text box.
- Click the list arrow attached to the text box. If valid System objects exist in the current folder, the names appear in the list. Select a System object from this list.
- Browse to a folder that contains a valid System object. If the folder is not on your MATLAB path, the software prompts you to add it.

If you need to create a System object, you can create one from a template by clicking **New**.

After you save the System object, the name appears in the **System object name** text box.

Use the full name of the user-defined System object class name. The block does not accept a MATLAB variable that you have assigned to a System object class name.

Programmatic Use

Block Parameter: `System`

Type: `character vector`

Value: name of the System object

Default: `' '`

New — Create a System object from a template

`Basic` (default) | `Advanced` | `Simulink Extension`

Select one of the options for a System object template.

Basic

Starts MATLAB Editor and displays a template for a simple System object using the fewest System object methods.

Advanced

Starts MATLAB Editor and displays a template for a more advanced System object using most of the System object methods.

Simulink Extension

Starts MATLAB Editor and displays a file that contains utilities for customizing the block for Simulink. This is the same file available in MATLAB when you select **New > System Object > Simulink Extension**.

After you save the System object, you can enter the name in the **System object name** text box.

Simulate using — Select the simulation mode

Code generation (default) | Interpreted Execution

Select the simulation mode.

Code generation

On the first model run, simulate and generate code for MATLAB System block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is Code generation, System Objects accept a maximum of 32 inputs.

Interpreted execution

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

Dependency — Dependency parameter for MATLAB System block

auto (default)

After you assign a valid System object class name to the block, the next time you open the block dialog box, the parameter is visible. This parameter appears for every MATLAB System block. You cannot remove it.

- If the block has no tabs, this parameter appears at the bottom of the dialog box.
- If the block has multiple tabs, this parameter appears at the bottom of the first tab of the dialog box.

Saturate on integer overflow — Specify whether overflows saturate

Off (default) | On

On

Overflows saturate to either the minimum or maximum value that the data type can represent. For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent. For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code. Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Dependency

This check box appears when you use the `showFiSettingsImpl` method in the System object.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Treat these inherited Simulink signal types as fi objects — Specify fi data types

Fixed-point (default) | Fixed-point & Integer

Select which inherited data types to treat fi data types,

Fixed-point

Treat fixed-point data types as fi data types.

Fixed-point & Integer

Treat fixed-point and integer data types as fi data types.

c See Variable-Size Signals for more information.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

You can define a System object and use it in a MATLAB System block for HDL code generation.

Tunable Parameter Support

HDL Coder supports tunable parameters with the following data types:

- Numeric
- Fixed point
- Character
- Logical

When using tunable parameters with the MATLAB System block, the tunable parameter should be a Simulink.Parameter object with the StorageClass set to ExportedGlobal.

```
x = Simulink.Parameter
x.Value = 1
x.CoderInfo.StorageClass = 'ExportedGlobal'
```

For details, see “Generate DUT Ports for Tunable Parameters” (HDL Coder).

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

If you use a predefined System object, the HDL block properties available are the same as the properties available for the corresponding block.

By default, the following HDL block properties are available.

ConstMultiplierOptimization	Canonical signed digit (CSD) or factored CSD optimization. The default is none. See also “ConstMultiplierOptimization” (HDL Coder).
------------------------------------	---

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is off. See also “DistributedPipelining” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
LoopOptimization	Unroll, stream, or do not optimize loops. The default is none. See also “LoopOptimization” (HDL Coder).
MapPersistentVarsToRAM	Map persistent arrays to RAM. The default is off. See also “MapPersistentVarsToRAM” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
ResetType	Suppress reset logic generation. The default is default, which generates reset logic. See also “ResetType” (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).
VariablesToPipeline	<p>Warning VariablesToPipeline is not recommended. Use <code>coder.hdl.pipeline</code> instead.</p> <hr/> <p>Insert a pipeline register at the output of the specified MATLAB variable or variables. Specify the list of variables as a character vector, with spaces separating the variables.</p>

Restrictions

- The DUT subsystem must be single-rate.
- Inputs cannot have non-discrete (constant or Inf) sample time.
- To find predefined System objects that are supported for HDL code generation when you use them in the MATLAB System block, see “Predefined System Objects Supported for HDL Code Generation” (HDL Coder).
- If you use a user-defined System object, it must support HDL code generation. For information about user-defined System objects and requirements for HDL code generation, see “HDL Code Generation for System Objects” (HDL Coder).

See also “Generate Code for User-Defined System Objects” (HDL Coder) and “HDL Code Generation for System Objects” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type support depends on block implementation.

Matrix Square

Compute square of input matrix

Library: Simulink / Matrix Operations
 DSP System Toolbox / Math Functions / Matrices and Linear
 Algebra / Matrix Operations

Description

The Matrix Square block computes the square of an M -by- N input matrix, u , by premultiplying with the Hermitian transpose. The equivalent MATLAB code is:

$$y = u' * u$$

The block treats length- M unoriented vector inputs as an M -by-1 matrix. When the input is an M -by- N matrix, the output of the block is an N -by- N matrix.

Applications

The Matrix Square block can be used in a variety of applications:

- General matrix squares — The Matrix Square block computes the output matrix, y , without explicitly forming u' . It is therefore more efficient than other methods for computing the matrix square.
- Sum of squares — When the input is a column vector ($N=1$), the operation of the block is equivalent to a multiply-accumulate (MAC) process, or inner product. The output is the sum of the squares of the input, and is always a real scalar.
- Correlation matrix — When the input is a row vector ($M=1$), the output, y , is the symmetric autocorrelation matrix, or outer product.

Ports

Input

Port_1 — Input matrix

M -by-1 matrix | 1-by- N matrix | M -by- N matrix

Input matrix, specified as an M -by-1, 1-by- N , or M -by- N matrix.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Output matrix

M -by- M matrix | N -by- N matrix

Output matrix, returned as an N -by- N or M -by- M matrix.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Output minimum — Minimum output value for range checking

`[]` (default) | scalar

Minimum output value for range checking that Simulink checks. Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: `OutMin`

Type: character vector

Values: `'[]'` | scalar

Default: `'[]'`

Output maximum — Maximum output value for range checking

`[]` (default) | scalar

Maximum output value for range checking that Simulink checks. Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: `OutMax`

Type: character vector

Values: `'[]'` | scalar

Default: `'[]'`

Output data type — Output data type

`Inherit: Inherit via internal rule`(default) | `Inherit: Inherit via back propagation` | `Inherit: Same as input` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the output data type for this block.

You can select one of these options:

- A rule that specifies how to inherit a data type, such as `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule” (DSP System Toolbox).
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector**Values:** 'Inherit: Same as input' | 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | fixdt(1,16,0) | '<data type expression>'**Default:** 'Inherit: Inherit via internal rule'**Lock output data type setting against changes by the fixed-point tools — Output data type locking**

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output data type** you specify on the block mask. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Integer rounding mode — Rounding mode for fixed-point operations**

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode (DSP System Toolbox) for fixed-point operations.

Programmatic Use**Block Parameter:** RndMeth**Type:** character vector**Values:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'**Default:** 'Floor'**Saturate on integer overflow — Behavior when integer overflow occurs**

off (default) | on

Select this check box to have overflows saturate to the maximum or minimum value that the data type can represent. If you clear this check box, the block wraps all overflows. See Precision and Range (DSP System Toolbox) for more information.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. The code generation process can generally detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Compatibility Considerations

Matrix Square Block Moved to Simulink Matrix Operations Library

Behavior changed in R2021b

The Matrix Square block has been moved from the **DSP System Toolbox > Math Functions > Matrices and Linear Algebra > Matrix Operations** to the **Simulink > Matrix Operations**. All existing models continue to work.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Memory

Output input from previous time step

Library: Simulink / Discrete
HDL Coder / Discrete

Description

The Memory block holds and delays its input by one major integration time step. When placed in an iterator subsystem, it holds and delays its input by one iteration. This block accepts continuous and discrete signals. The block accepts one input and generates one output. Each signal can be a scalar, vector, matrix, or N-D array. If the input is non-scalar, the block holds and delays all elements of the input by the same time step.

You specify the block output for the first time step using the **Initial condition** parameter. Careful selection of this parameter can minimize unwanted output behavior. However, you cannot specify the sample time. This block's sample time depends on the type of solver used, or you can specify to inherit it. The **Inherit sample time** parameter determines whether sample time is inherited or based on the solver.

Tip Avoid using the Memory block when both these conditions are true:

- Your model uses the variable-step solver ode15s or ode113.
 - The input to the block changes during simulation.
-

When the Memory block inherits a discrete sample time, the block is analogous to the Unit Delay block. However, the Memory block does not support state logging. If logging the final state is necessary, use a Unit Delay block instead.

Comparison with Similar Blocks

The Memory, Unit Delay, and Zero-Order Hold blocks provide similar functionality but have different capabilities. Also, the purpose of each block is different.

This table shows recommended usage for each block.

Block	Purpose of the Block	Reference Examples
Unit Delay	Implement a delay using a discrete sample time that you specify. The block accepts and outputs signals with a discrete sample time.	<ul style="list-style-type: none"> • “Engine Timing Model with Closed Loop Control” on page 13-147 (Compression subsystem)

Block	Purpose of the Block	Reference Examples
Memory on page 1-1130	Implement a delay by one major integration time step. Ideally, the block accepts continuous (or fixed in minor time step) signals and outputs a signal that is fixed in minor time step.	<ul style="list-style-type: none"> • “Building a Clutch Lock-Up Model” on page 13-151 (Friction Mode Logic/Lockup FSM subsystem) • “Capture the Velocity of a Bouncing Ball with the Memory Block” on page 12-81
Zero-Order Hold	Convert an input signal with a continuous sample time to an output signal with a discrete sample time.	<ul style="list-style-type: none"> • “Developing the Apollo Lunar Module Digital Autopilot” on page 13-210 • “Radar Tracking Using MATLAB Function Block” on page 13-237

Each block has the following capabilities.

Capability	Memory	Unit Delay	Zero-Order Hold
Specification of initial condition	Yes	Yes	No, because the block output at time $t = 0$ must match the input value.
Specification of sample time	No, because the block can only inherit sample time from the driving block or the solver used for the entire model.	Yes	Yes
Support for frame-based signals	No	Yes	Yes
Support for state logging	No	Yes	No

Bus Support

The Memory block is a bus-capable block. The input can be a virtual or nonvirtual bus signal subject to the following restrictions:

- **Initial condition** must be zero, a nonzero scalar, or a finite numeric structure.
- If **Initial condition** is zero or a structure, and you specify a **State name**, the input cannot be a virtual bus.
- If **Initial condition** is a nonzero scalar, you cannot specify a **State name**.

For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Elements”.

All signals in a nonvirtual bus input to a Memory block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus. See “Modify Sample Times for Nonvirtual Buses” and Bus-Capable Blocks for more information.

You can use an array of buses as an input signal to a Memory block. You can specify the **Initial condition** parameter with:

- The value 0. In this case, all the individual signals in the array of buses use the initial value 0.
- An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
- A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

For details about defining and using an array of buses, see “Group Nonvirtual Buses in Arrays of Buses”.

Ports

Input

Port_1 – Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array. The input can be continuous or discrete, containing real, or complex values of any data type Simulink supports.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 – Input delayed by one major integration time step

scalar | vector | matrix | N-D array

Output is the input from the previous time step.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Main

Initial condition – Initial condition

0 (default) | scalar | vector | matrix | N-D array

Specify the output at the initial integration step. This value must be 0 when you do not use a built-in input data type.

Programmatic Use

Block Parameter: InitialCondition

Type: character vector

Values: scalar | vector

Default: '0'

Inherit sample time – Inherit sample time

off (default) | on

Select to inherit the sample time from the driving block:

- If the driving block has a discrete sample time, the block inherits the sample time.
- If the driving block has a continuous sample time, selecting this check box has no effect. The sample time depends on the type of solver used for simulating the model.

When this check box is cleared, the block sample time depends on the type of solver used for simulating the model:

- If the solver is a variable-step solver, the block sample time is continuous but fixed in minor time step: [0, 1].
- If the solver is a fixed-step solver, the [0, 1] sample time converts to the solver step size after sample-time propagation.

Programmatic Use

Block Parameter: `InheritSampleTime`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Direct feedthrough of input during linearization — Output the input during linearization and trim

off (default) | on

Select to output the input during linearization and trim. This selection sets the block mode to direct feedthrough.

Selecting this check box can cause a change in the ordering of states in the model when using the functions `linmod`, `dlinmod`, or `trim`. To extract this new state ordering, use the following commands.

First compile the model using the following command, where `model` is the name of the Simulink model.

```
[sizes, x0, x_str] = model([],[],[],'lincompile');
```

Next, terminate the compilation with this command.

```
model([],[],[],'term');
```

The output argument, `x_str`, which is a cell array of the states in the Simulink model, contains the new state ordering. When passing a vector of states as input to the `linmod`, `dlinmod`, or `trim` functions, the state vector must use this new state ordering.

Programmatic Use

Block Parameter: `LinearizeMemory`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Treat as a unit delay when linearizing with discrete sample time — Linearize to unit delay for discrete inputs

off (default) | on

Select to linearize the Memory block to a unit delay when the Memory block is driven by a signal with a discrete sample time.

Programmatic Use**Block Parameter:** LinearizeAsDelay**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**State Attributes****State name — Unique name for block state**

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

Programmatic Use**Block Parameter:** StateName**Type:** character vector**Values:** unique name**Default:** ''**State name must resolve to Simulink signal object — Require state name resolve to a signal object**

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use**Block Parameter:** StateMustResolveToSignalObject**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point integer single

Merge

Combine multiple signals into single signal

Library: Simulink / Signal Routing

Description

The Merge block combines inputs into a single output. The output value at any time is equal to the most recently computed output of its driving blocks. Specify the number of inputs by setting the **Number of inputs** parameter.

Use a Merge block to interleave input signals that update at different times into a combined signal in which the interleaved values retain their separate identities and times. To combine signals that update at the same time into an array or matrix signal, use a Concatenate block.

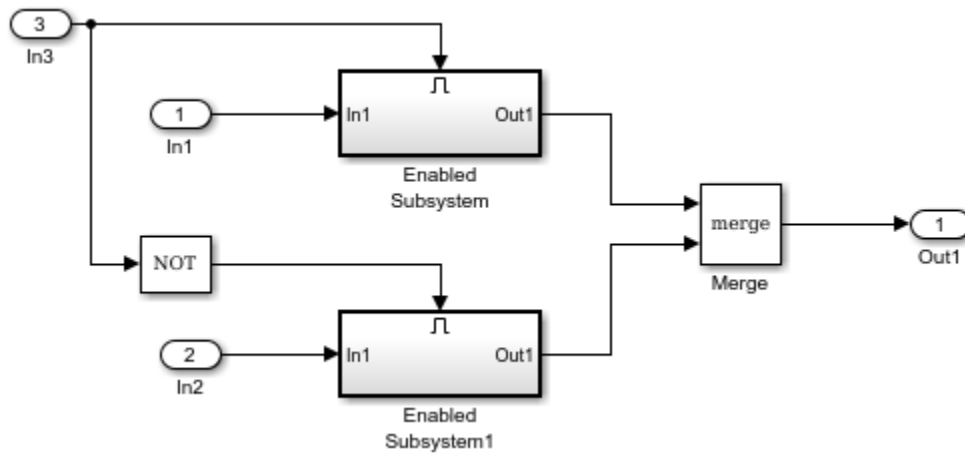

Guidelines for Using the Merge Block

When you use the Merge block, follow these guidelines:

- Always use conditionally executed subsystems to drive Merge blocks, without any intervening blocks.
- Ensure that at most one of the driving conditionally executed subsystems executes at any time step.
- Ensure that all input signals have the same sample time.
- Do not branch a signal that inputs to a Merge block.
- For all conditionally executed subsystem Output blocks that drive Merge blocks, set **Output when disabled** to held.
- If the output of a Model block is coming from a MATLAB Function block or a Stateflow chart, do not connect that output port to the input port of the Merge block.
- The Merge block supports merging signals in different tasks to a root Output block.

For each input of a Merge block, the topmost nonvirtual source must be a conditionally executed subsystem (not including a For Iterator or While Iterator subsystem).

The next diagram shows valid Merge block usage, merging signals from two conditionally executed subsystems.

Bus Support

The Merge block is a bus-capable block. The inputs can be virtual or nonvirtual bus signals subject to these restrictions:

- The number of inputs must be greater than one.
- **Initial output** must be zero, a nonzero scalar, or a finite numeric structure.
- The **Allow unequal port widths** check box must be cleared.
- All inputs must be buses and must be equivalent (same hierarchy with identical names and attributes for all elements).

All signals in a nonvirtual bus input to a Merge block must have the same sample time. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus.

Merging S-Function Outputs

The Merge block can merge a signal from an S-Function block only if the memory used to store the output from the S-Function block is reusable. Simulink displays an error message if you attempt to update or simulate a model that connects a nonreusable port of an S-Function block to a Merge block. See `ssSetOutputPortOptimOpts`.

Multi-tasked Root Outputs

A Merge block connected to a root Outputport block allows merging signals in different tasks by allowing those signals to write to the root Outputport block simultaneously. A Union sample time of the sources is assigned to the Merge block.

All the sources of the Merge block that are in the same task should be inside conditionally executed subsystems that should not output simultaneously in the same time step.

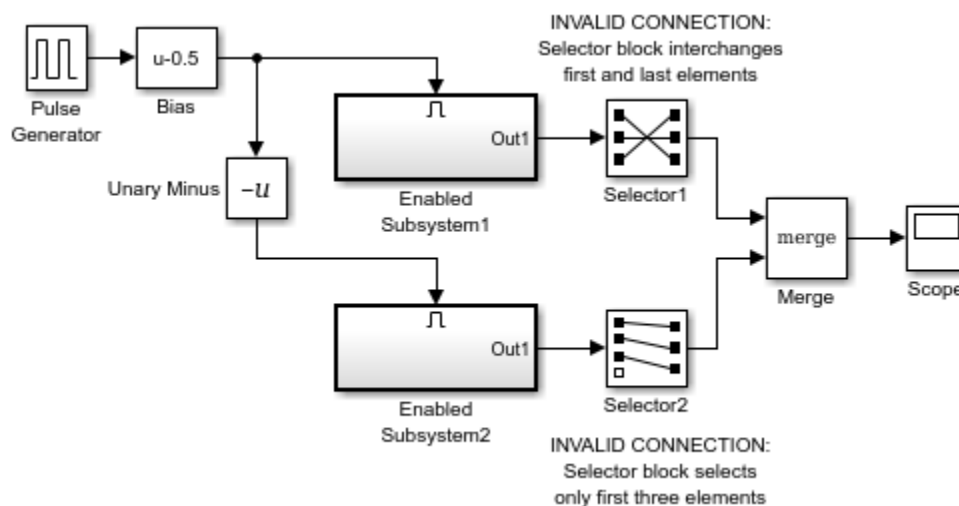

Limitations

- All signals that connect to a Merge block are functionally the same signal. Therefore, they are subject to the restriction that a given signal can have at most one associated signal object. See `Simulink.Signal` for more information.

- Run-time diagnostics do not run if the inputs to a Merge block are from a single initiator. For example, a single initiator could be a Stateflow chart executing function-call subsystems that are connected to a Merge block.
- Do not set the outputs of conditionally executed subsystems being merged to reset when disabled. This action can cause multiple subsystems to update the block at the same time. Specifically, the disabled subsystem updates the Merge block by resetting its output, while the enabled subsystem updates the block by computing its output.

To prevent this behavior, set the Output block parameter **Output when disabled** to held for each conditionally executed subsystem being merged.

- A Merge block does not accept input signals whose elements have been reordered or partially selected, as shown in the next diagram.

- Do not connect input signals to the block that have been combined outside of a conditionally executed subsystem.

You can use an array of buses as an input signal to a Merge block with these limitations:

- **Allow unequal port widths** — Clear this parameter.
- **Initial condition** — You can specify this parameter using:
 - The value 0. In this case, each of the individual signals in the array of buses use the initial value 0.
 - An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
 - A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

Ports

Input

Port_1 — First input signal

scalar | vector

First input signal merged with the other input signals.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Port_n – nth input signal

`scalar` | `vector`

nth input signal merged with the other input signals.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Output

Port_1 – Output signal

`scalar` | `vector`

Output signal merged from the input signals.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Parameters

Number of inputs – Number of input signals to merge

2 (default) | `integer`

Specify the number of input signals to merge. The block creates a port for each input signal.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: integer

Default: '2'

Initial output – Initial output value

[] (default) | `scalar` | `vector`

Specify the initial value of the output signal. If you do not specify an initial output value, then initial output depends on the initialization mode and the driving blocks.

In “Simplified Initialization Mode”, for an unspecified (empty matrix []) value of **Initial output**, the block uses the default initial value of the output data type. For information on the default initial value, see “Initialize Signal Values”. In “Classic Initialization Mode”, for an unspecified (empty matrix []) value of **Initial output**, the initial output of the block equals the most recently evaluated initial output of the driving blocks. Since the initialization ordering for these sources can vary, initialization can be inconsistent for the simulation and the code generation of a model.

Programmatic Use

Block Parameter: InitialOutput

Type: character vector

Values: `scalar` | `vector`

Default: '[]'

Allow unequal port widths — Allow inputs of unequal dimensions

off (default) | on

Select this parameter to allow the block to accept inputs having different numbers of elements from each other or from the output. The block allows you to specify an offset for each input signal relative to the beginning of the output signal. The width of the output signal is

$$\max(w_1+o_1, w_2+o_2, \dots, w_n+o_n)$$

where w_1, \dots, w_n are the widths of the input signals and o_1, \dots, o_n are the offsets for the input signals.

If you clear this parameter, the Merge block accepts only inputs of equal dimensions and outputs a signal of the same dimensions as the inputs.

Note Do not select this parameter unless your model is using Classic Initialization Mode.

Programmatic Use**Block Parameter:** AllowUnequalInputPortWidths**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Input port offsets — Offset for input signals**

[] (default) | vector

Enter a vector to specify the offset of each input signal relative to the beginning of the output signal.

Dependencies

To enable this parameter, select **Allow unequal port widths**.

Programmatic Use**Block Parameter:** InputPortOffsets**Type:** character vector**Values:** scalar | vector**Default:** '[]'**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

In the code generation workflow, when the Merge block receives a constant value and non-constant sample times, one of these conditions must hold. Otherwise Simulink displays an error.

- The source of the constant value is a grounded signal.
- The source of the constant value is a constant block with a non-tunable parameter.
 - There is only one constant block that feeds the Merge block.
 - All other input signals to the Merge block are from conditionally executed subsystems.
 - The Merge block and output blocks of all conditionally executed subsystems does not specify any initial outputs.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Introduced before R2006a

Entity Transport Delay

Introduce a delay in propagation of a SimEvents message

Library: Simulink / Continuous
SimEvents

Description

The Entity Transport Delay block delays an entity for a period of time, named *transport delay*. The first input is the entity that is transported from point A to point B on a constant-length moving surface whose speed changes over time. The value from the second input is the *instantaneous delay*. The speed of the surface is the reciprocal of instantaneous delay. The product of instantaneous delay and the speed is 1.

The block calculates the implemented transport delay by the distance-speed-time relationship, where the surface length (distance) is equal to the integral of the variable surface speed over the duration of the transport delay (time). For more information about this calculation, see Variable Transport Delay.

The Entity Transport Delay block connects SimEvents to Simulink using the input from a Simulink signal and computing the transport delay as a continuous process, and applying this delay to an entity in a discrete-event process. For an example that uses the Entity Transport Delay block, see “Modeling Cyber-Physical Systems” on page 13-640.

Ports

Input

Port_1 — Input entity

SimEvents entity

SimEvents entity or message. For more information on entities in SimEvents, see “Entities in a SimEvents Model” (SimEvents).

t_i — Instantaneous delay

scalar | vector | matrix

Instantaneous delay in the transport of the SimEvents entity. t_i is the reciprocal of the speed of the entity. For more information on the calculation of instantaneous delay, see “Variable Transport Delay” on page 1-2009.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | bus

Output

Port_1 — Delayed entity

SimEvents entity

SimEvents entity with the instantaneous delay t_i applied to it.

n — Number of delayed entities

real scalar

Secondary output signal of the block, which displays the number of entities processed in a time step.

Dependencies

To enable this port, enable the **Output number of entities in block, n** parameter

Data Types: double

Parameters

Capacity — Specify the capacity of the block

inf (default) | scalar

Specify capacity to accept entities to be delayed.

Programmatic Use

Block Parameter: Capacity

Type: character vector

Values: 'inf' | real scalar

Default: 'inf'

Output number of entities in block, n — Outputs the number of delayed entities present in the block

off (default) | on

Number of entities present in the block that are being delayed.

Programmatic Use

Block Parameter: ShowNumberEntitiesInBlock

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	yes

Extended Capabilities

C/C++ Code Generation

Introduced in R2019b

Message Merge

Combine message paths

Library: Simulink / Messages & Events

Description

The Message Merge block graphically combines multiple message lines into a single message line. Merging message lines does not change the messages themselves. You can specify the number of message lines to merge.

Use this block when you want to merge multiple incoming messages and output to a single destination such as a queue or a message storage block.

Ports

Input

Port_1 — Input message line to merge

scalar | vector | matrix

Input message port for messages entering the block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Port_2 — Input message line to merge

scalar | vector | matrix

Input message port for messages entering the block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Output

Port — Output message line

scalar | vector | matrix

Output message port for messages exiting the block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Parameters

Number of input ports — Specify the number message lines to combine

2 (default) | scalar

Determines the number of message input ports to be combined.

Programmatic Use

Block Parameter: NumberInputPorts

Type: character vector

Values: '2' | scalar

Default: '2'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Send | Queue | Entity Input Switch (SimEvents) | Entity Output Switch (SimEvents)

Topics

“Establish Message Send and Receive Interfaces Between Software Components”

Introduced in R2021a

Receive, Message Receive

Receive messages

Library: Simulink / Messages & Events
SimEvents

Description

The Receive block extracts data from received messages and writes them to the output signal port. If there are no new messages when the block executes, the block uses the **Value source when queue is empty** value. Receive and Message Receive blocks are identical blocks.

- Select `Hold last value` to hold data read from the last message.
- Select `Use initial value` to write default data.

Ports

Input

Port_1 — Input message

scalar | vector | matrix

The input port for the message.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `enumerated` | `bus` | `fixed point`

Output

Port_S — Show whether a message was received

scalar

Outputs 1 if the block receives a message successfully, and 0 otherwise.

Dependencies

To enable this port, select the check box labeled **Show receive status**.

Data Types: `double`

Port_1 — Output signal

scalar | vector | matrix

Output port for the signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `enumerated` | `bus` | `fixed point`

Parameters

Use internal queue — Select to use an internal queue

on (default for SimEvents) | off (default for Simulink)

Select this check box if you use an internal queue to receive messages.

Programmatic Use

Block Parameter: UseInternalQueue

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Overwrite the oldest element if queue is full — Specify queue overwriting policy

on (default for Simulink) | off (default for SimEvents)

Select this check box to choose between two queue overwriting policies.

- If you select the check box, an incoming message overwrites the oldest if the queue is full.
- If you clear the check box, the block does not accept new messages if the queue is full.

Dependencies

This parameter is visible when you select the box labeled **Use internal queue**.

Programmatic Use

Block Parameter: QueueOverwriting

Type: character vector

Values: 'on' | 'off'

Default: 'on' (for Simulink) and 'off' (for SimEvents)

Queue length — Specify the length of the message queue

16 (default) | scalar

Specify message queue capacity. The queue length can be specified as a positive integer between 1 and $2^{26}-1$ (both included).

Dependencies

This parameter is visible when you select the box labeled **Use internal queue**.

Programmatic Use

Block Parameter: QueueLength

Type: character vector

Values: '16' | scalar

Default: '16'

Queue type — Specify message queue sorting policy

FIFO (default) | LIFO | Priority

The block supports three message sorting policies:

- First-in-first-out (FIFO) — The oldest message in the storage departs first.
- Last-in-first-out (LIFO) — The newest message in the storage departs first.
- Priority — Messages or entities are sorted based on their priority.

The priority queue can be used only when the **Overwrite the oldest element if queue is full** check box is cleared.

Note Priority queue accepts only non-bus scalar and it does not support fixed point data type.

Dependencies

This parameter is visible when you select the box labeled **Use internal queue**.

Programmatic Use

Block Parameter: QueueType

Type: character vector

Values: 'FIFO' | 'LIFO' | 'Priority'

Default: 'FIFO'

Priority order — Specify message queue priority

Ascending (default) | Descending

Choose the direction of sorting messages based on priority.

- Ascending — Messages with smaller priority values appear in front of the queue.
- Descending — Messages with greater priority values appear in front of the queue.

Dependencies

This parameter is visible when you select the box labeled **Use internal queue** and **Queue type > Priority**.

Programmatic Use

Block Parameter: PriorityOrder

Type: character vector

Values: 'Ascending' | 'Descending'

Default: 'Ascending'

Show receive status — Show whether a message was received

off (default) | on

Select this check box to show whether a message was received. If this check box is selected the block outputs 1 if it receives a message successfully, and 0 otherwise.

Programmatic Use

Block Parameter: ShowQueueStatus

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Initial value — Set initial data value

[](unspecified) (default) | scalar | vector | matrix

Enter an initial data value for the queue before the arrival of the first message. The default value [] (unspecified) is treated as 0 with data type double.

To use this block to initialize a nonvirtual bus signal, specify the initial value as a MATLAB structure. For more information about initializing nonvirtual bus signals using structures, see “Specify Initial Conditions for Bus Elements”.

Programmatic Use**Block Parameter:** InitialValue**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Value source when queue is empty — Value source for empty queue**

Hold last value (default) | Use initial value

Specify the value to receive when received message queue is empty.

- **Hold last value (default)** — Holds data read from the last message.
Initially, if the block tries to receive a message and fails, it outputs the initial value.
- **Use initial value** — Writes default data.

DependenciesThis parameter is visible when you select the box labeled **Use internal queue**.**Programmatic Use****Block Parameter:** ValueSourceWhenQueueIsEmpty**Type:** character vector**Values:** 'Hold last value' | 'Use initial value'**Default:** 'Hold last value'**Sample time (-1 for inherited) — Specify the time interval between samples**

-1 (default) | scalar

To inherit the sample time, set this parameter to -1. See “Specify Sample Time” for more information.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** '-1' | scalar**Default:** '-1'**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point integer single string

Topics

“Simulink Messages Overview”

Introduced in R2016a

Send, Message Send

Create and send message

Library: Simulink / Messages & Events
SimEvents

Description

The Send block reads the value of an input signal, and sends a message that carries this value. In message-based communication, a message is a discrete-item of interest that carry data of any type that Simulink supports. Send and Message Send blocks are identical blocks.

Ports

Input

Port_Enable — External enable signal

scalar

Input port to enable the block to send a message. For any input value that is greater than 0 send is enabled. For any value less than or equal to 0, the send is disabled.

Dependencies

To enable this port, select the box labeled **Show enable port**.

Data Types: double

Port_1 — Input signal

scalar | vector | matrix

This block accepts inputs of any type that Simulink supports, including enumerated types and converts the input signal to a message. For more information, see “Data Types Supported by Simulink”.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Output

Port_1 — Output message

scalar | vector | matrix

The block outputs a message with constant priority 20.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Parameters

Show enable port — Display the enable port

off (default) | on

Select this check box to display enable port. For any input value that is greater than 0 send is enabled. For any value less than or equal to 0, the send is disabled.

Programmatic Use

Block Parameter: ShowEnablePort

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

“Simulink Messages Overview”

Introduced in R2016a

Message Triggered Subsystem, Message Polling Subsystem

Subsystem whose execution is controlled by message input

Library: Simulink / Messages & Events

Description

This block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes based on message input. The block has different names based on the timing of execution.

- A Message Triggered Subsystem block executes whenever a message is available at the control port, independent of the block sample time.
- A Message Polling Subsystem block periodically checks for messages and executes if a message is available at the control port.

Inside the subsystem, a Trigger block displays an output port that outputs a data signal carrying the message payload.

For an explanation of the Message Triggered Subsystem and Message Polling Subsystem block parameters, see Subsystem block parameters on page 1-1836. For an explanation of the Trigger block parameters, see Trigger block parameters on page 1-1939.

Message Triggered Subsystem

A Message Triggered Subsystem block enables event-based message triggers. The block executes whenever a message is available at the control port, independent of sample time. The block contains a Trigger block with the **Trigger type** set to message and the **Trigger time** set to on message available.

The block operates in two modes, scheduled and immediate.

- In scheduled mode, execution order of a subsystem can be scheduled in the Schedule Editor to model asynchronous behavior. You can defer subsystem execution to follow a specific Simulink task while staying at the same time step. A Queue block in front of the trigger port can buffer messages before they enter the subsystem. When a message arrives at the Queue block, it raises an event that triggers the subsystem to pull the message from the Queue block based on the schedule. If there is no Queue block between the message source and the trigger port, Simulink treats the trigger port as having an internal, overwriting-type queue with a capacity of 1, similar to the Receive block. The trigger port can be connected to a root-level Inport block for modeling a software component. The model must be configured as an export-function model.

To use scheduled mode, select the **Schedule as aperiodic partition** check box in the Trigger block.

- In immediate mode, the subsystem executes as soon as a message is available at the control port, which pushes the message to the subsystem without a queue buffering the message.

To use immediate mode, clear the **Schedule as aperiodic partition** check box in the Trigger block.

Message Polling Subsystem

A Message Polling Subsystem block executes conditionally at each time step based on whether a message is available at the control port. The block contains a Trigger block with the **Trigger type** set to message and the **Trigger time** set to on sample time hit.

The block tries at each time step to pull a message from the queue in front of the control port. If there is no Queue block between the message source and the control port, Simulink treats the control port as having an internal, overwriting-type queue with a capacity of 1, similar to the Receive block. If the queue is not empty, a message is pulled and the subsystem executes, with the message payload as input. Only one message is pulled at each time step. If more than one message is in the queue at the current time step, the next message is pulled at the next time step. If the queue is empty, the subsystem does not execute at that time step. You can set the sample time in the block dialog box of the Message Polling Subsystem block. See “Sample time” on page 1-0 .

Ports

Input

Trigger — Control signal and data input

scalar | vector | matrix

Placing a Trigger block with the **Trigger type** set to message in a Subsystem block adds an external message input port to the block.

Use the Trigger port to control execution of the subsystem and to pass data to the subsystem.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Out — Signal output

scalar | vector | matrix

Placing an Outport block in a Subsystem block adds an external output port to the block. The port label on the Subsystem block matches the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a half ^a integer ^a single ^a string ^a

Introduced in R2022a

MinMax

Output minimum or maximum input value

Library: Simulink / Math Operations
HDL Coder / Math Operations

Description

The MinMax block outputs either the minimum or the maximum element or elements of the inputs. You choose whether the block outputs the minimum or maximum values by setting the **Function** parameter.

The MinMax block ignores any input value that is NaN, except when every input value is NaN. When all input values are NaN, the output is NaN, either as a scalar or the value of each output vector element.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Provide an input signal from which the block outputs the maximum or minimum values.

- When the block has one input port, the input must be a scalar or a vector. The block outputs a scalar equal to the minimum or maximum element of the input vector.
- When the block has multiple input ports, all nonscalar inputs must have the same dimensions. The block expands any scalar inputs to have the same dimensions as the nonscalar inputs. The block outputs a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

Dependencies

To support matrix input, you must set the **Number of input ports** parameter to an integer greater than one. All nonscalar inputs must have the same dimensions.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_N — N-th input signal

scalar | vector | matrix

Provide an input signal from which the block outputs the maximum or minimum values.

When the block has multiple input ports, all nonscalar inputs must have the same dimensions. The block expands any scalar inputs to have the same dimensions as the nonscalar inputs. The block

outputs a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

Dependencies

To provide more than one input signal, set the **Number of input ports** to an integer greater than 1.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 – Minimum or maximum values of inputs

scalar | vector | matrix

When the block has one input, the output is a scalar value, equal to the minimum or maximum of the input elements. When the block has multiple inputs, the output is a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Function – Specify minimum or maximum

min (default) | max

Specify whether to apply the function min or max to the input.

Programmatic Use

Block Parameter: Function

Type: character vector

Values: 'min' | 'max'

Default: 'min'

Number of input ports – Specify number of input ports

1 (default) | positive integer

Specify the number of inputs to the block.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: positive integer

Default: '1'

Enable zero-crossing detection – Enable zero-crossing detection

on (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use**Block Parameter:** ZeroCross**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'on'**Sample time — Sample time value other than -1**

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Signal Attributes****Require all inputs to have the same data type — Inputs must have the same data type**

off (default) | on

Select this check box to require that all inputs have the same data type.

Programmatic Use**Block Parameter:** InputSameDT**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Output minimum — Minimum output value for range checking**

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output maximum — Maximum output value for range checking**

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output data type — Specify the output data type**

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | Inherit: Same as first input | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

When input is a floating-point data type smaller than single precision, the `Inherit: Inherit via internal rule` output data type depends on the setting of the “Inherit floating-point output type smaller than single precision” configuration parameter. Data types are smaller than single precision

when the number of bits needed to encode the data type is less than the 32 bits needed to encode the single-precision data type. For example, half and int16 are smaller than single precision.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'Inherit: Same as first input' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	yes

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

Architecture	Additional cycles of latency	Description
default Tree	0	Generates a tree structure of comparators.
Cascade	1, when block has a single vector input port.	This implementation is optimized for latency * area, with medium speed. See “Cascade Architecture Best Practices” (HDL Coder).

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
InstantiateStages	Generate a VHDL entity or Verilog module for each cascade stage. The default is off. See also “InstantiateStages” (HDL Coder).
SerialPartition	Specify partitions for Cascade-serial implementations as a vector of the lengths of each partition. The default setting uses the minimum number of stages. See also “SerialPartition” (HDL Coder).

Note To enable the **LatencyStrategy** setting for the MinMax block, you must specify **Tree** as the **HDL Architecture**.

Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , or <code>Zero</code> for the floating-point operator. The default is <code>inherit</code> . See also "LatencyStrategy" (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

MinMax Running Resettable

Introduced before R2006a

MinMax Running Resettable

Determine minimum or maximum of signal over time

Library: Simulink / Math Operations

Description

The MinMax Running Resettable block outputs the minimum or maximum of all past inputs u . You specify whether the block outputs the running minimum or maximum with the **Function** parameter.

The block can reset its state based on an external reset signal R . When the reset signal R is nonzero (`true`), the block resets the output to the value of the **Initial condition** parameter.

The input can be a scalar, vector, or matrix signal. The block outputs a signal having the same dimensions as the input. Each output element equals the running minimum or maximum of the corresponding input elements.

Ports

Input

u — Input signal

scalar | vector | matrix

Input signal as a scalar, vector, or matrix. Based on what you specify for the **Function** parameter, the block outputs the minimum or maximum value of all past inputs u .

If you specify a scalar value for the **Initial condition** parameter, the block expands the parameter to have the same dimensions as nonscalar input u .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `bus`

R — Reset signal

scalar | vector | matrix

The input port accepting the reset signal as a scalar, vector, or matrix. When the reset signal is nonscalar, it must have the same dimensions as input signal u . As long as the reset signal has a value of zero, the block outputs the running minimum or maximum value of input u . Whenever the reset signal has a nonzero value (`true`), the block resets the output to the value of the **Initial condition** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `bus`

Output

y — Running minimum or maximum value

scalar | vector | matrix

Output signal, specified as a scalar, vector, or matrix, where each output element equals the running minimum or maximum value of the corresponding input elements. Output signal **y** has the same data type and dimensions as input signal **u**.

When the block receives a nonzero (**true**) reset signal, the block resets the output to the value of the **Initial condition** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Function — Specify minimum or maximum

`min` (default) | `max`

Specify whether the block outputs the running minimum or maximum value of the corresponding input elements.

Programmatic Use

Block Parameter: `Function`

Type: character vector

Values: `'min'` | `'max'`

Default: `'min'`

Initial condition — Value to reset output to

`0.0` (default) | scalar or vector

Specify the initial condition value. When the reset input signal **R** is **true**, the block resets the output to the value you specify.

Programmatic Use

Block Parameter: `vinit`

Type: character vector

Values: scalar or vector

Default: `'0.0'`

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Model

Reference another model to create model hierarchy

Library: Simulink / Ports & Subsystems
HDL Coder / Ports & Subsystems

Description

The Model block references the specified model. It displays input and output ports that correspond to the top-level input and output ports of the referenced model. These ports allow you to connect the referenced model to other blocks in the parent model.

To determine whether the Model block is better suited for your goal than another block with similar functionality, see “Choose Among Types of Model Components” and “Compare Capabilities of Model Components”.

For instructions on how to reference a model with a Model block, see “Reference Existing Models”.

By default, the Model block displays a representation of the contents of the referenced model. For more information, see “Preview Content of Model Components”. To see the contents of a referenced model, double-click the Model block.

If you have a Simulink Coder license, you can conceal the implementation details of a referenced model by protecting the model. To protect a model, see “Protect Models to Conceal Contents” (Simulink Coder). To reference a protected model, see “Reference Protected Models from Third Parties”.

Ports

Input

Port_1 — Input that corresponds to root-level blocks of referenced model

scalar | vector | matrix | array | bus

The Model block has an input port for each input port of the model it references. The input ports of referenced models are defined by Inport and In Bus Element blocks. The name of the Model block port matches the name of the corresponding port in the referenced model. The input signal, message, or function call for each Model block port must be valid for the corresponding port in the referenced model. For more information, see “Model Reference Interface and Boundary”.

Tips

- Signal attributes in a referenced model are independent from the context of the Model block. For example, signal dimensions and data types do not propagate across the Model block boundary. To define signal attributes in a referenced model, define block parameters for root-level Inport and In Bus Element blocks.
- Function calls connected to an input port pass into the referenced model. To conditionally execute the referenced model based on a function call, see **Function Call** on page 1-0 .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Output

Port_1 — Output that corresponds to root-level blocks of referenced model

`scalar` | `vector` | `matrix` | `array` | `bus`

The Model block has an output port for each output port of the model it references. The output ports of referenced models are defined by Outport and Out Bus Element blocks. The name of the port on the Model block matches the name of the corresponding port in the referenced model. The output signals and messages of a Model block are the signals and messages connected to the Outport and Out Bus Element blocks in the referenced model. See “Model Reference Interface and Boundary”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Control

Conditional Execution

Enable — Control signal that enables referenced model

`scalar` | `vector` | `matrix`

The enable port appears at the top of the Model block. The port label is an icon that represents an enable signal.

The control signal that connects to the port determines when to execute the referenced model. For more information, see “Conditionally Execute Referenced Models”.

Dependencies

To enable this port, add an Enable block to the top level of the referenced model.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Trigger — Control signal that triggers referenced model

`scalar` | `vector` | `matrix`

The trigger port appears at the top of the Model block. The port label is an icon that represents a trigger signal.

The control signal that connects to the port determines when to execute the referenced model. For more information, see “Conditionally Execute Referenced Models”.

Dependencies

To enable this port, add a Trigger block to the top level of the referenced model and set its **Trigger type** to **rising**, **falling**, or **either**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Function Call – Control signal for function-call event

scalar

The function-call port appears at the top of the Model block. The port label displays the name of the referenced model as a function.

The function-call control signal that connects to the port determines when to execute the referenced model. For more information, see “Conditionally Execute Referenced Models”.

Dependencies

To enable this port, add a Trigger block to the top level of the referenced model and set its **Trigger type** to **function-call**.

Model Events Simulation**initialize – Control signal for model initialize event**

scalar

The initialize event port provides a function-call control signal that triggers a model initialize event, which initializes the states of the referenced model.

The referenced model can contain an Initialize Function block that corresponds to the model initialize event. For more information, see “Using Initialize, Reinitialize, Reset, and Terminate Functions”.

Dependencies

To enable this port, select **Show model initialize port** on page 1-0 .

reset – Control signal for model reset event

scalar

A reset event port provides a function-call control signal that triggers a model reset event, which resets the states of the referenced model.

The referenced model must contain a Reset Function block that corresponds to each model reset event. For more information, see “Using Initialize, Reinitialize, Reset, and Terminate Functions”.

To specify the port name, use the **Event name** parameter of the Event Listener block in the Reset Function block.

Dependencies

To enable this type of port, select **Show model reset ports** on page 1-0 .

reinit – Control signal for model reinitialize event

scalar

A reinitialize event port provides a function-call control signal that triggers a model reinitialize event, which reinitializes the states of the referenced model.

The referenced model must contain a Reinitialize Function block that corresponds to each model reinitialize event. For more information, see “Using Initialize, Reinitialize, Reset, and Terminate Functions”.

To specify the port name, use the **Event name** parameter of the Event Listener block in the Reinitialize Function block.

Dependencies

To enable this type of port, select “**Show model reinitialize ports**” on page 1-0 .

terminate – Control signal for model terminate event

scalar

The terminate event port provides a function-call control signal that triggers a model terminate event, which reads and saves the states of the referenced model.

The referenced model can contain a Terminate Function block that corresponds to the model terminate event. For more information, see “Using Initialize, Reinitialize, Reset, and Terminate Functions”.

Dependencies

To enable this port, select **Show model terminate port** on page 1-0 .

D – Control signal for scheduling periodic events

scalar

Periodic event ports provide function-call control signals that specify when to execute the model. For an example, see “Test Rate-Based Model Simulation Using Function-Call Generators”.

Each port label displays information about the periodic event, such as the sample time of the corresponding Inport block. For example, the Model block in this image displays periodic event ports and references a model with two discrete rates: 0.01 and 0.1.

**Dependencies**

To enable this type of port, set **Schedule rates with** on page 1-0 to Ports.

Parameters

To interactively modify Model block parameters, select the Model block. Then, in the Simulink Toolstrip, on the **Model Block** tab, click **Block Parameters**.

Main

Specify fundamental information for the Model block.

Model name — File name of referenced model

' ' (default) | character vector

Specify the file name of the referenced model. The file name must be a valid MATLAB identifier for a model, as defined in “Model Names”. The file extension is optional.

To select the model that you want to reference, click **Browse**. To view the specified model, click **Open Model**.

Programmatic Use

You can query the name of the referenced model in different formats:

- `ModelFile` — Model name with file extension. When you do not specify a file extension, the first match that Simulink finds on the MATLAB path determines the file extension.
- `ModelNameDialog` — Model name with or without file extension, depending on whether you specify a file extension.
- `ModelName` — Model name without file extension. If you specify a model name with a file extension for `ModelName`, Simulink retains the file extension by setting `ModelNameDialog` and `ModelFile`.

Parameter: `ModelNameDialog`

Type: character vector

Value: ' ' | '<filename>'

Default: ' '

Simulation mode — Simulation mode for model reference

Normal (default) | Accelerator | Software-in-the-loop (SIL) | Processor-in-the-loop (PIL)

Specify the simulation mode for the Model block. The simulation mode for the Model block can be different than the simulation mode of its referenced model and of other models in the model hierarchy.

- `Accelerator` — Create a MEX file for the referenced model and then execute the referenced model by running the S-function.
- `Normal` — Execute the referenced model interpretively, as if the referenced model is an atomic subsystem implemented directly within the parent model.
- `Software-in-the-loop (SIL)` — This option requires an Embedded Coder license. Generate production code based on the **Code interface** on page 1-0 parameter setting. The code is compiled for and executed on the host platform.
- `Processor-in-the-loop (PIL)` — This option requires an Embedded Coder license. Generate production code based on the **Code Interface** parameter setting. This code is compiled for and

executed on the target platform. A target connectivity API implementation supports the exchange of data between the host and target at each time step during the PIL simulation.

The corners of the Model block indicate the simulation mode of the Model block. For normal mode, the corners have empty triangles. For accelerator mode, the corner triangles are filled in. For SIL and PIL modes, the corners are filled in and the word (SIL) or (PIL) appears on the block icon.

Although you can specify any simulation mode for a model, when you reference that model, the Model block specifies the simulation mode of the referenced model instance. The simulation mode of a parent model can override the simulation mode of a Model block.

For more information, see “Choose Simulation Modes for Model Hierarchies”.

Programmatic Use

Parameter: SimulationMode

Type: character vector

Value: 'Normal' | 'Accelerator' | 'Software-in-the-loop' | 'Processor-in-the-loop'

Default: 'Normal'

Code interface — Option to generate code from top model or referenced model

Model reference (default) | Top model

Specify whether to generate the code from the top model or the referenced model for SIL and PIL simulation modes. To deploy the generated code as part of a larger application that uses the referenced model, specify Model reference. To deploy the generated code as a standalone application, specify Top model.

- Model reference — The code is generated from the referenced model as part of a model hierarchy. Code generation uses the `slbuild('model', 'ModelReferenceCoderTarget')` command.
- Top model — The code is generated from the top model with the standalone code interface. Code generation uses the `slbuild('model')` command.

Dependencies

To enable this parameter, set **Simulation mode** on page 1-0 to either Software-in-the-loop (SIL) or Processor-in-the-loop (PIL).

Programmatic Use

Parameter: CodeInterface

Type: character vector

Value: 'Model reference' | 'Top model'

Default: 'Model reference'

Model Events Simulation

Control when the referenced model executes and changes states.

Show model initialize port — Option to display initialize event port

off (default) | on

Select this parameter to display the initialize event port. Clear this parameter to remove the port.

Dependencies

To enable this parameter, reference a model that is not configured for conditional execution.

Programmatic Use**Block parameter:** ShowModelInitializePort**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Show model reinitialize ports — Option to display reinitialize event ports**

off (default) | on

Select this parameter to display the reinitialize event ports. Clear this parameter to remove the ports.

Dependencies

To enable this parameter, reference a model that is not configured for conditional execution and contains a Reinitialize Function block.

Programmatic Use**Block parameter:** ShowModelReinitializePorts**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Show model reset ports — Option to display reset event ports**

off (default) | on

Select this parameter to display the reset event ports. Clear this parameter to remove the ports.

Dependencies

To enable this parameter, reference a model that is not configured for conditional execution and contains a Reset Function block.

Programmatic Use**Block parameter:** ShowModelResetPorts**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Show model terminate port — Option to display terminate event port**

off (default) | on

Select this parameter to display the terminate event port. Clear this parameter to remove the port.

Dependencies

To enable this parameter, reference a model that is not configured for conditional execution. Then, select **Show model initialize port** on page 1-0 .

Programmatic Use**Block parameter:** ShowModelTerminatePort**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Schedule rates — Option to schedule periodic events**

off (default) | on

Control the execution of the referenced model with periodic events.

Depending on the value of the **Schedule rates with** parameter, selecting this parameter will either display the periodic event ports on the Model block or create partitions to use with the **Schedule Editor**. When the **Schedule rates with** parameter is not visible, its default value (Ports) applies.

Clearing this parameter hides the periodic event ports and does not create partitions.

Dependencies

To enable this parameter, reference a model with discrete sample times that is not configured for conditional execution and is not an export-function model. When the parent model is rate based and the referenced model is an export-function model, **Schedule rates** is automatically selected.

Programmatic Use

Block parameter: ScheduleRates

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Schedule rates with — Option to create partitions or periodic event ports

Ports (default) | Schedule Editor

Create ports or partitions.

- Ports — Display periodic event ports for discrete rates in the referenced model.

To manually specify port rates, use the `set_param` function to set the `AutoFillPortDiscreteRates` parameter of the Model block to 'off'. Then, specify the port rates with the `PortDiscreteRates` parameter.

- Schedule Editor — Create partitions for the referenced model to use with the **Schedule Editor**.

Dependencies

To enable this parameter:

- The parent model must not be an export-function model.
- The parent model must not use a fixed-step solver and single-tasking mode.
- Select **Schedule rates**. When the parent model is rate based and the referenced model is an export-function model, **Schedule rates** is automatically selected.
- Clear **Show model initialize port**, **Show model reset ports**, and **Show model reinitialize ports**.

Programmatic Use

Block parameter: ScheduleRatesWith

Type: character vector

Value: 'Ports' | 'ScheduleEditor'

Default: 'Ports'

Instance Parameters

Specify instance-specific values for model arguments.

Instance parameters — Display instance parameters and specify values for referenced model

number | workspace variable | mathematical expression | structure or structure field

Display instance parameters and specify instance-specific values. Instance parameters are block parameters that have been configured in the referenced model to use a different value for each instance of the model.

To specify instance-specific values, use the **Value** column in the table. To specify that a parameter value can be overridden by the parent model, select the **Argument** check box. For more information about configuring instance parameters in a referenced model and specifying instance-specific values at the Model block, see “Parameterize Instances of a Reusable Referenced Model”.

When changing instance-specific values, you can use a partial structure that has fields that correspond to only the instance parameters whose values you want to change. Instance parameters not included in the partial structure retain their values. In the structure, include the instance parameter names and values, specified as character vectors.

Programmatic Use**Block parameter:** ParameterArgumentValues**Type:** structure**Value:** structure**Default:** structure with no fields**Block parameter:** InstanceParameters**Type:** structure array**Value:** structure with fields: Name, Value, Path, and Argument.**Solver**

Specify local solver-specific values for model arguments. For more details on how to use this functionality, see “Use local solver when referencing model”.

Input Signal Handling — Handling of input signal

Auto (default) | Zero-order hold

Specify how to handle the signal. If you select **Auto**, Simulink chooses input handling based of the **Solver** you pick. **Auto** applies numerical compensation to the local solver to improve data exchanges between top and local solvers. **Zero-order hold** does not.

Programmatic Use**Block parameter:** InputSignalHandling**Type:** character vector**Value:** 'Use solver interpolant' | 'Zero-order hold'**Default:** 'Use solver interpolant'**Output Signal Handling — Handling of output signal**

Use solver interpolant (default) | Zero-order hold

Specify how to handle the output signal. If you select **Use solver interpolant**, Simulink chooses output handling based of the **Solver** you picked.

Programmatic Use**Block parameter:** OutputSignalHandling**Type:** character vector**Value:** 'Auto' | 'Zero-order Hold'**Default:** 'Auto'**Solver — Type of fixed-step solver**

auto (default)

Use this parameter to set the **Solver** configuration parameter in the “Solver Pane”.

Dependencies

This parameter only works when you select a fixed-step solver.

Step size — Step size of fixed-step solver

auto (default)

Use this parameter to set the **Fixed-step size (fundamental sample time)** configuration parameter in the “Solver Pane”.

Dependencies

This parameter only works when you select a fixed-step solver.

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a half ^a integer ^a single ^a string ^a
Direct Feedthrough	no
Multidimensional Signals	limited ^a
Variable-Size Signals	limited ^a
Zero-Crossing Detection	no

^a Actual data type or capability support depends on block implementation.

Tips

To programmatically determine whether a Model block references a protected model, use the `get_param` function to query the read-only `ProtectedModel` parameter of the Model block. If the referenced model is protected, the function returns 'on'. If the referenced model is unprotected, the function returns 'off'.

Compatibility Considerations

Specifying variant models in Model blocks is no longer supported

Warns starting in R2019a

Starting in R2019a, specifying variant models in Model blocks is no longer supported. The Model Variants block, which was a Model block preconfigured to specify variant models, is also no longer supported. Loading a model that contains these blocks converts them to Variant Subsystem blocks that contain Model blocks that represent the variant choices.

Variant Subsystem blocks provide these advantages:

- You can mix Model blocks and Subsystem blocks as variant choices.
- You can specify variants that have different numbers of input and output ports.

The Variant Subsystem block parameter **Analyze all choices during update diagram and generate preprocessor conditionals** behaves differently from the Model block parameter

Generate preprocessor conditionals. Instead of causing simulation and update diagram to compile the active variant only, the Variant Subsystem block parameter compiles all variants.

If you have scripts that use Model block parameters for variants, you must update them to use Variant Subsystem block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information about using the Model block for HDL code generation and best practices and limitations, see “Model Referencing for HDL Code Generation” (HDL Coder).

See also “Generate Black Box Interface for Referenced Model” (HDL Coder) and “Generate Parameterized Code for Referenced Models” (HDL Coder).

HDL Architecture

Architecture	Description
ModelReference (default)	When you want to generate code from a referenced model and any nested models, use the ModelReference implementation. For more information, see “How To Generate Code for a Referenced Model” (HDL Coder).
BlackBox	Use the BlackBox implementation to instantiate an HDL wrapper, or black box interface, for legacy or external HDL code. If you specify a black box interface, HDL Coder does not attempt to generate HDL code for the referenced model. For more information, see “Generate Black Box Interface for Referenced Model” (HDL Coder).

Black Box Interface Customization

For the **BlackBox** architecture, you can customize port names and set attributes of the external component interface. See “Customize Black Box or HDL Cosimulation Interface” (HDL Coder).

HDL Block Properties

BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . See also “BalanceDelays” (HDL Coder).
----------------------	---

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is off. See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is none. See also “DSPStyle” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
ReferenceModelPrefix	Prefix of the referenced model to insert in the generated code. The code generator applies this prefix to submodel file names and HDL identifiers. The default prefix is <code>modelName_</code> where <code>modelName</code> is the name of the referenced model. Note <ul style="list-style-type: none"> • If you specify an empty prefix, the code generator does not add a prefix to submodel file names. This can cause HDL compilation errors due to naming collisions between the models. • If you use the referenced model as the DUT, the code generator ignores the prefix that you specify.
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is 0, which implements fully parallel data paths. See also “Streaming” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type support depends on block implementation.

Model Info

Display model properties and text in model

Library: Simulink / Model-Wide Utilities
HDL Coder / Model-Wide Utilities

Description

The Model Info block displays model properties and text about a model on the mask of the block. Use the Model Info block dialog box to specify the content and format of the text that the block displays. You can select model properties to display on the block. In the text displayed on the block mask, Simulink replaces the property name with the current value of the property in the model.

Parameters

Specify Text and Properties to Display — Content and format of the text to display

no default

Use the **Enter text and tokens to display on Model Info block** edit box to specify the text and properties to display.

- In the edit box, enter any text you want to display on the block mask. Edit the default text Model Info.
- To display a model property on the block mask, select a property in the **Model properties** list and click the right arrow button.

The block adds a token of the form `%<modelpropertyname>` to the edit box. In the text the block mask displays, Simulink replaces the token with the value of the property.

- 1 For example, if you select **Description** in the **Model properties** list and click the right arrow button, then the token `%<Description>` appears in the right edit box.
- 2 You could add some explanatory text before the model property, e.g. "Model description:".
- 3 When you click **Apply** or **OK**, Simulink displays your new text and the current value of the model property on the block mask in the Model Editor.

See "Access Model Information Programmatically" for descriptions of the model properties.

If you are interested in source control information, for a flexible interface to source control tools, use a project. See "Source Control in Projects".

Block Characteristics

Data Types	
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Model Info block is ignored during code generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Best Practices

When using Model Info blocks in models targeted for HDL code generation, consider using only ASCII characters in the text that you enter to display on the Model Info block. If you have non-ASCII characters in the generated HDL code, RTL simulation and synthesis tools can fail to compile the code.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Multiport Switch

Select output signal based on control signal

Library: Simulink / Signal Routing
HDL Coder / Signal Routing

Description

The Multiport Switch block determines which of several inputs to the block passes to the output. The block bases this decision on the value of the first input. The first input is the control input and the remaining inputs are the data inputs. The value of the control input determines which data input passes to the output.

The table summarizes how the block interprets the control input and determines the data input that is passed to the output.

Control Input	Truncation	Setting for Data Port Order	Block Behavior During Simulation	
			Indexing to Select Data Input	Out-of-Range Condition
Integer value	None	Zero-based contiguous	Zero-based indexing	The control input is less than 0 or greater than the number of data inputs minus one.
		One-based contiguous	One-based indexing	The control input is less than 1 or greater than the number of data inputs.
		Specify indices	Indices you specify	The control input does not correspond to any specified data port index.
Not an integer value	The block truncates the value to an integer by rounding to zero.	Zero-based contiguous	Zero-based indexing	The truncated control input is less than 0 or greater than the number of data inputs minus one.
		One-based contiguous	One-based indexing	The truncated control input is less than 1 or greater than the number of data inputs.
		Specify indices	Indices you specify	The truncated control input does not correspond to any specified data port index.

For information on how the block handles the out-of-range condition, see “How the Block Handles an Out-of-Range Control Input” on page 1-1187.

Multiport Switch Configured as an Index Vector Block

An Index Vector is a special configuration of a Multiport Switch block in which you specify one data input and the control input is zero-based. The block output is the element of the input vector whose index matches the control input. For example, if the input vector is [18 15 17 10] and the control input is 3, the element that matches the index of 3 (zero-based) is 10, and that becomes the output value.

To configure a Multiport Switch block to work as an Index Vector block, set **Number of data ports** to 1 and **Data port order** to Zero-based contiguous.

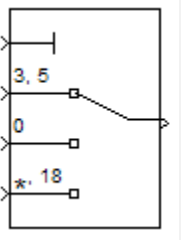

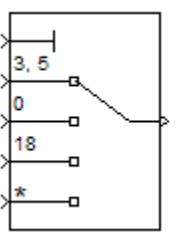

How the Block Handles an Out-of-Range Control Input

For an input with an integer value less than `intmax('int32')`, the input is out of range when the value does not match any data port indices. For a control input that is not an integer value, the input is out of range when the *truncated* value does not match any data port indices. In both cases, the block behavior depends on your settings for **Data port for default case** and **Diagnostic for default case**.

Note If the control input is larger than `intmax('int32')`, the block wraps the input value to an integer.

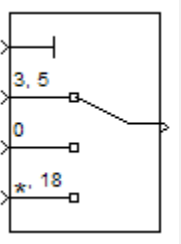

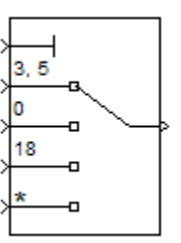

Behavior for Simulation

The following behavior applies only to simulation for your model.

Data Port for Default Case	Diagnostic for Default Case		
	None	Warning	Error
Last data port 	Use the last data port and do not report any warning or error.	Use the last data port and report a warning.	Report an error and stop simulation.
Additional data port 	Use the additional data port with a * label and do not report any warning or error.	Use the additional data port with a * label and report a warning.	Report an error and stop simulation.

Behavior for Code Generation

The following behavior applies to code generation for your model.

Data Port for Default Case	Diagnostic for Default Case		
	None	Warning	Error
Last data port 	Use the last data port.	Use the last data port.	Use the last data port.
Additional data port 	Use the additional data port with a * label.	Use the additional data port with a * label.	Use the additional data port with a * label.

Use Data Inputs That Have Different Dimensions

If two signals have a different number of dimensions or different dimension lengths, you can use the signals as data inputs to a Multiport Switch block. In the block dialog box, select the parameter **Allow different data input sizes**. In this case, the output of the block is a variable-size signal. If you do not select this parameter, the block generates an error.

For more information about the parameter, see “Allow different data input sizes (Results in variable-size output signal)” on page 1-0 . For more information about variable-size signals, see “Variable-Size Signal Basics”.

Rules That Determine the Block Behavior

You specify the number of data inputs with **Number of data ports**.

- If you set **Number of data ports** to 1, the block behaves as an *index selector* or *index vector* and not as a multiport switch. For more details, see “Multiport Switch Configured as an Index Vector Block” on page 1-1187.
- If you set **Number of data ports** to an integer greater than 1, the block behaves as a multiport switch. The block output is the data input that corresponds to the value of the control input. If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If all the data inputs are scalar, the output is a scalar.

Guidelines on Setting Parameters for Enumerated Control Port

When the control port on the Multiport Switch block is of enumerated type, follow these guidelines:

Scenario	What to Do	Rationale
The enumerated type contains a value that represents invalid, out-of-range, or uninitialized values.	<ul style="list-style-type: none"> Set Data port order to Specify indices. Set Data port indices to use this value for the last data port. Set Data port for default case to Last data port. 	This block configuration handles invalid values that the enumerated type explicitly represents.
The enumerated type contains only valid enumerated values. However, a data input port can get invalid values of enumerated type.	<ul style="list-style-type: none"> Set Data port for default case to Additional data port. 	This block configuration handles invalid values that the enumerated type does not explicitly represent.
The enumerated type contains only valid enumerated values. Data input ports can never get invalid values of enumerated type.	<ul style="list-style-type: none"> Set Data port for default case to Last data port. Set Diagnostic for default case to None. 	This block configuration avoids unnecessary diagnostic action.
The block does not have a data input port for every value of the enumerated type.	<ul style="list-style-type: none"> Set Data port for default case to Additional data port. 	This block configuration handles enumerated values that do not have a data input port, along with invalid values.

Limitations

- If the data inputs to the Multiport Switch block are buses, the element names of both buses must be the same. Using the same element names ensures that the output bus has the same element names no matter which input bus the block selects. To ensure that your model meets this requirement, use a bus object to define the buses and set the **Element name mismatch** diagnostic to error. See “Model Configuration Parameters: Connectivity Diagnostics” for more information.
- For arrays of buses, **Number of data ports** must be set to a value of 2 or greater.

Ports

Input

Port_1 – Control signal

scalar

The control signal can be of any data type that Simulink supports, including fixed-point and enumerated types. When the control input is not an integer value, the block truncates the value to an integer by rounding to zero.

For information on control signals of enumerated type, see “Guidelines on Setting Parameters for Enumerated Control Port” on page 1-1189.

For information on how the block handles the out-of-range condition, see “How the Block Handles an Out-of-Range Control Input” on page 1-1187.

Limitations

- If the control signal is numeric, the control signal cannot be complex.
- If the control signal is an enumerated signal, the block uses the value of the underlying integer to select a data port.
- If the underlying integer does not correspond to a data port, an error occurs.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `image`

1 – First data input

`scalar` | `vector` | `matrix` | N-D array

First data input, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports.

- If all the data inputs are scalar, the output is scalar
- If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If any two nonscalar signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see “Use Data Inputs That Have Different Dimensions” on page 1-1188
- If any data signal is of an enumerated type, all others must be of the same enumerated type.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `string` | `image`

2 – Second data input

`scalar` | `vector` | `matrix` | N-D array

Second data input, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports.

- If all the data inputs are scalar, the output is scalar
- If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If any two nonscalar signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see “Use Data Inputs That Have Different Dimensions” on page 1-1188
- If any data signal is of an enumerated type, all others must be of the same enumerated type.

Dependencies

To enable this port, set **Number of data ports** to an integer greater than 1.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `string` | `image`

N – Nth data input

scalar | vector | matrix | N-D array

Nth data input, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports.

- If all the data inputs are scalar, the output is scalar
- If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If any two nonscalar signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see “Use Data Inputs That Have Different Dimensions” on page 1-1188
- If any data signal is of an enumerated type, all others must be of the same enumerated type.

Dependencies

To enable the Nth input port, set **Number of data ports** to an integer value greater than or equal to N.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | string | image

*** – Data port for out-of-range inputs**

scalar | vector | matrix | N-D array

Input data port for out-of-range control signal inputs, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports. If any data signal is of an enumerated type, all others must be of the same enumerated type. If any two signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see “Use Data Inputs That Have Different Dimensions” on page 1-1188.

Dependencies

To create an additional data port for out-of-range control signal inputs, set **Data port for default case** to **Additional data port**. When you set **Data port for default case** to **Last data port**, the block uses the last data port for output when the control signal value does not match any data port indices.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Output**Port_1 – Selected data input, based on control signal value**

scalar | vector | matrix | N-D array

The block outputs one of the data inputs, selected according to the control signal value. The output has the same dimensions as the corresponding data input. When you select the **Allow different data input sizes** check box, the output of the block is a variable size signal.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | enumerated | string | image

Parameters

Main

Data port order — Type of ordering for data input ports

One-based contiguous | Zero-based contiguous | Specify indices

Specify the type of ordering for your data input ports.

- **Zero-based contiguous** — Block uses zero-based indexing for ordering contiguous data ports. This is the default value of the Index Vector block.
- **One-based contiguous** — Block uses one-based indexing for ordering contiguous data ports. This is the default value of the Multiport Switch block.
- **Specify indices** — Block uses noncontiguous indexing for ordering data ports.

Tips

- When the control port is of enumerated type, select **Specify indices**.
- If you select **Zero-based contiguous** or **One-based contiguous**, verify that the control port is not of enumerated type. This configuration is deprecated and produces an error. You can run the Upgrade Advisor on your model to replace each Multiport Switch block of this configuration with a block that explicitly specifies data port indices. See “Model Upgrades”.
- Avoid situations where the block contains unused data ports for simulation or code generation. When the control port is of fixed-point or built-in data type, verify that all data port indices are representable with that type. Otherwise, the following block behavior occurs.

If the Block Has Unused Data Ports and Data Port Order Is:	The Block Produces:
Zero-based contiguous or One-based contiguous	A warning
Specify indices	An error

Dependencies

Selecting **Zero-based contiguous** or **One-based contiguous** enables the **Number of data ports** parameter.

Selecting **Specify indices** enables the **Data port indices** parameter.

Programmatic Use

Block Parameter: DataPortOrder

Type: character vector

Values: 'Zero-based contiguous' | 'One-based contiguous' | 'Specify indices'

Default: 'One-based contiguous' (Multiport Switch) 'Zero-based contiguous' (Index Vector)

Number of data ports — Number of data input ports

1 | 3 | integer between 1 and 65535

Specify the number of data input ports to the block. The total number of input ports is the number you specify, plus one for the control signal input port, and plus one more if you set **Data port for default case** to Additional data port.

Dependencies

To enable this parameter, set **Data port order** to Zero-based contiguous or One-based contiguous.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: integer between 1 and 65536

Default: '3' (Multiport Switch) '1' (Index Vector)

Data port indices — Array of indices for data ports

{1,2,3} (default) | array of indices

Specify an array of indices for your data ports. The block icon changes to match the data port indices you specify.

Tips

- To specify an array of indices that correspond to all values of an enumerated type, enter the name of the type.

For example, `MyColors` is a valid entry if `MyColors` is the name of an enumerated type.

- To enter specific values of an enumerated type, use the `type_name.enumerated_name` format. Do not enter the underlying integer value.

For example, `{MyColors.Red, MyColors.Green, MyColors.Blue}` is a valid entry.

- To indicate that more than one value maps to a data port, use brackets.

For example, the following entries are both valid:

- `{MyColors.Red, MyColors.Green, [MyColors.Blue, MyColors.Yellow]}`
- `{[3,5],0,18}`
- If the control port is of fixed-point or built-in data type, the values for **Data port indices** must be representable with that type. Otherwise, an error appears at compile time to alert you to unused data ports.
- If the control port is of enumerated data type, the values for **Data port indices** must be enumerated values of that type.
- If **Data port indices** contains values of enumerated type, the control port must be of that data type.

Dependencies

To enable this parameter, set **Data port order** to Specify indices.

Programmatic Use

Block Parameter: DataPortIndices

Type: character vector

Values: array of indices

Default: '{1,2,3}'

Data port for default case — Port to use for out-of-range inputs

Last data port (default) | Additional data port

Specify whether to use the last data port for out-of-range inputs, or to use an additional port. An asterisk (*) next to the port name indicates the port the block uses when the control port value does not match any data port indices.

- **Last data port** — Block uses the last data port for output when the control port value does not match any data port indices.
- **Additional data port** — Block uses an additional data port for output when the control port value does not match any data port indices.

Tip

If you set this parameter to **Additional data port** and **Number of data ports** is 3, the number of input ports on the block is 5. The first input is the control port, the next three inputs are data ports, and the fifth input is the default port for out-of-range inputs.

Programmatic Use

Block Parameter: DataPortForDefault

Type: character vector

Values: 'Last data port' | 'Additional data port'

Default: 'Last data port'

Diagnostic for default case — Diagnostic action when control port value does not match data port indices

Error (default) | Warning | None

Specify the diagnostic action to take when the control port value does not match any data port indices.

- **None** — Produce no response.
- **Warning** — Display a warning and continue the simulation.
- **Error** — Terminate the simulation and display an error. In this case, the **Data port for default case** is used only for code generation and not simulation.

For more information, see “How the Block Handles an Out-of-Range Control Input” on page 1-1187.

Programmatic Use

Block Parameter: DiagnosticForDefault

Type: character vector

Values: 'None' | 'Warning' | 'Error'

Default: 'Error'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Signal Attributes

Require all data port inputs to have the same data type — Require all inputs to have the same data type

off (default) | on

Select this check box to require that all data input ports have the same data type. When you clear this check box, the block allows data port inputs to have different data types.

Programmatic Use

Block Parameter: InputSameDT

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).

- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output data type — Specify the output data type

Inherit: `Inherit via internal rule (default)` | `Inherit via back propagation` | **Inherit:** Same as first data input | `double` | `single` | `half` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `string` | `Simulink.ImageType(480,640,3)` | `<data type expression>`

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule**—Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:
 - Specify the output data type explicitly.
 - Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
 - To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- **Inherit: Inherit via back propagation** — Uses the data type of the driving block.
- **Inherit: Same as first data input** — Uses the data type of the first data input port.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Inherit via back propagation'` | `'Inherit: Same as first input'` | `'double'` | `'single'` | `'half'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'fixdt(1,16)'` |

'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'string' | Simulink.ImageType(480,640,3) |
'<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Specify the rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Choose one of these rounding modes.

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

See Also

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- off — Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- on — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
 - Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.
 - When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
 - In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.
-

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Allow different data input sizes (Results in variable-size output signal) — Allow input signals with different sizes

off (default) | on

Select this check box to allow input signals with different sizes.

- On — Allows input signals with different sizes, and propagate the input signal size to the output signal. In this mode, the block produces a variable-size output signal.
- Off — Requires that all nonscalar data input signals be the same size.

Programmatic Use

Parameter: AllowDiffInputSizes

Type: character vector

Value: 'on' | 'off'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

General	
CodingStyle	Specify whether to generate HDL code with case statements or if-else statements. By default, HDL Coder generates if-else statements. See also "CodingStyle" (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , or <code>Zero</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Using an Enumerated Type as Port Index

You can set **Data port order** to **Specify indices**, and enter enumeration values for the **Data port indices**. For example, you can connect the Enumerated Constant block to the Multiport Switch control port and use the enumerated types as data port indices.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

“Variable-Size Signal Basics”

Introduced before R2006a

MultiStateImage

Display image reflecting input value

Library: Simulink / Dashboard

Description

The MultiStateImage block displays an image to indicate the value of the input signal. You can use the MultiStateImage block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. You can specify pairs of input values and images to provide the information you want during simulation.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, select a dashboard block to connect. Then, on the block tab, click **Connect**. In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- You cannot connect a dashboard block to state activity or chart data in Stateflow during simulation.
- You cannot programmatically connect a dashboard block to state activity or chart data in Stateflow.

- Some signals do not have data available during simulation due to block reduction or optimization for accelerator mode simulations. To view such a signal using a dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display

signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Scale Mode — Specify how to scale image

Fill with fixed aspect ratio (default) | Fixed | Fill

Specify how to scale the image.

Fill with fixed Aspect Ratio scales the image to the size of the block while retaining its original aspect ratio.

Fixed displays the image with its fixed true size.

Fill adjusts the image to fill the block.

Programmatic Use

Block Parameter: ScaleMode

Type: string or character vector

Values: 'Fill with fixed aspect ratio' | 'Fixed' | 'Fill'

Default: 'Fill with fixed aspect ratio'

States — Match values with images to display

scalar and image

States match an image to display with a value of the connected variable or parameter. Each state consists of a **State** and an image, displayed as a **Thumbnail** in the **States** table for the MultiStateImage block.

- **State** — Connected variable or parameter value that causes the MultiStateImage block to display the corresponding image.
- **Thumbnail** — Image to display when the connected variable or parameter value matches the corresponding **State**.

Click the **+** button to add another state.

Programmatic Use

To programmatically configure `State` and `Thumbnail` parameter values for the `MultiStateImage` block, use the `States` parameter. Specify the value for the `States` parameter as an array of structures with the fields:

- `State` — State value.
- `Size` — 1-by-2 vector containing the width and height for the image in that order, in pixels, specified as a `uint64`.
- `Image` — Character array of Base64 encoded image data.
- `Thumbnail` — Character array of Base64 encoded image data for the thumbnail image to display in the **States** table in the block dialog.

Include a structure in the array for each state you want to specify for the block. In the example, the `myBase64Image` and `myBase64Thumbnail` variables contain character vectors of the Base64 image data for the block image and thumbnail..

```
state1.State = 1;  
state1.Size = [uint64(400) uint64(400)];  
state1.Image = myBase64Image;  
state1.Thumbnail = myBase64Thumbnail;  
state2.State = 2;  
state2.Size = [uint64(400) uint64(400)];  
state1.Image = myBase64Image2;  
state1.Thumbnail = myBase64Thumbnail2;  
msiStates = [state1 state2];
```

Block Parameter: States

Type: structure array

The block displays the default image when the connected signal value does not correspond to any of the specified states. Specify the `DefaultImage` parameter as a structure containing the fields:

- `Size` — 1-by-2 vector containing the width and height for the image in that order, in pixels, specified as `uint64`.
- `Image` — Character array of Base64 encoded image data.
- `Thumbnail` — Character array of Base64 encoded image data for the thumbnail image to display in the **States** table in the block dialog.

Block Parameter: DefaultImage

Type: structure

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: `LabelPosition`

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Mux

Combine input signals of same data type and complexity into virtual vector

Library: Simulink / Commonly Used Blocks
 Simulink / Signal Routing
 HDL Coder / Commonly Used Blocks
 HDL Coder / Signal Routing

Description

The Mux block combines inputs with the same data type and complexity into a vector output. The output mux signal is flat, even if you create the mux signal from other mux signals. However, you can use multiple Mux blocks to create a mux signal in stages.

A mux signal simplifies the visual appearance of a model by combining two or more signal lines into one line. Mux signals do not affect simulation or code generation.

Tip If inputs have different data types or complexity, use a Bus Creator block to visually group the signals in a virtual bus. For more information, see “Types of Composite Signals”.

Ports

Input

Port_1 — Input signal to include in mux signal

scalar | vector

Input signal to include in the mux signal, specified as a scalar or vector.

The input signals for a Mux block can be any combination of scalars and vectors, but they must have the same data type and complexity.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | image

Output

Port_1 — Output mux signal

vector

Output mux signal composed of the combined input signals, returned as a vector.

The elements of the output mux signal take their order from the port order of the input signals. For a description of the port order for various block orientations, see “Port Location After Rotating or Flipping”.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | image

Parameters

Number of inputs — Number of input signals

2 (default) | scalar | vector | cell array | comma-separated list of signal names

The number of input signals, specified as a scalar, vector, cell array, or comma-separated list of signal names. Some of these formats allow you to specify the signal names and sizes, as described by the following table.

Format	Block Behavior
Scalar	The number of inputs to the Mux block. When you use this format, the block accepts scalar or vector signals of any size. Simulink assigns each input the name <code>signalN</code> , where N is the input port number.
Vector	The length of the vector specifies the number of inputs. Each element specifies the size of the corresponding input. A positive value specifies that the corresponding port can accept only vectors of that size. For example, <code>[2 3]</code> specifies two input ports of sizes 2 and 3, respectively. If an input signal width does not match the expected width, an error message appears. A value of -1 specifies that the corresponding port can accept scalars or vectors of any size.
Cell array	The length of the cell array specifies the number of inputs. The value of each cell specifies the size of the corresponding input. A scalar value N specifies a vector of size N. A value of -1 means that the corresponding port can accept scalar or vector signals of any size.
Comma-separated list of signal names	A list of signal names separated by commas. Simulink assigns each name to the corresponding port and signal. For example, if you enter <code>position, velocity</code> , the Mux block has two inputs, named <code>position</code> and <code>velocity</code> .

Tip If you specify a scalar for the **Number of inputs** parameter and all of the input ports are connected, as you draw a new signal line close to input side of a Mux block, Simulink adds a port and updates the parameter.

Programmatic Use

Block Parameter: Inputs

Type: scalar, vector, cell array, comma-separated list of signal names

Values: integer, vector of port sizes, cell array, comma-separated list of signal names

Default: '2'

Display option — Block icon appearance

bar (default) | signal | none

Block icon appearance, specified as `bar`, `signal`, or `none`.

- `bar` — Displays no text
- `signal` — Displays the input signal names
- `none` — Displays the type of block (Mux)

Resize the block as necessary to fit the text on the block icon.

Programmatic Use

Block Parameter: `DisplayOption`

Type: character vector

Values: `'bar'` `'signals'` `'none'` `'bar'`

Default: `'bar'`

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).

OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
-----------------------	--

Complex Data Support

This block supports code generation for complex signals.

Restrictions

Buses are not supported for HDL code generation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type or capability support depends on block implementation.

Out Bus Element, Bus Element Out

Specify output that connects to external port

Library: Simulink / Ports & Subsystems
 Simulink / Sinks
 HDL Coder / Ports & Subsystems
 HDL Coder / Sinks

 OutBus.signal1

Description

The Out Bus Element block, also known as the Bus Element Out block, combines the functionality of an Outport block and a Bus Creator block. This block is of the Outport block type and all Out Bus Element blocks that use the same port share a dialog box.

The output of an Out Bus Element is a bus, regardless of the number and type of signals connected to it. You must connect an Out Bus Element block to each signal that you want the bus to contain.

The Out Bus Element block does not support mixing message and signal elements as inputs.

Create Port and Related Blocks

When you insert an Out Bus Element block, the block label populates with default values. The label consists of two interactive text fields: the port name and the bus element. To change the name of the port associated with the block, edit the first text field in the label by clicking the text.

 OutBus.signal1

To output multiple signals in a bus, create one Out Bus Element block for each signal that you want to include in the bus. In the Block Parameters dialog box, you can select the **Add a new signal**  or

Add a new sub-bus  buttons. Alternatively, hold **Ctrl** while you drag an existing Out Bus Element block to a new location. Upon releasing the mouse, click **Use Existing Port**.

If multiple blocks are associated with the same port and you change the name of the port, all blocks that share the port update to reflect the new port name.

To create a port, hold **Ctrl** while you drag an existing Out Bus Element block to a new location. Upon releasing the mouse, click **Create New Port**.

Modify Port Output

In the Block Parameters dialog box, you can:

- Change port and element names.
- Reorder bus elements by dragging and dropping an element in the list of elements.
- Remove blocks associated with selected elements by clicking the **Remove blocks of selected signals** button .

Specify Element Name

To change the name of the bus element associated with the block, edit the second text field in the label by clicking the text.

Tip To pass the block input to the external output port without nesting it in a bus, delete the text from the second text field in the label.

All element names associated with the port must be unique. You cannot specify the same element name more than once for a port. Simulink does not support overlapping writes to the same port.

To create hierarchy in the output bus, use dots in the part of the label that describes the bus element. Each dot indicates a new level of bus hierarchy.

To reduce the size of the label, you can display only the element name by selecting the block, pausing on the ellipsis, and selecting **Compact Notation** from the action bar. To show the bus hierarchy again, select **Expanded Notation** from the action bar.

Specify Attributes

To specify attributes, such as data type, pause on the name of a bus, signal, or message. Then, click the pencil button that appears.

When you specify attributes, they appear next to the name of the bus, signal, or message. Click an attribute summary to edit the attributes of the bus, signal, or message.

```
▼ Bus (dt: Bus: BusObject, dims: 1)
  element1 (dt: double, dims: [1], Fixed, real)
  element2 (dt: double, dims: [1], Fixed, real)
```

Log Output Data

When you save output data to the workspace or a file, bus data defined by groups of root-level Out Bus Element blocks are logged along with root-level Outport block data.

Ports

Input

Port_1 — Full or partial output for external port

scalar | vector | matrix | array | bus

Connect a bus, signal, or message to pass to the corresponding external output port of the parent subsystem or model.

When multiple Out Bus Element blocks are associated with the same external port, the input to this block is an element of the bus at the output port. The second text field in the label specifies the element name.

When one Out Bus Element block is associated with the external port, the input to this block is passed directly to the output port or nested in a bus at the output port. To pass the input of the block to the output port without nesting it in a bus, delete the text from the second text field in the label.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus

Parameters

To interactively edit the parameters of the block and the corresponding port, double-click the block.

Port name — Name of output port

OutBus (default) | port name

Specify a port name that is not already in use by another block or port. The name appears on the parent Subsystem or Model block. The name also appears next to the block. Multiple blocks can access the same port.

Programmatic Use

Block Parameter: PortName

Type: character vector

Values: 'OutBus' | '<port name>'

Default: 'OutBus'

Port number — Position of port on parent block

1 (default) | real integer

Specify the order in which the port that corresponds to the block appears on the parent Subsystem or Model block.

- If you add a block that creates another port, the port number is the next available number.
- Deleting all blocks associated with a port deletes the port. Other ports are renumbered so that they are sequential and do not skip any numbers.
- Specifying a port number that exceeds the number of ports creates a port for that number and for any skipped sequential numbers.

Programmatic Use**Block Parameter:** Port**Type:** character vector**Values:** real integer**Default:** '1'**Set color — Specify block background color**

Black (default) | White | Red | Green | Blue | Cyan | Magenta | Yellow | Gray | Light Blue | Orange | Dark Green | More Colors

Specify the block background color. This specification sets the color of blocks associated with selected bus elements, or of all blocks associated with the port if you do not select any bus elements.

Programmatic Use**Block Parameter:** BackgroundColor**Type:** character vector**Values:** 'black' | 'white' | 'red' | 'green' | 'blue' | 'cyan' | 'magenta' | 'yellow' | 'gray' | 'lightBlue' | 'orange' | 'darkGreen' | '[r,g,b]' where r, g, and b, are the red, green, blue values of the color in the range 0.0 to 1.0**Default:** 'black'**Filter — Filter set of displayed signals**

text

Specify a search term to use for filtering a long list of bus elements. Do not enclose the search term in quotation marks. The filter does a partial string search and supports regular expressions. To use a regular expression character as a literal, include an escape character (\). For example, to use a question mark, type sig\?1.

Attributes

To specify attributes, click the pencil button or attribute summary next to the name of a bus, signal, or message.

Data type — Data type

Inherit: auto (default) | double | single | half | int8 | uint8 | int16 | uint16 | ...

The data type can be inherited, specified directly, or expressed as a data type object such as a Simulink.NumericType object.

You can specify any of these options:

- Inherited data type
- Built-in Simulink data type — For example, specify single or uint8. See “Data Types Supported by Simulink”.
- Fixed-point data type — Use the fixdt function. For example, specify fixdt(1,16,0).
- Enumerated data type — Use the name of the type preceded by Enum:. For example, specify Enum: myEnumType.

- Bus data type — Use the name of the `Simulink.Bus` object preceded by `Bus:`. For example, specify `Bus: myBusObject`.
- Value type — Use the name of the `Simulink.ValueType` object preceded by `ValueType:`. For example, specify `ValueType: windVelocity`.
- Custom data type — Use a MATLAB expression that specifies the type. For example, you can specify a `Simulink.NumericType` object whose `DataTypeMode` property is set to a value other than `'Fixed-point: unspecified scaling'`.

When you specify a `Simulink.ValueType` or `Simulink.Bus` object, the object defines more than the data type. The object also defines properties such as **Min**, **Max**, and **Unit**. The property values specified by the `ValueType` object override the corresponding property values specified by a block. For example, suppose a block sets **Unit** to ft/s. When the **Data type** of the block specifies a `ValueType` object that has m/s as its unit, the block uses m/s instead of ft/s.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: auto' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'string' | 'Enum: <class name>' | 'Bus: <object name>' | 'ValueType: <object name>' | '<data type expression>'`

Default: `'Inherit: auto'`

Data mode — Data mode of bus elements

`inherit` (default) | `signal` | `message`

Specify the data mode of the elements of the bus.

- `inherit` — Bus elements inherit their data modes.
- `signal` — Bus elements must be signals.
- `message` — Bus elements must be messages.

For the In Bus Element block, if you choose `message` as the data mode, an envelope button appears next to the bus or bus element. Use the envelope button to specify custom queue properties for each message element. The Out Bus Element block does not support queue specifications.

Dependencies

To enable this parameter, the block must be at the top level of a model.

Programmatic Use

Block Parameter: `DataMode`

Type: character vector

Values: `'inherit' | 'signal' | 'message'`

Default: `'inherit'`

Bus virtuality — Virtual or nonvirtual bus

`inherit` (default) | `virtual` | `nonvirtual`

Specify whether to inherit the bus virtuality or define the bus as virtual or nonvirtual. For more information, see “Types of Composite Signals”.

This parameter determines whether the blocks inherit or define the bus virtuality. If the blocks define the bus virtuality and the virtuality of the input bus does not match, compiling the model produces an error.

Dependencies

To enable this parameter, set **Data type** to a Bus object.

Programmatic Use

Block Parameter: BusVirtuality

Type: character vector

Values: 'inherit' | 'virtual' | 'nonvirtual'

Default: 'inherit'

Dimensions — Signal dimensions

-1 (default) | integer | [integer, integer]

Specify the dimensions of a signal.

- -1 — The signal can have any dimensions.
- N — The signal must be a vector of size N.
- [R C] — The signal must be a matrix having R rows and C columns.

Programmatic Use

Block Parameter: PortDimensions

Type: character vector

Values: '-1' | integer | [integer, integer]

Default: '-1'

Dims mode — Option to allow only variable-size or fixed-size signals

Inherit (default) | Fixed | Variable

Specify the type of signals allowed.

- Inherit — Allow variable-size and fixed-size signals.
- Variable — Allow only variable-size signals.
- Fixed — Allow only fixed-size signals. Do not allow variable-size signals.

When the signal is variable-sized, the **Dimensions** parameter specifies the maximum dimensions of the signal.

Programmatic Use

Parameter: VarSizeSig

Type: character vector

Value: 'Inherit' | 'No' | 'Yes'

Default: 'Inherit'

Unit — Physical unit

inherit (default) | <Enter unit>

Specify the physical unit of the signal. For a list of supported units, see Allowed Unit Systems.

Programmatic Use

Block Parameter: Unit

Type: character vector

Values: 'inherit' | '<Enter unit>'
Default: 'inherit'

Sample time — Sample time

-1 (default) | scalar

Specify the discrete interval between sample time hits or specify another appropriate sample time such as continuous or inherited.

By default, the signal inherits its sample time. To set a different sample time, enter a valid sample time based on the table in “Types of Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar

Default: '-1'

Complexity — Numeric type

auto (default) | real | complex

Specify the numeric type of the signal. To choose the numeric type of the signal, select auto. Otherwise, choose a real or complex signal type.

Programmatic Use

Block Parameter: SignalType

Type: character vector

Values: 'auto' | 'real' | 'complex'

Default: 'auto'

Minimum — Minimum value

[] (default) | scalar

Lower value of the range that Simulink checks.

This number must be a finite real double scalar value.

Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Maximum — Maximum value

[] (default) | scalar

Upper value of the range that Simulink checks.

This number must be a finite real double scalar value.

Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Description — Description of bus or bus elements

no default

Use the description to document information about the bus or bus element, such as where it is used. This information does not affect Simulink processing.

Programmatic Use

Block Parameter: Description

Type: character vector

Values: ' ' | '<Enter text>'

Default: ' '

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used to simplify the Subsystem bus interfaces when you use the block in subsystems that generate HDL code, but is not included in the hardware implementation.

To learn more about using buses for HDL code generation, see “Buses” (HDL Coder) and “Use Bus Signals to Improve Readability of Model and Generate HDL Code” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.
